A total of 100 spine MRI reports were retrieved from our hospital database, all of which had been approved by fellowship-trained board-certified radiologists with 6 to 18 years of experience. To ensure compliance with HIPAA regulations, all reports were deidentified by removing unique identifying information. Using generative AI, AI-generated radiology reports were then produced by inputting the original reports into a new session without any prior questions having been posed. The reports were generated in four formats: (1) structured reports, (2) summary reports, (3) recommendations, and (4) patient-friendly reports. To evaluate the quality and accuracy of the AI-generated reports, they were compared with the original reports by a panel of radiologists in terms of: (1) the quality of the structured report, (2) the quality of the summary, (3) the concordance of the recommendations with those made by the radiologists, (4) the compatibility of the patient-friendly reports, and (5) the occurrence of artificial hallucinations. Two radiologists conducted qualitative and quantitative studies, independently (five-point scale).

##### RESULTS

The scoring of the AI-generated radiology reports were  $4.95 \pm 0.24$  for structured report and  $4.69 \pm 0.67$  for summary. The agreements of radiologist recommendations and generative-AI recommendations was 95.96% (score  $4.88 \pm 0.54$ ). The compatibility for patient-friendly reports was 83 % (score  $4.71 \pm 0.71$ ). There were 3% artificial hallucinations in patient-friendly reports. This amounted to 3.6 times higher prevalence of easy understandable for the generative-AI powered patient friendly reports ( $P < .001$ ).

##### CONCLUSION

s Generative AI was employed to reproduce radiology reports in various useful formats. The potential benefits of using AI assistants to generate these reports include improved report quality, greater efficiency in radiology workflows for producing structured reports, summaries, and recommendations, and a move toward patient-centered radiology.

## CLINICAL RELEVANCE/APPLICATION

The use of large language model in radiology reports can have a significant impact on the quality and efficiency of radiology workflows. By producing high-quality, easily understandable reports that can address patient questions, AI-generated reports can improve patient care and satisfaction, moving towards patient-centered radiology, which places a greater emphasis on meeting the needs and expectations of patients.

### S3B-SPMK-3 Performance of Deep Learning based Vertebral Compression Fracture Detection Algorithm in Patients with Acute and Chronic Fractures

#### PURPOSE

Although deep learning algorithms (DL) show promising detecting lesions, the robustness of DL in detecting vertebral compression fractures (VCFs) in patients with acute and chronic fractures was less well known. Therefore, the aim of this study was to investigate the robustness of a DL for detecting VCFs in patients with acute and chronic fractures.

#### METHODS AND MATERIALS

We included 178 patient CT cases (excluding those who underwent surgery with cement or screw) diagnosed with VCF at a tertiary medical center (KUMC, Seoul). Each vertebra's reference standard was established by two radiologists. A total of 1200 vertebral bodies (VBs) were labeled for use in the evaluation of which 1000 VBs were normal, 104 chronic and 171 acute. We utilized a deep learning-based quantitative spine analysis program (ClariVCF, ClariPi Inc., Seoul) in which the vertebral body was segmented automatically by using a pre-trained CNN model followed by measurement of vertebral heights at anterior, middle, and posterior portions of each vertebra. Vertebral height loss was then calculated by measuring the ratio of height at the anterior or middle portion to that of the posterior portion. In addition, a formula was used to compare the vertebral heights between the consecutive vertebra above and below. We evaluated the detection performance of DL for acute and chronic VCFs with sensitivity and specificity by using a criterion of 20% height loss ratio according to the Genant classification.

#### RESULTS

The detection performance of DL for the chronic VCFs was shown to be 94.23% (87.87-97.85%, 95% CI) in sensitivity and 86.91% (84.65-88.94%, 95% CI) in specificity. The performance was reduced for acute VCFs (N=171) to 78.95% (72.07-84.80%, 95% CI) in sensitivity and 86.91% (84.65-88.94%, 95% CI) in specificity. For the overall dataset, which included both acute and chronic VCFs, the sensitivity was 84.56% (79.71-88.64%, 95% CI) and the specificity was 86.91% (84.65-88.94%, 95% CI).

#### CONCLUSION

s The deep learning-based VCFs detection algorithm was more sensitive in detecting chronic VCFs than acute VCFs. However, the specificity remained unchanged for both chronic and acute.

## CLINICAL RELEVANCE/APPLICATION

It might be necessary to take cortical disruption or cortical step-off into account for acute VCFs, where some vertebral height loss might not be noticeable. This demonstrates the necessity for techniques other than height loss measurement. Additionally, a unique height loss measurement approach is necessary for each spinal location while taking into account the physiologic wedging of each vertebral level in order to prevent false positive results.

### S3B-SPMK-4 Describing the Effects of IV Contrast on CT Abdominal Body Composition Biomarkers

Participants  
Alexander Weston, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

#### PURPOSE

Automated measures of body composition from abdominal CT images are becoming more common to quantify frailty, obesity, and to predict disease outcomes. However, measures may be biased by the presence of intravenous (IV) contrast, possibly leading to prior studies avoiding reporting skeletal muscle density measurements (e.g., Magudia 2021, Radiology). We evaluated the effect of IV contrast phase on six biomarkers of abdominal body composition.

#### METHODS AND MATERIALS

We randomly sampled 244 persons with 258 abdominal CT radiologic exams (479 series) from a cohort representative of the general population. Series were manually annotated for IV contrast phase (noncontrast, arterial, venous, delayed, or nephrographic). We applied a deep-learning model to segment abdominal body composition centered at the L3 transverse process (previously validated mean Dice scores for subcutaneous fat area 0.98, visceral fat area 0.94, muscle area 0.96, and bone area 0.98). Muscle and bone density were defined as mean Hounsfield units (HU) of the segmented tissues. All available CT series were segmented and multiple acceptable series acquired at different IV contrast phases were used to calculate the difference in each body composition biomarker relative to the noncontrast CT series. Values are reported in scatter plots and significance was assessed using 2-sided paired-sample t-tests.

#### RESULTS

Based on manual review, 256/258 CT studies (99%) had one or more series with acceptable quality for body composition analysis and 95/256 studies (37%) had a noncontrast series for comparison. Skeletal muscle density measurements were higher in venous phase versus noncontrast (difference of 5.9HU, 95% CI: 4.72 - 7.15HU) and delayed phase versus noncontrast (difference of 8.5HU, 95% CI: 7.35 - 9.69HU), significant after Bonferroni correction. Vertebral bone density measurements were higher in venous phase versus noncontrast (difference of 8.2HU, 95% CI: 4.9 - 11.5HU) and delayed phase versus noncontrast (difference of 11.5HU, 95% CI: 7.5 - 15.6). No significant differences were observed between arterial phase versus noncontrast series.

#### CONCLUSION

s Skeletal muscle density and vertebral bone density measurements on abdomen CT are slightly higher in the presence of IV contrast.

## CLINICAL RELEVANCE/APPLICATION

A correction factor may be needed to account for IV contrast phase when measuring skeletal muscle density and vertebral bone

density biomarkers in CT-based body composition analysis.

### **S3B-SPMK-5 Distal Radius Fracture: Competent Radiology Reports Generated by ChatGPT Integrating RSNA Template Items and AO Classifier**

#### **PURPOSE**

While demand for radiology imaging grows worldwide, novel information technology tools promise an increase of reporting quality and as well quantity. Text report drafting tools are part of this development.

#### **METHODS AND MATERIALS**

In the present study, cases of distal radius fracture are defined. Command files for the writing of a report following a template of the Radiological Society of North America (RSNA) and Arbeitsgemeinschaft Osteosynthese (AO) are given to the natural language processing tool ChatGPT.

#### **RESULTS**

An overall high appraisal of ChatGPT radiology reports is obtained in an assessment by human radiologists. ChatGPT is able to adjust output files in response to minor changes in input command files. Shortcomings are the dealing with technical terminology and medical interpretation of findings.

#### **CONCLUSION**

In the future, text drafting tools might well support the clinical work of radiologists. ChatGPT is seen by us as a substantial step forward toward that aim.

#### **CLINICAL RELEVANCE/APPLICATION**

The amount of clinical imaging is growing because of reasons such as demographics and more complex imaging modalities. Tools which draft a text report allow the radiologist to increase output efficiency and to focus time on patient pathology.

### **S3B-SPMK-6 The Value of Incorporating Additional Carpal Tunnel Sequences in the Hand MRI for Patients Presenting with Trigger Finger Symptoms**

Participants

NA YOUNG LEE, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To determine the prevalence of carpal tunnel syndrome (CTS) in trigger finger patients and identify the MRI criteria necessary for its diagnosis, particularly in cases requiring surgical intervention by obtaining additional two sequence MRI of the carpal tunnel.

#### **METHODS AND MATERIALS**

Fifty-five hands in 49 patients underwent MRI for evaluation of trigger finger prior to surgery. The dataset included variables such as age, sex, patients' symptoms, and measurements of median nerve signal intensity (SI) and shape, cross-sectional area of the median nerve (MNA), and retinacular bowing. Patients who underwent carpal tunnel release were classified as having severe CTS. The statistical analysis of these factors was conducted using a suite of methods including the independent Student's t-test, Chi-square test, and logistic regression. ROC curves were also drawn to evaluate the precision of CTS diagnosis and to predict severe CTS.

#### **RESULTS**

A total of 22 hands underwent carpal tunnel release surgery for CTS with concomitant pulley release for trigger finger. The incidence of severe CTS in patients with trigger finger was observed to be 40%. One third of patients diagnosed with severe CTS exhibit the classical symptoms associated with CTS, including tingling sensations in their fingers. However, the remaining patients present with symptoms primarily related to trigger finger, such as pain in the fingers. Statistically significant differences were observed between patients with trigger finger and severe CTS, and those with trigger finger only groups, in relation to several key factors, including MNA, median nerve SI and shape, and retinacular bowing at the outlet ( $p < 0.001 \sim 0.005$ ). Among these factors, only MNA of proximal to inlet level (MNA-pi) and increased median nerve SI with nerve fascicle swelling exhibited a positive correlation with odds ratio of 1.657. Further analysis of ROC curves demonstrated a sensitivity, specificity, and accuracy of MNA-pi  $> 15 \text{ mm}^2$  of 77.27%, 72.73%, and 84.5%, and MNA of distal to outlet (MNA-do)  $> 13 \text{ mm}^2$  of 81.82%, 75.76%, and 84.8%.

#### **CONCLUSION**

Hand MRI is a highly accurate diagnostic modality for detecting severe CTS, which often requires surgical intervention.

#### **CLINICAL RELEVANCE/APPLICATION**

Incorporating two additional sequences of MRI of the carpal tunnel with hand MRI for preoperative evaluation of trigger finger has the potential to aid in the detection of severe CTS and in facilitating optimal surgical planning.

### **S3B-SPMK-7 Usefulness of the Floating Fat Sign in the Extensor Tendon Sheath for Predicting Extensor Pollicis Longus Tendon Rupture in Distal Radius Fracture**

#### **PURPOSE**

To evaluate the usefulness of the floating fat sign for predicting extensor pollicis longus (EPL) rupture in distal radius fracture (DRF).

#### **METHODS AND MATERIALS**

This retrospective study included patients with DRF, consisting of the EPL rupture ( $n = 9$ ) and non-rupture ( $n = 340$ ) groups. The floating fat sign was visually graded on a semi-quantitative Likert scale (0 to 2) for the second and third extensor compartments separately. The presence of bone fragment, Lister's tubercle fracture type, fracture gap, and presence of intra-articular fracture were assessed. Fisher's exact test was conducted to assess the correlation between the floating fat sign and EPL rupture.

Univariate and multivariate analyses were performed, followed by ROC curve analysis.

## RESULTS

The sum of floating fat sign scores of the second and third compartments was significantly correlated with the odds of EPL rupture ( $p = 0.001$ ). Male sex, conservative treatment, floating fat sign score of the second and third extensor compartments, and sum of floating fat sign scores of the second and third extensor compartments were significant variables associated with EPL rupture. The floating fat sign in the third compartment was an independent predictive indicator for EPL rupture ( $p = 0.002$ ). ROC curve analysis revealed that the AUC was the highest (0.835) for the multivariate model, followed by the univariate model of the sum of floating fat sign scores of the second and third compartments.

## CONCLUSION

The floating fat sign in DRF could be a predictive indicator for EPL rupture.

## CLINICAL RELEVANCE/APPLICATION

The presence of the floating fat sign in distal radius fracture may assist in predicting the risk of extensor pollicis longus tendon rupture, which could aid in developing a treatment plan or providing warning of potential tendon rupture.

## S3B-SPMK-8 Investigation of Buffer Thickness for Reducing Artifacts from the Table in Computed Tomography Examinations During the Extremities Three-Dimensional Imaging

Participants

Yoshiki Kamihoriuchi, Okayama-Shi, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

If the hand is directly positioned on the computed tomography (CT) table mat, it is often difficult to separate the hand from the CT table mat due to artefacts from the CT table mat at the three-dimensional (3D) imaging. The objective of this investigation was to determine the optimal thickness of the buffer material utilized for 3D imaging, to alleviate artifact generation consequent to hand separation from the CT table mat.

## METHODS AND MATERIALS

The wrist phantom was placed on a CT table mat. Styrofoam and medical non-woven gauze were used as buffers, and 10 scans were acquired each with no buffer (none), one piece of gauze (gauze) and 1, 2, 3, 4 and 5 mm of Styrofoam. The scan parameter was following (tube voltage 135 kV, tube current 100 mA, rotation time 1.0 second, helical pitch 0.637, slice thickness 1.0 mm, field of view 150). For the 3D image, we utilized images with a reconstruction interval of 0.5 mm and reconstructed them using three different bone functions (FC30 AIDR3D mild: FC30, Aice Bone mild: BM, and Aice Bone standard: BS). Three regions of interest (ROIs) were set up within an identical image section, both in the absence of buffer and with a 5 mm Styrofoam buffer. Subsequently, profile curves were measured and the maximum CT values at the phantom edge were compared. A comparative analysis of the full-width at half-maximum (FWHM) was conducted among three scenarios: no buffer, gauze, and 1 mm buffer. Visualization scores were evaluated at three levels to assess the degree of artifacts caused by the CT table mat during 3D image creation.

## RESULTS

The results obtained indicate statistically significant differences between the scenarios without buffer and with gauze, gauze and 1 mm buffer for all cases. In terms of the maximum CT values at the phantom edges, the following comparisons were made: FC30 (none: 340 (229-348) HU, 5 mm: 289 (282-295) HU), BM (none: 446 (358-451) HU, 5 mm: 380 (366-387) HU), and BS (none: 269 (227-275) HU, 5 mm: 219 (215-222) HU) ( $p$  It; 0.05 for all). Furthermore, the full-width at half-maximum (FWHM) was analyzed for FC30 (gauze: 0.77 (0.71-0.85) mm, 1 mm: 1.08 (1.07-1.18) mm), Bone Mild (gauze: 0.72 (0.63-0.81) mm, 1 mm: 1.00 (0.99-1.08) mm), and Bone Standard (gauze: 0.77 (0.71-0.85) mm, 1 mm: 1.08 (1.07-1.18) mm) ( $p$  It; 0.05 for all).

## CONCLUSION

By inserting a buffer material with a thickness of at least 1mm between the hand and the CT table mat at creating 3D imaging, the separation of the hand and the CT table mat can be achieved easier for regardless of the conditions.

## CLINICAL RELEVANCE/APPLICATION

It was confirmed that using a buffer material of 1 mm or more can significantly reduce the effects of artifacts from the CT table mat, which can improve the quality of 3D imaging of the hand and increase flexibility in positioning.

S3B-SPMS

### Multisystem Sunday Poster Discussions II

#### Sub-Events

#### S3B-SPMS-1 STIR-based Volume Measurement Methods for Staging Primary Lower Extremity Lymphedema: A Single-center Study of Asymmetric Volume Difference

##### Participants

MENGKE LIU, BEIJING, China (*Presenter*) Nothing to Disclose

##### PURPOSE

The staging of lower extremity lymphedema (LEL) is hard in clinical work. The perfect soft tissue contrast of Short Term Inversion Recovery (STIR) sequence of MRI enables quantitatively assess the clinical staging of primary LEL. This study aims to explore the clinical value of MRI-based asymmetric volume measurement in the clinical staging of primary LEL.

##### METHODS AND MATERIALS

92 patients with unilateral primary LEL underwent Short Term Inversion Recovery (STIR) sequence of MRI. The volume of the middle calf was calculated using the clinical dermatome method (VCl). Two radiologists measure the total volume (V), musculoskeletal volume (VM), and subcutaneous volume (VS) in the middle calves on MRI. The difference between the affected and unaffected calf regarding V (DV) and VS (DVS) was obtained. DV and DVS were defined as asymmetric volume difference. The volume of the middle calf (Vcl) and difference in volume (DVcl) were calculated using the clinical circumferential method. The relationship between asymmetric volume difference and clinical staging was evaluated. Interobserver consistency was assessed through intraclass correlation coefficient (ICC). Volume comparisons were performed using one-way analysis of variance (ANOVA) analysis or Kruskal-Wallis test among three groups. Spearman's correlation analysis was used to assess volume and clinical stage correlation. The receiver operating characteristic (ROC) curve was drawn to assess the value of asymmetric volume difference for clinical staging.

##### RESULTS

The asymmetric volume difference was statistically significant in stage I compared to stages II and III ( $p < 0.05$ ). The asymmetric volume difference (DV:  $r = 0.753$ ; DVS:  $r = 0.759$ ) correlated more with the clinical stage than the affected Vcl ( $r = 0.581$ ), V ( $r = 0.628$ ), VS ( $r = 0.743$ ) and DVcl ( $r = 0.718$ ). The area under ROC curve (AUC) for identifying the clinical stage by the asymmetric volume difference was greater than that for the affected Vcl, V, VS and DVcl, with DVS (AUC=0.951) having the highest area under the curve to distinguish between stages I and II.

##### CONCLUSION

s STIR-based asymmetric volume difference can be used as an adjunctive measure for clinical staging of LEL with good reproducibility, and DVS could be the best indicator for differentiating between stages I and II.

##### CLINICAL RELEVANCE/APPLICATION

STIR can quantitatively assess the severity of primary lower extremity lymphedema, facilitating clinical decision making and improving prognosis.

#### PSMA PET/CT for Localization of Prostate Cancer after Focal Therapy

##### PURPOSE

PSMA-ligand PET has become the first-line imaging tool for staging and re-staging patients with prostate cancer. However its role in patients with prostate cancer who underwent focal therapy (HIFU, irreversible electroporation, photodynamic therapy, cryoablation, and laser therapy) is still unknown. In this study, we aimed to investigate the diagnostic performances of PSMA PET/CT to detect and localize biochemical recurrence after focal therapy.

##### METHODS AND MATERIALS

This was a retrospective single center study. Patients with the following inclusion criteria were included: focal treatment for prostate cancer, 68Ga-PSMA-11 PET with contrast enhanced CT performed for biochemical recurrence, and no therapy between focal therapy and PET. Three independent blinded readers performed the PET image analysis and a per-region (T, N, M1a, M1b, M1c) centralized majority rule was applied (positivity rate). Inter-reader agreement of the positivity rates was calculated with Fleiss' kappa. In a sub-cohort of patients with a MRI and biopsy performed within 3 months of PSMA PET, diagnostic accuracy was evaluated on a per-patient and per-segment analysis on standard WB +60 min and the delayed +90 min pelvic images. A single radiologist blinded to PSMA and pathology performed MRI interpretation. Twelve prostatic segments were defined, and for every segment, suspicion for recurrence was assessed.

##### RESULTS

Of the 3329 patients with either a PSMA PET scan or focal therapy performed at UCLA, 100 patients met the inclusion criteria. PSMA-PET positivity rate per majority rule was 85/100 (85%) for prostate, 17/100 (17%) for pelvic lymph nodes and 20/100 (20%) for distant metastases. The inter-reader agreement for positivity rate by region was moderate (kappa=0.5). 29 patients had MRI and post-therapy biopsy data available. In these, Per-patient analysis showed a sensitivity of 92% for PSMA and 88% for MRI. Per-segment analysis performed on 297 validated segments resulted in a sensitivity, specificity, positive predictive value and negative predictive value of 53%, 90%, 74% and 78% for PSMA at +60 min, 55%, 92%, 79% and 79% for PSMA at +90 min and 29%, 92%, 72% and 65% for MRI (p<0.01), respectively. All Patients with PSMA SUVmax = 10 had GG =3 disease.

##### CONCLUSION

In this retrospective study of 100 patients treated with focal treatment for prostate cancer the PSMA-PET positivity rate was 85% for prostate. The sensitivity per-segment was 55% on delayed +90 min pelvic PSMA PET vs 29% for MRI with a similar specificity of 92%. results suggest that PSMA PET/CT has potential for localization of recurrent prostate cancer after focal therapy.

##### CLINICAL RELEVANCE/APPLICATION

PSMA PET appears promising for localization of biochemical recurrence after focal therapy.

S3B-  
SPNMMI-2

#### Manufacturing Iodine-loaded Polymeric Microcapsules: Proof-of-Concept for Theranostics in Peritoneal Carcinomatosis

##### Participants

Nils Grosse Hokamp, MD, PhD, Koln, Germany (*Presenter*) Research Grant, Koninklijke Philips NV; Speakers Bureau, Koninklijke Philips NV; Consultant, Bristol-Myers Squibb Company

##### PURPOSE

Peritoneal carcinomatosis refers to shedding of tumor cells to the peritoneal cavity and often is indicative of incurable and/or end stage disease. Treatment options at this advanced stage include hyperthermic intraperitoneal chemotherapy (HIPEC) alongside cytoreductive surgery. Aiming for continuous chemotherapeutic delivery options, this study intended to provide proof-of-concept of polymeric microcapsules that allow incorporation of chemotherapeutic agents and that are furthermore loaded with iodine in order to allow in-vivo tracing using computed tomography.

##### METHODS AND MATERIALS

For synthesis a solvent-emulsion evaporation technique has been used. Hydrophobic iodinated oils (e.g. Lipiodol) were used as inner phase of the capsule. A biodegradable polymer [poly(lactic-co-glycolic acid), PGLA] was used as outer shell material. A fluorescent dye was added for direct visualisation. Incorporation of hydrophilic drugs, was shown with an aqueous iodinated compound (iohexol), using a water-oil-water emulsion process. Light/fluorescence microscopy, UV/Vis spectroscopy and size distribution using a Coulter Counter were conducted in addition to spectral detector CT based quantification of iodine content (SDCT).

##### RESULTS

The synthesis yielded polymeric capsules containing CT-imageable iodinated compounds with tuneable diameter. The obtained

particle diameters were in the range of 0.1 - 15  $\mu\text{m}$ . Iodide concentration was further quantified using UV/vis spectroscopy. Here, Iodine to polymer ratio varied between 23 to 125 mg I/g corresponding to 0.01 to 0.03  $\mu\text{g}$  I/capsule); similar results were obtained using SDCT. In addition cytostatic drugs could be incorporated into the particles.

#### **CONCLUSION**

s Controlled formation of iodine-loaded polymeric microcapsules can be achieved. The capsules can be visualized using SDCT which furthermore allows for quantification of their iodine content (consistent with UV/vis-based measurements as standard of reference). Furthermore, cytotoxic drugs can be incorporated into these particles.

#### **CLINICAL RELEVANCE/APPLICATION**

The described syntheses provide proof-of-concept for in-vivo traceable and quantifiable microcapsules. Attempts to alter longevity of these systems might allow for a continuous therapy of peritoneal carcinomatosis. Alternatively, advanced manufacturing might allow for targeted drug delivery, e.g. by incorporating receptors into the outer shell.

## Abstract Archives of the RSNA, 2023

S3B-SPNPM

### Noninterpretive Skills (Beyond Imaging) Sunday Poster Discussions II

#### Sub-Events

#### **S3B-SPNPM-Disability, an Often-Overlooked Aspect of Equity, Diversity, and Inclusion Among Radiology Departments in Canada and the United States** 1

##### Participants

Ali Abbas, BS, Dallas, TX (*Presenter*) Nothing to Disclose

##### PURPOSE

Despite nearly a quarter of Canadians and Americans reported to be living with a disability, persons with disabilities continue to face both structural and cultural barriers with respect to careers in medicine. Equity, diversity, and inclusivity (EDI) statements can act as a first step in deconstruction of these cultural barriers. However, when compared to other EDI initiatives focused on gender, race, and ethnicity, persons with disabilities receive little attention.

##### METHODS AND MATERIALS

We conducted a cross-sectional analysis of all radiology residency program websites in Canada and the United States (US). Data was collected from each radiology department website including the presence or absence of an EDI statement or page; if present, we determined whether mention was made of persons with disabilities.

##### RESULTS

We reviewed the websites of 16 Canadian and 181 US radiology residency programs. Seven (44%) Canadian institutions had an EDI statement, with one (14%) mentioning persons with disabilities. In the US, 103 (57%) institutions had an EDI statement, with 42 (41%) mentioning persons with disabilities.

##### CONCLUSION

There were a significant proportion of radiology departments without EDI statements on their websites and an even smaller proportion that acknowledged persons with disabilities. Persons with disabilities are underrepresented in the medical profession and are often left out of radiology department EDI statements. This population faces many barriers to careers in medicine, underscoring the importance of physical and cultural accommodations.

##### CLINICAL RELEVANCE/APPLICATION

Patients with disabilities often report that healthcare providers lack understanding of their condition; thus, inclusion of persons with disabilities among the physician workforce may result in improved patient care. In recent years, there has been an increase in recruitment of medical students with disabilities. Therefore, it is important that post-graduate medical training programs implement the changes necessary to welcome and accommodate these individuals. An institution's public commitment to EDI, and specifically to patients and providers with disabilities, is central to implementing inclusive change going forward.

#### **S3B-SPNPM-Gender-specific Differences in Aspired Academic Qualification and Perceived Research Opportunities: Excerpts from a Nationwide German Survey** 2

##### Participants

Isabel Molwitz, MD, Hamburg, Germany (*Presenter*) Nothing to Disclose

##### PURPOSE

To assess gender-specific differences in aspired academic qualifications and perceived research opportunities.

##### METHODS AND MATERIALS

Questionnaires were sent to radiologists of different career levels via the German Roentgen Society, the European Society of Radiology's Radiological Trainee Forum, the Radiological Society of North America's Resident and Fellow Committee, and manually to 4500 radiologists of the largest German hospitals. Statistical analyses were conducted with age-adjusted regression analyses only for participants from Germany, as international responses were scarce.

##### RESULTS

Of 510 radiologists with German affiliations (female: 237, 46%, mean age 42 ±10 years) men were four times more likely to have a higher academic degree (PD, habilitation) than women (odds ratio 4.39 [95%-confidence interval 2.22-8.67]) and twice as likely to pursue such a degree (2.87 [1.47-5.61]). Stated reasons to pursue further academic qualification (PD) more frequently found among male participants were: to be eligible for a position as leading physician (2.56 [1.07-6.15]) and a research interest (2.36 [1.0-5.57]). There were no gender differences in motivations occurring from an interest in teaching (1.86 [0.84-4.14]), the wish for more opportunities (1.62 [0.73-3.59]), or a higher independency (0.95 [0.44-2.05]). Most male (84%) and female (74%) radiologists were satisfied with possibilities of congress participation. The odds for dissatisfaction were slightly smaller among men than among women (0.62 [0.39-0.98]). Among both genders, dissatisfaction was high concerning time off clinical duties for

research purposes (women: 64%, men 57%; 0.69 [0.41-1.16]). Most female respondents (51%) were dissatisfied with options to be involved in research projects, while most men (61%) were satisfied with them. Differences between both genders were not significant (0.60 [0.35-1.01]). Likewise, dissatisfaction with possibilities to develop their own projects and apply for funding was slightly higher among women (48% vs. 40%) but differences not of statistical significance (0.77 [0.45-1.35]).

## CONCLUSION

Among German radiologists, men pursue academic qualification more frequently, with eligibility for a position as leading physician being a gender-specific motivational difference. Dissatisfaction with research opportunities tend to be higher among women.

## CLINICAL RELEVANCE/APPLICATION

To achieve gender equality in science and among leading academic positions, it is essential to understand differences in motivation and integration in research among male and female radiologists. Women may want more support than currently provided, in terms of integration into research projects, developing their own projects, and applying for funding.

## S3B-SPNPM-Gender Representation in Radiology Practices in the United States

3

### Participants

Elizabeth Dibble, MD, (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate gender representation in radiology practices in the United States

## METHODS AND MATERIALS

The ACR Human Resources Commission fielded the 2022 Workforce Survey 11/2022-12/2022. The sample drew from the ACR members (35,601), non-members (12,551), and RBMA members (1,482). Structured closed-end questions were used, consistent with earlier surveys. Responses were group practice deduplicated and weighted and compared to 2021 survey results.

## RESULTS

524 fully qualified (decision-maker) respondents completed the survey: 77% male and 20% female. 1278 partially qualified respondents completed it: 65% male, 29% female, and .002% nonbinary. Significantly fewer partially qualified respondents preferred not to self-report gender in 2022 vs 2021 (5% vs 8%,  $p=0.0046$ ). 325 respondents answered questions about practice size and gender composition. The median number of non-practice-leader radiologists per practice was 15 (interquartile range (IQR) 7,30); full-time 13 (IQR 6,24), part-time 2 (IQR 0,5). The median number of practice-leader radiologists was 4 (IQR 1,7); full-time 4 (IQR 2,7), part-time 0 (IQR 0,0). These numbers were not different from 2021 ( $p>0.05$ ). Of full-time non-practice-leader radiologists per practice, the median number of females age <40=0 (IQR 0, 1), 40-65=1 (IQR 0, 3), and >65=0 (IQR 0,0); the median number of males age <40=2 (IQR 0,4), 40-65=6 (IQR 3,12), and 66+= 0 (IQR 0,1). The mean number of non-practice-leader radiologists increased slightly from 2021 to 2022 across all ages and represented genders, although this did not reach significance ( $p>0.05$ ). Of full-time practice-leader radiologists, the median number of females age <40=0 (IQR 0, 0), 40-65=0 (IQR 0,1), and 66+=0 (IQR 0,0); the median number of males age <40=0 (IQR 0,0), 40-65=3 (IQR 1,5), and 66+=0 (IQR 0,0). The mean number of practice-leader females increased slightly across all age groups from 2021 to 2022. The mean number of practice-leader males increased for age <40 ( $p=0.0458$ ), decreased for 40-65 ( $p>0.05$ ), and increased for 66+ ( $p>0.05$ ). The mean and median number of radiologists identifying as nonbinary was 0 for all queries.

## CONCLUSION

Female and nonbinary radiologists are underrepresented in radiology practices. Significantly fewer respondents in 2022 preferred not to self-report gender compared to 2021. The median number of female and nonbinary radiologist practice leaders is 0. The mean number of female practice leaders increased slightly across all age groups from 2021 to 2022, although this did not reach significance.

## CLINICAL RELEVANCE/APPLICATION

Female and nonbinary radiologists are underrepresented in US radiology practices in both leadership and non-leadership roles.

S3B-SPNR

### Neuroradiology Sunday Poster Discussions II

#### Sub-Events

#### **S3B-SPNR-1 Association of Body Mass Index and Waist Circumference with Multimodal Magnetic Resonance Imaging Indicators of Brain Health in 9- to 10-year-olds in the US**

#### **PURPOSE**

To investigate the relationship of pre-adolescents' Body Mass Index (BMI) and waist circumference (WC) with magnetic resonance imaging (MRI) indicators of brain health (cortical morphometry, resting-state functional connectivity, white matter (WM) micro- and cytostructure) over two years.

#### **METHODS AND MATERIALS**

We retrieved baseline and two-year follow-up clinical and neuroimaging information of a sociodemographic diverse cohort of 11,878 9- to 10-year-olds enrolled in the Adolescent Brain Cognitive Development (ABCD) study across 21 centers in the US. Inclusion required absence of neurodevelopmental/psychiatric diagnoses and traumatic brain injury. T1- and T2-weighted structural MRI, diffusion tensor imaging, resting-state functional MRI, and restriction spectrum imaging were quantified in a region-of-interest based approach. At both time points, cross-sectional linear regression determined the association of BMI/WC with fractional anisotropy (FA), neurite density (ND), cortical thickness and resting-state functional connectivity, after correction for age, gender, puberty, race/ethnicity, handedness, socioeconomic status and scanner device. In longitudinal analyses, multivariate regression was used to examine associations of baseline BMI with interval changes in neuroimaging metrics.

#### **RESULTS**

At baseline, 4,576 children (48.3% female) at an average age of 10.0 years (7.6 months) were included. 1,567 enrollees aged 12.0 years (7.7 months) had complete follow-up. At both point in time analyses, higher BMI/WC were associated with pervasive bilateral reductions of FA ( $P < .001$ ) as well as ND ( $P < .03$ ). With higher BMI/WC, especially prefrontal cortical thickness was reduced in both hemispheres ( $P < .04$ ). We found predominantly negative associations of BMI/WC with intra- and inter-network functional coupling of salience and cingulo-opercular networks ( $P < .005$ ). Over a mean follow-up period of 23.8 (1.6) months, we observed overall interval cortical thinning and increase in averaged FA and ND. Higher BMI at baseline was associated with lower interval increment in FA and ND of several commissural, projection and association WM tracts as well as reduced interval cortical thinning of prefrontal regions.

#### **CONCLUSION**

Higher BMI and waist circumference among children are associated with reduced WM micro- and cytostructural integrity, cortical thickness, and functional connectivity. Our longitudinal analysis suggests contribution of higher BMI to hindered interval development of WM micro- and cytostructure and cortex morphology.

#### **CLINICAL RELEVANCE/APPLICATION**

Our findings highlight the neurodevelopmental implications of pre-adolescents' higher weight and point to the need for early targeting of brain health indicators.

#### **S3B-SPNR-10 Spatiotemporal Discooordination of Brain Spontaneous Activity in Major Depression Disorder**

#### **PURPOSE**

Major depressive disorder (MDD) is a world-wide debilitating mental illness. Despite extensive research, the pathogenesis of MDD remains unknown. Spatiotemporal psychopathology (STPP) posits that the symptoms of MDD arise from aberrant spatiotemporal experiences in a patient's inner world, which may be reflected by their brain spontaneous activity. In the present study, we aim at determining the spatiotemporal discooordination of MDD patient's brain spontaneous activity using fMRI.

#### **METHODS AND MATERIALS**

91 MDD and 91 demography-matched HC were recruited in this study. The fMRI data were preprocessed via fMRIPrep and the timeseries were extracted over Schaefer400 parcels. Spatiotemporal topology (SPT) of the brain activity was measured by the Euclidean distance of each pair of parcels in a 3-dimension coordinate composed by two functional gradients (Margulies et al., 2016) and time delay (Mitra et al., 2014). SPT was then averaged across Yeo's 7 network atlas, resulting in 7 intra- and 21 inter-network SPT. Repeated measures ANOVA was performed to test the mean difference of the SPTs between MDD and HC. A machine learning approach was employed to investigate the efficacy of SPT in discerning between HC and individuals with MDD.

#### **RESULTS**

A significant difference in network-specific features between MDD and HC was found ( $F(27, 5040) = 2.9, p < .001$ ). Simple-effect test identified four inter-network SPT that showed a significant group effect, including control-somatomotor distance ( $F = 7.3, p = .007$ ), salience-dorsal attention distance ( $F = 11.1, p < .001$ ), salience-visual distance ( $F = 19.2, p < .001$ ), and somatomotor-visual distance ( $F = 19.2, p < .001$ ). The logistic model yielded an accuracy of 0.73 in predicting the group label, and the ROC curve showed an AUC value of 0.86.

## CONCLUSION

s SPT may reflect the homeostatic fluctuation of neuronal activity in the brain, and it is a theoretical-driven measure inspired by STPP. The significant difference in SPT were found in the visual and somatomotor network. The machine learning approach demonstrated the effectiveness of SPT features in differentiating between individuals with MDD and HC. While SPT topology presents theoretical validity and potential clinical value, it is no more than a general evaluation of the current state of the brain. As a result, the precise interpretation of its magnitude and direction is not yet apparent.

## CLINICAL RELEVANCE/APPLICATION

In the long run, SPT topology may serve as an important reference index in diagnosing MDD using low-cost fMRI scans. In addition, SPT topology could potentially function as a prognostic marker for MDD intervention. However, in its current stage, its main value lies in fundamental research, such as enhancing our understanding of the neural abnormalities of MDD.

## S3B-SPNR-11 --Mild Cognitive Impairment in Non-alcoholic Fatty Liver Disease is Associated with Abnormal Resting-state Functional Connectivity Between the Default Mode Network and Regions within the Reward System

Participants

Jie Li, MD, HangZhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

Mild cognitive impairment (MCI) is commonly seen in patients with nonalcoholic fatty liver disease (NAFLD), but the neural mechanisms have not been elucidated. In this study, we used resting-state fMRI (RS-fMRI) to investigate the characteristics of spontaneous neural activity in NAFLD patients with MCI.

## METHODS AND MATERIALS

A total of 74 NAFLD patients and 62 demographic-matched healthy controls (HC) were enrolled. According to the Montreal Cognitive Assessment (MoCA) score, the patients were divided into two groups: 43 patients with MCI\_NAFLD and 31 patients with nonMCI\_NAFLD. All participants underwent 3.0T RS-fMRI scan and neurocognitive psychological assessment, and patients underwent liver MRI proton density fat fraction (PDFF) and blood biochemical indexes measurement. DPABI software was used to process the RS-fMRI data and obtain the whole brain amplitude of low-frequency fluctuations (ALFF) map. One-way analysis of covariance and post-hoc tests were used to compare the differences in ALFF maps among the three groups. The abnormal regions were selected as the regions of interest (ROI) to compare the differences in whole-brain seed-based functional connectivity (FC) between the two patient groups, and the correlation between abnormal FC values and clinical variables was analyzed.

## RESULTS

Compared with nonMCI\_NAFLD patients, MCI\_NAFLD patients had reduced ALFF values in the right cerebellum and right cuneus, and increased ALFF values in the left posterior cingulate gyrus (PCC), and the ALFF values in these different regions were significantly correlated with MoCA scores. Compared with nonMCI\_NAFLD patients, MCI\_NAFLD patients had enhanced FC between the left PCC and the left lingual gyrus, left parahippocampal gyrus, left medial orbitofrontal gyrus, left middle frontal gyrus, left postcentral gyrus and right postcentral gyrus, and reduced FC between the left PCC and the left insula and right supplementary motor area. Among them, the FC values between the left PCC and the regions related to the reward system were correlated with cognitive function, emotional symptoms, PDFF values and insulin function in NAFLD patients. In particular, the ALFF values of the PCC completely mediated the correlation between the FC values between the PCC and the orbitofrontal cortex and MoCA scores.

## CONCLUSION

s The development of cognitive impairment in patients with NAFLD may be closely related to the dysfunction of the default mode network and dopamine pathway, in which visceral fat accumulation and insulin dysfunction also play a crucial role.

## CLINICAL RELEVANCE/APPLICATION

These special neuroanatomical abnormalities may help to shed light on the underlying pathophysiology and manifestations of MCI in patients with NAFLD.

## S3B-SPNR-12 Altered Functional Connectivity of Olfactory Neural Circuits in Subjective Cognitive Decline under Odor Stimulation

Participants

Yajing Zhu, Nanjing, China (*Presenter*) Nothing to Disclose

## PURPOSE

Olfactory involvement is an early feature of Alzheimer's disease. The purpose of this study was to investigate the functional connectivity(FC) changes of olfactory neural circuits in subjective cognitive decline (SCD) in olfactory task fMRI under specific odor stimulation.

## METHODS AND MATERIALS

A total 56 normal controls(NC) and 57 SCD were included.All subjects were tested with cognitive scale, olfactory behavior assessment, and olfactory task fMRI. The FC difference of olfactory neural circuits between the two groups was analyzed by the method of generalized psychophysiological interaction (gPPI).

## RESULTS

There was no significant difference in olfactory behavior between the two groups. In olfactory task-fMRI with specific odor stimulation, the FC from bilateral POCs to the right parahippocampal area in the SCD group was significantly reduced; while the FC from the right hippocampus to the right frontal lobe was significantly enhanced. The connectivities from bilateral POCs to the right parahippocampal area, the right parahippocampal, and the right hippocampal were significantly positively correlated with the memory cognitive threshold; the connectivities from bilateral POCs to the right parahippocampal area, the right parahippocampal, and the right fusiform gyrus were significantly positively correlated with the global cognitive function.

## CONCLUSION

s The olfactory behavior reflects the comprehensive performance of the olfactory function, while the olfactory task-fMRI reflects the FC of the olfactory neural circuits. The results of this study indicate that although the olfactory behavior of SCD is at a normal level, the FC of olfactory neural circuits(POC-hippocampus-frontal lobe) has changed.

## CLINICAL RELEVANCE/APPLICATION

The results of this study suggest that the FC changes of olfactory nerve circuits in SCD subjects under specific odor stimulation conditions, and the correlation between the connectivity of olfactory nerve circuits and the global cognitive function and memory function, prove that the FC changes of olfactory nerve circuits in SCD patients may be used as an early identification marker of high AD risk.

## S3B-SPNR- The Evaluation of Normal Aging on Regional Brain Metabolism as Measured by 18F-FDG Uptake 13

Participants

Eric Teichner, Glen Allen, VA (*Presenter*) Nothing to Disclose

## PURPOSE

To analyze age-related changes in glucose metabolism within nine brain regions using 18F-fluorodeoxyglucose positron emission tomography (FDG-PET), providing insights for recognizing and understanding neurological disease states in the context of normal aging, and laying a foundation for further research in age-related neurological disorders.

## METHODS AND MATERIALS

We included 79 subjects (mean age  $44.5 \pm 13.8$  years, 53.2% males, ages 21-75) with no history of medical conditions that could affect results, which included a negative history of cancer, chronic inflammatory disease, autoimmune disease, immunodeficiency syndromes, alcohol and drug abuse, or cardiovascular disease. Whole-body FDG-PET/CT imaging was performed 180 minutes after administering a 4.0 MBq/kg dose of FDG. Quantitative regional analysis of PET images was conducted using MIMneuro version 7.1.5. Acquired PET data was scaled to injected dose and body weight to produce standardized uptake value (SUV) images. We recorded individual SUVs for nine brain regions: brainstem, cerebellum, frontal lobe, lateral temporal lobe, medial temporal lobe, occipital lobe, parietal lobe, temporal lobe, and thalamus. Pearson's R was calculated, evaluating significance ( $P < 0.05$  threshold) for all variables.

## RESULTS

Age was inversely correlated with regional metabolism in all nine brain regions, showing significant age-dependent reductions of 18F-FDG uptake in brainstem ( $r = -0.323$ ,  $p = 0.004$ ), cerebellum ( $r = -0.338$ ,  $p = 0.002$ ), frontal lobe ( $r = -0.463$ ,  $p < 0.001$ ), lateral temporal lobe ( $r = -0.436$ ,  $p < 0.001$ ), medial temporal lobe ( $r = -0.384$ ,  $p < 0.001$ ), occipital lobe ( $r = -0.392$ ,  $p < 0.001$ ), parietal lobe ( $r = -0.453$ ,  $p < 0.001$ ), temporal lobe ( $r = -0.427$ ,  $p < 0.001$ ), and thalamus ( $r = -0.321$ ,  $p = 0.004$ ). These findings highlight the impact of normal aging on brain metabolism.

## CONCLUSION

s Research regarding the metabolic and physiological changes that occur in healthy individuals allows us to better recognize and understand neurological disease states. Our study demonstrates significant age-dependent reductions of 18F-FDG uptake in the brain among healthy individuals, emphasizing the importance of FDG-PET in understanding normal aging effects on brain metabolism. These findings serve as a foundation for future research in identifying and understanding age-related neurological disorders, ultimately aiding in the development of potential biomarkers and therapies for neurodegenerative diseases.

## CLINICAL RELEVANCE/APPLICATION

Understanding age-related changes in glucose metabolism in healthy individuals using 18F-FDG PET imaging can aid in diagnosing and treating age-related neurological disorders and developing potential biomarkers and therapies for neurodegenerative diseases.

## S3B-SPNR- Altered Hippocampal Intra-networks in Mild Cognitive Impairment: A Structural MRI Study in a 14 General Elderly Japanese Population

Participants

Sera Kasai, Hirosaki-Shi, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Although altered networks inside the hippocampus (hippocampal intra-networks) have been observed in dementia, the evaluation of hippocampal intra-networks using MRI is challenging. We employed conventional structural imaging and incident component analysis (ICA) to investigate the structural covariance of the hippocampal intra-networks. To our knowledge, there have been no population-based studies with large sample sizes to assess the association between MCI status and hippocampal intra-network connectivity. Our aim was to assess whether individuals with MCI have altered hippocampal intra-network connectivity as measured using source-based morphometry (SBM) that is a type of structural network when compared with cognitively normal older adults (CNOA).

## METHODS AND MATERIALS

This was a cross-sectional study of 2122 residents who participated in a population-based prospective study of cerebro- and cardiovascular diseases and dementia in a large population of older Japanese individuals with 3T MRI (median age 69 years, 60.9% female). The participants were divided into 218 patients with MCI and 1904 cognitively normal older adults (CNOA). By employing 3D T1-weighted imaging and ICA, we extracted the structural covariance intra-networks in the hippocampus.

## RESULTS

The ICA extracted 16 intra-networks from the hippocampal structural images, which were divided into two bilateral networks and 14 ipsilateral networks. Of the 16 intra-networks, four (one bilateral network and three ipsilateral networks) were significant predictors of MCI from the CNOA after adjusting for age, sex, education, disease history, and hippocampal volume/total intracranial volume ratio (Figure) ( $p < 0.01$ ). In addition, the networks predicted MCI independent of hippocampal volume ( $p < 0.01$ ), although hippocampal volume was also a predictor of MCI ( $p < 0.01$ ).

## CONCLUSION

s In this population-based study with a large sample size, we extracted four MCI-related hippocampal intra-networks based on SBM, which can be estimated using conventional structural imaging with 3T MRI. These hippocampal intra-networks predicted MCI independently of hippocampal volume, suggesting the altered networks may reflect a different pathology from that of brain atrophy.

#### **CLINICAL RELEVANCE/APPLICATION**

By using conventional structural imaging and ICA, we found that the relationship between hippocampal intra-networks and MCI was independent from the hippocampal volume. This method provides additional information for understanding cognitive impairment.

#### **S3B-SPNR-2 Early ASD Assessment Using DTI Analysis with Machine Learning**

Participants

Mohamed Khudri, Louisville, KY (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Autism Spectrum Disorder (ASD) impacts social skills, repetitive behaviors, speech, and nonverbal communication. Diffusion Tensor MRI (DT-MRI) can aid in accurate diagnosis, and this study aims to create an artificial diagnostic system that extracts connectivity markers from DT-MRI to improve early-stage precision in diagnosing autism.

#### **METHODS AND MATERIALS**

We developed a three-stage system to analyze DT-MRI. Firstly, FSL corrected eddy current distortions and isolated brain tissues from scans. Secondly, connectivity markers (e.g., Fractional Anisotropy, Mean diffusivity) were extracted from different brain regions using the John Hopkins White Matter Atlas. Significant markers were identified through MinMaxScalar and REC-CV feature reduction algorithms. Finally, the extracted features were fed to a Linear Support Vector Machine (LSVM)-classifier to diagnose subjects as ASD or control. Our system was validated through a five-fold cross-validation test on the Autism Brain Imaging Data Exchange-II (ABIDE-II) dataset, consisting of 126 autistic and 100 control subjects.

#### **RESULTS**

The proposed ML-Based system achieved an overall accuracy of 98.5% with a sensitivity of 97% and specificity of 98% on the ABIDE-II database.

#### **CONCLUSION**

s In conclusion, this study demonstrates the potential of DT-MRI in the diagnosis of ASD, and the use of connectivity markers can aid in understanding the development and progression of the disorder.

#### **CLINICAL RELEVANCE/APPLICATION**

Early and accurate diagnosis of ASD is crucial for improving the quality of life for individuals with the disorder. We believe that early intervention can lead to better outcomes, including the potential for individuals with ASD to achieve greater independence and higher IQs.

#### **S3B-SPNR-3 Clinical Quantitative Brain MRI: Quantifying Age-related Changes in Tissue Volume**

#### **PURPOSE**

The volumes of the brain and substructures change continuously throughout the human lifespan. Establishing normal development patterns can be useful for detecting abnormal developmental pathways by comparison. Our goal is to study the pattern of normal brain development for the general population of our hospital as stratified by sex using the high geometrical accuracy and precision of turbo spin echo-based quantitative MRI.

#### **METHODS AND MATERIALS**

This retrospective single-center cross-sectional study was conducted on healthy, ethnically diverse patients with normal brain imaging. The institution's IRB approved the study, and participants were imaged by 3.0-T MRI. Dual-echo turbo spin echo (DE-TSE; PD/T2-weighted) and single-echo turbo spin echo (SE-TSE; T1-weighted) images were used for the MRI parameter calculation. The image processing pipeline (IPP) consisted of a qMRI-based segmentation process that was programmed with Python (version 3.8.11) and the Anaconda Navigator (version 2.2.4). The IPP required a Fiji-based preparation step (version 2.1.1) to edit intracranial matter (ICM), which includes the in toto brain tissue and cerebrospinal fluid (CSF). Then, the IPP was applied consecutively for all subjects' MRIs. Finally, the mean volume for the ICM, brain, white matter (WM), gray matter (GM), and CSF were calculated. Statistical significance and Pearson correlation methods were used for the statistical analysis.

#### **RESULTS**

A total of 277 patients (146 females) with normal brain radiological reports were included in this study leading to 7 decadal age groups. The ICM, brain, GM, and CSF and CSF ventricles volumes were significantly different between the age groups (p-value 0.019, <0.001, <0.001, <0.001, <0.001 respectively). There was a significant negative association between age and the ICM, brain, and GM volumes (p-value 0.008, <0.001, and <0.001, respectively), while there was a significant positive association between age and CSF and CSF ventricles volume (p-value <0.001 and <0.001). Furthermore, the significant correlation between ICM, brain, GM, and CSF, CSF ventricle volumes, and age groups was different for male and female cohorts (0.028 and <0.001s, respectively).

#### **CONCLUSION**

s In an ethnically diverse cohort of 277 patients without neurological findings, we find that the volume of total GM decreases with age and appears to be largely replaced by CSF as the WM volume stays constant after twenty years of age.

#### **CLINICAL RELEVANCE/APPLICATION**

Clinical quantitative brain MRI is a valuable tool for quantifying age-related changes in brain tissue volume, characteristic of normal development, which can aid in early diagnosis and monitoring of age-related neurodegenerative diseases.

#### **S3B-SPNR-4 Evaluation of Brain Stiffness Change According to Brain Development using Virtual MR Elastography Based on DWI**

Participants

You Na Kim, MD, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

## **PURPOSE**

Viscoelastic property of brain have been demonstrated to be affected by aging and various neurological disease. Based on the knowledge that measured mechanical properties of brain reflect the microstructure composition and organization of neural tissue, magnetic resonance elastography (MRE) parameters representing mechanical properties can be a potential imaging marker for brain development. However, conventional MRE acquisition has been limited in children due to its invasive property and long scan time. The virtual MRE (vMRE) is an non-invasive and novel technique to measure tissue mechanical property based on diffusion weighted imaging (DWI). The purpose of this study was to evaluate change of brain stiffness according to brain development in children and young adults using vMRE.

## **METHODS AND MATERIALS**

We retrospectively reviewed 247 children and young adults (6 months~30 years, 119 females, 128 males) without structural brain abnormality. Shifted apparent diffusion coefficient was calculated from DWI ( $b=200$  and  $1500\text{sec}/\text{mm}^2$ ) and converted to DWI-based virtual shear modulus ( $\mu$ ). Brain stiffness was measured in whole brain and thirteen brain regions; cerebrum, cerebral gray/white matter, basal ganglia, thalamus, frontal/ parietal/temporal/occipital lobe, cerebellum, middle cerebellar peduncle, hippocampus, amygdala. Multiple comparison test and linear regression were conducted to investigate changes in brain stiffness according to brain development.

## **RESULTS**

Sexual dimorphism was not observed in any brain region. The virtual shear modulus ( $\mu$ ) of whole brain increased until the age of 16 years and then reached plateau. The DWI based mechanical property parameter of whole brain was increased 1.15% per year ( $R^2=0.642$ ,  $P < 0.001$ ) until 16-year-old. The change of brain stiffness according to brain development showed regional differences. Changes of brain stiffness showed the earliest plateau (8-year-old) in cerebral gray matter and continued to increase in the basal ganglia until 30-year-old. Although steepest increase in occipital lobe (1.85% increase/year,  $R^2=0.659$ ,  $P < 0.001$ ), there was no significant difference in pattern of stiffness change according to brain lobar area.

## **CONCLUSION**

s DWI-based brain stiffness parameters increased with brain development in pediatrics period with differences by region.

## **CLINICAL RELEVANCE/APPLICATION**

DWI-based brain stiffness parameters increased with brain development until 16-year-old and reached plateau. The change of stiffness showed different pattern across the regions.

## **S3B-SPNR-5 Developmental Abnormalities of Cortical Surface Area in Infants with Congenital Heart Disease Associated with Big Motion Impairments**

### **PURPOSE**

Neurodevelopmental abnormalities are the most common non-cardiac complications in infants with congenital heart disease (CHD), motor impairment is one of its common presentation. The cortical development of the infant brain lays the foundation for the individual's neurocognitive behavior. However, studies on the relationship between cortical development and its neural correlates with motor impairments in infants with CHD is still lacking. By utilizing cortical analysis techniques and machine learning methods, this study aims to investigate whether there are developmental abnormalities in cortical surface area in infants with congenital heart disease (CHD), and whether such abnormalities are correlated with big motion impairments.

### **METHODS AND MATERIALS**

In this study, 90 preoperative infants diagnosed with congenital heart disease (CHD) and 86 healthy controls (HCs) between the ages of 12 and 26 months were recruited. T1 and T2 images were acquired using a Philips 3T magnetic resonance imaging scanner. Imaging data were preprocessed using infant FreeSurfer that registered the cortical surface of each subject to the UNC 4D infant template and calculated the surface area of 68 brain regions from DK template. After that, multioutput Gaussian process regression (GPR) was utilized to characterize normative macrostructural development using surface area as inputs and age and sex as predictors. This model was trained on HC subjects and then applied to CHD samples. Individual Z-score maps were computed and extreme deviations from the normative model were calculated by applying a threshold of  $|Z| > 3.1$ . After identifying brain regions with extreme deviations, we further examined their relationship with big motion.

### **RESULTS**

Patient with CHDs shown deviations from normative development in cortical surface area in multiple brain regions including angular gyrus, temporal lobe, middle frontal lobe, precentral and postcentral gyrus in CHDs. Furthermore, significant correlation between abnormal cortical surface area in left precentral gyrus and superiortemporal gyrus and bilateral rostral middle frontal gyrus and big motion scores in CHDs.

### **CONCLUSION**

s Our study demonstrated cortical development abnormalities in infants with CHDs. The significant correlation between abnormal cortical surface area and motor impairments suggested cortical surface area may be an effective predictor of motor function and an important imaging biomarker of future neurodevelopment risk in CHDs.

### **CLINICAL RELEVANCE/APPLICATION**

Our study provides evidence for cortical development delay in infants with CHDs. and supported inclusion of cortical surface area in neuroprotective intervention studies.

## **S3B-SPNR-6 Comparing the Clinical Utility of Linear Versus Volumetric MRI in Enlarged Vestibular Aqueduct Syndrome Patients**

Participants

Amit Gupta, MD, Cleveland, OH (*Presenter*) Nothing to Disclose

## **PURPOSE**

Presently CT is established method (Cincinnati criteria) for diagnosis of EVAS. Recently studies showed that linear measurement on MR are similar to CT in terms of confidence of diagnosis and correlation with audiometric data. The purpose of this study was to confirm validity of linear MR measurements and explore role of volumetric MRI measurements in predicting the hearing outcomes in patients with EVAS.

## **METHODS AND MATERIALS**

A retrospective study design was used including 30 patients that fit the inclusion criteria for a total of 46 ears. Linear measurements were made using the vestibular aqueduct (VA) midpoint and VA opercular widths for determination of EVAS. Semiautomatic volumetric measurements were calculated from all slices containing both the VA and endolymphatic sac (VA-ELS) using MIM Software Platform (MIM Software Inc.). Air and bone conduction data was collected from medical records. Univariate and multivariate analyses were performed to assess for a correlation between volumetric measurements and audiometric hearing outcomes.

## **RESULTS**

Of the study population, 16 patients demonstrated bilateral EVA (53.3%). Average VA volume estimated by volumetric MRI analysis was 0.19 mm<sup>3</sup>; sd = 0.17 mm<sup>3</sup>. Volumetric MRI measurements significantly correlated to both midpoint length and operculum size for EVAS diagnosis. Univariate analysis and multivariate analyses adjusting for age, race, and gender did not reveal significant correlations between volumetric MRI measurements and audiometric hearing outcomes. Midpoint size and operculum size correlated only weakly with low frequency bone conduction hearing outcomes.

## **CONCLUSION**

These results suggests an excellent correlation between the linear and volumetric measurements for diagnosis of EVAS, however, with an unclear role for both MRI measurements in the predicting hearing outcomes. In our study, neither linear nor volumetric measurements showed strong correlations with audiometric hearing data.

## **CLINICAL RELEVANCE/APPLICATION**

Given the 3D structure of the VA-ELS, volumetric measurements may improve MRI diagnostic utility in EVAS. This study warrants further research into the relationship VA-ELS structure and hearing outcomes, and questions the previously published results on this topic.

## **S3B-SPNR-7 A Normative Model of the Brain from the Adult Colombian Population**

Participants

Jon Duque-Grajales, MEng, Medellin, Colombia (*Presenter*) Nothing to Disclose

## **PURPOSE**

The brain changes throughout life. There is an increasing interest in development of normative models based on anatomical brain features, which are related to the genetics of the population (Elliott et al. Nature, 2018). However, the normative models published so far have been mostly based on European descent population (Bethlehem et al. Nature, 2022, Rutherford et al. Elife, 2022). Here, we propose a normative model of brain aging in a Colombian adult population based on their brain volumes.

## **METHODS AND MATERIALS**

2256 healthy participants (age range: 18 - 80 years; 1058 females) were selected based on their radiological report in a retrospective cross-sectional study. This study was approved by the institution's ethical committee. Brain anatomical T1w MR were processed using FSL (V.5) (Smith et al. Neuroimage, 2004). The preprocessing included tissue segmentation and subcortical structures extraction. Additionally, we aggregate all the volumes in a new parameter, the delta age, defined as the deviation of the predicted age by a multiple linear model between the age and the volume of all brain structures. Participants with volumes above or below five mean absolute deviations from the mean population for the same sex were discarded. Six different models were evaluated as normative models based on their standardized mean squared error (SMSE) derived from a random five-fold cross-validation: centiles, locally estimated scatterplot smoothing (LOESS), Gaussian process (GP), generalized additive models of location shape and scale (GAMLSS) and linear quantile regression (quant).

## **RESULTS**

We derived one normative model per sex due to gender differences in 7 out of the 10 brain structures analyzed ( $p < 0.05$ ). Besides the GP model, all models had similar SMSE values for every structure (SMSE range, female: 0.684 - 1.136, male: 0.698 - 1.165). However, the LOESS model showed a consistent minimum SMSE across structures, having the best performance with the delta age.

## **CONCLUSION**

The LOESS model provided a consistent minimum SMSE across all brain structures. Nevertheless, the use of a composed metric aggregating the volumes from all brain structures, the delta age, outperformed the performance of the model on individual brain structures. Therefore, we propose a normative model of brain aging in a Colombian adult population based on a LOESS model in terms of the delta age, that could be evaluated on a larger dataset.

## **CLINICAL RELEVANCE/APPLICATION**

We derived a normative model of brain aging in a Colombian adult population based on the brain volume of different structures, providing a reference of brain aging which could highlight deviations from it in neurodegenerative and mental disorders.

## **S3B-SPNR-8 Can fMRI be Used to Develop Neuroimaging Biomarkers for the Risk of Developing Schizophrenia? A fMRI Study Investigating Neural Context-adaptation in Visual Perception, Object Categorization, and Reward Processing Across the Schizotypy Spectrum**

Participants

Anna Giarratana, MD, PhD, North Brunswick, NJ (*Presenter*) Nothing to Disclose

## PURPOSE

Schizophrenia can be understood to exist on a spectrum; from non-clinical individuals with higher levels of schizotypal personality traits to patients with schizophrenia. Studying schizotypy in non-clinical populations can be extremely informative, given that schizotypy is positively correlated with an increased liability for the eventual development of a schizophrenia spectrum disorder. By studying schizotypy, researchers may be able to detect biomarkers for early detection of psychosis and identify brain regions that may be targets for treatment. Our lab previously found using fMRI, that neural adaptation to reward range is impaired in both healthy individuals with stronger schizotypal personality traits and in patients with schizophrenia. However, it remained unclear whether these deficits are limited to the reward domain, or extend to other domains as well. To this end, we undertook the larger fMRI study described here.

## METHODS AND MATERIALS

We recruited 98 participants who scored within the top 10%, bottom 10%, and middle 20% of the schizotypy scale as assessed by the Schizotypal personality questionnaire - brief revised (BPQ-BRU). Participants underwent three different tasks while in the fMRI. We investigated reward processing, utilizing a variant of the Monetary Incentive Delay task previously used in our lab. We investigated visual processing, using a task previously used in a collaborators lab based on the concept of surround suppression. Finally, we investigated object categorization, using a novel face-house identification task we developed for this purpose.

## RESULTS

We find that participants exhibit neural adaptation in the context of reward, visual processing, and object categorization. However, while our previous studies showed that reward range adaptation is impaired in individuals with higher schizotypy, we find no such deficit in visual processing or object categorization.

## CONCLUSION

Our findings suggest that the inability of those on the schizophrenia spectrum to adapt to the range seen in reward tasks does not generalize to the visual domain. These results may indicate that the deficits seen are specific to the dopamine reward pathways of the brain.

## CLINICAL RELEVANCE/APPLICATION

These findings highlight reward adaptation as a possible functional neuroimaging biomarker, and a potential target for future studies to investigate interventions (i.e. behavioral interventions or brain stimulation) in an effort to decrease progression along the schizophrenia spectrum.

## **53B-SPNR-9 Multi-site rTMS Combined with Cognitive Training Modulates Effective Connectivity in Patients with Alzheimer's Disease**

### PURPOSE

Alzheimer's disease (AD) is an irreversible neurodegenerative disorder with recent understanding as a disconnection syndrome. As pharmacotherapy for AD is currently limited, attention has been paid to non-drug adjuvant interventions such as repetitive transcranial magnetic stimulation (rTMS). Multi-site rTMS associated with cognitive training (rTMS-COG) therapy has been shown to be probably effective for AD patients at early-stage. rTMS has been approved to be able to modulate local activity in a remote area that is functionally connected to cortical stimulation targets. However, the causal interactions between the stimulation targets and other brain regions has yet to be explored. The purpose of this study is to investigate the effective connectivity (EC) changes after multi-site rTMS- COG therapy.

### METHODS AND MATERIALS

Written informed consent of all participants were obtained according to the declaration of Helsinki before enrollment. 10Hz rTMS over left dorsal lateral prefrontal cortex (DLPFC) and lateral temporal lobe (LTL) were delivered for 4 weeks with COG. AD patients were divided into real (real rTMS+COG, n=11) or sham (sham rTMS+COG, n=8) group to underwent neuropsychological assessment, resting-state fMRI and 3D brain structural imaging before (T0), immediately at the end of (T4), and 4 weeks after treatment (T8). A 2x3 factorial design with "time" as within-subject factor (3 levels: T0, T4, T8) and "group" as between-subject factor (2 levels) were used to investigate the EC changes related to stimulation targets on the rest of brain, as well as the causal interactions among 7 resting state networks based on granger causality analysis (GCA).

### RESULTS

At voxel-level, the EC changes from left DLPFC out to left inferior parietal lobe and left superior frontal gyrus, as well as from left LTL out to left orbital frontal cortex had significant group x time interaction effect. At network level, significant interaction effect has been identified on the EC increment from limbic network out to default mode network. The EC decrease at voxel level and EC increase at network level were all associated with better functioning in the ability of daily living and cognition.

### CONCLUSION

Multi-site rTMS combined with cognitive training could modulate effective connectivity in patients with AD, doing better for the ability of daily living and cognitive function. Due to the longitudinal design, the sample size is limited. Further multi-center cohort study was further needed to validate our pilot study.

### CLINICAL RELEVANCE/APPLICATION

This study provides a novel explanation for the neurobiological mechanisms of multisite rTMS-COG therapy in AD patients and further shed light on the direction of targeted brain network modulation in future.

#### **S3B-SPOB-1 Risk of Malignancy in Ovarian-Adnexal Imaging Reporting Data System (O-RADS) Ultrasound (US) version 2022 Score 2 Unilocular and Bilocular, Smooth Ovarian Cysts Without Solid Components**

##### Participants

Luyao Shen, MD, Sunnyvale, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

Ovarian-Adnexal Imaging Reporting Data System (O-RADS) Ultrasound (US) version 2022 (v2022) downgraded smooth bilocular cysts without solid components <10 cm to the O-RADS US 2 with a lower expected risk of malignancy (ROM) of <1% based on results from IOTA5 trial (Timmerman et al. JAMA Oncol. 2023;9(2):225-233). We aim to assess the ROM of unilocular and bilocular, smooth cysts without solid components <10 cm in a non-selected patient population presenting to academic radiology departments in the United States.

##### METHODS AND MATERIALS

In this IRB-approved, retrospective study from 6 institutions, pelvic US over 5 years were consecutively reviewed to include exams with ovarian cystic lesions. Lesions without surgical, imaging, or clinical follow-up were excluded. Malignant lesions were diagnosed by histopathology, and benignity determined by histopathology, diagnostic on CT/MRI, resolution, decreased size >10%, or stability by imaging or normal clinical exam >2 years. Investigators blinded to the final outcome recorded imaging features and scores per the O-RADS US. Mann-Whitney and Fisher's exact tests were performed (two-tailed  $p < 0.05$  significant).

##### RESULTS

Of 14302 pelvic US reviewed, 913 patients had cystic ovarian lesions. Of those, 319 patients with 337 cystic lesions with smooth walls and septations without solid components <10 cm were included. The median age was 45 years (interquartile range 35-53), and there were 212 (66%) pre-menopausal and 107 (34%) post-menopausal patients. There were 292 unilocular cysts (275 patients) and 45 bilocular cysts (45 patients). Differences in patient age, menstrual status, and lesion size were not statistically significant between the 2 groups ( $p = 0.633$ ,  $0.865$ , and  $0.845$ , respectively). The ROM was 0.3% (1/292) for unilocular cysts and 2% (1/45) for bilocular cysts. ROM was not statistically significant between the 2 groups ( $p = 0.250$ ). The 2 malignant tumors (1 unilocular, premenopausal patient, and 1 bilocular cyst, postmenopausal patient) were both borderline serous tumors.

##### CONCLUSION

A 2% ROM was noted with bilocular cysts in our cohort, which is higher than expected range for O-RADS US v2022 score 2 (<1%). ROM difference between unilocular and bilocular, smooth ovarian cysts without solid components <10 cm is not statistically different. Further investigations in a larger cohort should be undertaken to confirm these initial results.

##### CLINICAL RELEVANCE/APPLICATION

In bilocular, smooth cysts without solid components, measuring less than 10 cm, the ROM is greater than the O-RADS US v2022 expected range of <1%. Borderline tumors can have this morphology. Our results suggest further investigation in a larger cohort is needed to help determine the appropriate risk categorization for bilocular cysts.

#### **S3B-SPOB-2 Ovarian-Adnexal Reporting and Data System (O-RADS) MRI Score Effects of DWI and ADC Values**

##### Participants

Marco Gennarini, Rome, Italy (*Presenter*) Nothing to Disclose

##### PURPOSE

The aim of this study is to evaluate the potential of integrating diffusion-weighted imaging (DWI) and quantitative assessment of apparent diffusion coefficient (ADC) into the O-RADS MRI system for prognostic purposes. Subsequently, to evaluate the validity and reproducibility of this approach among operators with different levels of experience in female pelvic imaging and to identify any correlations between the histology of malignant lesions and ADC values.

##### METHODS AND MATERIALS

The study included 173 patients with 213 indeterminate masses in the adnexa that underwent MRI examination between January 2015 and June 2022. 140 patients with 172 masses met the inclusion criteria, which required them to be over 18 years old, have undergone a standard MRI exam, have no acute symptoms, and have had subsequent surgery with histopathological examination or stable follow-up for at least one year. Two radiologists with 4 and 1 year of experience in female pelvic imaging, respectively, blindly evaluated all masses according to the O-RADS MRI score system. To perform a quantitative analysis, a circular ROI was placed on the ADC map obtained from single-exponential DWI. If the lesion had multiple solid components, 4 to 6 ROIs were placed, and the ROI with the lowest ADC value was recorded. Lesions without enhanced solid tissue, with fluid, adipose, blood or fibrotic content, were considered benign (O-RADS 2) and excluded.

## RESULTS

The study showed excellent agreement between the two radiologists in classifying adnexal masses according to the O-RADS MRI score system ( $K = 0.936$ ; 95% CI). Two ROC curves were used to determine the best cut-off value for the ADC between O-RADS MRI categories 3-4 and 4-5, which allowed for some masses to be upgraded or downgraded compared to their original classification. The AUC for O-RADS MRI scores 3 and 4 was 0.951, with an optimal ADC cut-off value of  $1.411 \times 10^{-3} \text{ mm}^2/\text{sec}$ . Three adnexal masses originally classified as O-RADS MRI score 3 were upgraded to score 4, and four lesions with an ROI ADC  $> 1.411 \times 10^{-3} \text{ mm}^2/\text{sec}$  were downgraded to score 3. All 30 adnexal lesions classified as O-RADS MRI score 5 remained in that category. The AUC for O-RADS MRI scores 4 and 5 was 0.630, with an optimal ADC cut-off value of  $0.849 \times 10^{-3} \text{ mm}^2/\text{sec}$ . Twenty-two adnexal masses originally classified as O-RADS MRI score 4 were upgraded to score 5, and 36 adnexal lesions, in accordance with TIC type 2, remained in O-RADS MRI score 4. There was a significant correlation between ADC values and the histotype of ovarian carcinoma ( $p \text{ value} < 0.001$ ).

## CONCLUSION

Our research reveals how DWI and ADC values can provide valuable prognostic information for the O-RADS MRI classification, leading to improved standardization and characterization of adnexal masses.

## CLINICAL RELEVANCE/APPLICATION

### S3B-SPOB-3 Comparison of O-RADS and Simple Rules Ultrasound Classifications to Predict Adnexal Malignancy

Participants

Andrew Nanapragasam, FRCR, London, United Kingdom (*Presenter*) Nothing to Disclose

## PURPOSE

This study compares performance of US O-RADS (version 2022) and Simple Rules (SR) criteria in a cohort of asymptomatic pathology-proven adnexal masses and evaluates O-RADS and SR inter-observer agreement in a subset of patients.

## METHODS AND MATERIALS

We conducted retrospective analysis in consecutive patients who underwent surgical resection between January 2008 and December 2018 at two adult university hospitals. US cine clips were available for all examinations. One experienced radiologist, blinded to diagnosis, categorized all US imaging by O-RADS and SR criteria. SR assessment assigned the following features as benign: unilocular/multilocular cyst with uniform thin septa irrespective of cyst content/size; cystic or solid mass with attenuating component; cystic mass with  $< 3 \text{ mm}$  nodule(s) or completely calcified nodule(s). Malignant features included: non-attenuating solid mass; cystic mass with non-attenuating nodule, nodule(s)  $\geq 3 \text{ mm}$ ; multilocular cysts with septa too close to be distinctly seen. A subset of cohort was randomly selected and reviewed by two blinded radiologists with fewer years of experience. Chi-square testing was used for comparison of ratios, and Kappa statistic for inter-observer agreement.

## RESULTS

791 adnexal masses in 762 patients were assessed, aged 18-92 ( $44 \pm 15$ ); 628 benign, 49 LMP, 114 malignant, measuring 1 to 39 cm ( $7.9 \text{ cm} \pm 4.2$ ). O-RADS categories were 2 ( $n=309$ ), 3 ( $n=165$ ), 4 ( $n=181$ ), 5 ( $n=136$ ) with malignant rates of 0.3%, 3%, 25%, and 82% respectively. Application of simple rules criteria identified 561 masses as benign and 230 as malignant. Combining O-RADS 4 and 5 categories as being malignant, sensitivity, specificity, NPV, PPV, and accuracy to detect invasive/LMP masses were 96% (CI:92-99%), 75% (CI:71-78%), 99% (CI:97-100%), 49% (CI:44-55%), and 79% (CI:76-82%). Corresponding results for SR were 96% (CI:91-98%), 89% (CI:85-91%), 99% (CI:98-100%), 68% (CI:61-74%), and 90% (CI:87-92%) with specificity, PPV, accuracy of SR being statistically significantly higher than O-RADS ( $p < 0.0001$ ). Inter-observer agreement between the three readers were 0.89, 0.91, and 0.93 for SR benign versus malignant categories and 0.71, 0.75, and 0.75 for O-RADS 2/3 from O-RADS 4/5.

## CONCLUSION

Adnexal mass ultrasound assessment with SR performs significantly better than O-RADS classification for specificity, PPV, and accuracy with similarly high sensitivity and NPV. High inter-observer agreement was found with both SR and O-RADS.

## CLINICAL RELEVANCE/APPLICATION

US risk stratification by experienced radiologists using SR criteria outperforms O-RADS and can result in a better triaging of patients to gynecologists versus gynecologists by predicting a more precise rate of malignancy.

S3B-SPPD

### Pediatric Imaging Sunday Poster Discussions II

#### Sub-Events

#### **S3B-SPPD-1 Reducing Iodine Load and Radiation Dose in Infants with Congenital Heart Disease with a Combination of 70kV Tube Voltage and Adaptive Statistical Iterative Reconstruction-V**

##### Participants

Chenglong Li, Xu Zhou, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To assess the effect of reduced iodine load to contrast enhancement and image quality of 70 kV tube voltage setting and adaptive statistical iterative reconstruction V (ASIR-V) technique in children with congenital heart disease(CHD).

##### METHODS AND MATERIALS

Totally 42 infants less than 2 year old with complex CHD were enrolled. All children were scanned at 22 noise index levels of automatic current modulation with 70kV on 256-row CT scanner. And pre-setting 50% ASIR-V was adopted to further reduce radiation dose. Two contrast protocols were set: group A, 350 mg I/mL of contrast media at a dose of 1ml/kg; group B: 270 mg I/mL of contrast media at a dose of 1ml/kg; Patients were selected to any one of the protocols randomly. Objective image qualities (density, noise) were measured in the great vessels and heart chambers by two experienced radiologists. The contrast-to-noise ratio (CNR) was calculated by measuring the density and noise of myocardial walls. Image quality was assessed by a five-point score. A score of <3 represents non-diagnostic. Effective radiation dose (ED) was calculated. Weighted Kappa test was used to analyze the image-reviewing consistency of the two reviewers.

##### RESULTS

The image-reviewing results of the two physicians showed good consistency ( $K=0.747$ ). Image quality score of 350mgI group and 270mgI group were  $4.3 \pm 0.3$  and  $4.1 \pm 0.4$  ( $p > 0.05$ ), respectively. For 350mgI group, CT values were  $436.50 \pm 89.5HU$ ,  $424.23 \pm 89.8HU$  and  $486.77 \pm 130.47HU$  in ascending aorta, descending aorta and pulmonary artery trunk, respectively. For 270mgI group, CT values were  $324.15 \pm 48.21HU$ ,  $312.37 \pm 67.7HU$  and  $326.77 \pm 90.45HU$ , respectively. However, all subjects showed at least more than standard diagnostic acceptability. The average ED (median) of 350mgI group and 270mgI group were  $0.48 \pm 0.15$  mSv and  $0.37 \pm 0.13$  mSv ( $P < 0.01$ ).

##### CONCLUSION

The use of low-tube-voltage combined with ASIR-V and low-dose contrast agent can reduce radiation dose and contrast medium without sacrificing image quality.

##### CLINICAL RELEVANCE/APPLICATION

Radiation dose and iodine load can be reduced in infants with congenital heart disease using 70 kVp and ASIR-V technique without compromising the contrast enhancement, image quality and diagnostic accuracy.

#### **S3B-SPPD-2 Automated Reconstruction and Segmentation of High-isotropic-resolution Fetal Brain MRI Data for Quantitative Brain Morphological Analysis**

##### PURPOSE

Fetal MRI has gained increasing importance in prenatal diagnosis because of its superior soft tissue contrast. To compensate for fetal and maternal motion and limited spatial resolution, two-dimensional (2D) images are acquired across each anatomical direction. In this study, we develop and present an automated pipeline that reconstructs a high-isotropic-resolution fetal brain volume from three 2D thick-slice images and segments it into multiple brain structures using state-of-the-art MR image analysis methods. The accuracy of the pipeline is validated by evaluating the correlation between brain structure volumes and gestational age.

##### METHODS AND MATERIALS

Sixty pregnant women with normal fetal brain, aged between 20 to 36 weeks of gestation, were enrolled with informed written consent and IRB approval to obtain T2-weighted images along axial, coronal, and sagittal directions using a turbo spin echo (TSE) sequence. The NiftyMIC method was employed to perform slice-to-volume motion correction and reconstruct a single fetal brain volume at 0.8 mm isotropic spatial resolution from the three 2D TSE images. The reconstruction process included brain masking, bias-field correction, volumetric reconstruction in each subject's native space, and transformation to the template space. A deep learning-based segmentation neural network named FetalBrainParcellation was then utilized to segment each high-resolution brain volume into eight brain structures, including cortical grey matter, deep grey matter, white matter, corpus callosum, brainstem, cerebellum, intra-axial cerebrospinal fluid (CSF), and extra-axial CSF. Finally, the Pearson correlation coefficient between the volume of each brain structure and the gestational age was computed.

##### RESULTS

The quality of reconstruction and segmentation results of all 60 subjects were visually confirmed by two expert pediatric

radiologists . The volume of each brain structure was highly ( $r>0.9$  for five structures,  $r>0.8$  for seven structures) and significantly ( $p<0.001$ ) correlated with the gestational age, which was consistent with previous studies.

#### **CONCLUSION**

s This study introduced a pipeline that automatically reconstructed and segmented fetal brain volumes and validated its robustness and accuracy for quantitative morphological analysis of normal fetal brains.

#### **CLINICAL RELEVANCE/APPLICATION**

The automated pipeline developed for reconstructing and segmenting fetal brain MRI data provides a novel tool for quantitative morphological analysis of fetal brains, which can aid in diagnosis and prognosis. Further research will assess its validity for fetal brains with pathologies and explore its potential clinical applications.

### Physics Sunday Poster Discussions II

#### Sub-Events

#### S3B-SPPH-1 Evaluating ChatGPT's Performance on a Radiology-physics Question Set

##### Participants

Jaydev K. Dave, PhD, Rochester, MN (*Presenter*) Research Grant, Koninklijke Philips NV; Equipment support, Lantheus Medical Imaging; Equipment support, General Electric Company; Research Consultant, Curvebeam LLC; Consultant, Rayscan, Inc.

##### PURPOSE

Recent reports have evaluated ChatGPT's (OpenAI, San Francisco, CA) performance on several standardized examinations. The purpose of this work was to evaluate the performance of this text-based AI language model on a radiology-physics question set.

##### METHODS AND MATERIALS

A radiology-physics question set with 135 questions (RAPHEX, Radiological and Medical Physics Society of New York) was used to assess ChatGPT's performance. All questions were in the multiple-choice format with single correct answer and three to four distractors. The questions covered different imaging modalities, and included questions with images ( $n = 27$ ), calculations ( $n = 36$ ), and regulatory limits/accreditation requirements ( $n = 17$ ). Freely available, March 23, 2023 version of ChatGPT was used in this study. The questions were entered in multiple choice format with the stem and the options into the chat dialogue box. The responses were evaluated and scored. The justification provided in the ChatGPT responses was also reviewed for correctness.

##### RESULTS

Out of 27 image-based question, there were 8 questions in which interpretation of images was required and given that images are not accepted as input in ChatGPT, there were no responses for these questions. Thus, these 8 questions were not considered in the scoring. Other image-based questions either included description of artifacts/image content in the question stem or images with tabulated data. For these questions, responses were provided by ChatGPT and so these were included for assessment. From the 127 questions included in the analysis, correct responses/explanation were obtained for 79 (62.2%). For 2 questions the correct responses were obtained; however, the justification was incorrect. Evaluating the proportion of correct responses as a function of question type revealed that correct responses were obtained for 63.2% of the questions with images (12/19), 50.0% of the questions that involved calculations (18/36), and 35.3% of the questions involving regulatory limits/accreditation requirements (6/17). Modality-wise, the proportion of correct cases was 88% for radiography, 50% for mammography, 36% for fluoroscopy, 60% for computed tomography, 83% for ultrasound, 67% for magnetic resonance imaging, 43% for nuclear medicine, and 72% for fundamental questions including safety and radiobiology.

##### CONCLUSION

Leaving aside questions that rely on image interpretation, ChatGPT scored 62.2% on a radiology-physics question set covering different modalities and question categories. Image-interpretation questions remain unanswered.

##### CLINICAL RELEVANCE/APPLICATION

Analyzing the performance of chatbots will help target evaluation criteria for maintenance of certification/online longitudinal assessment.

#### S3B-SPPH-10 Opportunistic Osteoporosis Screening with Bone Mineral Density Estimation on Computed Tomography using Multi-View Semi-Supervised Learning

##### Participants

Heng Guo, Hangzhou, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Computed tomography (CT) scans, which are widely used for other indications, can provide added-value for osteoporosis screening. We propose a novel method for estimating bone mineral density (BMD) using routine CT scans.

##### METHODS AND MATERIALS

We proposed DeepBMD that consists of automatic spine vertebrae instance segmentation and BMD regression in this work. Patients who underwent both a routine CT and a Dual-energy X-ray Absorptiometry (DXA) examination within one month between December 2020 and December 2022 were retrospectively included. This led to 3,586 CT scans (81% chest CT, 19% abdomen CT) and 3,805 DXA results with lumbar BMD values (L1 - L4). After excluding scans with low quality, metal implants and bone fractures, a dataset of 2,633 CT-DXA pairs in patient-level were obtained. An automated vertebrae instance segmentation tool was developed to distinguish vertebrae with DXA gold-standard or not. Finally, we got 4,889 vertebrae with DXA gold-standard, and 30,400 not. The paired dataset was randomly split into 60%, 10%, and 30% for training, validation, and testing. We developed a multi-view semi-supervised learning framework for BMD regression. Specifically, 3D and 2.5D vertebrae patches were extracted under different augmentation parameters. A hybrid network consisting of a CNN and a Vision Transformer was used to extract features. For

vertebrae without gold-standard, pseudo BMDs would be generated. An experienced clinical expert specialized in orthopedics checked the vertebrae identification results. The Pearson correlation coefficient, sensitivity, specificity, area under receiver operating characteristics (AUC) are reported.

## RESULTS

There are 1,005 osteoporotic patients (group A) and 1,628 non-osteoporotic patients (group B) in our dataset. Females account for 68.6% in group A and 48.6% in group B. The average ages of group A and group B are 65.56(±8.59) and 62.17(±9.12). For vertebrae identification, DeepBMD achieves a success rate of 98.7%, indicating that it is robust and reliable. DeepBMD achieves a great correlation coefficient of 0.909 on the testing set. According to the literature that a T-score of less than or equal to -2.5 is considered to be osteoporotic, DeepBMD achieves a sensitivity of 0.87, specificity of 0.90, and AUC of 0.96 for osteoporosis screening.

## CONCLUSION

The predictions of the proposed algorithm exhibit a strong correlation with DXA and can facilitate opportunistic osteoporosis screening.

## CLINICAL RELEVANCE/APPLICATION

Using routine CT for BMD estimation can provide the added-value for opportunistic osteoporosis screening. Beyond evaluating BMD in the lumbar vertebrae, our method can also assess the thoracic vertebrae, providing patients with a more comprehensive evaluation of their spine health.

## S3B-SPPH- 11 Development of a TOPAS Monte Carlo Model of a C-arm Cone Beam CT (CBCT) for Organ Dose Estimation

### PURPOSE

C-arm cone beam computed tomography (CBCT) used in an interventional radiology (IR) setting provides the radiologist with cross sectional images to assist in performing and verifying a radiological intervention. To accurately estimate the radiation dose to the patient, knowledge of the doses delivered to major radiosensitive organs is required. However, the current approaches for CBCT dosimetry are still under development. Replication of system specific complexities such as automatic exposure control (AEC), rotational geometries, beam hardening and scatter contributions make the simulation and estimation of CBCT radiation doses challenging. The main aim of this research was to develop a novel TOPAS Monte Carlo (MC) dosimetry model of a C-arm CBCT incorporating AEC, and validate it with measurements using an anthropomorphic phantom.

### METHODS AND MATERIALS

A MC model of a Siemens Artis Q C-arm CBCT system [Siemens, Erlangen, Germany] was developed in TOPAS, version 3.9. A TOPAS extension to incorporate AEC functionality was implemented into the MC model. The system's energy spectrum, CBCT rotational parameters, system geometry and tube filtration were simulated according to manufacturer specifications. Experimental data was obtained using the Body CBCT protocol and a physical CIRS ATOM® adult female anthropomorphic phantom. Verification of the dose distribution and AEC functionality of the MC model was carried out using thermoluminescent dosimeters (TLDs) placed in the tissue-equivalent organ sections of the phantom mimicking patient organs. Measured doses were compared with MC simulated doses for different sites within the phantom acquisitions.

### RESULTS

This study presents details of the development of a novel AEC module in TOPAS MC simulations for incorporation into a C-arm CBCT MC model. The AEC module, the first of its kind, will shortly be released for public use in TOPAS. The CBCT MC model has been applied to abdominal acquisition protocols in IR and validated through anthropomorphic phantom dose distributions and organ dose measurements.

### CONCLUSION

A novel AEC module has been successfully developed in TOPAS which can be easily incorporated into other imaging application models that employ such dose modulation. The MC model allows for a more realistic dosimetry estimation, advancing the current CBCT dosimetry approaches.

### CLINICAL RELEVANCE/APPLICATION

Few studies have documented radiation doses from C-arm CBCT exposures in adults. The novel AEC module developed in this research, and its validation using an anthropomorphic phantom, is a step towards personalised dosimetry in CBCT.

## S3B-SPPH- 12 Development of an Ultra-high-Resolution Dental Cone-beam CT System

### PURPOSE

The dental cone-beam computed tomography (DCBCT) systems have been clinically used since early 2000s. They provide detailed images that can help dentists diagnose and plan treatment for different dental conditions. The spatial resolutions of DCBCTs are generally higher than those of multi-slice CT systems; however, the spatial frequency limits evaluated by 5% modulation transfer function (5%MTF) are approximately 2 mm<sup>-1</sup> and those are not necessarily sufficient for observing micro structural abnormalities in oral region. This study aimed to develop a new DCBCT (DCBCTnew) that achieves a 5%MTF significantly higher than that of conventional DCBCT (DCBCTc) without increasing the radiation dose.

### METHODS AND MATERIALS

A contact geometry, in which the X-ray detector is close to the object, for reducing the focus penumbra was adopted in this system. Furthermore, since the dentition is generally located anteriorly in the head, a half scan orbit was used to prevent collisions between the occipital region and the detector. The scan duration was 6.5 s; during that, projection data with 520 views were obtained using a CsI-based detector with 1488 × 660 pixels. The pixel size at the iso-center was 0.081 mm. For the DCBCTnew and a DCBCTc, MTFs were measured from images obtained by scanning a copper wire with a diameter of 0.1 mm. The radiation dose of DCBCTnew was measured according to the standard method for the weighted CT dose index (CTDI<sub>w</sub>); then, the effective dose was estimated from the result. An oral region in an anthropomorphic head phantom was scanned using both DCBCTnew and DCBCTc.

## RESULTS

The 5%MTF of DCBCTnew was 3.80 mm<sup>-1</sup>, which was more than twice that of DCBCTc (1.65 mm<sup>-1</sup>). The estimated effective dose of DCBCTnew was 0.084 mSv which was significantly lower than reported ones (around 0.2 mSv) of the DCBCTc. The phantom images of DCBCTnew were remarkably sharper and clearer compared to those of DCBCTc.

## CONCLUSION

The developed DCBCT presented significantly higher spatial resolution and more suitable dental CT images to observe micro structures with a lower radiation dose, compared to a conventional DCBCT.

## CLINICAL RELEVANCE/APPLICATION

The developed DCBCT was able to provide high-resolution images with low dose scanning. This result suggested that there are sufficient rooms to improve the image quality of current clinical DCBCT systems.

## S3B-SPPH-13 A Dose Based Method to Optimize Virtual Monoenergetic Cone-beam Computed Tomography Imaging Parameters for Image-guided Radiotherapy

### PURPOSE

This study aims to optimize Virtual Monoenergetic (VM) cone-beam computed tomography (CBCT) protocols for Image Guided Radiation Therapy (IGRT) as functions of exposure and single frame acquisition rate while minimizing patient imaging dose.

### METHODS AND MATERIALS

First, 7 CBCT sets acquired at 80 kVp and 140 kVp with various exposures and frame rates were used to determine the average normalized Air Kerma (K<sub>air</sub>) per exposure (mAs) for the X-ray Imaging (XI) system of a Truebeam linac (Varian Medical System, CA) with a calibrated 0.6cc air Kerma Farmer chamber. Then, 6 combined dual (80 and 140 kVp) energy CBCT protocols were optimized, ensuring that their estimated cumulative K<sub>air</sub> resulted in a lower imaging dose than K<sub>air</sub> of the default 140 kVp-Pelvis CBCT protocol (K<sub>air</sub> =133 mGy). VM-CBCT projection images of a Catphan 604 (Phantomlab, NY) at specific energies were generated from DE-CBCT, and then were reconstructed using the Feldkamp-Davis-Kress (FDK) algorithm within an open-source TIGRE toolbox. The quality of VM-CBCT images at 50 keV were evaluated using quantitative metrics such as Hounsfield units (HU), contrast-to-noise ratios (CNR), and noise-level using in-house scripts.

### RESULTS

The average difference between estimated and measured cumulative K<sub>air</sub> for all combined DE-CBCT protocols was 2.2±2.1%. Qualitative evaluation of VM-CBCT images at 50 keV showed comparable image quality between those with high- and low-K<sub>air</sub>. The HU of 20% bone material in the all low-K<sub>air</sub> VM-CBCT with were within 35 HU of the theoretical value of 298 HU. Additionally, the CNR and noise level between high- and low- K<sub>air</sub> VM-CBCT images were within 1.6 (16.0±0.9) and 3 HU (19.3±1.0 HU) respectively.

### CONCLUSION

The proposed method of optimizing DE-CBCT acquisition parameters based on K<sub>air</sub> provides imaging dose estimate within 3%. VM-CBCT generated from optimized DE-CBCT with reduced K<sub>air</sub> showed comparable image quality to VM-CBCT generated from the highest K<sub>air</sub> DE-CBCT based on both qualitative and quantitative assessments. Ongoing research aims to explore the impact of further reducing the framerates in CBCT acquisition and evaluating the use of iterative reconstruction to determine imaging parameters with reduced imaging dose while maintaining image quality for clinical applications.

### CLINICAL RELEVANCE/APPLICATION

VM-CBCT has shown promise in improving visualization of soft tissues compared to standard CBCT. However, the increased imaging dose associated with VM-CBCT remains a concern. We propose to determine imaging parameters using air Kerma measurement-based approaches of optimizing DE-CBCT imaging parameters. This approach has the potential to substantially reduce imaging dose for VM-CBCT without deteriorating image quality for clinical applications.

## S3B-SPPH-2 Adaptive Deep Learning MR Image Enhancement for Flexible Rapid MR Protocol Design

Participants

Zechen Zhou, Seattle, WA (*Presenter*) Nothing to Disclose

### PURPOSE

Deep Learning (DL) based image enhancement approaches can restore the image quality for accelerated Magnetic Resonance (MR) scans. However, a single DL model might not allow flexible MR protocol setup to achieve higher acceleration and resolution. In this work, we propose a Proximal Gradient Descent based unrolled Network (PGDNet) that can adaptively resolve different levels of noise amplification and image blurring. Preliminary performance evaluations were compared with traditional DL methods on various acquisition tasks.

### METHODS AND MATERIALS

PGDNet (Fig. A, PGDNet) incorporates the image degradation model into the image restoration process to jointly estimate the degradation kernel and the high quality image, which maintains the data consistency with the acquired image while performing adaptive image enhancement. 356 MR acquisitions with paired fully sampled and undersampled (i.e. fewer number of phase encodings [NPE] or signal averages [NSA]) images were collected for training (#pairs for reduced NPE: 101, #pairs for reduced NSA: 193, #pairs for both: 18) and testing (#pairs for reduced NPE: 11, #pairs for reduced NSA: 29, #pairs for both: 4). Three different models were trained: 1) Enhanced Deep Residual Networks (EDSR) (Fig. A, EDSR) trained with all data pairs; 2) EDSR model fine-tuned with the reduced NPE data pairs as the super-resolution expert (SRE) model; 3) PGDNet trained with all data pairs. Quantitative PSNR and SSIM metrics were used to evaluate the accuracy of the model outputs on 3 acquisition tasks.

### RESULTS

In denoising tasks (Fig. B, reduced NSA scans), PGDNet can better preserve small structures, and prevent over-smoothing, particularly the trabecular bone textures in MSK cases. In deblurring tasks (Fig. B, reduced NPE scans), PGDNet can still achieve similar/superior performance compared to the EDSR SRE model, and show improved structural consistency with the reference image. Compared to EDSR and EDSR SRE, PGDNet demonstrates its adaptation and robustness in the joint denoising and deblurring tasks

(Fig. B, scans with reduced NSA and NPE). Quantitative measurements also supported the qualitative assessment.

## CONCLUSION

By explicitly leveraging the image degradation model, PGDNet outperforms the conventional DL methods in various acquisition tasks, particularly filling the gaps in acquisitions with both reduced NPE and NSA. This allows more flexible MR protocol design to achieve highly accelerated clinical exams or improved image quality for clinical diagnosis.

## CLINICAL RELEVANCE/APPLICATION

DL based image enhancement methods supporting different types of fast MR acquisitions allow more flexible rapid protocol design to achieve more efficient clinical workflow or improved image quality for clinical diagnosis.

### S3B-SPPH-3 Improving the Accuracy for Intracranial Aneurysm Detection in CT Angiography using the Combination of Artificial Intelligence-assisted Diagnostic System and Physician Intervention

#### PURPOSE

To investigate the diagnostic performance of two modes (head and neck artificial intelligence (AI)-assisted diagnostic (AIAD) system and AIAD + physician mode) in the detection of intracranial aneurysms (IA) using head and neck CT angiography (CTA).

#### METHODS AND MATERIALS

A total of 40 patients with suspected IA who underwent head and neck CTA, and digital subtraction angiography (DSA) were retrospectively included. DSA was used as the gold standard, and both the AIAD and AIAD + physician systems were used to perform IA diagnosis on CTA images. The sensitivity, specificity, and accuracy of the systems were calculated. The consistency of the IAs long diameter, short diameter, and aneurysm neck diameter between AIAD system and DSA were evaluated by Bland-Altman scatter diagram. The average post-processing and interpretation times of two modes were recorded.

#### RESULTS

The average post-processing and interpretation times of AIAD was  $2.5 \pm 0.6$  min per case vs.  $5.6 \pm 0.4$  min per case of AIAD + physician mode. Of the 40 patients (19 men;  $59.18 \pm 12.32$  years), 33 patients were diagnosed with IA by DSA, and 39 IAs were analyzed. For the diagnostic performance, on the per-patient basis, the sensitivity of the AIAD and AIAD + physician modes was 81.8%, 96.97%, respectively, and the accuracy of the two modes was 70%, 90%, respectively ( $P=0.025$ ). On the per-lesion basis, the sensitivity of the two modes was 74.36%, 89.74%, respectively and the accuracy was 65.96%, 85.11%, respectively ( $P=0.031$ ). In terms of the quantitative analysis, the consistency between AIAD automatic measurement and DSA manual measurement with Bland-Altman scatter diagram showed that most of the points were concentrated in the range of 1.96 times of the standard error.

## CONCLUSION

The AIAD + physician mode significantly improved the accuracy for the detection of IA in head and neck CTA, and AIAD system could serve as a reference standard for measuring the diameter of aneurysms.

## CLINICAL RELEVANCE/APPLICATION

AI-assisted diagnostic system + physician mode can improve the accuracy and work efficiency in the detection of IA, which have a major influence on daily clinical practice.

### S3B-SPPH-4 Assessing Racial and Age-Related Fairness in Chest X-Ray Classification Algorithms

Participants

Yonghan Ting, FRCC, Singapore, Singapore (*Presenter*) Nothing to Disclose

#### PURPOSE

Evaluate bias in two commercial (AI1, AI2) and one academic (AI3) chest x-ray classification algorithms. Estimate the fairness of these algorithms for different age and racial groups using the Aequitas package.

#### METHODS AND MATERIALS

- 500 anonymized chest x-rays were collected from patients aged above 18, across 6 races at an academic hospital center in Singapore.
- Ground truth was established by an experienced radiologist.
- X-rays were analyzed by two commercial and one academic CXR classification model for normal-abnormal classification on the CARPL.AI platform
- Aequitas package preloaded on this platform was used to evaluate algorithm performance on metadata classes, including age group and race, with reference groups selected based on the majority population characteristics.
- False negative rate (FNR) metric was used to calculate inter-class scores of bias.

#### RESULTS

- For age, AI1 showed FNR disparity for patients aged 48-99; AI2 showed FNR disparity for patients aged 19-31 and 48-99; AI3 showed FNR disparity across all age groups.
- For race, at a 60% disparity intolerance, FNR parity was observed for Chinese and Indian populations in AI1 and AI2, respectively; AI3 demonstrated FNR parity for Chinese and Malay groups.

## CONCLUSION

The study found the AI algorithms to have racial parity but at a reduced tolerance range. Both algorithms showed a certain degree of FNR disparity for certain age groups. We propose including bias evaluation as a core component of every AI solutions' validation pipeline.

## CLINICAL RELEVANCE/APPLICATION

By identifying disparities in the performance of these algorithms across different age groups and racial backgrounds, our findings can inform clinicians, healthcare institutions, and algorithm developers about the limitations and potential risks associated with the current AI-based diagnostic tools.

### S3B-SPPH-5 Improving Reconstruction in Accelerated MRI via Transferable Deep Learning

Participants

Yuxiang Zhou, PHD, Phoenix, AZ (*Presenter*) Nothing to Disclose

## PURPOSE

The objective of this study is to develop an attentive feature refinement-based transfer learning approach for vendor transfer in medical image, which will allow any pre-trained model to transfer knowledge across domains and adapt to novel domains with relatively limited datasets.

## METHODS AND MATERIALS

Variational Feedback Network (VFN) was adopted as the base architecture to conduct and evaluate the effectiveness of our proposed transfer learning strategy. We extend the transfer learning capability of VFN beyond existing transfer learning methods (i.e., pretrained weights finetuning) by selecting pretrained features that benefit reconstruction quality. To enable knowledge transfer from the source dataset to refine target tasks, we exploit the high-level features of reconstructions from VFN network. To refine the subsampled k-space, we propose a feature extraction and refinement (FER) module. We use more than 400 T1-weighted MRI ACR phantom images collected from MAGNETOM Skyra 3.0T (SIEMENS Healthcare) and Discovery 750W 3.0T (General Electric HealthCare) scanners as our two domains and analyze the transfer in both directions.

## RESULTS

The images were reconstructed with an acceleration factor of 4. Five AI models were development in this studied and tested on GE phantom dataset. The first model was trained with SIEMENS ACR data (400 samples) using the basic VFN network. The second model was trained with GE ACR data (100 samples) using the basic VFN network. The third model was trained with SIEMENS + GE ACR data (500 samples) using the basic VFN network. The fourth model was trained based model 1 but fine-tuned with GE dataset without feature supervision. The fifth model was trained based model 1 but fine-tuned with GE dataset with a feature extractor. The reconstruction quality is compared across implicit and explicit transfer learning methods. The testing results for GE 5 dataset of PSNR are 35.7 +/- 13.05, 43.73 +/- 15.6, 44.16 +/- 13.06, 42.61 +/- 13.76, 44.72 +/- 16.38, and SSIM 0.9024 +/- 0.12, 0.9718 +/- 0.06, 0.9806 +/- 0.03, 0.9631 +/- 0.08, 0.9893 +/- 0.09 for the above 5 models.

## CONCLUSION

s Out study indicates that the reconstruction quality by using our newly developed feature refinement-based transfer learning is significantly better than these reconstructed with conventional Variational Feedback Network (VFN) with limited datasets.

## CLINICAL RELEVANCE/APPLICATION

This study established and tested a new DL model of feature refinement-based transfer learning with strong ability to handle data heterogeneity and variability at speeding up MRI scans up to 4~8 times faster. This method will be able to shorten clinical MRI scan time for improved patient experience and reduced cost while maintaining the quality for diagnosis.

## S3B-SPPH-6 Viability of an AI-enabled 0.5T Scanner to Improve MR Access

Participants

Arjun Narula, MBBS, MD, Rohtak, India (*Presenter*) Nothing to Disclose

Saban Kurucay, Waukesha, WI (*Presenter*) Employee, General Electric Company

## PURPOSE

Access to MRI is known to have improved clinical outcomes. However, it is limited to high economic regions due to high cost, lack of infrastructure and unavailability of skilled labor. Lower field strength MRI along with lower gradient and RF specifications will reduce cost and infrastructure requirements. However, image quality from these derated systems have historically not been sufficient for clinical use. Recent developments in image acquisition and reconstruction with artificial intelligence (AI) could enable improvement of quality of images obtained from such systems to make it clinically viable. This abstract tests the hypothesis that an AI-enabled 0.5T system with low gradient and RF power would provide clinically sufficient information compared to a conventional 1.5T clinical scanner.

## METHODS AND MATERIALS

Routine brain and cervical spine exams were collected from 197 patients (1188 series in total) on 0.5T, low gradient and low RF AI-enabled scanner with custom made 14-channel HNU coil. The same patients were also scanned on a commercial 1.5T scanner. The scan duration of the 0.5T AI-enabled scanner was comparable to the clinical scanner and at the most less than 2 times the clinical scanner's scan duration. Comparisons were made to study the clinical sufficiency for diagnosis of the AI-enabled 0.5T scanner images to those obtained from 1.5T scanner by at least 4 radiologists from a pool of 10 global radiologists. The radiologists rated the images on a Likert scale between 1 and 9 (1: clinically useless, 5: diagnostic quality, 9: better than reference).

## RESULTS

The 0.5T scans were rated on an average as  $6.11 \pm 1.2$ ; significantly above diagnostic quality 5 ( $p < 1e-4$ ). On a subset of the data, conventional (non-AI) reconstructed images were compared with AI-reconstructed images. AI reconstruction significantly improved ( $p < 1e-14$ ) the rating average by  $2 \pm 0.96$  points on the Likert scale. Only a total of 81 series out of 1188 obtained an average rating below 5 (diagnostic) and were mostly due to motion artefacts. The rest were due to poor acquisition parameter choices in the early phase of the study.

## CONCLUSION

s This study has shown that AI-based image quality improvement can enable head and c-spine images from a 0.5T system to be diagnostically sufficient. Further assessment on other anatomies and additional AI methods for acceleration is required.

## CLINICAL RELEVANCE/APPLICATION

AI-enabled low-field systems can provide diagnostic image quality similar to clinically accepted 1.5T scanners and has good potential to help improve access of MRI to underprivileged regions.

## S3B-SPPH-7 Improving Juxta-vascular Pulmonary Nodule Detection Capability Using a Deep Learning-based AI Detection System in Low-dose Computed Tomography (LDCT)

Participants  
Fang Wang, Yinchuan, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the performance of a deep learning computer aided diagnostic (CAD) system to improve detection rate for juxta-vascular pulmonary nodules in LDCT.

#### **METHODS AND MATERIALS**

104 healthy patients who underwent low-dose chest CT screening using a 256slice wide-detector CT (Revolution, GE Healthcare) were enrolled. Protocols were adjusted so that effective dose was set to approximately 1.5 mSv. All DICOM images were sent to a deep learning (DL) computer aided diagnostic system (InferRead CT Lung Research, Infervision) for automatic pulmonary nodule detection. Three methods were used to read the images. Method A: Independent reading of axial images by two radiologists to detect juxta-vascular pulmonary nodule (JVPN) reaching consensus. Method B: DL assisted reading result was analyzed by radiologists to judge whether they were JVPN. Method C: Based on method B results, radiologists read the films by combining the axial images. The total number and locations of nodules for each patient detected in each method were recorded. Two senior chief radiologists' consensus readings were used as the gold standard nodules. The detection rate and false positive rate of each method were calculated respectively.

#### **RESULTS**

216 JVPNs were confirmed as gold standard. In method A, 158 nodules were detected, among which 156 were true positive JVPNs; in method B, 215 nodules were detected, among which 190 were true positive JVPNs; In method C, 212 nodules were detected, among which 208 were true JVPNs. In method C, the detection rate of all JVPNs was 96.29% which was higher than that in method A and B (72.22% and 87.96%). The false positive rate for juxta-vascular pulmonary nodules detected by method C (4%) was significantly lower than that by method A (12%) and B (24%).

#### **CONCLUSION**

s The screening method of image reading combined with DL-CAD results interpreted by radiologists significantly improves the detection rate and reduce false positive rate of juxta-vascular pulmonary nodules in LDCT screening.

#### **CLINICAL RELEVANCE/APPLICATION**

Reading combined with DL-CAD results interpreted by radiologists can improve the detection efficiency of juxta-vascular pulmonary nodules which could be used as a preferred method for LDCT screening of pulmonary nodules in high risk patients.

### **S3B-SPPH-8 Towards a Fully Autonomous Artificial Intelligence Volume-rendered Segmentation Workflow for CT Angiography of the Thoracic Aorta**

#### **PURPOSE**

Three-dimensional (3D) surface rendering enables global qualitative assessment of aortic anatomy. Generating a surface model for 3D visualization requires time-consuming manual or semi-automated segmentation, taking an average of 32 minutes per case at our institution. This amounts to 2.74 FTE of 3D lab technologist time. To decrease manual effort, we developed a deep learning model to automate aortic segmentation and 3D surface model creation from CTA images, integrating an artificial intelligence (AI)-assisted workflow into the clinical practice. We then compared the visual quality of AI-assisted and fully automated surface renderings of the thoracic aorta.

#### **METHODS AND MATERIALS**

An AI model was trained on 304 manually created segmentation maps created for clinical purposes at our institution. Processing time for the AI model was 6 minutes with GPU acceleration. In this IRB-approved study, we retrospectively analyzed the visual quality of 25 3D surface renderings for CTAs acquired at a single center. Twenty-five sets of renderings were then blindly assessed by two experienced cardiovascular radiologists, comparing deep learning segmentations to those that had been manually adjusted by an experienced 3D lab technologist. Comparisons were made using a 5-point Likert scale and covered multiple anatomic features as well as overall quality.

#### **RESULTS**

The renderings based on the AI-only segmentations were assessed to be equivalent to the AI-corrected renderings ( $p \geq 0.19$ ) across all anatomic regions except for the coronary arteries ( $p = 0.06$ ), which favored the AI-corrected results. The coronary arteries are not consistently segmented across all exams, which may have caused the model to underperform in these features. The overall reader agreement was very good (Gwet AC1 = 0.68).

#### **CONCLUSION**

s Fully automated AI-based segmentation of the thoracic aorta produces 3D renderings of equal quality compared to the existing manual process, which may allow for significant time savings by fully automating 3D postprocessing.

#### **CLINICAL RELEVANCE/APPLICATION**

An AI-only workflow yielded similar image quality for thoracic aorta segmentation indicating the potential to fully automate thoracic aortic CTA post-processing.

### **S3B-SPPH-9 Validation of the QuCAD Evaluation Tool to Quantify Wait-Time-Savings from a Computer-Aided Triage and Notification (CADt) Device**

Participants  
Elim Thompson, PhD, Silver Spring, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This work validates our queueing theory-based QuCAD evaluation tool designed to quantify the wait-time savings that a computer-aided triage and notification (CADt) device may bring to chest CT and chest CT angiography (CTA) pulmonary embolism (PE) STAT

cases from a tertiary academic medical center.

## **METHODS AND MATERIALS**

To validate the QuCAD evaluation tool, we retrospectively retrieved clinical reader timestamp data to characterize radiologists' work queue via the number of readers, image inter-arrival time to the PACS, and radiologists' effective reading time. The effective reading time of each radiologist was defined as the time between the opening of two consecutive readings. An exponential curve is fit to the distributions of inter-arrival times and effective reading times. We compared the wait-time savings predicted by QuCAD with the mean difference in clinical turnaround time from data before and after CADt adoption. Turnaround time is defined as the time from when an image entered the PACS to when the first review is completed by a radiologist. We stratified this comparison by cases arriving between 8am and 5pm (day shift) and those between 5pm and 8am (night shift).

## **RESULTS**

Between 2019 and 2022, 9,864 chest CT/CTA PE STAT cases were reviewed by 70+ radiologists. On average, 2 to 3 readers reviewed images at a given timepoint. The overall case arrival rate was 0.327/min, and the mean effective reading times were 20.1 min for positive PE studies and 14.9 min for negative PE cases. When having 2, 3, and 4 radiologists reviewing images, QuCAD predicts wait-time-savings for positive PE cases to be 14.9 min [95% CI: 13.3, 16.8], 1.27 min [1.00, 1.54], and 0.25 min [0.16, 0.33] respectively. From positive clinical PE cases, the mean difference in turnaround time before and after the use of CADt is 22.9 min during day shift hours. During night shift hours, the mean turnaround time difference drops to 8.26 min.

## **CONCLUSION**

Using 4 years of workflow data from a tertiary academic medical center, this study successfully validated the QuCAD tool designed to quantify potential wait-time-savings a CADt can bring to positive findings. Despite a large variability in clinical workflow, wait-time saving predictions from QuCAD estimates align with the turnaround time reduction from the clinical data.

## **CLINICAL RELEVANCE/APPLICATION**

CADt devices use artificial intelligence (AI) to process patient images and prioritize cases with suspected findings. Previous work developed an evaluation tool (QuCAD) that quantifies the time-saving benefits via queueing theory. This study validated QuCAD using timestamp data from a real clinic. QuCAD is now publicly available for evaluating the time-saving benefits of CADt devices.

S3B-SPVA

### Vascular Imaging Sunday Poster Discussions II

#### Sub-Events

#### **S3B-SPVA-1 Improving Image Quality of Blood Vessels through Deep Learning-Based Denoising and Enhancement Method Based on Low-Energy DSA**

##### PURPOSE

This work investigates the feasibility and efficacy of a novel approach that combines low-energy digital subtraction angiography (DSA) images with a new denoising and enhancement framework for improving the image quality of blood vessels while reducing ionizing radiation during surgical procedures.

##### METHODS AND MATERIALS

Between December 2021 and December 2022, 140 patients participated in a retrospective study on DSA intervention therapy for cerebral arteries, renal arteries, coronary arteries, and lower limb arteries. The study had IRB approval and waived written consent. These patients were randomly divided into training, validation, and test sets, with 98, 14, and 28 patients, respectively. The denoising and enhancement network framework consisted of a noise estimator, a denoising network, and a refinement network. The network was trained using only the noisy DSA image for joint denoising and enhancement. An ROI measuring 256 x 256 was placed over the arterial angiography region, with the non-angiographic region serving as the background. Measurements of pixel values and standard deviation were taken for the artery, and the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated for the ROI region. The image quality was assessed using the Peak Signal to Noise Ratio (PSNR) and Structural Similarity Index Measure (SSIM). Images obtained through low-energy transmission with deep learning-based denoising and enhancement were assigned to the prediction group, while images obtained through normal-energy X-ray fluoroscopy were assigned to the ground truth group for objective evaluations.

##### RESULTS

Effective use of deep learning techniques can reduce image noise and increase CNR and SNR. Low-energy DSA, when combined with denoising and enhancement network (PSNR:  $40.72 \pm 2.85$ dB; SSIM:  $0.9370 \pm 0.0440$ ; SNR:  $34.86 \pm 3.46$ ; CNR:  $5.10 \pm 4.48$ ), proves to be superior to low-energy DSA (PSNR:  $26.05 \pm 0.03$ dB; SSIM:  $0.3770 \pm 0.0436$ ; SNR:  $20.71 \pm 1.19$ ; CNR:  $2.37 \pm 2.56$ ); A single image of 1024 x 1024 with a processing speed can be achieved in 0.051 seconds.

##### CONCLUSION

s Low-energy DSA combined with deep learning denoising and enhancement techniques can enhance the contrast between arteries and surrounding tissues, optimize the quality of arterial images, reduce noise, and maintain real-time efficiency.

##### CLINICAL RELEVANCE/APPLICATION

Combining low-energy DSA with deep learning denoising and enhancement techniques can effectively reduce noise and enhance the shape of displayed arteries in real time, providing valuable assistance for various interventional procedures in clinical practice.

#### **S3B-SPVA-2 Quantitative Analysis of Lower Extremity Muscle Features Measured from Computed Tomography Angiography for Diagnosis of Peripheral Arterial Disease**

##### PURPOSE

To explore whether lower extremity muscle features can be used for the diagnosis of peripheral arterial disease (PAD).

##### METHODS AND MATERIALS

Data of patients with PAD who visited our hospital between July 2016 and September 2020 were retrospectively collected. Two radiologists evaluated PAD severity on digital subtraction angiography (DSA) and computed tomography angiography (CTA) images using the runoff score. With the DSA score as reference standard, the patients were divided into two groups: mild PAD (DSA score = 7) vs. severe PAD (DSA score > 7). After segmenting lower extremity muscles from CTA images, 95 features were extracted for: univariable analysis, logistic regression model (LRM) analysis, and sub-dataset analysis (to verify whether PAD diagnosis can be realized through only part of the lower leg images).

##### RESULTS

A total of 56 patients ( $69 \pm 11$  years; 38 men) with 56 lower legs were enrolled in this study. The lower leg muscles of the mild PAD group (36 patients) showed higher CT values ( $44.6$  vs.  $39.5$ ,  $P < 0.001$ ) with smaller dispersion ( $35.6$  vs.  $41.0$ ,  $P < 0.001$ ) than those in the severe PAD group (20 patients). The area under the curve (AUC) of the CTA score, LRM-I (model constructed with muscle features), and LRM-II (model constructed with muscle features and CTA score) for PAD diagnosis were 0.81, 0.84, and 0.89, respectively. The highest diagnostic performance was observed in the image subset of the middle and inferior segments of the lower extremity (LRM-I, 0.83; LRM-II, 0.90).

##### CONCLUSION

s Lower extremity muscle features can be used for PAD diagnosis.

**CLINICAL RELEVANCE/APPLICATION**

Quantitative analysis of lower extremity muscle features can be a useful supplement to the current clinical imaging diagnosis methods of PAD and compensate for the limitations of vascular stenosis diagnosis from the perspective of muscle ischemia evaluation.

## Abstract Archives of the RSNA, 2023

T2-SPBR

### Breast Imaging Tuesday Poster Discussions

#### Sub-Events

#### T2-SPBR-1 Federated Deep Learning Model Predicts Breast Cancer Risk from Mammography Images

##### Participants

Daly Avendano, MD, (*Presenter*) Nothing to Disclose

##### PURPOSE

To externally validate Mirai, a DL breast cancer risk model based on mammography studies, applied in the Hispanic population with two distinct mammography vendors, utilizing a federated learning approach.

##### METHODS AND MATERIALS

This study retrospectively reviewed a database of 58,321 consecutive screening mammograms obtained from 24,060 women who received care at the TecSalud health system between January 1, 2014, and December 31, 2021. The Mirai model was utilized without the need for data sharing, using a federated learning approach. Cancer outcomes were obtained through the institutional tumor registry or imaging follow-up. The primary objective of this study was to evaluate the performance of the Mirai model in predicting the risk of breast cancer at 1-5 years from the time of the mammogram. We assessed the C-index as a measure of predictive accuracy.

##### RESULTS

Among the 23,340 patients with breast cancer-negative mammograms, 23,170 had no evidence of cancer in the following 5 years, while 170 were diagnosed with cancer during this timeframe. Mirai's performance was evaluated using a concordance index, which was found to be 0.74 (95% CI 0.71 to 0.77).

##### CONCLUSION

Our evaluation of MIRAI risk predictions indicates that the model is well calibrated, with an accurate accumulation of risk and estimations of risk over time. Our findings demonstrate that MIRAI's predictions align well with the observed number of events among both the full patient cohort and the case-matched control group.

##### CLINICAL RELEVANCE/APPLICATION

Breast cancer risk assessment is the angular stone for personalized screening. Artificial intelligence models have demonstrated promising results. The use of fair algorithms is essential for accurately assessing the overall population and avoiding the underrepresentation of minority groups. To enhance the effectiveness of these algorithms and ultimately lead to better outcomes. By adopting these practices, we can establish more equitable and inclusive systems that benefit everyone.

#### T2-SPBR-2 Comparison of Quantitative Volumetric and Subjective BI-RADS Density Classification in Women with Dense Breasts

##### PURPOSE

Increased breast density is an independent risk factor for breast cancer. A radiation-free tool for breast density assessment would be advantageous, especially for younger women. The purpose of this study was to determine the level of agreement between automated breast density based on whole breast ultrasound tomography volumetric data and commercially available volumetric breast density from 3D mammography in dense breasts. We examined agreement of quantitatively derived BI-RADS density from these two modalities with subjective mammography density assessment by breast radiologists and technologists.

##### METHODS AND MATERIALS

448 women with heterogeneously or extremely dense breasts were enrolled in a prospective case collection registry between December 2016 and October 2019. Participants underwent their annual screening digital breast tomosynthesis (DBT) (Hologic) and same day SoftVue™ automated whole breast ultrasound tomography (SV). Technologists assessed breast density using the BI-RADS density composition scale. Radiologists interpreted the mammogram and SV simultaneously and included a final BI-RADS density assessment. Quantitative volumetric density data was gathered for each case from mammography with Volpara and from SV. The Volpara overall score was used. The SV density index, a number from 0 to 100 derived from the volume-averaged sound speed, was recorded for each breast and categorized as a through d. The densest rating from the two breasts was selected. Four-way and pairwise agreement was tested using Kendall's coefficient of concordance (W). Additional analysis was completed for the disagreement cohorts.

##### RESULTS

In women with dense breasts, there was statistically significant good agreement between SV, Volpara, the radiologists' and technologists' BI-RADS density assessments. When SV was analyzed with each of the 3 other methods, there was statistically significant agreement with slightly higher concordance values. The SV BI-RADS was at a lower density level than Volpara in 12.1% of cases and at a higher density level in 13.3%.

## CONCLUSION

s SV density index, algorithmically calculated from whole breast ultrasound transmission data, has good agreement with automated breast density assessments using 3D mammography. SV breast density index is comparable with both radiologist and technologist subjective BI-RADS assessments from mammography.

## CLINICAL RELEVANCE/APPLICATION

SV's ultrasound breast density offers accuracy comparable with DBT-based tools or rating by radiologists and technologists. Clinical risk assessment using breast density may be applied, especially to women under age 40, without unnecessary radiation.

### T2-SPBR-3 Association of Breast Density Measured on Low-dose Chest Computed Tomography with Subsequent Breast Cancer Risk in Screened Population

Participants

Hyo-Jae Lee, Hwasun, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

Few studies identified the relationship between CT breast density and breast cancer risk, often with limited numbers of study cohorts and based on computer-aided quantitative methods which require laborious inputs by a trained user. This study aimed to determine the association between CT breast density grading by radiologists and breast cancer risk in a large screened population, furthermore the results were compared with mammographic density.

## METHODS AND MATERIALS

In a retrospective cohort study using screened population in a tertiary hospital, women aged at least 40 years without a history of cancer who underwent both mammographic screening and low-dose chest CT in 2007-2016 were followed up through December 2022. Two board-certified radiologists with each special expertise in mammography and CT independently reviewed the breast density on mammography and CT images and classified each case into one of the four BI-RADS grades. The primary outcome focused on the occurrence of new cases of breast cancer, including both invasive breast cancer and ductal carcinoma in situ. The hazard ratio (HR) was calculated using Cox proportional hazard regression and adjusted for other covariates. To compare the relationship between breast densities on mammography and CT, the Spearman's correlation coefficient was adopted. Interreader agreements for the mammographic density and CT density grades were determined by using the Cohen weighted kappa statistic.

## RESULTS

Among 1576 women (mean age, 65 years  $\pm$  9), the ascertainment of 17 incident breast cancers was obtained. CT density grade 4 showed a higher risk of breast cancer compared with those with grade 1 and 2 (HR, 10.502 [95% CI:1.227, 89.918],  $p = 0.032$  for reader 1; 6.368 [1.227, 33.049],  $p = 0.028$  for reader 2). There was a significant correlation on breast density between mammography and CT ( $r = 0.770$  and  $0.941$ , for reader 1 and 2, respectively) and the interreader agreement was good (kappa =  $0.613$  and  $0.701$ , for mammography and CT, respectively).

## CONCLUSION

s In this preliminary result, CT density provided future breast cancer risk information and correlated well with that from mammography.

## CLINICAL RELEVANCE/APPLICATION

Low-dose chest CT scans for lung cancer screening can estimate breast density without sacrificing interreader agreement, and have an association with breast cancer risk, promising for future research on dedicated breast CT scans.

### T2-SPBR-4 Early Adulthood Adiposity, Attained Adiposity and Breast Parenchymal Complexity in Premenopausal Women

Participants

Sneha Das Gupta, PhD, (*Presenter*) Nothing to Disclose

## PURPOSE

Adiposity measures such as weight, body-mass index (BMI) and body fat% are associated with breast cancer risk. We assessed the relationship of breast parenchymal complexity with early adulthood adiposity, changes in adiposity over the life course, and attained adiposity among premenopausal women, while also accounting for breast density.

## METHODS AND MATERIALS

We analyzed routine screening digital mammograms (Selenia Dimensions; Hologic) from 325 premenopausal women without breast cancer, recruited at the Joanne Knight Breast Health Center, Washington University in St. Louis, MO from December 2015 to October 2016. Trained research personnel assessed attained adiposity measures, while weight at ages 18 and 30 were self-reported. A wide array of radiomic features were automatically extracted from each mammogram using a validated computational imaging pipeline, standardized, and fused into a breast parenchymal complexity signature (BPCS). Volumetric percent density (VPD) was calculated using the Volpara software. Spearman correlations ( $r$ ) and multivariable linear regression models were used to evaluate the associations of adiposity measures with BPCS, adjusting for potential confounders (age, race, family history of breast cancer and parity) and VPD.

## RESULTS

BPCS was moderately correlated ( $r = 0.61$ ) with VPD. Higher BPCS was significantly ( $p < 0.05$ ) associated with lower weight and BMI at age 18 and at age 30, independently of age, race, family history of breast cancer and parity; inverse associations with BPCS were also found for absolute and annual weight changes between age 18 and attained age as well as between age 30 and attained age ( $-0.60 < r < -0.15$ ; linear regression coefficients ( $b$ ) for adiposity measures ranging from  $-0.672$  to  $-0.008$ ). Attained weight, BMI and body fat were also significantly inversely associated with BPCS. When further adjusting for VPD, statistical significance was preserved, yet slightly attenuated, for most adiposity measures ( $-0.60 < r < -0.25$ ;  $-0.498 < b < -0.012$ ). Among all adiposity measures, strongest associations with BPCS were preserved for annual weight change from age 18 to attained age and annual weight change from age 30 to attained age.

## CONCLUSION

Our preliminary data suggest that adiposity in early adulthood, as well as weight gain from early adulthood to attained age are inversely associated with breast parenchymal complexity among premenopausal women, and may have a lifelong impact on breast parenchymal tissue patterns, beyond breast density.

## CLINICAL RELEVANCE/APPLICATION

Deeper understanding of the pathways through which early-adulthood adiposity modifies breast parenchymal tissue, and possibly breast cancer risk, can open new avenues for preventive interventions in premenopausal women.

## T2-SPBR-5 Predictive Performance of a Deep Learning Image-Based Five-Year Breast Cancer Risk Model Across Race/Ethnicity, Age, Breast Density and Family History of Breast Cancer

### Participants

Hari Trivedi, MD, Atlanta, GA (*Presenter*) Founder, Lightbox AI ; Consultant, Sirona Medical, Inc ; Consultant, Flatiron Health ; Consultant, PMX Inc ; Research support, Kheiron Medical Technologies ; Research support, Clairity, Inc ; Research support, Nightingale Open Science ;

## PURPOSE

Traditional breast cancer risk models demonstrate modest predictive accuracy and are limited by worse performance in races/ethnicities outside of European Caucasian ancestry. We measured the performance of a deep learning (DL) image-based five-year breast cancer risk model across race/ethnicity, age, breast density, and family history of breast cancer.

## METHODS AND MATERIALS

This retrospective study included 31,047 consecutive bilateral 2D full field digital screening mammograms from 11,536 patients from January 2011 through December 2016 from six screening facilities. These exams were not part of model training. Self-reported race and ethnicity were categorized as Black, Asian, Hispanic, White, or as all other races and ethnicities. To account for the large number of White, non-Hispanic patients, race and ethnicity were further classified as White/non-Hispanic (W/NH) or as patients of color and/or Hispanic ethnicity (POC/H). Age (<50 vs >50), breast density (dense vs not dense), and first-degree family history of breast cancer were extracted from electronic medical records. Cancer outcomes were obtained from local tumor registries and included DCIS and any invasive breast cancer. Model prediction was estimated across subgroups using areas under the receiver operating characteristic curve (AUCs).

## RESULTS

We found point estimate AUCs consistently at or above 0.73 across all subgroups. AUC by subgroup: W/NH 0.75 [95% CI 0.73, 0.77] (n = 27,323), POC/H 0.75 [95% CI 0.68, 0.82] (n = 2,529); age < 50 0.73 [95% CI 0.70, 0.76] (n = 13,742), age ≥ 50 0.74 [95% CI 0.72, 0.77] (n = 16,110); dense 0.75 [95% CI 0.75, 0.76] (n = 17,146), not dense 0.79 [95% CI 0.78, 0.80] (n = 13,052); 1st degree relative with breast cancer 0.77 [95% CI 0.73, 0.80] (n=6,713), 1st degree relative without breast cancer 0.79 [95% CI 0.76, 0.83] (n=10,618), 1st degree relative with breast cancer (unknown) 0.76 [95% CI 0.74, 0.78] (n=13,172).

## CONCLUSION

The DL model performed consistently at or above 0.73 AUC in all subgroups of race/ethnicity, age, breast density and first-degree family history of breast cancer. No differences in performance were identified in patients identifying as POC/H compared to those identifying as W/NH. Performance was significantly higher in not dense vs dense exams. No significant differences were found between other subgroups. This DL image-based model appears to reduce differences in performance associated with traditional risk models.

## CLINICAL RELEVANCE/APPLICATION

A DL based breast cancer risk prediction model can perform consistently across key patient subgroups and appears to reduce limitations of traditional risk assessment, such as differences in performance across race/ethnic groups.

## T2-SPBR-6 Artificial Intelligence for Mammography to Predict Future Breast Cancer Risk : Incorporating Longitudinal Changes to Enhance a Feasibility

### Participants

Sanghyup Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Employee, Lunit Inc

## PURPOSE

To investigate mammographic parenchymal patterns and longitudinal changes that are related to breast cancer beyond the mammographic breast density and develop an artificial intelligence (AI) model to predict future breast cancer risk.

## METHODS AND MATERIALS

We developed a mammography-based deep learning algorithm for an AI predictive model to show the risk score for future breast cancer. risk model using a total of 16,113 full-field digital mammograms (Hologic, 72.3%; Siemens, 27.7%) from 9,113 women in the United States, who underwent at least mammogram and have information of pathology-confirmed breast cancer outcomes within 5 years. To discover the feasibility of incorporating prior images to train longitudinal changes of mammographic parenchymal patterns, the baseline model (AI-1) trained prior mammograms of non-cancer women and women with breast cancer, respectively, and the other model (AI-2) additionally trained with paired current and prior examinations per woman. Discriminatory performance was assessed using C-indices and receiver operating characteristic (ROC) curves for 1- to 3-year outcomes. Mammographic breast density was evaluated for each mammogram according to the BI-RADS composition category.

## RESULTS

A total of 2,000 examinations, of which 500 cases were followed by a cancer diagnosis were evaluated with two AI predictive models. C-indices increased from 0.68 (95% CI: 0.65, 0.71) of AI-1 to 0.73 (95% CI: 0.70, 0.76) of AI-2 (P=0.004). The AI-2 model demonstrated the risk of breast cancer with AUC of 0.75 (95% CI: 0.70, 0.79) at 1-year, 0.76 (95% CI: 0.68, 0.83) at 2-year, and 0.73 (95% CI: 0.68, 0.78) at 3-year. The performance was comparable in fatty (C-index, 0.74; 95% CI, 0.70, 0.78) and dense (0.71; 0.65, 0.76) breasts. 1076 of 2000 examinations showed no longitudinal changes of mammographic density, and the

performance of AI-2 for this subgroup was similar (C-index, 0.72, 95% CI, 0.70, 0.76) to the overall performance.

## CONCLUSION

This preliminary study demonstrated the feasibility of the AI predictive model to identify mammographic parenchymal features of future breast cancer. Incorporation of longitudinal changes might be feasible to enhance risk stratification of breast cancer.

## CLINICAL RELEVANCE/APPLICATION

The image-based risk model has a potential to be used to improve personalized screening of breast cancer.

## T2-SPBR-7 Performance of Traditional Breast Cancer Risk Models Compared to a Deep Learning Model Overall and by Race/Ethnicity

### Participants

Hari Trivedi, MD, Atlanta, GA (*Presenter*) Founder, Lightbox AI ; Consultant, Sirona Medical, Inc ; Consultant, Flatiron Health ; Consultant, PMX Inc ; Research support, Kheiron Medical Technologies ; Research support, Clairity, Inc ; Research support, Nightingale Open Science ;

### PURPOSE

To compare the performance of traditional breast cancer risk models to a new deep learning (DL) image-based five-year breast cancer risk model overall and by race/ethnicity.

### METHODS AND MATERIALS

This retrospective study included 10,101 consecutive bilateral 2D full field digital screening mammograms from 8,688 patients from February 2015 through December 2016 from a U.S.-based center that operates six screening facilities. Patient race/ethnicity and traditional risk model scores (Breast Cancer Risk Assessment Tool [BCRAT] and Tyrer-Cuzick v6 [TC6]) were extracted from electronic medical records. Patient self-reported race/ethnicity was used to create two groups: White, non-Hispanic (W/NH) and patients of color and/or Hispanic (POC/H). Cancer outcomes were obtained from local tumor registries. Cancer rates were defined as total cancers (DCIS and any invasive cancer) diagnosed within five years after the index mammogram/total exams. Model predictions were estimated using areas under the receiver operating characteristic curve (AUCs) and compared across risk models overall and by race/ethnicity using Chi-squared tests. NCCN thresholds were used to categorize predicted five-year risk scores as follows: average risk < 1.7%, intermediate risk > 1.7% and < 3.0%, and high risk > 3.0%.

### RESULTS

DL model five-year predictions significantly outperformed BCRAT and TC6 five-year predictions. Overall AUC [95% confidence interval] and number of exams (n) by risk model: DL 0.75 [0.72, 0.77] (n = 10,101), BCRAT 0.62 [0.59, 0.65] (n = 10,101), and TC6 0.59 [0.56, 0.62] (n = 10,101). Observed five-year cancer rates by race/ethnicity: W/NH 4.4% and POC/H 4.2%. Predictions by BCRAT and TC6 models, but not DL model, exhibited statistically significant differences across race/ethnicity groups. Comparing risk group distributions for W/NH to POC/H generated chi-squared statistic and p-values of: BCRAT 162.36 (p<.00001), TC6 84.49 (p<.00001), DL 0.954 (p=.621). Compared to POC/H, W/NH patients were 3.8 times more likely to be labeled high risk by BCRAT and 2.3 times more likely by TC6. The DL model assessed a nearly identical percentage of W/NH and POC/H as high risk.

## CONCLUSION

An image-based DL model outperformed traditional risk models in predicting five-year breast cancer risk. Traditional risk models exhibited meaningful differences in performance across race/ethnicity that was not observed in the DL model.

## CLINICAL RELEVANCE/APPLICATION

A deep-learning based approach to breast cancer risk prediction outperforms traditional risk models and appears to remove differences in performance observed across racial/ethnic groups associated with traditional risk models

## T2-SPBR-8 Cryoablation, Ultraconservative Treatment for Low-risk Early Breast Cancer =2cm: Analysis of its Efficacy

### Participants

Maria José Roca Navarro, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate if in patients with Her2- luminal tumors =2cm and ultrasound negative axilla, after cryoablation guided by ultrasound, there is absence of infiltrating carcinoma in the lumpectomy specimen. To demonstrate that the placement of pre-surgical seed at the moment prior to cryoablation does not interfere subsequently in the disappearance of tumor cells by freezing.

### METHODS AND MATERIALS

Between April 2021 and March 2023 we performed preoperative cryoablation in 49 patients (aged 53-79 years) with 50 unifocal infiltrating ductal carcinomas (IDC) (between 4mm and 20mm). All IDCs were visible on ultrasound, were luminals low grade and ultrasound negative axilla. All patients were studied with mammography and tomosynthesis, staged and biopsied by ultrasound. MRI was performed to rule out extensive intraductal component in 16 of the 19 patients with associated intraductal carcinoma (DCIs) in the core needle biopsy (CNB). All of them underwent pre-surgical marking with ferromagnetic seed and cryoablation with 17G or 14G needle on the same procedure, taking advantage of the same anesthesia and cutaneous access. We used the ICEfx Galil Boston Scientific cryoablation system, applying the usual triple-phase protocol: freezing-passive thawing-freezing and duration of approximately 40 minutes. Subsequently we checked the correct placement of the seed with mammographic projection

### RESULTS

Out of 50 low-risk unifocal IDC: -31 were pure IDC (without associated intraductal component in the diagnostic CNB): in none there was residual IDC in the lumpectomy specimen after performing pre-surgical cryoablation. -19 were IDC mixed (with associated DCIs in the diagnostic CNB): In 4 cases residual IDC was found in the surgical specimen, with some IDC focus remaining in the periphery of the post-cryoablation necrosis. In 8 patients, DCIs foci were detected far from the cryoablation area. All the specimens were considered by the pathologist to have tumor-free margins. There was no relevant complication.

## CONCLUSION

s Cryoablation is effective in 100% of cases for pure infiltrating tumors = 2cm. The presence of nests of DCIs away from the cryoablation area or millimeter foci of IDC at the margin of steatonecrosis in mixed IDC does not indicate failure of the technique, as all surgical specimens were considered by the pathologist to have tumor-free margins. Subsequent standard adjuvant treatment will equalize the risk of relapse to conventional lumpectomy, so it may be an alternative therapy in selected patients.

## CLINICAL RELEVANCE/APPLICATION

In the near future, after evaluating studies with a larger number of cases and follow-up, in selected patients with luminal tumors = 2cm, cryoablation could be an alternative therapy thus avoiding surgery.

## T2-SPBR-9 Upgrade of MRI Detected Papillomas in Asymptomatic High Risk Patients, Patients with a History of Cancer, and Patients with Known Malignancy

### PURPOSE

The purpose is to evaluate the upgrade of papilloma identified on MRI biopsy in patients with breast cancer and high-risk patients with or without a history of breast cancer.

### METHODS AND MATERIALS

In this HIPAA-compliant IRB-approved retrospective study, all MRI-guided biopsies from 1/1/2011 to 1/31/2020 yielding papilloma were reviewed. Only patients with an imaging indication of high-risk screening, known breast malignancy, or history of breast malignancy were included. Other indications, including breast symptoms such as palpable masses or nipple discharge, were excluded. All included patients had a surgical excision with clear pathology or, at minimum, a 2-year follow-up MRI after biopsy. All cases without surgical excision or imaging follow-up were excluded. All MRI biopsy procedures were performed on a GE 1.5 T magnet using a Suros Atec 9-gauge vacuum-assisted biopsy device.

### RESULTS

Of the initial 258 MRI-guided biopsies demonstrating papilloma, 45.3% (117/263) met inclusion criteria. Of the 141 patients excluded, 90 biopsies were excluded because of breast symptoms. Most examinations, 57% (67/117), were performed for high-risk screening, including a personal history of breast cancer. The other 43% (50/117) of examinations were performed for extent of disease. Of the 117 biopsies, 4.3% (5/117) were upgraded to malignancy. One biopsy (1/117, 0.9%) was upgraded to invasive malignancy and four (4/117, 3.4%) were upgraded to DCIS. Of the 117 biopsies, 31.6% (37/117) demonstrated atypia or additional high-risk pathology at time of percutaneous biopsy while 68.4% (80/117) demonstrated benign papilloma. The upgrade rate of benign papilloma at biopsy was 3.8% (3/80) with all cases non-invasive. The upgrade rate of papilloma with atypia or additional high-risk lesion at biopsy was 5.4% (2/37) with one non-invasive and one invasive malignancy. Age, race, ipsilateral malignancy, lesion type, or additional high-risk lesion at biopsy were not associated with upgrade rate.

## CONCLUSION

s Surgical excision of biopsy-proven papilloma identified by MRI biopsy in asymptomatic high-risk patients and patients with known malignancy may not be necessary.

## CLINICAL RELEVANCE/APPLICATION

Excision is often recommended for papillomas in high-risk patients. In these patients with papillomas found on MRI, a low upgrade rate suggests surgical excision may not be necessary.

## Abstract Archives of the RSNA, 2023

T2-SPCA

### Cardiac Imaging Tuesday Poster Discussions

#### Sub-Events

#### T2-SPCA-2 Cardiac Magnetic Resonance Imaging Features of Myocardial Involvement in Psoriasis

##### PURPOSE

Psoriasis is a systemic chronic inflammatory condition, primarily affecting skin and joints, associated with increased risk of developing major cardiovascular events (MACEs). Inflammatory myocardial involvement in psoriasis (P-IMI) has been reported but not thoroughly investigated. The aim of our study was to describe the findings at cardiac magnetic resonance (CMR) imaging in a series of patients with psoriasis related myocarditis.

##### METHODS AND MATERIALS

One hundred consecutive patients (62M, mean age  $55 \pm 13.7$  years) with psoriasis were screened by 2D echocardiography for cardiac abnormalities. Among them, five male patients showed hypokinetic dilated cardiomyopathy (HDCM). All patients with HDCM underwent invasive coronary angiography (ICA), CMR and endomyocardial biopsies (EMB) with real time PCR for cardiotropic viruses and western blot analysis for myocardial expression of Toll-Like Receptor 4 (TLR-4) and Interleukin-17A (IL-17A). CMR exams were performed on a 1.5 T scanner. Protocol included cine-bSSFP, T2-weighted STIR, T2-prep sequences for T2 mapping, MOLLI sequences for T1 mapping, acquired before and after gadolinium administration and CE T1w IR for late gadolinium enhancement images.

##### RESULTS

All patients presented with heart failure with reduced ejection fraction (HFrEF, EF  $19 \pm 2.8\%$ ), NYHA Class III-IV and various ECG abnormalities. ICA showed normal coronary arteries in all patients. All five patients were diagnosed with acute/subacute myocarditis on CMR imaging according to the updated 2018 Lake Louise Criteria. Among them, two patients showed myocardial edema on T2WI, three patients had positive LGE, while all of them had increased T1 and T2 mapping relaxation times. EMB confirmed imaging findings as an active virus-negative lymphocytic myocarditis was revealed in all patients with positive anti-heart autoantibodies, overexpression of TLR-4 and enhancement of IL-17A at western blot analysis.

##### CONCLUSION

s P-IMI is an underrecognized condition in patients with psoriasis, presenting with severe ventricular dysfunction at echocardiography, lymphocytic myocarditis at EMB and with variable myocardial signal abnormalities at CMR.

##### CLINICAL RELEVANCE/APPLICATION

Timely detection of P-IMI is crucial due to its prognostic and therapeutic implications. CMR may play a pivotal role, as a reliable and accurate non-invasive tool to identify myocardial inflammation and ventricular dysfunction.

#### T2-SPCA-3 Left and Right Ventricle Feature Tracking CMR Strain in Patients with Thoracic Sarcoidosis

##### PURPOSE

Patients with sarcoidosis may have clinically silent disease in 20-25%. Early detection of disease is essential for adequate therapy and prevent negative outcomes. This study aims to assess cardiac magnetic resonance (CMR) feature tracking (FT) strain for detection of subclinical cardiac dysfunction in patients with biopsy-proven extracardiac sarcoidosis.

##### METHODS AND MATERIALS

This retrospective study included patients who underwent chest CT and CMR examinations for biopsy-proven extracardiac sarcoidosis. For comparison age-matched controls with normal CMR were included. All CMR studies were performed with 1.5T or 3T scanners (Siemens). Chest CT examinations were conducted with 64-256 slice scanners (Siemens, General Electric). CMR used a standard protocol with b-SSFP cine sequences in long (2,3,4chamber) and short axis views for volumes/function analysis. Late gadolinium enhancement (LGE) sequences in the same orientation were performed >10 min after administration of Gadovist (0.1 mmol/Kg). CMR image analysis including strain (Global longitudinal, circumferential, or radial strain) was performed with dedicated software (CVI 42). Chest CT was analyzed by based on established criteria for the diagnosis of sarcoidosis.

##### RESULTS

The cohort included 49 patients ( $58.2 \pm 9.5$ y, 26m). Subgroups were defined by extracardiac sarcoidosis with/without lymphadenopathy and parenchymal disease (+chest) or cardiac involvement (+CMR). Group 1 13/49 ( $56.7 \pm 8.6$ y, 8m) with +chest/+CMR, group 2 33/49 ( $57.7 \pm 9.4$ y, 16m) with +chest/-CMR and group 3 3/49 patients ( $70.3 \pm 9.0$ y, 2m) with -chest/-CMR for sarcoidosis. 10 studies ( $57.5 \pm 12.3$ y, 6m) served as controls. LVGLS was impaired in all three groups compared to controls. LVGLS was significantly different between Group 1 and controls ( $-13.0 \pm 5.1$  vs.  $17.9 \pm 1$ , p-value=0.0112) and Group 2 and controls ( $-13.8 \pm 3.3$  vs.  $17.9 \pm 1.7$ ; p-value=0.0124). LVGRS LAX was significantly different between Group 1 and controls ( $20.6\% \pm 9.6$  vs.  $31\% \pm 3.6$ ; p-value=0.0086) and Group 2 and controls ( $23\% \pm 7.2$  vs.  $31\% \pm 3.6$ ; p-value=0.022). Positive LGE was detected in 13 patients: subendocardial 3/13, midmyocardial 6/13, midmyocardial/subepicardial 1/13, subepicardial/transmural 1/13 and subendocardial/midmyocardial/subepicardial in 2/13.

## CONCLUSION

s In patients with biopsy-proven extracardiac sarcoidosis independent of cardiac involvement LV GLS and LV GRS are abnormal, even when LVEF is within normal range.

## CLINICAL RELEVANCE/APPLICATION

Therefore, LV strain can be used to detect subclinical LV dysfunction in patients with extracardiac sarcoidosis.

## T2-SPCA-4 Primary Chylopericardium: A Study Based on CT Lymphangiography

Participants

Yimeng Zhang, Beijing, China (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the diagnostic value of CT lymphangiography (CTL) in primary chylopericardium.

## METHODS AND MATERIALS

The clinical and imaging data of 39 patients with primary chylopericardium were retrospectively analyzed. All patients underwent CTL scan. CTL evaluated abnormal contrast distribution and reflux in the neck, chest, abdomen, pelvis and abnormalities in the pericardium, mediastinum, and lungs. The composition ratio of qualitative data was used for statistical description.

## RESULTS

All 39 patients with CTL showed abnormal iodine oil deposition and reflux at different sites: (1) neck: 11 cases of the end of thoracic duct, 3 cases of the end of right lymphatic duct, 24 cases of cervical trunk reflux, 25 cases of subclavian trunk reflux; (2) chest: 23 cases of bronchial mediastinal trunk reflux, 22 cases of anterior mediastinum, 12 cases of main pulmonary artery window, 29 cases of peritracheal and bronchial, 30 cases of subcarina, 24 cases of posterior mediastinum, 7 cases of thoracic duct trunk reflux, 15 cases of pericardial reflux, 11 of which were transbronchial mediastinal trunk reflux, and 10 cases of abnormal distribution of intercostal, pleural, and supra-diaphragm. (3) Abnormalities in the abdomen and pelvic region: 4 cases in the subdiaphragm, 18 cases of dilated and condensed iliac lymphatics on the contrast side, 21 cases of contralateral iliac reflux, 16 cases of abnormal distribution of contrast in the ipsilateral lumbar trunk, and 23 cases of contralateral lumbar trunk reflux. Extra-lymphatic manifestations of abnormalities: 39 cases showed fluid density in the pericardial cavity, 2 cases showed cloudy and swollen mediastinal soft tissues, 24 cases showed abnormalities in both lungs, 10 cases showed thickened lobular septa, 11 cases showed ground glass density, 10 cases showed thickened bronchovascular bundles, 5 cases showed thickened bronchial walls, 16 cases showed pleural effusion, and 11 cases showed pulmonary atelectasis or insufficiency. 16 patients were treated surgically and 7 cases were relieved after surgery.

## CONCLUSION

s CT lymphangiography can show the abnormalities of thoracic duct and accessory branches in primary chylopericardium, and abnormal lesions of mediastinum, pericardium and lungs in this disease, which can help to explore the pathogenesis, diagnosis and differential diagnosis of this disease.

## CLINICAL RELEVANCE/APPLICATION

Exploring the CTL presentation features of primary chylopericardium will help the pathogenesis study, diagnosis and differential diagnosis of this disease.

## T2-SPCA-5 The Application Value Influencing Factors of Coronary Artery Calcification Score Algorithm Based on Artificial Intelligence in Non-gated Chest CT

## PURPOSE

To explore the application value of artificial intelligence software in the measurement of coronary artery calcification score (CACS) of non-gated chest CT and its influencing factors.

## METHODS AND MATERIALS

A total of 237 patients who underwent both coronary computed tomography angiography (CCTA) and chest CT within one month were included in this study retrospectively. These Agatston scores and the time taken for each case were recorded. Take the gated-H CACS as the gold standard, the correlation and bias of AI, AI+L and gated-H CACS were compared by Spearman correlation analysis and Bland-Altman consistency analysis. Kappa test was used to evaluate the consistency of CACS risk categorization among AI, AI+L, gated-H and gated-L. The chi-square test was used to evaluate the accuracy of risk categorization among AI, AI+L and gated-H.

## RESULTS

The post-processing and calculating time on each case of AI was 42s (37~46s), reduced by 39%, 68% compared with gated-H, gated-L (all  $P < 0.001$ ), respectively. The checking and reediting times on each case of AI+L was 60s (51.5~68s), reduced by 15%, 55% compared with gated-H, gated-L (all  $P < 0.001$ ), respectively. The correlation of the gated-L, AI, AI+L-CACS with the gated-H CACS was  $r = 0.990, 0.646, 0.976$  (all  $P < 0.001$ ). The Bland-Altman plot (gated-H CACS minus gated-L, AI, AI+L-CACS) showed a mean difference of 29.5, 299.8, 102.1, and 95% limits of agreement of -310.7~369.6, -807.4 to 1405, -351.3 to 555.6. Kappa analysis showed that the CACS risk categorization consistency in gated-L and AI+L was better than that in AI, and the Kappa coefficients (?) were 0.732, 0.893 and 0.359, respectively,  $P < 0.001$ . The accuracy of CACS risk categorization in AI+L was 92.0%, which was significantly better than that in gated-L and AI (80.2% and 52.3%, respectively,  $P < 0.0001$ ).

## CONCLUSION

s AI non-gated chest CT CACS software greatly shortens the time for radiologists to measure CACS, and it is more likely to underestimate CACS by using AI merely. While the AI+doctor reading model can significantly improve the evaluating performance and the accuracy of risk categorization, which is more suitable for clinical risk grade screening of patients with coronary heart disease. In addition, high heart rate will have a negative impact on the accuracy of CACS risk categorization by AI software, which provides a basis for software optimization in the future.

## CLINICAL RELEVANCE/APPLICATION

AI non-gated chest CT CACS software greatly shortens the time for radiologists to measure CACS.

## T2-SPCA-6 Detection of Monosodium Urate Depositions Atherosclerotic Plaques in the Cardiovascular System by Dual-energy Computed Tomography

### PURPOSE

This study employed Dual-energy CT (DECT) material separation technology to quantitatively assess the urate accumulated in coronary plaques, and to compare this to the Coronary CTA (CCTA) Calcium score scan for distinguishing urate deposition from atherosclerosis. Additionally, this study aimed to explore the relationship between urate deposition and surrounding atherosclerotic plaques, and to confirm the contribution of urate deposition to the development of coronary atherosclerosis.

### METHODS AND MATERIALS

We investigated the role of dual-energy computed tomography (DECT) in diagnosis of coronary atherosclerotic plaques and urate depositions in the patients with clinically suspected coronary artery disease. The patients were examined with DECT imaging system, and their clinical data were collected.

### RESULTS

DECT showed among 872 patients, 441 patients had plaques in coronary arteries, the incidence of plaque was 50.6%. Among the patients with coronary plaques, there were 348 patients (78.9%) with simple atherosclerotic plaque (AP), 8 patients (1.8%) with simple urate depositions (UD), 85 patients (19.3%) with urate depositions and atherosclerotic plaques (UDAP). Compared with AP group, total plaque area and calcification score around the plaque in UDAP group were significantly increased, and urate deposition areas were correlated with surrounding atherosclerotic area ( $r=0.325$ ,  $p<0.001$ ). Compared with AP patients, cardiac ejection fraction in UDAP patients was slightly decreased ( $p<0.05$ ). There was no statistical difference in blood uric acid concentration and other clinical parameters between two groups.

### CONCLUSION

s Notably, patients with gout or a history of hyperuricemia were more likely to exhibit urate deposition in their atherosclerotic plaques. Furthermore, we observed a strong correlation between urate deposition and atherosclerotic plaques with larger volumes and higher calcification. Cardiac ejection fraction in UDAP patients was slightly decreased compared with AP patients.

## CLINICAL RELEVANCE/APPLICATION

DECT may provide a relatively simple method for detection and identification of coronary urate deposition at risk for cardiovascular diseases.

## T2-SPCA-7 Periaortic Adipose Radiomics Texture Features Associated with Increased Coronary Calcium Score: First Results on a Photon-Counting CT

### PURPOSE

Cardiovascular diseases remain the world's primary cause of death. Identifying and treating patients at risk of cardiovascular events is as important as ever. Adipose tissue counts as a classic risk factor for cardiovascular diseases. It has been linked to systemic inflammation and is suspected to contribute to vascular calcification. To further investigate this issue, the use of texture analysis of adipose tissue using radiomics features could prove a feasible option.

### METHODS AND MATERIALS

In this retrospective IRB-approved single-center study, 55 patients (mean age 55, 34 male, 21 female) were scanned on a first-generation photon-counting CT. On axial unenhanced images, periaortic adipose tissue surrounding the thoracic descending aorta was segmented manually. Patients were divided into three groups for feature extraction, depending on coronary artery calcification (Agatston Score 0, Agatston Score 1-99, Agatston Score =100). 106 features were extracted using pyradiomics. R statistics was used for statistical analysis, calculating mean and standard deviation with Pearson correlation coefficient for feature correlation. Feature selection was performed using Random Forest classification and visualized using Boxplots and heatmaps. Additionally, monovariate logistic regression predicting an Agatston Score > 0 was performed, selected features were tested for multicollinearity and a 10-fold cross-validation investigated the stability of the leading feature.

### RESULTS

Two higher-order radiomics features, namely "glcm\_ClusterProminence" and "glcm\_ClusterTendency" were found to differentiate between patients without coronary artery calcification and those with coronary artery calcification with respective mean values (Agatston Score 0/1-99/=100) of 92.77/79.23/77.05 for "original\_glcm\_ClusterProminence" ( $p = 0.019$ ) and 5.72/5.33/5.24 for "original\_glcm\_ClusterTendency" ( $p = 0.078$ ). As the leading differentiating feature "glcm\_ClusterProminence" was identified after assessing multicollinearity.

### CONCLUSION

s Changes in periaortic adipose tissue texture seem to correlate with coronary artery calcium score, supporting a possible influence of inflammatory or fibrotic activity in perivascular adipose tissue. Radiomic texture features may potentially aid as corresponding biomarkers in the future.

## CLINICAL RELEVANCE/APPLICATION

The possible correlation between PAAT texture and coronary artery sclerosis may allow the hypothesis of possible texture changes through inflammatory or fibrotic processes in perivascular adipose tissue influencing the process of arteriosclerosis. A radiomics signature could serve as an imaging biomarker for cardiovascular prevention in the future.

## Abstract Archives of the RSNA, 2023

T2-SPCH

### Chest Imaging Tuesday Poster Discussions

#### Sub-Events

**T2-SPCH-1 Baseline Whole-lung CT Features Deriving from Deep Learning and Radiomics: Prediction of Benign and Malignant Pulmonary Ground-glass Nodules**

#### PURPOSE

To develop and validate the model for predicting benign and malignant ground-glass nodules (GGN) based on the whole-lung baseline CT features deriving from deep learning and radiomics.

#### METHODS AND MATERIALS

This retrospective study included 385 GGN from 3 hospitals, confirmed by pathology. 239 GGN from Hospital 1 were used as the training and internal validation set. 115 and 31 GGN from Hospital 2 and Hospital 3 were used as the external test sets 1 and 2, respectively. Clinical and morphological features of GGN at baseline chest CT were evaluated, and the whole-lung radiomics features were extracted simultaneously. Besides, baseline whole-lung CT image features are further assisted and extracted using the convolutional neural network. Back propagation neural network was used to construct five prediction models based on different collocations of the features used for training. The area under the receiver operator characteristic curve (AUC) was used to compare the prediction performance among the five models. The Delong test was used to compare the differences in AUC between models pairwise.

#### RESULTS

The model integrated clinical-morphological features, whole-lung radiomic features, and whole-lung image features (CMRI) performed best among the five models, achieved the highest AUC in the internal validation set (Hospital 1), external test set 1 (Hospital 2), and external test set 2 (Hospital 3), which were 0.886 [95% confidence interval (CI): 0.841-0.921], 0.830 (95%CI: 0.749-0.893) and 0.879 (95%CI: 0.712-0.968), respectively. In all three sets, the differences in AUC between the CMRI model and other models were significant (all  $P < 0.05$ ).

#### CONCLUSION

The whole-lung baseline CT features were feasible to predict the benign and malignant GGN. The model combining clinical-morphological features, whole-lung radiomics, and whole-lung image features showed the best performance.

#### CLINICAL RELEVANCE/APPLICATION

The deep learning model based on whole-lung features can provide non-invasive and low-cost prediction and save the time of nodule segmentation.

**T2-SPCH-2 Deep Learning Models for Malignancy Estimation of Pulmonary Solid Nodules After Novel Classification**

#### PURPOSE

Identifying the malignancy of pulmonary solid nodules larger than 8mm remains a challenging task. Our study is to make a novel classification of pulmonary solid nodules based on the adjacent relationship between the pulmonary pleura and nodules and use deep learning models to diagnose the pathology-confirmed nodules divided by this classification on CT scans of the chest.

#### METHODS AND MATERIALS

A total of 453 patients with pathology-confirmed solid nodules were enrolled from 2014 to 2022 and were randomly separated into training, validation, and test cohorts. Then we made a classification of solid nodules. Nodules that were adjacent to the pleura in the largest cross-sectional area were included in the pulmonary pleura solid nodules (PPSN) group. Nodules that were adjacent to only the lung tissues were included in the isolated solid nodules (ISN) group. Two groups were also divided into three cohorts. The Swin Transformer as a deep learning model, was used to identify the malignancy.

#### RESULTS

Before classification, the area under the receiver operating characteristic curve (AUC), specificity, and sensitivity in the validation and independent test cohorts were 0.892 [95% CI: 0.864, 0.920], 0.765, and 0.858; 0.878 [95% CI: 0.831, 0.924], 0.741, and 0.871. After classification, AUC, specificity, and sensitivity in validation and independent test cohorts in the ISN group were 0.921 [95% CI: 0.884, 0.958], 0.809, and 0.868; 0.905 [95% CI: 0.873, 0.938], 0.809, and 0.868. In the PPSN group, AUC, specificity, and sensitivity in the validation and test cohorts were 0.875 [95% CI: 0.776, 0.974], 0.632, 0.934; 0.806 [95% CI: 0.735, 0.876], 0.425, 0.871. The AUC of two divided groups in the independent test cohort was significantly different as determined by the DeLong test ( $p = 0.012$ ). The AUC in the ISN group is greater than that in the whole group.

#### CONCLUSION

When using deep learning models to predict pulmonary nodules, it is necessary to consider the surrounding tissues of the tumor, and detailed classification may help improve the prediction effect.

## CLINICAL RELEVANCE/APPLICATION

After specific classification, the accuracy of using deep learning models to predict lung nodules surrounded by lung tissue would be improved.

### T2-SPCH-3 Prediction of Lung Malignancy Progression and Survival with Deep Learning Based on Pre-treatment FDG-PET/CT

#### PURPOSE

Artificial intelligence (AI) demonstrated potential for improved accuracy in the characterization of lung malignancies with fluorodeoxyglucose positron-emission tomography and computed tomography (FDG-PET/CT), but studies mostly relied on handcrafted features rather than deep learning, and focused on the prognostic utilities of CT and PET individually without investigating their additive value. The purpose of this study was to use deep learning with pre-treatment FDG-PET/CT to predict progression of lung malignancies and overall survival (OS).

#### METHODS AND MATERIALS

A retrospective review across three institutions identified patients with a pre-procedure FDG-PET/CT and an associated malignancy diagnosis. Lesions were manually and automatically segmented, and convolutional neural networks (CNNs) were trained using FDG-PET/CT inputs to predict malignancy progression. Performance was evaluated using area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, and specificity. Image features were extracted from CNNs and by radiomics feature extraction, and random survival forests (RSF) were constructed to predict OS. Concordance index (C-index) and integrated brier score (IBS) were used to evaluate OS prediction.

#### RESULTS

1168 nodules (n=965 patients) were identified. 792 nodules had progression and 376 were progression-free. The most common malignancies were adenocarcinoma (n=740) and squamous cell carcinoma (n=179). For progression risk, the PET+CT ensemble model with manual segmentation (accuracy=0.790, AUC=0.876) performed similarly to the CT only (accuracy=0.723, AUC=0.888) and better compared to the PET only (accuracy=0.664, AUC=0.669) models. For OS prediction with deep learning features, the PET+CT+clinical RSF ensemble model (C-index=0.737) performed similarly to the CT only (C-index=0.730) and better than the PET only (C-index=0.595), and clinical only (C-index=0.595) models. RSF models constructed with radiomics features had comparable performance to those with CNN features.

#### CONCLUSION

s CNNs trained using pre-treatment FDG-PET/CT and extracted performed well in predicting lung malignancy progression and OS. OS prediction performance with CNN features was comparable to a radiomics approach. The prognostic models could inform treatment options and improve patient care.

## CLINICAL RELEVANCE/APPLICATION

Features extracted from the deep learning models predict overall survival well. After prospective validation, this model based on FDG-PET/CT could predict lung malignancy progression and overall survival with high accuracy, and therefore help inform treatment options and improve patient care.

### T2-SPCH-4 Effect of Emphysema on Lung Nodule Detection Performance of AI Software

#### PURPOSE

Emphysema influences the appearance of the lungs in chest CT scans. It is unclear how well artificial intelligence (AI) based software performs in emphysema presence. The goal of this study is to check if there is a difference in lung nodule detection performance between an AI software and the human reader when emphysema is present.

#### METHODS AND MATERIALS

We selected 121 participants with (n=39) and without (n=82) emphysema (mean age 61±8, 48% men) from the Imaging in Lifelines cohort. Detection of nodules sized 30-300mm<sup>3</sup> by a commercial AI software was compared to human reading, and findings only detected by the reader or AI (discrepancies) were reviewed by an expert panel of two radiologists (gold standard). Using the gold standard, the detection performance was compared between AI and human reader for emphysema and non-emphysema groups, based on sensitivity, F1 score, and FP/scan. McNemar's test was utilized to check if there are differences between findings detected by AI and human reader.

#### RESULTS

The human reader detected 206 nodular findings and AI 223. The expert panel reviewed 211 discrepancies. Of these, 30 were actual lung nodules, 68 non-nodules, and 113 lymph nodes. In the emphysema group, AI sensitivity was 0.95 [95%CI 0.83-0.99] vs 0.87 [95%CI 0.73-0.94] for the human reader, with 0.51 FP/scan for AI vs 0.15 FP/scan for the human reader (for nodules p=0.45, for FPs p=0.01). In the non-emphysema group, AI's sensitivity was 0.87 [95%CI 0.77-0.93] vs 0.80 [95%CI 0.69-0.88] for the human reader, with 0.23 FP/scan for AI vs 0.28 FP/scan for the human reader (for nodules p=0.40, for FPs p=0.64). AI performance based on the F1 score was slightly lower than that of the human reader in participants with emphysema (0.77 [95%CI 0.68-0.84] vs 0.86 [95%CI 0.77-0.92] respectively), whereas performance of AI was slightly better than the human reader in non-emphysema participants (F1 score 0.81 [95%CI 0.74-0.87] vs 0.75 [95%CI 0.68-0.81] respectively).

#### CONCLUSION

s Overall, sensitivity of AI for lung nodules was higher than for the human reader but at the cost of higher false positive rate in emphysema presence. This resulted in slightly worse performance of AI (based on F1 score) in emphysema but slightly better than the human reader in non-emphysema.

## CLINICAL RELEVANCE/APPLICATION

AI software can sensitively detect lung nodules in individuals with and without emphysema at least as well as the human reader, but with a higher number of FPs in emphysema cases.

### T2-SPCH-5 CT-derived Radiomics Signatures as a Prognostic Factor in Osteosarcoma Patients with Pulmonary

## Metastasis Treated with Tyrosine Kinase Inhibitors

Participants

Shan Shui Zhou, Shanghai, China (*Presenter*) Nothing to Disclose

### PURPOSE

The tyrosine kinase inhibitors (TKIs) have become the main therapy in relapsed or advanced unresectable patients with osteosarcoma (OS). However, no accurate predictive biomarkers for response to TKIs have been found or reported. This study aims to explore the prognosis value of CT-based radiomics signatures and develop a multidimensional nomogram for predicting the progression-free (PFS) in OS patients with pulmonary metastasis treated with TKIs.

### METHODS AND MATERIALS

A total of 90 OS patients with pulmonary metastasis were retrospectively enrolled in this study and were randomly divided into a training cohort (60) and a testing cohort (30). A total of 854 radiomics features were extracted from the segmentation of regions of interest based on baseline chest CT images. The intra-class correlation coefficient (ICC) was implemented to evaluate the feature reproducibility and stability. Only features with ICC greater than 0.8 were retained. The random survival forest (RSF) was performed to select features and generate radiomics signatures. Kaplan-Meier survival analysis with log-rank test was implemented for univariate selection. Two multivariate cox proportional hazards regression models were established with radiomics signatures and clinical factors (R-model and C-model) respectively. A multidimensional nomogram was then built based on all predictive parameters (RC-model). The discrimination abilities, goodness of fit and clinical benefits of models were validated and compared on both training and testing sets.

### RESULTS

The R-model and radiomics signatures which was constructed with these 37 features showed good predictive ability and prognostic value in both training and testing cohorts (Training: C-index, 0.798, log-rank test,  $p < 0.0001$ ; Testing: C-index, 0.775, log-rank test,  $p = 0.04$ ). There are significant differences in C-index between the C-model from the R-model and RC-model in both training and testing cohorts (C-model: C-index, 0.567 and 0.556; RC-model: C-index, 0.798 and 0.773; all  $p < 0.05$ ). The calibration curves based on 12 and 24-month survival prediction showed better agreement between the predicted and actual probability of PFS in the R-model and RC-model than the C-model. The decision curve analysis curves showed that the R-model was similar to the RC-model, and gained much more net benefits than the C-model.

### CONCLUSION

Radiomics signature derived by chest CT images is a potential predictor for the response to TKIs in OS patients with pulmonary metastasis.

### CLINICAL RELEVANCE/APPLICATION

Radiomics could be promising for identifying whether OS patients with relapsed or advanced unresectable disease have a good prognosis after treatment with TKIs and personalize risk stratification and treatment decisions.

## T2-SPCH-6 Radiogenomics For EGFR Mutation Status Prediction in CT Images: Impact Of Model Design on Performance and Prospective Generalizability

### PURPOSE

We hypothesized that design choices could affect predictive performance and generalizability of radiogenomic models. We investigated the impact of feature extraction and selection approaches on models developed to predict EGFR mutation status (EGFRm+/-) in NSCLC, assessing robustness on two different input CT image types.

### METHODS AND MATERIALS

We analyzed CT images from CT and PET/CT studies of US patients with NSCLC from TCIA (25% EGFRm+). Two feature extraction techniques were compared: hand-crafted features from segmented lesions and deep features from a pre-trained ResNet applied to a bounding box around the largest tumor. Principal component analysis (PCA) or Least Absolute Shrinkage and Selection Operator (LASSO) was used to select 5 features prior to classification by a support vector machine, with model performances evaluated via 5-fold cross validation AUC. Splits were stratified by EGFRm and disease stage. Prospective generalizability was evaluated using a temporal split (80:20 based on shifted dates). AUCs were reported as median and interquartile range.

### RESULTS

When predicting EGFR status from diagnostic CT images ( $n=171$ ), hand-crafted features selected either with PCA or LASSO resulted in effective stratification: AUC of 0.80 (0.73 - 0.80) and 0.80 (0.69 - 0.82), respectively, and encouraging prospective generalizability (0.86 for PCA and 0.76 for LASSO). By contrast, deep features showed poor performance using either PCA (0.60 [0.60 - 0.67]) or LASSO (0.46 [0.44 - 0.66]) as well as poor prospective generalizability (0.68 and 0.38, respectively). When utilizing low-fidelity CT from PET/CT studies ( $n=134$ ), hand-crafted features selected with PCA resulted in an AUC of 0.75 (0.73 - 0.77) vs. 0.66 (0.64 - 0.76) for LASSO. However, LASSO showed better prospective generalizability (0.79 vs 0.76). In this dataset, deep features combined with PCA showed improved predictive power compared with LASSO: AUCs of 0.72 (0.69 - 0.8) and 0.47 (0.46 - 0.67), respectively. With regard to prospective generalizability AUCs were 0.73 and 0.44 for PCA and LASSO, respectively.

### CONCLUSION

Performance and prospective generalizability for predicting EGFR mutation status varied widely across design settings. Tumor-based hand-crafted features filtered by PCA performed better than deep feature-based approaches regardless of image type. The effectiveness of the hand-crafted feature models supports the potential of radiogenomics in early identification of patients likely to harbor EGFR mutations.

### CLINICAL RELEVANCE/APPLICATION

Treatment planning in NSCLC depends on EGFRm. Radiogenomic models may help to rapidly identify patients who may harbor EGFRm. However, rigorous analysis of model design is key to successful model development.

## T2-SPCH-7 Impact of Body Composition on Lung Tumor Growth

Participants  
Jiantao Pu, PhD, Pittsburgh, PA (*Presenter*) Nothing to Disclose

## PURPOSE

Lung nodules, a sign of lung cancer, are common abnormal findings on low-dose computed tomography (LDCT). After a lung nodule is detected, the next step is to assess its likelihood of being cancerous, usually by monitoring its growth rate through follow-up CT scans. A nodule's growth rate can suggest its chance of being malignant and indicate the need for further tests such as biopsy or positron emission tomography (PET). This study aims to investigate the potential impact of body composition tissues as depicted on LDCT on tumor growth over time.

## METHODS AND MATERIALS

We conducted a study involving 109 subjects (55 male and 54 female) who had undergone multiple LDCT lung cancer screenings and were found to have lung nodules on their baseline CT scans. The nodules identified on both baseline and follow-up scans were segmented, and their doubling time (DT) in days was calculated. These subjects were grouped based on a DT threshold of 365 days. We also segmented five different body composition tissues depicted on the baseline LDCT scans were segmented, including skeleton muscle (SM), subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT), intramuscular adipose tissue (IMAT), and bone, and computed their volumes and densities in Hounsfield unit (HU). The backward stepwise multivariable logistic regression analysis was used to identify the body composition features associated with DT while adjusting for potential confounding factors, such as age, gender, pack/year, and presence of emphysema. The multicollinearity was checked by the variance inflation factor (VIF), where  $VIF > 3.0$  indicates high collinearity. The area under the receiver operating characteristics (ROC) curve (AUC) was used to evaluate the performance of the prediction models using a 5-fold cross-validation method.

## RESULTS

The identified CT-derived body composition features significantly associated with DT include VAT volume ( $p=0.043$ ) and SAT volume ( $p<0.001$ ), while SM density is marginally significant ( $p=0.067$ ). Their combination achieved an AUC of 0.717 (95% CI: 0.619-0.814).

## CONCLUSION

Body composition characteristics are significantly associated with the growth rate of a lung nodule over time and may be considered as novel image biomarkers to facilitate the assessment of indeterminate lung nodules detected in the screening setting.

## CLINICAL RELEVANCE/APPLICATION

Approximately 50% of individuals who undergo LDCT lung cancer screening are found to have pulmonary nodules. Although the majority of lung nodules identified on CT scans (>95%) are not malignant, their presence can be worrisome for healthcare providers and anxiety-provoking for patients. Therefore, it is imperative to identify new biomarkers that can aid in the evaluation of indeterminate nodules.

## T2-SPCH-8 Preoperative CT-based Radiomics Model to Predict Tumor Status of Spread through Air Space in Non-small Cell Lung Cancer

Participants  
Kaihua Lou, Hangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

This study is to establish radiomics model that can predict the spread through air space (STAS) of non-small cell lung cancer before surgery, and to explore whether the model efficiency can be improved by peritumoral information.

## METHODS AND MATERIALS

A total of 373 patients were retrospectively collected from the two centers between January 2015 to June 2022. Patients in Center 1 were randomly divided into the training group and the internal test group in a 7:3 ratio, with Center 2 serving as the external test group. Classical tumor region of interest (ROI) and expanded tumor ROI were delineated for each lesion on Shenrui scientific research platform. Correlation analysis and logistic regression are used for feature screening, and support vector machine classifier is used for the establishment of prediction model, which is verified in both internal and external test groups. Receiver operating characteristic curve and area under the curve (AUC) are used to evaluate the effectiveness of the prediction model.

## RESULTS

In this study, five models were established to predict the STAS status of patients with non-small cell lung cancer, including one clinical model, two radiomics models (classic tumor radiomics model and expanded tumor radiomics model) and two combined models (classic tumor combined model and expanded tumor combined model). In the external test group, the seven screened radiomics features show relatively good performance in predicting the STAS state alone, and most of the features had AUC values greater than 0.80. Among the prediction models, the clinical model shows relatively poor prediction efficiency, with AUC value of 0.63; The classic tumor combined model showed a relatively good prediction efficiency, with the AUC value of 0.84, which was higher than that of the single radiomics model (AUC was 0.82 and 0.71, respectively) and the expanded combined tumor model (AUC was 0.76).

## CONCLUSION

The results of this study showed that the seven selected radiomics features showed good efficiency in the identification of STAS status alone. The classical tumor radiomics model and the classical tumor combined model can predict the STAS status of patients well, but the expanded tumor ROI does not significantly improve the efficacy of the model.

## CLINICAL RELEVANCE/APPLICATION

STAS status affects the choice of surgical methods and prognosis of patients. The model established in this study can predict STAS status before surgery, which is conducive to guiding the selection of clinical surgical methods.

## Abstract Archives of the RSNA, 2023

T2-SPER

### Emergency Radiology Tuesday Poster Discussions

#### Sub-Events

#### **T2-SPER-1 The Impact of Dermoid Size on the Chance of Torsion and the Diagnostic Performance of CT Observations in Emergency Department Patients**

##### Participants

Cameron Adler, MD, Scottsdale, AZ (*Presenter*) Nothing to Disclose  
Maitray D. Patel, MD, Phoenix, AZ (*Presenter*) Nothing to Disclose

##### PURPOSE

Evaluate performance of CT observations for diagnosing twisted dermoids based on dermoid size..

##### METHODS AND MATERIALS

Text search of consecutive CT reports and pathology records between 1/1/2010 and 5/31/2022 identified ED patients with an ovarian dermoid, symptoms relevant to possible ovarian torsion, and absence of CT observations indicating alternative diagnosis. Operative and clinical notes established outcome...Three abdominal radiologists blinded to history, outcome, and cohort creation independently evaluated a maximum-size-matched review cohort containing all twisted dermoids with approximately twice as many non-twisted dermoids, scoring 6 adnexal torsion CT observations using a Likert scale:••• tubal thickening••• whirlpool sign••• concentric or asymmetric wall thickening••• adnexal deviation••• uterine deviation••• pelvic fat infiltration..Observation diagnostic metrics (sensitivity/specificity/accuracy/PPV/NPV) were based on presence of the observation indicated by at least two of the reviewers..

##### RESULTS

325 patients had 350 studies (19 patients with 2 studies, 3 patients with 3 studies, 10 patients with bilateral dermoids), showing 39 twisted dermoids and 321 non-twisted dermoids. The 10.8% overall torsion prevalence varied by dermoid size:••• <40 mm = 0/180 (0%)••• 40-69 mm = 6/96 (6.3%)••• 70-99 mm = 16/43 (37.2%)••• 100-159 mm = 15/30 (50.0%)••• =160 mm = 2/11 (18.2%)..Tubal thickening and whirlpool sign had highest diagnostic performance in the review cohort (39 twisted averaging 97 mm and 70 non-twisted averaging 99 mm; 35.8% torsion prevalence).••• For 84 dermoids =70 mm: the review cohort had all 51 of 51 non-twisted and 33 of 33 twisted dermoids of this size-----Tubal thickening: 84.8%/70.6%/76.2%/65.1%/87.8%-----Whirlpool sign: 63.6%/84.3%/76.2%/72.4%/78.2%••• For 25 dermoids 40-69 mm: to achieve size match, the review cohort had 19 of the 90 non-twisted and 6 of the 6 twisted dermoids of this size-----Tubal thickening: 50.0%/89.5%/80.0%/60.0%/85.0%-----Whirlpool sign: 33.3%/94.7%/80.0%/66.7%/81.8%..Applying 40-69 mm diagnostic metrics to all 96 dermoids that size reduced tubal thickening PPV to 24.1% and reduced whirlpool sign PPV to 29.5%, reflecting more false positives due to low torsion prevalence..

##### CONCLUSION

s 10.8% of ovarian dermoids in ED patients with relevant symptoms and no other CT-identified cause for symptoms were twisted, involving no dermoids <40 mm, 6.3% of dermoids 40-69 mm, and 39.3% of dermoids =70 mm. Tubal thickening and whirlpool sign showed highest accuracy (80%), but with substantially lower PPV for dermoids <70 mm..

##### CLINICAL RELEVANCE/APPLICATION

Consider US confirmation of suspected dermoid torsion on CT when <70 mm due to low torsion prevalence.

#### **T2-SPER-2 Determination of the Most Suitable Monoenergetic Level of Virtual Monochromatic Images in Dual-source CT for the Diagnosis of Bowel Obstruction and Colitis**

##### Participants

Djamel Dabli, Nimes, France (*Presenter*) Nothing to Disclose

##### PURPOSE

To determine the monoenergetic level with the best image quality for the diagnosis of colitis and bowel obstruction in an emergency context.

##### METHODS AND MATERIALS

The images of 64 patients who benefited from an enhanced abdominal-pelvis scan in dual-energy CT (DECT) mode for the diagnosis of colitis or bowel obstruction were retrospectively analyzed. Acquisitions were performed on a third-generation dual-source CT (DSCT) scanner at portal phase. Acquisitions were performed at 100/Sn150kVp. Mixed images (simulating images at 120kVp) were generated as well as virtual monochromatic images (VMI) at 40/50/60/70keV. An objective image quality assessment was performed by measuring contrast, noise and contrast-to-noise ratio (CNR). Subjective analysis was performed by anonymous scoring of the images by two radiologists evaluating the noise, smoothing, overall quality and diagnostic quality on a Likert scale. The results were compared between the different images using the Mann-Whitney U test for paired samples.

##### RESULTS

Of all the patients, 33 had intestinal obstruction, and 31 had colitis. The mean age was  $65\pm 20$  and  $49\pm 22$  years, respectively. The maximum CNR was measured in VMI at 60keV for both examination types, but the difference was significant only compared to 70keV for bowel obstruction and to 40keV, 70keV and mixed images for colitis. A good inter-observer agreement for all subjective criteria was found with a kappa index higher than 0.86. The VMI at 60keV presented higher scores for all criteria for bowel obstruction and colitis with no significant difference in smoothing score compared to mixed images ( $p=0.119$  and  $p=0.888$ , respectively).

#### **CONCLUSION**

s VMI at 60keV could provide better image quality compared with other low monoenergetic levels and mixed images for the diagnosis of bowel obstruction and colitis.

#### **CLINICAL RELEVANCE/APPLICATION**

Improved diagnosis of colitis and digestive tract obstructions.Reduction of examination interpretation time in the emergency context by optimizing the DECT image workflow

#### **T2-SPGI-2 Improving Preoperative Prediction of High-risk Esophageal Varices in Cirrhotic Patients: A Logistic Regression Model Based on Dual Energy CT Combined with Platelets**

#### **PURPOSE**

To assess the significance of preoperative prediction of high-risk esophageal varices (EV) in cirrhotic patients using ultrafast synchronized KV/mA switching dual energy CT (DECT), and to investigate the effectiveness of regression models that incorporate quantitative DECT parameters in conjunction with platelet for preoperative prediction.

#### **METHODS AND MATERIALS**

59 cirrhotic patients who underwent upper abdominal enhanced DECT scanning (Revolution Apex CT, GE) and gastroscopy were retrospectively enrolled. The risk of EV bleeding was divided into a low-risk group (LRV, n=38) and a high-risk group (HRV, n=21) based on gastroscopic findings. Basic clinical characteristics, hepatic transient elastography parameters derived by ultrasound (US), and DECT parameters in EV including portal phase esophageal venous iodine concentration (ICev) was recorded for all patients. Non-parametric test was used to identify independent risk factors. Logistic regression models were constructed based on mixed models of DECT combined, and US combined with clinical factors, respectively. The receiver operating characteristic (ROC) curves, area under the ROC curve (AUC) and confusion matrix were calculated for assessing performance of two models.

#### **RESULTS**

A total of 59 patients were included, 38 with low-risk esophageal varices and 21 with high-risk esophageal varices. Non-parametric tests revealed significant differences between the high- and low-risk groups in terms of clinical characteristics including platelets (PLT), US factors including Liver stiffness, and DECT parameters including ICev. The mixed model of US and PLT showed a 78% precision and sensitivity of 61.9%, specificity of 86.8%, positive prediction rate of 39% and negative prediction rate of 86.8%, and an AUC of 0.817. The mixed model of DECT and PLT demonstrated a precision of 83.1%, sensitivity of 76.2%, specificity of 86.8%, positive prediction rate of 48.5% and negative prediction rate of 86.8%, and an AUC of 0.916.

#### **CONCLUSION**

s ICev based on DECT combined with platelets can effectively exclude high-risk EV and has higher diagnostic efficacy than liver stiffness combined with platelets.

#### **CLINICAL RELEVANCE/APPLICATION**

According to Baveno VI guidelines, patients with cACLD at liver stiffness <20 Kpa and platelet count >150,000/ul may not require gastroscopy. The predictive model constructed for combined ICev and PLT had better performance than the model combined liver stiffness and PLT, and was a potential model for non-invasive screening of high-risk EV in cirrhotic patients and avoiding gastroscopy.

#### **T2-SPGI-3 Feasibility Study of Quantitative Parameters of Single-source Dual Energy CT Spectrum Analysis Parameters to Predict Ki-67 Expression in Gastrointestinal Stromal Tumor**

#### **PURPOSE**

To investigate the feasibility of preoperative prediction of Ki-6 expression in gastrointestinal stromal tumors(GIST)by multi-quantitative parameters of single-source dual-energy CT.

#### **METHODS AND MATERIALS**

The imaging data of 64 patients with GIST confirmed by single-source dual-energy CT three-phase energy spectrum enhanced scan and surgical pathology immunohistochemical index including Ki-67 were retrospectively analyzed. According to the Ki-67 expression index(>6 for high expression, <6 for low expression) the patients were divided into high expression group n=28) and low expression group(n=36)The single energy CT value and iodine concentration IC value of the parenchymal area of the two groups were measured at 40-70 kV, and the normalized iodine concentration NIC)value and the slope of the energy spectrum curve were calculated. Univariate and multivariate Logistic regression analysis was performed on the two groups of patients to establish independent risk factors for predicting Ki-67 expression.

#### **RESULTS**

The CT values of 40-70 keV and NIC value in the arterial phase of the Ki-67 high expression group were higher than those in the low expression group, and the differences were statistically significant ( $P < 0.05$ ), while the differences in the slope of the energy spectrum were not statistically significant ( $P > 0.05$ ); The differences in the venous 40-70 keV CT values, slope of the energy spectrum and NIC values between the two groups were not statistically significant ( $P > 0.05$ ). The CT values of 40~70 keV and slope of the energy spectrum value in the delayed phase of the Ki-67 high expression group were lower than those in the low expression group, and the differences were statistically significant ( $P < 0.05$ ), while the differences in NIC values were not statistically significant ( $P > 0.05$ ). Univariate and multivariate logistic regression showed that arterial phase, delayed phase

40KeV,70KeV CT values,and standardized iodine concentration values were independent risk factors for predicting Ki67 high expression.

## CONCLUSION

s Preoperative single-source dual-energy CT spectral parameters are helpful in predicting the expression of Ki-67 in gastrointestinal stromal tumors before surgery.

## CLINICAL RELEVANCE/APPLICATION

-

### **T2-SPGI-4 Equilibrium Phase Imaging of the Abdomen on Photon-counting CT: Assessment of the Value of 50-keV vs 70-keV Imaging**

Participants  
Toru Honda, MD, Toyonaka Shi, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Equilibrium phase (EP) imaging of the abdominal CT has several diagnostic values but suffers from low contrast. The aim of this study was to perform the quantitative and qualitative assessments of virtual monochromatic images (VMIs) generated by photon counting CT (PCCT) during abdominal EP.

## METHODS AND MATERIALS

This study included 20 patients who underwent abdominal dynamic contrast-enhanced CT using PCCT for the assessment of liver and pancreatic diseases including four patients with hepatocellular carcinoma and seven patients with pancreatic solid tumor. Portal venous phase (PVP) imaging was reconstructed to VMIs at 70 keV and EP imaging was reconstructed at 50 keV and 70 keV. One radiologist placed regions of interest on the three images and signal-to-noise ratio (SNR) were measured for the liver parenchyma, portal vein, hepatic vein, pancreas, and adrenal glands, as well as calculating the contrast-to-noise ratio (CNR) of the hepatic vessels and lesions. Two radiologists assessed the image quality using a 5-point scale regarding image noise, sharpness, organ and lesion conspicuity, and overall image quality. Friedman's test was used for the comparison among the three imaging.

## RESULTS

The SNRs at 50 keV-EP imaging were significantly higher for the hepatic vessels ( $p < 0.05$ ), equivalent for the pancreas and adrenal glands, and significantly lower for the liver parenchyma compared with 70 keV-EP imaging ( $p < 0.05$ ). SNRs at the 50 keV- and 70keV-EP imaging were significantly lower than those at the 70 keV PVP imaging for all structures ( $p < 0.05$ ) except for the equivalent SNR for the portal vein at 50 keV-EP. CNRs of the hepatic vessels at 50 keV-EP were significantly higher than those at 70 keV-EP, but significantly lower than those at 70 keV-PVP ( $p < 0.05$ ). There were no significant differences among the three images in the CNR of the lesions. In the qualitative analyses, 70 keV-EP and -PVP imaging showed significantly better noise, sharpness, and overall image quality than 50 keV-EP imaging for both readers ( $p < 0.05$ ). The conspicuity of the hepatic vessels at 50 keV-EP were significantly higher than that at 70-keV EP for both readers ( $p < 0.05$ ), and equivalent to that at 70 keV-PVP for one reader. Conspicuity of the lesions and adrenal veins were significantly the highest at 50 keV-EP.

## CONCLUSION

s Although 50 keV-EP imaging had worse image quality, it provided the best conspicuity of hepatic or pancreatic lesions and adrenal veins compared with 70 keV-EP and 70 keV-PVP imaging.

## CLINICAL RELEVANCE/APPLICATION

Virtual monoenergetic imaging at 50 keV during the equilibrium phase of abdominal CT may be helpful for the assessment of hepatocellular carcinoma, pancreatic cancer, and adrenal veins.

### **T2-SPGI-5 The Extracellular Volume Fraction with Iodine (water) Image of Dual-energy Computed Tomography in Predicting P53 Expression of Rectal Cancer**

Participants  
Chen Anliang, Dalian, China (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the feasibility of extracellular volume (ECV) fraction determined with iodine(water) image of dual-energy computed tomography (DECT) for prediction of P53 expression of rectal cancer.

## METHODS AND MATERIALS

A retrospective analysis was performed on 41 rectal cancer patients confirmed with P53 expression according to their postoperative pathology results who received abdominal enhanced DECT in our hospital. They were divided into group 1 (high-group; 21 patients; 14 male, 7 female, mean age: 67.95 years, range: 52-91 years) and group 2 (low-group; 20 patients, 15 male, 5 female, mean age: 64.60 years, range: 44-89 years) according to their P53 expression. Three ROIs were placed in the largest layer of rectal cancer in iodine(water) images created from equilibrium-phase contrast-enhanced DECT images. The iodine values of the left external iliac artery or femoral artery at the same layer with lesions were also measured. The ECV fraction were calculated and were analyzed with independent sample t-test. The ROC curve was generated using the ECV fraction, and the area under curve (AUC) was calculated to analyze the diagnostic performance of using the ECV fraction in predicting P53 expression of rectal cancer.

## RESULTS

There was a statistically significant difference in the ECV fraction between high-group (45.83±9.76)% and low-group (55.81±12.83)% ( $p < 0.05$ ). The AUC, maximum Youden index and diagnostic threshold of using the ECV fraction for prediction of P53 expression of rectal cancer was 0.717, 0.407 and 56.73%, and the sensitivity and specificity were 55.0% and 85.7%, respectively.

## CONCLUSION

s ECV fraction determined with equilibrium contrast-enhanced iodine(water) image of DECT images was useful for predicting P53

expression of rectal cancer.

#### **CLINICAL RELEVANCE/APPLICATION**

ECV fraction created from gemstone spectral imaging (GSI) has a prospective clinical application in predicting the P53 expression of rectal cancer for the treatment decision-making.

#### **T2-SPGI-6 Assessment of the Liver Low-density Lesions with a Spectral CT**

##### **PURPOSE**

This study was aimed to compare and evaluate the image quality of intra-hepatic low-density lesions in spectrum computed tomography (CT) with different monochromatic energy images in the arterial phase, the portal vein phase, and the delayed phase, respectively, and to explore the exact monochromatic value of optimum image quality.

##### **METHODS AND MATERIALS**

Patients with intra-hepatic low-density lesions were prospectively enrolled in our institution. GE Revolution CT was used to perform enhanced upper abdominal scan. Adaptive statistical iterative reconstruction (ASIR-V) was set with 40%, 50%, 40%, and 30% for true non-enhanced abdominal scanning, enhanced abdominal scanning in the arterial phase, the portal vein phase, and the delayed phase, respectively. The arterial phase and the portal vein phase applied a spectral mode with fast switch 80/140 kV, and tube current was automatic (range from 100 to 600 mA). The average CT value and standard deviation (SD) of the lesions were measured and recorded at 50, 60, 70 and 80 keV in the arterial phase, the portal vein phase respectively, and the signal-to-noise ratio value was calculated and compared pair-to-pair. Paired-samples t-test was used to compare the mean value of SNR and SD in the arterial phase, the portal vein phase, and the delayed phase, respectively.  $P < 0.05$  was considered statistically significant.

##### **RESULTS**

A total of twenty patients were prospectively included finally (male: 5, female: 15; mean age: 65.4 years old), with a total of 35 lesions. For the arterial phase, the signal-to-noise ratio values of the lesion in the imaging with 80 keV was higher than those of 50, 60 and 70 keV ( $12.75 \pm 1.6$ ,  $0.49 \pm 1.18$ ,  $0.71 \pm 1.30$ ,  $0.94 \pm 1.41$ , respectively;  $? < 0.001$ ), and there was no statistically significant difference among the 50, 60, and 70 keV groups. For the portal vein phase, the signal-to-noise ratio values of 50, 60, 70, and 80 keV groups were  $1.32 \pm 1.08$ ,  $1.41 \pm 1.26$ ,  $1.49 \pm 1.44$ ,  $1.58 \pm 1.61$ , respectively; and there was no statistical difference among the different keV groups ( $? > 0.05$ ).

##### **CONCLUSION**

The image quality with 80 keV of single-energy imaging of spectrum CT was significantly better than that of other monochromatic energy (50, 60, 70 keV) imaging in the arterial phase. But for the portal vein phase imaging, there was no statistical difference in the imaging quality of the liver lesions in scans with different keV. As a result, it is supposed to reduce the radiation dose of scans by decreasing the keV in the portal vein phase without compromising the image quality prospectively, but not in the arterial phase.

#### **CLINICAL RELEVANCE/APPLICATION**

It is supposed to reduce the radiation dose of scans by decreasing the keV in the portal vein phase without compromising the image quality prospectively, but not in the arterial phase.

#### **T2-SPGI-7 The Difference Between Virtual Non-enhanced Imaging and True Nonenhanced Imaging: A Comparison Study**

##### **PURPOSE**

To compare the difference in image quality and radiation dose between virtual non-enhanced (VNE) images and true non-enhanced (TNE) images in the arterial and the portal phase.

##### **METHODS AND MATERIALS**

Sixty-four patients were enrolled in this prospective study. GE Revolution CT was used for enhanced upper abdominal scanning. Adaptive statistical iterative reconstruction (ASIR-V) were set with 40%, 50%, 40%, and 30% for true non-enhanced abdominal scanning, enhanced abdominal scanning in arterial phase, portal vein phase, and delayed phase, respectively. The effective radiation dose (ED) and the size-specific dose estimation (SSDE) of virtual non-enhanced images and true non-enhanced images were calculated respectively. The mean CT values and standard deviation (SD) of liver parenchyma, spleen parenchyma and renal cortex in VNE images and TNE images were measured, and the signal-to-noise ratio (SNR) was calculated.

##### **RESULTS**

For radiation dose, the ED of VNE images gained from portal vein phase was the highest, followed by VNE from arterial phase reconstruction, and the lowest ED belonged to TNE images ( $4.59 \pm 1.98$ ,  $3.81 \pm 1.44$ ,  $3.67 \pm 1.71$ , respectively). The differences of ED between the latter two were significant compared with the portal phase. The significant difference was detected only between VNE images from the arterial (SSDEa) and the portal phase (SSDEp) ( $1.47 \pm 2.27$  vs  $10.50 \pm 2.03$ ,  $? = 0.036$ ). For image quality: Liver There was no significant difference between the SNR of VNE images (SNRVNE) obtained from arterial phase and TNE (SNRTNE) ( $? = 0.083$ ). The SNRVNE obtained from portal phase was better than that obtained from arterial phase and the SNRTNE. (SNRTNE vs portal SNRVNE:  $7.26 \pm 1.32$  vs  $12.85 \pm 2.21$ ,  $? < 0.001$ ; arterial SNRVNE vs portal SNRVNE:  $6.53 \pm 1.98$  vs  $12.85 \pm 2.21$ ,  $? < 0.001$ ). Spleen: The SNRVNE obtained from arterial phase and portal phase were better than that of SNRTNE and the difference was statistically significant (all  $? < 0.001$ ). Kidney The SNRVNE obtained from arterial phase and portal phase were better than that of SNRTNE and the difference was statistically significant (all  $? < 0.05$ ).

##### **CONCLUSION**

In terms of the radiation dose, the dose of VNE from portal vein was still the highest for ED, but its SSDE was the lowest instead. In terms of image quality, the VNE images of some organs at certain phases (such as hepatic portal phase, splenic artery phase and portal vein phase, renal artery phase and portal vein phase) were better than that of TNE images.

#### **CLINICAL RELEVANCE/APPLICATION**

Spectral CT was comparable to conventional CT in image quality, and even superior than it in the imaging of some organs, while radiation dose needed to be further verified.

## **T2-SPGI-8 Efficiency Analysis of Dual-layer Spectral Detector CT Iodine Concentration Value Related Parameters in Diagnosis of Regional Lymph Node Metastasis of Gastric Adenocarcinoma**

### **PURPOSE**

To compare the tumor pathological characteristics and spectral CT quantitative parameters between patients with and without regional lymph node metastasis of gastric adenocarcinoma.

### **METHODS AND MATERIALS**

The clinical data and preoperative spectral CT images of 55 cases of gastric adenocarcinoma confirmed by pathology in a hospital from June 2021 to June 2022 were retrospectively collected. Patients were divided into metastatic lymph node lesion group (32 cases) and non-metastatic lymph node lesion group (23 cases) according to whether there were metastatic lymph nodes in all the lymph nodes examined in the pathological results. Then lymph nodes were taken as the research object, and all lymph nodes were divided into the metastatic lymph node group (25 lymph nodes) and the non-metastatic lymph node group (27 lymph nodes) according to the nature of lymph nodes recorded in the pathological report. The IC values and normalized IC (nIC) values of gastric cancer lesions and lymph nodes in the arterial and venous phases (ICa and ICp, nICa and nICp) were obtained. The difference of IC and nIC values between arterial and venous phases (  $\Delta$ IC and  $\Delta$  nIC) were calculated, and the arterial enhancement fraction (AEF, ratio of ICa and ICp of lymph nodes ) was calculated. Student's t test or Mann-Whitney U test was used to compare the differences of quantitative parameters between the two groups. The parameters with statistical differences were analyzed by the receiver operating characteristic (ROC) curve to obtain the diagnostic efficacy of each parameter in evaluating lymph node metastasis of gastric cancer, and the Z test was used to compare the area under the curve (AUC) of each parameter.

### **RESULTS**

The ICp, nICp,  $\Delta$ IC and  $\Delta$  nIC of the lymph node metastatic lesion group were higher than those of the lymph node non-metastatic lesion group (all  $P < 0.05$ ). The AUC were 0.738, 0.746, 0.811 and 0.821. There were significant differences in AUC between ICp and  $\Delta$ IC,  $\Delta$  nIC ( $Z=2.41, 3.29, P=0.016, 0.001$ ), and between nICp and  $\Delta$ IC,  $\Delta$  nIC ( $Z=2.10, 3.09, P=0.036, 0.002$ ) in gastric cancer lesions. The short diameter, ICa, nICa and AEF values of lymph nodes in the metastatic lymph node group were higher than those in the non-metastatic lymph node group (all  $P < 0.05$ ). The AUC were 0.821, 0.832, 0.734 and 0.863. There were statistically significant differences in AUC between nICa and ICa, AEF ( $Z=2.09, 2.41, P=0.037, 0.016$ ) in lymph nodes.

### **CONCLUSION**

The quantitative parameters related to IC values of spectral CT can be applied to evaluate the properties of regional lymph nodes in patients with gastric adenocarcinoma, where  $\Delta$ IC,  $\Delta$  nIC of lesions and AEF of lymph nodes have the best efficacy.

### **CLINICAL RELEVANCE/APPLICATION**

Stomach neoplasms; Adenocarcinoma; Lymphatic metastasis; Spectral CT; Iodine concentration

T2-SPGU

### Genitourinary Imaging Tuesday Poster Discussions

#### Sub-Events

#### T2-SPGU-1 From Biopsy to Resection: Using CT to Predict Histologic Upgrading of Renal Masses

##### PURPOSE

Despite the popularity of renal mass biopsy, discordance can occur between the biopsy nuclear grade and the surgical specimen grade. Nuclear grade affects recurrence and mortality rates, and any discordance can lead to suboptimal management. The rate of tumor growth has been used to predict upgrade despite limited literature evidence. This study aims to create a risk prediction model for upgrading of clear cell renal cell carcinoma (ccRCC) based on CT imaging features and compare its performance against tumor growth rate.

##### METHODS AND MATERIALS

This IRB-approved single-center retrospective case-control study included 114 patients (76 male, median age=62 years) who underwent renal mass biopsy followed by surgical resection. The upgrade group (n=57) was defined as low grade ccRCC (ISUP 1 or 2) on biopsy and high grade (ISUP 3 or 4) on subsequent nephrectomy, while the control group (n=57) had no upgrade. The average growth in largest dimension per month and tumor volume doubling time were calculated using available cross-sectional imaging prior to resection. Twenty-two imaging features were assigned utilizing pre-biopsy renal triphasic CT. Features that had inadequate differentiation following univariable logistic regression were excluded. Remaining features were included in a multivariable logistic regression model using a stepwise model selection. The predictive performance of the final risk prediction model was evaluated using repeated 10-fold cross-validation and compared with measures of tumor growth.

##### RESULTS

Arterial enhancement, delayed enhancement, relative arterial enhancement, relative delayed enhancement, arterial wash-in and imaging necrosis were significantly different between the groups ( $p<0.05$ ). Importantly, tumor growth rate and doubling time were not statistically different. Four features (1 qualitative, 3 quantitative) were included in the final risk prediction model: mass heterogeneity ("heterogeneous" or "homogeneous"; OR=0.53), arterial enhancement (OR=0.46), relative delayed enhancement (OR=0.64), and enhancement ratio (OR=4.01). Using this model, a nomogram was constructed to predict probability of upgrade. The final risk prediction model resulted in a mean AUC of 0.69 (SD=0.17). This model performed better than measures of tumor growth ( $p<0.001$ ).

##### CONCLUSION

A model using CT imaging features performed better than measures of tumor growth and can be used to stratify the risk of renal mass upgrade at the time of surgical resection.

##### CLINICAL RELEVANCE/APPLICATION

This model identifies patients appropriate for active surveillance (low likelihood of upgrade) or immediate surgery (high likelihood of upgrade), avoiding the need for follow up imaging to assess tumor growth rates.

#### T2-SPGU-2 Beyond the Knife: A Retrospective Study on Surveillance-Based Management of Bilateral Multifocal Renal Oncocytomas

##### Participants

Shiva Singh, MBBS, Bethesda, MD (*Presenter*) Nothing to Disclose

##### PURPOSE

Bilateral multifocal renal oncocytomas account for approximately 4-6% of renal oncocytomas, and their optimal management strategy is still not well-defined due to a lack of consensus guidelines. This study aims to compare clinical, functional, and oncological outcomes of active surveillance (AS) versus surgical management in patients with bilateral multifocal renal oncocytomas, and to determine the appropriate management strategy for this group of patients.

##### METHODS AND MATERIALS

We conducted an IRB-approved retrospective cohort study on 62 patients with histopathologically confirmed bilateral multifocal renal oncocytomas. Patients with genetic alterations as seen in Birt-Hogg-Dubé syndrome or inadequate follow-up were excluded. The cohort was divided into three subgroups based on management received: active surveillance (AS) only, single unilateral surgery followed by AS, and multiple/bilateral surgeries. Clinical and imaging data were analyzed for longitudinal monitoring of tumor growth, new tumor/recurrence, and renal function changes. Statistical analysis was conducted to compare outcomes between the three management strategies.

##### RESULTS

The median age of the patients (n=62) was 64 years (IQR 57.5-69), and 49 (79%) were males. Patients were followed for an average of 5.5 years (2.8-7.2 years), and the median number of tumors per patient was 7, with no metastasis observed in any

group. The overall median tumor growth rate was 0.3 cm/year (IQR 0.1-0.5), with no significant difference among the three management groups ( $p=0.73$ ). The median age at death was 78.5 years (IQR 74.5-81.3,  $p=0.37$ ), and no significant differences were found in serum creatinine levels between the three groups at the initial time point ( $p=0.67$ ), final time point ( $p=0.5$ ), or change in serum creatinine levels over the period of treatment ( $p=0.7$ ).

## CONCLUSION

s Management strategies for bilateral multifocal renal oncocytomas are challenging, and clinicians face difficulties in choosing between surgical management and active surveillance. Findings of our study suggest that active surveillance is a safe and viable alternative to surgical management in patients with bilateral multifocal renal oncocytomas, with no detrimental impact on clinical, oncological, or functional outcomes as compared to surgical management.

## CLINICAL RELEVANCE/APPLICATION

Active surveillance may be a safe alternative to surgical management of bilateral multifocal renal oncocytomas, especially for elderly patients or patients with comorbidities who are at a heightened risk of developing surgery-related adverse events.

## T2-SPGU-3 Predicting Growth Rate of Clear Cell Renal Cell Carcinoma: A Comprehensive Analysis using Machine-Learning

Participants

Pouria Yazdian Anari, MD, North Bethesda, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Von Hippel-Lindau (VHL) syndrome is associated with multiple benign and malignant neoplasms, including renal cell carcinomas (RCC), resections of which overtime can lead to end-stage renal disease (ESRD). Active surveillance is recommended for small renal masses to avoid unnecessary surgeries while preserving renal function. However, there is currently no reliable method to predict the growth rate of renal lesions.

## METHODS AND MATERIALS

A single-center retrospective study of 55 patients with VHL was conducted from 2015 to 2021. Prior to partial or radical nephrectomy, patients underwent two MRI scans, and tumors were pathologically confirmed. Two abdominal radiologists assessed lesions based on 12 unique anatomical and sequence-specific imaging parameters using preoperative MRI scans. Lesions were divided into slow-growing (SG) and rapid-growing (RG) groups based on a 0.5 cm/year growth rate threshold. A stacked ensemble technique was employed to combine XGBoost and Random Forest algorithms, creating models that associate radiomic signatures with tumor grades. Optimal algorithm parameters were determined using 5-fold cross-validation, and performance was assessed on 100 different random test and train set combinations (85% train, 15% test) to identify the best model. Results were reported using positive predictive value (PPV), sensitivity, F1 score, and area under the Receiver Operating Characteristic curve (AUC-ROC). by using inter class correlation between two readers, they had moderate agreement.

## RESULTS

The stacked ensemble machine-learning model demonstrated promising performance in predicting the growth rate of clear cell renal cell carcinoma in VHL patients. The model demonstrated high accuracy (90%) and promising performance metrics, including a precision of 0.97 for SG tumors, recall of 0.98 for RG tumors, and an F1 score of 0.92 and 0.88 for SG and RG, respectively. The macro average for precision and recall was 0.89 and 0.92, respectively, with an overall F1 score of 0.90. The Matthews Correlation Coefficient (MCC) was 0.52, indicating a moderate correlation between the model's predictions and the true growth rates.

## CONCLUSION

s This study demonstrates the potential utility of using a stacked ensemble machine-learning model for predicting the growth rate of clear cell renal cell carcinomas in VHL patients. The model's high performance suggests it could be a valuable tool for guiding patient management and improving clinical decision-making in the active surveillance of small renal masses.

## CLINICAL RELEVANCE/APPLICATION

This machine-learning model could help optimize patient care by reducing the need for unnecessary surgeries, preserving renal function, and enabling timely interventions for patients with renal neoplasms.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

T2-SPHN

### Head & Neck Imaging Tuesday Poster Discussions

#### Sub-Events

#### **T2-SPHN-1 Establishment of a Clinical Decision Model with High Cost-effectiveness to Detect Local Recurrent Nasopharyngeal Carcinoma using Deep Learning Model Based on Magnetic Resonance Images: A Multi-center Study in Endemic Area**

#### **PURPOSE**

Routine magnetic resonance examination during post-treatment follow-up is crucial and efficient to detect recurrence nasopharyngeal carcinoma (rNPC). We aim to investigate the feasibility of detecting local rNPC using unenhanced MR images in selected subpopulation with the aid of deep learning model and proposed layered management during follow-up.

#### **METHODS AND MATERIALS**

Deep learning models using 3D DenseNet or Resnet based on unique sequence or T1W and T2W combined sequences were developed and fine-tuned to detect local rNPC in training and validation sets from three centers. Diagnostic efficacy was compared among T1WIC model and other models using McNemar's Z-test in both internal or external cohorts. A clinical decision model (CDM) was optimized through imposing T1\_T2 combined model and T1WIC models by setting sensitivity not less than 90%. Patients would be grouped into positive, suspicious and negative according to predicted values derived from T1\_T2 combined model, patients of the former two groups were recommended to have enhanced MR examination. Economic analysis was compared among CDM, T1\_T2 combined model and conventional method.

#### **RESULTS**

There were no statistics differences in overall accuracy, sensitivity and specificity between T1WIC model and other models either in internal or external cohorts when using 3D DenseNet or Resnet (all  $p > 0.0167$ ), with all of the power of test more than 95%. The ROC curves showed that the area under curve of T1\_T2 combined model was slightly above or similar to those of T1WIC model in either internal and external test set when using DenseNet (0.9296 vs 0.9124 in internal test set, 0.9065 vs 0.9071 in external test set, all  $p > 0.0167$ ). Particularly, the CDM showed higher accuracy and sensitivity and lower specificity than those of T1\_T2 combined model either in internal (accuracy, 85.91% vs 84.99%; sensitivity, 90.36% vs 84.26%; specificity, 82.20% vs 85.59%) and external (accuracy, 86.14% vs 84.16%; sensitivity, 90.32% vs 84.95%; specificity, 82.57% vs 83.49%) cohort. The total cost of examination using clinical decision model was \$344,665 and \$342,838 based on the actual incidence of internal and external cohort with a hypothetical cohort of 1,000 patients, when relative to \$326,453 of T1\_T2 combined model and \$355,233 of conventional method.

#### **CONCLUSION**

Herein, we have demonstrated that detection of local rNPC during post-treatment surveillance using unenhanced MR images with the aid of deep learning model was feasible in selected patients.

#### **CLINICAL RELEVANCE/APPLICATION**

The proposed clinical decision model showed potential application value in clinical practice with high cost-effectiveness without losing sensitivity in detecting local rNPC, contributing to layered management during follow-up.

#### **T2-SPHN-2 Artificial Intelligence Model to Predict Bethesda Score in Thyroid Nodule CT Imaging**

#### Participants

Isabel Gomez Alonso, MD, Malaga, Estonia (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The purpose of this work is to predict the Bethesda score of thyroid nodules by performing radiomic analysis of these nodules on CT images.

#### **METHODS AND MATERIALS**

This retrospective cohort study was performed by selecting 57 adult patients with thyroid nodules who underwent a CT scan of the neck and a fine needle aspiration biopsy between 2013 and 2021. Segmentation of the thyroid nodules was performed by three PGY4 radiology residents using CT images. Subsequently, 3D Slicer was used to extract the radiomic data of every segmented section in each patient. Data were processed with Python, using logistic regression and Machine Learning algorithms to predict the different Bethesda scores (score II-V) based on the radiomic features obtained. Visual assessment of the nodules was also performed by the three PGY4 radiology residents. Results were processed using IBM SPSS Statistics software. The whole process was supervised by a 5 year experienced head and neck radiologist and a 30 year experienced neuroradiologist.

#### **RESULTS**

In differentiating Bethesda II and V nodules, both logistic regression and K means showed a low performance (45% precision, 33% sensitivity and 57% specificity for logistic regression and 51% precision for K means). Random Forest classifier displayed 69 %

precision, 100% sensitivity and 100% negative predictive value, being able to detect all Bethesda V nodules. Finally, Support Vector Machine classifier showed 77% precision (75% sensitivity, 77% specificity, 87% negative predictive value).

## CONCLUSION

s Texture analysis-based artificial intelligence algorithms have demonstrated a 77% precision in differentiating Bethesda II and V nodules on CT imaging.

## CLINICAL RELEVANCE/APPLICATION

Thyroid nodule management is complex and often requires to perform invasive diagnostic procedures. Radiologists using artificial intelligence models may help predicting nodule malignancy and, consequently, reducing limitations of current diagnostic algorithms.

### T2-SPHN-3 MRI-based Radiomics Nomogram for Distinguishing Solitary Fibrous Tumor from Schwannoma in the Orbit: A Two-center Study

#### PURPOSE

To investigate the value of magnetic resonance imaging (MRI) radiomics for distinguishing solitary fibrous tumor (SFT) from schwannoma in the orbit.

#### METHODS AND MATERIALS

A total of 140 patients from two institutions were retrospectively included. All patients from institution 1 were randomized into a training cohort (n = 69) and a validation cohort (n = 35), and patients from institution 2 were used as an external testing cohort (n = 36). One hundred and six features were extracted from T2-weighted imaging (T2WI) and contrast-enhanced T1-weighted imaging (CET1WI). A radiomics model was built for each sequence using least absolute shrinkage and selection operator logistic regression, and radiomics scores were calculated. A combined model was constructed and displayed as a radiomics nomogram. Two radiologists jointly assessed tumor category based on MRI findings. The performances of the radiomics models and visual assessment were compared via area under the curve (AUC).

#### RESULTS

Seven and two radiomics features were selected from T2WI and CET1WI, respectively. The radiomics nomogram combining the two radiomics scores performed well in discriminating between schwannoma and SFT, with significantly higher AUCs than the readers in the training (AUC 0.986 vs. 0.807,  $p < 0.001$ ), validation (AUC 0.989 vs. 0.788,  $p = 0.009$ ), and the testing (AUC 0.903 vs. 0.792,  $p = 0.018$ ) cohorts. Decision curve analysis demonstrated that the radiomics nomogram had better clinical utility than visual assessment.

## CONCLUSION

s MRI radiomics nomogram can be used for distinguishing between orbital SFT and schwannoma, which may help tumor management by clinicians.

## CLINICAL RELEVANCE/APPLICATION

& It is challenging to differentiate SFT from schwannoma in the orbit due to similar clinical and image features. & A radiomics nomogram based on T2WI and CET1WI has advantages over radiologists. & Radiomics can provide a non-invasive diagnostic tool for differentiating between the two entities.

### T2-SPHN-4 Pioneering a Multi-Modal Deep Learning Approach for Hypopharyngeal Cancer Segmentation: Comprehensive Evaluation and Performance Analysis using Diverse MRI Data Across Multiple Institutions

#### PURPOSE

Accurately annotating tumors is a time-consuming process, thus it is crucial to design an approach that can automate this process while maintaining accuracy. The study aims to develop and evaluate a multi-modality deep learning-based segmentation model for accurate and efficient delineation of hypopharyngeal cancer from T1-weighted image, contrast-enhanced T1-weighted image (T1c), and T2-weighted MRI scans. We utilized the nnU-Net architecture, ensembling techniques, and multi-institution datasets to improve the performance of our model.

#### METHODS AND MATERIALS

In this study, we used a dataset of 209 patients with hypopharyngeal cancer from National Taiwan University Hospital (NTUH) to train and ensemble three separate nnU-Net models on T1-weighted image, contrast-enhanced T1 (T1c), and T2-weighted MRI scans. To determine the best combination of models, we utilized nested five-fold cross-validation and ensembled the cross-validation results. The tumor annotations were performed by experienced oncologists on the patients treated between February 2011 and January 2015. We evaluated our model using various metrics on a testing dataset from Chang Gung Memorial Hospital (CGMH), which includes 91 patients treated between 2003 and 2013. The nnU-Net architecture was selected for this study due to its remarkable performance in various medical image segmentation challenges, which is expected to improve the segmentation results of hypopharyngeal cancer from multi-modality MRI scans. It consists of a 3D U-Net with an end-to-end pipeline that includes pre-processing, data augmentation, and post-processing.

#### RESULTS

The average tumor size in our training dataset from NTUH was 27.5 cm<sup>3</sup>. Our ensemble model achieved a mean Dice similarity coefficient (DSC) of 0.92 during training. On the independent testing dataset from CGMH our model achieved an overall DSC of 0.75 and a Hausdorff distance of 19 mm, demonstrating its robustness and generalizability.

## CONCLUSION

s The developed deep learning-based segmentation model can accurately and efficiently delineate hypopharyngeal cancer from multi-modalities and multi-institutional MRI scans, which has the potential to enhance clinical diagnosis and treatment planning for patients with hypopharyngeal cancer. The nnU-Net architecture and ensembling approach improve the segmentation performance and increase the robustness of the model, and have the potential to be applied to other cancer types and imaging modalities.

## CLINICAL RELEVANCE/APPLICATION

Our metric analysis showed that the model has the potential to efficiently optimize hypopharyngeal cancer segmentation workflows and to be implemented in clinical decision support.

### T2-SPHN-5 AI for Automatic Localization and 3D Segmentation of Lymph Node Metastasis in Head and Neck Cancer

Participants  
Miriam Rinneburger, MD, Cologne, Germany (*Presenter*) Nothing to Disclose

#### PURPOSE

Evaluation of an AI algorithm for localization and segmentation of lymph nodes (LNs) in contrast-enhanced computed tomography scans (CECTs) of the head and neck region on patients with head and neck cancer with confirmed LN metastasis.

#### METHODS AND MATERIALS

We searched our local database for patients sent from the otorhinolaryngological department from January 2000 to January 2021 for staging of a head and neck cancer who had at least one untreated LN metastasis confirmed through central necrosis, PET/CT-positivity, positive histology and/or progression/regression in a follow up scan. All 125 CECTs had a slice thickness of 1-2.5 mm, were conducted supine with venous contrast enhancement and reconstructed with a soft kernel. Patient age was 61,96 +/- 10,7 years, 25 patients were female and 100 male. On this cohort, we applied our existing 3D LN segmentation model. Independently, all LNs with a short axis diameter of = 5 mm were manually segmented by an experienced radiologist and double-checked by a second radiologist as a reference. Additionally, LN metastases were labelled to evaluate the AI model's performance specifically on LN metastases.

#### RESULTS

In 125 CECT scans of the head and neck, the AI model marked 4271 LNs whilst 3656 LNs were segmented manually. Out of 544 LNs manually labelled as a clinical metastasis, the model detected 486. Overall, an average localization rate (LR) of 83.56% with 12.8 false positives (FPs) per CT scan was achieved. On average, only one of these FPs had an SAD of = 5mm. The model showed a statistically significant ( $p = 0.0029$ ) higher localization performance for metastatic LNs with an LR of 89.0% whilst for non-metastatic LNs, it reached an LR of 82.8%. The average global Dice accounts to 0.58 per CT scan. Segmentation accuracy was higher for non-metastatic LNs with a global Dice of 0.65 while it accounts to 0.42 for LN metastases. Sensitivity was higher in metastatic (0.69) than in non-metastatic LNs (0.58).

#### CONCLUSION

Our existing AI model for 3D segmentation of cervical LNs generalizes well to metastatic LNs. Overall, LR and segmentation sensitivity are higher in metastatic than in non-metastatic LNs whilst Dice is slightly worse. Clinical applicability of this model for metastatic LNs appears feasible.

## CLINICAL RELEVANCE/APPLICATION

Automatic LN localization for N staging can speed up clinical practice. LN metastasis of head and neck cancer can differ from other malignancies in shape and texture. Thus, localization might need explicit training.

### T2-SPHN-6 Morphology-based Radiomics and Machine-Learning Models for Predicting Lymph Node Status in Oral Tongue Squamous Cell Carcinoma

#### PURPOSE

To develop machine-learning models based on morphological features extracted from preoperative magnetic resonance imaging (MRI) to predict lymph node status in oral tongue squamous cell carcinoma (OTSCC).

#### METHODS AND MATERIALS

This study retrospectively enrolled 90 OTSCC patients, of whom 45 and 13 patients, respectively, had confirmed lymph node metastasis (LNM) and extranodal extension (ENE). Fourteen morphological features and two customized metrics were derived from T2-weighted (T2W) images. Tumor maximum diameter and MRI-derived depth of invasion (DOI) were measured on contrast-enhanced T1-weighted (ceT1W) images. Information gain algorithm was applied to select the top five attributes. Models were created using six machine-learning methods, including neural network (NN), random forest (RF), logistic regression (LR), support vector machine (SVM), naïve bayes (NB), and AdaBoost. An internal stratified 10-fold cross-validation was performed to assess their performance.

#### RESULTS

For predicting LNM, the NN classifier, which included Situation, Elongation, Top Bottom Area, Least Axis Length, and Minor Axis Length, yielded the best model, with an AUC of 0.746 and accuracy of 72.2%. The performance of the NN model was slightly superior to that of MRI-derived DOI (0.746 vs. 0.655), although the difference was not significant ( $P=0.122$ ). For predicting ENE, the SVM classifier, which included situation, Elongation, Top Bottom Area, Least Axis Length, and Minor Axis Length, performed the best, with an AUC of 0.750 and accuracy of 85.6%.

#### CONCLUSION

Machine-learning models using MRI morphological features have potential in preoperative evaluation of cervical lymph node status in OTSCC.

## CLINICAL RELEVANCE/APPLICATION

Morphological features of tumors such as diameter and DOI measured on preoperative imaging are predictive of tumor staging and are more straightforward for clinical use than other radiomics features. Machine-learning models using MRI-derived morphological features could be a feasible noninvasive tool for predicting cervical lymph node status in OTSCC.

### T2-SPHN-7 Study on Automatic Detection Model of Cervical Lymph Node Metastasis in Oral Squamous Cell Carcinoma Based on Deep Learning

## **PURPOSE**

The purpose of this study was to establish a deep-learning model for automatically detecting metastatic LNs of oral squamous cell carcinoma patients(OSCC) from contrast-enhanced computed tomography (CT) images.

## **METHODS AND MATERIALS**

We collected 114 contrast-enhanced CT of oral cancer patients. The metastatic LNs of these patients have been pathologically confirmed, a total of 216. All CT scans are with a slice thickness of 0.625 mm and resolution is 512x512. For evaluation, we randomly split the 114 CT scans into 80 for training and 34 for testing. The above results were trained and verified by a deep learning model. Performance in segmenting lymph node stations and detecting metastasis were obtained.

## **RESULTS**

Performance in detecting metastatic lymph nodes showed FROC@1 of 0.3915, FROC@2 of 0.5183, FROC@3 of 0.6478, FROC@4 of 0.7408, FROC@5 of 0.8169, FROC@6 of 0.8535, mFROC of 0.6615, maxF1-score of 0.4385, the best performance of recall rate is 87.32%.

## **CONCLUSION**

A deep-learning model can be used to automatically detect metastatic lymph nodes in Contrast-enhanced CT images of patients with oral squamous cell carcinomas, which provides a new idea for the rapid detection of metastatic lymph nodes and realize the spread of knowledge of radiologists of head and neck imaging and improve the training efficiency of primary radiologists.

## **CLINICAL RELEVANCE/APPLICATION**

Ariji Y, Fukuda M, Kise Y et al. Contrast-enhanced computed tomography image assessment of cervical lymph node metastasis in patients with oral cancer by using a deep learning system of artificial intelligence. *Oral Surg Oral Med Oral Pathol Oral Radiol.* 2019 May;127(5):458-463. ### Imaging Informatics Tuesday Poster Discussions

#### Sub-Events

#### T2-SPIN-1 TransUNet for Fully Automated Abdominal Multi-Organ Segmentation

##### Participants

Khoschy Schawkat, MD, PhD, Boston, MA (*Presenter*) Nothing to Disclose

##### PURPOSE

The purpose of this study was to validate the efficacy of CNN-Transformer hybrid architectures for multi-organ segmentation when applied to an independent, in-house dataset consisting of abdominal CT scans. The goal is to achieve a fully automated and highly accurate abdominal multi-organ segmentation computational framework that can be applied to the routine clinical workflow.

##### METHODS AND MATERIALS

The dataset consisted of 200 abdominal CT scans with 59 axial non-contrast and 131 contrast-enhanced abdominal (20 arterial phase, 90 portal venous phase, 19 late venous phase, and 12 elimination phase) clinical CT image series. Each CT volume consists of 44-392 slices of 512 x 512 pixels. The organ segmentations were performed manually and semiautomatically with manual verification on the liver, pancreas, left and right kidney, and spleen using free software for medical image processing (3D Slicer, version 4.11.0). We use the TransUNet architecture for our network, and train it using 5-fold cross validation with splits of 160/20 scans. TransUNet is trained on 4 organs of interest; liver, pancreas, kidneys and spleen. The 4 highest individual performing models are then ensembled. We report the average dice scores on a test set of 20 scans.

##### RESULTS

DICE scores for the labelmaps generated by the network, when compared against our ground truth images, for the liver, pancreas, kidneys, and spleen were 96.51, 83.02, 94.08, and 95.42, respectively. All organs of interest outperform the original scores reported in the authors' paper.

##### CONCLUSION

s TransUNet, a U-Net structure in combination with transformers, achieves excellent performance in CT based multi-organ segmentation as shown in our independent in-house dataset.

##### CLINICAL RELEVANCE/APPLICATION

Large scale application of this fully-automated CT based multi-organ segmentation model allows for efficient assessment of volumetric and radiomics data.

#### T2-SPIN-2 Semi-Automated Longitudinal Performance Monitoring for Deployed Large Vessel Occlusion Detection Algorithm

##### Participants

Chintan Shah, MD, MS, Cleveland, OH (*Presenter*) Spouse, Employee, Merck & Co, Inc

##### PURPOSE

Real-world performance of artificial intelligence (AI) models can vary and degrade over time. However, local performance and monitoring are often overlooked and are resource-intensive. We built a semi-automated method in order to reduce the manual effort required for local performance monitoring of an AI algorithm, using intracranial large vessel occlusion (LVO) as a use case. We utilize a framework consisting of a combination of structured reporting (SR), language processing (LP), and manual review of reports to assess performance.

##### METHODS AND MATERIALS

Between January and May 2022, 1702 CTAs of the head and neck for stroke alert were processed with a commercial LVO detection algorithm (Viz LVO, Viz.ai). Scans were done at 17 different sites, including 12 hospitals, and 5 standalone ERs. Exams were interpreted by a neuroradiologist, asked to indicate concordance via an SR template. An analytical pipeline was developed for processing the reports utilizing KNIME analytics software (KNIME AG, Switzerland). Radiologist concordance was determined using SR when available. Language processing (LP) was then applied utilizing regular expression searches to identify positive or negative reports. LP results were reviewed to determine accuracy. Indeterminate reports were manually reviewed and categorized, as were those marked as discordant by either SR or LP. Summary performance statistics were calculated.

##### RESULTS

Radiologist compliance with the SR concordance statement was 57% (966/1702). Among the remainder, 74.3% (547/736) could be categorized as positive or negative reports utilizing LP, leaving 11% of original volume (189/1702) requiring manual review. Of exams marked as discordant in the SR template by the interpreting radiologist, 63% (42/67) were correctly categorized. The performance of LP in categorizing reports showed a sensitivity, specificity, negative- (NPV), and positive-predictive value (PPV) of 85, 95, 99,

and 47%, respectively. After SR, LP and manual review, the sensitivity, specificity, NPV, and PPV of the commercial LVO detection algorithm were 77, 96, 98, and 59%, respectively.

## CONCLUSION

s SR alone was insufficient due to incomplete compliance and errors in categorization. The combined pipeline substantially reduced the workload of manual review better than structured reporting alone. The benefits persist after accounting for LP errors, which occurred more often with discordant than concordant results. We were able to corroborate local performance in this large multi-hospital dataset similar to that previously published.

## CLINICAL RELEVANCE/APPLICATION

Incorrect AI inference can negatively impact patient care; local validation is necessary. A semi-automated pipeline can reduce the manual workload of this process.

## T2-SPIN-3 MRI-based Radiomic Features Fail to Accurately Predict Primary Tumor Histology of Brain Metastases in External Validation: An Investigation of Class Imbalance and the Impact of Oversampling Techniques

### PURPOSE

Growing research demonstrates the ability to predict histology or genetic information of various malignancies using radiomic features extracted from imaging data. Our aim was to investigate MRI-based radiomics in predicting the primary tumor of brain metastases through internal and external validation, using oversampling techniques to address class imbalance.

### METHODS AND MATERIALS

The local ethics committee approved this retrospective multicenter study. We included non-small and small cell lung cancer, melanoma, breast, and colorectal cancer (five-class classification). Internal train/validation/test data were acquired between 2003-2021 from 159 patients (422 metastases). External validation was performed with 67 patients (260 metastases) from the publicly available Stanford BrainMetShare dataset ([aimi.stanford.edu/brainmetshare](http://aimi.stanford.edu/brainmetshare)). Pre-processing included brain extraction, bias correction, co-registration, intensity normalization, and semi-manual binary tumor segmentation. 2889 radiomic and three location features were extracted from T1w, post-contrast T1w, FLAIR, and wavelet transforms for each sequence (eight decompositions). The internal dataset was split 80-20 into train/validation and test sets. Patients with multiple metastases were assigned to either the train/validation or test set to prevent data leakage. Various oversampling and machine learning techniques (five-fold cross-validation) were tested and evaluated on the test sets using accuracy, precision, recall, F1 score, AUC-ROC, and cross-entropy loss.

### RESULTS

Baseline (no oversampling) internal test set performance was suboptimal with accuracy, F1 score, and AUC-ROC of 0.48, 0.27, and 0.66, respectively. Accuracy and F1 score were slightly improved after random oversampling of the training partition (0.49 and 0.39, respectively). The models were not able to generalize to the external test set. Incorrect data partitioning (oversampling before train/validation/test split) resulted in a massive overestimation of model performance.

## CONCLUSION

s Radiomics models' capability to predict histologic or genomic data from imaging should be critically assessed.

## CLINICAL RELEVANCE/APPLICATION

Primary tumor histology of brain metastases is usually obtained by invasive biopsy, posing the risk of morbidity and mortality. AI methods could potentially noninvasively acquire this information.

## T2-SPIN-4 Unsupervised Learning of Chest Radiographs and Clinical Data Accurately Predicts Time to ICU Admission of COVID-19 Patients

### PURPOSE

To improve allocation of ICU resources to treat COVID patients, we developed an unsupervised learning pipeline that utilizes chest radiographs and clinical data to accurately predict time to ICU admission.

### METHODS AND MATERIALS

This HIPAA-compliant study was performed with a waiver for informed consent following institutional review board approval. The training dataset consisted of 1834 COVID positive patients from March 9 and July 20, 2020 and the external testing dataset consisted of 475 COVID positive patients between March 1 and July 18, 2020. A vision transformer (ViT) autoencoder model was used to extract unsupervised imaging features from chest radiographs before undergoing dimensionality reduction using PCA to concentrate pertinent imaging characteristics. We then combined these imaging features with age, sex and common comorbidities prior to feeding into a partially unsupervised deep clustering survival machine (DCSM) for time to ICU prediction. DCSM characterizes each instance's survival information as a weighted combination of the learned expert distribution, which allows our model to better capture patient heterogeneity.

### RESULTS

Of the 1834 patients (54.9 $\pm$ 19.8 years old, 51% Female), 493 were admitted to the ICU (27%) within 1.88  $\pm$  3 days. The DCSM model predicted time to ICU admission with a c-index of .731  $\pm$  .02 on the training dataset and .72  $\pm$  .01 on the external patient dataset.

## CONCLUSION

s We developed a pipeline with ViT autoencoder and DCSM models that incorporates radiography and clinical data to accurately predict time to ICU admission in COVID patients. This method can also be applied to other similar clinical problems.

## CLINICAL RELEVANCE/APPLICATION

An unsupervised learning approach does not require manual annotation by a radiologist or healthcare worker and can be readily

deployed in the clinical setting where it can be used to triage patients for ICU admission.

## **T2-SPIN-5 Peritumoral and Intratumoral Texture Features Based on Multiparametric MRI and Multiple Machine Learning Methods to Preoperatively Evaluate the Pathological Outcomes of Pancreatic Cancer**

### **PURPOSE**

Radiomics-based preoperative evaluation of lymph node metastasis (LNM) and histological grade (HG) might facilitate the decision-making for pancreatic cancer and further efforts are needed to develop effective models.

### **METHODS AND MATERIALS**

The pancreatic cancer patients from the main center (n = 126) were assigned to the training and validation sets at a 4:1 ratio. The patients from the other center (n = 40) served as external test sets. The multiparametric MRI used in this study were: T2-weighted imaging, diffusion-weighted imaging, and dynamic contrast enhancement T1-weighted imaging. Peritumoral and intratumoral radiomics features were extracted which contained first-order, shape-based, and texture features. The following three-step method was applied to reduce the feature dimensionality: SelectKBest (a function from scikit-learn package), least absolute shrinkage and selection operator (LASSO), and recursive feature elimination based on random forest (RFE-RF). Six classifiers (random forest, logistic regression, support vector machine, K-nearest neighbor, decision tree, and XGBoost) were trained and selected based on their performance to construct the clinical, radiomics, and combination models.

### **RESULTS**

12 significant features for LNM and 11 features for HG were obtained. Random forest and logistic regression performed better than the other classifiers in evaluating LNM and HG, respectively, according to the surgical pathological results. The best performance was obtained with the models that combined peritumoral and intratumoral features with area under curve (AUC) values of 0.944 and 0.892 in the validation and external test sets for HG and 0.924 and 0.875 for LNM.

### **CONCLUSION**

s Radiomics holds the potential to evaluate LNM and HG of pancreatic cancer. The combination of peritumoral and intratumoral features will make models more accurate.

### **CLINICAL RELEVANCE/APPLICATION**

Radiomics is a noninvasive diagnosis and prediction method with theoretically high accuracy. In this two-center study, radiomics models for predicting LNM and HD of pancreatic cancer are successfully developed, and they enable radiologists to preoperatively stratify the risk of pancreatic cancer and provide explicit guidance for surgical options.

## **T2-SPIN-6 CFTR Modulator Therapy Influences Body Tissue Composition in Adults with Cystic Fibrosis: AI-based CT Analysis**

Participants

Marko Frings, MD, Essen, Germany (*Presenter*) Nothing to Disclose

### **PURPOSE**

A poor nutritional status is associated with worse pulmonary function and survival in patients with cystic fibrosis. CF transmembrane conductance regulator (CFTR) modulators can improve both pulmonary function and body weight, but more data is required to assess its effects on body composition.

### **METHODS AND MATERIALS**

A pre-trained, deep-learning network was used to perform a fully automated body composition analysis (BCA) on chest CTs from adult patients with CF before (baseline) and after (longitudinal data) receiving triple-combination elexacaftor/ tezacaftor/ ivacaftor therapy. Muscle and adipose tissue were quantified and divided by bone volume to obtain body size-adjusted ratios. Results from BCA were correlated with lung function parameters and laboratory results.

### **RESULTS**

At baseline, chest CT-based BCA was conducted in 85 patients, with 34 (40%) receiving either mono or dual-combination CFTR modulator therapy. Mono/ dual-combination CFTR modulator therapy was associated with higher adipose tissue ratios. Muscle ratio correlated with percent predicted FEV1 ( $r=0.465$ ,  $p<0.001$ ) and six-minute walk test ( $r=0.392$ ,  $p<0.001$ ). ETI therapy improved percent predicted FEV1 (+ 12 points,  $p<0.001$ ) in patients with CF at 3 months, independent of baseline BCA results. Follow-up chest CT scans were performed in 18 patients after starting elexacaftor/ tezacaftor/ ivacaftor therapy. Triple-combination therapy was associated with an increase of the total adipose tissue ratio (+27%,  $p=0.007$ ). However, muscle ratio remained stable ( $p=0.304$ ).

### **CONCLUSION**

s Fully automated CT-based BCA showed significant correlations with pulmonary function and six-minute walk test. Our findings suggest that CFTR modulator therapies primarily affect adipose tissue, not muscle tissue, in adults with CF. BCA may provide information on the individual nutritional status of patients with CF each time a CT scan is performed.

### **CLINICAL RELEVANCE/APPLICATION**

Our work presents a state-of-the-art method to quantify all body tissues from routinely acquired chest CT scans, making body composition analysis useful for daily clinical practice.

T2-SPIR

### Interventional Radiology Tuesday Poster Discussions

#### Sub-Events

#### T2-SPIR-1 Preliminary Study on Changes in Biliary Microbiota Before and After Drainage of Malignant Biliary Obstruction

##### PURPOSE

To explore the changes in biliary microbiota before and after malignant biliary obstruction drainage, and to study the impact of biliary obstruction and drainage intervention on bile microbiota from the perspective of microbiota.

##### METHODS AND MATERIALS

42 patients with malignant biliary obstruction underwent percutaneous transhepatic catheter drainage (PTCD) in our department from January 2020 to December 2022. Under DSA guidance, a 22G drainage needle was inserted into the bile duct and confirmed by angiography to be located within the intrahepatic bile duct, after that 15-20ml of bile sample was extracted; Implantation of external or internal/external drainage tubes through guide wires; After 7 days, bile sample was extracted through a drainage tube; Two bile samples were sent for culture and next-generation sequencing. Collect and organize general patient information, including whether acute cholangitis has occurred and its severity, and whether antibiotics have been used for treatment.

##### RESULTS

Among the 42 patients, there were 20 cases of cholangiocarcinoma, 13 cases of pancreatic cancer, 3 cases of hepatocellular carcinoma, and 6 cases of hilar lymph node metastasis (gastrointestinal malignant tumor). The relative abundance of Burkholderia, Acinetobacter, Pseudomonas and Staphylococcus in the bile microbiota before drainage was high; After drainage, the abundance of Staphylococcus, Klebsiella, Enterobacteriaceae, Aeromonas, Paracoccus, Anaerococcus, Diplococcus, Campylobacter and Megabacterium in bile samples increased, and the diversity and evenness of other microbial species diversity in normal biliary tract decreased.

##### CONCLUSION

There is a stable microbiota in the normal biliary system, and the composition of the microbiota in malignant obstructive bile ducts is similar to that in non diseased bile ducts. After drainage, the abundance of Bacillus, Streptococcus, Staphylococcus and Klebsiella in bile increased, which inhibited the growth of other original bacteria in the bile duct ecology, leading to the reduction of species diversity and evenness of the microbial community. This imbalance of biliary microbiota can explain the clinical phenomenon that patients are more prone to biliary tract infections after biliary drainage.

##### CLINICAL RELEVANCE/APPLICATION

After biliary drainage, the microbial community in the bile duct undergoes dysbiosis, which may continue to occur with the invasion of more invasive dominant bacteria, leading to new biliary infections. Therefore, when patients continue to be infected, bile culture needs to be performed again and clinical medication needs to be adjusted.

#### T2-SPIR-2 Characterization of Power and Microwave Ablation Volumes Following Arterial Embolization in an In Vivo Porcine Liver Model

##### Participants

Hiro Sparks, MD, (*Presenter*) Nothing to Disclose

##### PURPOSE

Combination therapy using transarterial embolization and microwave ablation (MWA) is increasingly utilized to treat hepatocellular carcinomas larger than 3 cm in diameter. Predicting the size of a MWA zone after transarterial embolization is an important component of combination therapy treatment planning, specifically to minimize damage to critical structures while maintaining adequate tumor margins. Power-time settings found in manufacturer guidelines are not applicable in embolized liver lobes due to alterations in perfusion and related heat sink effects. This study aims to better characterize the relationship between ablation volume and power in an in vivo porcine liver model following embolization.

##### METHODS AND MATERIALS

With animal IRB approval, ten female Yorkshire swine, underwent either right (n= 5) or left (n= 5) hepatic artery embolization under fluoroscopic guidance. Subsequently, ultrasound guided MWA was performed in each liver segment (left lateral, left medial, right medial, right lateral) at either 30 Watts (W) (n=4 lobes), 60W (n=4), 65W (n=20), 90W (n=4), 120W (n=4), or 140W (n=4) continuously for 5 minutes (Certus 140 and PR-15, NeuWave Medical Inc, Madison, WI). Post-procedural volumetric segmentation was performed on standardized T1-weighted postcontrast images in arterial, venous, and delayed phases.

##### RESULTS

Paired Wilcoxon test demonstrated that ablation volumes in embolized lobes (16.9 +/- 8.9 cc) were significantly larger than non-embolized lobes (12.9 +/- 6.6 cc , P = 0.012, Figure 1). MWA power had a significant positive linear correlation with both embolized

(Pearson R,  $P < 0.01$ ) and non-embolized lobes ( $P < 0.01$ , Figure 2). The slope of the linear model corresponded to a 0.21 cc/W and 0.12 cc/W increase in ablation volume per unit wattage in embolized and non-embolized lobes, respectively. Embolization had a larger effect on ablation volumes at higher Wattage with a projected convergence of trendlines at 26.7 W, suggesting minimal effect of embolization at lower powered ablation. Model-derived ablation volumes at varying power are displayed in Table 1.

## CONCLUSION

s Linear models demonstrate a near two-fold increase in ablation zone volume per additional Watt when applied to embolized lobes relative to non-embolized lobes. Volumetric differences between embolized and non-embolized lobes were greater at higher power MWA.

## CLINICAL RELEVANCE/APPLICATION

In the setting of hepatic combination therapy, transarterial embolization decreased blood flow within the liver parenchyma and reduced heat dissipation during subsequent MWA. This work provides novel insight into of the interactions between power, embolization, and MWA volume, which are critically relevant to the safe planning of combination therapy.

## T2-SPIR-3 Relationships of Plasma Arginase-1 and Transcatheter Arterial Chemoembolization Resistance and Prognosis in Patients with Hepatocellular Carcinoma

### PURPOSE

To observe the plasma arginase-1 (Arg-1) levels in patients with hepatocellular carcinoma before transcatheter arterial chemoembolization (TACE) treatment, and to investigate the relationship between Plasma Arg-1 levels and TACE resistance and prognosis.

### METHODS AND MATERIALS

A total of 148 patients with HCC, treated with TACE, were included in the study. Pre-treatment enzyme-linked immunosorbent assay detected the patients' plasma ARG1 levels, and independent predictors of early TACE refractoriness were determined using a multivariate logistic regression model, based on which a predictive model was presented using a nomogram.

### RESULTS

The mean follow-up period was 13 (range 1-26) months; 120 (69.5%) of 148 patients developed TACE refractoriness. Risk of early TACE refractoriness was negatively correlated with plasma ARG1 levels, and multivariate analysis showed tumour size (OR=1.153, 95% CI=1.004-1.3249,  $P=0.044$ ), tumour number = 4 (OR=8.699, 95% CI=1.228-61.62,  $P=0.030$ ), platelet count (OR=0.981, 95% CI=0.969-0.993,  $P=0.002$ ), and plasma ARG1 levels (OR=0.267, 95% CI=0.110-0.698,  $P=0.007$ ) to be independent prognostic factors for early TACE refractoriness; the nomogram, based on four independent prognostic factors, showed good predictive accuracy for early TACE refractoriness incidence. The c-index value for nomogram of the entire cohort was 0.833 (95% CI = 0.760-0.905).

### CONCLUSION

s Plasma ARG1 levels correlated with early TACE refractoriness, higher levels being related to lower risk. The size and number of tumours and platelets, and plasma ARG1 levels were suggested to be prognostic factors affecting early TACE refractoriness. The nomogram could realise individualised prediction of the incidence of early TACE refractoriness.

## CLINICAL RELEVANCE/APPLICATION

This study aimed to investigate the association between pre-treatment plasma ARG1 levels and early transarterial chemoembolization refractoriness in hepatocellular carcinoma patients, by developing and validating a novel plasma ARG1-based nomogram for predicting early transarterial chemoembolization refractoriness. We believe that our study makes a significant contribution to the literature because we developed a nomogram based on ARG1 expression levels combined with different tumour parameters to predict the risk of early transarterial chemoembolization refractoriness in patients with hepatocellular carcinoma treated with transarterial chemoembolization.

## T2-SPIR-5 Freiburg Index of Post-TIPS Survival (FIPS): Independent External Validation in a Cohort of Patients from a Low Socio-economic South Asian Country

### PURPOSE

To externally validate the Freiburg Index of Post-TIPS Survival (FIPS) score in a new cohort of patients and assess its performance in predicting post-TIPS survival.

### METHODS AND MATERIALS

Study design: This is a retrospective study of patients who underwent TIPS placement between January 1, 2006, and January 31, 2022, at a tertiary care center. Study population: The study population consisted of 44 patients. This study adheres to the TRIPOD checklist to ensure transparent reporting and facilitate the interpretation and reproducibility of our findings. Predictor: The FIPS score was calculated for each patient in the validation cohort using the original FIPS score equation. Outcome: The primary outcome was post-TIPS survival at 28 days, 3 months and 6 months. Statistical analysis: The discrimination and calibration of the FIPS score were assessed using the c-statistic and calibration plot, respectively. The performance of the FIPS score was compared to its original validation study, as well as to other post-TIPS survival prognostic models.

### RESULTS

The FIPS score ranged from -4.2 to 2.44. The overall 6-month observed survival rate was 75.7%. Kaplan-Meier analysis showed that patients with a high-risk FIPS score ( $\geq 0.92$ ) demonstrated significantly reduced survival compared to those with a low-risk FIPS score ( $< 0.92$ ;  $p=0.018$ ). The FIPS score demonstrated good discrimination in predicting post-TIPS survival in comparison to the MELD 3.0 score (c-statistic = 0.825 for FIPS vs 0.752 for MELD 3.0, 95%). The calibration plot showed good agreement between the observed and predicted 1-year survival rates. FIPS score showed better calibration compared to MELD 3.0 (Brier score 0.131 for FIPS vs 0.221 for MELD 3.0). The observed-to-predicted ratio (O:P) for FIPS was 1.354 and that for MELD 3.0 was 1.065. The performance of the FIPS score in the validation cohort was comparable to its original validation study.

### CONCLUSION

s Our study provides an independent external validation of the FIPS score in a new cohort of patients undergoing TIPS placement. The FIPS score showed good performance in predicting post-TIPS survival, suggesting that it can be a valuable tool in clinical practice for estimating post-TIPS survival. Further studies are needed to explore the applicability of the FIPS score in other patient populations and settings.

#### **CLINICAL RELEVANCE/APPLICATION**

Transjugular intrahepatic portosystemic shunt (TIPS) is a commonly performed procedure for patients with complications of portal hypertension. The Freiburg Index of Post-TIPS Survival (FIPS) score is a prediction model that was developed to estimate post-TIPS survival in patients with variceal bleeding and/or ascites. However, its performance has not yet been validated in South Asian populations.

#### **T2-SPIR-6 CT-based Deep Learning Model of Hepatic Venous Pressure Gradient for Predicting the Prognosis of Hepatocellular Carcinoma with Transarterial Chemoembolization (CHANCE-CHESS): A Multicenter Cohort Study**

Participants

Yuqing Wang, Nanjing, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the impact of CT-based deep learning model of hepatic venous pressure gradient (HVPG) on prognosis of hepatocellular carcinoma (HCC) patients treated with transarterial chemoembolization (TACE) and systemic therapy.

#### **METHODS AND MATERIALS**

A total of 261 consecutive HCC patients treated with TACE and systemic therapy, and had a contrast-enhanced abdominal CT as part of their pre-surgical work-up, were retrospectively collected between January 2010 and December 2021. A CT-based HVPG Score, whose computed formula was:  $17.37 - 4.91 * \ln(\text{Liver/Spleen volume ratio}) + 3.8[\text{If presence of peri-hepatic ascites}]$ , was used to diagnose CSPH (HVPG=10mmHg) with a cut-off value 11.606. The 3D liver and spleen volume were automate calculated by a deep learning segmentation model, and the presence of peri-hepatic ascites was diagnosed by two independent investigators in portal-venous phase CT. Overall survival (OS) as study endpoint was analyzed by Kaplan-Meier and Cox regression.

#### **RESULTS**

Among 261 patients, 80(30.7%) were diagnosed with CSPH by CT-based HVPG Score. The median OS in CSPH group was significantly shorter than non-CSPH group (16.9 months vs. 20.7 months,  $P=0.022$ ). Multivariable analysis indicated that the presence of CSPH was a negative prognostic factor for OS (adjusted hazard ratio [HR], 1.423,  $P=0.045$ ).

#### **CONCLUSION**

s The segmentation model shows good performance in liver and spleen segmentation in HCC patients, which may help non-invasive HVPG assessment and other CT imaging studies in HCC patients. CT-based HVPG Score was significantly associated with poor outcome and should be taken into consideration when managing HCC patients underwent TACE and systemic therapy.

#### **CLINICAL RELEVANCE/APPLICATION**

This real-world study builds a non-invasive CT-based approach for CSPH diagnosis using deep learning model, and also highlights importance of CSPH management on clinical decision-making and trial design in HCC patients treated with TACE and systemic therapy.

#### **T2-SPMK-1 Adipose Distribution Patterns as Novel Prognostic Factors in Patients with HCC: A Systematic Review and Meta-analysis**

##### **PURPOSE**

Obesity is the established risk factor for several cancers, with hepatocellular carcinoma (HCC) being strongly associated with it. However, obesity is a heterogeneous disease with high individual differences in the distribution of adipose tissue. Quantifying associations between adipose distribution patterns and the prognosis of HCC might provide vital support for the individualized management of patients. Therefore, we aim to find the optimal indicator of pretreatment adipose distribution patterns for predicting the prognosis of HCC patients through meta-analysis.

##### **METHODS AND MATERIALS**

A systematic retrieve was performed to identify studies investigating the association of adipose distribution patterns and the prognosis of HCC from the inception of PubMed, Embase, Cochrane Library, and Web of Science databases to April 27, 2022. Relevant survival data were extracted to conduct the meta-analysis.

##### **RESULTS**

30 studies were included in our studies. A total of 6,783 people were enrolled in the study, including 2,456 patients with HCV and 1,228 patients with HBV. The pooled results indicated that only pretreatment high visceral to subcutaneous adipose tissue area ratio (VSR) (univariate analysis of OS: HR=1.42, 95%CI=1.28-1.58, P<0.00001; multivariate analysis of OS: HR=1.45, 95%CI=1.27-1.65, P<0.00001; univariate analysis of RFS: HR=1.30, 95%CI=1.08-1.56, P=0.006; multivariate analysis of RFS: HR=1.36, 95%CI=1.10-1.67, P=0.004) was both related to worse OS and RFS. Meanwhile, no significant heterogeneities were found and pooled results were relatively robust.

##### **CONCLUSION**

s Pretreatment VSR is the most valuable prognostic factor in adipose distribution patterns of HCC patients.

##### **CLINICAL RELEVANCE/APPLICATION**

This is the first meta-analysis to investigate how different adipose distribution patterns affect the prognosis of HCC patients. Our results demonstrate that pretreatment visceral to subcutaneous adipose tissue area ratio is the most valuable prognostic factor in adipose distribution patterns of HCC patients.

#### **T2-SPMK-2 Maintain Accuracy in Vertebral Density Measurement after Intravenous Injection using Material Decomposition Images in Dual-energy Spectral CT**

##### **PURPOSE**

To evaluate the ability of using the material decomposition (MD) images in dual-energy spectral CT in maintaining the vertebral bone mineral density (BMD) measurement accuracy in contrast-enhanced CT scans.

##### **METHODS AND MATERIALS**

Fifty-one abdominal patients (20 females, 31 males) who underwent dual-energy spectral CT imaging in the unenhanced and contrast-enhanced arterial phase (AP) and portal phase (PP) were included. The monochromatic images (40-140keV) and MD images using hydroxyapatite (HAP)-iodine as a base material pair were reconstructed. The HAP density was measured to represent BMD in the three imaging phases at the level of L1 with a region-of-interest (ROI) placed in a homogenous area of trabecular bone in the upper part of the vertebrae, excluding the cortex and focal inhomogeneous areas. The CT value in the same ROI was also measured using the 120kVp-like images to simulate measurement in conventional CT. Measurements in different imaging phases were statistically analyzed.

##### **RESULTS**

The CT value measurements for the L1 level vertebra in the unenhanced, AP and PP phases were 154.17±52.47HU, 175.44±58.40HU and 181.10±52.84HU, respectively. There were differences between the unenhanced and AP and the unenhanced and PP phases with p<0.05 showing iodine contrast involvement and contamination in the measurement. On the other hand, the HAP density measurement (in mg/cm<sup>3</sup>) in these three phases were 695.36±18.41, 695.34±23.35, and 694.95±16.88, respectively with virtually no change (p>0.05). Post hoc analysis showed that no significant differences were present in HAP (Iodine) (p=0.993).

##### **CONCLUSION**

s Our results showed that the conventional CT attenuation measurement in the vertebra after contrast injection may be skewed by the iodine involvement. The material density (HAP) measurement using the material decomposition in dual-energy spectral CT eliminated the iodine influence and provided quantitative and consistent measurement for BMD of the vertebra.

## CLINICAL RELEVANCE/APPLICATION

The material density (HAP) measurement using the material decomposition in dual-energy spectral CT may be used to provide a quantitative and consistent vertebral bone mineral density measurement.

### T2-SPMK-3 Opportunistic Deep Learning 3D-CT for Osteoporosis: Optimizing Multimodal Strategies for DXA Estimation

Participants  
Hanqing Yao, STANFORD, CA (*Presenter*) Nothing to Disclose

#### PURPOSE

Osteoporosis is a disease marked by reduced trabecular bone mass and increased fracture risk. Dual X-ray Absorptiometry (DXA) is the clinical standard for assessing spine bone mineral density (BMD) and diagnosing osteoporosis, but remains underutilized. With ~25 million annual CTs of the chest and abdomen in the US, there exists a potential to screen for osteoporosis using CT without incurring extra cost, patient time, or radiation exposure. We hypothesized that we can (1) optimize the structure of 3D spine ROIs from abdominal CTs for DXA T-score estimation; (2) predict osteoporosis incidence by combining image measures, scanner parameters, and demographic information.

#### METHODS AND MATERIALS

Our study comprised 447 CT scans on 432 patients (332 women, mean age 65) who received a contrast-enhanced CT scan within 6 months of DXA screening (301/146 train/test scans). To optimize our 3D ROIs, we evaluated four methods for automatically segmenting and extracting 3D HU measures - (1) entire vertebra segmentations; (2) only vertebral bodies excluding spinous/transverse processes; (3) only vertebral bodies with HU constraints to exclude cortical bones; (4) 1 cm radius spherical ROIs placed at the centroids of the vertebral bodies. We augmented HU measures with tube voltage, contrast phase, slice thickness, sex, age and race in a linear regression model to predict DXA T-scores.

#### RESULTS

Entire vertebra segmentations exhibited the highest correlation across all vertebral levels (L1-L4), with Pearson correlation coefficients of 0.59, 0.57, 0.52, and 0.52, which were significantly higher than correlations of the other 3D ROI methods ( $P < 0.001$ ). Including additional covariates improved the correlations at every level: 0.67, 0.68, 0.67, and 0.67 for L1-L4. Spine HU, tube voltage, and age-range buckets starting from 65 years old were significant predictors of T-scores ( $P < 0.001$ ) for all levels. Using a  $-2.5$  T-score osteoporosis threshold, we obtained area under the receiver operator characteristic curves (AUCs) of 0.69 (95% CI 0.59 - 0.79) for L1, 0.65 (95% CI 0.56 - 0.75) for L2, 0.66 (95% CI 0.57 - 0.75) for L3, and 0.63 (95% CI 0.54 - 0.72) for L4.

#### CONCLUSION

Optimizing the structure of 3D ROIs demonstrates the superiority of entire vertebra segmentations. Augmenting ROIs with scanner-based parameters can improve T-score estimates, highlighting the potential to correct for scanner-based variations. Our features significance analysis indicates that a combination of imaging, scanner-based, and demographic features are important for DXA estimation.

## CLINICAL RELEVANCE/APPLICATION

This study shows the feasibility of opportunistic CT to approximate DXA T-scores by accounting for scanner-based variations.

### T2-SPMK-4 Muscle Kinetics on Diffusion-weighted Imaging during Plantar Flexion for Age-related Muscle Quality in Healthy Calf Muscles

Participants  
Xinyue Zhang, Guangzhou, China (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the feasibility of muscle kinetics on DWI during exercise for assessing age-related muscle quality in healthy skeletal muscles.

#### METHODS AND MATERIALS

This prospective study recruited 43 healthy participants (20-60 years) from November 2021 to December 2022. A plantar flexion-tailored DWI protocol was sequentially implemented with one rest phase, one exercise phase, and recovery 1, 2, and 3 phases. Each phase was corresponding to one DWI scanning. Absolute apparent diffusion coefficient (aADC,  $\times 10^{-3}$  mm<sup>2</sup>/sec) of triceps surae (TRIC) was measured in the ADC maps by two radiologists to acquire aADC in the rest phase (aADCrest), aADC in the exercise phase (aADCexer), and aADC in recovery phases (aADCreco1, 2, and 3). Based on aADC, muscle kinetics on DWI was developed by additionally collecting relative ADC (rADC,  $\times 10^{-3}$  mm<sup>2</sup>/sec) and recovery duration: rADC in the exercise phase (rADCexer) as aADCexer - aADCrest; rADC in the recovery phases (rADCreco1, 2, and 3) as aADCreco1, 2, and 3 - aADCexer; recovery duration recorded as 1min, 2min, 3min, or >3min when first aADCreco showed no statistically significant difference from aADCrest. The independent or paired t-test was performed for comparing differences. The receiver operating characteristic curves were constructed for significant indices.

#### RESULTS

Two legs were imaged in all 43 participants (age range/mean, 23-58/41 $\pm$ 10 years; 22 male; 18 youth <40 years). Aged showed lower magnitudes of right-sided rADCexer, rADCreco1, rADCreco2, and rADCreco3 than youth with  $P < .05$ ; aged had longer recovery durations of >3min than 2min in youth for left leg. Right-sided rADCexer (0.76[0.60, 0.91];  $P = .005$ ) performed best for age-related muscle quality.

#### CONCLUSION

When implementing a plantar flexion-tailored DWI protocol, rADCexer performed best for age-related muscle quality in healthy TRIC.

## CLINICAL RELEVANCE/APPLICATION

Muscle kinetics on diffusion-weighted imaging during plantar flexion were feasible for assessing age-related muscle quality in healthy calf muscles.

## **T2-SPMK-5 Changes in Paraspinal Muscles Density in Young Patients with Chronic Non-specific Lower Back Pain Quantified by Using Dual-energy CT**

Participants

Jian Xiang, Changsha, Hunan, China (*Presenter*) Nothing to Disclose

### **PURPOSE**

The purpose of this study was to compare the muscle density of bilateral erector spinae muscles and multifidus muscles in chronic non-specific lower back pain patients with that of a normal control group.

### **METHODS AND MATERIALS**

This study was conducted as a prospective study and two groups of people were studied: CNLBP group, included 56 patients (age: 25.78±1.963, sex ratio: 21 Male/35 Female), control group, included 51 healthy volunteers (age: 25.12±1.812, sex ratio: 19 Male/32 Female). All individuals received spectral CT imaging on lumbar. Virtual monochromatic images at 70 keV were generated. CT value which indicated density of multifidus (L2/3 to L5/S1 levels) and erector spinae (L1/2 to L4/5 levels) muscles was measured in Hounsfield units (HU) on the left and right sides, and the mean value of left and right was calculated. Density of multifidus and erector spinae muscle among CNLBP patients and healthy volunteers were compared by using independent samples t-test.

### **RESULTS**

CNLBP group had lower muscle density at L4/5 level and L5/S1 level in multifidus muscle compared to control group (CNLBP vs. normal: 42.891±6.232 vs. 47.381±5.965 HU for L4/5,  $t=-3.8$ ,  $p<0.001$ ; 34.778±8.751 vs. 46.7265±6.264 HU for L5/S1,  $t=-8.049$ ,  $p<0.001$ ), however that for L2/3 (CNLBP vs. normal: 48.616±4.439 vs. 49.908±6.614 HU), L3/4 (CNLBP vs. normal: 47.034±5.109 vs. 48.931±6.961 HU) showed no statistical significance (both  $P>0.05$ ). The difference in density of the erector spinae muscle at each level between the CNLBP group and normal control group was not statistically significant (CNLBP vs. normal: 48.814±9.332 vs. 51.176±9.488 HU for L1/2; 48.779±3.481 vs. 49.086±4.373 HU for L2/3; 46.755±3.930 vs. 48.304±4.826 HU for L3/4; 43.421±7.018 vs. 45.352±6.209 HU for L4/5; all  $P > 0.05$ ).

### **CONCLUSION**

s Patients with CNLBP have lower density in the multifidus muscle at the L4/5 and L5/S1 levels than healthy volunteers.

### **CLINICAL RELEVANCE/APPLICATION**

The pathogenesis of CNLBP is unclear. Muscle density can be used to quantify the evaluation of fat and connective tissue infiltration. This study shows that the density of multifidus muscle at the L4/5 and L5/S1 levels is significantly lower in patients with CNLBP compared to healthy volunteers. Dual-energy CT measurement of muscle density can identify changes in the paravertebral muscles of patients with CNLBP, contributing the understanding of underlying mechanism, early diagnosis thus helping patients conducting interventions that can restore paravertebral muscle function and reduce recurrence of low back pain symptoms.

## **T2-SPMK-7 Non-expert usage of MRI-based Neuropathy Score Reporting and Data System (NS-RADS): Multi-Institutional Wider-usability Study of Peripheral Neuropathy Conditions**

Participants

Mina Guirguis, Dallas, TX (*Presenter*) Nothing to Disclose

Bayan Mogharrabi, BS, Dallas, TX (*Presenter*) Nothing to Disclose

### **PURPOSE**

The aim of our study was to determine inter-reader reliability and diagnostic performance of classification and severity scales of NS-RADS among radiology readers of differing experience levels after limited teaching of the scoring system by expert radiologists at their centers. We hypothesized that participants across a broad range of experiences can exhibit good accuracy and inter-reader reliability using the scoring system.

### **METHODS AND MATERIALS**

This is a multi-institutional, cross-sectional, retrospective study of MRI cases of nerves and proven peripheral neuropathy (PN) conditions. 31 radiology readers with varying degrees of training and experience levels were recruited from different institutions. Each reader attended and received a structured presentation that described the NS-RADS classification system containing imaging examples and illustrations, and a published article on this subject. After training, the readers were asked to perform NS-RADS scoring with designation of category, sub-category, and the most likely diagnosis. Inter-reader agreements were evaluated by Conger's kappa for all readers, trainees, and attendings. Diagnostic accuracy was calculated for each reader as the percent correct diagnosis. A linear mixed model was used to estimate and compare accuracy between the trainees and attendings.

### **RESULTS**

Across all 31 total (trainee and attending) readers evaluating 150 different MRI cases, the agreement was good for NS-RADS category and fair for NS-RADS subcategory. Inter-reader agreements of trainees were comparable to the attendings. The estimated accuracy for attendings was 0.73 with 95% CI (0.62, 0.81) and for trainees was 0.69 (0.58, 0.78) without significant difference in average accuracies between the trainees and attendings ( $p = 0.5$ ).

### **CONCLUSION**

s Non-expert radiologists interpreted PN conditions with good accuracy and fair to good inter-reader reliability using the NS-RADS scoring system previously validated by expert radiologists.

### **CLINICAL RELEVANCE/APPLICATION**

With limited training, the readers of differing experience and training levels can use NS-RADS scoring system in their practice to standardize MRI reporting and prudently aid in the management of PN patients.

## **T2-SPMK-8 Feasibility Assessment of Deep-learning-based Automatic Segmentation of Intercostal Muscles on**

## Computed Tomography Based on Bayesian U-Net

### PURPOSE

To assess the feasibility of deep-learning-based automatic segmentation of intercostal muscles (IMs) using Bayesian U-net on CT images in 110 patients suspected of lung cancer.

### METHODS AND MATERIALS

Using an original training dataset based on manual segmentation of IM in 10 arbitrarily selected cases, automatic segmentation with Bayesian U-Net was obtained in remaining 100 cases. Automatic segmentation was improved by updated training dataset created by manual modification in 10 cases selected in order of larger segmentation uncertainty among the remaining cases, in addition to the original one. For 95 cases, total IM volume (IMV) quantified with automatic segmentation based on final training dataset after similar process was repeated five times, were compared with quantitative pulmonary function and geographic data. For another 16 cases included as an external data set, predictive labels (PL) were generated using the identical final training dataset, and two ground truth (GT1 and GT2) was obtained with independent manual segmentation of right IM by two radiologists in median coronal cross-sections with a thickness of 10mm. Accuracy of IM segmentation by the Bayesian U-Net was assessed with Dice score (DS) as well as Bland-Altman plot analysis for regional IMV between the PL and each of GTs.

### RESULTS

The mean values and limits of agreement for regional IMV between PL and GT1 and between PL and GT2 were -1.2 and 0.3 to -2.6, and -1.7 and 0.4 to -3.7 mm<sup>3</sup>, indicating excellent concordance and slight underestimation tendency for PL. The DSs between GT1 and GT2, between GT1 and PL, and between GT2 and PL were 0.78, 0.77, and 0.80, respectively. Total IMV was larger in males (378.7 ± 66.9 cm<sup>3</sup>) as compared with females (246.7 ± 41.2 cm<sup>3</sup>, and correlated positively with height (r=0.69), body weight (r=0.70), BMI (r=0.48), forced vital capacity (r=0.56), and forced expiratory volume in 1 second (r=0.47).

### CONCLUSION

s Automatic segmentation of IM based on Bayesian U-Net was feasible and quantified total IMV correlated with body habitus and pulmonary function test parameters.

### CLINICAL RELEVANCE/APPLICATION

Automatic IM segmentation based on Bayesian U-Net can be applicable to evaluate the relation between IM impairment and respiratory functional disorder.

## T2-SPMK-9 Radiological Markers of Regenerative Maturity in Grade II Muscle Tears

Participants

Natalia Pugliese SR, Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

### PURPOSE

To establish radiological signs of regenerative maturity or immaturity of muscle tears using ultrasound (US) and magnetic resonance imaging (MRI).

### METHODS AND MATERIALS

Between August 2020 and April 2021, thirty six patients with grade 2 muscle tears diagnosed by ultrasound were included. Follow-up MRI and US was performed four weeks after diagnosis, and clinical follow-up four weeks later. According to the presence or absence of symptoms in these two instances, they were classified as immature or mature regeneration, respectively.

### RESULTS

At follow-up imaging, there were no significant differences (p= 0.08) regarding the characteristics of fibers between symptomatic and asymptomatic tears, with 12 (58%) of the asymptomatic tears showing effacement or retraction of the myotendinous junction. We found heterogeneous echogenicity in 13 (87%) symptomatic and 11 (52%) asymptomatic tears, and peripheral hypoechoogenicity in 1 (7%) symptomatic and 8 (38%) asymptomatic (p= 0.03). A positive Doppler signal was identified in 3 (14%) asymptomatic and 15 (100%) symptomatic (p <0.0001) tears. By MRI, the symptomatic tears showed greater signs of edema (p = 0.002), observing linear peripheral edema in 12 (57%) of the asymptomatic ones. The presence of positive Doppler was the variable statistically most related to the presence of symptoms, with an area under the ROC curve of 0.93 (95% CI 0.79-0.99).

### CONCLUSION

s Peripheral linear edema by MRI and US is a frequent finding in asymptomatic patients with regenerative maturity. The absence of a Doppler signal in the ultrasound controls one month after the muscle injury, was the best predictor of regenerative maturity.

### CLINICAL RELEVANCE/APPLICATION

Diagnostic imaging studies provide information that influences the decision to return to play, being the absence of Doppler, a useful predictor of regenerative maturity.

Printed on: 04/12/24

T2-SPMS

### Multisystem Tuesday Poster Discussions

#### Sub-Events

#### **T2-SPMS-1 Abbreviated Whole-Body MRI as a Novel Imaging Modality for Pediatric Lymphoma Follow-Up: A Multicenter Study**

##### Participants

Bingjie Zheng, MD, Zhengzhou, China (*Presenter*) Nothing to Disclose

##### **PURPOSE**

This multicenter prospective study aimed to evaluate the diagnostic confidence and reproducibility of a novel abbreviated 30-minute whole-body MRI (WB-MRI) for response assessment in children and adolescent patients with lymphoma.

##### **METHODS AND MATERIALS**

The study included 103 pediatric patients aged 0 to 18 years with pathologically confirmed lymphoma, who underwent both PET/CT and abbreviated WB-MRI at baseline and during follow-up. Image quality of abbreviated WB-MRI was evaluated using a 5-point Likert scale, and interobserver agreement was assessed. Sensitivity, specificity, and accuracy of abbreviated WB-MRI for detecting residual or recurrent disease were calculated, with PET/CT used as the reference standard.

##### **RESULTS**

The image quality of abbreviated WB-MRI was rated good or excellent in 97% of cases, with high interobserver agreement. Abbreviated WB-MRI demonstrated a sensitivity of 90%, specificity of 96%, and accuracy of 94% for detecting residual or recurrent disease, with excellent agreement between abbreviated WB-MRI and PET/CT findings.

##### **CONCLUSION**

s Abbreviated WB-MRI is a feasible and accurate imaging modality for follow-up of pediatric lymphoma patients undergoing various treatments, with high diagnostic performance and excellent image quality. The non-invasive nature and lack of radiation exposure make it a favorable option compared to PET/CT, especially for pediatric patients.

##### **CLINICAL RELEVANCE/APPLICATION**

The results of this study suggest that abbreviated WB-MRI is a clinically relevant and useful imaging modality for follow-up of pediatric patients with lymphoma, offering high diagnostic accuracy and image quality. Abbreviated WB-MRI has the advantage of being non-invasive and without radiation exposure, making it an attractive alternative to PET/CT for monitoring disease progression and response to treatment in pediatric patients.

T2-SPNMMI

### Nuclear Medicine & Molecular Imaging Tuesday Poster Discussions

#### Sub-Events

#### T2-SPNMMI- Diagnosis of Primary Chyluria by <sup>99</sup>Tcm-dextran Lymphography<sup>1</sup>

Participants

Qi Hao, Beijing, China (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the diagnostic value of <sup>99</sup>Tcm-dextran (DX) lymphography in primary chyluria.

#### METHODS AND MATERIALS

Fifty patients with primary chyluria admitted and diagnosed in our hospital from January 2011 to 2020 were retrospectively collected, and all patients underwent <sup>99</sup>Tcm-DX lymphography with complete imaging data to observe the lymphatic reflux in bilateral lymphatic vessels of lower limbs, bilateral iliac lymphatics, bilateral lumbar trunks and thoracic duct, as well as the presence of abnormal radiological distribution in both kidney areas, abdominopelvic region and chest.

#### RESULTS

Among 50 patients with primary chyluria, early visualization was seen in the renal area in 20 cases (40%), including 11 cases (22.0%) unilaterally and 9 cases (18.0%) bilaterally; 13 cases (26.0%) had unilateral or bilateral slow lymphatic reflux in the lower extremities, 6 cases (12.0%) had abnormal increased radioactivity in the abdomen, 5 cases (10.0%) had abnormal increased radioactivity in the chest; In this study, the thoracic duct visualization was divided into three types: type I: 22 cases (44.0%) with obstruction at the end of the thoracic duct, which showed persistent widening of the venous angle visualization or abnormal drainage, type II: 14 cases (28.0%) with no visualization at the end of the thoracic duct, and type III: 14 cases (28.0%) with transient visualization at the end of the thoracic duct.

#### CONCLUSION

<sup>99</sup>Tcm-DX is useful for observing abnormal renal reflux in patients with primary celiac disease, dynamically assessing systemic lymphatic reflux and thoracic duct reflux, and is a guide for the diagnosis of primary chyluria and for assisting in the search for its cause.

#### CLINICAL RELEVANCE/APPLICATION

It is a guide for the diagnosis of primary celiac disease and for assisting in the search for its cause.

#### T2-SPNMMI- PSMA PET Imaging Response Following a Single Dose <sup>225</sup>Ac J591 Therapy in Metastatic Castration Resistant Prostate Cancer: A Lesion and Patient Based Analysis<sup>2</sup>

Participants

Judith Stangl-Kremser, MD, PhD, New York, NY (*Presenter*) Nothing to Disclose

#### PURPOSE

Radionuclide therapy with <sup>225</sup>Ac-labeled PSMA targeting agents have been studied in clinical trials and emerged as a promising treatment option in the management of men with mCRPC. We hypothesized that bone, nodal or visceral metastatic sites may differ in response to this treatment.

#### METHODS AND MATERIALS

28 men with mCRPC were treated with <sup>225</sup>Ac-PSMA-J591 from 2017 to 2020 at our center on a prospective single ascending dose phase 1 trial (NCT03276572). Molecular imaging, assessing PSMA expression, was performed in most patients but was not used to select trial participants. We retrospectively analyzed 20 cases that had both a baseline <sup>68</sup>Ga-PSMA-11 PET/CT (bPET) and a post-treatment (fPET). On the patient-level, biochemical response was defined as  $\geq 50\%$  PSA decline after treatment (PSA50 response), and the overall response was assessed on the fPET using PERCIST criteria and on conventional imaging in cases with measurable disease using RECIST guidelines. For the lesion-based analysis, the SUV<sub>peak</sub> of the 3 most- and 3 least-avid lesions of the metastatic sites were measured. Pre- and post-treatment SUV<sub>peak</sub> as well as percentage decline of SUV<sub>peak</sub> were compared for every lesion. On the patient and lesion level, an objective imaging response was defined as complete or partial response. For the latter, the frequency of an objective imaging response was compared in bone, node, and visceral lesions.

#### RESULTS

Twenty patients were analyzed. Of those, 13 men (65%) had prior <sup>223</sup>Ra (n=5), <sup>177</sup>Lu-PSMA (n=10), two had both. The baseline PSA was 192.5 ng/mL (IQR: 69.1-887.3). 11 men had a PSA50 response and 7 an overall objective imaging response on the fPET. 8 cases had measurable disease; the majority had stable disease and one had progressive disease. Men with a biochemical response trended to have higher odds of having an imaging response. Overall, 204 lesions were measured on the bPET. The median SUV<sub>peak</sub> was 4.1 (IQR 1.6-10.5). The decline of post-treatment SUV<sub>peak</sub> was significant within all metastatic categories. The median

decline in SUVpeak from bPET to fPET was -40% (IQR -71;-1) in bone lesions, -52% (IQR -81;-14) in visceral lesions, and -23% (IQR -53;-6) in nodal lesions. The objective imaging response rate was different in bone lesions (52%), visceral lesions (71%), and nodal lesions (39%) (p=0.0273).

## **CONCLUSION**

s 225Ac-PSMA-J591 effectively treats all metastatic categories. However, bone and visceral lesions may respond better than nodal lesions. Our findings need further validation but are informative for trial design and patient counselling.

## **CLINICAL RELEVANCE/APPLICATION**

Metastatic patterns may influence treatment response to 225Ac-labeled PSMA targeting agents in men with mCRPC and should be considered in treatment planning.

## **T2-SPNMMI- High-risk Prostate Cancer Staging: Predictors of Extra-prostatic Spread in 18F-PSMA-1007 PET-CT Scans**

### **PURPOSE**

PSMA PET-CT has superior diagnostic accuracy over conventional imaging in staging patients with high-risk prostate cancer due to its ability to detect occult extra-prostatic disease. High-risk is defined as per the National Comprehensive Cancer Network: PSA = 20 ng/ml, Gleason score = 8, or a clinical stage of =T3. We sought to explore the predictors of bony and nodal spread in our patient cohort of high risk patients.

### **METHODS AND MATERIALS**

A total of 411 18F-PSMA PET-CT studies were identified through local PACS database search which were done during the 18-month period between 01/01/2021 - 30/06/2022. A total of 192 consecutive patients who underwent a staging PSMA PET-CT scan for high risk disease over an 18 month period were retrospectively reviewed (duplicate records, re-staging studies and patients who had undergone prior treatment were excluded). Medical record search was also done to acquire data for parameters such as PSA, prostate volume (PSA density) Gleason score, MRI Staging and PI-RADS. The data was then categorized based on the PSMA PET-CT reports into extra prostatic disease and confined prostatic disease. Extra prostatic disease is defined for the purposed of this study, as any nodal involvement and/or bone metastases.

### **RESULTS**

Of the 192 patients, 68 (35%) had evidence of malignant spread to nodes, bones or both (PMSA spread +ve). The remainder (124) showed no evidence of nodal or bony metastatic disease. There was significant difference in PSA levels (p < 0.01; Mann-Whitney U test) between positive (46.3 ; n=68) and negative (26 ; n= 124). A significant proportion (47%) of node positive scans on PSMA were reported to have no nodal involvement on MRI. 50% of patients Gleason score = 8 showed extra-prostatic spread on PSMA PET-CT.

### **CONCLUSION**

s PSA level and Gleason score were accurate predictors of extra-prostatic disease in patients with high-risk prostatic carcinoma. DRE staging was less accurate. A significant proportion of node positive PSMA scans were deemed to have no nodal involvement on MRI scans.

### **CLINICAL RELEVANCE/APPLICATION**

Within high-risk carcinoma of the prostate, Gleason score and PSA act as accurate predictors of extra-prostatic spread. The role of DRE staging alone as a parameter for high-risk classification needs to be explored further. Almost half of node positive disease on PSMA PET-CT were not picked up by MRI, reiterating the superiority of PET.

## Abstract Archives of the RSNA, 2023

T2-SPNPM

### Noninterpretive Skills (Beyond Imaging) Tuesday Poster Discussions

#### Sub-Events

#### **T2-SPNPM-1 Widening Disparities in Noninvasive Diagnostic Imaging Volume and wRVU Utilization for Medicare Across Hospital Referral Regions**

##### Participants

Aditya Khurana, MD, Scottsdale, AZ (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate all US Medicare imaging claims for potential healthcare disparities in medical imaging utilization across 306 US hospital referral regions (HRRs).

##### METHODS AND MATERIALS

All diagnostic imaging claims submitted to Medicare from 2013 to 2019 were extracted from the Medicare POSPUF dataset, including year, CPT code, wRVUs, and zip code. Dartmouth imaging atlas was used to assign each claim to an HRR via zipcode and gather the number of Medicare enrollees in each HRR. HRRs were aggregated into percentiles based on exam and wRVU utilization rates (highest 10th percentile, 25th, 50th, 75th, and 90th). Compound annual growth rates (CAGR) were calculated.

##### RESULTS

Imaging exams totaled 156,739,445 in 2013 and 176,297,932 (+19,558,487, +12.5%) in 2019. In 2013, there were 52,179,386 total imaging wRVUs, and 63,276,990 (+21.3%) in 2019. The exam utilization rate per 1,000 Medicare enrollees across all HRRs was 3188/1,000 US Medicare enrollees in 2013 and 3077 in 2019 (median 1940, standard deviation 948; -135/1,000 since 2013, CAGR -0.6%). The 2019 exam utilization rate across HRRs ranged from 288 in Terre Haute, IN to 9517 in Rochester, MN (33 fold, 188.3% difference). The exam utilization rate CAGR from 2013 to 2019 by HRR utilization rate percentile was 90th percentile +0.1%, 75th +0.2%, 50th -1.6%, 25th -1.9%, and 10th -2.9%. The wRVU utilization rate per 1,000 Medicare enrollees across HRRs was 1739 in 2013 and 2106 in 2019 (median 1940, standard deviation 948; +367.6 since 2013, CAGR +2.5%). The 2019 wRVU utilization rate across HRRs ranged from 237 in Sun City, AZ to 7237 in Rochester, MN (31 fold, 187.3% difference). The wRVU utilization rate CAGR from 2013 to 2019 by HRR wRVU percentile was 90th percentile +3.2%, 75th +3.7%, 50th +1.6%, 25th +1.6%, and 10th -0.01%.

##### CONCLUSION

s Imaging volume is decreasing and wRVUs are increasing in the US Medicare population, suggesting substitution of lower wRVU exams for those of higher wRVUs. Imaging utilization rates vary by more than 30 fold across HRRs, with the gap widening from 2013 to 2019 and HRRs with high percentile wRVUs per capita growing nearly 3.5% faster than others, annually. These findings could reflect variations in resources and/or allocation of some services across HRRs, and raise potential concern that imaging disparities across HRRs could be increasing, especially access to higher wRVU advanced imaging services.

##### CLINICAL RELEVANCE/APPLICATION

Variations in imaging across hospital referral regions are increasing, raising potential concern about healthcare access disparities for some imaging services, especially high wRVU services.

#### **T2-SPNPM-2 A Cross-sectional Analysis Examining the Disparities in Cancer Screening Among American Indians or Alaska Natives**

##### PURPOSE

American Indians or Alaska Natives (AIANs) represent 3% of the US population and have experienced continued systemic racism, resulting in limited access to health care, education, and other economic opportunities. Nationally, the incidence of cancer among AIANs is higher than among Whites for cancers including lung, colorectal, and cervical cancer. The purpose of this cross-sectional analysis is to examine potential disparities in cancer screening among AIANs.

##### METHODS AND MATERIALS

We performed a retrospective analysis of the 2021 National Health Interview Survey (NHIS) data, a nationally representative cross-sectional survey with a response rate of 50.9%. Multiple variable analysis was performed to evaluate the association between AIANs and Whites with respect to colorectal and breast cancer screening adherence.

##### RESULTS

For colorectal cancer (CRC) screening, 14,969 respondents between the age of 45-75 were included. 63% of eligible respondents reported receiving recommended CRC screening compared to 56% of AIANs. Compared to Whites, AIANs were less likely to report recommended CRC screening (OR 0.49, 95% CI 0.17, 0.83,  $p < 0.001$ ). For breast cancer screening, 9,164 respondents between the age of 40-74 were included. 89% of eligible respondents reported receiving routine screening mammography compared to 83% of AIANs. Compared to Whites, AIANs were less likely to report receiving routine mammography (OR 0.317, 95% CI 0.28, 0.36,  $p <$

0.001). For AIANs, patients who reported difficulty paying medical bills (OR 0.42, 95% CI 0.26, 0.69,  $p < 0.001$ ) and education levels of high school or lower (OR 0.12, 95% CI 0.067, 0.21,  $p < 0.001$ ) were less likely to report screening mammography use than their respective counterparts.

## **CONCLUSION**

s AIANs were less likely to report recommended CRC and breast cancer screening compared to Whites, which may partially explain the increased incidence of these cancers in the population.

## **CLINICAL RELEVANCE/APPLICATION**

Additional federal and state funding should be invested to reduce health disparities and improve the rates of cancer screening in the AIAN population.

## **T2-SPNPM-3 Prevalence of Financial Hardship among Radiology Outpatients and Role of Price Transparency**

Participants

Desiree Caballero, MSc, BS, Irvine, CA (*Presenter*) Nothing to Disclose

## **PURPOSE**

The aim of this study was to assess the prevalence of medical financial hardship among patients receiving outpatient imaging at a tertiary center in Southern California and its correlation with price transparency

## **METHODS AND MATERIALS**

Between November 2022 and March 2023 adult patients receiving outpatient advanced imaging (MRI, CT, PET/CT) at a tertiary academic center in Southern California were asked to complete a 15-minute survey screening for financial hardship. Multivariable logistic regression models were used to assess the association between financial hardship and price transparency.

## **RESULTS**

430 patients were included (mean age:57.7 (SD15.6); 57.6% female; 45.9% Caucasian; 5% Black;19.2% Asian; 21.3% Hispanic). There were 14.2% Spanish speakers, and 4.4% Vietnamese. A total of 1.4% were uninsured, 11.7% and 37.3% had Medicaid and Medicare, respectively and 47.2% had commercial insurance. Mean score for financial worry measured by Comprehensive Score for financial Toxicity (COST score) was 24 (SD11) and 34% reported imaging was a financial hardship for them and their family. Material hardship (e.g., medical debt) was reported by 46% with less than 1% declaring bankruptcy. Cost related care nonadherence and imaging nonadherence were reported by 46% and 4.3%, respectively. Having interest in knowing imaging out-of-pocket cost (OOPC) prior to receipt of imaging was associated with lower likelihood of imaging hardship (OR 0.28;95% CI 0.15,0.52), material hardship (OR 0.47; 95% CI 25, 88), and cost-related care nonadherence (OR, 0.40; 95% CI 0.18, 0.90). There was no significant association between knowing imaging OOPC estimate prior to receipt of imaging and financial hardship.

## **CONCLUSION**

s Financial hardship is common in outpatient radiology encounters. While those interested in knowing their imaging OOPC are less likely to experience financial hardship, knowing the OOPC does not impact financial hardship.

## **CLINICAL RELEVANCE/APPLICATION**

Given the high prevalence of financial hardship among radiology outpatients, interventions to mitigate financial hardship should be implemented at radiology practices. Price transparency alone may not decrease financial hardship.

## Abstract Archives of the RSNA, 2023

T2-SPNR

### Neuroradiology Tuesday Poster Discussions

#### Sub-Events

#### T2-SPNR-1 Is MRI Sensitive Enough to Avoid Lumbar Puncture for the Diagnosis of Creutzfeldt-Jacob Disease?

##### PURPOSE

To assess the yield of lumbar puncture (LP) to diagnose clinically suspected Creutzfeldt-Jacob disease (CJD) in the absence of suggestive MRI findings.

##### METHODS AND MATERIALS

This single-center retrospective study included 103 patients clinically suspected of having CJD who underwent MRI and LP within 3 months of each other between December 2014 and January 2023. MRIs were re-interpreted for the study by a fellowship-trained CAQ-certified neuroradiologist blinded to LP results and eventual CJD diagnosis. MRIs were categorized as negative, intermediate, or positive for findings suggestive of CJD. The diagnosis from imaging was then compared to the CJD diagnosis determined clinically by a CSF prion panel. Positive and negative predictive values (PPV, NPV), sensitivity, specificity, and accuracy were calculated. A chi-squared test was performed to examine the relationship between MRI prediction and clinical diagnosis, with a threshold of  $p < 0.05$ .

##### RESULTS

Of the 103 patients suspected, 25 were eventually diagnosed with CJD (24%). Of the 103 MRIs, 18 MRIs were positive, 13 were intermediate, and 72 were negative. The PPV for positive MRIs was 83% and the NPV was 96% (95% CI = 88 to 99%). 54% of the intermediate MRIs corresponded to patients who were eventually diagnosed with CJD. Specificity of MRI was 88%, sensitivity was 88%, and accuracy was 88%. MRI categories and eventual diagnosis of CJD were statistically significantly correlated (Chi-square = 56.18,  $p < 0.00001$ ).

##### CONCLUSION

In patients without MRI findings of CJD, the diagnostic yield of lumbar puncture is 4%. In these patients, the expense of a prion panel and an invasive procedure with potential complications may not be appropriate. MRI is an excellent screening tool in cases of clinically suspected CJD.

##### CLINICAL RELEVANCE/APPLICATION

Patients without MRI findings of CJD are very unlikely to have confirmation of the disease on lumbar puncture. Screening with MRI may be used to avoid performing an invasive procedure in patients suspected of CJD.

#### T2-SPNR-10 Not ADC but Advanced Diffusion MRI Parameters can Differentiate Brain Metastases from Glioblastomas

##### Participants

Kiyohisa Kamimura, MD, PhD, Kagoshima, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Our purpose was to determine whether advanced diffusion-weighted imaging (DWI) parameters, including time-dependent DWI parameters and microscopic fractional anisotropy ( $\mu$ FA) derived from double-diffusion-encoding (DDE) MRI, are useful for differentiating between glioblastomas and brain metastases.

##### METHODS AND MATERIALS

A retrospective study was conducted involving 102 consecutive patients with pathologically proven brain tumors (74 with glioblastoma and 28 with brain metastasis) using a 3T scanner and advanced DWI sequences. Time-dependent DWI was performed using a sequence with oscillating motion-probing gradients (effective diffusion time ( $\tau_{eff}$ ) = 7.1ms) and a pulsed gradient sequence ( $\tau_{eff}$  = 44.5ms). In addition to ADC maps at the two diffusion times (ADC7.1ms and ADC44.5ms), maps of the ADC change (cADC) and the relative ADC change (rcADC) between the two diffusion times (cADC = ADC7.1ms - ADC44.5ms), [rcADC = (ADC7.1ms - ADC44.5ms)/ADC44.5ms  $\times$  100 (%)] were generated. From the data acquired using a DDE MRI sequence, maps of  $\mu$ FA were generated. The average values of ADC44.5ms, ADC7.1ms, cADC, rcADC, and  $\mu$ FA within enhancing areas of each tumor were measured using a ROI analysis, and those indices were compared between glioblastomas and brain metastases. The diagnostic performances of the parameters were evaluated using ROC curve analysis, and their AUCs were compared using the DeLong's method.

##### RESULTS

There was no significant difference in ADC44.5ms nor ADC7.1ms between brain metastases and glioblastomas. The cADC ( $\times 10^{-3}$  mm<sup>2</sup>/s) and rcADC (%) of brain metastases were significantly higher than those of glioblastomas ( $0.25 \pm 0.12$  vs.  $0.14 \pm 0.03$ ;  $P < 0.0001$ ,  $23.6 \pm 9.4$  vs.  $14.5 \pm 5.7$ ;  $P < 0.0001$ ). The  $\mu$ FA of brain metastases were significantly higher than those of glioblastomas ( $0.472 \pm 0.148$  vs.  $0.371 \pm 0.134$ ;  $P = 0.0014$ ). The ROC curve analysis showed significance for cADC, rcADC, and  $\mu$ FA (AUC = 0.890, 0.834, and 0.705;  $P < 0.0001$ ,  $< 0.0001$ , 0.0014; respectively). The AUC for cADC, rcADC, and  $\mu$ FA were significantly

greater than that for ADC44.5ms ( $P < 0.001$ , respectively).

## CONCLUSION

The time-dependent DWI parameters and  $\mu$ FA provide valuable information to differentiate between glioblastomas and brain metastases, whereas conventional ADC does not. The cADC may be the most efficient DWI index for distinct differentiation of the two tumor types.

## CLINICAL RELEVANCE/APPLICATION

Time-dependent DWI parameters and  $\mu$ FA may be helpful for differentiation between glioblastoma and brain metastasis.

### T2-SPNR-11 Clinical Feasibility of Multi-pool Model-based CEST Imaging in the Evaluation of Glioma Grading and Tumor Proliferation: Comparison with Apparent Diffusion Coefficient and Magnetization Transfer Ratio Asymmetry

#### Participants

Yasukage Takami, Mikicho, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

Although magnetization transfer ratio asymmetry (MTR<sub>asym</sub>) analysis is often used as a chemical exchange saturation transfer (CEST), it is semiquantitative and entails some pitfalls. Recently, we developed new parameters for CEST imaging by the multi-pool model (MPM). The purpose of this study was to evaluate the clinical significance of the new parameters on CEST imaging by assessing the glioma grading and tumor proliferation on CEST imaging by MPM compared to conventional apparent diffusion coefficient (ADC) and MTR<sub>asym</sub>.

#### METHODS AND MATERIALS

22 patients with gliomas underwent the preoperative MRI. MPM assumes the magnetization transfer (MT) between free water pool, APT pool, and binding water MT pool. "APT density" x "APT transfer rate" x ("Free water T1" or "T2") was visualized as APT\_T1 or APT\_T2, respectively. The maximum values of the parameters on CEST imaging and the minimum values of ADC were measured respectively by regions of interest analysis. Ki-67 index and the presence of isocitrate dehydrogenase 1 (IDH1) mutation were obtained from tumor specimens.

#### RESULTS

There were significant positive correlations between MTR<sub>asym</sub> and Ki-67 index ( $r = 0.78$ ,  $p < 0.01$ ), and APT\_T1 and Ki-67 index ( $r = 0.68$ ,  $p < 0.01$ ). There existed significant negative correlations between T2/T1 and Ki-67 index ( $r = -0.52$ ,  $p < 0.05$ ), and ADC and Ki-67 index ( $r = -0.76$ ,  $p < 0.01$ ). Significant differences in APT\_T1 were observed between grades II and III ( $p < 0.05$ ) and grades III and IV ( $p < 0.05$ ), as well as between grades II and IV ( $p < 0.001$ ). Significant differences in MTR<sub>asym</sub>, T2/T1, and ADC were observed between grades II and IV ( $p < 0.001$ ). MTR<sub>asym</sub> and APT\_T1 of IDH1 mutant glioma patients ( $n = 10$ ) were significantly lower than that of IDH1 wild-type patients ( $n = 12$ ) ( $p < 0.001$ ). ADC and T2/T1 of IDH1 mutant glioma patients ( $n = 10$ ) were significantly higher than that of IDH1 wild-type patients ( $n = 12$ ) ( $p < 0.05$ ). APT\_T1 of IDH1 mutant glioblastoma patients ( $n = 2$ ) were significantly lower than that of IDH1 wild-type patients ( $n = 11$ ) ( $p < 0.05$ ). With respect to other parameters, there were no significant differences between IDH1 mutant glioblastoma patients and IDH1 wild-type glioblastoma patients.

## CONCLUSION

These preliminary results suggest that parameters on CEST imaging by MPM seem to correlate with the cell proliferation of gliomas as with MTR<sub>asym</sub> and ADC in patients with gliomas. APT\_T1 may be more useful than conventional parameters in evaluating the grade of glioma and the presence of IDH1 mutation in gliomas.

## CLINICAL RELEVANCE/APPLICATION

Parameters on CEST imaging by MPM appear to correlate with glioma cell proliferation as well as MTR<sub>asym</sub> and ADC. In assessing the grade of glioma and the existence of IDH1 mutation in gliomas, APT\_T1 may be more helpful than conventional parameters.

### T2-SPNR-12 Long-term Follow-up of Multinodular and Vacuolating Neuronal Tumors and Implications for Surveillance Imaging

#### Participants

Siddhant Dogra, MD, New York, NY (*Presenter*) Nothing to Disclose

#### PURPOSE

The majority of multinodular and vacuolating neuronal tumors (MVNTs) are diagnosed and followed up with imaging, without any change over time. However, there are no surveillance guidelines or quantitative volumetric assessments of these tumors. We evaluated MVNT volumes over long follow-up periods using segmentation tools with the aim of accurate quantitative assessment.

#### METHODS AND MATERIALS

All patients with "MVNT" or "multinodular and vacuolating neuronal tumor" in a brain MRI report in our system were reviewed. Patients with only one brain MRI or where MVNT was not clearly the most likely diagnosis were excluded. All MVNTs were manually segmented. For all follow-up exams, absolute and percent volume change from immediately prior and initial exams were calculated.

#### RESULTS

48 patients (32 women, median age 50.5 years at first scan) underwent 158 brain MRIs. Median duration between the first and last scan was 15.6 months (interquartile range [IQR] 5.7 months -29.6 months, maximum 6.4 years) and between consecutive scans was 6.7 months (IQR 3.3 months-12.4 months, maximum 4.9 years). Across all 48 individual patients, the median MVNT volume on the original scan was 0.40 cm<sup>3</sup> (IQR 0.16 to 0.77 cm<sup>3</sup>) while the median MVNT volume on the last scan was 0.34 cm<sup>3</sup> (IQR 0.14 to 0.75 cm<sup>3</sup>;  $p=0.94$ ). In comparison to the immediately prior scan, the median absolute change in volume across every follow-up scan was -0.02 cm<sup>3</sup> (IQR -0.06 to 0.02 cm<sup>3</sup>), while the median percent change in volume was -5.0% (IQR -13.7% to 7.9%). Pearson correlation coefficients between days since immediately prior scan versus absolute and percent volume change from immediately prior scan were  $r=0.05$  ( $p=0.60$ ) and  $r= 0.07$  ( $p=0.45$ ) respectively. For the relationship between days since the first scan versus

absolute and percent volume change from the first scan, values were  $r=-0.06$  ( $p=0.53$ ) and  $r=-0.04$  ( $p=0.67$ ) respectively (Figure 1).

## CONCLUSION

s MVNT segmentation across follow-up brain MRI exams did not demonstrate significant volume differences over the follow-up period, suggesting these tumors don't change or enlarge over time. Hence, frequent surveillance imaging of newly diagnosed MVNTs may not be necessary. In particular, no further contrast is needed after a stable follow-up contrast-enhanced exam.

## CLINICAL RELEVANCE/APPLICATION

We provide the first set of quantitative volumetric measurements demonstrating multinodular and vacuolating neuronal tumors do not significantly change over time.

## T2-SPNR-13 Pretreatment ADC for Prediction of Relapsed and Refractory Primary Central Nervous System Lymphoma

### PURPOSE

A subset of primary central nervous system lymphoma (PCNSL) has been shown to undergo an early relapsed/refractory (R/R) period after first-line chemotherapy. This study investigated the pretreatment clinical and MRI features to predict R/R in PCNSL, emphasizing the apparent diffusion coefficient (ADC) values.

### METHODS AND MATERIALS

This retrospective study investigated the pretreatment MRI features for predicting R/R in PCNSL. Only patients who had undergone complete preoperative and postoperative MRI follow-up studies were included. From January 2006 to December 2021, 52 patients from two medical institutions with a diagnosis of PCNSL were included (median follow-up time, 26.3 months). Among these, 24 (46.2%) had developed R/R (median time to relapse, 13 months). Cox proportional hazard regression analyses were performed to determine hazard ratios for all parameters.

### RESULTS

Significant predictors of R/R in PCNSL were female sex, complete response to first-line chemotherapy, and ADC value/ratio ( $P < 0.05$ ). Cut-off points of ADC values and ADC ratios for prediction of R/R were  $0.68 \times 10^{-3} \text{ mm}^2/\text{s}$  and 0.97, with AUCs of 0.78 and 0.77, respectively ( $P < 0.05$ ). Multivariate Cox proportional hazards analysis showed that failure of CR to first-line chemotherapy and low ADC values ( $< 0.68 \times 10^{-3} \text{ mm}^2/\text{s}$ ) were significant risk factors for R/R, with hazard ratios of 5.22 and 14.45, respectively ( $P < 0.05$ ). Kaplan-Meier analysis showed that lower ADC values and ratios predicted significantly shorter progression-free survival ( $P < 0.05$ ).

## CONCLUSION

s Pretreatment ADC values and ratios for prediction of R/R offer valuable objective information for the treatment planning in PCNSL.

## CLINICAL RELEVANCE/APPLICATION

Pretreatment ADC for prediction of relapsed and refractory PCNSL offers valuable information in the treatment planning.

## T2-SPNR-14 Development of a Deep Learning Model Integrating Multisequence MRI to Assess EGFR Mutation Subtype in Brain Metastases

Participants

Ye Li, Beijing, China (*Presenter*) Nothing to Disclose

### PURPOSE

There is a lack of studies evaluating epidermal growth factor receptor (EGFR) mutation status and subtype in non-small cell lung cancer (NSCLC) patients with brain metastasis (BM). The aim of this study was to establish a predictive model based on multisequence MRI using deep learning to identify wild-type (WT) EGFR, EGFR exon 19 deletion (19Del) and exon 21 point mutation (21L858R) simultaneously.

### METHODS AND MATERIALS

A total of 399 patients with proven brain metastases (BM) of non-small cell lung cancer (NSCLC) were retrospectively enrolled and divided into training ( $n=306$ ) and testing ( $n=99$ ) cohort separately based on two timepoints. All patients underwent brain MRI (including T2WI, T2 fluid-attenuated inversion recovery (T2-FLAIR), diffusion weighted imaging (DWI) and contrast-enhanced T1-weighted imaging (T1-CE)) scans. Radiomics features were extracted from each lesion based on four MR sequences. Then a novel algorithm that combined radiomics approach with graph convolutional networks (GCN) architecture (Radio-GCN) was designed for the prediction of EGFR mutation status and subtype. The receiver operating characteristic (ROC) curve analysis was used to evaluate the predication capabilities of each model.

### RESULTS

We extracted 1290 radiomics features of each MRI sequence. The Radio-GCN model showed an excellent discrimination power for identifying EGFR 19 Del, 21 L858R, and WT in lesion-wise with the AUCs of  $0.9955 \pm 0.0038$ ,  $0.971 \pm 0.013$  and  $1.0 \pm 0$  on independent testing cohort. It also yielded excellent AUCs of  $1.0 \pm 0$ ,  $0.9913 \pm 0.0086$  and  $1.0 \pm 0$  for predicting EGFR mutations respectively in patient-wise. The kappa coefficient reached 0.7352 and 0.8121 in two wises, respectively.

## CONCLUSION

s The study demonstrated that a Radio-GCN approach based on multisequence MRI can help to predict the EGFR mutation subtypes in NSCLC patients with BM, which is beneficial to guide individual treatment.

## CLINICAL RELEVANCE/APPLICATION

The constructed Radio-GCN model can be potentially considered as new tools to predict the EGFR mutation status and subtype in NSCLC patients with BM.

## **T2-SPNR-2 Myocardial Involvement Characteristics by Cardiac MR Imaging in Neurological and Non-Neurological Wilson Disease Patients**

Participants  
Xiaohu Li, MD, PhD, Hefei, China (*Presenter*) Nothing to Disclose

### **PURPOSE**

To explore the characteristics of myocardial involvement in Wilson Disease (WD) patients by cardiac magnetic resonance (CMR).

### **METHODS AND MATERIALS**

We prospectively included WD patients and age- and sex-matched healthy population. We applied CMR to analyze cardiac function, strain, T1 maps, T2 maps, extracellular volume fraction (ECV) maps and LGE images. Subgroup analyzes were performed for patients with WD with predominantly neurologic manifestations (WD-neuro+) or only hepatic manifestations (WD-neuro-).

### **RESULTS**

41 WD patients (age 27.9±8 years) and 40 healthy controls (age 25.4±2.9 years) were included in this study. Compared to the controls, the T1, T2, and ECV values were significantly increased in the WD group (T1 1085.1±39.1 vs. 1046.5±33.1 ms, T2 54.2±3.3 ms vs. 51.5±2.6 ms, ECV 31.8±3.6% vs. 24.3±3.7%) (all P < 0.001). LGE analysis showed that LGE in WD patients was mainly found in the right ventricular insertion point and interventricular septum. In addition, the WD-neuro+ group showed more severe myocardial damage compared with WD-neuro- group. The Unified Wilson Disease Rating Scale score was significantly correlated with ECV (Pearson's r = 0.64, P < 0.001).

### **CONCLUSION**

s CMR could detect early myocardial involvement in WD patients without overt left ventricle dysfunction. Furthermore, characteristics of myocardial involvement were different between WD-neuro+ and WD-neuro-, and myocardial involvement might be more severe in WD-neuro+ patients.

### **CLINICAL RELEVANCE/APPLICATION**

We found that CMR T1 mapping could detect early myocardial involvement in WD patients without overt left ventricle dysfunction. Furthermore, characteristics of myocardial involvement were different between WD-neuro+ and WD-neuro-, and myocardial involvement might be more severe in WD-neuro+ patients.

## **T2-SPNR-3 Efficacy of 3T Segmented Acquisition Fast Spin-Echo Diffusion-Weighted Imaging for Differentiating Pituitary Abscess from Other Sellar Cystic Lesions**

Participants  
SOICHIRO ISHIUCHI, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

### **PURPOSE**

Pituitary abscesses (PAs) are rare and often difficult to differentiate from other sellar cystic lesions (OSCLs). The split acquisition of fast spin-echo signals for diffusion-weighted imaging (SPLICE-DWI) sequence can reduce artifacts and distortion caused by susceptibility differences without sacrificing signal-to-noise ratio. We aimed to evaluate the efficacy of SPLICE-DWI for the differentiation between PA and OSCLs.

### **METHODS AND MATERIALS**

Our study included 5 PAs and 27 OSCLs (11 Rathke's cleft cysts, 11 cystic pituitary adenomas, and 5 craniopharyngiomas) in 32 consecutive patients who underwent sagittal T1-, T2- and contrast-enhanced T1- weighted imaging (T1WI, T2WI, CET1WI) and SPLICE-DWI at 3T. Two radiologists qualitatively evaluated the signal intensity of cystic components on T1WI, T2WI, and SPLICE-DWI using a 5-point grading system (from 1 [very hypointensity] to 5 [very hyperintensity]). They also assessed the presence of ring enhancement, pituitary stalk enlargement and sphenoid sinusitis, and the percentage of cystic components on CET1WI. In addition, two radiologists measured apparent diffusion coefficient (ADC) values of cystic components, and the difference in the mean ADC values between PA and OSCL groups was assessed. Interobserver agreement was determined by calculating the ? coefficient. Statistical analyses, including receiver operating characteristic curve (ROC) analysis were performed.

### **RESULTS**

Although the signal intensity of T1WI and T2WI, the presence of stalk enlargement, ring enhancement and sphenoid sinusitis, and the percentage of cystic components were not significantly different between PA and OSCL groups, the signal intensity of cystic components on SPLICE-DWI was significantly different (P = .04). Interobserver agreement for SPLICE-DWI was good (? = 0.77). Mean ADC value was significantly lower for PA than OSCL (0.62 ± 0.07 vs. 1.83 ± 0.70 x 10<sup>-3</sup>mm<sup>2</sup>/s, P = .002). The area under the ROC curve of the ADC value was 0.952.

### **CONCLUSION**

s Qualitative and quantitative assessment of SPLICE-DWI helps distinguish between PA and OSCLs.

### **CLINICAL RELEVANCE/APPLICATION**

SPLICE-DWI is a useful non-invasive imaging tool for diagnosing pituitary abscesses.

## **T2-SPNR-4 The Experience of a Tertiary Center in South Brazil with Opportunistic Central Nervous Diseases of Immunocompromised Patients**

### **PURPOSE**

Our aim is to present a wide spectrum of opportunistic diseases, including unusual pathologies, that can affect the central nervous system of immunocompromised patients in two tertiary centers at south Brazil.

### **METHODS AND MATERIALS**

This is a cross-sectional retrospective study performed at two public tertiary centers in South Brazil. We selected a miscellanea of

This is a cross-sectional retrospective study performed at two public tertiary centers in South Brazil. We selected a miscellanea of 10 illustrative cases of the various conditions that can affect the immunocompromised patients' central nervous system was selected.

## RESULTS

Amongst 322 patients evaluated during the last 5 years, 10 illustrative cases were selecting to represent a gamut of opportunistic infectious diseases that affect the central nervous system of immunocompromised patients. We show the following diagnosed cases: toxoplasmosis, progressive multifocal leukoencephalopathy (PML mimicking MSA-C), cryptococcosis, tuberculosis, nocardiosis, and paracoccidioidomycosis infections, HIV-encephalitis, HIV vasculopathy, AIDS-related lymphoma (mimicking toxoplasmosis), and a rare case of eosinophilic meningitis caused by *Angiostrongylus catus* (in a slug consumer).

## CONCLUSION

The Central Nervous System is frequently affected in immunocompromised patients, as many opportunistic diseases may involve the brain. The clinical manifestations are nonspecific and depend on the type and location of the lesions. As the diagnosis of these entities is frequently made with noninvasive methods, imaging studies, especially magnetic resonance imaging, are very useful tools for the diagnosis.

## CLINICAL RELEVANCE/APPLICATION

These pathological conditions can have similar clinical manifestations, so imaging plays a crucial role in the variable diagnostic conditions and the assessment of the extent of the disease, in order to decide the best therapeutic strategy to be followed.

## T2-SPNR-5 Usefulness of Amide Proton Transfer Imaging Combined With Pseudocontinuous Arterial Spin Labeling Imaging and Apparent Diffusion Coefficient Map in Differentiating Intracranial Malignant Tumors From Benign Tumors in Young Patients

### PURPOSE

We aimed to assess combined diagnostic value of amide proton transfer (APT), tumor blood flow (TBF) obtained by pseudocontinuous arterial spin labeling (pCASL), and apparent diffusion coefficient (ADC) for differentiating intracranial malignant tumors (MTs) from benign tumors (BTs) in young patients.

### METHODS AND MATERIALS

A total of 20 patients with intracranial tumors aged 0-30 years old were enrolled. Fifteen patients were categorized into MTs by WHO 5th edition classification grade 3 or 4, or ICD behavior code /3, and five patients were categorized into BTs by WHO grade 1 or 2. All the patients were scanned with APT, pCASL, and diffusion-weighted image and evaluated by histogram analysis. Maximum (max), minimum (min), mean, 10th, 25th, 50th, 75th, and 90th percentiles, skewness, and kurtosis of APT, TBF, and ADC values were obtained by the region of interest method. The parameters were compared between the groups by Mann-Whitney U test. Diagnostic performance was evaluated by receiver operating characteristic analysis.

### RESULTS

MTs included diffuse midline glioma H3K27-altered, grade 4 (2), Diffuse paediatric-type high-grade glioma H3-wildtype and IDH-wildtype, grade 4 (2), astroblastoma, MIN1-altered (1), germinoma (3), immature teratoma (2), astrocytoma, NOS, grade 3 (1), atypical teratoid/rhabdoid tumor, grade 4 (1), rhabdomyosarcoma, NOS (1), medulloblastoma, histologically defined, grade 4 (1), and mixed germ cell tumors (1). BTs included pilocytic astrocytoma, grade 1 (1), astrocytoma, IDH-mutant, grade 2 (1), angiocentric glioma, grade 1 (1), posterior fossa ependymoma, group A, grade 2 (1), and supratentorial ependymoma, NOS, grade 2 (1). Mean, 10th, 25th, and 50th percentiles of APT ( $p=0.025$ , respectively), and ADC min showed significant differences ( $p=0.042$ ), while no parameter of TBF showed significant difference between the groups. Median values of APT mean (%), TBF max (mL/100g/min), and ADC min ( $\times 10^{-3}$  mm<sup>2</sup>/sec) were 3.26, 23.73 and 1.14 for MTs, whereas 1.92, 20.83, and 1.03 for BTs. Mean, 10th, 25th, and 50th percentiles of APT, TBF max, and ADC min were the highest AUC values among all parameters of each sequence (0.840, 0.760, and 0.813, respectively) and AUC value for combination of those was 0.933.

### CONCLUSION

Combination of APT, pCASL, and ADC may be useful in differentiating intracranial MTs from BTs in young patients.

### CLINICAL RELEVANCE/APPLICATION

Combination of APT, pCASL, and ADC map may help differentiating malignant and benign intracranial tumors in young patients.

## T2-SPNR-6 A Fully Automated Deep-learning Model for Predicting the Molecular Subtypes of Posterior Fossa Ependymomas using T2-weighted Images

### PURPOSE

Accurate determination of posterior fossa ependymoma (PF-EPN) molecular subtypes (Group A [PFA] and Group B [PFB]) according to the 2021 WHO classification could guide clinical treatment strategies and determine prognosis. We aimed to develop and validate a deep-learning (DL) model to automatically segment PF-EPNs and predict PFA and PFB subtypes from preoperative MR images.

### METHODS AND MATERIALS

We retrospectively identified 227 PF-EPNs (development and internal test sets) with both available preoperative T2-weighted (T2w) MR images and molecular status to develop and test a 3D nnU-Net (here named T2-nnU-Net) for tumor segmentation and molecular subtype prediction. The network was externally tested using one external independent sets ( $n=31$ ) and prospectively enrolled cases (prospective validation set [ $n=27$ ]). The Dice similarity coefficient was used to evaluate segmentation performance. Receiver operating characteristic analysis for molecular subtype prediction was performed.

### RESULTS

For tumor segmentation, the T2-nnU-Net achieved a dice score of  $0.94 \pm 0.02$  in the internal test set. For molecular subtype prediction, the T2-nnU-Net achieved an AUC of 0.93 and accuracy of 0.89 in the internal test set, an AUC of 0.97 and accuracy of 0.90 in the external test set. In the prospective validation set, the model achieved an AUC of 0.93 and accuracy of 0.89. The T2-nnU-Net predictive performance was superior or comparable to that using demographic and multiple radiological features (AUCs

ranging from 0.88 to 0.93).

## CONCLUSION

s A fully automated DL model was developed and validated to accurately segment PF-EPNs and predict molecular subtypes using only T2w MR images, and it could help clinical decision-making.

## CLINICAL RELEVANCE/APPLICATION

We developed and validated a fully automated deep learning model to accurately segment posterior fossa ependymomas and predict molecular subtypes using only T2w MR images based on a large multicenter sample. The ability to noninvasively classify PFA and PFB subtypes has significant implications in determining treatment plans and predicting prognosis.

## T2-SPNR-7 Whole-tumor Histogram Analysis of Postcontrast T1-weighted and Apparent Diffusion Coefficient in Predicting the Grade and Proliferative Activity of Adult Intracranial Ependymomas

### Participants

Liu Xianwang, Lanzhou, China (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the value of histogram analysis of postcontrast T1-weighted (T1C) and apparent diffusion coefficient (ADC) in predicting the grade and proliferative activity of adult intracranial ependymomas.

### METHODS AND MATERIALS

Forty-seven patients with histologically proven adult intracranial ependymomas were retrospectively collected. The histogram parameters, including minimum, maximum, mean, and Perc.01, Perc.05, Perc.10, Perc.25, Perc.50, Perc.75, Perc.90, Perc.95, Perc.99, as well as standard deviation (SD), variance, coefficient of variation (CV), skewness, kurtosis, and entropy of T1C and ADC images were extracted from the whole tumor using FireVoxel software. Differences in histogram parameters between grade 2- and grade 3- adult intracranial ependymomas were compared. Receiver operating characteristic curves and logistic regression analyses were conducted to determine the differential diagnostic performance. Spearman's correlation analysis was used to evaluate the relationship between histogram parameters and the Ki-67 proliferation index.

### RESULTS

Grade 3 intracranial ependymomas showed significantly higher Perc.95, Perc.99, SD, variance, CV, and entropy of T1C (all  $p < 0.05$ ), lower minimum, mean, Perc.01, Perc.05, Perc.10, Perc.25, Perc.50 of ADC, higher CV and entropy of ADC (all  $p < 0.05$ ), compared to grade 2 intracranial ependymomas. Entropy (T1C) and Perc.10 (ADC) have a higher diagnostic performance with AUCs of 0.805 and 0.827 among the histogram parameters of T1C and ADC, respectively. The diagnostic performance was further improved by combining the entropy (T1C) and Perc.10 (ADC), with an AUC of 0.857. Significant correlations were observed between significant histogram parameters of T1C and ADC and the Ki-67 proliferation index ( $p = 0.001-0.044$ ).

### CONCLUSION

s Whole-tumor histogram analysis of T1C and ADC may be a promising approach in predicting the grade and proliferative activity of adult intracranial ependymomas.

### CLINICAL RELEVANCE/APPLICATION

Grading and proliferative activity significantly influence treatment decision-making in adult intracranial ependymomas. Whole-tumor histogram analysis of T1C and ADC are useful to preoperatively evaluate the grade and proliferative activity of adult intracranial ependymomas. The combination of entropy (T1C) and Perc.10 (ADC) achieved the best diagnostic performance.

## T2-SPNR-8 Radiomics-based Prediction of TERT Promoter Mutation in Intracranial Meningiomas

### Participants

Burak Akkurt, MD, PhD, Muenster, Germany (*Presenter*) Nothing to Disclose

### PURPOSE

In meningiomas, TERT promoter mutations are rare but qualify diagnosis of anaplasia, directly impacting adjuvant therapy. Effective screening for patients at risk for promoter mutations could enable more targeted molecular analyses and improve diagnosis and treatment.

### METHODS AND MATERIALS

Semiautomatic segmentation of the meningiomas was performed on preoperative magnetic resonance imaging. Discriminatory power to predict TERT promoter mutations was analyzed in grade 2/3 meningiomas using a random forest algorithm with an increasing number of radiomic features. Two final models with 5 and 8 features were built with both fixed and differing radiomics features. Each model has been fully developed 100 times to eliminate random effects and avoid overfitting.

### RESULTS

117 image sets including training (N=94) and test data (N=23) were analyzed. Established 5- and 8-feature models with both fixed and different radiomics features enabled prediction of TERT with similar but excellent performance. Of note, a significant increase in the average discriminatory power up to the fifth feature included was observed, while addition of further features up to N=8 features only slightly increased the performance. 5-feature (different/ fixed) model predicted TERT promoter mutation status with a mean AUC of 91.8%/94.3%, mean accuracy of 85.5%/88.9%, mean sensitivity of 88.6%/91.4%, mean specificity of 83.2%/87.0%, and a mean Cohen's Kappa of 71.0%/77.7%. 8-feature (different/ fixed) model predicted TERT promoter mutation status with a mean AUC of 92.7%/94.6%, mean accuracy of 87.3%/88.9%, mean sensitivity of 89.6%/90.6%, mean specificity of 85.5%/87.5%, and a mean Cohen's Kappa of 74.4%/77.6%.

### CONCLUSION

s Radiomics based machine learning enables prediction of TERT promoter mutation status in meningiomas with excellent discriminatory performance. Future analyses in larger cohorts should include grade 1 lesions as well as additional molecular

alterations.

#### **CLINICAL RELEVANCE/APPLICATION**

Radiomics might help in the non-invasive characterization of meningiomas, impacting diagnosis and therapy.

#### **T2-SPNR-9 Predicting Meningioma Recurrence/progression Based on MRI Radiomics**

Participants

Tao Han, Lanzhou, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Preoperative prediction of meningioma recurrence/ progression should help in the selection of surgical options and provides a basis for guiding meningioma patients to achieve individualized treatment. However, only a few radiological features have been identified to aid in prediction. The aim of this study was to develop and validate an MRI-based nomogram to predict meningioma recurrence/progression.

#### **METHODS AND MATERIALS**

This retrospective study collected 88 patients with surgically pathologically confirmed meningiomas, including 28 patients with postoperative tumor recurrence and 60 patients with non-recurrence. All cases were randomly divided into training and validation sets according to 7:3, and 1874 features were extracted from each of preoperative T2WI and T1WI-enhanced images, respectively, and least absolute shrinkage and selection operator (LASSO) regularization was used to determine the best combination of clinical and MRI features to predict meningioma recurrence/progression, and subsequently machine learning algorithms were applied to construct a meningioma recurrence risk assessment prediction model, using receiver operating characteristic (ROC) curve analysis to determine predictive performance, and calibration curve and decision curve analysis to validate the consistency and clinical validity of the nomogram.

#### **RESULTS**

Finally, twelve radiomics features closely related to the risk of meningioma recurrence were screened to construct a nomogram of the RF model, and the results showed that the model had good predictive performance with AUCs of 0.950 and 0.852 in the training and validation sets, respectively.

#### **CONCLUSION**

s The predictive model based on MRI radiomics features has good predictive performance in predicting meningioma recurrence/ progression and can be applied to clinical practice.

#### **CLINICAL RELEVANCE/APPLICATION**

Radiomics models based on T2WI and T1C are helpful for predicting meningioma recurrence/progression.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

T2-SPOB

### OB/Gynecology Tuesday Poster Discussions

#### Sub-Events

#### **T2-SPOB-1 Could the 40keV Monochromatic Images in Dual-Energy Spectral CT Increase the Value and Consistency of Peritoneal Cancer Index in Advanced Epithelial Ovarian Cancer for Junior Radiologists**

#### PURPOSE

To investigate the value of using 40keV virtual monochromatic images (VMI) in dual-energy spectral CT (DEsCT) to increase peritoneal cancer index (PCI) value in advanced epithelial ovarian cancer (EOC) for junior radiologists and their consistency with senior radiologists.

#### METHODS AND MATERIALS

Retrospectively analyzed 32 advanced EOCs (27 serous, 2 mucinous and 3 clear cell carcinomas, and 28 in stage III and 4 in stage IV) who underwent primary cytoreduction (11 in satisfied and 21 in dissatisfied groups). VMI of venous phase at 40keV and 70keV (equivalent to 120kVp) were reconstructed from abdominal and pelvic DEsCT. A senior and junior radiologist evaluated VMIs double-blindly in the degree of ascites, abdominal and pelvic anatomical structures using Sugarbaker PCI standards and performed CT-PCI scoring for the entire and upper abdomen separately. SPSS 27.0 and Medcalc 20.1.0 were used for statistical analyses. Binary logistic regression was used to analyze parameters influencing the outcome prediction of unsatisfactory tumor reduction surgery.

#### RESULTS

The satisfied group had lower serum CA-125 level than the unsatisfied group (112 vs. 654 u/ml,  $U=58$ ,  $P=0.023$ ). And the upper abdominal (2 vs. 6,  $U=43$ ,  $P=0.003$ ) CT-PCI scores than dissatisfied group. There was no significant difference in age, FIGO stage, histological type, and ascites degree between these two groups. The 70 keV CT-PCI score was an independent factor in causing initial tumor reduction dissatisfaction in advanced EOCs ( $OR=1.785$ , 95%  $CI=1.024-3.111$ ,  $P=0.041$ ). The 70keV CT-PCI scores of senior and junior radiologists were all lower than that of the 40keV (senior: mean difference = -1.81,  $t=-6.06$ ,  $P<0.001$ ; junior: mean difference = -2.84,  $t=-6.99$ ,  $P<0.001$ ). The CT-PCI scores of the junior was lower than that of the senior when using 70keV VMI (mean difference = -1.13,  $t=-4.52$ ,  $P<0.001$ ), but no significant difference using the 40keV VMI (mean difference = -0.09,  $t=-1.36$ ,  $P=0.184$ ).

#### CONCLUSION

The use of 40keV VMI improves CT-PCI scores for both senior and junior radiologists and reduces their differences.

#### CLINICAL RELEVANCE/APPLICATION

The 40keV VMI in DEsCT increase the value and consistency of PCI in advanced EOC for junior radiologists, help clinical evaluation of tumor load in patients with advanced EOC, and guide the development of clinical treatment strategies.

#### **T2-SPOB-2 OvCA Finder: An Interpretable Hybrid Model Integrating Multimodal Information for Ovarian Cancer Diagnosis**

Participants

Huiling Xiang, Guangzhou, China (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop an interpretable hybrid model (OvcaFinder) from multimodal information that allows preoperative identification of ovarian cancer.

#### METHODS AND MATERIALS

Consecutive patients with at least one pathology-confirmed adnexal lesion visible by transvaginal ultrasound were enrolled in this study. Ultrasound images of all lesions were independently assessed by five readers using the Ovarian-Adnexal Reporting and Data System (O-RADS). The following three models were built and internally validated using 724 cases from Hospital 1: a clinical model with variables including age, lesion diameter, and cancer antigen 125 concentration; an image-based DL predictive model; and our newly developed model, OvcaFinder, using multimodal information. The performance of the models was then externally validated using 387 cases from Hospital 2 and the diagnostic performances of the models were compared.

#### RESULTS

The readers achieved mean areas under the receiver operating characteristic curve (AUCs) of 0.927 and 0.904, using the O-RADS for the internal and external test datasets, respectively. OvcaFinder outperformed the clinical model (AUC, internal dataset: 0.978 vs. 0.936,  $p = .007$ ; external dataset: 0.947 vs. 0.842,  $p < .001$ ) and the image-based DL predictive model (AUC, internal dataset: 0.978 vs. 0.970,  $p = .152$ ; external dataset: 0.947 vs. 0.893,  $p < .001$ ). Readers assisted by OvcaFinder showed significant improvements in AUCs (internal dataset: 2.3-8.0%; external dataset: 1.9-5.3%) and a reduction in false positive rate (internal dataset: 13.3%,  $p = 0.029$ ; external dataset: 8.3%,  $p = 0.033$ ) than those without.

#### CONCLUSION

s OvcaFinder, an interpretable hybrid model that integrates multimodal information, could be used by radiologists as a non-invasive tool for reliably diagnosing ovarian cancer, thus improving radiologists' diagnostic performance and helping to determine the appropriate treatment strategies.

#### **CLINICAL RELEVANCE/APPLICATION**

OvcaFinder, a novel hybrid model constructed from multimodal information can effectively distinguish between ovarian cancer and benign lesions and thus significantly improve the diagnostic performance of radiologists.

#### **T2-SPOB-3 Subendometrial Enhancement and Peritumoral Enhancement in the Uterus: Assessment of the Optimal Timing with High Spatial-temporal Resolution Multiphase Contrast Enhanced-MRI**

Participants

Takahiro Tsuboyama, MD, (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The scanning protocol of dynamic contrast-enhanced MRI (DCE-MRI) for endometrial cancer has not been standardized due to the lack of evidence regarding the optimal timing for subendometrial enhancement (SEE) and peritumoral enhancement (PTE). The purpose of this study was to assess SEE and PTE with high spatial-temporal resolution multiphase DCE-MRI using differential subsampling with cartesian ordering (DISCO).

#### **METHODS AND MATERIALS**

Fifty women (mean age, 56.8; range, 25-91 years) who underwent DCE-MRI for the assessment of suspected uterine diseases were included. Nineteen of them were proved to have endometrial cancer. DCE-MR included 11 early phases obtained with DISCO (voxel size, 0.6\*1.0\*4.0 mm) in which the first 10 phases were acquired from 20 to 50 s after contrast injection with temporal resolution of 3 s, followed by 11th phase with a full k-space data sampling at 60 s. One radiologist placed regions of interest on the uterine structures, and time-intensity curves were generated. Enhancement ratios (ERs) and contrast ratios (CRs) were calculated and compared using Wilcoxon test and Friedman test. Correlation between the start of uterine enhancement and the start of the plateau or peak of SEE was evaluated using a correlation coefficient.

#### **RESULTS**

SEE was detected in 48 of the 50 patients. It showed various degree of peak ER (range, 0.59-3.56). During the early phases, it reached a plateau in 25 patients and showed a progressive enhancement in the other 23 patients. The plateau started variably from 32 to 47 sec after contrast injection and had a moderate positive correlation with the contrast arrival time at the uterus ( $r = 0.52$ ,  $P < 0.01$ ). The mean ER of SEE on each phase was increased with time and was significantly the highest at 60 sec ( $P < 0.01$ ). CR between SEE and inner myometrium also increased with time and was the highest during 41 to 60 sec. PTE was detected in 15 patients with an endometrial cancer and displayed significantly higher peak ER and significantly earlier start of a plateau compared with SEE ( $P < 0.01$ ). The highest CR between PTE and SEE was observed during 32-44 s.

#### **CONCLUSION**

s SEE may show optimal enhancement and contrast at 60 s after contrast injection and have different enhancement patterns from those of PTE. Given some varieties in the enhancement patterns of SEE and PTE among patients, DISCO may be useful to catch the optimal timing for the detection of SEE and PTE.

#### **CLINICAL RELEVANCE/APPLICATION**

Accurate assessment of SEE and PTE with high spatial-temporal resolution DCE-MRI using DISCO may increase the accuracies of preoperative staging of endometrial cancer.

#### **T2-SPOB-4 Diagnostic Ability of Single-Shot Fast Spin-Echo T2-Weighted MRI with Deep Learning Reconstruction for the Assessment of Myometrial Invasion in Endometrial Cancer: A Comparison with Standard Sequences using PROPELLER and Fast Spin-Echo Imaging**

Participants

Kengo Kiso, MD, Suita-City, Japan (*Presenter*) Nothing to Disclose

Takahiro Tsuboyama, MD, (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Single-shot fast spin-echo (SSFSE) T2-weighted MRI (T2WI) with deep learning reconstruction (DLR) is reported to achieve high image quality in an ultra-short acquisition time. The purpose of this study was to compare its diagnostic ability for the assessment of myometrial invasion in endometrial cancer with that of standard but time consuming T2WI using periodically rotated overlapping parallel lines with enhanced reconstruction (PROPELLER) and fast spin-echo (FSE) imaging.

#### **METHODS AND MATERIALS**

Seventy-two consecutive patients who underwent preoperative dynamic contrast-enhanced (DCE) MRI for endometrial cancer were included. For the standard T2WI, para-axial FSE and parasagittal PROPELLER imaging were obtained. Para-axial and -sagittal SSFSE T2WI with DLR (SSFSE-DLR-T2WI) were also acquired. Two radiologists independently assessed the following four MRI sets; standard T2WI, standard T2WI+DCE, SSFSE-DLR-T2WI, and SSFSE-DLR-T2WI+DCE. Noise, artifacts, the visibility of the junctional zone and serosa of the uterus and that of the tumor were compared between standard T2WI and SSFSE-DLR-T2WI using the Wilcoxon signed-rank test. The diagnostic accuracies of the four MRI sets regarding superficial and deep myometrial invasion of the endometrial cancer were compared using the receiver operating characteristic analysis and the Cochran's Q test.

#### **RESULTS**

SSFSE-DLR-T2WI was significantly better than standard T2WI regarding noise, artifacts, and the visibility of the uterine structures and the tumor for both readers ( $p < 0.01$ ). As for the diagnosis of myometrial invasion, mean AUCs of standard T2WI, standard T2WI+DCE, SSFSE-DLR-T2WI, and SSFSE-DLR-T2WI+DCE by the two readers were 0.76, 0.83, 0.72, and 0.80, respectively for superficial myometrial invasion, and 0.87, 0.92, 0.82, and 0.91, respectively for deep myometrial invasion. There were no significant differences in AUCs, sensitivities, specificities, and accuracies between standard T2WI and SSFSE-DLR-T2WI and between standard T2WI+DCE and SSFSE-DLR-T2WI+DCE for both readers. Sensitivities for superficial myometrial invasion were significantly

lower with standard T2WI than with standard T2WI+DCE and with SSFSE-DLR-T2WI+DCE for both readers ( $p < 0.05$ ).

#### **CONCLUSION**

s For the assessment of myometrial invasion in endometrial cancer, SSFSE with DLR can provide better image quality and equivalent diagnostic accuracies compared with standard T2WI.

#### **CLINICAL RELEVANCE/APPLICATION**

Standard T2WI can be replaced by SSFSE with DLR for the assessment of myometrial invasion in endometrial cancer, which can reduce the examination time considerably.

T2-SPPD

### Pediatric Imaging Tuesday Poster Discussions

#### Sub-Events

#### T2-SPPD-1 Pediatric H3K27 Altered Diffuse Midline Gliomas: Imaging Features in 37 Children of One Institution

##### Participants

Elzbieta Jurkiewicz, MD, Warsaw, Poland (*Presenter*) Nothing to Disclose

##### PURPOSE

Pediatric diffuse midline glioma (PDMG) arises from the thalamus, hypothalamus, pineal gland, brainstem, cerebellum, and spinal cord. Regardless of the location, the prognosis of PDMG is poor with a 2-year survival rate of <10%. According to the 2021 WHO classification, pediatric diffuse high-grade gliomas are recognized as: diffuse midline glioma, H3K27-altered, diffuse hemispheric glioma, H3G34-mutant, diffuse pediatric high-grade glioma, H3-wildtype/IDH-wildtype and infant-type hemispheric glioma. The overexpression of EZHIP, or an EGFR mutation, are also observed in these tumors. The possibility of surgical resection is often limited, due to the involvement of critical brain structures. Radiation or chemotherapy is standard. We present MR examinations of 37 patients with diffuse midline glioma, H3 K27-altered, aged from 40 months to 17 years; median age 9.6 years.

##### METHODS AND MATERIALS

All patients were examined on a 1.5 T scanner with a protocol including T2/FLAIR images, DWI, SWI, and T1-weighted images with and without contrast injection. We characterized the structural MR imaging features of these tumors: presence of calcifications, hemorrhage, necrosis, and leptomeningeal spread. The presence and degree of contrast enhancement were also assessed. A biopsy was performed in all patients. Pathological/microscopic and molecular characterization was carried out in all children.

##### RESULTS

Tumors were located in the pons in 28 patients, midbrain in 12, thalamus in 6, medulla oblongata in 6, and in the spinal cord in one child. All tumors were hypointense on T1- and heterogeneously hyperintense on T2/FLAIR images. Contrast enhancement was seen in 16 patients (punctate or rim), restriction on diffusion in 9. Exophytic component was noted in one child. Hydrocephalus was present in 5, necrosis in 9, and hemorrhagic component in 3 patients. Leptomeningeal spread at the time of diagnosis was diagnosed in one case. The mutations c.83A>T H3F3A were recognized in 35 children and mutations c.83A>T HIST1H3B (H3C2) in 2 patients.

##### CONCLUSION

We found that midline gliomas with histone H3 K27M mutation centered within the thalamus and brainstem were solid with infrequent exophytic component and hemorrhage.

##### CLINICAL RELEVANCE/APPLICATION

Molecular characterization of the PDMG may be relevant to individual patients for personalized molecular therapies based on genomic analysis of the tumors.

#### T2-SPPD-2 [11C] Methionine PET in Diagnosing Pediatric Low-grade Gliomas

##### PURPOSE

Positron emission tomography (PET) imaging of the brain with amino acid tracers, such as [11C] Methionine (MET), is helpful in the evaluation of brain tumors. Although MET-PET has been extensively used in adults and some pediatric brain tumors, data on MET-PET imaging of pediatric low-grade gliomas (pLGG) are scarce. This study aimed to investigate the diagnostic performance of MET-PET in diagnosing pLGGs.

##### METHODS AND MATERIALS

Fifteen patients with newly diagnosed pLGG and twenty-six previously treated pLGG patients were evaluated with MET-PET and magnetic resonance imaging. Biopsy or tumor resection was performed in all patients within 6 months of the MET-PET. Qualitative and semi-quantitative analysis that included tumor to brain uptake ratios (TBR) were performed. TBR was consisted of TBRmax, TBRpeak, and TBRmean analyses. TBR >1 was used to define a positive MET-PET test.

##### RESULTS

The sensitivity of MET-PET for diagnosing newly diagnosed pLGG was 87% for TBRmax and TBRpeak, 80% for TBRmean, and 94% for qualitative interpretation. The sensitivity of MET-PET for diagnosing previously treated pLGG was 100% for TBRmax and TBRpeak, 81% for TBRmean, and 96% for qualitative interpretation. The sensitivity for the combined cohort was 95% for both TBRmax and TBRpeak, 80% for TBRmean, and 95% for qualitative evaluation.

##### CONCLUSION

Both quantitative and qualitative MET-PET have high sensitivity in diagnosing pLGG, both newly diagnosed and previously treated.

**CLINICAL RELEVANCE/APPLICATION**

With its high sensitivity, MET-PET can be used to complement equivocal MRI.

## Abstract Archives of the RSNA, 2023

T2-SPPH

### Physics Tuesday Poster Discussions

#### Sub-Events

#### **T2-SPPH-1 Quantification of Radial and Azimuthal Variation in Spatial Resolution due to Patient Positioning on Energy Integrating and Deep Silicon Photon Counting Detector CT**

##### Participants

Aria Salyapongse, BS, Madison, WI (*Presenter*) Nothing to Disclose

##### PURPOSE

Mispositioning in CT degrades spatial resolution. Existing CT technologies address this degradation using scan modes that increase view angle sampling. In this work, we investigate spatial resolution loss away from isocenter for a prototype deep silicon photon-counting detector (PCD) CT scanner and compare with existing energy-integrating detector (EID) CT.

##### METHODS AND MATERIALS

We performed three sets of scans on a wire phantom at four radial positions in the bore (isocenter, 6.7 cm, 11.8 cm, and 17.1 cm off isocenter). The acquisition modes were: 120 kV EID CT, 120 kV high-definition (HD) EID CT, and 120 kV PCD CT. HD mode used double the projection view angles as the "regular" EID scan mode. Diameter of the wire was calculated by taking the full width of half max (FWHM) of a profile drawn over the radial and azimuthal directions of the wire. Change in apparent size of the wire was assessed by taking the ratio of the radial or azimuthal diameter at each position to the radial or azimuthal diameter at isocenter.

##### RESULTS

The deep silicon PCD CT had the smallest change in the ratio of the wire diameter for both radial (ratio of  $1.00 \pm 0.09$  versus  $1.15 \pm 0.01$  and  $1.21 \pm 0.04$ ,  $p < .001$ ) and azimuthal (ratio of  $0.99 \pm 0.09$  versus  $1.36 \pm 0.01$  and  $1.12 \pm 0.01$ ,  $p < .001$ ) directions versus EID and HD EID respectively. HD EID CT had a smaller change in the ratio of the wire diameter in the azimuthal direction compared with EID CT ( $p < .001$ ), and a larger change in the radial direction compared with EID CT ( $p < .001$ ).

##### CONCLUSION

s Deep silicon PCD CT exhibits less change in spatial resolution in both the radial and azimuthal directions compared with both regular and HD modes on EID CT.

##### CLINICAL RELEVANCE/APPLICATION

Deep silicon PCD CT better preserved spatial resolution away from isocenter compared to EID CT which could translate into better bone and lung detail in regions located far away from isocenter.

#### **T2-SPPH-10 Accuracy of Volume and Linear Dimension Measurements of Hepatic Lesions with Dual Energy CT**

##### Participants

Jimmy Zhou, PhD, Los Angeles, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

It has been proposed to use the volumes of hepatic lesions as a better metric than linear dimensions. However, as compared to linear dimensions, lesion volumes are more susceptible to segmentation error, hence the measurement accuracy remains unknown. We aimed to study the accuracy of both lesion volume and linear dimension measurements with dual energy CT using a simulated multi-phase liver phantom.

##### METHODS AND MATERIALS

The liver was simulated using material composition following ICRU 44. It was embedded in an abdomen phantom containing thoracic and lumbar spines. 34 lesions of iodine, iron, fat, and cyst were placed in the liver with known volumes (0.09 - 8.57 cc) and maximum linear dimensions (MLD) (10- 35 mm). The lesions are of various shapes (ellipsoidal and lobular), and contrast (-100 to 30 HU). The non-contrast, arterial, and venous phases were simulated by perfusing the parenchyma with different iodine concentrations (0, 0.68, and 1.89 mg/cc) in three consecutive slabs (40 - 50 mm thickness each). A GE Revolution CT was used at the dual-energy mode in three repeats with CTDIvol of 14 mGy (slice thickness 2.5 mm). 28 visually discernable lesions were contoured using GE AW-3.2 with auto segmentation and careful user correction for monochromatic reconstructed images of 50- 100 keV.

##### RESULTS

Compared with the known values, the overall volumes were overestimated across different energies by 9.4% +12.5%, whereas the overall MLDs were found underestimated by 4.7% +8.3%. The cyst and fat volumes were found most accurate with 3.1%+5.7% and 8.8%+8.1%, respectively, whilst the corresponding MLDs were with accuracies of 1.1%+1.8%, and 9.7%+9.5%. The iron and iodine volumes were measured higher than the ground truth by 12%+10% and 10%+14%, respectively, whilst the corresponding MLDs were found lower by 6.3%+6.7% and 3.2%+8.3%. The optimal energy for the volumes of the cyst, fat, iron, and iodine was found

to be  $\leq 70$  keV, 55 keV, 65 keV, and 70 keV, respectively. For MLD measurements, the results were less dependent on energy with the overall accuracy of 4.7%+8.4%.

## CONCLUSION

s With the fast-kVp switch dual-energy CT, the liver lesion volumes were overestimated by 9.4% +12.5%, and the optimal energies were identified with better accuracy. The MLD were underestimated with overall accuracy of 4.7% +8.3% and the results were found less dependent on energy.

## CLINICAL RELEVANCE/APPLICATION

Provide hepatic lesion volume and linear dimension accuracy in multiphase liver CT scans.

## T2-SPPH-11 Assessment of a Low-Dose Single-Scan Dynamic CT Myocardial Perfusion Technique using a Helical Scan Mode

Participants

Negin Hadjiabdolhamid, Irvine, CA (*Presenter*) Nothing to Disclose

## PURPOSE

This study assessed the reproducibility and accuracy of a low-dose single-scan dynamic CT myocardial perfusion technique using a fast-pitch helical scan mode available on standard CT scanners.

## METHODS AND MATERIALS

A total of 6 Yorkshire Swine ( $48.7 \pm 7.4$  Kg) were assessed under rest and stress conditions. Using a 320-slice CT scanner, 6 and 6 pairs of repeated CT perfusion measurements were obtained in helical and volume scan modes (100 kVp, 200 mA, and 2.5 s scan time), respectively. Myocardial perfusion measurements derived from a previously validated single-volume myocardial CT perfusion technique were used as a reference for accuracy assessment of measurements obtained from helical scans. Each helical pair was acquired following the acquisition of a volume pair, under the same perfusion conditions. Both contrast (0.5 mL/kg; 370 mgI/mL) and a diluted contrast/saline chaser (0.5 mL/kg; 30:70 contrast/saline) were injected peripherally at a rate of 5 mL/s. Following bolus tracking and triggering, a single scan was acquired at the peak of the aortic enhancement. Both the bolus tracking and the single scan data were used to derive perfusion in mL/min/g using a first-pass analysis model. The coronary perfusion territories of the left anterior descending (LAD), left circumflex (LCx) and right coronary artery (RCA) were automatically assigned for vessel-specific regional perfusion analysis. The reproducibility and accuracy of myocardial perfusion measurements in each coronary perfusion territory were assessed via regression analysis. The average CT dose index (CTDI) of perfusion measurements was recorded.

## RESULTS

The first (P<sub>Hel1</sub>) and second (P<sub>Hel2</sub>) helical CT perfusion measurements were related by  $P_{Hel2} = 0.89P_{Hel1} + 0.13$  ( $r = 0.91$ ; RMSE = 0.21 mL/min/g; RMSD = 0.20 mL/min/g) for the LAD, LCx, and RCA perfusion territories. The myocardial perfusion measurements obtained from helical and volume scans were also related by  $P_{Hel} = 0.98P_{Vol} + 0.02$  ( $r = 0.99$ ; RMSE = 0.04 mL/min/g; RMSD = 0.05 mL/min/g) when assessed in the whole myocardium, and by  $P_{Hel} = 0.95P_{Vol} + 0.04$  in LAD, LCx, and RCA perfusion territories. The average CTDI of CT perfusion measurement was 30.1 mGy and 13.3 mGy for helical and volume acquisitions, respectively.

## CONCLUSION

s A standard CT scanner in a helical scan mode can provide reproducible and accurate myocardial perfusion measurement in mL/min/g using a low-dose single-scan dynamic CT myocardial perfusion technique, which enables the clinical applicability of the technique.

## CLINICAL RELEVANCE/APPLICATION

Using a standard CT scanner in a helical mode, this technique will provide a noninvasive tool that allows comprehensive concurrent evaluation of coronary anatomy and physiology for routine assessment of coronary artery disease.

## T2-SPPH-12 Urinary Stone Differentiation using Material Decomposition Images in Dual Energy CT Urography

## PURPOSE

To evaluate the feasibility of differentiating urinary stones using material decomposition (MD) images in dual energy CT urography (DECTU).

## METHODS AND MATERIALS

108 consecutive patients (mean age:  $48.22 \pm 14.69$ y, male vs female: 75 vs 33) with suspected urinary stones and underwent triphasic DECTU were included. MD images with various basis material pairs at nephrographic (ENP) and excretory (EEP) phase were transferred to an AW4.7 for analysis. For stones larger than 3mm, regions of interest were defined as the largest circumference on the axial section of the images. MD densities of stones were measured using the GSI Viewer. Stones were divided into the pure calcium oxalate (pCaO: n=34), mixed calcium oxalate (mCaO: n=14) and mixed calcium phosphate (mCaP: n=70) according to the results of Fourier infrared spectrometer. One way ANOVA or Kruskal-Wallis H test was used to compare the MD density among the three stone groups with adjusted significance level. Thresholds for differentiating urinary stones were determined using receiver operating characteristics (ROC) analysis.

## RESULTS

The MD densities of stones using different basis material pairs are listed in Tab.1. Significant differences on Calcium (Water) MD images at ENP were found between pCaO and mCaO; mCaO and mCaP. While COD (HAP) MD images at ENP provided higher ability to distinguish pCaO from mCaP. The ranges of AUC of using MD density on ENP images were 0.68-0.75 (Tab.2) and MD density on COD (HAP) based images at ENP provided higher ability to differentiate and display the three stones (Fig.1).

## CONCLUSION

s MD density on COD (HAP) based images at ENP provide relatively high accuracy in distinguishing calcium oxalate from calcium phosphate.

## CLINICAL RELEVANCE/APPLICATION

Material decomposition images may play a role in identifying calcium oxalate stones and calcium phosphate, especially COD (HAP) MD images.

### T2-SPPH-13 Diagnostic Value of CT Lymphangiography in Patients with Primary Chyluria

Participants

Qi Hao, Beijing, China (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the application value of CT lymphangiography in diagnosis in patients with primary chyluria.

#### METHODS AND MATERIALS

Clinical and CTL imaging data of 79 patients diagnosed with primary chyluria were collected retrospectively. For CTL, the indexes were: Distribution of abnormal lymphatic vessels in the kidney: unilateral or bilateral kidney, renal sinus, renal parenchymal, suprahilum area and subhilum area; ? Distribution of perirenal and retroperitoneal abnormal lymphatic vessels: retroperitoneal, lumbar trunk, renal perivascular area, fatty capsule, adrenal area, etc; ? Distribution of dilated lymphatic vessels and lymphatic reflux in chest, abdomen and pelvis. The clinical characteristics and CTL signs of patients with primary chyluria were statistically described by the composition ratio of classification variables.

#### RESULTS

CTL showed abnormal lipiodol deposition in kidney in 74 cases (93.7%), single kidney in 55 cases (69.6%), bilateral kidneys in 19 cases (24.1%), renal sinus in 74 cases (93.7%), renal parenchyma in 37 cases (46.8%); suprahilum area in 61 cases (77.2%), 52 cases (65.8%) were unilateral and 9 cases (11.4%) were bilateral; subhilum area in 61 cases (77.2%), 47 cases (59.5%) were unilateral and 14 cases (17.7%) were bilateral; retroperitoneal area in 78 cases (98.7%); lumbar trunk area in 76 cases (96.2%), 20 cases (25.3%) were unilateral and 56 cases (70.9%) were bilateral; perivascular area in 72 cases (91.1%), 45 cases (57.0%) were unilateral and 27 cases (34.2%) were bilateral; fatty capsule in 14 cases (17.7%), 13 cases (16.5%) were unilateral and 1 case (1.3%) were bilateral; adrenal area in 12 cases (15.2%); bladder in 31 cases (39.2%), perivesical area in 12 cases (15.2%), perivascular area of the iliac in 73 cases (92.4%), abdominal and pelvic wall in 14 cases (17.7%), perineal area in 12 cases (15.2%), perirectal area in 14 cases (17.7%), mesentery in 26 cases (32.9%), intestinal wall in 11 cases (13.9%), intestinal canal in 5 cases (6.3%), peripancreatic area in 15 cases (18.9%), perisplenic area in 2 cases (2.5%), perihepatic area in 7 cases (8.8%), hilum of the lung in 1 case (1.3%), mediastinum in 14 cases (17.7%), pericardium in 1 case (1.3%), extrapleural area in 25 cases (31.6%), chest wall in 2 cases (2.5%), skeleton in 2 cases (2.5%), end of thoracic duct in 70 cases (88.6%).

#### CONCLUSION

s CTL can evaluate the distribution and range of intrarenal, perirenal and retroperitoneal dilated lymphatic vessels accurately, and evaluate the abnormal lymphatic vessels in the chest, abdomen and pelvis in patients with primary chyluria.

## CLINICAL RELEVANCE/APPLICATION

CTL can provide image basis for the diagnosis, grading and treatment of primary chyluria.

### T2-SPPH-2 Application of Silver Nanotriangles as a Novel Contrast Agent in Tumor Computed Tomography Imaging

Participants

Huiquan Yang, Nanjing, China (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aimed to prepare chitosan-coated silver nanotriangles (AgNTs) and assess their computed tomography (CT) contrast property by in vitro and in vivo experiments.

#### METHODS AND MATERIALS

AgNTs with a range of sizes were synthesized by a seed-based growth method, and subsequently characterized by transmission electron microscopy (TEM), ultraviolet-visible absorption spectroscopy and dynamic light scattering. The X-ray attenuation capability of all prepared AgNTs was evaluated using micro CT. The CT contrast effect of AgNTs with the highest X-ray attenuation coefficient was investigated in MDA-MB-231 breast cancer cells and a mouse model of breast cancer.

#### RESULTS

The TEM results displayed that all synthesized AgNTs were triangular in shape and their mean edge lengths ranged from 60 to 149 nm. All AgNTs tested exhibited stronger X-ray attenuation capability than iohexol at the same mass concentration of the active elements, and the larger the AgNTs size, the higher the X-ray attenuation coefficient. AgNTs with the largest size were selected for further research, due to their strongest X-ray attenuation capability and best biocompatibility. The attenuation coefficient of breast cancer cells treated with AgNTs increased in a particle concentration-dependent manner. In vivo CT imaging showed that the contrast of the tumor injected with AgNTs was significantly enhanced.

#### CONCLUSION

s Our findings suggested that AgNTs could serve as an excellent contrast agent for CT imaging.

## CLINICAL RELEVANCE/APPLICATION

The current study provided a new thought for the development of highly efficient tumor CT contrast agents.

### T2-SPPH-3 Improvement of Demonstrating Submillimeter Vessels by a Newly Developed Photon Counting Detector CT: Comparison with an Energy Integrating CT in a Vessel Phantom Model

Participants

Shota Kondo, Hiroshima, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Demonstrating submillimeter vessels is not easy for the conventional energy integrating detector CT (EID-CT). PCD-CT offers several advantages over conventional EID-CT, including improvements in spatial resolution, image noise, and contrast resolution of materials including iodine as PCD-CT directly measure photon energy of each incident photon using a single semiconductor layer. The purpose of our study was to evaluate diagnostic capability of a newly developed PCD-CT on the visualization of submillimeter vessels compared with conventional EID-CT in a vessel phantom model.

## METHODS AND MATERIALS

We used a prototype PCD-CT scanner developed by Canon Medical Systems for this phantom study. A phantom (outer diameter 200 mm) including simulated 0.5, 1.0, 1.5, 2.0, 3.0, 5.0, and 10.0 mm vessels was scanned with a PCD- and EID-CT (Aquilion Precision, Canon Medical Systems). The simulated vessels were filled with diluted iodine contrast material (15mgI/ml). The scanning parameters for PCD-CT and EID-CT were matched: 120 kV, 9.5-9.7mGy CTDIvol. Both scans were reconstructed with hybrid-iterative reconstruction. PCD-CT scans were reconstructed using 1024- [ultra-high resolution (UHR) mode] while EID-CT scans were reconstructed using 512 matrix sizes. Modulation transfer function (MTF) was calculated using the simulated vessel with diameter of 10.0 mm. Profile curves were generated along a horizontal line crossing through the center of each simulated small vessel (diameter less than 3.0 mm) and the slope at the 50% point of each curve was calculated.

## RESULTS

The margin of each simulated vessel was clearly demonstrate on PCD-CT- compared with EID-CT image. PCD-CT could barely demonstrate the simulated vessel with diameter of 0.5 mm but EID-CT could not .The MTF for PCD-CT showed higher response than for EID-CT in all frequency domains. The slope value for simulated small vessels was higher on PCD-CT than on EID-CT image especially for smaller vessels.

## CONCLUSION

s PCD-CT with UHR mode showed higher spatial resolution and better demonstration of submillimeter vessels than conventional EID-CT in a phantom model.

## CLINICAL RELEVANCE/APPLICATION

PCD-CT with UHR mode may be able to demonstrate more detailed vascular anatomy such as the perforating branches of the brain than EID-CT; and PCD-CT has the potential to bring advances to medical practice.

## T2-SPPH-4 Quantification of Lower Extremity Blood Flow using a Low-dose CT Perfusion Technique

Participants

Alireza Shojazadeh, MD, Irvine, CA (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the reproducibility and accuracy of lower extremity perfusion measurements with a low-dose first-pass analysis (FPA) dynamic CT perfusion technique.

## METHODS AND MATERIALS

A total of sixteen Yorkshire Swine ( $46.3 \pm 7.2$ kg) were used in this study with twenty-two CT acquisitions for accuracy and thirty-three acquisition pairs for reproducibility assessments. In each animal, acquisition pairs were obtained at baseline blood flow and under various levels of femoral artery stenosis severity induced by a vascular occluder. Reference flow measurements were recorded for each acquisition using an ultrasound flow probe for comparison and accuracy assessment of the technique. Contrast agent (370 mg/mL iodine, 1 mL/kg) and saline chaser (0.5 mL/kg) were both injected peripherally at a rate of 5 mL/s. Bolus tracking was used, and a pre-contrast (120kVp; 50mA) and post-contrast (120kVp; 200mA) helical scan were acquired at the base and approximately the peak of the aortic enhancement (CT angiogram), respectively. The pre- and post-contrast helical scan data were then used as analytical inputs into a first-pass analysis model to derive perfusion in mL/min/g. The accuracy and reproducibility of lower extremity perfusion measurement were then assessed via linear regression, Bland-Altman analysis, and paired sample t-test (p-value). The average CT dose index (CTDI) for the perfusion measurements was recorded.

## RESULTS

The first (P1) and second (P2) CT perfusion measurements were related by  $P2 = 0.97 P1 + 0.00$  ( $r = 0.97$ ,  $RMSE = 0.11$  mL/min/g and  $RMSD = 0.11$  mL/min/g,  $P$ -value= 0.56). The blood flow calculation derived from the CT perfusion technique (QCT) and the reference standard ultrasound blood flow measurement (QUS) were related by  $QCT = 0.93 QUS + 9.83$  ( $r = 0.96$ ,  $RMSE = 16.34$ ,  $RMSD = 32.20$ ,  $P$ -value= 0.09). The average CTDI of perfusion measurement using this technique was only 9.1 mGy.

## CONCLUSION

s This study shows that the low-dose quantitative CT perfusion technique can accurately measure lower extremity perfusion (mL/min/g) using only two helical scans. The CT angiogram and perfusion measurements can be used as a comprehensive technique for morphological and physiological assessment of limb ischemia.

## CLINICAL RELEVANCE/APPLICATION

Quantitative assessment of blood flow in peripheral extremities provides clinicians with a promising diagnostic tool for evaluating vascular diseases. Simultaneously acquiring CT angiography and providing accurate blood flow measurement can improve risk assessment and critical decision-making for patients across a wide spectrum of disease severity.

## T2-SPPH-5 Noise Reduction at Coronary CT Angiography with Photon-counting Detector CT: A Structured Phantom Study

Participants

Toru Higaki, PhD, Minami-ku, Hiroshima, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Photon-counting detector CT (PCD-CT) features a semiconductor detector that enables high-resolution imaging with a high-density

detector element, and low-noise imaging based on electrical noise cancellation. We developed a photon-counting detector CT scanner whose detector is made of CdZnTe. Here we evaluate the noise characteristics of PCD-CT using a structured phantom that simulates coronary CT angiography (CCTA).

## **METHODS AND MATERIALS**

Our CCTA structured phantom shown in Fig.1 uses a 3D printer (KEYENCE Agilista-3200). The vessels were filled with iodine contrast medium diluted to 20 mgI/ml. One simulated coronary artery harbored a 70% stenotic lesion, the other a stent graft (Medtronic, BeStent, 3.0 mm × 15 mm). We scanned the phantom on a PCD-CT scanner (Canon Medical Systems) in normal-resolution mode. The detector-element size was approximately the same as that of conventional EID-CT, the slice thickness was about 0.6 mm, the tube voltage was 120 kV, and the tube current was 250 mA. Comparisons were with a conventional energy-integrating detector CT (EID-CT, Aquilion ONE GENESIS, Canon Medical Systems). The structured phantom was scanned with a protocol that resulted in similar radiation exposure. All images were reconstructed with hybrid iterative reconstruction. To evaluate the image quality we measured the noise power spectrum (NPS) as a metric of the noise characteristics and the task-based modulation transfer function (MTF) as a metric of spatial resolution.

## **RESULTS**

The radiation dose (CTDIvol) was approximately 9.5 mGy. The image noise of PCD-CT was lower than of EID-CT (SD: 8.9 v.s. 13.8 HU, Fig. 2 left). The spatial resolution of PCD-CT and EID-CT were comparable (Fig. 2 right). Comparison of the images in Figs. 3 and 4 confirmed the low image noise on PCD-CT scans.

## **CONCLUSION**

Our PCD-CT suppressed the electrical noise and reduced the image noise on CCTA images.

## **CLINICAL RELEVANCE/APPLICATION**

As the normal resolution mode of PCD-CT can reduce the image noise it may be useful for reducing the radiation dose of CCTA.

### **T2-SPPH-6 Radiation Dose and Image Quality at Coronary CT Angiography using a 256-detector Scanner at Different Heart Rates**

Participants

Yuta Hirose, Adachi, Japan (*Presenter*) Nothing to Disclose

## **PURPOSE**

To retrospectively assess radiation dose and image quality (IQ) at coronary CT angiography (CCTA) with a 256-detector CT scanner in patients with different heart rates (HRs).

## **METHODS AND MATERIALS**

From January 2022 through January 2023, consecutive 158 patients were included who underwent prospectively ECG-gated axial scanning of CCTA using the high-definition scan mode with the latest 256-detector CT scanner (Revolution CT Apex, GE). Each patient was classified into one of the following 3 groups based on mean HR and HR variability (HRV), defined as difference between maximum and minimum HRs, during the scanning: Group A, mean HR < 65 bpm and HRV < 20 bpm; Group B, mean HR = 65 bpm and HRV < 20 bpm; Group C, HRV = 20 bpm. Scan window was automatically selected based on mean HR and HRV just before the examination with dedicated software as follows: Group A, mid-diastole; Group B, end-systole to mid-diastole; Group C, entire cardiac cycle of a single heartbeat. Axial images of 0.625-mm slice were reconstructed with a deep-learning algorithm at optimal cardiac phase automatically selected with dedicated software. A motion correction algorithm was applied only when motion artifact remained significant. Standard deviation (SD) of CT value was measured in the ascending aorta as image noise. Two independent radiologists subjectively assessed IQ of the right coronary artery (RCA), left anterior descending artery (LAD), and left circumflex artery (LCX) regarding motion artifact using a 4-point scale (1, poor; 4, excellent; 2-4, acceptable). One-way ANOVA test was used to compare body mass index (BMI), SD, and dose-length product (DLP) and Kruskal-Wallis test was used to compare the IQ scores with Bonferroni correction among Groups A-C at the scanning. Weighted  $\kappa$  test was used to quantify inter-reader agreement.

## **RESULTS**

Whereas BMI ( $P = 0.557$ ) and SD ( $P = 0.065$ ) were comparable among Groups A-C, DLP was significantly higher in Group C than in Groups A and B ( $P < 0.05$  for both) but comparable between Groups A and B at the scanning ( $P = 0.341$ ). The IQ score for RCA was significantly higher in Group A than in Group B ( $P < 0.001$ ) and for LAD and LCX, in Group A than in Groups B and C ( $P < 0.05$  for all); otherwise, comparable among Groups A-C ( $P > 0.05$  for all). IQ was acceptable in all vessels except one RCA in Group A and one RCA and one LCX in Group C. Inter-reader agreement was good ( $\kappa = 0.76$ ).

## **CONCLUSION**

IQ regarding motion artifact was best in Group A but acceptable in all Groups whereas radiation dose was significantly increased in Group C at the CCTA.

## **CLINICAL RELEVANCE/APPLICATION**

Whereas acceptable IQ regarding motion artifact can be preserved at CCTA with the latest 256-detector CT scanner, adequate use of beta blockers to lower HR and HRV can reduce radiation dose and improve IQ and diagnostic performance.

### **T2-SPPH-7 Reproducibility of an Automated Lobar Lung Tissue Assignment Technique using Non-contrast CT**

Participants

Sabee Y. Molloy, PhD, Irvine, CA (*Presenter*) Research Grant, Canon Medical Systems Corporation

## **PURPOSE**

Lobar segmentation is necessary for regional ventilation and perfusion analysis. This study evaluated the reproducibility of a vessel-specific minimum-cost path (MCP) technique used for lobar segmentation based on non-contrast CT.

## **METHODS AND MATERIALS**

A total of 16 Yorkshire Swine (49.88±4.69 kg) were used in this study with 46 independent CT acquisitions. A helical scan mode was used (100kV, 50 mA, 24 cm Z-coverage and 2.5s scan time). Following image acquisition, lung tissue segmentation and pulmonary arterial tree centerline extraction was performed. The pulmonary arterial tree was then divided into six lobar subtrees for lobar assignment. The MCP technique was used to assign lobar territories by assigning every voxel of the lung tissue to the nearest arterial tree segment. The reproducibility of the MCP technique was evaluated by quantitatively comparing the MCP-derived lobar territories between two CT acquisitions by tissue mass and volume, using linear regression, root mean square error (RMSE), root mean square deviation (RMSD) and paired sample t-test (p-value). An interobserver and intraobserver analysis of the lobar measurements were also performed.

## RESULTS

The lobar mass measurements from the first (MLOBE1) and second (MLOBE2) CT acquisitions were correlated by  $MLOBE1 = 0.99MLOBE2 + 1.76$  ( $r = 0.99$ ) with a p-value of 0.120, RMSE = 7.99 g and RMSD = 7.91 g. The lobar volume measurements from the first (VLOBE1) and second (VLOBE2) CT acquisitions were correlated by  $VLOBE1 = 0.98VLOBE2 + 2.66$  ( $r = 0.99$ ) with a p-value of 0.160, RSME = 15.26 mL and RMSD = 14.94 mL. The calculated whole lung mass measurements from the first (MLUNG1) and second (MLUNG2) CT acquisitions were correlated by  $MLUNG1 = 0.89 MLUNG2 + 76.32$  g ( $r = 0.96$ ) with a p-value of 0.306, RMSE= 29.13 g and RMSD= 26.10 g. The calculated whole lung volume measurements from the first (VLUNG1) and second (VLUNG2) CT acquisitions were correlated by  $VLUNG1 = 0.99 VLUNG2 - 3.27$  ( $r = 0.98$ ) with a p-value of 0.396, RMSE = 60.52 mL, RMSD = 59.49 mL.

## CONCLUSION

s The whole lung and lobar mass and volume measurements show excellent reproducibility using a vessel specific assignment technique. This technique can potentially be used for automated lung lobar segmentation, enabling regional ventilation and perfusion analysis for clinical applications.

## CLINICAL RELEVANCE/APPLICATION

Assessment of lobar mass or volume in the lung lobes may allow for efficient treatment planning and region-specific treatment strategies for diseases such as pulmonary embolism and chronic thromboembolic pulmonary hypertension.

### T2-SPPH-8 Reproducibility of a Low-Dose Single-Volume Dynamic CT Myocardial Perfusion Technique

#### Participants

Negin Hadjiabdolhamid, Irvine, CA (*Presenter*) Nothing to Disclose

#### PURPOSE

The current methods for accurate diagnosis and assessment of the physiological effects of coronary artery disease (CAD) are limited. There have been previous reports of dynamic CT perfusion techniques capable of assessing CAD, but high radiation dose has hampered widespread clinical implementation of currently existing methods. This study assessed the reproducibility of myocardial perfusion measurements in mL/min/g using a low-dose single-volume dynamic CT myocardial perfusion technique.

#### METHODS AND MATERIALS

A total of 13 Yorkshire Swine (54.3±12.3 kg) were used in this study. Thirty-four pairs of prospective CT measurements were made under rest and stress conditions. One or two acquisition pairs were acquired in each animal with a 10-minute delay between each acquisition. Contrast (0.5 mL/kg; 370 mgI/mL) and a diluted contrast/saline chaser (0.5 mL/kg; 30:70 contrast/saline) were injected peripherally at 5 mL/s, followed by bolus tracking, triggering, and acquisition of a single volume scan (100 kVp; 200 mA) using a 320-slice CT scanner. The delay time for acquisition of the single volume scan after triggering was determined using a previously validated contrast injection timing method. Following CT acquisition, both the bolus tracking and single volume scan data were used to derive perfusion in mL/min/g using a first-pass analysis model. After which, the coronary perfusion territories of the left anterior descending (LAD), left circumflex (LCx) and right coronary artery (RCA) were automatically assigned using a previously validated minimum-cost path technique. The reproducibility of CT myocardial perfusion measurement within the LAD, LCx, RCA, and the whole myocardium was assessed via regression analysis. The average CT dose index (CTDI) of perfusion measurement was also recorded.

## RESULTS

The first (Pmyo1) and second (Pmyo2) single-volume CT perfusion measurements were related by  $Pmyo2 = 1.01Pmyo1 - 0.03$  ( $r = 0.99$ ; RMSE=0.08 mL/min/g; RMSD=0.07 mL/min/g) for the whole myocardium, and by  $Preg2 = 0.86Preg1 - 0.13$  ( $r = 0.91$ ; RMSE=0.31 mL/min/g; RMSD=0.29 mL/min/g) for the LAD, LCx, and RCA vessel-specific perfusion territories (Preg). The average CTDI of the single-volume CT perfusion measurement was 10.5mGy.

## CONCLUSION

s The low-dose single-volume dynamic CT myocardial perfusion technique provides reproducible myocardial perfusion measurement in mL/min/g only requiring bolus tracking and a single whole-heart volume scan data.

## CLINICAL RELEVANCE/APPLICATION

This technique is a noninvasive tool that reproducibly measures myocardial perfusion and provides coronary CT angiogram, which allows for simultaneous anatomic-physiologic assessment of myocardial ischemia.

### T2-SPPH-9 High Temporal Resolution and Low-dose Dynamic Imaging of Airway using Photon-counting-detector CT

#### Participants

Jelena Mihailovic, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

#### PURPOSE

Dynamic CT imaging can provide valuable information for diagnosing airway abnormalities. Existing dynamic CT techniques for airway imaging are susceptible to cardiac and respiratory motion artifacts due to limited temporal resolution. In this work, we aim to implement and evaluate a low-dose dynamic scanning technique with a temporal resolution as fast as 66 milliseconds for airway imaging using a dual-source photon-counting-detector (PCD)-CT.

## **METHODS AND MATERIALS**

An inflatable pig lung phantom (BioQuest, USA) that can mimic respiratory cycles through manual ventilation was used. Tubes with known diameters (2 and 3 mm) were attached to the lung as a measurement reference. The phantom was scanned on a whole-body PCD-CT scanner (Naeotom Alpha, Siemens) with two scanning modes, a dual-source prospectively-gated adaptive sequential mode with a slow (30 bpm) electrocardiogram (ECG) signal and a traditional dynamic cine mode, each at three dose levels (volume CT dose index (CTDI<sub>vol</sub>) = 0.8, 1.6, and 3.5 mGy). For the slow-ECG-gated mode, in order to utilize the rapid temporal resolution used for cardiac CT while providing multi-phase imaging and reconstruction of an entire breathing cycle, an ECG simulator was modified to generate a much slower signal simulating breathing cycles of 30 rpm. This slow ECG-gated mode has a temporal resolution of 66 ms, similar to cardiac CT. The techniques used for both dynamic CT scanning modes were adjusted to a low tube potential (90 kV) to achieve the lowest possible radiation dose. The rotation time was 0.25 seconds and field of view (FOV) 300 mm. Since the acquisition is performed with detector collimation of 144x0.4 mm minimum slice thickness for dynamic scan was 0.6 mm, while for adaptive sequential mode 0.4 mm. The diameters of the tubes were measured and compared with the truth to compare the impact of motion at the two scan modes.

## **RESULTS**

Motion artifacts were significantly reduced on images acquired from the slow ECG-gated scans compared to the traditional cine-mode scans. On the slow ECG-gated dynamic images, the shape of the attached tubes was maintained, which provided a more accurate measurement of diameter than images from the cine-mode scans:  $3.10 \pm 0.02$  mm and  $1.9 \pm 0.02$  mm for ECG-gated scans, and  $3.9 \pm 0.6$  mm and  $2.6 \pm 0.5$  mm for cine-mode scans, for tubes of 3 and 2 mm, respectively.

## **CONCLUSION**

Compared to conventional dynamic CT acquired in a cine mode, the proposed slow ECG-gated dynamic imaging technique on PCD-CT can achieve a better temporal resolution, which reduces motion artifacts and improves visualization and quantitation of airways.

## **CLINICAL RELEVANCE/APPLICATION**

Implementation of a slow ECG-gated imaging method on the dual-source PCD-CT may provide dynamic images of airways with reduced motion artifacts.

T2-SPRO

### Radiation Oncology Tuesday Poster Discussions

#### Sub-Events

#### T2-SPRO-1 Preoperatively Identify Glypican-3 Positive HCC: Via Multi-phase CE-MRI Delta Radiomics

##### Participants

Yifan Pan, Fuzhou, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the value of multi-phase contrast enhanced magnetic resonance imaging (CE-MRI) based delta radiomics for identifying the glypican-3 (GPC3) positive hepatocellular carcinoma (HCC).

##### METHODS AND MATERIALS

One hundred and twenty-six patients with pathologically-confirmed HCC (GPC3 positive : GPC3 negative = 95 : 31; training cohort: n = 88; test cohort: n = 38) were retrospectively recruited. Basic information was obtained from our medical records. Preoperative Multi-phase CE-MRI images were reviewed by abdominal radiologists and semantic features were evaluated. The 3D volume of interest (VOI) of whole tumor was segmented on non-contrast T1 weighted imaging (T1-NC), arterial phase (AP), portal venous phase (PVP), delayed phase (DP), hepatobiliary phase (HBP). Radiomic features were extracted from each phase and 3 types delta features (standardized subtraction, direct subtraction, and relative subtraction) were calculated. Feature data were resampled using Synthetic Minority Over-sampling Technique (SMOTE) algorithm. A two-step feature selection strategy was applied. First, minimal-redundancy-maximal-relevance (mRMR) was used to select 20 features and then recursive feature elimination (RFE) was used for further selection. Radiomics models were built using logistic regression and support vector machine. By combining the best radiomics model and clinical risk factors, a nomogram was constructed and evaluated.

##### RESULTS

Univariate analysis showed that serum alpha-fetoprotein (AFP) levels > 400 ng/ml ( $p = 0.013$ ) was significantly related to GPC3 positive HCC. The optimal radiomic model composed of 8 delta radiomic features had an AUC of 0.805 in training cohort and 0.851 in test cohort. Additionally, the nomogram integrated the radiomics score and AFP achieved the best performance (training cohort: AUC = 0.844; test cohort: AUC = 0.862). Calibration curve showed good agreement between the nomogram predicted probabilities and actual outcomes of GPC3 expression in both training and test cohort. Decision curve analysis further demonstrate the clinical practicality of the nomogram.

##### CONCLUSION

s Multi-phase CE-MRI based delta radiomics model can non-invasively predict GPC3 positive HCC and could be a useful method for individualized diagnosis and treatment.

##### CLINICAL RELEVANCE/APPLICATION

Multi-phase CE-MRI based delta radiomics model can non-invasively predict GPC3 positive HCC and could be a useful method for individualized diagnosis and treatment.

## Abstract Archives of the RSNA, 2023

T2-SPVA

### Vascular Imaging Tuesday Poster Discussions

#### Sub-Events

#### **T2-SPVA-1 Assessment of the Utility of CT Angiographic Reports for Evaluation of Deep Inferior Epigastric Artery in Preparation for Rectus Flap Surgery**

##### Participants

David Polito, MD, Morton Grove, IL (*Presenter*) Nothing to Disclose  
Collin Larkin, MSc, (*Presenter*) Nothing to Disclose

##### **PURPOSE**

Current radiology literature details the anatomy of the deep inferior epigastric artery (DIEP) and reporting requirements. However, the surgical requirements are specific, and our current literature is short of addressing those. We aim to compare imaging and surgical findings of DIEP perforators on CT angiographic (CTA) studies for improving radiology reports tailored to help in the surgical flap selection.

##### **METHODS AND MATERIALS**

Retrospective review of CTA from 1/2021 to 1/2023 for indication of DIEP evaluation for breast reconstruction planning. There were 95 studies, and 40 were included after excluding examinations with a large field of view, >3 mm slice thickness, and suboptimal image quality. The CTA was reviewed for anatomy of DIEP: origin, branching pattern, number of perforators, and their sizes. Two readers- one abdominal imaging fellow and a fellowship-trained radiologist reviewed the studies independently. The medical records were queried for factors that affect flap selection, including prior abdominal surgery, preoperative surgical choices, patient preference, clinical indication, operative findings, the reason for selecting or rejecting a flap, and post-operative complications. Descriptive statistics and kappa statistics were performed.

##### **RESULTS**

The patients ranged from 30-71 years of age. The readers reported 68-80% studies were of good quality. Inter-reader agreement for assessment of branching type and number of >1.5mm perforators on each side was moderate (Cohen's kappa value ranging 0.41-0.5). Though there were smaller number of patients with perforators that were >1.5 mm diameter and below the umbilicus that was crucial in surgical decision making, there were more perforators (up to 6) that were below the umbilicus but <1.5 mm size criteria. Sixteen patients had bilateral flap reconstruction, 9- unilateral flap of which 4 had combined rectus flap and latissimus TRAM flap surgeries. Nine patients had post-operative complications, which were ischemia and necrosis due to thrombosis of perforator or intimal tearing of the perforator during surgery.

##### **CONCLUSION**

s CTA is a viable modality for presurgical planning in anticipation of breast reconstruction and has acceptable inter-reader agreement and correlation with surgical findings. It is essential to revise our radiology reports to include DIEP perforators up to 4 perforators that are >1.5 mm thickness at the subfascial plane and below the umbilicus to help the surgeons in decision-making.

##### **CLINICAL RELEVANCE/APPLICATION**

Awareness of anatomy and reporting of the crucial details about the number and course of DIEP perforators can help in surgical planning and avoid accidental vessel tears or injury during surgery, leading to necrosis and failure of flap reconstruction.

#### **T2-SPVA-2 Deep Learning for Cerebral Artery Segmentation in 3D MRA using the Spatial Distribution Probability Map**

##### Participants

Yun Peng, Nanchang, China (*Presenter*) Nothing to Disclose

##### **PURPOSE**

Thanks to the development of computational capability, deep learning based segmentation has attracted increased attention over the past few years. This study aims to develop a novel approach for the segmentation of cerebral arteries by incorporating the a-prior knowledge of the spatial distribution of cerebral arteries in the deep learning network.

##### **METHODS AND MATERIALS**

Patients who had undergone time-of-flight magnetic resonance angiography (TOF-MRA) for both the physical examination and the suspicion of cerebrovascular diseases at two different branches of a hospital were retrospectively identified. 50 healthy patients evaluated in 2022 are included. The ground truth images were first manually generated by four junior radiologists. To reduce errors, all labels were checked and corrected by two senior radiologists. The proposed network was trained with the data set of 40 patients and evaluated with the test set of 10 patients. In this study, we develop a U-net based network which embeds a trainable spatial distribution probability map (SDPM) into the network. The SDPM provides the overall location knowledge of the cerebral arteries to correct the predictions of the non-target vessels or predictions with high uncertainty. It refines the prediction for

ambiguous artery edges and reduces mislabeled vessels caused by brain imaging under different equipment and parameters. Additionally, the SDPM is trainable so that it improves the initial SDPM, which is calculated using the overall spatial distribution of cerebral arteries. The performance was assessed by the dice similarity coefficient (DSC), the false negative (FN) rate and the false positive (FP) rate.

## RESULTS

The proposed model is compared with three models: 3D Unet, 3D Res-Unet and 3D Vnet. The average DSC of the proposed model in the test set was 0.89, while the average DSC of the 3D Unet, 3D Res-Unet and 3D Vnet were 0.77, 0.80 and 0.85, respectively. The FP rate of the proposed model is 0.156, which is better than the results of 3D Res-Unet (0.171) and 3D Vnet (0.162). The 3D Unet has the best performance on FP rate, however its FN rate is 0.306. The FN rate of the proposed model is 0.126, which also outperforms the results of 3D Res-Unet (0.241) and 3D Vnet (0.132).

## CONCLUSION

By embedding the trainable SDPM into the Unet structure, the proposed model provides a fully automated segmentation method with high accuracy for cerebral arteries. Future work includes developing a cerebral aneurysm detection model using the proposed SDPM method.

## CLINICAL RELEVANCE/APPLICATION

The fully automated segmentation of cerebral arteries with high performance helps to improve clinical diagnostic efficiency and accuracy of cerebrovascular diseases, such as the cerebral aneurysm and stenosis.

## T2-SPVA-3 MRI Relaxation Properties of Ferumoxytol: A Comparison of Brand Name vs Generic

Participants

Rianne Van der Heijden, MD, PhD, Rotterdam, (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the MRI relaxation properties of brand name ferumoxytol (Feraheme®, AMAG Pharmaceuticals) with generic ferumoxytol (Sandoz).

## METHODS AND MATERIALS

A phantom experiment was performed using both brand name and generic ferumoxytol agents. Each agent was diluted in saline and also adult bovine whole blood at 5 concentrations ranging from 0.3-2.1mM within 30 ml vials, for a total of 20 vials. Prior to imaging, vials were placed in an MR compatible water bath at 37°C and imaged at both a 1.5T and 3.0T on clinical MRI systems (1.5T Artist, 3.0T Premier, GE Healthcare, Waukesha, WI) using a phase array torso coil (AIR coil). The protocol consisted of coronal acquisitions using 2D fast spin echo (FSE) inversion recovery with multiple inversion times to measure R1, 2D FSE sequence with multiple echoes to measure R2, and 3D multi-echo spoiled gradient echo chemical shift-encoded method (IDEAL-IQ) to measure R2\*. Relaxation rate constants, R1, R2, R2\* were measured in a manually drawn region of interest centrally located in each vial in three slices using Matlab. Differences in relaxivity between the agents were tested with chi-square with 2 or 3 degrees of freedom depending on the fitted model.

## RESULTS

The dependences of R1, R2 and R2\* on ferumoxytol concentrations were linear in saline and non-linear in blood. R1 values (represented by the slope of the equation and SE (s-1mM<sup>-1</sup>)) of saline for AMAG and Sandoz, respectively at 1.5 T (16.3 ± 2.2; 14.3 ± 1.3; p=.22) and 3.0 T (9.5 ± 0.04; 8.8 ± 0.01; p<.001). R2 values of saline for AMAG and Sandoz respectively at 1.5 T (59.4 ± 0.35; 60.0 ± 4.9; p=.82) and 3.0 T (61.3 ± 3.9; 57.8 ± 1.8; p=.13). R2\* values of saline for AMAG and Sandoz respectively at 1.5 T (59.4 ± 2.1; 72.0 ± 3.3; p<.001) and 3.0 T (64.2 ± 3.3; 65.3 ± 4.5; p=.92). R1 relaxivity of blood followed a quadratic relationship for AMAG and Sandoz respectively at 1.5 T (6.7x<sup>2</sup>+1.23x+7.4; 8.3x<sup>2</sup>-1.9x+7.6; p=.22) and 3.0 T (1.4x<sup>2</sup>+6.6x+0.8; 1.6x<sup>2</sup>+5.4x+0.7; p<.001), where x=concentration. R2 relaxivity of blood for AMAG and Sandoz respectively at 1.5 T (20.1x<sup>2</sup>+45.7x+12; 20.7x<sup>2</sup>+35.5x +13.3; p=.07) and 3.0 T (15.9x<sup>2</sup>+41.6x +15.2; 30.2x<sup>2</sup>+6.8x +22.7; p=.44). R2\* relaxivity of blood for AMAG and Sandoz respectively at 1.5 T (60.0x<sup>2</sup>-3.31x+108.5; 41.7x<sup>2</sup>+30.0x+80; p<.001) and 3.0 T (43.9x<sup>2</sup>+24.2x+57; 38.5x<sup>2</sup>+26.2x+56; p<.001).

## CONCLUSION

There were no statistically significant differences between the AMAG and Sandoz agents for most relaxivity values and those with differences were small and of doubtful clinical relevance.

## CLINICAL RELEVANCE/APPLICATION

Ferumoxytol is increasingly being used for MR angiography and in patients with contraindications to gadolinium. The use of generic agents may reduce cost without any clinically relevant differences in the relaxation properties.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

T5A-SPBR

### Breast Imaging Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPBR-1 Screening after Breast Conserving Surgery with Acellular Dermal Matrix Reconstruction: Mammography, Ultrasonography and MRI**

##### Participants

Dawon Jung, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the findings of postoperative images of patients who underwent breast reconstruction with acellular dermal matrix (ADM) and assess which imaging modality is more feasible to detect local tumor recurrence: mammography(MG), ultrasound(US), or MRI.

##### METHODS AND MATERIALS

This retrospective study included consecutive women who were first diagnosed with breast cancer and underwent breast-conserving surgery between Jan 2015 and Aug 2021 and immediate reconstruction with MegaDerm®, followed by at least one MG, US, and MRI. Postoperative images were analyzed by breast radiologists and classified as positive for BI-RADS categories 0, 4, and 5 and negative for BI-RADS categories 1,2, and 3. The reference standard was defined with 1-year follow-up Imaging findings and pathologic reports. Diagnostic performances of each imaging modality was evaluated. Imaging features of ipsilateral recurrent breast cancers were reviewed.

##### RESULTS

207 women (mean age 46 years) were enrolled with a total 725 MG, 1097 US and 621 MRI. During the follow-up, the mean numbers of MG, US, and MRI scans of 3.5, 5.3, and 3.0 respectively, and a mean follow-up interval of 35.5 months (range 13-71 months). Among 207 women, total recurrence occurred in 15 (7.2%) patients and 11 (5.3%) patients recurred on the same breast. Sensitivity was 80 % for MG and 100% for both US and MRI. Specificity was 99% for MG, 99.4% for US and 96.9% for MRI. Diagnostic accuracy was 98.6% for MG, 99.4% for US and 96.9% for MRI. All 11 ipsilateral recurrence were suspicious on both US and MRI, while 3 cases (27.3%) were considered as benign on MG. All ipsilateral recurrences showed masses/nom-mass lesions with hypervascularity and enhancement, near the ADM.

##### CONCLUSION

Screenings with MG, US and MRI are useful imaging tool, after breast conserving surgery with ADM reconstruction. Especially, US and MRI are helpful modalities for the ipsilateral recurrence.

##### CLINICAL RELEVANCE/APPLICATION

After breast conserving surgery with ADM reconstruction, screening with MG, US and MRI might be hindered by ADMs. However, all screening modalities are useful, especially US and MRI. The most common findings of ipsilateral recurrence was mass/nom-mass lesion with hypervascularity and enhancement, near the ADM.

#### **T5A-SPBR-2 The Observation of VM1 Gadolinium Tumor Markers Placed in Fibroadenomas Over Time**

##### PURPOSE

Fibroadenomas are one of the most common breast masses, affecting nearly 10% of women. These benign tumors most often appear in the 3rd and 4th decades of life, but can arise at any age. Fibroadenomas can be recognized on imaging by their characteristic smooth, solid, ovoid appearance, being narrower in the A/P diameter, and with discrete internal echoes. Gadolinium (Gd) tumor markers are the only markers visible on all imaging modalities. These markers also have the benefit of remaining stable during radiation treatment. Often, they are surgically resected, however, if they are placed in benign tumors, they may remain in the patient (pt) indefinitely. In this study, we followed scans of pts with Gd tumor markers placed in biopsy-proven fibroadenomas. It was hypothesized that over time, the marker would remain the same intensity, would not migrate, and that the tumor bed would be unchanged.

##### METHODS AND MATERIALS

Charts of pts who had VM1 Gd tumor markers placed between 2016 and 2020 for breast masses were reviewed. Initial scans were assessed, and those with masses characteristic of fibroadenomas were separated. Pts with biopsy-proven fibroadenomas were included. Subsequent imaging studies were reviewed, and the implanted tumor marker, as well as the tumor bed, were assessed for changes over time.

##### RESULTS

Thirty-six pts who had VM1 tumor markers placed for discrete breast masses were identified and seven had biopsy-proven fibroadenomas diagnosed during the study period. Three pts had scans suitable for analysis, two had subsequent surgical resections, and two pts were lost to follow-up. One pts had imaging for six-months following VM1 marker placement, one pt had

imaging for two years, and one pt had imaging for seven subsequent years. In these three pts, the VM1 tumor marker did not change in position, brightness, or intensity, nor did the fibroadenoma change in size or internal characteristics.

## CONCLUSION

In this study, we assessed the stability of VM1 Gd tumor markers placed in fibroadenomas. Although only a small group of pts were assessed, our study demonstrated that VM1 Gd tumor markers remain stable over time with regard to position and appearance. Additionally, the fibroadenomas in which the markers were placed did not change over time. Further studies should seek to include more pts over longer follow-up periods.

## CLINICAL RELEVANCE/APPLICATION

This study shows unresected VM1 Gd tumor markers remain stable in appearance and in place for up to seven years in subsequent imaging. The VM1 Gd marker is available as the first new FDA approved soft tissue marker in nearly 10 years and is visible on all imaging modalities (MRI, ultrasound, tomo, X-Ray). This information will aid radiologists in localizing breast masses over time and assessing them for future change.

## 5A-SPBR-3 The Value of Imaging Combined with Clinicopathological Features in the Diagnosis of High-risk Breast Lesions

Participants  
Jiayin Zhou, Shanghai, China (*Presenter*) Nothing to Disclose

## PURPOSE

Comparing the diagnostic and predictive value of imaging features of different modes for breast high-risk lesions (HRLs) to improve image recognition and assist in clinical decisions.

## METHODS AND MATERIALS

We retrospectively reviewed 230 HRLs detected by mammography, ultrasound, and MRI before biopsy at the XXX Hospital from January 2017 to March 2018. The clinical features, imaging data according to the Breast Imaging Reporting and Data System (BI-RADS) lexicon, and tumor upgrade rates were received. Based on the different risks of upgrade reported, the lesions were classified into high-risk I (HR-I, with atypical hyperplasia (AH)) and high-risk II (HR-II, without AH). We analyzed the association between clinicopathological and imaging factors and upgrade. We used the receiver operating characteristic (ROC) curve to compare the efficacy of three imaging modes for predicting upgrade.

## RESULTS

We included 230 HRLs in 230 women in the study, and the overall upgrade rate was 20.4% (47/230). The upgrade rate was higher in HR-I compared to HR-II (38.5% vs. 4.1%,  $P < 0.01$ ). In patients with AH, estrogen receptor-positive (ER+) patients accounted for 81.0% (64/79). For all HRLs and HR-I, in clinical characteristics, age, maximum size of lesion, and menopausal status were significantly associated with upgrade ( $P < 0.05$ ). In imaging factors, MRI background parenchymal enhancement (BPE), signs of MRI and ultrasound were significantly correlated with upgrade ( $P < 0.05$ ). Patients with negative MRI or ultrasound manifestations had lower upgrade rates ( $P < 0.01$ ). For HR-II, only BPE showed a significant difference between groups ( $P = 0.001$ ). Multifactorial analysis of all HRLs showed that age and BPE were independent predictors of upgrade ( $P < 0.01$ ). AUCs for predicting upgrade in mammography, ultrasound, and MRI were 0.606, 0.590, and 0.913, respectively, indicating that MRI diagnosis was significantly better than mammography and ultrasound ( $P < 0.001$ ).

## CONCLUSION

HRLs with AH had a higher rate of upgrade and increased ER expression. Among three imaging modes, MRI was more effective than ultrasound and mammography in diagnosing the upgrade of HRLs. Older age and moderate to marked BPE can indicate malignant upgrade. MRI can provide a certain value for the diagnosis and follow-up of HRLs.

## CLINICAL RELEVANCE/APPLICATION

We explored the relationship between the imaging signs of different modes and the upgrade of HRLs, helping to suggest the correlation between HRLs and the risk of breast cancer, and providing references for clinical decision-making in the follow-up treatment of HRLs.

## 5A-SPBR-4 Outcomes of Pre-operative MRI versus Ultrasound in Axillary Nodal Staging: Association with Clinicopathological Breast Cancer Features

Participants  
Firouzeh Arjmandi, MD, Dallas, TX (*Presenter*) Nothing to Disclose

## PURPOSE

To compare the diagnostic accuracy of MRI versus ultrasound (US) in breast cancer axillary nodal evaluation in the same patient cohort.

## METHODS AND MATERIALS

All breast cancer (BCA) patients that underwent dynamic contrast-enhanced breast MRI (N=529) for baseline staging between 2.2013-3.2016 at 2 hospitals (university and safety net) were reviewed. Race, clinicopathological features, size, and radiologist axillary assessment on imaging prior to biopsy [suspicious=Rad(+), benign=Rad(-)] were collected. Radiologist imaging assessment (regardless of biopsy result) was compared to surgical pathology [(SLNB or axillary node dissection (ALND), pN]. We collected the sequence of US and MRI evaluation of axilla in diagnostic order to identify initial detection of a suspicious lymph node (LN) in 319/529 patients. Chi-square test was used to compare hormone status, multifocality, axillary imaging modality [MRI first vs US first] and Mann-Whitney-U to compare age, tumor size, and Ki67% between defined groups.

## RESULTS

Mean age was 51.3 (SD±23.6) years and tumor size was 37.4 mm (SD± 23.6). Patients received US first (includes US+MRI and US+MRI+US groups) in 80.6% and MRI first [(includes MRI alone (MRI) and MRI followed by US (MRI+US)] in 19.4%. Axillae were Rad(+) in 52.4% and Rad(-) in 48.0%. FN values were calculated in Rad(-). Negative predictive value (NPV) for patients that

underwent MRI first vs. US first was 85.1% vs. 70.1% ( $p < 0.05$ ). Hispanics and Blacks were more likely to have FN on MRI (22.2% and 18.2%) compared to non-Hispanic Whites ( $p = 0.8$ ) and on US, Hispanics were more likely than non-Hispanic Whites (37.5% vs. 27.7%,  $p = 0.2$ ). On both MRI and US, FNs were higher in younger age, higher clinical T stage (cT) and lower Ki67. FNs were lowest in triple negative (TNBC) and highest in HER2+ ( $p = 0.2$ ,  $p = 0.4$ , respectively). Unifocal tumors had significantly lower FNs compared to multifocal/centric (21.2% vs. 44.7%,  $p = 0.009$ ) in the US first group but not in MRI first (14.7% vs. 15.4%,  $p = 1$ ). Overall sensitivity and specificity in MRI first was 93.4% and 72.7% ( $p < 0.001$ ) and in US first was 72.3% and 74.2% ( $p = 0.8$ ), respectively.

## CONCLUSION

s MRI performs better than US for LN metastasis with better NPV and higher sensitivity. For both MRI and US, FNs are highest in Hispanics (followed by Blacks on MRI), increase in younger age and higher cT, and are lowest in TNBC and highest in HER2+ subtypes.

## CLINICAL RELEVANCE/APPLICATION

MRI performs better than US in LN metastasis, and NPV is affected by clinicopathological factors in both. MRI should be considered especially in higher cT stage.

## T5A-SPBR-5 Evaluation of the Differential Diagnosis Ability of Breast BI-RADS Class 4 Lesions Based on MRI and Clinical Features

Participants

Hua He, MMedSc, Yinchuan, China (*Presenter*) Nothing to Disclose

## PURPOSE

The development of breast cancer is influenced by many factors. Different imaging parameters can provide comprehensive information about the lesion, which can help more accurate diagnosis and individualized treatment. This study explores the predictive value of nomogram based on MRI and clinical features in the differential diagnosis of benign and malignant breast BI-RADS 4 lesions.

## METHODS AND MATERIALS

A total of 98 BI-RADS 4 patients, including 68 cases assigned to a malignant group and 33 cases assigned to a benign group, were prospectively enrolled, and their their MRI and clinical information were collected. Two physicians jointly analyzed the characteristics of conventional MRI. T1, T2, proton density (PD), and ADC values were obtained from three different regions interest (ROIs). Logistic regression analyses were used to select features and build models, and a nomogram was constructed with the best model.

## RESULTS

Using the ROI delineation method at the most obvious enhancement to measure the ADC value revealed the best diagnostic performance in diagnosing BI-RADS type 4 mass lesions. The diagnostic efficiency of the maximum level drawing method of the quantitative relaxation model was better than that of the whole drawing method and the most obvious enhancement method. The best relaxation model (model A) was composed of two parameters: T2stand and  $\Delta T1\%$ stand (AUC=0.887), and the BI-RADS model (model B) was constructed by two MRI features of edge and TIC curve (AUC=0.793). Using the quantitative parameters of SyMRI and DWI of the best ROC method combined with DISCO enhanced MRI features to establish a joint diagnostic model (model C: edge, TIC curve type, ADClocal, T2stand,  $\Delta T1\%$ stand) showed the best diagnostic efficiency (AUC=0.953). The nomogram also had calibration curves with good overlap.

## CONCLUSION

s The combined diagnosis model of SyMRI and DWI quantitative parameters combined with DISCO can improve the diagnostic efficiency of BI-RADS 4 types of mass lesions. Also, the line diagram based on this model can be used as an auxiliary diagnostic tool.

## CLINICAL RELEVANCE/APPLICATION

In this study, a preoperative diagnostic model of breast BI-RADS class 4 lesions was constructed by combining clinical, imaging and pathological multimodal indicators, and the data complementary information of different modalities was directly obtained in a non-invasive manner, and the data complementarity from single modality to multimodal quantitative diagnosis was transformed, which could greatly improve the accuracy of preoperative diagnosis of BI-RADS 4 lesions compared with traditional MRI technology.

## T5A-SPBR-6 Lymph Node Status in Breast Cancer Patients: Can Tumor Features Predict it More Accurately than Direct Axillary Imaging Evaluation

Participants

Panagiotis Kapetas, MD, PhD, Vienna, Austria (*Presenter*) Nothing to Disclose

## PURPOSE

To compare the diagnostic performance of tumoral imaging and clinical characteristics with the direct evaluation of the axillary lymph nodes (LNs) for the prediction of the LN status in breast cancer (BC) patients.

## METHODS AND MATERIALS

This retrospective, IRB-approved study included 513 patients with histologically confirmed invasive BC and a histological confirmation of their LN status (either pre-therapeutic, for patients undergoing neoadjuvant treatment, or at the time of surgery for all others). By search of the local PACS, the diagnostic examinations (mammography-MG, ultrasound-US and magnetic resonance imaging-MRI) of the patients were identified. Further clinical information (age, tumor proliferation index Ki-67 and hormone- and HER2-receptor status) were recorded as well. 4 readers (2 breast fellows and 2 experienced radiology residents who had completed both stages of their breast imaging rotation), blinded to the LN status of the patient, independently evaluated the images, assessing both the tumor according to BI-RADS descriptors and the depicted LNs, using standardized criteria. Logistic regression was used to identify independent predictors of metastatic LNs, both among the tumor and the LN descriptors and create respective models, based on the different imaging modalities and their combinations. The diagnostic performance of the models was evaluated using ROC curve analysis. Histopathology served as the standard of reference.

## RESULTS

114 patients (22.2%) had metastatic LNs. None of the clinical or tumoral MRI-based features reached predictive statistical significance. From the tumor-based models, the one combining MG and US features performed significantly better than the others, however at an AUC of 0.593. All models based on LN features (cortical thickening in US and MRI, short axis >1cm in MG) performed significantly better than the ones based on tumoral ones, with AUCs ranging between 0.648 and 0.719. There was no significant difference between the individual LN-based models, which were able to correctly predict 75.1-78.5% of all cases.

## CONCLUSION

s Tumor characteristics in BC patients are less predictive of the LN status as compared to the imaging evaluation of the axillary LNs per se.

## CLINICAL RELEVANCE/APPLICATION

Direct imaging assessment of axillary lymph nodes in breast cancer patients remains more accurate than the prediction of their status based on imaging and clinical tumor features.

## T5A-SPBR-7 Mammographic Changes within Two Years Following Novel Breast Intraoperative Radiation Therapy

Participants

Kassandra Tulenko, BA, Charlottesville, VA (*Presenter*) Nothing to Disclose

## PURPOSE

Intraoperative radiation therapy (IORT) is accelerated partial breast irradiation (APBI) that involves a single dose of RT at the time of breast conserving surgery (BCS). Precision Breast intraoperative radiation therapy (PB-IORT) is a novel form of IORT that combines CT-on-rails imaging to guide high dose rate (HDR) balloon brachytherapy to deliver 12.5 Gy of radiation to the lumpectomy bed at the time of BCS. The goal of the present study is to describe the short-term mammographic appearance of participants treated with PB-IORT.

## METHODS AND MATERIALS

All patients were part of a multi-institutional clinical trial with an inclusion criteria of age  $\geq$ 45 years, N0, and invasive or in situ tumors < 3 cm. Participants received annual diagnostic mammograms post PB-IORT and additional imaging was performed if warranted clinically. All participants with 2 years of follow-up were included in this study. Mammograms were reviewed and categorized by breast density and radiographic changes, including scar formation, trabecular thickening, fat necrosis, seroma, skin thickening, skin retraction, calcifications, asymmetry, or mass. Presence of suspicious findings (BI-RADS 4 or 5) and biopsy results were also recorded.

## RESULTS

The cohort included 567 mammograms in 291 participants. The median timing of mammograms included in the study was 23 months post IORT (6 to 30 months). Median age was 64 years (46 to 83 years) and mean tumor size was 9.76mm +/- 6.56mm. Scar and trabecular thickening were the most frequent imaging findings, occurring in 286 (98.3%) and 230 (79.0%) participants respectively. Fat necrosis occurred in 187 (64.3%), seroma in 80 (27.5%), skin thickening in 115 (39.5%), skin retraction in 140 (48.1%), calcifications in 78 (26.8%), asymmetry in 3 (1.0%), and mass in 6 (2.1%) of participants. Thirteen biopsies were performed in 12 participants: 8 were benign, 2 were atypical and 3 were malignant. When stratified by breast density, there were no statistically significant differences of mammographic findings or biopsy frequency between the dense and non-dense groups.

## CONCLUSION

sParticipants who underwent PB-IORT developed mammographic findings of scar, trabecular thickening, seroma, fat necrosis, skin thickening and skin retraction. Breast density does not have a significant impact on post PB-IORT imaging findings or biopsy rate. This study is unique as it compares post treatment mammographic findings with respect to breast density. Knowledge of the spectrum of radiographic changes after IORT can facilitate image interpretation and guide management.

## CLINICAL RELEVANCE/APPLICATION

Knowledge of the spectrum of imaging findings, biopsy rate, and impact of breast density after IORT can facilitate image interpretation and guide management.

## T5A-SPBR-8 Nomogram Based on US and Clinicopathologic Characteristics: Axillary Nodal Evaluation Following Neoadjuvant Chemotherapy in Patients with Node-Positive Breast Cancer

Participants

Xiao-Qing Pei, PhD, MD, Guangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

To avoid surgical over-treatment of the axilla in breast cancer patients with lymph node (LN) conversion following neoadjuvant chemotherapy (NAC), this study is designed to develop a convenient modality to predict the axillary response to NAC.

## METHODS AND MATERIALS

In this a multi-center study, breast cancer patients with biopsy-proven positive node receiving NAC followed by axillary lymph node dissection (ALND) were identified. A total of 1019 patients were randomly assigned to the training and validation groups at a ratio of 7:3. Clinicopathologic and ultrasound (US) characteristics of both primary tumors and LNs were used to develop corresponding prediction models, and a nomogram integrating clinicopathologic and US predictors was generated to predict the axillary response to NAC.

## RESULTS

Axillary pathological complete response (pCR) was achieved for 47.79% in patients with initially node-positive breast cancer. The expression of estrogen receptor, human epidermal growth factor receptor -2, Ki-67 score, and clinical nodal stage were independent predictors for the nodal response to NAC. Location and radiological response of primary tumors, cortical thickness and shape of LNs on US were also significantly associated with nodal pCR. In the validation cohort, the discrimination of US model (AUC,

0.76; sensitivity, 68.67%; specificity, 75.00%) was superior to clinicopathologic model (AUC, 0.68; sensitivity, 74.67%; specificity, 53.85%). AUCs of the nomogram based on clinicopathologic and US characteristics was 0.85, with a sensitivity of 83.33% and specificity of 73.72%.

## **CONCLUSION**

s US characteristics of primary tumors and axillary LNs were independently associated with axillary status after NAC for breast cancer with initially positive-node. The nomogram constructed with readily available clinicopathologic features and US characteristics improved the predictive capability.

## **CLINICAL RELEVANCE/APPLICATION**

Even if patients with excellent response to chemotherapy may be potential candidates for omission of ALND, it is difficult to determine status of axillary LNs following NAC. Nomogram incorporating routine clinicopathologic and US characteristics of breast tumors and axillary LNs can predict nodal pCR after NAC and may be a feasible modality to aid in surgical decisions-making for axilla.

## **T5A-SPBR-9 The Value of IVIM-DWI and DCE-MRI in Predicting Molecular Subtypes of Breast Cancer**

### **PURPOSE**

To explore the value of IVIM-DWI and DCE-MRI in predicting the molecular subtypes of breast cancer.

### **METHODS AND MATERIALS**

187 patients with suspected breast cancer admitted to our hospital from March, 2019 to December, 2021 were enrolled in this study. Pathological examination was performed after MRI to observe the expression of ER, PR, HER-2 and Ki-67. The quantitative parameters of IVIM-DWI (ADCstandard, ADCslow, ADCfast, f) and DCE-MRI (Ktrans, Kep, Ve) were measured. SPSS software was used to analyze the relationship between all parameters and the expression of ER, PR, HER-2 and Ki-67 as well as the correlation between all parameters and the prognostic factors of breast cancer. The differences in parameters of IVIM-DWI and DCE-MRI of different molecular subtypes were compared. Receiver operating characteristic curve (ROC) was plotted for parameters with statistical significance and the area under curve (AUC) was calculated.

### **RESULTS**

180 cases of breast cancer were included. Containing 15 cases of LuminalA, 45 cases of LuminalB (HER-2-), 68 cases of LuminalB (HER-2+), 30 cases of HER-2 over expression, and 22 cases of triple negative. DCE:Kep and Ktrans showed statistically significant differences between HER-2 positive and negative groups and Ki-67 high and low expression groups, but no statistically significant differences between ER and PR positive and negative groups, while Ve was significantly different between ER, PR, HER-2 positive and negative groups, but was not different between Ki-67 high and low expression groups. Kep still had predictive value for HER-2 status and Ve still had statistical significance for PR status prediction in Logistic multivariate regression analysis. The prediction threshold of Kep ( $p < 0.001$ , AUC=0.878) and Ve ( $p < 0.001$ , AUC=0.84) was 0.602 (specificity=87.5%, sensitivity=72.7%) and 0.547 (specificity=96.1%, sensitivity=58.6%), respectively. IVIM: ADCstandard and ADCslow showed statistical significance between positive and negative groups of ER, PR and HER-2, but no statistical significance between high and low expression groups of Ki-67 ( $p > 0.05$ ). Kep, Ktrans, Ve, ADCstandard and ADCslow showed statistically significant differences among different molecular subtypes of breast cancer.

### **CONCLUSION**

s Kep, Ktrans, Ve, ADCstandard and ADCslow have certain predictive value for different molecular subtypes, and can provide an important reference for clinical development of personalized treatment.

### **CLINICAL RELEVANCE/APPLICATION**

Provide a non-invasive prediction method for the preoperative diagnosis of molecular subtypes of breast cancer, which lays a foundation for the accurate diagnosis of breast cancer and the formulation of personalized treatment programs.

T5A-SPCA

### Cardiac Imaging Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPCA-1 Association of Liver Multiparameter Quantitative Metrics Determined by Dual Layer Spectral Detector CT with Coronary Plaque Scores: A Preliminary Study**

#### PURPOSE

To explore potential impacts of the extent and severity of coronary artery plaques on the liver quantitative metrics measured by dual-layer spectral detector CT (SDCT).

#### METHODS AND MATERIALS

Patients who underwent an unenhanced SDCT scan of the upper abdomen and coronary computed tomography angiography (CCTA) were enrolled. The segmental stenosis score (SSS) and segmental involvement score (SIS) were used to evaluate the extent and severity of plaques and then grouped by SIS and SSS. The CT attenuation of liver assessed by polychromatic images and spectral metrics of the liver were assessed by virtual mono-energetic images at 40keV and 70keV, the slope of spectral attenuation curve and effective atomic number (written as CT40keV, CT70keV, ?HU and Zeff, respectively). Logistic regression model was used to evaluate association of liver quantitative metrics with SIS and SSS.

#### RESULTS

644 patients were enrolled, including low SIS (<5) group (n=451), high SIS (≥5) group (n=193), low SSS (<5) group (n=461) and high SSS (≥5) group (n=183). Except for the CT70poly value (p=0.115) in SSS group, other liver spectral steatosis metrics were significantly different between SIS and SSS groups (All p<0.05). Compared with other collinearity spectral metrics, Zeff was more closely correlated with the SIS and SSS. Zeff was divided into four groups according to the interquartile interval. Compared with the patients in the lowest quartile of Zeff, the adjusted odds ratios (ORs) and 95% confidence intervals (CIs) for SIS were 2.401 (1.284-4.493), 3.215 (1.661-6.224), and 4.126 (2.152-7.911) for those in the second, the third, and the fourth quartile of Zeff, whereas the corresponding ORs (95% CI) for SSS were 2.098 (1.130-3.894), 3.078 (1.602-5.916), and 3.582 (1.876-6.840) for the upper three quartiles of Zeff, especially among these who were < 60 years old, male and VAT/SAT < 1.18.

#### CONCLUSION

The quantitative parameter Zeff from SDCT, was an independent factor of the extent and severity of coronary artery plaques. Liver fat quantification may be useful for evaluating risk and prognosis of coronary artery disease.

#### CLINICAL RELEVANCE/APPLICATION

Liver multi-parameter metrics measured by SDCT may help to achieve the screening and primary prevention of high-risk population of coronary artery disease.

#### **T5A-SPCA-2 Feasibility of Fast Manual Left Atrial Long-axis Strain Using Cardiac Computed Tomography in Patients with Paroxysmal Atrial Fibrillation**

#### Participants

Takaaki Hosokawa, Toon, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

Left atrial (LA) function is important for the prognosis of patients with atrial fibrillation (AF). LA strain (LAS) is a sensitive parameter that reflects the complex LA function. Recently, it can be evaluated using cardiac computed tomography (CT). However, LAS analysis requires a dedicated software and experience owing to complex LA anatomy (pulmonary veins and appendages). Semi-automatic fast long-axis strain is a novel simplified method for LAS analysis that improves reproducibility and reduces analysis time; however, it requires a dedicated software, limiting its availability. We hypothesized that LAS could be evaluated manually without using a dedicated software with fast long-axis strain. We aimed to assess the feasibility of fast manual LA long-axis strain (FM-LALS) in patients with paroxysmal AF (PAF).

#### METHODS AND MATERIALS

In this study, 40 patients with PAF who underwent cardiac CT and echocardiography were retrospectively enrolled. CT data of the entire cardiac cycle was reconstructed every 5% of RR intervals (RR; 0-95%). LA reservoir and pump strain were evaluated by conventional semi-automatic LAS (cLAS) and FM-LALS. FM-LALS was derived by measuring the distance between the left atrioventricular junction and LA posterior wall in three phases (end-diastole, end-systole, and mid-diastole). Moreover, LAS was assessed using speckle tracking echocardiography (STE). We assessed the correlations between cLAS, FM-LALS, and STE. Inter-observer reproducibility was evaluated in 15 randomly selected patients by two radiologists.

#### RESULTS

FM-LALS showed an extremely strong correlation with cLAS (r = 0.93-0.94, p < 0.001). FM-LALS and cLAS showed moderate to strong correlations with STE (r = 0.67-0.77, p < 0.001). FM-LALS and cLAS showed good to excellent reproducibility (intra-class

correlation coefficient 0.85-0.91). FM-LALS significantly reduced the analysis time compared to cLAS (median 92 vs 146 s,  $p < 0.001$ ), while cLAS consumed an additional 4 min for pre-processing.

## CONCLUSION

s FM-LALS enables rapid and highly reproducible LAS analysis without using a dedicated software and is useful as a highly available LAS analysis method in patients with PAF.

## CLINICAL RELEVANCE/APPLICATION

FM-LALS can be assessed rapidly and easily without using a dedicated software, providing high clinical availability.

## T5A-SPCA-3 Dual Energy Computed Tomography to Evaluate Coronary Pericoronary Adipose Tissue Attenuation in Acute Aortic Dissection Patients

### PURPOSE

Pericoronary adipose tissue (PCAT) attenuation is an indicator of active inflammation of perivascular adipose tissue and is supposed to increase in acute aortic dissection(AAD) patients. We aimed to investigate the PCAT attenuation values in acute aortic dissection patients with or without atherosclerosis of the coronary arteries.

### METHODS AND MATERIALS

Consecutive patients with chest pain were prospectively enrolled and underwent coronary computed tomography angiography (CCTA) and/or aorta computed tomography angiography. The patients were divided into two groups, AAD and non-AAD, according to the results of CTA. The PCAT attenuation values of three major epicardial coronary vessels were measured. The PCAT attenuation values were compared between the AAD and non-AAD subjects according to the atherosclerosis of the coronary arteries. Similarly, the PCAT attenuation values of the AAD patients were compared between the preoperative and postoperative steady states.

### RESULTS

A total of 136 patients (42 female, 94 male; mean age,  $63 \pm 11.9$  years) were divided into two groups according to the presence of aortic dissection on CTA. PCAT<sub>RCA</sub>, PCAT<sub>LAD</sub> and PCAT<sub>LX</sub> were significantly higher in AAD subjects than in non-AAD subjects, regardless of the presence of atherosclerosis of the coronary arteries ( $-85.1 \pm 9.3$  HU vs.  $-92.9 \pm 10.0$  HU;  $-83.2 \pm 7.4$  HU vs.  $-89.9 \pm 9.1$  HU;  $-77.5 \pm 8.4$  HU vs.  $-85.6 \pm 7.9$  HU,  $p < 0.05$  all). The preoperative PCAT<sub>RCA</sub>, PCAT<sub>LAD</sub> and PCAT<sub>LX</sub> were higher in the AAD patients than in postoperative steady-state subjects ( $-82.9 \pm 8.7$  HU vs.  $-97.6 \pm 8.8$  HU;  $-79.8 \pm 7.6$  HU vs.  $-92.8 \pm 6.8$  HU;  $-74.6 \pm 7.1$  HU vs.  $-87.7 \pm 6.9$  HU,  $p < 0.05$  all). According to multivariable logistic regression analysis, PCAT<sub>RCA</sub> and PCAT<sub>LAD</sub> were the parameters showing consistent difference between the AAD and non-AAD patients (OR=0.010; 95%CI:0.001 to 0.189;  $p=0.002$ , OR=0.115; 95%CI:0.023 to 0.563;  $p=0.008$ , OR=0.156; 95%CI: 0.032 to 0.770;  $p=0.023$  and OR=0.014; 95%CI:0.001 to 0.177;  $p=0.001$ , OR=0.041; 95%CI:0.008 to 0.210;  $p < 0.001$ ).

### CONCLUSION

s PCAT<sub>RCA</sub>, PCAT<sub>LAD</sub> and PCAT<sub>LX</sub> were significantly higher in AAD patients than in non-AAD patients regardless of atherosclerosis of the coronary artery. Similarly, in AAD patients with atherosclerosis of the coronary artery, PCAT<sub>RCA</sub>, PCAT<sub>LAD</sub> and PCAT<sub>LX</sub> were significantly higher preoperatively than postoperatively.

## CLINICAL RELEVANCE/APPLICATION

It provides more clinical evidence for the relationship between macrovascular adipose tissue and extracardiac adipose tissue, and can provide more information for drug treatment for the mutual disease.

## T5A-SPCA-4 iPSC-based Engineered Heart Tissue for Myocardial Repair - An In-vivo Pilot Study

### PURPOSE

Chronic heart failure as a result of myocardial infarction remains a major burden on the healthcare systems of the industrialized countries and the respective average life expectancy of their citizens. This calls for therapies targeting the regeneration of the underlying loss of cardiomyocytes. The aim of the project was a proof of concept for the remuscularization of the myocardium by the use of engineered heart tissue based on induced pluripotent stem cells (iPSC) in a macaque model (non-human primate).

### METHODS AND MATERIALS

Engineered heart tissue was implanted as functional tissue patches to 14 macaques in two cohorts. An epicardial midventricular position of the left ventricle was chosen for implantation. The heart function was quantified using 3T MRI. After two baseline measurements the first cohort received a single dose (40x20x1 mm cell cluster consisting of 40 million myocytes) and a monthly follow-up for three months. The second cohort received a five-fold dose (48x48x2.5 mm, 200 million cells) and an additional fourth follow-up measurement after six months. The evaluation was carried out by two different examiners. The animal experiments were carried out as part of an approved study.

### RESULTS

After three months the systolic and diastolic wall thickness of the left ventricle of all animals increased ( $7 \pm 1$  mm to  $9 \pm 2$  mm  $p=0.001$ ). At the end of the follow-up the left ventricular mass increased ( $12 \pm 2$  g to  $13 \pm 3$  g,  $p=0.11$ ). The left ventricular ejection fraction increased ( $59 \pm 3\%$  to  $60 \pm 5\%$   $p=0.001$ ) without a significant change in the cardiac output. The right ventricular ejection fraction and wall thickness did not change significantly. The longitudinal strain the 4-chamber view and vertical longitudinal axis did not show any significant changes during the observation period.

### CONCLUSION

s The implantation of artificial heart tissue from iPSC resulted in a sustained increase in left ventricular mass and wall thickness in healthy animals without any adverse effects.

## CLINICAL RELEVANCE/APPLICATION

iPSC-based functional myocardial patches are a promising therapy of infarct-related chronic heart failure. This proof-of-concept

study in a non-human primate shows feasibility and safety of this innovative approach. It is the first step towards its application in patients.

## **T5A-SPCA-5 Cardiac CT-based Radiomics Analysis can Predict Left Ventricular Adverse Remodeling after TAVI in Patients with Severe Aortic Stenosis**

### **PURPOSE**

To develop a radiomics model based on cardiac computed tomography (CT) to predict left ventricular adverse remodeling in patients who underwent transcatheter aortic valve implantation (TAVI) with severe aortic stenosis.

### **METHODS AND MATERIALS**

A total of 293 patients (45.7% female) (mean age: 73.1 $\pm$ 7.6 years) with severe aortic stenosis confirmed by transthoracic echocardiography were retrospectively enrolled. All patients underwent TAVI and had a follow-up time of more than 3 months for evaluating left ventricular remodeling. The patients were randomly assigned to the training (n=205) and validation cohort (n=88). Adverse remodeling was defined as a 15% increase in the baseline value of left ventricular end-diastolic volume or a 10% decrease in left ventricular ejection function. The volume of interest comprising the left ventricle wall and papillary muscle was segmented on cardiac CT images of diastolic phase. Radiomic features were extracted using the least absolute shrinkage and selection operator (LASSO) regression analysis method, and clinical variables were screened via logistic regression. The model's performance was evaluated using a receiver operating characteristic curve (ROC) and decision curve analysis.

### **RESULTS**

Thirty-one features were extracted from 216 (73.7%, 216/293) non-adverse remodeling cases and 77 (26.3%, 77/293) adverse remodeling cases, among which 6 radiomic features and 2 clinical features were manually screened to construct a radiomic model, a clinical model, and a nomogram model. The 14 features extracted by random forests were used in the composed model. The radiomics nomogram model and composed model both achieved a better diagnostic performance than the clinic model in the validation cohort with the AUCs being 0.89 (95% confidence interval [CI]: 0.874-0.893) and 0.819 (95% confidence interval [CI]: 0.808-0.833), respectively. Moreover, the decision curve analysis demonstrated that the composed model had a better net benefit than others.

### **CONCLUSION**

The developed radiomics-based analysis showed outstanding predictive effectiveness for adverse remodeling of severe aortic stenosis patients after TAVI. Radiomics based on cardiac CT could serve as a valuable tool for predicting left ventricular adverse remodeling after TAVI in patients with severe aortic stenosis.

### **CLINICAL RELEVANCE/APPLICATION**

The radiomics-based analysis developed in this study demonstrated exceptional predictive efficacy for adverse remodeling in severe aortic stenosis patients undergoing TAVI. Our findings suggest that the radiomics analysis based on cardiac CT may serve as a useful tool for predicting left ventricular adverse remodeling after TAVI in this patient population.

## **T5A-SPCA-6 Fat Fraction Analysis as a Novel Method for the Assessment of Pericoronary Adipose Tissue Inflammation**

### **Participants**

Caterina Monti, MD, PhD, Milan, Italy (*Presenter*) Travel support, Bracco Group  
Francesco Secchi, MD, PhD, Milano, Italy (*Presenter*) Nothing to Disclose

### **PURPOSE**

The aim of our study was to assess pericoronary adipose tissue via the analysis of its fat fraction (FF), comparing it to conventional biomarkers such as pericoronary fat attenuation index (FAI) and the degree of coronary stenosis.

### **METHODS AND MATERIALS**

We retrospectively included all consecutive patients who underwent a dual-energy, unenhanced computed tomography (CT) scan for calcium scoring at our institution. For each patient, we processed the FF maps through a dedicated software, and segmented regions of interest around each coronary artery, namely the left anterior descending artery (LAD), circumflex artery (LCX) and right coronary artery (RCA) to obtain FF and FAI. We retrieved data concerning coronary stenosis from CT reports.

### **RESULTS**

Overall, 99 patients were included, 32 (32%) of whom females, with a median age of 66 years (interquartile range, IQR, 58-74 years). For each coronary artery, pericoronary FF displayed moderate, negative correlations with FAI (LAD:  $r=-0.617$ ,  $p<0.001$ ; LCX:  $r=-0.493$ ,  $p<0.001$ ; RCA:  $r=-0.506$ ,  $p<0.001$ ). Pericoronary FF displayed a weak negative correlation with coronary stenosis at the LAD ( $r=-0.220$ ,  $p=0.035$ ), whereas at the LCX and RCA no significant correlations were observed ( $p=0.572$ ).

### **CONCLUSION**

Our proof-of-concept analysis indicates that epicardial adipose tissue FF, which can be easily computed on dual-energy, unenhanced CT scans, could represent an additional biomarker of cardiovascular risk and coronary inflammation.

### **CLINICAL RELEVANCE/APPLICATION**

Evaluating pericoronary fat fraction at dual energy CT could provide data concerning the status of coronary arteries even from unenhanced cardiac CT.

#### **T5A-SPCH-1 Prediction Model of PD-L1 Expression in Primary Lung Adenocarcinoma based on Artificial Intelligence Analysis Software**

##### **PURPOSE**

To constitute a stratified prediction model of PD-L1 expression in primary lung adenocarcinoma based on artificial intelligence analysis software.

##### **METHODS AND MATERIALS**

The imaging data of 129 patients with primary lung adenocarcinoma confirmed by operation were analyzed retrospectively. The imaging features of the lesions, CT quantitative parameters and texture features were automatically obtained by the artificial intelligence analysis software. The expression of PD-L1 in pathological specimens was detected by IHC. The patients were divided into PD-L1 positive expression group (TPS=1%) and PD-L1 negative expression group (TPS<1%). SPSS26.0 software was used for statistical analysis. Logistic regression analysis was used to screen the predictive factors and construct predictive model. ROC analysis was used to evaluate the efficacy of the model. P values less than 0.05 were considered statistically significant.

##### **RESULTS**

The volume and proportion of solid components in PD-L1 positive expression group were significantly higher than those in negative expression group ( $P<0.001$ ). The mass of solid components between the two groups was 5.57 and 1.59mg $\times$ 10<sup>3</sup> respectively. The difference was statistically significant ( $P<0.001$ ). The proportion of solid components in the positive expression group was also significantly higher than that in the negative group, which were 0.73 and 0.41 respectively ( $P<0.001$ ). The total mass of positive group and negative group was 6.40, 2.76 mg $\times$ 10<sup>3</sup> respectively. The maximum and average CT values in PD-L1 positive expression group were higher than those in negative expression group ( $P<0.001$ ). There were significant differences in skewness and entropy between the two groups ( $P=0.001,0.002$ ). The solid components, CT values and texture features were included in the Logistic regression analysis to constitute a prediction model. The ROC curve analysis showed that the AUC value of the combined variables was 0.887, the sensitivity was 74.5%, and the specificity was 90.2%. The difference was statistically significant ( $P<0.001$ ).

##### **CONCLUSION**

The imaging quantitative features based on artificial intelligence analysis software can be used to predict the expression of PD-L1 in primary lung adenocarcinoma, and the prediction model of multi-parameter combination variables is the best.

##### **CLINICAL RELEVANCE/APPLICATION**

At present, the clinical detection of PD-L1 mainly depends on IHC. For patients who are unable to operate or puncture biopsy, it is difficult to detect PD-L1. Therefore, the wide application of ICIs therapy is limited. As the AI is more widely used in clinic, it is of great clinical significance to build a hierarchical prediction model of PD-L1 based on artificial intelligence analysis software.

#### **T5A-SPCH-2 Clinical Values of Deep Learning-based Lung Nodule Detection System for Metastasis Evaluation in Patients with Colorectal Cancer: In-depth Analyses of Effects on Thoracic Radiologists**

##### Participants

Chul Hwan Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### **PURPOSE**

This study aimed to evaluate the clinical values of a deep learning-based computer-aided diagnosis (DL-CAD) system with in-depth analyses of radiologists' performance and reading time in pulmonary metastasis evaluation on chest computed tomography (CT).

##### **METHODS AND MATERIALS**

The multi-reader study with a randomized cross-over design was performed during two reading sessions. For the six experienced thoracic radiologists, 64 chest CT scans from patients with colorectal cancer, including 77 pulmonary nodules, were prepared based on a pilot study's sample size calculation. Each reader evaluated nodule presence, size, and location with or without a commercially available DL-CAD system with a 4-week washout period. The reading platform automatically measured the reading time. Per-nodule sensitivity, false-positive per scan, and readers' reading time with or without the DL-CAD system were compared using logistic regression, Poisson regression, and linear mixed model, respectively. Inter-reader agreements for nodule detection and size measurement were analyzed with Fleiss kappa ( $k$ ) and concordance correlation coefficient (CCC).

##### **RESULTS**

Using the DL-CAD system, the pooled sensitivity of six readers for lung nodules significantly improved (from 0.703 [95% CI, 0.651-0.756] to 0.842 [95% CI, 0.782-0.902],  $p <0.001$ ), reading time significantly reduced (from 212.8 s [95% CI, 198.9-226.7] to 165 s [95% CI, 151.1-178.8],  $p <0.001$ ), and inter-reader agreements for nodule detection ( $k$ , 0.682-0.884,  $p <0.001$ ) and size measurement (CCC, 0.385-0.543,  $p <0.001$ ) enhanced. The improved sensitivity was significant for nodules located in the

intraparenchymal (from 0.597 [95% CI, 0.359-0.836] to 0.986 [95% CI, 0.959-1.013],  $p = 0.002$ ) and perivascular (from 0.553 [95% CI, 0.383-0.723] to 0.649 [95% CI, 0.472-0.826],  $p = 0.006$ ) areas and those  $< 6$ mm in axial diameter (from 0.669 [95% CI, 0.611-0.728] to 0.823 [95% CI, 0.750-0.895],  $p < 0.001$ ). However, there was no significant change in the pooled false-positive per case without versus with the DL-CAD system (0.094 [95% CI, 0.052-0.168] vs. 0.094 [95% CI, 0.054-0.163],  $p > 0.999$ ).

## CONCLUSION

s With the DL-CAD system, the readers showed significantly improved performance for pulmonary nodule detection and reduced CT reading time without a false-positive increase in pulmonary metastasis evaluation on chest CT.

## CLINICAL RELEVANCE/APPLICATION

The DL-CAD system show good enough performance to be clinically utilized as an assistant in the setting of pulmonary metastasis screening.

## T5A-SPCH-3 Lymphatic Plastic Bronchitis: A Study Based on CT and MR Lymphangiography

Participants

Yan Zhang, Beijing, China (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the diagnostic value of CT lymphangiography (CTL) and non-contrast MR lymphangiography (MRL) in lymphatic plastic bronchitis.

## METHODS AND MATERIALS

The clinical and imaging data of 31 patients with lymphatic plastic bronchitis diagnosed by clinical, imaging and pathological results were retrospectively analyzed. All patients underwent CTL and MRL. The McNemar test was used to compare the parameters between CTL and MRL.  $P < 0.05$  was statistically significant. The Kappa test was used to evaluate the consistency of CTL and MRL in evaluating lymphatic plastic bronchitis.

## RESULTS

MRL showed that the abnormal lymphatic reflux in the right lymphatic duct, thoracic duct, cervical trunk and subclavian trunk was better than CTL ( $P < 0.05$ ), and the diagnostic consistency was general (Kappa  $< 0.40$ ). There was no significant difference between MRL and CTL in the detection of abnormal lymphatic reflux in the lymphatic trunk. MRL was superior to CTL in detecting lymphatic abnormalities such as cystic changes at the end of the thoracic duct, spot-like or tubular changes at the end of the right lymphatic duct, cystic changes at the end of the right lymphatic duct, and cystic changes in the mediastinum ( $P < 0.05$ ), and the diagnostic consistency was poor, fair, fair, and moderate (Kappa  $< 0.60$ ), respectively. MRL and CTL showed abnormal signs in the lung: CTL was superior to MRL in showing the thickening of interlobular septum, lung nodules and airway stenosis ( $P < 0.05$ ), and the diagnostic consistency was moderate, moderate and poor (Kappa  $< 0.60$ ). There was no significant difference between CTL and MRL in atelectasis, consolidation in lobar and segmental distribution, consolidation in non-lobar and segmental distribution, and the thickening of the bronchovascular bundle ( $P > 0.05$ ), and the diagnostic consistency was very good, very good, good, good (Kappa  $> 0.60$ ). There was no significant difference between CTL and MRL in ground glass opacity, airway wall thickening and intralobular interstitial thickening ( $P > 0.05$ ), and the diagnostic consistency was average, fair and poor (Kappa  $< 0.40$ ).

## CONCLUSION

s The MRL is superior to CTL in showing the abnormalities of the thoracic duct, the right lymphatic duct and other abnormal lymphatic vessels. CTL is superior to MRL in the detection of pulmonary abnormalities. The combination of CTL and MRL can provide more comprehensive imaging information for diagnosing and treating lymphatic plastic bronchitis.

## CLINICAL RELEVANCE/APPLICATION

The combination of CTL and MRL can provide more comprehensive imaging information for diagnosing and treating lymphatic plastic bronchitis.

## T5A-SPCH-4 Spectral Imaging of Thymic Epithelial Tumours: A Combined Radiomics Nomogram to Predict Histologic Subtypes

## PURPOSE

The aim of this study is to develop and compare performance of radiomics signatures using texture features extracted from spectral CT images for preoperative predicting risk categorization of thymic epithelial tumours (TETs).

## METHODS AND MATERIALS

Between August 2021 and December 2021, a total of 93 patients with histopathologically confirmed TETs were enrolled in this retrospective study, all patients underwent spectral CT scans with arterial phase (AP) and venous phase (VP) before treatment. Iodine concentrations were derived from iodine-based material-decomposition CT images and normalized to the iodine concentration in the aorta. Selecting the feature subset with mRMR method, retaining 30 features with minimum Redundancy Maximum Relevance. Multivariable logistic regression, filtering the independently discriminative feature, and constructing the final model. Cross-validation, proving texture analysis was valuable in discriminating one group from another group and the result was not due to overfitting. A radiomics nomogram for evaluating the risk categorization was developed by combining the selected radiomics features with age and spectral parameters. Receiver operating characteristic (ROC) curves were used to evaluate the diagnostic performance of the radiomics nomogram.

## RESULTS

Of the 93 patients, 38 had low-risk thymoma (LRT), 26 had high-risk thymoma (HRT), and 49 had thymic carcinoma (TC). The radiomics model, age, spectral parameters constituted a radiomics nomogram, with an AUC value of 0.86(0.79~0.94) for LRT vs HRT+TC and 0.81(0.72~0.91) for LRT+HRT vs TC. Diagnostic performance for LRT vs HRT+TC, the sensitivity, specificity, and accuracy reached 87.27%, 66.79%, and 78.49%, respectively. For LRT+HRT vs TC, they reached 68.97%, 82.81% and 78.49%, respectively.

## CONCLUSION

s The combined radiomics nomogram exhibited good performance in the individual prediction of TETs, and might be used for surgical management of TETs.

#### **CLINICAL RELEVANCE/APPLICATION**

For preoperative predicting risk categorization of thymic epithelial tumours.

#### **T5A-SPCH-5 Conjugate Gradient (CG) Reconstruction vs. Grid Reconstruction: Capabilities for Acquisition Time Reduction, Image Quality and Nodule Detection on Pulmonary Thin-Section MR Imaging with Ultra-Short TE at In Vitro and In Vivo Studies**

##### **Participants**

Yoshiharu Ohno, MD, PhD, (*Presenter*) Research Grant, Canon Medical Systems Corporation; Research Grant, Daiichi Sankyo Co, Ltd; Research Grant, Ministry of Education, Culture, Sports, Science and Technology

##### **PURPOSE**

Pulmonary thin-section MR imaging with UTE (UTE-MRI) has been reported its' clinical potential as substitution for thin-section CT for lung nodule detection or characterization in the last several years. However, one of its' drawbacks are relatively longer acquisition time because of high numbers of 3D radial sampling and grid reconstruction method. In this situation, we develop and clinically set conjugate gradient (CG) reconstruction for UTE-MRI to overcome this drawback. The purpose of this study was to directly compare utility for acquisition time reduction with keeping image quality and nodule detection capability among UTE-MRI obtained with different sampling spoke numbers and reconstructed with CG and grid reconstructions at in vitro and in vivo studies.

##### **METHODS AND MATERIALS**

At in vitro study, commercially available MR phantom for evaluation of image distortion was scanned by UTE-MRI sequence with original (n=1), 1/2, 1/4 and 1/6 sampling spoke numbers at five times, and each UTE-MRI data was reconstructed with CG and grid reconstructions. Moreover, at in vivo study, 40 patients suspected with lung nodule underwent thin-section CT and UTE-MRI by same sequence with original, 1/2, 1/4 and 1/6 sampling spoke numbers. Then, all UTE-MRI data were also reconstructed with CG and grid reconstructions. Standard protocol in this study was UTE-MRI obtained with original sampling spoke number and reconstructed with grid reconstruction. To determine the influence of sampling spoke number reduction and reconstruction method difference at in vitro study, full width at half maximum (FWHM) of each phantom was measured. At in vivo study, lung signal-to-noise ratio (SNR), overall image quality, artifact and probability for nodule presence were assessed by ROI measurement or 5-point scales. FWHM and SNR were compared between each UTE-MRI and standard protocols by Student's t-test. All qualitative indexes were compared by Wilcoxon's signed rank test between each UTE-MRI and standard protocols.

##### **RESULTS**

FWHM and SNR of standard protocol had significant differences with those of all UTE-MRI protocols except UTE-MRIs obtained with original and 1/2 sampling numbers and reconstructed with CG reconstruction ( $p < 0.05$ ). Each qualitative index of standard protocol had significant differences with those of all UTE-MRI protocols except UTE-MRIs obtained with original and 1/2 sampling numbers and reconstructed with CG reconstruction ( $p < 0.05$ ).

##### **CONCLUSION**

s CG reconstruction is useful for reducing acquisition time without any influence on image quality and nodule detection on UTE-MRI.

#### **CLINICAL RELEVANCE/APPLICATION**

CG reconstruction is useful for reducing acquisition time without any influence on image quality and nodule detection on UTE-MRI.

#### **T5A-SPCH-6 Low-Field (0.55T) Fourier-Decomposition Magnetic Resonance Imaging for Ventilation and Perfusion Defect Evaluation of Pulmonary Diseases**

##### **Participants**

Dante Capaldi, PhD, San Francisco, CA (*Presenter*) Nothing to Disclose

##### **PURPOSE**

Low field (0.55T) MRI has recently shown great potential for lung imaging, with reduced susceptibility artifacts and superior image quality for anatomical assessment as compared to higher field MRI. Fourier decomposition MRI (FDMRI) offers a non contrast enhanced, free breathing method to generate both pulmonary ventilation and perfusion maps over a short tidal breathing duration. Our objective was to evaluate for both pulmonary ventilation and perfusion in volunteers and lung disease patients using low field FDMRI. As patients with lung pathology are more frequently known to have ventilation or perfusion defects, we hypothesize that FDMRI ventilation and perfusion defects would be visible and elevated in these patients as compared to our volunteers.

##### **METHODS AND MATERIALS**

We prospectively enrolled 17 patients with heterogeneous lung disease diagnoses (57±17yrs, interstitial lung disease=4, sarcoidosis=1, bronchiectasis=1, non small cell lung cancer=4, chronic thromboembolic pulmonary hypertension=2, emphysema=1, benign nodules=4) and four volunteers (48±17yrs) who provided written informed consent. Multi slice coronal plane (anterior, center, posterior) free breathing 1H MRI were acquired over a period of 90s per plane using an optimized balanced steady state free precession sequence on a 0.55T scanner (MAGNETOM Free.Max, Siemens Healthineers, Erlangen, Germany). FDMRI analysis was performed using an inhouse software (MATLAB) and the ventilation (VDP) and perfusion defect percent (QDP) were generated using a hierarchical k means clustering approach to extract the ventilation and perfusion defect volumes and a seeded region growing algorithm to segment the thoracic cavity volume. Quantitative comparisons between volunteers and patients with lung disease were performed using unpaired t tests.

##### **RESULTS**

Low field FDMRI ventilation and perfusion maps showed visible ventilation heterogeneity (i.e. V/Q mismatch) in the lung disease patients, such as visible ventilation defects in fibrotic sarcoidosis patients and perfusion defects in a patient with pulmonary hypertension, as compared to the volunteers. Quantitatively as compared to the volunteers, both VDP (volunteer=1.9±0.6%, disease=5.1±3.8%;  $p=0.03$ ) and QDP (volunteer=2.5±0.3%, disease=7.8±4.4%;  $p=0.03$ ) were significantly elevated in lung disease patients.

## CONCLUSION

s In patients with lung disease, low field fMRI ventilation and perfusion defects were qualitatively visible and quantitatively elevated, as compared to volunteers.

## CLINICAL RELEVANCE/APPLICATION

Low field (0.55T) free breathing MR ventilation/perfusion (MRVQ) holds promise to functionally evaluate pulmonary diseases without needing intravenous/inhaled contrast agents or ionizing radiation.

## T5A-SPCH-7 Free Breathing 19F MRI Detects Lobar Differences in Ventilation Kinetics

Participants

Courtney Wing, MD, Wellington, FL (*Presenter*) Nothing to Disclose

## PURPOSE

This study was conducted to interpret lobar ventilation kinetics in both healthy supine subjects using a free-breathing 19F MRI ventilation technique.

## METHODS AND MATERIALS

5 healthy volunteers completed a single MR session on a Siemens 3T Prisma. 1H ultrashort-echo time (UTE) MRI sequences were used for registration and masking, and ventilation images with 19-Fluorine (19F) MRI were obtained while the subjects breathed a normoxic mixture of 79% perfluoropropane and 21% oxygen (O<sub>2</sub>). 0.4 second spiral 19F MR imaging was performed during a free breathing recovery breath. The 19F spiral data were denoised using a low-rank matrix recovery approach. Lobar ventilation mapping was created via manual segmentation tools available using 3D Slicer software on the UTE images. Time constants for wash-in and wash-out kinetics (t<sub>1</sub>(s), t<sub>2</sub>(s), respectively) taken from right upper lobe (RUL), right middle lobe (RML), right lower lobe (RLL), left upper lobe (LUL), and left lower lobe (LLL) were used to measure physiologic lobar differences in ventilation kinetics among healthy supine patients.

## RESULTS

19F gas wash-in and wash-out rate constants (t<sub>1</sub>(s), t<sub>2</sub>(s)) were used to measure efficiency of gas exchange in the inspiratory and expiratory phases. On average, bilateral lower lobes demonstrated the most rapid wash-in and wash-out rates in supine subjects (average t<sub>1</sub>(s) RLL = 69.42, RML = 73.3, RUL = 83.5, LUL = 68.0, LLL = 58.1, average t<sub>2</sub>(s) LUL = 27.5, LLL = 22.8).

## CONCLUSION

s This follows known physiologic principles in standing patients, in which maximum perfusion in the lower lung zones allows for the largest potential for gas exchange. In order to maintain the most efficient rates of gas exchange in bilateral lower lobes, "standing" pulmonary perfusion ratios must be maintained. This may be explained by supine pulmonary blood flow regulatory mechanisms that are not yet studied. Ventilation mapping with free-breathing 19F MRI is sufficiently sensitive to detect known lobar differences in ventilation kinetics among healthy supine subjects.

## CLINICAL RELEVANCE/APPLICATION

Free breathing 19F MRI has already been proven valuable in monitoring treatment outcomes in CF as well as progression of disease. Here, we offer its utility in studying regional ventilation kinetics in supine subjects, which is not possible with current standard ventilation-space MRI techniques. 19F also lacks dependence on hyperpolarization protocols needed for current functional MRI (Helium-3 (3He), Xenon-129 (129Xe)), so it can be offered at institutions that may lack the resources for hyperpolarization protocols.

## T5A-SPCH-8 Assessment of Lung Density in Preterm Infants Using Three-dimensional Ultrashort Echo-time MRI

## PURPOSE

Postnatal Lung development is important in infants, especially in preterm children, while relevant imaging data is scarce. Recent studies have shown that normalized lung signal intensity using UTE-MRI could be correlated to lung density comparable to CT, so we aim to explore the quantitative ability of UTE-MRI for assessing lung tissue density and analyze the differences in lung signal intensity among premature infants.

## METHODS AND MATERIALS

A prospective recruitment from March 2021 to October 2022 was conducted at the West China Second University Hospital of Sichuan University for infants aged 0-2 years. A total of 101 subjects were enrolled and divided into three groups based on gestational age (GA): extremely-to-very preterm group (GA<28 weeks, n=33), mid-to-late preterm group (GA>28 weeks and <37 weeks, n=34), and full-term group (GA=37 weeks, n=34). All subjects underwent pulmonary MRI using a 3.0-Tesla pediatric-specific MRI scanner (UIH uMR Alpha), including UTE sequence scanning. The lung-to-muscle ratio (LMR) was used to normalize lung signal intensity and quantify lung tissue density, and investigate the anterior-to-posterior(A-P) gradient of lung tissue and the inter-group differences among premature infants.

## RESULTS

LMR-A and LMR-P based on UTE-MRI were found to be linearly correlated (R<sup>2</sup>=0.582, P<0.001), indicating a A-P gradient in lung density. There is a gradually decreased tendency of the mean LMR in full-term, mid-to-late preterm, and extremely-to-very preterm infants, the whole lung LMR averages were 45.1, 48.7 and 50.8, respectively, with a statistically-significant difference between extremely-to-very preterm and full-term group (P=0.045), and a nearly statistically-significant difference between extremely-to-very preterm and mid-to-late preterm group (P=0.083), but the difference between mid-to-late preterm and full-term group was not statistically significant (P=0.290).

## CONCLUSION

s UTE-MRI shows the quantitative ability for assessing lung tissue density, and extremely-to-very preterm infants had lower lung tissue density compared to term infants.

## CLINICAL RELEVANCE/APPLICATION

Our study reflects that, the extremely-to-very preterm infants with GA<32 weeks, especially those with bronchopulmonary dysplasia (BPD), may have persistent structural abnormalities, such as alveolar simplification and impaired vascular growth, thereby lead to hyperinflation or cysts manifested as reduced signal intensity on UTE-MRI. Our results provides structural evidence for that, extremely-to-very preterm infants may have persistently reduced lung function compared to full-term infants, and have higher risk to get early-onset chronic obstructive pulmonary disease (COPD) , as previous studies suggested.

### Emergency Radiology Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPER-1 Optic Nerve Sheath Diameter Measurement for Predicting Raised Intracranial Pressure in Pediatric Patients: A Meta Analysis**

##### **PURPOSE**

This meta-analysis was aimed to evaluate the diagnostic performance of optic nerve sheath diameter (ONSD) for diagnosis of raised intracranial pressure (ICP) in pediatric patients.

##### **METHODS AND MATERIALS**

A database search of PubMed and EMBASE was performed to identify relevant studies. Bivariate modelling and hierarchical summary receiver operating characteristics (HSROC) modelling were performed to evaluate diagnostic performance. A pooled diagnostic odds ratio (DOR) with a 95% confidence interval (CI) not including 1 was considered informative. Subgroup analysis was performed according to the modality (ocular ultrasound vs. brain computed tomography [CT]/magnetic resonance imaging [MRI]). We performed meta-regression analyses for heterogeneity exploration.

##### **RESULTS**

Eleven studies including 546 patients were included. According to pooled DORs, ONSD was informative for evaluation of the raised ICP (DOR, 47; 95% CI, 11-206). ONSD showed a pooled sensitivity of 0.88 (95% CI, 0.79-0.94), a pooled specificity of 0.86 (95% CI, 0.70-0.95), and an area under the HSROC curve of 0.93 (95% CI, 0.91-0.95) for diagnosis of raised ICP. According to the subgroup analysis, ocular ultrasound (sensitivity, 0.91 [95% CI, 0.81-0.96]; specificity, 0.86 [95% CI, 0.65-0.96]) showed higher sensitivity and comparable specificity than ONSD measured on brain CT/MRI (sensitivity, 0.75 [95% CI, 0.51-0.99]; specificity, 0.91 [95% CI, 0.74-1.00]). On meta-regression analysis, study design, number of patients, and reference standard were sources of heterogeneity.

##### **CONCLUSION**

ONSD may be a useful method for predicting raised ICP in pediatric patients.

##### **CLINICAL RELEVANCE/APPLICATION**

We recommend that measurement of ONSD be performed using ocular ultrasound for more accurate diagnosis of raised ICP in pediatric patients.

#### **T5A-SPER-2 Is it Necessary to Perform Triple Rule-out Computed Tomography Angiography that Includes Abdominal Aorta in Patients with Chest Pain: A Study with More than 1000 Patients**

##### **PURPOSE**

To investigate whether it is necessary to perform the triple rule-out (TRO) computed tomography angiography (CTA) that includes abdominal aorta in patients with chest pain.

##### **METHODS AND MATERIALS**

A total of 1482 patients with nontraumatic chest pain (chief complaints: chest pain, difficulty in breathing, or hemoptysis) were included in this retrospective study. Four hundred and fourteen patients underwent the conventional TRO-CTA scans, and 1068 patients underwent TRO-CTA that included the abdominal aorta (TRO-CTA<sub>WAA</sub>) under the request of clinicians. All scanning parameters were the same only the scanning range for the third phase in TRO-CTA was different: conventional TRO-CTA covered only the thoracic aorta, while TRO-CTA<sub>WAA</sub> extended to the entire aorta. Patient etiology was investigated and the detection rates of major vessel abnormalities (aortic dissection, aneurysm, penetrating ulcer, vascular occlusion, and thrombosis) between the two groups and within the TRO-CTA<sub>WAA</sub> group (thoracic aorta vs. entire aorta) were compared using chi square tests and paired chi square tests. The radiation dose (CTDI<sub>vol</sub> and DLP) between the two groups was compared using analysis of variance (ANOVA).

##### **RESULTS**

The TRO-CTA<sub>WAA</sub> had significantly higher detection rate of major artery abnormalities than the TRO-CTA group (38.8% Vs. 8.5%,  $P < 0.001$ ). Within the TRO-CTA<sub>WAA</sub> group, only 28.4% abnormalities happened in thoracic aorta, which means the vessel abnormalities of 111 patients (27%) in this group would be missed with the conventional scan range. The TRO-CTA<sub>WAA</sub> group had slightly higher CTDI<sub>vol</sub> ( $5.64 \pm 1.44$  mGy) and DLP ( $473.64 \pm 146.50$  mGy\*cm) values for the complete examination than the TRO-CTA group ( $5.25 \pm 1.38$  mGy and  $453.03 \pm 139.22$  mGy\*cm, respectively). However, the differences were not statistically significant (all  $P > 0.05$ ).

##### **CONCLUSION**

TRO-CTA with scan range including the abdominal aorta significantly improves the detection rate for major vessel abnormalities in patients with chest pain with minor radiation dose increase.

**CLINICAL RELEVANCE/APPLICATION**

For chest pain patients, the scan range of triple rule-out CTA should be extended to include abdominal aorta since about quarter of the major vessel abnormalities happen beyond the thoracic aorta.

#### **T5A-SPGI-1 Correlation between Triglyceride/high-density Lipoprotein Cholesterol Ratio and Spectral Parameters Measured on a Fast kVp Switching Dual-energy CT**

##### Participants

Anjie Xie, Xiamen, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the correlation between triglyceride/high-density lipoprotein cholesterol (TG/HDL-C) ratio and spectral parameters measured on a fast kVp switching dual-energy CT

##### METHODS AND MATERIALS

This study included 50 patients with non-alcoholic fatty liver disease (NAFLD) and 46 healthy individuals, all received TG and HDL-C examination and TG/HDL-C was calculated. According to TG/HDL-C, the individuals were divided into two groups: low-ratio group (TG/HDL-C  $\leq$ 1.5, n=56), and high-ratio group (TG/HDL-C >1.5, n=40). Abdominal spectral imaging was performed on all individuals. Virtual monochromatic images at 50keV, 70keV, 90keV, and 100keV were reconstructed, the CT value of liver at 50-100 keV (HU50-100 keV) and that of spleen at 70keV were measured and the CT value of liver/ CT value of spleen ratio (HUL/S) was calculated. Mann Whitney U or two-sample t test was used to compare the differences between two groups, Spearman or Pearson correlation analysis was used to analyze the correlation between TG/HDL-C ratio and CT quantitative parameters, and ROC curve was used to analyze the performances of those parameters in predicting TG/HDL-C ratio.

##### RESULTS

Correlation analysis showed that TG/HDL ratio was negatively correlated with HU50keV, HU70keV, HU90keV, HU100keV, HUL/S, and the correlation coefficients were -0.4171 (-0.5740 to -0.2307,  $p < 0.0001$ ), -0.6129 (-0.7272 to -0.4655,  $p < 0.0001$ ), -0.6878 (-0.7830 to -0.5612,  $p < 0.0001$ ), -0.7006 (-0.7923 to -0.5778,  $p < 0.0001$ ), -0.7513 (-0.8291 to -0.6450,  $p < 0.0001$ ). HU50keV, HU70keV, HU90keV, HU100keV, and HUL/S in high-ratio group were lower than those in low-ratio group ( $p < 0.05$ ). When using HU50keV (threshold 68.625), HU70keV (57.71), HU90keV (58.785), HU100keV (55.89) and HUL/S (threshold 1.105) to predict TG/HDL-C ratio, the sensitivities were 0.804, 0.821, 0.625, 0.732 and 0.804, the specificities were 0.69, 0.714, 0.952, 0.8821 and 0.833, and AUC were 0.723, 0.803, 0.832, 0.835 and 0.837, respectively.

##### CONCLUSION

Conclusion The quantitative spectral parameters (HU50keV, HU70keV, HU90keV, HU100keV, HUL/S) were all correlated with TG/HDL-C ratio and had high performance to predict TG/HDL-C in NAFLD patients.

##### CLINICAL RELEVANCE/APPLICATION

Spectral imaging can help predict cardiovascular events in NAFLD patients, which is valuable for therapy and prognosis.

#### **T5A-SPGI-2 Opportunistic Screening for Bone Mineral Density Changes using Virtual Non-calcium of Spectral CTE in Patients with Inflammatory Bowel Disease**

Shaotong Wang, Xian, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Objective The purpose of this study was to explore the feasibility of opportunistic screening for bone mineral density (BMD) changes in patients with inflammatory bowel disease using virtual non-calcium of spectral computer tomography enterography (CTE)

##### METHODS AND MATERIALS

Materials and Methods Twenty patients (10 males, 10 females, average age  $38.2 \pm 11.5$ ) confirmed with inflammatory bowel disease (IBD) were prospectively enrolled. And 19 patients with non-inflammatory bowel disease (10 males, 9 females, mean age  $37.8 \pm 10.1$ ) were enrolled as control group. Patients were excluded if they had the following conditions: (a) no informed consent; (b) fracture in spine; (c) primary or metastatic bone tumors in the spine; (d) incomplete CT images; (e) Severe degenerative changes. Dual energy CTE was performed at 100/Sn150kVp using a 3rd generation dual-source CT scanner (SOMATOM Force, Siemens Healthcare). Dual energy images were reconstructed with a) virtual non-contrast images (VNC), b) virtual non-calcium images (VNCA). The CT value for contrast media (CM), the contrast agent density (CaD) which correspond to the CT value of calcium density, CT value of 50% mixed-energy imaging (CTmix) and fat fraction (FF) for 1st lumbar were measured, respectively.

##### RESULTS

Results FF and CaD of IBD group were significantly higher than those of control group ( $p < 0.05$ ). But CM and CTmix were similar between two groups ( $p > 0.05$ ). The results were shown in Table 1.

## CONCLUSION

s Conclusion FF and CaD measurements on VNCA images in spectral CT could provide feasibility of BMD quantification in patients with IBD by spectral CTE.

## CLINICAL RELEVANCE/APPLICATION

Clinical application Spectral CTE prescribed for IBD evaluation could also provide opportunistic screening for BMD changes, extending the clinical application of Spectral CT without additional radiation to patients.

## T5A-SPGI-3 Feasibility of Diagnosing Non-alcoholic Fatty Liver Disease using Spectral Imaging and Multi-material Decomposition Technique on Dual-energy CT

Participants

Anjie Xie, Xiamen, China (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the feasibility to diagnose non-alcoholic fatty liver disease (NAFLD) using multi-material decomposition (MMD) measured liver fat fraction (FF) and spectral parameters.

## METHODS AND MATERIALS

Fifty patients with clinically diagnosed NAFLD (reference of ultrasound examination or liver biopsy results) and 46 without NAFLD volunteers (N-NAFLD) were included in this study. Abdominal spectral imaging was performed on all individuals. Then visceral fat content (FV) and visceral fat content percentage (FCV) were measured by an auto measurement software. The FF in the left lobe of liver (FFL), right anterior lobe of liver (FFRA), and right posterior lobe of liver (FFRP) were measured using MMD. Virtual monochromatic images at 50keV, 70keV, 90keV, and 100keV were reconstructed, the CT value of liver at 50-100 keV (HU50-100 keV) and that of spleen at 70keV were measured. CT value of liver/ CT value of spleen ratio (HUL/S) and slope of spectral curve ? HU which was defined as  $(HU_{100keV}-HU_{40keV})/(100-40)$  were calculated. Differences between groups were compared using Mann Whitney U. Receiver operating characteristic curves were used to analyze the performances of those parameters in the diagnosis of NAFLD, sensitivity, specificity and area under the curve (AUC) were calculated.

## RESULTS

Comparing to N-NAFLD group, NAFLD group had higher FFL, FFRA, FFRP, FV, FCV ( $p<0.05$ ), and lower HU50keV, HU70keV, HU90keV, HU100keV, HUL/S ( $p<0.05$ ). ?HU was not statistically different between two groups. When using FFL (threshold of 0.981%), FFRP (1.065%), FFRA (4.2635%), and FV (68.8%), FVC (13013mm<sup>2</sup>), HU50keV (67.29 HU), HU70keV (58.05 HU), HU90keV (54.8 HU), HU100keV (55.678 HU), and HUL/S (1.1) to diagnose NAFLD, the sensitivities were 0.96, 0.96, 0.96, 0.52, 0.92, 0.978, 1, 1, 0.935 and 0.978, the specificities were 0.957, 0.935, 1, 0.891, 0.674, 0.72, 0.8, 0.84, 0.94 and 0.88, the AUC were 0.991, 0.989, 0.999, 0.743, 0.873, 0.84, 0.934, 0.978, 0.984 and 0.968, respectively. Therein, FFL, FFRA, FFRP had highest diagnostic performances.

## CONCLUSION

s CT spectral scanning could provide additional quantitative parameters for diagnosis of NAFLD, and FF measured by MMD had highest performance.

## CLINICAL RELEVANCE/APPLICATION

MMD technique in spectral imaging mode has great potential in rapid and non-invasive diagnosis of NAFLD.

## T5A-SPGI-4 Photon Counting CT of the Abdomen and Pelvis: A Clinical Comparison of Image Quality to Dual Energy CT Across Different Virtual Monoenergetic Images

Participants

Winston Joe, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose

## PURPOSE

Photon counting detector computed tomography (PCCT) represents the latest step forward in CT technology with early experience demonstrating improvements in spatial resolution, artifact reduction, material decomposition, and dose reduction, yet there are few studies documenting how these advancements translate to improved clinical utility, especially when compared to prior state of the art dual energy integrating detector CT (DECT). The purpose of this work is to evaluate the spectral capabilities of PCCT by comparing image quality of PCCT to that of DECT across a range of virtual monoenergetic images (VMI).

## METHODS AND MATERIALS

In this institutional review board-approved retrospective study, we identified patients who underwent both routine contrast enhanced CT of the abdomen and pelvis on a clinical PCCT scanner (NAEOTOM Alpha, Siemens Healthineers) and a clinical DECT (SOMATOM FORCE, Siemens Healthineers) since December 2021 ( $n = 12$ ). Individual subjects received the same iodine contrast dose for both examinations. PCCT was performed at a tube voltage of 120 kVp, and DECT performed with a tube voltage pair of 100/150 kVp. Subsequently, VMIs from both scans were reconstructed at 40, 50, 60, 70, 100, and 150 keV. For both PCCT and DECT examinations, contrast-to-noise ratios (CNR) were calculated relative to the psoas musculature for select organs and vessels (aorta, liver, spleen, renal cortex, and pancreas). Quantitative signal-to-noise ratios (SNR) were calculated. PCCT versus DECT were evaluated with respect to CNR and SNR at each virtual monoenergetic image reconstruction. Average radiation doses were compared between PCCT and DECT.

## RESULTS

PCCT has superior CNR of the aorta at 40 keV and SNR at 40 keV and 50 keV and superior CNR and SNR for renal cortex at 40 keV. There was no significant difference in CNR of the liver or pancreas for all evaluated VMIs, while DECT showed slightly improved CNR in the spleen at 100 keV and 150 keV. PCCT achieved a statistically significant 16% radiation dose reduction compared to DECT.

## CONCLUSION

s At lower keV virtual monoenergetic images, PCCT offers improved CNR and SNR with respect to the aorta and renal cortex. Comparable contrast and signal to noise characteristics were observed for the liver, spleen, and pancreas at lower keV

reconstructions. Importantly, these findings were achieved at a statistically significant 16% radiation dose reduction compared to DECT.

#### **CLINICAL RELEVANCE/APPLICATION**

At low keV monoenergetic image reconstructions, PCCT enables quantitatively comparable to improved image quality compared to DECT while allowing for a statistically significant reduction in radiation dose.

#### **T5A-SPGI-5 Longitudinal Intra Individual Consistency of Virtual Unenhanced Images Derived from Spectral Detector CT**

##### **Participants**

Nils Grosse Hokamp, MD, PhD, Köln, Germany (*Presenter*) Research Grant, Koninklijke Philips NV; Speakers Bureau, Koninklijke Philips NV; Consultant, Bristol-Myers Squibb Company

##### **PURPOSE**

Virtual non-contrast images (VNC) images obtained from different dual energy approaches are frequently suggested to serve as problem-solvers in case of missing true unenhanced acquisitions and even as replacement of the latter. While *ex vivo* consistency have been reported as accurate in literature, data on longitudinal, intra-individual consistency is lacking, yet another helpful measurement of their clinical utility. The objective of this study is the evaluation of longitudinal, intraindividual consistency of virtual unenhanced images (VNC) reconstructed from spectral detector CT (SDCT) in large patient cohort.

##### **METHODS AND MATERIALS**

Baseline and follow-up examinations of 166 patients with malignant melanoma were retrospectively included, resulting in a total of 323 scans. All patients underwent clinically indicated SDCT examinations of the chest and abdomen. In all patients, contrast administration, image acquisition and reconstruction were performed using a standardized protocol. Using additional cross-sectional follow-up imaging (=3 months), macroscopic tumor burden was excluded. A total of 35 ROI in parenchymatous organs, vessels and connective tissue were placed in contrast-enhanced scans (to allow for exclusion of unrepresentative tissues such as fasciae or vessels). To allow for identical ROI placement, baseline and follow-up images were displayed side-by-side using a dedicated software for oncologic image analysis (MintLesion Research, MintMedical, Heidelberg). The software then automatically copied and pasted all ROI on VNC images and collected attenuation and its standard deviation in VNC images for all ROI. Data was statistically assessed using a normalized deviation parameter:  $NDP = \frac{|(TP1;TP2)|}{\text{mean}(TP1;TP2)}$ .

##### **RESULTS**

As suggested earlier, a difference = 1 standard deviation was considered indicative of excellent reproducibility and found in 85% of cases. Good reproducibility (indicated by  $NDP = 2$  standard deviations) was found for 91% of all ROI. While good reproducibility was found for arterial vessels and all parenchymatous organs of the upper abdomen as well as connective tissues; differences in pelvic organs and venous vessels showed greater variation.

##### **CONCLUSION**

s SDCT-derived VNC reconstructions demonstrate little intraindividual, longitudinal variations and good reproducibility. These findings substantiate the validity of VNC calculations and further underline the clinical applicability of VNC reconstructions.

#### **CLINICAL RELEVANCE/APPLICATION**

VNC are more commonly used as a replacement for a true unenhanced acquisition, our data provides further substantiation that this is a valid approach.

#### **T5A-SPGI-6 Four-Dimensional Esophageal Computed Tomography Imaging: Assessment of Treatment Effect for Esophagogastric Junction Outflow Disorders after Per-oral Endoscopic Myotomy**

##### **Participants**

Hikaru Nishiyama, Toon, Japan (*Presenter*) Nothing to Disclose

##### **PURPOSE**

Per-oral endoscopic myotomy (POEM) is a novel minimally invasive treatment method for Disorders of EGJ outflow (disorders of EGJO). However, there is no consensus on the method for evaluating the therapeutic effect of esophageal achalasia treatment other than the subjective clinical symptom score called the "Eckardt score". This study aimed to examine the clinical feasibility of four-dimensional esophageal computed tomography imaging (4D-ECT) for assessing treatment effect for esophageal achalasia after POEM.

##### **METHODS AND MATERIALS**

This prospective study included 24 patients with esophageal achalasia or EGJO obstruction who underwent 4D-ECT using 320-detector-row CT scanner before and after POEM. The patients were seated on the chair in a semi-reclining position at a 45-60 degree angle. Dynamic volume CT scan was performed during swallow of 5% diluted contrast medium (Ioversol, 320mgI/mL). Scanning was performed in sequence over a 10 s duration for swallow, and scan range was from thoracic esophagus to gastric cardia including lower esophageal sphincter (LES). CT images were reconstructed in 102 phases at an interval of 0.1 s. The maximum esophageal length and area at LES level. The volume integral with time (VIT) of contrast medium during scanning was calculated to evaluate esophageal clearance. Additionally, the Eckardt score was recorded to assess treatment effect of POEM. These results were compared between pre- and post-POEM using Wilcoxon signed-rank test.

##### **RESULTS**

For all patients, POEM were successful without major complications, and the median Eckardt score was significantly improved after POEM (7.0 [5.0-8.8] vs. 0.5 [0-1.0],  $p < 0.0001$ ). The median of maximum esophageal length at LES level was significantly longer (2.1 [0.7-4.9] vs. 7.7 [5.6-9.4] mm,  $p = 0.0001$ ), and the median of maximum esophageal area at LES level was significantly larger after POEM (2.0 [0.2-10.8] vs. 23.0 [12.4-47.0] mm<sup>2</sup>,  $p = 0.0001$ ). The VIT was significantly smaller after POEM (602.1 [216.4-717.3] vs. 92.9 [50.3-333.1] ml;  $p < 0.0001$ ).

##### **CONCLUSION**

s 4D-ECT allowed for the quantitative assessment of improving both impaired relaxation of LES and esophageal clearance after POEM.

#### **CLINICAL RELEVANCE/APPLICATION**

4D-ECT is a novel imaging technique for the assessment of esophageal dynamics, and provides quantitative parameters for evaluating esophageal morphology, motility, and clearance. 4D-ECT enables quantitative and objective assessment of treatment effect for EGJO disorders after POEM.

#### **T5A-SPGI-7 Quantitative Spectral Computed Tomography Parameters as Pre-operative Prediction Factors for Ki-67 Expression in Hepatocellular Carcinoma**

##### **PURPOSE**

To investigate the performance of spectral parameters measured by a dual-energy CT for predicting the Ki-67 expression in hepatocellular carcinoma (HCC).

##### **METHODS AND MATERIALS**

This study retrospectively analyzed 91 patients with HCC who underwent both Ki-67 immunohistochemistry and two-phase contrast-enhanced spectral CT imaging. These patients were divided into two groups according to the positive rate of Ki-67 (Ki-67%): high expression (Ki-67% > 20%, n = 51) and low expression (Ki-67% = 20%, n = 40). CT values on 100 and 140 keV monochromatic energy images (HU100-140keV), normalized effective atomic number (Neff-Z), water density (Dwater) and fat density (Dfat) were measured and calculated. Receiver Operating Characteristics (ROC) curves were utilized for evaluating the predicting performance, area under curve (AUC), sensitivity and specificity were calculated, and multi-variable logistic regression analysis were conducted.

##### **RESULTS**

In prediction of Ki-67 expression, the AUCs of Neff-Z, Dfat, HU100-140keV and Dwater were 0.650, 0.677, 0.692-0.750, 0.777, with thresholds of 0.68, 995.28, 64.42-48.79 and 1035.17 respectively. The corresponding sensitivities were 0.647, 0.804, 0.529-0.824 and 0.961, respectively. The specificities were 0.600, 0.525, 0.825-0.625 and 0.475, respectively. Dwater was an independent predicting factor for high Ki-67 expression (OR=1.286, P<0.001), and had the highest prediction efficiency with area under the curve (AUC) of 0.777. The multi-variable analysis combining spectral CT parameters and morphological characteristics improved the prediction efficiency (AUC=0.814).

##### **CONCLUSION**

s Spectral CT provides a non-invasive method to evaluate the proliferation status of HCC cells, and the efficiency would be improved by combining spectral CT parameters and morphologic features.

#### **CLINICAL RELEVANCE/APPLICATION**

Ki-67 was a significant marker for HCC prognosis and clinical decision, however current method to evaluate Ki-67 always needs surgery, which is detrimental for assessing patients who lost surgery chance. Contrast-enhanced spectral imaging on dual-energy CT provides various parameters to predict cell proliferation in HCC with good performance, shedding lights in clinical diagnosis and therapeutic strategy decision.

#### **T5A-SPGI-8 Imaging, Pathological and Molecular Characteristics of Programmed Cell Death Ligand 1 Positive Hepatocellular Carcinoma**

Participants  
Azusa Kitao, MD, PhD, Kanazawa, Japan (*Presenter*) Nothing to Disclose

##### **PURPOSE**

Immunotherapy has been rapidly developed and is being applied for increasing number of hepatocellular carcinoma (HCC) patients. The purpose of this study is to clarify the imaging, pathological and molecular characteristics of hepatocellular carcinoma showing programmed cell death ligand 1 (PD-L1) expression, for the prediction of immunotherapy reactivity.

##### **METHODS AND MATERIALS**

We enrolled surgically resected 353 HCCs from April 2008 to July 2018 at our institution and classified into PD-L1 positive HCCs and PD-L1 negative HCCs by immunohistochemistry. We compared the qualitative and quantitative findings on dynamic CT and gadoteric acid-enhanced MRI, pathology and immunohistological expression of P53, beta-catenin, glutamine synthetase and organic anion transporting polypeptide 1B3 (OATP1B3). Mann-Whitney test, chi-square test, multivariable analysis and Pearson's correlation analysis were used for statistical analyses.

##### **RESULTS**

PD-L1 positive HCC (n=82) frequently showed arterial phase rim enhancement or heterogenous hypo-hyperenhancement compared to PD-L1 negative HCC (n=271) (52.4% vs 29.0%, P<0.001, odds ratio=5.00, 95% CI 2.34-10.68). Apparent diffusion coefficient (ADC) in PD-L1 positive HCC was lower than in PD-L1 negative HCC ( $1.13 \times 10^{-3}$  mm<sup>2</sup>/s vs  $1.30 \times 10^{-3}$  mm<sup>2</sup>/s, P=0.01, odds ratio=0.45 [cutoff value  $1.18 \times 10^{-3}$  mm<sup>2</sup>/s], 95% CI 0.24-0.82). Patients with PD-L1 positive HCC showed higher serum AFP level than those without PD-L1 positive HCC (median 20 ng/ml vs 10 ng/ml, P<0.001). Poorly differentiated HCC was frequent in PD-L1 positive HCC (37.8% vs 19.9%, P<0.001). PD-L1 expression grade showed a significant positive correlation with P53 expression grade (P<0.0001, R=0.36), however, no correlation with the other molecules.

##### **CONCLUSION**

s Imaging characteristics of PD-L1 positive HCC are arterial phase rim enhancement or heterogenous enhancement and lower ADC value. PD-L1 positive HCC showed higher serum AFP level, higher percentage of poorly differentiated HCC and a positive correlation with p53 expression, indicating aggressive biological natures.

#### **CLINICAL RELEVANCE/APPLICATION**

Imaging characteristics of PD-L1 positive HCC with more aggressive natures, namely arterial phase rim enhancement or

imaging characteristics of PD-L1 positive NSCLC with more aggressive natures, namely arterial phase rim enhancement or heterogenous enhancement in dynamic CT and low ADC value will be useful to predict immunotherapy response in personalized medicine.

T5A-SPGU

### Genitourinary Imaging Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPGU-1 An MRI-based Grading System for Preoperative Risk Estimation of Positive Surgical Margin after Radical Prostatectomy**

##### Participants

Lili Xu, Beijing, China (*Presenter*) Nothing to Disclose

##### PURPOSE

This study aimed to construct a simplified grading system based on MRI features to predict positive surgical margin (PSM) after radical prostatectomy (RP) and then validate it internally.

##### METHODS AND MATERIALS

Patients who had undergone prostate MRI followed by RP at our institution between January 2017 and January 2021 were retrospectively enrolled as the derivation group, and those between February 2021 and November 2022 were enrolled as the validation group. One radiologist evaluated tumor-related MRI features, including the capsule contact length (CCL) of lesions, capsular irregularity or bulge, neurovascular bundle asymmetry, obliteration of rectoprostatic angle, frank extraprostatic extension (EPE), and apex abutting. Binary logistic regression and decision tree analysis were used to select risk features for PSM among the significant variables from univariate analysis. The area under the curve (AUC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of different systems were calculated and then compared. The interreader agreement of the scoring systems was evaluated using the kappa statistic.

##### RESULTS

A total of 42 (29.8%) and 32 (36.4%) patients had PSM in the derivation and validation cohorts, respectively. The first grading system was proposed (mrPSM1) using two imaging features, namely, CCL = 20 mm and apex abutting. After combining the radiologist's perspective, the grading system was updated by adding frank EPE (mrPSM2) as follows: Grade 1, CCL < 20 mm without apex abutting; Grade 2, CCL = 20 mm or apex abutting; Grade 3, CCL = 20 mm and apex abutting, or frank EPE. In the derivation group, the AUC was 0.705 for mrPSM1 and 0.713 for mrPSM2. In the validation group, our grading systems showed slightly higher AUC than Park et al.'s model (0.672-0.686 vs. 0.646,  $p > 0.05$ ) and significantly higher specificity (0.732-0.750 vs. 0.411,  $p < 0.001$ ). The kappa value was 0.764 for mrPSM1 and 0.776 for mrPSM2. Decision curve analysis showed a higher net benefit for mrPSM2.

##### CONCLUSION

s The proposed grading systems based on MRI have feasibility in predicting PSM and are easily interpretable.

##### CLINICAL RELEVANCE/APPLICATION

Our proposed MRI-based grading systems for PSM might benefit the management of prostate cancer.

#### **T5A-SPGU-2 Prediction of Clinically Significant Prostate Cancer from Equivocal PI-RADS Category 3 Patients with a Deep Learning Approach: A Retrospective Multicenter Study**

##### PURPOSE

The presence of clinically significant prostate cancer (csPCa) is equivocal for patients with Prostate Imaging Reporting and Data System (PI-RADS) category 3, and therefore need confirmations of biopsy pathology. We aim to develop deep learning models for identifying csPCa and PCa from equivocal PI-RADS category 3 patients, and thereby reduce unnecessary biopsies.

##### METHODS AND MATERIALS

This retrospective multicenter study included bi-parameter MRI images of consecutive men patients from 6 centers. Deep learning models for predicting PCa and csPCa were constructed separately. Each model was first pretrained using 1144 PI-RADS 1~2 and 4~5 patients and then retrained using 238 PI-RADS 3 patients in randomly selected three centers, and finally tested using 185 PI-RADS 3 patients of the other three centers.

##### RESULTS

The deep learning models achieved excellent predicting performances in each external testing cohort with the area under the receiver operating characteristic curves of 0.795 (95%CI, [0.700,0.891]), 0.963 (95%CI, [0.915,1]) and 0.922 (95%CI, [0.810,1]) for predicting PCa, and 0.827 (95%CI, [0.703, 0.952]) and 0.926 (95%CI, [0.846, 1]) for predicting csPCa. Especially, 71.1% to 92.2% of non-csPCa patients were identified by our model, who would have safely spared from invasive biopsy or RP procedure.

##### CONCLUSION

s Our model offers a noninvasive clinical tool to predict csPCa from PI-RADS 3 patients, thereby reducing the unnecessary invasive

biopsies and improving the effectiveness of biopsies.

#### **CLINICAL RELEVANCE/APPLICATION**

1 The AttenNet models included channel attention and soft attention modules. 2 The AttenNet models had relatively strong generalization and reliability. 3 The AttenNet models were developed by a transfer learning strategy.

#### **T5A-SPGU-3 Performance of an Ultra-fast Deep-learning Accelerated MRI Screening Protocol for Prostate Cancer Compared to a Standard Multiparametric Protocol**

Participants

Benedict Oerther, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To establish and evaluate an ultra-fast MRI screening protocol for prostate cancer in biopsy-naïve men regarding PI-RADSv2.1 classification in comparison to the standard multiparametric protocol.

#### **METHODS AND MATERIALS**

This prospective monoinstitutional study included consecutive patients with suspected prostate cancer without prior biopsy. A PI-RADSv2.1 conform mpMRI protocol was acquired in a 3 T MRI scanner (tripplanar T2 TSE, axial T1 DIXON native and contrast-enhanced, DWI, DCE; scan time: 23min, 43sec). Additionally, two deep-learning accelerated sequences (axial T2-weighted TSE and diffusion-weighted „ZOOMit“) were acquired (scan time: 3min 28sec). Two experienced readers independently evaluated the images for image quality (Likert-scale; 1=non-diagnostic, 5=excellent) and the presence of prostate cancer according to PI-RADSv2.1 criteria. In a first reading session, only the screening protocol (axial T2-weighted and ZOOMit imaging was available). Subsequently, the full conventional mpMRI protocol was assessed (blinded to the results of the first session) and served as a reference standard. Intrareader-agreement was assessed using weighted kappa statistics.

#### **RESULTS**

The final cohort after exclusions consisted of 77 patients. Diagnostic performance of the screening protocol was excellent with a sensitivity and specificity of 87.5%/100% and 100%/100% (cut-off = PI-RADS 4) for reader 1 and reader 2, respectively. Mean image quality was 4.4 (R1) and 3.9 (R2) for the standard protocol vs. 4.6 and 4.7 for the accelerated T2- and diffusion-weighted images ( $p < 0.05$ ). Intrareader-agreement was substantial ( $k=0.72$ ) for reader 1 and excellent ( $k=0.98$ ) for reader 2.

#### **CONCLUSION**

s An abbreviated screening protocol for prostate cancer in biopsy-naïve men proved similar diagnostic performance and better imaging quality compared to the conventional extensive mpMRI protocol, requiring just 15% of scan time.

#### **CLINICAL RELEVANCE/APPLICATION**

Ultra-fast deep-learning accelerated MRI protocols can render prostate cancer screening more time efficient.

### Head & Neck Imaging Tuesday Poster Discussions I

#### Sub-Events

#### T5A-SPHN-1 CT Diagnosis of Cricoarytenoid Joint Dislocation

##### Participants

Xueming Zeng, Nanjing City, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the value of CT in diagnosis of cricoarytenoid joint dislocation, and evaluate the diagnostic points of different types of dislocation.

##### METHODS AND MATERIALS

41 patients who had been diagnosed with cricoarytenoid joint dislocation retrospectively reviewed, all patients were treated by reduction forceps, and the voice returned to normal or significantly improved. Including respiratory phase and phonation phase CT images. ?Observe the exposure of arytenoid articular surface of cricoid cartilage on VR images: complete exposure means total dislocation, incomplete exposure means subluxation; posterior part exposure means anterior dislocation, anterior part exposure means posterior dislocation; lateral part exposure means medial dislocation, medial part exposure means external dislocation (respiratory phase). ?Observe laryngoscopic video of each case, judge the direction of dislocation (anterior and posterior) according to morphology of vocal folds; compare the results with CT judgment. ?The characteristics of MPR CT images in each case were analyzed based on VR images.

##### RESULTS

? On VR images, there were 38 cases of cricoarytenoid subluxation (92.7%, 38/41), 3 cases of complete dislocation (7.3%, 3/41); 32 cases (78.0%, 32/41) of left dislocation, 9 cases (22.0%, 9/41) of right dislocation; Posterior dislocation in 37 cases (90.2%, 37/41), anterior dislocation in 4 cases (9.8%, 4/41); There were 32 cases of medial dislocation (78.0%, 32/41), 2 cases of external dislocation (4.9%, 2/41), 7 cases without obvious internal/external dislocation (17.1%, 7/41). 3 cases of complete dislocation were left posterior and internal dislocation. ?On laryngoscopy, there were 24 cases of posterior dislocation (58.5%, 24/41), 12 cases of anterior dislocation (29.3%, 12/41), 5 cases were difficult to assess (12.2%, 5/41). Laryngoscopy diagnosis were consistent with CT in 20 cases (55.6%, 20/36), inconsistent in 16 cases (44.4%, 16/36). ?On MPR CT images, dislocated arytenoid cartilage ridged on the top of cricoid cartilage plate in all 3 cases of complete dislocation. The manifestations of 38 cases of cricoarytenoid joint subluxation on MPR CT images are shown in Table 1. ( Fig.1~6)

##### CONCLUSION

s VR images can display dislocation of cricoarytenoid joint visually and accurately. MPR images can compensate for the poor evaluation of VR in younger patients.

##### CLINICAL RELEVANCE/APPLICATION

This study is based on the diagnostic method of limb joint dislocation and has high diagnostic accuracy. Reduction forceps adopts different techniques for total dislocation and subluxation, only CT can distinguish them currently.

#### T5A-SPHN-2 Identification of Methicillin-resistant Staphylococcus Aureus (MRSA) via Head and Neck Imaging

##### PURPOSE

It is currently unclear how methicillin-resistant Staphylococcus aureus (MRSA) infection presents in medical imaging uniquely from other types of acute infection. The characteristics of MRSA neck infections in radiological exams have not yet been established. This study aimed to compare the presentation of MRSA positive patients to that of patients with other types of acute neck infection in radiological exams.

##### METHODS AND MATERIALS

A retrospective review of children and young adults aged 0 to 24 years who underwent medical imaging for suspected acute infection at our pediatric hospital between January 2013 and September 2022 was conducted. A blinded radiologist reviewed initial and follow-up head and neck CT and MR imaging of patients with and without MRSA infection. Noted features included nodal necrosis, pattern of fat stranding, discrete abscess, and retropharyngeal edema. MRSA diagnosis was determined using microbiology lab results.

##### RESULTS

A total of 18 patients were reviewed, with a mean age of  $6.4 \pm 7.7$  years old (range 0-24) at time of diagnosis. 7 patients were female and 12 patients were male. 8 patients were positive for MRSA (MRSA-P), and 10 patients were MRSA negative but had acute neck infection (MRSA-N). Statistical analysis was conducted using SPSS 28.0.1.0 (142). No significant difference was found in age or sex between MRSA-P and MRSA-N groups. More MRSA-P patients (5/8, 62.5%) had nodal necrosis compared to the MRSA-N group (2/10, 20.0%), a borderline significant difference in proportions of 0.425,  $p = 0.145$ . All but one MRSA-P patients

(7/8, 87.5%) had a diffuse pattern of fat stranding compared to the MRSA-N group (6/10, 60.0%), but we failed to find a significant difference in proportions ( $p > 0.10$ ). A higher number of MRSA-P patients (7/8, 87.5%) had discrete abscess compared to MRSA-N patients (5/10, 50.0%), with the 0.375 difference in proportions being borderline significant,  $p = 0.152$ . More MRSA-P patients (4/8, 50.0%) had retropharyngeal edema compared to the MRSA-N patients (1/10, 10.0%), with a borderline significant difference in proportions of 0.400,  $p = 0.118$ .

## CONCLUSION

s MRSA neck infections show a higher proportion of observed nodal necrosis, diffuse pattern of fat stranding, discrete abscess, and retropharyngeal edema than acute neck infections unrelated to MRSA. However, these differences are not necessarily significant and further investigation with a larger patient sample size is needed to validate the significance of our findings and establish their potential use in clinical practice.

## CLINICAL RELEVANCE/APPLICATION

The differences in presentation between neck infections due to MRSA vs. other pathogens in head and neck MR and CT exams will allow for enhanced ability to identify MRSA from other types of neck infection.

## T5A-SPHN-3 MRI in the Evaluation of Facial Dermal Fillers

### PURPOSE

To ascertain with MRI the presence of filler injected in facial soft tissue and to evaluate contrast-enhancement in filler-related complications.

### METHODS AND MATERIALS

45 pts after filler augmentation underwent MRI. 19 pts (10 after temporary and 9 after permanent filler) had no problem while 26 pts had filler-related problems. TSE-T1-weighted, TSE-T2-weighted, fat-saturated TSE-T2-weighted and TIRM scans on axial and coronal plane were performed. In filler-related complications, fat-suppressed TSE-T1-weighted scans were performed after i.v. administration of Gadolinium-DOTA. Skin biopsy was performed in patients with soft tissue enhancement and in 5 pts without any enhancement who haven't any clinical improvement after antibiotic therapy. Fisher's exact test was used for statistical analysis. In complicated cases, cervical lymph node enlargement was evaluated (longitudinal axis >10mm).

### RESULTS

MRI always identified and quantified the filler in soft tissue. Temporary dermal fillers appeared as spots hypointense on T1-weighted and hyperintense on T2-weighted images. Permanent fillers appeared as hypointense spots on T1-weighted images while the signal intensity on T2-weighted images varied. In patients with complications, on T2-weighted images they appeared hyperintense in 20 pts and hypointense in 16 pts. When a positive subcutaneous contrast-enhancement was detected (9 pts), skin biopsy always found an inflammatory granulomatous reaction which wasn't found in 5 pts without contrast-enhancement. Fisher's exact test found a significant correlation ( $P < 0.001$ ) between subcutaneous contrast-enhancement and granulomatous reaction. Cervical lymph nodes enlargement was found in 16 complicated patients and their levels determined (IA, IB, IIA, IIB).

## CONCLUSION

s MRI is a useful and non-invasive tool for visualization of facial dermal filler and i.v. Gadolinium administration is advised in complicated cases.

## CLINICAL RELEVANCE/APPLICATION

MRI criteria to evaluate patients after facial dermal filler implants in normal and pathological cases and to diagnose a possible granulomatous reaction using i.v. administration of paramagnetic contrast media.

## T5A-SPHN-4 Feasibility of Paranasal Sinus MR Imaging at 0.5T: Comparison with CT and 1.5T MR

Participants

Harsh Agarwal, PhD, Bangalore, India (*Presenter*) Employee, Samsung Electronics Co, Ltd

### PURPOSE

CT is imaging modality of choice for medical and surgical management of the paranasal sinus (PNS) such as for inflammation, ESS and DNS. It is however associated with radiation exposure especially to eyes and in young individuals. Usage of CT also limits the repeat imaging follow-up of the PNS patients. It has been shown that MRI can be used in place of CT and can give additional information about various soft tissues in sinus. However due to the sensitivity of MRI to metal such as that present in dental crowns can limit the use of MRI. 0.5T is impacted much less by the metal and can be used to replace CT for sinus evaluation.

### METHODS AND MATERIALS

Over the period of 3 weeks, all patients who visited the diagnostic centre for PNS CT was given an option to participate in IRB approved MRI study. Further patients undergoing MRI exam and have sinus related issues were given option to participate in the study. These patients were scanned with thin section CT and high-resolution thin slice MRI scan (Cor T2w, Cor T2 STIR, Ax T2, Cor T1w) at both 1.5T commercial MRI scanner and 0.5T MRI scanner. 2 expert radiologists reviewed the CT, and MR images from 1.5T and 0.5T independently and reported their findings. These findings were then compared to access if any clinical finding is missing in any of CT, 1.5T and 0.5T MRI reports.

### RESULTS

3 patients were scanned at CT and both the MRI scanners and additional 5 patients were scanned at both the MRI scanners. Scans were successfully completed. No clinical finding was missed at either of the CT, 1.5T and 0.5T MRI reports of the two radiologists. MRI was preferred by the two-radiologist due to additional soft tissue information in MRI. One patient has large dental cap which was causing susceptibility artifact in 1.5T MRI over the maxillary sinus but reduced extent of artifact was observed for 0.5T MRI with clear diagnosis over the maxillary sinus area.

## CONCLUSION

s Compared to CT 1.5T and 0.5T MRI showed similar clinical diagnosis for medical and surgical management of the sinus patients.

Unlike 1.5T MRI 0.5T is minimally affected by the metal and can be used in imaging with metal embeddings like dental fillings and crown. Therefore 0.5T can potentially replace CT for imaging management of sinus diseases and clinically superior for soft tissue tumors and fungal soft tissue involvement.

#### **CLINICAL RELEVANCE/APPLICATION**

CT imaging for PNS leads to unwanted exposure to eyes and in young patients where DNS surgery is typically performed. The usage of 0.5T MRI will enable sinus imaging even in the presence of metal such as dental crowns and braces. AI augmented 0.5T MRI could be more accessible to cities and patients where MRI was previously not accessible.

#### **T5A-SPHN-5 Feasibility, Diagnostic Efficacy, and Safety of Core Needle Biopsy as a First-Line Biopsy Method for Cervical Lymph Nodes**

##### **PURPOSE**

The role of ultrasound-guided core needle biopsy (CNB) as a first-line method for cervical lymph nodes (LNs) has not yet been established. This retrospective study aimed to determine the feasibility, diagnostic efficacy, and safety of ultrasound-guided CNB as a first-line biopsy method for cervical LNs in patients with cervical nodal disease of non-thyroid origin.

##### **METHODS AND MATERIALS**

From March 2017 to October 2022, CNB was routinely applied as a first-line biopsy method by an experienced radiologist to 1331 cervical LNs in 995 consecutive patients with cervical nodal disease of non-thyroidal origin. CNB was performed by using 18-gauge, single- or double action spring-activated needles and the number of CNB sampling was 2-4 times in most cases. The hydrodissection technique was selectively used for high risk LNs located adjacent to large vessels and critical neck nerves. The results of CNB were categorized into four categories of inadequate, benign, indeterminate, and malignant. The feasibility of CNB was evaluated by the technical success rate. The diagnostic efficacy was evaluated by the inadequacy rate and diagnostic accuracy (sensitivity, specificity, and accuracy) for malignant LNs. The diagnostic accuracy was estimated by two criteria for test positivity (criterion 1, malignant; criterion 2, malignant or indeterminate) in 1097 LNs with final diagnoses (634 benign and 463 malignant LNs). The safety of the CNB procedure was evaluated by the major and minor complication rates.

##### **RESULTS**

The technical success rate was 99.4 % (987/995 patients) and CNB procedure technically failed in six patients with small LNs adjacent to the lung apex and two patients with poor cooperation. The CNB results were inadequate in 15 (1.1%), benign in 659 (49.5 %), indeterminate in 53 (4.0 %), and malignant in 604 (45.4 %) of 1331 LNs. The sensitivity, specificity, and accuracy of CNB for malignant LNs were 95.3%, 100%, and 97.3% with criterion 1 and those were 99.5%, 97.4%, and 98.8 % with criterion 2. The sensitivity and specificity of CNB for diagnosis of lymphoma were 73.2% and 100% with criterion 1 and those were 98.2%, 97.4% with criterion 2. There were no major complication such as large symptomatic hemorrhage requiring admission or needle tract seeding. Minor complication (asymptomatic small hematoma) was found only in 8 (0.8%) patients.

##### **CONCLUSION**

s CNB was technically feasible, effective, and safe as a first-line biopsy method for cervical LNs in patients with cervical nodal disease of non-thyroid origin with high diagnostic accuracy for malignant nodal disease.

#### **CLINICAL RELEVANCE/APPLICATION**

CNB can be used as an effective first-line diagnostic method for LNs in patients with cervical nodal disease of non-thyroid origin.

#### **T5A-SPHN-6 Stellate Ganglion Block with CT Guidance for Post-COVID Parosmia**

Participants

Adam Zoga, MD, MBA, Philadelphia, PA (*Presenter*) Nothing to Disclose

##### **PURPOSE**

Long term anosmia and parosmia are known late sequelae of COVID-19. While promising treatments for anosmia have evolved, parosmia is often refractory to pharmaceutical and topical therapies, leading to mood disorders, weight loss, and decreased quality of life. We worked with ENT colleagues to assess the potential benefits of CT-guided stellate ganglion block (SGB) in patients with long term post-COVID parosmia.

##### **METHODS AND MATERIALS**

Subjects were referred from an ENT olfactory subspecialist after at least 6 months of post-COVID parosmia, refractory to pharmaceutical/topical therapies. Situs was selected based upon hand dominance. CT guidance was used to position a 25-gauge spinal needle anterior to the lateral margin of the longus coli muscle at the level of T1 and positioning was confirmed with iodinated contrast. 1cc Lidocaine was injected and any Horner's syndrome was documented. In this location, 40mg of Depo Medrol and 2cc of were injected at the stellate ganglion. Change in symptoms was monitored through scheduled survey responses.

##### **RESULTS**

54 subjects presented for SGT (74% female, mean age 46 and range 14-71). Follow-up was obtained for 65% (37/54) of patients among whom 59% (22/37) reported improved symptoms at 1 week post injection. 82% (18/22) experienced progressive improvement with significant increase in mean reported improvement by 1 month post procedure ( $p=0.02$ , Figure 1). At 3 months, responders to SGB reported a mean of 49% improvement in symptoms (range 10-100%). 26 subjects returned for a contralateral injection with at least a 6 week interval. Of these, 100% (8/8) who reported no improvement after the 1st injection had no improvement after the 2nd injection. 86% (12/14) of subjects who reported some improvement after the 1st injection reported additional improvement after subsequent contralateral injection. For all injections, a Horner's syndrome was confirmed by exam in 95% (76/80), and all signs of Horner's syndrome resolved within 30 minutes of the injection. No complications or adverse events were reported.

##### **CONCLUSION**

s Percutaneous SGB shows promise for patients with long term post-COVID parosmia, and CT provides ideal efficiency and guidance. For patients with improvement post SGB, and 2nd contralateral treatment may provide additional benefit.

## CLINICAL RELEVANCE/APPLICATION

CT-guided stellate ganglion block is a new, minimally invasive and potentially impactful image guided therapy for patients with longstanding post-COVID parosmia.

## T5A-SPHN-7 Preoperative Prediction of Pathologic Response to Neoadjuvant Immunotherapy in Resectable Locally Advanced Head and Neck Squamous Cell Carcinoma Using Multiparametric MRIC<sub>13</sub> + CHAR<sub>10</sub>

Participants

Yaqin Zhang, MD, PhD, Zhuhai, China (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to evaluate the value of quantitative changes in MRI imaging after neoadjuvant immunotherapy in predicting pathologic response in resectable locally advanced head and neck squamous cell carcinoma (HNSCC) patients.

### METHODS AND MATERIALS

Fifteen patients with resectable locally advanced HNSCC who were enrolled in the prospective phase Ib clinical trial were included in the current retrospective analysis. In this current analysis, patients have underwent contrast-enhanced MRI and diffusion-weighted MRI scanning before neoadjuvant immunotherapy and radical resection of the tumor respectively. Response to neoadjuvant immunotherapy was based on histopathological evaluation of the resected specimen. The volume of the primary tumor and the value of the apparent diffusion coefficient (ADC) was measured. The difference between the two groups of treatment response (good response and poor response) was assessed using Fisher's exact test and the Mann-Whitney U test. The ability of the relative changes of the ADC value and tumor volume to discriminate between different pathologic response groups was quantified using the area under the receiver operating characteristic curve.

### RESULTS

Good response was found in 33.3% of all patients. Relative changes in primary tumor volume ( $V_{\text{primary}}$   $p=0.001$ ) and in DW-MRI parameters ( $ADC_{\text{primary}}$   $p=0.03$ ) after neoadjuvant immunotherapy were significantly different between the groups of good response and poor response. When the relative changes in tumor volume were used for predicting treatment response, the area under the receiver operating characteristics curve (AUC) was 0.98 with a sensitivity of 100% and a specificity of 90%. Change in ADC value achieved an AUC of 0.89 with a sensitivity of 100% and a specificity of 71% for the prediction of treatment response.

### CONCLUSION

Changes in tumor volume and ADC value after neoadjuvant immunotherapy can help identify patients with good response to neoadjuvant immunotherapy in HNSCC.

## CLINICAL RELEVANCE/APPLICATION

Accurate preoperative prediction of pathologic response to Neoadjuvant immunotherapy in patients with HNSCC could guide clinical selection and the patients could also be spared from ineffective and unnecessary toxicity. Although the use of MRI to evaluate the progression of immunotherapy has been explored in other types of tumors, information on HNSCC is limited. As far as we are aware, there are no published studies that use the gold standard of surgical histopathology to assess the response of neoadjuvant immunotherapy for HNSCC on imaging. The results of this study showed that the changes of tumor volume and ADC value can effectively evaluate the immunotherapy response of HNSCC in clinical work.

T5A-SPIN

### Imaging Informatics Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPIN-1 Transitioning to Fully-Supervised Pre-Training with Large-Scale Radiology ImageNet for Improved AI Transferability in Three-Dimensional Medical Segmentation**

##### Participants

Zongwei Zhou, PhD, Baltimore, MD (*Presenter*) Nothing to Disclose

##### PURPOSE

Fully-supervised pre-training has experienced long-standing success in the realm of computer vision, largely attributable to the extensive annotated ImageNet dataset. This research examined the transferability of medical AI fully supervised pre-trained on a similarly sized Radiology ImageNet.

##### METHODS AND MATERIALS

We first constructed a large-scale dataset by assembling 3,410 publicly available abdominal CT scans with partially annotated 25 organs and 6 tumors. We then completed the missing annotations using an efficient human-in-the-loop approach, resulting in Radiology ImageNet. This dataset enabled us to pre-train an AI model using full supervision. Segmentation, partitioning an image into multiple segments, can be viewed as a per-voxel classification. Therefore, the per-voxel annotations in our Radiology ImageNet (2,109 million annotated voxels) provided an order of magnitude larger than the per-image annotations in ImageNet (14 million images). AI transferability was evaluated on three medical segmentation tasks, i.e., 19 cardiovascular structures, 22 muscles, and 18 organs, using two external datasets, i.e., TotalSegmentator and JHH, comprising 6,062 CT scans. Dice Similarity Coefficient (DSC) was used as the evaluation metric. For a comprehensive comparison, we benchmarked fully-supervised pre-training against three dominant AI models pre-trained on 5,050, 5,022, and 888 unlabeled CT scans, respectively.

##### RESULTS

Fully-supervised pre-training demonstrated improved transfer learning performance compared to self-supervised counterparts, with increases from 86.5% to 90.9%, 89.9% to 94.4%, and 85.8% to 90.4% for the segmentation of cardiovascular structures, muscles, and organs in CT scans, respectively, using the TotalSegmentator dataset. As the annotated CT scans became more limited, fully-supervised pre-training achieved substantially better performance than self-supervised pre-training, with improvements of 17.5%, 12.1%, and 16.6% for 5-shot, 10-shot, and 20-shot transfer learning in the JHH dataset.

##### CONCLUSION

We created Radiology ImageNet and demonstrated its importance in the field of medical image analysis. Pre-training medical AI on this dataset led to an improved transferability for segmenting various anatomical structures in the human body. Our investigation suggested that fully-supervised pre-training mitigated the marked difference between self-supervised and segmentation tasks. This highlighted the potential of fully supervised pre-training to advance precision medicine.

##### CLINICAL RELEVANCE/APPLICATION

Medical AI, pre-trained on our Radiology ImageNet, excelled in the segmentation of anatomical structures, executing its vast potential in robotic surgery and treatment planning.

#### **T5A-SPIN-2 Nomogram based on CT-derived extracellular volume to predict pathological grading of hepatocellular carcinoma: a multicenter study**

##### PURPOSE

To evaluate the potential of CT-derived extracellular volume (ECV) to predict the pathological grading of hepatocellular carcinoma (HCC), and to develop two nomograms that combine clinical factors to predict high-grade HCC preoperatively.

##### METHODS AND MATERIALS

A total of 230 patients diagnosed with HCC were collected from Hospital X and Hospital Y. Due to the presence of multiple lesions in some patients' livers, a total of 238 lesions were included in the study. Due to the imbalance in data, we have used oversampling techniques (SMOTE) to balance it. After balancing, patients from Hospital X were included in the training and internal validation sets at a ratio of 7:3, while patients from Hospital Y were used as an independent external validation set. Absolute enhancement values of the liver tumor and the abdominal artery were calculated using non-contrast enhanced and delayed phase images. The ECV was calculated using the following formula:  $ECV (\%) = \frac{HU_{tumor} - HU_{aorta}}{HU_{aorta} - HU_{Hct}} [100 - Hct(\%)]$ . Two machine learning algorithms (logistic regression and random forest) were selected for modeling the nomogram.

##### RESULTS

According to the logistic regression algorithm, CT-derived ECV is an independent predictive factor for distinguishing high and low-grade HCC, with statistically significant differences ( $p < 0.001$ ). In the training, internal, and external validation cohorts, the AUCs of CT-ECV for evaluating the pathological grading of high-grade HCC were 0.895, 0.832, and 0.740, respectively. The logistic

regression-nomogram model had AUCs of 0.899, 0.853, and 0.750 in the training, internal, and external validation cohorts, respectively. The random forest-nomogram model had AUCs of 0.905, 0.847, and 0.812 in the training, internal, and external validation cohorts, respectively. Both models had satisfactory goodness of fit in the training and validation cohorts, and good clinical net benefit.

## CONCLUSION

s CT-derived ECV may represent a new quantitative CT marker for the identification of HCC pathological grading, providing incremental diagnostic value. The nomogram presents the predicted results in a visual and easy-to-understand manner, which helps physicians and patients better understand the disease progression and prognosis.

## CLINICAL RELEVANCE/APPLICATION

ECV is an indicator that reflects the changes in the microenvironment of liver tumors, which can calculate the percentage of extracellular space in the total volume of liver tumor tissue through contrast agent kinetic characteristics. The level of ECV is closely related to the malignancy and prognosis of liver tumors, and therefore has important significance in the diagnosis and treatment of liver tumors.

## T5A-SPIN-3 Deep Learning for Automated Measurement of Patellofemoral Anatomic Landmarks

### PURPOSE

To train a deep learning model to identify patellofemoral anatomic landmarks and enable the automated measurement of anatomical parameters.

### METHODS AND MATERIALS

This is an IRB-approved retrospective study with CT knee imaging from 483 patients acquired from April 2017-May 2022. Patients were selected from two cohorts: a pathological cohort of patients scheduled for knee arthroplasty (KA), and one of patients with healthy knee anatomy. 14,652 CT images were annotated with the location of 7 patellofemoral landmarks by trainees and approved by a senior musculoskeletal radiologist. A two-stage deep learning model was trained to predict landmark coordinates. A modified ResNet50 architecture was used, with an additional supervision mechanism. Models were initialized with self-supervised learning pre-trained weights on the RadImageNet radiological imaging database.

### RESULTS

Spatial accuracy is critical for model performance, as all patellofemoral measurements are calculated based on the predicted landmark coordinates. The mean absolute error between predicted and ground truth landmarks was 3.70 pixels in the healthy cohort and 5.33 pixels in the KA cohort at a 512x512 resolution. Various patellofemoral parameters were calculated, including transepicondylar axis (TEA) length, TEA-posterior femur axis angle, sulcus medial asymmetry ratio, and sulcus angle. There was no statistically significant difference ( $p>0.05$ ) between the predicted and ground truth measurements for all four parameters in both cohorts, except for the sulcus angle in the healthy cohort.

## CONCLUSION

s We have developed a deep learning model that accurately identifies key anatomic landmarks of the patellofemoral compartment with 3-5 pixel accuracy on a 512x512 image and produces measurements with no statistically significant difference from human-derived measurements on healthy and pathological knees. This work represents the first deep learning regression model for automated patellofemoral annotation trained on both physiologic and pathologic CT imaging at this scale. This novel model has the potential to enhance our ability to analyze anatomy of the patellofemoral compartment at scale.

## CLINICAL RELEVANCE/APPLICATION

KA procedures are among the most common surgeries, but morbidity has been associated with patellofemoral compartment-related complications in up to 20% of cases. Understanding this anatomy is crucial for restoring anatomic knee morphology and function, but patellofemoral anatomy has not been well-characterized. Developing a tool that enables the automated annotation of key landmarks would enable the measurement of anatomical parameters at scale in a precise, reproducible, and time-sensitive fashion free of inter- and intra-rater variability.

## T5A-SPIN-4 Development of a Small-data Deep-learning Model Based on an MTANN for Soft Tissue Sarcoma Diagnosis in MRI

### PURPOSE

Deep learning requires a large number of training cases (i.e., 10k to 100k), which makes the development of AI for rare cancer less feasible. Our purpose was to develop a "small-data" deep-learning model based on a massive-training artificial neural network (MTANN) to accurately discriminate between benign and malignant soft-tissue tumors in MRI.

### METHODS AND MATERIALS

We collected T2-weighted MRI of 146 patients with 96 benign and 50 malignant soft-tissue tumors in this study, where tumors were segmented by a radiologist and reviewed by an orthopedic surgeon. The proposed scheme used a patch-wise neural network called an MTANN which was trained in a patch-to-pixel manner. Desired teaching images were generated with a Gaussian-blurred manual tumor segmentation mask for malignancy and a completely dark image for benignancy. During the training phase, the input was a 3D image patch extracted from input MR images. The neural network predicted a probability of malignancy for the input patch. The cross-entropy was used as the loss function to train the model. Once the MTANN model was trained, the entire image was computed as the likelihood map of malignancy by shifting the patch-wise window over the input image in a convolutional manner. Finally, a fully-connected classification layer with the image features extracted from the likelihood maps in a feature-scoring layer was used to classify the known tumor.

### RESULTS

Our small-data MTANN model was able to be trained with only 77 benign and 40 malignant soft-tissue tumors. Our experiment showed that our MTANN model outperformed several state-of-the-art radiomics and other deep learning models in discriminating between benign and malignant tumors and achieved an area under the curve (AUC) of 0.78 which was higher than that (0.73) of the best-performing state-of-the-art model with a p-value  $<0.05$ .

## CONCLUSION

Our small-data patch-wise deep-learning model based on an MTANN showed higher performance in discriminating between benign tumors and malignant soft-tissue tumors, which are rare cancer, in MRI, compared with several state-of-the-art radiomics and deep-learning models.

## CLINICAL RELEVANCE/APPLICATION

Our small-data MTANN deep-learning model makes the development of deep learning for rare cancer possible. It can potentially prevent non-expert radiologists from diagnosing rare cancer inaccurately.

## T5A-SPIN-5 Deep Learning-enabled CT Number Neutralization in Heterogeneous Tube Voltage CT Imaging: A Pilot Study

### PURPOSE

Depending on types of examinations and image applications, CT images are frequently taken with various tube voltages which results in differing Hounsfield units for the same tissue. This causes difficulties in quantification of imaging biomarkers in various applications. We postulated that application of deep learning might enable neutralization of CT numbers in heterogeneous tube voltage CT imaging. This study presents a pilot experimental result.

### METHODS AND MATERIALS

We used datasets of abdomen which were acquired from Siemens Somatom Force Dual Energy CT where A tube has 80 kV and B tube has 150 kV tube voltage. Among the total of 211 cases, 200 were used for training/validating and 11 were used for testing. A generative deep learning model architecture was employed consisting of a generator and a discriminator. The generator was designed to have five residual blocks and a skip connection which connects the first block with the last block. It takes in 80 kV CT images and outputs 150 kV CT images. Since true 150 kV CT images are available, the discriminator is given both images, generated-150 kV CT images made by the generator and real-150 kV CT images and trained to discern between the two. The loss is fed back into the generator to produce more accurate 150 kV CT images. The average Hounsfield unit for 80 kV, generated-150 kV and real-150 kV are compared using t-test on homogeneous regions of organs, such as liver, aorta and thoracic spine in order to observe statistical difference between them. Also scatter plot was used to compare between generated-150 kV and real-150 kV with linear equation and R-squared calculated.

### RESULTS

The average Hounsfield unit for 80 kV, generated-150 kV and real-150 kV were 80.4, 61.6 and 63.0 for liver, 513.4, 181.1 and 180.0 for aorta, and 226.6, 111.6 and 111.5 for thoracic bone, respectively. For all tissues, p-value between 80 kV and real-150 kV was less than 0.001, indicating both are significantly different and p-value between generated-150 kV and real-150 kV ranged from 0.14 to 0.77, indicating both are not significantly different. The scatter plot results in a linear equation  $y = 1.01 * x - 2.28$  and  $R^2 = 0.9911$ .

## CONCLUSION

From given 80 kV CT images, the network was able to produce generated-150 kV CT images statistically indistinguishable to that of real-150 kV CT images. Our study demonstrated the application of deep learning enabled neutralization of CT numbers from CT images taken with different tube voltage settings.

## CLINICAL RELEVANCE/APPLICATION

The work has shown the ability to convert 80 kV CT images to 150 kV CT images. In the future, it could be possible to convert any CT images taken with a different kV to single standard kV CT images, and thus neutralize CT numbers in heterogeneous tube voltage CT imaging.

## T5A-SPIN-6 Improved Prognostic Prediction of Pancreatic Cancer Using Multi-Phase CT by Integrating Neural Distance and Texture-Aware Transformer

Participants

Hexin Dong, Beijing, China (*Presenter*) Nothing to Disclose

### PURPOSE

Pancreatic ductal adenocarcinoma (PDAC) is a highly lethal cancer in which the tumor-vascular involvement greatly affects the resectability and, thus, overall survival of patients. We propose a novel learnable neural distance that describes the precise relationship between the tumor and vessels. Combined with dynamic tumor-related texture features in multi-phase contrast-enhanced CT (CECT), We aim to develop a new deep learning-based CT imaging-derived biomarker for predicting PDAC survival.

### METHODS AND MATERIALS

We conducted a multicenter study with 1,070 patients to validate our method, using one center (892 patients) for training and the other three centers (178 patients) for independent testing. The CECT protocol included non-contrast, pancreatic, and portal venous phases. We constructed a prognostic biomarker - NDTAT-PDAC - which captures both tumor enhancement patterns and tumor-vascular involvement for OS prediction. The marker was tested in both nested 5-fold cross-validation and external validation cohorts to evaluate its performance, robustness, and clinical usefulness.

### RESULTS

The continuous NDTAT-PDAC score performed a c-index of 0.656 (95% CI 0.639-0.673) and a AUC of 0.695 (95% CI 0.672-0.718) in the nested 5-fold cross-validation cohort, and a c-index of 0.710 and a AUC of 0.792 in the external validation cohort. We used univariate and multivariate Cox proportional-hazards models to evaluate our signature and other clinicopathologic factors in the independent test set. The proposed risk stratification was a significant prognostic factor, along with other factors like pathological TNM stages. After selecting significant variables ( $p < 0.05$ ) in univariate analysis, our proposed staging remained strong in multivariable analysis (HR=1.847,  $p=0.027$ ) after adjusting for important prognostic markers like pT (HR=2.438,  $p < 0.0001$ ) and resection margins (HR=1.681,  $p=0.091$ ). Notably, our proposed marker remained the strongest among all pre-operative markers, such as tumor size and CA 19-9.

## **CONCLUSION**

s We developed a new deep learning-based CT imaging-derived biomarker for predicting PDAC survival. The new biomarker was the strongest predictor of overall survival among preoperative factors and it has the potential to be combined with established clinical factors to select patients at higher risk who might benefit from neoadjuvant therapy.

## **CLINICAL RELEVANCE/APPLICATION**

Our novel tool sets a new standard in this area, and can benefit clinicians by selecting patients who might benefit from neoadjuvant chemotherapy with aggressive tumor types. Our represents a significant advancement in the development of prognostic models and may lead to improved clinical decision-making, ultimately resulting in better patient outcomes.

#### **T5A-SPIR-1 A Multi-institutional One-year Prospective Follow-up of Fluoroscopic, Cholangioscopy-assisted Large Bore Gallstone Extraction for Inoperable Calculous Cholecystitis**

##### Participants

Venkatesh Balaji, BA, New York, NY (*Presenter*) Nothing to Disclose

##### PURPOSE

The aim of this study is to assess for recurrent cholelithiasis on one-year imaging post percutaneous large bore (24-30 French) gallstone extraction for a subset of patients who are poor surgical candidates for cholecystectomy.

##### METHODS AND MATERIALS

This is a multi-institutional Institutional Review Board approved prospective observational review of patients at two large academic centers who present with acute calculous cholecystitis and were deemed high-risk surgical candidates. Review parameters include procedural technical and clinical data, clinical presentation, average hospital length of stay, and post-intervention symptom reduction. Technical success was defined as the removal of all stones during the procedure. Clinical success was defined as stone-free on 12-month follow-up imaging.

##### RESULTS

Fifteen patients (mean age 77.9yr, range 52-94yr; 8 male and 7 female) underwent large bore sheath (24-30Fr) cholangioscopy assisted gallstone extraction. The size of the gallstones ranged from 0.5-4.0cm. All patients had prior transhepatic or transperitoneal cholecystostomy access for 3-6 weeks prior to gallstone extraction. All patients' indwelling accesses were upsized to 24Fr or 30Fr sheaths using the NephroMax balloon sheath system (Boston Scientific, Marlborough, MA). There was 86.7% technical success rate with no major procedure-related complications. 86.7% were symptom and pain-free immediately post-procedure. There were no major complications. Median hospital stay was 1-day post-procedure. Of the fifteen patients, twelve patients had 12-month follow-up US or CT. 75% did not have recurrent cholelithiasis on imaging.

##### CONCLUSION

Majority of patients were stone-free and asymptomatic on one-year follow-up imaging after percutaneous fluoroscopic-guided large bore (24 -30 French) gallstone extraction.

##### CLINICAL RELEVANCE/APPLICATION

High risk patients diagnosed with calculous cholecystitis who are poor candidates for cholecystectomy may benefit from a cholangioscopy-assisted large bore gallstone extraction for symptom reduction. This proved to be a safe and effective procedure with no major complications and a median hospital stay of 1 day. The majority of cases achieved technical and clinical success with no recurrent cholelithiasis.

#### **T5A-SPIR-2 Combined Multiple Regional Anesthesia for Microwave Ablation of Liver Tumors Initial Experience**

##### Participants

Man Lu, PhD, Chengdu, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the feasibility and safety of combined multiple regional anesthesia (CMRA) in reducing pain and intravenous analgesic requirements during and following the ultrasound guided microwave ablation (US-guided-MWA) of liver tumors.

##### METHODS AND MATERIALS

A total of 75 patients with 99 liver tumors who received US-guided-MWA of liver tumors were recruited. They were randomly divided into three groups: A, B, C. Before ablation, patients in group A received hepatic hilar block (HHB), Transversus abdominis plane block (TAPB) and local anesthesia (LA). Patients in group B received HHB+LA. Patients in group C received TAPB+LA. Numerical Rating Scale (NRS) scores, morphine intake, complications and the factors influent perioperative pain were evaluated.

##### RESULTS

All the patients were successfully received the US-guided-MWA. The maximum NRS score for pain during ablation of the three groups were  $2.36 \pm 1.19$ ,  $3.28 \pm 1.59$  and  $4.24 \pm 1.42$  respectively ( $P < 0.01$ ), while the number of patients used morphine were 4/25, 8/25, 13/25 respectively ( $P < 0.01$ ). NRS scores of the three groups at 4, 8, 12, 24 and 36 hours after operation all showed a trend of rising first and then decreasing, and the order at each time point was:  $A < C < B$ . The patients with larger tumor, more tumors, longer procedure and ablation time experienced more pain ( $P < 0.05$ ). There were no major complications occurred among the three groups.

## CONCLUSION

s For patients not suitable for or unwilling to undergo general anesthesia, combined multiple anesthesia is an effective and safe way to control pain during and after microwave ablation of liver tumors. Factors influencing pain during microwave ablation include tumor size, number of tumors, procedure time, ablation time and shortest distance from lesional edge to live capsule.

## CLINICAL RELEVANCE/APPLICATION

Percutaneous thermal ablation is now a frontline treatment option for liver tumors. During the procedure, general anesthesia and conscious sedation are often used for pain control. But some patients can't use general anesthesia. Regional anesthesia is a crucial component of anesthesia. Especially in the last 2 or 3 decades, the practice of regional anesthesia regimens has changed considerably and it is extensively be applied to provide peri-procedural pain control. Our study presents a feasibility and safety study of combined multiple regional anesthesia (CMRA) in an effort to reduce pain and intravenous analgesic requirements during and following the ultrasound guided microwave ablation (US-guided-MWA) of liver tumors. For patients not suitable for or unwilling to undergo general anesthesia, CMRA is an effective and safe way to control pain during and after US-guided-MWA of liver tumors.

### **T5A-SP1R-3 Radiofrequency Ablation Followed by Cavity Creation and Cement Augmentation with Steerable Devices in the Management of Painful Spinal Metastases**

Participants

Claudio Pusceddu, MD, Cagliari, Italy (*Presenter*) Nothing to Disclose

## PURPOSE

In the treatment of spinal metastases, cement distribution following radiofrequency ablation can be unpredictable due to several tumor factors. Achieving satisfactory filling of the vertebrae requires advanced devices to prevent cement leakage. This study aimed to assess the safety and efficacy of using steerable technologies with an articulating radiofrequency ablation (RFA) probe and targeted cavity creation before vertebral augmentation to manage painful spinal metastases.

## METHODS AND MATERIALS

Sixteen patients (mean age, 67 years) underwent RFA with vertebral augmentation after the creation of a targeted balloon cavity for metastatic spinal disease. The patients were followed up for six months, and pain and functional mobility were assessed pre-treatment and post-treatment using the Visual Analogue Score (VAS) and Functional Mobility Scale (FMS). Data on complications, predictability of cement distribution, anatomical restoration, and local recurrence were collected. Technical success was defined as successful intraoperative ablation and predictable cement distribution after cavity creation without major complications.

## RESULTS

Sixteen patients with 21 lesions in the thoracolumbar spine were treated. All treatments were technically successful and were followed by targeted cavity creation and vertebral augmentation. A significant reduction in median VAS score was observed one week after RFA treatment ( $p < 0.001$ ). Of the seven patients who reported limited painful ambulation before treatment, six reported normal ambulation one month after treatment, while the remaining patient reported no improvement. Patients who reported wheelchair use before treatment improved to normal ambulation (four/eight) or limited painful ambulation (four/eight). The improvement in mobility before and after treatment was statistically significant ( $p = 0.002$ ). Technical success was achieved in all the combined procedures.

## CONCLUSION

s The combination of RFA and vertebral augmentation with a steerable platform that allows the creation of a targeted cavity before cement injection is a safe and effective procedure for managing painful spinal metastases. The procedure resulted in improved quality of life as assessed by the VAS and FMS.

## CLINICAL RELEVANCE/APPLICATION

New technique combined with steerable devices to cement and treat complex vertebral metastases with radiofrequency ablation

### **T5A-SP1R-4 Minimally Invasive Treatment of Vertebral Metastases with Combined CT-Guided Percutaneous Microwave Ablation, Pedicle Screw Fixation, and Vertebroplasty**

## PURPOSE

The purpose of this retrospective study was to assess the safety and effectiveness of the combined approach of percutaneous microwave ablation (MWA) guided by CT and pedicle screw fixation followed by vertebroplasty (MASFVA) for the treatment and stabilization of painful vertebral metastases involving vertebral pedicles.

## METHODS AND MATERIALS

We retrospectively evaluated the records of 11 patients with 16 vertebral metastatic lesions who underwent MASFVA between January 2015 and January 2018. The technical success, complication rate, and pain relief using the visual analogue scale (VAS) and Oswestry Disability Index (ODI) were analyzed along with local tumor control.

## RESULTS

Technical success was achieved in all cases without any significant complications. The VAS and ODI scores improved significantly after the procedure (VAS from  $6.8 \pm 0.7$  to  $0.6 \pm 0.6$  and ODI from  $3.1 \pm 0.7$  to  $1.2 \pm 0.4$ ). All patients could walk independently without neurological complications one week after the procedure. During the 12-month follow-up, no new bone fractures or local disease recurrence occurred.

## CONCLUSION

s The combination of MWA, percutaneous pedicle screw fixation, and vertebroplasty is a safe and effective treatment for painful vertebral metastases with vertebral pedicle involvement, providing both pain relief and local tumor control.

## CLINICAL RELEVANCE/APPLICATION

First description of combined treatment of vertebroplasty, microwave ablation and pedicle fixation in complex vertebral metastases

with pedicle extension.

## **T5A-SPIR-5 Evaluation of Ice-ball Size and Temperature Change During Cryoablation in a Lard Phantom**

### **PURPOSE**

Cryoablation is a minimally invasive technique to treat various kinds of soft tissue tumors. It may be applied in tissues with various water and fat composition. Whether the fat concentration of the ablation target or environment will influence the ice-ball size and temperature change has not yet been explored. In this in-vitro study, we aim to evaluate how different concentrations of lard affect temperature change and ice ball size during cryoablation.

### **METHODS AND MATERIALS**

We constructed a phantom with 6 glass bottles, including one bottle of 0.9% normal saline (NS) as control, and the others contains 100ml of agar phantoms with lard and NS mixed in five different fractions (0%, 10%, 40%, 70% and 100% of lard). A total of 6 Endocare V-Probes (Cryocare cryoablation system, Varian Medical system, Palo Alto, California, US), with 2.5cm cool-tip, were placed into each bottle aiming at the center. The freezing started simultaneously in 6 bottles with a starting temperature at 20°C. The temperature readings of the probes were documented every 10 seconds during the 9-minute freezing. Axial CT scans of the bottles were done before and 3, 6, 9 minutes after initiation of freezing, and the largest diameter of the ice-ball in each bottle was measured with the longitudinal view (coronal view) in the 1mm reconstructed image.

### **RESULTS**

The probe temperature of the NS and 0% lard agar phantom (which contains 0.9% NS agar) have a similar freezing rate, reaching -80°C at about 320 seconds of freezing, and stabilized until 540 second. The rest of the agar phantoms that contain lard showed an increased freezing rate with increased concentration of lard, and all stabilized at around -150°C after 490 seconds of freezing until 540 second. The ice ball diameter was largest in the 0% and 10% lard agar phantom, both reaching 3.4 cm at 9 minutes of freezing. We observed a marked decrease in diameter of the ice ball with increased concentration of lard, with only 0.9cm at 9 minutes in the 100% lard agar.

### **CONCLUSION**

s Different concentrations of lard may affect the temporal temperature change and ice ball size during cryotherapy.

### **CLINICAL RELEVANCE/APPLICATION**

This ex-vivo study demonstrated that the fat composition may influence the temperature change and ice-ball size during cryoablation and should be taken into consideration when treatment planning.

## **T5A-SPIR-6 Oligoprogression in Neuroendocrine Liver Metastases - CT-guided HDR-brachytherapy to Delay Systemic Therapy Escalation**

### **Participants**

Uli Fehrenbach, MD, Berlin, Germany (*Presenter*) Grant, Siemens AG; Grant, Bayer AG; Grant, Ipsen SA; Grant, Asahi Intecc Co, Ltd; Grant, ESGAR; Grant, General Electric Company

### **PURPOSE**

Heterogeneous growth behavior of hepatic metastases are not uncommon in gastroenteropancreatic neuroendocrine tumors (GEP-NETs). Rapid progression of one or two metastases make therapy escalation necessary despite the otherwise stable disease. If these progressive metastases could be controlled by local therapy, the patients could be managed further with their current strategy. The present study aims on determining the period by which CT-guided high-dose-rate brachytherapy (CT-HDR-BT) of rapidly growing liver metastases can delay the indication of systemic therapy escalation.

### **METHODS AND MATERIALS**

In this retrospective, monocentric observational study a total of 23 patients from our ENETS center of excellence were retrospectively included. A total of 37 CT-HDR-BT sessions were performed in these patients. In addition to the parameters described in previous studies (local tumor control (LTC), progression-free survival (PFS), overall survival (OS)), this study evaluated the delay of a systemic therapy escalation.

### **RESULTS**

Median follow up was 46 months. 82% OS was shown after 102 months. Mean LTC was 64 months (95%-CI: 55-74; median was not reached), median PFS (not RECIST based) was 6 months (95%-CI: 2-10) and mean OS was 75 months (95%-CI, 55-96; median not reached). No further escalation of therapy (Watch and wait- and/or SSA-therapy) after CT-HDR-BT was necessary in 6/23 cases (26%). A median delay of 19 months (median; 95%-CI, 9-29 months) to the escalation of systemic therapy could be achieved.

### **CONCLUSION**

s In oligotopic progression of liver metastases and otherwise stable disseminated GEP-NET, CT-HDR-BT as a safe one-time procedure can delay the onset of systemic therapy escalation. This offers a significant interval without drug related side effects and costs and saves the patients systemic treatment options for a later date.

### **CLINICAL RELEVANCE/APPLICATION**

Our study reveals that CT-HDR-BT can significantly postpone the need for systemic therapy escalation in patients with oligotopic progression of neuroendocrine liver metastases. This approach offers patients a valuable interval without the burden of drug-related side effects and associated costs, while also preserving other therapeutic options for future disease progression. As systemic therapy options for this condition are limited, CT-HDR-BT may prove to be a safe and effective alternative in select cases.

## **T5A-SPIR-7 Synergistic Effect of OK-432 in Combination with Anti-PD-1 Antibody for Residual Tumors after Radiofrequency Ablation of Hepatocellular Carcinoma**

### **PURPOSE**

Radiofrequency ablation (RFA) is widely used in clinical practice for solid malignant tumors. However, for medium-to-large or irregular tumors, RFA often suffered from incomplete tumor ablation. To solve this clinical problem, we proposed a new treatment strategy of OK-432 in combination of anti-programmed cell death protein 1 (aPD-1) antibody to treat the residual tumors after incomplete RFA (iRFA) of hepatocellular carcinoma (HCC).

## **METHODS AND MATERIALS**

The effect of OK-432 on immature dendritic cells (iDCs) was evaluated by flow cytometry analysis, western blot, and ELISA in vitro. CCK-8 kit and ELISPOT were used to assess the killing effect of OK-432-induced CD8+ T cells in combination with aPD-1 antibody for hepa1-6 cells. In vivo experiment, the mouse models with HCC were treated by: (1) pseudo iRFA+phosphate buffered saline (PBS); (2) iRFA+PBS; (3) iRFA+OK-432; (4) iRFA+aPD-1; (5) iRFA+OK-432+aPD-1. Tumor progression was assessed by ultrasound imaging, which was confirmed by subsequent histopathology. The immune response to the treatments was evaluated by flow cytometry analysis, immunohistochemical staining, and ELISA.

## **RESULTS**

OK-432 significantly increased the maturation level of DCs and the abundance of conventional type 1 DCs (cDC1s). OK-432-induced CD8+ T cells in combination with aPD-1 antibody significantly enhanced the killing ability of CD8+ T cells for hepa1-6 cells. The combined therapy of OK-432 with aPD-1 antibody significantly increased the infiltration and function of CD8+ T cells, and significantly decreased the number of FoxP3+ regulatory T cells in residual tumors after iRFA of HCC. The smallest tumor volumes and the longest survival were observed in the iRFA+OK-432+aPD-1 antibody group compared with other four groups.

## **CONCLUSION**

s The combined therapy of OK-432 with aPD-1 antibody induced a strong anti-tumor immune response, which significantly inhibited the residual tumors after iRFA of HCC.

## **CLINICAL RELEVANCE/APPLICATION**

This concept may provide a new strategy to increase the curative efficacy of RFA for medium-to-large or irregular HCCs.

T5A-SPMK

### Musculoskeletal Imaging Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPMK-1 Application of Magnetic Resonance Diffusion Kurtosis Imaging in Microstructural Complexity of the Pubovisceral Muscle in Pelvic Floor Dysfunction Female**

##### Participants

Huiqing Zhou, Jinan, China (*Presenter*) Nothing to Disclose

##### PURPOSE

This study aimed to explore the microstructural complexity of the pubovisceral muscle in patients with pelvic floor dysfunction using the DKI technique.

##### METHODS AND MATERIALS

Fourteen patients with pelvic floor dysfunction [aged 47-67 years, mean (50.5±2.4) years] were included as group A. Twenty-six young healthy nulliparous female volunteers [aged 22-33 years, mean (25±2) years] were included as group B, and seven healthy middle-aged multiparous female volunteers [aged 46-69 years, median age 51 years] were included as group C. All three groups underwent DKI examination, and the parameter values of each group were measured and compared by three physicians with 5 years above of MRI diagnostic experience. The inter-observer consistency was evaluated using the Kendall W coefficient, and the differences in the measurement values of each parameter among the researchers were compared using single-variable ANOVA. Independent sample t-tests or U-tests were used to compare the differences in parameter values of the left and right pubovisceral muscle and DK parameters among the three groups.

##### RESULTS

The DKI parameter values of both pubovisceral muscles in the three groups were successfully measured. The consistency among the three observers was good, with W coefficients of 0.834-0.994 for the parameter values of both pubovisceral muscles. There was no significant statistical difference in the measurement values of the parameters of the bilateral pubovisceral muscles among the three physicians, with P values of 0.155-0.978. There was no significant statistical difference in the parameter values of the left and right pubovisceral muscles within each group, with P values of 0.224-0.957. There were statistically significant differences in the DK parameters (MK, AK, RK) between group A and group B for the left and right pubovisceral muscles ( $P < 0.001$ ), There were statistically significant differences between group A and group C for bilateral AK and RK, and left-side MK values ( $P < 0.05$ ), There were statistically significant differences between group B and group C for bilateral RK values ( $P < 0.05$ ).

##### CONCLUSION

s DKI can detect microscopic differences in the pubovisceral muscle between patients with pelvic floor dysfunction and normal individuals. DKI has high sensitivity and can detect changes in the microstructure of tissues in the absence of significant morphological or signal changes.

##### CLINICAL RELEVANCE/APPLICATION

DKI technology is widely used and well-established in central nervous system. Drawing on its application in brain tissue, this study applied DKI technology to the pelvic floor muscles and evaluated the DKI parameter values of pubovisceral muscle in healthy young females, females with pelvic floor dysfunction, and healthy middle-aged females.

#### **T5A-SPMK-2 Neurovascular Crossovers between Leash of Henry and Deep Branch of Radial Nerve: Implications for Diagnostic Imaging and Neurointervention**

##### Participants

Aurea Mohana-Borges, MD, MSc, (*Presenter*) Nothing to Disclose

##### PURPOSE

To identify the crossing patterns of the LoH and DBRN, specifically the ascending branch of the radial recurrent artery (RRAab) and the transverse muscular vessels to the mobile wad by high-resolution ultrasound (HRUS), using B-mode and Doppler.

##### METHODS AND MATERIALS

In this cross-sectional study, HRUS was performed in the short axis of the DBRN in asymptomatic participants, bilaterally and in two different forearm positions (pronation and supination), enrolled over a 6 month period. Inclusion criteria included asymptomatic volunteers of both genders over 15 years of age. Exclusion criteria were as follows: a) previous interventional procedure or surgery in the radial tunnel and elbow, and b) incidental masses compressing the nerve. HRUS was performed with an 18-5 MHz linear transducer (Philips, Affiniti 50) by a single musculoskeletal radiologist with more than 20 years of experience. B-mode and Doppler cine clips taken in the short axis of the nerve were acquired and saved for offline analysis. Images were evaluated in consensus by two radiologists. The crossings were evaluated in the nerve segment between the origin from the radial nerve to the superior arcade of the supinator muscle. They were classified as occurring above or below the DBRN. The pattern was characterized as

unrelated when no observed vessel was seen crossing the nerve. Welch's test was used as appropriate.

## RESULTS

The study population consisted of 102 nerves from 55 asymptomatic participants (median age, 37.0 years; interquartile range [IQR], 23.5 - 51.0 years; age range, 16-63 years; 29 [52.7%] women), with 48 participants with bilateral evaluation. Eight DBRN relationships were excluded from the analysis because of Doppler unavailability (N= 6 limbs, 3 right sides) and the undetectability of the muscular branch on B-mode (N= 2 limbs bilaterally). Age was not significantly different between women (median 37 years, IQR, 24.0 - 50.0 years) and men (median 36.5 years, IQR, 22.8 - 52.8 years) with  $p=0.74$ . The neurovascular crossings were as follows: a) RRAab above DBRN = 15 (14.7%) and muscular branch above= 12 (11.7%), below= 0 (0%), and unrelated= 3 (2.9%), and b) RRAab below DBRN = 87 (85.3%) and muscular branch above= 53 (52.0%), below= 28 (27.4%), and unrelated= 6 (5.9%).

## CONCLUSION

There is a predominant pattern of neurovascular crossings, with the RRAab mainly crossing below the DBRN from an inferomedial position and the transverse vessels of LoH crossing above the nerve, proximal to the arcade of Frohse.

## CLINICAL RELEVANCE/APPLICATION

Anatomic variations in the relationship of the neurovascular crossover of the Leash of Henry (LoH) and the deep branch of the radial nerve (DBRN) are relevant for diagnostic imaging and interventional procedures, but poorly described in the literature.

## T5A-SPMK-3 Undifferentiated and Preclinical Rheumatoid Arthritis and Longitudinal Thigh Muscle Loss: Deep-Learning Derived Data from Osteoarthritis Initiative

### PURPOSE

Undifferentiated Arthritis (UA) and Preclinical Rheumatoid Arthritis (Pre-RA) are considered as early-stage inflammatory arthropathy before clinical RA occurrence. Pre-RA is retrospectively defined as the early stage prior to development of clinical RA. UA is defined as a type of arthritis when criteria for RA or other connective tissue diseases are not met. UA/Pre-RA could potentially cause generalized muscle degeneration by provoking systemic inflammation and autoimmunity akin to established RA that is clearly associated with Rheumatoid Cachexia. Aim of this study was to investigate the association of UA/Pre-RA with longitudinal changes in muscle quality.

### METHODS AND MATERIALS

All the 4,796 participants of the Osteoarthritis Initiative (OAI) were initially included as established RA were excluded from this cohort. OAI participants were categorized to UA, Pre-RA (not exclusionary to the OAI), and control groups in baseline (Fig. 1). Longitudinal 4-year changes of thigh muscles quality in Pre-RA and UA groups were compared with their propensity score (PS)-matched control groups. PS matching was conducted to minimize the potential effect of confounding variables. For measurement of thigh muscle quality, we used our previously validated deep learning model to segment and quantify all available MRIs of thigh muscles at baseline, year 2-4 of the cohort. Outcome measures were MRI biomarkers of thigh muscle mass [i.e., cross-sectional area (CSA)] and composition [i.e., intramuscular adipose tissue (intra-MAT) and contractile percentage (non-fat muscle CSA/total muscle CSA)] in the thigh muscle groups (Fig. 2).

### RESULTS

After PS-matching of the groups for confounding variables (Table 1), regression models of comparison of MRI biomarkers of total thigh muscles between Pre-RA and control group over a 4-year period showed that presence of Pre-RA is associated with decreased CSA (MD, 95% CI: -220.12 mm<sup>2</sup>, -310.58 - -129.66) but a similar change in intra-MAT (MD, 95% CI: 11.57 mm<sup>2</sup>, -167.16 - 190.30) and contractile percentage (MD, 95% CI: -0.50 %, -1.98 - 0.97) (Table 2). On the other hand, comparison of MRI-derived biomarkers between UA and matched control group showed that neither of changes in CSA, intra-MAT, and contractile percentage are significantly different between the groups (Table 2).

### CONCLUSION

Presence of Pre-RA is associated with a longitudinal decrease in CSA but not increase in Intra- or Inter-MAT akin to rheumatoid cachexia seen in established RA patients. Causal effect of Pre-RA on muscle quality requires further attention.

### CLINICAL RELEVANCE/APPLICATION

Results of this study could promote the role of secondary preventive treatment (e.g., low dose DMARD) to mitigate accelerated muscle degeneration among Pre-RA subjects.

## T5A-SPMK-4 Improving Sonographic Visualization of the Ulnar Nerve and Morphology

### PURPOSE

Cubital Tunnel Syndrome (CuTS) is defined as ulnar nerve compression in the cubital tunnel of the elbow, the second most common upper extremity peripheral nerve entrapment. CuTS often remains undiagnosed until patients present with progressive motor deficits, usually indicating severe nerve injury. Quantitative diagnostic criteria for ultrasound have been developed for other nerve entrapment syndromes, including carpal tunnel syndrome, however greater variability of diagnostic criteria is in use for the diagnosis of CuTS. New transducer technology may enable better imaging of the ulnar nerve and development of new diagnostic criteria for CuTS. Our study aimed to objectively evaluate this newer transducer technology compared to conventional transducers in the evaluation of the ulnar nerve and to assess a reproducible ratio for more reliable nerve measurement.

### METHODS AND MATERIALS

Seven fresh frozen cadaveric specimens were examined using both 18 MHz and 24 MHz transducers (GE Healthcare, Milwaukee, WI). The number of ulnar nerve fascicles was measured in each specimen just proximal to the cubital tunnel with both transducers. Two examiners assessed the number of nerve fascicles with consensus agreement reached on the final count. The cross-sectional area of the ulnar nerve was measured proximally at both the cubital tunnel and distally at the anatomical location where the ulnar artery and nerve meet in the distal forearm.

### RESULTS

The 24 MHz probe visualized more fascicles of the ulnar nerve (mean 8.7, std dev 2.3) compared to the 18 MHz transducer (mean

4.4, std dev 2.7,  $p < 0.005$ ). The mean of the proximal ulnar nerve cross-sectional area (CSA) measured 7.08 mm (std dev 2.40). The mean distal ulnar nerve CSA was 5.08 mm (std dev 1.21,  $p = 1.21$ ). The cross-sectional area of the proximal ulnar nerve was not found to be statistically different compared to the distal CSA of the ulnar nerve, 7.1 mm<sup>2</sup> (std dev 2.4) vs. 5.1 mm<sup>2</sup> (std dev 1.2),  $p = 0.112$ .

## CONCLUSION

A higher frequency 24 MHz transducer can visualize more fascicles of the ulnar nerve at the cubital tunnel compared to a conventional 18 MHz transducer. Utilizing this 24 MHz transducer, there was no statistical difference in the measurement of the cross-sectional area of the ulnar nerve proximal and distal to the cubital tunnel in our cadaver specimens. Further investigation of ulnar nerve morphology and of the ratio of nerve measurement of symptomatic cubital tunnel syndrome patients and normal controls with new higher frequency transducers may enable the development of better diagnostic criteria for CuTS.

## CLINICAL RELEVANCE/APPLICATION

Nerve fascicle count and size in addition to the use of nerve ratios for size assessment may help to more accurately differentiate demyelinating neuropathies from nerve entrapment.

## T5A-SPMK-5 Improved Visualization of the Brachial Plexus MR Neurography with Deep Learning Reconstruction in Conventional and Accelerated Sequences: Study of Healthy Volunteers

Participants  
ILKWON KO, Bucheon, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

To prospectively compare the effectiveness of deep learning reconstruction (DLR) for brachial plexus MR imaging with that of a conventional and accelerated MR imaging protocol in healthy volunteers.

## METHODS AND MATERIALS

This prospective study included 14 healthy volunteers (7 men, 7 women; mean age,  $24.3 \pm 3.5$  [SD] years) who underwent 3-T brachial plexus contrast enhanced STIR sequence. Examinations included conventional sequence with parallel factor (PF) 3 (scan time, 7 minutes 5 seconds) and accelerated sequences with PF 5 (4 minutes 39 seconds), Standard (PF3) and accelerated sequences (PF 5) were acquired with and without DLR. Two musculoskeletal radiologists qualitatively evaluated examinations for brachial plexus visualization (1-3, none to full), and motion artifact, visualization of the supraspinatus and axillary nerve (1-4, none to complete), which was scored individually at three separate regions along the brachial plexus: supraclavicular (extraforaminal roots, trunks, and proximal divisions), retroclavicular (distal divisions), and infraclavicular (cords). Interobserver agreement between two readers for the image quality were assessed using weighted kappa statistics. Comparisons of quantitative scores were performed with use of student T-test.  $P < .05$  was deemed statistically significant.

## RESULTS

A total of 28 brachial plexus images were included in 14 subjects. Standard (PF3) and accelerated sequences (PF 5) with DLR enabled significantly improved visualization of the brachial plexus ( $P < .001$ ) and motion artifact ( $P < .05$ ) in the all three regions for two readers except for PF3 at the supraclavicular area ( $p = 0.09$ ) and retroclavicular area ( $p = 0.06$ ) in reader 1. For visualization of the axillary nerve, only PF5 with DLR images significantly improved image quality ( $p = 0.007-0.037$ ). However, there was no improvement in image quality with DLR for visualization of suprascapular nerve in PF3 and PF5 ( $p = 0.07-0.71$ ) except for PF3 at the retroclavicular area in reader 2 ( $p = 0.0014$ ). Agreement between image two readers ranged from a kappa of 0.5-0.83 in brachial plexus visualization 0.5-0.77 in motion artifact, 0.59-0.91 in suprascapular nerve and 0.58-0.85 in axillary nerve.

## CONCLUSION

Accelerated sequences with DLR effectively reduce scan time and artifacts, providing similar subjective image quality to conventional sequences for brachial plexus MR imaging.

## CLINICAL RELEVANCE/APPLICATION

Accelerated sequences with DLR may provide an alternative to standard sequences for clinical brachial plexus MRI

## T5A-SPMK-6 The Diagnostic Value of Multimodal Imaging for Primary Lower Limb Lymphedema

Participants  
MENGKE LIU, BEIJING, China (*Presenter*) Nothing to Disclose

## PURPOSE

To retrospectively analyze the imaging characteristics of primary lower limb lymphedema on CT and MRI multi-modal sequences, compare the diagnostic value of multi-modal imaging examinations for lower limb lymphedema, and identify the optimal techniques or methods for displaying lymphedema.

## METHODS AND MATERIALS

A retrospective analysis was conducted on patients with primary lower extremity lymphedema (LEL) admitted to our lymphatic surgery department from January to December 2019. All patients underwent both CT and MRI examinations of the lower extremities. The MRI multi-modal sequences included Short Time Inversion Recovery (STIR) and mDIXON sequences. Image analysis and scoring were independently performed by two radiologists, including assessment of skin thickening, fat separation, fascial effusion (effusion above and below the fascia). Skin thickening was defined as dermal thickness  $> 2$ mm; fat separation was defined as abnormal signal and density shadows distributed in a mesh-like or honeycomb-like pattern around the fat lobules; fascial effusion was defined as abnormal signal or density shadows in a strip or crescent shape on the fascial surface or below the fascia. The frequency of appearance of CT and MR manifestations in the affected limb was recorded. The sensitivity of lesions displayed by CT and MR sequence were evaluated as clear, general, or unidentifiable, and the best imaging method for displaying edema was selected. The frequency differences of multi-modal imaging manifestations of lower extremity lymphedema were compared using chi-square test or Fisher's exact test.

## RESULTS

A total of 36 patients were included in the study. There was no statistically significant difference in the detection rate of skin thickening among other imaging methods ( $P>0.05$ ). The detection rate of fascial superficial lymphatic fluid by mDIXON-FAT was significantly lower than that by other imaging methods ( $P<0.05$ ), and there was no statistically significant difference in the detection rate of fascial superficial lymphatic fluid among other imaging methods ( $P>0.05$ ). STIR had higher sensitivity than CT and mDIXON sequences for detecting fat septa, subfascial/epifascial effusion, and dilated tubular shadows

## CONCLUSION

s Multi-modal imaging has high diagnostic value for primary lower extremity lymphedema. The STIR sequence is more sensitive than other CT and MRI sequences for detecting primary lower extremity lymphedema, and can be used as the preferred imaging sequence for the diagnosis and evaluation of lymphedema

## CLINICAL RELEVANCE/APPLICATION

Multi-modality imaging can accurately diagnose primary lower extremity lymphedema, with STIR sequence having the highest sensitivity for detecting edema

## T5A-SPMK-7 Optimization of keV for Radiomics Extracted from Spectral Virtual Monochromatic Images to Predict Osteoporosis

Participants

Jinling Wang, Changsha, China (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the effect of radiomics obtained from different virtual monochromatic images (VMIs) by dual-energy computed tomography (CT) on the prediction of osteoporosis.

## METHODS AND MATERIALS

A retrospective study of 62 participants who underwent both single source dual-energy CT and quantitative computed tomography (QCT) lumbar-spine examination were enrolled. With QCT as the reference standard, the patients were divided into two groups according to the guidelines introduced by the International Society for Clinical Densitometry (ISCD) and American College of Radiology (ACR), osteoporosis ( $n=16$ ) of the spine was defined as a BMD value  $<80$  mg/cm<sup>3</sup>, and non-osteoporosis ( $n=46$  [osteopenia and normal]) was defined as a BMD value  $\geq 80$  mg/cm<sup>3</sup>. Radiomics scores (RSs) for osteoporosis prediction were constructed from 11 sets of VMIs (40-140 keV, 10 keV interval). Receiver operating characteristic (ROC) curves were drawn and the area under the curves (AUCs) was calculated to evaluate the discriminatory power of RS for each VMI.

## RESULTS

The AUC values for osteoporosis prediction with RS of 40-140 keV VMIs were 0.995, 0.996, 1.000, 1.000, 1.000, 1.000, 0.793, 0.787, 0.807, 0.821, 0.846. The accuracies of RS of VMIs were 0.952, 0.968, 0.984, 1.000, 1.000, 1.000, 0.705, 0.721, 0.746, 0.742, 0.770. The sensitivities of RS of VMIs were 0.882, 0.938, 0.941, 1.000, 1.000, 1.000, 0.400, 0.375, 0.444, 0.444, 0.545. The specificities of RS of VMIs were 0.978, 0.978, 1.000, 1.000, 1.000, 1.000, 0.765, 0.774, 0.796, 0.792, 0.820. The negative prediction values of RS of VMIs were 0.957, 0.978, 0.979, 1.000, 1.000, 1.000, 0.867, 0.891, 0.896, 0.894, 0.891. And the positive prediction values of RS of VMIs were 0.938, 0.938, 1.000, 1.000, 1.000, 1.000, 0.250, 0.200, 0.267, 0.267, 0.400.

## CONCLUSION

s The RS obtained from multiple VMIs in dual-energy CT had a good ability to predict osteoporosis. And the RS of 40-90 keV VMIs showed higher performance than the RS of 100-140 keV VMIs.

## CLINICAL RELEVANCE/APPLICATION

The prevalence of osteoporosis in the population is increasing year by year. One of the reference standards for the diagnosis of osteoporosis today is the volumetric BMD measured by QCT, but the QCT post-processing process is very complex and requires additional phantom calibration, etc. Spectral CT imaging provides VMIs to improve the image quality thereby radiomics efficacy, however the optimized keV for radiomics extraction was still obscure. Our proposed RS models obtained from 40-90 keV VMIs can serve as useful tools for osteoporosis prediction and have the potential to be applied in clinical treatment planning in the future.

## T5A-SPMK-8 Quantitative Analysis of Bone Mineral Density in Patients with Chronic Kidney Disease by Revolution CT Substance Separation Technique

Participants

Na Gao, Yinchuan, China (*Presenter*) Nothing to Disclose

## PURPOSE

Patients with chronic kidney disease are prone to fracture and other serious complications. Early and accurate measurement of Bone mineral density (BMD), an important index of bone mass in human body, is of great clinical significance for predicting the risk of fracture in patients with CKD. X-ray attenuation images of Revolution CT scanned by high and low voltages can be expressed as density maps of two substances, thus realizing substance separation of single voxel. Therefore, this study explored the value of Revolution CT in the diagnosis of BMD in patients with CKD.

## METHODS AND MATERIALS

Total abdominal energy spectrum plain scan data of 48 patients with CKD were collected. According to the principle of three quantiles, the patients were divided into three groups: Group A (= 48 years old), Group B (49-61 years old) and Group C (= 62 years old). GSI scanning mode combined with 40% ASiR-V, at automatically modulated tube current (Smart mAs), noise index was 9. Using GSI Viewer software, the images of HAP (FAT)-based material pairs were reconstructed from 0.625mm thick images, and the Region of interest (ROI) was placed in the middle layer of L3 vertebral body (ROI was about 100mm<sup>2</sup>), and the HAP concentration was recorded. One-way analysis of variance was used to compare the concentration of HAP in vertebral body of L3 in different age groups of patients with CKD. Pearson correlation analysis was used to analyze the concentration of HAP in vertebral body of L3 in three age groups. The difference was statistically significant with  $P < 0.05$ .

## RESULTS

The concentrations of HAP in vertebrae of L3 were (185.12±11.83)mg/cm<sup>3</sup>, (138.55±12.58)mg/cm<sup>3</sup>, (96.38±10.16)mg/cm<sup>3</sup> in each age group of patients with CKD, and there was statistical differences between three groups(P < 0.05). There was a negative correlation between the age of the three groups and the concentrations of HAP (r=-0.309,-0.211,-0.028, P < 0.05).

## CONCLUSION

s The HAP concentration measured by energy spectrum CT in L3 vertebral cancellous of patients with CKD is related to age, and the HAP concentration in vertebral body of CKD patients gradually decreases with age after 48 years old.

## CLINICAL RELEVANCE/APPLICATION

Revolution CT based material imaging technology provides a new idea for BMD measurement. HAP (FAT) as a base material pair can reflect the change of BMD with age. For patients with CKD, Revolution CT can find the changes of bone mass as early as possible, and provide basis for making personalized diagnosis and treatment plans.

## T5A-SPMK-9 The Effect of Different Monochromatic Energy on Quantitative Parameters of Osteoporosis in Chronic Kidney Disease

Participants

Hua He, MMedSc, Yinchuan, China (*Presenter*) Nothing to Disclose

## PURPOSE

Dual-energy X-ray absorptiometry (DEXA) is the "gold standard" for measuring bone mineral density (BMD). However, this method can not completely and accurately reflect the true changes of bone density. Multi-parameter imaging of energy spectrum CT can provide a new idea for BMD measurement, therefore, this study explored the diagnostic value of different monochromatic energy of Revolution CT in osteoporosis.

## METHODS AND MATERIALS

48 patients with CKD were collected by GSI scanning mode combined with 40% ASiR-V, at automatically modulated tube current (Smart mAs), noise index was 9. Using GSI Viewer software, the HAP (FAT) base material pair image was reconstructed from 0.625mm layer thickness image, and the base material and monochromatic energy joint image were selected. the images of HAP (FAT)-based material pairs were reconstructed from 0.625mm thick images. And the Region of interest (ROI) was placed in the middle layer of L3 vertebral body (ROI was about 100mm<sup>2</sup>, the distance from the edge of vertebral body is at least 5mm, avoiding vertebral venous plexus, bone island and other structures). The HAP concentrations in L3 vertebral body of 120Kvp-like images and 11 groups of monochromatic energy images at 40-140keV (10keV intervals) were recorded. The HAP concentration under different monochromatic energy and mixed energy was analyzed by one-way ANOVA, the difference was statistically significant with P < 0.05.

## RESULTS

The HAP concentration at 70keV and 80keV were (140.01±8.41)mg/cm<sup>3</sup> and (117.05±7.27)mg/cm<sup>3</sup>, respectively, and there was not significantly different from that at 120kvp-like (137.74±4.94)mg/cm<sup>3</sup> (P > 0.05).

## CONCLUSION

s The concentration of HAP in L3 vertebrae of patients with CKD was affected by different single energy of energy spectrum CT, and the concentration of HAP in L3 vertebrae was stable under single energy of 70keV and 80keV.

## CLINICAL RELEVANCE/APPLICATION

Through this study, we can understand the influence of different monochromatic energy on BMD measurement.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

T5A-SPMS

### Multisystem Tuesday Poster Discussions I

#### Sub-Events

#### T5A-SPMS-1 A Cross-sectional Study to Quantify Cardiac, Hepatic and Pancreatic Iron Overload on MR Imaging in Beta Thalassemia Major Patients

#### PURPOSE

Regular blood transfusions are the mainstay in beta thalassemia major; however, it may cause cardiac and hepatic hemosiderosis - the most common cause of death in these patients. Chelation requires constant adjustments to avoid either iron or chelator toxicity. In recent years, various MRI methods have been validated for quantifying iron overload.

#### METHODS AND MATERIALS

31 beta-thalassemia major patients (22 males and 9 females) (age range 8-18 years) receiving regular blood transfusions and chelation therapy were enrolled. Patients were scanned on 3-Tesla MRI and mFFE T2\* and R2\* weighted sequences were acquired with parameters mentioned in Figure 1. LIC and MIC values were calculated using the formulae:  $0.032 \times R2^* - 0.14$  and  $(0.0254 \times R2^*) + 0.202$  respectively. They were then graded as follows: For LIC Normal < 2, Light 2-7, Moderate 7-15, Severe >15. For MIC Normal <1.16, Light 1.16-1.65, Moderate 1.65-2.71, Severe >2.71. For pancreas Normal <30, Mild 30-100, Moderate 100-400, Severe >400.

#### RESULTS

This is an interim analysis of an ongoing study. Liver R2\* had a very weak but insignificant positive correlation with SF levels ( $r = 0.167$ ,  $p = 0.397$ ). Cardiac R2\* had a moderate but significant positive correlation with SF levels ( $r = 0.535$ ,  $p = 0.003$ ). Pancreatic T2\* had a weak but insignificant positive correlation with SF levels ( $r = 0.281$ ,  $p = 0.165$ ). LIC had a very weak but insignificant positive correlation with SF levels ( $r = 0.146$ ,  $p = 0.459$ ). MIC had a moderate but significant positive correlation with SF levels ( $r = 0.427$ ,  $p = 0.024$ ). Liver T2\* had a weak but insignificant positive correlation with serum total bilirubin levels ( $r = 0.258$ ,  $p = 0.223$ ). LIC had a very weak but insignificant positive correlation with SGPT ( $r = 0.170$ ,  $p = 0.439$ ). LIC had a weak but insignificant positive correlation with SGOT ( $r = 0.270$ ,  $p = 0.212$ ). No statistically significant difference in mean SF, LIC and MIC values between 2-weekly, 3-weekly and 4-weekly transfusion regimens.

#### CONCLUSION

LIC had a very weak positive correlation with serum ferritin. Whereas, MIC had a moderate and significant positive correlation with serum ferritin. Pancreatic T2\* and R2\* values had a weak positive correlation with serum ferritin. LIC showed a weak and insignificant positive correlation with liver function tests (LFTs). No statistically significant difference was seen in the mean serum ferritin, LIC and MIC values between 2-weekly, 3-weekly and 4-weekly transfusion regimens. However, a larger sample size is required to determine true statistical significance and we plan to achieve the same in the near future.

#### CLINICAL RELEVANCE/APPLICATION

At present, our study shows that T2\*/R2\* MRI prove to be a valuable non-invasive method for evaluating iron overload, especially when compared to a liver biopsy.

## Abstract Archives of the RSNA, 2023

T5A-SPNMMI

### Nuclear Medicine & Molecular Imaging Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPNMMI-1 Differential FDG Uptake in the Brain at Early and Delayed Imaging Assessed by Dual Time-point Total-body PET**

##### Participants

Shashi Singh, MD, Palo Alto, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

The purpose of the study was to examine the changes in the global FDG uptake in the brain from early to delayed scans in dual time-point imaging (DTPI) before and after treatment in patients with lymphoma, using total-body PET/CT. We also assessed uptake in the brain before and after 2 cycles of chemotherapy.

##### METHODS AND MATERIALS

FDG-PET/CT data from 20 patients referred for initial staging of non-Hodgkin's lymphoma at UC Davis- age 12 to 74.9 years (mean =  $44.12 \pm 19.70$  years; males = 9; females = 11) were analyzed. It included 40 scans conducted 60 and 120 minutes following intravenous injection of 8 mCi of FDG. Interim scans after 2 cycles of chemotherapy (6/20 patients) were assessed at both 60 and 120 minutes after injection of 8 mCi of FDG. The FDG-PET/CT scans were analyzed using OsiriX MD software v. 12.5.2 (Pixmeo SARL, Bernex, Sweden). A region of interest was manually placed on fused PET/CT images for global assessment of FDG uptake in the entire brain, including the supratentorial region, cerebellum, midbrain, and medulla but excluding spinal cord. Metabolic activity was assessed by calculating global SUVmean across all slices. Finally, global SUVmean scores were compared at 60 and 120 minutes of scan in both baseline and post-treatment scans.

##### RESULTS

For the baseline scans, an overall increase in FDG uptake in the brain was observed from 60 minutes to 120 minutes. The average SUVmean at 60 minutes was  $7.48 \pm 2.10$  (range: 3.81 to 11.99) whereas at 120 minutes was  $8.51 \pm 2.32$  (range: 4.36 to 12.88) at baseline. The difference in the average SUVmean at 120 minutes and 60 minutes was found to be  $1.03 \pm 0.66$  (range: 0.45 to 3.17) ( $p < .00001$ ) and the average 60-120 min percent change was  $14.32 \% \pm 10.25 \%$  (range: 7.28 % to 53.21 %). Similarly, for post-treatment scans, an overall increase in FDG uptake in the brain was observed from 60 minutes to 120 minutes. The average SUVmean at 60 minutes was  $6.97 \pm 2.45$  (range: 3.71 to 10.43) whereas at 120 minutes was  $7.56 \pm 2.47$  (range: 4.40 to 11.18). The difference between the average SUVmean at 120 minutes and 60 minutes was found to be  $0.59 \pm 0.30$  (range: 0.006 to 0.84) ( $p = 0.00518$ ) and the average 60-120 min percent change was  $9.64 \% \pm 6.21 \%$  (range: 0.08 % to 18.76 %).

##### CONCLUSION

s FDG uptake in the brain increases from 60 minutes to 120 minutes during DTPI of the brain with total body FDG PET/CT. Therefore, early imaging of the patients with suspected brain tumors may help to identify the lesions more clearly than delayed imaging due to relatively lower background uptake. In addition, this study demonstrated an initial possible decrease in brain uptake after 2 cycles of chemotherapy.

##### CLINICAL RELEVANCE/APPLICATION

It may be possible to distinguish the lesions more clearly with early imaging than with delayed imaging in patients with suspected brain tumors.

#### **T5A-SPNMMI-2 Comparison of Diagnostic Image Quality and Radiation Dose of Directly Contrast-enhanced CT for FDG-PET Image Attenuation and Co-registration to Sequential Non-enhanced PET/CT Followed a Dedicated Diagnostic CT**

##### PURPOSE

To compare diagnostic image quality and extent of attenuation correction artifacts due to iodinated contrast in PET images and total radiation dose of the CT-component of sequential partial body (head to thigh) non-enhanced CT F-18 Fluorodeoxy (FDG) - PET/CT followed by a dedicated diagnostic contrast-enhanced CT (thorax/abdomen/neck) (cePET/CT) protocol to directly intravenous contrast-enhanced FDG-PET/CT protocol (head to thigh) (dicePET/CT) in the same oncological patient population.

##### METHODS AND MATERIALS

An inter-group comparison of 48 patients (m=20, f=28, initial mean age 65.8 y; 33-81 y) undergoing cePET/CT and dicePET/CT in clinical oncological routine on the same PET/CT scanner (Siemens mCT128) within an average of 529 d (76 - 949d) were compared. PET-image quality were objectively (standard uptake value SUVc cerebellum, SUVbp blood pool, SUVlu lung and SUVli liver) and subjectively evaluated for the presence of attenuation artifacts. Average effective CT radiation dose (aeCTRD) of the CT component for both groups were determined.

##### RESULTS

Average dose for scePET/CT and dcePET/CT was 3.48 and 3.50 MBq/kg, respectively. Significant attenuation artifacts in PET image quality was seen in both groups only by mis-match in the brain and liver (n=2) not in the vasculature. No significant differences were found in the SUV values for the scePET/CT and dcePET/CT - SUVc 12.3 vs. 12.3 (p=0.93), SUVbp 3.0 vs. 3.2 (p=0.07), SUVlu 0.80 vs. 0.85 (p= 0.13), SUVli 3.9 vs. 4.1 (p= 0.08). aeCTRD for scePET/CT and dcePET/CT was 15.03 mSv vs. 7.08 mSv, respectively (Difference 52.3%).

## CONCLUSION

s If a ceCT in the FDG-PET/CT protocol is needed, a direct contrast enhanced CT protocol is favorable due to significant radiation dose reduction without constraints in PET image quality and quantitative analysis since a non-enhanced CT head-to-thigh for attenuation correction can be omitted and attenuation artifacts due to intravenous enhancement is negligible.

## CLINICAL RELEVANCE/APPLICATION

If a ceCT in the FDG-PET/CT protocol is needed, a direct contrast enhanced CT protocol is favorable due to significant radiation dose reduction.

## T5A-SPNMMI-3 Evaluating the Ability of ChatGPT to Create a Differential Diagnosis from Transcribed Radiological Findings in Nuclear Medicine

Participants

Gillean Cortes, DO, Orange, CA (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the accuracy and reliability of ChatGPT3.5 and ChatGPT4 in creating a differential diagnosis from transcribed radiological findings of specific nuclear medicine cases.

## METHODS AND MATERIALS

A sample of 50 cases specific to nuclear medicine imaging was selected from a radiology textbook, from which the answers were used as the gold standard. The history and case images were converted into standardized prompts that contained purely descriptive language of the cases and a query for the most likely diagnosis, the top three differential diagnoses, and the corresponding explanations and references from the medical literature. These prompts were entered into the ChatGPT3.5 and ChatGPT4 algorithms. The output diagnoses were analyzed for accuracy by comparison with the original literature and reliability through manual verification of the generated explanations and citations. The top 1 accuracy and the top 3 accuracies were defined as the percentage of generated responses that matched the original diagnosis and the complete differential provided by the original literature. An additional differential diagnosis score was defined as the proportion of differentials that matched the original literature's answers for each case. Comparisons were made between the results of the two algorithms using a one-tailed two proportion z-test method.

## RESULTS

The top 1 accuracy and top 3 accuracy for ChatGPT3.5 versus ChatGPT4 were 60.0% compared to 70.0% (p = 0.15) and 12.0% compared to 10.0% (p = 0.37), respectively. The average differential diagnosis score of ChatGPT3.5 versus ChatGPT4 was 58.1% compared to 58.7% (p = 0.48). ChatGPT3.5 and ChatGPT4 hallucinated 41.5% versus 8.3% (p = 0.00006) of the references provided and generated 6 total false statements versus 4 total false statements, respectively.

## CONCLUSION

s While ChatGPT has shown some potential in generating accurate diagnoses, this technology requires further development before it can be implemented into clinical and educational practice. It is important to acknowledge that the most recent version of ChatGPT has made slight improvements in the accuracy of its diagnoses as well as reducing the hallucination effect.

## CLINICAL RELEVANCE/APPLICATION

ChatGPT and Large Language Models have the potential to impact clinical and educational medicine. Knowledge of the accuracy and possible errors of these algorithms can provide a better understanding of the limitations of these tools.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

T5A-SPNPM

### Noninterpretive Skills (Beyond Imaging) Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPNPM-The Association Between Food Security and Mammography Screening: Cross-Sectional Survey 1 Results from the National Health Interview Survey**

#### Participants

Jade Anderson, MD, Madison, WI (*Presenter*) Nothing to Disclose

#### PURPOSE

In one prior randomized control trial, providing food vouchers and a food pantry to food insecure individuals was associated with a 94.6% cancer treatment completion percentage. There is limited data about food insecurity within the cancer screening setting. To inform the potential need for food insecurity interventions, our study evaluated the association between food security and mammographic screening among eligible participants.

#### METHODS AND MATERIALS

Female survey respondents aged 40-74 in the 2019 National Health Interview Survey (NHIS) without history of breast cancer were included. Food insecurity was assessed using the Six-Item Food Security Scale developed by the National Center for Health Statistics. Scores from the six questions were aggregated to assign food security status. Individuals with low or very low food security were defined as food insecure. Proportion of patients who reported mammographic screening within the last year was estimated, stratified by food security status. Multiple variable logistic regression analyses were conducted to evaluate the association between food security and mammography screening, adjusted for potential confounders. All analyses were performed accounting for complex survey design features.

#### RESULTS

9,139 weighted survey respondents met inclusion criteria. Due to lack of money for food, 11.8% of participants indicated that the food they bought wouldn't last, 10.9% couldn't afford to eat balanced meals, and 10.1% worried that food would run out. 90.1% were classified as having high or marginal food security of whom 56.6% reported mammography screening. 6.1% were classified with low food security of whom 42.1% reported screening. 3.8% were classified with very low food security of whom 43.1% reported screening. In our unadjusted analyses, participants with low food security (OR 0.56, 95%CI 0.44 to 0.70,  $p<0.001$ ) and very low food security (OR 0.58, 95%CI 0.44 to 0.77,  $p<0.001$ ) were less likely to report mammography screening within the last year. In our adjusted analyses, participants with very low food security (OR 0.54, 95%CI 0.33 to 0.88,  $p=0.013$ ) were less likely to report mammography screening within the last year.

#### CONCLUSION

In a nationally representative cross-sectional survey, 9.9% of eligible participants experienced food insecurity. In our unadjusted and adjusted analyses, food insecurity was associated with significantly reduced mammography screening percentages.

#### CLINICAL RELEVANCE/APPLICATION

Radiology practices should consider screening patients for food insecurity and other social determinants of health using validated instruments. Evidence-based food insecurity interventions should be made available to participants experiencing food insecurity.

#### **T5A-SPNPM- Can ChatGPT help promote health literacy?: Generating, summarizing and simplifying patient-facing 2 information about breast cancer prevention and screening**

#### Participants

Hana Haver, MD, (*Presenter*) Nothing to Disclose

#### PURPOSE

Disparities in health literacy are known to impact patient decision-making, particularly in the context of breast cancer prevention and screening. We evaluated the use of the large language model ChatGPT as a tool to generate and simplify responses to common questions about breast cancer.

#### METHODS AND MATERIALS

ChatGPT was asked to simplify responses to 25 fundamental questions about breast cancer prevention and screening to a 6th grade reading level from a prior study by Haver et al. (Radiology 2023). The simplified responses were evaluated for clinical appropriateness by a fellowship-trained breast radiologist. Language complexity was assessed on the Flesch Reading Ease scale and readability was assessed on 5 scales: Flesch-Kincaid Grade Level, Gunning-Fog Index, Coleman-Liau Index, Automated Readability Index, and the Simple Measure of Gobbledygook. Paired t-tests of mean language complexity and mean readability scores for the original and simplified for each question were analyzed. Based on NIH guidelines, we considered language complexity score of  $<60$  and readability score  $>8$ th grade reading level to be too difficult for the average adult patient.

#### RESULTS

For ChatGPT's original responses, the average language complexity was 45 and the average readability of 13.2 grade level which was considered too difficult for the average adult patient. The responses that had been simplified by ChatGPT to a "6th grade" reading level had improved readability metrics with an average language complexity of 59 (higher is better) and 11th grade readability level ( $p < 0.005$  across all scales compared to original responses) [Figure 1]; these were still considered too difficult for the average adult patient, however. The simplified responses were appropriate 88% of the time upon review by a board-certified breast imaging radiologist, which is the same as that of the original responses by ChatGPT, as reported previously by Haver et al. (Radiology 2023).

## CONCLUSION

s ChatGPT provides health information about breast cancer screening that is accurate and appropriate 88% of the time, albeit at high reading levels inappropriate for the average adult patient. When provided with an appropriate prompt, ChatGPT can simplify its responses' readability by >2 grade levels while retaining the appropriateness of its responses. With improved prompt engineering, these readability levels will likely be able to be further improved, which our group is actively working on next.

## CLINICAL RELEVANCE/APPLICATION

ChatGPT's answers to questions about breast cancer are difficult to read. This model can be prompted to simplify this information, though it underestimates the readability level of the output.

## T5A-SPNPM- Ecodesign and Operational Strategies to Reduce MRI Energy Consumption: Cost Savings and Reduced Carbon Footprint

Participants

Sean Woolen, MD, MS, San Francisco, CA (*Presenter*) Research Grant, Siemens AG; Investigator, Siemens AG

## PURPOSE

To determine the energy, cost, and carbon savings that could be achieved through different MRI scanner power management strategies.

## METHODS AND MATERIALS

Four outpatient MRI scanners from three vendors were individually equipped with power meters (1-Hz sampling rate). Power measurement logs were extracted over 39 days. Data were segmented into off, idle, prepared-to-scan, scan, or Eco-Power (one vendor's power-saving mode) modes for each scanner. Energy, cost (assuming a mean cost of \$0.14 per kWh), and carbon savings were calculated for the lowest scanner activity modes.

## RESULTS

Projected annual energy-consumption per scanner ranged from 82.7-171.1 MWh, with 72-91% defined as non-productive. Power draws for each mode were measured as  $6.4 \pm 0.1$  kW (Eco-Power),  $7.3 \pm 0.6$  kW to  $9.7 \pm 0.2$  kW (off),  $9.5 \pm 0.9$  to  $14.5 \pm 0.5$  kW (idle),  $17.3 \pm 0.5$  to  $25.6 \pm 0.6$  kW (prepared-to-scan), and  $28.6 \pm 8.6$  to  $48.3 \pm 11.8$  kW (scan). Switching MRIs from idle to off mode for 12 overnight hours reduced power-consumption by 25-33%, translating to a potential annual savings of 12.3-21.0 MWh, \$1,717-\$2,943 USD, and 8.7-14.9 mt CO<sub>2</sub>eq. The Eco-Power mode further reduced consumption by 28% compared to off mode, potentially saving an additional 11.0 MWh, \$1,533 USD, and 7.8 mt CO<sub>2</sub>eq per year for 12 hours overnight. Turning off a fleet of 30 MRIs for 12 hours overnight offers a potential savings of 367.9-630.7 MWh, \$51,509-\$88,301 USD, and 260.9-447.2 mt CO<sub>2</sub>eq. Overnight implementation of Eco-Power mode on all outpatient MRI in the U.S. could save U.S. healthcare 73,354.1 MWh, \$10.3 million USD, and 52,008 mt CO<sub>2</sub>eq.

## CONCLUSION

s Powering down MRIs when not needed can make radiology departments more energy efficient and gain substantial sustainability and cost benefits.

## CLINICAL RELEVANCE/APPLICATION

Our data details how an ecodesign approach by scanner vendors and strategic changes to routine MRI operations by healthcare systems can be effectively used to reduce cost and impact environmental sustainability. These results should help radiologists, healthcare administrators, and corporate partners understand the benefits of energy-efficient MRI operations.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

T5A-SPNR

### Neuroradiology Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPNR-1 Multisequence MRI-Based Radiomics Signature as Potential Biomarkers for Predicting KRAS Mutations in Brain Metastases**

##### Participants

Xinna Lv, Beijing, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Kirsten rat sarcoma virus (KRAS) has evolved from a genotype with predictive value to a therapeutic target recently with the observation of novel agents. The aim of this study was to establish non-invasive radiomics models based on MRI to discriminate Kirsten rat sarcoma virus (KRAS) from epidermal growth factor receptor (EGFR) or anaplastic lymphoma kinase (ALK) mutations in lung cancer patients with brain metastases (BM), then further explore the optimal sequence for prediction.

##### METHODS AND MATERIALS

This retrospective study involved 317 patients with proven BM of lung cancer (218 patients in the training cohort and 99 patients in the testing cohort) who had confirmed of KRAS, EGFR or ALK mutations. Radiomics features were separately extracted from T2WI, T2 fluid-attenuated inversion recovery (T2-FLAIR), diffusion weighted imaging (DWI) and contrast-enhanced T1-weighted imaging (T1-CE) sequences. Synthetic minority oversampling technique was used in the training cohort to separately balance KRAS to EGFR or ALK mutations in consideration of the unbalanced nature of the training dataset. The maximal information coefficient and recursive feature elimination method were used to select informative features based on these four regular sequences respectively. Then we separately construct four radiomics models for differentiating KRAS from EGFR or ALK mutations using random forest classifier. ROC curves were used to validate the capability of the models in the training and testing cohorts.

##### RESULTS

The four radiomics models for discriminating KRAS from EGFR mutations all worked well, especially DWI and T2WI model with AUCs of 0.942 and 0.949, 0.942 and 0.954 in the training and testing cohorts. The T1-CE and T2-FLAIR models yielded AUCs of 0.918 and 0.954, 0.956 and 0.838 in the two cohorts. When KRAS compared to ALK mutations, the AUCs were 0.947 and 0.850, 0.917 and 0.824, 0.896 and 0.795, 0.892 and 0.790 in DWI, T2-FLAIR, T2WI and T1-CE sequences in training and testing cohorts respectively. The DWI and T2-FLAIR models showed excellent performance in distinguishing KRAS from ALK mutation.

##### CONCLUSION

The radiomics classifiers integrating MRI may have potential to discriminate KRAS from EGFR (DWI and T2WI model) or ALK mutations (DWI and T2-FLAIR model) that could guide targeted therapy.

##### CLINICAL RELEVANCE/APPLICATION

Radiomics classifiers integrating multisequence MRI may have potential to identify KRAS mutations, which are helpful to guide clinical therapeutic strategies and facilitate the discovery of new approaches capable of achieving this long-sought goal of cure in populations of patients with KRAS-mutant lung cancer.

#### **T5A-SPNR-10 Prediction of IDH and EGFR Mutation Status in Diffuse Glioma Patients Using Dynamic Susceptibility Contrast Imaging-derived Oxygenation and Microvascular Transit Time Heterogeneity Biomarkers**

##### Participants

Yunhwa Roh, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To obtain tumor microvascular and oxygenation information and evaluate their potential for noninvasive assessment of IDH and EGFR mutation status in diffuse glioma patients using perfusion MRI.

##### METHODS AND MATERIALS

This retrospective single-institution study included patients with adult diffuse glioma who had undergone preoperative dynamic susceptibility contrast (DSC) perfusion MRI. Contrast-enhancing lesion (CEL) and non-enhancing lesion (NEL) were segmented using deep learning segmentation. Imaging parameters of cerebral blood volume (CBV), cerebral blood flow (CBF), capillary transit time heterogeneity (CTH), oxygen extraction fraction (OEF), and cerebral metabolic rate of oxygen (CMRO2) were obtained using the capillary function-based perfusion model (Cercare Medical Neurosuite) for CEL and NEL, respectively. The diagnostic abilities of the imaging biomarkers for predicting IDH and EGFR mutation status were independently assessed. Predictors were selected using logistic regression analysis, and performance was measured with the area under the receiver operating characteristics curve (AUC) analysis.

##### RESULTS

Abstract 5110: Predicting IDH and EGFR Mutation Status in Diffuse Glioma Patients Using Dynamic Susceptibility Contrast Imaging-derived Oxygenation and Microvascular Transit Time Heterogeneity Biomarkers

A total of 110 patients were included (mean age, 58.8 years; range, 25-82; 49 women), with 25 cases of IDH mutation. Of the 85 patients with IDH wild-type glioblastoma, 34 patients showed EGFR mutation. Lower rCBV (Odds ratio [OR] 0.69; 95% confidence interval [CI]: 0.55-0.82,  $P < .001$ ) and lower rCMRO2 (OR 0.7; 95% CI: 0.54-0.85,  $P = .002$ ) measured in CEL were predictive for the presence of IDH mutation. The combination of rCBV and rCMRO2 showed an AUC of 0.85 in predicting IDH mutation status. In IDH-wild type gliomas, higher rCMRO2 (OR 1.15; 95% CI: 1.02-1.31,  $P = .029$ ) in CEL and higher rCBF (OR 1.38; 95% CI: 1.06-1.87,  $P = .023$ ) in NEL was predictive of EGFR mutation. The combination of the parameters showed an AUC of 0.66 in predicting EGFR mutation status.

## CONCLUSION

s Perfusion MRI utilizing the cerebral metabolic rate of oxygen, vascular density, and flow parameters provided the diagnostic value of predicting IDH and EGFR mutation status in glioma patients. Lower rCMRO2 is indicative for IDH mutation, while higher rCMRO2 is indicative for EGFR mutation.

## CLINICAL RELEVANCE/APPLICATION

The molecular status of IDH and the EGFR mutation have prognostic significance in glioma. Our study on perfusion MRI used a capillary function-based model and calculated the cerebral metabolic rate of oxygen (CMRO2) along with vascular density and flow parameters. The tumor oxygenation parameters enabled noninvasive diagnosis of IDH and EGFR mutation status, which may support the clinical standard of care in glioma patients.

## 15A-SPNR-11 Role of DOTATATE PET/MRI in Evaluating WHO grade 3 Meningiomas: Potential for Differentiating Secondary Progressive and De novo Tumors

Participants

Joon Tae Kim, New York, NY (*Presenter*) Nothing to Disclose

## PURPOSE

MRI has significant limitations in meningioma evaluation, especially in intermediate- and high-risk tumors. [68-Ga]-DOTATATE PET has demonstrated high utility in meningioma evaluation and treatment planning. While rare, and thus understudied, WHO grade 3 meningiomas (WHO3-M) are particularly aggressive with higher propensity for recurrence, metastases, and worse clinical outcomes compared to lower grade meningiomas. There thus exists a marked unmet need for improved targeted imaging strategies in the management of WHO3-M. Here, we evaluate the clinical, pathology, imaging characteristics and outcomes of patients with WHO3-M in our larger prospective cohort of patients with meningiomas undergoing DOTATATE PET/MRI and explore differences in PET findings between patients with de novo versus secondary progressive WHO3-M, as the latter are known to have worse prognosis.

## METHODS AND MATERIALS

Inclusion criteria were patients with WHO3-M who underwent DOTATATE PET/MRI. Clinical chart review was performed to document clinical course, surgical and radiation (RT) therapy, WHO grade, and molecular pathology. Progression free survival (PFS) was determined by applying RANO criteria to follow-up MRI. Mann-Whitney Tests were used to determine statistical significance.

## RESULTS

15 patients were included, 8 with secondary progressive and 7 with de novo WHO3-M. Secondary progressive cohort had significantly higher per-patient number of surgeries (4.0 vs 1.6;  $p = 0.012$ ) and a trend for higher number of RT courses (2.5 vs 1.6;  $p = 0.23$ ), higher cumulative RT dose (106 vs 68.3;  $p = 0.31$ ), and decreased PFS (20.9 vs 37.7 months;  $p = 0.17$ ). Secondary progressive tumors had distinct molecular pathology profiles with higher number of mutations (3.6 vs 1.3;  $p = 0.037$ ). DOTATATE PET demonstrated significantly higher SUV in secondary progressive tumors (17.1 vs 12.4;  $p = 0.0052$ ).

## CONCLUSION

s This is the first study evaluating clinical characteristics and the utility of DOTATATE PET/MRI in WHO3-M and comparing secondary progressive and de novo cohorts. In addition to distinct molecular profiles, we report significantly increased SUV in secondary progressive WHO3-M compared to de novo WHO3-M. This work further supports DOTATATE PET/MRI as a useful management strategy in WHO3-M and raises the possibility of differentiating secondary progressive and de novo WHO3-M with PET/MRI in the clinical context. This work raises important questions regarding meningioma biology such as the potential role of SSTR2 signaling in WHO3-M.

## CLINICAL RELEVANCE/APPLICATION

DOTATATE PET/MRI may be of particular clinical benefit in WHO3 meningiomas, improving diagnosis and treatment planning as well as identifying the secondary progressive subtype which conveys worse clinical outcomes.

## 15A-SPNR-12 Radiomics Nomogram Based on Multiparametric MRI Features for Preoperative Prediction of MGMT Promoter Methylation Status in Glioblastomas

## PURPOSE

Preoperative identification of O6-methylguanine-DNA methyltransferase (MGMT) promoter methylation status is of great clinical significance in selecting potential patients who might benefit from therapy. This study aimed to establish and validate a radiomics nomogram using the radiomics features and clinical characteristics for preoperative prediction MGMT promoter methylation status in glioblastomas.

## METHODS AND MATERIALS

216 patients in local institution and 68 patients from The Cancer Genome Atlas (TCGA) were enrolled. 851 radiomics features were extracted from the apparent diffusion coefficient (ADC) and isotropic volumetric contrast-enhanced T1 (ISO-CE-T1) weighted images, respectively. The features were selected using Mann-Whitney U-test, followed by refining using least absolute shrinkage and selection operator (LASSO) regression combing 10-fold cross-validation. Three radiomics signatures were built based on ADC, ISO-CE and joint radiomics features. The optimal radiomics signature with age and sex were processed by multivariate logistic regression analysis to construct a prediction model, which was developed in the training dataset and tested in the test and independent external validation dataset from TCGA. A radiomics nomogram was plotted to represent the prediction model. The performance of the radiomics nomogram was evaluated using discrimination, calibration, and decision curves.

## RESULTS

Three radiomics signatures comprising of five, five and six robust features were built. The joint signature showed the highest area under the curve (AUC) of 0.811/0.790 in the test and validation dataset. The accuracy, sensitivity, specificity and AUC were 84.62%, 82.76%, 86.11%, 0.903(0.804-0.963) and 80.88%, 81.25%, 80.56%, 0.845(0.737-0.922) in the test and external validation dataset, respectively. The radiomics nomogram with clinical data outperformed the radiomics signature alone. The Hosmer-Lemeshow test concluded that the radiomics nomogram showed goodness of fit (all  $p > 0.05$ ). Decision curve analysis demonstrated the clinical value of the radiomics nomogram.

## CONCLUSION

The radiomics nomogram based on multiparametric MRI features is a promising approach for preoperatively predicting the MGMT promoter methylation status in glioblastomas noninvasively. The combination of radiomics features from different sequences and the addition of clinical characteristics to the nomogram showed incremental predictive value.

## CLINICAL RELEVANCE/APPLICATION

This study aimed to find imaging biomarkers for noninvasively predicting the MGMT promoter methylation status for a tailored treatment plan and prognosis assessment in GBM patients from the initial stage of the tumor diagnosis.

### 13 T5A-SPNR- Diagnostic Performance of T1p Imaging and Diffusion-weighted Imaging (DWI) in Glioma IDH Mutation Status Prediction: A Pilot Study

#### Participants

Guanxun Cheng, PhD, Shenzhen, China (*Presenter*) Nothing to Disclose

Guanxun Cheng, Shenzhen, China (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study is to evaluate the diagnostic performance of T1 relaxation time in a rotating frame (T1 $\rho$ ) and apparent diffusion coefficient (ADC) in glioma IDH mutation status prediction

#### METHODS AND MATERIALS

15 glioma patients (10 IDH-wild-type gliomas, 5 IDH-mutant-type gliomas) were prospectively imaged with multiparametric MRI on 3-T, including T1 $\rho$  imaging and DWI before surgery. In addition, since T1 $\rho$  relaxation time (T1 $\rho$ ) depends not only on the structure characteristics, but also on spin lock frequency (FSL), we have set up three different spin lock frequencies (FSL = 100Hz, 200Hz, 500Hz) to compare whether there are differences between them. For ADC and T1 $\rho$  measurement, place the target ROIs, avoid tumor necrosis, cysts, and hemorrhagic areas by the help of conventional MR sequences and SWI images. Statistical significance was tested by using the Mann-Whitney U test. Receiver operating characteristic curve (ROC) analysis was performed to evaluate the diagnostic performance.

#### RESULTS

Table 1 summarizes the characteristics of the evaluated tumor patients. A total of 15 glioma patients (five male and ten female) were included in this study, containing five IDH-m patients (4 with diffuse astrocytomas, WHO grade II; 1 with anaplastic astrocytoma, WHO grade III) and ten IDH-w patients (WHO grade II/III/IV, 1/2/6; 1 can't be graded due to imperfect molecular pathological detection). Differences in mean ADC values and T1 $\rho$  relaxation time (T1 $\rho$ ) between IDH-m and IDH-w groups are shown in Table 2 and depicted in Figure 1 and 2. Mean ADC values of the tumor parenchymal area of IDH-w gliomas were significantly lower than that of IDH-m gliomas ( $0.852 \times 10^{-3} \text{mm}^2/\text{s}$  vs  $1.324 \times 10^{-3} \text{mm}^2/\text{s}$ , respectively;  $p = 0.019$ ). Whether FSL (spin lock frequency) is equal to 100, 200 or 500 Hz, the T1 $\rho$  values of the tumor parenchyma of IDH-w gliomas were significantly lower than that of IDH-m gliomas (87.50/86.72/84.21ms vs 112.92/120.67/122.17ms, respectively;  $p < 0.05$ ). The AUC value of the ADC (0.880) revealed lower diagnostic performance compared with the T1 $\rho$  relaxation time. The AUC value (0.960) of the T1 $\rho$  (FSL=100Hz) was the same as that of T1 $\rho$  (FSL=500Hz). Logistic regression analysis showed that the combination of the ADC and T1 $\rho$  (FSL=500Hz) did not improve the diagnostic performance.

#### CONCLUSION

This pilot study demonstrates that the T1 $\rho$  values may be a feasible noninvasive imaging parameter for predicting the glioma IDH mutation status. Different spin-lock frequencies have similar diagnostic performance to IDH mutation status.

#### CLINICAL RELEVANCE/APPLICATION

All patients included in the study were in accordance with the ethical standards of the institutional and/or national research committee.

### 14 T5A-SPNR- A Deep Learning Framework Enables Non-invasive Detection of Tumor Mutational Burden in Brain Metastases

#### PURPOSE

Brain metastases (BM) are the most common central nervous system malignancy and are an emerging unmet need in modern oncology. While precision medicine for BM has demonstrated impressive responses, many patients are not able to benefit from this treatment paradigm given the morbidity associated with tissue sampling. Tumor mutational burden (TMB), defined as the number of non-synonymous somatic mutations per megabase (Mb), is a predictive biomarker for efficacy of immune checkpoint inhibition (ICI) for BM. Here, we present a non-invasive technique, using deep neural networks (DNN), to quantify TMB within BM to inform rational use of ICI.

#### METHODS AND MATERIALS

We conducted our experiments on 297 multiparametric MRI (mpMRI) scans of BM patients of diverse histologies from MGH/DFCI, split into 75% train : 15% validation : 10% test. Consistent with prior literature, we binarized the TMB by defining values greater than 12 per Mb as "high", and the converse as "low". We limited our initial analysis to FLAIR, T1 pre- and T1 post-contrast MRI sequences. We employed a multi-step preprocessing pipeline involving skull stripping, isotropic resampling, registration, N4 bias correction and intensity normalization. We additionally investigated several unique input strategies to our DNN that incorporated combinations of MRI sequences and slice orientations, using the corresponding maximum intensity projection (MIP) image stack. We

conducted our experiments both with and without five-fold cross validation, utilizing several classification architectures, and cross entropy loss with weighted sampling.

## RESULTS

Using a resnet18 architecture, our best performing model achieved an area under the receiver operating characteristics curve (AUROC) of 0.88 on the held-aside test set and comprised the axial FLAIR MIP image as input. Across all types of inputs and architectures investigated, our AUROCs ranged from 0.72 - 0.88. These results were consistent across each fold for the five-fold cross validation experiments.

## CONCLUSION

To fully translate clinically actionable genomic alterations within BM into clinical medicine, non-invasive biomarkers are desperately needed. To this end, we demonstrate that a DNN displays strong performance in quantifying TMB within BM. We are optimizing performance of this model with an expanded mpMRI dataset, as well as performing additional studies to noninvasively identify oncogenic drivers in BM (e.g. CDK, PI3K pathway alterations), which can help guide choice of targeted therapy.

## CLINICAL RELEVANCE/APPLICATION

We developed a deep learning model, using mpMRI, that achieves strong performance in quantifying TMB status within BM, which can augment clinical decision making through facilitating rational use of ICI in patients.

### **T5A-SPNR-2 Usefulness of Pituitary High-resolution 3D MRI using Deep-learning-based Reconstruction for Pre- and postoperative Evaluations in Patients with Pituitary Adenoma/pituitary Neuroendocrine Tumor**

Participants

Yuka Ishimoto, Hirosaki-Shi, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

In the management of pituitary adenomas, an MRI sequence with high sensitivity for detecting small lesions and high precision for delineating the normal pituitary glands is desirable. The recently developed deep-learning-based reconstruction (DLR) improves the image quality of thin-slice MRI. The previous investigators applied DLR to a 2D spin-echo sequence and showed that for the postoperative evaluation of pituitary adenoma, 1-mm-slice-thickness 2D CE-T1WI with DLR (1-mm 2D T1WI with DLR) showed greater diagnostic performance than conventional 2D CE-T1WI with 3-mm slice thickness. However, there were no study which applied DLR to a 3D fast spin-echo sequence. Therefore, for contrast-enhanced (CE) MRI, we assessed the diagnostic value of T1-weighted 3D fast spin-echo sequence (CUBE) with DLR for evaluating pituitary adenoma.

## METHODS AND MATERIALS

We assessed 24 patients with pituitary or residual adenoma who underwent 3D CUBE with and without DLR (imaging time: 5 min, 7 sec), 1-mm-slice-thickness 2D spin-echo T1WI (1-mm 2D T1WI) with DLR, and 3D spoiled gradient echo sequence (SPGR) as CE-T1WI. For these MRI sequences, the depiction of the pituitary adenoma and parasellar region (cavernous sinus) was scored by two neuroradiologists, and the contrast-to-noise ratio (CNR) between the pituitary adenoma and the brain parenchyma was calculated.

## RESULTS

Scores for the depictions of pituitary or residual adenoma were significantly higher with 3D CUBE with DLR than with 3D CUBE without DLR, 1-mm 2D T1WI with DLR, and 3D SPGR ( $P < .001$ ). In one patient, 3D CUBE with DLR identified a microadenoma that was not observed on other sequences (1-mm 2D T1WI with DLR and 3D SPGR) (Figure). The score for the depiction of the boundary between the adenoma and the cavernous sinus was higher with 3D CUBE with DLR than with 1-mm 2D T1WI with DLR and 3D SPGR. For the evaluation of adenomas, 3D CUBE with DLR provided better interobserver agreement than 1-mm 2D T1WI with DLR (0.75 vs. 0.41). For the CNR, the 3D CUBE with DLR was significantly higher than that with 3D SPGR, but there were no significant differences between the 3D CUBE with DLR and the 1-mm 2D T1WI with DLR.

## CONCLUSION

For 3D evaluation of the pituitary and parasellar regions, DLR may be a useful method to shorten the acquisition time while maintaining sufficient image quality. Compared to 1-mm 2D T1WI with DLR, 3D CUBE with DLR provided better image quality for depicting pituitary adenoma, with better interobserver agreement.

## CLINICAL RELEVANCE/APPLICATION

Deep learning-based reconstruction technique can allow 3D fast spin-echo T1WI with high spatial resolution, which is superior to 1-mm-slice-thickness 2D T1WI for the pre- and postoperative evaluation of pituitary adenomas.

### **T5A-SPNR-3 Meningiomas: Correlation between Tumors' Cellularity and Recurrence**

Participants

Luiz Borella, Itatiba, Brazil (*Presenter*) Nothing to Disclose

## PURPOSE

Meningiomas are the most frequent tumors of the central nervous system. According to the World Health Organization, they can be categorized into 3 categories. There are benign tumors or grade I lesions. Secondly, grade II or atypical meningiomas (intermediate). Lastly, grade III meningiomas (malignant). In recent years, tools to predict patient's outcome have been proposed. In this study, we evaluate the meningioma's densities on CT and their mean values in ADC and correlate these variables with tumor recurrence. The main hypothesis was the greater the cellularity of the tumor (reflected by higher CT density and lower ADC mean value), more frequent tumors' recurrence.

## METHODS AND MATERIALS

We listed 32 patients of our institution with histological diagnosis of meningioma that were submitted to CT and MRI evaluation before and after surgical exploration, between 2012 and 2020. To predict tumors' cellularity, we measure their CT density and ADC mean value using the largest ROI possible to englobe the lesion.

## RESULTS

To find statistical correlation between tumors' cellularity and recurrence, we discriminated CT densities (in HU) and ADC mean values (in 10<sup>-3</sup> mm<sup>2</sup>/s) and the patient's outcome in "recurrence" and "non-recurrence". We applied two different analyses: Pearson's correlation test found that there is correlation between CT density and tumor recurrence, classified as moderated and directly proportional. Also, there is correlation between ADC mean value and tumor recurrence, classified as moderated and inversely proportional ( $r = + 0.49$ ,  $p < 0.05$ ). Logistic regression also demonstrates correlation between CT density and tumor recurrence, and between ADC mean value and tumor recurrence ( $p = 0.01$ ;). This test demonstrated ROC curve 84.4% (sensitivity = 80%, specificity = 83.3%).

## CONCLUSION

Our analysis showed moderated correlation between tumor's presumed cellularity (reflected by higher CT density and lower ADC mean value) and meningiomas' recurrence.

## CLINICAL RELEVANCE/APPLICATION

Measuring CT densities and ADC mean values, especially before surgical exploration, can be used as tools to predict meningiomas' recurrence. Tumors with higher cellularity can be submitted to follow-up exams more often than the others.

## T5A-SPNR-4 Diffusion Kurtosis Imaging in Detecting Changes in the White Matter of the Brain Non-visible on Conventional MRI in Patients with Brain Gliomas

### PURPOSE

Ki-67/MIB-1 labeling index (LI) characterizes cellular proliferation and is used in glioma grading and predicting glioma prognosis (Louis et al., 2021; Louis et al., 2007). Some researchers consider diffuse gliomas as a systemic disease of the brain rather than a local tumor. Application of antibodies specific to the R132H protein, which is present in cells of gliomas with IDH-1 mutation and absent in normal neuroglial cells, showed the presence of tumor cells in brain regions significantly distant from the glioma, including the opposite brain hemisphere (Agarwal et al., 2011; Sahm et al., 2012). The aim of this study was to assess the ability of diffusion kurtosis imaging (DKI) to find a correlation between Ki-67/MIB-1 LI of gliomas and diffusion kurtosis parameters in the normal-appearing on conventional MRI white matter of the opposite hemisphere of the brain.

### METHODS AND MATERIALS

84 patients with newly diagnosed brain gliomas underwent 3T MRI before treatment. In all cases, the diagnosis was confirmed by biopsy or surgical resection. 49 patients had high-grade gliomas (HGG), and 35 patients had low-grade gliomas (LGG). The age of patients with HGG was 43.8±14.7, and with LGG was 37.7±9.6. DKI was performed using b values of 0, 1000, and 2500 s/mm<sup>2</sup> and 60 gradient directions. The following parameters were obtained using DKI: mean kurtosis (MK), axial kurtosis (AK), radial kurtosis (RK), kurtosis anisotropy (KA), mean diffusivity (MD), axial diffusivity (AD), radial diffusivity (RD), fractional anisotropy (FA), relative anisotropy (RA). The Spearman correlation coefficient was calculated between Ki-67/MIB-1 LI of gliomas and diffusion kurtosis parameters in the normal-appearing on conventional MRI white matter of the opposite hemisphere of the brain ( $p < 0.05$  significance level). Conventional MRI included T1, T1+Gd, T2, T2-FLAIR weighted images.

### RESULTS

Statistically significant correlation of glioma Ki-67/MIB-1 LI was found with ( $r = -0.28$ ,  $p = 0.01$ ), RD ( $r = 0.3$ ,  $p = 0.02$ ), FA ( $r = -0.27$ ,  $p = 0.003$ ) and RA ( $r = -0.27$ ,  $p = 0.004$ ) in the white matter of the opposite hemisphere of the brain. A decrease of RK ( $p < 0.05$ ) and an increase of RD ( $p < 0.05$ ) in the white matter of the opposite hemisphere of the brain with higher Ki-67/MIB-1 LI of gliomas can be due to the decreased axonal density. A decrease of both FA ( $p < 0.05$ ) and RA ( $p < 0.05$ ) with higher Ki-67/MIB-1 LI of gliomas can reflect higher cellularity and decreased axonal density in the contralateral white matter.

## CONCLUSION

DKI demonstrated a potential to detect changes in the white matter of the brain non-visible on conventional MRI in patients with gliomas.

## CLINICAL RELEVANCE/APPLICATION

Understanding the changes occurring in brain areas distant from the tumor is crucial for treatment and patient care.

## T5A-SPNR-5 Covariance Structural Abnormalities: The Key Networks of Heterogeneous Mild Traumatic Brain Injury - A Result from Longitudinal Study with EZ-MAP for Detection of Regional FA Abnormalities

Participants

Yanan Zhu, Ankang, China (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the covariance structural abnormalities of heterogeneous mild traumatic brain injury (mTBI) at subacute phase and 1-3 months, 6-12 months post-injury.

### METHODS AND MATERIALS

: Diffusion tensor imaging tractography of whole brain and conventional MR were performed in 72 mTBI patients of subacute phase, 27 mTBI patients of 3 months and 21 mTBI patients of 6-12 months post injury. 46 age- and gender-equivalent healthy controls were also involved, 10 healthy controls and 11 healthy controls were scanned respectively 1 month, 6-12 months later. Voxelwise assessment methods of Enhanced Z-score Microstructural Assessment of Pathology (EZ-MAP) were used to detect regional FA abnormalities in each patient's fractional anisotropy (FA) maps. All subjects were administered the following neuropsychological tests: the Mini-Mental state examination (MMSE), Hamilton Depression (HAMD), Fatigue Severity Scale (FSS), Clinical Dementia Rating (CDR), Postconcussive Symptoms Scale (PSS), the Trail Making Test A, the Trail Making Test B, State Trait Anxiety Inventory (STAI-Y). Pearson's correlation coefficients between the FA values of covariance location with clinical measurements at all 3 time points post injury were calculated.

### RESULTS

Respectively, 29.17% of subacute phase, 37.03% of 3 months post injury, 38.09% of 6-12 months post injury mTBI patients had abnormal brain MRI. During the period of post injury from subacute phase to 6-12 months, general pattern of reduced FA and

/raised MD were present in various white matter tracts such as Body of corpus callosum, Splenium of corpus callosum, Fornix, Cerebral peduncle L, Anterior limb of internal capsule L, Posterior limb of internal capsule L, Anterior corona radiata L, Superior corona radiata L, Anterior limb of internal capsule R, Anterior corona radiata R, and Superior corona radiata R. In subacute phase, raised FA in Posterior limb of internal capsule L, Cerebral peduncle L, Anterior corona radiata R and Superior corona radiata R were in correlation with better clinical performance in MMSE, Traveling-A, and CDR.

## CONCLUSION

s Covariance structural abnormalities were the key networks of heterogeneous mild traumatic brain injury, serving as indicator and predictor of mTBI.

## CLINICAL RELEVANCE/APPLICATION

To assess covariance structural abnormalities provided a new method to serve as indicator and predictor of heterogeneous mTBI.

### **T5A-SPNR-6 Abnormal Functional Connectivity in Mild Traumatic Brain Injury at Subacute Phase and 1-3 Months Post-injury by Independent Component Analysis**

Participants

Yanan Zhu, Ankang, China (*Presenter*) Nothing to Disclose

## PURPOSE

To examine the resting state networks of homogeneous mTBI patients and investigate the dynamic changes of brain networks at both subacute phase and 1-3 months post-injury

## METHODS AND MATERIALS

: A total of 60 first-episode mTBI patients at subacute phase (within 21 days post-injury) were recruited from the Local Emergency Department, and 35 mTBI patients who conducted the follow-up 1-3 month post-injury were enrolled. 43 healthy volunteers who matched with age, sex, and educational level were recruited as normal controls. Neuropsychological tests and self-reported symptoms were assessed within 24 hours after MR scan for all the participants. Independent component analysis (ICA) was carried out by using Multivariate Exploratory Linear Optimized Decomposition into Independent Components (MELODIC) implemented in FSL. A dual regression approach was used to perform voxel-wise comparisons of functional connectivity between groups. the Pearson's correlation coefficients between the averaged Z score in regions and clinical measurements both at subacute and 1-3month post injury subgroup were calculated.

## RESULTS

Decreased functional connectivity within the default mode network (DMN) and increased network strengthen in the frontoparietal network (FPN) in mTBI patients at subacute phase were found, and the abnormality of the DMN function was specifically predicated by with the individual cognitive impairments. After 1-3months post-injury, increased connectivity in the DMN and decreased connectivity in the dorsal attention network (DAN) emerged. Reduced functional connectivity in the anterior cingulate cortex was correlated with aggravated syndrome of fatigue.

## CONCLUSION

s Alterations of connectivity in multiple intrinsic networks exist early after and during recovery of injury, which may underlie the mechanisms of the reduced and improved performance in neurocognitive testing.

## CLINICAL RELEVANCE/APPLICATION

Whole brain functional connectivity, especially DMN, can serve as indicator and predictor to monitor disease progression or recovery of mTBI.

### **T5A-SPNR-7 Local and Global Functional Connectome Disruption in Patients with Gliomas**

## PURPOSE

To explore the disruption of functional connectome patterns in patients with brain tumors, based on resting-state functional magnetic resonance imaging (rs-fMRI) data in patients with gliomas.

## METHODS AND MATERIALS

Fifty-four patients with newly diagnosed or recurrent gliomas were included (M = 34, Mean Age = 50.8 yr). Manual segmentation of solid lesions was performed on T1w and T2w MRI scans following RANO criteria. Rs-fMRI was acquired before surgery on a 3T scanner. Whole-brain network measures of centrality, modularity, integration and segregation were computed for a set of Regions of Interest (ROIs) including the Harvard Oxford (HO) anatomical atlas and tumor-related ROIs (i.e., edema, solid tumor, necrotic core). A  $p < 0.05$ , two-sided, FDR corrected threshold was used for statistical analysis; analysis was performed on connectivity matrices representing multiple sparsity levels ranging from 50% to 100%.

## RESULTS

In newly diagnosed patients (n = 18), we found a decrease of Integration (Degree, Global Efficiency) and Centrality (Betweenness centrality), and an increase of Segregation (Clustering Coefficient) in the tumor ROIs respect to healthy brain regions. Such an integration/segregation imbalance pattern seems to follow a gradient moving from the edema to the solid tumor and the necrotic core (i.e., less altered in the edema, more altered in the necrotic core). In the entire "Network" composed by all the brain regions of the HO atlas plus all the tumor ROIs, its indexes fit between those of the healthy grey matter (frontal poles, blue bars) and the tumor ROIs, confirming the relevance of the alteration induced by the tumor across the whole brain functioning system. In patients at recurrence (n = 36), the same pattern was found, though with a less clear separation between tissue classes within the tumor. This might be due to an altered environment caused by functional plastic rearrangement and the neurocognitive effects of multiple interventions (i.e., surgery, chemotherapy, radiation damage).

## CONCLUSION

s We found significant alteration of functional connectome measures in brain regions affected by the tumor (i.e., tumor mass, necrotic core and edema), with a decrease of network integration and an increase of network segregation measures. Notably, a

linear change in integration/segregation ratio was observed from the necrotic core to the edema, possibly reflecting tumor progression and therefore possibly capturing neuronal damage.

#### **CLINICAL RELEVANCE/APPLICATION**

Connectome-level markers of glioma functional behavior could deepen our understanding of glioma pathophysiology, provide insight on neurocognitive sequelae, as well as be investigated as a potential marker of tumor progression.

#### **T5A-SPNR-8 Value of Contrast-Enhanced T1 WI Histogram Analysis in the Differential Diagnosis of Prolactin and Non-Prolactin Pituitary Macroadenomas**

Participants

Wei Wang, Zhengzhou City, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Based on the World Health Organization's classification for pituitary neuroendocrine tumors in 2022, this study aims to investigate the value of contrast-enhanced T1 weighted imaging (CE-T1WI) histogram analysis in distinguishing prolactin pituitary macroadenomas and non-prolactin pituitary macroadenomas.

#### **METHODS AND MATERIALS**

A retrospective analysis was conducted on data from 10 patients with prolactin pituitary macroadenomas and 13 patients with non-prolactin pituitary macroadenomas who were diagnosed by histopathology. All procedures of this study were approved by the Ethics Committee of our hospital. Written informed consent was obtained from all patients. The 3D Slicer software was used to draw the region of interest (ROI) of the tumor at the best plane, followed by gray-level histogram analysis to extract seven histogram parameters including Perc.10%, Perc.90%, kurtosis, mean, median, maximum and minimum values. Independent sample T-tests or Mann-Whitney U-tests were used to compare metric data between the two groups. Receiver operating characteristic (ROC) curves were plotted, and the area under the curve (AUC) was calculated to evaluate the diagnostic performance of the relevant parameters in distinguishing prolactin pituitary macroadenomas from non-prolactin pituitary macroadenomas.

#### **RESULTS**

In CE-T1WI histogram parameters, Perc.10%, mean, minimum value, and total parameters showed significant differences between the two groups of tumors with P values of 0.014, 0.0347, 0.0057, and <0.001, respectively. Table 1 presented the mean values and standard deviations of each parameter in the two groups. The area under the ROC curve, sensitivity, and specificity for each parameter were 0.808 (0.700, 0.923), 0.769 (0.700, 0.923), and 0.892 (0.800, 0.846), respectively, indicating good diagnostic accuracy. The AUC for the total parameter model was 0.954 (0.800, 1.000), significantly higher than that of individual parameters, suggesting that the combination of multiple parameters can improve the diagnostic accuracy.

#### **CONCLUSION**

s CE-T1WI histogram analysis has certain value in the differential diagnosis of prolactin pituitary macroadenomas and non-prolactin pituitary macroadenomas, and can be used as an auxiliary method for distinguishing pituitary nerve prolactinomas.

#### **CLINICAL RELEVANCE/APPLICATION**

Since prolactin pituitary macroadenomas can be treated with medication only, while non-prolactin pituitary macroadenomas require surgery, which can be invasive, accurately differentiating between the two can help avoid unnecessary surgical trauma.

#### **T5A-SPNR-9 Effective Atomic Number as a Novel Quantitative CT Imaging Marker for Differentiating Glioblastomas, Brain Metastases and Primary Central Nervous System Lymphomas**

Participants

Tsubasa Nakano, Kagoshima, Japan (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To determine whether dual-energy CT parameters including effective atomic number (Zeff) and electron density (ED) could be quantitative imaging markers for differentiating glioblastomas (GBMs), brain metastases and primary central nervous system lymphomas (PCNSLs).

#### **METHODS AND MATERIALS**

This study included 102 consecutive patients with pathologically proven GBMs (n = 56), metastases (n = 23) and PCNSLs (n = 23). For all patients, preoperative non-contrast dual-energy CT examination was performed using a spectral detector CT scanner. Images of conventional CT (CTconv), ED, Zeff were obtained. These CT images and MR images (T2WI, FLAIR, ADC map and post-contrast T1WI) were co-registered using SPM12. For each lesion, semiautomatic tumor segmentation was performed to delineate contrast enhanced area of tumors using ITK-SNAP, and VOIs were placed on each image. The mean CTconv, ED, Zeff and ADC values were compared between 3 groups using Mann-Whitney U test. ROC curve analysis was performed to assess the diagnostic abilities of each parameter and their combinations.

#### **RESULTS**

Zeff showed significant difference across all three groups, whereas ED showed no significant between-group differences. CTconv and ADC showed significant differences between GBMs and PCNSLs and between metastases and PCNSLs, but not between GBMs and metastases. Between GBMs and metastases, only Zeff showed significant difference (P = 0.02), and the area under the ROC curve (AUC) for their differentiation was 0.667. In discriminating between metastases and PCNSLs, Zeff showed the best diagnostic performance (AUC = 0.827), followed by ADC (0.761) and CTconv (0.701). The AUC further improved up to 0.921 when Zeff was combined with ADC. Between GBMs and PCNSLs, the AUCs were 0.744, 0.681 and 0.798 for CTconv, Zeff and ADC, respectively. Although Zeff had lower diagnostic performance compared to CTconv and ADC, AUC improved up to 0.829 with the combination of CTconv, Zeff and ADC.

#### **CONCLUSION**

s Our preliminary results suggested that Zeff can be a novel quantitative CT imaging marker that captures inherent characteristics of the tumors which are not reflected in conventional images, and it may be useful for differentiating GBMs, brain metastases and

PCNSLs.

**CLINICAL RELEVANCE/APPLICATION**

The effective atomic number can be a novel quantitative CT imaging marker for differentiating GBMs, brain metastases and PCNSLs.

T5A-SPOB

### OB/Gynecology Tuesday Poster Discussions I

#### Sub-Events

#### T5A-SPOB-1 Does Abdominal Fat Distribution Impact Endometrial Cancer Prognosis

##### Participants

Kristine Fasmer, PhD, MSc, Bergen, Norway (*Presenter*) Nothing to Disclose

##### PURPOSE

To quantify abdominal fat distribution from clinically acquired computed tomography (CT) scans at primary diagnosis and at follow-up in a large endometrial cancer (EC) cohort, and to explore its relation to disease progression and prognosis.

##### METHODS AND MATERIALS

From CT images of 293 EC patients at primary diagnosis ( $n_{\text{primary}}$ ), total- (TAV), subcutaneous- (SAV), visceral abdominal fat volume (VAV), and visceral-to-total abdominal fat ratio (VAV/TAV) were derived using iNTuition (TeraRecon Inc., USA). The obesity markers were assessed in relation to body mass index (BMI) using Spearman's rank order correlation ( $\rho$ ), and to tumor histology from surgical specimen (endometrioid EC (EEC) grade 1-3, non-endometrioid EC (NEEC)) using Mann-Whitney U test. Time-dependent receiver operating characteristic curves, and Cox hazards ratios (HRs) were used to assess the obesity markers in relation to progression-free survival (PFS). Delta ( $d$ ) fat changes from primary diagnosis to follow-up 13 (2-41) [median (range)] months after diagnosis, were derived for 152/263 patients ( $n_{\text{follow-up}}$ ) with follow-up CT.  $d$ TAV,  $d$ VAV,  $d$ SAV, and  $d$ (VAV/TAV) were compared for patients with progression versus patients with no signs of progression, using Mann-Whitney U-test.

##### RESULTS

At primary diagnosis ( $n_{\text{primary}}=293$  patients), TAV, VAV, and SAV were all highly correlated to BMI ( $\rho=0.78$ ), while VAV/TAV ratio was not ( $\rho=-0.12$ ). Patients with high-risk histology (EEC grade 3/NEEC) had significantly lower TAV, SAV, and BMI ( $p=0.03$ ), while higher VAV/TAV ratio ( $p=0.001$ ) than patients with low-risk histology (EEC grade 1-2). High VAV/TAV ratio ( $=36\%$ ) predicted poor PFS both in univariable analysis ( $HR=2.4$ ,  $p=0.04$ ), and when stratified for surgicopathologic International Federation of Gynecology and Obstetrics (FIGO) stage I-IV ( $HR=2.8$ ,  $p=0.02$ ). At follow-up ( $n_{\text{follow-up}}=152$  patients), median TAV, VAV, and SAV were significantly lower than at primary diagnosis ( $p<0.001$  for all), while no significant difference was observed for VAV/TAV ratio ( $p=0.31$ ). Patients experiencing progression had a larger reduction in visceral fat compartments ( $d$ VAV= $-19\%$ ,  $d$ VAV/TAV= $-2\%$ ), than patients with no signs of progression ( $d$ VAV= $-11\%$ ,  $d$ VAV/TAV= $0\%$ ,  $p=0.04$  for both).

##### CONCLUSION

High VAV/TAV ratio, measured at primary diagnosis, is associated with high-risk histology and reduced survival in EC. Patients experiencing disease progression have a more pronounced reduction in visceral fat volume than patients with no signs of progression at follow-up.

##### CLINICAL RELEVANCE/APPLICATION

Abdominal fat distribution markers from preoperative abdominal CT predict endometrial cancer prognosis, and higher visceral fat loss during/following therapy is associated with disease progression.

#### T5A-SPOB-2 Early Treatment Response is Captured by Whole-tumor MRI Radiomics in Patient-derived Organoid Endometrial Cancer Models

##### Participants

Kristine Fasmer, PhD, MSc, Bergen, Norway (*Presenter*) Nothing to Disclose

##### PURPOSE

Radiomics can capture microscale information in medical images beyond what is visible to the naked human eye. Using a clinically relevant mouse model for endometrial cancer, the purpose of this study was to develop and validate a radiomic signature (RS) predicting response to standard chemotherapy.

##### METHODS AND MATERIALS

Mice orthotopically implanted with a patient-derived grade 3 endometrioid endometrial cancer organoid model (O-PDX) were allocated to chemotherapy (combined paclitaxel/carboplatin,  $n=11$ ) or saline/control ( $n=13$ ). During tumor progression, the mice underwent weekly T2-weighted (T2w) MRI. Segmentation of primary tumor volume (vMRI) allowed radiomic feature extraction from whole-volume tumor masks. A radiomic prediction model employing least absolute shrinkage and selection operator (LASSO) statistics for predicting treatment group (chemotherapy vs. control) was derived using endpoint images in the orthotopic O-PDX, and subsequently applied on the earlier study timepoints (RS\_O at baseline, and week 1-3). For external validation, the radiomic prediction model was further tested in a separate T2w-MRI dataset on segmented whole-volume subcutaneous tumors (RS\_S) from the same O-PDX model, imaged at three timepoints (baseline, day 3 and day 10/endpoint) after start of chemotherapy (combined paclitaxel/carboplatin) ( $n=8$  tumors) or saline/control ( $n=8$  tumors).

## RESULTS

The RS\_O yielded rapidly increasing area under the receiver operating characteristic curves (AUCs) for predicting treatment groups, from baseline until endpoint; AUC=0.38 (baseline); 0.80 (week 1), 0.85 (week 2); 0.96 (week 3) and 1.0 (endpoint). In comparison, vMRI yielded AUCs of 0.37 (baseline); 0.69 (week 1); 0.83 (week 2); 0.92 (week 3) and 0.97 (endpoint). When tested in the external validation dataset, RS\_S yielded high accuracy for prediction of treatment group at day 10/endpoint (AUC=0.85), and tended to yield higher AUC than vMRI (AUC=0.78, p=0.18). Neither RS\_S nor vMRI predicted treatment groups at day 3 in the external validation set (AUC=0.56 for both).

## CONCLUSION

We have developed and validated a radiomic signature that was able to capture treatment response prior to a decrease in tumor volume. This study supports the promising role of preclinical imaging with radiomic tumor profiling to detect early treatment response in cancer models.

## CLINICAL RELEVANCE/APPLICATION

Radiomic MRI signatures capture treatment response prior to visible decrease in tumor volume in a preclinical endometrial cancer model and represent a promising approach for capturing early treatment response.

## T5A-SPOB-3 Magnetic Resonance Imaging of Primary Ovarian Carcinosarcoma: Is the Mille-feuille Sign" Useful in Diagnosis

Participants

Yuriko Watanabe, MD, Tochigi, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Primary ovarian carcinosarcoma (POC) is a rare and aggressive variant of ovarian cancer with a poorer prognosis than that of high-grade serous ovarian cancer. Thus, preoperative imaging diagnosis is crucial; however, few reports on MRI of POC exist. Kurokawa et al. proposed a new morphologic classification of ovarian tumors on imaging and reported that the mille-feuille sign, with a layered structure in the cystic tumor, indicates ovarian metastasis from colorectal carcinoma with high specificity and is useful in the differential diagnosis of primary ovarian carcinoma (*Eur J Radiol.* 2020; 124: 108823). In this presentation, we analyzed the MRI findings of 12 cases of POC and investigated the imaging features, including a new morphologic classification.

## METHODS AND MATERIALS

MRI scans of 12 POC patients were obtained. The following features were evaluated: (1) tumor size; (2) ADC values of the solid component; (3) intratumoral hemorrhage; (4) signal intensities compared to the skeletal muscle and heterogeneity of the solid component on T2WI; (5) heterogeneity of enhancement of the solid component on Gd-enhanced T1WI; and (6) tumor morphology on T2WI and Gd-enhanced T1WI, according to the following four categories: "mille-feuille sign," "solid and cystic," "multicystic without nodules," and "multicystic with nodules." Among (3)-(6), three radiologists who were blinded to prior clinical information were evaluated. In case of disagreement among the readers, the diagnosis was determined through a majority decision. Interobserver agreement for subjective image quality was calculated using the Fleiss' kappa statistic.

## RESULTS

(1) tumor size: mean, 133.7±127.5 mm, (2) ADC values: mean, 0.80±0.26×10<sup>-3</sup> mm<sup>2</sup>/s, (3) intratumoral hemorrhage: 11/12 (?=0.54), (4) heterogeneously high intensity: 12/12 (?=1), (5) heterogeneous enhancement: 12/12 (?=1), (6) tumor morphology on T2WI: solid and cystic (n=10) and mille-feuille sign (n=2) (?=0.56), tumor morphology on Gd-enhanced T1WI: solid and cystic (n=7) and mille-feuille sign (n=5) (?=0.89).

## CONCLUSION

POC shows relatively large ovarian tumors with hemorrhage, heterogeneous solid components, and low ADC values. Gd-enhanced T1WI showed solid and cystic or mille-feuille signs with excellent interobserver agreement. We considered the mille-feuille sign as a suspicious finding for POC in addition to ovarian metastasis from colorectal carcinoma.

## CLINICAL RELEVANCE/APPLICATION

Primary ovarian carcinosarcomas (POCs) are aggressive and have a poor prognosis; therefore, preoperative imaging diagnosis is crucial. The "mille-feuille sign" on Gd-enhanced T1WI can be useful to suspect POC preoperatively.

## T5A-SPOB-4 Habitat-based Radiomics Enhances the Ability to Predict Lymphovascular Interstitial Infiltration in Cervical Cancer: A Multicenter Study

## PURPOSE

As lymph-vascular space invasion (LVSI) was closely related to lymph node metastasis and prognosis, the preoperative assessment of LVSI in cervical cancer is crucial for patients. As such, we investigated the potential of habitat analysis as a novel tumor biomarker in predicting LVSI in cervical cancer.

## METHODS AND MATERIALS

This retrospective study of 300 patients with cervical cancer who had received surgical treatment at two institutions, with data from institution 1 as the training (n = 198) cohort and institution 2 as the validation (n = 102) cohort. Based on the voxel and entropy values of CE-T1WI images clustered by K-means method, the VOI was divided sub-regions and the radiomics features were extracted from the sub-regions respectively. Pearson correlation coefficient and LASSO regression methods were used for feature selection. Pearson correlation coefficient and LASSO regression methods were used for feature selection. The SVM machine learning model was used to construct prediction models for each sub-region radiomics features and the model effects were evaluated by an external test cohort.

## RESULTS

The voxels and entropy values of CE-T1WI images are clustered into 3 sub-regions. In the training cohort, AUCs of the SVM models based on the radiomics features derived from all tumor, Habitat1, Habitat2 and Habitat3 were 0.805 (95% CI: 0.745 - 0.864), 0.873(95% CI: 0.824 - 0.922), , 0.869 (95% CI: 0.821 - 0.917) and 0.870(95% CI:0.821 - 0.920), respectively. Comparing with all

tumor, the predictive performances of Habitat1-3 were higher with statistical significant. The Habitat3 model archived the highest AUC in the external test cohort (0.780 [95% CI: 0.692 - 0.869]). The difference was not statistical significant ( $p=0.073$ ). The accuracy, sensitivity, specificity, positive predictive value and negative predictive value for LVSI were 0.745, 0.741, 0.75, 0.769 and 0.720, respectively.

#### **CONCLUSION**

s A tumor sub-regional habitat-based radiomics model could obtain higher predictive performance for LVSI in cervical cancer the radiomics derived from all tumor, which might be a potential noninvasive approach to facilitate treatment decision-making in clinical settings

#### **CLINICAL RELEVANCE/APPLICATION**

Pretreatment acknowledge of LVSI status in patients with cervical cancer can facilitate personalized therapeutic strategy. The current work provided a noninvasive approach for assessing LVSI without radiation, which is very important for the women of childbearing age, who have the intention for fertility preservation.

T5A-SPPD

### Pediatric Imaging Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPPD-2 Abnormal Brain Functional Connectivity in Children with Spastic Cerebral Palsy: A Resting-state Functional Magnetic Resonance Imaging Study**

#### **PURPOSE**

Cerebral palsy (CP) is the most common dyskinesia syndrome in children, and spastic cerebral palsy (SCP) is the most common clinical type. Existing neuroimaging studies have found that there are extensive structural and functional changes in children with SCP. However, few studies focus on the intrinsic functional features of network organization throughout the brain. Therefore, the purpose of this study was to use degree centrality (DC) analysis at the voxel level to characterize the potential pattern of intrinsic connectivity disorders in the whole brain functional network in children with SCP.

#### **METHODS AND MATERIALS**

34 children with SCP and 17 demographically matched healthy controls (HCs) participated in the study. All subjects were evaluated for gross motor function and hand function, and underwent resting state functional magnetic resonance imaging. DC is a graph theory-based measure that represents the total number of functional connections between a voxel and other voxels. We used DC analysis and seed-based functional connectivity (FC) analysis to identify abnormal FC.

#### **RESULTS**

The DC values of the left supplementary motor area (SMA), bilateral medial cingulate gyrus (MCC) and left precuneus were significantly lower than the HCs group. Further seed-based FC analysis showed that, compared with the HCs group, when seed was located on the left SMA, the SCP group showed decreases connections with the left anterior cingulate gyrus, para-hippocampal gyrus, ventrolateral prefrontal cortex and right anterior cingulate gyrus, thalamus, amygdala, and putamen. When seed was located in the left precuneus, the SCP group showed decreases connections with the left thalamus, right hippocampus, precuneus, lingual gyrus, and putamen. When seed was located in the left MCC, the association with the left insula, precuneus, medial prefrontal cortex, right putamen and thalamus was reduced in the SCP group. When seed was located in the right MCC, the association between the left cuneus and the right lingual gyrus, precuneus and thalamus was reduced in the SCP group. Correlation analysis showed that the FC between the left SMA and the right putamen was negatively correlated with the hand function evaluation grade.

#### **CONCLUSION**

The brain functional network in children with SCP had extensive internal connectivity disorders, including the damage of the default brain network, the central executive network and the salient network in addition to the sensorimotor network.

#### **CLINICAL RELEVANCE/APPLICATION**

The changes of brain functional network provide a basis for understanding the pathophysiological mechanism of SCP motor and cognitive impairment, and may provide a new therapeutic target for the treatment of children with SCP.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

T5A-SPPH

### Physics Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPPH-1 Assessing Coronary Artery Calcium Scoring in Lung Cancer Screening: A Dynamic Cardiac Phantom Study**

##### Participants

Chao Guo, PhD, Los Angeles, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

Calcification of coronary arteries is strongly associated with cardiovascular diseases. Low dose lung cancer screening (LCS) is gaining popularity in practice. For asymptomatic patients, the feasibility of using LCS scans for coronary artery calcium scoring (CACs) has not been explored apart from incidental findings. We aimed to quantify the calcium score using LCS scans in comparison with the ground truth obtained by ECG gated CACs.

##### METHODS AND MATERIALS

The CIRS Dynamic Cardiac Phantom was utilized with 12 calcification inserts of various density (50, 100, 250 and 400 mg/cc) and diameters (1.2, 3 and 5 mm). Scans were performed with simulated ECG with the heart rate from 50 to 100 beats per minute, using the non-gated LCS (CTDIvol = 0.17 mGy) and gated CACs (CTDIvol = 1.74 mGy) protocols. The gated CACs scans served as the ground truth. A FOV of 200 mm was used throughout this study. Additionally, 4 seconds breath motion was added during the LCS scan for comparison purposes. Siemens SyngoVia was used to score the calcifications by individual readers.

##### RESULTS

The visibility of calcium inserts from LCS scans were affected by cardiac motion, which caused blurring and distortion, particularly for small-diameter inserts. As compared with the ground truth, Agatston scores were found lower by 39.5% to 56.7% depending on the heart rate. Within the non-gated scans, the added breathing motion generated additional score difference up to 17.6%. It was found that the calcification detectability is sensitive to the insert density. Calcifications of density higher than 250 mg/cc were detectable. However, inserts with densities 100 mg/cc or lower were not detectable at any heart rate.

##### CONCLUSION

As compared to the ground truth, CAC score using non gated LCS scans is underestimated by 39.5% to 56.7%. It was found that calcium density exceeds 250 mg/cc was detectable. However, calcifications with a density lower than 100 mg/cc cannot be scored with CACs and LCS protocols, regardless of heart rate. Although heart rate may affect the calcium scoring, major calcifications can still be accurately assessed with a significant reduction in patient dose.

##### CLINICAL RELEVANCE/APPLICATION

Using coronary artery calcium scoring as a screening tool has the potential to detect major coronary artery events. Incorporating it into lung cancer screening exams could provide an opportunity for further simultaneous diagnosis.

#### **T5A-SPPH-10 CNN-Based Metal Artifact Reduction Method with Mask for Planning CT in Radiation Treatment**

##### Participants

Won Jin Lee, Ulsan, Korea, Republic Of (*Presenter*) Nothing to Disclose

Juhyeong Ki, Ulsan, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

For radiation treatment of cancer, CT scans are essential. Metal artifacts are generated during CT scans by metal objects inserted into the body for various reasons, which make accurate dose calculation for radiation therapy impossible. Recently, many metal artifacts reduction methods applying deep learning have been proposed. However, compared to other human body parts, metal artifacts are not effectively removed by the existing methods in the head neck area, which has a relatively complex structure and has strong artifacts due to the insertion of dental filling and implant. In this study, we proposed a CNN-based deep learning model using a pre-trained mask extraction model that reduces strong metal artifacts in the head neck area.

##### METHODS AND MATERIALS

The training process was divided into two steps. In first step, a model to extract masks including bone and metal was trained using supervised contrastive learning (SCL) with 30 patients. The tissue pixel distribution includes more of patient's identity and effects of metal artifacts than the bone pixel distribution. Therefore, a bone mask was obtained by separating the tissue distribution from the bone distribution through SCL. In second step, a model for reducing metal artifacts was trained with 85 patients. Metal and bone have a wide pixel range, while tissues concentrate in narrow range of values, resulting in a more than ten-fold difference in the MSE for each area. Therefore, Instead of calculating the loss for the entire image including bones, metal, and tissues, a masked MSE was applied using the bone mask extracted in the first step. As a result, a weighted masked MSE was applied to remove metal artifacts from both tissue and bone.

## RESULTS

In the evaluation metrics for the synthetic dataset, our proposed model showed average scores of MSE, SSIM, PSNR, and PCC of 0.000106, 0.9986, 42.4130, and 0.9944. Overall evaluation values showed improved results than baseline and others. In the qualitative results, the proposed model showed higher performance compared to a commercial software and other models in real-world data.

## CONCLUSION

In this study, we proposed a CNN-based metal artifacts reduction model with weighted masked MSE. Our proposed model demonstrated the best performance on both generated and real-world data, effectively removing strong artifacts near metal as well as stripe-shaped artifacts located far from metal.

## CLINICAL RELEVANCE/APPLICATION

Our proposed model effectively resolves severe artifacts in complex structures such as head neck regions. Therefore, the proposed model is expected to be applied to CT metal artifact reduction in radiation treatment planning process, especially dose calculation for patients with metal implants inserted in the head neck where strong artifacts appear.

## T5A-SPPH-11 Reconstruction of Fast Acquisition MRI with Under-sampled K-space Data by Using Massive-Training Artificial Neural Networks (MTANNs)

Participants

Kenji Suzuki, PhD, Yokohama, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Accelerated MRI acquisitions by taking fewer samples in the K-space involves a trade-off between image quality degradation and acquisition time. We aimed to reduce artifacts in MR images reconstructed from under-sampled k-space data in fast-acquisition MRI by using our MTANN deep learning.

## METHODS AND MATERIALS

We developed a scheme consisting of several iterable cross-domain massive-training artificial neural network (MTANN) modules, namely, an MTANN in the image space (iMTANN) with multiple kernels and multiple frequency-specific MTANNs in the K-space (kMTANNs) to improve the image quality in both spaces in fast acquisition MRI with under-sampled k-space data. A public dataset used in this study contains 20 full k-space volumes of 795 images. Simulated accelerated under-sampled (1/8) MR images were created with a universal sampling pattern. Our MTANN model was trained with the simulated under-sampled MR data as input and the corresponding fully-sampled MR data as "teaching" images.

## RESULTS

To evaluate the image quality quantitatively, we used the structural similarity index (SSIM) and mean squared error (MSE) between the predicted MR and fully-sampled MR images. Compared with the state-of-the-art XPDNet, the SSIM and MSE for our scheme were improved from 0.885 and 31.95 to 0.900 and 23.97, respectively. The differences were statistically significant ( $P < 0.05$  in paired t-tests). In the comparison experiment, our hybrid MTANN preserved the anatomical structure of the knee better than XPDNet. XPDNet changed the appearance of the original anatomical structures, causing significant errors in the reconstruction of MR images, whereas our hybrid MTANN removed the artifacts substantially while preserving those important anatomical structures from the under-sampled MR images.

## CONCLUSION

Our hybrid MTANN improved the image quality by reducing truncation artifacts substantially in 8-times faster acquisition MRI, while anatomic structures were preserved well.

## CLINICAL RELEVANCE/APPLICATION

Our scheme was able to shorten the acquisition time of MRI by a factor of 8, while preserving important anatomical structures, which improves the throughput of MR exams.

## T5A-SPPH-12 Feature Map Visualization for Explaining Black-Box Deep Learning Model in Liver Tumor Segmentation

Participants

Ze Jin, PhD, Yokohama, Japan (*Presenter*) Nothing to Disclose

Tianyi Qu, Yokohama, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

A chief limitation of current artificial-intelligence (AI)-aided diagnosis is the lack of transparency in a black-box deep learning model in the AI system, it would lose radiologists' trust in AI decisions. To address this issue, we developed an explainable AI (XAI) method to visualize the functions of groups of hidden units in a massive-training artificial neural network (MTANN) model for liver tumor segmentation in CT.

## METHODS AND MATERIALS

The dataset used in this study came from the public LITS database which contained dynamic contrast-enhanced CT scans. Seven and 24 cases were selected for training and testing, respectively. To segment liver tumors, a patch-based MTANN model was trained with input liver CT images and corresponding "gold-standard" manual liver segmentation by radiologists as "teaching" images. Our proposed sensitivity-based structure optimization algorithm was applied to the trained model to obtain a compact yet comparable model from a larger one by removing "redundant" hidden units of the model. After the optimization, we grouped the hidden units into several groups of similar functions by using an unsupervised hierarchical clustering algorithm. In this way, the functions of the model were characterized by visualizing the feature maps of each group. Light, gray, and dark pixels in the feature maps indicated enhancement, doing nothing, and suppression, respectively.

## RESULTS

We used a Dice score to compare the performance of the models. The initial MTANN model with 80 hidden units (Dice = 0.714) was

optimized with our algorithm and resulted in a compact model with 9 hidden units (Dice=0.701). These 9 hidden units were clustered into three groups by using the clustering algorithm according to a distance function among the weighted feature maps of the hidden units. Their functions were revealed and explainable by visualizing the feature maps as follows: (a) enhancing the liver area, (b) suppressing non-tumor areas, and (c) suppressing the liver's boundary and reducing the false positive pixels inside the liver. In addition, our experimental analysis by tumor sizes did not change the functions of three groups, demonstrating the robustness of our method. The modified model using only groups A and B achieved a higher performance in tumor segmentation, as they showed improved agreement with the tumor region boundary.

## CONCLUSION

This study demonstrated how our optimization and clustering algorithm could be used to understand and explain the functions of the MTANN model in liver tumor segmentation. It provided a valuable tool to analyze the behavior of black-box models better.

## CLINICAL RELEVANCE/APPLICATION

Our XAI method aiming to improve the transparency of an MTANN deep learning model would help radiologists gain their trust in AI's decisions.

## T5A-SPPH-13 Weakly Supervised Deep Learning Model for Automatically Delineating the Skeleton and Soft Tissue Organs from Whole-Body Diffusion Weighted Imaging (WBDWI)

Participants

Antonio Candito, PhD, MSc, London, United Kingdom (*Presenter*) Nothing to Disclose

## PURPOSE

WBDWI is a non-invasive, radiation-free, and quantitative technique for staging and therapy response assessment in patients with malignant bone lesions and metastatic visceral disease. The technique offers excellent contrast between disease and tissue background and allows measuring the Total Diffusion Volume (TDV in millilitres) and the Apparent Diffusion Coefficient (ADC), a surrogate imaging biomarker of tumour cellularity. However, clinicians still need to perform tedious and time-consuming delineations to obtain these biomarkers. Therefore, the development of automated segmentation tools is desirable. As an initial step, we have developed a supervised deep learning model from "weak annotations" for automatically delineating the skeleton and soft tissue from WBDWI data.

## METHODS AND MATERIALS

A 3D patch-based U-Net model was developed for delineating ten body regions from WBDWI: six skeleton regions (long bones, pelvis, lumbar/thoracic/cervical spine, ribcage) and bladder, kidneys, liver and spleen. WBDWI multi-centre datasets were used to train and validate the U-Net model: a dataset of 189 patients with Advanced Prostate Cancer (APC with baseline and follow-up scans) and 35 patients with Multiple Myeloma (MM with only baseline scan). The network employed a 2-channel input (i) the ADC map and (ii)  $b=0$  s/mm<sup>2</sup> image, derived from the mono-exponential fitting of the diffusion data. Annotations were automatically defined through a set of uncertainty maps (non-binary segmentations) derived from a computationally expensive atlas-based segmentation algorithm.

## RESULTS

The trained U-Net model was able to generate the body region segmentation maps within 20 seconds on CPU (2.4 GHz Quad-Core). On average, the dice score for skeleton regions on 15 test datasets was 0.62, with precision and recall of 0.67 and 0.72, respectively. Average dice score for soft tissue organs was 0.75, with precision and recall of 0.73 and 0.78, respectively.

## CONCLUSION

Our deep learning model could facilitate the development of signal-based automated tool for delineation and quantification of malignant bone lesions and metastatic visceral disease in patients with APC and MM.

## CLINICAL RELEVANCE/APPLICATION

Our model could assist clinicians in detecting and quantifying disease from WBDWI in patients with MM, APC, advanced breast and melanoma cancer, and, for screening subjects with high-cancer risk.

## T5A-SPPH-2 Optimizing Image Quality in Breast Screening: A Medical Physics 3.0 Approach

Participants

Niall Phelan, MS, (*Presenter*) Nothing to Disclose

## PURPOSE

In order to maximize sensitivity and specificity in population based breast screening, image quality should be optimized but equally must be consistent for all women screened. Imaging optimization projects have largely been underpinned by equipment performance metrics, established by technical image quality and dose indicators from physics quality control (QC) tests. However, the correlation between phantom image quality and impact on the clinical outcome is poorly understood and tenuous in many cases. We have applied the principles of Medical Physics 3.0 to combine medical physics QC data with screening outcome data to drive optimization and consistency of technical quality in a national breast screening programme.

## METHODS AND MATERIALS

The screening programme data management system enables collection and analysis of performance data including cancer detection rate (CDR) by individual mammography system for quality audit and reporting. However the requirement to accumulate sufficient data means these reviews can only be done retrospectively. We have used CDR analysis of more than 2 million screening examinations as a proxy indicator for comparison of equipment performance, correlated with routine medical physics image quality tests to monitor and audit quality and consistency.

## RESULTS

Following a large scale imaging equipment replacement with two new mammography system types, we observed that while the performance of both systems was consistent with previous system types and exceeded programme standards for cancer detection, significant differences were observed between them. This result offered an opportunity to review and standardize technical

performance to achieve consistency across the programme. Experimental imaging and simulation studies were carried out to determine improved automatic exposure control (AEC) system set-up which was then implemented across the programme by the vendor. Operational radiation dose increased but remained lower than European (EUREF) guidelines. Subsequent retrospective analysis demonstrated convergence of technical image quality and CDR for the two systems.

## CONCLUSION

s Differences in mammography equipment technical performance were identified through medical physics QC monitoring and correlated with screening outcome data, providing an opportunity for successful optimization and quality improvement.

## CLINICAL RELEVANCE/APPLICATION

Using Medical Physics 3.0 principles to incorporate the use of aggregated screening data and clinical outcome measures in support of medical physics quality assurance processes has demonstrated potential to deliver optimization of quality for individual women and for the screened population.

### T5A-SPPH-3 Diagnostic Value of Direct Lymphangiography in Primary Chyluria: A Retrospective Study

Participants

Qi Hao, Beijing, China (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the diagnostic value of direct lymphangiography (DLG) in primary chyluria.

## METHODS AND MATERIALS

Thirty-seven patients diagnosed as primary chyluria were recruited in this retrospective study. All patients were examined by DLG. The DLG examination was performed using the American GE Innova 2000-IQ DSA machine. According to the patient's clinical condition, one side of the foot was selected for lipiodol injection, and if the patient had combined lower limb lymphedema, the healthy side of the foot was selected. The patient was placed in a supine position, and a mixture of methylene blue and 2% lidocaine (1:1) was injected intradermally and subcutaneously between the roots of the 1st to 3rd toes on one side of the foot about 1-2 ml. A blue-stained shallow lymphatic was found under the skin, and the lymphatic was entered by puncture with a lymphography needle, and a total of about 7-15 ml of lipiodol was injected at a flow rate of 6-8 ml/h. The lipiodol development and regurgitation were observed dynamically under DSA until the lipiodol entering at the end of the thoracic duct was revealed, and the observation time ranged from 1.5 to 4.0h. For DLG, the indexes were: Distribution, reflux and dilatation of abnormal lymphatic vessels in the urinary system, chest and abdomen. The DLG signs of primary chyluria patients were statistically described by composition ratio of classification variables.

## RESULTS

DLG showed ipsilateral iliac lymphatic tortuosity and dilatation in 30 cases (81.1%); contralateral iliac lymphatic reflux in 17 cases (45.9%); ipsilateral lumbar trunk tortuosity and dilatation and reflux in 19 cases (51.4%); contralateral lumbar trunk reflux in 21 cases (56.8%); ipsilateral pelvic sinus reflux in 17 cases (45.9%); contralateral pelvic sinus reflux in 21 cases (56.8%); thoracic duct reflux obstruction in 37 cases (100.0%); 7 cases (18.9%) of bronchial mediastinal trunk reflux, including 1 case (2.7%) of hilar reflux and 3 cases (8.1%) of intercostal reflux (Figure 11%); 4 cases (10.8%) of perineal reflux; 1 case (2.7%) of abdominal reflux; 21 cases (56.8%) of cervical trunk and subclavian trunk reflux.

## CONCLUSION

s DLG is able to visualize lymphatic reflux and abnormal reflux dynamically, evaluate lymphatic vessel morphology accurately, and achieve a diagnostic rate of 81.8% for primary chyluria.

## CLINICAL RELEVANCE/APPLICATION

DLG can provide an important imaging basis for the diagnosis and preoperative evaluation of primary chyluria.

### T5A-SPPH-4 Retrospective Analysis of Doses Delivered during Embolization Procedures over the Last 10 Years

Participants

Joel Greffier, PhD, Nimes, France (*Presenter*) Nothing to Disclose

## PURPOSE

This study aimed to retrospectively analyze dosimetric indicators recorded since 2012 for thoracic, abdominal or pelvic embolizations to evaluate the contribution of new tools and technologies in dose reduction.

## METHODS AND MATERIALS

Dosimetric indicators (dose area product (DAP) and air kerma (AK)) from 1449 embolizations were retrospectively reviewed from August 2012 to March 2022. A total of 1089 embolizations were performed in an older fixed C-Arm system (A1), 222 in a newer fixed C-Arm system (A2) and 138 in a 4DCT system (A3). The embolization procedures were gathered to compare A1, A2 and A3.

## RESULTS

DAP were significantly lower with A2 compared to A1 for all procedures (median -50% +/- 5%,  $p < 0.05$ ), except for uterine elective embolizations and gonadal vein embolization. The DAP values were significantly lower with A3 than with A1 ( $p < 0.001$ ). CT scan was used for guidance in 90% of embolization procedures.

## CONCLUSION

s This monocentric retrospective analysis of the doses delivered during thoracic, abdominal and pelvic embolization procedures over a 10-year period showed the contribution of the new IR tools in dose reduction and patient management. The last C-arm technology reduced the image noise and improved image quality, allowing a 50% reduction of the air kerma and showing a significant dose reduction. The implementation of a CT scan inside the IR room allowed a more precise 3D guidance without increasing the dose delivered to the patients.

## CLINICAL RELEVANCE/APPLICATION

The last C-arm technology reduced the image noise and improved image quality, allowing a 50% reduction of the air kerma and showing a significant dose reduction. The implementation of a CT scan inside the IR room allowed a more precise 3D guidance without increasing the dose delivered to the patients.

## T5A-SPPH-5 Relationship between Presurgical DTI Motor Tract Maps and Intraoperative Evoked Potentials

Participants

Juan José Sanchez Fernandez, DPhil, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

### PURPOSE

To study the accuracy of DTI in the presurgical identification of the motor tract and its correlation with evoked potentials obtained during brain tumor surgery.

### METHODS AND MATERIALS

54 pyramidal tractographies based on DTI images were performed before and after surgery in patients with glioma tumours histologically confirmed (17 diffuse anaplastic gliomas, 8 oligoastrocytomas and 29 multiform glioblastoma) which were immediately adjacent or in direct contact to the pyramidal tract. During surgery, central sulcus was identified and confirmed by evoked potentials. For evoked potential a direct phase technique for cortical stimulation with high frequency (250Hz) monopolar electrodes was used. For cortical stimulation an 8 contacts electrode was used whereas a current waveform with eight electromyograms was used for evoked potentials continuous monitoring. When resection approaches the pyramidal tract, subcortical stimulators were used and the electromyographic response was observed after subcortical stimulation. The minimum distance ratio between the resection cavity and subcortical stimulation intensity, in relation to the pyramidal tract, was studied using regression and ANOVA correlation analysis. The p-value was considered as  $p < 0.05$

### RESULTS

The distance between the resection cavity and the motor tract in tractographic sequences postoperatively were 2.5 to 23.7 mm. The results were correlated with data obtained from cortical evoked potentials monitored during surgery. There was a significant linear correlation of 1.08 by applying a regression test between distance and stimulus intensity ( $R^2 = 0.8202$ ,  $P < 0.001$ ).

### CONCLUSION

Correlation was demonstrated between the electrophysiological and DTI in the analysis of the pyramidal tract by imaging based on the use of direct subcortical stimulation. The DTI should be systematically included in the standard imaging protocol for the study of brain tumours both for etiologic diagnosis to treatment planning in order to preserve the maximum motor tract as possible.

## CLINICAL RELEVANCE/APPLICATION

The identification by DTI of the corticospinal tract prior to brain glioma surgery allows the neurosurgeon an accurate planning of the maximum tumour removal with motor tract preservation. Monitorization with intraoperative evoked potentials showed correlation with presurgical tractography MR studies.

## T5A-SPPH-6 CRLM-GAN: The Optimization Effect on Automatic Segmentation of T2-weighted Images for Colorectal Liver Metastases Combining with Transfer Learning and Generative Adversarial Network under Small-scale Sample

### PURPOSE

Colorectal cancer liver metastase (CRLM) is a ubiquitous digestive tract tumor, it is estimated that more than 50% colorectal cancer patients will eventually develop liver metastases during the course of illness. As for the diagnosis of CRLM, T2WI can serve as an important supplementary modality beyond the conventional examination of contrast-enhanced CT or DWI MRI. In this study, we proposed a modified hybrid auto-segmentation model based on transfer learning (TL) and generative adversarial network (GAN), i.e. CRLM-GAN, to explore the optimization effect under small-scale sample, thus expanding the application potential of T2WI images in intelligent diagnosis for CRLM.

### METHODS AND MATERIALS

A retrospective cohort was enrolled involving 70 patients with pathologically confirmed CRLM. All the images were acquired by the axial fast recovery, fast spin-echo and T2WI sequence, sourced from a 1.5-T MRI scanner using an 8-channel phased array body coil. In the fore-end of the network, UNet++ was employed as the generator to initially segment probabilistic maps. Then the generated probabilistic maps and real labels were multiplied with the original images respectively, resulting in the predicted tumor and the real tumor images. Both of them were input into the discriminator-a pre-trained ResNet-50 to extract and fuse the deep convolutional features. Ultimately, a comprehensive loss function was computed by combining the binary cross-entropy, Dice, and the multiscale loss. Moreover, Tversky Loss was incorporated into the training to optimize the final results.

### RESULTS

20% of the patients were used for the independent testing, and the model performance was assessed by five typical metrics, with Dice, Jaccard, Recall, Precision, F1-score of 0.7163, 0.5580, 0.5898, 0.9118, 0.7040. Our method achieved an average improvement of 6.23%, 4.32%, and 4.32% for the Dice, Jaccard, and F1-score compared with UNet. In contrast to UNet++, the three indicators increased by 2.29%, 1.91%, and 1.86%, respectively. When taking into account the addition of the Tversky loss, the Dice and Jaccard still improved by 0.16% and 0.20%, separately.

### CONCLUSION

This study designed a novel segmentation network based on TL and GAN. The results demonstrated that it can significantly enhance the accuracy under small-scale sample. Future work will focus on the generalization of the model in multi-center and medium-sized samples, so as to further expand the application scope.

## CLINICAL RELEVANCE/APPLICATION

The work provides a relatively reliable auto-segmentation tool for radiologists in the case of small samples. Besides, it also extends the application value of T2WI images in intelligent diagnosis on CRLM, compared to the auto-segmentation of routine image

modalities such as CT or DWI.

## **T5A-SPPH-7 Two-stage Few-shot Segmentation Framework on Lung Nodule CT Images**

Participants

Mengxiao Geng, Shenzhen, China (*Presenter*) Nothing to Disclose

### **PURPOSE**

Although deep learning has demonstrated remarkable results for lung nodules, it is limited by the need for extensive manual labeling and high computational costs. Similarly, traditional active contour-based methods require manual adjustment and can be sensitive to the selection of initial contours. As such, there is a need for novel segmentation frameworks that address these challenges.

### **METHODS AND MATERIALS**

Our proposed few-shot segmentation framework (FSSF) combines deep learning with an optimized active contour model to segment lung nodules. First, deep learning is used to obtain prior position information based on a small amount of data. This prior information is then input as the initial contour into the optimized active contour model (OACM), which significantly enhances the segmentation accuracy of the deep network for lung nodules in small sample situations. Specifically, the active contour model includes heat kernel convolution to reduce computational complexity, while adaptive weighted functions and high-order total variation maintain segmentation accuracy. To solve the model efficiently, we used the alternating direction method of multipliers to split it into subproblems. In the experiment, the clinical CT dataset was acquired from Guangdong Provincial People's Hospital using a Siemens CT scanner (SENSATION 16 SLICE). The dataset included 199 subjects (102 males and 97 females, aged  $58.9 \pm 11.89$  years [range of 32-89]) who were collected from January to December 2020. To evaluate the proposed few-shot segmentation method, lung CT images from 10 patients were used for presegmentation model training, with 20 slices selected as test images.

### **RESULTS**

Our proposed method was compared against state-of-the-art methods such as U-Net, WBHV, WBHV+, ICTM, and ICTM+ in terms of their segmentation effectiveness. The results demonstrate that our proposed method showed significant improvement compared to other methods, with Dice improving by 6.9%, JS improving by 9.9%, and  $\delta$  improving by 7.0%. Compared to the state-of-the-art methods, our method still achieves much better performance.

### **CONCLUSION**

Compared to other segmentation methods, our proposed method demonstrates superior performance in both visual and quantitative evaluations.

### **CLINICAL RELEVANCE/APPLICATION**

CT image segmentation of pulmonary nodules is a useful technique for early detection, quantitative evaluation, and monitoring of lung cancer and other diseases. This technique separates nodules from surrounding tissue and calculates morphological features, providing support for clinical medicine.

## **T5A-SPPH-8 Improving Image Quality in Low-dose Abdominal and Pelvic CT Angiography Using Deep Learning Image Reconstruction: Comparison with Filtered Back-projection and Iterative Reconstruction**

### **PURPOSE**

To evaluate image quality among the traditional FBP, adaptive statistical iterative reconstruction (ASIR-V) and deep learning image reconstruction (DLIR, TrueFidelity) algorithms in low-dose abdominal and pelvic CT angiography (CTA).

### **METHODS AND MATERIALS**

Forty-six abdominal and pelvic CTA patients were included. All patients underwent low-dose CTA with 80kVp and smart tube current modulation (100-720mA). Images were reconstructed using FBP, ASIR-V with strength of 50% (AV-50) and 100% (AV-100), TrueFidelity with medium (TF-M) and high (TF-H) strength. The CT value and standard deviation (SD) value of abdominal aorta, psoas major muscle and subcutaneous fat were measured, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. The CT value skewness in psoas major muscle with uniform density was also measured to reflect the image texture change. A 5-point scoring method was used to evaluate the granularity, fuzziness and beam hardening artifacts of all images. The above indexes of the five image groups were compared.

### **RESULTS**

The volume CT dose index was low at  $1.09 \pm 0.37$  mGy. CT values were all similar among the five groups ( $P > 0.05$ ). But, SD values were different among groups with FBP being the largest and AV-100 the smallest which resulted in different SNR and CNR values opposite of the SD values. AV-100 and TF-H also had the best score in granularity while FBP had the worst. However, AV-100 had significantly higher skewness and fuzziness than other four groups ( $P < 0.001$ ), with FBP and DL-M had the smallest and TF-H marginally higher. The TF-H group had the best beam hardening artifact score while FBP and AV-50 group had the worst ( $P < 0.001$ ).

### **CONCLUSION**

Compared with FBP and ASIR-V, TrueFidelity reconstruction algorithm better balances image noise, smoothness, image texture, and artifacts in low-dose abdominal and pelvic CTA, with TF-H provides the best overall image quality.

### **CLINICAL RELEVANCE/APPLICATION**

TrueFidelity with high (TF-H) strength reconstruction algorithm provides the best image quality in low-dose abdominal and pelvic CTA.

## **T5A-SPPH-9 Metal Artifact Reduction for Head and Neck CBCT with Attentional Dual Encoder Fusion UNet**

Participants

Jungmok Lee, Ulsan, Korea, Republic Of (*Presenter*) Nothing to Disclose

### **PURPOSE**

Since the insertion of metallic implants in surgical method has been grown, there also have been severe metal artifact in CT and CBCT. So the metal artifact reduction methods became on the rise. In addition, the application of convolutional neural network based structure in metal artifact reduction has shown a great performance, still it lacks of extracting features which both efficiently removes artifact and restores the tissue structure. In this study, we propose the dual encoder fusion UNet structure for effective cone-beam CT metal artifact reduction, which can extract both the artifact removal feature and tissue structure feature through dual encoder network.

## **METHODS AND MATERIALS**

Our model architecture is based on UNet architecture with two encoders. The first encoder mostly focuses on removing metal artifact rather than restoring the tissue structure, and the second encoder focuses on restoring the tissue structure instead of removing metal artifacts. Two bottleneck features are fused through attentional fusion, which consist of spatial and global attention. Similar to bottleneck feature fusion, the encoder features for skip connection is fused using attentional fusion. Our model was trained in generated synthetic dataset for 100 epochs with mean squared error and auxiliary loss. Auxiliary loss was calculated by direct mean squared error between the encoder feature and target. And our model was evaluated on mean squared error(MSE), peak signal-to-ratio(PSNR), pearson correlation coefficient(PCC), and structural similarity(SSIM). The quantitative analysis has also done in real patients.

## **RESULTS**

Compared to single encoder architectures with similar parameter numbers, our model has shown the noticeable performance in both synthetic data real patients without ground truth. The evaluation metric(MSE, PSNR, PCC, SSIM) in synthetic data is 0.000086, 41.859071, 0.993072, 0.993681. Our model has removed the metal artifact effectively, and shown the best structure restoration in real patients while other models has made the greyish artifacts for the restoration.

## **CONCLUSION**

s In this study, we proposed the dual encoder UNet architecture for effective metal artifact reduction, and it has shown that model can focus on both effective artifacts reduction and tissue structure restoration. We also showed that attention-fused features helps in performance of artifact removal and tissue restoration.

## **CLINICAL RELEVANCE/APPLICATION**

We expect that our proposed model can be successfully applied to the metal artifact reduction especially in CBCT for radiation treatment, since there is no artifact reduction software for CBCT at this moment.

### Radiation Oncology Tuesday Poster Discussions I

#### Sub-Events

#### **T5A-SPRO-1 The Application Value of Energy Spectrum CT Iodine-water Scatter Plot in Predicting Surgical Margins of Pancreaticoduodenectomy**

#### **PURPOSE**

To predict the surgical margins of pancreaticoduodenectomy by analyzing the energy spectrum CT iodine-water scatter plot of patients with duodenal malignant tumors and adjacent normal tissues, and to guide the optimal selection of clinical surgical targets.

#### **METHODS AND MATERIALS**

28 patients with duodenal malignant tumor were selected as research objects, and the patients were retrospectively collected with surgical pathological confirmation and complete energy spectrum CT scan data before surgery, and multi-point delineation and analysis of iodine-water scatter plots were performed in the solid part of duodenal malignant tumor and the area of interest of surgical margin. Statistical analysis of iodine-water scatter plot and postoperative pathology diagnosis rate.

#### **RESULTS**

There was a clear demarcation between the solid part of the lesion and the iodine-water scatter plot of the surgical margin, and the diagnosis rate with the postoperative pathology was 100%, with a statistically significant difference ( $p < 0.05$ ).

#### **CONCLUSION**

s The negative/positive surgical margins of pancreaticoduodenectomy can be distinguished by using energy spectrum CT iodine-water scatter plot to maximize the preservation of normal tissues around the margins.

#### **CLINICAL RELEVANCE/APPLICATION**

The application value of energy spectrum CT iodine-water scatter plot in predicting surgical margins of pancreaticoduodenectomy

T5A-SPVA

### Vascular Imaging Tuesday Poster Discussions I

#### Sub-Events

#### T5A-SPVA-1 Magnetic resonance Lymphangiography - An Initial Clinical Experience

##### PURPOSE

Lymphedema is defined by chronic accumulation of fluid in soft tissue. Due to an increasing number of lymphonectomies associated with breast or pelvic surgery in the past years, secondary lymphedema has become more prevalent. Many patients fail conservative treatment and need surgery, e.g. lymphaticovenous anastomosis (LVA). For surgical treatment planning, visualization of lymphatic vessels is crucial. Established lymphography procedures like lymphoscintigraphy and indocyanine lymphography suffer from poor spatial resolution or in case of conventional lymphangiography require surgical isolation. Magnetic resonance lymphangiography (MRL) is an emerging imaging technique, allowing non-invasive visualization of lymphatic vessels. We report on our initial experience with MRL in patients with suspected lymphedema including patients after microsurgical therapy.

##### METHODS AND MATERIALS

11 consecutive patients (11 female; mean age 46 years) undergoing MRL between 05-2022 and 04-2023 were included. In 10/11 (91%) patients with suspected lymphedema final work-up confirmed the diagnosis. 9/10 had secondary lymphedema (7 after lymphonectomy, 1 after liposuction; 1 postpartum) and 1/10 patients had idiopathic lymphedema. The remaining patient suffered from chronic venous obstruction. 10/11 (91%) showed edema in the lower extremities, 1/11 (9%) in the upper extremities. 3 patients underwent LVA-surgery prior to MRL resulting in a total of 10 anastomoses. MRL was performed on a 1.5 T system. For evaluation of the extent of edema a T2w TSE DIXON was obtained. To visualize the lymphatic system a T1w GRE with fatsat was obtained after interstitial transpedal injection of a gadolinium-based contrast agent (Gadobutrol). Analysis included location and extent of edema, technical success rate and qualitative assessment of the MRL images.

##### RESULTS

In all patients MRL was technically successful without complications and allowed direct visualization of the lymphatic vessels. 8/10 LVAs were identified on MRL. In one patient, lymphatic inflow to iatrogenic lymphoceles after liposuction was directly visualized by MRL. Based on MRL 9/10 patients were correctly diagnosed with lymphedema. MRL correctly identified the one patient with chronic venous obstruction. MRL led to either performed or scheduled LVA surgery in 6/10 cases. Three patients continued to be treated conservatively.

##### CONCLUSION

MRL appears to be a safe and precise for diagnosis of lymphedema and allows reliable visualization of the lymphatic vessels including LVAs.

##### CLINICAL RELEVANCE/APPLICATION

MRL seems to be a promising addition to established lymphography procedures, particularly for treatment planning in patients scheduled for LVA or for postoperative follow-up after LVA.

#### T5A-SPVA-2 Validation of Correlation between Signal Intensity Gradient from Time-of-flight Magnetic Resonance Angiography and Wall Shear Stress by Phase-contrast Magnetic Resonance

##### PURPOSE

Arterial wall shear stress (WSS) contributes to atherosclerosis from its inception, progression, and disruption of plaque. However, there is no useful, non-invasive clinically accessible screening tool to measure arterial WSS. We aimed to investigate whether the signal intensity gradient (SIG) from Time-of-Flight Magnetic Resonance Angiography (TOF MRA) is associated with WSS determined by phase contrast Magnetic Resonance (PC MR), using both an experimental and human studies for both carotid and vertebral arteries.

##### METHODS AND MATERIALS

For the experimental study, we measured WSS in 4-sized tubes (4 to 11 mm diameters) with variable flow rates using both PC MR and TOF MRA. For the human study, all subjects were examined with the TOF MRA and PC MR in the carotid and vertebral arteries, and their arterial WSS and SIGs were determined in the same segment. The viscosity of water was set as 1 centiPoise (cP, 20?), and whole blood viscosity was calculated subject-specifically using hematocrit. Pearson's correlation coefficients, and line fitting equations were used for statistical analysis.

##### RESULTS

The experimental study applied various flow rates of water, ranging from 0.06 to 12.75 mL/s. The WSS ranged from 0.1 to 1.6 dyne/cm<sup>2</sup>. The correlation between WSS from PC MR and SIG of TOF MRA was significant, showing a coefficient 0.86, (p<0.001, R<sup>2</sup>=0.75). For the WSS in human arteries, 28 subjects were enrolled (11 females, mean age of 62 years). The arterial WSS ranged from 1.9 to 21.0 dyne/cm<sup>2</sup>. Both carotid and vertebral arteries showed significant correlations between WSS and SIG, with coefficients of 0.85, 0.86, 0.91, and 0.81 in the right, left carotid and vertebral arteries, respectively).

## CONCLUSION

s TOF MRA SIG provides in vivo hemodynamic information that measures arterial shear stress concurrently. Future studies are needed for a feasibility of generalization in various MR machines and persons of different races and ethnicity.

## CLINICAL RELEVANCE/APPLICATION

The SIG is a surrogate measure of arterial WSS and it could be obtained from TOF MRA. There is no technical hurdle to get it, unlike the cardiac pacing and velocity encoding (VENC), and it usually takes less than 5 minutes for the whole arteries examined. The signal intensity of TOF MRA contains hemodynamic information including arterial WSS. We authors believe there can be a pragmatic application of SIG in clinical and experimental fields in the future.

## T5A-SPVA-3 Single-phase Steady-state Ferumoxytol-enhanced MR Angiography of Neck, Chest, Abdomen, and Pelvis: A Feasibility Study

### Participants

Soheil Kooraki, MD, Los Angeles, CA (*Presenter*) Nothing to Disclose

## PURPOSE

Comprehensive vascular imaging is often required as part of the pre-multi visceral transplant workup. This study aimed to assess the feasibility of single-phase steady-state Ferumoxytol-enhanced (Fe-MRA) for vascular mapping of neck, chest, abdomen and pelvic arteries and veins.

## METHODS AND MATERIALS

In this IRB-approved, HIPAA-compliant, single-center study, eleven patients (5 females, median age of 24 years, ranging from 5-93) underwent a single-phase Fe-MRA of neck, chest, abdomen, and pelvis as part of the pre-multi visceral transplant assessment. The Fe-MRA was achieved by slow intravenous infusion of 4 mg/kg ferumoxytol and using a 1.5 or 3 Tesla MR scanner. The time from localizer image acquisition to completion of the angiographic acquisition was measured. Two radiologists independently scored images for overall quality, motion artifact, diagnostic confidence for assessment of arterial and venous segments, using a 5-point Likert scale (5: excellent, 4: good, 3: diagnostic, 2: limited, 1: non-diagnostic). Inter-observer agreement was assessed using Intraclass Correlation Coefficient.

## RESULTS

The scans were technically successful, with an average scan time of 11 minutes (ranged 5-25 minutes) and without any major adverse effects. The overall image quality was excellent in 7, good in 3 and diagnostic in one patient(s), and there were no non-evaluable vascular segments in any of the scans. A total of 545 named vascular segments were scored, of which the image quality for diagnostic confidence was good to excellent in 91.7% (500/545). There were not any motion artifacts to impede the diagnostic assessment (all scores = 3). There was excellent inter-reader agreement for scoring diagnostic confidence in each vascular segment (all  $\kappa > 0.9$ ).

## CONCLUSION

s This study demonstrated the feasibility, high image quality and diagnostic confidence of Fe-MRA for comprehensive vascular mapping in pre-multi visceral transplant workup. The scan can be completed in as little as 5 minutes.

## CLINICAL RELEVANCE/APPLICATION

Non-nephrotoxic Fe-MRA is a quick and feasible method for comprehensive vascular mapping in patients who are undergoing multi-visceral transplant, with the advantage of obtaining both arteriogram and venogram in a single-phase image.

#### **T5B-SPBR-1 Artificial Intelligence DWI without Segmentation Has Comparable Diagnostic Performance with Standard Breast MRI in the Differentiation of Malignant and Benign Breast Tumors**

##### Participants

Mami Iima, MD, PhD, Kyoto, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Our aim was to develop a machine-learning model that can differentiate benign and malignant breast tumors using diffusion-weighted MRI.

##### METHODS AND MATERIALS

This prospective study included 530 breast lesions. 334 breast lesions with confirmed histology or no enlargement on follow-up were analyzed. The data was divided into dataset for train and 10-fold cross-validation (139 malignant 67 benign) and test dataset (85 malignant, 43 benign) with no overlap of patients. 3T breast MRI DWI was acquired with 5 b values up to 1500 s/mm<sup>2</sup> in addition to DCE-MRI. Only the lesion slice was selected without lesion segmentation. To develop a deep-learning model that can differentiate between benign and malignant tumors, we compared various combinations of basic data augmentations: A: random elastic deformation, B: random affine transformation/random noise, and C: mix-up. The small 2D CNN model was also compared to 3D CNN and ResNet18. The diagnostic performance of the deep learning model obtained from DW images and standard breast DCE MRI based on BI-RADS was evaluated using ROC analysis.

##### RESULTS

The augmentations improved accuracy in all experiments (AUC:0.86-0.90 VS. 0.86 in validation dataset, and AUC:0.85-0.88 VS. 0.87 in test dataset) except augmentation C (AUC:0.86 and 0.83). The result using 2D CNN resulted in a better AUC than 3D CNN (AUC:0.88-0.90 VS. 0.72-0.75). All results of 10-fold cross validations showed small 2D CNN with data augmentation A and B to be the best model (AUC: 0.90), and it was also the best against test dataset (AUC:0.88) that was comparable to standard breast MRI (0.89 and 0.87). Specificity tended to be higher in the deep learning model with 2D CNN from DW images than in standard breast MRI (85% VS. 81% in validation dataset, and 81% VS. 74% in test dataset), with higher sensitivity in standard breast MRI (80% VS. 98% in validation dataset, and 86% VS. 99% in test dataset).

##### CONCLUSION

While some studies evaluated the diagnostic performance of breast MRI using deep learning, so far as we know, no study has yet evaluated using only breast DWI with a deep learning model. AI can achieve good performance comparable to standard breast MRI for differentiating between malignant and benign breast tumors. DWI-AI provided better specificity than standard breast DCE-MRI, while the sensitivity was slightly inferior. Those results underline the great potential of supplementing the diagnostic performance of standard breast MRI with variable specificity, without additional reading time by breast radiologists, and beneficial in patients who are allergic to contrast agents.

##### CLINICAL RELEVANCE/APPLICATION

A machine-learning model with diffusion-weighted MRI has the potential to improve specificity in distinguishing between benign and malignant breast tumors.

#### **T5B-SPBR-3 Breast Lesion Morphology Assessment with High and Standard b Values in Diffusion-weighted Breast MRI at 3.0 Tesla**

##### Participants

Sara Christner, MD, Wurzburg, Germany (*Presenter*) Nothing to Disclose

##### PURPOSE

This investigation compared diffusion weighted imaging (DWI) with b values of 800 and 1600 s/mm<sup>2</sup> to dynamic contrast-enhanced imaging (DCE) for lesion morphology assessment in high-resolution breast MRI at 3.0 Tesla - an area that has been occupied traditionally by DCE.

##### METHODS AND MATERIALS

Multiparametric breast MRI was performed in 91 patients with 93 histopathologically proven lesions (31 benign, 62 malignant). Two radiologists evaluated three datasets per patient independently and assessed lesion visibility and BIRADS morphology criteria. Bland-Altman analyses were conducted for lesion size comparisons. In addition, diagnostic accuracy was calculated for each reader and dataset.

##### RESULTS

The overall diagnostic accuracy for lesion morphology assessment was significantly higher for DWI 800 (0.88) and DWI 1600 (0.89) than for DCE (0.78) (p < 0.001).

The visibility of carcinomas was considered better compared to benign findings in both DWI800 and DWI1600 ( $p < 0.001$ ) with no  $b$  value-dependent difference. Similarly, mass lesions were easier assessable compared to non-mass lesions, irrespective of the DWI images'  $b$  value ( $p < 0.001$ ). Intra-reader reliability for the analysis of morphologic BIRADS criteria among DCE and DWI datasets was at least moderate ( $\kappa = 0.557$ ), while at least substantial inter-reader agreement was ascertained over all assessed categories ( $\kappa = 0.776$ ). In pairwise Bland-Altman analyses, the measurement bias between DCE and DWI800 was 0.7 mm, whereas the difference between DCE and DWI1600 was 2.8 mm. DWI1600 images allowed for higher specificity than DCE ( $p = 0.007/0.062$ ).

## CONCLUSION

s DWI can be employed for reliable morphologic lesion characterization in high-resolution breast MRI. The use of high  $b$  values increases diagnostic specificity, while lesion size assessment is more precise with standard 800 s/mm<sup>2</sup> images.

## CLINICAL RELEVANCE/APPLICATION

Given ongoing concerns regarding the safety of Gd-based contrast media and continuing efforts on abbreviated breast MRI protocols, morphology assessment using DWI shows promising results in the differentiation of malignant from benign breast lesions.

## T5B-SPBR-4 Association of Preoperative MRI with Breast Cancer Treatment and Survival: A Single Institution Observational Study

Participants

Berat Bersu Ozcan, MD, Dallas, TX (Presenter) Nothing to Disclose

## PURPOSE

To evaluate the association between preoperative breast MRI with surgery type, contralateral cancer, recurrence-free (RFS) and overall survival (OS) in women with early stage breast cancer.

## METHODS AND MATERIALS

In this single institution, retrospective study, we identified women with Stage I-III breast cancer diagnosed between 03/01/2014-03/31/2021 with available follow-up. Patient and tumor characteristics were recorded. Two cohorts were created based on the use of preoperative MRI (PMRI) versus not (NoMRI) with Wilcoxon signed-rank and  $\chi^2$  tests utilized for cross-group comparisons. Kaplan-Meier method and log-rank tests were used to compare RFS and OS in women with and without MRI. Multivariable Cox proportional hazards model analysis was performed to evaluate RFS and OS by preoperative MRI status while controlling for other variables that could adversely impact outcomes.

## RESULTS

593 eligible patients were included [322 (54.3%) with PMRI, 271 (45.7%) noMRI]. Mean patient age was younger (53.8±11.8 vs 59.3±12.6 years,  $p < 0.001$ ) and dense breasts more common (51.4% vs 22.0%,  $p < 0.001$ ) in PMRI group. Seventeen bilateral cancers (2.9%) were in PMRI (14/17, 82.4% only detected on MRI) vs 10 (1.7%) in no-MRI ( $p = 0.34$ ). No significant difference between clinical Tstage rates (cT0-2 88.8% ; 91.9% ,  $p = 0.22$ ) or invasive molecular subtype (luminal A, 22.7% vs 28.5%; luminal B, 56.3% vs 46.6%; HER2, 5.4% vs 4.1%; triple negative, 15.5% vs 20.7%,  $p = 0.13$ ) in MRI vs no-MRI groups, respectively. PMRI group had higher rates of cN+ (27.3% vs 18.1%,  $p < 0.01$ ), and neoadjuvant therapy (41.3% vs 18.8%,  $p < 0.001$ ). Total mastectomy (57.8% vs 51.3% ,  $p = 0.12$ ), margin positivity (6.2% vs 7.4%,  $p = 0.57$ ), recurrence (10.2% vs 7.0%,  $p = 0.17$ ) and death rates (8.1% vs 7.7%,  $p = 0.88$ ) were similar in PMRI vs noMRI, respectively. At median follow-up of 69 months (IQR, 61-75), time to recurrence was [24 (IQR, 18-48) vs 23 (IQR, 9-30) months,  $p = 0.05$ ] . Mastectomy rates remained comparable after adjusting for age and breast density ( $p = 0.28$ ). Contralateral cancers were identified sooner and more frequently in the no-MRI group [4 (2.1%) vs 2 (0.9%) cancers, 21±20 vs 48±13 months].

## CONCLUSION

s In this single-institution retrospective study, the use of preoperative MRI is not associated with improved surgical margin, RFS or OS. At surveillance contralateral cancers are identified earlier and more frequently in the noMRI group.

## CLINICAL RELEVANCE/APPLICATION

Detecting clinically and mammographically occult contralateral breast cancers on preoperative MRI may help decrease contralateral cancer events at early surveillance.

## T5B-SPBR-5 Delineating Benign from Malignant Breast Lesions with Tumor Subregion Complexity using Fractal Analysis

## PURPOSE

To assess the feasibility of using fractal analysis in habitat analysis for the differential diagnosis of benign and malignant breast lesions, and to evaluate its diagnostic performance compared to conventional heterogeneity features extracted from the whole tumor.

## METHODS AND MATERIALS

A retrospective study was conducted on 97 patients with histologically confirmed breast lesions (75 malignant, 22 benign). Diffusion-weighted imaging (DWI) and dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) were acquired, and three tumor habitats were defined based on perfusion and cellularity characteristics. Fractal dimensions (FDs) were calculated for each habitat, and diagnostic performance was compared using the area under the receiver operating characteristic curve (AUC).

## RESULTS

The FD of hypervascular habitat (FD 1) showed a statistically significant difference ( $p < 0.001$ ) between malignant and benign lesions. The AUC of FD 1 (0.925, 95% CI 0.854 - 0.969) was higher than that of the conventional heterogeneity of the whole lesion (0.671, 95% CI 0.568 - 0.763), indicating improved diagnostic performance. Hypervascular cellular habitat, characterized by relatively low ADC and high wash-in, demonstrated a remarkable ability to discriminate breast cancer from benign lesions.

## CONCLUSION

s This pilot study reveals that FD features generated by habitat analysis could better differentiate benign from malignant breast

lesions compared to conventional heterogeneity features extracted from the whole tumor. The predictive model combining tumor habitats MRI and fractal analysis could prove useful as a screening tool, suggesting that fractal analysis may play an essential role in identifying patients whose breast lesions are more likely to behave aggressively.

#### **CLINICAL RELEVANCE/APPLICATION**

Fractal analysis of MRI tumor habitats enhances differential diagnosis of breast lesions, aiding in personalized treatment decisions.

#### **T5B-SPBR-6 Utilizing a Continuous Time Random Walk Diffusion Model to Differentiate Benign and Malignant Breast Lesions and Predict Prognostic Factors**

##### **PURPOSE**

This exploratory study aimed to assess the potential of a Continuous Time Random Walk (CTRW) diffusion model in distinguishing between benign and malignant breast lesions and to examine the relationships between CTRW parameters and pathologic factors.

##### **METHODS AND MATERIALS**

Eighty five patients with histopathologically confirmed breast lesions (88 breast lesions, 70 malignant and 18 benign lesions) were included in this prospective study. MRI examinations were conducted with a 3.0T scanner (uMR 790, United Imaging Healthcare, Shanghai, China) to acquire 16 b value (0, 10, 20, 30, 50, 70, 100, 150, 200, 400, 800, 1200, 1500, 2000, 2500, 3000 s/mm<sup>2</sup>) DWI. The CTRW parameters (Dm, a, and β) and ADC were compared between benign and malignant lesions using the Mann Whitney U test. Spearman correlation was employed to assess the relationships between the parameters and prognostic factors. Additionally, binary logistic regression and receiver operating characteristic (ROC) curve analysis were used to evaluate the diagnostic performance of individual ADC or CTRW parameters and their combinations. A P value < 0.05 was considered significant.

##### **RESULTS**

Malignant lesions had a significantly lower ADC value ( $1.078 \pm 0.254 \times 10^{-3}$  mm<sup>2</sup>/sec) compared to benign lesions ( $1.418 \pm 0.296 \times 10^{-3}$  mm<sup>2</sup>/sec) (P < 0.001). The CTRW parameters Dm, a, and β were also significantly lower (P<0.001, P<0.001, and P=0.024, respectively) in malignant lesions ( $1.019 \pm 0.285 \times 10^{-3}$  mm<sup>2</sup>/sec,  $0.852 \pm 0.092$ , and  $0.843 \pm 0.088$ , respectively) relative to benign lesions ( $1.437 \pm 0.307 \times 10^{-3}$  mm<sup>2</sup>/sec,  $0.948 \pm 0.065$ , and  $0.886 \pm 0.054$ , respectively). ROC analysis revealed that combining all the CTRW parameters (Dm, a, and β) yielded the best AUC of 0.833 and the highest sensitivity (94.3%) for differentiation of malignant lesions. Spearman correlation analysis demonstrated that β had a significantly positive association with Ki 67 expression (r = 0.263, P = 0.028) and a significantly negative correlation with ER and PR expression (r = -0.363, P = 0.002 and r = -0.413, P < 0.001, respectively). Additionally, Ki 67 expression was negatively correlated with Dm and ADC (r = -0.326, P = 0.006, and r = -0.313, P = 0.008, respectively), while PR expression was positively correlated with Dm and ADC (r = 0.282, P = 0.018 and r = 0.253, P = 0.034, respectively).

##### **CONCLUSION**

Our study highlighted the significant diagnostic value of the advanced non Gaussian CTRW model in breast cancer malignancy and prognostic factors, enhancing diagnostic performance for breast lesions.

#### **CLINICAL RELEVANCE/APPLICATION**

CTRW parameters could serve as noninvasive quantitative imaging markers to evaluate malignancy and prognostic factors of breast lesions.

#### **T5B-SPBR-7 Do Breast Oedema and Shrinkage Pattern during NAC Provide Additional Value for Predicting Treatment Response in Locally Advanced Luminal Breast Cancer?**

##### **PURPOSE**

To explore the predictive value of oedema and shrinkage patterns for the neoadjuvant chemotherapy (NAC) response in luminal breast cancer and whether they have added value when combined with traditional MRI features such as tumour size and apparent diffusion coefficient.

##### **METHODS AND MATERIALS**

Patients with luminal breast cancer were consecutively enrolled in this retrospective study to assess the relationship between MRI features and treatment response (including pCR and Miller-Payne [M-P] grade). Patients were classified into the development cohort and validation cohort. The traditional MRI features, breast oedema and shrinkage pattern were assessed before and early NAC (within 2 cycles of NAC). Oedema was divided into four categories (grade 1: no oedema, grade 2: peritumoral oedema, grade 3: prepectoral or subcutaneous oedema, grade 4: diffuse oedema), and regression was refined into two categories (concentric shrinkage and eccentric shrinkage). Univariate and multivariable analyses were used to identify independent imaging markers for pCR and MP grade. Prediction models were developed and evaluated for discrimination, calibration, and clinical applicability.

##### **RESULTS**

In total, 267 eligible patients were consecutively enrolled and divided into the development cohort (n=187) and validation cohort (n=81). Early diffuse oedema was a shared unfavourable biomarker in the prediction of both M-P grade and pCR (OR = 0.36 and 0.27). Peritumoral oedemas before and early NAC were another predictors of non-pCR (OR = 0.69 and 0.23), while unchanged or increased oedema grade during NAC (OR = 0.25 and 0.20) were another predictors of ineffective treatment, respectively. The addition of oedema improved the predictive value of tumour size for M-P grade (AUC from 0.64 to 0.71) and pCR (AUC from 0.67 to 0.74). The shrinkage pattern showed potential predictive value for M-P grade (P = 0.049) and pCR (P = 0.041) in the univariate analysis but was not an independent indicator. Prediction models showed comparable performance for predicting M-P grade and pCR in both the development (AUC = 0.82 and 0.81) and validation cohorts (AUC = 0.79 and 0.78).

##### **CONCLUSION**

Breast oedema is a valuable predictor of treatment response in luminal breast cancer in that it improves the performance of tumour size. The predictive value of the shrinkage pattern remains to be further studied.

#### **CLINICAL RELEVANCE/APPLICATION**

The goal of this work is to develop an MRI-based model for a more accurate prediction of response to NAC in patients with luminal

breast cancer. The model utilizes conventional MRI features instead of radiomics and novelty is introduced to the model by describing four types of edema that have long been shown to be predictive and prognostic that are readily available in clinics.

### **T5B-SPBR-8 Diagnosis of Breast Lesions on MRI using BI-RADS and Kaiser Scores in Mass and Non-Mass Enhancement: Benefit of KS and KS+ for Readers with Different Experience Levels**

Participants

Jiejie Zhou, PhD, MD, Wenzhou, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Kaiser score (KS) is a machine learning-derived clinical decision rule based on MRI BI-RADS descriptors, which provides the structure of an intuitive flowchart to guide the reader through a stepwise lesion assessment. The main considered features are root sign, DCE pattern, internal enhancement, and peritumoral edema. This study is aiming to: (1) compare the diagnostic performance of three readers with different experiences for breast cancer using BI-RADS and KS systems; (2) evaluate the benefit of the modified KS+ when diffusion was considered; and (3) separately assess the diagnostic performance in mass and NME lesions.

#### **METHODS AND MATERIALS**

A total of 630 patients including 393 malignant and 237 benign pathological confirmed lesions were analyzed. Based on the morphology, the cases were separated into 458 masses and 172 NMEs. Three radiologists with different levels of experience in breast MRI (3, 6, and 13 years) reviewed the cases to make a diagnosis using BI-RADS descriptors and KS. Of the 630 cases, 596 cases (434 mass and 162 NME) had DWI, and the apparent diffusion coefficient (ADC) was measured to modify KS to KS+. For lesions with  $ADC = 1.4 \times 10^{-3} \text{ mm}^2/\text{s}$ , the KS was reduced by 4. The diagnostic AUC of KS and KS+ made by three readers in mass and NME were compared to evaluate the benefit of KS+.

#### **RESULTS**

The diagnostic performance increased with years of experience among three readers. When using BI-RADS, AUC was 0.878, 0.915, and 0.941 for mass, and 0.771, 0.838, 0.902 for NME for Reader-1, 2, and 3, respectively (Table 1). When using KS compared to BI-RADS, the AUC was improved for the less experienced Readers. For Reader-1, AUC was increased from 0.878 to 0.916 for mass ( $p=0.005$ ), and from 0.771 to 0.822 for NME ( $p=0.124$ ). For Reader-2, AUC was about the same for mass (0.915 to 0.921) and increased from 0.838 to 0.883 for NME ( $p=0.114$ ). For the most experienced Reader-3, the results made by BI-RADS and KS were about the same. When ADC was considered to change to KS+, the AUC was significantly improved for all three readers for the mass lesions, but AUC was about the same for NME.

#### **CONCLUSION**

The benefit of KS was more remarkable for mass than for NME, especially for the less experienced reader. The root sign and internal enhancement were not well defined for NME, and since many NMEs would show the plateau DCE pattern, this feature was not helpful either. When considering ADC to modify KS to KS+, again, the benefit was mostly seen for mass, possibly due to the use of the cut-off threshold of  $1.4 \times 10^{-3} \text{ mm}^2/\text{s}$  developed from mass lesions.

#### **CLINICAL RELEVANCE/APPLICATION**

Kaiser Score provides an intuitive method for lesion interpretation, which is mostly helpful for mass lesions read by less experienced readers. KS+ is mainly applicable to mass lesions. For NME, the KS criteria need to be improved.

### **T5B-SPBR-9 A Pilot Study on the Correlation between the Parameters of Oscillating Gradient Spin Echo based Diffusion Weighted MRI and Pathological Lymphatic Vessel Invasion in Breast Cancer**

Participants

Lanqing Yang, Chengdu, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To explore the value of oscillating gradient spin echo (OGSE) based diffusion weighted MRI in predicting the lymphatic vessel invasion (LVI) status in patients with breast cancer.

#### **METHODS AND MATERIALS**

22 biopsy proved breast cancer patients were prospectively enrolled in this study. They all received preoperative clinical routine breast MRI, including T2 weighted imaging (T2WI), T1 weighted imaging (T1WI), diffusion weighted imaging (DWI), and contrast dynamic enhancement (DCE); and OGSE DWI sequences, including pulsed gradient spin echo (PGSE), OGSE(N=1), and OGSE (N=2). Patients were grouped into LVI negative (n=16) and positive (n=6) groups, with reference to pathological reports of surgical specimens. ROIs delineation was independently performed by two radiologists on three largest slices of tumor on  $b=1000 \text{ s}/\text{mm}^2$  images. Then, four quantitative parameters of Vin (intracellular volume fraction), Dex (mean extracellular diffusivity), D (mean cell size) and cellularity were derived from MATLAB software. Interobserver agreement assessment, independent t test, Mann-Whitney U test, ROC analysis, and spearman correlation analysis were used for statistical analyses.

#### **RESULTS**

The overall interobserver agreement was excellent for two radiologists of Dex value (intraclass correlation coefficient,  $ICC=0.865$ ). Patients with LVI positive status had significantly lower Dex value compared with LVI negative group ( $1.686 \pm 0.170$  vs.  $2.107 \pm 0.183 \times 10^{-3} \text{ mm}^2/\text{s}$ ,  $P=0.007$ ). ROC results showed that Dex presented a high AUCs of 0.958 in predicting LVI status. In addition, there was also significant strong negative correlation between LVI status and the value of Dex, with a spearman rank correlation coefficient of 0.710 ( $P=0.014$ ). Other parameters including Vin, D, and cellularity showed no significant difference between two groups.

#### **CONCLUSION**

Dex (mean extracellular diffusivity) value calculated from OGSE DWI sequences could help to predict the LVI status of breast cancer.

#### **CLINICAL RELEVANCE/APPLICATION**

lymphatic vessel invasion (LVI) is a high-risk factor for blood metastasis of breast cancer, which suggests that breast cancer

patients have a higher risk of recurrence and metastasis, and a poor prognosis. Preoperative evaluation of LVI status with MRI could help risk stratification, thus may guide the clinical management of patients with breast cancer.

#### **T5B-SPCA-1 Vascular Enhancement and Radiation Dose on 256-slice CT Angiography with Reduced Iodinated Contrast Volume for Pre-operative TAVI: Comparison of 64-slice CT Angiography with Standard Iodinated Contrast Volume**

Participants  
Takayuki Yoshiura, BA, RT, Hiroshima, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

Multi-slice CT is now the standard noninvasive imaging method for preoperative evaluation of transcatheter aortic valve implantation (TAVI). The purpose of this study is to evaluate the vascular attenuation and radiation dose on 256-slice CT with reduced iodinated contrast volume for pre-operative TAVI as compared to 64-slice CT with standard iodinated contrast volume.

#### METHODS AND MATERIALS

The study included 52 patients who underwent pre-TAVI CT scan with the 64-slice CT (Lightspeed VCT; GE Healthcare, Milwaukee, Wisconsin) and 47 patients who underwent pre-TAVI CT scan with the 256-slice CT (Revolution Apex; GE Healthcare, Milwaukee, Wisconsin). A contrast dose was injected at 450 mgI/kg over 22 seconds on 64-slice CT and 300 mgI/kg over 20 seconds on 256-slice CT, respectively. Measurements were performed on the CT enhancement of the ascending aorta (AAO), abdominal aorta (Abd AO), both subclavian arteries (SCA), and both femoral arteries (FA) as well as for the image noise of muscle tissue; then the contrast-to-noise ratio (CNR) and signal-to-noise ratio (SNR) were calculated. The volume CT dose index (CTDIvol) and dose length product (DLP) were recorded for both CT scans.

#### RESULTS

Despite the reduced iodinated contrast volume on 256-slice CT, the vascular enhancement of both SCA were significantly higher than those for 64-slice CT ( $p < 0.01$ ), with no significant differences in the other access routes in both CT scans. The CNR for AAO, Abd AO and both SCA was significantly higher the 256-slice CT, with no significant differences in the other access routes ( $p > 0.01$ ). The SNR was significantly higher the 256-slice CT for Abd AO and both SCA, with no other significant differences. The radiation dose for 64-slice and 256-slice CT scans were 82.4 mGy and 68.3 mGy for CTDIvol, and 2342.9 mGy-cm and 2066.7 mGy-cm for DLP, respectively. The radiation dose with 256-slice CT was obtained lower values.

#### CONCLUSION

The 256-slice CT with reduced iodinated contrast volume for pre-operative TAVI resulted in reduction of radiation dose and maintained or improved the vascular enhancement of the aortic annulus and access route vessels, compared to 64-slice CT, despite using approximately 52% less iodinated contrast volume.

#### CLINICAL RELEVANCE/APPLICATION

256-slice CT with reduced iodinated contrast volume for pre-operative TAVI maintains image quality and reduced radiation dose.

#### **T5B-SPCA-2 Estimation of High Coronary Artery Calcium (CAC) Score from Aortic Arch Calcification: An Efficient Tool for Selection of Non-optimal Candidates for Coronary CTA?**

Participants  
Pietro Giacomo Lacaita, MD, Innsbruck, Austria (*Presenter*) Nothing to Disclose

#### PURPOSE

Overutilization of healthcare resources is causing a high economic burden. Patients with high-CAC scores  $>1000$  AU are not optimal candidates for coronary CTA and can be more efficiently examined with other modalities (myocardial perfusion testing or a direct-to-ICA strategy). Therefore the objective of our study was to evaluate whether a 4-scale aortic arch calcification severity score predicts high-CAC scores ( $>1000$  AU and  $>800$  AU).

#### METHODS AND MATERIALS

162 patients referred to coronary/aortic CT Angiography and non-enhanced CAC score were enrolled (age 76.3 years, 45% females). Patients with prior PTCTI/STENT and CABG were excluded. The severity of aortic arch calcification was scored on a 4-point scale as 0=absent, 1=minimal ( $<25\%$  of circumference), 2=mild (25-50%), 3=moderate (50-75%) and 4=severe (100% of circumference) on thoracic CT (coronal MPR reformations).

#### RESULTS

In 130 patients, the absence of aortic arch calcification was highly accurate to rule out  $CAC > 1000$  AU (sens. 100%). No or minimal (grade 1) calcification had a high NPV of 95.6%, and no, minimal and mild (grade 1+2) a NPV of 86.96% to rule out  $CAC > 1000$  AU. There was a moderate correlation between grading of aortic arch calcification severity and CAC ( $r = 0.663$ ,  $p < 0.001$ ) by CT. In

patients with severe aortic arch calcium (grade 4), the prevalence of CAC >1000 was with 32/45 (71.1%) significantly higher as compared to other groups with 13/45 (28.8%)( $p < 0.001$ ). The AUC for the 4-scale aortic arch calcium severity score to predict CAC >1000 was  $c = 0.84$  ( $p < 0.001$ ; 95%CI:0.771-0.91) and similar for prediction of CAC>800 AU with  $c = 0.813$  ( $p < 0.001$ ;95% CI:0.686-0.865). AUC for prediction of CAC >1000 was slightly lower with  $c = 0.792$  for moderate-to-severe (grade 3+4) and  $c = 0.775$  for severe (grade 4) aortic arch calcification ( $p < 0.001$  for both).

## CONCLUSION

s Patients with moderate-to-severe aortic arch calcium have a high probability of CAC >1000 AU, but not those with no, minimal and mild calcifications. The absence of aortic arch calcium rules out CAC>1000 AU.

## CLINICAL RELEVANCE/APPLICATION

Estimation of aortic arch calcium severity is a valuable tool for a quick decision-making on the optimal non-invasive testing strategy (coronary CTA vs myocardial perfusion testing or a direct-to-ICA approach) for coronary artery disease in clinical routine.

## T5B-SPCA-3 Using 7.0T Cardiac MR to Explore Cangai Volatile Oil Treat Different Degrees of Myocardial Hypertrophy in Rats Exposed to Chronic Hypobaric Hypoxia at Plateau

Participants

Boshen Liang, Chengdu, China (*Presenter*) Nothing to Disclose

## PURPOSE

This study was intended to investigate whether cardiovascular magnetic resonance (CMR) imaging could reveal the protective effect of Cangai volatile oil (CAVO) on the heart of rats with chronic hypobaric hypoxia at plateau. On this basis, further explore the therapeutic effect of CAVO on isoproterenol induced myocardial hypertrophy in rats.

## METHODS AND MATERIALS

Seventy rats were randomized into the Control group (CON), plateau group (P group), P+ CAVOh (plateau + CAVOh), P+ CAVOI(plateau + CAVOI), P+MH (plateau+ myocardial hypertrophy,PM), P+MH+CAVOh(PM+ CAVOh), P+MH+CAVOI (PM+CAVOI). Except the Control group (altitude: 500 m), rats in other groups were transported to Yushu (altitude: 4,250m) for two months, where the group of PM,PM+CAVOh,PM+CAVOI were underwent intraperitoneal injection of ISO (3 mg/kg for 14 days) and P, P+CAVOh,P+CAVOI group were underwent intraperitoneal injection of saline in the same time. Left ventricular function, global strain of the rats can be measured by 7.0T high-field CMR and analyzed using the cine tissue tracking. Biochemical tests, histopathology and electronic microscopy were used to evaluate the protective effect of CAVO on the heart tissue of cardiac damage rats exposed to a high-altitude environment.

## RESULTS

The left ventricular ejection fraction (LVEF) and global strains were improved in all group after treat by CAVO compared with the Hypobaric Hypoxia group ( $p < 0.05$ ). Furthermore, the oxidative stress injuries were after CAVO treatment, evidenced by the increases of SOD, GSH-Px, while the decreases of MDA and LDH contents (all  $p < 0.05$ ). The results of western blot indicated that CAVO treatment dramatically restrained Keap-1, COL-1,  $\alpha$ -SMA protein expressions in cardiac tissues of mice, NRF2, HO-1 protein expression increased.

## CONCLUSION

s CAVO can reduce cardiac damage caused by hypobaric hypoxia and ventricular hypertrophy induced by Isoprenaline (ISO) at plateau through oxidative stress-related indicators, this effect can be measured by 7.0T high-field CMR.

## CLINICAL RELEVANCE/APPLICATION

This experiment provides a new treatment approach for different degrees of ventricular hypertrophy in plateau for clinical practice.

## T5B-SPCA-4 Feasibility Analysis of Non-ECG-triggered Chest LDCT using a kV-independent Reconstruction Algorithm for Predicting Cardiovascular Disease Risk in Patients Receiving Maintenance Hemodialysis

## PURPOSE

This study aimed to explore the feasibility and accuracy of non-electrocardiogram (ECG)-triggered chest low-dose computed tomography (LDCT) with a kV-independent reconstruction algorithm in assessing the degree of coronary artery calcification (CAC) and the risk of cardiovascular diseases in patients receiving maintenance hemodialysis (MHD).

## METHODS AND MATERIALS

181 patients receiving MHD who needed chest CT and coronary artery calcium score (CACS) scans underwent non-ECG-triggered, automated tube voltage selection, high-pitch chest LDCT scan using a kV-independent reconstruction algorithm (research scan) and ECG-triggered standard CACS scan (standard scan) sequentially. The image quality, radiation doses, CACS and cardiac risk classifications of the two scans were compared.

## RESULTS

Among the 181 patients, 89, 83, and 9 underwent scanning at 100, 110, and 120 kV, respectively. Excluding those scanned at 120 kV, 172 patients were enrolled. The Visual Scores (VSs) of the research scan showed high interobserver agreement (ICC = 0.944; 95% CI: 0.925-0.958). A significant difference was observed between the non-ECG-triggered VS and the standard CACS Agatston score (AS) on cardiac risk classification ( $\chi^2 = 34.333$ ,  $P < 0.001$ ; weighted kappa value = 0.813; 95% CI: 0.756-0.869). The accuracy of cardiac risk classification of non-ECG-triggered VS was 77.91% (134/172), considering the cardiac risk classification of standard CACS AS as the gold standard. Although the ASs obtained from the research scan were lower than those obtained from the standard scan ( $739.90 \pm 1098.38$  vs  $801.56 \pm 1129.60$ ;  $P < 0.001$ ), the agreement and correlation of them were excellent, and ICCs and Pearson's correlation coefficients were both  $> 0.96$ . No significant difference was observed in cardiac risk classifications between the two scans ( $\chi^2 = 3.933$ ,  $P = 0.269$ ), and the agreement was excellent (weighted kappa value = 0.936; 95% CI: 0.903-0.970). The accuracy of cardiac risk classification based on non-ECG-triggered AS was 92.44% (159/172). The effective radiation doses (ED) of the standard scan and the research scan were  $1.34 \pm 0.74$  mSv and  $1.04 \pm 0.35$  mSv. With the equivalent image quality, the average ED and CTDIvol of the research scan were reduced by 21.77% and 59.93%, respectively.

## CONCLUSION

s A CT protocol using the non-ECG-triggered, automated tube voltage selection, high-pitch chest LDCT protocol with a kV-independent reconstruction algorithm can accurately demonstrate the degree of CAC, maintain the overall cardiac risk classification and significantly reduce the radiation exposure of patients.

## CLINICAL RELEVANCE/APPLICATION

This protocol can implement one-stop scanning of the chest and CACS and significantly reduce the radiation dose.

### **T5B-SPCA-5 The feasibility of Free-breathing, Non-ECG with Cardiovascular Magnetic Resonance Multitasking for the Assessment of Left Ventricular Function**

#### PURPOSE

To evaluate the feasibility of cine images acquired through cardiac magnetic resonance (CMR) Multitasking, free of ECG gating and breath holding, in measuring left ventricular (LV) volume indexes and mass, compared with those measured through multi-breath-hold bSSFP sequence in clinical setting.

#### METHODS AND MATERIALS

A total of 30 healthy volunteers and 20 patients were enrolled for CMR examination. Each subject underwent bSSFP sequence with multiple breath-hold and Multitasking sequence under free breathing respectively. LV function indexes were measured on both images and compared with two sequences. Image quality was assessed by image quality score and contrast-to-noise (CNR).

#### RESULTS

LV ejection fraction (EF) was not significantly different between the two sequences in both healthy volunteers ( $p=0.451$ ) and patients ( $p=0.709$ ). However, LV end-diastolic mass (EDM) was overestimated by Multitasking in both healthy volunteers (bSSFP:  $56.2 \pm 9.3$  g, Multitasking:  $58.3 \pm 9.1$  g,  $p=0.005$ ) and patients (bSSFP:  $65.6 \pm 13.5$  g, Multitasking:  $67.9 \pm 14.1$  g,  $p=0.013$ ). CNR of the myocardium and the blood pool showed no difference between Multitasking and bSSFP sequences ( $p=0.478$ ). Moreover, both sequences achieved acceptable and comparable image quality score in LV function measurements.

#### CONCLUSION

s The feasibility of Multitasking for quantification of the LV functions without ECG gating or breath holding was tested successfully in healthy volunteers and patients.

## CLINICAL RELEVANCE/APPLICATION

Multitasking may become an alternative technique to bSSFP in certain conditions.

### **T5B-SPCA-6 Novel Technique of Multi-slice Acquisition of Simultaneous Myocardial T2-weighted Imaging (T2WI) and Multi-echo T2 Mapping using Deep Resolve Reconstruction (MS-T2WI/Map)**

#### Participants

Yui Tanaka, RT, Suita Osaka, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

Myocardial T2-weighted image (T2WI) and T2 mapping, which are used to assess the edema and inflammation, require the long acquisition time, and mapping is acquired only single slice per single breath hold. Deep Resolve (DR) technique, which is novel reconstruction with denoising and increased sharpness based on deep learning architecture, permit the shortening scan time with maintaining image quality. The aim was to evaluate the feasibility of multi-slice acquisition of simultaneous T2WI and T2 mapping using DR technique (MS-T2WI/Map) for myocardial T2 characterization.

#### METHODS AND MATERIALS

We obtained the MS-T2WI/Map and conventional single-slice T2 map and T2WI in 10 volunteers and 14 patients with cardiomyopathy at short-axial slice, and volunteers underwent in repeated three times. MS-T2WI/Map consists of triple-contrast spin-echo (TE=13, 56 and 107 msec) with black-blood and fat suppression, and can acquire simultaneously 3 slices in a single breath-hold. The obtained images were reconstructed using DR method. T2 map was obtained using 3 TE images. Further, images with TE=56 msec yield T2WI. In T2WI, image quality using the 4-point scale and contrast ratio (CR) between myocardium and muscle were evaluated. In T2 map, we measured the T2 values at septal wall and obtained coefficient of variation (CV) in three times. In patients, the detection of focal abnormality in T2WI and T2 value (defined as  $>2SD$  of normal) were also evaluated.

#### RESULTS

The mean acquisition time of MS-T2WI/Map was 26 sec, which was 75% shorter than the conventional scans. There were no significant differences in image quality of T2WI between both scans. CR in MS-T2WI/Map showed good correlation with that in reference (volunteers:  $r=0.68$ , patients:  $r=0.86$ ). T2 values obtained from MS-T2WI/Map underestimated compared with conventional T2 map, but there were good correlation and agreement between two methods (volunteers:  $r=0.94$ , patients:  $r=0.65$ ). Further, CV in MS-T2WI/Map showed comparable reproducibility with conventional map. Abnormal myocardial changes were identified in all participants with MS-T2WI/Map in similar to conventional T2-based imaging.

#### CONCLUSION

s MS-T2WI/Map with DR is a promising tool for shortening acquisition time with equivalent image quality and T2 measurement to conventional sequences, enabling the multi-slice simultaneous myocardial T2 characterization in single-breath-hold.

## CLINICAL RELEVANCE/APPLICATION

MS-T2WI/Map permits the simultaneous myocardial T2WI and T2 map with equivalent image quality and quantification to conventional methods, enabling multi-slice assessment of focal disease. Our proposed method is useful and practical approach for the reduction of acquisition time and the integrated assessment of both T2WI and T2 map.

### **T5B-SPCA-7 Improving In-stent Stenosis Visibility for Prototype Photon Counting Detector CT with High-**

## resolution Plaque Kernel

### Participants

Yoshinori Funama, PhD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

### PURPOSE

Photon counting detector CT (PCD-CT) with dedicated high-resolution (HR) plaque kernel is newly introduced for improving in-stent stenosis visibility in coronary CT angiography. PCD-CT with HR-plaque kernel enable improved visualization and accurate assessment of coronary plaques. The present study aimed to investigate the performance of PCD-CT with HR-plaque kernel as compared with conventional energy-integrating detector CT (EID-CT) in terms of lumen size and in-stent stenosis visibility.

### METHODS AND MATERIALS

A vessel tube with non-calcified plaque in a 3.0-mm stent was scanned by using EID-CT (FUJIFILM Healthcare Corporation, Tokyo, Japan) and prototype PCD-CT (Ultra-High Resolution mode, FUJIFILM Healthcare Corporation) with HR-plaque kernel at 3 stent directions (0, 45, and 90 degrees). The tube voltage and tube current-time product were set at 120 kVp and 300 mAs. A rectangular region of interest was set across both sides of the stent struts with a 50% stenotic portion on multiplanar reformation (MPR) images. The profile curves were obtained from two types of PCD- and EID-CT images. The lumen size was calculated from the distance between the inner strut positions. The 50% stenotic portion was also measured using the profile curve.

### RESULTS

The lumen sizes for PCD-CT and EID-CT images were 2.13 and 1.80 mm at 0 degree, 2.20 and 1.17 mm at 45 degrees, 2.27 mm and 1.67 mm at 90 degrees. The lumen sizes for PCD were wider than those for EID-CT regardless of the stent directions. The measurements of in-stent stenosis were 67.6% - 72.7% at 0 - 90 degrees in PCD-CT. For EID-CT, the measurements of in-stent stenosis were 90.7% - 90.0% at 0 - 90 degrees. The stenotic portion for PCD-CT images enabled more accurate measurements than that for EID-CT. PCD-CT images and MPR images showed fewer blooming artifacts and better plaque conspicuity and iodine enhancement than EID-CT images.

### CONCLUSION

s PCD-CT images with HR-plaque kernel showed improved lumen size and accurate measurements of in-stent stenotic portion as compared with conventional EID-CT images regardless of the stent directions.

### CLINICAL RELEVANCE/APPLICATION

The PCD-CT with HR-plaque kernel provide better visibility of the coronary plaque and iodine enhancement and accurate assessment of the stenotic portion on coronary CT angiography.

T5B-SPCH

### Chest Imaging Tuesday Poster Discussions II

#### Sub-Events

#### **T5B-SPCH-1 A Study Design for Quantitative Characterization of Pulmonary Gas Exchange in Long COVID Using Hyperpolarized <sup>129</sup>Xe MRI**

##### Participants

Aiah Alatoum, MBBS, Iowa City, IA (*Presenter*) Nothing to Disclose

##### PURPOSE

The use of hyperpolarized Xenon (HP-Xe) was approved by the FDA (Xenoview™) for MRI-based evaluation of lung function in adults and pediatric patients over 12 years. Quantitative characterization of ventilation and gas exchange metrics is critical in ensuring the accuracy and reliability of HP-Xe MRI as a diagnostic tool. This study provides a framework for quantitative validation using dual-energy computed tomography (DECT).

##### METHODS AND MATERIALS

15 participants with a history of COVID-19 (diagnosed 17+–5 months prior) of varying severity, were recruited. HP-Xe imaging of regional ventilation and gas exchange and contrast-enhanced perfusion imaging was performed on a 3T scanner. Gas exchange HP-Xe using a 1-point Dixon technique was used to estimate Xenon transfer into the pulmonary tissues and plasma (Membrane), as well as the red blood cells (RBC). The ratio of these signals, (RBC: Membrane), was used as the surrogate marker for gas exchange. The participants also underwent ventilation/perfusion (V/Q) imaging on DECT using non-contrast Total Lung Capacity (TLC) to virtual non-contrast Functional Residual Capacity (FRC) warping for V and DECT perfused blood volume (PBV as a surrogate for Q) at FRC. The heterogeneity of gas exchange was characterized using the 2nd moments of the normalized V and PBV distributions vs. V/Q ratio in the log scale (lnSDV and lnSDQ) in a 50-compartment model, similar to classical techniques for VQ matching. These metrics rely on absolute quantification of true ventilation and perfusion and have been adapted to the normalized CT-derived datasets.

##### RESULTS

Our study confirmed, as shown in previous literature, the correlation between RBC: Membrane from HP Xenon MRI and DLCO ( $R^2 = 0.74$ ,  $p=0.0005$ ) in our 15 participants. The baseline data from the 7 participants in the preliminary analysis showed that the RBC: Membrane ratio from HP-Xe MRI was significantly correlated to the CT-derived lnSDQ ( $R^2 = 0.58$ ,  $p=0.047$ ), indicating agreement between modalities in assessing heterogeneity of gas exchange.

##### CONCLUSION

Preliminary data supports quantitative comparisons between hyperpolarized Xe MRI and CT-derived assessments of gas exchange. Cross-sectional analyses using disease severity at diagnosis, longitudinal follow-up, and comprehensive assessment of spatially-matched ventilation and perfusion distributions are in process for direct regional comparisons between modalities.

##### CLINICAL RELEVANCE/APPLICATION

Hyperpolarized Xe imaging provides a non-ionizing alternative to DECT, allowing for regular follow-up in patients with persistent symptoms beyond their initial diagnosis.

#### **T5B-SPCH-2 Quantitative Chest of Marijuana Use**

##### PURPOSE

Recreational and medical marijuana use has increased in recent years, in part due to legalization driven by arguments that marijuana is relatively safe and with numerous health benefits. We aimed to investigate marijuana's effect on the lungs through quantitative analysis as well as image review.

##### METHODS AND MATERIALS

By searching the electronic medical record, we identified patients who were marijuana users who never smoked; current smokers; and non-marijuana never smokers, who underwent chest CT in our healthcare system in 2019. We generated a random sample of 100 marijuana users as well as 100 each age- and sex- matched controls from the current smoker and never smoker groups. Quantitative CT lung density analysis was performed to measure total lung volume (TLV) and percent high attenuation area (HAA, -600 to -250 HU). We defined >3% HAA as abnormal. A thoracic radiologist reviewed chest CTs in a blinded fashion for presence of emphysema.

##### RESULTS

TLV was higher in smokers than marijuana users and non-smokers ( $p<.01$  for both). By visual analysis, 62% of smokers had emphysema versus 4% of marijuana users ( $p<.001$ ). Marijuana users were more likely to have increased HAA (18%) compared to smokers (7%) or non-smokers (9%),  $p=0.04$ . In a multivariable analysis, larger pulmonary artery (PA) size (OR 1.1 per mm,  $p=0.01$ ) and marijuana use (OR 3.5 versus smoking,  $p=0.02$ ) were associated with increased HAA.

## CONCLUSION

s While emphysema and hyperinflation were common in smokers, they were rare in marijuana users. However, marijuana users had more high-attenuation, which also correlated with enlarged pulmonary arteries, suggesting a vasoactive effect of marijuana on the pulmonary arterial system.

## CLINICAL RELEVANCE/APPLICATION

While it does not appear to cause emphysema, marijuana use does affect the lungs, potentially through the pulmonary arterial system, and may not be as safe as initially assumed.

## T5B-SPCH-3 High Spatial Resolution Data Improves Diagnostic Performance of Machine-Learning Radiomics Model: Prediction for Invasive Adenocarcinoma of the Lung

Participants

Masahiro Yanagawa, MD, PhD, Suita, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

First, to construct two machine-learning radiomics models to predict invasive adenocarcinoma (IVA) using training data from normal-spatial resolution (NR) and high spatial resolution (HR), respectively. Second, in another test cohort, to validate diagnostic performance of two models (model-NR and -HR) while comparing results by two independent radiologists with and without model-HR.

## METHODS AND MATERIALS

Enrolled were 447 patients with 465 nodules (n=97, non-IVA; and n=368, IVA) who underwent 160-row high-spatial-resolution CT (Aquilion Precision, Canon Medical Systems). All CT images were reconstructed using iterative reconstruction method with NR data (512×512 matrix size, 0.5-mm slice thickness) and HR data (2048×2048 matrix size, 0.25-mm slice thickness), respectively. 465 nodules were divided into the training set (n=61, non-IVA; n=165, IVA) and the test set (n=36, non-IVA; n=203, IVA). Two models were developed by selecting 15 significant factors from 172 radiomics features in the training set, using correlation analysis and variance inflation factor, and establishing a random forest. In the test set, the area under the receiver operator characteristic curves (AUC) were statistically analyzed using DeLong's test to compare between model-NR and -HR. To compare accuracy (acc), sensitivity (sen), and specificity (spc) of two radiologists (R1, R2) with and without model-HR using McNemar test. P values <0.05 were considered significant.

## RESULTS

In the training set, AUC of the model-HR (0.839) was significantly higher than model-NR (0.723) (p<0.05). In the test set, AUC of the model-HR (0.863) was also significantly higher than model-NR (0.718) (p<0.05). Without the model-HR, acc, sen, and spc of the radiologists were as follows: R1, 77.0%, 79.3%, and 63.9%; and R2, 83.7%, 85.7%, and 72.2%, respectively. With the model-HR, acc, sen, and spc of the radiologists were as follows: R1, 86.6%, 93.1%, and 52.8%; and R2, 83.7%, 86.7%, and 66.7%, respectively. Acc and sen of R1 was significantly higher with than without the model-HR (p<0.0001). Acc and sen of R2 was equal or higher with than without the model-HR, but not significant (p>0.50). Spc of R1 and R2 tended to decrease with AI, but not significant (p>0.21).

## CONCLUSION

s High spatial resolution significantly improved diagnostic performance of IVA by the machine-learning radiomics model. When used by radiologists, the present model tended to increase the accuracy and sensitivity of IVA diagnosis at the expense of specificity.

## CLINICAL RELEVANCE/APPLICATION

Machine-learning radiomics model trained by high spatial resolution data can greatly enhance diagnostic performance of invasive adenocarcinoma, providing support to radiologist, especially in improving accuracy and sensitivity.

## T5B-SPCH-4 Radiological-Histological Correlation on Ultra-High-Resolution CT Using Cadaveric Human Lungs: Nodule and Airway Analysis

Participants

Akinori Hata, PhD, Suita, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the performance of ultra-high-resolution CT (UHR-CT) to evaluate nodules and airways (bronchioles and bronchi) compared with conventional CT (C-CT) using cadaveric human lungs.

## METHODS AND MATERIALS

Image data of 20 cadaveric lungs were acquired by C-CT and UHR-CT at radiation dose with a noise level equivalent to the diagnostic reference level image (CTDIvol: 9.1mGy). C-CT images were reconstructed with 512 matrix, 0.5 mm thickness, and hybrid iterative reconstruction (hIR). UHR-CT images were reconstructed with three settings; UHR-512: same as C-CT; UHR-DLR: 1024 matrix, 0.25 mm thickness, and DLR; UHR-2048: 2048 matrix, 0.25 mm thickness, and hIR. Two specimens per lung were obtained and examined using hematoxylin and eosin stains. The CT images were evaluated for nodules and airways on a 5-point scale comparing with histology (1=Not identifiable, 2=Barely identifiable, 3=Identifiable, but difficult to assess detail, 4=Partially consistent with histology, 5=Nearly consistent with histology). For identifiable nodules, error rates were calculated as the absolute difference between diameters on CT and true diameters on histology divided by the true diameters. Objective noise was evaluated by measuring standard deviation. The Wilcoxon signed-rank test with Bonferroni correction was used for statistical analyses.

## RESULTS

In total, 70 nodules (median 1195  $\mu$ m, range 235 - 8803  $\mu$ m) and 91 airways (median 855  $\mu$ m, range 204 - 3324  $\mu$ m) in 40 specimens were evaluated. In terms of nodules, UHR-2048, UHR-DLR, UHR-512, and C-CT scored significantly higher in that order (C-CT, 2.6±1.1; UHR-512, 2.9±1.2; UHR-DLR, 3.4±1.4; UHR-2048, 3.6±1.5; all p<0.002). The error rate on UHR-CTs tended to be lower than that of C-CT, but there was no significant difference (C-CT, 0.17±0.13; UHR-512, 0.13±0.16; UHR-DLR, 0.12±0.13; UHR-2048, 0.12±0.10; all p>0.05). In terms of airways, UHR-DLR and UHR-2048 scored significantly higher than C-CT and UHR-512

(C-CT,  $1.9 \pm 1.5$ ; UHR-512,  $2.1 \pm 1.5$ ; UHR-DLR,  $2.9 \pm 1.7$ ; UHR-2048,  $2.7 \pm 1.7$ ). UHR-DLR tended to score higher than UHR-2048, but there was no significant difference ( $p=0.022 > 0.0083$  [Bonferroni correction]). Objective noise was significantly larger for UHR-2048, UHR-512, UHR-DLR, and C-CT in that order (C-CT,  $21 \pm 4$ HU; UHR-512,  $41 \pm 5$ HU; UHR-DLR,  $33 \pm 6$ HU; UHR-2048,  $50 \pm 4$ HU; all  $p < 0.001$ ).

## CONCLUSION

s UHR-CT images with high resolution reconstruction setting outperformed C-CT in the assessment of nodules and airways. Hybrid IR with 2048 matrix showed a better score than DLR with 1024 matrix for nodule assessment.

## CLINICAL RELEVANCE/APPLICATION

UHR-CT is suitable for the assessment of nodules and airways in detail. Hybrid IR with 2048 matrix may be the most advantageous for the assessment of the fine morphology of nodules.

## T5B-SPCH-5 Comparison of Sensitivity of Spectral CT Iodine Substance Map and Conventional CTPA in Detecting Subsegmental Thrombus

### PURPOSE

To compare the sensitivity of spectral CT iodine-based substance map and conventional CTPA in detecting arterial emboli below the pulmonary segment.

### METHODS AND MATERIALS

20 patients with pulmonary embolism were examined by energy spectrum CT material separation technique. The iodine-based substance map and CTPA map (including MPR, MIP, and VRT) were reconstructed on the post-processing workstation by using the volume data on the post-processing workstation, and the number of pulmonary emboli in the area with reduced iodine content on the iodine-based substance map was found correspondingly, which was consistent with CTPA. The number of emboli found on the map was compared, and statistical software was used to analyze the difference between the two.

### RESULTS

Among the 20 patients with pulmonary embolism, a total of 160 areas with reduced iodine content were found on the iodine-based map in the vascular distribution area by segment and sub-segment (a total of 121 emboli were found directly, and only 39 indirect emboli in the area with reduced iodine content were found); In contrast, 126 emboli were directly displayed on the CTPA map; a total of 160 emboli were found through the combined observation of the iodine-based map and CTPA. Using paired T test, it was found that the comparison between the iodine-based map and the CTPA map and between the two groups' combined application and CTPA was statistically significant ( $P < 0.05$ ); while the iodine-based map and the combined application of the iodine-based map and CTPA map There was no statistical difference between the two ( $P > 0.05$ ).

## CONCLUSION

s Spectral CT iodine-based substance map is better than CTPA in detecting emboli in patients with pulmonary embolism below the lung segment, The combined application of the two can significantly improve the detection rate of emboli in pulmonary embolism below the lung segment.

## CLINICAL RELEVANCE/APPLICATION

Spectral CT iodine-based substance map is better than CTPA in detecting emboli in patients with pulmonary embolism below the lung segment, The combined application of the two can significantly improve the detection rate of emboli in pulmonary embolism below the lung segment.

## T5B-SPCH-6 Motion Artifact Correction using a New Deep Learning Reconstruction (MC-DLR) in the Chest Computed Tomography

Participants

Yoichiro Ota, RT, Yokohama, Japan (*Presenter*) Nothing to Disclose

### PURPOSE

A new motion correction method, motion correction - deep learning reconstruction (MC-DLR), has been developed using a deep learning framework to estimate patient motion in chest computed tomography (CT). This study aimed to assess the effect of MC-DLR in emergencies.

### METHODS AND MATERIALS

This single-institution retrospective study was approved by our institutional review board. The requirement for written informed patient consent was waived. The subjects included 20 emergency cases (15 of whom were male patients, with a median age of 78) during July and August 2022. All CT scans were obtained using a 320-row CT scanner (Aquilion One Genesis, Canon Medical Systems, Otawara, Tochigi, Japan) at 120 kVp using automatic exposure control. Two types of images were reconstructed, with and without MC-DLR, both with a  $512 \times 512$  matrix size and 0.5-mm slice thickness. A technologist developed a multi-planer image obtained at the sino-tubular junction of the ascending aorta in each CT image (Fig.1). Six radiologists and six technologists measured the maximum aortic diameter and its perpendicular diameter on each image, in a randomized and independent manner, without any prior information. Additionally, they scored the motion artifact of the aorta using a four-step scale (0 = none, 1 = slight, 2 = mild, 3 = severe). Three certified chest radiologists compared all CT images with and without MC-DLR sets side by side and graded the motion artifact in the ascending aorta, coronary arteries, the left lower lobe of the lung, and other areas of the lung using a four-step scale. The total artifact score was determined as the sum of these individual scores. We compared these aortic diameters and scores using a paired t-test.

### RESULTS

The mean artifact score in the MPR image evaluation decreased significantly from  $1.64 \pm 0.96$  in the image without MC-DLR to  $1.32 \pm 1.03$  in the image with MC-DLR ( $p < 0.001$ ). The mean aortic diameter did not differ significantly between the two image sets, measuring  $33.0 \pm 3.3$  mm without MC-DLR and  $33.0 \pm 3.5$  mm with MC-DLR. However, the mean perpendicular diameter increased significantly, measuring  $30.7 \pm 3.3$  mm without MC-DLR and  $31.4 \pm 3.5$  mm with MC-DLR ( $p < 0.001$ ). When CT images were

evaluated by certified radiologists, the total motion artifact score decreased significantly from  $6.8 \pm 2.8$  in the images without MC-DLR to  $4.6 \pm 2.9$  in those with MC-DLR ( $p < 0.001$ ).

## CONCLUSION

s MC-DLR, a new motion correction method, decreases motion artifacts in chest CT images.

## CLINICAL RELEVANCE/APPLICATION

Obtaining high-quality CT images is often challenging in emergency cases. MC-DLR effectively reduces motion artifacts in post-processed images, improving the image quality.

## T5B-SPCH-7 A Two-stage Deep-learning Framework in CT Denoising Based on Structure-unaligned Paired Dataset in Real World

### PURPOSE

In real world, soft tissue is hardly appreciable during lung cancer low-dose CT (LDCT) screening due to significant noise. Currently, deep learning-based LDCT denoising methods have achieved promising results, but they are mostly performed based on structurally aligned synthesized paired datasets, thus cannot be translated into real clinical practice. In this paper, we propose an LDCT denoising method based on clinically structure-unaligned but paired datasets (LDCT and normal dose CT (NDCT) in the same patient) in real world to improve the lesion detection and characterization.

### METHODS AND MATERIALS

An initial cohort of 64 patients who had received consecutive LDCT and NDCT was enrolled in this study, and they were randomly divided into training (46) and testing (18) cohorts. We propose a two-stage training approach. A Gaussian noise perturbation was first added to the NDCT to generate structurally aligned simulated LDCT and used for the training of generator. In the second stage, the model is trained on a clinically structure-unaligned paired dataset using the Wasserstein generative adversarial network (WGAN) framework, with the initial weights of the generator obtained in the first stage of training. In addition, we introduce an attention mechanism in the proposed network to capture richer context dependencies to improve the quality of the CT.

### RESULTS

Validated on a clinical CT dataset, our proposed method outperformed other available methods [CycleGAN, Pixel2Pixel, block-matching and 3D filtering (BM3D)], in noise removal and detail retention, and also peak signal-to-noise ratio (PSNR), structural similarity index measure (SSIM) and root mean square error (RMSE) metrics. The probability density profile of the denoised CT using our method best fits the reference NDCT. Also, our two-stage model outperforms one-stage WGAN-based model in both objective and subjective evaluations, which further demonstrates the higher effectiveness of the two-stage training approach.

## CONCLUSION

s The proposed method removes noise from LDCT well and has good detail retention, which will potentially enhance the lesion detection and characterization in surrounding soft-tissues in the lung cancer LDCT screening. In both qualitative and quantitative evaluation, the proposed method outperforms the comparison method.

## CLINICAL RELEVANCE/APPLICATION

Although lung nodules can be sensitively detected in LDCT, soft tissue lesions are hardly appreciable due to significant noise. From the perspective of health economics, if the noise levels of LDCT can be further reduced without increasing the radiation dose, more lesions could be detected in the same test, which will be of great significance to the whole lung cancer screening population, collectively.

## T5B-SPCH-8 Assessment of Lung Perfusion using Dynamic Digital Radiography and Comparison with Nuclear Medicine Lung Scintigraphy

### PURPOSE

Assessment of lung perfusion is an important element in the preoperative evaluation of patients being considered for lung transplant or resection. Dynamic digital radiography (DDR) is a newer radiographic technique acquiring rapid sequential diagnostic radiographs of the chest throughout multiple respiratory cycles. The regional lung perfusion can be estimated using DDR by assessing pixel signal changes throughout the cardiac cycle. This study will compare the results of the differential lung perfusion estimated using DDR with the same results obtained from Nuclear Medicine (NM) lung scintigraphy, a conventional imaging modality.

### METHODS AND MATERIALS

A retrospective review of patients evaluated with both nuclear medicine lung scintigraphy and DDR was performed. The DDR examinations were performed between January 14, 2022 and April 25, 2023. Each patient had a lung scintigraphy perfusion study within 6 months of the DDR examination. The percent differential of perfusion between the lungs was calculated using both modalities and the results were analyzed for statistical correlation.

### RESULTS

Results for 53 patients were reviewed (mean age - 56 years, 21 females). The mean absolute percent differential in perfusion between the right and left lungs was ( $14.6 \pm 24.9\%$ ) using DDR and ( $16.4 \pm 25.7\%$ ) using lung scintigraphy. There was only one patient in which there was a discrepancy between the two modalities in determining which lung was better perfused. The perfusion results obtained using the two modalities were strongly correlated ( $r = 0.923$ ,  $p < .001$ , 95% CI [0.870, 0.955]).

## CONCLUSION

s Differential lung perfusion estimated by DDR is strongly correlated with the same result obtained using lung scintigraphy. The speed and cost effectiveness of DDR make it an attractive option for clinicians, potentially reducing wait times and healthcare cost for patients.

## CLINICAL RELEVANCE/APPLICATION

Dynamic digital radiography (DDR) is a novel functional imaging modality for assessment of lung perfusion, with strong correlation to

nuclear medicine lung scintigraphy making it a faster and more cost-effective option for preoperative evaluation of lung transplant/resection candidates.

T5B-SPER

### Emergency Radiology Tuesday Poster Discussions II

#### Sub-Events

#### **T5B-SPER-1 Triple-rule-out CT Angiography with Dual-energy Spectral Imaging for Evaluation of Acute Chest Pain: Improving Image Quality Monochromatic Images at Optimal Energy Level**

##### **PURPOSE**

To evaluate the clinical value of using monochromatic images in dual-energy spectral CT in triple-rule-out CT angiography (CTA).

##### **METHODS AND MATERIALS**

Thirty consecutive patients with acute chest pain (HR<65BPM) underwent prospective ECG-triggered triple-rule-out CTA with spectral mode on a Discovery CT750HD scanner. A biphasic contrast injection (Iohexol, 350mgI/ml) was used for enhancement scans: 0.8ml/kg at 4.5ml/s flow rate in 1st phase and 20ml at 3.0ml/s in 2nd phase, followed by 30ml of saline. Monochromatic images were reconstructed with 50%ASiR and analyzed using Gemstone Spectral Imaging (GSI) viewer on an AW4.6. Region-of-interest was placed on coronary artery, pulmonary artery, thoracic aorta and muscle to measure CT number and standard deviation, and to calculate the contrast-to-noise ratio (CNR) and signal-to-noise ratio (SNR) as function of energy for arteries. The optimal energy levels (in keV) for obtaining the best CNR for the arteries were obtained. CNR values at the optimal energy were compared with those at 70keV (simulating 120kVp imaging). Two senior radiologists also evaluated the image quality at these two energies using a 5-point scoring system in consensus. The measurements between the two energies were statistically compared.

##### **RESULTS**

The optimal energies for achieving the highest CNR for coronary artery, thoracic aorta and pulmonary artery were 65.9±1.06keV, 65.2±1.86keV and 62.7±1.51keV, respectively. SNR and CNR values at the optimal energies for these arteries values were significantly higher than the corresponding values in the 70keV images (all p<0.05). Image quality scores for these 3 arteries at the optimal energies were also judged to be better than those at 70keV for coronary artery, aorta pulmonary artery (all p<0.05).

##### **CONCLUSION**

s Monochromatic images at 65keV in triple-rule-out CTA with spectral imaging yielded the highest CNR for coronary artery and thoracic aorta. Monochromatic images at 62keV in triple-rule-out CTA with spectral imaging yielded the highest CNR for pulmonary artery and highest diagnostic confidence.

##### **CLINICAL RELEVANCE/APPLICATION**

Dual-energy spectral CT with optimal energy level selection may improve image quality for imaging coronary artery, pulmonary artery and thoracic aorta in triple-rule-out CTA.

#### **T5B-SPER-2 Prediction Of Enhancement Peaking Time Of Pulmonary Artery Computed Tomography Angiography: Based On Physiological Data And Random Forest Model**

##### Participants

Tuo He, Xi'an, China (*Presenter*) Nothing to Disclose

##### **PURPOSE**

To develop and validate a random forest model for preoperative prediction of contrast peaking time in pulmonary computed tomography angiography using patient physiological data.

##### **METHODS AND MATERIALS**

A total of 511 patients with 53 sets of physiological data (including baseline, clinical, hemodynamic, radiographic structural) and pulmonary artery contrast peaking time were enrolled. Peaking times were extracted from time-density curves obtained from previous low-dose contrast tests performed with pulmonary CTA. The region of interest was placed in the pulmonary artery trunk. The prediction model was developed in a primary cohort that consisted of 409 patients. Least absolute shrinkage and selection operator (LASSO) regression model was used for data feature selection, and signature building. Random forest method was used to develop the predicting model. An independent validation cohort contained 102 consecutive patients, 10-fold cross-validation was used to validate the peaking time prediction model. The predictive efficacy of the model was assessed using the area under the receiver operating characteristic (ROC) curve (AUC), sensitivity, and specificity in primary and validation cohort. All examinations were performed on a 256-row Revolution CT. Statistical analysis was conducted with R software. The reported statistical significance levels were all two-sided, with statistical significance set at 0.05.

##### **RESULTS**

16 selected feature variables including COPD history, cardiac function classification (NYHA), hypothyroidism, hypertension classification and risk stratification, coronary heart disease history, valvular disease history, Injection site, Sex, Age, Contrast agent does, Superior vena cava size (long diameter and short diameter), Pulmonary artery width, Pulse rate and Diastolic pressure were significantly associated with peaking time. The AUC, sensitivity and specificity of the peaking time prediction based on the

proposed model was 0.795, 0.047, 0.997 in the primary cohort, and 0.738, 0.056, 0.796 in the validation cohort.

#### **CONCLUSION**

s A random forest model that incorporates various physiological data may be used to preoperatively predict contrast peaking time to optima contrast use in pulmonary CTA.

#### **CLINICAL RELEVANCE/APPLICATION**

The empirical time method, small-dose contrast agent test method, and the dynamic tracking threshold trigger method are commonly used in the current peak time calculation for contrast-enhanced examinations. However, these methods have the disadvantages of insufficient accuracy, increased contrast injection and increased radiation dose to the patient, respectively. In contrast, the prediction of peak time by random forest models can perfectly solve these drawbacks mentioned above.

T5B-SPGI

### Gastrointestinal Imaging Tuesday Poster Discussions II

#### Sub-Events

#### **T5B-SPGI-1 High Resolution CT Imaging with a 1024 Matrix: Impact of Matrix Size, Slice Thickness, Reconstruction Algorithm, and Reslicing on Radiomic Feature Quantification in Hepatocellular Carcinoma**

##### Participants

Masatoshi Hori, MD, PhD, Kobe, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation

##### PURPOSE

Following the emergence of ultra-high-resolution (UHR) CT or photon-counting CT systems, 1024-matrix abdominal imaging has become clinically relevant. These depictions offer superior spatial resolution compared to conventional images. However, the impact of matrix size, slice thickness, reconstruction algorithm, and reslicing on radiomic evaluations remains poorly understood. The aim was to elucidate the consequences of these parameters on CT radiomic feature quantification in hepatocellular carcinoma (HCC).

##### METHODS AND MATERIALS

This retrospective analysis involved 29 subjects (16 males, 13 females; median age, 73 years) diagnosed with HCC, who underwent contrast-enhanced CT during late arterial and portal venous phases employing super-high-resolution mode with a UHR CT scanner (Aquilion Precision; Canon). Lesions exhibited a median diameter of 32.6 mm (range, 11.1-113.6mm). UHR CT images with a 1024-matrix were reconstructed utilizing filtered back projection and hybrid iterative reconstruction. Slice thicknesses comprised 0.5, 1.0, and 5.0 mm. CT images with a 512-matrix were also reconstructed with the normal-resolution simulation algorithm. A representative tumor was three-dimensionally segmented per patient. Subsequently, 120 radiomic features, with and without reslice at 1-mm voxel, were calculated in three dimensions for each image set. Features were categorized as first-order (n=19), shape (n=26), and texture (n=75). A linear mixed-effects model evaluated the impact of imaging parameters on features, deeming P-value < 0.05 divided by 120 for Bonferroni correction significant.

##### RESULTS

Within both arterial and portal venous phases, among 120 features, slice thickness significantly impacted 30 (25.0%) and 28 (23.3%) features, respectively. The 1024-matrix affected 19 (15.8%) and 18 (15.0%) features, whereas reslicing influenced 14 (11.7%) and 16 (13.3%) features, respectively. Conversely, the reconstruction algorithm exerted minimal effect on 2 (1.7%) and 0 (0.0%) features.

##### CONCLUSION

Slice thickness emerged as the most influential factor affecting the measurement values of features. Subsequently, when employing UHR images (1024 matrix) compared to conventional-resolution images (512 matrix), significant differences were observed in 15-16% of feature measurements in both arterial and portal venous phases. The effects of reslicing were discernible in approximately 10% of features, while the impact of the reconstruction algorithm was minimal.

##### CLINICAL RELEVANCE/APPLICATION

Radiomic features procured from UHR CT employing a 1024 matrix diverge from those garnered through conventional CT. Slice thickness prevails as the primary determinant, with the 1024-matrix as the subsequent influencer.

#### **T5B-SPGI-2 Predictive Value of LI-RADS v2018 Combined ADC for Hepatocellular Carcinoma and Other Primary Hepatic Malignancies in the LI-RADS M Classification**

##### PURPOSE

To investigate the predictive value of LI-RADS v2018 MR imaging features, ADC values to identify hepatocellular carcinoma (HCC) and other hepatic primary malignancy (OM) in the LI-RADS M (LR-M) classification.

##### METHODS AND MATERIALS

MR imaging of 142 patients with primary liver cancer were classified as LR-M by two radiologists, 62 in the HCC group and 80 in the OM group. Comparing ADC and general clinical data including age, gender, location, AFP, CA19-9, length diameter of patients between the two groups, as well as LI-RADS MR imaging features: nonperipheral "washout", enhancing "capsule", nodule-in-nodule, mosaic architecture, blood products in mass, fat in mass, rim APHE, peripheral "washout", delayed central enhancement, targetoid restriction, bile duct dilatation. ADC were converted to dichotomous variables by ROC curves, and the independent predictors of HCC and OM in LR-M were screened by single-factor and multi-factor regression analysis, and the predictive value of each independent predictor and predictive model was analysed by ROC curves.

##### RESULTS

Elevated AFP (42/62, 67.7%), enhancing "capsule" (41/62, 66.1%) and blood products in mass (13/62, 21%) were seen in a higher rate in the HCC group, with ADC =  $1.083 \times 10^{-3}$  mm<sup>2</sup>/s. The OM group showed elevated CA19-9 (42/80, 52.5%), a higher rate of

delayed central enhancement(51/80,63.8%), targetoid restriction (41/80,51.3%) and bile duct dilatation (41/80,51.3%), and ADC  $>1.083 \times 10^{-3} \text{ mm}^2/\text{s}$ . The differences in these parameters were statistically significant ( $P < 0.05$ ). Multi-factor regression analysis showed that AFP, enhancing "capsule", ADC classification, and bile duct dilatation were independent predictors of the HCC and OM groups, and ROC curves showed the highest AUC of 0.950 for the prediction model, with a sensitivity of 85.5% and a specificity of 91.2%.

## CONCLUSION

The ADC classification is an independent predictor for differentiating HCC and OM in the LR-M classification. Combined with elevated AFP, enhanced capsule, and bile duct dilatation, ADC classification can effectively improve the ability to distinguish HCC from OM.

## CLINICAL RELEVANCE/APPLICATION

LI-RADS v2018 combined with ADC values can effectively predict hepatocellular carcinoma (HCC) and other hepatic primary malignancy (OM) in the LR-M classification.

## T5B-SPGI-3 Association of CEUS and CT/MRI LI-RADS Major Feature with Hepatocellular Carcinoma: Comparison of Cirrhosis and Hepatitis B Risk Factors using Individual Participant Data Meta-analysis

Participants

Robert Adamo, Toronto, ON (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the association of LI-RADS major features with HCC and positive predictive value (PPV) for HCC of LI-RADS categories in patients with cirrhosis, HBV-related cirrhosis, and non-cirrhotic chronic-HBV using Individual Participant Data (IPD) meta-analysis.

## METHODS AND MATERIALS

IPD was extracted from studies evaluating CT, MRI and contrast-enhanced ultrasound (CEUS) for diagnosis of HCC using LI-RADS (v2014-2022) (protocol link). Mixed models were applied. Odds ratios (ORs) for each major feature and PPV for each LI-RADS category were determined using multivariable logistic regression in three subgroups: Group-A (cirrhosis), Group-B (HBV-related cirrhosis), and Group-C (HBV without cirrhosis). Risk of bias was assessed using QUADAS-2.

## RESULTS

29 studies (3453 patients) were included: Group-A (3453/4448 patients/observations), Group-B (1106/1232), and Group-C (721/781). CT/MRI major features [threshold growth not assessed, low data] were all associated with HCC: Group-A OR ranges 1.84-5.25; Group-B OR ranges 2.36-8.18; Group-C OR ranges 2.63-5.92. CEUS features associated with HCC: Group-A OR ranges 2.78-6.90, Group-B OR 9.88, and Group-C insufficient data ( $n=44$ ). In CT/MRI and CEUS, the PPVs were comparable for LI-RADS categories 4 (LR-4) and 5 (LR-5) between Group-A, Group-B, and Group-C. Twenty-two studies (79%) had high risk of bias in at least one QUADAS-2 domain.

## CONCLUSION

CT/MRI, LI-RADS major features (other than TG) were independently associated with HCC in patients with non-HBV cirrhosis, HBV-cirrhosis, and non-cirrhotic HBV, suggesting that LI-RADS major features are applicable in patients with HBV, regardless of cirrhosis status. CEUS, there were insufficient data to evaluate differences among groups. CT/MRI and CEUS, PPV was comparable between groups for LR-4 and LR-5.

## CLINICAL RELEVANCE/APPLICATION

The CT/MRI LI-RADS major features show similar independent associations with HCC, and the positive predictive value (PPV) for LR-4 and LR-5 in CT/MRI and CEUS is comparable between cirrhosis (Group A), HBV-related cirrhosis (Group B), and non-cirrhotic HBV (Group C) patients. Therefore, this study supports the current LI-RADS v2018 approach, which does not adjust major imaging features based on different patient populations.

## T5B-SPGI-4 Nontarget Y90 Transarterial Radioembolization (TARE): Can It Affect Post-Treatment HCC Localization and LIRADS-Treatment Response Algorithm (LR-TRA)?

Participants

Charis Wang, BA, (*Presenter*) Nothing to Disclose

## PURPOSE

In a prior study, we assessed the accuracy of the LIRADS-TRA in categorizing post-therapy response of HCC treated with TARE with yttrium-90, using liver explant pathology as the reference standard. However, Y90 TARE can cause variable non-target/background liver radiation features, confounding congruent LR-TRA assessment between readers. This study aimed to assess multireader variability of post-treatment lesion localization and the confounding effect of non-target radiation on the LR-TRA.

## METHODS AND MATERIALS

96 patients who had liver explant pathology after Y90 treatment for HCC between Oct 2015 and Oct 2021 were identified using data science tools. Patients with less than 90 days between Y90 treatment and pre-transplant MRI or CT were excluded due to immediate post-treatment enhancement confounding LR-TRA assessment. From the remaining 69 patients, there were 64 MRIs and 5 CTs completed before liver transplant, with 9 excluded for technical issues. Using post-contrast sequences, three readers independently reviewed each patient's exams and indicated the location of the pre-treatment lesion on the post-treatment image with an arrow. Arrow locations were compared and marked as congruent or noncongruent. Fisher's exact test was used to analyze interreader congruency of post-treatment lesion localization LR-TRA assessments of treatment response, and the respective correlations with the presence of non-target post-radiation changes.

## RESULTS

Lesion localization data was obtained for 60 exams. Among the 34 patients without nontarget changes, 32 (94.1%) demonstrated lesion localization congruency; while among the 26 patients without nontarget changes, only 13 (50%) were congruent ( $p < 0.001$ ). For LIRADS TRA classification, 76.5% (26/34) were congruent on exams without nontarget changes, while 42.3% (11/26) were

noncongruent. ( $p=0.05$ ). LR-TRA classification noncongruency was highest for the equivocal vs nonviable subcohort (30.8%; 8/26).

## CONCLUSION

s Although non-target/background liver post-treatment (Y90) radiation changes can be variable, its presence can significantly impact interreader congruency for lesion localization and LIRADS-TRA classification.

## CLINICAL RELEVANCE/APPLICATION

The effect of non-target radiation changes on accurate lesion localization and LR-TRA classification should be taken into account when assessing therapeutic response of HCC treated with TARE with Y90.

## T5B-SPGI-5 LI-RADS Treatment Response Algorithm v2023 versus v2018: Assessing Diagnostic Performance and Inter-reader Agreement in Patients with Hepatocellular Carcinoma Treated with Stereotactic Body Radiotherapy

### PURPOSE

To evaluate the accuracy and inter-reader agreement of the updated LI-RADS Treatment Response Algorithm (LR TRA) v2023 for assessing tumor viability of hepatocellular carcinoma (HCC) treated with stereotactic body radiotherapy (SBRT) using explant as the gold standard.

### METHODS AND MATERIALS

This retrospective IRB approved study included patients who underwent SBRT for treatment of HCC between 2008 and 2021 with subsequent liver transplantation. Five readers independently reviewed all treated lesions according to LR TRA v2023, LR TRA v2018 and mRECIST. Observations were characterized as Viable, Non-viable, Nonprogressing (using v2023), or Equivocal (using v2018) based on LR TRA and complete response, partial response, stable disease, or progressive disease based on mRECIST. Predictive values for Viable and Nonviable categories were compared to pathology results using 100% as complete pathologic necrosis and less than 100% as incomplete pathologic necrosis. Performance metrics for assessing Viability and Nonviability of treated observation were calculated for each reader and reader agreement was determined for v2023 and v2018.

### RESULTS

44 lesions in 27 patients (median age: 63 [59-65 years]; 25 males) were included. Overall reader agreement for final category was 33%, 31%, and 30% for v2023, v2018 and mRECIST, respectively. Reader agreement amongst faculty and trainees for v2023, v2018 and mRECIST was 33%, 29%, and 31% and 42%, 33%, and 41%, respectively. There was increased reader agreement amongst faculty assigning Viable category from v2018 to v2023 (v2018: 25%; v2023: 35%) compared to Non-viable and Equivocal/Nonprogressing category (Nonviable v2018 to v2023: 37% to 37% and Equivocal v2018 to Nonprogressing v2023: 22% to 28%, respectively). Sensitivity and negative predictive value for predicting complete necrosis was 69% and 71% (v2023) and 63% and 70% (v2018), respectively, when Nonprogressing/Equivocal category were treated as Viable, accounting for subject clustering. Sensitivity and positive predictive value for predicting incomplete necrosis was 96% and 62% (v2023) versus 94% and 62% (v2018), respectively, when the Nonprogressing/Equivocal category was treated as Nonviable.

### CONCLUSION

s LR TRA v2023 demonstrates improvement in reader agreement using newly defined terminology for persistently enhancing SBRT-treated HCC. LR TRA v2023 demonstrates similar diagnostic performance compared to v2018 for predicting incomplete and complete necrosis.

## CLINICAL RELEVANCE/APPLICATION

SBRT-treated HCC undergo slow necrosis and show persistent post-treatment APHE which should not be retreated. LR-TR Nonprogressing is a new category aiming to improve reporting consistency to reduce unnecessary early retreatment.

## T5B-SPGI-6 Intelligent Radiomics for Individualized Evaluation of Target in Patients with Advanced Hepatocellular Carcinoma

Participants

Mingguang Yang, Chongqing, China (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the use of intelligent imaging methods to develop intelligent imaging markers based on CT images and construct a visualization Nomogram to individually predict the efficacy of ronvatinib in patients with advanced hepatocellular carcinoma.

### METHODS AND MATERIALS

This study retrospectively analyzed 168 patients with hepatocellular carcinoma treated with ranvastinib and divided them into two independent study cohorts. First, image features were extracted from baseline CT images of 79 patients in cohort 1 using image omics analysis. A nested 10-fold cross-validation and Cox proportional hazard regression model were used to construct intelligent image omics markers combined with LASSO algorithm to predict treatment failure time TTF and overall survival OS in advanced HCC patients receiving targeted therapy. The efficacy of intelligent imaging markers was verified in a cohort of 89 patients.

### RESULTS

The nested 10-fold cross-verified training was repeated for 100 rounds, and the average consistency index C-index was 0.682 (t test  $P < 0.001$ ). Ultimately, intelligent imaging markers consisting of eight image features were significantly associated with TTF and OS ( $P < 0.001$ ), and were able to classify advanced HCC patients receiving targeted therapy into low-risk and high-risk groups, with 1-year treatment failure rates of 53.2% and 6.8%, respectively. The 2-year survival rates were 62.3% and 15.6%, respectively. Multivariate analysis showed that smart imaging markers were independent prognostic factors for TTF (HR: 4.840, 95%CI: 2.554-7.468,  $P < 0.001$ ) and OS (HR: 4.325, 95%CI: 2.034-11.225,  $P < 0.001$ ). A Nomogram integrated with intelligent imaging markers and clinicopathological parameters further improves the prediction performance.

### CONCLUSION

s Intelligent imaging markers based on CT images can effectively predict treatment failure time and overall survival in advanced HCC

patients receiving targeted therapy with ranvatinib. A Nomogram model was synthesized by fitting intelligent imaging markers and clinicopathological parameters to guide individualized targeted therapy for patients with advanced HCC.

#### **CLINICAL RELEVANCE/APPLICATION**

In this study, intelligent imaging markers based on CT images combined with artificial intelligence technology can be used to guide individualized targeted therapy for patients with advanced HCC.

#### **T5B-SPGI-8 Machine Learning for Malignant versus Benign Focal Liver Lesions on US and CEUS: A Systematic Review and Meta-Analysis**

Participants

Carlos Alberto Campello Jorge, MD, Campo Grande, MS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To perform a meta-analysis of the diagnostic performance of learning (ML) algorithms (conventional and deep-learning algorithms) for the classification of malignant versus benign focal liver lesions (FLLs) on US and CEUS.

#### **METHODS AND MATERIALS**

Available databases were searched for relevant published studies through September 2022. Studies met eligibility criteria if they evaluate the diagnostic performance of ML for the classification of malignant and benign focal liver lesions on US and CEUS. The pooled per-lesion sensitivities and specificities for each modality with 95% confidence intervals were calculated.

#### **RESULTS**

A total of 8 studies on US, 11 on CEUS, and 1 study evaluating both methods met the inclusion criteria with a total of 34,245 FLLs evaluated. The pooled sensitivity and specificity of ML for the malignancy classification of FLLs were 81.7% (95% CI, 77.2-85.4%) and 84.8% (95% CI, 76.0-90.8%) for US, compared to 87.1% (95% CI, 81.8-91.0%) and 87.0% (95% CI, 83.1-90.1%) for CEUS. In the subgroup analysis of studies that evaluated deep learning algorithms, the sensitivity and specificity of CEUS (n=4) increased to 92.4% (95% CI, 88.5-95.0%) and 88.2% (95% CI, 81.1-92.9%). Studies assessing multiple malignant and benign etiologies for FLLs had no lower diagnostic performance than those comparing only one etiology in each group for both methods.

#### **CONCLUSION**

s The diagnostic performance of ML algorithms for the malignant classification of FLLs was high for both US and CEUS with overall similar sensitivity and specificity. The similar performance of US may be related to the higher prevalence of DL models in that group.

#### **CLINICAL RELEVANCE/APPLICATION**

Machine learning algorithms applied for the classification of focal liver lesions demonstrated high accuracy for both CEUS and US.

T5B-SPGU

### Genitourinary Imaging Tuesday Poster Discussions II

#### Sub-Events

#### T5B-SPGU-1 Global Variation in Magnetic Resonance Imaging of the Prostate using PI-QUAL: A Multicentre Study

##### Participants

Francesco Giganti, MD, PhD, London, United Kingdom (*Presenter*) Nothing to Disclose

##### PURPOSE

High variability in prostate MRI quality reduces the accuracy of this technique in the detection of prostate cancer. The Prostate Imaging Quality (PI-QUAL) score is the first standardised scoring system that evaluates image quality using five points, where a score of 5 means the scan is of optimal diagnostic quality and a score of 1 means that all sequences are below the minimum standard for diagnostic quality. We aimed to assess prostate MRI quality following the application of PI-QUAL in the scans from different centres across the world undergoing quality control as part of an ongoing trial. We determined whether appropriate modifications to MRI protocols could optimise their diagnostic quality.

##### METHODS AND MATERIALS

For each scanner, centres submitted 5 consecutive MRI scans and the MRI protocols (Phase 1). Submitted data were evaluated in consensus by two expert genitourinary radiologists using PI-QUAL. Feedback was provided for scanners not reaching PI-QUAL 5, and centres were invited to resubmit a new study using the modified protocol (Phase 2).

##### RESULTS

In Phase 1, 41 centres from 18 countries submitted a total of 355 MRI images from 71 scanners, with 9 (13%), 39 (55%) and 23 (32%) scanners scoring a PI-QUAL score of 3, 4 and 5, respectively. Of the 48/71 (68%) scanners which received feedback to improve, the dynamic contrast enhanced sequences were those with the highest variability (44/48, 92%), followed by diffusion-weighted imaging (20/48, 42%) and T2-weighted imaging (19/48, 40%). 36 centres from 17 countries resubmitted revised studies, resulting in a total of 62/64 (97%) scanners completing Phase 2, scoring PI-QUAL 5.

##### CONCLUSION

We observed significant variation in prostate MRI quality, particularly with dynamic contrast enhanced sequences. Basic evaluation and modifications to MRI protocols using PI-QUAL can lead to substantial improvements in the global quality of prostate MRI.

##### CLINICAL RELEVANCE/APPLICATION

There is significant global variation in prostate MR image quality, particularly in the dynamic contrast enhanced sequences. However, quality can be optimised with basic modifications to MRI protocols. Basic changes using the PI-QUAL score (that includes adherence to technical recommendations outlined in the PI-RADS guidelines) markedly improved the quality of scanners, with 97% and 3% of scans obtaining a PI-QUAL score of 5 and 4, respectively.

#### T5B-SPGU-2 More with Less: A Quality Improvement Initiative to Evolve Multiparametric MR Prostate Imaging beyond the Endorectal Coil

##### PURPOSE

To establish a consistent, efficient, and patient-friendly 3 Tesla MRI protocol for performing high-quality prostate MRI without an endorectal coil (ERC).

##### METHODS AND MATERIALS

As part of the ACR Prostate MR Image Quality Improvement Collaborative, this single-center quality improvement (QI) project audited image quality across three project phases: pre-improvement, improvement, and post-improvement. Approximately 30 exams were audited each week (1114 exams total). All prostate exams were obtained on a 3T Siemens Magnetom Skyra (Syngo MR E11, Siemens Healthineers, Erlangen, Germany) with multiplanar T2-weighted imaging, DWI and ADC maps, and DCE imaging series following PI-RADS v2/2.1 guidelines. During the pre-improvement phase, our QI team regularly observed the imaging department using Gemba Walks, mapped out the imaging process, performed current state analysis, investigated root causes, and identified key drivers. Four months of pre-improvement exams were audited to quantify baseline performance and establish our SMART goal: achieving PI-QUAL = 4 for 85% of non-ERC MRI exams by the end of the 9-month Collaborative. In the improvement phase, interventions were implemented in rapid Plan-Do-Survey-Act cycles. A prostate phantom was developed for intervention testing to minimize the effects of patient variability. Progress was tracked on a run chart plotting the percentage of cases achieving PI-QUAL = 4. During the post-improvement phase, we tracked image quality to see how well the results were sustained. Educational materials for training technologists were developed by comparing image quality between ERC and non-ERC exams.

##### RESULTS

Pre-improvement, 64.8% (318/491) of baseline exams achieved PI-QUAL = 4. Performance improved to 79.4% (181/228) after

introducing a 200-lb. weight-limit for ERC usage and switching to R/L phase encoding. This increased further to 89.1% (212/238) after enabling the abdomen shimming mode and expanding the shim box to encompass the full pelvis. Following the Collaborative, these improvements have been sustained for three months with 93.9% (245/261) of exams achieving PI-QUAL = 4.

## CONCLUSION

Following the structured and data-driven QI process laid out by the ACR Learning Network, we can now routinely obtain high-quality prostate MRI without an ERC, and in some cases, forgoing the ERC even offers advantages.

## CLINICAL RELEVANCE/APPLICATION

While providing prostate MRI exams without an ERC offers clear advantages for patients, staff, and clinical workflow, it's crucial to ensure sufficient image quality for accurate diagnosis. Therefore, transitioning away from ERC usage in prostate MRI requires a thoughtful and evidence-based improvement process.

## T5B-SPGU-3 Association of Quantitative Multiparametric MRI Parameters and Aggressive Prostate Cancer Morphologies

Participants

Daniel Kim, Los Angeles, CA (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the relationship between 3 Tesla quantitative multiparametric magnetic resonance imaging (qmpMRI) and pathologic features of aggressive prostate cancer (PCa) including cribriform morphology and intraductal carcinoma (IDC).

## METHODS AND MATERIALS

This IRB-approved, HIPAA compliant study involved patients with PCa who underwent robotic radical prostatectomy between 2019 and 2022 and pre-operative mpMRI. Both mpMRI and whole mount histopathology (WMHP) were re-reviewed during a multidisciplinary meeting to assess imaging and pathology lesion matching and the presence of cribriform and IDC. All UCLA and PIRADSV2.1=3 lesions on mpMRI were contoured and the following quantitative parameters were extracted: mean apparent diffusion coefficient (ADC,  $\times 10^{-6} \text{mm}^2/\text{s}$ ) and perfusion parameters including  $K_{\text{trans}}$  (min-1),  $K_{\text{ep}}$  (min-1),  $i\text{AUC}$  (mMsec). The cohort was divided into three subcohorts with increasing aggressiveness: (1) cribriform-/IDC-, (2) cribriform+/IDC-, and (3) cribriform+/IDC+. The cohort was also divided a binary manner into cribriform-/IDC- (subcohort 1) and cribriform+/IDC $\pm$  (subcohort 2 and 3). We used one-way ANOVA to assess group differences, Jonckheere test to evaluate trends, and a classification and regression tree (CART) model to estimate the discrimination ability by using all qmpMRI parameters.

## RESULTS

The study cohort comprised of 130 patients (mean age and PSA:  $62.6 \pm 7.2$  years and  $9.3 \pm 6.2$  ng/mL) with 141 PCa lesions on mpMRI with 41/141, 49/141, and 51/141 in subcohorts 1, 2, and 3, respectively. The mean ADC and  $i\text{AUC}$  were  $892 \pm 202$  and  $5.4 \pm 2.5$ ,  $826 \pm 209$  and  $6.7 \pm 3.0$ ,  $763 \pm 163$  and  $6.9 \pm 3.5$  in subcohorts 1, 2, and 3, respectively (mean ADC,  $p=0.007$ ;  $i\text{AUC}$ ,  $p=0.037$ ). The mean ADC,  $K_{\text{ep}}$ , and  $i\text{AUC}$  of cribriform+/IDC $\pm$  (subcohort 2 and 3) were  $794 \pm 188$ ,  $1.9 \pm 1.3$ , and  $6.8 \pm 3.2$  which were significantly different compared to cribriform-/IDC- (subcohort 1) with  $p=0.007$  (mean ADC),  $p=0.019$  ( $K_{\text{ep}}$ ),  $p=0.011$  ( $i\text{AUC}$ ). As aggressive PCa hosts increased cellularity and increased vascularity leading to low diffusion and high perfusion parameters, the Jonckheere test confirmed that mean ADC ( $p=0.004$ ) was negatively correlated, and  $K_{\text{ep}}$  ( $p=0.048$ ) and  $i\text{AUC}$  ( $p=0.037$ ) were positively correlated with increasing PCa aggressiveness. Using mean ADC and  $i\text{AUC}$  cutoffs of 893 and 5.7, the CART model correctly allocated 62%, 60%, and 45% of PCa lesions to subgroups 1, 2, and 3.

## CONCLUSION

3T qmpMRI diffusion and perfusion parameters were significantly correlated with increasingly aggressive PCa histological findings including presence of cribriform and IDC.

## CLINICAL RELEVANCE/APPLICATION

Quantitative mpMRI parameters show significant association with aggressive prostate cancer morphologies aiding to the diagnostic performance of mpMRI.

### Head & Neck Imaging Tuesday Poster Discussions II

#### Sub-Events

#### **T5B-SPHN-1 Diagnosing Cervical Lymph Node Metastasis in Oral Squamous Cell Carcinoma based on Third-generation Dual-source, Dual-energy Computed Tomography**

#### **PURPOSE**

To investigate the potential of dual-energy computed tomography (DECT) parameters in identifying metastatic cervical lymph nodes in oral squamous cell carcinoma (OSCC) patients and to explore the relationships between DECT and pathological features.

#### **METHODS AND MATERIALS**

Clinical and DECT data were collected from patients who underwent radical resection of OSCC and cervical lymph node dissection between November 2019 and June 2021. Microvascular density was assessed using the Weidner counting method. The electron density (ED) and effective atomic number (Z<sub>eff</sub>) in non-contrast phase and iodine concentration (IC), normalized IC, slope of the energy spectrum curve (?HU), and dual-energy index (DEI) in parenchymal phase were compared between metastatic and non-metastatic lymph nodes. Student's t-test, Pearson's rank correlation and receiver operating characteristic curves were performed.

#### **RESULTS**

The inclusion criteria were met in 399 lymph nodes from 103 patients. Metastatic nodes (n=158) displayed significantly decreased ED, IC, normalized IC, ?HU, and DEI values compared with non-metastatic (n=241) nodes (all p < 0.01). Strong correlations were found between IC (r = 0.776), normalized IC (r = 0.779), ?HU (r = 0.738), DEI (r = 0.734), and microvascular density. Area under the curve (AUC) for normalized IC performed the highest (0.875) in diagnosing metastatic nodes. When combined with the width of nodes, AUC increased to 0.918.

#### **CONCLUSION**

s DECT parameters IC, normalized IC, ?HU, and DEI reflect pathologic changes in lymph nodes to a certain extent, and aid for detection of metastatic cervical lymph nodes from OSCC.

#### **CLINICAL RELEVANCE/APPLICATION**

1. Electron density, iodine concentration, normalized iodine concentration, ?HU, and dual-energy index values showed significant differences between metastatic and non-metastatic nodes. 2. Strong correlations were found between iodine concentration, normalized iodine concentration, slope of the spectral Hounsfield unit curve, dual-energy index, and microvascular density. 3. DECT qualitative parameters reflect the pathologic changes in lymph nodes to a certain extent, and aid for the detection of metastatic cervical lymph nodes in patients with OSCC and aid clinical decision-making.

#### **T5B-SPHN-2 To Evaluate the Role of the 18 F FDG PET/CT in the Evaluation of the Post Head and Neck Surgery Prognosis and Survival**

#### **PURPOSE**

The aim of the study was to evaluate the various clinical and preoperative PET/CT findings in evaluation of the overall survival (OS) and for the evaluation of the distant metastasis for the diagnosis of the disease free survival (DMFS) in the cohort of head and neck squamous cell carcinoma patients who were treated with surgery. This study also correlates the prognostic model of OS and DMFS, by which there can be validation of the prognostic model with an independent cohort.

#### **METHODS AND MATERIALS**

This was the retrospective study comprising of the 382 patients who had diagnosed head and neck squamous cell carcinoma, and this was further divided into training (n=?318) and validation (n=?64) cohorts. This was based on the various parameters like various PET/CT parameters which were analysed: clinical parameters, SUV<sub>max</sub>, SUV<sub>mean</sub>, metabolic tumor volume (MTV), total lesion glycolysis, and distance parameters for the primary tumor and lymph nodes and these were defined by 2 segmentation methods (relative SUV<sub>max</sub> threshold and absolute SUV threshold). The Cox analyses was also performed for OS and DMFS in the training cohort. The concordance index (c-index) was used to identify highly prognostic parameters in this study. All these prognostic parameters were externally tested in the validation cohort and were validated.

#### **RESULTS**

In multivariable analysis, the various important parameters for OS were T stage and nodal MTV, with a c-index of 0.64 (P?<?0.001). For the DMFS, the various parameters were T stage, nodal MTV, and maximal tumor-node distance, with a c-index of 0.76 (P?<?0.001). There were many combinations of parameters and all this were validated externally with c-indices of 0.63 (P?<?0.001) and 0.71 (P?<?0.001) for OS and DMFS, respectively.

#### **CONCLUSION**

s The nodal MTV and the maximal tumor-node distance was significantly correlated with the risk of DMFS. And this parameter was associated with significant increase in the higher risk of death. These all prognostic factors will be used as tailor-made concept for

the individualized treatment

#### **CLINICAL RELEVANCE/APPLICATION**

PET-CT is the important modality for the evaluation of the post operative status of the head and neck cancers

#### **T5B-SPHN-3 Multi-parametric MRI-based Radiomics Approach with Deep Transfer Learning for Preoperative Prediction of Ki-67 Status in Sinonasal Squamous Cell Carcinoma**

Participants

Naier Lin, MS, Shanghai, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Preoperative prediction of Ki-67 status in sinonasal squamous cell carcinoma (SNSCC) is critical for individualized treatment. Based on comparison of different machine learning (ML) models, we developed the model that integrates traditional hand-crafted (HC) features and deep transfer learning (DTL) features from multi-parametric MRI to predict Ki67 status in SNSCC.

#### **METHODS AND MATERIALS**

231 SNSCC patients were retrospectively reviewed [training cohort (n= 185), test cohort (n = 46)]. Clinical data and conventional MRI characteristics were analyzed to choose the independent predictor. HC and DTL radiomics features were extracted from fat-saturated T2-weighted imaging, contrast-enhanced-T1WI and apparent diffusion coefficient map. In this study, ResNet50 was chosen as the pretrained CNN model and it was trained on the ILSVRC-2012 dataset. Then, HC and DTL features were fused to formulate the deep learning-based radiomics (DLR) features. After features selection and radiomics signature (RS) building, we compared the predictive ability of RS-HC, RS-DTL and RS-DLR.

#### **RESULTS**

No independent predictors were found based on clinical and conventional MRI characteristics. After features selection, 42 HC and 10 DTL radiomics features were retained. The ML algorithm of Support Vector Machine (SVM), LightGBM and ExtraTrees (ET) were the best classifier for RS-HC, RS-DTL and RS-DLR, respectively. In the training cohort, the predictive ability of RS-DLR was higher than those of RS-DTL and RS-HC. In the test set, the area under curve (AUC) of RS-DLR was also the highest (AUC = 0.817, 95% CI: 0.697 - 0.937), better than those of RS-DTL (AUC = 0.650, 95% CI:0.487 - 0.812) and RS-HC (AUC = 0.803, 95% CI: 0.679 - 0.927).

#### **CONCLUSION**

s Based on ET algorithm classifier, the integrated RS-DLR, which combine the HC and DTL features from multiple MR sequences, yielded more biological information about tumor and showed great potential in improving the prediction of Ki67 status in SNSCC.

#### **CLINICAL RELEVANCE/APPLICATION**

As a noninvasive and convenient method, the integrated RS-DLR represented an opportunity to advance precise prediction for the proliferation status in SNSCC preoperatively and benefit individualized treatment.

#### **T5B-SPHN-4 The Value of Synthetic MRI in Differentiating Metastatic and Non-metastatic Lymph Nodes in Nasopharyngeal Carcinoma, Compared with Size Criteria**

#### **PURPOSE**

The accurate diagnosis of metastatic lymph nodes (LNs) affects the target delineation and dose distribution of radiotherapy in nasopharyngeal carcinoma (NPC). The purpose was to explore the potential value of synthetic MRI (SyMRI) combined with histogram analysis in diagnosing LN metastasis (LNM) and how it compares to size criteria.

#### **METHODS AND MATERIALS**

Fifty-three consecutive patients with pathologically proven NPC were enrolled in this prospective study, and 377 cervical LNs with a maximum short axis diameter (MSAD) = 4 mm were evaluated. All patients underwent standard treatment and the median follow-up time after treatment was 36.13 (17.62, 42.19) months. Two senior radiologists (with 21 and 18 years of tumor-imaging experience) independently evaluated and labelled LNs, and any disagreement was resolved by discussion. A cervical LN was considered to be metastatic if it resolved after the patients completed treatment or showed stable size after treatment but progressed during the follow-up MRI. A cervical LN was considered to be non-metastatic if it showed stability in size after the completion of treatment and the patient remained disease-free during the follow-up MRI (Fig.1). Therefore, 297 and 80 LNs were diagnosed with metastatic and non-metastatic. Histogram features were extracted from the T1, T2, and proton density (PD) maps and MSAD was recorded. According to the Size criteria for cervical LNs, MASD of LNs = 5 mm in the retropharyngeal region, = 11 mm in level II and = 10 mm in other levels of neck were considered metastatic, otherwise, LNs were divided into the non-metastatic group. The dataset was assigned in a 7:3 ratio to either training group or validation group. Multivariate logistic regression analysis and ROC analysis were used to explore the performance in the diagnosis of cervical LNs and level II LNs. Then the DeLong test was used, and nomogram and calibration curves were constructed.

#### **RESULTS**

T1\_10th Percentile, T1\_Variance, PD\_10th Percentile, and PD\_Minimum were used to construct SyMRI model (AUC: 0.895 and 0.903 in the train and validation group), which is higher than Size criteria model (AUC: 0.824 and 0.797), with both P = 0.023. Moreover, SyMRI + Size criteria model showed the highest performance (AUC: 0.941 and 0.938) compared with SyMRI model only (both P = 0.043) and Size criteria model only (both P = 0.007).

#### **CONCLUSION**

s SyMRI derived histogram parameters could effectively differentiate metastatic from non-metastatic whether in cervical LNs or level II LNs. Moreover, the combination of SyMRI and Size criteria could significantly improve diagnostic performance.

#### **CLINICAL RELEVANCE/APPLICATION**

The model built by SyMRI makes it possible to effectively evaluate individual LN within the MRI scan.

## **T5B-SPHN-5 Uniting Dual-Modal MRI/Chemiluminescence Nanotheranostics: Spatially and Sensitive Self-Reporting Photodynamic Therapy in Oral Cancer**

### **PURPOSE**

In order to achieve precise and efficient diagnosis and treatment of tumors, the integrated nanosystem has been recognized by many interdisciplinary fields and has broad development prospects. However, there are still many challenges in real-time monitoring of targeted delivery and efficacy control of nanomedicines. Firstly, the unpredictable in vivo behaviors of nanotheranostics, that is, real-time tracking where, when, and how nanodrugs delivered. Next, limited by the uncontrollability of the therapeutic dose, how to monitor the treatment behavior and control the curative effect is the main bottlenecks. Therefore, inspired by the Boolean logic idea, designing sequence-activated nanotheranostics strategy is expected to become a breakthrough to solve the above difficulties and realize high-performance diagnosis and treatment applications.

### **METHODS AND MATERIALS**

A sequence-responsive MRI/chemiluminescence (CL) dual-mode strategy was constructed through uniform spatio-temporal resolution. The nanotheranostics system Pa-MnCH-A@P was prepared by combining the Mn<sup>2+</sup> chelated photosensitizer (Pa) and the CL molecule (CH-A) through FNP technology. Then we explored the structural characterization, spectral properties, MR properties and CL properties of the nanomaterials. The human oral squamous cell carcinoma cell CAL27 was selected as cell model of the tumor to further explore the PDT properties and CL imaging to further explore the photodynamic properties and chemiluminescence imaging properties in cells, as well as the dual-modality imaging were performed in tumor model of oral cancer in mice.

### **RESULTS**

We innovatively combined MR and CL imaging through FNP (flash nanoprecipitation) technology to quantitatively monitor in vivo distribution and PDT performance, overcoming the dilemma between spatial resolution and sensitivity.

### **CONCLUSION**

Based on near-infrared fluorescence imaging, chemiluminescence imaging, magnetic resonance imaging and photodynamic therapy, this research combined diagnosis and treatment to construct nanotheranostics system. We successfully designed nanoprobe Pa-MnCH-A@P to real-time tracking unpredictable biological distribution and behavior in vivo and PDT feedback, which expanded the application of sequence-activated nanotheranostics system.

### **CLINICAL RELEVANCE/APPLICATION**

Integration of diagnosis and treatment of oral cancer.

## **T5B-SPHN-6 The Impact of the COVID 19 Pandemic on Nasopharyngeal Carcinoma Extent at FDG PET/MR Staging: The NPCOVIPET Study**

### **PURPOSE**

To evaluate the impact of coronavirus disease 2019 (COVID-19) pandemic on disease extent in nasopharyngeal carcinoma (NPC) patients using 18 fluorodeoxyglucose (FDG) positron emission tomography (PET)/magnetic resonance imaging (MRI) staging as surrogate measure.

### **METHODS AND MATERIALS**

Retrospective observational study including biopsy-proven, newly diagnosed NPC patients using whole-body FDG PET/MR staging in two selected intervals: May 1, 2017 to January 31, 2020 (Group A), and February 1, 2020 to June 30, 2021 (Group B). Data regarding primary tumour, regional lymph nodal (N) status and number of involved regional lymph nodal stations, and presence and number of distant metastases (M) were collected.

### **RESULTS**

Three hundred ninety patients were included (201 in Group A vs 189 in Group B, respectively). The median intervals to PET/MR from the initial symptom in group A and group B were 2.5 (0.1-60.4) and 3.4 (0.2-56.3) months, respectively ( $p>0.05$ ). The median intervals to treatment from the initial symptom in group A and group B were 2.8 (0.2-60.5) and 3.6 (0.3-56.3) months, respectively ( $p>0.05$ ). No significant difference was observed in terms of T classification, N classification, overall stage, N stations and M stations between the two groups ( $p>0.05$ ). For the the involved neck node levels, more patients had developed level Vc metastasis in the group B ( $p=0.044$ ).

### **CONCLUSION**

For NPC, staging by PET/MR and therapy were not significantly delayed after quarantine restrictions initiated. Although the overall stage was not affected, more NPC patients had developed level Vc metastasis in the era of COVID-19.

### **CLINICAL RELEVANCE/APPLICATION**

None

## **T5B-SPHN-7 Use of 18F-FDG PET/MR as an Initial Staging Procedure for Nasopharyngeal Carcinoma**

### **PURPOSE**

The purpose of this study was to determine the clinical value and cost-effectiveness of PET/MR as an initial staging procedure for nasopharyngeal carcinoma (NPC) compared with the conventional work-up (CWU).

### **METHODS AND MATERIALS**

From May 2018 to March 2021, 1020 consecutive patients with biopsy-proven, newly diagnosed NPC in our center were enrolled in this study. Among them, 343 patients underwent PET/MR before treatment and the remaining 677 patients only underwent CWU. For PET/MR and CWU, charges were used as issued in 2021 by the Medical Insurance Administration Bureau of Zhejiang, China. Incremental cost-effectiveness ratio (ICER) measured cost of using PET/MR per percent of patients who avoided a false-positive (FP).

## **RESULTS**

For the whole group, the de novo metastatic disease rate was 5.2% (53/1020). A total of 187 patients with FP results were observed. More patients with FP results were observed in the CWU group (25.6% vs. 4.1%,  $p < 0.001$ ). The mean interval from pathological diagnosis to initiation of treatment was 13.1 days in the CWU group versus 7.9 days in the PET/MR group ( $p < 0.001$ ). Mean cost per patient was \$417 for CWU and \$1585 for PET/MR. The ICER was \$54 for each percent of patients who avoided a FP.

## **CONCLUSION**

s Compared with CWU, PET/MR reduced FP risk and decreased workup of incidental findings, allowing for earlier treatment start. PET/MR may be cost-effective in initial staging procedure for NPC.

## **CLINICAL RELEVANCE/APPLICATION**

None

Printed on: 04/12/24

T5B-SPIN

### Imaging Informatics Tuesday Poster Discussions II

#### Sub-Events

#### T5B-SPIN-1 Knee Osteoarthritis Deep Learning Models Demonstrate Greater Biases Based on Sex Than Race

##### Participants

Bardia Khosravi, MD, MPH, Rochester, MN (*Presenter*) Nothing to Disclose

##### PURPOSE

Deep learning (DL) models for chest x-ray (CXR) diagnosis have demonstrated biases against historically disadvantaged groups across sex, and race, raising concerns about the equitable use of these tools. It is unclear, however, if similar biases exist for DL models in other body parts like the knee. The purpose of our study was to evaluate for sex and race-based bias in a DL model for knee osteoarthritis (OA) severity grading.

##### METHODS AND MATERIALS

We used the Osteoarthritis Initiative (OAI) dataset of weight-bearing AP knee radiographs for DL model development and testing. We first trained a YOLO-v5 object detection model to localize the right and left knees using 4,490 bilateral knee radiographs with bounding box annotations split at the patient-level into 70%/10%/20% splits for training/validation/test sets. We then used this localization model to crop knee joints from 19,777 knee radiographs used to train and test the knee OA severity grading (groundtruth Kellgren-Lawrence grades [KLG] provided by OAI); there were 42% males and 81% white patients. These images were split based on race and sex at the patient level, using 20% for testing and the rest for five-fold cross-validation (Figure 1A). The model's performance was evaluated on the test set with AUROC subgroup analysis based on sex and race (white vs. not white).

##### RESULTS

The knee joint localization model achieved a mean average precision (mAP) of 0.97. The OA grading model had an average AUROC of 0.91 on the five validation folds and an AUROC of 0.90 on the entire test set. Subgroup analysis showed biases favoring males for all KLG groups, except for KLG 3, which favored females; for example, for KLG 1 grading, AUROC for males was 0.8 compared to 0.76 for females (Figure 1B). Race-based bias was less pronounced, with no difference in AUROC between white and non-white patients for KLG 0 and 2, and differences of 0.02 for KLG 1, 3, and 4 (Figure 1C).

##### CONCLUSION

Our DL OA severity grading model performed at a state-of-the-art level, but demonstrated sex-based biases favoring males in 4/5 KLG categories, echoing previous findings for DL models for CXR diagnosis. The model demonstrated less pronounced race-based biases, however, indicating that demographic-based biases in DL models may vary between specific diagnostic use cases and body parts. We recommend further study to elucidate the mechanisms behind these demographic biases in DL models in radiology.

##### CLINICAL RELEVANCE/APPLICATION

We show that deep learning models can diagnose knee osteoarthritis with high accuracy, but can also exhibit biases based on sex and, to a lesser extent, race. Evaluation of demographic bias is critical to ensure the equitable use of these exciting technologies that hold much promise to transform medical imaging.

#### T5B-SPIN-2 Radiobiometry": Deep-learning-based re-identification of Patients from De-identified Medical Images

##### PURPOSE

When two radiographs are presented for follow-up evaluation, a radiologist must ensure they are from the same patient, which is not a trivial task. In some cases, patients may be misregistered, potentially leading to a medical error. Thus, the purpose of the study was to develop and assess a deep-learning "radiobiometry" method to determine whether two radiographs are from the same or different patients.

##### METHODS AND MATERIALS

Convolutional Neural Networks (CNN) were trained with contrastive learning to distinguish radiographs of different patients. Using the MIMIC-CXR dataset, CNNs for frontal chest radiographs and multi-view chest radiographs (frontal and lateral) were trained. Additionally, CNNs were trained on radiographs from the Osteoarthritis Initiative (OAI) for 4 other anatomic regions: pelvis, bilateral knees, bilateral hands, and right hand.

##### RESULTS

After preprocessing, 247,522 frontal chest radiographs from 64,564 patients of the predefined MIMIC-CXR training set were used to train the frontal chest-radiograph CNN. This model was tested on 3,630 images from 292 patients of the internal test set, as well as the test set of the ChestX-ray8 dataset consisting of 25,596 images from 2,797 patients. A further 120,973 lateral chest radiographs from MIMIC-CXR were used in combination with the frontal radiographs above to train the multi-view chest-radiograph CNN. This was similarly evaluated on the internal test set with an additional 1,501 lateral images. For CNNs trained on OAI data, 4-fold cross-validation was performed on 26,524, 11,357, 6,165, and 1,799 radiographs of bilateral knees, pelvis, bilateral hands, and

right hand, from 4,796, 4,763, 3,504, and 1,000 patients, respectively. In all-pairs-similarity evaluation, all models achieved a test AUROC and rank-1 accuracy in excess of 0.99. Despite a minor drop in performance, the multi-view chest-radiograph CNN maintained an AUROC and rank-1 accuracy of over 0.99 when matching radiographs of differing laterality.

## CONCLUSION

While falling short of mature biometric modalities with enormous and specialized datasets, initial results using modestly sized medical imaging datasets demonstrate the potential for radiographs as a novel biometric modality for identification and authentication systems. While radiobiometry can be useful for verifying patients in radiology clinical practice, it may also raise concerns for the re-identification of public anonymized medical imaging data.

## CLINICAL RELEVANCE/APPLICATION

"Radiobiometry" systems for identifying patients from radiographs can help to reduce bookkeeping errors in clinical follow-up evaluation, protecting against misdiagnoses while consolidating mislabeled imaging records.

## T5B-SPIN-3 Efficient Deformable Registration with Local Self-similarity for Multi-Phase Abdominal CT Images

Participants

Tony C. W. MOK, ??, China (*Presenter*) Nothing to Disclose

## PURPOSE

We developed a fast deformable multi-phase abdominal CT registration algorithm, which addresses the non-linear misalignment of the intra-patient multi-phase abdominal CT images in real time.

## METHODS AND MATERIALS

Our model is a learning-based method. The training data includes 1,503 cases of three-phase (non-contrast, arterial, and venous) CT volumes from one hospital, including 399 with pancreatic ductal adenocarcinoma (PDAC), 751 with non-PDAC, and 353 normal. We trained the model in a semi-supervised manner. To address the large non-linear misalignment and inhomogeneous image intensity across multi-phase CT, we developed a novel multi-level convolutional neural network to learn to maximize the local self-similarity of the images. To further improve the registration accuracy, we leverage anatomical delineations segmented by a robust multi-organ segmentation model to co-supervise the registration model. The model was independently evaluated on a combined internal test set of 25 cases (5 PDAC, 15 non-PDAC, and 5 normal).

## RESULTS

The registration accuracy, robustness and smoothness of the deformation field are quantified with the Dice coefficient (DSC) of six anatomical delineations (Left and right kidneys, spleen, liver, stomach, and pancreas), the 30% lowest DSC (DSC30), and the standard deviation of the Jacobian determinant (SDLogJ), respectively. In arterial to non-contrast phase registration, our method's registration accuracy (DSC 93.6%) and robustness (DSC30 91.5%) are higher than the mean performance (DSC 92.7% and DSC30 88.8%) of the best-performing conventional multi-modal registration tool (DEEDs). Similar trends are observed in the venous to non-contrast phase registration. Our method outperforms the conventional image registration by a significant margin of 1.2% and 1.4% in DSC and DSC30, respectively, while maintaining a comparable smoothness in the solution (SDLogJ 0.152 vs 0.154). Our method circumvents the costly iterative optimization in the conventional method, which requires a mean running time of 119.5 seconds, and achieves real-time registration (0.33 sec per registration) for multi-phase CT images.

## CONCLUSION

Our method can efficiently register multi-phase abdominal CT images, outperforming the registration performance of the conventional method by a significant margin.

## CLINICAL RELEVANCE/APPLICATION

Our time-efficient registration method can be used in image fusion of multi-phase abdominal images, facilitating daily work of radiologists in imaging reading across multiple phases, and aggregating diverse image features for learning-based diagnostic systems. Our work suggests good feasibility in high-throughput environments that need to process dozens to thousands of multi-phase CT scans.

## T5B-SPIN-4 Identifying Metastatic Lymph Node Stations using a Local-Global Deep Hybrid Network with Prior-guided Supervision in Esophageal Cancer Patients

Participants

Dazhou Guo, New York City, NY (*Presenter*) Nothing to Disclose

## PURPOSE

The diagnosis of lymph node (LN) metastasis in computed tomography (CT) is an essential yet challenging task in esophageal cancer staging and treatment planning. Although criteria (e.g., RECIST, morphological/texture features) are proposed to predict LN metastasis, the diagnostic accuracy remains low with sensitivity <50% and specificity <75%, as reported in previous studies. Deep learning (DL) has the potential to address this issue by learning from large-scale labeled data. However, due to the practical surgery procedure in LN dissection, it is difficult to pair the metastasis of individual LN reported in the pathology report to the LN instance found in the CT image. Hence, in this study, we first use pathology reports to determine the lymph node station (LNS) metastasis, then develop a multiple instance deep learning (MIDL) model to predict LNS metastasis.

## METHODS AND MATERIALS

We collected data from 1,205 esophageal cancer patients who underwent preoperative contrast-enhanced CT scans. Using a recently developed automatic mediastinal LNS segmentation model, we segmented LNS 1 to 8 based on the IASLC protocol. For each LNS, we cropped the local CT region of interest (ROI) to generate station-wise CT patches, labeling the LNS as metastatic if at least one metastatic LN was indicated in the pathology report. We trained a 3D CNN-Transformer hybrid network using these CT patches. To incorporate LN position priors, we segmented LN instances (with a short axis =5mm) and added them as auxiliary input to the MIDL model. We also proposed a lymph node prior attention loss to supervise the transformer's attention map using LN instance masks. We conducted a five-fold cross-validation to evaluate the MIDL model's performance, reporting sensitivity, specificity, and AUC as classification metrics.

## RESULTS

The proposed MIDL model exhibited an overall AUC of 0.8574, significantly outperforming the second best comparing method (MobileNetV2) by 4.78% (0.8574 vs. 0.8096). The specificity was assessed at a threshold yielding a recall of 0.8, at which point the MIDL model achieved a specificity of 0.7735 (MobileNetV2: 0.6553). Additionally, the sensitivity was evaluated at a threshold leading to a specificity of 0.8, where the MIDL model obtained a sensitivity of 0.7719 (MobileNetV2: 0.6309).

## CONCLUSION

s The proposed MIDL model can substantially improve the LNS metastasis prediction and has the potential to play an essential role in cancer staging, treatment planning, and prognostic analysis.

## CLINICAL RELEVANCE/APPLICATION

The proposed algorithm can identify the metastasis lymph node stations in CT scan with high accuracy. The model may be applied in the clinical workflow to assist the diagnosis and treatment for esophageal cancer patients.

## T5B-SPIN-5 Fully Automated CT-Based Body Composition Tools Identify Increased Risk Factors for Adverse Health Outcomes in Socioeconomically Disadvantaged Individuals

Participants

Matthew Lee, MD, Phoenix, AZ (*Presenter*) Nothing to Disclose

## PURPOSE

Socioeconomic disadvantage is associated with adverse health outcomes. The purpose of this study is to evaluate the relationship between socioeconomic disadvantage and CT-based body composition (BC) measures derived from a panel of fully automated artificial intelligence (AI) tools to identify individuals at increased risk for death and major adverse cardiovascular events (MACE).

## METHODS AND MATERIALS

A fully automated panel of AI body composition tools quantifying abdominal aortic calcium (AoCa, Agatston score), abdominal fat (visceral adipose tissue area [VAT], visceral-to-subcutaneous fat ratio [VSR]), and muscle attenuation (muscle HU; mean at L3 level) was applied to non-contrast CT examinations in asymptomatic adults undergoing screening CT colonography (CTC). Patients were partitioned into 5 socioeconomic groups based on the national area deprivation index (ADI). One-way analysis of variance was used to compare means across groups. Odds ratios (ORs) were generated from high specificity (90% specificity) BC thresholds with more disadvantaged groups being compared to the least disadvantaged group (ADI<20) for each body composition measure.

## RESULTS

7785 asymptomatic adults (mean age, 57 years; 4361:3424 F:M) underwent screening CTC from April 2004-December 2016. Median ADI was 31 (IQR 22-43). Significant correlation was observed for all measures (all  $p<0.001$ ). More socioeconomically disadvantaged groups had significantly higher AoCa, higher VAT, higher VSR, and lower muscle attenuation. Compared with the least disadvantaged group, mean differences for the most disadvantaged group (ADI>80) were: AoCa=567, VAT=27 cm<sup>2</sup>, VSR=0.1, and muscle HU=-6 HU (all  $p<0.05$ ). Compared with the least disadvantaged group, the most disadvantaged group had significantly higher odds of having high-risk body composition measures: AoCa OR=3.8, VAT OR=2.5, VSR OR=2.0, and muscle HU OR=3.1 (all  $p<0.001$ ).

## CONCLUSION

s Fully automated CT-based AI body composition tools show that socioeconomic disadvantage is associated with high-risk BC measures and can be used to identify individuals at increased risk for death and MACE.

## CLINICAL RELEVANCE/APPLICATION

Fully automated AI body composition tools are promising for opportunistic screening to identify markers of increased risk of death and MACE associated with socioeconomic disadvantage using data that typically go unused in clinical practice offering added value without additional patient time or dose.

## T5B-SPIN-6 Deep learning-based Model for Prediction of Hepatocellular Carcinoma Recurrence in Pre-operative Computed Tomography after Curative Surgery

## PURPOSE

Curative surgery is the treatment of choice for early-stage hepatocellular carcinoma (HCC) yet recurrence occurs in over 70% of cases. Recurrence, particularly within the first 5 years, is associated with poor prognosis and currently, few clinical risk scores can accurately predict recurrence. While histological microvascular invasion (MVI) predicts recurrence, it can only be confidently ascertained from surgical specimens thus unable to provide pre-treatment prognostication. Here, we developed a deep learning-based model for the prediction of HCC recurrence.

## METHODS AND MATERIALS

Chinese patients with resected histology-confirmed HCC were recruited from 5 centers in Hong Kong. They were randomly divided in an 8:2 ratio to training and internal validation. A residual-network deep learning-based model to predict HCC recurrence was developed through the training-validation-testing approach utilizing pre-operative CT and clinical data (age, sex, comorbidities, and baseline blood tests). The model was externally tested using an independent cohort from Taiwan. Area-under-curve (AUC), positive and negative predictive values (PPV/ NPV) were calculated and survival analyses were also performed and compared with tumour MVI status.

## RESULTS

This interim analysis included 1,254 patients (82.9% male, age 62.2 +/- 10.8 years, median follow-up 7.8 [5.8-10.0] years), with 368 (29.3%) and 710 (56.6%) developing recurrence within 1 and 5 years respectively. Of those, 551 (43.9%), 140 (11.2%), and 563 (44.9%) patients were included in the training, internal validation, and external testing cohorts. The model was trained for 42 epochs and the model achieved AUCs of 0.855 (95% CI 0.682-0.907; PPV 75.4%; NPV 84.3%) and 0.803 (95% CI 0.631-0.859; PPV 89.7%; NPV 55.1%) for predicting HCC recurrence at 1 and 5 years. In the external testing cohort, the deep learning-based model achieved AUCs of 0.775 (95% CI 0.536-0.840; PPV 49.7%; NPV 85.2%) and 0.733 (95% CI 0.539-0.766; PPV 87.0%; NPV 45.8%)

for HCC recurrence at 1 and 5 years, significantly higher than MVI (AUCs 0.617 [0.496-0.725]; PPV 32.9%; NPV 88.5% and 0.560 [0.418-0.688]; PPV 67.9%% NPV 46.4%) respectively. Furthermore, the deep learning-based model had superior discriminative ability on 1 and 5-year recurrence risk compared with MVI (49.7% vs 32.9% and 87.0% vs 67.9% respectively, both  $p < 0.05$ ).

#### **CONCLUSION**

s Our deep learning-based model can accurately predict HCC recurrence after curative surgery in early-stage HCC outperforming MVI in risk stratification.

#### **CLINICAL RELEVANCE/APPLICATION**

Deep Learning can combine radiological images and clinical data and develop models that have the potential to become novel tools for pre-treatment prognostication for short- and intermediate-term outcomes in HCC.

T5B-SPIR

### Interventional Radiology Tuesday Poster Discussions II

#### Sub-Events

#### **T5B-SPIR-1 Timing Matters: Which CT Phase for Colorectal Liver Metastasis Segmentation is Better for Ablative Margin Quantification in Predicting Local Outcomes?**

##### Participants

Jessica A. Marques Silva, MD, Houston, TX (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the use of three-dimensional minimal ablative margin (MAM) quantified by tumor segmentation using hepatic arterial (HAP) versus portal venous (PVP) phases CT for predicting residual tumor and local tumor progression (LTP) following colorectal liver metastasis (CLM) thermal ablation.

##### METHODS AND MATERIALS

This two-institution retrospective study included patients undergoing microwave and radiofrequency ablation between 2010 and 2021 with intraprocedural pre-ablation HAP and PVP and post-ablation PVP CT. Patients with follow-up less than one year without residual tumor or LTP were excluded. Tumors were segmented on pre-ablation HAP and PVP CT and ablation zones were segmented on post-ablation PVP CT. MAMs were quantified by a biomechanical deformable image registration method. Prognostic value of MAM in predicting residual tumor and one-year LTP was investigated using area under the receiver operating characteristic curve (AUC) and the association with LTP was tested using Fine-Gray subdistribution hazard regression model.

##### RESULTS

A total of 80 patients (mean age, 60 years  $\pm$  12 [SD]) with 151 CLMs were included. During a median follow-up of 27.3 months, 5 residual tumors were noted, and the LTP rate was 15.7% (23/146). The median tumor volume was 1.6 mL and 1.2 mL segmented on HAP and PVP CT, respectively ( $P=0.006$ ), with corresponding median MAM of 2.2 mm and 4.0 mm, respectively ( $P=0.007$ ). The AUC in predicting residual tumor and one-year LTP by HAP and PVP were 0.75 (95% confidence interval [CI]: 0.67, 0.84) and 0.81 (95% CI: 0.74, 0.89), respectively ( $P=0.006$ ). MAM of 0 mm on PVP CT was an independent predictor of LTP with a subdistribution hazard ratio of 7.7 (95%CI: 3.0, 19.6;  $P<0.001$ ), compared to 4.7 (95%CI: 1.8,12.0,  $P=0.001$ ) on HAP CT.

##### CONCLUSION

Ablative margin quantification using intraprocedural portal venous phase CT for colorectal liver metastasis segmentation significantly outperformed arterial phase CT in predicting ablation outcomes.

##### CLINICAL RELEVANCE/APPLICATION

Ablative margins should be quantified on intraprocedural portal venous phase CT instead of arterial phase CT, as the latter may overestimate tumor size.

#### **T5B-SPIR-2 Microwave Ablation in Hepatocellular Carcinoma: Dynamics of Extracellular Vesicles and Immunological Response**

##### Participants

Thomas J. Vogl, MD, PhD, Frankfurt, Germany (*Presenter*) Nothing to Disclose

##### PURPOSE

To characterize extracellular vesicles by liquid biopsy in preinterventional patients with primary and secondary hepatic malignancies treated with microwave ablation (MWA).

##### METHODS AND MATERIALS

Blood samples of 38 HCC patients and 15 patients with hepatic metastases were collected immediately pre and postinterventional. Subsequently, the characterization of 37 surface epitopes of EVs by magnetic bead-based particle sorting and fluorescence-associated cell scanning (FACS) was conducted.

##### RESULTS

The HCC-group before intervention revealed an activation of T-cell-associated EV protein expressions with significantly increased CD40, CD86 and CD8, ( $p=0.022$ ;  $p=0.003$  and  $p=0.024$ , respectively) vs. the non-HCC group. Additionally, the pre- and post-interventional HCC group showed an increment of the B-cell associated marker CD20 vs. the non-HCC group,  $p=0.005$  and  $p=0.014$ , respectively. The tumor cell associated surface epitopes, CD44, CD133 and CD24 were significantly higher expressed in the pre-interventional HCC vs. non-HCC group ( $p=0.029$ ,  $p=0.009$ ,  $p=0.004$ ). Regarding the clinical parameters, the HCC group showed a significantly higher expression of CD9 in patients with recurrent HCC, nonalcoholic steatohepatitis (NASH)-related HCC and cirrhotic HCC. Furthermore, the subgroup analysis of HCC patients showed a significantly lower expression of CD44 in NASH-related HCC and cirrhotic HCC. Pre-interventional cytokine levels of TH1 and Treg cells (IL2 and IL17) correlated strongly with elevated CD44 levels

in HCC patients. Additionally, pre-interventional IL6 levels correlated strongly with a high expression of CD19 and CD86. Regarding the post-interventional changes increased CD19, CD20 and CD44 levels correlated strongly with an elevated CD4/CD8 ratio and negatively correlated with CD4/CD8 ratio changes.

#### **CONCLUSION**

s EV surface expressions correlated with cytokine levels in pre-interventional HCC patients showed a CD4+ TH1 response, associated with CD44 expression.

#### **CLINICAL RELEVANCE/APPLICATION**

EV surface expressions can be used as a prognostic parameter in MWA of HCC.

### **T5B-SPiR-3 Microwave Ablation versus Laser-induced ThermoTherapy in the Treatment of Hepatocellular Carcinoma: Evaluation of Therapy Response and Survival Rates**

Participants

Thomas J. Vogl, MD, PhD, Frankfurt, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To retrospectively compare CT-guided microwave ablation (MWA) with MR-guided laser-induced thermal ablation (LITT) of hepatocellular carcinoma (HCC) regarding therapy response and overall survival (OS)

#### **METHODS AND MATERIALS**

In total, 303 patients (64f, 239m) were treated with 521 sessions of thermal ablation: 250 patients (52f, 198m; mean: 66±10 years) with 445 CT-guided MWAs and 53 patients (12f, 41m; mean: 67.5±8 years) with 76 MR-guided LITTs. Diameter of HCC lesions, technical success, complete ablation, local tumor progression and OS rates were evaluated in all cases.

#### **RESULTS**

Mean tumor diameter was 2.16 cm in the MWA group vs. 2.4 cm in the LITT group. Technical success was achieved in all ablations in both groups. Complete ablation was achieved in 97.7% of the tumors in the MWA group and in 98.7% in the LITT group. In the MWA group 6% of the patients and in the LITT group 3.8% developed local tumor progression. The 1-, 3-, and 5-year OS rates starting at the date of ablation were 86.6%, 53.4% and 40.4% in the MWA group and 85%, 37.7% and 17% in the LITT group, respectively. (p-value:0.001). No peri-procedural deaths were reported in both groups.

#### **CONCLUSION**

s Image-guided thermal ablation like LITT and MWA are both effective and safe for the local treatment of HCC. Patients in the MWA group had an overall longer survival time, but with higher rate of local tumor progression than the patients in the LITT-group.

#### **CLINICAL RELEVANCE/APPLICATION**

Both MWA and LITT provide long OS with low complication rates in patients with HCC

### **T5B-SPiR-4 Transarterial Chemoembolisation (TACE) for Unresectable or Recurrent Hepatic Cholangiocarcinoma: Added Value of Local Thermal Ablation**

Participants

Thomas J. Vogl, MD, PhD, Frankfurt, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To retrospectively evaluate the local tumor control and survival rates after targeted local therapy using transarterial chemoembolisation (TACE) with or without local thermal ablation in patients with unresectable or recurrent hepatic cholangiocarcinoma (CCA).

#### **METHODS AND MATERIALS**

From January 2007 to December 2017, 152 patients (69 males and 83 females; mean: 58.7 years) with cholangiocarcinoma (CCA) were retrospectively evaluated. The study included patients with both unresectable (80.2%) and recurrent lesions (19.8%). Patients were treated with at least three therapeutic cycles of TACE (3-26 cycles). 32 patients received combined TACE and local thermal ablation. Local tumor response was assessed by contrast-enhanced magnetic resonance imaging (CE-MRI) based on the modified RECIST criteria (mRECIST) and the survival evaluated using the Kaplan-Meier method.

#### **RESULTS**

The mean survival for all patients was 28.7 months (CI:21.8-35.7). Patients who received additional ablation sessions showed significantly longer survival compared to those who received only TACE (median 28 and 18 months respectively; P< 0.007). The tumor response after three cycles of TACE was either stable (35.5%), partial response (41.4%) progressive (23%) or complete response (0%) and the response at the last follow up was 25.7%, 15.2%, 59.2% and 3.5 % respectively. The following significant prognostic factors were found: nodal and/or systemic metastases, pre-therapeutic tumor load, initial local tumor response and associated application of local thermal ablation.

#### **CONCLUSION**

s Targeted therapy of unresectable or recurrent CCA using TACE with an added value of thermal ablation treatment may provide a therapeutic option for local tumor control and may improve patient's survival.

#### **CLINICAL RELEVANCE/APPLICATION**

TACE is a relevant targeted therapy tool in the regional treatment of CCA.

## **T5B-SPIR-5 KRAS Gene Mutation Influence after Ablation of Colorectal Cancer Lung Metastases: Prediction of Local Recurrence and Chemotherapy-free Survival Time**

### **Participants**

Marcelo Liberato Coelho Mendes De Carvalho, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

### **PURPOSE**

The primary objectives of the study were to evaluate if KRAS gene mutation predicts local recurrence in patients undergoing ablation of colorectal cancer lung metastases and to evaluate the chemotherapy-free interval of these patients. The secondary objective was to assess overall survival rate of these patients.

### **METHODS AND MATERIALS**

This is a retrospective observational study of the medical records of patients who underwent lung ablation of colorectal cancer metastases, performed at a quaternary hospital. Radiofrequency (RFA) and microwave (MWA) ablations were used. Intraoperative planning and overlaps were defined by the assistant team of interventional radiologists, based on the size and location of the metastases. A review of pre-, intra-, and post-procedure images was performed by one of the authors. The data were then charted in Microsoft® Excel® and exported for statistical analysis to IBM® SPSS® Statistics version 20. Statistical significance was evaluated using Fisher's exact test.

### **RESULTS**

Data were obtained from the medical records of 59 patients who underwent ablation of lung metastases from colorectal cancer. The gender distribution was homogeneous (30 men and 29 women), and mean age was 60.8 years. In 31 cases the initial location of the cancer was in the rectum, in 17 in the sigmoid, and in 11 in the colon and cecum. Before ablation, 50 patients had had a chemotherapy cycle, and 11 had had a surgical resection. RFA was performed in 58 patients, and MWA in 1. There were no complications in 55 patients, and 4 had pneumothorax. The number of nodules ablated varied, as follows: 1 nodule in 40 patients, 2 in 10 patients, 3 in 4 patients and 4 in 5 patients. There was recurrence in 27 patients: 2 local and 25 distant. There was no statistically significant association between KRAS gene mutation and local (p 0.407), distant (p 0.710) or global (p 0.999) recurrence. There was no statistically significant association between local recurrence (p 0.999) and proximity to the bronchi or vessels. The chemotherapy-free interval was 19.3 months (95% CI: 14.8-23.8), and overall survival (OS) at 67 months of follow-up was 49.3% (1-year OS: 93%; 3-year OS: 80%).

### **CONCLUSION**

Ablation of lung metastases is an effective and safe method. Mutation of the KRAS gene did not show to be a predictive factor in the rate of recurrence of lung metastases from colorectal cancer. Ablation allows an overall survival similar to surgical treatment. The longer chemotherapy-free interval provides better quality of life for patients.

### **CLINICAL RELEVANCE/APPLICATION**

Mutation of the KRAS gene determines a higher rate of local recurrence after liver ablations, but there was no description in the literature about its influence in pulmonary ablative treatments.

## **T5B-SPIR-6 Percutaneous Cryoablation of Progressing Extra-abdominal Desmoid Tumors (DT)**

### **Participants**

Andrea Vanzulli, MD, Tradate, Italy (*Presenter*) Nothing to Disclose

### **PURPOSE**

To evaluate the efficacy of percutaneous cryoablation of extra-abdominal desmoid tumors (DT) progressing after first-line treatments, including active surveillance, non-steroidal anti-inflammatory drugs and chemotherapy.

### **METHODS AND MATERIALS**

We retrospectively evaluated baseline and post-treatment MRI and/or CT imaging of 19 patients with progressing extra-abdominal DT (average diameter 80,2 mm; range 40-125 mm) treated with percutaneous cryoablation at our Institution between May 2021 and November 2022, with a median imaging follow-up time of 149 days. Response to treatment was evaluated both with standard and modified (m) RECIST1.1 criteria, as tumor shrinkage alone does not take into account tissue viability/necrosis and therefore incompletely describes responses to local treatments. Tumor locations included the cervical district (3), the thoracic (3) and abdominal wall (11), the lumbo-sacral (1) and gluteal region (1).

### **RESULTS**

Both standard and modified RECIST1.1 criteria classified all 19 patients as non-progressive. According to standard RECIST 1.1, 16 patients showed stable disease (SD) and 3 patients displayed a partial response (PR). According to modified RECIST criteria, 9 patients presented with SD, 4 patients with PR and one patient with a complete response (CR), with 2 RECIST-SD patients being reallocated to PR and CR categories, respectively. Five patients didn't have adequate pre-treatment imaging and couldn't therefore be categorized with mRECIST. No major periprocedural complications were registered, with 84% of patients reporting significant improvement of symptoms and quality of life.

### **CONCLUSION**

Desmoid tumors are rare (5-6 cases/million/year), locally aggressive fibroblastic proliferations characterized by infiltrative growth and a tendency to local recurrence. Although unable to metastasize, DT can cause significant morbidity through invasion of surrounding structures, causing chronic pain, functional impairment, and deformities. Due to high rates of recurrence after surgery and frequent spontaneous regression or stabilization, active surveillance generally represents the first-line treatment. Available therapeutic strategies achieve poor response rates, with many patients suffering from disease progression. In such context, cryoablation is emerging as a feasible and effective treatment to reduce tumor burden of extra-abdominal DT progressing after multiple lines of treatment. Furthermore, we report that mRECIST outperform standard RECIST1.1 criteria to evaluate DT response to cryoablation.

### **CLINICAL RELEVANCE/APPLICATION**

To the best of our knowledge, this study represents one of the biggest case series of progressing extra-abdominal DT treated with

percutaneous cryoablation.

## **T5B-SP1R-7 Response Post Local Tumor Ablation in HCC is Dependent Upon Interferon-gamma Linked Pathways with Associated C-X-C Chemokine Ligand Family Proteins**

### **Participants**

Matthias Stechele, MD, Munich, Germany (*Presenter*) Nothing to Disclose

Maurice Heimer, MD, Munich, Germany (*Presenter*) Nothing to Disclose

### **PURPOSE**

To uncover post-therapeutic systemic pathways and their potential as biomarkers in HCC patients treated by CT-guided local tumor ablation.

### **METHODS AND MATERIALS**

Twenty-four consecutive HCC patients treated with CT-guided high-dose rate brachytherapy (HDR-BT) (1x15 Gy) were included in this prospective IRB-approved study. Ninety-two proteins were quantified in blood samples acquired at baseline and 48hr post-HDR-BT and analyzed with a multimarker tool (Olink proteomics Target 96 immuno-oncology panel with Proximity Extension Assay technology). Ratios post-therapy in comparison to baseline (reported as fold change; FC) were calculated to detect a threshold of 30 % elevation or decrease. Patients were classified as responders (R, n=12) in absence of local progression within 6m and no systemic progression within 2yr observed on follow-up MRI or CT imaging. Non-responders (NR, n=12) had recurrence within 6m and/or tumor progression with more than 3 nodules or individual lesion diameter more than 3 cm or extrahepatic disease within 2yr. Statistical analyses was performed comparing the two groups using paired and unpaired t-tests.

### **RESULTS**

For all patients regardless of outcome, the most prominent pathway change was a decrease in interferon-gamma (IFN- $\gamma$ , FC 0.48, p=0.001) and 2 downstream members of the CXC family (CXCL9 FC 0.73, p=0.001 and CXCL10 FC 0.65, p=0.001). Moreover, non-responders showed increased values in pro-neutrophil and angiogenic CXCL5 in comparison to a decrease for responders (NR FC 1.51, R FC 0.78, p=0.043) and increased values in pro-tumorigenic CXCL12 in comparison to responders (NR FC 1.06, R FC 0.89, p=0.042). Accompanying CXCL5, granzyme-B, an additional neutrophil marker was significantly decreased in responders (FC 0.57, p=0.003), but unchanged in non-responders (FC 1.01, p=0.942). No significant differences were seen between responders and non-responders for other IFN- $\gamma$  pathway-associated proteins including CXCL1, CXCL9, CXCL10, CXCL11 and CXCL13.

### **CONCLUSION**

s HDR-BT induces decreases of circulating IFN- $\gamma$  and associated pathway chemokines potentially contributing to inhibition of immune cell infiltration, alteration of neutrophil activation, and angiogenesis post-therapy. Chemokine ligands CXCL5 and CXCL12 may enable differentiation between responders and non-responders post-therapy and potentially serve as biomarkers for response prediction.

### **CLINICAL RELEVANCE/APPLICATION**

Elucidating the molecular pathways associated with interventional oncologic therapies can potentially generate biomarkers predicting outcome and offer rational targets for combination adjuvant therapy.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

T5B-SPMK

### Musculoskeletal Imaging Tuesday Poster Discussions II

#### Sub-Events

#### **T5B-SPMK-1 High-Resolution Bone Image from Shoulder MRI using Deep Neural Network on 3-D Accelerated Dixon GRE (CAIPIRINHA Dixon)**

#### Participants

Jooyeon Kim, MD, Seoul, Korea, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### PURPOSE

To test the feasibility of generating high-resolution bone image resembling CT from shoulder 3-D CAIPIRINHA Dixon MRI data using deep neural network.

#### METHODS AND MATERIALS

In this IRB-approved retrospective study, patients with 3.0T MRI for shoulder pain were enrolled. Those without CT or 3D VIBE CAIPI-DIXON were excluded. The 3D VIBE CAIPI-DIXON protocol was ; TR/TE 12.7 /2.5,+3.6ms; FA 10°; FOV 159 x 159 mm; spatial resolution 0.4x0.4 mm<sup>3</sup>; acquisition time 3.02 min (Magnetom Vida, Siemens Healthineers, Germany). The dicom files were reconstructed using a commercially available DNN-based denoising and resolution enhancement algorithm (SwiftMR, AIRS Medical, Korea). The in-phase and opposed phase CAIPI-Dixon original PACS image ("CAIPI-i-ori", "CAIPI-o-ori"), and the corresponding CAIPI-Dixon after DNN processing images ("CAIPI-i-dn", "CAIPI-o-dn") were viewed after gray-scale inversion, and quantitatively and qualitatively evaluated by two radiologists. The images were first orthogonally rotated to measure the diameters of the glenoid. Studies were scored from 1 to 5 for the clarity of the cortical outline and trabecular bone of the humeral head and glenoid, any pseudolesion, visibility of fractures. The humeral head, glenoid neck, deltoid, and infraspinatus muscles were marked with regions of interest. ROIs were drawn on vacant quadrants for noise. CT was used to compare the glenoid dimension measurements, ROI values, SNR, and CNR. For statistical analysis, Kruskal-Wallis and Spearman tests were used ( $p < 0.05$ ).

#### RESULTS

Final group included 10 patients (4 females, mean age 60.6 years). The glenoid diameters measured from CAIPI-i-dn, o-dn, CAIPI i-ori, o-ori, and CT did not differ significantly ( $p > 0.05$ ). CAIPI-i-dn, o-dn, and CAIPI-o-ori had higher humerus cortical scores than CAIPI-i-ori (4.94±0.236, 3.611±0.195, 4.39±0.916, vs 3.00±0.29). CAIPI-i-o-dn showed higher glenoid cortical scores than CAIPI-i-o-ori (4.17±1.043 than 3.56±1.247,  $p < 0.05$ ). SNR of humerus and glenoid significantly improved with CAIPI-dn compared to CAIPI-ori (4 from 1.07,  $p < 0.05$ ). CT density negatively correlated with CAIPI-o-dn ROI in the humerus and glenoid (correlation coefficient -53.3, and -60.3,  $p < 0.05$ ). ICC value of the semiquantitative scores of CAIPI-i- o-dn (eg. cortical and trabecular outline) was 79.5 among the two readers. ICC value of quantitative scores (eg. ROI) was 96.4 ( $p < 0.05$ ).

#### CONCLUSION

s Combining 3D VIBE CAIPI-DIXON MRI and the DNN algorithm enabled high resolution cortical and trabecular bone imaging.

#### CLINICAL RELEVANCE/APPLICATION

High resolution CT-like bone images could be generated from 3D MRI with DNN processing. Cortical and trabecular information can be obtained. Quantification may be comparable to that of CT.

#### **T5B-SPMK-2 Multivariable Logistic Regression Analysis of Risk Factors for Pericollapse Stage of Osteonecrosis of the Femoral Head: Collapse-related Changes with CT and MRI**

#### PURPOSE

We aimed to determine the diagnostic values of collapse-related changes to distinguish between Association Research Circulation Osseous (ARCO) stage 2 and 3A (named as pericollapse stage) in patients with osteonecrosis of the femoral head (ONFH).

#### METHODS AND MATERIALS

A retrospective analysis was conducted in 124 hips with ONFH of either ARCO stage 2 (n = 49; 23 females; mean age, 50.7 years) or 3A (n = 75; 20 females; mean age, 53.2 years), in patients who underwent CT and MRI from May 2017 to August 2022 in our hospital. We assessed four types of collapse-related changes; on CT- 1) bone resorption area, 2) cystic change, and on MRI- 3) bone marrow edema, 4) joint effusion. We compared these collapse-related changes between stage 2 and 3A, analyzed the diagnostic performance of each variable for detecting stage 3A, and finally performed multivariate analysis to find the best predictor variable for stage 3A. ARCO stage 3A referred to the pericollapse stage as a period from the occurrence of subchondral fracture to early collapse (=2mm).

#### RESULTS

All four types of collapse-related changes were significantly more common in stage 3A than in stage 2 (bone resorption area [72.0% vs. 4.1%]; cystic change [52.0% vs. 0.0%]; bone marrow edema [93.5% vs. 43.6%]; joint effusion [76.0% vs. 24.5%],  $p < 0.001$  in all). The sensitivity, specificity, and diagnostic accuracy for stage 3A were 72.0%, 96.0%, and 81.0% for bone resorption area;

52.0%, 100%, and 71.0% for cystic change; 93.0%, 56.0%, and 76.0% for bone marrow edema; and 76.0%, 76.0%, and 76.0% for joint effusion. In the multivariate analysis, bone resorption area (OR=32.952, p=0.002), cystic change (OR=26.281, p=0.008), and joint effusion (OR=9.603, p=0.004) were independent predictors of stage 3A. Combination model of bone resorption area and cystic change showed the best area under the curve (AUC, 0.900) for stage 3A.

## CONCLUSION

s Collapse-related changes were significantly more frequent in stage 3A than in stage 2. Bone resorption area and cystic change were highly specific findings favoring stage 3A, while bone marrow edema and joint effusion were highly sensitive findings for stage 3A. Among them, bone resorption area was the best single predictor for stage 3A by multivariate logistic regression analysis. Combination of bone resorption area and cystic change was the best model in diagnosis of stage 3A with AUC of 0.900.

## CLINICAL RELEVANCE/APPLICATION

The accurate diagnosis of ARCO stage 3A is essential for future treatment plan in ONFH. It is often difficult to clearly distinguish this pericollapse stage by subchondral fracture alone. Imaging findings of collapse-related changes on CT and MRI can help to detect stage 3A as pericollapse period.

## T5B-SPMK-3 Application of Deep Learning Reconstruction Algorithm (AiCE) in Low-dose CT Scanning of Sacroiliac Joints

### PURPOSE

To explore the effect of deep learning reconstruction(DLR) in improving the image quality and reducing radiation dosage of low-dose sacroiliac joint CT scans by comparing with hybrid iterative reconstruction(HIR).

### METHODS AND MATERIALS

A total of 76 patients who underwent sacroiliac joint CT scans in our hospital from May 2021 to March 2022 were prospectively included. All patients gave written informed consent for the acquisition of low-dose CT(LDCT) after a clinically indicated standard-dose CT(SDCT). The SDCT series were reconstructed with HIR and the LDCT were reconstructed with DLR and HIR. The effective dose(ED) and size-specific dose estimate(SSDE) were calculated. All images were evaluated objectively, including the background noise(BN) of images, signal to noise ratio(SNR) and contrast to noise ratio(CNR) of the first sacral vertebra and iliac bone. Subjective 5-point Likert scale was used to score the reconstructed images of the three groups, and bilateral sacroiliac joints were grade according to the New York classification standard. All patients were divided into 3 groups(normal weight, overweight and obese groups) according to the BMI. The differences of objective and subjective evaluation were compared among the 3 kinds of reconstructed images.

### RESULTS

The ED and SSDE of LDCT were significantly lower than those of SDCT (p<0.001) and the reduction rates of ED and SSDE increased with the increase of the BMI. The BN, SNR, CNR and subjective scores showed significant differences (p<0.001) among SD-HIR, LD-HIR and LD-DLR images. The BN values were lower, and SNR and CNR values were higher on LD-DLR than those of SD-HIR and LD-HIR images (p<0.05). The subjective scores of LD-DLR images were significantly higher than those of LD-HIR images (p<0.001), and had no significant differences compared with SD-HIR (p=0.808). In addition, the diagnostic consistency of SD-HIR and LD-DLR images for sacroiliac arthritis grading was superior with Kappa value=0.888 (p<0.001).

## CONCLUSION

s The use of DLR can reduce the radiation dose and improve the image quality of sacroiliac joint CT, with comparable efficacy of diagnosis to HIR. Thus, DLR algorithm is helpful to improve the safety of CT scanning of sacroiliac joint.

## CLINICAL RELEVANCE/APPLICATION

The DLR algorithm, Deep Learning Reconstruction algorithm(AiCE), can help improve image quality and detect sacroiliac joint diseases with extremely low radiation dose for pelvis area of patients.

## T5B-SPMK-4 Anatomic Variants of the Acetabular Labrum of the Hip

### Participants

Brandon Knight, BS, Houston, TX (*Presenter*) Nothing to Disclose

### PURPOSE

The acetabular labrum is a ring of fibrocartilaginous tissue continuous with the distal edge of the acetabulum and completed inferiorly in its arc by the transverse acetabular ligament. Tears of the acetabular labrum can occur due to various factors and are diagnosed by clinical signs and imaging. Because of their similar appearance on imaging to non-pathologic labral variants, such as labral sulci, proper differentiation of labral tears from non-pathologic anatomic variants is essential for correct diagnosis and prevention of unnecessary treatment. However, few studies have collected observational data on labral sulci. This study aimed to observe the prevalence and locations of non-pathologic anatomic variants of the acetabular labrum, including sublabral sulci and transverse sulci. Teaching points will also be highlighted in the identification of sulci.

### METHODS AND MATERIALS

Hip MR imaging from 109 patients who presented to our hospital system for hip arthroscopy was retrospectively analyzed. Surgical findings were used to determine the presence of labral tears, while MR imaging was available and reviewed for all cases to determine the presence of labral sulci, which was then confirmed by surgical findings of labral sulci or by a lack of abnormal surgical findings at that location (with imaging findings being analyzed alongside surgical findings when available). Prevalence, location, and other attributes were observed of these anatomic variants, as well as of labral tears and paralabral cysts.

### RESULTS

After retrospective analysis, 130 acetabular labral tears out of 135 total cases were found in surgery, with 19% of those cases associated with paralabral cysts. A total of 43% of the patient population was observed to have at least one sublabral sulcus. The majority of sulci were found in the posteroinferior quadrant. Among all patients a total of 64 sublabral sulci were found, with some patients presenting with multiple sulci unilaterally or bilaterally. In 44% of cases, 49% of patients displaying at least one transverse

sulcus were found on imaging.

## CONCLUSION

s Normal anatomic variants occur commonly in the hip joint, including sublabral sulci and transverse sulci, and may be mistaken on imaging for acetabular labrum tears. Understanding their prevalence improves the proper differentiation of these anatomic variants from labral tears, increasing the specificity of acetabular labral tear diagnosis and thus decreasing false positive rates and improving patient outcomes.

## CLINICAL RELEVANCE/APPLICATION

Acetabular labral tears account for a large proportion of groin/hip pain patients and may be mistaken for sulci on imaging. Properly differentiating labral sulci and labral tears on imaging increases the specificity of labral tear diagnosis.

## T5B-SPMK-5 Additional Pain Generators on Lumbosacral Plexus Magnetic Resonance Neurography

### PURPOSE

Pain in sciatic nerve distribution is a common cause of disability worldwide with a reported prevalence of 43%. Identifying the cause of sciatica-type symptoms is clinically problematic, particularly when the symptoms are non-discogenic in origin. Magnetic resonance imaging (MRI) of the lumbosacral plexus has become a study of choice for sciatica, providing excellent anatomic detail and allowing comprehensive assessment of peripheral nerves, however, it demonstrates positive nerve findings in only 36-45% of patients according to literature. Our aim was to evaluate the prevalence of additional pain generators in patients undergoing lumbosacral plexus MRI, that commonly contribute to sciatica symptoms.

### METHODS AND MATERIALS

A retrospective review of 125 lumbosacral plexus MRI examinations performed from September 2015 through September 2022 on a 3T scanner was undertaken. The studies were independently reviewed in a blinded fashion by 3 radiologists. The findings were graded on a 0-3 scale depending on the presence or absence of particular non-neurologic pain confounders and the diagnostic quality of the study. Fleiss' Kappa (FK) was used to evaluate the interreader agreement.

### RESULTS

The presence of additional pain generators was demonstrated in 91% of examinations. Common etiologies observed included labral tears (62.4%, FK 0.7), hamstring tendinopathy/tears (57.6%, FK 0.72), gluteus tendinopathy/tears (56%, FK 0.63), greater trochanteric bursitis (40%, FK 0.65), ischiofemoral impingement (20.8 %, FK 0.75), sciatic nerve compression or variant anatomy (11.2%, FK 0.77), paralabral cysts (8%, FK 0.8), and moderate/severe hip osteoarthritis (8%, FK 0.72). Other incidental findings observed included disc herniation with nerve root compression (4%), sacral insufficiency fractures (1.6%), femoral head avascular necrosis (0.8%), and calcific tendinosis (0.8%). Of note, lumbosacral nerve abnormalities were only detected in 48% of the study group.

### CONCLUSION

s Lumbosacral plexus MRI examinations permit accurate detection and localization of additional pain generators in patients with non-discogenic sciatica. Our study demonstrated substantial interreader agreement regarding the presence or absence of sciatica/buttock pain confounders and a high level of confidence in their detection by radiologists.

## CLINICAL RELEVANCE/APPLICATION

Extra-neural causes of sciatica can be consistently identified on lumbosacral plexus MR neurography studies, both on conventional T1/T2-weighted and lumbosacral plexus-specific series. This becomes particularly important when no nerve pathology is detected, as it can serve as a cost-effective initial imaging strategy.

## T5B-SPMK-6 Deep Learning-based Fully Automated Fat Quantification of the Supraspinatus Muscle on MRI

Participants

Woonyoung Baek, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

### PURPOSE

The purposes were to (1) measure the total volume and fat-fraction (FF, %) of the supraspinatus muscle (SSm) with deep learning (DL)-based fully automated fat quantification algorithm from a 6-point Dixon sequence according to retraction grade and tear severity; and (2) determine the whether the standard assessment for muscle fatty infiltration at a single image slice is representative.

### METHODS AND MATERIALS

Between December 2020 and November 2022, 107 patients were retrospectively enrolled in this study with extended oblique sagittal T1-weighted images and FF map generated from 6 point Dixon sequence including total SSm. A DL-based fully automated muscle segmentation using a FF map was developed by modifying our institute's previously developed muscle segmentation method. The total volume and fat content of SSm were obtained from this algorithm. The FF at a single image slice was measured by manually drawing an ROI at a Y view or Fossa view (2~3 slices medial to Y view). Then, the FF of SSm at a single slice image (FFy or FFfo) and total MR slices (FFt) were compared. The influence of retraction grade and tear severity was evaluated.

### RESULTS

Total supraspinatus volume and fat fraction were easily measured with a DL-based fully automated segmentation algorithm using a FF map. A comparison of FFy, FFfo and FFt was done by using the Wilcoxon signed rank test ( $P < 0.001$ ). There was significant difference if FFy was included, and no significant difference between FFfo and FFt. Dividing the patients by retraction grade and fat degeneration grade, there was significant difference in grade 0 of retraction ( $P < 0.001$ ) and grade 1 of fat degeneration ( $P < 0.001$ ). Dividing by tear severity, there was significant difference in patients with no tear ( $P < 0.001$ ) and partial tear ( $P = 0.014$ ). Regarding the FFt as the gold standard, we verified the value of Y view and the proposed method (fossa view). Both methods showed high correlation with FFt (Y-view correlation coefficient=0.894 ( $P < 0.001$ ) and fossa view correlation coefficient=0.874 ( $P < 0.001$ )). But the precision is slightly decreased at proposed method, referring to Bland-Altman plot.

### CONCLUSION

s Regardless of retraction grade and fat degeneration, the FF evaluated through the proposed method provides a better representation of the total FF of the entire SSm than the conventional method with high accuracy. However, the precision was slightly lower than Y view.

#### **CLINICAL RELEVANCE/APPLICATION**

DL based automatic quantification could allow accurate and rapid fat quantification of total SSm. If we should choose to pick one MR slice instead of measuring the fat fraction of the entire SSm, fossa view could be a better representation than conventional view. It could be a more accurate preoperative factor to predict surgical outcome.

#### **T5B-SPMK-7 CT with Tin-filtration for Bone Imaging: Dose Optimization using an Ex-vivo Pig Model**

##### **PURPOSE**

CT via tin-filtration (CTTF) is an effective strategy in reducing radiation dose without sacrificing image quality. A parametric study via an ex-vivo pig model may be the most clinically relevant approach to better understand the trade-off between image quality and radiation dose. As skeletal assessment is a common clinical application for CT, we began by optimizing CTTF for bone imaging. As such, the objective of this study was to utilize an ex-vivo pig model to characterize the image quality of CTTF as a function of radiation dose for bone imaging.

##### **METHODS AND MATERIALS**

We imaged a pig shoulder (1.7 kg) using Siemens SOMATOM Force dual-source CT scanner at different volume CT dose index (CTDIvol). The following parameters were used for image acquisition: tube voltage of 100kV with the tin filter (100Sn), rotation time of 250 ms, and ultra-high pitch of 2.45, and slice thickness of 3 mm. We conducted a parametric study by adjusting the mAs settings to achieve 5 different levels of CTDIvol. Specifically, we used the following five mAs settings: 242, 182, 122, 60, and 30. Reconstruction kernel Br69, ADMIRE strength of 3 were used for bone image reconstruction. We used the 3D slicer software to generate the 3D volume renderings. For the CTTF images acquired at each CTDIvol, we calculated the contrast-to-noise ratio (CNR) of the bone-to-muscle; and judged the CTTF image quality based on the following three subjective criteria: (1) clarity of the depicted anatomy (i.e., foreground bone versus background soft tissue); (2) image noise; and (3) contours of the 3D surface renderings.

##### **RESULTS**

The CNRs of bone-to-muscle were 6.9, 6.2, 4.8, 3.4, and 2.9 at CTDIvol dose levels of 0.8 mGy, 0.6 mGy, 0.4 mGy, 0.2 mGy, and 0.1 mGy, respectively. However, despite this decreasing CNR, we found that the CTTF images at radiation doses as low as 0.2 mGy were deemed of comparable subjective quality to the CTTF images at the maximum dose of 0.8 mGy.

##### **CONCLUSION**

s Based on our parametric study, we conclude that there was no substantial deterioration in subjective image quality of CTTF when the radiation dose was reduced down to CTDIvol = 0.2 mGy. We postulated that the inherent high contrast between the foreground bone and the background soft tissue combined with a strong non-linear dose reduction by ADMIRE was able to overcome the decreasing CNR to maintain diagnostic image quality at ultra-low radiation dose during CTTF bone imaging.

#### **CLINICAL RELEVANCE/APPLICATION**

The results of our study are the initial steps in optimizing CT with tin-filtration for bone imaging.

#### **T5B-SPMK-8 Clinical and MRI-based Radiomics Models for Predicting Hidden Blood Loss during Surgery for Spinal Metastasis**

Participants

Weili Zhao, Beijing, China (*Presenter*) Nothing to Disclose

##### **PURPOSE**

To evaluate the role of clinical and MRI-based radiomics models for predicting the risk of hidden blood loss (HBL) in patients undergoing spinal metastasis surgery.

##### **METHODS AND MATERIALS**

Consecutive patients who underwent surgery for spinal metastasis between January 2018 and December 2021 at our institution were retrospectively analyzed. Baseline demographic, clinical, and surgical data were collected. HBL was calculated using the Gross formula. Potential clinical risk factors were accessed using univariate and multivariate logistic regression analyses. Radiomics features were extracted from sagittal T1-weighted and fat-suppressed T2-weighted imaging sequences, and manual delineation was performed by two radiologists. The datasets were Z-score normalized, and features with intraclass correlation coefficient values  $\leq 0.80$  were excluded. The least absolute shrinkage and selection operator method was employed for optimal feature selection. Clinical, radiomics, and combined clinical-radiomics models were established. Clinical utility of the best prediction model was evaluated using calibration and decision curves.

##### **RESULTS**

A total of 202 patients were included, 149 and 53 of whom were classified as low and high HBL. Extraspinal metastases, New York Heart Association grade, operation site, and operation time were identified as independent predictors of high HBL ( $P < 0.05$ ). The best predictive efficacy was shown in the combined clinical and T2WI-based radiomics model (AUC value of 0.893 and 0.816, and ACC of 80.2% and 77.3% respectively in the training and validation cohort). Additionally, the proposed clinical-radiomics nomogram demonstrated good clinical utility.

##### **CONCLUSION**

s Our combined clinical-radiomics model may serve as a promising prediction tool for the risk of HBL in patients undergoing spinal metastasis surgery, and guide perioperative planning to improve surgical outcomes.

#### **CLINICAL RELEVANCE/APPLICATION**

- Our study aimed to develop and evaluate the predictive efficacy of clinical and MRI-based radiomics models for high HBL during

spinal metastasis surgery. • The combined clinical and T2WI-based radiomics model achieved the best predictive performance in both the training and testing cohorts. • Our proposed clinical-radiomics nomogram demonstrated promising clinical utility in guiding the indications of preventative and treatment interventions in such patients.

### **T5B-SPMK-9 Musculoskeletal Diffusion Tensor Imaging in Adolescent Elite Rowers and Association of Imaging Findings with Rowing Technique**

Participants

Jonas Alexander Leppig, MD, 10247 Berlin, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Muscular overuse injuries are a common health issue in elite athletes. Changes in the muscular microenvironment can be depicted by Diffusion Tensor Imaging (DTI). We hypothesize that the biomechanics of different rowing techniques plays a role in tissue injury and tested our hypothesis by examining the lumbar spine muscles of adolescent rowers using DTI.

#### **METHODS AND MATERIALS**

Sixteen male elite rowers underwent 3 Tesla multiparametric MRI of the lumbar spine 6 hours after cessation of training. Axial diffusivity (AD), radial diffusivity (RD), apparent diffusion coefficient (ADC), and fractional anisotropy (FA) were calculated for the erector spinae (ES) and multifidus (MF) muscles. These DTI parameters were correlated with demographic data, training data, and low back pain (LBP) questionnaire scores.

#### **RESULTS**

ADC values in ES and MF were significantly higher ( $p = 0.039$ ) and FA values significantly lower ( $p < 0.001$ ) in sweep rowers compared to scull rowers. Training-related LBP episodes in the last 12 months were reported by 88.9% of participants. There was no significant association between DTI parameters and training volume or LBP questionnaire scores.

#### **CONCLUSION**

s Our DTI results show that lumbar spine muscle diffusivity is higher in sweep rowers than in scull rowers. Altered muscle diffusivity is suggestive of microscopic tissue disruption and might be attributable to biomechanical differences between rowing techniques.

#### **CLINICAL RELEVANCE/APPLICATION**

The differences identified with DTI are not detectable with conventional MRI techniques. Therefore, DTI might have a role in the early noninvasive detection of overuse injuries in athletes before symptoms develop.

T5B-SPMS

### Multisystem Tuesday Poster Discussions II

#### Sub-Events

#### **T5B-SPMS-1 Virtual Non-calcium Imaging for Qualitative and Quantitative Assessment of Bone Marrow Involvement in Multiple Myeloma: Our Experience with Dual-energy Computed Tomography**

#### Participants

Alessandro Onori, MD, Rome, Italy (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The aim of this study was to compare the diagnostic performance of virtual non-calcium imaging (VNCA) and Conventional Computed Tomography imaging (CCT) in the evaluation of bone marrow (BM) involvement in patients affected by multiple myeloma and to investigate the impact of VNCA values on patients' prognoses.

#### **METHODS AND MATERIALS**

In this mono-centred retrospective study, consecutive patients with MM who underwent Dual Energy Computed Tomography (DECT) in the last 12 months were enrolled. Two readers randomly and independently reviewed two datasets of images per patient (VNCA and monochromatic 120kVp-like) for the presence of BM involvement. The number and dimension of BM lesions were compared on a per segment analysis. CT numbers of BM lesions and unaffected bone were measured on VNCA images. Results were stratified according to the disease status (stable or progression).

#### **RESULTS**

Significantly more lesions (n=748) were identified on VNCA images compared to CCT (n=502) (p<0,0001). No significant differences were observed for lesions' dimensions (18,72±9,68 mm, p=0,6352). VNCA CT numbers showed a significant difference between lesions in patients with stable disease and lesions in patients with progressive disease (-143,67±202,63 HU vs 4,54±51,95 HU; p=0,0087). There was almost perfect agreement for both number and dimension of the lesions among readers (ICC = 0.93 [95% CI 0.84-0.71] and ICC = 0.89 [95% CI 0.75-0.96], respectively).

#### **CONCLUSION**

s VNCA is superior to CCT in identifying BM involvement in MM and ROI-based analysis of the lesions could also be an interesting tool for its prognostic implications.

#### **CLINICAL RELEVANCE/APPLICATION**

VNCA imaging may be a promising technique to easily assess with good confidence the presence of bone lesions in patients with MM. Quantitative analysis and its prognostic implications may be useful for risk stratification and for personalized therapeutical planning.

## Abstract Archives of the RSNA, 2023

T5B-SPNMMI

### Nuclear Medicine & Molecular Imaging Tuesday Poster Discussions II

#### Sub-Events

**T5B-SPNMMI-1** **Semi-quantification Approach of Amyloid PET: A Study of Familial Alzheimer's Disease Associated with Heterozygous NPC1 Mutation**

#### PURPOSE

Many studies try to develop model to compare and integrate visual reading of amyloid PET with independent semi-quantification methods. Here we describe new semi-quantification approach of amyloid PET in a family with apparently autosomal dominant Alzheimer's disease (AD) harbouring a novel NPC1 mutation in heterozygous state.

#### METHODS AND MATERIALS

All 5 living siblings were evaluated. We performed clinical assessment, neuropsychological tests, genetic analysis, assessment of cerebrospinal fluid markers. Patients n. 1, 2, 4 and 5 underwent early and late amyloid PET that should be read using qualitative analysis but also investigated by innovative visual and automatic semi-quantification analyses using: Standardized Uptake Values Ratio, the ratio of counts in one or more regions of interest to a reference region; Evaluation of Brain Amyloidosis, evaluates the geometric distribution of contrast without fixed, reference or segmentation ROIs and measures the geometric properties of the iso-intensity surfaces, the changes are related to the amyloid burden; Time-delayed ratio, a level of contrast between early and late scans; uptake and baseline ROIs are extrapolated from the early scan and track high-flow districts.

#### RESULTS

In 4 of them, a diagnosis of AD was defined according to biomarkers (A+, T+, N+) and serum oxysterol analysis. Early PET images of patients n.1 and 2 showed rather severe hypoperfusion in bilateral temporal, posterior parietal, posterior cingulate and precuneus cortices. In these patients, late amyloid PET images detected high rate of amyloid burden in bilateral frontal, temporal, posterior parietal, precuneus and posterior cingulate areas and final likelihood for positive scan. In patient n.4, early PET scan showed a mild hypoperfusion in left temporal, left posterior parietal and right precuneus cortices. In this patient, late amyloid PET images showed a moderate amyloid accumulation in left temporal, left posterior parietal and left frontal cortices with a positive scan. Finally, slight amyloid accumulation in frontal cortex consistent with negative scan without clear perfusion pattern of AD was found in patient n.5.

#### CONCLUSION

The present results demonstrated that early and late acquisitions images supported use of amyloid PET to study cerebral perfusion and amyloid deposition. Finally, the new semi-quantitative approach of amyloid PET provides data on the regional amyloid deposition allowing a better longitudinal evaluation of patients that could benefit from already available drugs against NPC1.

#### CLINICAL RELEVANCE/APPLICATION

This study supports use of early amyloid PET acquisitions and of this novel semi-quantitative approach on regional amyloid deposition to improved longitudinal assessment of patients.

**T5B-SPNMMI-2** **In Vivo Assessment of Regional Tau Deposition, Gray Matter Volume and Cognition in Alzheimer Disease: A Head-to-head 18F-flortaucipir PET/MR study**

#### PURPOSE

Despite the associations of A $\beta$  deposition with connectivity alterations, atrophy, and cognition, the exact role of tau and regional atrophy on cognition in Alzheimer's disease remains unclear. This study aimed to investigate the relationship between regional tau pathology, gray matter volume in vivo and their effects on cognitive function improving effective clinical trials and future therapeutic strategies for AD.

#### METHODS AND MATERIALS

Thirty-four patients with amyloid-positive mild cognitive impairment or dementia and 23 healthy controls underwent standardized clinical and neuropsychological assessments followed by 18F-flortaucipir positron emission tomography imaging and 3D T1-weighted magnetic resonance imaging. The regional tau standardized uptake value ratio and gray matter volumes (GMV) were measured. Group differences in the two imaging modalities were compared. Partial correlations and mediation analysis were then performed in brain regions showing an association between cognition and both 18F-flortaucipir uptake and gray matter volume.

#### RESULTS

The 18F-flortaucipir retention was observed in the entorhinal cortex, hippocampus, parietal lobe, temporal lobe, precuneus and posterior cingulate. The regional tau deposition was associated with GMV in medial temporal and lateral temporal regions (range standardized  $\beta$ s of residual=-0.45--0.77,  $p<0.05$ ) in MCI/AD patients. Both increased 18F-flortaucipir SUVR and decreased GMV in the medial temporal lobes and medial parietal lobes were related to cognitive impairment. The GMV of the entorhinal cortex and medial parietal lobes mediated the effect of local region 18F-flortaucipir SUVR on cognitive impairment (mediation effect=0.54,0.93; explained variance=32.86%, 37.94%, respectively). The GMV of the medial parietal lobes and medial temporal lobes mediated the

effect of distant region 18F-fortaucipir SUVR on cognitive impairment (mediation effect=0.75-0.85; explained variance=57.01%-58.14%).

## CONCLUSION

s Tau pathology was associated with local and distant areas of brain atrophy in the brains of MCI and AD patients. The mediation analysis enabled data fusion across multiple imaging modalities (PET and MRI), local and distant atrophy played a mediating role between tau binding and cognitive impairment in these patients.

## CLINICAL RELEVANCE/APPLICATION

tau PET/MR can be a potentially useful imaging biomarker for predicting the risk of developing clinical AD based on more than one pathology and determining when is the optimal time for anti-tau target treatment.

## T5B- SPNMMI-3 Validation of SSTR2 Expression and Assessing Correlation of Variable F18-FDG PET/CT Parameters in EBV Associated Nasopharyngeal Cancer

Participants

Thangalakshmi Sivathapandi, MD, Johns Creek, GA (*Presenter*) Nothing to Disclose

## PURPOSE

Epstein-Barr virus (EBV), a known nasopharyngeal carcinoma (NPC) driver, promotes somatostatin receptor 2 (SSTR2) expression via NFkB, detectable by immunohistochemistry. To assess the correlation of EBV associated NPC and SSTR2 expression and evaluate the association between F18-FDG PET CT parameters and EBV associated NPC

## METHODS AND MATERIALS

In this retrospective study done between 2017-2022, SSTR2 immunohistochemistry on our cohort of EBV NPC (n=15), HPV-positive sinonasal SCC (n=7, HPVSCC), and virus-negative sinonasal SCC (n=8, VNSCC), reviewed by two board-certified pathologists. The F18-FDG PET/CT was reviewed by two board-certified nuclear medicine physicians. Histopathology was scored as positive or negative in a binary system. H-score was calculated using the intensity and extent of tumor staining. The association between various parameters of F18-FDG PET/CT (primary tumor and nodes) and SSTR2 expressing EBV positive nasopharyngeal carcinoma were analyzed

## RESULTS

Using a positive/negative system, 93.3% EBVNPC (n=14/15), 14% HPVSCC (n=1/7), and 25% VNSCC (n=2/8) demonstrated multifocal to diffuse strong SSTR2 expression. The sensitivity, specificity, negative predictive value, and positive predictive values for SSTR2 IHC were 93.3%, 80%, 92.3%, and 82.4%, respectively. The median H-score for EBVNPC was 180 (range 12-295; mean 179), whereas the median H-scores for HPVSCC and VNSCC were 0 (range 0-56; mean 8) and 0 (range 0-125; mean 31), respectively (p<0.001). No significant association was found between SUV max, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) between EBV associated and other types of HNSCC (p value>0.005). The SUV max range for primary tumor was found to be 6.67-29.95 and SUV max range for metastatic nodes was 4.11-25.53. Among the 15 EBVNPC patients 53% of patients had overlap of primary tumor uptake with physiologic FDG brain activity

## CONCLUSION

s EBV associated NPC showed stronger expression of SSTR2 comparing to HNSCC in other subsites. No significant difference in F18-FDG PET/CT parameters between EBV positive NPC and other types of HNSCC. Future directions would include assessing the role of Cu64-DOTATATE PET/MRI in evaluation of EBV positive NPC and its impact on radiation therapy planning.

## CLINICAL RELEVANCE/APPLICATION

The strong correlation between EBV positive NPC and SSTR2 expression infers that Ga68/Cu64- DOTATATE PET imaging could be a valuable tool in accurate staging, therapy planning and surveillance of these patients. Peptide receptor radionuclide therapy (PRRT) using therapeutic nuclide-labeled DOTA-peptide may be a potential therapeutic tool in these patients with metastases

## Abstract Archives of the RSNA, 2023

T5B-SPNPM

### Noninterpretive Skills (Beyond Imaging) Tuesday Poster Discussions II

#### Sub-Events

#### **T5B-SPNPM- Radiologist's Impact on the Frequency of Pediatric Head CT for Trauma: A Machine Learning Model Analysis using a Nationwide Claims Database** 1

##### Participants

Kanako Kumamaru, MD, PhD, Tokyo, Japan (*Presenter*) Research Grant, General Electric Company

##### PURPOSE

The purpose of this study is to develop a machine-learning model that can predict factors that independently affect the frequency of pediatric head CT for trauma (pHCTT). The study also aims to evaluate the impact of the number of radiologists per population (radiologist density) on the frequency of pHCTT.

##### METHODS AND MATERIALS

The study used data on the number of outpatient pHCTT performed in 254 medical areas in Japan for the fiscal year 2020, extracted from the national open database of health insurance claims. Over a hundred regional variables, such as population, number of hospitals, and number of pediatricians, were used to train 34 algorithms to predict the number of pHCTT per 10,000 child population, without including radiologist density measure. The best-performing machine-learning algorithm, based on poisson deviance ranking, was then identified. We compared the radiologist density between medical areas that exceeded the predicted pHCTT frequency and those that fell below the prediction, as an indicator of radiologist's impact on pHCTT frequency.

##### RESULTS

A total of 18,313 outpatient pHCTT were performed in 2020 in Japan, with a large variability in the number of pHCTT per 10,000 child population across medical areas (range: 0-114, median: 2.94). The random forest regressor model showed the highest prediction power with a poisson deviance of 11.61 on cross-validation, identifying total population density, the proportion of elderly people, the total number of stroke care units, growing care units, and CT examinations per population as strong predictors. The number of doctors working in clinics per population also had a significant influence on the prediction. The radiologist density was significantly lower in the medical areas where pHCTTs were performed more frequently than predicted, compared to the medical areas where pHCTTs were performed below the prediction (radiology density, median (IQR): 27.5 (19.5, 49.5) vs. 48 (22, 76),  $p=0.037$ ).

##### CONCLUSION

The number of pHCTT per child population varied significantly across different medical areas. In medical areas where pHCTTs were performed more frequently than predicted by the machine-learning algorithm, the radiology density was lower, which may suggest the impact of radiologists on appropriate pediatric imaging.

##### CLINICAL RELEVANCE/APPLICATION

Increasing the number and involvement of radiologists may reduce the variability in the frequency of pediatric head CT for trauma and promote appropriate utilization.

#### **T5B-SPNPM- Computed Tomography-based Sarcopenia: Diagnostic Cutoff Values in Patients with Chronic Liver Disease and Mortality: A systematic Review and Meta-analysis** 2

##### Participants

Joao Rafael Vicentini, MD, (*Presenter*) Nothing to Disclose

##### PURPOSE

Sarcopenia is a known complication of patients with Chronic Liver Disease (CLD). The assessment of psoas muscle mass by Computed Tomography (CT) can be done using the Psoas Muscle Index (PMI). This method is easy to perform using regular CT scans and not easily altered by ascites. We aimed to investigate the influence of sarcopenia diagnosed by CT using the PMI method as a predictor of mortality in patients with CLD after liver transplantation.

##### METHODS AND MATERIALS

The protocol was registered with the international prospective register of systematic reviews (PROSPERO CRD42022370684). We systematically searched PubMed, Scopus, and Cochrane Central Register of Controlled Trials from inception to November 2022 with the following search terms: (sarcopenia OR muscle mass OR psoas muscle) AND (chronic liver disease OR CLD OR cirrhosis OR liver transplantation OR liver transplant) AND (Computed Tomography OR CT OR psoas muscle). Cochran's Q test and I<sup>2</sup> statistics were used to assess for heterogeneity; P values inferior to 0.10 and I<sup>2</sup>>25% were considered significant for heterogeneity. We used a fixed-effect model for outcomes with low heterogeneity (I<sup>2</sup> < 25%). We calculated standard effect estimates and random effects (odds ratio) for meta-analysis with binary outcome data. Clustering was performed by the Mantel-Haenszel method.

##### RESULTS

The initial search yielded 1,414 results. After removal of duplicate records and ineligible studies, 163 remained and were fully reviewed based on inclusion criteria. Of these, a total of 11 studies were included in qualitative synthesis and 4 studies were included in quantitative analysis (meta-analysis) comprising 382 patients. Patients diagnosed by CT scan using the PMI method with muscle mass loss after liver transplantation had a 4.1 times higher risk of death than non-sarcopenic patients (Random effects model OR 4.1386; 95% CI 2.4215- 7.0730; P< 0.0001). Heterogeneity among studies was assessed by visual inspection of the graphs, the I2 statistic, Cochran's Q test, and Tau2. Interpretatively, a scale with an I2 value close to 0% indicates no heterogeneity. The other criteria also did not reject the hypothesis of homogeneity among the articles.

## CONCLUSION

s Patients with sarcopenia diagnosed by CT using the PMI method had a fourfold increase in mortality risk after liver transplantation.

## CLINICAL RELEVANCE/APPLICATION

The findings reinforce the need to identify sarcopenic patients preoperatively to optimize liver transplantation outcomes. Opportunistic diagnosis by CT using Psoas Muscle Index (PMI) can be helpful in this setting.

## T5B-SPNPM- Autonomous AI-based CXR Interpretation for Predicting Congestive Heart Failure: A Multicenter Study

### Participants

Emiliano Garza Frias, MD, Monterrey, NL (*Presenter*) Nothing to Disclose

## PURPOSE

Favorable treatment outcomes of a progressive disease like heart failure (HF) depend on early detection. We conducted a multicenter study to assess if an autonomous AI model can help identify chest radiography (CXR) signs of HF in patients without a previous cardiovascular history or diagnosis.

## METHODS AND MATERIALS

Our retrospective, standalone study included 1455 patients (age range 69 +- 13 years; M:F 670:785) with an AP/PA CXR. A total of 751 patients had the CXR taken within one year before their HF diagnosis. The rest (n= 704) of the CXR were selected from patients without any NT-proBNP exam, echocardiography or HF diagnosis after the radiological examination date. All patients belong to 17 sites including two quaternary care hospitals and 15 community hospitals and outpatient clinics. 1455 deidentified CXRs were processed with the AI algorithm for HF (qXR-HF, Qure.AI) to obtain information on enlarged cardiac silhouette, pleural effusion, and an HF-index. CXRs were stratified based on their lead time from HF diagnosis (<3 months, 3-6 months, 7-9 months, 9-12 months). Data were analyzed using R version 3.6.2 to derive accuracy, sensitivity, specificity, and area under the curve (AUC) for the receiver operating characteristics (ROC).

## RESULTS

Among the 1455 patients, 751 patients had HF while the remaining 704 patients did not have HF. We report 0.80 ROC AUC (95% CI 0.78-0.82), 0.70 accuracy, 0.57 sensitivity, and 0.83 specificity for the overall AI performance for predicting HF. AI AUCs (< 3 months: 0.83; 4-6 months: 0.81, 7-9 months: 0.79, 10-12 months: 0.79), specificity (constant: 0.83) and accuracy (0.77-0.78) remained stable, but sensitivity declined with increasing lead time from HF diagnosis (< 3 months: 0.6; 10-12 months: 0.5). The performance of CXR-AI derived HF index was significantly higher compared to enlarged cardiac silhouette (0.75) and pleural effusion (0.74, p<0.01).

## CONCLUSION

s Our autonomous AI model can help identify signs of HF up to 12 months prior to the clinical diagnosis of HF with a high and consistent AUC and accuracy, regardless of patient gender, age group (>45 years), and imaging site.

## CLINICAL RELEVANCE/APPLICATION

Detection of HF signs with an autonomous CXR-based AI algorithm can help in early diagnosis and treatment of unsuspected HF.

### Neuroradiology Tuesday Poster Discussions II

#### Sub-Events

#### **T5B-SPNR-1 Systematic Review of the Determination of EGFR Status in Glioblastomas by Feature Characterization on MR**

##### **PURPOSE**

Glioblastoma (GBMs) is the most common and deadly type of adult brain tumor. The clinical treatment for GBMs varies depending on genetic profile. There has been a push to identify imaging markers of genes implicated in GBMs. Epidermal growth factor receptor (EGFR) represents one such gene. Multiple studies have described relative cerebral blood volume (rCBV) as a potential marker for EGFR status, but a systematic review of those studies has not been performed. The objective of this review is to objectively summarize the current literature on the potential for rCBV to serve as a marker for EGFR status in patients with diagnosed GBM.

##### **METHODS AND MATERIALS**

A systematic review was conducted following PRISMA guidelines with a strategy to identify articles pertaining to radiologic markers of GBM. Examples of pertinent MeSH terms to be used are as follows: "glioma", "glioblastoma", "EGFR", "epidermal growth factor receptor", and "magnetic resonance imaging." Studies were included or excluded based on pre-established criteria. A primary review will be conducted by two separate independent researchers blinded to each other's results to determine which papers meet inclusion/exclusion criteria. Discrepancy between reviewers will be resolved via consensus. The bias of studies will be assessed via QUADAS2 bias assessment tool.

##### **RESULTS**

A preliminary review was conducted to collect papers from Pubmed and Scopus databases. This search resulted in 14 papers eligible for primary review, including 1864 of tumors, with (818) EGFR amplified and (1046) EGFR wild type tumors. Chi square analysis will be done to compare cerebral blood volumes and/or tumor location. Odds ratios and forest plots will be generated for inter group comparisons.

##### **CONCLUSION**

Based on preliminary review, a direct correlation is expected to be observed between EGFR amplification and increased rCBV. Significant differences in location, diffusion coefficient, transfer coefficient, and relative plasma volume may also be shown.

##### **CLINICAL RELEVANCE/APPLICATION**

Identifying rCBV as a radiologic marker of EGFR status in GBM patients will allow for non-invasive and faster identification of the best treatment plan.

#### **T5B-SPNR- BT-RADS Posttreatment Brain Tumor Response: An Interobserver Agreement Analysis**

10

#### Participants

JEAN LEVI RIBEIRO DE PAIVA, CAMPINAS, Brazil (*Presenter*) Nothing to Disclose

##### **PURPOSE**

In recent years, synoptic reporting has been shown to improve the consistency, reproducibility, quality, readability, and clarity of radiological reports; which is supported by the success of previous models such as BI-RADS. In light of these favorable results, Weinberg et al proposed a brain tumor reporting data system (BT-RADS) to assess the treatment response of brain tumors. In this study, we evaluate the consistency of the BT-RADS model by measuring the agreement of the reports between two radiologists.

##### **METHODS AND MATERIALS**

We compiled a list of brain MRI studies from patients with brain tumors, along with relevant medical records, and provided it to two radiologists for categorization. The first one had one year of experience as a radiologist, while the second one, a university professor specialized in neuroradiology, had over thirteen years of experience. For each study, the radiologists gave a report based on the BT-RADS model unbeknownst to the score given by their peers in the same studies.

##### **RESULTS**

Both radiologists reviewed 85 exams, of which 23 were BT-RADS 0 by default. The BT-RADS 0 score is meant for studies that will serve as a baseline for future studies; this includes the first study after surgery or before chemoradiotherapy. Sixty-two studies remained for analysis. We applied Cohen's Fleiss' kappa to measure inter-rater reliability between the two radiologists. The Cohen's kappa value was equal to 0.94, with a confidence interval of 95% and an alpha value of  $p=0.05$ . The lower bound was 0.88, while the upper bound was 0.99. We also calculated Fleiss' kappa for each category, and each showed a high agreement rate, except for category 3c.

##### **CONCLUSION**

Our analyses showed a strong inter-rater reliability agreement despite the difference in experience between the two observers.

## CLINICAL RELEVANCE/APPLICATION

The BT-RADS demonstrated a high inter-observer agreement rate, despite the experience gap between the two radiologists. This finding is promising for the validation of BT-RADS for future broad use. The BT-RADS model is still in development, so some changes in its protocol are still expected to happen.

## T5B-SPNR-11 Leveraging CT Imaging and Machine Learning: Enhancing Prognostic Accuracy for Functional Outcomes in Anterior Circulation Large Vessel Occlusion Stroke Patients

Participants  
Burak Ozkara, MD, Houston, TX (*Presenter*) Nothing to Disclose

### PURPOSE

We aimed to predict the functional outcome of acute ischemic stroke patients with anterior circulation large vessel occlusions (LVOs) using only imaging parameters in machine learning (ML) models, regardless of how they were treated or the severity of the stroke at admission, and to investigate the precision of imaging parameter utilization in ML models.

### METHODS AND MATERIALS

Patients with acute ischemic stroke (AIS) due to anterior circulation LVO, as confirmed by computed tomography angiography (CTA) and CT perfusion (CTP) scans, were screened in this retrospective study. Demographic and clinical data, such as sex, age, race, admission NIHSS score, modified Rankin Score (mRS) at 90 days, and treatment information, were extracted. Radiological variables were collected by a neuroradiologist, who recorded the spatial location, and assessed the baseline ASPECTS, occluded vessel, occluded segment, occlusion laterality, and presence of hyperdense MCA. Additional data, such as rCBF, T<sub>max</sub>, CBV, mismatch volume, mismatch ratio, hypoperfusion index, DSA collateral score, clot burden score, single-phase CTA collateral score, and multiphase CTA collateral score, were extracted. These data were used as input, and the outcome was mRS at 90 days, which was dichotomized as mRS 0-2 (good outcome) and mRS 3-6. To address missing data, imputation techniques were employed for both infinite values and missing values using k-nearest neighbor imputation. The sample was divided into training (60%), validation (20%), and test (20%) sets. CatBoost, XGBoost, and Random Forest ML algorithms were employed. The SHAP method was employed to determine the relative importance of predictor elements.

### RESULTS

180 patients were included. 88 patients had an mRS between 3-6 and 92 had an mRS between 0-2. The best algorithm was XGBoost, with an area under the receiver operating characteristic curve of 0.907 (95% CI: 0.686 - 0.979) and an area under the precision recall curve of 0.827 (95% CI: 0.703 - 0.951). The top three most significant features were multiphase CTA collateral score, CBV < 42%, and mismatch volume.

### CONCLUSION

Our model was highly accurate using only imaging parameters, indicating that imaging parameters may be as accurate as conventional predictors. The multiphase CTA collateral score was the most predictive variable, highlighting the importance of collaterals and demonstrating that incorporating them into ML models could lead to accurate prediction.

## CLINICAL RELEVANCE/APPLICATION

This study emphasizes the importance of imaging parameters, particularly collateral circulation markers, in predicting functional outcomes for AIS patients, regardless of stroke severity at admission or treatment method that physicians can tailor to improve patient prognosis.

## T5B-SPNR-12 Decoding the Enigma of Distal Medium Vessel Occlusions: Harnessing Machine Learning for Prognostic Predictions in Acute Ischemic Stroke Patients

Participants  
Burak Ozkara, MD, Houston, TX (*Presenter*) Nothing to Disclose

### PURPOSE

We hypothesized that machine learning (ML) algorithms using CT perfusion (CTP) and clinical variables as input parameters can successfully predict the outcome in distal medium vessel occlusion (DMVO) acute ischemic stroke (AIS) patients regardless of the preferred treatment method, given CTP's expected impact on stroke diagnosis and management.

### METHODS AND MATERIALS

DMVO-AIS patients with available CTP scans were screened in this retrospective cohort study. Demographic, clinical, and radiologic data were collected, including blood samples and radiologic variables such as occlusion location, ASPECTS, rCBF, T<sub>max</sub>, CBV, mismatch volume, hypoperfusion index, and diffusion-weighted imaging (DWI) volume on follow up MRI within seven days of symptom onset. These data were used as input, and the outcome was National Institutes of Health Stroke Scale (NIHSS) shift score (admission NIHSS score - discharge NIHSS score). Patients with an NIHSS shift score above the median score and patients with an NIHSS shift score below the median score were assigned to the favorable outcome group and the unfavorable outcome group, respectively. Since admission and discharge NIHSS scores are directly related with our outcome, NIHSS shift, they were not included in the predictor variables. Data preprocessing involved imputation of missing values, scaling of continuous variables, normalization, and encoding of categorical variables. Recursive feature elimination (RFE) was used for feature selection. Five supervised machine learning algorithms were employed. SHAP were used to examine the relative weights of predictor variables.

### RESULTS

There were 35 patients who had a favorable outcome and 34 patients who had an unfavorable outcome. RFE produced ten features, the top three most important of which were mismatch volume, T<sub>max</sub> > 6s, and DWI volume. XGBoost showed the best performance in predicting unfavorable outcome with an area under the curve of receiver operating characteristic curve of 0.865 and an area under the precision-recall curve of 0.811.

### CONCLUSION

In patients with DMVO-AIS, our ML model trained on baseline quantitative CTP parameters and laboratory data was able to

predict the short-term outcome, NIHSS shift score. The most important variable was the mismatch volume in the best-performing model. Notably, neither the admission NIHSS score nor the patient's age were used in our model to predict the prognosis of AIS patients, despite the fact that these factors are normally very important predictors of prognosis.

#### **CLINICAL RELEVANCE/APPLICATION**

We were able to accurately predict the prognosis of DMVO-AIS patients using CT perfusion parameters, demonstrating the importance of imaging. These preliminary findings may aid clinicians in predicting patient prognoses.

#### **T5B-SPNR-13 Effect of Statins on Different Intracranial Plaques Its Influencing Factors: A High-Resolution Magnetic Resonance Vessel Wall Imaging Study**

##### **PURPOSE**

High-resolution magnetic resonance vessel wall imaging (HRMR-VWI) is a non-invasive examination that can evaluate intracranial atherosclerotic plaque stability. This study applied HRMR-VWI to evaluate the effect of statins on vulnerable and stable intracranial plaques and explore the influencing factors of statin therapy.

##### **METHODS AND MATERIALS**

Between July 2017 and August 2021, patients with intracranial atherosclerosis treated with statins underwent HRMR-VWI. The plaque characteristics were measured using PACS system and Vessel Explorer software, including plaque length, thickness, burden, luminal stenosis, plaque enhancement, and plaque location. According to the baseline plaque enhancement, each plaque was classified into a vulnerable plaque group or stable plaque group. The plaque characteristics before and after treatment were compared by using the signed-rank test and paired-samples t-test. The plaque characteristics after treatment between the two groups were compared by using Wilcoxon rank sum test. According to the tri-sectional quantiles of plaque enhancement rate change, each plaque was classified into a good or poor effect group. The baseline plaque characteristics between the two groups were compared by using the independent-samples t-test or Wilcoxon rank sum test. Multiple linear regression was used to investigate the relationship between baseline plaque characteristics and the effect of statin therapy.

##### **RESULTS**

This study included 53 patients with a total of 107 plaques, including 61 stable plaques and 46 vulnerable plaques. In the vulnerable plaque group, plaque enhancement ( $P < 0.001$ ), plaque burden ( $P < 0.023$ ), and luminal stenosis ( $P < 0.027$ ) in the follow-up period were significantly reduced compared to baseline. The extent of reduction in plaque enhancement was significantly higher in the vulnerable plaque group than that in the stable plaque group ( $P < 0.025$ ). Compared with the poor effect group, the baseline plaque burden was greater ( $P < 0.025$ ) and luminal stenosis was higher ( $P < 0.024$ ) in the good effect group. Multiple linear regression showed that plaques located in anterior circulation ( $B = 0.16$ ,  $P = 0.014$ ) and those with obvious enhancement at baseline ( $B = -0.0218$ ,  $P = 0.007$ ) were positively correlated with a decreased rate of plaque enhancement after statin treatment.

##### **CONCLUSION**

This study confirmed by HRMR-VWI that statins have certain effects on vulnerable plaques, and their efficacy is better than that on stable plaques. The treatment benefit may be greater for plaques located in the anterior circulation and have a higher baseline enhancement degree.

#### **CLINICAL RELEVANCE/APPLICATION**

This result may provide a theoretical basis for individualized treatment for patients with intracranial artery stenosis.

#### **T5B-SPNR-14 Automated Machine Learning Based on Clinical Factors and Multimodal Radiomics of Diffusion Kurtosis Imaging and Conventional Magnetic Resonance Imaging Predicts the Functional Outcome of Acute Ischemic Stroke**

##### **PURPOSE**

This study aimed to investigate the predictive value of the radiomics from diffusion kurtosis imaging (DKI) for the functional outcome of acute ischemic stroke (AIS) patients and develop a prediction model based on radiomics and clinical factors using automated machine learning to accurately predict the functional outcome.

##### **METHODS AND MATERIALS**

The clinical and imaging data of 203 patients with AIS were retrospectively collected and randomly divided into the training cohort ( $n = 163$ ) and testing cohort ( $n = 40$ ). Based on the modified Rankin Scale (mRS) at three months after hospital discharge, the functional outcome was dichotomized into good (mRS = 2) and poor (mRS > 2). Radiomics features were extracted from DKI parametric maps, T2 fluid-attenuated inversion recovery (FLAIR), diffusion-weighted imaging (DWI) and apparent diffusion coefficient (ADC) maps and categorized into four feature sets (set 1: DWI and ADC maps; set 2: T2 FLAIR, DWI and ADC maps; set 3: DKI parametric maps including mean diffusivity, mean kurtosis and fractional anisotropy maps; set 4: all of the above features). The tree-based pipeline optimization tool (TPOT) was applied to establish the prediction models based on the simple feature sets and the combination of the radiomics score and clinical factors, respectively. For each feature set, TPOT was repeated 10 times to obtain a best model. Then the best models were validated on the testing cohort. The area under the curve (AUC), average precision, accuracy, sensitivity and specificity were used to evaluate the performance of the models.

##### **RESULTS**

Four radiomics models and four radiomics-clinical models were developed by TPOT. The models combining radiomics score from DKI parametric maps and clinical factors achieved the best performance in the testing cohort (AUC = 0.923, average precision = 0.896, accuracy = 0.775, sensitivity = 0.800, specificity = 0.760). The 5 most important factors were radiomics score, baseline National Institute of Health stroke scale score, age, infarct volume and baseline mRS. In addition, the AUC of DKI-based radiomics model was higher than the models based on conventional magnetic resonance imaging.

##### **CONCLUSION**

The DKI-based radiomics could further improve the performance for predicting the AIS outcome compared with conventional magnetic resonance imaging. The models developed by TPOT based on radiomics score from DKI parametric maps and clinical factors could predict the functional outcome of AIS patients with a high discriminatory accuracy.

## CLINICAL RELEVANCE/APPLICATION

The model developed by TPOT could assist clinicians to accurately predict the outcome of AIS patients and formulate individual treatment plans at the early stage of onset, which may improve the prognosis of AIS patients.

### **T5B-SPNR-2 Double Expressor Lymphoma Subtype in Primary Central Nervous System Lymphoma: Its MR Imaging Features and Clinical Relevance**

Participants

Goh Sasaki, PhD, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Unlike most B-cell lymphomas, double-expressor lymphomas (DELs) can lead to increased risk of relapse and worse prognosis. To date, there are no studies evaluating MRI findings in primary central nervous system lymphoma (PCNSL) patients with DEL (PCNSL-DEL). We aimed to determine whether PCNSL-DEL has MR imaging and clinical features compared to non-DEL.

## METHODS AND MATERIALS

This retrospective study included 36 patients with PCNSL, 16 of whom were pathologically confirmed with DEL and 20 with non-DEL. All patients underwent preoperative 3-T MRI including diffusion-weighted imaging (DWI) and dynamic susceptibility contrast (DSC) perfusion studies. Cerebral blood volume (CBV), leakage-corrected CBV (cCBV) and K2 were calculated by using a block-circulant deconvolution method. The regions of interest (ROIs) were placed at enhancing lesions with high DWI intensity, while control ROIs were set at the contralateral portions. Mean apparent diffusion coefficient (ADC), CBV, cCBV ratios and K2 value were compared between DEL and non-DEL groups using the Mann-Whitney U test. The Kaplan-Meier method was used to estimate progression-free survival (PFS) differences.

## RESULTS

Compared with non-DEL group, DEL group had significantly lower mean CBV ratio ( $0.23 \pm 0.55$  vs.  $0.25 \pm 0.27$ ,  $p = 0.016$ ) and cCBV ratio ( $1.48 \pm 0.98$  vs  $2.08 \pm 0.80$ ,  $p = 0.028$ ). There was no significant difference in ADC ratio ( $1.07 \pm 0.23$  vs  $0.97 \pm 0.22$ ,  $p = 0.14$ ) and K2 ( $481 \pm 287$  vs  $421 \pm 276$ ,  $p = 0.336$ ) between the two types of PCNSL. PFS was shorter for DEL than non-DEL, but there was no significant difference.

## CONCLUSION

s In PCNSL, DEL has lower CBV and cCBV and tends to have shorter PFS than non-DEL.

## CLINICAL RELEVANCE/APPLICATION

DSC perfusion imaging is a promising tool for identifying DEL, a subtype of PCNSL.

### **T5B-SPNR-3 MRI Histogram Analysis of TERT Mutation Status in Patients with IDH-wildtype Glioblastoma**

## PURPOSE

TERT mutation is an important predictor of poor prognosis in IDH wild-type glioblastoma patients. To investigate the value of MRI histogram analysis in predicting TERT mutation status of IDH wild-type glioblastoma.

## METHODS AND MATERIALS

POPULATION and SEQUENCE: T1WI contrast-enhanced (T1C) and T2WI images of 182 patients with IDH-wildtype glioblastoma confirmed by surgery and molecular pathology were retrospectively collected. IMAGE ANALYSIS: Two radiologists imported images in the Dicom format into Firevoxel (current version: 416C, NYU School of Medicine, NY, <https://wp.nyu.edu/firevoxel/downloads/>) to independently analyze the entire lesion. Subsequently, the largest lesion slice was selected. Based on the T1WI and T2WI images, two radiologists manually traced the ROIs in all 182 GBM margin along the axial T1C without the surrounding brain tissue, and oedema. The software automatically generated a grayscale histogram of the ROI. Histogram analysis was performed using the largest slices to obtain the following histogram parameters: maximum, minimum, mean, standard deviation (SD), variance, coefficient of variation (CV), skewness, kurtosis, entropy, and 1st-99th percentiles. The necrotic/necrotic ratio of the maximum tumor layer was calculated by delineating the necrotic/necrotic area. STATISTICAL TESTS: Pearson's and Spearman's - rho correlation analysis was used to analyze the correlation. Receiver operating characteristic (ROC) analysis was used to evaluate the utility of the T1C histogram parameter in the TERT mutation state. All statistical analyses were performed using SPSS (IBM SPSS Statistics version 25.0; Chicago, IL, USA) software.

## RESULTS

In the T1C histogram features, the maximum value, standard deviation, variance, 99th percentile and coefficient of variation (CV) were positively correlated with TERT mutation status ( $P < 0.05$ ). ROC curve analysis showed that when  $CV=0.319$ , the AUC value was the highest (0.775; 95% confidence interval (CI) :0.702-0.848), and the sensitivity and specificity were 0.803 and 0.729, respectively. In addition, CV was positively correlated with the ratio of maximum level necrosis to cystic degeneration.

## CONCLUSION

s Preoperative T1C histogram analysis has predictive value for TERT mutation status in IDH wild-type GBM patients.

## CLINICAL RELEVANCE/APPLICATION

CV in the T1C histogram can objectively and comprehensively reflect the intrinsic heterogeneity of the tumor, and can predict the TERT mutation status of IDH wild-type glioblastoma before surgery. We performed interpretative analysis of the histogram characteristic parameters and concluded that CV was positively correlated with the ratio of necrosis to cystic degeneration at the maximum tumor level.

### **T5B-SPNR-4 Impaired Peritumoral Cerebrovascular Reactivity Measured with Arterial Spin Labeling in Gliomas. Emerging Techniques in the Pre-surgical Workup of Brain Tumors**

Participants

Marta Calvo-Imirizaldu, MD, Pamplona, Spain (*Presenter*) Research Grant, Siemens AG

## PURPOSE

The purpose of our study was to evaluate the feasibility of cerebrovascular reactivity (CVR) mapping with arterial spin labeling (ASL) technique using a breath-holding task, and its potential to depict infiltrative tumor beyond the limits of contrast enhancement and non-enhancing components.

## METHODS AND MATERIALS

16 newly diagnosed patients with grade 4 brain gliomas (WHO 2021, biopsy confirmed) who underwent presurgical brain MRI were prospectively recruited. A non-invasive PCASL sequence with apnea challenge consisting of 10 cycles of 21s of apnea/breath-hold task and 42s of normal breathing was added to the clinical protocol, for CVR mapping. All studies were performed in a 3T Siemens Skyra MRI scanner with 32-channel head coil. Informed written consent was obtained. Automatic segmentation masks of gray matter (GM), white matter (WM), were obtained in SPM, with a threshold of 0.9. Contrast enhanced tumor (CE) and non-contrast enhanced tumor (nCE) masks were manually drawn by an experienced neuroradiologist on each patient T1 weighted image. Several expanding volume-of-interest (VOI) rings of 6 mm width were evaluated in the peritumoral area to assess the infiltrative lesion. Cerebral blood flow (CBF) and CVR of the affected side, contralateral hemisphere, tumor lesion (merging CE and nCE components when applicable) and in the perilesional expanding VOIs were recorded. CVR was evaluated as percentage signal change (PSC) in CBF. Data were analysed for normality using Shapiro-Wilk test. Differences in CBF were assessed in the tumor lesion versus the homologous contralateral region, with paired T-test. Differences in CVR were assessed for the tumor and perilesional VOIs with paired T-test, corrected for multiples comparisons using false discovery rate test.

## RESULTS

A total of 16 patients were included (11 men, mean age  $56.19 \pm 10.73$  years). Mean CBF in the tumor was  $57.62 \pm 38.12$  ml/100g/min, significantly higher compared to the contralateral side ( $p = 0.021$ ). CVR in the tumor was decreased compared to the contralateral homologous region (ipsilateral PSC =  $22.03 \pm 14.25$  vs contralateral PSC =  $31.94 \pm 11.04$  PSC;  $p = 0.028$ ). Perilesional CVR was also impaired in the periphery of the tumor, reaching a plateau in the last two VOIs (18 to 24 mm from the tumor). Significant differences in CVR between the contralateral and ipsilateral VOIs were found ( $p$ -values, VOI 6mm = 0.009, VOI 12mm = 0.028, VOI 18mm = 0.029, VOI 24mm = 0.045).

## CONCLUSION

s CVR mapping is feasible with ASL and can provide information about the perilesional environment of the tumor that may help to detect infiltrative disease.

## CLINICAL RELEVANCE/APPLICATION

Trying to precisely delineate the infiltrative glioma region for an accurate complete resection is a challenge in glioma imaging.

## T5B-SPNR-5 The Cavernous Sinuses Lesions - A South Brazilian Experience

### PURPOSE

We aim to present our experience at South Brazil of the various and unusual pathologies that can affect the cavernous sinuses. They have great clinical importance, and this review and iconographic essay help us to keep these conditions in mind at the moment we face them in our daily practice.

### METHODS AND MATERIALS

This is a cross-sectional retrospective study performed at two large institutions in South Brazil. We did a research from April 2013 to April 2023, then selected a miscellanea of 16 very illustrative and representative cases of the variable conditions that can affect the cavernous sinuses.

### RESULTS

Our research showed as results inflammatory/infectious, neoplastic, vascular, and cryptogenic pathologies, as we illustrate: fusiform aneurysm, carotid cavernous fistula, septic thrombosis, hemangioma, dermoid cyst,, adenoid cystic carcinoma, hypertrophic pachymeningitis, macroadenoma, lymphoma, meningioma, plexiform neurofibroma, mucormycosis, oculomotor mononeuropathy, and Tolosa-Hunt.

### CONCLUSION

s The cavernous sinuses are interconnected venous plexuses situated in the floor of the middle cranial fossa on either side of the sella turcica and sphenoid sinus. They can communicate with the orbit, pterygopalatine fossa, infratemporal fossa, nasopharynx and posterior cranial fossa through various foramina, fissures and channels at the base of the skull. In addition, it contains important vascular and nerve structures, including the internal carotid arteries, the oculomotor and abducens cranial nerves, and the ophthalmic and maxillary branches of the trigeminal nerve. These pathological conditions can have similar clinical manifestations, so imaging plays a crucial role in the diagnosis, assessment of the extent of the disease, biopsy planning, when necessary, and aid in the decision of the best therapeutic strategy to be followed, including radiotherapy, microsurgery or clinical treatment.

### CLINICAL RELEVANCE/APPLICATION

Because of all these reasons, the diagnosis may be very challenging and knowing these possibilities in advance must make us aware to keep them in mind for prompt suspicion.

## T5B-SPNR-6 Clinical Significance of Apparent Diffusion Coefficient in Differential Diagnosis of Primary Central Nervous System Lymphoma and Meningioma

### PURPOSE

To analyze the clinical significance of apparent diffusion coefficient in differential diagnosis of primary central nervous system lymphoma and meningioma.

### METHODS AND MATERIALS

Thirty-five patients with primary central nervous system lymphoma and 35 patients with meningioma confirmed by surgery and pathology were selected as Group A and Group B respectively. The average ADC value, the minimum ADC value, the maximum ADC

value and the contralateral normal white matter, the average (contralateral) ADC value were obtained, logistic regression analysis and ROC curve were used to analyze the diagnostic efficacy of each index.

## RESULTS

The mean ADC value, minimum ADC value, maximum ADC value and contralateral ADC value in group A were statistically different ( $P < 0.05$ ); the minimum ADC value and contralateral ADC value in group B were not statistically different ( $P > 0.05$ ), while the rest of items were statistically different ( $P < 0.05$ ); the mean ADC value, minimum ADC value and maximum ADC value in group A were lower than those in group B ( $P < 0.05$ ). The logistic regression analysis showed that the maximum ADC value was an independent risk factor, while the mean ADC value and the minimum ADC value were protective factors ( $P < 0.05$  and  $P < 0.01$ , respectively). The AUC of the combined indices was 0.926, with an accuracy of 93.5%, sensitivity of 90.3%, and specificity of 94.7% ( $P = 0.000$ ).

## CONCLUSION

Different ADC values in tumor parenchyma provide the molecular imaging basis for noninvasive differential diagnosis of primary central nervous system lymphoma and meningioma, and the combined diagnosis of the three parameters can effectively improve the diagnostic efficiency by using logistic regression model.

## CLINICAL RELEVANCE/APPLICATION

Accurate differential diagnosis of primary central nervous system lymphoma and meningioma is essential for early intervention and survival. Conventional MRI findings of some primary central nervous system lymphoma often overlap with meningiomas and are difficult to differentiate. Diffusion-weighted imaging (DWI) can reflect the characteristics of the lesions from the molecular diffusion level before the morphology. The apparent diffusion coefficient (ADC) of DWI can quantitatively reflect the density and malignant degree of the tumor cells. This study was to investigate the value of ADC in the differential diagnosis of primary central nervous system lymphoma and meningioma, and to provide valuable reference for the early diagnosis and early intervention of the two diseases.

## T5B-SPNR-7 Comparison between Postcontrast T1-weighted Thin-slice 2D Spin Echo and 3D SPACE Sequences in the Detection of Brain Metastases at 1.5T and 3T

### PURPOSE

The accurate detection of metastatic brain lesions (MBL) before radiotherapy is critical. Although spin echo (SE) are superior to gradient echo sequences in detecting small MBL, thin-slice whole-brain coverage is time consuming. The sampling perfection with application optimized contrasts using different flip angle evolution (SPACE) sequence shares many advantages with SE, but with faster acquisition and greater resolution while achieving whole-brain coverage.

### METHODS AND MATERIALS

Fifty-six patients with MBL were included and underwent a standard protocol (1.5T  $n = 37$ , 3T  $n = 19$ ), including postcontrast T1-weighted SE and SPACE (postcontrast order: SE first  $n = 26$ , SPACE first  $n = 30$ ). Rating was performed by 3 raters in 2 sessions  $> 6$  weeks apart; images were de-identified and order randomized, only SE or SPACE per-subject per-session. The true number of MBL was determined using all available imaging including follow up. Intraclass correlations were determined; consistency for intra-rater (SE vs. SPACE) and agreement for inter-rater (same sequence). A paired t-test was used to evaluate postcontrast sequence order.

### RESULTS

A total of 135 MBL were identified (mean/subject 2.41, SD 6.4). Relatively fewer lesions were identified on the first postcontrast sequence (SE/SPACE), however the difference was not significant ( $p = 0.08$ ). Intra-rater consistency (SE vs. SPACE) was excellent (ICC: R1, 0.984; R2, 0.971; R3, 0.946), as was inter-rater agreement, with ICC values of 0.984 and 0.969 for SE and SPACE sequences, respectively. Finally, agreement between individual sequences and the true number of lesions was excellent (SE ICC: R1, 0.981; R2, 0.973; R3, 0.977; SPACE ICC: R1, 0.984; R2, 0.971; R3, 0.965).

### CONCLUSION

The emergence of fast computer-assisted treatment planning of targeted radiosurgery techniques in the management of MBL requires precise, fast and reliable MRI workup. The reliable detection of MBL with MRI depends on a number of factors, particularly pulse sequence and contrast agent type, dose and application delay. Although SE sequences are superior to gradient echo sequences in the detection of small brain metastases, they have relatively long acquisition times and are prone to artifacts. To our knowledge this is the first comparison between thin-slice T1-weighted SE and SPACE sequences in the detection of brain metastases at 1.5 Tesla and 3 Tesla. Our results show that T1-weighted SPACE is not inferior to standard thin slice SE sequences in the detection of brain metastases.

### CLINICAL RELEVANCE/APPLICATION

The T1-weighted SPACE sequence has several advantages over other sequences commonly used in the detection of metastatic brain lesions while maintaining excellent consistency with ratings on standard thin-slice spin echo images.

## T5B-SPNR-8 Predicting IDH-Mutation in Low Grade Glioma using Different MRI Sequences

### PURPOSE

Low grade gliomas are classified by analyzing molecular characteristics such as IDH mutation status. In this retrospective study we applied radiomics to different MRI sequences to determine which one is the most suitable.

### METHODS AND MATERIALS

In our retrospective study, we used MR images of 106 patients with histologically confirmed glioma. All MR images were acquired with four MRI sequences each: T1 without and with administration of a contrast agent (T1 native and T1 CE), T2 and Flair. We performed image segmentation of the tumours semi-automatically using the open-source software platform 3D Slicer and extracted a total of 107 radiomic features from each of the images. We subsequently tested different conventional machine learning algorithms and a neural network to predict the IDH mutation status and to find the most suitable MR sequence for this task.

### RESULTS

In our analyses, the T1 CE sequence was found to be the most suitable for predicting IDH mutation status. Using independent test data and a 9-feature model constructed with Lasso (Least Absolute Shrinkage and Selection Operator) regression, we achieved an AUC of 0.849, an accuracy of 0.801, a sensitivity of 0.849, and a specificity of 0.704. The second-best results were achieved with the Flair sequence, and the T2 sequence proved to be the most unsuitable.

## CONCLUSION

Although radiomics applied to different MRI sequences is suitable to predict the IDH mutation in low grade gliomas, the most accurate results were achieved analyzing T1 CE sequences.

## CLINICAL RELEVANCE/APPLICATION

MRI based radiomics helps predicting molecular status of low grade gliomas.

## T5B-SPNR-9 Tumor Characteristics, Brain Functional Activity and Connectivity of Tinnitus in Patients with Vestibular Schwannoma: A Pilot Study

Participants

Jiayu Huang, Beijing, China, China (*Presenter*) Nothing to Disclose

## PURPOSE

Tinnitus in patients with vestibular schwannoma (VS) can negatively affect their mental health, focus, sleep quality, and social life. However, the mechanism of tinnitus is still unclear. Therefore, this study aims to explore the correlation between preoperative clinical characteristics of VS, postoperative changes in brain function, and tinnitus in patients with VS.

## METHODS AND MATERIALS

We collected data from 80 VS patients before surgery and from 28 VS patients before and after surgery, and recruited 28 healthy controls. We used paired t-tests to identify brain regions where patients had significant changes in amplitude of low frequency fluctuations (ALFF) and regional homogeneity (ReHo) after surgery. Tinnitus severity was evaluated using the Tinnitus Handicap Inventory (THI) and Visual Analog Scale (VAS). And Pearson correlation were applied to assess the relationship between the changes in ALFF and ReHo and the changes in THI and VAS scores postoperatively. Finally, we also conducted seed- and ROI-based functional connectivity (FC) analyses.

## RESULTS

Prior to surgery, VS patients with tinnitus had smaller tumors ( $t = 3.293$ ,  $p < 0.001$ ), more solid tumor ( $p = 0.033$ ), and less extrusion into the cerebellum brain stem ( $p = 0.001$ ) than those without tinnitus. After surgery, 28 VS patients showed a significant reduction in ALFF in the left cerebellum crus 2 (ROI 1) and a significant reduction in ReHo in the left cerebellum crus 1 (ROI 2) and the right precuneus (ROI 3). Conversely, ReHo was significantly increased in the right precentral gyrus (ROI 4) (cluster-level  $p$  value family-wise error [pFWE]  $< 0.05$ ). Additionally, the changes in ALFF values were negatively correlated with changes in the VAS score on the left side ( $r = -0.32$ ,  $p < 0.05$ ). Moreover, the FC strengths of patients between ROI 2 and the left and right posterior cingulate gyrus respectively were significantly decreased after the surgery (FDR correction,  $p < 0.05$ ).

## CONCLUSION

Preoperative tinnitus in patients with VS may be influenced by tumor size, tumor nature, and degree of extrusion into the cerebellum brain stem. Additionally, the functional activities of the default mode network, the somatomotor network, and the cerebellum are altered postoperatively. Notably, the changes in ALFF in the left cerebellum are correlated with tinnitus severity.

## CLINICAL RELEVANCE/APPLICATION

Clinical characteristics and brain regions related or unrelated to hearing can influence tinnitus symptom in VS patients, which may be potential therapeutic targets for tinnitus in VS patients.

#### **T5B-SPOB-1 Uterine Sarcoma or Degenerating Fibroid? Validating the New Consensus MRI Algorithm for Evaluating Atypical Uterine Masses**

##### Participants

Aja Green Walker, BS, Chicago, IL (*Presenter*) Nothing to Disclose

##### PURPOSE

The purpose of our study is to evaluate the validity of a recently published consensus MRI diagnostic algorithm (PMID: 36194109) for differentiating benign degenerating leiomyomas and malignant uterine sarcomas.

##### METHODS AND MATERIALS

Atypical uterine masses on pelvic MRI were identified through the Radiology information system and report search engine using "atypical leiomyoma", "atypical fibroid", and "sarcoma", and the electronic medical record was reviewed for pathologic proof. Two radiologists blinded to clinical, surgical, and pathologic reports retrospectively and independently reviewed 40 pelvic MRI examinations dated 1/2007-9/2022 to determine if the masses by imaging were benign or malignant, using the 2022 consensus atypical uterine mass flow chart. Imaging features assessed included: peritoneal metastases, abnormal lymph nodes, intermediate/high signal intensity (SI) at T2-weighted imaging, high DWI SI (equal or higher SI than endometrium or lymph nodes on high b value imaging), and ADC value =  $0.905 \times 10^{-3}$  mm.

##### RESULTS

Of the 40 atypical uterine mass cases, 24 masses were benign (22 leiomyomas, 1 adenomyoma, and 1 borderline ovarian tumor) and 16 masses were malignant (6 leiomyosarcomas, 6 carcinosarcomas, 3 endometrial sarcomas, and 1 low grade uterine sarcoma). Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) to determine if masses were benign or malignant were 75%, 95.8%, 92.3%, and 85% for reader 1, and 81.2%, 91.7%, 86.7%, and 88% for reader 2 respectively. Interreader agreement was strong, kappa: 0.89. Endometrial sarcomas had higher T2 signal and higher ADC values than leiomyosarcomas.

##### CONCLUSION

The new consensus pelvic MRI algorithm for evaluating atypical uterine masses has good specificity, sensitivity, PPV, and NPV for determining malignancy, particularly for uterine sarcomas that are predominantly myometrial origin (leiomyosarcoma), with ADC =  $0.905 \times 10^{-3}$ mm. However, if ADC is near but not below  $0.905 \times 10^{-3}$ mm, the mass may be malignant, especially if using b value lower than 1000. If the atypical uterine mass is predominantly endometrial, morphology should guide suspicion.

##### CLINICAL RELEVANCE/APPLICATION

The 2022 consensus algorithm to distinguish benign from malignant atypical uterine masses has important clinical implications, as surgical and medical management for degenerating fibroids is very different from uterine sarcomas.

#### **T5B-SPOB-2 Comprehensive Assessment of Postoperative Recurrence and Survival in Patients with Cervical Cancer: Nomograms**

##### PURPOSE

To investigate the value of nomograms based on clinical parameters, inflammatory indicators, intravoxel incoherent motion diffusion weighted imaging (IVIM-DWI) and MRI-derived radiomics in predicting recurrence-free survival (RFS), disease-free survival (DFS), cancer-specific survival (CSS) and overall survival (OS) in cervical cancer patients after surgery.

##### METHODS AND MATERIALS

A retrospective analysis of 181 cervical cancer patients operated at our hospital between January 2015 and January 2021 with continuous follow-up was completed. The parameters of IVIM-DWI and radiomics were measured, analyzed and screened. The logistic regression with LASSO regularization was used to calculate radiomics score (Rad-score). Multivariate Cox regression analysis was used to construct nomogram models for predicting postoperative RFS, DFS, CSS and OS in cervical cancer patients, with internal and external validation.

##### RESULTS

Clinical stage, parametrial infiltration, internal irradiation, D-value and Rad-score were independent prognostic factors for RFS; Squamous cell carcinoma antigen, internal irradiation, D-value, f-value and Rad-score were independent prognostic factors for DFS; Maximum tumor diameter, lymph node metastasis, platelets, D-value and Rad-score were independent prognostic factors for CSS; Lymph node metastasis, systemic inflammation response index, D-value and Rad-score were independent prognostic factors for OS. The AUCs of each model predicting RFS, DFS, CSS and OS at 1, 3 and 5 years were 0.985, 0.929, 0.910 and 0.833, 0.818, 0.816 and 0.832, 0.863, 0.891 and 0.804, 0.812, 0.870, respectively.

## CONCLUSION

s Nomograms based on clinical and imaging parameters showed high clinical value in predicting postoperative RFS, DFS, CSS and OS of cervical cancer patients and can be used as prognostic markers.

## CLINICAL RELEVANCE/APPLICATION

The model may help predicting postoperative RFS, DFS, CSS and OS of cervical cancer patients.

### **T5B-SPOB-3 Cer-ConvN3Unet: An End-to-end Multimodal Pipeline for Auto-detection and Auto-segmentation of Cervical Cancer based on ConvNeXt and Double U-Net**

## PURPOSE

Cervical cancer is a common gynecological pelvic tumor with an incidence rate of 3.1% and mortality rate of 3.4%, ranking eighth and ninth among all cancers worldwide. The routine MRI examination typically includes multi-planar T2WI, DWI and CE-T1WI. Hence, it is of paramount importance to extract the multimodal information for subsequent volume calculation, radiomics analysis, radiotherapy dose optimization, surgical preparation, and etc. In this study, we proposed an innovative two-phase pipeline for auto-detection and auto-segmentation on multimodal cervical cancer MRI images, which integrated the advantages of ConvNeXt and Double U-Net, thereby providing an end-to-end multimodal outlining tool for gynecologists.

## METHODS AND MATERIALS

Totally 100 patients underwent pelvic MRI examinations consisting of T2WI, DWI and CE-T1WI. Patients with no contraindications received an intramuscular injection of 10mg raceanisodamine hydrochloride before image acquisition to reduce bowel motion artifacts. 2533 DWI slices, 2448 T2 slices, and 7176 CE-T1 slices were obtained by extracting 3D MRI images layer-by-layer from axial plane. In the auto-detection phase, a six-classifier was designed based on ConvNeXt blocks for the multimodal recognition. In the second stage, the whole identified tumor slices were separately input into auto-segmentation module developed by 3-channel Double U-Nets. The accuracy, precision, recall, Kappa and F1-score were used to evaluate the classification performance, while DSC and Jaccard were applied to quantitative analysis the segmentation performance.

## RESULTS

20 patients were excluded from the modeling process for independent testing. The initial auto-detection module achieved the average results of 92.37%, 83.60%, 77.65%, 75.70%, 0.8045 for accuracy, precision, recall, Kappa and F1-score. And no error occurred in the distinguishment between the three modalities. Entering into segmentation stage, the mean values of DSC and Jaccard on DWI, T2, CE-T1 were (83.25%, 71.49%), (78.62%, 65.17%), (73.62%, 58.81%), respectively.

## CONCLUSION

s Strict independent experiments demonstrated that the end-to-end multimodal pipeline was capable of getting high recognition and segmentation accuracy with less manual intervention. In the future, the clinical utility will be further optimized in large-sample and multi-center prospective cohorts and generalized to more MRI modalities.

## CLINICAL RELEVANCE/APPLICATION

The pipeline has high potential to be an alternative tool for gynecologists in routine MRI image reading and processing of cervical cancer. Meanwhile, it can also serve as the basis for a series of scientific research works related to tumor lesions, liberating from labor-intensive manual delineation.

### **T5B-SPOB-4 Intratumoral and Peritumoral MRI Radiomics Nomogram for Predicting Parametrial Invasion in Patients with Early-stage Cervical Adenocarcinoma and Adenosquamous Carcinoma**

Participants

Le Fu, Shanghai, China (*Presenter*) Nothing to Disclose

## PURPOSE

To develop a comprehensive model based on MRI intra- and peritumoral radiomics signatures and independent risk factors for predicting parametrial invasion (PMI) in patients with early-stage cervical adenocarcinoma (AC) and adenosquamous carcinoma (ASC).

## METHODS AND MATERIALS

In total, 747 patients with IB to IIB cervical AC and ASC who underwent radical trachelectomy/hysterectomy were retrospectively reviewed and divided into the primary, internal validation cohort, and external validation cohorts. The original (Ori) and original-wavelet (Ori-Wav) feature-based radiomics signatures from the primary tumor (RST) and 3 mm- and 5 mm-peritumoral regions (RS3 and RS5) were respectively built to investigate their diagnostic values in predicting PMI. The feature selection includes the following steps: 1) feature reproducibility assessment; 2) Pearson correlation test; 3) maximum relevance and minimum redundancy (mRMR); 4) the least absolute shrinkage and selection operator (LASSO). Finally, a nomogram was constructed by integrating optimal intra- and peritumoral signatures and independent risk factors.

## RESULTS

FIGO stage, disruption of the cervical stromal ring (DCSRMR), parametrial invasion on MRI (PMSMR), and serum CA-125 were found to be independent risk factors. The combined nomogram constructed by integrating independent risk factors, Ori-Wav features-based RST, and RS5 yielded AUCs of 0.874 (0.810-0.922), 0.885 (0.834-0.924) and 0.966 (0.887-0.995) for assessing PMI in the primary, internal and external validation cohorts, respectively. Furthermore, the combined nomogram was significantly superior to radiomics signatures and clinical models for assessing PMI in the three cohorts.

## CONCLUSION

s This study demonstrated that the combined nomogram can preoperatively, accurately, and noninvasively identify PMI in patients with early-stage cervical AC and ASC

## CLINICAL RELEVANCE/APPLICATION

As important parts of cervical cancer, AC and ASC have an increasing incidence and mortality, especially in young women. The

As important parts of cervical cancers, AC and ASC have an increasing incidence and mortality, especially in young women. The preoperative and accurate identification of PMI can facilitate precise treatment decisions of chemoradiotherapy or radical hysterectomy in patients with early-stage cervical AC and ASC. The combined nomogram integrating independent risk factors, Ori-Wav features based RST, and RS5 can preoperatively, accurately, and noninvasively identify PMI in patients with early-stage cervical AC and ASC.

### Pediatric Imaging Tuesday Poster Discussions II

#### Sub-Events

#### **T5B-SPPD-1 Radiation Dose Reduction of Newborns without Anti-scatter Grids in X-ray Fluoroscopic Imaging Systems with Flat Panel Detectors: A Newborn Whole Body Phantom Study of Dosimetry and Visual Assessment**

#### **PURPOSE**

Anti-scatter grids (ASG) effectively improve image contrast by absorbing scattered X-ray caused by a thick adult body. We hypothesized that removal of ASG would reduce radiation dose of a thin newborn body without loss of diagnostic value in X-ray fluoroscopic examinations. Our purpose was to compare radiation dose and visibility of image findings of a peripherally inserted central catheter (PI catheter), a nasogastric tube (NG tube) and contrast agent using a newborn whole body phantom between with and without ASG in X-ray fluoroscopic imaging systems with flat panel detectors.

#### **METHODS AND MATERIALS**

This study consisted of dosimetry and visual assessment. A newborn whole body phantom was used. In the dosimetry, continuous fluoroscopy for 300 seconds and twenty consecutive radiographs were performed with and without ASG. The entrance surface dose (ESD) of each dosimetry was measured by dosimeters placed on the chest and abdomen of the phantom, respectively. In visual assessment, the PI catheter and NG tube with and without inserting guidewire were placed on the phantom, respectively. Cylinders filled in contrast agent diluted by water (1/2, 1/4, 1/6, 1/8 and 1/10 dilutions) were inserted into the rectum of the phantom. Images of the PI catheter, NG tube and contrast agent were obtained by performing fluoroscopy and radiography with and without ASG, respectively. The obtained images were visually scored on a four-point scale by two observers (a board-certified diagnostic radiologist and a radiological technologist). We used the Wilcoxon signed-rank test to identify any significant differences between with and without ASG in the mean ESD and the mean visual scores. A P-value less than 0.05 was considered significant. Inter- and intra-observer agreement were calculated by weighted kappa statistics.

#### **RESULTS**

There were significant differences in the mean ESD between with and without ASG in both the fluoroscopy (chest, 1.7 vs. 1.1 mGy; abdomen, 2.0 vs. 1.3 mGy) and the radiography (chest, 3.5 vs. 2.0 mGy; abdomen, 4.1 vs. 2.4 mGy), respectively ( $P < .05$ ). There was no significant difference in the visual scores between with and without ASG in all comparisons of two observers ( $P > .05$ ). Inter- and intra-observer agreement were almost perfect in all comparisons (range, 0.87-1.00).

#### **CONCLUSION**

Removal of ASG significantly reduced radiation dose of a newborn phantom with acceptable image quality in X-ray fluoroscopic imaging systems with flat panel detectors.

#### **CLINICAL RELEVANCE/APPLICATION**

Radiation dose reduction of newborn infants could be achievable in X-ray fluoroscopic examinations without loss of diagnostic value by removal of ASG.

#### **T5B-SPPH-1 Simultaneous Denoising and Super Resolution in Clinical CT Images using Deep learning with Simulated Training Data**

##### Participants

Muhan Shao, Niskayuna, NY (*Presenter*) Nothing to Disclose

Bruno De Man, PhD, MSc, Niskayuna, NY (*Presenter*) Employee, General Electric Company

##### PURPOSE

Improved CT image resolution and noise characteristics can improve visualization of small anatomical structures, including small lung nodules and coronary artery calcifications. This work reports a deep learning (DL)-based simultaneous denoising and super-resolution approach and its initial evaluation on clinical images.

##### METHODS AND MATERIALS

A challenge for DL-based denoising and super-resolution applied to clinical images is the lack of easy ways to generate high quality training data. We propose a method to build super-resolution digital phantoms based on sharpened and denoised clinical patient images, and then simulate the CT imaging chain and generate the relatively low-resolution training inputs. We also shrink the image voxel size of the phantom to introduce miniature anatomical structures beyond the intrinsic resolution of the clinical image. Here, we report initial evaluation of the method as applied to clinical data. Thirteen patient cardiac images were acquired using clinical settings. Ten cases were used for training a deep convolutional neural network (CNN), one for validation, and two for evaluation. During inference, the network was applied to patient CT images reconstructed with filtered back-projection (FBP) images for a 20 cm field of view.

##### RESULTS

The CNN network was tested on two datasets. The first contains the held-out testing cases where low-resolution data were simulated from the high-resolution phantoms. The second is composed of the real CT images acquired using clinical settings. In both cases, the enhanced images produced by the CNN network are visually sharper and contain less noise than their corresponding input images. Compared to the real CT input image, the network output improves the full width at half maximum by ~20% along a small blood vessel. The contrast-to-noise ratio between ascending aorta and the surrounding tissue is increased by ~32% (from 52.2 dB to 69.1 dB).

##### CONCLUSION

Simultaneous CT image denoising and resolution enhancement was achieved by using a DL method on clinical cardiac data. To overcome the difficulty in acquiring high quality data as training labels, we trained the model on simulation data and adapted the model to images reconstructed using standard clinical settings. This technique greatly facilitates the creation of high-resolution, low noise CT images in clinical applications.

##### CLINICAL RELEVANCE/APPLICATION

Deep learning-based denoising and super-resolution approach may provide improved image quality and clinical diagnosis confidence for CT imaging.

#### **T5B-SPPH-10 Improving Image Quality by Comparing Two Magnetic Resonance Imaging Sequence in Chest: Free-breathing T1-weighted STAR-VIBE and Breath-holding T1-Weighted 3D VIBE Dixon**

##### Participants

Zhanli Ren, Xianyang, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To explore the feasibility of magnetic resonance imaging (MR) with free-breathing T1-weighted STAR-VIBE sequence for improving image quality in chest compared with breath-holding T1-weighted 3D VIBE-dixon sequence.

##### METHODS AND MATERIALS

Thirty patients for chest MR examination were prospectively collected in our hospital. All patients underwent MR examination (MAGNETOM 3.0T SKYRA MR scanner, Siemens Healthcare, Germany), which included T1-weighted breath-holding 3D VIBE-dixon sequence (3D-VIBE) and free-breathing T1-weighted STAR-VIBE (STAR-VIBE). The signal intensity (SI) and standard deviation (SD) of ascending aorta, main pulmonary artery and descending aorta were measured at the level of main pulmonary artery. The signal-to-noise ratio ( $SNR=SI/SD$ ) and coefficient of variation ( $CV=SD/SI$ ) of signal intensity were calculated. The image quality was subjectively scored double-blindly using a 5-point scoring system by two radiologists who had five or more years of working experience.

##### RESULTS

There was no significant difference in population characteristics between STAR-VIBE sequence and 3D-VIBE sequence ( $P > 0.05$ ). The signal-to-noise ratio (SNR) of ascending aorta, pulmonary artery and descending aorta with free-breathing T1-weighted STAR-VIBE sequence were significantly higher than those with breath-holding T1-weighted 3D VIBE-dixon sequence ( $P < 0.05$ ), while the coefficient of variation of signal intensity with free-breathing T1-weighted STAR-VIBE sequence were significantly lower than those with breath-holding T1-weighted 3D VIBE-dixon sequence ( $P < 0.05$ ). The subjective scores of image quality by the two MR radiologists had excellent consistence (kappa value  $> 0.80$ ,  $P < 0.05$ ), the subjective score of free-breathing T1-weighted STAR-VIBE sequence were significantly higher than those of T1-weighted breath-holding 3D VIBE-dixon sequence ( $P < 0.05$ ).

## CONCLUSION

s Magnetic resonance imaging with free-breathing T1-weighted STAR-VIBE sequence can significantly optimize and improve image quality in chest compared with breath-holding T1-weighted 3D VIBE-dixon sequence.

## CLINICAL RELEVANCE/APPLICATION

In thoracic magnetic resonance imaging, free-breathing T1-weighted STAR-VIBE sequence can be used to improve image quality for those patients with dyspnea, which can obtain better image quality.

## T5B-SPPH-11 Quantitative Evaluation of the Accuracy of MR Thermometry in the Presence of RNS Using a 3D Printed Realistic Head Phantom

Participants

Chen Lin, PhD, Jacksonville, FL (*Presenter*) Nothing to Disclose

## PURPOSE

The Responsive Neurostimulator (RNS), a device for seizure treatment, is implanted on the skull. It can cause severe artifacts in brain MRI, including MR thermometry, which is used for monitoring tissue temperature change during intervention procedures such as laser interstitial thermal therapy (LITT). The purpose of this study is to evaluate the impact of temperature mapping in the brain due to RNS.

## METHODS AND MATERIALS

To simulate MR-guided LITT of brain lesions in the presence of RNS, a realistic head phantom was 3D printed based on head CT images. Two indentations for mounting RNS were created at clinically appropriate locations. The inside of head phantom was filled with polyacrylic acid (PAA) gel per ASTM F2182 standards to mimic brain tissue. Black ink was when preparing the gel to increase the absorption of laser light. MR-guided LITT was performed on the phantom using a Philips 1.5T MR scanner with the Visualase™ MRI-guided laser ablation system and a laser probe with a 15mm diffuser. In each LITT session, the laser was turned on for 2 minutes at 50% of the maximum power of 10 watts. Four NetOptix fiber optic temperature sensors (FOTS) were placed 10mm away and shielded from direct laser exposure. Temperature maps (TMAP) were acquired with a 4ch flex coil and a 3D GRE sequence with receiver bandwidth of 100Hz/pixel. Five LITT sessions were performed with cooling periods in between. In sessions 1 and 5, no RNS was present in order to evaluate the accuracy and reproducibility of MR thermometry. In sessions 2 and 3, the RNS was implanted on the ipsilateral side of the ablation zone with different distances from the region of temperature mapping. In session 4, the RNS was moved to the contralateral side.

## RESULTS

The temperature changes at the tips of the four FOTS measured by both FOTS and MR thermometry, were plotted and compared. Both FOTS and TMAP were reproducible in sessions 1 through 5. The differences in the measured temperature change in MR thermometry without and with RNS appeared to be within the variation of MR thermometry itself. Good correlations of TMAP results without and with RNS at ipsilateral side close to ablation zone and the TMAP results between the first and last sessions both without RNS were observed. There was a large systematic difference between FOTS and TMAP for each session. The sources of such a difference require further investigation as subsequent testing and calibration of FOTS found them to be accurate.

## CONCLUSION

s Despite the systematic difference between FOTS and TMAP, MR thermometry results are consistent without and with RNS at clinically acceptable locations.

## CLINICAL RELEVANCE/APPLICATION

MR thermometry at 1.5T is relatively robust with regard to the potential artifact and impact from RNS.

## T5B-SPPH-12 Four Different Iterative Reconstruction Algorithms on Abdominal CT Image: A Comparative Study on Image Quality of Inferior Vena Cava

Participants

Chunyu Gu, Xianyang, China (*Presenter*) Nothing to Disclose

## PURPOSE

To compare the image quality of inferior vena cava in abdominal CT reconstructed with 4 algorithms, filtered back projection (FBP), adaptive statistical iterative reconstruction (ASIR) and a new model-based iterative reconstruction (MBIRn) with noise reduction setting (MBIRNR40) and with setting balancing both noise and spatial resolution (MBIRSTND).

## METHODS AND MATERIALS

40 adult patients underwent standard-dose upper abdominal enhancement scan on a Discovery™ CT750 HD. Images in the 180s delay phase were reconstructed by FBP, 40%ASIR (40% ASIR and 60% FBP blends), MBIRNR40 and MBIRSTND algorithms at 0.625mm image thickness. The CT value and SD value of the subcutaneous fat of the anterior abdominal wall, left erector spinae muscle, inferior vena cava and hepatic veins (left branch and right branch) were measured to calculate the contrast-to-noise ratio (CNR) of the inferior vena cava and hepatic veins, using those of 40%ASIR as the reference standard. Two radiologists with more than 10 years of experience used 5-point scoring system to assess the subjective noise and smoothness of the inferior vena cava and hepatic veins.

## RESULTS

The CT values of FBP, ASIR, MBIRNR40 and MBIRSTND were not statistically different. Image noises (in HU) in the inferior vena cava were  $31.1 \pm 5.15$ ,  $23.39 \pm 3.77$ ,  $10.75 \pm 1.45$ ,  $6.14 \pm 1.32$  with FBP, 40%ASIR, MBIRSTND and MBIRNR40, respectively ( $P < 0.05$ ); The corresponding CNR values were  $10.53 \pm 2.95$ ,  $13.29 \pm 3.62$ ,  $16.25 \pm 4.79$  and  $23.3 \pm 17.39$  ( $P < 0.05$ ). The subjective image scores of MBIRNR40 and MBIRSTND were significantly higher than 40%ASIR ( $P < 0.05$ ).

## CONCLUSION

s Under the condition of standard-dose abdominal scanning, MBIRNR40 and MBIRSTND were higher than ASIR in subjective noise and vascular smoothness scores, with MBIRNR40 image having the highest subjective noise score and MBIRSTND image having the highest degree of vascular smoothness.

## CLINICAL RELEVANCE/APPLICATION

MBIRNR40 and MBIRSTND reconstruction algorithms can improve the CT image quality for inferior vena cava and hepatic veins.

## T5B-SPPH-13 Longitudinal Relaxivity Estimation of Gadolinium-Based Contrast Agents at 64 mT

### PURPOSE

Point of care (POC) MRI scanners have been shown to improve accessibility to imaging for patients in different clinical environments, particularly in the neurocritical care units<sup>1</sup>. The use of contrast agents is prevalent at conventional field strengths (e.g., 1.5 and 3 T) for enhancing visualization and characterization of pathologies. However, the use of contrast agents at ultra-low-field (ULF) has not been characterized to the same extent as at conventional field strengths. Gadopixelenol is a high relaxivity gadolinium-based contrast agent (GBCA) that has demonstrated similar pathology enhancement compared to other commercially available GBCAs at half the dose<sup>2</sup>. The aim of this study is to estimate the longitudinal relaxivity of gadopixelenol at 64mT.

### METHODS AND MATERIALS

The study was performed using a 64 mT portable MR system (Swoop®, Hyperfine, Inc., Guilford, CT) fitted with a standard head coil and two phantoms, each comprised of different concentrations of gadolinium-based contrast agents (GBCAs) namely gadobutrol (Gadavist, Bayer HealthCare Pharmaceuticals, Whippany, NJ), and gadopixelenol (Elucirem, Guerbet LLC, Princeton, NJ). Data were obtained using an inversion recovery fast spin-echo (FSE) sequence with TR = 4 s, TE = 5.9 ms, voxel size = 1.56 mm x 1.56 mm x 5.0 mm, and inversion times (TI) in 12 intervals ranging from 100 ms to 800 ms. Longitudinal relaxation rates (R1) were calculated using a three-parameter nonlinear curve fitting algorithm (MATLAB, Natick, MA) of the median signal magnitude as a function of TI. Longitudinal relaxivity ( $r_1$ ) was obtained as the rate of change of R1 with respect to GBCA concentration. The median signal magnitude values were used for quantitative analysis to mitigate the influence of outliers.

### RESULTS

The average longitudinal relaxivities of gadopixelenol and gadobutrol were  $32.6 \text{ mM}^{-1} \cdot \text{s}^{-1}$  and  $8.7 \text{ mM}^{-1} \cdot \text{s}^{-1}$ , respectively. These values of  $r_1$  for gadopixelenol were observed to be higher at 64 mT than those reported at 0.47 T and 1.5 T<sup>2</sup>.

## CONCLUSION

s The relaxivity of gadopixelenol was observed to be greater than 3 times that of gadobutrol. These values indicate that optimizing sequence parameters would enable a significant improvement in contrast to noise (CNR) ratio when using gadopixelenol, with the potential to enhance visualization of pathologies, such as metastatic tumors and multiple sclerosis, using POC MRI.

## CLINICAL RELEVANCE/APPLICATION

Contrast-enhanced POC MRI critically ill patients for whom conventional imaging would not be possible.

## T5B-SPPH-2 Quantifying Accuracy in Deformable Image Registration: An Informed Selection of CT Image Pairs with Applications in Longitudinal Imaging

### PURPOSE

Image registration to align images for comparison reads has broad applications in assessment for interval change, including cancer screening and treatment response assessment. The accuracy of this registration has a meaningful impact on the validity of downstream image processing and automated tasks such as new lesion detection and lesion monitoring. We compare 3 metrics of deformable registration accuracy to inform the selection of a CT image pair (simulated baseline/follow-up) and evaluate CNN performance in new liver lesion detection in simulated longitudinal CT.

### METHODS AND MATERIALS

We used two public CT datasets: 1) diseased liver (DL) a subset of DeepLesion [1] 2) healthy liver (HL) from potential liver donors [2]. We registered each DL scan with each HL scan using sequential translation, affine, and B-spline transformations, creating image pairs that simulate a new liver lesion from healthy baseline. We utilized 3 metrics to define 3 subsets of the registered image-pairs; each metric informed the selection of one simulated baseline from a pool of candidate healthy scans. Our metrics: 1) Dice Similarity Coefficient (DSC) on liver segmentations 2) the product of DSC and mutual information in liver only (DSC-MI-liver), and 3) the product of DSC and mutual information in full CT (DSC-MI-full). We trained 3 models (ResNet50 architecture), one on each data subset, and compared performance on an image classification task that relies on quality registration: automated new lesion detection in paired image-patches. 5-fold cross validation and one-way ANOVA compared AUC. Ref: 1. doi: 10.1117/1.JMI.5.3.036501; 2. Med Image Anal 69 (2021) 101950

### RESULTS

Of 10,594 CT studies (4,427 patients) in DeepLesion, we registered 1595 DL scans (819 patients with liver lesions < 3cm longest diameter) with each of 20 registered HL scans (20 patients), creating 31,804 registered image pairs. Each metric selects a data subset of 1595 HL/DL image pairs, simulating baseline/follow-up. The model using the DSC metric outperformed the DSC-MI-liver and DSC-MI-full models, with AUC 0.928, 0.916, and 0.901, respectively ( $p=0.0379$ ).

## CONCLUSION

s When comparing similarity metrics for quantifying image registration accuracy, DSC outperformed DSC-MI-liver and DSC-MI-full in the selection of simulated baseline/follow-up CT images for new liver lesion detection.

## CLINICAL RELEVANCE/APPLICATION

In longitudinal imaging, image registration supports the assessment for interval change, including treatment response assessment. The quantification of registration accuracy can inform the selection of a comparison study.

### T5B-SPPH-3 Evaluation of Deep Learning Denoising Algorithms for Digital Mammography by Assessing Objective Task-based Performance using Computer Simulations

Participants

Stephen Glick, PhD, (*Presenter*) Nothing to Disclose

#### PURPOSE

Recent research suggests that degradation of image quality with reduced radiation exposure in full-field digital mammography (FFDM) can be mitigated by post-processing mammograms with denoising algorithms based on convolutional neural networks. In this work we use an in silico study to assess a deep learning denoising method and evaluate microcalcification detection accuracy when denoising is applied to scans of reduced dose.

#### METHODS AND MATERIALS

A previously published deep learning denoiser was trained and tested using an anthropomorphic breast phantom and simulated Monte Carlo mammography images containing small (100-240 micron) microcalcifications within a cluster containing 5-10 microcalcifications. Two different algorithms were tested, one with training on a dataset composed of 100% signal absent (SA) images (i.e., no MCC cluster), and one with training on a dataset composed of 50% signal absent (SA) and 50% signal present (SP). Human reader studies were conducted to assess and compare image quality in a set of binary signal detection 4-AFC experiments, with 4-AFC proportion of correct (PC) responses being the performance metric.

#### RESULTS

Microcalcification detection accuracy was decreased significantly when reducing the phantom dose from a full-dose level to a half-dose level. Deep learning denoising visually reduces the noise in the half-dose images, with a similar appearance to the full-dose images. For the algorithm trained on 100% SA images, no improvement in task-based performance (i.e., PC) was observed between half-dose images and denoised half-dose images. However, a statistically-significant improvement in PC was observed when using the algorithm trained on 50% SA and 50% SP. (see Figure below)

#### CONCLUSION

Deep-learning denoising algorithms applied to FFDM produced visually appealing images and improved global similarity metrics of MSE and SSIM. However, task-based assessment of microcalcification detection shows that deep-learning denoising applied to half-dose FFDM images resulted in decreased performance compared to that with full-dose FFDM images. In addition, our findings conjecture that deep learning denoising algorithms may benefit from enriching training datasets with signal-present regions of interest, at least in cases involving the detection of microcalcification clusters with smaller size microcalcifications.

## CLINICAL RELEVANCE/APPLICATION

A study of Deep Learning denoising shows; 1) global metrics such as MSE and SSIM might not correlate with task-based performance; and 2) the importance of adequately including images with features of diagnostic interest when training the network.

### T5B-SPPH-4 Fast and Robust Ring Artifact Correction in Photon-counting CT using a Conditional Score-based Diffusion Model with Hijacked Reverse Diffusion

#### PURPOSE

Diffusion models have emerged as the current state-of-the-art, outperforming even generative adversarial networks (GANs), for a wide range of image generation tasks and show great potential for denoising and artifact correction in medical imaging. However, long inference times have so far been a limiting factor. We propose an accelerated conditional score-based diffusion model and evaluate its performance for the task of image-domain ring artifact correction in photon-counting CT.

#### METHODS AND MATERIALS

Diffusion models exhibit an inherent tradeoff between speed and image quality negotiated by the number of steps, or noise scales, in the diffusion process. We suggest mitigating this tradeoff by "hijacking" the reverse diffusion at some step  $n$ . For a total number of steps  $N$ , we inject the condition image diffused  $N-n$  steps into step  $n$  of the reverse diffusion. We demonstrate the clinical utility of diffusion models and our suggested hijacking approach for the task of ring artifact correction in photon-counting CT. A conditional score-based diffusion model (cSBDM) is trained on 2576  $512 \times 512$  slices from 6 neuro patients scanned by CT systems from various vendors. Artificial ring artifacts are injected directly in the image domain to generate paired data. The NCSN++ network was trained to estimate the time-dependent conditional score function on extracted  $256 \times 256$  patches, with a batch size of 32, and  $N=2000$ , on one A6000 GPU for 150000 iterations. The predictor-corrector scheme was used for sampling. The network is evaluated on  $1024 \times 1024$  images of skull, water, and Lungman phantoms scanned by a prototype photon-counting system from GE HealthCare with the default ring correction disabled.

#### RESULTS

Our results indicate strong performance across the phantoms considered. On a A6000 GPU with batch size 1, cSBDM\_2000 (full diffusion) takes about 11 minutes and cSBDM\_5 (hijacked at step 1995) takes about 1.6 seconds. In other words, our suggested method achieves 400 times faster sampling. This gain in evaluation speed appears to come with a negligible drop in performance and image quality.

#### CONCLUSION

This work has suggested a ring artifact correction technique in photon-counting CT using a conditional score-based diffusion model. By hijacking the reverse diffusion, we achieve 400 times faster sampling than a vanilla cSBDM, with negligible drop in performance, pushing the required time on a medium range GPU from 11 minutes to 1.6 seconds per slice and thereby making the approach clinically viable. The method is robust to previously unseen anatomy.

## CLINICAL RELEVANCE/APPLICATION

With photon-counting CT scanners now clinically available, the proposed method improves workflow by correcting for ring artifacts without the need for time-consuming detector calibration.

### **T5B-SPPH-5 Deep Learning Image Reconstruction Algorithm to Improve the Quality of Vascular Imaging during the Peak Phase of Brain CT Perfusion**

Participants

Fang Wang, Yinchuan, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To explore the degree of deep learning image reconstruction (DLIR) algorithm to improve the peak arterial quality of CT perfusion (CTP) images in acute stroke cases.

#### **METHODS AND MATERIALS**

Clinically suspected acute stroke patients were selected for one-stop CTP imaging and randomly divided into two groups. The scanning tube voltage was 80 kV, and the current of low and high dose tube was set to 50 and 150 mA, respectively. Low dose scan data image reconstruction used DLIR 3 different intensities (low, medium and high), and only FBP was used for high dose scan data images reconstruction. Objective evaluation and subjective evaluation (point system) Image quality: The objective evaluation mainly measures the normal measurement of arterial peak period, the CT value and noise of the middle cerebral artery, calculates the signal-to-noise ratio (SNR) and the contrast noise ratio (CNR); the subjective evaluation uses arterial reinforcement, small artery detail display, image noise and venous pollution, each with 0-2 points: 0, poor; 1, medium; 2 points, good. Radiation dose was compared by t-test and image objective score by one-way ANOVA (ANOVA). The subjective scores of image quality were compared using the Kruskal-Wallis test.  $P < 0.05$  were considered to be statistically significant.

#### **RESULTS**

The mean effective radiation dose between the high dose and low dose scanning regimen was 3.25 and 1.08 mSv, respectively, significant ( $t = -1303.629$ ,  $P < 0.001$ ). The image obtained at low dose gradually decreased with the increase of DLIR intensity, and the image SNR and CNR were gradually increased ( $F = 5.397, 3.450, 2.934$ ,  $P < 0.05$ ). The noise of high-intensity DLIR images and high-dose FBP images was ( $33.9 \pm 2.7$ ), ( $40.5 \pm 11.3$ ), SNR ( $14.3 \pm 6.8, 12.2 \pm 1.9$ ), and CNR ( $13.1 \pm 6.5$  and  $10.6 \pm 1.8$ ), respectively. The differences were statistically significant (t-values were -1.961, -0.989, -1.288, and P-values  $< 0.05$ ). The subjective scores of high intensity DLIR images and high dose FBP images were ( $6.17 \pm 0.4$ ) and ( $4.31 \pm 0.5$ ), respectively, which were statistically significant ( $Z = -4629$ ,  $P < 0.001$ ).

#### **CONCLUSION**

The application of high-intensity DLIR algorithm is beneficial to achieve low-dose brain CTP, which can significantly improve the image quality and improve the peak period vascular assessment.

#### **CLINICAL RELEVANCE/APPLICATION**

Deep learning algorithm improves the quality of vascular imaging in the peak period of low-dose cerebral perfusion artery, and provides clinical basis for the realization of one-stop cerebrovascular and cerebral perfusion imaging.

### **T5B-SPPH-6 Class-wise Combination of Data Augmentation Can Enhance Learning on Class Imbalanced Dataset**

Participants

Helen Hong, PhD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Data augmentation (DA) plays an essential role in enhancing learning efficiency and avoiding overfitting in medical image analysis, particularly faced with limited training data or class imbalance. However, recent studies indicate that the effect of DA can differ among classes. We investigated the individual class effects of MixUp and AugMix DAs on focal liver lesions (FLLs) classification in CT images, and proposed a class-wise combination of these DAs with different ratios for each class to address class imbalance.

#### **METHODS AND MATERIALS**

Our dataset included CT scans from 502 colorectal cancer patients with 1290 FLL images with 676 cysts, 130 hemangiomas, and 484 metastases. We proposed a class-wise combination of MixUp and AugMix DAs by applying them at different rates for each class. For the major classes, cyst and metastasis, MixUp and AugMix are applied at an equal ratio of 50% each, while for the minor class, hemangioma, the rate is adjusted to 75% MixUp and 25% AugMix. We trained a VGG-16 network on these augmented training images to classify FLLs. To evaluate the effectiveness of our method in class imbalance learning, we assessed the accuracy, F1 score, sensitivity, and specificity and analyzed the t-SNE feature distribution of the classification results.

#### **RESULTS**

Our performance evaluation and feature distribution analysis showed that MixUp improved the sensitivity of the major classes by augmenting the data in the boundary area between classes, while AugMix enhanced the sensitivity of the minor class by augmenting the data within the class itself. By applying these two DAs in different ratios for each class, our method improved the F1 score and the sensitivity for cyst and hemangioma compared to using MixUp and AugMix alone.

#### **CONCLUSION**

We observed that MixUp and AugMix had different effects on each class within the class imbalanced dataset for FLL classification in CT images. By applying these two DAs at different ratios for each class, our method enhanced the learning efficiency for both major and minor classes in class imbalance learning. (This work was supported by the National Research Foundation of Korea Grant funded by the Korea government (No. RS-2023-00207947))

#### **CLINICAL RELEVANCE/APPLICATION**

Our proposed method can be applied to various medical image analysis tasks to enhance learning efficiency by utilizing multiple DA methods.

## **T5B-SPPH-8 Evaluation of Extracellular Volume Changes using Conductivity Tensor Imaging**

### **PURPOSE**

Changes in extracellular volume (ECV) could be an effective biomarker of a disease state, such as fibrosis, edema, and cell swelling. Conductivity tensor imaging (CTI) using MRI has been developed to improve the limitations of existing MR-based conductivity imaging. Without injecting currents into the imaging object, CTI utilizes information on intracellular and extracellular compartments to produce both low-frequency and high-frequency conductivity images. The ECV fraction is one of the parameters that needs to be measured in CTI. In addition, it would have clinical utility if it can be measured reliably. The purpose of this study was to experimentally verify CTI parameters, with a specific focus on ECV fraction, by using a phantom with position-dependent ECV fractions.

### **METHODS AND MATERIALS**

Giant vesicle suspension (GVS) was prepared using the reverse phase method. An acrylic phantom was used for the CTI imaging experiment. The changes in ECV were controlled by the GVS chambers with four different densities: electrolyte only and low (GVS #1), middle (GVS #2), and high (GVS #3) densities of GVS. The CTI experiment was performed using a 9.4T MR scanner with a single-channel body coil. A multi-echo spin-echo MR pulse sequence was applied to the phantom to acquire B1 phase maps to reconstruct high-frequency conductivity (sH) images. The single-shot spin-echo echo-planar imaging sequence was used for multi-b-value diffusion-weighted imaging

### **RESULTS**

Figure 1 shows the CTI parameters obtained from the imaging experiment of the GVS phantom. MR image shows the morphology of the phantom. The signal intensity was found to be highest in the chamber with electrolyte only, but there was no clear difference in signal intensity between the chambers with different GVS densities. The sH image did not show a clear difference in terms of contrast between the four different densities of GVS. However,  $a$ ,  $d_{\text{ew}}$ , and  $sL$  all showed clear differences in contrast depending on the densities of GVS. Specifically, the contrast of these parameters was decreased as the density of GVS increased. Meanwhile, the contrast of  $d_{\text{iw}}$  was slightly increased with increasing of GVS density. There was no contrast in the chamber of electrolyte only due to the absence of GVS.

### **CONCLUSION**

The ECV fraction is a key parameter for measuring CTI because the electrolytes inside and outside of the giant vesicle have similar ionic concentrations. As the vesicle density increased, the ECV decreased, resulting in decreased low-frequency conductivity.

### **CLINICAL RELEVANCE/APPLICATION**

Changes in the extracellular space can be indicators of disease progression, such as fibrosis, edema, and cell swelling. CTI can provide information about changes in the extracellular space, such as the ECV fraction.

## **T5B-SPPH-9 Explore the Influence of Different Strength of Iterative Reconstruction on Image Quality: A Comparative Volume Model Experiment**

### **PURPOSE**

To explore the influence of different strength of adaptive statistical iterative reconstruction Veo (ASiR-V) for image resolution and noise using Japanese Industry Standards Phantom (JIS Phantom) on GE Revolution APEX.

### **METHODS AND MATERIALS**

No GSI scanning experiments were performed on JIS phantom based on GE Revolution APEX CT. The image spatial/density resolution parts of the phantom were selected for the comparative study of different reconstruction algorithms. The scan tube voltage was 120kV, the speed was 0.5s, the detector width was 80mm, the helical pitch was 0.992, and the layer thickness was 0.625mm. The scanning dose is 11.5 (CTDIvol, mGy). Reconstruction was performed using with different ASiR-V weights (0%, 30%, 60% and 90%). For the image spatial resolution/density resolution parts of the body model, AdvancedWorkstation 4.7 (GE Healthcare) were used for objective assessment (SD) and subjective scoring (5-point scale for noise and resolution, respectively, with 1 being the worst, 5 being the best, and 3 or more being used for diagnosis) with  $P < 0.05$  considered as statistically significant difference.

### **RESULTS**

The SD of the different strength of ASiR-V were (18.30±1.79, 14.98±1.48, 11.37±1.21, 8.07±0.98)HU for ASiR-V 0, 30, 60 and 90%, with significant differences between the groups ( $p < 0.05$ ). The image spatial resolution score of (3,3,2,2); The image density resolution score of (3,3,3,2); The subjective scores of noise of (2,2,3,4). From the subjective results, the image resolution decreased with increasing weight of ASiR-V. Subjective and objective assessments both showed that noise decreased with increasing weight of ASiR-V. When the ASiR-V rises to 90%, the spatial resolution and the density resolution decreased. When ASiR-V 60, It can effectively reduce the noise while maintaining the resolution. The ASiR-V 60 image quality is significantly better than other reconstruction algorithms.

### **CONCLUSION**

In the non-spectral scan of Revolution APEX CT, 60% ASiR-V performs the best in image quality (resolution and noise).

### **CLINICAL RELEVANCE/APPLICATION**

The images obtained with 60% ASiR-V are more advantageous than the different ASiR-V weights (0%,30%, 90%), especially to effectively reduce the noise while maintaining the image resolution, providing a wider range of clinical application scenarios.

#### T5B-SPRO-1 Models for Assessing Postoperative Risk Factors in Patients with Cervical Cancer

##### PURPOSE

To develop and evaluate the nomogram models based on clinical parameters, inflammatory indicators, intravoxel incoherent motion diffusion weighted imaging (IVIM-DWI) and MRI-radiomics that assist in the assessment of parametrial infiltration (PI), lymph node metastasis(LNM), deep myometrial invasion (DMI), lymphovascular space invasion(LVSI), type of pathology, degree of differentiation and Ki-67 expression levels in cervical cancer patients accurately before the operation.

##### METHODS AND MATERIALS

Between December 2016 and December 2022, a total of 180 cervical cancer patients operated at our hospital and continuously followed-up were enrolled and randomly divided into a training cohort (n=120) and a validation cohort(n=60). The parameters of IVIM-DWI (ADC, D, D\* and f) and radiomics features were extracted from the pretreatment axial T2WI and sagittal LAVA-FLEX sequences for each patient. Logistic regression with the least absolute shrinkage and selection operator (LASSO) penalty was applied to select key features and construct radiomic score (Rad-score). Multivariate logistic regression analysis was used to develop the nomogram models for predicting pathology outcomes preoperatively in cervical cancer patients and then the models were validated internally and externally.

##### RESULTS

The diagnostic efficacy of the combined models incorporating clinical and imaging parameters was significantly better than the MRI alone. The AUCs of the combined model and MRI were 0.981 vs 0.868, 0.848 vs 0.639 and 0.896 vs 0.780 for the assessment of parametrial infiltration (PI), lymph node metastasis (LNM) and deep muscular invasion (DMI), respectively. Moreover, The combined model based on the clinical and imaging parameters performed equally well in assessing lymphovascular space invasion (LVSI), type of pathology, degree of differentiation and Ki-67 expression levels, with AUCs of 0.796, 0.854, 0.806 and 0.839; 0.840, 0.856, 0.810 and 0.832 in the training and validation sets respectively.

##### CONCLUSION

The nomogram models based on clinical and imaging parameters outperformed MRI in preoperative risk assessment in patients with cervical cancer and can be used as early biomarkers for predicting preoperative pathology outcomes, which can facilitate further clinical decision-making.

##### CLINICAL RELEVANCE/APPLICATION

The nomogram models based on clinical and imaging parameters can be used as early biomarkers for predicting preoperative pathology outcomes, which can facilitate further clinical decision-making.

#### **T5B-SPVA-1 Comparison of 4D Flow MRI-derived Aortic Flow Profiles in Patients with Abdominal Aortic Aneurysms below and above Intervention Threshold**

##### **PURPOSE**

To compare 4D flow MRI-derived aortic flow profiles in patients with abdominal aortic aneurysms (AAA) below and above intervention threshold.

##### **METHODS AND MATERIALS**

We prospectively performed 4D flow MRI of the abdominal aorta at 3T in 22 male AAA patients (72±9 years). Maximum aneurysm diameters were assessed using non-contrast 3D MR angiography. Based on the threshold for intervention, patients were divided into two groups: patients under surveillance with aortic diameters <5.5 cm (n=11) and ii) patients with diameters ≥5.5 cm with indication for therapeutic intervention (n=11). 4D flow MRI-derived flow rates and velocities were determined at the level of the maximum aneurysm diameter. Presence or absence of vortical flow in the infrarenal aorta was evaluated using a 3-point scale (0: no vortex, 1: local vortex, 2: global vortex). Data were statistically compared using unpaired Mann-Whitney U tests.

##### **RESULTS**

Mean AAA diameters of patients above intervention threshold were significantly higher as compared to patients under surveillance (4.3±0.7 cm vs. 5.8±0.5, p<0.001). Peak flow rate was significantly higher in patients above intervention threshold when compared to patients under surveillance (165±40ml vs. 108±37, p<0.05). Forward and backward stroke volume of patients above intervention threshold were also significantly higher as compared to patients under surveillance (50 ±18 ml vs. 30±16 ml and -16±8 vs. -10±0.9 ml, both p<0.008). Pathological vortical flow patterns were present in all (11/11) patients (100%) above surgical threshold as compared to 6/11 patients (55%) under surveillance, resulting in average vortical flow ratings of 1.5±0.5 vs. 0.9±1.0.

##### **CONCLUSION**

s Quantitative and qualitative 4D flow MRI-derived blood flow profiles are significantly altered in AAA patients above intervention threshold when compared to AAA patients under surveillance.

##### **CLINICAL RELEVANCE/APPLICATION**

Our 4D flow MRI study revealed in about half of the patients under surveillance pathological flow profiles, warranting to investigate if these pathological flow profiles may serve an imaging biomarker to predict future aortic dilation.

#### **T5B-SPVA-2 Micro-vascularity of the Feet and Toes using Non-contrast MR Perfusion**

Participants

Mitsue Miyazaki, PhD, La Jolla, CA (*Presenter*) Nothing to Disclose

##### **PURPOSE**

To develop novel non-contrast 3D MR perfusion techniques for assessing micro-vascularity of the feet and toes in human subjects.

##### **METHODS AND MATERIALS**

All experiments were performed on a clinical 3T scanner using non-contrast MR perfusion using arterial spin labeling (ASL). Seven healthy subjects (30 to 72 years old, 5 males and 2 females) were enrolled and bilateral feet were imaged with tag-on and tag-off alternating inversion recovery spin labeling for determining perfusion in micro-vascularity. We compared an ASL technique with 1-tag pulse against 4-tag pulses. For perfusion, we determined signal increase ratio (SIR) at varying inversion times (TI) from 0.5 to 2 sec. SIR versus TI data were fit to determine perfusion metrics of peak height (PH), time to peak (TTP), mean transit time (MTT), apparent blood volume (aBV) and apparent blood flow (aBF) in the distal foot and individual toes. Using analysis of variance (ANOVA), effects of tag pulse and ROI on the mean perfusion metrics were assessed.

##### **RESULTS**

Using MR perfusion techniques, SIR versus TI data showed well-defined leading and trailing edges, with a peak near TI of 0.75 to 1.0 sec and subsiding quickly to near zero by TI of 2 sec, particularly when 4-tag pulses were used. In our normal subjects imaged with 1-tag pulse, the overall (of all ROIs and subjects) mean ± standard deviation values of PH, TTP, MTT, aBV, and aBF were 6.5±4.5%, 0.65±0.26 sec, 0.60±0.23 sec, 8.4±4.6 %·sec, and 15.0±9.0 %, respectively. When imaged with 4-tag pulse sequence, we found a significantly greater values in PH (13.4±7.3 %, p<0.00001), TTP (0.60±0.25 sec, p=0.005), aBV (13.7±6.3 %·sec, p<0.00001), and aBF (25.4±16.1 %, p=0.008).

##### **CONCLUSION**

s Feasibility of MR perfusion imaging of the distal foot was studied, and advantages of the 4-tag pulse technique were studied, showing greater SIR and perfusion metrics compared to 1-tag pulse technique. This will likely benefit those with low perfusion due

to aging or diseases such as PAD and diabetic foot.

**CLINICAL RELEVANCE/APPLICATION**

Our study demonstrated the feasibility of a novel application of a 3D ASL technique for the feet and toes, with a greater possibility of evaluation of diabetic foot.

#### W2-SPBR-1 Differentiation of Benign and Malignant Breast Lesions Using Diffusion-Weighted Imaging with a Fractional Order Calculus Model

##### PURPOSE

Purpose: The purpose of this study is to demonstrate the efficacy of a new set of parameters ( $D$ ,  $\beta$ , and  $\mu$ ) obtained from a fractional order calculus (FROC) diffusion model in improving the accuracy of differentiating between benign and malignant breast lesions.

##### METHODS AND MATERIALS

Materials and Methods: A total of 103 patients were recruited, and MR measurements were performed using a 3-T MR scanner (uMR790, United Imaging Healthcare, Shanghai, China). The MRI protocol included T2WI, contrast-enhanced T1WI, and DWI with 12  $b$  values (0, 50, 100, 200, 400, 600, 800, 1200, 1600, 2000, 2500, and 3000  $s/mm^2$ ). FROC-DWI derived metrics were calculated using a fitting formula previously reported. The metrics were then statistically compared between two subgroups with the Mann-Whitney U test, and receiver operating characteristic (ROC) analysis was performed to assess the performance of individual parameters in diagnosing malignant breast lesions.

##### RESULTS

Results: The statistical results of each FROC-derived metric were shown in Table 1, with  $D$  and  $\beta$  values significantly lower in malignant lesions than in benign lesions ( $P < 0.001$ ), and  $\mu$  values significantly higher in malignant lesions than in benign lesions ( $P < 0.001$ ). The AUCs of  $D$ ,  $\beta$ , and  $\mu$  for diagnosing malignant lesions were 0.84, 0.79, and 0.77, respectively, with  $D$  showing significantly higher AUC than  $\beta$  and  $\mu$ . The combination of  $D$  and  $\beta$  values exhibited better diagnostic efficiency than individual parameters in differentiating benign from malignant lesions (AUC: 0.86, 95% CI 0.77-0.92, sensitivity: 93.88%, specificity: 68.52%) (Fig 1).

##### CONCLUSION

Conclusion: In conclusion, this study demonstrates the feasibility of using FROC-derived diffusion parameters to differentiate between benign and malignant breast lesions, with  $D$ ,  $\beta$ , and  $\mu$  showing significant differences between the two subgroups. The combination of  $D$  and  $\beta$  values resulted in the highest diagnostic accuracy in terms of AUC for predicting malignancy.

##### CLINICAL RELEVANCE/APPLICATION

This study demonstrates the efficacy of a new set of parameters ( $D$ ,  $\beta$ , and  $\mu$ ) obtained from a fractional order calculus (FROC) diffusion model in improving the accuracy of differentiating between benign and malignant breast lesions.

#### W2-SPBR-2 Preoperative Diagnosis of Multifocal, Multicentric and Contralateral Breast Cancer: Additional Benefit of Diffusion-Weighted Magnetic Resonance Imaging

##### Participants

HAJUNG KIM, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the diagnostic performance of dynamic contrast enhanced (DCE) MRI and diffusion weighted (DW) MRI, named multi-parametric MRI, for the diagnosis of multifocal, multicentric and contralateral breast cancer in patients with newly diagnosed breast cancer.

##### METHODS AND MATERIALS

Between June 2019 to June 2021, our database search identified consecutive women who were diagnosed with invasive breast cancer, underwent MRI, and had at least one DCE MRI detected additional lesion. Two experienced breast radiologists retrospectively measured apparent diffusion coefficient (ADC) values. A BI-RADS category = 4 was considered positive result. The reference standard was histopathology or 1-year follow-up. The ADC cut-off for differentiation between benign and malignant lesions was calculated and performance measures of DCE MRI alone and multi-parametric MRI were compared. In addition, we validated ADC value of  $1.3 \times 10^{-3} mm^2/s$ , recommended by the European Society of Breast Radiology (EUSOBI) guideline.

##### RESULTS

Among finally included 219 patients (mean age, 50.9 years) with 298 lesions, 169 (57%) were benign (mean size, 1.4cm) and 129 (43%) were malignant (mean size, 1.7cm). There were 45 masses (27%) and 124 nonmass (73%) among benign lesions and 33 (26%) masses and 76 (74%) nonmass among malignant lesions. The median ADC of benign lesion was  $1.23 \times 10^{-3} mm^2/s$  and median ADC of malignant lesion was  $0.88 \times 10^{-3} mm^2/s$  ( $P < .001$ ). The best ADC cut-off to differentiate benign from malignant lesions determined using ROC-curve was  $1.0 \times 10^{-3} mm^2/s$ , which yielded sensitivity of 74.4% and specificity of 76.9%. The area under the ROC curve was 0.80 (95% CI: 0.75-0.86). With DCE MRI alone, sensitivity was 98.5% (127 of 129, 95% CI: 96.3, 100.0),

specificity was 29.6% (50 of 169, 95% CI: 22.7, 36.5) and accuracy was 59.4% (177 of 298, 95% CI: 53.8, 64.9). In comparison, multi-parametric MRI showed decreased sensitivity of 75.2% (97 of 129, 95% CI: 67.7, 82.6;  $P = .01$ ), but improved specificity of 76.3% (129 of 169, 95% CI: 69.9, 82.7;  $P < .001$ ) and accuracy of 75.8% (226 of 298, 95% CI: 70.9, 80.7;  $P < .001$ ). With ADC value of  $1.3 \times 10^{-3}$  mm<sup>2</sup>/s, sensitivity of 96.2% (124 of 129; 95% CI: 92.8, 99.4), specificity of 38.5% (65 of 169, 95% CI: 31.1, 45.8) and accuracy of 63.4% (189 of 298, 95% CI: 57.9, 68.9) were observed.

## CONCLUSION

s Multi-parametric MRI can increase the specificity and maximize accuracy of DCE MRI detected additional lesions in patients with newly diagnosed breast cancer.

## CLINICAL RELEVANCE/APPLICATION

In patients with newly diagnosed breast cancer, multi-parametric MRI with implementation of DW MRI can help increase specificity and accuracy of DCE MRI detected additional lesions.

### W2-SPBR-3 The Application Value of Synthetic MRI in the Diagnosis of BI-RADS 4 Breast Lesions

Participants

Hua He, MMedSc, Yinchuan, China (*Presenter*) Nothing to Disclose

## PURPOSE

In recent years, quantitative research on T1 and T2 relaxation time in breast MRI has become a hot topic in breast imaging. Synthetic MRI (syMRI) can simultaneously obtain quantitative T1, T2 relaxation times, and proton density (PD), and provide quantitative indicators for distinguishing benign and malignant breast lesions. However, the diagnostic efficacy of this technology in BI-RADS 4 lesions is still unclear. This study aims to explore the application value of synthetic MRI imaging technology in the diagnosis of BI-RADS 4 solid lesions by comparing the relaxation time of benign and malignant breast lesions.

## METHODS AND MATERIALS

Retrospectively analyzed 79 patients with BI-RADS 4 solid lesions confirmed by biopsy or surgery, including 56 malignant and 23 benign lesions. Preoperative breast MRI T1WI, T2WI, DWI, DISCO enhancement, and MAGIC examination were performed. The relaxation values and standard deviation (SD) of T1, T2, PD, R1, and R2 were measured for each lesion. Independent-samples t-test (normal distribution data) or Mann-Whitney U test (skewed distribution data) was used to compare the differences in MAGIC parameters between benign and malignant lesions. The receiver operating characteristic (ROC) curves were used to evaluate the diagnostic value of statistically significant parameters for BI-RADS 4 lesions.

## RESULTS

The SD of T2 and T2 values of malignant BI-RADS 4 lesions were lower than those of benign lesions, and the R2 value was higher than that of benign lesions, with statistically significant differences ( $P < 0.05$ ). There was no statistically significant difference in T1, PD, R1 values and their SD values between benign and malignant lesions ( $P > 0.05$ ). The area under the ROC curve (AUC) of T2's SD for distinguishing BI-RADS 4 lesions was 0.703, higher than that of T2 values (AUC=0.659) and R2 (AUC=0.654).

## CONCLUSION

s This study also showed that the quantitative relaxation time values of T2, T2's SD, and R2 provided by SyMRI have good reproducibility among different observers and the same observer, which can serve as effective indicators for long-term follow-up studies or multi-center studies of BI-RADS 4 lesions.

## CLINICAL RELEVANCE/APPLICATION

This study used SyMRI for imaging and preoperative quantitative diagnosis of BI-RADS 4 breast lesions, and the MAGIC sequence could obtain five quantitative spectra and multiple contrast images in one scan, which met the requirements of routine clinical morphological evaluation and tissue quantitative diagnosis. This approach significantly shortened the examination time for patients and is suitable for routine clinical examination promotion.

### W2-SPBR-4 The Value of Different Delineation Methods for the Region of Interest in SyMRI and DWI Quantitative Discrimination Diagnosis: Providing Support for Standardized Measurement Schemes of Breast Lesions

Participants

Zhijun Wang, MMedSc, Yinchuan, China (*Presenter*) Nothing to Disclose

## PURPOSE

Breast cancer is a highly heterogeneous disease, and different region of interest (ROI) selection methods may affect the measurement results of quantitative parameters. This study aims to explore the diagnostic value of three different ROI delineation methods in measuring SyMRI and DWI quantitative parameters for discriminating between benign and malignant breast lesion types.

## METHODS AND MATERIALS

122 patients diagnosed with mass lesions by breast MRI received routine MRI and SyMRI examination before surgery. Two physicians used three ROI delineation methods: whole-volume method, maximum layer method, and tumor-enhancing region method. The first physician repeated the measurements one month later. The inter-class correlation coefficient (ICC) was calculated to evaluate the reproducibility of the measurement results. The differences in various parameters between benign and malignant breast lesions were compared, and the receiver operating characteristic (ROC) curve was used to evaluate the diagnostic efficacy of SyMRI, DWI, and the combination of the two for differentiating benign and malignant lesions. The comparison of AUCs was performed using the Delong test.

## RESULTS

The ADC values, T1 values, T2 values, and PD values measured by the same radiologist twice and by different radiologists had good repeatability (ICC range: 0.929-0.992) using different ROI delineation methods. Multivariate logistic regression analysis indicated that ADC<sub>local</sub>, T2<sub>tumor</sub>, and PD<sub>local</sub> were independent predictors of breast cancer, with odds ratios (ORs) of 0.001, 0.917, and 1.267, respectively, and P-values of 0.013, 0.039, and 0.043, respectively. The ROC curve analysis showed that the ADC<sub>local</sub> +

T2tumor + PDlocal had the highest AUC (0.953) for discriminating between benign and malignant breast lesion types, with a sensitivity of 95.2%, a specificity of 84.2%, an accuracy of 91.0%, a positive predictive value of 93.0%, and a negative predictive value of 88.8%. There was no statistically significant difference in the diagnostic performance between ADClocal + T2tumor + PDlocal and ADClocal alone (AUCs of 0.953 and 0.942, respectively,  $P=0.143$ ).

## CONCLUSION

s Different measurement methods for the region of interest in SyMRI and DWI sequences will affect the quantitative diagnosis results of breast lesions. ADClocal, T2tumor, and PDlocal are independent predictors of breast cancer, and the multi-parameter combined diagnostic model (ADClocal+T2tumor+PDlocal) has the highest diagnostic performance for discriminating between benign and malignant breast lesion types.

## CLINICAL RELEVANCE/APPLICATION

The results of this study provide a theoretical basis for standardizing the measurement scheme of the region of interest for breast lesion assessment.

### **W2-SPBR-5 Multiparametric MRI Model with Synthetic MRI, DWI Multi-quantitative Parameters and Differential Sub-sampling with Cartesian Ordering (DISCO) Enables BI-RADS 4 Lesions Diagnosis with High Accuracy**

Participants  
Zhijun Wang, MMedSc, Yinchuan, China (*Presenter*) Nothing to Disclose

## PURPOSE

In the 5th edition of the Breast Imaging Reporting and Data System (BI-RADS), BI-RADS4 lesions are considered suspicious for malignancy, with a wide range of malignant transformation and malignancy ranging from 2% to 95%, and clinical doctors are advised to perform biopsy or surgical resection. The accuracy of conventional MRI using morphological features and TIC for diagnosis is low, leading to unnecessary invasive treatments for some benign lesions, which increases the economic and psychological burden on patients. This study aims to observe the value of synthetic MRI combined with diffusion-weighted imaging (DWI) and DISCO-enhanced imaging for distinguishing between benign and malignant BI-RADS4 lesions.

## METHODS AND MATERIALS

A retrospective analysis was conducted on 79 cases of breast tumors confirmed by biopsy or surgical pathology, with a total of 89 BI-RADS4 lesions diagnosed by preoperative breast synthetic MRI (using MAGIC technology), DWI, and DISCO-enhanced imaging, including 63 malignant lesions (malignant group) and 26 benign lesions (benign group). The differences in MAGIC parameters, apparent diffusion coefficients (ADC), DISCO-enhanced imaging morphological characteristics, and time-intensity curves (TIC) were compared between the groups. Logistic regression analysis and receiver operating characteristic (ROC) curve were used to evaluate the efficacy of MAGIC, DWI, DISCO-enhanced parameters, and the combination of the three in distinguishing between benign and malignant BI-RADS4 lesions.

## RESULTS

There were significant differences in lesion morphology, internal enhancement features, TIC, ADC, T2, and R2 values between the groups (all  $P<0.05$ ), while the difference in other parameters was not statistically significant (all  $P>0.05$ ). After logistic regression analysis, among the relevant parameters, ADC had the highest efficacy in distinguishing between benign and malignant BI-RADS4 lesions, with an area under the curve (AUC) of 0.845; while the MAGIC+ADC+DISCO model had the highest diagnostic efficacy, with an AUC of 0.908.

## CONCLUSION

s SynMRI combined with DWI and DISCO-enhanced imaging have a certain value for distinguishing between benign and malignant BI-RADS4 lesions, and the diagnostic efficacy is better when the three are combined.

## CLINICAL RELEVANCE/APPLICATION

The application of MAGIC, DWI, and DISCO-enhanced quantitative parameters for preoperative quantitative diagnosis of BI-RADS4 breast lesions can significantly improve the diagnostic efficacy of benign and malignant lesions and reduce the probability of unnecessary surgery in benign patients.

### **W2-SPBR-6 MR Imaging Features Associated with High and Low Expression of Tumor-Infiltrating Lymphocytes: Stratified Analysis According to Molecular Subtypes**

Participants  
Jiejie Zhou, PhD, MD, Wenzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

It is known that the expression of tumor-infiltrating lymphocytes (TILs) is different in different molecular subtypes of breast cancer (BC); and thus, the studies analyzing the mixed subtypes would be heavily dependent on the composition of subtypes, and the obtained results are not generalizable. To investigate the association of MRI features with TILs and subtypes, three analyses were performed: (1) Comparison of the rate of high vs. low TILs in 3 subtypes: Hormonal-Receptor positive, HER2 negative (HR+/HER2-), HER2 positive (HER2+), and Triple negative (TN); (2) Comparison of the MR imaging features among 3 subtypes; (3) In each subtype, the comparison of imaging features between high vs. low TILs cases.

## METHODS AND MATERIALS

A total of 457 patients with pathologically diagnosed BC were included in this study. Breast MRI with 3.0 T scanner was performed, including T2, DWI, and DCE-MRI. The expression of TILs was evaluated on HE-stained slides according to the recommendations by an International TILs Working Group 2014. The percentage of TILs in the stroma adjacent to the tumor cells was assessed, stratified as low ( $< 10\%$ ) and high ( $= 10\%$ ). MRI features, including morphology as mass or non-mass enhancement (NME), shape, margin, internal enhancement, peritumoral edema, and the DCE kinetic pattern were assessed and compared between groups.

## RESULTS

Of the 241 HR+/HER2- cases, 82% had low TILs, and only 18% had high TILs. There were 134 HER2+ cases, 63% low TILs and 37% high TILs. Of the 82 TN, 56% had low TILs and 44% had high TILs. The composition of high TILs was significantly increased from HR+ to HER2+ to TN ( $p < 0.001$ ). For MRI features among the 3 subtypes (Table 1), the size was smaller for HR+/HER2- ( $p < 0.001$ ); HER2+ was more likely to present as NME ( $p = 0.031$ ); homogeneous enhancement was more seen in HR+ ( $p < 0.001$ ); and the peritumoral edema was present in 45% HR+, 71% HER2+, and 80% TN ( $p < 0.001$ ). The MRI features between low and high TILs in each subtype are listed in Table 2. In HR+/HER2-, the peritumoral edema was more likely to be present in high TILs (70%) than in low TILs (40%,  $p < 0.001$ ). In TN, high TILs were more like to present a regular shape (33%) than low TILs (13%,  $p = 0.029$ ); and more like to present the circumscribed margin (19%) than low TILs (2%,  $p = 0.009$ ).

## CONCLUSION

s HER2+ and TN cancers have significantly higher TILs compared to HR+ cancers. In HR+, high TILs cases were more likely to present peritumoral edema. In TN, high TILs cases were more likely to present regular shapes and circumscribed margins.

## CLINICAL RELEVANCE/APPLICATION

TILs expression increases from HR+ to HER2+ to TN. MRI features in different molecular subtypes show substantial variations. When building MR radiomics models to predict TILs, different models should be built for different subtypes.

## W2-SPBR-7 Interpretation of Unenhanced Breast MRI with Diffusion-Weighted Imaging for Breast Cancer Detection: Effect of Training on the Performance and Agreement of Radiologists

Participants

Su Min Ha, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate whether training improves the performance and agreement of radiologists interpreting unenhanced breast magnetic resonance imaging (MRI) with diffusion-weighted imaging (DWI).

## METHODS AND MATERIALS

A reader study of 96 breasts (35 screening-detected cancer cases and 61 benign or negative cancer cases) of 48 asymptomatic women was performed. High-resolution DWI (in-plane resolution  $< 1.3 \times 1.3$  mm) was performed using a 3.0-T system and b values of 0, 800, and 1200 sec/mm<sup>2</sup>. Sixteen breast radiologists independently reviewed DWI, apparent diffusion coefficient maps, and T1-weighted MRI and recorded the Breast Imaging Reporting and Data System (BI-RADS) assessment category for each breast. After a 2-hour training session and 5-month washout period, they re-evaluated the BI-RADS assessment categories. A BI-RADS category of 4 or more was considered a positive reading. The diagnostic performance of each reader for each breast during the first review and that during the second review were compared. Inter-reader agreement regarding the final assessment was evaluated using a multi-rater  $\kappa$  analysis.

## RESULTS

Before training, the mean sensitivity, specificity, and accuracy of 16 readers who performed unenhanced MRI assessments were 70.7% (95% confidence interval [CI]: 59.4-79.9), 90.8% (95% CI: 85.1-94.2), and 83.5% (95% CI: 78.6-87.4), respectively. After training, significant improvements in specificity (95.2%; 95% CI: 90.8-97.5;  $P = 0.001$ ) and accuracy (85.9%; 95% CI: 80.9-89.8;  $P < 0.001$ ) were observed, but no difference in sensitivity (69.8%; 95% CI: 58.1-79.4;  $P = 0.58$ ) was observed. Regarding inter-reader agreement, the  $\kappa$  values were 0.57 (95% CI: 0.52-0.63) before training and 0.68 (95% CI: 0.62-0.74) after training, with a difference of 0.10 (95% CI: 0.02-0.18), which was statistically significant ( $P = 0.01$ ).

## CONCLUSION

s Minimal training improved the performance and agreement of interpretations by radiologists using unenhanced MRI with DWI.

## CLINICAL RELEVANCE/APPLICATION

To use DWI as an effective screening tool, besides the need for standardization of DWI acquisition, training for standardized interpretation is required.

## W2-SPBR-8 Standardizing Qualitative and Quantitative Breast Parenchymal Enhancement Assessment in Breast MRI

Participants

Gustav Mueller-Franzes, MSc, Aachen, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

Despite being a crucial research focus in the field of breast cancer studies, Background Parenchymal Enhancement (BPE) lacks standardized qualitative and quantitative assessments, which poses an obstacle in its evaluation as a breast cancer risk marker. The purpose of this study was to examine the relationship between and to compare qualitative and quantitative assessments of BPE.

## METHODS AND MATERIALS

In this retrospective study of 5773 breast MRI examinations from 3207 women acquired between January 2010 and December 2019, the BPE was rated as part of the clinical routine as minimal, mild, moderate, and strong following the ACR BI-RADS guidelines. For the quantitative assessment of BPE, the fibroglandular tissue (FGT) was segmented in the pre- and post-contrast T1-weighted sequences. Four quantitative BPE calculation methods were identified as most commonly used by previous studies and were applied to the given dataset. Correlation and agreement between qualitative and quantitative assessments were calculated using the Spearman correlation ( $r$ ) coefficient.

## RESULTS

The mean age of the patients was 60 years  $\pm$  10 [SD] and the average volumetric fraction of FGT to the full breast was 17%  $\pm$  12 [SD]. Radiologists rated the BPE in 3787 (66%) of the examinations as minimal, 1380 (24%) as mild, 543 (9%) as moderate, and 63 (1%) as marked. Among the four quantitative BPE definitions tested, the definition that measured the relative difference in the

signal intensity before and after contrast agent injection had the highest correlation to human rating with  $r=0.56$ . The lowest correlation ( $r=0.50$ ) to expert radiologists was found for the BPE definition that measured the ratio of the enhancing FGT volume to the entire breast volume.

## CONCLUSION

The agreement between qualitative and quantitative BPE assessments was found to be, at most, fair. Further studies are needed to investigate the consequences of differences between qualitative and quantitative assessment as well as the differences among quantitative definitions on the prognostic value as a diagnostic marker for breast cancer and treatment response.

## CLINICAL RELEVANCE/APPLICATION

Given the at most fair agreement between qualitative and four quantitative assessments of BPE demonstrated in our study, and the known relation between BPE and breast cancer risk, it is essential to further research the relation between breast cancer risk and quantitative BPE measurements.

## W2-SPBR-9 Optimising Axillary Management following Neoadjuvant Chemotherapy in Patients with Breast Cancer

Participants

Anum Pervez, MBBS, FRCR, BSc, London, United Kingdom (*Presenter*) Nothing to Disclose

## PURPOSE

Optimal management of the axilla in breast cancer following neoadjuvant chemotherapy (NAC) remains uncertain. Current practice at our institution is dictated by the initial nodal burden. For N1 disease (=3 nodes), a sentinel lymph node biopsy (SLNB) is performed and in N2 disease (=4 nodes) patients proceed to an immediate axillary nodal clearance (ANC). However, this pathway fails to take into account response to NAC. If there is node normalization on the post-treatment MRI, an ANC is arguably overtreatment. Whereas, an SLNB becomes undertreatment in cases of limited MRI response as patients undergo a second stage completion ANC. In this study, we examine the predictive role of the post-treatment MRI. We also investigate the importance of HER-2 status and how, in combination with the post-treatment MRI, it can offer a more tailored approach.

## METHODS AND MATERIALS

A retrospective analysis was performed on NAC patients between 2017-2022. Ultrasound guided-core biopsy confirmed axillary nodal involvement, along with the tumor HER-2 status. The baseline MRI was reviewed with registration of number of abnormal nodes, followed by the post-treatment MRI and surgical histopathology.

## RESULTS

148 patients identified with node positive axillary disease prior to NAC, of which 54 were HER-2 positive. 103 (70%) had node normalization on imaging. The post-treatment MRI demonstrated 86% specificity and 42% sensitivity. MRI also showed 82% positive predictive value (PPV) but 50% negative predictive value (NPV) for residual axillary disease. Of the HER-2 positive patients, 44 (81%) had node normalization on imaging with 28/44 (63%) complete pathological response at surgery. In particular, in N2 disease and node normalization ( $n=12$ ), 67% were HER-2 positive. Hence HER-2 positive patients are more likely to respond to NAC, irrespective of initial nodal burden. In our study, 22 patients with N1 disease could have undergone an immediate ANC rather than a two-stage completion ANC. Whereas 12 patients with N2 disease could have avoided an ANC all together.

## CONCLUSION

We have established high specificity and PPV of the post-treatment MRI. Thus, a core biopsy should be offered for initial N1 status and residual axillary disease, with a positive result leading to an immediate ANC rather than the traditional SLNB. In addition to this, consideration should be given to de-escalating axillary treatment with an SLNB rather than an immediate ANC in the subset of patients with N2 disease, imaging node normalization and a HER-2 positive status.

## CLINICAL RELEVANCE/APPLICATION

Persistent MRI nodal disease should be a reason to offer a core biopsy, followed by an immediate ANC if positive. Whereas, immediate ANC may be avoided in N2 disease with MRI node normalization and HER-2 positive status.

W2-SPCA

### Cardiac Imaging Wednesday Poster Discussions

#### Sub-Events

#### W2-SPCA-1 Diagnostic Performance of 4D-CT Myocardial Maximum Principal Strain to Detect Reduced Myocardial Viability

##### Participants

Shigeo Okuda, MD, Tokyo, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

A new technique enables to demonstrate myocardial maximum principal strain (MPS) on 4D-CT. The purpose of this study is to evaluate the diagnostic performance of MPS to detect reduced myocardial viability defined by late gadolinium enhancement (LGE) in patients with known coronary artery disease.

##### METHODS AND MATERIALS

A total of 82 patients (63 men, 66.3±9.6 years old) with a history of myocardial infarction were prospectively enrolled in this study at five university hospitals. ECG-synchronized 4D-CT studies were performed with wide-detector scanners (Aquilion ONE, Canon, Japan). Full-cardiac cycle CT data was reconstructed into 20 phases at 5% intervals. The MPS was demonstrated on the color chart of AHA-17 segments excluding the apex (#17) on a workstation (Ziostation 2, Ziosoft, Tokyo, Japan). The LGE was also obtained in cardiac MRI which was performed during the period before or after 3 months of the 4D-CT. On LGE of MRI, the reduced myocardial viability was defined as the segments with a >50% extent of LGE in the myocardial wall. The MPS color charts were independently interpreted by two other readers with more than 10 years-experience of cardiac imaging for detecting segments which had >50% LGE extent on MRI. The readers were provided three sets of MPS chart and MRI LGE for directly comparing between them before blind reading as a training. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy were calculated for detecting segments demonstrating LGE extent with >50% LGE on the 79 patients. The quantitative MPS values were statistically compared between two groups with or without >50% LGE using Mann-Whitney U test.

##### RESULTS

A total of 1264 segments were analyzed, including 316 (25 %) segments with >50% LGE extent. The sensitivity, specificity, accuracy, PPV and NPV averaged between two observers to diagnose segments with >50% of LGE were calculated as follows: 81.0% (256/316), 48.2% (492/948), 35.9% (256/712), 89.1% (492/552), and 59.1% (748/1264), respectively. The agreement of reduced MPS between two readers was 83.9% and kappa coefficient of 0.556 on the presence of >50% LGE extent of myocardial wall. The mean MPS value in segments with preserved viability was significantly higher than one with reduced viability (40.0 ± 15.7 vs. 32.0 ± 13.6, p<0.0001).

##### CONCLUSION

Because of its excellent NPV, the myocardial MPS analysis can be used for detecting viable myocardium with a good agreement between two readers.

##### CLINICAL RELEVANCE/APPLICATION

4D-CT myocardial maximum strain analysis can be a new option to evaluate and quantify myocardial viability particularly in patients with contraindication for cardiac MRI.

#### W2-SPCA-2 Exploring the Impact of Flip Angle and Contrast Agent on Single Breath-hold Cardiac Magnetic Resonance Compressed Sensing Cine for Biventricular Strain Analysis

##### Participants

Fuyan Wang, Hangzhou, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Compressed sensing (CS) cine has been shown to provide comparable images to conventional balanced steady-state free precession (bSSFP) cine. As an important tool for strain analysis, cardiovascular magnetic resonance (CMR) cine-based tissue tracking could reliably detect the displacement of myocardial segments. However, the effects of CS technique on feature tracking (FT) need to be carefully studied. In this study, we aimed to investigate the impact of gadolinium contrast agent and flip angle on biventricular strain analysis of single breath-hold CS cine in patients with different kinds of cardiac dysfunction.

##### METHODS AND MATERIALS

102 participants with 12 different cardiovascular etiologies (75 men, with a mean age of 46.5 ± 17.1 (SD) years) were enrolled in this study. Each patient underwent four consecutive cine sequences with same slice localization, including the reference multi-breath-hold bSSFP (bSSFPref) cine, the single breath-hold CS cine with the same flip angle as bSSFPref before (CS45) and after (eCS45) contrast enhancement, and the CS cine (eCS70) with 70-degree flip angle after contrast agent injection.

## RESULTS

Global strain parameters of both ventricles, including global radial strain (GRS), global circumferential strain (GCS), and global longitudinal strain (GLS), obtained from CS cine were found to be significantly lower than those obtained from bSSFP (all  $p < 0.001$ ). However, the GRS and GCS values of the left ventricle derived from both CS45 and eCS70 cine sequences showed no difference. Similarly, the GRS, GCS, and GLS values of the right ventricle obtained from eCS45 and eCS70 cine sequences showed no significant difference as well. Evaluation of CS45 and eCS45 cine sequences demonstrated that the use of contrast agents can result in a reduction in GRS and GCS values of both ventricles (all  $p < 0.001$ ), but did not have any effect on the GLS values.

## CONCLUSION

Despite the use of contrast agents and increased flip angle, CS cine consistently produced lower values for GRS, GCS, and GLS of both ventricles compared to conventional bSSFP cine. However, the impact of contrast agents on left ventricular GRS and GCS can be compensated by increasing the flip angle of CS cine. In contrast, increasing the flip angle of CS cine did not affect the GRS, GCS, and GLS values of the right ventricle. Furthermore, the administration of contrast agents resulted in a reduction of biventricular GRS and GCS values derived from CS cine.

## CLINICAL RELEVANCE/APPLICATION

Feature tracking based on routine CMR cine could reliably detect the displacement of myocardial segments, however, the effect of drastically increased using compressed sensing cine on strain analysis need to be carefully studied.

## W2-SPCA-3 Single Breath-hold Assessment of Cardiac Function and Strain using a 3-dimensional Cine Enhanced SENSE by Static Outer-volume Subtraction Acquisition

### PURPOSE

To validate the clinical feasibility of a novel 3-dimensional (3D) ultrafast cardiac magnetic resonance (CMR) protocol for the assessment of ventricular function and strain in a single breath-hold.

### METHODS AND MATERIALS

A total of 26 patients were enrolled prospectively, and all patients underwent CMR using both the standard breath-hold 2D cine balanced steady-state free precession acquisition (2D cine bSSFP) and single-breath-hold 3D cine Enhanced sensitivity encoding (SENSE) by Static Outer-volume Subtraction acquisition (3D cine ESSOS). Images of 3D cine were reconstructed and the left ventricular ejection fraction (LVEF), right ventricular ejection fraction (RVEF), global circumferential strain (GCS), global radial strain (GRS) and global longitudinal strain (GLS) of 3D and 2D cine were assessed by post-processing software. The difference and agreement of the two sequences were assessed.

### RESULTS

Two patients could not hold their breath well and the image quality could not satisfy the quantitative analysis. The 3D cine images of the remaining 24 patients were of good quality and allowed quantification. Mean acquisition time was  $23 \pm 1$ s versus  $273 \pm 20$ s for 3D and 2D cine imaging, respectively. LVEF by 3D and 2D cine were 58.27 (95% confidence interval [CI], 50.85 to 61.89) and 59.03 (95% CI, 51.15 to 61.67), respectively, with excellent agreement (intraclass correlation coefficient [ICC]: 0.99, 95% CI, 0.98 to 0.99) and insignificant bias. RVEF by 3D and 2D cine were 52.20 (95% CI, 44.17 to 53.76) and 51.65 (95% CI, 44.93 to 53.72), respectively, with excellent agreement (ICC: 0.83, 95% CI, 0.65 to 0.92) and insignificant bias. GCS by 3D and 2D cine were -15.95 (95% CI, -17.58 to -13.18) and -18.20 (95% CI, -19.60 to -15.30), respectively, with acceptable agreement (ICC: 0.77, 95% CI, 0.54 to 0.89) and insignificant bias. GRS by 3D and 2D cine were 28.20 (95% CI, 21.08 to 31.05) and 31.15 (95% CI, 23.05 to 33.95), respectively, with excellent agreement (ICC: 0.83, 95% CI, 0.64 to 0.92) and insignificant bias. GLS by 3D and 2D cine were -10.4 (95% CI, -13.45 to -6.75) and -16.10 (95% CI, -17.93 to -11.78), respectively, with acceptable agreement (ICC: 0.76, 95% CI, 0.53 to 0.89) and insignificant bias. Although the differences in cardiac function and strain between 2D and 3D cine were statistically significant, their differences were within the clinically acceptable range.

### CONCLUSION

We demonstrate that the image quality of 3D cine is slightly lower than 2D cine, but it can realize the rapid acquisition of cine images and good consistency. 3D cine ensures rapid assessment of cardiac function and strain.

## CLINICAL RELEVANCE/APPLICATION

ESSOS sequence can be used as an examination method for heart disease screening and for patients who cannot tolerate a long examination.

## W2-SPCA-4 Coronary Stent Evaluation by CCTA using Super-Resolution Deep Learning Reconstruction: Compared with Invasive Coronary Angiography

### PURPOSE

To evaluate the impact of a novel super-resolution deep-learning reconstruction (SR-DLR) algorithm on the visible and diagnostic performance of coronary CT angiography (CCTA) in stents evaluation.

### METHODS AND MATERIALS

This retrospective study included 20 patients with 28 coronary stents who underwent CCTA on a 320-row scanner. Raw data were reconstructed with hybrid iterative reconstruction (HIR, AIDR 3D, FC04), DLR (AiCE), and SR-DLR (PIQE). The maximum visible in-stent lumen diameter were measured. CT attenuation profiles across the stents were generated, then the width of the edge rise distance (ERD) and the edge rise slope (ERS) were measured. The diagnostic confidence was evaluated using a 4-point scale (1=poor, 4=excellent). The patency of stent were evaluated and in-stent restenosis was defined as  $\geq 50\%$  stenosis. Invasive coronary angiography served as reference standard.

### RESULTS

SR-DLR images showed the largest in-stent lumen diameters among all reconstruction approaches (all  $P < 0.05$ ). There was no significant difference in the ERD between different reconstruction approaches ( $P = 0.10$ ), but the ERS on SR-DLR images ( $416.05 \pm 135.45$  HU/mm) was greater than that on HIR images ( $170.27 \pm 90.24$  HU/mm;  $P < 0.05$ ) or DLR images ( $195.06 \pm 96.35$

HU/mm;  $P < 0.05$ ). The diagnostic confidence was comparable for SR-DLR and DLR ( $3.70 \pm 0.79$  vs.  $3.60 \pm 0.56$ ,  $P = 0.40$ ), but higher than HIR ( $3.30 \pm 0.65$ , all  $P < 0.05$ ). SR-DLR images provided optimal diagnostic performance in the evaluation of in-stent patency, the diagnostic accuracy were 86.7%, 83.3% and 76.7% for SR-DLR, DLR and HIR images, respectively (all  $p < 0.05$ ).

## CONCLUSION

s Compared with HIR and DLR algorithm, SR-DLR improves the visible and diagnostic performance of CCTA in stents evaluation.

## CLINICAL RELEVANCE/APPLICATION

SR-DLR algorithm improves the diagnostic accuracy and confidence of coronary stent evaluation.

## W2-SPCA-5 Optimizing Residual-Dense Blocks for Myocardial Delayed Enhancement CT Denoising for Future Edge-Based AI

Participants

Takuma Kobayashi, Suita, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

In myocardial delayed enhancement (MDE) CT, post hoc denoising methods using residual-dense networks (RDN)s have been reported to improve diagnostic performance. RDNs maintain hierarchical information and deepen the network using residual-dense blocks (RDBs). Optimization of the number of RDBs for each target task is crucial. This study aimed to determine the effect of the number of RDBs on MDE CT denoising. As the number of blocks was reduced, we evaluated denoising precision, inference time, and image similarity to the reference 20-block (RDB20) image.

## METHODS AND MATERIALS

We retrospectively reviewed 100 consecutive cases who underwent MDE CT. RDNs were trained on a denoising task using pre- and post-additive averaged images as teacher data. We prepared models with 1, 3, 5, 10, and 20 blocks, using RDB20 as a reference. For the hold-out test group (other 40 patients), we performed inference on five models to create denoised images and recorded processing times. We measured CT values and standard deviations (SD) of the blood pool and myocardium, determined image noise and contrast noise ratios for the blood pool and myocardium, and assessed image similarity using structural similarity (SSIM), peak signal to noise ratio (PSNR), learned perceptual image patch similarity (LPIPS), and visual information fidelity (VIF) compared to the reference RDB20 image. We used the Wilcoxon signed-rank sum test with Holm's multiple testing correction for comparisons.

## RESULTS

The RDN achieved 30% image noise from only one block, gradually increasing with increasing blocks ( $p < .001$  for all), especially in the low-frequency range. Processing time per patient was 24.6s in RDB20, and significantly decreased to 12.6s (51%) in RDN10, 6.6s (27%) in RDB5, 4.2s (17%) in RDB3, and 1.8s (7%) in RDB1, respectively. Increased RDBs achieved significantly high similarity with reference ( $p < .001$  for all); RDB10 showed an SSIM of 0.99996, PSNR of 77.9, LPIPS of 0.0006, and VIF of 0.83, indicating high similarity to RDB20 with half computation costs.

## CONCLUSION

s Increasing RDBs significantly improved denoising effects and similarity to the reference image. However, computational costs also increased.

## CLINICAL RELEVANCE/APPLICATION

Our findings on optimizing the trade-off between denoising effects and computational costs in RDNs can guide the development of edge-based AI denoising applications in clinical settings.

## W2-SPCA-7 Super-resolution Deep-learning Reconstruction: Image Quality and Myocardial Homogeneity in Coronary Computed Tomography Angiography

Participants

Sung Min Ko, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

The present study aimed to investigate whether super-resolution deep learning reconstruction (SR-DLR) has advantages in the overall image quality including signal-to-noise ratio (SNR), contrast to noise ratio (CNR) and sharpness as well as intensity homogeneity on coronary CTA with 4 different approaches; filtered-back projection (FBP), hybrid iterative reconstruction (IR), DLR and SR-DLR.

## METHODS AND MATERIALS

Sixty-three patients (mean age,  $61 \pm 11$  years; range, 18-81 years; 40 men) who had undergone coronary CT angiography between June-October 2022 were retrospectively included. Image reconstruction was performed using FBP, hybrid IR, DLR, and SR-DLR. Image noise, SNR, and CNR were quantified in both proximal and distal segments of the major coronary arteries. The left ventricle myocardium contrast homogeneity was analyzed. Two independent reviewers scored the overall image quality, image noise, image sharpness, and myocardial homogeneity.

## RESULTS

Image noise in HU was significantly lower ( $p < 0.001$ ) for the SR-DLR ( $11.2 \pm 2.0$ ) compared to those associated with other image reconstruction methods including FBP ( $30.5 \pm 10.5$ ), hybrid IR ( $20.0 \pm 5.4$ ), and DLR ( $14.2 \pm 2.5$ ). SR-DLR significantly improved SNR and CNR in both the proximal and distal segments of the major coronary arteries (Fig.1). No significant difference ( $p = 0.345$ ) was observed in the myocardial CT attenuation with SR-DLR. Conversely, FBP and hybrid IR (both,  $p < 0.001$ ) resulted in inhomogeneous myocardial CT attenuation (Fig.2). Two reviewers graded subjective image analyses with SR-DLR images higher than other image reconstruction techniques (Fig. 3-4).

## CONCLUSION

s SR-DLR improved image quality, demonstrated clearer delineation of distal segments of coronary arteries, and was seemingly

accurate for quantifying CT attenuation in the myocardium.

#### **CLINICAL RELEVANCE/APPLICATION**

The results of this study demonstrate that SR-DLR achieves higher image quality, better visualization of small distal segments of coronary arteries, and minimum inhomogeneous myocardium attenuation on coronary CT angiography than those associated with FBP, hybrid IR, and DLR.

Printed on: 04/12/24

### Chest Imaging Wednesday Poster Discussions

#### Sub-Events

#### W2-SPCH-1 Image Quality Evaluation of Ultra-low Dose Chest CT Based on Deep Learning Image Reconstruction: A Phantom Study

##### Participants

Jingjing Hong, Guangzhou, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate whether the image quality with the deep learning image reconstruction (DLIR) algorithm in ultra-low dose chest CT achieve that of clinical low dose with filtered back projection (FPB) or adaptive statistical iterative reconstruction-Veo (ASIR-V).

##### METHODS AND MATERIALS

Catphan 500 / 600 phantom was scanned on revolution Apex CT continuously for 10 times with clinical low dose protocol of chest screening (group A, 0.78mGy) and two ultra-low dose levels (group B, 0.48mGy and group C, 0.24mGy). Group A was reconstructed using FPB and ASIR-V at 50% strength (50%ASIR-V); Group B and C were reconstructed with DLIR at medium and high levels (DLIR-M, DLIR-H). Noise (SD), spatial resolution line pairs, noise power spectrum (NPS), task-based transfer function (TTF) and detectability index ( $d'$ ) were calculated. Two radiologists independently performed the image quality evaluation using Likert 5 scale. The values of measurements were compare with Kruskal-Wallis nonparametric test with Bonferroni correction.

##### RESULTS

Noise magnitude and NPSnoise of DLIR(M, H) in group B and C were significantly lower than FPB and 50%ASIR-V in group A ( $P < 0.01$ ), and those of DLIR-M in group B were the lowest. Compared with the FPB images of Group A, the  $f_{peak}$  and  $f_{ave}$  of NPS in B and C groups are shifted toward lower frequencies, and the noise texture of DLIR-M in Group B was best maintained(Group B:  $f_{peak} = 0.22mm^{-1}$ ,  $f_{ave} = 0.31mm^{-1}$ ; Group A:  $f_{peak} = 0.28mm^{-1}$ ,  $f_{ave} = 0.31mm^{-1}$ ). The TTF<sub>CNR</sub>, TTF<sub>10%</sub> of the high-, medium- and low-contrast inserts in group B and C were greater than those of FPB and 50%ASIR-V in group A (except for the TTF<sub>10%</sub> of the low-contrast insert of DLIR-H in group C), however, only TTF<sub>50%</sub> of the low contrast insert in group B performed best.  $d'$  was higher with DLIR-M and DLIR-H in group B and DLIR-H in group C than with FPB and 50%ASIR-V in group A for three inserts. The distinguishable line pairs per centimeter were 6 LP/mm at all dose levels. The subjective image quality scores of DLIR-M and DLIR-H in group B were not significantly different from those of FPB and 50%ASIR-V in group A ( $P > 0.05$ ), while that of DLIR-M and DLIR-H in group C were slightly lower ( $P < 0.05$ ). The two radiologists showed good consistency ( $\kappa$  value was 0.75).

##### CONCLUSION

s DLIR algorithm can provide comparable image quality at ultra-low dose than FPB and ASIR-V at clinical low dose, and reduce radiation dose was up to 70%, which provides the possibility for lung cancer screening and pulmonary nodule follow-up by CT.

##### CLINICAL RELEVANCE/APPLICATION

Low-dose DLIR can reduce radiation dose and provide theoretical basis and scan parameter selection for clinical chest CT imaging.

#### W2-SPCH-2 Comparison of CT and Wide-angle Stationary Digital Chest Tomosynthesis in the Detection of Pulmonary Nodules

##### PURPOSE

Lung cancer remains the number one cause of cancer death. Screening remains underutilized despite the clear evidence of benefit. A need exists for a safe, mobile, low radiation dose, intra-procedural method to localize biopsy instruments within target nodules. This retrospective cross sectional reader feasibility study evaluates the ability of clinicians to identify pulmonary nodules using a wide angle carbon nanotube x-ray enabled stationary digital chest tomosynthesis system.

##### METHODS AND MATERIALS

A "LUNGMAN" phantom with pulmonary nodules was scanned with both CT and the tomosynthesis system. Nodules of varied size (3, 5, 8, 10, 12 mm) and radiodensity (HU-800, -600, +130) were placed randomly into different lobes of the phantom. For each test case, 3 nodules (one of each density) were randomly placed into the phantom. A total of 8 nodule test cases were recorded. CT scanning was performed under the ACR recommended lung cancer screening protocol. Chest tomosynthesis imaging was performed with a custom built "wide-angle" CNT system consisting of a meter long x-ray source with 60 independent activated x-ray sources opposite a digital detector, representing a 40 degree angular span. Imaging was performed at 120kV and total mAs of 2.358. Tomosynthesis images were reconstructed into the coronal plane with 3 mm slice thickness and presented to readers on PACS compliant monitors. Two board certified radiologists participated as readers. Each scan (CT or tomosynthesis) was independently reviewed, and the positions of lung nodules were documented by each reader.

##### RESULTS

The specificity of both the CT and tomosynthesis in detecting any sized pulmonary nodules was 1. For actionable pulmonary

nodules, or those 8 mm or greater in size, both the CT and tomosynthesis had a specificity of 1. The sensitivity of CT and tomosynthesis in detecting any sized pulmonary nodules is 0.929 and 0.708, respectively. The sensitivity of CT and tomosynthesis in detecting actionable pulmonary nodules is 0.958 and 0.850, respectively. The sensitivity of tomosynthesis increases with dense pulmonary nodules, with actionable pulmonary nodules of HU+130 being detected with a sensitivity of 1.

## CONCLUSION

Wide-angle tomosynthesis was found to consistently identify dense nodules of at least 8 mm in size. Further studies are needed to evaluate the sensitivity and specificity of the system to actionable lung nodules. With system and carbon nanotube array optimization, we hypothesize the detection rate for nodules will improve. Additional study is needed to evaluate its use in target and tool co-localization and target biopsy.

## CLINICAL RELEVANCE/APPLICATION

The development of an effective, low-radiation and mobile method for pulmonary nodules could improve screening of lung cancer.

### W2-SPCH-3 Value of Deep Learning Reconstruction Algorithm Combined with Low Tube Voltage in Routine Lung CT Scanning

#### Participants

Lv Ren-feng LV, Dalian, China (*Presenter*) Nothing to Disclose

#### PURPOSE

To study the effect of deep learning reconstruction (DLIR) algorithm combined with low tube voltage (100 KVp) on lung CT scan image quality and radiation dose.

#### METHODS AND MATERIALS

50 patients with routine lung CT scans were selected and were divided into 120 KVp group and 100 KVp group according to the difference of tube voltage, 25 patients in each group. Among them, Group A: Tube voltage 120 KVp, adaptive statistical iterative reconstruction (ASiR-V, 30%) algorithm, reconstruction mode (lung). The raw data of 100KVp group were reconstructed according to different reconstruction algorithm and reconstruction mode, Group B: Deep learning reconstruction (DLIR-H) algorithm, standard reconstruction mode (Std). Group C: Deep learning reconstruction (DLIR-H) algorithm, standard reconstruction mode (Std) + image enhancement filter (LU). All scans using a tube current of 100 ma, other parameter settings are the same. The thickness of 1.25mm was reconstructed image. The CT values, noise (SD), CTDI, within the subcutaneous fat and lung tissue on both sides of the same location were recorded, signal noise ratio (SNR) and radiation dose (ED) were calculated, two chest doctors evaluated the image quality subjectively and made statistical analysis of the data between the three groups.

#### RESULTS

There was no statistical difference in the CT values measured in all three groups of lung images ( $P > 0.05$ ); The SD, SNR and image quality evaluation were statistically different between the three image groups ( $P < 0.05$ ), the noise of the images of B and C groups is significantly lower than that of group A, group C images provide better sharpness and clearly shows the structure and branches of lung markings; The radiation dose of the 100 KVp group was significantly lower than the 120 KVp group ( $P < 0.05$ ).

## CONCLUSION

Using tube voltage 100 KVp combined with DLIR algorithm significantly reduces the radiation dose. Compared with ASiR algorithm, using DLIR algorithm combined with image enhanced filter (LU) reconstruction mode can significantly lower the image noise, and improved the display ability of lung tissue and lung markings.

## CLINICAL RELEVANCE/APPLICATION

Routine low-dose lung CT examination used low tube current combined with iterative algorithm, the noise suppression and radiation dose reduction are not obvious, DLIR algorithm combined with low tube voltage imaging can significantly reduce the radiation dose, the DLIR algorithm standard reconstruction mode combined with image enhancement filtering (LU) can provide a good contrast image of the lung tissue. Due to the significant noise suppression of the DLIR algorithm, the application of routine lung CT physical examination and lung nodule screening using a tube voltage of 80 KVp or even lower becomes possible.

### W2-SPCH-4 CT Pulmonary Angiograms (CTPA) in Pregnant Patients: Multicenter Study on Imaging Findings, Management, and Follow-up of Patients beyond an Optimal and Suboptimal CTPA

#### PURPOSE

Risk of pulmonary embolism (PE) is increased in pregnancy. However, CTPA usage is limited given the risks of radiation exposure to the mother and fetus. The aim of this study was to assess the frequency of suboptimal CTPAs in pregnant population, the factors related to sub-optimality, and factors contributing to patients' outcome.

#### METHODS AND MATERIALS

Our IRB approved, retrospective study included 440 consecutive CTPA examinations of pregnant patients scanned between 2015-2021 at one of the five participating quaternary and community hospitals. For the control group, we included 474 consecutive, female patients who underwent CTPA. All CTPA exams were reviewed for diagnostic evaluability (optimal or suboptimal) as well as the presence of PE. In addition, we recorded patients' age, gestational age at the time of CTPA, weight, imaging data (Doppler US, chest radiograph, and ventilation perfusion scan), and information on patient and pregnancy outcomes following CTPA.

#### RESULTS

PE positive CTPA rates in pregnant (3.4%) and non-pregnant (9.7%) patients were significantly different ( $p=0.004$ ). The frequency of suboptimal CTPA (11.2%, 49/440) in pregnant and non-pregnant patients (11.2% vs 8.2%;  $p=0.657$ ) was not significantly different. Pregnant patients with suboptimal CTPA had higher weight (92 kg vs 77 kg), and advanced gestational age ( $\geq 20$  weeks vs  $< 20$  weeks) in comparison with optimal CTPA. Additional imaging including CXR (46.9%), Doppler (46.9%), repeat CTPA (10.2%), and V:Q (2.0%) were performed in less than 50% of patients with suboptimal CTPA. Although patients with suboptimal CTPA had a higher rate of hospitalization than those with optimal CTPA (40.8% vs 29.9%), it was not significantly different. Non-PE findings such as pneumonia, edema, and pleural effusions, were more frequent findings in CTPAs. CTDI<sub>vol</sub> and DLP were significantly higher

in suboptimal CTPA (CTDI: 9 vs 8, DLP: 271, 238,  $p < 0.001$ ).

## CONCLUSION

The low rate of PE-positive CTPA in pregnant patients comparing to non-pregnant patients as well as additional testing performed following suboptimal CTPA suggest over-utilization of CTPA in pregnant population. Pregnancy does not attribute to higher suboptimality rate in CTPAs. However, suboptimal CTPA is more expected in patients with higher body weight and age of pregnancy. Although not statistically significant, the higher rate of hospitalizations among patients with suboptimal CTPA suggests presence of a more severe underlying disease. Suboptimal CTPA exposes extra radiation dose to patients comparing to optimal CTPA.

## CLINICAL RELEVANCE/APPLICATION

Over-utilization of CTPA in pregnant populations leads to unnecessary exposure of radiation and contrast to mother and fetus.

## W2-SPCH-5 Performance Evaluation of a 3D Camera System for Automated Patient Positioning in Routine Chest and Abdominal CT

### PURPOSE

Patient out-of-center positioning in computed tomography (CT) scanning is a common issue, possibly resulting in inferior image quality and/or increased patient dose due to suboptimal tube current modulation. Automated patient positioning, using a three-dimensional (3D) camera promises more accurate and robust positioning. This study aimed to compare manual versus 3D camera based patient positioning in the clinical workflow.

### METHODS AND MATERIALS

A total of 6618 routine thoracic and abdominal scans of adult patients were included in the study. The scans were performed on 2 CT scanners, one of which was equipped with a 3D camera system (Naeotom Alpha CT by Siemens Healthineers), which automatically positions the patient; the 3D camera was used in the 1597 scans. The patient positioning after each scan, as well as the corresponding patient effective diameter (ED), were calculated by DOSE (Qaelum), the dose monitoring system used in the hospital. An extensive study was performed by evaluating the positioning of each scan taking into account the scan region, the patient size (in terms of ED) and the gender. A vertical bidirectional offset from the CT isocenter smaller than 10 mm (threshold) was defined as 'accurate positioning', since no significant impact on image quality and patient dose was found in literature. Before using the positioning calculations of DOSE, a validation was executed.

### RESULTS

Mean manual patient positioning was 16.55 mm 95% CI [16.05, 17.06], while positioning with the 3D camera resulted in a significantly different ( $p < 0.0001$ ) mean positioning of -3.33 mm, 95% CI [-4.27, -2.39]. Positioning distribution indicated a more centralized positioning with the 3D camera (53%) compared to manual positioning (31%). Sub-analysis regarding the scan region resulted in significant differences ( $p = 0.001$ ) between manual and automatic positioning in both thorax and abdomen exams. Patient size comparisons showed that small patients ( $ED = 28\text{cm}$ ) were on average worse positioned compared to medium ( $28\text{cm} < ED < 31\text{cm}$ ) and large ( $ED = 31\text{cm}$ ) patients, in both manual and automatic positioning. Still, automatic positioning was significantly ( $p = 0.001$ ) more accurate. Gender wise comparison provided evidence of the superiority of the automatic positioning in all patients, independent on the gender.

### CONCLUSION

Automated patient positioning using a 3D camera resulted in a significantly more accurate positioning of the patient in the CT scanner, compared to manual positioning. Sub-analyses regarding scan region, patient size and gender showed an overall improvement, indicating the camera based positioning is robust.

## CLINICAL RELEVANCE/APPLICATION

Automated 3D camera positioning was shown to provide more accurate and robust positioning in routine CT practice.

## W2-SPCH-6 The Effect of Pitch and Rotation Time on the Quantitative Analysis of Lung Nodules by Artificial Intelligence in Low-dose Lung CT Screen

Participants

Xuan Su, Xi'an, China (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the influence of the choice of pitch and rotation time on the quantitative analysis of lung nodules by artificial intelligence in low-dose lung CT screening.

### METHODS AND MATERIALS

A thorax anthropomorphic phantom (Lungman, Kyoto Kagaku Inc.) was scanned by with a 256-row CT (Revolution CT, GE Healthcare), which contained 9 simulated nodules (CT value, 100 HU, -630HU and -800HU; diameter: 8mm, 10mm, 12mm). Six groups of images were obtained with same tube voltage and current (120kV, 45mA) but different combination of pitch and rotation time (Group 0: 0.984, 0.28s; Group 1: 0.992, 0.35s; Group 2: 0.992, 0.28s; Group 3: 1.375, 0.5s; Group 4: 1.531, 0.5s; Group 5: 0.984, 0.35s). The images with different group were analyzed by an artificial intelligence software (Intelligent 4D Imaging System for Chest 5.5, YITU Healthcare). The CT value, SD of pulmonary nodules and air in front of sternum at the same slice were measured. CT dose index (CTDI), the product of dose length (DLP) of each scan were recorded. Signal-to-noise ratio ( $SNR = \frac{CT_{\text{nodule}}}{SD_{\text{nodule}}}$ ) and contrast signal to noise ratio ( $CNR = \frac{CT_{\text{nodule}} - CT_{\text{air}}}{SD_{\text{air}}}$ ) were calculated. All statistical analyses were performed using SPSS statistical software (version 22.0).

### RESULTS

Changing pitch and rotation time at low dose has no effect on the size of lung nodules measured by AI (mean diameter,  $P > 0.05$ ; diameter difference percentage,  $P > 0.05$ ); changing the scan pitch and rotation speed does not affect the CT of lung nodules Measurement of values (average CT value,  $P > 0.05$ ; percentage difference in CT value,  $P > 0.05$ ). The changes of scanning pitch and rotation speed have no effect on the image quality ( $SNR$ ,  $P > 0.05$ ;  $CNR$ ,  $P > 0.05$ ). The CT effective dose is different under

different conditions (CTDL,  $P < 0.05$ , DLP,  $P < 0.05$ ), the DLP value is the lowest when the scanning pitch is 0.984 and the rotation speed is 0.28s (DLP = 27.79 (mGy \* cm)).

## CONCLUSION

s In low-dose lung screening, changes in scan pitch and rotational speed will not affect image quality. Choosing a distance of 0.984 and a rotational speed of 0.28s can provide lung screening with lower radiation dose.

## CLINICAL RELEVANCE/APPLICATION

In clinical workflow, it is of great significance to minimize radiation dose while keep image quality constantly.

## W2-SPCH-7 A Comparative Study on the Image Quality of Part-solid Nodules in the Lung between Virtual Non-contrast Based on Biphasic Ultrafast Synchronized KV/mA Switching Dual Energy CT and Conventional Non-contrast Scan

Participants

Jingjing Hong, Guangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

This study explored the feasibility of using virtual non-contrast (VNC) images obtained from ultrafast synchronized KV/mA switching dual energy CT (DECT) in both pulmonary arterial and venous phase to evaluate part-solid nodules (PSN) in the lung, and compared their performance with true non-contrast (TNC) images.

## METHODS AND MATERIALS

46 Cases of Partial Solid Nodules with lung enhanced CT examination who underwent TNC scan and biphasic enhanced DECT scan (arterial and venous), and VNC images were reconstructed from DECT. The CT values, and standard deviation (SD) of the PSN and Ipsilateral erector spinae muscle (ESM), as well as diameter of lesion, were measured in VNC and TNC images. The signal-noise-ratio (SNR, CTSN/SDSN) and contrast-noise-ratio [CNR, (CTESM - CTPSN) / SDESM] of PSN were calculated. Record the effective radiation dose in TNC and VNC mode. Two experienced radiologists subjectively assessed the IQ(image quality) of VNC and TNC images using a 5-point scale (1, poor; 2, fair; 3, moderate; 4, good; 5, excellent). Non-parametric test was used to compare the subjective and objective image parameters and effective radiation dose of images in different scanning phases. The Kappa test was used to assess consistency of subjective score between groups

## RESULTS

There were no significant differences in The diameter, CT value, SD, SNR and CNR between TNC and VNC images in arterial/venous phase ( $P > 0.05$ ). The TNC ( $4.79 \pm 0.33$ ) had the highest the subjective score, followed by VNC images ( $4.04 \pm 0.26$ ) in venous phase and VNC images in arterial phase ( $3.71 \pm 0.45$ ), with significant differences observed among the three groups (all  $P < 0.001$ ), however, all scores were up to diagnosis requirements. The consistency of subjective scores between radiologists was strong ( $K = 0.63 \sim 0.73$ ). The effective radiation dose of VNC mode [ $(10.74 \pm 0.93)$  mSv] was lower than that of conventional mode [ $(15.21 \pm 1.89)$  mSv] ( $P < 0.001$ ), about 30% reduction.

## CONCLUSION

s DECT with arterial/venous phase VNC can provide similar image quality as TNC, and the radiation dose is significantly reduced by 30%.

## CLINICAL RELEVANCE/APPLICATION

Ultrafast synchronized KV/mA switching dual energy CT (DECT) arterial/venous phase VNC spectral technology can basically replace conventional non-contrast scan images, provide comparable image quality for patients with lung diseases, and significantly reduce the radiation dose to patients.

## W2-SPCH-8 Value of Deep Learning Reconstruction of Chest Low-dose CT for Image Quality Improvement and Lung Parenchyma Assessment on Lung Window

## PURPOSE

To explore the performance of low-dose computed tomography (LDCT) with deep learning reconstruction (DLR) for the improvement of image quality and assessment of lung parenchyma.

## METHODS AND MATERIALS

Sixty patients underwent chest regular-dose CT (RDCT) followed by LDCT during same patient encounter. RDCT images were reconstructed with hybrid iterative reconstruction (HIR) and LDCT images were reconstructed with HIR and DLR, both using lung algorithm. Radiation exposure was recorded. Image noise, signal-to-noise ratio, and subjective image quality of normal and abnormal CT features were evaluated and compared using the Kruskal-Wallis test with Bonferroni correction.

## RESULTS

The effective radiation dose of LDCT was significantly lower than that of RDCT ( $0.29 \pm 0.03$  vs  $2.05 \pm 0.65$  mSv,  $p < 0.001$ ). The mean image noise  $\pm$  standard deviation was  $33.9 \pm 4.7$ ,  $39.6 \pm 4.3$  and  $31.1 \pm 3.2$  HU in RDCT, LDCT HIR-Strong and LDCT DLR-Strong, respectively ( $p < 0.001$ ). The overall image quality of LDCT DLR-Strong was significantly better than that of LDCT HIR-Strong ( $p < 0.001$ ) and comparable to that of RDCT ( $p > 0.05$ ). LDCT DLR-Strong was comparable to RDCT in evaluating solid nodules, increased attenuation, linear opacity, and airway lesions (all  $p > 0.05$ ). The visualization of subsolid nodules and decreased attenuation was better with DLR than with HIR in LDCT but inferior to RDCT (all  $p < 0.05$ ).

## CONCLUSION

s LDCT-DLR can effectively reduce image noise and improve image quality. LDCT-DLR provides good performance for evaluating pulmonary lesions, except for subsolid nodules and decreased lung attenuation, compared to RDCT-HIR.

## CLINICAL RELEVANCE/APPLICATION

DLR enables LDCT maintaining image quality even with very low radiation doses

SEN enables EDR, maintaining image quality even with very low radiation doses.

W2-SPER

### Emergency Radiology Wednesday Poster Discussions

#### Sub-Events

#### **W2-SPER-1 Imaging Findings of Elder Abuse on the Trauma Service: A retrospective Case-control Study of Two Institutions**

#### Participants

Omar Yaghi, Boston, MA (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Elder abuse is common and consequential for its victims, with impact ranging from reduced quality of life to physical injury and death. Screening is a recognized strategy for detection, but less effective in elders with diminished ability to communicate or psychosocial reasons to fear disclosure. This study aimed to identify imaging findings of elder abuse.

#### **METHODS AND MATERIALS**

Preliminary data from this retrospective case control study identified 17 patients above 60 years of age with keywords "assault" and "abuse" from two institutional trauma registries from 2015-2022, as well as 17 age and gender matched controls. Demographic information, clinical information, and imaging findings were reviewed.

#### **RESULTS**

Majority of the abuse victims were women (71%) and White (88%), with mean age of 74 years (range 61-91 years). Known risk factors for elder abuse were common. The alleged abuser was most frequently the patient's child, followed by partner. Blunt trauma was more common (14/17). Rib fractures (7/17), head (8/17) and facial (5/17) injuries were the most frequent imaging findings. Central injuries (to neck, torso) were more common in elder abuse victims compared to control trauma patients, while the latter more frequently had extremity injuries. Abuse victims with extremity injuries demonstrated tendency towards distal injury particularly of the upper extremity (forearm, hand), while control patients tended towards proximal injury (humerus, femur).

#### **CONCLUSION**

s This study demonstrated that radiologists can be helpful in assessment of elder abuse, identified injuries to the head/face, central body, and distal upper extremity as warning signs of elder abuse, and highlighted the importance of further research to identify imaging patterns of abuse in this vulnerable population.

#### **CLINICAL RELEVANCE/APPLICATION**

Radiologists can help in recognition of elder abuse by identifying injuries occult to physical examination in victims who are unable or unwilling to disclose abuse.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

W2-SPGI

### Gastrointestinal Imaging Wednesday Poster Discussions

#### Sub-Events

#### W2-SPGI-1 A Pilot Study on the Classification of Focal Liver Lesions using Normalized Viscoelastic Parameters with Intrinsic MR Elastography

##### PURPOSE

Evaluate the accuracy of nonlinear inversion-intrinsic magnetic resonance elastography (NLI-iMRE), which uses natural pressure pulse and cardiac induced motion, for determining the viscoelastic properties of liver lesions and distinguishing between benign and malignant tumors.

##### METHODS AND MATERIALS

This prospective, cross-sectional study was approved by an institutional review board and patient consent was obtained. Adult patients undergoing 3T clinical MRI for characterization of liver lesions were included. A 4D-phase contrast quantitative sequence with retrospective cardiac gating was acquired to encode motion. Using the 3D displacement field at eight cardiac cycle phases, viscoelastic parameters  $G'$  (storage modulus),  $G''$  (loss modulus), and  $|G^*|$  (magnitude of the complex shear modulus) were computed within the imaging volume using the subzone-based NLI-iMRE reconstruction method. To ensure comparability between subjects, viscoelastic properties were calculated for the liver and spleen, and liver properties were normalized by the mean spleen property values. The composite reference standard included lesion classification by clinical MRI or histopathology. Unpaired t-tests and receiver operating characteristic (ROC) curves were used to compare benign and malignant lesions.

##### RESULTS

34 patients with 34 lesions were included. Normalized  $G'$  values showed significant differences between hemangiomas and LR-4 ( $p < 0.01$ ), LR-5 ( $p = 0.02$ ), and metastasis ( $p < 0.01$ ) and between focal nodular hyperplasias (FNH) and LR-4 ( $p < 0.01$ ), LR-5 ( $p = 0.03$ ), and metastasis ( $p < 0.01$ ). The  $|G^*|$  values showed significant differences between FNH and LR-4 ( $p < 0.0001$ ), LR-5 ( $p = 0.03$ ), and metastases ( $p = 0.04$ ). ROC curves were used to differentiate benign and malignant lesions, with the area under the curves for  $G'$ ,  $G''$ , and  $|G^*|$  being 0.90, 0.61, and 0.71, respectively.

##### CONCLUSION

This study shows that cardiac activated iMRE which has the advantage of not requiring external mechanical stimulation, is a promising method for differentiating benign and malignant liver lesions using normalized  $G'$  and  $|G^*|$ , with results consistent with prior findings from extrinsic MRE studies, while the normalized  $G''$  did not show a meaningful trend for different lesion types.

##### CLINICAL RELEVANCE/APPLICATION

This study found that NLI-iMRE accurately distinguishes between benign and malignant liver lesions using viscoelastic properties, with normalized  $G'$  and  $|G^*|$  values showing significant differences between lesion types. This non-invasive method, based on standard clinical imaging sequences, has the potential for clinical use without the need for external actuation.

#### W2-SPGI-2 Multimodal Imaging Evaluation of Hepatic Alveolar Echinococcosis in Children

##### Participants

Hai Hua Bao, Xining, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Hepatic alveolar echinococcosis (HAE) has an aggressiveness similar to that of malignant tumors. Children have a rich blood supply to the liver, and the lesions grow rapidly after infection, which makes the disease serious and difficult to treat. The purpose of this study is to investigate the growth characteristics of HAE in children through various imaging techniques.

##### METHODS AND MATERIALS

Fifty pediatric patients (age range 1-14 years, mean age  $11.24 \pm 2.82$  years) diagnosed with HAE at the Affiliated Hospital of Qinghai University from 2014 to 2020 were included for imaging (low-dose abdominal CT plain + enhancement, abdominal T1WI, T2WI, MR enhancement, DWI) and clinical examination, we obtained morphological features of the lesions based on images, imaging staging and PNM staging, intrahepatic vascular and bile duct invasion, marginal zone continuity and ADC values, and assessed the liver function and systemic nutritional status of the children based on clinical test results such as glutamate transaminase (ALT) and hemoglobin (Hb), and comprehensively evaluated the growth characteristics of HAE lesions in children.

##### RESULTS

All children underwent CT plain scan(1), of which 41 had CT-enhanced scans(2), and a total of 27 had MR scans(3-8). Both the right and left lobes of the liver were invaded in 48% of the cases, the left lobe only in 14%, and the right lobe only in 38%. 96% of cases had calcification formation; 52% of cases had vascular and bile duct involvement (Table 1); P1 stage lesions accounted for the most PNM staging and parenchymal type accounted for the most imaging staging; P1 stage lesions had higher marginal zone activity than P2+P3 stage (There was no statistically significant difference in ADC values between P2 and P3 phases, so the joint

comparison with P1 phase ;P4 phase had a small sample size, so no statistics were done). Large lesions, parenchymal lesions, and P2 stage lesions have a greater impact on liver function in pediatric patients; parenchymal lesions have a greater impact on the nutritional status of the children.

## CONCLUSION

s CT images can clearly show the calcification within the lesion, MR images can clearly show the invasion of hepatic vessels and bile ducts by the lesion, DWI and ADC values can determine the activity of the marginal zone of the lesion, and the characteristics of HAE lesions can be effectively evaluated by using multimodal imaging techniques.

## CLINICAL RELEVANCE/APPLICATION

HAE infection is asymptomatic in the early stage, and most of them are in the advanced stage when there are obvious symptoms, and children are poorly tolerated and difficult to treat surgically, early diagnosis and knowledge of its growth characteristics are crucial for clinicians to choose the appropriate treatment plan and thus reduce the mortality rate.

## W2-SPGI-3 Amide Proton Transfer-Weighted MRI in Preoperative Assessment of Microvascular Invasion of Hepatocellular Carcinoma

Participants

Luo Luo, Yangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study was to explore the potential of APTw imaging in predicting microvascular invasion (MVI) of hepatocellular carcinoma.

## METHODS AND MATERIALS

32 patients with surgical pathologic confirmed hepatocellular carcinoma were studied. All patients underwent liver MR scanning on a 3.0-tesla scanner. Images at 52 frequencies were acquired for APTw, including 49 frequencies ranging from -600 to 600 Hz with an increment of 25 Hz. The applied saturation B1 power was 2 $\mu$ t and the saturation duration was 2000ms. Three identical ROIs were placed in the solid component of tumor for each patient on unsaturated M0 images and were copied on MTRasym mapping. Large cystic cavities, large areas of necrosis were excluded from ROI selections. Averaged MTRasym values were used for further analysis. The inter-class correction coefficient (ICC) was used to evaluate the inter-observer agreement of measuring APTw value between two radiologists. The comparisons between APTw value for MVI- and MVI+ groups were analyzed using the independent t test. Receiver operating characteristic (ROC) curves were generated for each APTw parameter value to assess the areas under the curve (AUC).

## RESULTS

MVI was pathologically confirmed from tumor resection including 13 cases with MVI (MVI+) and 15 without MVI (MVI-). The ICC of two observers' measurements of APTw was 0.912. The APTw value of MVI+ group was significantly higher than that of MVI- group [ (1.33 $\pm$ 0.76) % vs (0.32 $\pm$ 1.06)%; P=0.008]. The cut-off APTw value for differentiating MVI+ and MVI- groups was 0.30% (sensitivity, 60%; specificity, 100%; AUC, 0.782, 95%CI: 0.609, 0.955)

## CONCLUSION

s APTw imaging showed promising ability in differentiating MVI+ and MVI- hepatocellular carcinoma.

## CLINICAL RELEVANCE/APPLICATION

APTw could serve as a robust technique to predicting MVI of hepatocellular carcinoma without the use of contrast agents and providing additional auxiliary value for the selection of clinical treatment methods of hepatocellular carcinoma patients.

## W2-SPGI-4 Free Breathing Acquisition using Radial Sampling and Compressed Sensing Improves Success Rate and Image Quality of Gadoteric Acid Enhancing Liver MRI in Elderly Patients

Participants

Masaya Kutsuna, Shizuoka, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

To compare successful rate of examination and clinical image quality of liver dynamic MR images using gadoteric acid in elderly patients between free breathing acquisition using radial sampling and compressed sensing and conventional breath-hold acquisition.

## METHODS AND MATERIALS

This retrospective single-center study included 100 patients older than 60 years who underwent liver MR examination using gadoteric acid using free breathing acquisition (FB group, n = 50) or conventional breath-hold acquisition (BH group, n = 50). All included examinations were performed on a 3.0-T MR scanner (Ingenia Elition, Philips). The representative parameters of FB group were as follows: pseudo-golden angle free breathing sequence using compressed sensing with soft-gating (SmartSpeed 4D-FreeBreathing); temporal resolution, 10 sec/phase; C-SENSE factor, 4. The parameters for BH group were as follows: spoiled gradient echo with compressed sensing (eTHRIVE); scan time, 14.9 sec; C-SENSE factor, 6. As qualitative analysis, all images of arterial (AP), portal venous (PVP), and transitional phase (TP) were evaluated by 2 independent radiologists using a 5-point scale (1 - 5, 5 is excellent quality) in terms of motion artifact, streak artifact, sharpness of liver edge, and overall quality. The cases with an overall quality score of 3 or above were regarded as diagnosable and successful examinations. As quantitative analysis, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were evaluated by board-certified another radiologist placing region-of-interest to each 5 segments of liver. P value less than 0.05 was regarded as statistically significant.

## RESULTS

The success rate was 100% (50/50) for the three phases in FB group, while in BH group, 82% (41/50, p = 0.005) for AP, 98% (49/50, p = 1.0) for PVP, and 100% (50/50, p = 1.0) for TP (Figure A). In the qualitative analysis, BH group showed better score in motion artifact and sharpness of liver edge in the three phases (p lt; 0.005, Figure B). There was no significant difference of overall quality in AP (p = 0.09). The SNR and CNR of BH group showed higher in PVP and TP. In the AP, the SNR and CNR of FB group tended to be higher but not significant (p = 0.19-0.76). Two representative cases were shown in Figure C.

## CONCLUSION

s Free breathing acquisition using radial sampling and compressed sensing improved success rate and clinical image quality of gadoteric acid enhancing liver MRI in elderly patients compared with conventional breath-hold acquisition.

## CLINICAL RELEVANCE/APPLICATION

Free breathing acquisition improves quality of liver MR examination using gadoteric acid in elderly patients and has potential to improve diagnostic performance of hypervascular hepatic lesions.

## W2-SPGI-5 The Comparison of the Application Value of Small-field Multi-excitation Planar Echo Sequence DWI and Conventional Single-excitation Planar Echo Sequence DWI in Rectal Cancer

Participants

Zhang Haini, Xuzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

To compare the image quality of reduced field of view (rFOV) image reconstruction using image-space sampling function (IRIS) diffusion weighted imaging (DWI) sequence and full field of view (fFOV) single-shot echo-planar imaging (SSEPI) diffusion weighted imaging (DWI) sequence in exploring whether rFOV IRIS-DWI can improve the image quality of rectal cancer.

## METHODS AND MATERIALS

All patients who underwent rectal MRI examination in our institution were retrospectively analyzed, being performed in a 3.0T MR scanner (Ingenia Elition, Philips, Netherlands). All DWI images were uploaded to Philips Intelligence Space Portal post-processing workstation (version V10.1) for evaluation and analysis. One senior radiologist with more than 20 years of experience in rectal cancer MRI randomly evaluated the images of two sequences. Image quality evaluation included subjective and objective evaluation. Subjective image quality included overall quality, artifacts, distortion, lesion contrast and anatomical details according to a 5-point scale reference. And, the objective evaluation included maximum area of tumor, average maximum area of tumor, tumor volume, ADC value, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). SPSS 26.0 statistical software was used for data analysis. The subjective scores of image quality between rFOV IRIS-DWI and fFOV SSEPI-DWI were compared by paired Wilcoxon S rank sum test. The comparison of the objective image quality between the two DWI sequences was used by paired sample t test.  $P < 0.05$  indicated the difference was statistical significance.

## RESULTS

Thirty patients with rectal cancer were enrolled this retrospectively study. The overall quality, distortion, artifacts, lesion contrast and anatomical details in the rFOV IRIS-DWI sequence were significantly better than the fFOV SSEPI-DWI sequence ( $P < 0.05$ ). The total scores of the subjective evaluation in the rFOV IRIS-DWI sequence and fFOV SSEPI-DWI sequence were 20.6 and 17.4, respectively. The ADC values in rFOV IRIS-DWI sequence and fFOV SSEPI-DWI sequence were  $0.85 \times 10^{-3} \text{mm}^2/\text{s}$ ,  $1.07 \times 10^{-3} \text{mm}^2/\text{s}$ , respectively. The result showed significant difference between two groups with  $P = 0.000$ . The maximum area and average maximum area of rFOV IRIS-DWI sequence were larger than the fFOV SSEPI-DWI sequence ( $P < 0.05$ ). The SNR and CNR in rFOV IRIS-DWI sequence and fFOV SSEPI-DWI sequence were 37.7, 73.1 and 0.85, 0.82, respectively, and the SNR of the two groups were statistically different ( $P = 0.000$ ).

## CONCLUSION

s Compared to fFOV SSEPI-DWI sequence, rFOV IRIS-DWI sequence significantly improved the image quality in rectal cancer patients.

## CLINICAL RELEVANCE/APPLICATION

Rectal cancer; DWI sequence; Image quality; ADC values

## W2-SPGI-6 Diagnostic Accuracy of Liver MR Elastography for Assessment of Liver Fibrosis in Children with AIH and Post LTx

Participants

Paulina Opyrchal, Warsaw, Poland (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the diagnostic accuracy of MRE in liver fibrosis staging using liver biopsy as the reference standard in pediatric patients with AIH and post LTx.

## METHODS AND MATERIALS

Overall, 48 patients with AIH and 25 patients post-LTx were included in the study. The median age of patients with AIH was 14.54 (range 2.82-17.98), the group included 22 boys and 26 girls. The median age of patients post-LTx was 14.16 (range 7.89-17.94), the group included 11 boys and 14 girls. All patients underwent MR elastography and liver biopsy. The liver stiffness value on MRE was independently measured by two radiologists. The weighted arithmetic mean was calculated from elastograms obtained at 4 levels of the liver in the axial plane. Biopsy samples were separately evaluated by two pathologists to stage liver fibrosis according to the Ischak fibrosis scale. Statistical analysis was performed, ROC curves were plotted with the optimal cut-off values and corresponding AUCs were calculated to evaluate sensitivity and specificity, inter-rater agreement was determined.

## RESULTS

In patients with AIH MRE detected fibrosis stage 4 or higher with a sensitivity of 100% and specificity of 70.6% for cut-off value  $>2.92$ , AUC 0.88,  $p < 0.05$ , and fibrosis stage 5 or higher with a sensitivity of 83% and specificity 89% for cut-off value  $>3.65$ , AUC 0.90,  $p < 0.05$ . In patients post-LTx MRE detected fibrosis stage 4 or higher with a sensitivity of 100% and specificity of 90.5% for cut-off value  $>3.06$ , AUC 0.95,  $p < 0.05$  and fibrosis stage 5 or higher with sensitivity 100% and specificity 83% for cut-off value  $>3.06$ , AUC 0.91,  $p < 0.05$ . The weighted Kappa value calculated for inter-observer agreement between radiologists was 0.90.

## CONCLUSION

s MRE is a non-invasive technique that has high sensitivity and specificity in detecting advanced stages of liver fibrosis with a very

good intraobserver strength of agreement.

#### **CLINICAL RELEVANCE/APPLICATION**

It may be possible to reduce the number of liver biopsies in patients with elevated liver stiffness identified with MRE.

### **W2-SPGI-7 The Role of Four-dimensional Flow MR Imaging as an Add-on Tool to Endoscopy for Predicting Actual Bleeding in Cirrhotic Patients with Esophageal Varices**

Participants

Eunju Kim, Gwang-Ju, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate whether four-dimensional (4D) flow MRI with quantitative hemodynamic parameters could be used as an add-on tool to endoscopy for predicting actual bleeding in cirrhotic patients with esophageal varices.

#### **METHODS AND MATERIALS**

All the cirrhotic patients who were attributable to hepatitis B and/or C virus underwent 4D flow MRI using a 3-T scanner (Skyra; Siemens Healthcare, Erlangen, Germany). The velocity-encoding sensitivity for x, y, and z flow-encoding directions was set to 30 cm/s, 20 cm/s, and 20 cm/s, respectively. A total of 109 cirrhotic patients with endoscopically confirmed esophageal varices were divided into groups A (negative red color (RC) sign with no variceal bleeding, n = 60, 35 - 81 years), group B (negative RC sign with variceal bleeding, n = 13, 41 - 80 years), group C (positive RC sign with no variceal bleeding, n = 10, 49 - 81 years), and group D (positive RC sign with variceal bleeding, n = 26, 48 - 81 years). The presence of variceal bleeding was defined as the occurrence of active bleeding within one year after initial diagnosis of esophageal varices based on the endoscopic and clinical findings. The quantitative parameter of 4D flow MRI included the net flow rate (mL/s), mean flow rate (mL/s), peak flow rate (mL/s), and net forward volume (mL) in each vessels. The 4D flow MR parameters were compared among the groups using Mann-Whitney U test, and the receiver operating characteristic (ROC) curve analysis was performed to evaluate the diagnostic performance.

#### **RESULTS**

The values of all 4D flow MR parameters in the PV of patients with a positive RC sign were significantly lower than those of patients with a negative RC sign ( $P < 0.05$ ). The patients with variceal bleeding in group B and D showed lower values in all MR parameters in the PV than those of patients with no variceal bleeding in group A and C, respectively ( $P < 0.05$ ). However, there were no significant differences among the groups regarding the MR parameters in the SV and SMV. In the ROC analysis for evaluating the diagnostic performance of actual variceal bleeding in order to distinguish patients with variceal bleeding from patients with non-variceal bleeding, the area under the curve (AUC) values were 0.762 and 0.770 ~ 0.787 in endoscopy alone and MR alone, respectively. However, in the combination of endoscopy and 4D flow MRI, the AUC value increased significantly to 0.844 ~ 0.864 ( $P < 0.05$ ).

#### **CONCLUSION**

s The 4D flow MRI can be useful as an additional tool to endoscopy in predicting actual bleeding in cirrhotic patients with esophageal varices.

#### **CLINICAL RELEVANCE/APPLICATION**

4D flow MRI could significantly contribute to improving the diagnostic accuracy of endoscopy in predicting actual bleeding in cirrhotic patients with esophageal varices.

### **W2-SPGI-8 Intensive Respiratory Instruction Reduces Transient Motion Artifact in Liver Dynamic MR Examination using Gadoteric Acid**

Participants

Satoshi Funayama, MD, PhD, Hamamatsu, Japan (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To validate the efficacy of intensive respiratory instruction during liver MR examination using gadoteric acid, especially whether it reduces transient severe motion artifact (TSMA).

#### **METHODS AND MATERIALS**

This retrospective study reviewed 493 patients who underwent liver dynamic MR examination using gadoteric acid before and after intensive respiratory instruction (IRI) was started on May 2022. To determine population size, power analysis was performed based on the reported frequency of TSMA (7.2%) and breath-hold failure in case of extracellular contrast agent (2.2%) (power = 0.7, significant level = 0.05). All examinations were performed on a 3.0-T MR scanner (SIGNA Premier, GE Healthcare). The dual arterial phase was acquired using spoiled gradient echo sequence (LAVA-FLEX) with compressed sensing (HyperSense) with scan time of 11 sec/phase. The detail of the IRI procedure was as follows. First, patients were instructed to start deep breathing before starting of acquisition for pre or contrast agent injection and continue it until breath-hold command. Technologists started the injection after confirming 4 or 5 times of patients' deep breathing through the abdominal bellows signal curve. The breath-hold command was started when contrast agent reached abdominal aorta on FluoroTrigger real time imaging and the patient was in expiratory phase. In the conventional procedure, only auto breath-hold command was played on the scanner. To evaluate respiratory motion, abdominal bellows curve was classified into 6 classes (type 1 - type 6, Figure A) on pre, arterial (AP), and portal venous phase (PVP). A board-certified radiologist evaluated motion artifact using 5-point scale (1 - 5; 5, the best) on pre, first arterial (AP1), second arterial (AP2), and PVP. The motion artifact score of 3 or less was regarded as TSMA.

#### **RESULTS**

Finally, 450 patients were included (225 for conventional group [Conv group]; 225 for IRI group). The successful breath-hold was more frequent in IRI group in AP ( $p < 0.001$ ) and PVP ( $p < 0.001$ ) (Figure A). The frequency of TSMA was 6.7% (Conv group) and 1.3% (IRI group,  $p = 0.007$ ) for AP1; 7.1% (Conv group) and 1.8% (IRI group,  $p = 0.01$ ) for AP2. The motion artifact score was significantly higher (better image quality) in IRI group on AP1 ( $p < 0.001$ ) and AP2 ( $p < 0.001$ ). The score was not significantly different on pre ( $p = 1.0$ ) and PVP ( $p = 0.341$ ) (Figure B).

**CONCLUSION**

s Intensive respiratory instruction improved success rate of breath-hold and significantly reduced transient severe motion artifact.

**CLINICAL RELEVANCE/APPLICATION**

Intensive respiratory instruction improves quality of arterial phase in liver dynamic MR examination using gadoxetic acid and has potential to improve diagnostic performance of hypervascular hepatic lesions.

## Abstract Archives of the RSNA, 2023

W2-SPGU

### Genitourinary Imaging Wednesday Poster Discussions

#### Sub-Events

#### W2-SPGU-1 Impact of Image Quality on Detection of Extraprostatic Extension on MRI: Evaluation with a Deep Learning-based AI Algorithm

Participants

Yue Lin, BA, Bethesda, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess impact of image quality on extraprostatic extension (EPE) detection on MRI using a deep learning-based AI algorithm.

#### METHODS AND MATERIALS

This retrospective study included consecutive patients who were imaged with mpMRI and subsequently underwent radical prostatectomy (RP) from January 2007 to August 2022. One genitourinary radiologist prospectively evaluated each case using a previously published and validated grading system to assess the presence of EPE on mpMRI. EPE grade of 0 = no suspicion of EPE, 1 = long curvilinear contact or capsular irregularity/bulge, 2 = both long curvilinear contact and capsular irregularity/bulge, 3 = frank EPE. An EPE grading score =1 was considered as positive EPE call on mpMRI. Histopathologic EPE evaluation was performed at RP according to the International Society of Urological Pathology (ISUP) consensus statement. For each patient, T2WI and ADC maps were individually classified as non-diagnostic vs. diagnostic by an in-house AI algorithm. Fisher's exact tests were performed to compare EPE detection metrics (i.e., specificity) between non-diagnostic and diagnostic images.

#### RESULTS

A total of 812 patients (median age 62 [interquartile range 57-67] years; median prostate specific antigen level 6.7 [4.6-10.3] ng/mL) were evaluated. The median time from mpMRI to RP was 3 (1-5) months. At radical prostatectomy, 23% (188/812) of patients had EPE at pathology and 41% (133/324) of positive EPE calls on mpMRI were found to have EPE. For T2WI quality analysis, 35% (284/812) of sequences were classified as non-diagnostic and 65% (528/812) were categorized as diagnostic by the AI algorithm. For ADC maps, 32% (260/812) were classified as non-diagnostic and 68% (552/812) as diagnostic. Compared to non-diagnostic T2WI, diagnostic scans were associated with lower MRI/pathology mismatch for prediction of EPE (34% [97/284] vs. 28% [149/528],  $P=0.093$ ) and lower false positive rate (28% [80/284] vs. 21% [111/528],  $P=0.024$ ). Diagnostic T2WI also had significantly higher specificity for detection of EPE at mpMRI than non-diagnostic images (73% [294/405] vs. 63% [139/219],  $P=0.023$ ). No significant difference in EPE evaluation were observed between diagnostic and non-diagnostic ADC maps.

#### CONCLUSION

Our study successfully employed a deep learning-based AI algorithm to classify image quality of prostate MRI and demonstrated that preoperative T2WI quality is crucial for accurate EPE evaluation. Better quality T2WI was associated with higher specificity and fewer false positive calls for prediction of EPE at final pathology.

#### CLINICAL RELEVANCE/APPLICATION

Preoperative T2WI quality is critical for ruling out EPE at pathology using MRI, and AI can be used to objectively assess the quality of prostate MRI scans.

#### W2-SPGU-2 Histopathological Validation of Prostate Cancer Characterization with Magnetic Resonance Fingerprinting and Apparent Diffusion Coefficient Mapping

#### PURPOSE

To evaluate the utility of magnetic resonance fingerprinting (MRF) and apparent diffusion coefficient (ADC) mapping for characterizing prostate lesions with histopathological validation.

#### METHODS AND MATERIALS

This institutional review board-approved retrospective study included prospectively collected data of 91 biopsy-naive men with elevated PSA-levels suspected of having prostate cancer (PCa; 65.7 +/- 7.8 years). All patients underwent a multiparametric MRI examination at a 3T Philips Ingenia scanner (Philips Healthcare, Best, the Netherlands) and were classified by trained radiologists following the PI-RADS 2.1 scoring system. T1 and T2 mapping was performed using 2D fast imaging with steady-state precession-based MRF with spiral readout. ADC maps were calculated based on b-values = 100, 400, 800 s/mm<sup>2</sup>. Zonal segmentation of the prostate was performed using a convolutional neural network with subsequent revision by a trained radiologist. Lesions were manually segmented and correlated with histopathology after targeted biopsy/prostatectomy. Systematic differences of T1-/T2-relaxation times and ADC values between different histopathological ISUP scores were assessed using one-way analysis of variance with Tukey type post hoc comparisons to adjust for multiple testing.

#### RESULTS

32 patients were classified as PI-RADS 2, 21 as PI-RADS 3, 21 as PI-RADS 4 and 17 as PI-RADS 5. In total 89 lesions were

segmented, 72 in the peripheral zone (PZ), 17 in the central gland. In 3 patients clinically insignificant PCa was found in histology that had previously not been described on imaging. 4 patients did not undergo biopsy/surgery. Mean ADC values decreased significantly with increasing ISUP scores (e.g. mean ADC in PZ  $1.5 \cdot 10^{-3} \text{mm}^2/\text{s}$  vs. mean ADC in ISUP 3 lesion  $1.0 \cdot 10^{-3} \text{mm}^2/\text{s}$ ;  $p < 0.0001$ ). Mean T1-/T2-relaxation times decreased significantly particularly with higher ISUP scores, i.e.  $\geq 3$  (e.g. mean T1-/T2-relaxation time in PZ 1759.1/50.5 ms vs. mean T1-/T2-relaxation time in ISUP 3 lesion 1541.5/30.9 ms;  $p < 0.0001$  /  $p = 0.0012$ ).

#### **CONCLUSION**

s ADC and MRF based relaxometry allow quantitative characterization of prostate lesions that correlate with histopathology. MRF based relaxation times might aid in the diagnosis of clinically significant PCa. Further validation studies are needed.

#### **CLINICAL RELEVANCE/APPLICATION**

There is growing interest in the clinical application of quantitative imaging techniques for more objective assessment of prostate lesions. MRF is a fast and efficient method that promises to differentiate low- and intermediate/high-grade PCa in the future. In particular, with regard to the application of artificial intelligence and deep learning this could be an interesting approach in addition to traditional ADC assessment.

## Abstract Archives of the RSNA, 2023

W2-SPHN

### Head & Neck Imaging Wednesday Poster Discussions

#### Sub-Events

#### W2-SPHN-1 Evaluating the Application of Multiplexed Sensitivity Encoding (MUSE) Diffusion Weighted Imaging (DWI) in Nasopharyngeal Tumors: Comparison with Single-shot DWI with and without Deep Learning Reconstruction

##### Participants

Akinori Hata, PhD, Suita, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the image quality of multiplexed sensitivity encoding (MUSE) diffusion weighted imaging (DWI) for the evaluation of nasopharyngeal tumors comparing with single-shot DWI with and without deep learning reconstruction (ssDWI-DL and ssDWI).

##### METHODS AND MATERIALS

This study retrospectively evaluated patients with nasopharyngeal tumors who underwent MRI from July 2022 to February 2023. All patients underwent ssDWI, ssDWI-DL, MUSE, and fat-suppressed T2-weighted imaging. Two radiologists evaluated the image quality on a 5-point scale (1=no-diagnostic quality, 2=substantial deficits in image quality, 3=moderate, 4=good, and 5=excellent) in terms of the distortion of the original tumor, lymph node morphology, and overall image quality. Apparent diffusion coefficient (ADC) values were calculated in the original tumor and the lymph node. The image quality scores and ADC values were compared among ssDWI, ssDWI-DL, and MUSE using the Wilcoxon signed rank test and paired t-test, respectively. Bonferroni correction was used for the multiple comparisons.

##### RESULTS

A total of 23 patients (age  $70 \pm 17$  years; 5 women) were included in this study. In terms of the original tumor, MUSE showed a significantly higher score than ssDWI and ssDWI-DL (ssDWI,  $2.89 \pm 0.88$ ; ssDWI-DL,  $2.85 \pm 0.90$ ; and MUSE,  $3.78 \pm 0.75$ ). MUSE, ssDWI-DL, and ssDWI showed significantly higher scores in that order for the lymph node and overall image quality (lymph node; ssDWI,  $2.14 \pm 0.54$ ; ssDWI-DL,  $3.06 \pm 1.12$ ; MUSE,  $3.36 \pm 0.78$ ; overall image quality; ssDWI,  $1.80 \pm 0.29$ ; ssDWI-DL,  $2.74 \pm 0.64$ ; MUSE,  $3.26 \pm 0.56$ ). There was no significant difference among ssDWI, ssDWI-DL, and MUSE (ssDWI,  $1.03 \pm 0.35$ ; ssDWI-DL,  $1.00 \pm 0.31$ ; MUSE,  $0.98 \pm 0.30$ ).

##### CONCLUSION

ssMUSE was advantageous in evaluation of nasopharyngeal tumors by decreasing the image distortion compared with ssDWI and ssDWI-DL.

##### CLINICAL RELEVANCE/APPLICATION

MUSE may be useful for imaging of nasopharyngeal tumors or lesions that are in contact with air and where distortion affects image quality.

#### W2-SPHN-2 An MRI-based Lymph Node Regression Grading Scheme for Nasopharyngeal Carcinoma after Radiotherapy

##### PURPOSE

To assess the prognostic value of magnetic resonance imaging (MRI)-based lymph node regression grade (LRG) in risk stratification of patients with nasopharyngeal carcinoma (NPC) after radiotherapy (RT).

##### METHODS AND MATERIALS

This study retrospectively enrolled 387 patients newly diagnosed with NPC between January 2010 and January 2013. A four-category MRI-LRG system based on the areal analysis of RT-induced fibrosis and residual tumor was established. Univariate analysis was performed with the Kaplan-Meier method and compared using the log-rank test. Multivariate analyses were conducted using Cox regression models to calculate the hazard ratios (HRs) with 95% confidence intervals (CIs) and adjusted p-values. Survival curves were calculated using the Kaplan-Meier method and compared using the log-rank test.

##### RESULTS

The MRI-LRG scores sum (LRG-sum) was an independent prognostic factor for progression-free survival (PFS) (HR, 2.50; 95% CI 1.28-4.90). LRG-sum =9 and >9 showed poorer 5-year PFS than LRG-sum =2 (66.1, 42.9, and 77.6%, respectively,  $p < 0.001$ ). A survival clustering analysis (SCA)-based decision tree model showed more complex interactions among LRG-sum and pretreatment and post-RT EBV DNA, yielding four patient clusters with differentiated disease progression risks (5-year PFS of 89.5, 76.4, 57.6, and 27.8%, respectively), which showed better risk stratification than post-RT EBV DNA alone.

##### CONCLUSION

The MRI-LRG system adds prognostic information and may be used as a reliable and non-invasive way to stratify treatment

s The MRI-LRG system adds prognostic information and may be used as a reliable and non-invasive way to stratify treatment modalities for patients with NPC.

#### **CLINICAL RELEVANCE/APPLICATION**

Residual nodal disease after definitive radiotherapy (RT) has been associated with poor survival outcomes in patients with nasopharyngeal carcinoma. Here the authors propose a magnetic resonance imaging-based lymph node (LN) regression grade (MRI-LRG) system to quantitatively evaluate the LN response to RT. Patients with high LRG after therapy maintain a high risk of disease failure when compared to patients with low LRG, underscoring the prognostic value of MRI-LRG system in nasopharyngeal carcinoma after RT.

#### **W2-SPHN-3 Application of Dual-energy CT Spectral Quantification in Diagnosing of Cervical Lymph Node Metastasis in Papillary Thyroid Carcinoma**

##### **PURPOSE**

To evaluate the value of spectral quantitative measurements on dual-energy CT (DECT) for preoperative diagnosis of metastasis to the cervical lymph nodes (LNs) in patients with papillary thyroid carcinoma (PTC).

##### **METHODS AND MATERIALS**

Twenty-two consecutive patients with thyroid nodules who underwent spectral imaging on dual-energy CT before surgery were collected. Virtual monochromatic images at energy of 70 keV, water-calcium and fat-hydroxyapatite (HAP) decomposition images were reconstructed. For each lymph node, DECT-derived water and fat concentration were measured. Student's t test was used for continuous variables. Receiver operating characteristic (ROC) analysis was performed to evaluate the diagnostic efficacy of the continuous variables. The area under the curve (AUC), optimal cut-off value and the corresponding sensitivity and specificity were calculated.

##### **RESULTS**

A total of 18 LNs (8 metastatic, 10 non-metastatic) from 15 patients (9 patients with PTC, 6 patients with benign thyroid nodules) were detected by spectral CT imaging with the reference of postoperative pathologic examination. Assessment of quantitative measurements revealed significant differences between metastatic and non-metastatic LNs in water concentration ( $1032.91 \pm 10.65$  mg/cm<sup>3</sup> vs  $1042.11 \pm 6.20$  mg/cm<sup>3</sup>;  $t=2.296$ ,  $P=0.036$ ) and fat concentration ( $986.85 \pm 8.02$  mg/cm<sup>3</sup> vs  $997.12 \pm 7.94$  mg/cm<sup>3</sup>;  $t=2.714$ ,  $P=0.015$ ), respectively. The AUCs of water and fat concentration for diagnosing lymph node metastasis were 0.750 and 0.838, respectively. The optimal cut-off values of water and fat concentration were 1031.48 mg/cm<sup>3</sup> (sensitivity, 62.5%; specificity, 100.0%) and 990.67 mg/cm<sup>3</sup> (sensitivity, 75.0%; specificity, 90.0%).

##### **CONCLUSION**

s Quantitative assessment with dual-energy spectral CT showed promising value for preoperative diagnosis of metastatic cervical lymph nodes in patients with PTC.

#### **CLINICAL RELEVANCE/APPLICATION**

Preoperative assessment of LN metastasis in PTC by CT spectral imaging is of great clinical value to locate metastatic LNs accurately and reduce unnecessary lateral neck dissections.

#### **W2-SPHN-4 Amide Proton Transfer Imaging of Differentiation in Malignant and Benign Parotid Tumors**

##### **PURPOSE**

To assess the usefulness of amide proton transfer weighted imaging (APT<sub>w</sub>) in the differentiation of parotid gland tumors

##### **METHODS AND MATERIALS**

Patients with parotid gland tumors who underwent APT<sub>w</sub> were retrospectively enrolled and divided into groups according to pathology. Two radiologists evaluated the APT<sub>w</sub> image quality independently with quality score=2 were enrolled. The maximum and average value of APT (APT<sub>max</sub> and APT<sub>mean</sub>) were measured (Figure 2). The APT<sub>max</sub> and APT<sub>mean</sub> were compared in differentiating between malignant and benign tumors (BTs), and in characterizing pleomorphic adenomas (PAs), Warthin tumors (WTs) and malignant tumors (MTs). Independent sample t test, Kruskal-Wallis H test and Receiver-operating-characteristic (ROC) analysis were used for statistical analysis.

##### **RESULTS**

Seventy three patients were included for image quality evaluation (Figure 1). 32/73 parotid tumors and 29/73 were considering for score 4 and 3 respectively. After excluding lesions with quality score<2, the APT<sub>mean</sub> and APT<sub>max</sub> of MTs were ( $4.15 \pm 1.33$ )% and ( $7.43 \pm 1.61$ )%, higher than BTs ( $2.74 \pm 1.04$ )% and ( $5.25 \pm 1.54$ )% respectively ( $p<0.05$ ). The area under the corresponding curve (AUC) of APT<sub>mean</sub>, and APT<sub>max</sub> was 0.819 and 0.821 respectively. MTs indicated significantly higher APT<sub>mean</sub> and APT<sub>max</sub> than PAs ( $p<0.05$ ) and WTs ( $p<0.05$ ). (Table 3-6)

##### **CONCLUSION**

s Both APT<sub>max</sub> and APT<sub>mean</sub> can differentiate BTs and MTs, However, the images of parotid glands still needs to be improved to reduce artifacts. Most APT<sub>w</sub> images in parotid tumors had acceptable image quality to APT<sub>w</sub> value evaluation.

#### **CLINICAL RELEVANCE/APPLICATION**

APT imaging is an usefulness method that can be performed without contrast enhancement for the differentiation of parotid tumors.

#### **W2-SPHN-5 Differentiation of Common Benign Parotid Gland Tumors by T2WI-Based Texture Analysis and Susceptibility-Weighted Imaging**

##### **PURPOSE**

To evaluate the role of T2WI-based texture analysis and its combination with susceptibility-weighted Imaging (SWI) in characterizing pleomorphic adenoma (PA) and Warthin's tumor (WT).

## METHODS AND MATERIALS

Thirty-seven patients (21 PA and 16 WT) who underwent T2WI and SWI at 3.0T (Ingenia CX, Philips Healthcare, the Netherlands) were retrospectively enrolled (Table 1). Two radiologists assessed MRI sequences retrospectively. Fat-suppressed T2-weighted image was used for texture analysis (TA) on the software 3D-Slicer and Intratumoral susceptibility signal intensities (ITSS) were measured in minimum intensity projection (SWI-MinP) according to the previous study. The ROI for TA was drawn to cover the lesion as completely as possible on each slice excluding necrotic and blood vessels (Figure 1). Histogram parameters including mean, median, entropy, skewness, kurtosis, maximum, minimum and 10th, 90th percentiles were calculated. The interobserver reliability was assessed via intraclass correlation coefficient (ICC) (good agreement if ICC > 0.75). The mean values from the two observers were used for the subsequent analysis. The independent sample t-test or Mann-Whitney U test was used to compare the differences in histogram parameters and ITSS between PA and WT. The diagnostic value was determined on receiver operating characteristic (ROC) analysis. Logistic regression was used to calculate the AUC of TA parameters combined with ITSS.

## RESULTS

Interobserver reliability between the two observers was good (Table 2~3). WT showed significantly lower values on mean, entropy and significantly higher values on skewness and kurtosis than PA ( $p < 0.05$ ). The differences in ITSS grades were statistically significant between PA and WT ( $p < 0.05$ ) (Table 2~3). The area under the corresponding curve (AUC) of mean, entropy, skewness, kurtosis and ITSS were 0.779, 0.726, 0.754, 0.687 and 0.718 respectively. The combined AUC of entropy and ITSS could improve diagnostic performance which was statistically different from ITSS ( $p = 0.04$ ) (Table 4~5, Figure 2).

## CONCLUSION

Mean, entropy, skewness, kurtosis and ITSS allowed the identification of PA and WT. The combination of four significant histogram parameters and ITSS may suggest the improvement in diagnostic performance.

## CLINICAL RELEVANCE/APPLICATION

PA and WT are the most common benign tumors in the parotid gland. PA can recur and had a tendency to be malignant. WT rarely has malignant transformation and only needs to be treated tumor resection.

## W2-SPHN-6 MR Imaging with 15-channel Dental Coil Compared with Standard 20-channel Coil in Patients with Head and Neck Tumors and Suspected Bone Invasion

Participants

Iris Burck, MD, Frankfurt, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

To compare the diagnostic accuracy of a high-resolution 15-channel dental coil with that of a standard 20-channel head and neck coil in MRI diagnosis of head and neck tumors with suspected bone invasion.

## METHODS AND MATERIALS

A total of 37 patients (20 men and 17 women; mean age,  $65.8 \pm 15.0$  years; range: 28-95 years) with head and neck tumors and clinical suspicion of bone invasion underwent staging MRI with both coils in the same examination before surgery. Two specialized radiologists with 4 and 10 years of experience retrospectively evaluated both image datasets for bone infiltration. Additionally, subjective image quality, metal artefacts, and delineation of the tumors were rated on a 5-point-rating-scale. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of tumor lesions were calculated to quantitatively measure image quality. Sensitivity and specificity of the different coils in detecting bone invasion were evaluated by comparing the imaging results with postoperative histopathologic findings. Interobserver agreement was calculated using the Cohens Kappa.

## RESULTS

SNR and CNR values of tumor lesions were significantly higher with the 15-channel dental coil compared to the standard 20-channel head and neck coil (SNR averaged 12.1 versus 9.9, CNR 3.6 versus 1.5). The 15-channel dental coil was found to be more sensitive than standard head and neck coils (100% vs. 72%) and was more specific (98% vs. 88%) in detecting tumor bone invasion. Of 21 histopathologically confirmed tumors with bone invasion, 16 were detected using the standard 20-channel head and neck coil and 21 were detected using the 15-channel dental coil. The 15-channel dental coil was superior in terms of image quality, metal artifacts, lesion delineation, and assessment of jaw infiltration. A high degree of interinvestigator agreement was noted for overall image quality ( $\kappa = 0.93$ ), artifact reduction ( $\kappa = 0.82$ ), lesion delineation ( $\kappa = 0.80$ ), and assessment of jaw infiltration ( $\kappa = 0.89$ ).

## CONCLUSION

MR imaging with 15-channel dental coils has significantly better image quality and accuracy in detecting head and neck cancer compared with 20-channel head and neck coils.

## CLINICAL RELEVANCE/APPLICATION

The use of a 15-channel dental coil improves diagnostic accuracy in the detection and characterization of head and neck cancer especially with bone infiltration and contributes to more accurate cancer treatment.

## W2-SPHN-7 The Imaging Quality Assessment of Synthetic MRI in Nasopharyngeal Carcinoma: A Preliminary Study

## PURPOSE

To compare the imaging quality between the conventional and synthetic T1WI and T2WI.

## METHODS AND MATERIALS

Fifty-nine patients with nasopharyngoscope-confirmed nasopharyngeal carcinoma (NPC) were prospectively included between August 2018 and May 2019. The image quality was evaluated by two radiologists (1 and 2, with 21 and 2 years of tumor-imaging experience, respectively). The patient order was randomized, as was the review order of the conventional or synthetic T1WI and T2WI images. The image quality was assessed based on following 4 factors on a 5-point Likert scale. (1) Sharpness of the lesion edge (1 = not sharp; 2 = a little sharp; 3 = moderately sharp; 4 = well sharp; 5 = very sharp); (2) Lesion conspicuity (1 = difficult to find; 2 = minimally perceivable; 3 = recognizable; 4 = easy to detect, good contrast of lesion; 5 = excellent contrast of lesion); (3) Motion artifacts (1 = severe, difficult to diagnose; 2 = a little severe, accessible to diagnose; 3 = moderate; 4 = mild; 5 =

absence of artifacts); (4) Overall image quality (the three factors above added together, 1 = unacceptable; 2 = poor; 3 = moderate; 4 = good; 5 = excellent). As for overall image quality, ratings of = 3 were considered acceptable overall. The Wilcoxon signed-rank test was adopted to compare the image quality scores between conventional and synthetic T1WI and T2WI. The inter-class agreement of image scores between two radiologists was evaluated by Kappa value (0.21-0.30, fair; 0.41-0.60, moderate; 0.61-0.80, good; 0.81-1.00, excellent).

## **RESULTS**

The interobserver agreements of image quality scores for conventional and synthetic T1WI and T2WI were good or excellent (Kappa values = 0.637-0.919). There were no statistically significant differences between conventional and synthetic T2WI in sharpness of the lesion edge, lesion conspicuity, motion artifacts, and overall image quality ( $P = 0.074-0.835$ , Table). However, conventional T1WI showed higher image quality than synthetic T1WI (all  $P = 0.007$ , Table). As for diagnostic quality scoring, all synthetic T1WI and T2WI images had scores = 3, which showed acceptable image quality in clinical practice.

## **CONCLUSION**

s Synthetic T1WI and T2WI may be acceptable for clinical use in nasopharynx, and with its ability to generate other contrast images (including PDWI, FLAIR and so on) and three quantitative maps (T1, T2 and PD maps) in a single scan, SyMRI has good prospects for clinical application.

## **CLINICAL RELEVANCE/APPLICATION**

The application of SyMRI in clinical could shorten the scan time while maintain acceptable image quality, which can reduce workload and increase productivity.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

W2-SPIN

### Imaging Informatics Wednesday Poster Discussions

#### Sub-Events

#### W2-SPIN-1 Reproducibility of Automated Segmentation of Abdominal Anatomical Structures on CT using the Total Segmentator

##### Participants

Lorraine Abel, MD, Basel, Switzerland (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the reproducibility of segmentation results of TotalSegmentator, an artificial intelligence based segmentation algorithm, on various anatomical structures across multiphasic computer tomography (CT) exams.

##### METHODS AND MATERIALS

We retrospectively collected 1483 multiphasic abdominal CT exams acquired at the University Hospital in Basel between 01.01.2012 and 31.12.2022, each consisting of non-contrast (NC), arterial (ART), and portal venous (PV) phase, totaling 4449 image series. Using the AI-based segmentation model TotalSegmentator (<https://github.com/wasserth/TotalSegmentator>), the volume of 34 abdominal organs and additional structures (including bone, muscles) were obtained on all 4449 series. Similarity of the segmentation across all contrast phases was evaluated for each exam with two metrics: the spatial overlap in terms of Dice Similarity Coefficient (DSC) and the difference of segmented volumes. Volume differences below 5% were considered reproducible, as they are not typically clinically relevant and lie close to human inter-rater variability. Thus, non-inferiority and non-superiority testing was performed using a 5% margin.

##### RESULTS

Overall, the automated segmentation demonstrated high reproducibility in terms of mean DSC regarding comparison of PV versus ART 0.887 (95% CI: 0.882, 0.891), ART versus NC 0.867 (95% CI: 0.861, 0.872) and PV versus NC 0.853 (95% CI: 0.848-0.859) for all structures. The liver showed the lowest variability among abdominal organs, with a DSC of 0.920 (95% CI: 0.917, 0.923). Reproducibility was particularly high for bones and muscles with a mean DSC of 0.922 (95% CI: 0.919, 0.926) and 0.939 (95% CI: 0.936, 0.942) respectively. Lower DSC scores were observed mainly in cases with anatomically relevant pathologies (e.g. organ bleeding) which blur the organ boundaries, and in smaller structures. The volume of 31 of the 34 structures varied less than 5% ( $p < 0.05$ ) between contrast phases: a volume difference greater than 5% was observed exclusively for the adrenal glands and the gallbladder when comparing NC to PV.

##### CONCLUSION

The automated segmentations produced by TotalSegmentator demonstrated high reproducibility for most of the evaluated abdominal structures when comparing different contrast phases in multiphasic abdominal CTs. Small and variable structures demonstrated lower reproducibility. Also, relevant pathologies blurring the organ boundaries hampered the segmentation performance.

##### CLINICAL RELEVANCE/APPLICATION

A clinically reliable automated segmentation tool (TotalSegmentator) segmenting multiple organs and structures while being aware of its disadvantages may further support radiological research and ultimately enhance the clinical impact of radiology.

#### W2-SPIN-2 Deep Learning Assisted Curation of the CANDID-III Dataset with Free-text Reports

##### PURPOSE

This project aims to curate the CANDID-III dataset, which consists of adult chest radiographs with comprehensive labels derived from both manual and AI-assisted annotation.

##### METHODS AND MATERIALS

The CANDID-II dataset is an in-development chest radiograph dataset containing 33,486 anonymized free-text radiological reports. CANDID-III inherited the same 45 radiological labels from the CANDID-II dataset, which were mapped to UMLS ontology for standardization, forming the manually labelled portion of the CANDID-III dataset. An ensemble transformer-based label extraction model, combining three individual natural-language processing (NLP) algorithms, was trained and validated on the CANDID-II dataset in an 80:20 proportion. Each algorithm was individually trained on every radiological label, and the highest accuracy algorithm was chosen on a per-label basis for inclusion into the final ensemble model. The model was then used to automatically label the remaining CANDID-III dataset. An evaluation set of 552 reports, with balanced sampling across radiological findings from the AI-labeled portion of the CANDID-III dataset, was assessed by selected annotation team members, including a final-year radiology trainee and a fourth-year postgraduate medical doctor. Label-specific 'mention' F1 scores were calculated for the final ensemble model, with 'not mentioned' as negative and 'indeterminate, absent, present' as combined positive classifications.

##### RESULTS

The completed CANDID-III dataset contains 322,473 images and 220,977 anonymized free-text radiological reports from 94,210 unique patients (1:1.04 M:F ratio). AI-assisted annotation was performed on 88% of the CANDID-III dataset. For the AI-assisted annotation portion of the CANDID-III dataset, the labelling model has a macro-F1 score of 0.88 and micro-F1 score of 0.94 across all findings. Seven labels are shared with CheXpert, with F1 scores ranging from 0.93 to 1.0. F1 scores for 30 CANDID-III labels are above 0.90, while 8 labels range between 0.80 and 0.90.

## CONCLUSION

The CANDID-III dataset provides a large, comprehensively labeled, and high-quality adult chest radiograph dataset with anonymized free text reports. The dataset adds numerous new clinically significant radiological annotations that are labelled to a high accuracy. It contributes to the repertoire of publicly available chest radiograph datasets for AI development. Instructions to access the dataset can be accessed at DOI: 10.17608/k6.auckland.22726004.

## CLINICAL RELEVANCE/APPLICATION

The CANDID-III dataset can be used to train and test AI algorithms for a variety of applications including triaging, lung cancer screening, image generation, and automated preliminary detection of radiographic abnormalities.

## W2-SPIN-3 Estimating the Impact of Chest Radiograph Triage using AI: A Real-life Multicenter Diagnostic Cohort Study

### PURPOSE

Radiology worklist prioritization with AI can potentially reduce the turnaround time for remarkable cases. This study externally tested a chest radiograph (CXR) artificial intelligence (AI) tool for relocating remarkable CXRs to the top of the worklist and compared this model to the current standard, where CXRs are sorted due to a priority level set by the ordering physician.

### METHODS AND MATERIALS

In this retrospective external validation study, we included consecutive CXRs from the radiology departments of four hospitals in Denmark. The reference standard was based on two thoracic radiologists independently labelling all CXRs into remarkable or unremarkable CXRs. In case of disagreement, a third thoracic radiologist independently adjudicated the results. A commercially available CE-marked and partly FDA-cleared AI model was post-processed to output at probability score for CXR remarkableness. Binary clinical priority levels (urgent/routine) were extracted from the local RIS and compared to the AI tool priority (remarkable/unremarkable) output using McNemar tests, i.e., 'urgent' was juxtaposed to 'remarkable' and 'routine' to 'unremarkable'.

### RESULTS

The analysis was performed on 1990 consecutive CXRs after exclusion of 77 primarily due to insufficient lung visualization and 7 due to processing error by the AI. Of these; 1276 (64%) were remarkable and 717 (36%) unremarkable according to the reference. The AI model achieved an AUC of 0.926 [95% CI: 0.915-0.937]. At a pre-specified 90% sensitivity threshold the model predicted 1148 (57.7%) as remarkable with a sensitivity of 90% [88.2-91.5%], a negative predictive value (NPV) of 81.0% [77.8-83.9%], positive predictive value (PPV) of 87.2% [85.3-88.9%] and specificity of 76.5% [73.2-79.5%]. This binary clinical priority level had 1422 (71.5%) classified as 'urgent' giving a sensitivity of 78.5% [76.2-80.7%], NPV of 51.8% [47.6-55.9%], PPV of 70.5% [68.0-72.8%] and specificity at 41.2% [37.5-44.9%] ( $p < 0.001$  for all comparisons).

### CONCLUSION

An AI model achieved an excellent discrimination between unremarkable and remarkable CXRs in a consecutive multicenter cohort. The AI model was superior to the clinical priority levels for identifying remarkable and unremarkable CXRs.

## CLINICAL RELEVANCE/APPLICATION

This AI tool, specifically post-processed to output a probability score for remarkableness, can be used to prioritize CXR worklists, which can confer a significant benefit in terms of worklist prioritizing compared to the traditional clinical priority levels used today.

## W2-SPIN-5 Automatic Detection of Endotracheal Tube Positioning on Chest Radiograph

### PURPOSE

Endotracheal tubes (ETTs) are poorly positioned in up to 25% of out of operating room intubations [1]. Misplacement of ETTs can lead to pneumothoraces and inadequate ventilation. Rapid identification of ETT positioning is essential to minimize adverse outcomes. Current deep learning (DL) methods involve classification of correct vs incorrect ETT placement or crude bounding box localization. These methods lack the ability to accurately identify both the carina and ETT tip [2]. The purpose of this study is to evaluate a DL model that automatically measures the distance between the tip of the ETT and the carina.

### METHODS AND MATERIALS

In this retrospective study, a region proposal keypoint convolutional neural network (R-CNN) was trained on a subset of the publicly available CLiP dataset consisting of 1320 frontal CXRs. The CLiP dataset contains 30083 radiographs from the NIH Clinical Center. The model identifies two keypoints corresponding to the tip of the ETT and the carina on each radiograph. Various augmentation techniques (brightness, contrast, noise, rotation) were applied to the training set. Predictive performance on a held-out test set with 5-fold cross-validation was evaluated by comparing the distance between ground truth and predicted keypoints.

### RESULTS

The model correctly identifies  $98.9 \pm 0.20\%$  (mean  $\pm$  SD) of these keypoints on a held-out test set consisting of 109 images. A correctly identified keypoint is defined as a prediction that falls within one centimeter of the corresponding ground truth keypoint. The average error in distance for each individual keypoint detection was  $0.72 \pm 0.24$  cm. This is comparable to inter-radiologist error, which has been reported as 0.7 cm [3]. The mean absolute error in ETT to carina measurement was  $0.35 \pm 0.12$  cm. For classification of correct vs incorrect placement, the model achieved an accuracy of  $93.1 \pm 0.9\%$  (precision  $95.4 \pm 2.7\%$ ; recall  $95.5 \pm 2.4\%$ ; NPV  $86.1 \pm 8.2\%$ ; specificity  $86.9 \pm 6.6\%$ ; F1  $95.4 \pm 0.6\%$ ).

### CONCLUSION

A deep learning model can correctly identify the tip of an ETT and the carina on CXR. It can accurately measure the distance

between carina and ETT, thereby detecting misplaced ETTs at the time of image acquisition.

#### **CLINICAL RELEVANCE/APPLICATION**

This method has the potential to expedite the detection of misplaced ETTs, thereby facilitating prompt interventions and improving patient outcomes. Furthermore, our findings surpass those of prior classification-only strategies, as our approach offers an estimate of the distance required to either advance or withdraw the ETT. Lastly, this versatile technique can be adapted for use in a wide range of measurement tasks on 2D imaging.[1] doi.org/10.1038/s41597-021-01066-8[2] doi.org/10.1016/j.acra.2022.04.022 [3] doi.org/10.1007/s10278-021-00495-6

## **W2-SPIN-6 Opportunistic Breast Cancer Screening using Non-contrast CT Imaging**

#### **PURPOSE**

To develop a non-contrast CT based opportunistic breast cancer screening approach as an alternative to mammography for detecting breast cancer using artificial intelligence.

#### **METHODS AND MATERIALS**

Our proposed model is a two-stage approach. In the first stage, we locate and crop out the two breasts using a breast segmentation model, which is trained using nnUNet. In the second stage, a customized multi-task U-net is employed to process the single cropped breast, producing simultaneous segmentation and classification results. The segmentation results include the breast and tumor masks, while the classification result outputs the approximate probability of breast cancer. The training dataset for the second stage includes 411 cancerous breasts and 411 healthy breasts as normal control, with confirmation through pathology reports. The external test dataset includes 386 cancerous cases from another institution and 905 normal cases from three other institutions (473/230/202). Additionally, the breast tumor masks were annotated on corresponding contrast-enhanced CT images by experienced radiation oncologists and then transferred to non-contrast CT.

#### **RESULTS**

The proposed model achieved a performance comparable to the recently reported mammography-based AI breast cancer screening system. For the 5-fold cross-validation on the internal dataset, the model achieved an AUC of 0.970 (95% confidence interval (CI) 0.958-0.982), sensitivity of 0.824 (95% CI 0.783-0.866), and specificity of 0.982 (95% CI 0.966-0.994), which were superior to the mammography-based AI system. In addition, the proposed model demonstrated advantages in generalization ability on the external test dataset, with an AUC of 0.939 (95% CI 0.922-0.955), sensitivity of 0.762 (95% CI 0.717-0.805) and specificity of 0.961 (95% CI 0.949-0.974) compared to mammography-based AI system.

#### **CONCLUSION**

The proposed non-contrast CT based opportunistic breast cancer screening approach using a two-stage model achieves a performance comparable to the recently reported mammography-based AI screening system, providing a promising way for opportunistic breast cancer screening.

#### **CLINICAL RELEVANCE/APPLICATION**

The proposed approach of using non-contrast CT for breast cancer screening has the potential to overcome the limitations of mammography-based screening in developing countries where medical resources are limited. This could improve early detection and ultimately contribute to prolonged survival rates for breast cancer patients. Further studies are needed to confirm the effectiveness of this approach and to optimize its implementation in clinical settings.

#### **W2-SPIR-1 Gastrointestinal Tract Perforation after Radiofrequency Ablation for Hepatic Tumor: Incidence and Risk Factors**

##### Participants

Kyowon Gu, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the incidence of gastrointestinal (GI) tract perforation after radiofrequency ablation (RFA) for hepatic tumor and to assess its risk factors.

##### METHODS AND MATERIALS

The study included a retrospective cohort (n = 4,799) of patients with malignant tumors underwent RFAs (n = 7,206) between November 2008 and May 2020. Among them, 69 cases with thermal injury of GI tract were identified through a search of electronic medical records system. These patients were divided into presence of perforation (n = 8) or not (n = 61) based on the imaging review of following computed tomographic (CT) findings: (a) gastrointestinal wall defect and (b) pneumoperitoneum. Risk factors for GI tract perforation based on clinical, technical, and follow-up CT were identified with multivariate logistic regression analysis.

##### RESULTS

The incidence of thermal injury of GI tract and its perforation during observation period was 0.9% (69 of 7206) and 0.1% (8 of 7206), respectively. All perforation cases were not identified on CT immediately after RFA. The median time to its development was 7 days (range, 1-31 days). The type of adjacent GI tract and presence of diabetes mellitus were significantly different between the two groups (p < 0.05). Among the various risk factors, the type of adjacent GI tract (small bowel) was only significant factor for GI tract perforation after ablation (Odds ratio, 22.69; 95% confidence interval, 2.60-198.34; p = 0.005 [reference standard, stomach]).

##### CONCLUSION

GI tract perforation after RFA for hepatic tumor was rare, but it occurred late. Thus, the careful follow-up is needed when we treat the index tumor adjacent small bowels.

##### CLINICAL RELEVANCE/APPLICATION

GI tract perforation is a rare complication of liver RFA but can be missed on immediate post-ablation CT. Careful follow-up is recommended especially when the tumor is near small bowel and for DM patients.

#### **W2-SPIR-2 CT-guided Percutaneous Radiofrequency Ablation Therapy for Liver Malignancies Adjacent to the Heart: A Safety and Efficacy Analysis in 42 cases**

##### Participants

Hong-Tao Hu, MD, PhD, Zhengzhou, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To explore the safety and effectiveness of CT-guided percutaneous radiofrequency ablation (RFA) in the treatment of hepatic malignancies adjacent to the heart.

##### METHODS AND MATERIALS

From January 2019 to December 2020, 412 patients who underwent RFA for hepatic malignancies were retrospectively analyzed, of which 42 patients had lesions less than 5 mm from the border of the heart. During the follow-up period, the complete ablation rate within 1 month and 24 months and the treatment-related complications within 30 days were recorded, and the complete ablation rate of adjacent cardiac lesions and non-adjacent cardiac lesions was calculated. Univariate and multivariate Logistic regression analyzes were used to analyze the relevant prognostic factors affecting complete ablation.

##### RESULTS

A total of 42 patients had 61 lesions. The average tumor size of 42 adjacent cardiac lesions was 3.01±1.04cm, and the total diameter of intrahepatic lesions was 3.60 (2.98, 4.73)cm. During the 1-month follow-up, the complete ablation rates of lesions adjacent to the heart and non-adjacent to the heart were 85.7% (36/42) and 89.5% (17/19). The follow-up time ranged from 12 to 26 months, and 2 patients were lost to follow-up. The complete ablation rate of adjacent cardiac lesions was 82.5% (33/40), and the complete ablation rate of non-adjacent cardiac lesions was 88.2% (15/17). Univariate and multivariate Logistic regression analysis showed that liver metastases and not receiving preoperative TACE were independent risk factors affecting the rate of complete ablation (P<0.05). No serious complications related to RFA occurred during the treatment, and the overall safety was controllable.

## CONCLUSION

s CT-guided radiofrequency ablation of tumors adjacent to the heart is safe and effective.

## CLINICAL RELEVANCE/APPLICATION

It provides a new safe and effective method for liver tumors near the heart

## W2-SPIR-3 Artificial Intelligence for Rapid Prediction of Tumor Coverage after RF Ablation of Hepatocellular Carcinoma

### PURPOSE

To assess the technical success of radiofrequency ablation (RFA) in patients with hepatocellular carcinoma (HCC), we developed an artificial intelligence (AI) model to promptly estimate the percent tumor coverage without the need for segmentation or registration tools.

### METHODS AND MATERIALS

From 550 patients in the OPTIMA trial (patients with solitary HCC lesions between 3-7cm, randomized to RFA or RFA+LTLD), 185 patients were selected with well-defined pre-RFA tumor and devascularized (ablation) zones on enhanced CT, 1-month post-RFA. The isocenter of the tumor and of the ablation zones were identified and 2D axial images were extracted from CT and cropped with the region of interest (tumor/ablation) at the center. Images were augmented (Gaussian-noise and rotation applied), with a total of 1,456 image pairs available for training and testing. Feature extraction was performed on the image pairs using a Siamese network with CNN VGG16 and ImageNet weights, and predictive modeling was achieved using a 30-tree random forest classification algorithm. The percent of the tumor covered (ground-truth) was determined by semi-automatic 3D tumor and ablation zone image segmentation and elastic registration (3DSlicer). Cases were split into 4 classes: =50%, 50-70%, 70-90%, or =90% tumor coverage, depicting incomplete, partially incomplete, acceptable, or complete ablation given the technical difficulty of the ablation and potentially desired immune response. Training was done on 80% of cases (n=1,168 image pairs), and 20% of cases were set aside for testing (n=288 image pairs). The model was validated on 16 interventional radiology cases from a separate institution, with the key difference that confirmation images were taken immediately post-ablation in the external validation set.

### RESULTS

Overall model accuracy was 90% (AUC = 0.98, true positive rate = 0.87, and true negative rate = 0.96) reliably predicting the class of percent tumor coverage. Visual review of the test cases suggests that those with poor tumor coverage might be subject to an atypically rapid ablation zone shrinkage 1-month post-RFA whereas validation cases showed a more coherent percent tumor coverage immediately post-RFA, consistent with the AI model design.

## CONCLUSION

s An AI model that uses 2D images at the center of the tumor and 1-month post ablation can accurately estimate ablation tumor coverage for immediate estimation of technical RFA success.

## CLINICAL RELEVANCE/APPLICATION

Clinical tools for ablation confirmation need to be efficient to hope for adoption and treatment optimization. AI models can achieve ablation confirmation without applying resource-intensive segmentation and registration models.

## W2-SPIR-4 Percutaneous Image-guided Liver Tumor Ablations: Analysis of the Registry of the German Society for Interventional Radiology and Minimally Invasive Therapy (DeGIR) 2018-2021

Participants

Sebastian Zensen, MD, Essen, Germany (*Presenter*) Nothing to Disclose

### PURPOSE

Percutaneous image-guided tumor ablations are an essential tool in the treatment of liver malignancies. The aim of this evaluation was to analyze the use, technical success and complications of those interventions based on data from the prospectively managed multinational registry of the German Society for Interventional Radiology and Minimally Invasive Therapy (DeGIR, Deutsche Gesellschaft für Interventionelle Radiologie und minimal-invasive Therapie).

### METHODS AND MATERIALS

A total of 5792 percutaneous liver ablation procedures from 133 centers in Germany and Austria were examined. Median age was 67 years (IQR 58-75 years), 31.4% (1821/5792) of patients were female. For image guidance, CT was used in 91.4% (5293/5792), MRI in 2.4% (137/5792), ultrasound in 3.8% (222/5792), and combined imaging in 2.4% (140/5792). Ablation of the tumor with a safety margin was considered technical success.

### RESULTS

Microwave ablation (MWA) was used in 64.3% (3725/5792), and radiofrequency ablation (RFA) in 33.5% (1940/5792). A total of 3999 cases reported tumor etiology, in which 61.4% (2456/3999) were performed for liver metastases and 36.2% (1446/3999) for hepatocellular carcinoma (HCC). The median lesion diameter was 19 mm (IQR 12-27 mm). 90.6% (5247/5792) ablations were technically successful. The rate of technically successful ablations was significantly higher in MWA (93.4%, 3481/3725) than in RFA (84.8%, 1645/1940,  $p < 0.0001$ ). The total complication rate was 2.9% (170/5792). Compared to RFA, which had a complication rate of 1.0% (19/1940), MWA had a considerably higher complication rate of 3.9% (147/3725,  $p < 0.0001$ ). In 37.2% (2156/5792) of ablations additive needle track ablation was performed. Ablations with needle track ablation did not have a significantly higher rate of major complications (23.2%, (22/95) vs. 26.7% (20/75),  $p = 0.60$ ).

## CONCLUSION

s MWA is the most frequent ablation method ahead of RFA. Percutaneous image-guided liver tumor ablations have a high technical success rate, which is higher for MWA than RFA. Though generally low, the rate of complications is higher with MWA than RFA.

## CLINICAL RELEVANCE/APPLICATION

For the treatment of liver malignancies, percutaneous image-guided liver ablations such as microwave ablation and radiofrequency

for the treatment of liver malignancies, percutaneous image-guided liver ablations such as microwave ablation and radiofrequency ablation are efficient treatment options with low complication rates.

## **W2-SPIR-5 Estimation of Recurrence and Survival in Breast Cancer Cryoablation: A Retrospective Multisite Analysis of Patients Excluded from Prospective Cryoablation Clinical Trials**

Participants

Karim Oueidat, MD,BEng, Providence, RI (*Presenter*) Nothing to Disclose

### **PURPOSE**

Estimation of recurrence and survival in breast cancer cryoablation patients excluded from clinical trials.

### **METHODS AND MATERIALS**

Cryoablation is a well-tolerated minimally-invasive alternative to surgical excision for treating breast cancer. In keeping with clinical trial inclusion criteria, the optimal candidate would have a unifocal invasive ductal carcinoma without significant intraductal component, less than 1.5 cm in size, Nottingham grade 1-2 of 3, ER/PR+ and HER2-, at least 0.5-1 cm from the overlying skin and 0.3 cm from the underlying muscle. Requiring only local anesthesia, cryoablation may be particularly useful in patients with medical comorbidities placing them at higher risk for surgery with general anesthesia. Patients included in this study were excluded from cryoablation clinical trials. A retrospective review of ipsilateral breast tumor recurrence (IBTR) encompassing true recurrence (TR) and new primary (NP) events was done for n=123 patients treated outside of clinical trials across 7 institutions over 5.4 years; all patients were women and median age was 72 (range 37-99). To control for death before recurrence, a Competing Risk Analysis (CRA) model was used; Kaplan Meier (KM) estimation was used.

### **RESULTS**

All procedures were technically successful. There were a total of 6 (4.9%) minor procedure complications rated 1 on CTCAE scale. In all, there were 8 TRs, 6 NPs, and 10 deaths before TR or NP, and 11 deaths total—only 1 death was cancer related. Using CRA, the cumulative incidence of TR was 4.1% at 1 year, 8.2% at year 2, and 11.8% at year 3. The cumulative incidence of NP was 2.7% at year 1 and 7% at year 2. Together, the cumulative incidence of IBTR was 6.7% at year 1, 13.1% at year 2, and 17.9% at year 3. Finally, the cumulative incidence of death was 2.9% at year 1, 5.9% at year 2, 14.6% at year 3 and 21.7% at year 4.

### **CONCLUSION**

Breast cancer cryoablation is a safe and feasible alternative to surgical excision for select patients, including older patients, patients excluded from trials and patients who are considered high-risk for general anesthesia and surgery.

### **CLINICAL RELEVANCE/APPLICATION**

Cryoablation is an alternative to surgical excision for patients with breast cancer, even when considered suboptimal for cryoablation in select cases, and this may be particularly true for patients with medical comorbidities placing them at higher risk for surgery with general anesthesia.

## **W2-SPIR-6 Retrospective Analysis of MRI-guided Transurethral Ultrasound Ablation (TULSA) in Prostate Cancer Lesions at the Extreme Apex**

### **PURPOSE**

Maintenance of urinary continence when treating prostate cancer (PCa) at the extreme apex is a challenge for surgery, radiation, and focal therapy. Regulatory studies of TULSA spared 3mm at the apex, and the performance of dual ultrasound frequency MRI-controlled ablation in short target radii near the external sphincter is not yet known. This single-center retrospective analysis reports functional, imaging, and cancer surveillance outcomes in TULSA patients with extreme apical lesions.

### **METHODS AND MATERIALS**

Men with apical PCa lesions abutting or involving the external sphincter were identified among 138 men with ≥6 months follow-up after lesion-targeted or whole-gland TULSA. The target volume was defined based on disease factors and patient preference, using intraoperative DWI, ADC, and T2w images. A 10mm margin was targeted around the visible lesion when feasible. At the sphincter, a 5mm margin was targeted, including ≈50% of the external sphincter. Patients were followed with daily communication for 2 weeks, PSA every 3 months, and MRI, IPSS, IIEF at 6-9 months. Post-TULSA mpMRI was assessed for local recurrence using PI-RR.

### **RESULTS**

42 patients with treatment of apical lesions (37 primary PCa, 5 salvage) were identified, with median age of 63 (IQR 59-68) years, and follow-up availability of 9 (6-16) months. The proportion of men with primary GG 1-5 PCa were: 7%, 54%, 20%, 12%, and 7%, all having an MRI visible lesion. Median target volume was 29cc (IQR 22-34, range 10-70), with 99% (IQR 98-99%) of the target volume achieving a lethal thermal dose =240CEM43. PSA decreased from median 6.7 (IQR 4.7-9.7) to 0.9 (0.3-2.0) ng/mL. 93% of patients with follow-up mpMRI (n=28) had no evidence of residual disease; PI-RR scores 1-5 were: 8, 18, 0, 2, 0. Both men with PI-RR=4 underwent a repeat TULSA; 6 months after repeat ablation both had PI-RR=2 with PSA of 0.2 and 1.0 ng/mL. All patients are pad-free; two experienced urine leakage resolved by 3 months. 82% maintained baseline erection firmness sufficient for penetration (IIEF Q2=2). IPSS symptom scores were stable. 10 patients experienced Grade 1-2 adverse events (LUTS, mild hematuria, bladder spasms, and hydrocele) resolving within 4 weeks with oral medication. Two patients had Grade 3 events requiring endoscopic intervention (1 retention, 1 retention and bladder neck contracture). No grade =4 events and no rectal injuries occurred.

### **CONCLUSION**

This retrospective analysis demonstrates promising safety and efficacy of TULSA in patients with extreme apical lesions, preserving urinary continence despite ablation near the external sphincter.

### **CLINICAL RELEVANCE/APPLICATION**

TULSA is a promising prostate cancer treatment with minimal impact on urinary continence for thermal ablation of extreme apical lesions.

## Abstract Archives of the RSNA, 2023

#### W2-SPMK-1 Clinically Relevant Incidental Findings Detected on MRI Lumbar Spine Examinations: Our Experience in 1450 Studies

##### Participants

Dinesh Baviskar, MD, , India (*Presenter*) Nothing to Disclose

##### PURPOSE

The purpose of our study was to evaluate the types of incidental findings encountered during evaluation of MRI lumbar spine examinations and to ascertain their clinical relevance in view of the presenting symptoms.

##### METHODS AND MATERIALS

A total of 1450 patients (male-to-female ratio, 626:824; age range, 12-97 years) with history of low back pain / suspected herniated intervertebral disk, who underwent MRI of the lumbar spine between 1st June 2022 - 31st December 2022 were evaluated by trained Radiologists. The examinations were evaluated for the presence of any incidental findings. We defined incidental finding as any abnormal finding detected outside the Lumbar spine, bony canal, its contents and the paraspinal soft tissues. Incidence of the incidental imaging findings were calculated. For analysis, the relationship of incidental findings with clinical data of patient was used.

##### RESULTS

Overall, 128 patients (8.8%) had clinically relevant incidental findings. Uterine fibroids were the commonest (3.2% of total examinations) incidental findings seen in the females, whereas heterogeneous signal in the prostatic parenchyma was the commonest (3.8% of total examinations) findings in the male patients. Other findings encountered were - Pelvic Kidney, Adenomyosis of uterine myometrium, Pelvic congestion, Ovarian cyst, Dermoid cyst, Uterine polyp, Renal mass lesion, lymphadenopathy, etc.

##### CONCLUSION

Clinically relevant incidental findings detected on MRI examination of the lumbar spine were common and associated with symptoms confused with lumbar spine / backache causes. Most of the findings were benign, but we encountered one renal lesion which was later proven to be Renal cell carcinoma. An awareness of the prevalence of the clinically relevant incidental findings detected at MRI of the lumbar spine exams are helpful for diagnosing lesions which might be the primary cause of the presenting symptoms.

##### CLINICAL RELEVANCE/APPLICATION

Awareness about incidental findings on radiology examinations is very vital, particularly in cases where the symptoms might be overlapping and the primary cause might be the incidental finding detected on imaging. The clinical significance of these incidental finding has to be ascertained to avoid delay in initiating prompt and appropriate treatment to aid patient care.

#### W2-SPMK-2 The Diagnostic Value of Electron Density Map from Dual-layer Detector Spectral CT in Acute and Chronic Osteoporotic Vertebral Fractures

##### PURPOSE

To evaluate the diagnostic efficacy of electron density map (EDM) obtained from dual-layer detector spectral CT in acute and chronic osteoporotic vertebral fractures (OVFs).

##### METHODS AND MATERIALS

Retrospective study was performed on 48 patients with 53 acute and 57 chronic OVFs that were confirmed by MR. All the patients underwent DLCT plain scanning, and quantitative parameters such as electron density(ED), effective atomic number(zeff) and the attenuation of conventional 120 kVp polyenergetic image(PI) and 40, 70 and 100 keV virtual monoenergetic images(VMI) were measured. CT signs are evaluated by the radiologist, including endplate interruption sign, bone cortical folds, increased vertebral density, intravertebral gas shadow, anteroposterior diameter of vertebral body increased and vertebral compression degree. The quantitative parameters and CT signals between acute and chronic OVFs were compared using independent- samples t test or Chi-Square test. Logistic regression analysis was used to identify the independent risk factors and built predictive model. ROC curve was used to analyze the efficacy in the differential diagnosis of acute and chronic OVFs.

##### RESULTS

There were significant differences between acute and chronic OVFs in endplate interruption sign, bone cortical folds, increased vertebral density, intravertebral gas shadow and vertebral compression degree (all  $P < 0.05$ ). There were significant differences between acute and chronic OVFs in PI, 40, 70 and 100keV VMI attenuation value, zeff and ED (all  $P < 0.05$ ). Attenuation values of PI (OR=0.876,  $P=0.023$ ), ED (OR=10.446,  $P=0.024$ ), bone cortical folds (OR=0.023,  $P=0.012$ ), increased vertebral density

(OR=0.020, P=0.012) were independent risk factors for acute OVs. The combined model obtained the highest AUC (0.977) by combining attenuation values of PI, ED, bone cortical folds and increased vertebral density, with a sensitivity of 98.1%, and a specificity of 94.7%.

## CONCLUSION

s In the differential diagnosis of acute and chronic OVs, the diagnostic efficacy of EDM is higher than the CT values in PI and VMI; The efficacy is further enhanced when EDM is combined with CT values in PI, bone cortical fold, vertebral density increasing.

## CLINICAL RELEVANCE/APPLICATION

EDM can help clinicians make treatment decisions and improve patient prognosis by differentiating between acute and chronic OVs.

## W2-SPMK-3 Paraspinal Muscle Activation Quantified by Intravoxel Incoherent Motion Imaging (IVIM): Influence of Exercise Intensity on Muscle Perfusion in Adolescent Athletes

Participants

Adrian Marth, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose

## PURPOSE

Intravoxel incoherent motion (IVIM) imaging provides information on the perfusion of the muscular microstructure. This study aims to reveal relationships between IVIM signal changes and different levels of exercise intensity in adolescent athletes.

## METHODS AND MATERIALS

Twenty male athletes with a mean age of 15.7 years (SD 1.2) underwent magnetic resonance imaging (MRI) of the lumbar spine muscles at rest and after ergometer training at low intensity (50 Watt, n = 6), moderate intensity (100 Watt, n = 8) or high intensity (150 Watt, n = 6). IVIM images were analyzed to calculate the diffusion coefficient (D), pseudo-diffusion coefficient (D\*) and perfusion fraction (f). Analysis of covariance was used to compare mean values at rest and different exercise intensity levels.

## RESULTS

After exercise, IVIM parameters increased with exercise intensity and were significantly elevated compared with baseline (all p <0.05). The increase in f and D differed significantly between low and moderate intensity (p = 0.02 and p = 0.007), but not between moderate and high intensity (p = 0.58 and p = 0.22), while the increase in D\* showed significant differences between each intensity level (p = 0.008 and p = 0.003).

## CONCLUSION

s IVIM parameters detected changes in muscular perfusion after activation. Our findings demonstrate a relationship between microvascular blood flow, blood volume and exercise intensity.

## CLINICAL RELEVANCE/APPLICATION

While these results need to be further validated, they suggest that IVIM parameters can further our understanding of physiological muscle response after activation. Moreover, IVIM may have a role in identifying individuals susceptible to impaired muscle perfusion.

## W2-SPMK-4 In Vivo Comparative Study of Fast kVp Switching Dual-energy Computed Tomography Based Two-material Decomposition Technique and Quantitative Computed Tomography in the Measurement of Lumbar Bone Mineral Density

## PURPOSE

To evaluate the feasibility of the fast kVp switching dual-energy computed tomography (DECT) based hydroxyapatite (HAP) - water decomposition technique in measuring human lumbar bone mineral density (BMD), and to investigate its accuracy in comparison with quantitative computed tomography (QCT).

## METHODS AND MATERIALS

This study was approved by our institutional review board and the requirement to obtain informed consent was waived. A total of 118 consecutive patients who simultaneously underwent both DECT and QCT of the spine were retrospectively enrolled in our study. The patients were 19-88 years old, 56 males and 62 females. The density of HAP (water) was measured along with BMD in the trabecular bone of lumbar level 2-4 by DECT and QCT, respectively. The regions of interest (ROI) were drawn by a radiologist who had 5 years of experience in general radiology. A musculoskeletal radiologist with more than 10 years of experience checked every case that the general radiologist measured. Pearson correlation analysis and paired sample t test were conducted to assess the correlation and difference between DECT- and QCT-derived BMD, respectively. Bland-Altman analysis would be done to evaluate the agreement between two measurements if paired sample t test shows no significant difference between them.

## RESULTS

Strong linear correlation was observed between DECT- and QCT-derived BMD (r = 0.962, p<0.01). DECT-derived BMD (L2, 110.76±35.83mg/cm<sup>3</sup>; L3, 103.05±36.19mg/cm<sup>3</sup>; L4, 105.53±34.57mg/cm<sup>3</sup>; L2-4, 106.56±35.57mg/cm<sup>3</sup>) was slightly lower than QCT-derived result (L2, 124.04±49.96mg/cm<sup>3</sup>; L3, 115.08±49.74mg/cm<sup>3</sup>; L4, 117.21±48.79mg/cm<sup>3</sup>; L2-4, 118.92±49.50mg/cm<sup>3</sup>) and the difference was statistically significant (p<0.01).

## CONCLUSION

s Fast kVp switching DECT based HAP-water decomposition technique enables in vivo BMD quantification of human lumbar vertebrae, and its measurement is slightly lower than QCT.

## CLINICAL RELEVANCE/APPLICATION

Osteoporosis is the most common chronic metabolic bone disease, which is associated with low bone mineral density (BMD). As BMD is an important life-long monitoring index for osteoporosis and fractures, especially for the women and older people. Therefore, it is important to obtain accurate BMD measurement. Besides dual-energy X-ray absorptiometry (DXA) and quantitative computed

tomography (QCT), dual-energy computed tomography (DECT) is considered to be another potential technique to assess BMD. It is needed to evaluate the diagnostic performance of the new method.

## **W2-SPMK-5 Fast kVp-switching Dual-energy Computed Tomography Water-(hydroxyapatite) Display of Vertebral Fractures: Impact on Diagnostic Accuracy of Radiologists with Varying Levels of Experience in Correlation to Magnetic Resonance Imaging**

### **PURPOSE**

To evaluate whether a fast kVp-switching dual-energy computed tomographic (DECT) water-hydroxyapatite (HAP) decomposition technique can improve the detection rate of acute vertebral compression fractures in patients with that at magnetic resonance imaging (MRI) depending on the level of experience of the reading radiologist.

### **METHODS AND MATERIALS**

Fifty consecutive patients who underwent both DECT and MRI of the spine within 3 days after trauma were retrospectively enrolled in our study. Four independent radiologists with varying levels of experience blindly evaluated gray-scale CT scans for the presence of fractures and their suspected age. Then, water-(HAP)images were assessed by the same readers to detect bone marrow edema. Findings were compared with those from fat-suppressed T2-weighted MR images (the standard of reference). Sensitivity, specificity, accuracy, positive predictive value and negative predictive value analyses for diagnostic performance and matched pair analyses were performed on vertebral fractures and patient levels.

### **RESULTS**

In total, fifty-four fractures were classified as fresh and 38 as old at MR imaging. The diagnostic performance of all readers in the detection of fresh fractures improved with the addition of water-(HAP)reconstructions compared with that with conventional CT alone. The diagnostic accuracy of the least experienced reader with CT alone, 76%; accuracy with water-(HAP)images, 87%. The most experienced reader improved his accuracy with water-(HAP) images from 84% to 93% , coming closer to that with MR imaging. The number of vertebrae rated as unclear decreased by 70%-92% or from 12-23 to 1-7 in absolute numbers across readers. The number of patients potentially referred to MR imaging decreased by 71%-91% (from 11-14 to 1-4 patients). Considering the real decision-making gain with the water-HAP decomposition technique on a patient level, 10 to 11 MR examinations could have been avoided.

### **CONCLUSION**

s Fast kVp-switching DECT based water-HAP decomposition technique can improve the ability of the radiologists with variable levels of experience to detect acute vertebral compression fractures.

### **CLINICAL RELEVANCE/APPLICATION**

Single-energy CT of the spine is the standard examination for fast exclusion or closer assessment of suspected vertebral fractures. However, it is sometimes difficult to distinguish between acute and chronic fractures, where further MRI is usually recommended for the differential diagnosis. Compared with single-energy CT, DECT based water-hydroxyapatite decomposition technique can help the radiologists to improve the detection rate of acute vertebral compression fractures, so as to reduce the number of patients requiring further MR scanning.

## **W2-SPMK-6 Comparative Analysis of Cancellous Bone Mineral Density between Vertebral Body and Pedicle Screw Trajectory using Quantitative Computed Tomography**

### **PURPOSE**

To evaluate quantitative computed tomography (QCT) for analysis of cancellous bone mineral density (BMD) of vertebral body and pedicle screw trajectory and to investigate whether there's any difference between them.

### **METHODS AND MATERIALS**

This study was approved by our institutional review board and the requirement to obtain informed consent was waived. A total of 99 consecutive participants (20~80 years old, 48 males and 51 females) who underwent lumbar QCT examinations were retrospectively analyzed. Each pedicle screw trajectory was further divided into intrapedicular segment (R1) and intracorporeal segment (R2). BMD of R1, R2, and the vertebral body (R3) were all measured in the trabecular bone of lumbar level 2,3 and 4 by a commercial QCT BMD analysis system. One-way ANOVA analysis was conducted to assess the differences of BMD among R1, R2, and R3. The paired t test was performed to evaluate the difference of BMD between R3 and the global pedicle screw trajectory.  $P < 0.01$  was considered statistically significant for all used tests.

### **RESULTS**

Mean pedicle screw trajectory BMD (R1,  $173.66 \pm 71.84$  mg/cm<sup>3</sup>; R2,  $113.81 \pm 48.83$  mg/cm<sup>3</sup>; global,  $143.73 \pm 55.49$  mg/cm<sup>3</sup>;) showed significant difference between R1-R2 ( $P < 0.01$ ) and there was no significant difference at both sides (left,  $143.14 \pm 70.06$  mg/cm<sup>3</sup>; right,  $144.33 \pm 66.56$  mg/cm<sup>3</sup>;  $P > 0.01$ ) or different lumbar levels (L2,  $141.25 \pm 50.32$  mg/cm<sup>3</sup>; L3,  $138.31 \pm 56.85$  mg/cm<sup>3</sup>; L4,  $151.64 \pm 58.62$  mg/cm<sup>3</sup>;  $P > 0.01$ ). Average BMD of R3 was not significantly different between lumbar level 2, 3 and 4 (L2,  $124.28 \pm 47.04$  mg/cm<sup>3</sup>; L3,  $115.36 \pm 46.34$  mg/cm<sup>3</sup>; L4,  $117.19 \pm 48.33$  mg/cm<sup>3</sup>;  $P > 0.01$ ). Mean R1-R3 was significantly different (R3,  $118.94 \pm 47.24$  mg/cm<sup>3</sup>;  $P < 0.01$ ) while comparison of R2-R3 did not reach significance ( $P > 0.01$ ). The global pedicle screw trajectory BMD was higher than R3 and the difference was statistically significant ( $p < 0.01$ ).

### **CONCLUSION**

s QCT allows for BMD assessment both of the vertebral body and pedicles. BMD of the global pedicle screw trajectory is significantly higher than that of the same segmental vertebral body.

### **CLINICAL RELEVANCE/APPLICATION**

Pedicle screw fixation is the standard technique for spine stabilization with a potential complication of screw loosening. The screw fixation strength is clearly related to the bone mineral density (BMD) of vertebrae. Currently in clinical only BMD of the vertebral body was estimated, which may not represent the situation in the screw trajectory. Our study shows there's a significant difference of BMD between them. It indicates that measuring BMD of the screw trajectory using quantitative computed tomography (QCT) is needed to predict screw loosening.

## **W2-SPMK-7 The Value of Magnetic Resonance Image Compilation (MAGIC) Sequence in the Diagnosis of Sacroiliac Joint Bone Marrow Edema and Activity in Early Axial Spondyloarthritis**

Participants

Zhaorong Tian, MD, Yinchuan, China (*Presenter*) Nothing to Disclose

### **PURPOSE**

The study explored the feasibility of using Magnetic resonance image compilation (MAGIC) parameters to quantitatively evaluate changes of sacroiliac joint in axial spondyloarthritis (SpA), in order to provide a quantitative index for the evaluation of sacroiliac joint inflammatory activity in SpA. and to evaluate the correlations of MAGIC parameters with BASDAI and SPARCC scores.

### **METHODS AND MATERIALS**

A total of 68 SpA patients with sacroiliitis and 35 healthy controls were enrolled. All patients were scanned using a SIGNATM Architect 3.0T MRI scanner by T1WI, FS-T2WI and MAGIC sequence of the sacroiliac joints. According to whether subchondral bone marrow edema was present in the FS-T2WI sequence, the 68 patients were divided into an active group (40 cases) and an inactive group (28 cases). The T1, T2 and PD values of the subchondral bone marrow were measured in the active group, the inactive group, and the healthy control group using the MAGIC sequence. The T1, T2 and PD values of the active, inactive, and healthy groups were compared using one-way analysis of variance (ANOVA). Receiver operating characteristic (ROC) curves were used to analyze the diagnostic efficacy of T1, T2 and PD values for sacroiliitis. The correlations of the T1, T2 and PD values with the BASDAI and SPARCC scores were analyzed using Spearman's rho.

### **RESULTS**

T2 and PD values of active groups ( $119.00 \pm 9.56$ )ms, ( $86.03 \pm 14.79$ )pu were both higher than inactive groups ( $96.61 \pm 8.86$ )ms, ( $68.12 \pm 7.77$ )pu, higher than those in the healthy control group ( $78.94 \pm 6.20$ )ms, ( $53.71 \pm 6.69$ )pu, ( $T=15.332, T=15.972, all p < 0.001$ ); The T1 values ( $531.04 \pm 60.28$ )ms in the active group were lower than those in the inactive group ( $691.50 \pm 72.44$ )ms, lower than those in the healthy control group ( $933.23 \pm 100.98$ )ms, ( $T=-11.517, p < 0.001$ ). The areas under the ROC curves (AUCs) of T1, T2 and PD values between the active and inactive groups were  $0.976$  (95%CI,  $0.949-0.991$ ),  $0.988$  (95%CI,  $0.970-0.997$ ),  $0.887$  (95%CI,  $0.842-0.923$ ), respectively. The T1, T2 and PD values of the SpA patients were positively correlated with BASDAI scores, and the correlation coefficients (r) were  $-0.771$ ,  $0.914$  and  $0.846$  (all  $p < 0.001$ ), respectively. And positively correlated with SPARCC scores, and the correlation coefficients (r) were  $-0.924$ ,  $0.915$  and  $0.938$  (all  $p < 0.001$ ), respectively.

### **CONCLUSION**

MAGIC imaging can be helpful in quantitatively assessing the activity of sacroiliitis in SpA patients. In particular, T1 and T2 values of high value in distinguishing active sacroiliac arthritis.

### **CLINICAL RELEVANCE/APPLICATION**

MAGIC parameters can be used to quantitatively assess the activity of SpA, and provided imaging bases for the clinical diagnosis of sacroiliitis.

## **W2-SPMK-8 Performance of SPECT MRI for Assessing Spinal Pain Generator Compared to MRI and SPECT CT Alone**

### **PURPOSE**

Back pain is a common disease and affects a large portion of the musculoskeletal patient population. The imaging modalities used to assess the cause of the pain is usually MRI of the spine. More recently the use of SPECT CT has been shown to be useful in assessing the pain generators (3). Unfortunately despite these imaging modalities a large proportion of patients remain symptomatic and do not respond to standard care including physiotherapy and pain management with targeted nerve root injections. The cause of the back pain which can be related to nerve root compression is readily assessed on MRI. However, axial vertebral spondylosis and facet joint disease can be better assessed using SPECT CT. The SPECT CT assesses the osteoblastic activity of the bone and has been shown to demonstrate areas of increased bone remodelling related to stress and degenerative changes. The SPECT component of the study is registered with a low dose CT scan for attenuation correction and localisation. The aim of our study is to assess the utility of retrospective fusion of SPECT and MRI compared to SPECT CT and MRI alone in patients with chronic back pain refractory to initial medical management.

### **METHODS AND MATERIALS**

Between January 2014 and December 2022, 552 patients with chronic back pain initially assessed with spine MRI and SPECT CT were retrospectively reviewed. The initial diagnosis, patients history and management were reviewed. Out of the 552 patients, 138 (25%) were selected for their lack of response to initial management (targeted injection and/or physiotherapy) after 12 months with ongoing back pain. The baseline MRI and SPECT were retrospectively fused using a semi-automated software (Hermes Software®) and images were reviewed by two experienced readers blinded to the initial diagnosis. Potential pain generators were recorded and readers confidence graded using Likert score (graded 1 to 5). Results were compared to MRI and SPECT CT alone.

### **RESULTS**

In our preliminary analysis to date, SPECT MRI detected new sites of pain generators in 105 out of 138 patients (76%) compared to MRI or SPECT CT alone. The readers assessed that in 16 patients (15.3%) this would have potentially altered management. Readers confidence was higher for SPECT MRI compared to MRI and SPECT CT alone.

### **CONCLUSION**

Retrospective fusion of SPECT with MRI improves detection of pain generators in the spine and readers confidence.

### **CLINICAL RELEVANCE/APPLICATION**

The new sites of pain generator assessed on SPECT MRI would potentially impact patient's management. Further studies would be needed to assess if the potential new sites would be the cause of the absence of response to treatment.

W2-SPMS

### Multisystem Wednesday Poster Discussions

#### Sub-Events

#### W2-SPMS-1 Prospective Evaluation of 3T Whole Body MRI and 18F-FDG PET/CT in the Assessment of Multiple Myeloma

##### Participants

Alice Rossi, MD, Meldola, Italy (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the clinical relevance and diagnostic performance of Whole body-MRI (WB-MRI) and fluorine 18 (18F) fluorodeoxyglucose (FDG) PET/CT for the detection of bone marrow infiltration (BMI) in myeloma patients.

##### METHODS AND MATERIALS

Between January 2021 and March 2023, we enrolled myeloma patients in a prospective trial who underwent a 3 Tesla WB-MRI (conducted in accordance with the Myeloma Response Assessment and Diagnosis System, MY-RADS) and PET/CT to assess BMI, para and extramedullary disease, as well as clinico-laboratoristic data collection, all within a month. Two specialized haematologists agreed on management strategies based on International Myeloma Working Group (IMWG) standards after evaluating all the data. This was used to assess the diagnostic performance of WB-MRI and PET/CT.

##### RESULTS

The study included 135 patients (78 Male; mean age, 63 years  $\pm$  12 [SD]) divided into 3 clinical groups: 35 with a newly diagnosed High Risk Smoldering Multiple Myeloma (HR-SMM- group 1); 37 had a newly diagnosed Multiple Myeloma (MM- group 2); 38 were in follow-up after autologous stem cell transplantation and 25 were affected by relapsed/refractory MM with clinical or laboratorist data suspicious for relapse or progression (group 3). HR-SMM analysis showed discordance between the two imaging modalities in 23/35 (66%). 10 diffuse patterns of BMI without any overt focal lesions in WB-MRI (4 correlate with a nonspecific diffusion pattern in PET/CT) and 1 WB-MRI with an equivocal focal lesion emphasized the HR-SMM diagnosis. WB-MRI identified focal bone lesions in 4 patients, 3 of which were confirmed by PET/CT, and resulted in the diagnosis of MM and a change in treatment approach (11%). Analysis of the 100 patients in groups 2 and 3 revealed that WB-MRI and PET/CT were consistent in 79% of the instances and inconsistent in 21% of the cases. In 16/21 (76%, 12 cases of micronodular or diffuse pattern) of these, there was agreement with WB-MRI, whereas in 5/21 (24%) of cases, PET/CT accurately identified 3 positive and 2 negative cases. Overall sensibility and specificity of WB-MRI in the detection of MM was of 94% and 98%, whilst for PET/CT was 81% and 94%. WB-MRI led to an overall changing in therapeutic path in 49/135 cases (36%), PET/CT in 42/135 (31%), WB-MRI plus PET/CT in 53/135 (39%).

##### CONCLUSION

Our data highlight the pivotal role of functional imaging in the evaluation of BMI in myeloma patients with a superior sensibility of WB-MRI. The two techniques may play a complimentary role in cases of suspected relapsed or progressing MM.

##### CLINICAL RELEVANCE/APPLICATION

Our prospective trial supports the utmost role of WB-MRI and FGD PET/CT in the assessment of patients affected by high risk smoldering multiple myeloma and multiple myeloma at both diagnosis and relapse.

W2-SPNMMI

### Nuclear Medicine & Molecular Imaging Wednesday Poster Discussions

#### Sub-Events

**W2-SPNMMI-1** **The Impact of Preoperative [18F]FET-PET in Former Low Grade Glioma: Reclassification According to WHO CNS 2021**

#### PURPOSE

Amino acid PET with [18F]-fluoroethylthiosine (FET) is frequently used in the initial assessment of high grade glioma and suspected tumor recurrence. In low-grade gliomas, [18F]FET-PET can identify metabolically active tumor components and thus determine the surgical strategy. This study sheds light on the prognostic value of [18F]FET-PET for therapy-naive patients with low-grade gliomas.

#### METHODS AND MATERIALS

Retrospectively, all therapy-naive patients from 01/2012-03/2022 with [18F]FET-PET before microsurgical resection, diagnosed as former low-grade gliomas (WHO grade II according to WHO classification at the date of diagnosis) were included in the analysis. Diagnosis was updated following WHO CNS 2021. The [18F]FET-PET/CT or PET/MRI were quantitatively evaluated. In cases in which dynamic imaging was available, late uptake kinetics were graded as increasing vs. indifferent/decreasing. The primary oncologic outcome measure was progression-free survival (PFS).

#### RESULTS

Out of 103 patients, 26 patients were diagnosed with an oligodendroglioma and 57 patients with a WHO grade 2 astrocytoma IDH-mutated. 20 patients initially diagnosed as IDH-wildtype low grade tumors, were reclassified as IDH-wild-type glioblastoma following the new WHO 2021 classification. TBRmax values are significantly higher in oligodendrogliomas compared to IDH-mutated astrocytoma ( $p < 0.001$ ). Quantitative uptake parameters cannot predict the IDH status in this cohort. Increasing late kinetics is associated with a significantly longer PFS compared to indifferent/decreasing kinetics ( $p = 0.015$ ) in the entire cohort. In the subgroup of IDH-mutated astrocytomas without adjuvant treatment, patients with a TBRmax  $> 1.9$  showed significantly longer PFS compared to patients with lower TBRmax ( $p < 0.01$ ).

#### CONCLUSION

Preoperative [18F]FET-PET aids in tumor characterization in low-grade gliomas and can provide prognostic metrics.

#### CLINICAL RELEVANCE/APPLICATION

Prospective studies need to demonstrate whether [18F]FET-PET can be used as a decision support for or against adjuvant therapy after microsurgical resection.

**W2-SPNMMI-2** **Association of ctDNA Levels and PET Radiomics Features in Patients with HPV-positive Head and Neck Squamous Cell Carcinoma**

#### Participants

Mitsuaki Tatsumi, MD, PhD, Suita, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

Circulating tumor DNA (ctDNA), which is circulating in the blood after being shed from cancer cells in the body, has recently gained attention as an excellent tumor marker. The purpose of this study was to evaluate if ctDNA levels associated with PET radiomics features in patients (pts) with human papillomavirus (HPV)-positive head and neck squamous cell carcinoma (HNSCC).

#### METHODS AND MATERIALS

This study included 50 pts with oropharyngeal SCC (OPSCC) and 5 with SCC of unknown primary (SCCUP) before treatment. All of them had blood sampling to test ctDNA levels and FDG PET-CT examinations. ct-HPV type16 DNA (ctHPV16DNA) was analyzed as ctDNA using the droplet digital PCR system. Radiomics features in PET-CT included SUVmax, metabolic tumor volume (MTV), and texture features of the primary tumor (PT) and the largest metastatic lymph node (LN), and MTV of whole-body lesions (wbMTV) in each pt. Fifty-six TFs were evaluated in this study, and entropy, homogeneity, low- and high- gray-level zone emphasis (LGZE, HGZE), and short- and long- run emphasis (SRE, LRE) were included as recommended by Orhac, et al (JNM 2014). ctHPV16DNA levels were compared to TFs of PTs and other PET parameters in OPSCC pts (Group A) or TFs of the largest lesions (PTs or LNs) and other PET parameters in OPSCC and SCCUP pts (Group B). Spearman rank correlation test and multiple regression analysis were used to confirm the associations between ctHPV16DNA levels and PET parameters.

#### RESULTS

ctHPV16DNA levels correlated with wbMTV ( $r = 0.52$  and  $0.53$ , respectively,  $p < 0.0005$  for both), but not with SUV or MTV in Group A and B. In Group A, ctHPV16DNA levels exhibited a weak negative correlation with LGZE ( $r = -0.35$ ,  $p < 0.05$ ) among 56 TFs evaluated. In Group B, the largest lesions consisted of 40 PTs and 15 LNs (10 from OPSCC). ctHPV16DNA levels exhibited a weak negative correlation with LGZE ( $r = -0.36$ ,  $p < 0.01$ ) or contrast ( $r = -0.29$ ,  $p < 0.05$ ). Multiple regression analysis revealed that

wbMTV ( $p < 0.0001$ ) and HGZE ( $p < 0.005$ ) were the significant factors for ctHPV16DNA levels in Group B. The parameter ctHPV16DNA/wbMTV to reduce the effect of tumor volume had a weak negative correlation with LGZE ( $r = -0.29$ ,  $p < 0.05$ ) in Group B. These results were not obtained in Group A.

#### **CONCLUSION**

s This study demonstrated that ctHPV16DNA levels correlated with the whole-body tumor burden visualized on FDG PET-CT in pts with HPV-positive HNSCC. ctHPV16DNA levels exhibited a weak correlation with the tumor heterogeneity, especially in the large OPSCC or LN lesions. This study provides new insights into the quantitative connection between gene expression and imaging biomarkers.

#### **CLINICAL RELEVANCE/APPLICATION**

ctHPV16DNA levels were demonstrated to correlate with the whole-body tumor burden and tumor heterogeneity in HPV-positive HNSCC.

W2-SPNPM

### Noninterpretive Skills (Beyond Imaging) Wednesday Poster Discussions

#### Sub-Events

#### **W2-SPNPM- An Accelerating Emergency: Trends in Nationwide Emergency Department Imaging Volume from 2008 to 2020** 1

#### Participants

Husayn Ramji, MD, Oklahoma City, OK (*Presenter*) Nothing to Disclose

#### PURPOSE

The emergency department (ED) is an essential provider of urgent and emergent care worldwide. As the demand and use of the ED has increased, so has the volume of patients seeking care and receiving diagnostic imaging. This study aims to benchmark multi-year multi-modality trends in imaging utilization in progressively overcrowded EDs, in order to inform future imaging guidelines, awareness, and stewardship efforts.

#### METHODS AND MATERIALS

This IRB exempt retrospective study utilized imaging data from the National Hospital Ambulatory Medical Care Survey (NHAMCS) for years 2008-2020. Data for X-ray, CT, Ultrasound, MRI, and the summation of all modalities in an "Any" category, as well as their year-by-year utilization rates, underwent normality testing followed by least squares regression analysis. Data was weighted, and analysis was performed using JMP Pro (SAS Institute Inc, Clara, NC) and SPSS (SPSS Inc, Chicago, IL).

#### RESULTS

From 2008-2020, there were statistically significant increases in the number (in thousands) of X-ray, CT, MRI, Ultrasound, and summation of Any imaging taking place in the ED. However, there were only statistically significant increases in utilization rates for CT (14.60% to 21.61%, +48.0%,  $p < 0.001$ ), MRI (0.58% to 1.04%, +79.3%,  $p < 0.001$ ), Ultrasound (3.1% to 5.7%, +83.8%,  $p < 0.001$ ), and Any (46.61% to 53.39%, +14.6%,  $p < 0.001$ ). The rate of utilization of X-ray did increase but was not found to be significant (35.52% to 37.57%, +5.7%,  $p > 0.05$ ).

#### CONCLUSION

Multiple modalities have seen significant increases in utilization in the ED from 2008-2020. Possible factors contributing to these increases includes increased access to technology, duplicate scans, challenges in health information exchange, communication or information gaps, or even ordering physician preference. Future studies utilizing NHAMCS data could consider stratifying the data by geographic region, patient variables such as insurance status, and comparing modality utilization by indication.

#### CLINICAL RELEVANCE/APPLICATION

Identifying trends in imaging utilization in nationwide cohorts can help inform future imaging stewardship guidelines and awareness campaigns. Further study should elucidate the underlying contributing factors to increase imaging in EDs nationwide.

#### **W2-SPNPM- An Examination of NIH Funded Radiology Research between Clinical Radiologists and Non-Clinicians** 2

#### PURPOSE

Research in radiology is conducted by both clinical radiologists and non-clinical researchers. Little is currently known about the balance of research grant funding between clinician and non-clinician researchers, and the scale of grants awarded to clinician-scientists. This project seeks to characterize differences in funding and funding trends between clinician and non-clinician scientists in radiology.

#### METHODS AND MATERIALS

Data on National Institutes of Health (NIH) grants awarded for all radiology projects were obtained from the NIH Reporter from 2012 through early 2023. A list of all practicing clinical radiologists was obtained from the National Plan and Provider Enumeration System (NPPES) from the Centers for Medicare and Medicaid Services. Using NPPES data, all available NIH grants were categorized based on whether the principal investigator was a practicing/billing radiologist.

#### RESULTS

A total of \$5.01 Billion of NIH grant funding was awarded for radiology research between 2012 and early 2023 across a total of 11,056 projects, awarded to a total of 1762 unique principal investigators. Among those principal investigators, 264 (14.98%) were practicing radiologists. A total of \$700 million in financing was provided to 1613 projects led by practicing radiologists, accounting for 13.97% of all funds awarded for radiology research by the NIH. Clinician and non-clinician researchers received a median of four grants, with a mean of 6.2 and 6.3 grants and mean grant funding of \$2.6 million and \$2.9 million, respectively. While increased grant funding was seen across all radiology projects, the greatest growth was seen among clinician-researchers, with the number of grants and total funding increasing from \$40.7 million across 102 grants in 2012 to \$93.9 million across 224 grants in 2022. Among clinician researchers, 192 (72.7%) identify as male, and the remaining 72 (27.3%) identify as female. Primary specialties of clinician researchers within radiology are as follows: 138 (52.3%) within diagnostic radiology, 12 (4.5%) within interventional

radiology, and 114 (43.2%) within radiation oncology.

## **CONCLUSION**

As imaging volumes continue to rise, with greater pressure placed on meeting the increased imaging volume demands, clinician scientists continue to offer great value and contribute significantly to the scientific advance of radiology. Despite comprising a relatively small percentage of grants and funding amongst the overall radiology specialty, clinical radiologists are seeing stronger increases in grant funding in recent years.

## **CLINICAL RELEVANCE/APPLICATION**

The proportion of NIH grant funding to clinical radiologists relative to the whole specialty, as well as funding levels and trends over time are currently not well known.

## **W2-SPNPM- Accuracy of Disclosed Financial Relationships by Physicians publishing in Radiology Journal in 2021**

3

## **PURPOSE**

Transparency of physician-industry relationships is required by law. The United States Congress passed the Physician Payments Sunshine Act in 2010, which requires drug, device, and medical supply manufacturers to report payments over a certain amount (\$12.69 for 2023) made to healthcare providers. The physicians are expected to disclose payments received from the medical industry when publishing. This study aims to assess the accuracy and completeness of self-disclosures by authors in the journal Radiology.

## **METHODS AND MATERIALS**

Manuscripts published in Radiology journal between January 1 and May 31, 2021 were retrospectively reviewed, and self-reported author disclosures were cross-referenced with the Open Payments database between 2019-2021.

## **RESULTS**

A total of 68 articles having 513 authorships by US physicians were published in Radiology journal during the inclusion period, out of which 199 (39 %) received payments from the industry. There were 2918 payments totaling \$32,826,946.99 made to these 199 authorships. The median total amount received per authorship was \$10,598.7 (IQR = \$748.70 - \$120,386.01). Out of the 199 authorships receiving payments, 128 (64 %) did not disclose OPD-recorded relationships. 51 (26 %) authorships disclosed some of the OPD-recorded payments and 20 (10 %) disclosed all payments. The total undisclosed payments amounted to \$15,452,628.72 in research, \$4,579,475 in ownership and \$3,102,833.69 in general payments with a median undisclosed amount per authorship being \$2,726.

## **CONCLUSION**

Our study shows that over a recent six-month period, 64 % of US physician authors with manuscripts published in Radiology did not disclose any industry relationship and another 26% disclosed only some of their payments. There is a significant discrepancy between physician authors' financial relationships with industry and their self-reported disclosures of the same.

## **CLINICAL RELEVANCE/APPLICATION**

Publishing physicians are expected to disclose financial relationships with the medical industry. Our study uncovers a significant lack of transparency, both in terms of the number of authors who did not disclose and the total undisclosed amount, from physician authors of Radiology in 2021.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

W2-SPNR

### Neuroradiology Wednesday Poster Discussions

#### Sub-Events

#### W2-SPNR-1 **Impact of IA on Care Metrics for Stroke Patients during the COVID19 Pandemic: A Retrospective Analysis**

##### PURPOSE

The COVID-19 pandemic has presented unprecedented challenges to the healthcare system, including the management of time-dependent pathologies such as stroke. We aimed to evaluate the impact of implementing the AI software, RAPID.AI, for image analysis in patients with stroke due to large cerebral vessel occlusion (LVO) during the pandemic.

##### METHODS AND MATERIALS

We created two groups of patients with LVO who received intravenous reperfusion therapy plus endovascular (TEV) or direct TEV. Group 1 included patients admitted between January 2019 and June 2020, and Group 2 included patients admitted from July 2020 to December 2021 and studied with RAPID.AI. We analyzed demographic data, risk factors, temporal metrics, National Institute of Health Stroke Scale (NIHSS) score at admission, modified functional Rankin Scale (mRS) score at 90 days, and compared data according to arrival time.

##### RESULTS

Group 1 comprised 153 patients, and Group 2 comprised 133 patients. No significant differences were identified regarding age, gender, admission NIHSS, or risk factors. However, the median door-to-image time was significantly shorter in Group 2 (19 minutes vs. 25 minutes,  $p < 0.0001$ ), and the door-recanalization time was also shorter in Group 2 (73 minutes vs. 85 minutes,  $p = 0.042$ ). Between 8:00 a.m and 8:00 p.m patients admitted in Group 2 had a shorter imaging time despite including a chest CT. Patients admitted to Group 2 between 8:01 p.m. and 7:59 a.m. had longer onset-admission times, higher NIHSS scores, and lower proportions of mRS = 2 at 90 days. As a limitation to the study, the measures implemented to shorten the door-image time were not analyzed.

##### CONCLUSION

Our study demonstrates that the measures implemented during the pandemic together with the use of AI for image analysis in stroke patients during the COVID-19 pandemic resulted in improved door-to-image and door-to-recanalization metrics. Additionally, the use of AI compensated for delays in patient arrival, providing specific information for decision-making. These findings highlight the potential utility of AI in improving stroke care and outcomes during times of crisis.

##### CLINICAL RELEVANCE/APPLICATION

AI software can improve care metrics for stroke patients with large cerebral vessel occlusion, enhancing decision making.

#### W2-SPNR-10 **Radiomics Features on Computed Tomography Combined with Clinical and Radiological Factors Predicting Hemorrhage Expansion**

##### PURPOSE

To develop an optimal model based on either intra- and peri-hematoma radiomics features as well as clinical data to predict hematoma expansion (HE) and compare their prediction performance.

##### METHODS AND MATERIALS

Clinical and radiological data of 406 ICH patients were collected retrospectively, who underwent initial NCCT within 6 hours of ictus and follow-up CT within 48 hours after initial NCCT. The data were randomized into a training set and a testing set at a ratio of 7:3. Radiomics features were extracted from the intra- and perihematoma regions. Univariate and multivariable logistic regression analyses were implemented to screen clinical and radiological factors. Then radiomics (single or combined) models, a radiomics-radiologic model, and an integrated model were constructed in the training cohort using FAE. The receiver operating characteristic curve and Delong test evaluated the predictive performance of radiomics features from different regions.

##### RESULTS

The predictive performance of intra- and perihematoma features was comparable in the training area under the receiver operating characteristic curve (AUC) 0.613 versus 0.645, which had no statistical difference. By incorporating intra- and perihematoma features, the model achieved an AUC of 0.620 in the test cohort. Regression analysis identified 4 risk factors, including 2 radiographic features and 3 clinical features. The radiological-radiomics (RR) model using radiographic features combined with the radiomics features achieved an area under the curve (AUC) of 0.744 in the test set. After incorporating the 2 clinical predictors and RR, the AUC of the radiologic-radiomics-clinical (RR-CL) model for discriminating early HE was 0.768. The RR-CL model's prediction performance was better than the RR model, while the predictive nomogram combining the radiomics features with clinical-radiological characteristics performed best. Delong test proved that the performance of radiomics-based features was boosted by incorporating radiological factors, with the volume of hematoma and blend sign ( $p < 0.05$ ). While, the clinical factors, with time from onset to scan, NEUT and PT being the most important contributors, made the RR-CL equivalent to RR model in diagnostic efficiency.

## CONCLUSION

s NCCT models based on multivariable, clinical, and radiological features could improve the discrimination of early HE. The combined model was the best-recommended model to identify ICH patients at risk of early HE. And NEUT in the model may indicate early inflammatory reaction within perihematomal.

## CLINICAL RELEVANCE/APPLICATION

The combined model was the best-recommended model to identify ICH patients at risk of early HE.

## W2-SPNR-11 Comparison of Ultra-High-Resolution and Normal-Resolution CT-Angiography for Intracranial Aneurysm Detection in Patients with Subarachnoid Hemorrhage

### PURPOSE

Ruptured intracranial aneurysms (IAs) are the leading cause for atraumatic subarachnoid hemorrhage. In case of aneurysm rupture, patients may face life-threatening complications and require aneurysm occlusion. Detection of the aneurysm in CT imaging is therefore essential for patient outcome. This study provides an evaluation of the diagnostic accuracy of Ultra-High-Resolution CT-Angiography (UHR-CTA) and Normal-Resolution CT-Angiography (NR-CTA) concerning IA detection and characterization.

### METHODS AND MATERIALS

Consecutive patients with atraumatic subarachnoid hemorrhage who received Digital Subtraction Angiography (DSA) and either UHR-CTA or NR-CTA were retrospectively included. Three readers evaluated CT-Angiography datasets regarding image quality, diagnostic confidence and presence of IAs. Sensitivity and specificity were calculated on patient-level and segment-level with DSA-imaging serving as reference standard. Additionally, the CTA patient radiation exposure (effective dose) was assessed and compared.

### RESULTS

108 patients were identified (mean age=57.8±14.1years, 65 women). UHR-CTA revealed significantly higher image quality and diagnostic confidence ( $p<0.001$ ) for all readers and significantly lower effective dose ( $p<0.001$ ). Readers correctly classified =55/56 patients on UHR-CTA and =44/52 patients on NR-CTA. We noted significantly higher patient-level sensitivity for UHR-CTA compared to NR-CTA for all three readers (Reader 1: 41/41[100%] vs. 28/34[82%], Reader 2: 41/41[100%] vs. 30/34[88%], Reader 3: 41/41[100%] vs. 30/34[88%],  $p=0.04$ ). Segment-level analysis also revealed significantly higher sensitivity for UHR-CTA compared to NR-CTA for all three readers (Reader 1: 47/49[96%] vs. 34/45[76%], Reader 2: 47/49[96%] vs. 37/45[82%], Reader 3: 48/49[98%] vs. 37/45[82%],  $p=0.04$ ). Specificity was comparable for both techniques.

### CONCLUSION

s We found Ultra-High-Resolution CT-Angiography to provide higher sensitivity than Normal-Resolution CT-Angiography for the detection of intracranial aneurysms in patients with aneurysmal subarachnoid hemorrhage while improving image quality and reducing patient radiation exposure.

## CLINICAL RELEVANCE/APPLICATION

In addition to achieving the universally sought-after reduction of radiation dose, the increased detection of intracranial aneurysms in UHR-CT imaging may facilitate therapeutic decisions and hence improve patient outcome.

## W2-SPNR-12 Delay Filling of Intracranial Blood Flow Distal to Thrombus Predict Clinical Outcome after Endovascular Thrombectomy

### PURPOSE

Delay filling of intracranial blood flow evaluated by multiphase CT angiography (mCTA) can provide complementary information of hemodynamics. To investigate the relationship between phase of delay filling (PDF) and thrombolysis before EVT, and whether phases of delay filling (PDF) can help to predict clinical outcomes of patients with endovascular thrombectomy (EVT).

### METHODS AND MATERIALS

In this retrospective study, patients with AIS treated with EVT were enrolled. All the patients underwent mCTA on admission. Based on the PDF, patients were classified into red PDF group (PDF with red on ColorViz of mCTA) and non-red PDF group (PDF with green or blue on ColorViz of mCTA). PDF of mCTA was acquired on the FastStroke research prototype. Chi-square test and Mann-Whitney test was applied to compare the difference between two groups. P value  $<0.05$  was considered significant for all tests.

### RESULTS

A total of 99 patients underwent EVT were included. In red PDF group, the percentage of thrombolysis before EVT was higher than non-red PDF group (8/28[28.57%] vs 2/60[3.33%],  $P = 0.005$ ). Mismatch volume and Tmax > 10 seconds volume of red PDF group were lower than non-red PDF group (Mismatch volume: 129.00 [59.00-180.00] ml vs 152.80 [112.90-214.43] ml;  $Z = -2.209$ ,  $P = 0.027$ ; Tmax > 10 seconds volume: 41.00 [0.00-76.00] ml vs 59.00 [24.00-98.30] ml;  $Z = -2.285$ ,  $P = 0.022$ ). Clinical outcomes of red PDF group were more favourable than non-red PDF group (Score 6: 1 [2.94%] versus 5 [8.77%]; Score 5: 4 [11.76%] versus 5 [8.77%]; Score 4: 5 [14.72%] versus 5 [8.77%]; Score 3: 1 [2.94%] versus 18 [31.58%]; Score 2: 11 [32.65%] versus 10 [17.55%]; Score 1: 9 [26.47%] versus 13 [22.81%]; Score 0: 3 [8.82%] versus 1 [1.75%];  $P = 0.041$ ).

### CONCLUSION

s PDF was associated with thrombolysis before EVT, mismatch volume and Tmax > 10 seconds volume. More favourable outcomes was found in patients with red PDF than patients non-red PDF.

## CLINICAL RELEVANCE/APPLICATION

Phase of delay filling depicts the compensatory capacity of intracranial blood flow, and it may be associated with thrombolysis before EVT. Moreover, later delay filling of blood flow may indicate the poor outcome of patients.

## W2-SPNR-13 3.0T Three-dimensional High Resolution Vessel Wall MRI for Displaying Lenticulostriate Artery Changes of Cerebral Small Vessel Disease

Participants  
Yukun Zhang, Dalian, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To observe the value of 3.0T three-dimensional high resolution vessel wall MRI (3D HR-VMI) for displaying lenticulostriate artery (LSA) changes of cerebral small vessel disease (CSVD), and to explore the feasibility of taking LSA changes as imaging markers of CSVD.

#### **METHODS AND MATERIALS**

Fifty-eight CSVD patients (CSVD group, 26 males and 32 females with an average age of  $63.0 \pm 7.2$  years) and 35 cases of other diseases with CSVD total burden scores of 0 (control group, 15 males and 20 females with an average age of  $62.6 \pm 7.2$  years) were enrolled. The imaging characteristics, including the number, length, and tortuosity of LSA were observed on 3D HR-VMI reconstruction images (Fig.1). The general information and imaging characteristics were compared between 2 groups and logistic regression analysis was performed, the independent risk factors for the occurrence of CSVD and CSVD total burden scores were evaluated (Fig.2).

#### **RESULTS**

There were significant differences in the incidence of hypertension and the numbers of LSA between groups (both  $P < 0.05$ ). CSVD total burden scores were negatively correlated with the number of LSA in CSVD patients ( $r = -0.48$ ,  $P < 0.001$ ). Hypertension and decreased number of LSA were independent risk factors for the occurrence of CSVD (Fig. 3), while aging, alcohol consumption and a decrease in the number of LSA were independent risk factors for the increase of CSVD total burden scores (Fig. 4).

#### **CONCLUSION**

s 3.0T 3D HR-VMI could clearly display LSA changes of CSVD. Decreased number of LSA was an independent risk factor for the occurrence of CSVD and increased CSVD total burden scores, which could be taken as an imaging marker of CSVD.

#### **CLINICAL RELEVANCE/APPLICATION**

Early detection and characterize LSA in the brain may provide valuable information on risk stratification and therapeutic interventions for patients with cerebral small vessel disease.

#### **W2-SPNR-14 Predictive Value of Intracranial Atherosclerosis Coexisted with Atherosclerotic Plaques in Different Carotid Segments for Subsequent Vascular Event: A Magnetic Resonance Imaging Study**

Participants  
Richen Zhao, Nanjing, China, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study aimed to examine the association between coexisting intracranial and extracranial carotid artery atherosclerotic plaque characteristics among different carotid segments, as detected using MR vessel wall imaging, and subsequent vascular events.

#### **METHODS AND MATERIALS**

Patients who recent cerebrovascular symptoms in anterior circulation and at least one carotid plaque were consecutively enrolled. All patients underwent multi-contrast MR vessel wall imaging for extracranial carotid arteries and 3D time-of-flight MR angiography for intracranial arteries at baseline. After baseline examination, all patients were followed-up for at least 1 year to record the vascular events. The coexisting cerebrovascular atherosclerosis was defined as the presence of atherosclerosis in both intracranial artery in anterior circulation and extracranial artery. Univariate and multivariate Cox regressions were used to calculate the hazard ratio (HR) and corresponding 95% confidence interval (CI) of co-existing plaques in predicting subsequent vascular events.

#### **RESULTS**

In total, 122 patients (mean age:  $62.2 \pm 11.9$  years; 89 males) were recruited. During the median follow-up time of 12.0 months, 36 (29.5%) patients experienced vascular events. Coexisting intracranial artery stenosis and atherosclerotic plaques in carotid bulb segment of carotid artery (HR, 2.51; 95% CI, 1.14-5.54;  $P = 0.023$ ) was significantly associated with subsequent vascular events, respectively. After adjusting for baseline confounding factors, this association remained statistically significant (HR = 3.08, 95% CI 1.18-8.07,  $P = 0.022$ , respectively). No significant association was found between intracranial stenosis coexistent with atherosclerotic plaque in other segments of carotid artery and vascular events (all  $P > 0.05$ ).

#### **CONCLUSION**

s Coexisting intracranial artery stenosis and atherosclerotic plaque in the segment of carotid bulb was independently associated with subsequent vascular event.

#### **CLINICAL RELEVANCE/APPLICATION**

Our findings indicate that coexisting intracranial artery stenosis and atherosclerotic plaque in the segment of carotid bulb was independently associated with subsequent vascular event, indicating that coexisting intracranial stenosis and atherosclerotic plaque in carotid bulb may have a higher predictive value for vascular events than coexisting plaques in other carotid artery segments. Our findings indicate that it is valuable to assess the segmental distribution of coexisting intracranial and extracranial atherosclerosis.

#### **W2-SPNR-2 Low Proportion of Calcification in Large Volume Plaque as a Marker of Carotid Plaque Vulnerability in Embolic Stroke of Undetermined Source**

Participants  
Yu Sakai, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Current focus has centered on non-calcified inflammatory plaque components [intraplaque hemorrhage (IPH) and lipid rich necrotic core (LRNC)] in nonstenotic carotid plaque in patients with embolic stroke of undetermined source (ESUS). Although calcified

inflammatory plaque components, such as spotty calcifications, are associated in acute coronary syndromes, its role in ESUS-carotid plaque is unclear. We investigated the relationship of spotty calcifications and low calcific plaque burden in nonstenotic carotid plaque ipsilateral to stroke side in patients with ESUS.

## **METHODS AND MATERIALS**

Calcific carotid plaques were identified on neck CTAs from a retrospective dataset comprised of patients with unilateral anterior circulation ESUS. Blinded to stroke side, each carotid plaque calcification was manually scored (e.g., arc), annotated using 3D-Slicer, and segmented using a semi-automated plaque composition software (Elucid Bioimaging). Plaques were scored for presence of a spotty calcification (calcification <3mm in length and <90° arc of the lumen). IPH and LRNC volumes are summed as plaque inflammation (Inflmvol). Plaque burden (PB) is the sum of all plaque components (IPH, LRNC, calcification, matrix). Subgroup analysis of plaques with high plaque burden (HPB) was performed and defined as all cases above the median PB (median=858mm<sup>3</sup>). Plaques were defined as low relative calcific PB (Low%Calc) if the calcific plaque volume comprised  $\geq 2\%$  of total PB (1st quartile). Mann-Whitney U and Chi-squared tests were performed to test plaque features ipsilateral versus contralateral to stroke side.

## **RESULTS**

86 patients met criteria (mean age= 66.8; N=41 women). No statistically significant differences were observed between carotid plaques ipsilateral versus contralateral to stroke side for presence of spotty calcifications ( $p=0.42$ ), Inflmvol ( $p=0.70$ ), or Low%Calc plaque ( $p=0.26$ ). Among plaques with HPB (N=66), there was no significant difference between ipsilateral versus contralateral plaques with spotty calcifications ( $p=0.76$ ) or Inflmvol ( $p=0.57$ ). Plaques identified as Low%Calc ipsilateral to stroke side were significantly more frequent than on the contralateral side [10/11 (91%),  $p = 0.02$ ].

## **CONCLUSION**

s Plaques with low relative calcific plaque burden may be a stronger vulnerable carotid plaque feature in patients with ESUS rather than the presence of spotty carotid plaque calcifications.

## **CLINICAL RELEVANCE/APPLICATION**

Volumetric based categories of plaque classifications should be considered when determining potential imaging biomarkers of nonstenotic culprit carotid plaque to capture the multidimensional and complex patterns of vulnerable plaque in patients with ESUS.

## **W2-SPNR-3 Deep Learning-enabled Identification of Large Vessel Occlusion on Four-dimensional Computed Tomography Angiography(4D-CTA)**

### **PURPOSE**

To assess the role of deep learning in aiding the detection of large vessel occlusion (LVO) on four-dimensional computed tomography angiography (4D-CTA).

### **METHODS AND MATERIALS**

This retrospective study involved 104 LVO patients and 105 non-LVO patients in the construction of the deep learning models. Another 30 LVO patients and 31 non-LVO patients formed the time-independent validation set. Four phases (arterial phase P1, arterial-venous phase P2, venous phase P3 and late venous phase P4) extracted from 4D-CTA were combined using two different input methods, namely combined input and superimposed input. Totally 26 deep learning models were constructed using a modified HRNet network. Assessment metrics included the areas under the curve (AUC), accuracy, sensitivity, specificity and F1 score. Kappa analysis was performed to assess inter-rater agreement between the best model and radiologists of different seniority.

### **RESULTS**

The P1+P2 model (combined input) had the best diagnostic performance. In the internal validation set, the AUC was 0.975 (95%CI: 0.878-0.999), accuracy was 0.911, sensitivity was 0.889, specificity was 0.944, and the F1 score was 0.909. In the time-independent validation set, the model demonstrated consistently high performance with an AUC of 0.942 (95%CI: 0.851-0.986), accuracy of 0.902, sensitivity of 0.867, specificity of 0.935, and an F1 score of 0.901. The best model showed strong consistency with the diagnostic efficacy of three radiologists of different seniority ( $k=0.84, 0.80, 0.70$  for 8, 5, and 1 year of diagnostic experience, respectively).

### **CONCLUSION**

s The proposed deep learning algorithm derived from 4D CTA can be very highly effective in detecting LVO, alerting radiologists to speed up the diagnosis. In particular, the combination of the arterial and arterial-venous phases can improve detection efficacy.

### **CLINICAL RELEVANCE/APPLICATION**

We introduced a high-performance deep learning algorithm for detecting large vessel occlusions in 4D-CTA, showing that the combination of multiple phases improved the detection of LVO and the combination of the arterial-venous phase with the arterial phase yielded the best deep learning model performance. The diagnostic efficacy of the best deep learning model was in good agreement between radiologists of different years of experience and was slightly better than that of less experienced trainee radiologist. Our results showed that deep learning can be very effective in facilitating accelerated screening and diagnosis of LVO in urgent clinical settings.

## **W2-SPNR-4 Investigation of Radiologic Characteristics between Branch Atheromatous Disease and Cerebral Small Vessel Disease: A High-resolution Magnetic Resonance Vessel Wall Imaging Study**

Participants  
Peipei Chang, Dalian, China (*Presenter*) Nothing to Disclose

### **PURPOSE**

To compare lenticulostriate arteries (LSAs) morphology and other imaging features of branch atheromatous disease (BAD) and cerebral small vessel disease (CSVD) and to investigate whether the imaging features can distinguish the different etiological mechanisms of cerebral infarction in basal ganglia.

### **METHODS AND MATERIALS**

Fifty patients with suspected acute cerebral infarction in the LSA territory were prospectively enrolled. All subjects underwent multimodal magnetic resonance imaging (MRI) examination and were divided into BAD and CSVD groups, depending on whether there was plaque in the middle cerebral artery by high-resolution vascular wall MRI (3D HR VMI). The morphological characteristics of visible LSAs (the number of stems and branches, length, distance, and tortuosity) were quantitatively analyzed by two radiologists. Typical image features indexes of CSVD including white matter hyperintensities (WMHs), lacunes, enlarged perivascular spaces (EPVS), microscopic bleedings (CMBs) were assessed. Global cerebral blood flow (CBF) values obtained by arterial spin labeling (ASL) were used to analyze the whole brain differences of perfusion between two groups. To assess the imaging parameters between groups, independent-samples t test, nonparametric tests and Chi-square test were used. Binary logistic regression was used to explore the influencing factors of BAD and CSVD.

## RESULTS

There were significant differences in the sex, MRs (Modified Rankin Scale) and NIHSS (National Institutes of Health Stroke Scale) scores between the two groups, showing more significant neurological impairment in BAD group. The LSA branches of BAD were significantly reduced compared with the contralateral side, while with no significant difference to those observed in the CSVD group. CSVD was more likely to have EPVS. The length and distance of LSAs were influencing factor of BAD and CSVD.

## CONCLUSION

There are fewer LSA branches in BAD, and the length and distance of LSA are the influencing factors of BAD and CSVD.

## CLINICAL RELEVANCE/APPLICATION

The morphological characteristics of LSAs and image features indexes of CSVD might provide method to distinguish the different underlying mechanisms of cerebral infarction in basal ganglia.

## W2-SPNR-5 Clinical Evaluation of Deep-learning Model for Classifying Stroke Patients of Emergent Large Vessel Occlusion on Non-contrast CT

### PURPOSE

The purpose of this clinical study is to evaluate the clinical applicability of a deep learning (DL) model that classifies patients with emergent large vessel occlusion (ELVO) through analysis of non-contrast CT (NCCT) images only. In clinical practice, if patients of suspected ELVO can be quickly screened through analysis of only NCCT images that can be scanned without contrast media, it has the advantage of improving the prognosis by reducing the time required for treatment of ELVO patients. Therefore, clinical effectiveness was evaluated by comparing the accuracy to classify ELVO patients through reading NCCT images with or without referring to the result of DL-based software by clinician.

### METHODS AND MATERIALS

The NCCT of 744 patients (ELVO positive: 519 cases) were used for learning the DL model. The primary endpoint of clinical test was the statistical difference of the sensitivity and specificity of ELVO patient classification according to whether or not the DL model results were referenced. 477 patients (ELVO positive: 112 cases) were registered in the clinical evaluation, and a reference standard was created based on the final diagnosis results. A wash-out period of 2 weeks was set between the two readings depending on whether or not the DL model was referenced, and both results of reading were derived by the consensus of five stroke experts. The sensitivity and specificity were calculated by comparing the both readings of consensus to the reference standard. Finally, through McNemar's test, statistical differences were evaluated according to whether or not the results of the DL model were referenced.

### RESULTS

In the classification result of ELVO patient, the sensitivity of experts' consensus was 75.89% when reading by only NCCT and 91.96% when the result of DL model was referred. In addition, the specificity of the experts' consensus was 83.01% when read only by NCCT and 92.6% when referring to the DL model results. As the result of the McNemar's test to compare the primary endpoint, it was confirmed that both sensitivity ( $p=0.0009$ ) and specificity ( $p<0.0001$ ) were significantly improved when the results of the DL model were referred to. Therefore, the primary endpoint of the clinical test was successfully accomplished.

### CONCLUSION

It was confirmed that the accuracy was significantly higher when referring to the results of the DL-based software in NCCT-based ELVO patient classification. Therefore, it is highly recommended to use for assisting clinicians in clinical environment.

### CLINICAL RELEVANCE/APPLICATION

This deep-learning model has been integrated into the commercial Heuron ELVO software. It will be a useful tool for clinicians to make fast decision, especially, it will be valuable in remote regions where clinical expert may be limited.

## W2-SPNR-6 Single-phase plus Dynamic CTA Accurately Identifies Favorable Outcomes in Patients with Acute Ischemic Stroke

### PURPOSE

Sufficient collateral blood supply is crucial for favorable outcomes in patients with acute ischemic stroke (AIS) after endovascular treatment. In clinical practice, imaging of collaterals is often performed with single-phase computed tomography angiography (CTA) that is unable to precisely time the acquisition time-points, leading to the mislabeled collateral status. Dynamic CTA (dCTA) derived from CT perfusion source images is a novel method that contains more time points than single-phase CTA, and allows complete tracking of the transit of contrast bolus. We hypothesized that single-phase plus dCTA would predict clinical outcomes better than single-phase CTA.

### METHODS AND MATERIALS

Patients with AIS due to proximal middle cerebral artery occlusion or internal carotid artery occlusion after endovascular treatment were included. Patients underwent non-contrast CT, whole-brain CT perfusion, and single-phase CTA. dCTA were computed from CT perfusion source images with KWIA denoising, vessel filtering and MIP along 3 views. The pial collateral status was scored using Alberta Stroke Program Early CT Score on collaterals with single-phase CTA, dCTA, and single-phase plus dCTA. Good clinical outcomes included 90-day modified Rankin Scale (mRS) score of 0-2. Association between the pial collateral status and functional

outcomes was assessed using multivariable binary logistic regression. Then, hypoperfusion intensity ratio (HIR) were computed on CT perfusion and combined with pial collateral status to assess the total collateral status. 3 groups were defined: good collaterals (good pial collaterals and HIR), poor collaterals (poor pial collaterals and HIR) and mixed collaterals (remainder of patients). The predictive ability of total collateral status on functional outcomes were analyzed by receiver operating characteristic curve.

## RESULTS

One hundred and forty-four patients with a mean age of 68.5 years were included. Pial collateral status as assessed with single-phase plus dCTA was more strongly associated with functional outcomes (OR=3.14 [95% CI 1.65-5.96];  $p<0.001$ ) than with dCTA (OR=2.34 [95% CI 1.29-4.27];  $p=0.005$ ) or with single-phase CTA (OR=1.90 [95% CI 1.21-2.98];  $p=0.005$ ). Furthermore, good total collateral status could predict good functional outcomes (Area Under Curve (AUC)=0.67 for single-phase CTA and HIR, AUC=0.69 for dCTA and HIR, AUC=0.70 for single-phase plus dCTA and HIR).

## CONCLUSION

s dCTA provides a more detailed assessment of collaterals than single-phase CTA. Collateral status is a strong predictor of clinical outcomes in patients treated by endovascular treatment.

## CLINICAL RELEVANCE/APPLICATION

dCTA derived from CT perfusion source images may be used to select AIS patients for endovascular treatment.

## W2-SPNR-7 Disparities in Access to Endovascular Thrombectomy for Patients with Large Vessel Occlusion

Participants

Mihir Khunte, Providence, RI (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the racial, socioeconomic, and geographic disparities that exist in both access to high volume endovascular care centers (ECCs) and receiving thrombectomy once admitted to an ECC in patients with large vessel occlusion (LVO).

## METHODS AND MATERIALS

A retrospective study was performed for the years 2016 - 2019 of the National Inpatient Sample for all adult inpatient admissions with LVO. International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) diagnosis, and procedural coding system (PCS) were used to identify patients with LVO. Patient characteristics such as gender, age, race, and income quartile and hospital characteristics such as region, rural/urban status, and size were recorded. Hospitals that performed  $\geq 10$  EVT procedures in one year were classified as high-volume endovascular capable centers (ECCs).

## RESULTS

There were 727,010 patients with LVO during the 2016-2019 period. A total of 428,745 (59.0%) patients were admitted to a high volume ECC. Black patients were admitted to high volume ECCs at higher rates than white patients (61.0% vs 58.3%) but after adjusting for other factors using a multivariable logistic regression model, we found that when comparing Black to White patients, the OR of admission to a high volume ECC was 0.94 (95% CI 0.88 - 1.02). Among patients admitted to a high volume ECC, black patients were less likely to receive thrombectomy than white patients (17.6% vs 19.2%). This trend remained true after adjusting for other variables including the occlusion site. Comparing high volume ECC patients with private insurance to those with Medicare, the OR of receiving EVT was 1.13 (95% CI 1.06-1.20).

## CONCLUSION

s Our study shows that disparities existed both in accessing an ECC after LVO and receiving thrombectomy after admission to an ECC. While Black patients with LVO were more likely to be admitted to a high volume ECC than white patients, they were less likely to receive EVT once admitted. Age, sex, income, region of the U.S., and insurance status also played a role in determining whether a patient received thrombectomy after admission to a high volume ECC.

## CLINICAL RELEVANCE/APPLICATION

EVT is an important treatment strategy for selected patients with LVO but significant barriers exist in accessing appropriate treatment.

## W2-SPNR-8 Trends in Use of Endovascular Thrombectomy in Anterior Circulation Large-vessel-occlusion by Age

Participants

Mihir Khunte, Providence, RI (*Presenter*) Nothing to Disclose

## PURPOSE

To assess trends in US nationwide use of endovascular thrombectomy (EVT) in patients with large vessel occlusion (LVO) in different age groups.

## METHODS AND MATERIALS

The National Inpatient Sample database was queried to identify adult patients (18 years or older) with a primary diagnosis code for cerebral infarction due to unilateral internal carotid artery (ICA) or middle cerebral artery (MCA) thrombosis or embolism. The International Classification of Diseases, Tenth Revision, Clinical Modification [ICD-10-CM] diagnosis and procedural coding system (PCS) was used to identify patients with LVO and the interventions performed from 2016-2020. Patients with additional coding for occlusions in the vertebral, basilar, cerebellar, posterior cerebral, and anterior cerebral arteries were excluded. For each age category, trends in EVT utilization were evaluated and compared using Pearson's chi-square test.

## RESULTS

Among 316,290 patients with ICA/MCA occlusion from 2016-2020, 68,780 (21.7%) received EVT and 71,260 (22.5%) received tPA. The proportion of anterior circulation LVO patients receiving EVT increased from 15.7% in 2016 to 27.6% in 2020. The rate of EVT increased most in patients aged 75 to 84 years (14.6% in 2016 to 27.4% in 2020) and 85 years and older (12.6% in 2016 to 26.3%

in 2020). The proportion increased by 10.3 percentage points in patients younger than 55 years (19.0% in 2016 to 29.3% in 2020), 10.1 percentage points in patients aged 55 to 64 (17.2% in 2016 to 27.3% in 2020), 11.3 percentage points in patients aged 65 to 74 (16.7% in 2016 to 28.0% in 2020). In contrast to in 2016, in 2020, the rate of EVT was not statistically significantly different between age groups ( $P = 0.328$ ).

## CONCLUSION

Our study results show a significant increase in use of EVT in patients with anterior circulation LVO across all age groups, with approximately 27.6% of patients receiving EVT in 2020.

## CLINICAL RELEVANCE/APPLICATION

From 2016-2020, there has been a significant increase in the use of EVT in older patients above 75 years of age with the rate of EVT use nearing that in younger patients.

## W2-SPNR-9 Trends in the Use of Intravenous Thrombolysis and Endovascular Thrombectomy in Patients with Large Vessel Occlusion Stroke from 2016-2020 and the Impact of COVID-19 Pandemic

Participants

Mihir Khunte, Providence, RI (*Presenter*) Nothing to Disclose

## PURPOSE

To study the use of intravenous thrombolysis (IVT) and endovascular thrombectomy (EVT) nationally in the United States in patients with large-vessel-occlusion (LVO) in 2020, compared it to the previous 4 years, and evaluated their use specifically in COVID-positive patients.

## METHODS AND MATERIALS

The National Inpatient Sample database was queried to identify adult patients (18 years or older) with a primary diagnosis code for cerebral infarction due to unilateral internal carotid artery (ICA) or middle cerebral artery (MCA) thrombosis or embolism. The International Classification of Diseases, Tenth Revision, Clinical Modification [ICD-10-CM] diagnosis and procedural coding system (PCS) was used to identify patients with LVO and the interventions performed from 2016-2020. Patients with additional coding for occlusions in the vertebral, basilar, cerebellar, posterior cerebral, and anterior cerebral arteries were excluded. In the 2020 data, patients with a concomitant diagnosis of coronavirus disease 2019 (COVID-19) were identified. Rates of EVT and IVT were assessed by COVID-19 status.

## RESULTS

A total of 316,290 patients were hospitalized for acute ischemic stroke with an ICA/MCA occlusion from 2016-2020. Of these patients, 21.7% ( $N = 68,780$ ) received thrombectomy and 22.5% ( $N = 71,260$ ) received IVT. From 2019 to 2020, the fraction of patients receiving thrombectomy increased 2.1 percentage points from 25.5% in 2019 to 27.6% in 2020 ( $p = 0.020$ , Figure 1). Meanwhile, rates of thrombolysis remained relatively constant, (22.4% in 2016 vs 21.7% in 2020,  $p = 0.128$ , Figure 1). Among the 63,785 patients presenting with ICA/MCA occlusion in 2020, 1,170 (1.8%) had a co-diagnosis of COVID-19. The rate of EVT among COVID-19 and non-COVID-19 stroke patients with LVO in 2020 was 29.1% and 27.6% respectively ( $p = 0.605$ ). In addition, the proportion of patients receiving IVT was 21.8% and 21.7% for COVID-19 and non-COVID-19 stroke patients respectively ( $p=0.962$ ).

## CONCLUSION

The proportion of patients with an MCA/ICA LVO receiving IVT and EVT did not decline in 2020 compared to the previous four years. Specifically, COVID- positive patients received recanalization therapies in similar proportion to COVID-negative patients for the whole year.

## CLINICAL RELEVANCE/APPLICATION

COVID-positive patients with acute ischemic stroke received recanalization therapies in similar proportion to COVID-negative patients in 2020.

#### W2-SPPD-1 Does Follow-up MRI after Esophageal Button Battery Ingestion Cause Thermal Injury: An In-vitro Study

#### PURPOSE

The button battery (BB) is a dangerous pediatric foreign body, and an ingested esophageal BB should be removed immediately. However, severe complications such as tracheoesophageal or aortoesophageal fistula may develop after endoscopic BB removal and patients require follow-up with magnetic resonance imaging (MRI). Since the injured area after BB removal can contain metallic debris such as iron, radiologists should be aware of the risk of thermal injury from the metallic debris during MRI examinations. This in vitro study investigated temperature and histological changes before and after MRI examination of tissues injured by BB.

#### METHODS AND MATERIALS

Two each of the following three types of chicken pectoralis minor muscle were prepared: untreated control; MRI-scanned BB injury; and non-MRI-scanned BB injury. The negative pole surface of an unused 3-V BB was brought into contact with the muscle tissue and left for 10 h to generate a BB injury. Computed tomography (CT) and histological Perls' Prussian blue staining were performed to confirm the presence of metallic debris in the injured area after BB removal. Temperatures were measured before and after MRI of BB-injured muscle specimens after BB removal and in untreated control specimens using a needle-type digital thermometer. Temperatures were measured at five sites for each specimen. MRI was performed according to the non-enhanced mediastinal sequence at our hospital, assuming tracheoesophageal and aortoesophageal fistula. Hematoxylin-eosin and Perls' Prussian blue staining were used to compare MRI-scanned and non-MRI-scanned BB injuries histologically. These steps were performed at room temperature (20-22°C).

#### RESULTS

BB injury showed high attenuation (mean: 242 Hounsfield units) on CT suggestive of the presence of metallic debris. Histologically, BB injury showed positive staining for Perls' Prussian blue, representing evidence of Fe<sup>3+</sup>. Both BB-injured specimens with or without MRI scans showed coagulation necrosis. Temperature before MRI was 21.7 ± 0.1°C for both BB-injured and control specimens. Temperature after MRI was 22.2 ± 0.2°C for both BB-injured and control specimens. No difference in histopathological findings was seen between specimens with or without MRI scans.

#### CONCLUSION

No temperature increase or histopathological findings suggestive of thermal injury due to metallic debris during MRI of BB injury were evident. However, radiologists should be aware of the potential for thermal injury from MRI as long as foreign metal is present in the body.

#### CLINICAL RELEVANCE/APPLICATION

Follow-up of esophageal BB injury by endoscopy or esophagography is invasive, and safer noninvasive MRI is needed.

#### **W2-SPPH-1 Comparison of Image Quality and Radiation Dose between Adrenal Virtual Monoenergetic Spectral and Conventional Images using New Fast kVp Switching Dual-energy CT**

##### Participants

Jianping Yang, Yinchuan, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Radiation dose has long been a concern for radiologists, this study aims to compare the image quality and radiation of adrenal gland by energy spectrum CT and conventional CT scanning.

##### METHODS AND MATERIALS

Forty patients (22 males and 18 females) with suspected adrenal disease were prospectively collected, with a age of  $45.6 \pm 8.4$  years (range, 21-76 years). Group A and group B were randomly divided into two groups according to different scanning methods. Group A (n=20) used rapid kV switch (80/140 kV) energy spectral CT (Revolution CT, GE Healthcare) at 320mA tube current. Group B (n=20) used non-spectral scanning at tube voltage 120kV, smart150-650mA. Both groups fixed noise index (NI) 11 and 40% pre-ASiR-V, thickness 1.25mm. The background noise (SD), signal noise ratio (SNR) and contrast signal noise ratio (CNR) of right adrenal junction, left adrenal junction, liver, spleen, abdominal aorta (celiac axis level), erector spinae and abdominal fat in group A (70keV monochromatic images) and group B (120kV image) were measured and compared respectively. The subjective image scores were assessed blindly by two experienced physicians using a 5-point system. The difference of SD, SNR and CNR among different groups were compared by independent sample t test.

##### RESULTS

The SD of right adrenal junction, left adrenal junction, liver, spleen and portal vein in group A (70keV monochromatic images) were  $22.08 \pm 4.77$ ,  $22.37 \pm 3.56$ ,  $18.32 \pm 2.34$ ,  $24.49 \pm 7.77$  and  $27.22 \pm 2.78$  HU respectively. The corresponding SD values in the group B were  $20.12 \pm 2.81$ ,  $18.60 \pm 3.88$ ,  $16.35 \pm 2.16$ ,  $18.35 \pm 3.09$  and  $22.09 \pm 3.12$  HU respectively, were significantly different between the two groups ( $P < 0.05$ ). The SNR and CNR of bilateral adrenal junction, liver, spleen and abdominal aorta in group A were higher than group B, not significantly different between the two groups ( $P > 0.05$ ). The CTDI of group A and B were  $8.43 \pm 1.98$  and  $9.10 \pm 2.09$  mGy\*cm, compared with spectral energy CT scanning, the radiation dose of conventional CT scanning is increased by 3.7%, but the difference was not statistically significant ( $P > 0.05$ ). The subjective scores of two observers to group A and group B imaging were  $4.73 \pm 0.22$ ,  $4.70 \pm 0.34$  and  $4.79 \pm 0.34$ ,  $4.78 \pm 0.51$  respectively, the difference was not statistically significant ( $P > 0.05$ ).

##### CONCLUSION

The quality of adrenal on 70keV monochromatic images is similar to conventional 120kV image, and the radiation dose is lower than conventional 120kV CT scans, while energy spectrum CT can obtain more information.

##### CLINICAL RELEVANCE/APPLICATION

Energy spectrum scanning can not only guarantee image quality and radiation dose, but also provide more quantitative analysis of energy spectrum parameters for doctors.

#### **W2-SPPH-10 A Practical Approach to Sustainable Radiology**

##### PURPOSE

To examine the effect of regenerative energy and energy efficient imaging technology on the energy balance in MRI.

##### METHODS AND MATERIALS

We built an energy saving bungalow with a 29.8 kWp rooftop solar array and a 10 kWh Li-Ion Battery. MR imaging was carried out using a 0.35T permanent magnet system with water-cooled gradients, installed in 2019 (Siemens Magnetom C!, Siemens Healthineers/Germany) and a 0.4 T permanent magnet system with air-cooling (Aperto Lucent Plus, Fujifilm healthcare/Japan) installed in 2022. Energy consumption was measured using the power management system of the solar array.

##### RESULTS

The 0.35T MRI consumed 9.5 kW/h during scan procedures (including cooling). Annual consumption of the imaging system was 16.100 kWh in 2020. Energy consumption including all practice components in 2020 was 38.810 kWh. Energy production of the solar array was 30.846 kWh in 2020. Net energy consumption for the whole project was therefore 8.397 kWh in 2020. The state of the art 0.4T MRI consumes 5 kW/h. In February 2023, the imaging system consumed 1.495,36 kWh. Compared with February 2020 (1.951,21 kWh), this is a reduction by 5.618 kWh or 23,4%. If all other parameters are kept constant, we expect a total practice net energy consumption of 2.780 kWh in 2023.

##### CONCLUSION

s Using state of the art imaging technique and rooftop solar energy production, an energy neutral MRI site is possible.

#### CLINICAL RELEVANCE/APPLICATION

Optimizing the energy balance is a challenge. Radiology, as an energy intense discipline, can contribute considerably to sustainable medical care. For developing countries, energy neutral operation can help to provide medical care independent from (unstable) power grids.

#### W2-SPPH-11 Quantitative Knee Evaluation using Deep-Learning in a Low-Field 0.55T MRI: In Vivo Study of Healthy Controls

##### PURPOSE

To evaluate the performance of standard in-practice DL (bone, and cartilage segmentation) algorithms to generate bone shape and cartilage thickness maps in addition to compartment-wise cartilage thickness values in healthy controls at 0.55T

##### METHODS AND MATERIALS

Unilateral knees of four healthy controls (Age:  $28 \pm 3.8$  years, BMI:  $24.08 \pm 2.88$ , 2 females) were included in this IRB approved study. The subjects underwent MRI scanning on a 0.55T (MAGNETOM Free.Max, Siemens Healthineers, Erlangen, Germany), with knee wrapped in a Contour-S coil. Sagittal 3D PD fat-saturated SPACE images were acquired with FOV  $160 \times 160$  mm<sup>2</sup>, resolution  $0.6 \times 0.6 \times 0.6$  mm<sup>3</sup>, and 224 slices (TR/TE = 800/36 ms). The images underwent a modified 2D-CNN architecture<sup>1</sup> and a 3D V-Net architecture<sup>2</sup> respectively to segment the bones (femur, tibia, patella) and cartilages (femoral, tibial, patellar). Both the DL architectures were previously trained and validated on similar image contrasts at 3.0T and were inferred on the 0.55T images. Mean cartilage thickness values for three cartilages were automatically computed using a Euclidean distance transform<sup>3</sup>. The overall segmentation quality was assessed using a 5-point Likert scale by a musculoskeletal radiologist with over three years of experience.

##### RESULTS

Without any sort of pre-trainings, as an initial inference run, both the segmentation models were able to segment the three major bones and cartilage masks with moderate to substantial ability, demonstrated in figure 1. The cartilage thickness values estimated for femoral, tibial, and patellar cartilages were  $1.40 \pm 0.84$ ,  $1.54 \pm 0.62$ , and  $2.18 \pm 0.62$  mm respectively. The cartilage segmentation algorithm outperformed the bone segmentation module, in the femoral and tibial regions, in terms of precision in detecting smaller cartilage regions with confusing boundaries. However, both the segmentation modules, especially the cartilage one, suffered in the detection of the patellar region, due to non-sufficient training in low-SNR images. Nevertheless, it demonstrates a decent baseline of quantitative capabilities with possibilities for improvement using further training with 0.55T images, along with comparative assessment with paired 3T segmented data.

##### CONCLUSION

s Initial results demonstrate a moderate-to-substantial technical feasibility of translating existing quantitative deep-learning-based image segmentation techniques from 3T to 0.55T for knee MRI, especially in terms of measuring cartilage thickness.

#### CLINICAL RELEVANCE/APPLICATION

The 0.55T low-field-value-MRI, can be technically useful for evaluating knee cartilage thickness and bone features aided by established DL algorithms, with potential for further improvement in biomarker quantification performance.

#### W2-SPPH-12 Feasibility of ZTE-based Silent and Motion-robust Techniques for Neuroimaging

##### PURPOSE

Conventional MRI generates high levels of acoustic noise from the rapidly changing imaging gradients. This loud acoustic noise presents challenges for sensitive populations such as pediatrics and patients with hyperacusis including inner ear disorders, autism, and depression. Acquisition strategies including radial zero-echo time (ZTE) have been shown to reduce acoustic noise. Radial sampling methods can provide motion robustness or even allow correction, making the radial ZTE approach appealing. We present progress in developing multi-contrast ZTE imaging protocols with motion correction.

##### METHODS AND MATERIALS

T1w and T2w 3D radial ZTE acquisitions with intermittent magnetization preparation pulses were acquired on a 3T clinical MRI (Premier, GE Healthcare) in two normal healthy volunteers under written consent and IRB approval. Each acquisition was performed twice, and volunteers were instructed to remain still for the first acquisition and to periodically move during the second. A modified HEALPix radial view order provided coverage of angles within each segmented readout. Motion was estimated from the k-space data using a deep learning approach and corrected during image reconstruction. Conventional Cartesian imaging was performed using 3D gradient echo T1w MPRAGE and 3D T2w FSE CUBE. Acoustic noise measurements of the maximum sound pressure level (SPL) were performed at the head coil in the MRI bore during volunteer scans.

##### RESULTS

T2w and T1w ZTE images provided qualitatively similar image contrast to the Cartesian acquisitions. As expected, conventional Cartesian images were heavily impacted by subject motion however the ZTE combined with motion correction allowed for recovery of image quality with only modest loss compared to images when no motion was present. This included visualization of the middle cerebral arteries in T2w as well as sulci and ventricles on T1w. ZTE T2w and T1w (peak average SPL 71dBc and 69dBc respectively) were considerably quieter than the conventional Cartesian T2w and T1w (peak average SPL 89dBc and 87dBc respectively).

##### CONCLUSION

s We present progress to date on developing a ZTE-based silent and motion-robust neuroimaging protocol. ZTE with intermittent magnetization preparation and the HEALPix radial view order and motion correction provided motion robust standard T1w and T2w contrasts. The modified ZTE approach allowed SPL levels well below conventional Cartesian protocols while allowing motion correction. Future work will include studies in pediatrics and autism.

#### CLINICAL RELEVANCE/APPLICATION

Sensitive patient populations struggle with MRI due to loud acoustic noise and inability to hold still. This work proposes a ZTE MRI

sensitive patient populations struggle with fMRI due to loud acoustic noise and inability to hold still. This work proposes a 2TE fMRI acquisition and deep learning reconstruction to overcome these challenges.

## **W2-SPPH-13 Comparison of Deep Learning-Based Accelerated Diffusion Weighted Imaging with Conventional Diffusion Weighted Imaging in Female Pelvic Imaging**

Participants

Lillian Chiu, MD, Brooklyn, NY (*Presenter*) Nothing to Disclose

### **PURPOSE**

To compare deep learning based accelerated diffusion weighted images (DL-DWI) and conventional DWI (c-DWI) of the female pelvis using qualitative and quantitative metrics.

### **METHODS AND MATERIALS**

Consecutive patients who had MRI of female pelvis from 12/16/2023-2/3/2023 were included if they had axial c-DWI and a prototype DL-DWI (Siemens, Erlangen, Germany, Bae et al, Eur J Radiol. 2022) acquired on 3T MRI. Exclusion criteria: prior hysterectomy/oophorectomy. c-DWI used b50, 400, 1000 s/mm<sup>2</sup> and DL-DWI used b50, 800, 1000 s/mm<sup>2</sup>. Axial T2, c-DWI or DL-DWI, and associated ADC maps of each were blinded, randomized and evaluated by 3 fellowship trained radiologists (17, 3, and 1 y exp) using a 5pt Likert scale (1 non diagnostic to 5 excellent quality) for strength of fat suppression, sharpness of uterine margin, conspicuity of ovary, conspicuity of endometrium, quality with respect to susceptibility artifact or other artifacts, and conspicuity of fibroids on b1000 DWI and ADC. The ADC value from a 1 cm diameter ROI of the myometrium and fibroid if present were also collected by a trainee and confirmed by a fellowship trained radiologist. Wilcoxon signed rank test was used to compare Likert scores. Paired T test and Bland Altman plot were used to compare ADC values.

### **RESULTS**

108 pts met criteria. Mean acquisition times: c-DWI: 2.44±0.45 min, DL-DWI: 1.03±0.16 min. Significantly different image quality scores: Strength of fat suppression (R1 c-DWI 4.96, DL-DWI 4.89, p=0.03, R3 c-DWI 4.33, DL-DWI 4.04, p<.001), Sharpness of uterine margin (R1 c-DWI 4.22, DL-DWI 4.28, p=0.04, R2 c-DWI 3.58, DL-DWI 3.74, p=0.02, R3 c-DWI 4.30, DL-DWI 4.56, p=0.01), Conspicuity of ovary (R1 c-DWI 4.26, DL-DWI 4.44, p=0.01, R3 c-DWI 4.31, DL-DWI 4.71, p<.001), Conspicuity of endometrium (R2 c-DWI 3.26, DL-DWI 3.10, p=0.05), Susceptibility artifact (5 excellent quality) (R1 c-DWI 3.80, DL-DWI 4.00, p=0.03, R2 c-DWI 3.60, DL-DWI 4.07, p<.001), Other artifact (5 excellent quality) (R3 c-DWI 4.34, DL-DWI 4.15, p=0.03), Conspicuity of fibroid on DWI (R3 c-DWI 3.93, DL-DWI 4.52, p<.001), Conspicuity of fibroid on ADC (R3 c-DWI 4.11, DL-DWI 4.65, p<.001). Mean ADC value of myometrium was c-DWI 1250±220 mm<sup>2</sup>/s, DL-DWI 1620±270 mm<sup>2</sup>/s, p<.001. Mean ADC value of fibroids (59/108) was c-DWI 890±210 mm<sup>2</sup>/s, DL-DWI 1170±220 mm<sup>2</sup>/s, p<.001.

### **CONCLUSION**

s Image quality scores were similar between c-DWI and DL-DWI. All readers scored DL-DWI significantly higher than c-DWI for sharpness of uterine margin. ADC values were significantly higher on DL-DWI than c-DWI which may be due to smoothing process in DL reconstruction vs slightly different b values obtained.

### **CLINICAL RELEVANCE/APPLICATION**

Deep learning accelerated DWI showed excellent and comparative image quality despite 2 fold reduction in acquisition time.

## **W2-SPPH-2 Meningioma Grade Discrimination using a Novel Ultrafast T2 Mapping Technique**

### **PURPOSE**

Meningioma grade plays a significant role in treatment planning and prognosis prediction. Despite the numerous prior studies, preoperative diagnosis of meningioma grade remains challenging. Many studies demonstrated the unique value of T2 mapping MRI for characterizing disease pathology, yet often limited by the long scan time. In this study, we employed a deep learning-based single-shot ultrafast T2 mapping technique, which can acquire whole-brain T2 maps within 32 s, and conventional apparent diffusion coefficient (ADC) maps for the WHO grade discrimination of meningiomas.

### **METHODS AND MATERIALS**

Sixty-nine patients were enrolled, among which 59 were diagnosed with low-grade meningiomas (LGM, grade 1, 57.34 ± 9.40 years) and ten with high-grade meningiomas (HGM, grade 2 and 3, 58.18 ± 9.36 years). All the MRI examinations were performed on a 3.0 T scanner (MAGNETOM Prisma, Siemens Healthcare, Erlangen, Germany) with a 64-channel head coil. Axial T2 mapping, T2-dark-fluid imaging, diffusion-weighted imaging, and contrast-enhanced T1-weighted imaging were performed for all patients. With 3D Slicer (version 4.10.2, [www.slicer.org](http://www.slicer.org)), regions of interest were manually delineated on each slice of T2 maps by the consensus of two blind neuroradiologists. Necrosis, large vessels, and calcification were excluded. From each ROI, we calculated the following histogram parameters using FeAture Explorer (FAE; <https://github.com/salan668/FAE>): mean, median, maximum, minimum, ten percentiles (P10), 90 percentiles (P90), interquartile range (IQR), range, entropy, skewness, kurtosis, uniformity, and variance. Parameters were compared using the independent t-test or Mann-Whitney U test. Multivariate logistic regression and receiver operating characteristic (ROC) analysis were performed to evaluate their diagnostic efficiency. The significance level of p value is 0.05.

### **RESULTS**

Compared to HGM, there were significantly higher T2 (p = 0.021) and ADC (p = 0.012-0.002) histogram parameters in LGM. ADC P10 had the highest area under the ROC curve (AUC = 0.811) among all the ADC parameters and T2 kurtosis showed an AUC of 0.564. Notably, the combination of T2 and ADC exhibited the best diagnostic performance (AUC = 0.868).

### **CONCLUSION**

s It has been demonstrated that T2 and ADC histogram parameters could be used to distinguish LGM from HGM, which is consistent with previous studies. Furthermore, the multivariate logistic regression model combining T2 and ADC was suggested to have the best diagnostic efficiency.

### **CLINICAL RELEVANCE/APPLICATION**

Meningioma grade is an essential factor that affects the treatment planning and recurrence rate. The combination of T2 and ADC

values could provide significant value for the non-invasive prediction of meningioma grade.

### **W2-SPPH-3 Deep Learning-Based Spatial Resolution Improving Algorithm (Precise IQ Engine: PIQE) for MRI: Capability for Scan Time Reduction and Image Quality Improvement as Compared with Deep Learning Reconstruction (DLR) with and without New Fine Reconstruction Algorithm**

Participants

Yoshiharu Ohno, MD, PhD, (*Presenter*) Research Grant, Canon Medical Systems Corporation; Research Grant, Daiichi Sankyo Co, Ltd; Research Grant, Ministry of Education, Culture, Sports, Science and Technology

#### **PURPOSE**

Deep learning reconstruction (DLR) with and without fine reconstruction algorithm (i.e. fine recon) has been clinically set for denoising MR images with and without increasing spatial resolution. In this time, deep learning-based spatial resolution improving algorithm with denoising (Precise IQ Engine: PIQE) is developed for MRI. The purpose of this study was to directly compare utilities of PIQE for scan time reduction and image quality improvement of MRI as compared with DLR with and without fine recon.

#### **METHODS AND MATERIALS**

Sixty-eight consecutive patients suspected with 28 brain tumors, 14 musculoskeletal diseases, 14 uterine or ovarian tumors and 12 prostatic cancers were prospectively scanned with conventional MR protocols and new MR protocols, which were obtained same sequences with reducing matrix sizes ranged from 50% to 70%. Then, each conventional MR data was reconstructed with DLR with and without fine recon, and all new protocol data were reconstructed with PIQE as well as DLR with and without fine recon (total five data sets). To compare scan time reduction and quantitative spatial resolution improvement among all protocols, mean examination time including reconstruction time and edge slope width (ESW) between two different structures were compared among five protocols by Tukey's HSD test. To evaluate qualitative spatial resolution improvement, overall image quality and diagnostic confidence level were assessed by 5-point scales and compared among all protocols by Wilcoxon's signed rank test.

#### **RESULTS**

Mean examination times of new MR protocols were significantly shorter than that of conventional protocols ( $p < 0.05$ ), although mean examination time had no significant differences among all new protocols. Mean ESW of new protocol with PIQE ( $1.1 \pm 0.3 \text{ mm}$ ) was significantly smaller than that of all protocols except conventional protocol with DLR and fine recon ( $1.4 \pm 0.4 \text{ mm}$  = other ESWs =  $1.8 \pm 0.4 \text{ mm}$ ,  $p < 0.05$ ). Overall image quality and diagnostic confidence level of new protocol with PIQE were significantly higher than those of others except conventional protocol with DLR and fine recon (overall image quality:  $p < 0.0001$ , diagnostic confidence level:  $p < 0.0001$ ). Artifact of new protocol with PIQE was significantly smaller than those of others without conventional protocol with DLR and fine recon ( $p < 0.0001$ ).

#### **CONCLUSION**

s PIQE has superior potential to DLR with and without fine reconstruction for reducing temporal resolution and improving spatial resolution, although fine reconstruction can only improve image quality of DLR at conventional protocol.

#### **CLINICAL RELEVANCE/APPLICATION**

PIQE has superior potential to DLR with and without fine reconstruction with reducing temporal resolution and improving spatial resolution.

### **W2-SPPH-4 Early Detection of Myocardial Involvement by Noncontrast T1 $\rho$ Mapping of Cardiac Magnetic Resonance in Type 2 Diabetes Mellitus**

Participants

Xiaohu Li, MD, PhD, Hefei, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the feasibility of T1 $\rho$  in detecting myocardial fibrosis in type 2 diabetes mellitus (T2DM) patients by comparing with native T1 and Extracellular volume (ECV) fraction.

#### **METHODS AND MATERIALS**

35 T2DM patients free of cardiovascular symptoms and preserved ventricular systolic function and 30 healthy controls were prospectively enrolled for T1 mapping, T2 mapping T1 $\rho$  mapping, and late gadolinium enhancement (LGE) examination. ECV mps were calculated using pre- and post-contrast T1 maps. Global native T1, T1 $\rho$ , ECV and 2D global longitudinal strain (GLS) values were generated in respective maps. Receiver operating curves were used to show the diagnostic performance of ECV, T1 $\rho$ , GLS and native T1 in distinguishing T2DM patients and controls. The Student's t-test, Pearson's chi-squared test, Pearson correlation coefficient ( $r$ ) and Delong test were used in this study.  $P < 0.05$  indicates statistical significance.

#### **RESULTS**

The global ECV and T1 $\rho$  of T2DM group (ECV =  $32.1 \pm 3.2\%$ , T1 $\rho$  =  $53.1 \pm 2.0 \text{ msec}$ ) were significantly higher than those of controls (ECV =  $26.2 \pm 1.6\%$ , T1 $\rho$  =  $51.6 \pm 3.8 \text{ msec}$ ) (all  $P < 0.001$ ), whether there was no significant difference in native T1 between T2DM and controls ( $P = 0.264$ ). The GLS decreased significantly in T2DM patients ( $-16.5 \pm 2.4\%$  vs.  $-18.3 \pm 2.6\%$ ,  $P = 0.015$ ). The T1 $\rho$  and native T1 were associated with ECV (Pearson's  $r = 0.50$  and  $0.25$ , respectively, both  $P < 0.001$ ), the native T1, T1 $\rho$ , and ECV were associated with hemoglobin A1c (Pearson's  $r = 0.41$ ,  $0.52$ , and  $0.61$ , respectively, all  $P < 0.05$ ), the ECV were associated with diabetes duration (Pearson's  $r = 0.41$ ,  $P = 0.016$ ). The AUC of ECV, T1 $\rho$ , GLS, and native T1 were  $0.869$ ,  $0.810$ ,  $0.659$ , and  $0.524$ , respectively.

#### **CONCLUSION**

s In T2DM patients, T1 $\rho$  may be a new noncontrast cardiac magnetic resonance technique for identifying myocardial diffuse fibrosis, and T1 $\rho$  may be more sensitive than native T1 in the detection of myocardial diffuse fibrosis.

#### **CLINICAL RELEVANCE/APPLICATION**

It has shown that T1 $\rho$  mapping allow early detection of myocardial diffuse fibrosis in diabetic monkeys. However, T1 $\rho$  has not been

reported in patients with type 2 diabetes mellitus (T2DM). In this project, the purpose of this study is to evaluate the feasibility of T1\* in detecting myocardial diffuse fibrosis in T2DM in a comparison with myocardial native T1 and ECV.

## **W2-SPPH-5 Changes in Brain Susceptibility in Wilson's Disease Patients: A Quantitative Susceptibility Mapping Study**

Participants

Xiaohu Li, MD, PhD, Hefei, China (*Presenter*) Nothing to Disclose

### **PURPOSE**

To reveal changes in the susceptibility of the caudate nucleus (CN), putamen (Put), and globus pallidus (GP) in patients with neurological and hepatic Wilson's disease (WD) by quantitative susceptibility mapping (QSM).

### **METHODS AND MATERIALS**

We retrospectively analyzed brain MRI images of 33 patients diagnosed with Wilson's disease (WD) and 20 age-matched controls. All subjects underwent brain T1-weighted, T2-weighted, and QSM images using a 1.5T MRI scanner. The QSM maps were calculated using STISuite toolbox. The quantitative susceptibility of the CN, Put, and GP was analyzed using region-of-interest analysis on QSM maps. The differences among the neurological WD patients, hepatic patients, and controls were compared.

### **RESULTS**

Susceptibility values were significantly higher in all examined structures (CN, Put, GP) in patients with neurological WD compared to controls (all  $P < 0.05$ ) and hepatic WD patients (all  $P < 0.05$ ). No statistically significant differences were found in susceptibility values between patients with hepatic WD and controls (all  $P > 0.05$ ).

### **CONCLUSION**

The QSM technique is a valuable tool for detecting changes in susceptibility in the brain of WD patients, indicating abnormal metal deposition. Notably, our findings suggest that neurological WD patients exhibit more severe susceptibility changes than hepatic WD patients. Therefore, QSM can be utilized as a complementary method to detect brain injury in WD patients.

### **CLINICAL RELEVANCE/APPLICATION**

Quantitative magnetic susceptibility imaging (QSM) is an advanced MRI technique for magnetic susceptibility evaluation, providing accurate quantitative measurements of the spatial distribution of magnetic susceptibility

## **W2-SPPH-6 Vendor-independent MRI Pulse Sequence Development to Increase Comparability in Cross-vendor Imaging Studies**

Participants

Simon Konstandin, PhD, Bremen, Germany (*Presenter*) Nothing to Disclose

### **PURPOSE**

Magnetic Resonance Imaging is a complex and versatile imaging method, given by the ability to visualize various contrasts and physiological processes. MRI research is commonly achieved by implementing new pulse sequences in vendor-specific development environments. During the last years, vendor-independent MRI frameworks gained attention. Previously, we introduced a vendor-independent MRI pulse sequence development framework that provides a product-like experience on-site, called gammaSTAR [Cordes C et al. Magn Reson Med 2020;83(4):1277-90.]. Until today, none of these frameworks was able to run the same MRI sequence on the MRI hardware of the three largest MRI vendors: Siemens, GE and Philips. In this abstract, for the first time, we show cross-vendor use of gammaSTAR MRI sequences on all three platforms.

### **METHODS AND MATERIALS**

A modular web frontend (free version here: [gamma-star.mevis.fraunhofer.de](http://gamma-star.mevis.fraunhofer.de)) is used to implement MRI sequences and export them into a generalized sequence format. This does not consist of fixed hardware instructions, but holds the fundamental calculation logic of the implemented MRI sequence, allowing for product-like interaction with the MRI sequence and protocol. gammaSTAR driver software is implemented using the vendors development environments to interpret the gammaSTAR sequences and translate events into the vendor-specific hardware commands.

### **RESULTS**

MRI experiments show the feasibility of running MRI sequences developed in the vendor-independent gammaSTAR framework on Siemens, GE and Philips MRI scanners. Image quality is similar to corresponding product MRI sequences and the framework allows for the same protocol interaction and positioning. Low cross-vendor comparability of conventional MRI arises from underlying implementation differences. The use of the same MRI sequence for execution on different MRI hardware allows, for the first time, a comparison of the exact same MRI sequence in a multi-vendor scenario.

### **CONCLUSION**

MRI sequences developed in gammaSTAR were for the first time executed on hardware platforms of all three major MRI vendors. This will eventually open up science and improve the significance of multi-vendor clinical trials by harmonizing imaging technology.

### **CLINICAL RELEVANCE/APPLICATION**

The current state of vendor-centric MRI pulse sequence development limits reuse of MRI applications for different MRI models, software versions. The execution of generalized MRI sequences on MRI hardware of the three largest MRI vendors presents a chance for higher comparability in multi-vendor clinical trials, between follow-ups acquired in different clinics and re-use of MRI sequences for opening up science and accelerating the way of innovation into clinical practice.

## **W2-SPPH-7 The Value of Energy Spectrum CT in Analyzing the Distribution Characteristics of Abdominal Fat in Patients with Chronic Kidney Disease**

Participants

Hua He, MMedSc, Yinchuan, China (*Presenter*) Nothing to Disclose

## PURPOSE

Different fat distribution between men and women can lead to different risks of metabolic diseases and cardiovascular diseases between men and women. In this study, the characteristics of abdominal fat distribution in patients with chronic kidney disease (CKD) and the influence of gender on fat distribution were analyzed by energy spectrum CT.

## METHODS AND MATERIALS

Forty-three patients with CKD were divided into groups according to sex. All patients were treated with GSI scanning mode combined with new iterative algorithm (ASiR-V), noise index(NI=9), automatically modulated tube current (Smart mAs), slice thickness 0.625 mm. All cases were reconstructed by post processing workstation ADW4.7. The "X Section" software was used to manually sketch the abdominal cavity on the horizontal umbilical cross-sectional image, and the CT value range of adipose tissue was  $-200 \sim 0$  Hu. The software automatically calculated the area of corresponding tissues in the sketched range, and recorded the total fat area (TFA), visceral fat area (VFA) and subcutaneous fat area (SFA) = TFA-VFA. The body measurements of patients were recorded, and the differences of body measurements and abdominal fat indexes were compared between the two groups by independent sample T test.

## RESULTS

BMI ( $23.32 \pm 0.72$ ) kg/m<sup>2</sup> of male was higher than that of female ( $20.59 \pm 0.69$ ) kg/m<sup>2</sup>, and the difference was statistically significant ( $P < 0.05$ ). TFA and SFA were ( $358.61 \pm 20.20$ ) cm<sup>2</sup>, ( $171.07 \pm 7.17$ ) cm<sup>2</sup> of male were higher than that of female ( $265.08 \pm 20.13$ ) cm<sup>2</sup> and ( $131.26 \pm 12.23$ ) cm<sup>2</sup> respectively, and the difference was statistically significant ( $P < 0.05$ ), but there was no significant difference in visceral fat between the two groups ( $P > 0.05$ ).

## CONCLUSION

s The total fat area and subcutaneous fat area in male patients with CKD are higher than those in female patients, but the visceral fat area is not affected by gender.

## CLINICAL RELEVANCE/APPLICATION

Different sex patients with chronic kidney disease abdominal fat distribution characteristics are different, we should pay attention to the individualized assessment of ectopic fat in patients, for clinical patients with chronic kidney disease to develop individualized weight loss program to provide basis.

## W2-SPPH-8 Egress Pathways of Intrinsic CSF Outflow Altered by Physical Exercise in Healthy Humans

Participants

Mitsue Miyazaki, PhD, La Jolla, CA (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate egress pathways of intrinsic CSF outflow and their quantitative metrics using a spin-labeling MRI technique on healthy adults with active and sedentary lifestyles. We also examined changes in the CSF outflow metrics in sedentary adults after they increased their physical activity levels for three weeks.

## METHODS AND MATERIALS

Eighteen healthy adults with informed consent were enrolled in this study using a clinical 3-Tesla MRI scanner. We classified participants into two groups based on reported time spent sitting per day (active group  $< 7$  hours or an average of  $5.3 \pm 0.7$  and sedentary group = 7 hours or an average of  $10.4 \pm 1.7$ ). To reveal the effect of exercise, the sedentary individuals were asked to increase their activity to at least about 3.5 hours per week for 3 weeks. To elucidate intrinsic CSF outflow pathways and quantitative metrics, we studied a signal increase ratio (SIR) of time-resolved images at various inversion times (TI). Our hypothesis is that intrinsic CSF egress pathways of 1) dura mater to superior sagittal sinus (SSS), via parasagittal dura (PSD), and 2) the lower PSD pathway from the perivascular space of subcortical or bridging veins. We also measured quantitative outflow metrics at 5 segmented region-of-interests (ROIs); upper PSD, middle PSD, lower PSD, SSS, and entire SSS.

## RESULTS

The active lifestyle group shows greater intrinsic CSF outflow metrics in peak height (PH), relative CSF volume (rCFV), and relative CSF flow (rCFF) ( $p < 0.05$ ) in all above ROIs than the sedentary lifestyle group. However, the sedentary group shows increased outflow metrics after 3 weeks of increased physical activity. This improvement was notable at the PSD, where outflow metrics were highest among the active group and after exercise in sedentary group. These quantitative CSF results indicate a new pathway of CSF outflow from the lower PSD to the SSS that is most evident in physically active individuals.

## CONCLUSION

s The results show that physical exercise alters CSF outflow metrics to a greater degree in the lower PSD pathway, which may be responsible for the perivascular space of cortical veins or subpial space.

## CLINICAL RELEVANCE/APPLICATION

Our findings in healthy adults with active and sedentary lifestyles reveal differences in quantitative CSF outflow metrics related to activity levels. These quantitative outflow findings at the lower PSD add credence to the hypothesis of a distinct, recruitable second pathway of CSF egress from the subpial space to the SSS, with potential implications for future use as a biomarker for cognitive decline and/or therapeutic targeting in aging and neurodegeneration.

## W2-SPPH-9 A Robust Spectroscopic Imaging Sequence for 7T Brain Glioma Evaluation

Participants

Jullie Pan, PhD, Columbia, MO (*Presenter*) Nothing to Disclose

## PURPOSE

To implement a robust fast targeted spectroscopic imaging sequence at 7T for brain tumors. While 3T single voxel spectroscopy is an excellent acquisition, with limited scan time, small voxel targets, and the need to place single voxels by the technologist can be difficult. These problems can be better managed with higher SNR at 7T; however, 7T can be difficult for spectroscopy with limited

RF and susceptibility. We implement the decoupled transceiver coil and a high degree shim insert with an efficient spatial encoding strategy to assess its performance in glioma patients.

## **METHODS AND MATERIALS**

With IRB oversight, tumor patients were recruited from Tumor Board review (10 patients recruited; 9 completed). An 8 channel pTx Siemens 7T Terra, decoupled transceiver and very high order shim (VHOS) insert was used. After whole brain MP2RAGE imaging and RF shimming, the target regions were identified. For optimal shimming, single slices were studied, shimmed using a high accuracy field map with the VHOS insert. A moderate echo TE=40ms spectroscopic imaging sequence encoded with a noncartesian rosette trajectory was used (32x32 resolution, 4.5min single slice). First level SAR monitoring was used. Automated LCModel curve fit was used to determine metabolite ratios. Values of maximum Ch/NAA value in the region of the lesion were used to identify 3 groups of abnormality:  $\geq 1.7$ ,  $\geq 0.9$  to  $< 1.7$  or  $< 0.9$ . All studies were blinded to clinical and imaging data to independently compare clinical to spectroscopic imaging group.

## **RESULTS**

Fig. 1 shows data from a patient with two regions of interest. Based on literature and the patient data, the ratios for Ch/NAA and Ch/Cr were used for initial classification (control value for parenchymal Ch/NAA  $0.56 \pm 0.17$ , Ch/Cr  $1.03 \pm 0.15$ ). The spectroscopic group based on the maximum Ch/NAA in the region of tumor was compared with their clinical group, either active tumor, treatment effect or no change, Table 1. N=5 patients with Ch/NAA  $\geq 1.7$  were classified with active tumor; 1 patient classified as normal had low Ch/NAA  $< 0.9$ . The remaining 3 patients ( $0.9 \leq \text{Ch/NAA} < 1.7$ ) were clinically described as treatment effect (1), progression (1) or no change (1); the last "no change" patient was identified 6mos later to have progression.

## **CONCLUSION**

s At 7T with the decoupled transceiver and high degree shim insert, the spectroscopic imaging was able to identify patients with active tumor. An intermediate threshold for Ch/NAA of 0.9 to 1.7 identified those with treatment effect or very early recurrence. With additional data, better classification may be possible.

## **CLINICAL RELEVANCE/APPLICATION**

We have implemented 7T methods that can acquire robust spectroscopic images in glioma patients which can contribute to a better or earlier understanding of the tumor state.

W2-SPRO

### Radiation Oncology Wednesday Poster Discussions

#### Sub-Events

#### W2-SPRO-1 Deep Learning Prediction of Post-Radiation Magnetic Resonance Images to Inform Stereotactic Radiotherapy of Breast Cancer Metastases to the Brain

#### PURPOSE

Changes on standard multiparametric MRI (mpMRI), including T1-weighted unenhanced (T1w) and contrast-enhanced (T1wCE), T2-weighted (T2w), Fluid-Attenuated Inversion Recovery (FLAIR), and Apparent Diffusion Coefficient of water (ADC) images are mechanistically relatable to voxel-level tumor response to Radiation Therapy (RT). While Stereotactic Radiosurgery (SRS) provides high local control rates for the management of Breast Cancer Metastases to the Brain (BCMB), tools to enable voxel-level optimization of RT dose plans for local tumor control with minimal toxicity to normal tissues do not exist. We have trained deep learning "forward models" to predict post-SRS T1w, T1wCE, T2w, FLAIR and ADC maps from the corresponding 5 pre-SRS mpMRIs and the delivered RT dose map. We also trained an "inverse model" to predict the delivered RT dose map from 5 pre-SRS and 5 post-SRS mpMRI images. The overarching goal is to enable the radiation oncologist to compute the RT dose map to achieve prescribed post-SRS values of ADC, T1wCE, T1w, T2w and FLAIR within the GTV, simulate mpMRI outcomes and iteratively optimize RT plans for local control of BCMB.

#### METHODS AND MATERIALS

Planning CT images and associated RT dose maps, and T1w, T1wCE, T2w, FLAIR images and ADC maps acquired pre-SRS, post-SRS, and at tumor recurrence were curated from 27 BCMB patients (18 Training, 9 Test) with confirmed controlled and locally recurrent metastases. Patients were treated with SRS dose of 1-40 Gy between 2013-2019. After co-registration to the planning CT, all mpMRIs were intensity-calibrated, variance-normalized and scaled. A pix2pix framework used to predict post-SRS MRIs from pre-SRS MRIs and the RT dose map (5 forward models). Another pix2pix model was trained to predict the RT dose map from pre-SRS and post-SRS MRIs (inverse model).

#### RESULTS

On testing, forward model accuracy for predicting the direction of post-SRS intensity change within the Gross Tumor Volume (GTV) was highest for T1wCE (83%), followed by T1w (77%), FLAIR (75%), T2w (68%), and ADC (46%). In agreement with expectations, higher RT doses within the GTV are predicted by the inverse model to achieve greater suppression of intensity on T1wCE and/or higher ADC within the GTV post-SRS.

#### CONCLUSION

s We have demonstrated the feasibility of predicting post-RT mpMRI images from pre-RT mpMRIs and the delivered RT dose map. For a given set of pre-RT mpMRIs, we have also demonstrated the feasibility of predicting the RT dose map that would be required to achieve prescribed post-RT intensities within the GTV.

#### CLINICAL RELEVANCE/APPLICATION

We present a new paradigm in RT planning, viz., voxel-level optimization of SRS dose to achieve prescribed post-SRS mpMRI characteristics of treated tumors using the presented forward and inverse models.

### Vascular Imaging Wednesday Poster Discussions

#### Sub-Events

#### W2-SPVA-1 Tele-robotic Ultrasound Usability Testing on a Phantom

##### PURPOSE

Annually, 16 million North American patients struggle to access diagnostic ultrasound (US) services due to sonographer shortages. Rural and remote patients are required to travel excessive distances to access diagnostic US services, which can be time-consuming and expensive resulting in patients failing to attend their appointments. The aim of this study is to validate a proof-of-concept tele-robotic US system which serves to make diagnostic healthcare more accessible.

##### METHODS AND MATERIALS

The equipment used in the study included the Kinova Gen 3 robot, Clarius L7 US probe, the Inverse3 (input device), and an advanced deep-vein thrombosis (DVT) phantom. First, seven sonographers performed freehand DVT scans on the phantom. After successful training, each sonographer performed a teleoperated DVT scan, where they controlled the robot using the input device. The required US images, clot diameter, and scan duration were recorded for the freehand and teleoperated scans. The users then completed a survey, where various parameters were ranked on a scale of 1-5, with 5 being optimal. Next, each user performed three teleoperated scans with three random and counter-balanced latencies (0, 300, 600 ms). They started at a standardized position, located the clot, and measured its diameter. The duration of each test was recorded.

##### RESULTS

The clot diameters collected using freehand and teleoperated US were  $1.1 \pm 0.2$  cm and  $1.0 \pm 0.3$  cm, respectively. The time associated with performing the freehand and teleoperated DVT scans were  $8.7 \pm 3.8$  min and  $8.0 \pm 2.0$  min, respectively. The usability survey yielded the following average rankings for input device features: naturalism and usable workspace, 3.4; ergonomics, 3.9; ease of use, 4.3. The rankings for the robotic system features were: smoothness, 3.1; naturalism, 3.4; range of motion, 3.6; and control accuracy, control ease, and synchronicity, 3.7. The clot diameter collected with teleoperated US were  $1.2 \pm 0.24$  cm,  $1.1 \pm 0.32$  cm, and  $1.1 \pm 0.24$  cm for 0, 300, and 600 ms latencies, respectively. The duration of the tests subject to 0, 300, 600 ms latencies were  $1.3 \pm 0.69$  min,  $1.4 \pm 0.69$  min, and  $1.9 \pm 0.68$  min, respectively.

##### CONCLUSION

This study provides a proof-of-concept for the use of teleoperated diagnostic US as sonographers were able to measure the clot diameter within 0.1 cm of their freehand equivalent without increasing the time required for the scan. Latencies up to 600 ms did not affect the accuracy of the resultant clot diameter or scan time.

##### CLINICAL RELEVANCE/APPLICATION

The results of this proof of concept study encourages the continued pursuit of teleoperated US research as there is a strong potential it could result in more patients obtaining diagnostic US, improved outcomes from earlier diagnosis, and safer pregnancies.

#### W2-SPVA-2 Diagnostic Accuracy of Photon-Counting CT Angiography in Lower Extremity Peripheral Artery Disease: A Head-to-Head Comparison with Invasive Angiography

##### PURPOSE

CT Angiography (CTA) has gained increasing importance in assessing the presence and severity of peripheral artery disease (PAD). However, the diagnostic performance of the lower leg vasculature remains challenging due to small vessel diameters and impaired image quality caused by the blooming of calcified plaques. Recently introduced photon-counting detector CT (PCD-CT) technology may overcome these limitations. Therefore, we aimed to investigate and compare the diagnostic accuracy of PCD-CT for PAD of the lower leg with invasive digital subtraction angiography (DSA) as the reference standard.

##### METHODS AND MATERIALS

Consecutive patients with suspected PAD of the lower leg, who underwent CT and DSA within 48 hours, were prospectively included. Five series were reconstructed using dedicated vascular kernels (Bv40, Bv44, Bv48, Bv56, and Bv60). DSA of the lower extremities was acquired in two orthogonal orientations as the gold standard. To assess and compare the diagnostic performance of the different PCD-CT reconstructions, two interventional radiologists assessed all PCD-CT and DSA data independently in random order. They were blinded to the type of reconstruction. First, overall image quality was rated on a 5-Point Likert scale (5=excellent). Secondly, the presence and diagnostic confidence (5-Point Likert scale; 5=excellent) of potentially hemodynamic-relevant stenosis ( $\geq 50\%$ ) was assessed.

##### RESULTS

Among twenty-three patients included in the final analysis ( $70 \pm 11$  years, 39% female), six hemodynamic-relevant stenoses were detected on DSA. The highest overall image quality was found for the Bv56 and the Bv60 kernel (4 [4-4]; 4 [3-5];  $p=0.001$ ), followed by softer kernels. Also, the Bv56 kernel yielded the highest sensitivity (83.33%) and specificity (94.12%) for the detection of potentially relevant stenosis with the highest diagnostic confidence (4 [3-5];  $p=0.001$ ) and inter-reader agreement ( $k=0.7$ ),

similarly followed by Bv60 and softer kernels.

#### **CONCLUSION**

s PCD-CT CTA with a sharp vascular kernel (Bv56) allows for detecting relevant stenosis in the lower leg vasculature with high diagnostic accuracy and confidence. These results can potentially strengthen the role of CTA in the workup of patients with known or suspected PAD and reduce the number of invasive diagnostic DSA.

#### **CLINICAL RELEVANCE/APPLICATION**

CTA is important in the workup of PAD but remains challenging due to small vessel caliber and potential blooming artifacts. PCD-CT CTA with a sharp vascular kernel may improve image quality and, thus, patient management. Using PCD-CT may ultimately reduce the need for invasive diagnostic procedures.

## Abstract Archives of the RSNA, 2023

W5A-SPBR

### Breast Imaging Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPBR- Correlation between Sarcopenia Evaluated with CT and Toxicity in Patients Affected by Breast Cancer** **1** during Adjuvant Chemotherapy

##### PURPOSE

Recent evidences suggest that in severe depletion of skeletal muscle, known as sarcopenia, the anti-cancer therapy is associated with poor prognosis and toxicity. Sarcopenia, often unrecognized, affects patients with low, normal or high body mass index (BMI). Aim of this study was to evaluate the association between lumbar skeleton muscle status (LSMI) evaluated with CT scans and toxicity in breast cancer patients receiving standard adjuvant chemotherapy

##### METHODS AND MATERIALS

22 breast cancer women (mean age:55) receiving epirubicin-based chemotherapy were enrolled in a prospective study. Skeletal muscle cross-sectional area at the third lumbar vertebra was measured by CT scans and sarcopenia was defined using the cut off point for LSMI of <38.5 cm<sup>2</sup>/m<sup>2</sup>. BMI and BSA were measured at every cycle of chemotherapy. CT scan was performed before the first and fourth cycle of chemotherapy. Toxicity was assessed after every cycle of treatment and it was graded according to the National Cancer Institute Common Toxicity Criteria. Serum samples were evaluated at every cycle to determine drug concentrations.

##### RESULTS

Before the first cycle of chemotherapy, 86.36% of patients were classified as sarcopenic. The sarcopenia mean value was 32.22 cm<sup>2</sup>/m<sup>2</sup> (SD: 5.78), and no differences by age and BMI were found. The BMI mean value was 23.97 (SD: 4.32). After the fourth cycle of chemotherapy the BMI mean value was 24.19 (SD: 4.74; range) and the sarcopenia mean value was 32.18 (SD: 5.68). 18% of patients reported severe toxicities (grade 3 or 4). Sarcopenia mean values were found significantly different (p-value 0.048) in patients with severe toxicity compared with patients with absent/mild toxicities (mean value: 27.17, SD, 3.27 versus 33.30, SD, 5.55, respectively). Changes in LSMI were associated with significant changes in toxicities (p-value 0.004). In 18% of patients with a severe toxicity, a decrease in LSMI values after the 4th cycle of chemotherapy was always detected.

##### CONCLUSION

s Preliminary analysis of available data showed an association between sarcopenia and toxicities, suggesting also that sarcopenia could be considered an early condition in breast cancer.

##### CLINICAL RELEVANCE/APPLICATION

If the association between changes in sarcopenia and toxicities will be confirmed in larger population, the measure of LSMI with CT scan could be used to personalized the dose of chemotherapy

#### **W5A-SPBR- Complex Interplay of MRI and Clinicopathology Variables in pCR Prediction across Breast Cancer** **2** Subtypes

#### Participants

Sarah Eskreis-Winkler, MD, Teaneck, NJ (*Presenter*) Nothing to Disclose

##### PURPOSE

Breast cancers exhibit different rates of pathologic complete response (pCR) according to tumor receptor status: HR+/HER2-, HER2+, and triple negative (TNBC). Deep learning (DL) models using MR have been developed for pCR prediction, but the comparative performance of pCR prediction for different subtypes has not yet been investigated. Herein, we build pCR prediction models for each subtype, compare performance across subtypes, and explore relationships to clinicopathology (CP) models.

##### METHODS AND MATERIALS

This IRB-approved HIPAA-compliant study included 719 breast MRs performed between 2014-2018 on breast cancer patients prior to neoadjuvant chemotherapy. Tumor subtype, pCR status, and CP variables were collected, including age, race, cancer history, clinical stage, nuclear grade, histological grade, and histology. A ResNet50-based architecture was built to predict pCR for each subtype using MR. Data was randomly split 80/10/10 into training, tuning and testing. Pre-contrast, post-contrast, subtraction, and T2 images were co-registered; tumor ROIs were automatically segmented and passed through the model. Final hyperparameters: 25 epochs; learning rate 2e-4, batch size 64. A penalized logistic regression model was built to predict pCR using CP variables alone. Patients were randomly assigned to training and testing with an 80/20 split. ROC curves were generated and AUCs were calculated for each subtype, for the MR and CP models. DeLong's test assessed statistical significance of differences in model performance.

##### RESULTS

Breast MRs included 210 HR+/HER2- (5050 axial slices), 349 HER2+ (8325 axial slices) and 160 TNBC (4521 axial slices) cases. Test set AUCs for the MR models were 0.62 for HR+/HER2-, 0.48 for HER2+, and 0.78 for TNBC. The best AUC (i.e. TNBC) was

statistically significantly higher than to the worst AUC (i.e. HER2+) ( $p < 0.001$ ). For the CP model, test set AUCs were 0.80 for HR+/HER2-, 0.68 for HER2+, and 0.55 for TNBC.

## CONCLUSION

s DL-based MR model performance for pCR prediction varies by subtype with the TNBC (AUC = 0.78) significantly outperforming HER2+. In contrast, the CP model exhibited poor performance for TNBC (AUC = 0.55). This suggests synergistic potential for pCR prediction using medical images and CP. We are actively working to develop a composite model that integrates multimodality inputs to optimize pCR prediction across all patients and all tumor subtypes.

## CLINICAL RELEVANCE/APPLICATION

DL-based MR models for pCR prediction perform better on some tumor subtypes than others, providing complimentary information to clinicopathology variables. This suggests synergistic potential for pCR prediction using a multimodality approach, enabling optimization of treatment planning for all breast cancer patients.

## W5A-SPBR- What is the Optimal Post Contrast Timing of Breast MRI to Evaluate Residual Tumor during the Course of Neoadjuvant Chemotherapy

3

### PURPOSE

Patients undergoing neoadjuvant chemotherapy (NAC) are often monitored using dynamic contrast enhanced (DCE)-MRI, a sensitive tool for residual tumor assessment. NAC can have antiangiogenic effects that can impact accurate assessment of residual tumors. Purpose of this study is to evaluate the optimal post contrast timing to evaluate residual tumor during the course of NAC.

### METHODS AND MATERIALS

An IRB approved study was performed. Publicly available 351 MRI exams from 117 breast cancer patients undergoing NAC in the ACRIN 6698 multi-institution trial were used for this study. The average age of patients was 49 y.o. (+/- 11). Of 117 patients, 36 patients (30.8%) achieved pathologic complete response (pCR) and 81 patients (69.2%) did not (non-pCR). Of 117 patients, 36 patients (30.7%) had triple negative tumors (ER-, PR-, HER2-), 30 patients (25.6%) had HER2+ tumors and 51 patients (43.6%) had ER+/HER2- tumors. The MRI exams included those from pretreatment [T0], early NAC treatment [T1], and mid-NAC treatment [T2]. For each tumor, we calculated the time to peak (TTP) to achieve maximal tumor enhancement and evaluated changes in TTP over the course of NAC treatment. TTP was calculated by segmenting the tumor and calculating the phase with maximum signal intensity measured within the tumor. TTP subanalysis was performed comparing patients with tumors that achieved pCR vs non-pCR and between subtypes of breast cancer. Statistical significance was determined with  $p < 0.05$  from a 2-tailed paired t-test.

### RESULTS

The TTP increased significantly over the course of NAC treatment. The TTP at T1 was 265 sec (+/- 151), at T2 was 314 s (+/- 314) and at T3 was 385 s (+/- 183). The average TTP increase of 159 s (+/- 146) from T0 to T2 was statistically significant ( $p < 0.05$ ). Tumors of patients that achieved pCR had significantly greater change in TTP from T0 to T1 compared to non-pCR [183 s (+/- 147) vs. 15 s (+/- 103),  $p < 0.05$ ]. Patients with triple negative and HER2+ tumors had greater change in TTP from T0 to T1 compared to ER+/HER2- tumors [90 s (+/- 212) and 63 s (+/- 209) vs. 5 s (+/- 229)] but was not statistically significant.

## CONCLUSION

s The optimal post contrast timing of breast MRI increases with NAC likely due to antiangiogenic treatment effects. DCE-MRI protocol should include delayed post dynamic sequences inclusive of 314 s to 385 s to enable maximal tumor enhancement to best evaluate residual tumor during NAC, particularly in triple negative and HER2+ tumors. A significant increase in TTP from T0 to T1 could be a possible novel biomarker of pCR but needs further studies.

## CLINICAL RELEVANCE/APPLICATION

In the setting of NAC, the most optimal timing of breast MRI is likely on the delayed post contrast images and should be part of the evaluation to most accurately assess residual breast tumor.

## W5A-SPBR- Correlation of MRI and Pathological Responses after Neoadjuvant Chemotherapy with Disease-Free Survival in Breast Cancer Patients: Subtype Analysis

4

### Participants

Almir Bitencourt, MD, PhD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

Ricardo Fernandes Da Cunha, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

### PURPOSE

To correlate response evaluation after neoadjuvant chemotherapy (NAC), assessed by magnetic resonance imaging (MRI) and pathology, with disease-free survival (DFS) in breast cancer patients, according to the subtype.

### METHODS AND MATERIALS

This single-center, IRB-approved, retrospective cohort study included consecutive breast cancer patients who underwent NAC and preoperative breast MRI. Pathologic response was assessed through the residual cancer burden (RCB) system, and absence of invasive carcinoma in the breast and axilla was defined as complete pathological response (pCR or RCB=0). Radiological complete response (rCR) was defined as the absence of abnormal enhancement in the tumor site on MRI. Kaplan-Meier estimator was used to estimate the disease-free survival. Cox regression analysis was used to estimate hazard ratio (HR) values.

### RESULTS

750 patients were included with mean age of 47 years (range: 26-90 years). The most common immunophenotype was Luminal ( $n=362$ ; 48.3%), followed by triple-negative ( $n=198$ ; 26.4%) and Her-2 overexpressed ( $n=190$ ; 25.3%). Most patients ( $n=474$ ; 63.2%) had clinical stage III at diagnosis. Overall, 34.5% of the patients had rCR, while 30.3% had pCR. During a mean follow-up of 72 months, patients who had both rCR and pCR had a better DFS curve, while patients with non-rCR and non-pCR had worse DFS curve, and those who had rCR or pCR presented an intermediate curve (LogRank  $p=0.001$ ). The statistically significant difference on DFS curves persisted for triple-negative (LogRank  $p < 0.001$ ) and Her-2 overexpressed subtypes (LogRank  $p = 0.014$ ), but not for luminal tumors (LogRank  $p=0.495$ ). Cox regression showed a higher risk of recurrence in patients with non-rCR and non-pCR (HR:

8.686;  $p=0.003$ ), those who had non-pCR and rCR (HR: 7.658;  $p=0.008$ ), and those who had pCR and non-rCR (HR: 3.644;  $p=0.109$ ), when compared to patients with rCR and pCR.

## CONCLUSION

The association of MRI and pathological responses after NAC might better stratify the risk of recurrence and prognosis in breast cancer patients, particularly for the triple-negative subtype.

## CLINICAL RELEVANCE/APPLICATION

Association of response evaluation after neoadjuvant chemotherapy by pathology and MRI allows better stratification of prognosis than both criteria used alone.

## W5A-SPBR- Features of MRI Screen-Detected Breast Cancers

5

### PURPOSE

Breast cancer is a leading cause of death in women in the United States. Supplemental screening with breast MRI in addition to mammography is recommended annually for patients who have greater than 20% lifetime risk for breast cancer. While there is robust data regarding features of screen-detected breast cancer using mammography, there is limited data regarding MRI screen-detected cancers. This study aims to identify features of breast cancers initially detected by MRI.

### METHODS AND MATERIALS

In this institutional review board-approved retrospective study, breast MRIs performed between August 1, 2016 and July 30, 2022 identified 51 screen-detected breast cancers in 48 patients. Clinical and imaging features of all eligible cancers were recorded, as well as frequency of cancer type and clinical stage.

### RESULTS

During the study period, 51 MRI-screen detected cancers were identified in 48 patients. Most cancers (33/51, 64.8%) were invasive and most (45/51, 88.2%) were stage 0 or I at diagnosis. At the end of the study period, 1/48 (2.1%) had metastasis (in a patient with recurrent angiosarcoma), 1/48 (2.1%) had died from other causes, and 46/47 (97.9%) had no evidence of disease following treatment. Final pathology showed that 26/51 (51.0%) of MRI screen-detected cancers were invasive ductal carcinoma, 6/51 (11.8%) invasive lobular carcinoma, 1/51 (2.0%) angiosarcoma and 18/51 (35.3%) DCIS. MRI-screen detected cancers most commonly presented as a mass (26/51, 51%) or non-mass enhancement (NME) (25/51, 47.1%), with only 1/51 (2%) presenting as a focus. Internal T2 signal was hypointense to fibroglandular tissue in 4/51 (7.8%), isointense in 29/51 (56.9%) and hyperintense in 18/51 (35.3%). Of those cancers that presented as a mass, the majority 15/27 (55.6%) had an irregular shape, 13/27 (48.1%) had irregular margins, and 15/27 (55.6%) had homogeneous internal enhancement. Of those that presented as NME, the majority 13/24 (54.2%) were linear NME and had homogeneous internal enhancement 15/24 (62.5%). Many of the cancers were in patients who had prior MRI exams (37/51, 72.5%).

### CONCLUSION

MRI screen-detected cancers were most often invasive, rather than in situ, cancers. Cancers detected by MRI screening had an excellent prognosis in our study population, supporting the clinical utility of breast MRI in the early diagnosis of breast cancer. Common MRI presentations included an irregular mass and linear non-mass enhancement.

## CLINICAL RELEVANCE/APPLICATION

Screening MRI often detected small, invasive breast cancers, underscoring its clinical importance in women at high risk for breast cancer. Understanding the most common imaging presentations of MRI-screen-detected cancers may guide interpretation and diagnostic performance of the exam.

## W5A-SPBR- Does the Addition of MRI Help in Cancer Detection in Women with Low Breast Tissue Density in a Population-based High-risk Breast Screening Program

6

Participants

David Martin, MD, Ottawa, ON (*Presenter*) Nothing to Disclose

### PURPOSE

The High-Risk Ontario Breast Screening Program (HROBSP) screens women ages 30-69 who are confirmed to be at high risk of developing breast cancer (gene mutation carriers or lifetime risk  $\geq 25\%$ ) with annual mammography and breast MRI. Mammographic breast tissue density (BTD) is an independent risk factor for breast cancer, and the sensitivity of mammography is diminished in women with dense versus fatty breasts. We aimed to compare cancer detection rate (CDR) according to BTD and determine if breast MRI in HROBSP patients with fatty BTD is necessary given the improved sensitivity of mammography.

### METHODS AND MATERIALS

IRB approved retrospective review of all HROBSP breast MRIs performed at our institution from 04/04/2016 to 06/05/2022 was conducted. For each study, BI-RADS<sup>®</sup> BTD was recorded, and charts were reviewed to identify patients with breast cancers diagnosed during the screening period. Imaging was reviewed to determine if the cancer was seen on mammography, MRI or both.

### RESULTS

6468 MRIs were reviewed (2082 patients) over 6-year study period. 66 cancers were detected in all (cancer detection rate (CDR)=10.2/1000); 5(7.6%) detected in category A, 20(30.3%) in B, 34(51.5%) in C and 7(10.6%) in D. 468(7.2%) MRIs were performed in 12.5%(260/2082) women with category A, who had 4 cancers (80%) detected on MRI alone and 1 cancer on both mammography and MRI. There was no difference in CDR by BTD (CDR for category A=10.7/1000, B=8.6/1000, C=11.8/1000, and D=9.1/1000,  $p=0.7$ ).

### CONCLUSION

Adjunctive screening with breast MRI in HROBSP patients is necessary for women with category A density breasts, despite the increased sensitivity of mammography in this patient population.

## CLINICAL RELEVANCE/APPLICATION

The HROBSP program with yearly mammography and breast MRI aids in early detection of breast cancer in all women, regardless of breast density.

### W5A-SPBR- Outcomes of Supplemental Breast MRI in a High Risk Screening Program

7

Participants

Stamatia Destounis, MD, Rochester, NY (*Presenter*) Medical Advisory Board, iCad, Inc

#### PURPOSE

The Tyrer-Cuzick (TC) model has increasingly been used to identify high-risk women in breast imaging centers. The accuracy of the model has been studied in several patient cohorts, but, outcomes of using the TC model to make supplemental breast MRI recommendations are less reported. We studied the incidence of breast cancer and tumor characteristics at a community-based breast imaging center to better understand the outcomes of the risk assessment program.

#### METHODS AND MATERIALS

A retrospective analysis of patients participating in the risk assessment program starting in December 2016 was performed. Patients with a TC lifetime risk score >20% were offered supplemental MRI screening and are defined as high-risk (HR) in this study. Data were collected from the electronic health record, including Breast MRI data and cancer outcomes, and was matched to the risk assessment and imaging studies data. We limited our cohort to those with at least 5 years of follow-up. Patients with history of breast cancer prior to the first risk assessment, patients who were under 40 or over 79 years old, and patients without a valid TC score were excluded.

#### RESULTS

There were 54,706 patients who met study inclusion criteria with median age of 57, at median follow-up time of 5.2 years during which 2,259 cancers arose. The HR group was comprised of 8,737 (15.5%) patients (median age 52); LR group had a median age of 58 ( $P < 0.001$ ). Of HR patients, there were 2,108 (24.1%) who had breast MRI with a high-risk exam indication (median age 51). Odds ratio (OR) for breast cancer for the total HR group compared to the LR group was 1.50 (95% CI: 1.36 to 1.67,  $P < 0.0001$ ). OR for the HR group who were getting MRI compared to the LR group was 1.47 (95% CI: 1.21 to 1.78,  $P < 0.0001$ ). OR for the HR group who were not getting MRI compared to the LR group was 1.51 (95% CI: 1.35 to 1.70,  $P < 0.0001$ ). When considering tumor size of T2 or greater as large, the OR for a larger tumor when comparing the HR group to the LR was 0.57 (95% CI: 0.39 to 0.84,  $P = 0.0038$ ). For the HR group with MRI the OR was 0.39 (95% CI: 0.17 to 0.91,  $P = 0.029$ ) and the OR for HR group without MRI was 0.63 (95% CI: 0.42 to 0.96,  $P = 0.030$ ). Though not statistically significant, 12.9% of cancers in the LR group were node positive, compared to 6.4% in the HR group with MRI ( $P = 0.0698$ ).

#### CONCLUSION

Supplemental MRI screening in high-risk women can lead to earlier detection of breast cancer, finding tumors at lower stage that may lower the burden of disease. Further investigation in how to improve the uptake of high-risk interventions such as breast MRI screening will be beneficial.

## CLINICAL RELEVANCE/APPLICATION

This study reports the impact of offering supplemental breast MRI as part of a large breast screening program. This high-risk cohort had an increased cancer rate and smaller tumors.

### W5A-SPBR- Application Value of Imaging Manifestations Combined with Tumor-Related Diffusion-Weighted Imaging Models in Predicting Molecular Subtype of Breast Invasive Ductal Carcinoma

8

#### PURPOSE

To evaluate and compare the value of MR imaging manifestations and 6 tumor-related DWI models in predicting the molecular subtypes of breast invasive ductal carcinoma (IDC).

#### METHODS AND MATERIALS

This study included 100 patients with breast IDC confirmed by pathological examination in our hospital. All the patients underwent routine MRI and multiple-b-value DWI examinations on a 3T scanner (MAGNETOM Vida, Siemens, Erlangen, Germany). The scanning parameters are shown in Table 1. The patients were divided into three groups, including luminal ( $n=72$ ), HER-2 overexpressing ( $n=13$ ), and triple-negative ( $n=15$ ) subtypes. The value in predicting the molecular subtype of IDC was evaluated in terms of imaging manifestations and quantitative parameters of DWI models. All the 14 quantitative parameters (CTRW\_a, CTRW\_β, CTRW\_D, FROC\_β, FROC\_D, FROC\_μ, DKI\_D, DKI\_K, IVIM\_D, IVIM\_D\*, IVIM\_f, Mono\_ADC, SEM\_a, and SEM\_DDC) of the 6 DWI models were calculated by an in-house developed software called BoDiLab based on Python 3.7. All ROI measurements were done on the ITK-SNAP. Univariate and multivariate regression analysis were performed to screen independent predictive factors for different molecular subtypes, and a combined model was established, which was then visualized with a nomogram. ROC curves were used to assess the diagnostic performance of each parameters or model in discriminating molecular subtypes. All the analysis was performed using the software SPSS 26.0 and R language.

#### RESULTS

Margin burr and rim enhancement were independent imaging manifestation-related predictors of triple-negative breast cancer (TNBC) ( $P < 0.05$ ), which showed high diagnostic performance when combined with CTRW\_a and DKI\_K (AUC/sensitivity/specificity value of 0.870/80.0%/88.2%) (Figure 1). Luminal IDC was more likely to appear with margin burrs ( $P < 0.05$ ), and the diagnostic performance was higher when combined with CTRW\_a, DKI\_K, and IVIM\_f. HER-2-overexpressing IDC was commonly accompanied by peritumoral edema ( $P < 0.05$ ), and IVIM\_f showed high diagnostic value for this subtype (Table 2, 3). Nomogram for predicting the TNBC and luminal subtype were shown in figure 2.

#### CONCLUSION

The combined diagnostic model based on imaging manifestations and multiple DWI quantitative parameters has high diagnostic value in predicting the molecular subtype of breast IDC, and the parameters may be used as non-invasive biomarkers in future clinical practice.

#### **CLINICAL RELEVANCE/APPLICATION**

This study explored the value of MRI manifestations combined with different DWI quantitative parameters in predicting the molecular subtypes for breast IDC, which may have guiding significance for the formulation of individualized treatment strategies in clinical practice.

## Abstract Archives of the RSNA, 2023

W5A-SPCA

### Cardiac Imaging Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPCA- Diagnostic Accuracy of Spectral CT Aortograms for the Detection of Acute Myocardial Infarction** 1

##### Participants

Dene Ellis, BMBS, London, United Kingdom (*Presenter*) Nothing to Disclose

##### PURPOSE

Acute myocardial infarction (MI) presentation is often atypical and unclear, justifying further investigations for other causes of chest pain. Thus, in modern practice CT aortograms (CTAs) are essential to exclude acute aortic syndrome (AAS). Despite being a non-dedicated study for the assessment of coronary heart disease (CHD), new spectral CT technologies may enable interrogation of coronary abnormalities or discernible myocardial perfusion defects. The aim of this study is to assess the diagnostic performance of gated-spectral CTAs in diagnosing acute MI. This will help to determine the prevalence of acutely presenting CT-imaging features by measuring myocardial Hounsfield Unit (HU) values indicative of evolving regional ischaemia.

##### METHODS AND MATERIALS

Retrospective consecutive cohort analysis was conducted to include acute chest pain patients that underwent urgent gated-spectral CTAs as a triple rule-out test for AAS at a large tertiary centre, over 12 months (Jan-Dec 2022). CTAs performed for reasons other than acute pain (e.g. trauma) were excluded. Data sources included patients' electronic records and the institution's PACS, to collate patients' demographics, clinical information, imaging findings, outcomes of further investigations and definitive management. This enabled correlation with troponin levels, ECG, and echocardiographic observations. On CTAs, LV myocardial hypo-enhancement HU was measured after visual assessment by two cardiac-trained radiologists to localise culprit diseased coronary arteries.

##### RESULTS

In a total of 309 CTAs, n=30 (9.7%) studies showed regional myocardial hypo-enhancement, confirmed later as acute MI. Of those, n=18/30 (60%); underwent urgent invasive angiography, where n=13 received percutaneous interventions and n=7 required urgent coronary artery bypass graft (CABG) surgery. Two patients died shortly after CTA acquisition, one of which had a post-mortem examination confirming a large territory MI. CTA yields an 90.9% sensitivity, 99.3% specificity and 98.4% accuracy in identifying acute MI (prevalence-adjusted). Ischaemic myocardial regional hypo-enhancement was (HU=50, SD=17.7) significantly lower ( $p<0.001$ ) than healthy myocardium (HU=126, SD=19.4).

##### CONCLUSION

At our institution, gated-spectral CTA has been utilised to investigate equivocal acute chest pain presentations in the emergency setting. The benefits of its excellent diagnostic accuracy can be achieved by educating reporting radiologists and cardiologists.

##### CLINICAL RELEVANCE/APPLICATION

Gated-spectral CTA can preclude the need for post-mortem examination, but it is most beneficial in reducing time-to-intervention by avoiding unnecessary further tests, especially in equivocal NSTEMI cases.

#### **W5A-SPCA- Measurement Accuracy of Aortic Valve Annulus with and without Whole-heart Motion Correction Algorithm in Multi-slice CT for Pre-operative TAVI: Compared to 3D Transesophageal Echocardiography** 2

##### Participants

Takayuki Yoshiura, BA, RT, Hiroshima, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Accurate measurements of the aortic valve annulus with multi-slice CT (MSCT) are required for the success of pre-operative transcatheter aortic valve implantation (TAVI) procedure. The whole-heart motion correction (MC) algorithm is useful for reducing aortic annulus motion artifacts and is expected to measurement accuracy. The purpose of this study is to investigate the measurement accuracy of the aortic valve annulus with and without MC algorithm in MSCT compared to three-dimensional transesophageal echocardiography (3D TEE).

##### METHODS AND MATERIALS

We retrospectively analyzed 15 patients who underwent TAVI. The three mutually perpendicular planes so that the cross-sectional plane just passed through the plane of the lowest point of the aortic valve leaflet attachment, and the resulting section was the aortic annulus plane. The axial plane was reconstructed for the minimum aortic annulus diameter, and the valsalva and aortic annulus diameter were measured using 256-slice CT (Revolution Apex; GE Healthcare, Milwaukee, Wisconsin). We created an annulus plane on 3D TEE (EPIQ CVx; Koninklijke Philips Ultrasound, USA) using the same method as CT, and measured the minimum diameter of the valsalva and aortic annulus in the sagittal plane. All CT images were using the with and without MC algorithms and

compared to 3D TEE measurements.

## RESULTS

The measured mean diameter of aortic valve annulus for axial plane was 30.00 mm and 28.61 mm for with and without MC algorithms. The measured mean diameter of aortic valve annulus for the sagittal plane was 30.22 mm for 3D TEE, showing a significant difference between without MC algorithm and 3D TEE ( $p < 0.01$ ), but not between with MC algorithm and 3D TEE ( $p > 0.05$ ). The measured mean diameter of aortic annulus for the axial plane was 20.20 mm and 19.53 mm for with and without MC algorithms. The measured diameter of aortic annulus for the sagittal plane was 20.50 mm for 3D TEE, showing a significant difference between without MC algorithm and 3D TEE ( $p < 0.01$ ), but not between with MC algorithm and 3D TEE ( $p > 0.05$ ).

## CONCLUSION

MC algorithm in MSCT enabled the accurate measurements of aortic valve annulus for pre-operative TAVI.

## CLINICAL RELEVANCE/APPLICATION

The application of MC algorithm in MSCT is useful for the accurate measurements of aortic valve annulus for pre-operative TAVI.

## W5A-SPCA-3 Association between Coronary Sinus Flow Estimated by Dynamic Coronary CT Angiography and 13N-ammonia PET-derived Myocardial Flow Reserve

### PURPOSE

Coronary sinus (CS) flow is regulated by global myocardial blood flow (MBF) and directly affects myocardial flow reserve (MFR) reduction. We devised a new method for CS flow quantification using 320-row dynamic coronary CT angiography (CCTA) and investigated the relationship between CS flow determined via CCTA and MBF or MFR values obtained via 13N-ammonia positron emission tomography (NH3-PET).

### METHODS AND MATERIALS

Forty patients with moderate to severe coronary artery stenosis on dynamic CCTA who subsequently underwent adenosine-stress NH3-PET were enrolled in this study. Time-attenuation curves of the CS and the ascending aorta were extracted from dynamic CCTA data. The upslope of the CS was defined as the initial slope of the CS attenuation increase divided by that of the ascending aorta. CS start time (s) was defined as the timepoint between the peak aortic attenuation and the initial increase in CS attenuation. Global MBF was calculated from dynamic NH3-PET data. Global MFR was defined as the ratio of adenosine-stress MBF to the rest MBF.

### RESULTS

The CS upslope was moderately positively correlated with rest MBF (Pearson correlation coefficient  $r$ , 0.443;  $p = 0.004$ ), and CS start time was moderately negatively correlated with MFR ( $r$ , -0.540;  $p < 0.001$ ). The diagnostic performance predicting MFR  $< 2.0$  according to the following criteria: CS starting time  $> -0.36$  seconds was 86% sensitivity, 76% specificity, and an area under the curve of 0.83.

### CONCLUSION

Dynamic CCTA-estimated CS flow measurements were significantly correlated with NH3-PET-derived MBF and MFR values. A delayed CS start time can be used to predict a significant decrease in MFR in coronary artery disease.

### CLINICAL RELEVANCE/APPLICATION

This method may help estimate MFR even in facilities that do not have a PET scanner.

## W5A-SPCA-4 Impact of Super-Resolution Deep Learning Reconstruction Technique on Dynamic Myocardial Computed Tomography Perfusion Imaging

Participants

Tomoro Morikawa, MD, Toon-shi, Japan (Presenter) Nothing to Disclose

### PURPOSE

Super-resolution deep-learning reconstruction (SR-DLR) is a novel computed tomography (CT) image reconstruction technique using a deep convolutional neural network that allows for improvement of spatial resolution on CT images as with ultra-high-resolution CT. This study aims to evaluate the impact of SR-DLR on the image quality and hemodynamic parameter of dynamic myocardial computed tomography perfusion (CTP) by comparing with hybrid iterative reconstruction (HIR) and DLR.

### METHODS AND MATERIALS

This retrospective study included 26 patients who underwent dynamic myocardial CTP with pharmacological stress using 320-detector-row CT scanner for assessing coronary artery disease. The CTP images were reconstructed with HIR, DLR, and SR-DLR. For qualitative image quality assessment, overall visual score was evaluated on 4-point scale (1=poor, 4=excellent). For quantitative image quality assessment, CT attenuation and standard deviation in the myocardium (septum and lateral wall) and blood pool were recorded to calculate the image noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR). Additionally, the CT attenuation profile across the myocardium and blood pool was generated to measure the edge rise slope (ERS) and edge rise distance (ERD). For hemodynamic parameter assessment, overall CT-derived myocardial blood flow (CT-MBF) was quantified. These results were compared among three different CTP images reconstructed by HIR, DLR, and SR-DLR.

### RESULTS

The mean visual image quality score on SR-DLR was better than on HIR and DLR (3.6 vs 2.2 and 2.8;  $p < 0.01$ ). The median image noise on SR-DLR was significantly lower than on HIR and DLR (15.6 vs 23.1 and 17.8;  $p < 0.01$ ). The mean SNR and CNR on SR-DLR were significantly higher than on HIR and DLR (SNR: 9.7 vs 7.3 and 7.9,  $p < 0.01$ ; CNR: 28.5 vs 20.1 and 23.4,  $p < 0.01$ ). The median ERD on SR-DLR was significantly shorter than on HIR and DLR (2.3 vs 3.0 and 2.6;  $p < 0.01$ ), and the mean ERS on SR-DLR was significantly steeper than on HIR and DLR (168.4 vs 126.1 and 151.2;  $p < 0.01$ ). There was no significant difference in mean CT-MBF among the three different CTP images reconstructed by HIR, DLR, and SR-DLR (2.37, 2.38 vs 2.39 mL/g/min).

## CONCLUSION

SR-DLR was superior to HIR and DLR with respect to the image noise and the sharpness of myocardial margins without altering CT-MBF quantification in dynamic myocardial CTP imaging.

## CLINICAL RELEVANCE/APPLICATION

SR-DLR allows for improving the image noise and sharpness more effectively than conventional reconstruction techniques in dynamic myocardial CTP imaging without requiring hardware changes. SR-DLR has a potential to improve the detectability of myocardial perfusion abnormality by taking advantage of the high spatial resolution and noise reduction capability.

## W5A-SPCA- Deep-Learning Image Reconstruction Algorithm: Impact on Plaque Analysis in Coronary Computed Tomography Angiography

Participants

Domenico De Santis, MD, Roma, Italy (*Presenter*) Nothing to Disclose

## PURPOSE

Plaque composition in Coronary Computed Tomography Angiography (CCTA) relies on plaque density measurements and subsequent partition in different components: lipid, fibro-fatty, and calcified. Newly developed deep-learning image reconstruction algorithms (DLIR) hold promises to replace iterative reconstructions in CCTA, granting high image quality, low dose, and no detrimental effect on image texture; however, different strength levels may have an impact in plaque features extraction. The aim of this study was to assess the influence of DLIR at different strength levels on coronary plaque analysis.

## METHODS AND MATERIALS

Forty consecutive patients (mean age  $61.9 \pm 15.4$  y) who underwent clinically indicated retrospectively ECG-gated CCTA were included in the study. CT scans were performed on a 128-row CT scanner (Revolution EVO, GE Healthcare) with the following parameters: tube voltage, 100 kV; tube current: 200 mA; detector collimation: .625 mm, rotation time: .6 s, automatically adjusted spiral pitch from .16 to .30, and matrix:  $512 \times 512$  pixels. A fixed amount (60 mL) of iodinated contrast medium (Iomeprol 400) was intravenously administered at a flow-rate of 5 mL/s. Raw data were reconstructed using ASiR-V 50% and DLIR at three strength levels (DLIR\_L, DLIR\_M, and DLIR\_H). Plaque analysis was performed using a dedicated software (SurePlaque, Canon Medical Systems, Japan): plaque burden, plaque volume, mean density, and plaque composition were assessed on a per-vessel analysis. Statistical analysis was performed by means of Kruskal-Wallis H Test, followed by Dunn's test for pairwise comparisons.

## RESULTS

Fifty-seven plaques were analyzed for each reconstruction, for a total of 228 plaques. Total plaque burden was 61.1%, plaque volume was 132 mm<sup>3</sup>, and mean density was 179 HU. DLIR at different strength levels did not show statistically significant differences in the three parameters (all  $P = .906$ ). In terms of plaque composition, no differences have been found for fibro-fatty and calcified components ( $P = .503$  and  $= .821$ , respectively). The mean density of lipid plaques was statistically different among the four algorithms ( $P = .013$ ), in particular pairwise comparison showed difference between DLIR\_L and DLIR\_H ( $P = .009$ ).

## CONCLUSION

DLIR has no impact on overall plaque analysis compared to routinely applied ASiR-V; DLIR\_L might return lower density values for lipid plaque component.

## CLINICAL RELEVANCE/APPLICATION

DLIR grants reliable coronary plaque analysis; therefore, it can be safely implemented in CCTA examinations. DLIR\_L impact on lipid component should not hinder plaque analysis, since lower lipid density values broaden the density differences with fibro-fatty plaque component.

## W5A-SPCA- Evaluation of Dual-Source Photon-Counting CT Virtual Monoenergetic Imaging of Coronary Arteries in TAVI Patients

Participants

Daniel Overhoff, MD, Mannheim, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

Transcatheter aortic valve implantation (TAVI) is a widely utilized valve replacement procedure. The coronary arteries must be assessed before each procedure, which is usually done using invasive catheter angiography. The photon counting detector-CT (PCD-CT) yields the possibility to evaluate the specifications of the valve and the coronary arteries with a one-stop-shop approach. The aim of this study was to evaluate the impact of low energy virtual monoenergetic images (VMI+) objective image parameters (vessel enhancement, noise (standard deviation of vessel attenuation), signal to noise ratio (SNR), contrast to noise ratio (CNR)) of the coronary arteries in pre-TAVI CT examinations.

## METHODS AND MATERIALS

We retrospectively analyzed 125 pre-TAVI CT datasets from a first generation Dual-Source PCD-CT (Naeotom alpha, Siemens Healthineers, Forchheim Germany). The coronary arteries were analyzed in virtual monoenergetic images ranging from 40 to 100 keV in 15 keV steps. Maximum vessel density Hounsfield Units (HU) were measured for Left main (LM), Right coronary artery (RCA), Left circumflex (LCX) and Left anterior descending (LAD) at the proximal vessel segment. Signal-to-noise ratio and contrast-to-noise ratio were calculated.

## RESULTS

A total of 125 patients (73 male/52 female) were included in the final assessment. Maximum intraluminal enhancement of coronary arteries was measured for 40keV ( $1123 \pm 312$  HU) with decreasing density values with increasing keV values (100keV  $220 \pm 55$  HU). SNR showed a significant reciprocal values with highest SNR at 100keV compared to 40keV ( $14.55 \pm 9.47$  vs  $10.68 \pm 6.68$   $p < 0.001$ ). The CNR, in turn, demonstrated significantly improved values at lower keV levels. (40keV vs 100keV/  $26.37 \pm 10.15$  vs  $8.50 \pm 3.50$   $p < 0.001$ ). There were no significant gender differences in the above changes.

## CONCLUSION

s PCD-CT virtual monoenergetic images offer the possibility to improve the image quality for the assessment of the coronary arteries in pre-TAVI-CT. The highest vascular contrast and CNR are achieved at 40keV. SNR is highest at 100keV and decreases at lower keV levels.

#### **CLINICAL RELEVANCE/APPLICATION**

PCD-CT virtual monoenergetic images yield the possibility of potential reduction of contrast media and an optimization of image quality with reduction of radiation dose for the analysis of coronary arteries in TAVI patients.

W5A-SPCH

### Chest Imaging Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPCH- Impact of Different AI User Interfaces on Lung Nodule and Mass Detection on Chest Radiographs 1**

##### **PURPOSE**

To explore the impact of different user interfaces (UIs) for artificial intelligence (AI) outputs on radiologist performance and user preference in detecting lung nodules and masses on chest radiographs.

##### **METHODS AND MATERIALS**

A retrospective paired-reader study with a 4 week washout period was used to evaluate three different AI UIs compared with no AI output. Ten radiologists (8 radiology attendings and 2 trainees) evaluated 140 chest radiographs (81 with histologically confirmed nodules and 59 confirmed as normal by CT), with either no AI or one of three UI outputs: 1) text only, 2) combined AI confidence score and text, or 3) combined text, AI confidence score and image overlay. Areas under the receiver operating characteristic curve (AUCs) were calculated to compare radiologist diagnostic performance with each UI with performance without AI. Radiologists reported their user interface preference.

##### **RESULTS**

AUC improved when radiologists used the text-only output compared with no AI (0.87 vs 0.82, p-value<0.001). There was no difference in performance for the combined text and AI confidence score output compared with no AI (0.77 vs 0.82, p-value=0.46) and for the combined text, AI confidence score and image overlay output compared with no AI (0.80 vs 0.82, p-value=0.66). Eight of the 10 radiologists (80%) preferred the combined text, AI confidence score and image overlay output over the other two interfaces.

##### **CONCLUSION**

s Text only UI output significantly improved radiologist performance compared with no AI in the detection of lung nodules and masses on chest radiographs, but user preference did not correspond with user performance.

##### **CLINICAL RELEVANCE/APPLICATION**

Understanding the impacts of how different user interfaces may alter reader performance is a crucial aspect of AI implementation in radiology.

#### **W5A-SPCH- Physics-based Data Augmentation to Improve Chest X-ray Abnormality Classification 2**

##### **PURPOSE**

Many AI methods to detect chest X-ray (CXR) abnormalities have demonstrated promising results by adopting image pre-processing techniques (e.g., histogram equalization (HE), contrast limited adaptive histogram equalization (CLAHE), and unsharp masking (UM)). However, those methods showed limited diagnostic performance when applied to CXRs with different image characteristics from various X-ray scanners. Here, we propose an X-ray physics-based data augmentation (i.e., XPA) that perturbs CXRs during AI training to overcome this problem.

##### **METHODS AND MATERIALS**

Unlike conventional image pre-processing methods (e.g., HE, CLAHE, and UM) that normalize CXRs before AI training and testing, XPA randomly perturbs image characteristics on training CXRs by applying a series of image processing methods (e.g., gamma correction for contrast perturbation) to mimic hardware-related changes (e.g., voltage, current, etc.) during AI training. Seven datasets from different X-ray machines (digital radiography (DR) or computed radiography (CR)) and institutions were collected. One dataset was from a Vietnam hospital and annotated by a radiologist as normal or abnormal (e.g., opacity, etc.) for AI (7,202 CXRs for training; 1,278 CXRs for testing (VHDR1)). Four datasets were from Indonesian hospitals, including a dataset acquired from a portable X-ray machine (IHCR1,Portable:204; IHCR2 :227; IHCR3:356; IHDR2:1,909 CXRs) and annotated for AI testing. Two datasets (i.e., Shenzhen (SZDR3) and Montgomery (MGCR4)) were from public domains as testing data. We trained four AI models (EfficientNet-B6) using HE, CLAHE, UM, and proposed XPA to classify CXRs as normal or abnormal and compared their diagnostic performance. To check the capability of each method to cover CXRs from different machines, only the CXRs acquired using the DR system in the Vietnam hospital were utilized for training.

##### **RESULTS**

For VHDR1 (internal test dataset), the diagnostic performance of all AI models was not statistically significant (i.e., p-value>0.05). However, in most of the test datasets, the AI model with XPA outperformed the others, including the datasets acquired from the different CR detectors (IHCR2, IHCR3, and MGCR4), portable X-ray machine (IHCR1,Portable; AUC: 0.950 for XPA; 0.924 for HE; 0.920 for CLAHE; 0.891 for UM; p-value<0.05), and DR detectors (IHDR2 and SZDR3).

##### **CONCLUSION**

s The diagnostic performance of the AI model was improved with XPA for the CXR datasets from different X-ray machines (i.e., DR,

CR, and portable machines) compared to those of the other AI models with conventional image pre-processing methods.

#### **CLINICAL RELEVANCE/APPLICATION**

The proposed AI showed potential clinical usage when the CXRs were acquired using various X-ray scanners.

### **W5A-SPCH- Investigating the Feasibility of Using AI to Detect Unreported Chronic Disease Findings on Chest X-Ray in a Retrospective Aged Patient Dataset**

Participants

Jonathan S. Luchs, MD, Woodbury, NY (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study evaluates the feasibility of using an artificial intelligence (AI) model to retrospectively identify 27 chronic disease findings in an aged patient chest X-ray (CXR) dataset. The aim of this study was to investigate the ability of the AI model to identify findings not previously reported in the radiologists' report. This aims to validate the usefulness of AI as a quality improvement device to improve the characterization of patient cardiovascular disease risk.

#### **METHODS AND MATERIALS**

The study dataset consisted of 1,261 CXRs from patients  $\geq 65$  years, collected from outpatient clinics. CXR images were retrospectively processed by the AI for the presence of predefined chronic disease findings. As a comparison, the radiologist report was manually reviewed for the presence/absence of these findings, with findings considered absent if they were not mentioned in the report. In cases where there was a discrepancy between the model and report, a radiologist adjudicator evaluated the CXR scan to determine ground truth (GT), i.e. if the finding was overcalled or under called by the AI model/radiologist.

#### **RESULTS**

Reported prevalence of findings varied between the AI model and report. The AI model reported 505, 731, 650 and 783 instances of cardiomegaly, unfolded aorta (UA), aortic arch calcification (AAC) and spine arthritis (SA), compared to 194, 12, 622 and 562 in the report, respectively. There were 133, 48 and 29 instances of lower, upper, and diffuse interstitial thickening reported by the AI model, compared to 554, 553 and 557 in the report, respectively. Across all findings, Cohen's Kappa agreement was 0.17, indicating slight agreement. Comparison with the GT showed that cardiomegaly, UA, AAC and SA were underreported in the report compared to the AI model (report sensitivity (sens): 0.32, 0.02, 0.54, 0.44, vs. AI model sens: 0.83, 0.86, 0.75, 0.75, respectively). This resulted in 68%, 98%, 46%, and 56% of these findings being missed by the report, while 17%, 14%, 25%, and 25% were missed by the AI model. Conversely, diffuse, lower and upper interstitial thickening were over reported compared to the AI model, as shown by reduced specificity of the report (report; 0.58, 0.58, 0.58 vs. AI; 0.99, 0.92, 0.96, respectively).

#### **CONCLUSION**

AI models in medical imaging have typically focused on radiological finding detection to provide diagnostic assistance to radiologists. Here we present evidence that a quality improvement AI device can enhance patient care and management through the detection of under and over reporting of chronic disease findings.

#### **CLINICAL RELEVANCE/APPLICATION**

Chronic diseases are often incidentally detected on CXR but not reported due to their low-risk nature. However, these findings can be significant predictors of patient health risk.

### **W5A-SPCH- Multiclass Labelling of Foreign Hardware on Chest Radiographs using a Convolutional Neural Network**

#### **PURPOSE**

To assess the accuracy of transfer learning with a pre-trained convolutional neural network (CNN) in detecting multiple classes of medical devices and other foreign bodies on chest radiographs.

#### **METHODS AND MATERIALS**

A total of 2000 de-identified, publicly available chest radiographs were binary labelled for the presence of 18 different types of foreign bodies by two radiology fellows. The images were split into training and validation data sets (80:20 ratio). A pre-trained ResNet50 convolutional neural network model based on weights obtained from ImageNet was loaded from the TensorFlow environment. The top layer was removed and replaced with a single densely connected layer. The ResNet50 pretrained model expects a 224 x 224 x 3 channel input. The x-ray images were down sampled to 224 x 224 using simple averaging.

#### **RESULTS**

After several epochs the neural network could correctly classify the presence or absence of different medical devices or foreign objects with an accuracy of 78-99% on the validation data set, and 10/17 classes were detected with  $>90\%$  accuracy. This model did show high average specificity (98% [93-100%]) but variable sensitivity (57% [11-100%]) across classes, likely attributable to the small size of the dataset and high similarity in form and position of several devices.

#### **CONCLUSION**

Transfer learning using a pre-trained neural network permits high accuracy classification of foreign bodies and medical devices on chest radiographs without the need for hyperparameter tuning. Larger datasets and improved annotation will be required to further improve the performance of future models.

#### **CLINICAL RELEVANCE/APPLICATION**

These findings represents an important step towards more accurate and rapid confirmation of device presence in comparatively undifferentiated CXRs.

### **W5A-SPCH- Radiomics Analysis for Predicting Progression of Part-Solid Nodules on CT**

Participants

Shiny Weng, BA, BA, Berkeley, CA (*Presenter*) Nothing to Disclose

## PURPOSE

Radiomics, with its diverse set of features, has the potential to reveal novel avenues for identifying malignant nodules and detecting subtle patterns not visible to the naked eye. In clinical practice, identifying progressive nodules is crucial for detecting malignancies. Hence, this study aims to explore the statistical significance of radiomic and clinical features in predicting overall growth in part-solid nodules (PSNs).

## METHODS AND MATERIALS

In this retrospective study, institutional chest CT scans between 2015 and 2019 were collected. Corresponding radiology reports were used to extract ground truth labels for nodules' growth status (i.e., increase vs. unchanged), as well as other related information such as nodule size, location, slice, component sizes, and compared studies. An automated NLP pipeline was used for the extraction, and manual review was used to ensure the dataset's accuracy. Additionally, associated CT scans were run through a commercial nodule characterization algorithm. The parameters generated from this algorithm, such as nodule size and location, were then compared and matched with the extracted features from the original radiology reports.

## RESULTS

The final dataset consists of 1276 PSNs, and ground truth labels are available for 1009 PSNs (830 unchanged, 166 growing, 13 decreasing). From this dataset and using radiomic (from pyRadiomics) and clinical features (e.g., patient age, gender), we developed various ML models for predicting growth in PSNs, of which Random Forests achieved the highest AUC of 0.78 on the validation set. Moreover, in the statistical analyses of the association of radiomic and clinical features with nodule progression, 88 radiomic features were statistically significant ( $p < 0.05$ ) based on a Mann-Whitney U Test. Such radiomic features include Surface Volume Ratio, Zone Variance, and Small Dependence High Gray Level Emphasis, all of which had high feature importance for identifying progressive nodules in the Random Forests model. Among clinical features, Patient Age exhibited high feature importance. 75 features were used for the Random Forests model, which were selected using random forest importance, recursive feature elimination, and univariate selection.

## CONCLUSION

We developed a model to identify nodule progression from a predictive set of radiomic and clinical features, achieving an AUC of 0.78 on the validation set. Additionally, we have assembled a labeled dataset of 1009 PSNs, which includes various attributes such as nodule size, type, and location.

## CLINICAL RELEVANCE/APPLICATION

By employing radiomics, statistical analysis, and machine learning, we may produce accurate early characterization of growing adenocarcinoma spectrum nodules and optimize management and outcomes.

## W5A-SPCH- Artificial Intelligence System for Identification of Overlooked Lung Metastasis in Abdominal CTs of Patients with Malignancy

6

## PURPOSE

To evaluate whether an artificial intelligence (AI) system can identify metastatic nodules in basal lungs covered by abdominal CTs initially overlooked by radiologists.

## METHODS AND MATERIALS

We retrospectively analyzed abdominal CT images with the following inclusion criteria: a) CTs obtained from patients with any solid organ malignancy between March 1st and 31st, 2019 in a single institution; b) abdominal CT interpreted as negative for metastasis in covered basal lungs. Patients who underwent chest CT on the same day with abdominal CT, and patients lost to follow-up within 3 years without clinical diagnosis of lung metastasis. The reference standards for the diagnosis of lung metastasis were confirmed by the review of medical records and subsequent CT images. An AI system that can automatically detect lung nodules in CT images was retrospectively applied. The AI results were reviewed by a radiologist to confirm the lesion is a true lung nodule with the possibility of metastasis. The detection yield (the proportion of true-positive results among entire patients), sensitivity, and positive predictive value (PPV) of the AI system and the radiologist who reviewed AI results were evaluated, for the identification of patients with basal lung metastasis overlooked during the initial interpretation.

## RESULTS

A total of 878 patients (66% men; mean age 65 years) were included. The most common primary malignancy was hepatocellular carcinoma (411, 47%), followed by stomach (169, 19%) and colorectal cancer (11%). Lung metastases were diagnosed in 69 patients (7.8%) within 3 years from the abdominal CT. Among them, 12 patients (1.4%) had overlooked metastasis in the basal lungs covered by the abdominal CT. The AI system identified 319 lesions in 176 patients (positive rate, 20%). Among the 319 AI results, 261 (81.8%) were true lung nodules by the radiologists' review, and 25 (7.8%) were metastatic nodules overlooked during the initial interpretation. The detection yield, sensitivity, and PPV of the AI system to identify patients with overlooked basal lung metastasis were 1.4% (12/878), 100% (12/12), and 6.8% (12/176), respectively. Meanwhile, the radiologist's review of AI results resulted in the detection yield, sensitivity, and PPV of 1.4% (12/878), 100% (12/12), and 14% (12/86), respectively.

## CONCLUSION

In patients with solid organ malignancies, an AI system exhibited excellent sensitivity for the identification of metastases in basal lungs covered by abdominal CTs that radiologists initially overlooked.

## CLINICAL RELEVANCE/APPLICATION

An AI system may help radiologists not overlook small lung basal lung metastasis in abdominal CTs by providing feedback to the radiologists in case of suspicions, which could be an efficient method to reduce interpretation errors.

## W5A-SPCH- Surveillance Breeds Conformity! Multicenter, Post-market Surveillance of a Multi-finding AI Algorithm for the Interpretation of Chest Radiographs

7

Participants

Giridhar Dasegowda, MBBS, Boston, MA (Presenter) Nothing to Disclose

## PURPOSE

Post-market surveillance of AI algorithms can help assess real world performance and impact of AI algorithms. We performed a multicenter, post-market surveillance (PMS) of a multi-finding AI algorithm for the interpretation of chest radiographs (CXRs).

## METHODS AND MATERIALS

Our retrospective, multicenter study included 2066 consecutive CXRs obtained from 7 practices across 7 geographically diverse states in India. CXRs belonged to 1167 men and 899 women with a mean age of  $46 \pm 17$  years. All centers had Qure.AI CXR algorithm implemented in routine clinical interpretation of CXRs. For a fraction of CXRs, AI outputs were either unavailable due to technical difficulties or not used due to low confidence interval for the findings. All consecutive CXRs from the centers were de-identified and uploaded on the annotation platform. An experienced thoracic radiologist blinded to the AI output evaluated the CXRs to establish the ground truth. We compared the performance of AI-aided and unaided clinical interpretation of CXRs. Sensitivity, specificity, ROC AUC with 95% confidence interval were used to evaluate the performance.

## RESULTS

The AI output had a better standalone performance compared to radiology reports (AUC of 0.72 - 0.90, sensitivity 44%-83% and specificity 81%-100%). The overall reporting performance for cardiomegaly, nodule, opacities, blunted costophrenic angle, cavity and to differentiate normal from abnormal CXRs compared to the ground truth had an AUC of 0.62 - 0.75, 28%-88% sensitivities and 56%-100% specificities. The performance of radiologists improved significantly with AI-aided reporting over those CXRs reported without AI outputs at the time of reporting with an effective increase in 6%-19% in AUC ( $p < 0.01$ ).

## CONCLUSION

Our PMS study demonstrates an overall improvement in the radiologists' performance with AI-aided interpretation of CXRs.

## CLINICAL RELEVANCE/APPLICATION

In the real-world application, the assessed AI algorithm improves the interpretation of for CXRs.

## W5A-SPCH- The Path to Successful AI Adoption in Radiology: Investigating Hurdles in The Computer-Assisted Diagnosis Implementation within Hospital Settings

### PURPOSE

To demonstrate that AI implementation in hospital radiological practice requires careful business assessment and planning: from the end-user experiences to training and workflow adjustments.

### METHODS AND MATERIALS

Radiologists who agreed to participate in quantitative and qualitative surveys were prospectively recruited from December 2022 to April 2023. To identify the challenges in AI adoption, this study measured the CAD technology acceptance and diffusion using an extended diffusion framework, namely the Extended Technology Acceptance Model (ETAM) based on 1) Unified Theory of Acceptance and Use of Technology (UTAUT) and 2) Diffusion of Technology (DOI). This integrated model evaluated the interaction of CAD and radiologists by incorporating the latent structures of trust, accuracy, efficiency, adoption, and diffusion from a behavioral, psychological, and social perspective. Following the ACR Data Science Institute Artificial Intelligence survey (2020), this study also collected information on AI usage, demographics, and AI performance evaluation.

### RESULTS

A total of 10 radiologists participated in qualitative interviews and 68 radiologists participated in quantitative surveys (~5% response rate). The overall perception of clinical AI usage is higher than national usage (39% versus 26%). The findings highlighted several challenges facing the adoption of AI in radiology. While most participants expressed trust in AI innovation, they demonstrated major hurdles in AI adoption, including interpretation time and time management issues. The major concerns are in the poor integration and usability caused by the lack of radiologists' involvement in user testing. As a result, many participants used AI only as a second reader or triage tool.

### CONCLUSION

While the potential benefits of AI in healthcare are widely acknowledged, it is important to recognize that the adoption of AI technology is not guaranteed simply by implementing AI tools. Successful AI adoption requires careful consideration of factors such as user training, workflow integration, and the development of appropriate governance and validation frameworks.

### CLINICAL RELEVANCE/APPLICATION

As the use of AI solutions for improving diagnostic accuracy gains significant attention, the need for an operational framework that would involve radiologists as end-users becomes increasingly apparent. Such a framework would guide the deployment, interoperability, and validation of AI in clinical practice, ultimately contributing to the development of safe and effective AI-based diagnostic tools. This study documents operational issues and proposes initial guidelines for clinical implementations.

## Abstract Archives of the RSNA, 2023

W5A-SPER

### Emergency Radiology Wednesday Poster Discussions I

#### Sub-Events

#### W5A-SPER-1 Identifying and Communicating Urgent Findings in Emergency Radiology: A Scoping Review

#### PURPOSE

To determine existing published standards for the identification and communication of critical actionable imaging findings in emergency radiology. To identify the associated facilitators and barriers to the communication and management of critical imaging findings.

#### METHODS AND MATERIALS

A scoping review of published literature was performed through 2 databases (PubMed, Embase) with search terms pertaining to critical findings in emergency radiology. Articles and guidelines published in all languages from January 2010 to September 2022 were considered. Screening of database hits using pre-established inclusion criteria was performed by 3 analysts with reconciliation of discordance by consensus. A gray literature search for societal guidelines and high-impact policies was added to the database search. Data extraction included the following: year, country, resource type, scope/purpose, participants, context, standards to identifying/communicating critical findings, facilitators/barriers, method type, recommendations, applicability, and disclosures.

#### RESULTS

60 records were included in the final analysis, including 12 societal/commission guidelines. Among the included guidelines, no standardized lists of critical findings were identified, however, recommendations to create a local policy for critical findings were made in 5/12 guidelines. Reference to critical findings policies from the Joint Commission (16/60 articles), and ACR (30/60 articles) were most frequent. Standards used by centres for critical findings often applied a formal list of findings or classifications based on acuity. Among standards based on acuity (n=12), a 3-tier classification system was most common. Standards for communication included direct closed-loop communication for high acuity findings, with more flexible communication channels for less acute findings. Interventions for critical findings management most frequently fell into 4 categories: electronic (n=7), hybrid electronic/admin (n=5), feedback/education (n=5), and administrative (n=2).

#### CONCLUSION

There are variable standards, policies, and interventions for the management of critical findings in emergency radiology. ACR and Joint Commission standards were most frequently applied. Interventions applied EMR-based strategies, call-centres, and traditional phone/fax. Further research should seek to evaluate consistency and efficiency of closed-loop communication protocols, provider satisfaction, and patient outcomes.

#### CLINICAL RELEVANCE/APPLICATION

Summarizes the policies around critical results reporting in emergency radiology. Provides a guide for consensus building, innovation and rapid adoption towards greater patient safety, and provider satisfaction.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

W5A-SPGI

### Gastrointestinal Imaging Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPGI-1 Sensitivity of MRI to Detect Microscopic Fat in Adrenal Adenomas: Comparison of 2D Dual Gradient-echo and 3D DIXON Techniques**

##### Participants

Abdullah Khan, MD, Sacramento, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

To compare the sensitivity of 2D dual gradient-echo and 3D DIXON chemical shift MRI (CSI) for detecting microscopic fat in adrenal adenomas.

##### METHODS AND MATERIALS

We performed a retrospective study of 35 patients (15 male, 20 female, mean age 61.8 years) with adrenal nodules who underwent both 2D dual gradient-echo and 3D DIXON T1-weighted CSI on a 1.5T scanner. The signal intensity (SI) of the nodules was obtained using a single ROI in the center of the nodule (comprising at least 2/3rds the nodule diameter) and the signal intensity index (SII) was calculated [ $100 \times (SI \text{ in phase} - SI \text{ out of phase}) / SI \text{ in phase}$ ]. Reference standard for the diagnosis of 29 adenomas was made by no change in nodule size or growth  $< 3\text{mm/year}$  in long axis for at least 1 year on follow up imaging ( $n=19$ ), unenhanced CT attenuation of  $< 10 \text{ HU}$  ( $n=8$ ), or pathology ( $n=2$ ). The mean time to imaging follow up was 4.5 years (range 1.1-10.5 years). The diagnosis of metastasis was made by pathology ( $n=1$ ) and nodule growth  $> 3\text{mm/year}$  in a patient with known cancer ( $n=1$ ). There was one pheochromocytoma diagnosed by pathology. Three nodules had no adequate reference standard. Sensitivity for the diagnosis of adrenal adenoma was determined using a SII of  $> 16.5\%$ .

##### RESULTS

There were 35 nodules (mean size 22 mm, range 11-55 mm). The SII was higher on 2D CSI compared to 3D DIXON in 80% (28/35) of nodules by a mean of 14.4%. Of the 29 adenomas, the SII was higher on 2D CSI compared to 3D DIXON in 90% (26/29) of nodules. Among adenomas, the mean SII was 48% on 2D CSI and 33% on 3D DIXON ( $p=.02$ ). Sensitivity for the diagnosis of adenoma was 89.7% (26/29; 95% CI 72.7-97.8%) for 2D and 75.9% (22/29; 95% CI 56.5-89.7%) for 3D DIXON. None of the 3 non-adenomas had SII  $> 16.5\%$  on either technique.

##### CONCLUSION

s 2D dual gradient-echo CSI has a higher sensitivity for detection of microscopic fat in adrenal nodules and the diagnosis of adrenal adenoma than the 3D DIXON technique. The sensitivity of 2D dual gradient-echo CSI for adrenal adenoma is approximately 90%.

##### CLINICAL RELEVANCE/APPLICATION

Adrenal MRI protocols should include 2D dual gradient-echo CSI and not rely solely on 3D DIXON techniques for the diagnosis of adrenal adenomas.

#### **W5A-SPGI-2 The Impact of Acceleration Factors of AI-assisted Compressed Sensing on the Image Quality of Balanced Turbo Field Echo Sequence for Renal Artery**

##### Participants

Haonan Zhang, Dalian, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To explore the accelerated renal artery imaging based on B-TFE using the AI-assisted Compressed Sensing (ACS) compared with a parallel imaging technique (SENSE), and to determine an optimal acceleration factor of ACS to achieved both of the reduction of scan time and a favorable image quality.

##### METHODS AND MATERIALS

This study has been approved by the local IRB. 10 healthy volunteers (3 males, 7 females, age  $48.10 \pm 15.52$  years) were recruited in this study. Renal artery MR imaging based on B-TFE sequence were performed in a 3.0 T MR scanner (uMR Omega, Shanghai United Imaging Healthcare Co., Ltd, Shanghai, China). Two kinds of acceleration technique were compared with SENSE 3 and ACS with four acceleration factors (3, 5, 7 and 9). Scan parameters are shown in table 1. After image reconstruction, the subjective independent scoring was performed according to vascular signal, diagnostic certainty and artifact. Five-point scoring criteria of image quality was used (Table 2), and the score more than 3 was considered to meet the clinical demand. The Kappa test was used to evaluate the consistency of the scores between the two radiologists. If the consistency is good, select the subjective scores of senior physicians for subsequent analysis. Then regions of interest were placed manually on the right blood vessels and the renal medulla to measure the signal intensity (Figure 1f). Meanwhile, signal to noise ratio (SNR) and contrast to noise ratio (CNR) were also calculated. One-way ANOVA was used to verify the differences in SNR, CNR and subjective scores under different AF condition

## RESULTS

Renal artery imagings based on B-TFE sequence with SENSE and ACS were shown in Figure 1a-1e. Score measured by two observers are in good agreement ( $p = 0.777$ ). SNR, CNR and subjective scores from five fast sequences were shown in Table 3. Compared with SNR, CNR and subjective scores from SENSE, there are no significantly different among those of ACS with acceleration factors 3, 5, 7 (Table. 4). The scan time of ACS7 is 158 second, which is about 27.85% of SENSE 3 (219 second).

## CONCLUSION

s Taken the scan time and image quality into consideration, ACS with acceleration factor of 7 is recommended for clinical renal artery imaging based on B-TFE sequence.

## CLINICAL RELEVANCE/APPLICATION

ACS factor of 7 is recommended for clinical renal artery imaging based on B-TFE sequence. Scanning time is significantly shortened, and the success rate is improved.

## W5A-SPGI-3 Evaluating the Impact of Different Acceleration Factors of AI-Assisted Compressed Sensing Technology in Liver Breath-Holding MRI Sequences

Participants

Nan Wang, Dalian, China (*Presenter*) Nothing to Disclose

## PURPOSE

The aim of this study was to investigate the effects of varying acceleration factors in Artificial Intelligence (AI)-assisted compressed sensing (ACS) technology applied to liver breath-holding MRI sequences.

## METHODS AND MATERIALS

Nine healthy volunteers participated in the study, undergoing liver MRI examinations (t1-quick3d-iso-fs, t1-quick3d-wfi-water) employing a recently developed ACS technology with different acceleration factors (Table 1, 2). The study utilized a 3.0T scanner (uMR Omega, Shanghai United Imaging Healthcare Co., Ltd., Shanghai, China). Two observers placed regions of interest (ROIs) on the left outer lobe, left inner lobe, right anterior lobe, right posterior lobe at the level of the first hepatic hilum, and the right vertical spinal muscle at the same phase direction and level (Figure 1). Signal intensity and standard deviation for each liver lobe and vertical spinal muscle were measured, followed by the calculation of image signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). Both observers assessed image quality for all groups using a 5-point subjective scale (5 representing excellent image quality, 1 representing poor image quality). Kolmogorov-Smirnov tests were used to evaluate the normality of the mean values obtained by both observers. For normally distributed data, one-way ANOVA and post-hoc LSD tests were employed, while non-normal data were analyzed using Kruskal-Wallis H tests. A  $p$ -value  $< 0.05$  was considered statistically significant.

## RESULTS

Variations in acceleration factors did not yield significant differences in SNR and CNR for t1-quick3d-iso-fs and t1-quick3d-wfi-water sequences ( $p > 0.05$ ). However, subjective scores differed significantly among images with varying acceleration factors for both sequences ( $p < 0.05$ ). Post-hoc multiple comparisons indicated that subjective image quality scores for t1-quick3d-iso-fs were significantly higher for uCS5, ACS5, and ACS6 compared to ACS8, ACS9, and ACS10 ( $p < 0.05$ ). Similarly, subjective image quality scores for t1-quick3d-wfi-water were higher for PI2.8 and ACS3 compared to ACS5, ACS7, and ACS9 ( $p < 0.05$ ).

## CONCLUSION

s The t1-quick3d-iso-fs sequence is recommended with a 6-fold acceleration factor for ACS, saving 2 seconds of scanning time. The t1-quick3d-wfi-water sequence is recommended with a 3-fold acceleration factor for ACS, resulting in better subjective image quality scores.

## CLINICAL RELEVANCE/APPLICATION

In liver breath-holding sequences, reducing the scanning time by a few seconds can significantly improve the scanning success rate.

## W5A-SPGI-4 Deep Learning Reconstruction Improves Image Quality of Acquired and Computed Diffusion-weighted MR Imaging of the Liver

Participants

Hirimitsu Onishi, MD, PhD, Suita, Japan (*Presenter*) Research Grant, General Electric Company; Speakers Bureau, General Electric Company

## PURPOSE

Image noise is the main problem in diffusion-weighted (DW) MR imaging. Deep learning reconstruction (DLR) can improve the image quality of MR imaging. The aim of this study was to determine whether DLR can improve the image quality of acquired and computed DW images of the liver.

## METHODS AND MATERIALS

This retrospective study included 44 consecutive patients with suspected focal liver lesions who underwent liver MR examinations with a 3.0-T system. DW images of the whole liver were acquired at b-values of 0 and 1000 s/mm<sup>2</sup> during breath-hold (TR/TE = 4500/76 msec, 5 mm thickness, and 96×96 matrix). Computed high b-value DW images (b = 1500 s/mm<sup>2</sup>) were synthesized from the acquired DW images. One radiologist measured the signal-to-noise ratio (SNR) of the liver parenchyma and the contrast-to-noise ratio (CNR) between malignant tumors and parenchyma on acquired and computed DW images with and without DLR. Another radiologist assessed image quality using a five-point visual scoring system (1 [unacceptable] to 5 [excellent]). Results were compared using paired t-test for quantitative assessment and Wilcoxon signed rank test for visual assessment of image quality.

## RESULTS

Both acquired and computed DW images with DLR had significantly higher SNRs and CNRs than DW images without DLR; mean SNR was 13.6 versus 9.4 for acquired images ( $P < .001$ ) and 8.1 versus 5.9 for computed images ( $P < .001$ ), and mean CNR was 56.6

versus 37.2 ( $P < .001$ ) and 33.7 versus 23.6 ( $P < .001$ ), respectively. Qualitative analyses showed that DLR significantly improved image noise and image sharpness ( $P < .001$  for each), but did not change motion artifacts and signal loss just below the heart. DW imaging with DLR also demonstrated superior overall image quality compared to DW imaging without DLR; median score was 4 versus 2 for acquired images ( $P < .001$ ), 3 versus 2 for computed images ( $P < .001$ ).

## CONCLUSION

s DLR efficiently reduced image noise and significantly improved the image quality of both acquired and computed DW MR images of the liver.

## CLINICAL RELEVANCE/APPLICATION

Deep learning reconstruction improves the image quality of liver diffusion-weighted images with a short acquisition time and can greatly contribute to the efficiency of liver MR examinations.

## W5A-SPGI-5 Radiologic Response and Association with Prognosis in Patients Treated with Transarterial Radioembolization or Stereotactic Body Radiation Therapy for HCC

Participants

Sangyun Lee, MS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

Transarterial radioembolization (TARE) and stereotactic body radiation therapy (SBRT) are locoregional therapies for potentially resectable and unresectable HCC. A limited number of studies have evaluated radiologic treatment response and association with prognosis in radiation-based therapy-treated HCC. We evaluated the radiologic appearance of post-TARE and SBRT-treated images of HCCs to assess treatment response and identify its association with prognosis.

## METHODS AND MATERIALS

We retrospectively identified 104 patients (77 males; mean age  $\pm$  SD, 65.9  $\pm$  12.6 years) treated with SBRT (68 patients, 83.4%) and TARE (36 patients, 34.6%) from 2015 to 2022. Pre- and post-treatment contrast-enhanced CT or MRI scans performed 3 months after treatment were evaluated for treatment response according to the following rules: no intralesional APHE as nonviable; stability or decrease in size and/or degree of intralesional APHE as non-progressing; new or increased size of intralesional APHE as viable disease. Pre- and post-treatment AFP levels, tumor and APHE component size, portal vein tumor thrombus, etiology of liver disease, overall survival (OS) and progression-free survival (PFS) were recorded. Cox proportional hazards model and Kaplan-Meier curves with log-rank test were used for statistical analysis.

## RESULTS

The mean size of HCC was 4.9 cm, and 25 patients (24%) had portal vein tumor thrombus. The mean AFP level was 2314.3 ng/mL. Median follow-up was 20.6 months (range, 3-142), with 29 (27.9%) deaths and 69 (66.3%) disease progressions. Sixty-three (60.6%) patients achieved non-viable disease at least once during follow-up. At the first 3-month follow-up, 40 (38.5%), 43 (41.3%), and 21 (20.2%) patients had nonviable, non-progressing, and viable disease, respectively. In univariate analysis, radiologic response at 3 months and nonviable disease ever during follow-up were significantly associated with OS, but only radiologic response at 3 months was the independent factor in multivariate analysis ( $p = 0.009$ ). For PFS, viable disease at the first 3-month follow-up, nonviable disease ever during follow-up, tumor size, male sex, and initial AFP level were the independent predictors in multivariate analysis ( $p = 0.034$ ). The type of radiotherapy did not affect OS or PFS. The 2-year cumulative OS for non-viable, non-progressing, and viable disease was 96.6%, 72.6%, and 67.9%, respectively.

## CONCLUSION

s Response to radiotherapy at 3 months and during follow-up assessed by changes in radiologic APHE significantly correlated with OS and PFS.

## CLINICAL RELEVANCE/APPLICATION

Persistent APHE 3 months after radiotherapy for HCC may indicate a poor prognosis.

## W5A-SPGI-6 Comparing Early Treatment Response as Assessed by RECIST 1.1, mRECIST, and Choi Criteria in HCC Treated with Atezolizumab plus Bevacizumab

Participants

Seung Hoon Choi, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

Atezolizumab plus bevacizumab (Ate/Beva) is endorsed as first-line systemic therapy for unresectable HCC ineligible for transplantation or locoregional therapy. Given the anti-angiogenic effect of the regimen, RECIST version 1.1 may underestimate the treatment response, potentially leading to unnecessary early discontinuation of the therapy. We aimed to compare RECIST 1.1, modified RECIST (mRECIST), and Choi criteria in assessing early treatment response in Ate/Beva-treated HCCs and their correlations with overall survival (OS) and progression-free survival (PFS).

## METHODS AND MATERIALS

From May 2022 to December 2022, 42 patients (36 men; mean  $\pm$  SD age, 61.9  $\pm$  12.9 years) who received Ate/Beva for unresectable HCC without prior systemic therapy were retrospectively included. Pre-treatment and the first post-treatment contrast-enhanced CT or MRI scans, performed after completion of at least three cycles of Ate/Beva, were reviewed by two abdominal radiologists to assess treatment response according to RECIST 1.1, mRECIST, and Choi criteria. OS and PFS were recorded. Kaplan-Meier curves with log-rank test and Cohen's kappa were used for the statistical analysis.

## RESULTS

The median time from the start of Ate/Beva to the first response assessment was 99 days (range, 51-182 days). Responders (patients with a complete or partial response) were 10 (23.8%), 13 (31.0%), and 18 (42.9%) when evaluated by RECIST 1.1, mRECIST, and Choi criteria, respectively. One (2.4%) and two (4.8%) patients classified as having progressive disease (PD) by RECIST 1.1 were re-assessed as stable disease and partial response by mRECIST and Choi criteria, respectively. The inter-reader

agreement ? for RECIST 1.1, mRECIST, and Choi criteria was 0.85, 0.75, and 0.85, respectively. Responders identified by RECIST 1.1 did not show a significant correlation with OS ( $p = 0.082$ ), while those identified by mRECIST and Choi were correlated with prolonged OS ( $ps = 0.049$ ). Responders identified by all three criteria showed a significant correlation with PFS ( $ps = 0.029$ ). Cumulative 1-year PFS rates for responders were 72%, 76.4%, and 78.4% for RECIST 1.1, mRECIST, and Choi, respectively, and 74.4%, 72.4%, and 66.7% for non-responders.

## CONCLUSION

s In Ate/Beva-treated HCC, only a small number of PDs identified by RECIST 1.1 were re-classified as non-PD by mRECIST and Choi, indicating similar performance in the assessment of treatment failure. mRECIST and Choi criteria identified more early responders to treatment than RECIST 1.1 and significantly correlated with prolonged OS and PFS.

## CLINICAL RELEVANCE/APPLICATION

mRECIST and Choi criteria may be more accurate than RECIST 1.1 in identifying early responders to Ate/Beva and may better assess prognosis.

## W5A-SPGI-7 Value of Liver Volumetry for the Evaluation of Treatment Response to Hepatic Artery Infusion Chemotherapy Compared with RECIST 1.1 Criteria in Uveal Melanoma Patients with Liver Metastases

### Participants

Sebastian Zensen, MD, Essen, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

In uveal melanoma patients with liver metastases, short-term evaluation of treatment response to hepatic artery infusion chemotherapy (HAIC) using the Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 criteria is often challenging due to the diffuse metastatic spread to the liver. Because of the diffuse organ involvement, liver enlargement can frequently be observed and easily assessed by liver volumetry. Therefore, this study aims to compare RECIST 1.1 and LV for the evaluation of HAIC treatment response.

## METHODS AND MATERIALS

Treatment response was evaluated in 143 patients by RECIST 1.1 and liver volumetry on CT imaging performed before and after first HAIC. The mean age was  $65.1 \pm 10.9$  years, 54% were female. To establish an appropriate threshold to differentiate between stable disease (SD) and progressive disease (PD) in liver volumetry, various increases in liver volume were assessed. Overall survival (OS) was calculated from first HAIC to patient death using Kaplan-Meier test. Multivariate analysis was performed for RECIST 1.1 and liver volumetry.

## RESULTS

The median OS (mOS) was 13.5 months (95% CI 11.2-15.8 months). In liver volumetry, a threshold of 10% increase in liver volume was suited to identify patients with significantly reduced OS (SD: 103/143 patients, mOS 15.9 months; PD: 40/143 patients, 6.6 months;  $p < 0.001$ ). Compared to RECIST 1.1, liver volumetry is the only significant prognostic factor that can identify a decreased OS.

## CONCLUSION

s In uveal melanoma patients with liver metastases, a threshold of 10% increase in liver volume is suitable to identify patients with a significantly shortened life expectancy by liver volumetry.

## CLINICAL RELEVANCE/APPLICATION

Liver volumetry is an appropriate method for evaluating treatment response in uveal melanoma patients with liver metastases and offers advantages over RECIST 1.1 criteria.

## W5A-SPGI-8 DW-MRI of the Abdomen for the Preoperative Detection of Liver Metastasis from Pancreatic Cancer to Prevent Futile Surgeries: A Meta-analysis

### Participants

Stephan Altmayer, PhD, Stanford, CA (*Presenter*) Nothing to Disclose

## PURPOSE

Recent studies have shown the superior diagnostic performance of diffusion-weighted magnetic resonance imaging (DW-MRI) for detecting liver metastasis. Despite the advantage of DW-MRI, the most recent 2022 National Comprehensive Cancer Network guidelines do not routinely recommend performing MRI on all patients who may have resectable disease. Our purpose was to perform a systematic review and meta-analysis to evaluate if diffusion-weighted magnetic resonance imaging (DW-MRI) adds value compared to contrast-enhanced computed tomography (CECT) alone in the preoperative evaluation of pancreatic cancer.

## METHODS AND MATERIALS

MEDLINE, EMBASE, and Cochrane databases were searched for relevant published studies through October 2022. Studies met eligibility criteria if they evaluated the per-patient diagnostic performance of DW-MRI in preoperative patients with pancreatic cancer compared to CECT. Our primary outcome was to determine the proportion of futile surgeries potentially prevented using DW-MRI, defined as those in which CECT was negative and DW-MRI was positive for liver metastasis. The secondary outcome was to determine the proportion of cases in which DW-MRI changes management, a composite outcome that includes false positive liver metastasis on CECT, indeterminate lesions on CECT, and the primary outcome. Per-patient sensitivity and specificity of DW-MRI were also calculated using a random-effects model.

## RESULTS

9 studies met the inclusion criteria with a total of 1121 patients, 172 of which had liver metastasis (15.3%). The average size of the hepatic lesions was smaller than 10 mm in all 6 studies that reported this data. The mean time between CT and MRI was reported for 7 out of 9 studies and was often fewer than 28 days. The proportion of futile surgeries potentially reduced by DW-MRI was 6.0% (95% CI, 3.0-11.6%), yielding a number necessary to treat of 16.6. The proportion of cases that DW-MRI changed management was 18.1% (95% CI, 9.9- 30.7), corresponding to an NNT of 5.5. The heterogeneity was high for both primary (of I2 =

86%) and secondary (I2 = 94%) outcomes. The per-patient sensitivity and specificity of DW-MRI was 92.4% (95% CI, 87.4-95.6%) and 97.3% (95% CI, 96.0- 98.1) with no heterogeneity.

#### **CONCLUSION**

s The potential NNT of DW-MRI to prevent potential futile surgeries in patients with pancreatic cancer and occult liver metastasis on CECT was 16.6.

#### **CLINICAL RELEVANCE/APPLICATION**

A significant number of subcentimeter liver metastases are not identified in the preoperative staging of pancreatic cancer with CECT. DW-MRI may add value in the evaluation of this patients with a potential NNT to prevent one futile pancreatic resection of CECT of 16.

### Genitourinary Imaging Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPGU- Quantitative PSMA PET and Multiparametric MRI features may help Predict Aggressive Prostate Cancer on Whole-Mount Histopathology** 1

##### Participants

Ida Sonni, MD, Los Angeles, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

Two aggressive histopathological subtypes of prostate cancer (PC) include intraductal carcinoma (IDC) and the large cribriform growth pattern. The goal of this analysis was to assess which quantitative features of preoperative 68Ga-PSMA-11 PET/CT (PSMA PET) and multiparametric magnetic resonance imaging (mpMRI) correlate and predict cribriform/IDC patterns on post robotic prostatectomy (RALP) whole mount histopathology (WMHP).

##### METHODS AND MATERIALS

With IRB approval and HIPAA compliance, we derived a study cohort of PC patients who underwent PSMA PET <3 months prior to RALP and WMHP with description of the presence/absence of cribriform/IDC pattern between 05/2019 and 08/2022. A nuclear medicine physician contoured all PC lesions on PSMA PET, after matching them with a GU pathologist on WMHP. PSMA PET metrics (SUV<sub>max</sub>, SUV<sub>mean</sub>, tumor volume, total lesion activity - TLA) were extracted. A sub-analysis was conducted on patients with available quantitative measures on pre-surgical mpMRI. All PIRADS=3 lesions on mpMRI were contoured and quantitative parameters were extracted: mean apparent diffusion coefficient (ADC,  $\times 10^{-6} \text{mm}^2/\text{s}$ ), K<sub>trans</sub> (min<sup>-1</sup>), K<sub>ep</sub>(min<sup>-1</sup>), iAUC (mMsec). All matching lesions were categorized as sub-cohort 1 (SC 1) cribriform+/IDC-, (SC 2) cribriform+/IDC+, and (SC 3) cribriform-/IDC-. One way-ANOVA assessed significant differences among the imaging parameters in the three sub-cohorts. The area under the curve (AUC) from ROC analysis was used to assess the ability of imaging metrics to predict the presence of aggressive PC features on WMHP.

##### RESULTS

The PSMA PET analysis comprised 77 patients (82 lesions) with mean PSA at time of RALP of 9.07 ng/ml  $\pm$  5.8. On WMHP, SC 1, 2 and 3 comprised 21/83, 41/83, and 20/83 lesions with significant differences in SUV<sub>mean</sub> and TLA among these sub-cohorts ( $p=0.003$  and  $0.039$ ). On AUC analysis, SUV<sub>mean</sub> predicted the aggressive PC features on WMHP with 67% accuracy. The PSMA PET/mpMRI cohort comprised 52 patients (53 lesions) with mean PSA at time of RALP of 9.67 ng/ml  $\pm$  6.76. On WMHP, SC 1, 2 and 3 comprised 17/53, 25/53, and 10/53 lesions with significant differences in SUV<sub>mean</sub> on PSMA PET and ADC on mpMRI among the three sub-cohorts ( $p=0.031$  and  $0.018$ ). On AUC analysis, SUV<sub>mean</sub> and ADC predicted aggressive PC on WMHP with 65% and 63% accuracy, respectively

##### CONCLUSION

Significantly elevated SUV<sub>mean</sub> on PSMA PET and lower ADC on mpMRI predicted the presence of aggressive PC features (cribriform pattern and IDC) on WMHP with moderate AUC on ROC analysis.

##### CLINICAL RELEVANCE/APPLICATION

The ability to predict the presence of pathology features of aggressive PC is critical in case WMHP is not available. Presurgical PSMA PET and mpMRI quantitative parameters can help identify these features with moderate accuracy.

#### **W5A-SPGU- Diagnostic Value of Very Early Diffusion Weighted Changes at MRI after Single-Dose Ablative Radiation Therapy (SDART) for Organ-confined Prostate Cancer** 2

##### Participants

Cammillo Talei Franzesi, Milan, Italy (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate diagnostic value of diffusion-weighted (DWI) MRI early changes, 1 hour after treatment, in patients with organ confined unfavorable prostate cancer (PCa) treated with Single-Dose Ablative Radiation Therapy (SDART), in comparison with biochemical markers (PSA and testosterone).

##### METHODS AND MATERIALS

Twenty four patients treated with a single fraction of 24 Gy to the whole prostate with urethra sparing in association with androgen deprivation therapy (ADT) were prospectively enrolled. MRI was performed before SDART (time 0), one-hour post-SDART (time 1), and 3-month after treatment (time 2). All patients were examined on a 3.0-T MRI scanner (Ingenia; Philips Healthcare) with a phased-array external coil, with bowel preparations and 20mg of butyl-scopolamine (Buscopan) intravenously administered; the bladder was filled with 120cc of saline solution, to simulate the same conditions during irradiation. MRI was performed with axial T1-weighted TSE sequences and high resolution multi-planar T2-weighted TSE sequences. Diffusion weighted imaging (DWI) was acquired with six b-values (0,50,100,150,800,1600mm<sup>2</sup>/s) and Apparent Diffusion Coefficient (ADC) (0,800) maps were calculated.

Finally, axial contrast-enhanced dynamic imaging was obtained during intravenous injection of gadobutrol (0.1 mmol/kg, flow rate of 2.5 ml/s). ADC values were calculated at time 0,1, and 2 by placing region-of-interests (ROI) on ADC maps and the results were compared with PSA and testosterone blood levels at time 0 and 2.

## **RESULTS**

Median patient's age was 78 years (range 61-84). Median prostate volume was 36.2 cc (range 10-60). An increase of ADC value of tumor lesion of 27% (range 7%-69%) and 54% (range 20%-83%) was registered at time 1 and time 2 respectively, compared to the baseline. Median prostate volume was found unchanged at time 1, while decreased by about 25% (range 9%-59%) at time 2. At 3-months follow-up, all patients were found bNED with PSA and testosterone levels of <0.01 ng/ml and <0.20 ng/ml, respectively, and 9 of them obtained a complete response.

## **CONCLUSION**

s Our findings demonstrated high diagnostic value of DWI imaging with good correlation between very early changes (one-hour after treatment) in ADC values after SDART and later tumor response (biochemical and imaging) in patients with unfavorable PCa.

## **CLINICAL RELEVANCE/APPLICATION**

DWI with ADC values could be used as an early biomarker of treatment outcome in patients treated with SDART of the whole prostate with urethra sparing.

W5A-SPHN

### Head & Neck Imaging Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPHN- Operating Characteristics of ATA 2015 Thyroid Nodule Risk Malignancy in Colombian Population** 1

##### Participants

Nicole Erazo Morera, MD, Bogota, Colombia (*Presenter*) Nothing to Disclose

##### PURPOSE

Determine the operating characteristics of the ATA 2015 ultrasound risk classification of thyroid nodules in Colombian population, to see if it can be standardized and applied as it is in American population.

##### METHODS AND MATERIALS

We conducted a retrospective quantitative diagnosing test study, where the operating characteristics for the ATA 2015 risk stratification scale was determined. The study was carried out between Sept 2020- Sept 2021. Population: Patients with thyroid nodules with thyroid US in the imaging department of the HUSI (a fourth level institution in Bogotá, Colombia) with an indication for biopsy or surgical removal of the nodule according to ATA 2015. Data collection was carried out by two radiologists from the Radiology Department of the HUSI, one of them with 6 yrs of experience and one of them in training with 3 yrs of experience. Patients with very low and low suspicion nodules according to the 2015 ATA classification were defined as negative whereas intermediate and high suspicion of malignancy were defined as positive. These results were compared with a mixed gold standard, where true negatives are Bethesda II or surgical specimen with benign pathological report, and true positives are Bethesda V/VI or surgical piece positive for malignancy.

##### RESULTS

For a "high" risk in the ATA classification, the Likelihood Ratio values for both cases yield results close to 4, being slightly higher when risk III of the BETHESDA classification is excluded. For the "intermediate" classification, the two combinations have a Likelihood Ratio close to 1, indicating an indeterminate result for those that cannot be classified as malignant and benign. For the "low" and "very low" classification, the LR is below 1, when risk III of the BETHESDA classification is excluded and taken into account.

##### CONCLUSION

The present study demonstrates that the ATA 2015 sonographic risk stratification scale can be used and implemented in the Colombian population in a similar way to the American population. It is especially applicable if the thyroid nodule evaluated by ultrasonography presents characteristics of "low" or "high" risk of malignancy with a confidence of 95% for an established risk of 5-10% or 70-90% respectively. The category with the lowest sensitivity and specificity is the "intermediate" which is not statistically significant in any of the analyses.

##### CLINICAL RELEVANCE/APPLICATION

Validation, of an already used risk stratification scale, in the Colombian population, understanding in which cases there must be a careful appliance (specifically intermediate risk nodule) in this population base.

#### **W5A-SPHN- Utility of Radiomics Features in Predicting Human Papillomavirus Status in Head and Neck Squamous Cell Carcinoma: A Systemic Review and Meta-analysis** 2

##### Participants

Golnoosh Ansari, MD, Baltimore, MD (*Presenter*) Nothing to Disclose

##### PURPOSE

Human papilloma virus (HPV) is one of the main risk factors and a potential prognostic indicator for head and neck squamous cell carcinoma (HNSCC). We sought to analyze the value of radiomics features in the determination of HPV status in HNSCC as an alternative to immunohistochemical typing.

##### METHODS AND MATERIALS

A systemic search was conducted on PubMed, Scopus and other major web-based repositories using the search terms HPV, Radiomics, HNSCC, head and neck, papilloma and oropharyngeal SCC. Diagnostic accuracy measures, and the confusion matrix of each study were extracted and the data were utilized to perform meta-analysis based on the random effects model. Fagan's nomogram was used to determine clinical utility. Deek's funnel plot was used to determine publication bias.

##### RESULTS

Twenty six articles were included in the systemic review and 14 were used for the meta-analysis. The median radiomics quality score was 9 out of 36, showing an overall poor quality in the currently available literature. There was no significant publication bias among the publications included in the meta-analysis. The overall sensitivity of the included studies equaled 0.772 (0.73, 0.809)

and the overall specificity equaled 0.763 (0.714, 0.806). The I2 statistic showed that heterogeneities for sensitivity and specificity were medium (I2 = 56.91%, and 55.44%, respectively). Only one percent of the heterogeneity witnessed was due to threshold effect.. Diagnostic odds ratio equaled (DOR) 10.932 (7.847, 15.23). Using a radiomics model generated on cross-sectional imaging would increase the post-test probability to 82% from 58% with a positive likelihood ratio of 3 when the pretest was positive. When the pretest was negative the post-test probability decreased to 29% with a negative likelihood ratio of 0.3.

## CONCLUSION

s Radiomics features showed moderate success in the determination of HPV status in HNSCCC and could be employed when conventional para-clinical laboratory methods are not available. More studies, especially those trained and tested on multiple independent datasets, are needed to determine the clinical utility of radiomics trained machine learning models in this regard.

## CLINICAL RELEVANCE/APPLICATION

As currently there are no FDA-approved diagnostic modalities for the determination of HPV status in HNSCC, radiomics features may be able to act as a means of "virtual biopsy" and alleviate the need for IHC staining.

### W5A-SPHN- Baseline Amide Proton Transfer MRI in Predicting Tumor (T) Classification for Nasopharyngeal Carcinoma based on TNM Staging System

Participants  
Qian Lijuan, Wuhan, China (*Presenter*) Nothing to Disclose

## PURPOSE

Nasopharyngeal Carcinoma (NPC) is classified into high and low stages with different prognoses and treatments. Conventional nasopharyngeal MRI is used to identify the diagnosis and staging of nasopharyngeal carcinoma such as adjacent soft-tissue invasion and skull base invasion. However, it is influenced by some subjective factors and experience levels. Thus, We aimed to investigate the potential value of APTw imaging in predicting the stage of NPC and to determine the associations between APTw MRI parameters and nasopharyngeal carcinoma (NPC) stages, compared with diffusion-weighted imaging (DWI).

## METHODS AND MATERIALS

In this single-center prospective study, participants with pathologic analysis-confirmed nasopharyngeal carcinoma with no previous treatment, lesions larger than 1 cm, and adequate MRI quality were enrolled from June 2022 to February 2023. All participants underwent preoperative APTw MRI and DWI. ROI delineation was then reviewed and approved by a two senior radiologist. The average APT (APTmean) and 90th percentile (APT90), 10th percentile (APT10), Kurtosis, Skewness, and ADC value were obtained. The unpaired student's t-test was used to evaluate the between-group difference of the derived parameters. The multivariate logistic regression and receiver operating characteristic curve (ROC) were employed to evaluate the diagnostic performance of these quantitative parameters.

## RESULTS

All patients were staged according to the eighth edition of the AJCC/UICC TNM staging system. 76 participants (mean age, 49 years±19[SD]; 61 men,15 female) were evaluated: 56 with high-stage and 20 with low-stage nasopharyngeal carcinoma. T3 and T4 NPC were classified as high-stage, and T2 and T1 NPC were classified as low-stage. High-stage NPC showed a significantly higher APTmean than low-stage NPC (3.76 vs 2.83 p =0.01). APT90 and Skewness, Kurtosis can significantly differ among high and low-stage (5.37 vs 4.37, p=0.04; 0.23 vs -0.02, p=0.04; 3.24 vs 2.69, p=0.006). The area under the receiver operating characteristic curve (AUC) of APTw for differentiating low- and high NPC was 0.789 (0.656-0.922). Our measurements showed good interreader agreement: ICC 0.944 (0.938 < ICC < 0.95). ADC value of the high-stage NPC showed no significant difference with the low-stage (0.70 vs 0.75, p=0.11).

## CONCLUSION

s This study demonstrated APTw MRI may be used as an imaging biomarker for improving the accuracy in the assessment of nasopharyngeal carcinoma AJCC stage.

## CLINICAL RELEVANCE/APPLICATION

The molecular imaging technique, APT MRI is a promising noninvasive method for evaluating and staging NPC and can provide additional information to improve the diagnostic accuracy of conventional nasopharyngeal MRI.

### W5A-SPHN- Comparative Study on Diagnostic Accuracy of MRI and Intra Oral Ultrasound in Assessing Depth of Invasion (DOI) of Tongue Carcinoma with Histopathological Examination as Gold Standard

## PURPOSE

To compare the diagnostic accuracy of magnetic resonance imaging and intra oral ultrasound in detecting the depth of invasion in tongue carcinoma patients and correlating it with histopathological examination as gold standard. To assess the nodal status with preoperative imaging based on established sonographic features of malignancy and to establish DOI cut-off for node positivity status To nitpick the confounder responsible for changes in DOI values

## METHODS AND MATERIALS

COMPARATIVE CROSS SECTIONAL STUDY FROM 2021 TO 2023

## RESULTS

Our study results are in concordance with Yoon et al which was the first pilot study post 8th edition in which a very high correlation coefficient of 0.95 was achieved between USG and HPE. Meta-analysis by Marchi et al in 2020 showed pooled correlation coefficient of 0.96 for USG and 0.87 for MRI. They concluded that USG stands tall with higher pooled r and r to z transformed values.

## CONCLUSION

s Biopsy prior to imaging - significant confounding factor resulting in higher values on preoperative imaging than the actual depth of invasion Both intra oral USG and MRI are effective tools for preoperative assessment of depth of invasion in oral tongue

malignancies and strong correlation was achieved with histological values.

#### CLINICAL RELEVANCE/APPLICATION

Intra oral USG > MRI owing to the perilesional edema found on T2 weighted MRI images.

### W5A-SPHN- The Value of Texture Features based on Dynamic Contrast-enhanced Magnetic Resonance Imaging in Predicting the Efficacy of Radiotherapy and Chemotherapy in Nasopharyngeal Carcinoma

#### PURPOSE

the purpose of this study was to explore the value of texture features based on DCE-MRI in predicting the efficacy of radiotherapy and chemotherapy in primary NPC.

#### METHODS AND MATERIALS

1. Subjects Forty-nine patients with NPC who underwent nasopharyngeal/cervical DCE-MRI examination and confirmed by pathology were analyzed retrospectively. According to the follow-up of MR and/or pathology after 6 months of treatment, the efficacy of radiotherapy and chemotherapy of NPC was divided into two groups: poor prognosis group (residue or recurrence) (n=22) and good prognosis group (no residue and recurrence) (n=27). 2. Image analysis A 3.0T MR (Signa HDxt, GE Medical Systems, Milwaukee, WI, USA) scanner was used with an 8-channel phased array coil in the head and neck. The permeability parameters of the DCE-MRI images: Ktrans, Kep, and Ve functional maps were imported into 3D Slicer software. Two imaging diagnostic physicians manually sketched the ROI. (Fig. 1, 2). Record the texture feature parameters of each functional map respectively.

#### RESULTS

1. DCE- measured by two observers. The texture feature parameters of the MRI function map are consistent (ICC values are all >0.75) (Table 1). 2. the Minimum Ktrans signal intensity and JointAverageKep of the good prognosis group were higher than those of the poor prognosis group, while the values of AutocorrelationKtrans, JointAverageKtrans, SumAverageKtrans, AutocorrelationKep, and SumAverageKep were lower than those of the poor prognosis group, and the difference was statistically significant (Table 2). However, there is no difference in the texture parameters of the Ve signal intensity map. 3. ROC analysis of Ktrans and Kep signal intensity map texture parameters to identify NPC efficacy (Table 3). The area under the curve predicted by the threshold of Autocorrelation, JointAverage, and SumAverage of Kep signal strength was the largest, which was 0.684, the sensitivity was 81.48%, and the specificity was 59.09% (figure 3).

#### CONCLUSION

The texture feature based on DCE-MRI has potential value in predicting the efficacy of radiotherapy and chemotherapy in nasopharyngeal carcinoma before treatment.

#### CLINICAL RELEVANCE/APPLICATION

nasopharyngeal carcinoma is a tumor with significant geographical distribution and is a common malignant tumor of the head and neck in southern China. Radiotherapy and chemotherapy are considered the first choice of treatment, but there are still patients with poor prognoses (residue or recurrence) due to treatment failure. Early prediction of the efficacy of radiotherapy and chemotherapy can optimize the treatment plan of NPC patients and improve the survival cycle, which has significant clinical significance.

### W5A-SPHN- Multi-parameter Quantitative Magnetic Resonance in Early Assessment of Radiation Induced Parotid Damage in Nasopharyngeal Carcinoma Patients after Intensity Modulated Radiotherapy

#### Participants

Zhifeng Xu, Foshan, China (Presenter) Nothing to Disclose

#### PURPOSE

The aim of this study was to investigate the value of Intravoxel Incoherent Motion Imaging (IVIM) and 3D Pulsed Continuous Arterial Spin Labeling (ASL) in assessing dynamic changes of parotid gland (PG) in nasopharyngeal carcinoma (NPC) patients after radiotherapy (RT).

#### METHODS AND MATERIALS

A total of 18 patients with NPC underwent Intensity-Modulated Radiotherapy (IMRT) were enrolled. All patients underwent conventional MRI, and IVIM and ASL imaging for bilateral PGs within 2 weeks before RT (pre-RT), 1 week and 3 months after RT (post-RT). Pure diffusion coefficient (D), pseudo-diffusion coefficient (D\*), perfusion fraction (F) and blood flow (BF) were analyzed.

#### RESULTS

From pre-RT to 1W post-RT, D and CBF values both increased significantly [change rate, 39.28% (38.23%) and 60.84% (54.88%)], and continued to increase significantly from 1W post-RT to 3M post-RT [change rate, 55.44% (40.56%) and 120.39% (128.74%)]. From pre-RT to 1W post-RT, F value increased significantly [change rate, 28.13% (44.66%)], and then decreased significantly from 1W post-RT to 3M post-RT, whereas no significant differences were found between pre-RT to 3M post-RT. From pre-RT to 1w post-RT and 1M post-RT, D\* value decreased significantly [change rate, -41.86% (51.71%) and -29.11% (42.67%)]. No significant difference was found between different post-RT time intervals. There was a significant positive correlation between percentage change in  $\Delta$ CBF1W and radiation dose (R=0.548, p=0.001).

#### CONCLUSION

Both IVIM-DWI and ASL can help to detect/predict radiation-induced parotid damage in early stage after RT. They may contribute to clarify the correlations between damage of PGs and patient-/treatment-related variables by assessing individual microcapillary perfusion and tissue diffusivity.

#### CLINICAL RELEVANCE/APPLICATION

To reveal the mechanism of parotid radiation injury, realize early non-invasive diagnosis, and allow patients to obtain timely treatment to improve the quality of life of patients

## **PURPOSE**

Image-defined sarcopenia is linked to increased mortality among patients with cancer. Nevertheless, its effect on patients with nasopharyngeal carcinoma (NPC) is incompletely established. This study's aim was to investigate the prognostic significance of MRI-defined sarcopenia at the level of the third cervical vertebra (C3) on the survival of patients undergoing concurrent chemoradiotherapy (CCRT) ± inducing chemotherapy (IC) for NPC treatment

## **METHODS AND MATERIALS**

1,307 patients from two tertiary centers who had stage II-IVa NPC diagnosis between July 1, 2010, and September 30, 2019, were included in this retrospective study. Sarcopenia was defined using skeletal muscle index (SMI) determined through baseline MRI at the C3 level. The association of sarcopenia with overall survival (OS) and progression-free survival (PFS) was assessed by computing the Hazard ratios (HRs). Using 1:1 propensity score matching (PSM) analysis, Cox regression models were adjusted for age, body mass index (BMI), sex, and treatment. The PSM analysis revealed 331 pairs. We also conducted a stratification analysis using BMI and treatment strategies.

## **RESULTS**

The patients' median (range) age was 48 (18-80) years, with 821 patients (62.8%) presenting with sarcopenia. Before and after PSM, sarcopenia was an independent risk factor for both OS and PFS (all  $P < 0.05$ ). However, BMI was not substantially linked to tumor progression and overall mortality (all  $P > 0.05$ ). Sarcopenic patients showed lower rates of OS (HR = 2.00, 95% CI: 1.54-2.60,  $P < 0.001$ ) and PFS (HR = 1.67, 95% CI: 1.35-2.07,  $P < 0.001$ ) in contrast with nonsarcopenic patients. Similar findings were obtained after PSM. According to stratification analysis, being overweight was linked to a protective effect in nonsarcopenic patients only. In addition, sarcopenic patients showed similar OS and PFS regardless of the treatment modality.

## **CONCLUSION**

Sarcopenia is underrecognized in NPC patients. Measurement of sarcopenia using routine MRI scans in NPC patients provided significant prognostic information, outperforming BMI. Patients with sarcopenia failed to benefit from an additional IC regimen.

## **CLINICAL RELEVANCE/APPLICATION**

Sarcopenia could be used as a marker for predicting NPC patients' prognoses before treatment utilizing MRI images.

W5A-SPIN

### Imaging Informatics Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPIN-1 Automated Quantification of Uncertainty for Emphysema Evaluation from CT Images using Hybrid Bayesian Deep Learning**

##### Participants

Antonio Porras Perez, PhD, (*Presenter*) Nothing to Disclose

##### PURPOSE

Emphysema quantification from computed tomography (CT) images is important to evaluate chronic obstructive pulmonary disease (COPD). Although volume-adjusted lung density (ALD) can be used for prognosis, it has shown sensitivity to variations between scanners and there are no metrics of its reliability. We present a hybrid Bayesian deep learning model to predict lung density from CT images that can quantify both the aleatoric and the epistemic uncertainty, which are associated with the imaging protocol and the prediction, respectively. These measures of reliability can be used during clinical evaluation.

##### METHODS AND MATERIALS

Inspiratory lung CTs from 1,936 COPD Gene participants (age 59.36±9.00 years; 1,038 female) were used. The data were randomly split into training (80%), validation (10%) and test images (10%). We trained a model to predict lung density at the 15th percentile of the CT histogram (Perc15) and quantify ALD. Our model consisted of convolutional blocks that quantify CT image features followed by fully connected layers. The final layer was Bayesian and weights were trained as probabilistic distributions instead of point estimates. ALD was calculated as the product of predicted Perc15 and the ratio of observed versus expected lung volume. Aleatoric and epistemic uncertainty were estimated over 50 stochastic forward passes in the test set. Deep learning ALD (DL-ALD) was compared to conventional ALD, and Cox proportional hazards models were used to determine the association between uncertainty and mortality.

##### RESULTS

The average root mean squared error for DL-ALD was 4.70 (95% CI: 4.68, 4.73). The mean aleatoric uncertainty was 23.77 (95% CI: 13.04, 34.51). The mean epistemic uncertainty was 1.22 (95% CI: 0.73, 1.71). DL-ALD was significantly associated with mortality ( $p < 0.001$ ) when adjusting for age, body mass index, smoking status, gender, and race. Adjusting for DL-ALD and demographics, epistemic uncertainty had a significant positive association with mortality ( $p = 0.013$ ) but aleatoric uncertainty did not ( $p = 0.134$ ).

##### CONCLUSION

DL-ALD performs as well as conventional ALD in predicting survival but it provides measures of uncertainty. This represents a substantial improvement over conventional methods that cannot estimate uncertainty. Aleatoric uncertainty associated with imaging protocol was higher than uncertainty from the model. Additionally, higher model uncertainty was associated with increased mortality risk, suggesting a need for reliability metrics to improve survival prediction through ALD.

##### CLINICAL RELEVANCE/APPLICATION

Uncertainty estimation when evaluating emphysema through hybrid Bayesian deep learning improves reliability of lung density measures over conventional image intensity-based analysis.

#### **W5A-SPIN-2 Deep Learning Model for Acute Respiratory Distress Syndrome (ARDS) Detection in the Pediatric Intensive Care Unit (PICU) Setting**

##### Participants

Vahid Khalkhali, MSc, Philadelphia, PA (*Presenter*) Nothing to Disclose

##### PURPOSE

Acute respiratory distress syndrome (ARDS) is a significant cause of morbidity and mortality in the pediatric intensive care unit (PICU). ARDS diagnosis involves chest x-ray criteria combined with clinical and laboratory parameters. Machine learning models have demonstrated utility in the detection of ARDS on chest radiographs.

##### METHODS AND MATERIALS

In this retrospective, IRB-approved study, we identified 368 children admitted to the PICU with a diagnosis of ARDS, at a large pediatric academic center from 2014 to 2019. A single randomly selected radiograph from all patients admitted to the PICU without a diagnosis of ARDS during 2018 was used to establish the control cohort, ( $n = 1127$ ). The train:validation:test ratio was 60/20/20. Using transfer learning, we utilized a pretrained convolutional neural network (CNN) structure to determine the diagnosis of ARDS (PyTorch, version 1.2). The criterion was to minimize weighted cross-entropy loss. Area under the receiver operating characteristics (AUROC) was the main performance metric. Two pediatric radiologists independently assigned labels of ARDS to the training-set, and interrater reliability was calculated. Correlations between radiologists and the models were calculated using

Pearson correlation and Cohen's Kappa. All statistical analysis used Type-I error of 5% and power of 80%.

## RESULTS

The interrater reliability between the radiologists was 94.5% (Cohen's Kappa of 85.8%) for the training cohort. The ARDS diagnostic performance of two radiologists yielded an AUROC (balanced accuracy) of 72.5%, while the DenseNet161 model achieved 86.0% (AUROC of 92.5%) and ensemble of models reach to 83.7% (AUROC of 93.5%). Radiologist diagnoses were only 81% correlated (Cohen's Kappa 51.6%) with the DenseNet161 model and 83% (Cohen's Kappa 60.5%) with ensemble of models. While Pearson correlation between two radiologists were high (> 90%) on the test set, the difference between the detection of different models were statistically significant ( $p < 0.01$ ).

## CONCLUSION

Using transfer learning, we trained a CNN to reliably detect ARDS in the PICU and compared its performance with the diagnostic rates of two experienced radiologists. Machine learning can automatically detect ARDS on chest radiographs, with a performance which parallels those of radiologists.

## CLINICAL RELEVANCE/APPLICATION

Deep learning detection of ARDS could improve the triage of patients in the intensive care unit before the availability of dedicated pediatric radiologist reads.

## W5A-SPIN-3 Predicting the Occurrence of Immune Checkpoint Inhibitor-related Pneumonitis on Non-small Cell Lung Cancer Patients via Deep Learning

Participants

Janardhana Ponnathapura, MD, Winston Salem, NC (*Presenter*) Nothing to Disclose

## PURPOSE

Immune-checkpoint inhibition (ICI) has conveyed a paradigm shift in advanced lung cancer treatment in recent years. However, ICI therapy related pneumonitis, which is an immune related adverse event (irAE), can limit delivery of treatment to some patients. With overall incidence of nearly 6%, it is considered one of the more common irAEs resulting in a significant burden of morbidity and mortality in the lung cancer population. Predicting ICI-pneumonitis is crucial for identifying at-risk patients and adjusting their treatment to prevent the occurrence of ICI-pneumonitis. We in this study try to predict ICI-pneumonitis based on patients' imaging and clinical data.

## METHODS AND MATERIALS

We collected data from 1,254 lung cancer patients who received immunotherapy between 2015 and 2021. In the dataset, 53 patients developed ICI-pneumonitis and were included in this study. Another 41 patients who received immunotherapy without developing ICI-pneumonitis were randomly selected and used as a control group. We proposed a deep learning framework to predict ICI-pneumonitis based on deep learning features and radiomics features. A vision transformer was first pre-trained on over 25,000 CT scans from the NLST dataset and then used to extract deep learning features. Radiomics features were extracted using the Python pyradiomics package after lung segmentation. After feature selection, 17 deep features and 20 radiomic features were used for prediction. A network with three fully connected layers was trained for ICI-pneumonitis prediction using five-fold cross-validation.

## RESULTS

Using only deep learning features, we achieved an AUC of 0.934 (95%CI: [0.883, 0.986]). Similarly, with only radiomics features, the prediction AUC was 0.928 (95%CI: [0.873, 0.982]). When combining deep features with radiomics features, the prediction accuracy further improved to an AUC of 0.958 (95%CI: [0.917, 0.999]).

## CONCLUSION

Our proposed method can predict the occurrence of ICI-pneumonitis with high accuracy, indicating the potential for using deep learning to predict ICI-pneumonitis in advanced lung cancer patients receiving immunotherapy. This approach could be valuable for treatment planning in the future.

## CLINICAL RELEVANCE/APPLICATION

Prediction of ICI pneumonitis will have an important positive impact as early detection and timely recognition are critical to initiate prompt treatment and prevent further morbidity and mortality for these oncology patients.

## W5A-SPIN-4 SAMConvex: Fast Discrete Optimization for Deformable CT Registration using Multi-scale Self-supervised Anatomical Embedding and Correlation Volume

Participants

Zi Li, Hangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

Deformable image registration is a fundamental medical image analysis task. Estimating displacement vector field via a cost volume computed in the feature space suffers excessive computation burdens. Moreover, existing feature descriptors only extract local features incapable of representing the global semantic information that is important for handling large transformations. To address these issues, we propose SAMConvex, a fast coarse-to-fine discrete optimization method for CT image registration. It includes a decoupled convex optimization procedure to obtain deformation fields based on a self-supervised anatomical embedding (SAM) feature extractor that captures both local and global information.

## METHODS AND MATERIALS

Our proposed model, named SAMConvex, consists of two major components: (1) A discriminative feature extractor based on a SAM that encodes global and local embeddings for each voxel. The global embeddings memorize the 3D contextual information of body parts on a coarse resolution level, while the local embeddings differentiate adjacent structures with similar appearances. (2) A lightweight correlation pyramid that constructs multi-scale 6D cost volume by taking the inner product of SAM embeddings. With coarse-to-fine strategy, we estimate a sequence of deformation fields. The final field is computed via the composition of all the

deformation fields. We conduct the registration in 3 levels of resolutions. The registration performance is extensively evaluated in two inter-patient registration datasets, i.e., Abdomen CT (20 patients for train and 10 for test), and HeadNeck CT (62/10 patients for train/test) and intra-patient Lung CT (35 patients, each with inspiratory and expiratory breath-hold CT pairs). The average Dice score computed for the labeled organs is used to evaluate the accuracy.

## RESULTS

SAMConvex outperforms state-of-the-art registration methods, such as LapIRN, and Deeds, over all three datasets with an average 2.4% Dice score improvement as compared to the second-best performing method (Deeds). E.g., SAMConvex is consistently better than the second-best (Deeds) and third-best (LapIRN) registration methods on most examined abdominal organs, in 11 out of 13 organs. Moreover, as an optimization-based method, SAMConvex only takes ~2s for one paired scans, as compared to ~100s required by Deeds.

## CONCLUSION

The proposed deep registration model (SAMConvex) demonstrates state-of-the-art accuracy, good generalization, and high computation efficiency over previous leading models.

## CLINICAL RELEVANCE/APPLICATION

The proposed algorithm can accurately register the CT scans. The method can be applied in various downstream tasks such as longitudinal lesion quantification and image-guided radiotherapy.

## W5A-SPIN-5 Effective Opportunistic Screening for Colorectal Cancer using Abdominal or Chest Noncontrast CTs

Participants

Mingyan Qiu, PhD, Hangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

We designed an AI model for detecting colorectal cancer (CRC) using noncontrast chest or abdominal CT scans, which offers the advantage of opportunistic screening a broad asymptomatic population.

## METHODS AND MATERIALS

The training data consisted of 1,561 3D noncontrast abdominal CTs from a single hospital, including 566 cases with pathology-confirmed CRC and 995 cases without CRC. The initial CRC masks in the training set were manually annotated on the venous phase CT by an experienced radiologist (10-yr), referring to reports as needed. We then employed a robust image registration method to register the annotated mask from venous to noncontrast CT for model training. Our AI model is a UNet for segmentation of CRC and colorectum, which is further enhanced by a classification branch and is trained end-to-end to classify the patient as CRC or normal. To improve the differentiation of CRC tumor from colorectal content and normal tissues, we designed a content augmentation method and a contrastive loss. The model performance was evaluated on an internal hold-out test cohort comprising 147 patients with CRC and 153 normal cases, and external test cohorts comprising 181 abdominal CTs with CRC, one chest CT with CRC, and 2,477 normal chest CTs from three centers. One radiologist specialized in CRC imaging (20-yr) is invited for the reader study on the hold-out test cohort.

## RESULTS

On the internal test cohort, the model had an area under the curve of 0.978, sensitivity of 91.2%, and specificity of 97.4%; while the radiologist's sensitivity was 79.6% and specificity was 97.4%. Moreover, the model outperformed the radiologist in detecting early-stage CRC (T1 33.3% vs. 16.7%, T2 75.0% vs. 50.0%). On the external test cohorts, the model's sensitivity was 80.7% and 100% for abdominal CTs and chest CT, respectively; and the specificity was 99.6% for normal chest CT. Additionally, a preliminary comparison shows that our approach has comparable performance and may even outperform the established CRC screening tests in both sensitivity and specificity, such as CT colonography (Sens 90%, Spec 86%) and FIT (Sens 74%, Spec 95%).

## CONCLUSION

The proposed model could detect colorectal cancer tumors on chest and abdominal noncontrast CT scans with a high sensitivity and specificity, exceeding the sensitivity of an experienced radiologist specialized in CRC imaging.

## CLINICAL RELEVANCE/APPLICATION

Our study aims to investigate a novel, non-invasive, opportunistic screening solution for colorectal cancer using noncontrast CT and AI. The multi-center experimental results show that our solution achieves both high sensitivity and specificity, indicating that opportunistic population-based CRC screening in asymptomatic adults could potentially be performed in abdominal and chest CT.

## W5A-SPIN-6 Deep Learning Analysis of Chest Radiographs to Predict Coronary Artery Calcium and Triage Patients Deferrable from CT

Participants

Yisak Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

To develop a deep learning (DL) model to predict the coronary artery calcium (CAC) using chest radiographs (CRs), validate its performance in patients from different institution and investigate the clinical utility of the model as a triage tool for deferring additional computational tomography (CT) scan.

## METHODS AND MATERIALS

We retrospectively searched adult patients who had undergone both a calcium score CT and posteroanterior chest radiography within a 3-month period from three different institutions; a total of 4,858 radiographs (age  $60.6 \pm 12.2$ ; women 2,458) from institution A, 4,109 radiographs (age  $61.0 \pm 12.3$ ; women 1,823) from institution B, and 979 radiographs (age  $57.0 \pm 11.3$ ; women 334) from institution C. Patients from institution A and B were used as a developmental cohort, and institution C as an external test cohort. The total Agaston scores calculated from CT were divided into 5 grades: 0, 1-100, 11-100, 100-400, and over 400, and considered ground truth labels. Images were cropped to fit the lung and heart area and normalized using energy bands and a region of interest obtained by heart segmentation. total of six different image sets were generated; original, lung area and heart area for

non-normalized and energy bands normalized. Separate DL models based on DenseNet-161 were individually trained for each of six image sets and the final performance was calculated using ensemble these six models. Conditional Ordinal Regression for Neural Networks (CORN) method was used for 5 ordinal CAC grade classification.

## **RESULTS**

Binary classification between under and over 100 CAC scores attained AUCs of 0.81, 0.79, 0.83, 0.77 on validation dataset, internal test A, internal test B and external test respectively. All test datasets showed more than 99% sensitivity at a threshold of sensitivity rate 99% attained from validation, and showed specificity of 27%, 28%, 18% and 26% for validation dataset, internal test A, internal test B and external test respectively. Using a threshold of sensitivity rate 99% attained from validation dataset, the DL model correctly identified 23.7% (66 of 278) and 14% (101 of 722) of patients in the internal test set A and B as CAC score under 100 so that additional CT scan may be deferred. Among them, true individuals showing CAC score under 100 (NPV) were 100% (66 of 66) and 98% (99 of 101) in the internal test set A and B respectively. On the external test set, DL model was able to defer 21.5% of all patients (212 of 977), and the NPV was 99.1% (210 of 212).

## **CONCLUSION**

s DL model could predict the CAC from CRs and could be used for helping clinical decision-makings such as taking additional CT.

## **CLINICAL RELEVANCE/APPLICATION**

The proposed model may assist in deferring additional CT scans using CRs by triaging patients with a under 100 CAC score.

## Abstract Archives of the RSNA, 2023

W5A-SPIR

### Interventional Radiology Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPIR-1 Uncovering Hidden Lesions - Incidental Ring Hyperenhancing Liver Micronodules in Computed Tomography during Hepatic Arteriography Guidance in Percutaneous Thermal Ablation of Colorectal Liver Metastasis**

##### Participants

Jessica A. Marques Silva, MD, Houston, TX (*Presenter*) Nothing to Disclose

##### PURPOSE

To describe and evaluate the nature of incidental ring hyperenhancing liver micronodules (RHLMs) detected on computed tomography during hepatic arteriography (CTHA) in patients with colorectal liver metastases (CLM) undergoing percutaneous ablation.

##### METHODS AND MATERIALS

Twenty-two CLM patients who underwent 24 CTHA-guided percutaneous thermal ablation sessions (AS) for 41 CLMs were included. CTHA images were obtained before and after ablation for tumor targeting and ablation margins assessment. Two radiologists independently reviewed pre-ablation images, and the interobserver agreement was assessed using Cohen's kappa. Incidental RHLMs were defined as small nodules with continuous ring enhancement visible in late arterial phase on three planes, with an average Hounsfield Unit at least twice that of adjacent liver parenchyma, not detected on baseline imaging. The nature of incidental RHLMs was determined by histological confirmation and/or follow-up image assessment. A biomechanical deformable image registration (DIR) method was used to map incidental RHLMs and newly detected CLMs on follow-up CT imaging. RHLMs were considered as CLMs if their segmentations overlapped.

##### RESULTS

The median time from baseline contrast-enhanced cross-sectional and/or functional imaging to AS was 29.4 days ( $\pm 19.1$  days). 25 incidental RHLMs with a mean largest diameter of 0.8 cm (range 0.3-1.7) were identified in 41.7% (10 of 24) of the AS. The agreement between two observers on identifying incidental RHLMs was almost perfect ( $\kappa = 0.907$ ). 4 incidental RHLMs were ablated during the AS given their similarity to targeted CLMs. Of the remaining 21 incidental RHLMs, 71.4% (15 of 21) disclosed to be CLMs, with 20% (3 of 15) confirmed by histology and 80% (12 of 15) by follow-up imaging using a DIR method at a mean time of 52 days ( $\pm 27.8$  days) post-ablation. The nature of the last 28.6% (6 of 21) incidental RHLMs was unknown, but no intrahepatic progression was observed on follow-up after chemotherapy.

##### CONCLUSION

Incidental RHLMs can be an early indicator of small CLMs, as confirmed by histology and DIR-based imaging analysis. Further investigation is needed to evaluate their relevance, as CLM resection is the only potentially curative treatment for liver-limited disease.

##### CLINICAL RELEVANCE/APPLICATION

The presence of incidental ring hyperenhancing liver micronodules on computed tomography during hepatic arteriography can indicate early-stage colorectal liver metastasis, which could impact the treatment approach.

#### **W5A-SPIR-2 Added Value of Kupffer-phase Imaging of Sonazoid-enhanced Ultrasound in Liver Ablation**

##### Participants

Dae Woong Kim, MD, Gwangju, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the usefulness of Kupffer-phase imaging (KPI) in Sonazoid-enhanced ultrasound (SZUS) for local ablation of liver tumors and to identify factors related to tumor conspicuity on the KPI of SZUS.

##### METHODS AND MATERIALS

A total of 73 patients with 112 liver tumors (95 HCCs and 17 non-HCCs), who underwent gadoteric acid-enhanced MRI (Gd-EOB-MRI), B-mode planning US (BPUS), and SZUS-assisted radiofrequency ablation (RFA) from January 2020 to February 2023, were included. RFA was performed by an experienced radiologist using SZUS/MR image fusion, 30 to 50 minutes after intravenous injection of Sonazoid. The characteristics of both patients and liver tumors were evaluated. Tumor conspicuity was assessed sequentially using a 4-point scoring scale on hepatobiliary phase (HBP) of Gd-EOB-MRI, BPUS, and KPI of SZUS at 1-week intervals by the consensus of two experienced abdominal radiologists. The tumor echogenicity on BPUS were classified into hypoechoic and non-hypoechoic groups. Conspicuity scores of 1 and 2 were classified as the poor conspicuity group, while scores of 3 and 4 were classified as the good conspicuity group. We also investigated factors related to tumor conspicuity on the KPI of SZUS, as well as the technical success rate of RFA.

## RESULTS

The mean size of tumors was  $13.1 \pm 5.9$  mm. There was no significant difference in size or location between HCCs and non-HCCs. The tumor conspicuity score on KPI of SZUS ( $2.88 \pm 0.85$ ) was higher than that of BPUS ( $1.85 \pm 0.74$ ). The correlation between tumor conspicuity on KPI of SZUS and HBP of Gd-EOB-MRI was higher than that of BPUS and KPI of SZUS (HCCs [ $r_s=0.38$ ,  $p<0.001$ ], non-HCCs [ $r_s=0.76$ ,  $p<0.001$ ], and total [ $r_s=0.44$ ,  $p<0.001$ ] versus HCCs [ $r_s=0.33$ ,  $p<0.001$ ], non-HCCs [ $r_s=0.31$ ,  $p=0.224$ ], and total [ $r_s=0.34$ ,  $p<0.001$ ]). The factors related to tumor conspicuity on KPI of SZUS were hypoechogenicity on BPUS and good conspicuity on HBP of Gd-EOB-MRI ( $p=0.034$  and  $p=0.01$ , respectively). The technical success rate of RFA using KPI was 97.3%.

## CONCLUSION

s KPI of SZUS could be a valuable tool for successful liver ablation in cases where the tumor is not clearly visible on BPUS but is well-defined on the HBP of Gd-EOB-MRI.

## CLINICAL RELEVANCE/APPLICATION

When liver tumors are not clearly visible on ultrasound, performing liver ablation can be challenging. Although SZUS has the potential to improve tumor conspicuity, it is not widely used in liver ablation due to various limitations including its high cost, unpredictable effect on improving tumor visibility, short duration of the vascular phase, and long waiting time for KPI. However, using KPI of SZUS for liver ablation can significantly reduce procedure time and improve the technical success rate, especially when liver tumors are clearly visible on HBP of Gd-EOB-MRI.

## W5A-SPIR-3 Post Embolization Syndrome Following Histotripsy: An Indicator of Immune Activation

### Participants

Nathan Loudon, MD, Ann Arbor, MI (*Presenter*) Nothing to Disclose

### PURPOSE

Post-embolization syndrome (PES) is a reported phenomenon that can occur following transarterial chemoembolization (TACE) or radioembolization (TARE). It is thought to occur as a result of immune and inflammatory response to cell death during tumor necrosis. The most commonly described symptoms are pain, fever, and leukocytosis. The purpose of this study was to determine whether these symptoms would be seen following histotripsy at higher or lower frequency compared to TACE or TARE.

### METHODS AND MATERIALS

This was a single center IRB approved retrospective cohort study which compared post-embolization syndrome symptoms of fever, right upper quadrant abdominal pain, and leukocytosis among patients who underwent ablation of liver tumors using histotripsy ( $n=10$ ), TARE ( $n=32$ ), or TACE ( $n=34$ ). Our analysis considered size of largest lesion, tumor type, LR category, and BCLC staging.

### RESULTS

When adjusted for the size of the lesion and tumor type (HCC vs non-HCC), the odds of experiencing fever were 7.17 times higher in patients who underwent histotripsy compared to TACE (95% CI = 1.16 - 52.33,  $p=.039$ ), and 50 times higher compared to TARE (95% CI = 5.74 - 1589.36,  $p=.003$ ). The odds of experiencing abdominal pain were 14.70 times higher in the histotripsy group compared to TACE (95% CI = 2.09 - 302.12,  $p=.02$ ) and 50 times higher compared to TARE (95% CI = 7.02 - 1307.34,  $p=.001$ ). The histotripsy group had a smaller change in WBC from pre to post treatment compared to TACE (2.49, 95% CI = 0.34 - 4.64,  $p=0.024$ ), and no statistically significant difference in WBC change compared to TARE.

### CONCLUSION

s As histotripsy becomes a more widely available treatment offered to patients it is important to understand the range of expected clinical symptoms which can occur following ablation. This study suggests that patients who undergo histotripsy are more likely to experience fever and abdominal pain following ablation compared to TACE and TARE.

### CLINICAL RELEVANCE/APPLICATION

Histotripsy is a novel ablation modality and as such its expected post-treatment symptoms are still being elucidated. Pre-clinical data have shown that histotripsy is highly immunogenic on both a local and systemic level. PES is thought to be a result of inflammatory and immune response to tumor ablation. Studying the incidence of PES in this population could provide valuable insights into the clinical manifestations of immune activity following ablation.

## W5A-SPIR-4 Prediction of Initial Lung Microwave Ablation Zone Through Tumor and Ablation Characteristics

### Participants

Daniel Kim, Los Angeles, CA (*Presenter*) Nothing to Disclose

### PURPOSE

To investigate the effect of tumor and ablation characteristics on dimensions and size of lung microwave ablation zone and establish a prediction model.

### METHODS AND MATERIALS

This IRB-approved, HIPAA compliant study cohort involved patients who underwent CT-guided lung microwave ablation for their malignancy between 2012 to 2023. All patient demographics, treatment history, tumor characteristics, ablation duration, and maximum temperature ( $T_{max}$ ) reached were recorded. The peripheral location was defined as the area within 2cm from the edge of the visceral pleura. Ablation images without specific intraprocedural labels indicating post-initial ablation or cases without complete ablation details were excluded. The initial ablation zone was represented by the elliptical ground-glass opacity surrounding the target site and its dimensions were measured. Dataset was divided into 70% training and 30% test set and univariate and multivariate linear regression models were used to build a prediction model for the major axis, minor axis, and area of the ablation zone.

### RESULTS

This study cohort was composed of 89 lesions that underwent microwave ablations. Of these ablations, 25 were with history of

prior lung radiation therapy (Hrad) (28%) and 7 with history of prior lung surgery (Hsurg) (8%), and 45 lesions were located at the peripheral region. The median duration of the initial ablation was 1.5 minutes ranging from 0.5 to 10 minutes, the power used was 65W for all ablations, and mean of Tmax was 100±17°C. The measured mean major, minor axes, and area were 3.1±0.8cm, 1.8±0.5cm, and 4.7±2.5cm<sup>2</sup>. A parsimonious prediction model was built keeping only the predictors with p<0.15. For the major axis, duration (p<0.001), Tmax (p=0.002), Hsurg (p<0.001), and Hrad (p=0.102) were predictors. For minor axis, duration (p<0.001), Tmax (p<0.001), Hsurg (p=0.001), and peripheral location (p=0.099) were predictors. For the area, duration (p<0.001), Tmax (p<0.001), and Hsurg (p<0.001) were predictors. The fitted model equation for major axis was:  $3.176 + 0.597 \cdot \log(\text{duration}) - 0.003 \cdot (\text{Tmax}) - 0.302 \cdot (\text{Hrad}) + 1.146 \cdot (\text{Hsurg})$  with test root mean square error (RMSE)=0.55, R<sup>2</sup>=0.29. The equation for minor axis was:  $1.575 + 0.332 \cdot \log(\text{duration}) + 0.001 \cdot (\text{Tmax}) + 0.022 \cdot (\text{Hsurg}) + 0.106 \cdot (\text{peripheral})$  with test RMSE=0.53, R<sup>2</sup>=0.33. The equation for area was:  $5.772 + 2.431 \cdot \log(\text{duration}) - 0.021 \cdot (\text{Tmax}) + 1.658 \cdot (\text{Hsurg})$  with test RMSE=2.11, R<sup>2</sup>=0.40.

## CONCLUSION

s Lung tumor and ablation characteristics are shown to be significant predictors of microwave ablation dimensions and size which can be used to establish a prediction model.

## CLINICAL RELEVANCE/APPLICATION

Estimate of lung microwave ablation dimensions and size can aid in effective treatment of lung tumors.

## W5A-SPIR-5 Efficacy and Safety of Tract Cautery for Lung Microwave Ablation

Participants

Daniel Kim, Los Angeles, CA (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the efficacy and safety of tract cautery for lung microwave ablation through comparison of post-procedure complication rate.

## METHODS AND MATERIALS

This IRB-approved, HIPAA compliant study involved patients who underwent lung microwave ablation for their malignancy between 2012 to 2021. All patient demographics, treatment history, tumor characteristics, ablation details were collected. The study cohort was divided into whether tract cautery was conducted during probe removal. Immediate, persistent, and enlarging pneumothorax (PTX) were each defined as the observation of PTX on CT or chest radiograph during the termination of procedure, detection of non-expanding PTX, and expanding PTX for 3-5 hours post-procedure. Other complications including pleural effusion, delayed complication (more than one week), and post-procedural interventions needed for management of complications were recorded. A subgroup analyses of patients with no history of radiation therapy were also included. Univariate and multivariate logistic regression models were used to compare differences in complication rates.

## RESULTS

This study cohort was composed of 171 lung microwave ablation sessions of 62 patients (mean age 59±12). 58/171 were with history of radiation therapy of the lung (33.9%) and 33/171 were with history of lung surgery (19.3%). 80 ablations exhibited immediate PTX, 45 persistent PTX, 19 enlarging PTX, 26 pleural effusion, 8 delayed complications, and 14 required interventions. Tract cautery was conducted in 126/171 ablations. Patients who did not receive tract cautery had 10 times the odds of exhibiting delayed complications than patients who did receive tract cautery (p=0.003). Ablations with tumor size less than 1cm and history of emphysema had 5.9 times (p=0.035) and 5.7 times (p=0.032) the odds of requiring interventions. Increasing the total ablation time by 1 minute was associated with a 24% reduction in odds of delayed complications. Furthermore, a subgroup of ablations composed of patients without history of lung radiation therapy included 81 ablations with and 32 without tract cautery. This subgroup showed ablations conducted without tract cautery had 3.0 times the odds of exhibiting enlarging PTX (p=0.026) and 5.3 times the odds of requiring interventions (p=0.026) compared to ablations conducted with tract cautery.

## CONCLUSION

s Utilizing tract cauterization in lung microwave ablation shows significant reduced incidence of post-ablation delayed complications and enlarging PTX and interventions in patient without history of lung radiation therapy.

## CLINICAL RELEVANCE/APPLICATION

Tract cautery proves to be a useful method in reducing complications and interventions required for management of complications.

## W5A-SPIR-6 Pre-ablation Biopsy and the Effect of Histopathologic Grade on Thermal Ablation Outcomes for Hepatocellular Carcinoma

Participants

Abinaya Ramakrishnan, Los Angeles, CA (*Presenter*) Nothing to Disclose

## PURPOSE

Thermal ablation has been increasingly used as a minimally invasive treatment for hepatocellular carcinoma (HCC), with clinical outcomes comparable to surgical resection. While prior studies have analyzed the influence of size, location, and morphology on ablation outcomes, few have examined the role of histopathologic grade. This is partly because standard of care in LI-RADS 5 HCCs does not require biopsy. In this study, we determined the relationship between histopathological grade of the tumor on the clinical outcome after thermal ablation using time to local tumor progression-free survival (LTPFS) and overall survival (OS).

## METHODS AND MATERIALS

Between February 2015 to November 2022, 186 patients with nodular LI-RADS 5 HCCs that underwent ablation (MWA=165, RFA=21 with biopsies within prior 3 months) were included in this single-center, retrospective cohort study. All tumors were histologically classified using WHO criteria as Poor (n=25), Moderately (n=119), or Well (n=42) differentiated. Patients underwent continuous follow-up imaging to determine local tumor progression free survival (LTPFS). After retrospective review of medical records and follow-up MRI examinations, the rates of LTPFS and OS hazard ratios from Kaplan-Meier method were calculated and compared among the groups.

## RESULTS

Pre-ablation histopathologic grade was identified as a significant predictor for post-thermal ablation outcomes. Poorly-differentiated HCCs had significantly shorter LTPFS compared to well-differentiated HCCs (hazard ratio [0.21, 0.07-0.6],  $p=0.008$ ). Poorly-differentiated HCCs also had shorter LTPFS compared to moderately-differentiated HCCs (hazard ratio [0.68, 0.33-1.39],  $p=0.28$ ), although this difference was not significant. In terms of OS, poorly-differentiated HCCs had significantly shorter OS compared to well-differentiated HCCs [0.20, 0.07-0.59,  $p=0.0035$ ],  $p=0.0082$ ) and moderately-differentiated HCCs [hazard ratio [0.61, 0.3-1.25],  $p=0.0035$ ).

## CONCLUSION

s Poorly-differentiated HCCs was an important prognostic biomarker correlating with shorter LTPFS as well as OS after thermal ablation of HCC. While not currently considered standard of care, HCC biopsy prior to ablation can help tailor more aggressive patient-specific treatment planning and surveillance protocol.

## CLINICAL RELEVANCE/APPLICATION

Pre-ablation biopsies in HCC patients can play a critical role in the management of patients post-ablation. Poorly differentiated tumors may benefit from more aggressive treatment and surveillance given shorter LTPFS and OS.

W5A-SPMK

### Musculoskeletal Imaging Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPMK- Radiomics Analysis based on Dual-energy CT Hydroxyapatite (HAP)-fat Decomposition Technique for Osteoporosis Prediction** 1

##### Participants

Jinling Wang, Changsha, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To develop and validate a radiomics model based on the hydroxyapatite (HAP)-fat material decomposition (MD) images of dual-energy CT for osteoporosis prediction.

##### METHODS AND MATERIALS

83 patients who underwent dual-energy CT included L1-L5 and quantitative computed tomography (QCT) were collected. With QCT as the reference standard, the patients were divided into two groups according to the guidelines introduced by the International Society for Clinical Densitometry (ISCD) and American College of Radiology (ACR), osteoporosis of the spine was defined as a BMD value  $<80$  mg/cm<sup>3</sup>, and non-osteoporosis (osteopenia and normal) was defined as a BMD value  $\geq 80$  mg/cm<sup>3</sup>. Radiomic features were selected from HAP-fat MD images of dual-energy CT. A radiomics model was constructed from linear combinations of the selected features weighted by their coefficients. The ROC curve was performed to evaluate the performance of the radiomics model.

##### RESULTS

The radiomics model, which comprised 8 selected radiomics features (shape\_Maximum2DDiameterColumn, shape\_Maximum2DDiameterSlice, shape\_Sphericity, firstorder\_10Percentile, firstorder\_90Percentile, firstorder\_Skewness, gldm\_LargeDependenceHighGrayLevelEmphasis, gldm\_LargeDependenceLowGrayLevelEmphasis) based on HAP-fat MD images of dual-energy CT, showed excellent differential ability with AUC of 0.999 (95%CI, 0.987-1.000), sensitivity of 0.983, specificity of 1.000, negative prediction value of 0.960, positive prediction value of 1.000 in the cohort. The discrimination performance of the radiomics model to identify osteoporosis from non-osteoporosis (osteopenia and normal) showed high accuracy of 98.8% in the cohort.

##### CONCLUSION

The radiomics model comprised 8 selected radiomics features had excellent ability to predict osteoporosis based on dual-energy CT HAP-fat MD images.

##### CLINICAL RELEVANCE/APPLICATION

The prevalence of osteoporosis in the population is increasing year by year. One of the reference standards for the diagnosis of osteoporosis today is the volumetric BMD measured by QCT, but the QCT post-processing process is very complex and requires additional phantom calibration, etc. Our proposed radiomics model based on HAP-fat material decomposition images can serve as a useful tool for osteoporosis prediction and has the potential to be applied in clinical treatment planning in the future.

#### **W5A-SPMK- A Phantom Study of Optimal Scanning Parameters for Dual-energy CT Measurement of Human Lumbar Spine Bone Density** 2

##### PURPOSE

To explore the best scanning parameters of dual-energy CT (DECT) for measuring the bone density of human lumbar spine using the European spine phantom (ESP) and fresh pig subcutaneous fat to simulate normal weight and obese people.

##### METHODS AND MATERIALS

Different volumes of fresh pig subcutaneous fat were selected and wrapped around the ESP to simulate the lower abdominal condition (without rib influence) in normal weight and obese people; six fresh pig ribs were selected and wrapped around the ESP and fat on both oblique sides to simulate the upper abdominal condition (with rib influence) in normal weight and obese people. The ESP number 145 containing three hydroxyapatite (HAP) inserts with densities of 50,100,200 mg/cm<sup>3</sup> were labeled as L1,L2, and L3. Spectral scanning of two simulated phantoms were performed by Revolution CT. A total of 20 sets of spectral scans were performed. Each set was repeated 10 times and mean values of HAP-H<sub>2</sub>O of ESP L1-3 were measured. The data distributed normally and the differences between the measured and actual values of ESP L1-3 vertebrae were compared using an independent sample t-test. Relative error (RE) and Root mean square error (RMSE) of BMD measurements were calculated for different scanning conditions in normal and obese populations. These can reflect the accuracy of the measurement very well. CTDIVOL values under different energy spectrum scanning conditions were recorded.

##### RESULTS

For the upper abdomen (fat area 140 cm<sup>2</sup>, with rib influence) in normal weight, there was no statistical difference ( $P > 0.05$ ) in

BMD for each vertebra at 0.8s/rot with different tube currents. The set of 0.8s/rot and 190 mA led to the smallest RE and the smallest RMSE for L1 and 2 vertebral BMD was obtained at 190 mA. For the lower abdomen (fat area 240 cm<sup>2</sup>, without rib influence) in normal weight, there was no statistical difference between the 0.8s/rot with 190 mA and 275 mA ( $P > 0.05$ ). The RE in 190 mA was smaller than that in 275 mA, and the RMSE in 190 mA was also smaller than that in 275 mA. For the upper and lower abdomen (fat area 340 cm<sup>2</sup>) in obese weight, there were no statistical difference between the 0.8s/rot with 315 mA and 355 mA ( $P > 0.05$ ). The RE in 315 mA was smaller than that in 355 mA, and the RMSE in 315 mA was also smaller than that in 355 mA. With the increase of tube current, the CTDIVOL value of the same tubular speed increases.

## CONCLUSION

While using Revolution CT to measure lumbar spine bone density, 0.8s/rot at 190 mA might be the best scanning parameter for normal weight population, and 0.8s/rot at 315 mA might be the best scanning parameter for obese population.

## CLINICAL RELEVANCE/APPLICATION

This study proposes the optimal scanning parameters for measuring lumbar spine bone density in normal and obese populations based on simulating human abdominal fat and ribs.

## W5A-SPMK- Clinical Impact of the Results of Spine Biopsy in Patients with Suspected Discitis-Osteomyelitis

3

Participants

Joey Mustafa, Forest Park, IL (*Presenter*) Nothing to Disclose

## PURPOSE

Vertebral osteomyelitis is a serious and potentially life-threatening condition that is challenging to diagnose and treat. Image-guided biopsy is often performed to identify the causative microorganism. Previous studies have primarily focused on the yield of the cultures from these biopsies, but the impact of these results on clinical management has not been thoroughly studied. The objective of this study is to evaluate the impact of image-guided biopsy on the clinical management of vertebral osteomyelitis.

## METHODS AND MATERIALS

This retrospective study was conducted using patient data from a single academic institution in the USA, and included patients who underwent CT-guided biopsy for suspected vertebral osteomyelitis between January 2013 and April 2022. The study aimed to calculate the positivity rate of the biopsy sampling and assess how the biopsy results impacted the clinical management of patients with vertebral osteomyelitis. Specifically, the study examined whether clinicians changed the management of vertebral osteomyelitis through narrowing or broadening of antibiotic regimens based on the biopsy results.

## RESULTS

The study included 92 patients who underwent CT-guided bone biopsy for suspected vertebral osteomyelitis. Cultures from biopsy sampling were positive in 35% of patients. In 18% of all cases, the antibiotic regimen was changed based on the biopsy results and the specific organism identified. In contrast, the biopsy results had no significant impact on the subsequent antibiotic protocol in 82% of cases ( $\chi^2=40.96$ ;  $P<0.0001$ ), either because the cultures were negative, the organism could have been predicted without biopsy, or other clinical factors.

## CONCLUSION

The study highlights the challenges in diagnosing and treating vertebral osteomyelitis, as well as the limitations of image-guided biopsy in impacting the clinical management of this condition. The biopsy results did not lead to a change in the antibiotic regimen for the vast majority of cases. The risks and benefits of biopsy should be carefully considered in light of this knowledge.

## CLINICAL RELEVANCE/APPLICATION

Spine biopsies can be challenging procedures and the yield of such procedures may be low. This is the only study we are aware of that examines the clinical impact of biopsies performed for suspected discitis-osteomyelitis and the results show that biopsy/culture results do not change clinical management in the majority of patients.

## W5A-SPMK- Prediction of High-Risk Cytogenetic Status in Multiple Myeloma using Dual-energy Spectral Computed Tomography

4

Participants

Siya Shi, Guangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

To explore the predictive value of quantitative parameters derived from dual-energy spectral computed tomography (DESCT) for a high-risk cytogenetic (HRC) status in multiple myeloma (MM) patients.

## METHODS AND MATERIALS

This study involved 24 MM patients with 102 lesions who had undergone spinal DESCT. Among them, 5 patients with 18 lesions were diagnosed with HRC status, including the presence of at least one of the following cytogenetic abnormalities (CAs): del(17p), t(4;14), t(14;16), t(14;20), gain(1p), or p53 mutation. The quantitative parameters of DESCT parameters were generated by the regions of interest defined on lesions. Univariate logistic regression was performed to determine the relevant variables with HRC status. The least absolute shrinkage and selection operator (LASSO) was used to build a model for predicting the HRC status. Waterfall plot was used to visualize the performance of the model. Receiver operating characteristic (ROC) analysis was performed to determine potential utility of the model and the sensitivity and specificity determined by the Youden Index were also calculated.

## RESULTS

Statistical differences were observed according to univariate logistic regression including Mono 40- Kev, Ca (Fat), Ca (Water), Fat (Ca), Fat (HAP), HAP (Fat), HAP (Water), Water (Ca), Water (HAP) and Effective atomic number (Eff-Z) (all  $P < 0.05$ ). Fat (HAP) and Water (Ca) were selected according to LASSO to build a prediction model for HRC status. Waterfall plot demonstrated the favorable predictive performance of the model. ROC analysis indicated the area under the curve was 0.799 (95% confidence interval: 0.656-0.942) with sensitivity of 0.722, specificity of 0.857 and Youden index of 0.579.

## CONCLUSION

s Analysis of DESCT offers potential as a quantitative method to predict the HRC status in MM.

## CLINICAL RELEVANCE/APPLICATION

The DESCT quantitative parameters could be used to predict HRC in MM patients and to facilitate treatment selection and prognosis prediction.

## W5A-SPMK- Opportunistic Screening for Acute Vertebral Fractures on Routine Abdominal or Chest CT using an Automated Deep Learning Model

Participants

Jonghun Woo, MD, Bucheon-Si, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

To develop an opportunistic screening model based on deep learning algorithm to detect recent vertebral compression fractures in abdominal or chest CT

## METHODS AND MATERIALS

This retrospective single center design study collected 1309 coronal reformatted images from abdomen, pelvis or chest CT, performed within the preceding two months in patients recently diagnosed with a vertebral compression fracture or normal spine on spinal MRI. They consists of 504 recent fracture labeled images (119 patients, mean age  $61.6 \pm 19.2$ [SD], M: F=64:55) and 805 normal unlabeled images (115 patients, mean age  $56.2 \pm 15.0$ [SD], M: F=68:47) from September 2018 to April 2022. One radiologic resident and one board certified musculoskeletal radiologist participated in image selection and manual labeling the fractured segment on each CT images. Image selection in recent fracture group was made on the condition that two out of three radiologic findings suggestive of a recent fracture such as cortical step-off, impaction of trabeculae, or visual fracture line were included and three images per each fractured vertebral segment were obtained. For the CT image of the normal patient group, 7 images were obtained at the same interval between the most anterior vertebral body and the posterior vertebral body in the coronal scan. The labeled 480 images and unlabeled 700 images was split randomly into training set, validation set, and internal test set in a ratio of 75%:10%:15%, respectively. Remained labeled 24 images and unlabeled 105 images was included for secondary internal validation set. The primary outcome was test accuracy, precession, and F1 score. Neuro-T (version 2.3.3; Neurocle Inc), a commercially available software was used in establishing algorithm

## RESULTS

For training, validation and internal test set, the algorithm achieved 99.86 % test accuracy, 91.22 % precision, and 89.18 % F1 score, respectively for detection of recent vertebral compression fracture. Then in secondary internal validation set, our system achieved 99.90% test accuracy, 74.93 % precision and 78.30 % F1 score, respectively.

## CONCLUSION

s Automated deep learning model showed high accuracy in test set and also in internal validation set. If this algorithm is applied opportunistically to daily abdomen or chest CT evaluation, it will be helpful for early detection of vertebral compression fracture.

## CLINICAL RELEVANCE/APPLICATION

Automated deep learning model showed high accuracy in test set and also in internal validation set. If this algorithm is applied opportunistically to daily abdomen or chest CT evaluation, it will be helpful for early detection of vertebral compression fracture.

## W5A-SPMK- Detection of Bone Marrow Edema in Vertebral Compression Fractures using Deep Learning Segmentation Quantitative Material Density Imaging in Fast kVp-switched Dual Energy CT

Participants

Reisuke Nishihara, Hiroshima, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Water (hydroxyapatite. [HAP]) material density images derived from dual energy CT (DECT) are used to detect bone marrow edema (BME) in vertebral compression fractures (VCF). However, task-irrelevant anatomy is also enhanced in water (HAP) images, and this can affect BME detection accuracy. This study investigates the diagnostic performance of BME in VCF using water (HAP) density images with deep learning (DL) bone segmentation.

## METHODS AND MATERIALS

172 vertebral bodies, from the images of 20 patients who underwent both DECT and MRI between Dec 2021 and Feb 2023 for suspected VCF, were included in this study. Vertebral bodies with heights of less than 4 mm, and those imaged after percutaneous vertebroplasty, were excluded. DECT was performed using a 256-row fast kVp switching dual energy CT (Revolution CT, GE HealthCare). Virtual monochromatic images (VMI, 70 keV with 0.625 mm-slices) were reconstructed and processed using dedicated software (Spectral Bone Marrow [SBM], GE HealthCare). SBM generates a bone mask using a DL-based DECT bone segmentation algorithm. This mask defines bone regions upon which water (HAP) material density images are overlaid on the base VMI. The window width and level of the color overlay images are set to optimize visualization of bone marrow. This fully automatic procedure yields 2.5 mm-slice axial, sagittal and coronal water (HAP) density-VMI fused images. Presence of BME was assessed by MRI. Two radiologists, blinded to the MRI results, evaluated each vertebral body for the presence of BME on the water (HAP) density-VMI fused image using a binary classification. Sensitivity, specificity, positive predicted value (PPV) and negative predicted value (NPV) were assessed using MRI as reference standard. Regions of interest (ROI) were placed on each vertebral body. Cut-off values of water (HAP) density were calculated using ROC analysis.

## RESULTS

The DECT-based algorithm detected BME with 100% sensitivity, 98% specificity, 96% PPV and 100% NPV. A cutoff value of 996.6 mg/cm3 provided 96 % sensitivity and 99% specificity.

## CONCLUSION

s The DECT BME detection algorithm demonstrates excellent performance in VCF, as evidenced by quantitative analysis as well as concordance with radiologist impressions.

#### **CLINICAL RELEVANCE/APPLICATION**

Currently, BME diagnosis in VCF is mainly performed using MRI. This work demonstrates that, thanks to advances in deep learning-based segmentation, quantitative projection-based material decomposition direct from projection views, and VMI-water (HAP) image fusion, DECT may provide a viable alternative. DECT may improve patient throughput vs MRI owing to shorter scan time and increase availability because of lower cost per scan.

### **W5A-SPMK- The Value of Trabecular Bone Score in the Reclassification of Bone Quality in Chinese Postmenopausal Women**

#### **PURPOSE**

To explore the clinical value of trabecular bone score (TBS) in the reclassification of bone quality in Chinese postmenopausal women.

#### **METHODS AND MATERIALS**

The retrospective study included Chinese postmenopausal women who had dual X-ray absorptiometry (DXA) examination between September 2022 and April 2023. DXA images were analyzed to measure bone mineral density (BMD) at lumbar spine (LS), left hip (LH), and femoral neck (FN). was calculated by the TBS iNsite software (version 3.0.0.15). The degradation of bone microstructure was determined following the cutoff values: TBS = 1.310 (normal); 1.230 = TBS = 1.310 (partially degraded); and TBS < 1.230 (degraded). The DXA parameters and clinical characteristics were compared among different BMD categories (normal, osteopenia, osteoporosis) by using rank sum test. Factors related to TBS were determined by Spearman correlation analysis. P < 0.05 was considered statistically significant.

#### **RESULTS**

A total of 300 subjects were included in this study, with 100 subjects per bone mass category. There was no significant difference in the age between any two of the groups (P>0.05). The TBS was significantly lower in osteoporosis ( $1.212 \pm 0.075$ , P < 0.001) and osteopenia groups ( $1.291 \pm 0.085$ , P < 0.001) than in normal BMD group ( $1.345 \pm 0.097$ ). Significant differences for BMI, weight and DXA parameters were also observed between any two of the groups. For normal BMD group, 3% of subjects still showed degraded microstructure. The number was obviously increased in both osteopenia (7.67%) and osteoporosis (19.66%) groups. For partially degraded microstructure, 8%, 11.33% and 11.34% of subjects were observed in normal BMD, osteopenia and osteoporosis groups, respectively. Spearman correlation analysis showed that the factors related to low TBS were age, weight, BMI, BMD and T-score.

#### **CONCLUSION**

s TBS and BMD were significantly lower in the osteoporosis group than in osteopenia and normal BMD groups. Low TBS was associated with age, weight, BMI, and BMD at lumbar spine, left hip and femur neck. It was notable that a proportion of Chinese postmenopausal women with osteopenia and normal BMD still suffered from degraded microstructure according to their TBS.

#### **CLINICAL RELEVANCE/APPLICATION**

BMD and TBS are essentially two different and independent indices to describe bone quantity and quality, respectively. Patients with osteopenia may also have degraded bone, which is at higher risk of fracture but not easily detected in clinical. However, in combination of BMD, TBS is able to uncover the presence of these patients. Therefore, TBS is also of great value for the clinical management of Chinese patients with osteoporosis and those at risk of fracture, as well as for treatment decisions and recommendations.

### **W5A-SPMK- TBS Helps Identify Degraded Bone Microstructure in Chinese PHPT Patients**

8

#### **PURPOSE**

To explore the value of trabecular bone score (TBS) in evaluating the bone microstructure in Chinese primary hyperparathyroidism (PHPT).

#### **METHODS AND MATERIALS**

We performed a retrospective study of Chinese PHPT patients who were diagnosed between August 2022 to April 2023. The patients all underwent dual-energy X-ray absorptiometry (DXA) examination. Patients without DXA or TBS examination, and suffering from disease that might affect bone metabolism were excluded. Normal control and case groups were matched for age and sex. TBS for each subject was evaluated based on their lumbar spine DXA image by the TBS iNsite software (version 3.0.0.15). The integrity of bone microarchitecture was evaluated based on different TBS cutoff values: TBS = 1.310 (normal microstructure), 1.230 = TBS = 1.310 (partially degraded microarchitecture), and TBS < 1.230 (degraded microarchitecture). The difference of DXA parameters, including TBS and BMD, and clinical information between the groups were analyzed by T-test and Rank sum test. P<0.05 was considered as significant.

#### **RESULTS**

A total of 18 Chinese PHPT patients (female: male = 7: 2) and 35 age- and sex-matched controls were included in the study. The bone mass index (BMI) of the included patients was at 15-35kg/m<sup>2</sup>. There were 21 and 14 subjects with normal BMD and bone mass loss in the control group, respectively. Clinical characteristics, including height, weight and BMI, were not significantly different between the groups. A significant difference was observed for lumbar spine BMD (P = 0.000) and TBS (P=0.026), as well as left hip (LH) and femoral neck (FN) BMD (P = 0.000 for both) between the control and case groups. In particular, in terms of the mean value, TBS of PHPT groups indicated degraded microstructure, while no degradation was observed in the control group. BMD and TBS were significantly correlated in both groups (PHPT: r=0.891, p=0.000; control group: r=0.569, p=0.000).

#### **CONCLUSION**

s Lumbar spine BMD and TBS was significantly lower in Chinese PHPT patients than control group. In addition, there was a significant correlation between TBS and BMD in PHPT and the control group. In the basis of BMD, TBS could be used to better evaluate the microstructure of Chinese PHPT patients and therefore their fracture risk.

#### **CLINICAL RELEVANCE/APPLICATION**

BMD does not reflect bone microstructure and hence bone strength. Trabecular bone score (TBS) is a textural index that evaluates pixel gray-level variations in the lumbar spine DXA image, providing an indirect index of trabecular microarchitecture. TBS could be a useful tool to evaluate the bone microstructure of Chinese PHPT patients, providing a better evaluation of their fracture risk.

W5A-SPMS

### Multisystem Wednesday Poster Discussions I

#### Sub-Events

#### W5A-SPMS- Correlation between Volumetric CT Tumor Burden and Circulating Tumor DNA as Response Parameters in Patients with Advanced Metastatic Melanoma Undergoing Immunotherapy 1

#### PURPOSE

Circulating tumor DNA (ctDNA) is a promising tool for treatment monitoring of patients with advanced melanoma, as it may serve as a measure of tumour burden. There is a need to understand the correlation between visual tumour burden assessed by imaging and ctDNA levels. Thus, the purpose of our study was to compare ctDNA values with volumetric tumor burden assessed by computed tomography as indicators for therapy response in melanoma patients undergoing immunotherapy.

#### METHODS AND MATERIALS

In this retrospective, institutional review board approved study, a total of 35 patients (19 male, 16 female, age 63 +/- 17) with histologically confirmed metastatic melanoma (AJCC v8 stages III/IV) underwent systemic immunotherapy. All patients received a baseline and at least 2 subsequent staging CT examination after initiation of therapy. This resulted in a total of 107 CT examinations, including a body CT scan (neck, chest and abdomen) as well as cranial CT or MRI. The volumetric tumor burden was measured separately in different anatomical regions (bones, lung, liver, lymph node, cutaneous and brain metastases) using a dedicated commercially available software tool. The total tumor burden as well as subgroup analysis of different metastatic sites were correlated with the plasma ctDNA levels at each follow-up time point. The detection of somatic mutations in plasma DNA included hotspot analyses in 5 different genes: BRAF, EGFR, KRAS, NRAS, PIC3CA.

#### RESULTS

Lymph node metastases were the most common metastatic site (53.6%), followed by lung metastases (30.7%) and subcutaneous metastases (26.9%) and brain metastases (26.9%). The mean ctDNA level was 0.99 %/mL and the mean volumetric total tumor burden was 118 mL. There was a statistically significant difference for relative changes in total tumor burden and ctDNA levels between non-responders (progressive disease [PD]) and responders (partial response [PR] and complete response [CR]). A strong and statistically significant correlation was observed between relative changes of ctDNA levels and total tumor burden ( $r=0.87$ ;  $p<0.05$ ). Of note, subgroup correlation of the two most frequent sites of metastasis (lymph node, lung) between tumor burden and ctDNA levels was moderate ( $r=0.6$ ;  $p<0.05$ ).

#### CONCLUSION

Changes in both total tumor burden and ctDNA can be used for precise response assessment in advanced melanoma patients undergoing immunotherapy. Given the strong correlation between the two markers, inherent challenges of immunotherapy response assessment such as pseudo-progression could be identified and differentiated earlier.

#### CLINICAL RELEVANCE/APPLICATION

Combining imaging with other biomarkers is vital to address inherent challenges of immunotherapy response assessment such as pseudo-progression.

SPNMMI-1

#### Immuno-PET Imaging of B7-H4 Immune Checkpoint in Prostate Cancer

##### PURPOSE

B7-H4 is an immune checkpoint sibling of PD-L1 that suppresses T-cells' tumor-killing functions. In addition to cancer cells, B7-H4 is also expressed by tumor-associated macrophages (M<sup>?</sup>), comprising 30-50% of tumor stromal cell populations. This study aimed to design and develop a novel B7-H4 immunoPET probe and perform the first proof-of-concept B7-H4 immunoPET imaging.

##### METHODS AND MATERIALS

Anti-B7-H4 mAb was functionally characterized and tested using ELISA assay. The antibody was conjugated with chelator NODAGA-NHS and labeled with radioisotope copper-64 (<sup>64</sup>Cu). Tumor xenografts were generated in C57BL/6J mice by subcutaneously injecting TRAMP-C2 prostate cancer cells on the right flank. 5 mice/group were intraperitoneally injected with either PBS, B7-H4 mAb (10mg/kg) to block B7-H4, or chlodronate liposome (15mg/kg) to cause M<sup>?</sup> depletion. MicroPET imaging was performed post-tail vein injection of 100 $\mu$ Ci <sup>64</sup>Cu-B7-H4-mAb. Radiotracer uptake was measured as the maximum percentage injected dose per gram body weight (max %ID/g). Statistical significance was determined using two-way ANOVA with Tukey correction for multiple testing.

##### RESULTS

Immunoconjugation yielded a chelator-to-antibody ratio of 1.8-2.2 and 94-98% radiochemical purity of radiotracer <sup>64</sup>Cu-B7-H4-mAb with an average specific activity of 2645.45 mCi/ $\mu$ mol. The immunoreactivity of <sup>64</sup>Cu-B7-H4-mAb was similar to that of naked B7-H4 mAb, with unaffected potency in targeting B7-H4 protein moiety. PET imaging demonstrated tumor uptake of radiotracer as 13.12  $\pm$  4.867, 36.38  $\pm$  5.71, and 42.16  $\pm$  11.95 %ID/g at 4-, 24-, and 48 hours, respectively. By comparison, the radiotracer uptake in B7-H4 blocked tumors was 10.56  $\pm$  2.26, 25.92  $\pm$  6.28, and 27.20  $\pm$  11.01 %ID/g at 4-, 24-, and 48 hours, respectively. Blocking B7-H4 in vivo significantly reduced radiotracer uptake at the 48-hour time point (p=0.0088). Depletion of M<sup>?</sup> also demonstrated a non-significant tendency of reduced tumor uptake radiotracer (8.34  $\pm$  4.37, 26.04  $\pm$  4.08, 35.42  $\pm$  10.22 at 4-, 24-, and 48 hours, respectively). Immunohistochemical staining of B7-H4 demonstrated significantly stronger protein levels in untreated tumors compared to B7-H4 blocked or M<sup>?</sup> depleted group.

##### CONCLUSION

The new <sup>64</sup>Cu-B7-H4-mAb radiotracer showed preferential tumor accumulation. In vivo B7-H4 blocking and M<sup>?</sup> depletion reduced the tumor accumulation of the new radiotracer; however, a statistically significant difference was only observed between the control and the blocked group at 48 hours.

##### CLINICAL RELEVANCE/APPLICATION

The new B7-H4 immunoPET probe is a clinically translatable imaging biomarker that could inform clinical trial design immediately. B7-H4 PET imaging could guide clinical decision-making to improve therapeutic benefits.

SPNMMI-2

#### Prostate-specific Membrane Antigen (PSMA) as a Novel Theranostic Target in Glioblastoma Multiforme (GBM): Feasibility Study in a Preclinical Xenograft Model

##### Participants

Steven Pan, BSc, New York, NY (*Presenter*) Nothing to Disclose

##### PURPOSE

Glioblastoma (GBM) is the most common and aggressive primary malignant brain tumor. Accurate differentiation of viable tumor versus treatment-related change and delivery of targeted therapies is critical to improving clinical outcomes. Prostate specific membrane antigen (PSMA) has recently entered clinical practice as a theranostic (ie diagnostic PET and radionuclide) target in malignancies such as prostate cancer, and PSMA expression in GBM has recently been shown. The purpose of our study was to confirm PSMA expression in GBM with immunohistochemistry (IHC), and to evaluate PSMA as a radionuclide target in a mouse model of GBM.

##### METHODS AND MATERIALS

IRB and IACUC approval was obtained for the human tissue and in vivo mouse model components of the study. IHC was performed in tissue specimen from six GBM patients to validate PSMA expression. Subcutaneous xenografting of a mosaic tumor model consisting of a PSMA+ endothelial cell line and a GBM stem cell line was performed in 5 mice. Three mice were treated with 1 mCi of [<sup>177</sup>Lu]-PSMA, and tumor localization of radionuclide was validated using post-treatment single-photon computerized tomography (SPECT) imaging. Treatment response was assessed with longitudinal monitoring of tumor size using calipers to measure length (L) and width (W), and estimating ellipsoid volume (V) through the modeling formula,  $V = 0.5 \times L \times W^2$

##### RESULTS

In 5/5 (100%) patient tumor specimen, IHC demonstrated PSMA expression in both tumor stroma as well as tumor vasculature,

noting inter-patient heterogeneity. Post-therapy [Lu177]-PSMA SPECT demonstrated specific localization of radionuclide in the subcutaneous tumor xenograft in 3/3 (100%) mice, validating in vivo expression of PSMA in our mosaic model as well as delivery of radionuclide to the tumor site. Treated tumors demonstrated reduction in tumor volume and slowed growth compared to the untreated control group, although no animal demonstrated complete tumor killing.

#### **CONCLUSION**

s We validated previous pilot studies showing PSMA expression in human GBM specimen. We further demonstrate feasibility of PSMA-targeted radionuclide therapy in our in vivo mouse xenograft model, with evidence of partial response. Our findings support further evaluation of PSMA as an emerging theranostic target in GBM, both as a standalone approach and in combination with other therapeutic strategies. Future directions include correlative studies between PSMA expression and clinical outcomes to further elucidate its potential for personalized therapies and a predictor for clinical outcomes.

#### **CLINICAL RELEVANCE/APPLICATION**

This study combines human GBM tissue and mouse model investigations to validate PSMA as an emerging theranostic target in GBM and has the potential to improve clinical outcomes.

W5A-SPNPM

### Noninterpretive Skills (Beyond Imaging) Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPNPM-1 Burnout Among Radiology Physicians: A Systematic Review and Call to Action**

Participants

Nader Ashraf, MD, Riyadh, Saudi Arabia (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Burnout is on the rise among physicians, including radiologists, with prevalence rates exceeding 50%. Burnout in healthcare can result in medical errors, malpractice suits, low patient satisfaction, and poor care delivery. Hence, we aimed to systematically review studies reporting the prevalence of burnout in physicians in the radiology department and to provide an overview of the factors associated with burnout among radiologists.

#### **METHODS AND MATERIALS**

Searches were run from inception until November 13th, 2022, in multiple databases. This systematic review included studies that addressed the prevalence of burnout in radiologists of any sample size, using a valid method of assessment, reporting estimates of overall burnout syndrome or its subdimensions, and were cross-sectional, observational, or prospective survey peer-reviewed studies, without restrictions on publication time or language, following the PICOS framework. Data were extracted into a standardized Excel® sheet and descriptive statistics were generated by the same program.

#### **RESULTS**

Twenty-two cross-sectional studies involving 4230 radiology physicians in 7 countries published between 1996 and 2022 reporting on burnout were included. Fifteen studies (68.2%, n = 3181) were conducted in the United States. The studies had a range of participants from 26 to 460, with a median of 156 and an interquartile range of 89-265. Only 81.8% of the studies identified the gender of their sample, with 57.7% males and 42.3% females. The overall burnout prevalence estimates were reported by 13 studies (59.1%) and varied from 33% to 88%. High burnout prevalence estimates were reported by only 5 studies (22.7%) and ranged from 5% to 62%. Still, the prevalence estimates from these studies cannot be combined nor compared due to the variability in burnout assessment techniques, definitions, and outcomes, as well as statistical heterogeneity.

#### **CONCLUSION**

We identified 22 studies with a high degree of heterogeneity reporting prevalence estimates on burnout among radiologists. Burnout in radiology is increasing globally, with prevalence estimates reaching 88% and 62% for overall and high burnout, respectively, and a myriad of factors identified to be contributing to the increased prevalence. This data should be used as a starting point for discussion to evaluate and resolve these difficulties in the global radiology work environment.

#### **CLINICAL RELEVANCE/APPLICATION**

With the modest number of studies included and the significant methodological discrepancies, there is a need for further high-quality and methodologically robust studies conducted with standardization of burnout definition and assessment techniques.

#### **W5A-SPNPM-2 Exploring the Potential of Microsoft Bing Chatbot for Answering Patient Questions Regarding Radiologic Examinations and Procedures**

Participants

Ian Kuckelman, BS, MPH, Madison, WI (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the accuracy and completeness of AI chatbot responses to questions commonly asked by patients regarding radiologic examinations and procedures.

#### **METHODS AND MATERIALS**

We developed ten conversational-style questions for three common radiologic examinations and procedures (CT abdomen, MRI spine, and bone biopsy) and asked them to the Microsoft Bing Chatbot in two trials across three different settings, "More Creative", "More Balanced", and "More Precise". Two reviewers, one an attending radiologist with eight years of experience and the other a fourth-year medical student, independently compared the responses provided by the Chatbot to a gold-standard resource—radiologyinfo.org—and rated them for accuracy and completeness on a scale of 1-3, (1-incorrect/incomplete, potentially harmful; 2-mostly correct/complete, unlikely to cause confusion or harm; and 3-entirely correct/complete). Descriptive statistics were calculated. Differences in accuracy and completeness ratings were compared by chatbot setting and exam type with a Kruskal-Wallis test. Inter-rater reliability was assessed using Cohen's kappa statistic.

#### **RESULTS**

Of the 180 total responses collected, 166 (92%) were rated as "entirely correct" and 14 (8%) as "mostly correct". For

completeness, 119 responses (66%) were rated "complete" and 61 (34%) "mostly complete." Both reviewers rated all responses as either "entirely correct/complete" or "mostly correct/complete", with no responses rated as "inaccurate" or "incomplete" by either reviewer. Neither completeness nor accuracy differed significantly by chatbot setting or exam type. Inter-rater agreement was moderate with a Kappa of 0.66.

## CONCLUSION

Our study shows that the Microsoft Bing Chatbot has potential as a tool for patient education regarding radiologic examinations and procedures. Directing patients to this online resource represents a potentially cost-effective way for health systems and providers to provide patients with important information regarding how to prepare for a procedure, as well as reduce patient anxiety and improve overall experience. Limitations include potential variability of responses based on question phrasing and the omission of important information not explicitly requested.

## CLINICAL RELEVANCE/APPLICATION

AI-powered chatbots show potential as a tool for patient education associated with radiologic examinations and procedures.

### W5A- SPNPM-3 **Can ChatGPT Answer Questions about Lung Cancer and Screening**

Participants

Hana Haver, MD, (*Presenter*) Nothing to Disclose

## PURPOSE

The recent surge of worldwide interest in dialogue-based artificial intelligence (AI) large language models (LLM) such as ChatGPT is prompting evaluation of information available on such platforms. Early studies have found that ChatGPT provides generally appropriate clinical recommendations in areas ranging from cardiovascular disease, antibiotic selection for infectious diseases and breast cancer. Lung cancer remains a leading cause of death in the United States, so we sought to evaluate how ChatGPT would respond to fundamental questions about lung cancer prevention, screening and the Lung CT screening Reporting and Data System (Lung-RADS).

## METHODS AND MATERIALS

In February 2023, we submitted 25 questions to ChatGPT and asked it to generate three answers, as inconsistencies among answers are reported. Three fellowship-trained cardiothoracic radiologists graded each set of responses based on clinical judgment as 1) "appropriate," 2) "inappropriate," or 3) "inconsistent" if the responses contained inappropriate or varied information, respectively. Final appropriateness for each set was determined by the majority of reviewer responses, which were summarized using descriptive statistics.

## RESULTS

ChatGPT-generated responses were determined to be appropriate for 76% (19/25) questions in both contexts by three fellowship-trained cardiothoracic radiologists. Four of 25 (16%) generated responses were characterized as inappropriate and 2/25 (8%) as inconsistent in both hypothetical contexts (Table 1). Inappropriate and inconsistent responses were related to lung cancer screening indication and frequency as well as those related to the Lung-RADS lexicon.

## CONCLUSION

ChatGPT demonstrates the potential to automate provision of healthcare information related to lung cancer prevention and screening. ChatGPT performed more poorly on topics about lung cancer compared to previous reports on clinically appropriate information to questions about cardiovascular disease and breast cancer. This difference could be due to lack of information about lung cancer versus cardiovascular disease in the model's training dataset. Radiologist oversight remains critical, given the inappropriate and inconsistent radiology-specific information. Future study of applications for LLMs to improve healthcare education and counseling is encouraged.

## CLINICAL RELEVANCE/APPLICATION

ChatGPT generates largely appropriate answers to questions about lung cancer prevention and screening, though gaps remain in specific radiology topics and physician oversight remains imperative.

## Abstract Archives of the RSNA, 2023

W5A-SPNR

### Neuroradiology Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPNR- Assessment for Carotid Atherosclerotic Plaque using Vessel Wall Magnetic Resonance Imaging: A Multi-reader ROC Study to Determine Optimal Sequence for Detecting Vessel Wall Calcification**

#### PURPOSE

We aimed to compare conventional vessel wall MR imaging techniques and quantitative susceptibility mapping to determine the optimal sequence for detecting carotid artery calcification.

#### METHODS AND MATERIALS

Twenty-two patients who underwent carotid vessel wall MR imaging and neck CT were enrolled. Four slices of 6-mm sections from the bilateral internal carotid bifurcation were subdivided into 4 segments according to clock position (0-3, 3-6, 6-9, and 9-12) and assessed for calcification. Two blinded radiologists independently reviewed a total of 704 segments and scored the likelihood of calcification using a 5-point scale on T1-, T2-, PD-weighted imaging, the first echo-time images of FLASH, and quantitative susceptibility mapping. Quantitative susceptibility mapping was calculated using phase images of FLASH. The observer performance for detecting calcification was evaluated by a multireader, multiple-case receiver operating characteristic study. Weighted  $\kappa$  statistics were calculated to assess interobserver agreement with respect to calcification scoring.

#### RESULTS

Quantitative susceptibility mapping had a mean area under the receiver operating characteristic curve of 0.85, which was significantly higher than that of any other sequence ( $p < 0.01$ ) and showed substantial interreader agreement ( $\kappa = 0.68$ ). When a segment with a score of 3-5 was defined as positive and a segment with a score of 1-2 was defined as negative, the sensitivity and specificity of QSM were 0.75 and 0.87, respectively.

#### CONCLUSION

Quantitative susceptibility mapping was the most reliable MR sequence for the detection of plaque calcification.

#### CLINICAL RELEVANCE/APPLICATION

A low signal on quantitative susceptibility mapping is a reliable marker of carotid plaque calcification.

#### **W5A-SPNR- Contribution of Cerebral Microbleeds and Sleep Quality to Persistent Post-concussive Working-Memory Decline Through Glymphatic Clearance Dysfunction**

Participants

Yung-Chieh Chen, MD, PhD, Taipei, Taiwan (*Presenter*) Nothing to Disclose

#### PURPOSE

Cerebral microbleeds (CMBs) and sleep disorders are linked to persistent cognitive decline after a concussion (mild traumatic brain injury, mTBI). However, the pathomechanism is not fully understood. We hypothesized that the inefficient glymphatic clearance function may contribute to prolonged working-memory dysfunction, which may be partially attributed to both poor sleep and concussion-related CMBs.

#### METHODS AND MATERIALS

We conducted a 1-year prospective magnetic resonance imaging (MRI) and neuropsychological study on patients with concussion (N=61) and demographically matched controls (N=61). Susceptibility-weighted MRI was used to detect CMBs. The diffusion tensor imaging analysis along the perivascular space (DTI-ALPS) index was used to evaluate glymphatic function. The Pittsburgh sleep quality index (PSQI) and digit span (DS) scores were employed to assess participants' sleep quality and working memory, respectively. The baseline DTI-ALPS index, PSQI scores, and the demographic data were used to train the machine learning-based model to predict the 1-year DS score.

#### RESULTS

Patients with CMBs demonstrated a lower DTI-ALPS index compared with patients without CMBs and controls. Additionally, patients demonstrated poorer sleep quality than controls. The 1-year DS score was significantly correlated with both glymphatic diffusivity (DTI-ALPS;  $r=0.592$ ,  $p<0.001$ ) and sleep quality (PSQI;  $r=-0.551$ ,  $p<0.001$ ) assessed at baseline. Potential baseline biomarkers, such as the number of CMBs, DTI-ALPS index, and PSQI score, the confounding factors, including age, sex, education level, and duration from injury to MRI, were employed as the potential feature factors to predict long-term working memory function (1-year DS score). We then developed several machine learning-based models using the key features selected by the Lasso method to predict the DS score at the 1-year follow-up. Among the models, the Gaussian Process Regression method yielded the best predictions of the 1-year DS score, with an  $R^2$  value of 0.78 and a root-mean-squared error of 2.8827.

#### CONCLUSION

s CMB and poor sleep quality are contributing factors for glymphatic dysfunction, as measured using the DII-ALPS index, and related to persistent postconcussive working-memory impairment. Our systematic analyses not only further our understanding of glymphatic dysfunction after concussion but also provide a framework for precise and personalized predictions of protracted cognitive decline.

#### **CLINICAL RELEVANCE/APPLICATION**

The study highlights the importance of monitoring sleep quality and glymphatic function in patients with concussion, and suggests a potential therapeutic target for preventing persistent cognitive dysfunction after concussion.

#### **W5A-SPNR- Magnetic Resonance Imaging in Traumatic Brain Injury Patients and Associations with In-hospital Outcomes: Analysis of a National Representative Sample** 12

##### **PURPOSE**

Magnetic Resonance Imaging (MRI) has gained increasing attention due to its superior ability to visualize brain tissue injury. Several studies have demonstrated the superior diagnostic accuracy of MRI compared to computed tomography (CT) which is the most used imaging modality in the acute setting. The presence of intracranial hemorrhage has been associated with poor outcomes in traumatic brain injury patients. Therefore, the appropriate use of imaging modalities is crucial in predicting outcomes and providing optimal care. We aim to study the use of MRI in Traumatic Brain Injury (TBI) patients and their associations with in-hospital outcomes.

##### **METHODS AND MATERIALS**

The National Inpatient Sample (NIS) was queried for MRI use, discharge disposition, length of hospital stays, intracranial hemorrhage, and in-hospital mortality among those with TBI in 2015. The effect of MRI use on these endpoints was evaluated using bivariate and multivariate regression analysis independently, controlling for significant baseline differences in demographics, comorbidities, and hospital status.

##### **RESULTS**

A total of 45293 patients admitted with a diagnosis of TBI were included in this study. 25.7 %, 35.6%, 24.0%, and 14.6% of the patients were in age groups 20-40, 40-65, 65-80, and >80, respectively. 55% of the patients were female. 58% were Whites, while Hispanic, Black, and other races accounted for 17%, 14%, and 9%, respectively. In the unadjusted analysis, inpatient CT brain was associated with lower rates of mortality (unadjusted OR 0.657, 95% CI 0.163-2.651) compared to those who did not have a CT scan. Inpatient CT use was also associated with lower odds of short hospital stays (unadjusted OR 0.810, 95% CI 0.729-0.900) compared to those who did not. After adjusting for confounders, MRI and CT use was not significantly associated with in-hospital mortality, discharge disposition, length of stay, or inpatient complications.

##### **CONCLUSION**

s We present that there seems to be no difference in inpatient outcomes and complications when MRI is used in the evaluation of traumatic brain injuries. Clinical decision-making regarding the use of MRI versus CT scan in TBI patients should be based on the severity of the injury and clinical presentation. Further research is needed to explore the long-term outcomes.

#### **CLINICAL RELEVANCE/APPLICATION**

The clinical relevance of comparing MRI use versus CT scan in TBI patients lies in the potential to improve in-hospital outcomes. The appropriate imaging modality can provide accurate and timely diagnosis, which can lead to better treatment decisions and improved patient outcomes. Understanding the associations between these imaging modalities and in-hospital outcomes can aid in clinical decision-making and lead to better patient care.

#### **W5A-SPNR- Quantitative Analysis of Calcification in Cerebral Microvasculature by Micro-computed Tomography** 13 (microCT)

##### **PURPOSE**

Vascular calcification (VC) is a predictor of both cardiovascular and cerebrovascular events. While it is known that coronary VC results in impaired vasomotor response and reduced myocardial perfusion, less is known about the prevalence and impact of VC in brain microcirculation. We examined the distribution of intracranial calcification in a cohort of human cadavers using micro-computed tomography (microCT). We aimed to exhibit the feasibility of quantifying calcification volume (CV) in cadaveric brain vasculature using microCT and apply this method to compare CV across brain regions in which VC has been incidentally noted in case studies.

##### **METHODS AND MATERIALS**

In a cohort of elderly human donor cadavers with and without dementia documented at time of death, brain tissue was sampled bilaterally from basal ganglia (BG), substantia nigra (SN), subventricular zone (SVZ), hippocampus (Hc), and posterior cingulate cortex (PCC). Samples were scanned by microCT at 10  $\mu$ m resolution. 3D-reconstructed images were segmented into standardized regions of interest (ROI) and thresholded at the level of calcium detection (130 Hounsfield units). CV was defined as voxel quantity  $\geq$ 130 HU within each ROI; CVs exceeding .01% per ROI were considered "positive". Findings were confirmed by histologic evaluation using Alizarin red calcium-binding stain.

##### **RESULTS**

All subjects exhibited parenchymal and/or vascular calcification in at least one region. Calcification volume exceeding .01% per ROI for the no dementia cohort (n=6) was 83% globus pallidus (GP), 66% SN, 17% SVZ, 17% Hc, and 33% PCC compared to the dementia cohort (n=6) which was 100% GP, 33% SN, 50% SVZ, 100% Hc, and 100% PCC. Prevalence of Hc and PCC was significantly greater in subjects with documented dementia compared to age-matched subjects (n=12, p<0.01).

##### **CONCLUSION**

s Our findings demonstrate the utility of microCT for quantifying CV in human brain tissue. All subjects exhibited calcification in at least one brain region, indicating that intracranial calcification is more prevalent than published estimates (~30% in general population). Consistent with the literature, VC was most prevalent in the GP. Subjects with dementia exhibited significantly higher Hc and PCC CVs than age-matched subjects without dementia. This finding supports recently published evidence of increased Hc

and BG calcification in human cadaveric brains with Alzheimer's disease relative to age-matched controls. Expansion of our study cohort remains ongoing in order to further investigate this relationship.

#### **CLINICAL RELEVANCE/APPLICATION**

Analyzing the patterns of VC in cerebral vasculature using microCT can aid in the development of therapeutics against cerebrovascular and neurodegenerative diseases.

#### **W5A-SPNR- Geometric versus Hemodynamic Indexes for Rupture-destined Aneurysms: A Retrospective Cohort and a Repeated-measures Study** 14

##### **PURPOSE**

A proper stratification of intracranial aneurysms is critical in identifying rupture-destined aneurysms and unruptured intracranial aneurysms. We aimed to determine the utility of geometric and hemodynamic indexes in differentiating two types of aneurysms, and to examine the characteristics of natural evolutionary changes of unruptured aneurysms.

##### **METHODS AND MATERIALS**

Rupture-destined aneurysms was defined as having subsequent SAH, and unruptured intracranial aneurysms was examined using follow-up TOF-MRA. In addition to geometric indexes, signal intensity gradient, an in-vivo approximated wall shear stress from TOF-MRA, was measured in aneurysms. The difference between the maximum and minimum values of signal intensity gradient in an aneurysm compared to parent arterial values was designated as delta-signal intensity gradient ratio.

##### **RESULTS**

This study analyzed 20 rupture-destined aneurysms in 20 patients and 45 unruptured intracranial aneurysms in 41 patients with follow-up TOF-MRA. While geometric indexes did not show differences between the two groups, the delta-SIG ratio was higher in the rupture-destined aneurysms ( $1.5 \pm 0.6$  vs.  $1.1 \pm 0.3$ ,  $P=0.032$ ). The delta-signal intensity gradient ratio showed a higher area under the receiver operating characteristics curve for SAH than the size ratio ( $0.72$  [95% CI,  $0.58-0.87$ ] vs.  $0.56$  [95% CI,  $0.41-0.72$ ],  $P=0.033$ ). The longitudinal re-examination of TOF-MRA in the unruptured intracranial aneurysms showed evidence of aneurysmal growth with hemodynamic stability.

##### **CONCLUSION**

s The delta-signal intensity gradient ratio showed higher discriminatory results between the two groups compared to geometric indexes. Aneurysmal rupture risk should be assessed by considering both geometric and hemodynamic information.

#### **CLINICAL RELEVANCE/APPLICATION**

The study's findings have clinical implications for the management of intracranial aneurysms, as the early identification of RDAs can help prevent catastrophic hemorrhage. The use of hemodynamic information, in addition to geometric indexes, can aid in the proper categorization of aneurysms and assessment of rupture risk. The study also highlights the importance of longitudinal re-examination of UIAs to track changes in geometry and hemodynamics over time. The study found evidence of aneurysmal growth with hemodynamic stability in the UIA group, indicating the need for regular follow-up imaging to monitor changes and assess rupture risk. Overall, the study's findings suggest that the delta-SIG ratio may be a useful marker for differentiating between RDAs and UIAs, and that a comprehensive assessment of both geometric and hemodynamic information is necessary for the proper management of intracranial aneurysms.

#### **W5A-SPNR- Cerebral Artery Wall Shear Stress and Clinical Outcome in Lenticulostriate Infarction: A Retrospective Cohort Study** 2

##### **PURPOSE**

There is no previous study for a relationship between cerebral arterial wall shear stress and a clinical outcome in lenticulostriate infarction. We aimed to investigate whether the signal intensity gradient (SIG), as a surrogate marker of wall shear stress, from Time-of-Flight Magnetic Resonance Angiography (TOF-MRA) in cerebral arteries is associated with a functional independence.

##### **METHODS AND MATERIALS**

This multicenter, retrospective cohort study design enrolled 294 patients with lenticulostriate infarction from January 2015 to March 2021 at three stroke centers in Korea. A favorable clinical outcome was defined as the modified Rankin Scale 0-2 at the seventh day or discharge. The arterial SIG were measured concurrently in both internal carotid, anterior/middle/posterior cerebral, vertebral arteries, and one basilar artery (BA) from TOF-MRA which was performed in acute stage.

##### **RESULTS**

Among the enrolled patients, 148 (50.3%) were allocated as the favorable outcome. The favorable outcome group showed mean values of SIG in the BA as  $8.7 \pm 2.7$  SI/mm, while the unfavorable group showed  $7.2 \pm 2.2$ ,  $P < 0.001$ . The mean values of SIG in the BA were associated with the favorable outcome, showing odds ratio of 1.20 and 95% confidence intervals 1.06-1.37,  $P = 0.005$ . All other cerebral arteries except posterior cerebral arteries showed associations between arterial SIG and the favorable outcome.

##### **CONCLUSION**

s Cerebral arterial SIG showed independent associations with clinical outcome in patients with lenticulostriate infarction. Future studies are needed for a feasibility of generalization in different races and ethnicities, and for other subtypes of ischemic stroke.

#### **CLINICAL RELEVANCE/APPLICATION**

This finding suggests that whole cerebral arterial perfusion might be important to keep patients functionally improving. As far as the authors are aware, there has been no study evaluating the relationship between the measured hemodynamic values of all major cerebral arteries and the clinical prognosis in patients with ischemic stroke. We hope that this study will serve as a culprit to study the pathogenesis and progression of lenticulostriate infarction from a different perspective.

#### **W5A-SPNR- Increased Risk of Subsequent Stroke in Emergency Department TIA Encounters with Incomplete Neurovascular Imaging** 3

## PURPOSE

Multisociety guidelines recommend urgent brain and neurovascular imaging in patients with transient ischemic attack (TIA) within 48 hours to identify and treat modifiable risk factors for stroke. Prior research has suggested that a majority of patients with TIA presenting to the emergency department (ED) do not receive prompt neurovascular imaging. The purpose of this study was to examine the association between incomplete neurovascular imaging during a TIA encounter and risk of subsequent ischemic stroke.

## METHODS AND MATERIALS

We identified Medicare beneficiaries discharged from EDs with a TIA diagnosis using the 100% standard analytic files between 2016-2017 and International Classification of Diseases 10th Edition (ICD-10) codes. Imaging performed during the ED encounter was identified using current procedural terminology codes. Patients with incomplete neurovascular imaging were defined as missing either all or a component of a brain and neck cross-sectional vascular imaging exam within 48 hours of their initial ED encounter. The association between incomplete neurovascular imaging during the TIA encounter and outcome of ischemia stroke over subsequent 90 days was tested in a multivariable logistic regression model, adjusting for patient demographics, comorbid disease severity, socioeconomic indicators, and hospital-level factors.

## RESULTS

107,730 beneficiaries were discharged from EDs with a TIA diagnosis during the study period. Within 48 hours of the ED encounter, 41,110 (38.2%) of patients had an incomplete neurovascular imaging work-up. New stroke diagnoses within 90 days of the ED TIA encounter were observed in 4.4% (2,900/66,620) of patients who received neurovascular imaging, compared with 7.0% (2,873/41,110) of patients with incomplete neurovascular imaging. Incomplete neurovascular imaging was associated with higher odds of ischemic stroke within 90 days (OR 1.3 [95% CI: 1.22-1.38]) as was receiving care at rural (OR 1.41 [95% CI: 1.26-1.58]) and small hospitals < 100 beds (OR 1.35 [95% CI: 1.19-1.52]), and residing in the lowest income quartile counties (OR 1.12 [95% CI: 1.02-1.23]).

## CONCLUSION

TIA encounters with incomplete neurovascular imaging are associated with higher odds of subsequent stroke within 90 days.

## CLINICAL RELEVANCE/APPLICATION

Increasing access to urgent neurovascular imaging in the TIA population may be an area to target to help detect and treat modifiable risk factors for stroke.

## W5A-SPNR- Predictors of Positive Remodeling in Patients with Acute Ischemia Stroke

4

### PURPOSE

The aim of this study was to compare the differences in the culprit plaques characteristics between positive remodeling (PR) and non-positive remodeling (NPR) patterns in patients with acute ischemia stroke (AIS), and to evaluate potential relative risk factors for PR of intracranial atherosclerosis (ICAS).

### METHODS AND MATERIALS

Patients with AIS recruited and underwent the HR-VWI scan within 2 weeks after onset. Plaque morphological parameters, as well as clinical variables of both PR and NPR groups were compared using non-parametric tests. A binary logistic regression model was used to analyze the parameters promoting the development of PR, and further determine the independent predictors of PR. The sensitivity and specificity of the model were tested by receiver operating characteristic curve.

### RESULTS

In all, 84 eligible patients (mean age 58.07±1.35 years, 66 (78.6%) were male) were assigned to the PR (n=28, 33.3%) or NPR (n=56, 66.4%) group according to remodeling ratio (RR). Compared with the NPR group, the PR group had a greater plaque area (P<0.001), greater wall area (WA) (P<0.001), longer plaque length (P=0.018), larger RR (P<0.001), higher blood glucose (P=0.01) and a greater number of HBP (P=0.16). Binary Logistic regression analysis showed that plaque area was independently associated with PR (OR 3.71, 95% CI, 1.49-9.24).

### CONCLUSION

HR-VWI can identify positive remodeling in ICAS with large plaque area, suggesting a high burden of intracranial vascular lesions and promoting PR.

### CLINICAL RELEVANCE/APPLICATION

To evaluate the effect of plaque morphological properties and clinical parameters on cerebrovascular remodeling patterns to improve the classification of cardiovascular risk.

## W5A-SPNR- Early Brain Amyloid Accumulation on PET in Military Instructors Exposed to Sub-concussive Blast Injuries

5

### PURPOSE

Traumatic brain injury (TBI) is the leading cause of disability in young adults. Recurrent TBI is associated with a wide range of neurologic sequelae, but the contributing factors behind the development of such chronic encephalopathy are poorly understood. Purpose: To quantify early amyloid beta (A $\beta$ ) deposition in the brain of otherwise healthy adult men exposed to repeated subconcussive blast injury using amyloid PET.

### METHODS AND MATERIALS

In this prospective study from January 2020 to December 2021, military instructors routinely exposed to repeat blast events were evaluated at two different time points: baseline, prior to blast exposure from breacher or grenade, and approximately 5 months after baseline, after blast exposure. Age-matched healthy controls not exposed to blasts and without a history of prior brain injury were evaluated at similar two time points. Neurocognitive evaluation was performed with standard neuropsychological testing for both groups. Analysis of PET data consisted of SUV measurements in six relevant brain regions, and whole brain voxel-based

statistical approach.

## RESULTS

All participants were men (9 controls, 9 blast-exposed). The median age of the controls was 33 years.; IQR: [32, 36]. That of the blast-exposed group was 33; IQR: [30, 34] ( $p=0.824$ ). In the latter, four brain regions showed significantly increased amyloid deposition after blast exposure: infero-medial frontal lobe, precuneus, anterior cingulum and superior parietal lobule (P values=0.004, 0.02, 0.002, and 0.003 respectively). No amyloid deposition was observed in the controls. Discriminant analysis based on regional changes of amyloid accumulation correctly classified all 9 healthy controls as a healthy controls (100%) and 7 of the 9 blast-exposed (78%) as a blast-exposed. Based on the above voxel-based analysis, whole brain parametric maps of early abnormal early amyloid uptake were obtained. Conclusion: Early brain amyloid accumulation was identified and quantified on PET in otherwise healthy adult men exposed to repetitive subconcussive traumatic events.

## CONCLUSION

Early brain amyloid accumulation was identified and quantified on PET in otherwise healthy adult men exposed to repetitive subconcussive traumatic events.

## CLINICAL RELEVANCE/APPLICATION

Our results might have direct clinical implications; if the individuals that are at risk of developing amyloid-related neurotoxicity can be identified, therapies to clear A $\beta$  in the brain might reduce or slow the development of long-term secondary traumatic encephalopathy.

## W5A-SPNR- Dynamic Changes of Intrinsic Brain Activity in Acute Carbon Monoxide Poisoning

6

### PURPOSE

To investigate the dynamic changes of intrinsic brain activity in acute carbon monoxide (CO) poisoning patients using dynamic amplitude of low-frequency fluctuation analysis (dALFF).

### METHODS AND MATERIALS

28 CO poisoning patients and 26 healthy controls (HC) with similar educational backgrounds and handedness were recruited. MRI scans were performed on a Siemens Magnetom Prisma 3.0 tesla scanner. Clinical cognitive function was evaluated by Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment Basic (MoCA-B). We examined the dALFF differences between patients and HCs, as well as correlations between dALFF and cognitive function scores.

### RESULTS

Compared to HC, elevated dALFF in left superior frontal gyrus (SFG), left medial frontal gyrus (MFG), and left supplementary motor area (SMA) were identified in CO poisoning group. Additionally, static ALFF analysis identified lowered intrinsic brain activity in left inferior occipital gyrus in CO poisoning group. dALFF values in left superior frontal gyrus were negatively correlated to MoCA-B scores in CO poisoning group.

### CONCLUSION

Our results revealed that increased instability of intrinsic brain activity were present in patients suffering from carbon monoxide poisoning. Variance of dALFF in prefrontal cortex was associated with cognitive ability in patients with CO poisoning.

### CLINICAL RELEVANCE/APPLICATION

The findings of current study may deepen the understanding of neurobiological mechanism of CO poisoning and provide possible additional radiological diagnosis approach to carbon monoxide poisoning and related cognitive impairment.

## W5A-SPNR- Optimizing Traumatic Brain Injury Prognosis Prediction: Leveraging Machine Learning with CT Imaging and GFAP/UCH-L1 Blood Biomarkers

7

Participants  
Burak Ozkara, MD, Houston, TX (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study was to develop an interpretable machine learning (ML)-based predictive model that combines clinical variables, blood biomarkers, and imaging biomarkers to improve the prognostic prediction, triage management, and treatment strategy in traumatic brain injury (TBI) patients.

### METHODS AND MATERIALS

In this retrospective cohort study, 662 patients transported to the emergency department with a trauma alert and suspected TBI were screened. Data extraction from electronic medical records included demographic and clinical information. Blood samples were collected and analyzed for GFAP and UCH-L1 using a sandwich enzyme-linked immunosorbent assay. Non-contrast head CT scans were assessed by neuroradiologists for TBI common data elements (CDEs). The collected data was used as input for the ML models. Three outcomes were designed to predict: discharged or admitted for further management (prediction 1), in hospital mortality (prediction 2), and course of hospital stay (prediction 3). Machine learning models, including XGBoost, Random Forest, decision tree, support vector machines, and logistic regression, were trained using the training sets to compare their performances. Cross-validation and hyperparameter tuning were employed. SHapley Additive exPlanations (SHAP) values were used to evaluate the relative significance of predictor factors.

### RESULTS

A total of 440 patients were finally included. Random Forest models achieved the best performance. For prediction 1 (discharged or admitted for further management), the test set accuracy was 0.95, and the Kappa value was 0.88. For prediction 2 (deceased or not deceased), the accuracy was 0.98, with a Kappa value of 0.49. In prediction 3 (admission only, prolonged stay, or neurosurgery performed), the Random Forest model achieved an accuracy of 0.82 and a Kappa value of 0.72 during the testing phase. SHAP analyses showed that the three most important features for prediction 1 were other major extracranial injury, hemorrhage, UCH - L1. The top three features for prediction 2 were Glasgow Coma Scale, age, GFAP. GFAP, subdural hemorrhage

volume, and pneumocephalus were the five most significant features for prediction 3.

## CONCLUSION

Our study demonstrates the potential of ML models in predicting the hospital course and mortality of TBI patients using non-contrast CT CDEs and blood biomarkers GFAP and UCH - L1. Blood biomarkers like GFAP and UCH - L1 were among the significant variables for prediction, demonstrating the originality of our study.

## CLINICAL RELEVANCE/APPLICATION

These models may help physicians tailor individualized care plans and provide more accurate prognostic information for patients.

## W5A-SPNR- Asymmetric Cerebral Perfusion Abnormalities are Hallmark in Chronic Traumatic Brain Injury Imaging 8

Participants

Farzaneh Rahmani, MD, MPH, Saint Louis, MO (*Presenter*) Nothing to Disclose

## PURPOSE

Advanced MRI methods identify biomarkers of grey or white matter damage including perfusion defects, diffusion abnormalities or atrophy. These biomarkers might improve sensitivity for detection of chronic traumatic brain injury (TBI), even when acute evidence of the insult are subtle or absent on conventional imaging sequences.

## METHODS AND MATERIALS

Sixty-seven participants (29 men and 38 women, age: 47.1±13.5) with a history of traumatic brain injury were enrolled from individuals referred to the Neuroevolution LLC. under IRB exemption #Pro00071328. Participants were required to be at least 18 years old and have a T1-weighted brain MRI acquired within 3 months of the date of injury. Additionally, 60 participants (26 men and 34 women, age:47.8±13.1) had arterial spin labeling (ASL) perfusion and 55 had diffusion MRI (dMRI) scans available. Volumetric assessments were done using the Neuroreader program which is FDA-cleared, yielding absolute, normalized and standardized volumes for 83 cortical and subcortical brain structures. The Neuro Reader index (NR-index was defined as the regional z-score divided by the size of the normative database, while the left-right asymmetry scores were calculated as described in prior work. ASL-MRICloud was used to extract relative regional cerebral blood flow (rCBF) and their respective z-score maps. Abnormal white matter (WM) fractional anisotropy (FA) was identified through comparison of automated ROI defined regions to age and sex-matched references.

## RESULTS

Regions with highest prevalence of abnormal NR-index included the bilateral cerebellar grey matters, lateral ventricles, pallidi and the right temporal lobe. Significant left-right asymmetry was seen in the frontal lobes in 31%, in parietal lobes in 25%, in occipital lobes, and in temporal lobes in 31% of the participants, while the pallidi were most likely to demonstrate left-right asymmetry among subcortical regions. Similarly, Figure 1 demonstrate a significant left-right asymmetry in the average perfusion z-score map of all participants, with a distinct right frontal: left parietal, coup-contrecoup pattern. WM FA was found to be abnormally low (<-2 z-score) in 7.3% and 9.1% of participants in the right and left internal capsules. Rate of FA abnormality was even lower in the splenium (3.6%) and genu (1.8%) of IC, right and left parietal WM (0% AND 3.6), and right and left frontal WM (1.8% and 0%).

## CONCLUSION

Asymmetric abnormalities in brain perfusion are common in chronic post TBI setting and their prevalence exceeds those of volumetric or diffusion abnormalities.

## CLINICAL RELEVANCE/APPLICATION

This work establishes the added importance of advanced neuroimaging techniques, namely perfusion imaging, in identifying evidence of chronic TBI.

## W5A-SPNR- Differences in Corpus Callosum White Matter Integrity in mTBI Patients with and without PTSD Comorbidity 9

Participants

Priya Santhanam, PhD, Olney, MD (*Presenter*) Nothing to Disclose

## PURPOSE

This study aims to compare corpus callosum diffusion tensor imaging (DTI) findings in mild traumatic brain injury (mTBI) patients who presented either with or without post-traumatic stress disorder (PTSD) symptomology.

## METHODS AND MATERIALS

DTI and clinical data were obtained from retrospective chart review of 451 civilian patients (mean age 43 years, range 13-82) with clinically diagnosed mTBI. Patients were identified as having PTSD if presenting with signs and symptoms consistent with the Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-V) diagnostic criteria. The corpus callosum and its subregions (anterior/inferior, anterior, mid-body, posterior, posterior-inferior) were defined by hand tracing in Olea Sphere (v3.0 SP12). Fractional anisotropy (FA) values were compared between patients with mTBI only and those with mTBI+PTSD by Mann-Whitney U test.

## RESULTS

FA was lower in patients with mTBI+PTSD as compared to those with mTBI only in the corpus callosum overall and within all subregions. Statistical comparisons between groups found FA was significantly lower in the whole corpus callosum ( $p < 0.001$ ) as well as in the anterior/inferior ( $p = 0.003$ ), anterior ( $p < 0.001$ ), mid-body ( $p = 0.006$ ), posterior ( $p = 0.007$ ), and posterior/inferior ( $p = 0.017$ ) subregions individually.

## CONCLUSION

Patients with mTBI and comorbid PTSD had reduced white matter integrity across the corpus callosum. While the contribution of PTSD to brain injured patients is not well-understood, some prior research indicates a possible influence of PTSD in military TBI

populations. Further examination is needed to determine any mechanism for concomitant trauma and PTSD in civilian patients.

**CLINICAL RELEVANCE/APPLICATION**

White matter integrity in the corpus callosum of trauma patients may be further compromised for those with mTBI and PTSD comorbidity.

### OB/Gynecology and Pediatric Imaging Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPOB- Black Hole Pattern on Diffusion Weighted Images (DWI) May Help Predict Placental Invasiveness in Women at High Risk for Placenta Accreta Spectrum (PAS) Disorders**

##### Participants

Charis Bourgioti, MD, Athens, Greece (*Presenter*) Nothing to Disclose

##### PURPOSE

To quantify placental inhomogeneity using 'black hole' pattern on diffusion weighted imaging (DWI) in women at high risk for placenta accreta spectrum (PAS) disorders; to investigate its predictive ability for presence and degree of placental invasiveness.

##### METHODS AND MATERIALS

Between 3/2018 and 9/2022, 59 pregnant women underwent dedicated prenatal MRI for placental evaluation with a 3.0T unit. All women underwent C-section within 6 weeks from MRI. DWI data were prospectively compiled for review by two experienced genitourinary radiologists and manual placental segmentation for each participant was performed. Black hole, a pattern previously observed by the readers only on high b value DWI, was defined by consensus as a discrete intraplacental areas of signal loss on high b value (1500) images. A semi-automated algorithm using 28.70 as a threshold pixel value was applied to locate placental holes and calculate the total number of placental voxels (3D), total number of hole voxels, volume of hole voxels (mm<sup>3</sup>) and % of hole voxels/total placental voxels. Statistical analysis was performed for possible association of the above parameters with presence and grade of PAS. Intraoperative/histological findings were the standard of reference. Statistical significance (p) was set to 0.05.

##### RESULTS

Fifty women (mean age:37 years, mean gestational age:33 weeks) were evaluable and formed the study group. Significant differences were detected between normal placenta and presence of PAS regarding the total number of placental voxels (p=0.02), number of hole voxels (p=0.02) and volume of holes (p=0.03). Total number of hole voxels and hole volume were significantly lower in normal placentas than in accreta/increta (grade I/II, p=0.04, p=0.04) or percreta (grade III, p=0.005, p=0.01) cases. No differences were detected in the above parameters for PAS grading.

##### CONCLUSION

s Total number of voxels and volume of intraplacental black holes on DWI, may serve as yet another prognosticator for PAS disorders.

##### CLINICAL RELEVANCE/APPLICATION

Quantification of placental inhomogeneity on functional MRI may enable the development of deep learning algorithms for predicting PAS disorders.

#### **W5A-SPOB- Evaluating Fetal Bowel Wall Function by Ultrasound Microvascular Flow Imaging**

2

##### PURPOSE

This study summarized the characteristics of fetal mesenteric blood flow perfusion at various gestational weeks, and aimed to establish the feasibility of microvascular flow (MV-Flow) technology in evaluating intestinal wall blood flow and function.

##### METHODS AND MATERIALS

This retrospective study analyzed 35 meconium peritonitis (MP) fetuses and 160 healthy fetuses in our medical center from March 2020 to December 2022. The vascular index (VI) of superior mesenteric artery region obtained by automatic ellipse method and manual method were compared. The correlation between the region of interest VI and gestational weeks was analyzed. A subgroup analysis of MP operative group vs. MP non-operative group was performed, and a prediction model for surgical treatment was established.

##### RESULTS

There was no difference in VI value of the mesenteric blood perfusion region between automatic ellipse method and manual method (51.40±8.58% vs 50.82±8.05%, p=0.534). There was no significant change in VI as the gestational age increased (correlation coefficient=0.005, p=0.946). Compared with MP non-operative group, the operative group has significantly more cesarean deliveries (100% vs 52.9%, p=0.003), shorter pregnancy duration (34.76±2.16w vs. 37.48±1.55w, p<0.001), lower infant weight (2762.14±452.76kg vs. 3225.88±339.98kg, p=0.003), more persistent ascites cases (92.9% vs. 52.9%, p=0.021), more intestinal wall echo reduction cases (57.1% vs. 5.9%, p=0.004), and lower VI (18.57±5.51% vs. 39.41±7.02%, p<0.001). In risk factor analysis, VI value was significantly associated with surgical treatment after birth (OR=0.689;95% CI: 0.511-0.929). A prediction model for surgical treatment of newborns was established: Logit (P)=8.86 - (0.37\* VI) +(1.49\* ascites). The AUC of the ROC curve of the prediction model is 0.857 (95% CI: 0.75-0.95), with 78.6% sensitivity, and 88.2% specificity.

## **CONCLUSION**

s MV-Flow imaging can quantify the fetus bowel wall blood flow perfusion. There is no correlation between the VI value of mesenteric regional blood flow perfusion and gestational week. In fetuses with meconium peritonitis, the VI value of mesenteric blood flow is significantly reduced, suggesting the increased possibility of intestinal wall necrosis and post-natal surgical treatment.

## **CLINICAL RELEVANCE/APPLICATION**

The findings of the current study provide information about evaluating fetus bowel wall function using ultrasound MV-Flow imaging, which could improve the prenatal diagnosis of meconium peritonitis in the fetus, and predict surgical treatment after birth.

### Pediatric Imaging Wednesday Poster Discussions I

#### Sub-Events

#### W5A-SPPD- Usefulness of the Air Gap Methods during Pediatric Computed Tomography 1

##### Participants

Takanori Masuda, PhD, Okayama, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Purpose: The air gap methods can be used as the primary scatter reduction method in order to reduce patient dose. The purpose of this study was to compare the radiation dose and image noise between conventional setting and air gap setting methods during the pediatric chest computed tomography (CT).

##### METHODS AND MATERIALS

We used newborn pediatric anthropomorphic phantom with a 64 detector-row CT scanner with helical scan modes from the apex of the lung to the diaphragm. Compare with the conventional setting (group A), the pediatric anthropomorphic phantom was positioned 10 cm away from the table using a plastic with low X-ray absorption in air gap methods (group B). A real-time skin dosimeter (RD - 1000; TORECK CO, Kanagawa, Japan) was placed and inserted into the phantom center of the body, the surface of the body back, and the right and left mammary glands. The phantom was then scanned 10 times using each protocol. The measured dose values of the RD - 1000 were compared for each methods.

##### RESULTS

The measured dose values of the group A were 1.44 at the center, 1.46 at the back, and 1.64 at the mammary gland, respectively. The measured dose values of the group B were 1.30 at the center, 1.35 at the back, and 1.53 at the mammary gland, respectively. Compared with the Group A, it was possible to reduce the exposure dose by approximately 10% at the group B ( $p < 0.05$ ). The image noises were 9.3 HU at the group A and 8.0 HU at the group B. Compared with the Group A, it was possible to reduce the image noise by approximately 15% at the group B ( $p < 0.05$ ).

##### CONCLUSION

By using the air gap methods, it is possible to reduce the exposure dose and image noise approximately 10 % during pediatric chest CT.

##### CLINICAL RELEVANCE/APPLICATION

The reduction of the radiation dose and image noise according to the as low as reasonably achievable (ALARA) principle requires optimizing the scan protocol by using air gap methods.

Printed on: 04/12/24

W5A-SPPH

### Physics Wednesday Poster Discussions I

#### Sub-Events

#### **W5A-SPPH- Comparison of Conventional and Compressed SENSE Sequences on MRI of Brain in Paediatric Population** 1

##### **PURPOSE**

To compare the quality and image acquisition time between conventional and Compressed SENSE sequences on magnetic resonance imaging (MRI) of brain in paediatric population.

##### **METHODS AND MATERIALS**

Thirty children (below the age of 18 years) undergoing MRI of brain were included in this study after obtaining Ethical clearance from the institute. In addition to the routine clinical protocol for brain, one Compressed SENSE sequence was added. 2D - T1, T2, and FLAIR axial sequences were acquired for brain using conventional and Compressed SENSE techniques. One of each sequence was acquired in 10 patients undergoing an MRI brain study on a 3T MRI using coil 32 channel coil for adults and paediatric 8ch head coil for neonates. Two consultant radiologists (with 35 years and 5 years of experience in radiology) independently scored the image quality using the 5-point Likert scale based on resolution, visualisation of anatomical regions, grey-white matter differentiation, sharpness of the image and artefacts. The subjective criteria details for image quality as per the 5-point Likert scale were: non-diagnostic (1), poor (2), moderate (3), good (4) and excellent (5). 2D T1 sequence was acquired with parameters as FOV 230\*183\*130mm, voxel size 0.575\*0.75, TE-20ms, TR-2000ms, CS factor-2, 2D T2 sequence was acquired with parameters FOV 230\*230\*149mm, voxel size 0.55\*0.65, TE-3000ms, TR-80ms, CS factor-2.2 and 2D FLAIR was acquired with parameters FOV 210\*168\*149mm, voxel size 0.7\*1.42mm, TE-140ms, TR-11000ms, CS factor-2.

##### **RESULTS**

The time reduction achieved with 2D T1 at 2 reduction factor were 60 seconds(24%), with 2D T2 at reduction factor of 2.2 66 seconds(47.83%) and with 2D FLAIR at reduction factor 2 66 seconds(40%). Inter-rater agreement for overall diagnostic confidence was rated higher for Compressed SENSE (k - 0.632) than conventional (k - 0.464). Nonsignificant statistical difference was found regarding image quality and image contrast ratio between both techniques.

##### **CONCLUSION**

s Compressed SENSE has potential in reducing the image acquisition time without compromising the image quality and diagnostic confidence. Motion artefacts are also reduced with reduction in time with the use of Compressed SENSE sequence.

##### **CLINICAL RELEVANCE/APPLICATION**

Acceleration achieved with compressed SENSE sequences can cause an overall reduction in the acquisition time without compromising image quality. This consequently results in reduction of anaesthetic dose administered which is of clinical concern in paediatric population.

#### **W5A-SPPH- Preliminary Study on the Clinical Staging of Primary Lower Extremity Lymphedema by STIR Soft Tissue Radial Measurements** 10

##### Participants

MENGKE LIU, BEIJING, China (*Presenter*) Nothing to Disclose

##### **PURPOSE**

Exploring the value of magnetic resonance-based measurement of two-dimensional radial data of the limb in assessing the clinical staging of primary lower extremity lymphedema (PLEL)

##### **METHODS AND MATERIALS**

A retrospective collection of 132 patients diagnosed with primary LEL by our hospital was made, and all patients underwent MR examination of the lower extremities. Short Time Inversion Recovery (STIR) sequences were used to measure the total longitudinal and transverse soft tissue diameter (TD), musculoskeletal diameter (MD) and subcutaneous soft tissue diameter (S) of the lower leg, and the difference between TD and SD on the affected and the healthy side (DTD, DSD) were calculated respectively. The patients were staged according to the International Society of Lymphology (ISL) clinical staging criteria in 2020. Statistical analysis of all measurements was performed to determine the feasibility of MRI measurements for clinical staging of PLEL

##### **RESULTS**

The correlation between the transverse diameter TD (R=0.492), SD (R=0.596), DTD (R=0.608), and DSD (R=0.620) and clinical stage was significantly greater than that between the longitudinal diameter TD (R=0.430), SD(R=0.532), DTD (R=0.547), and DSD (R=0.519), and the highest correlation between the transverse diameter DSD and clinical stage. The values of TD, SD, DTD and DSD in stage I were significantly lower than those in stage II and III (P<0.05), but there was no significant difference between stage II and III (P>0.05). The area under the curve (AUC) of the transverse diameter to identify clinical stage was greater than

that of the longitudinal diameter, with the transverse DSD (AUC=0.930) having the highest AUC value to identify stage I with stage II.

## CONCLUSION

Based on the fact that MRI measurement of soft tissue trajectories can be used as a quantitative method for clinical staging of unilateral PLEL. We recommend the subcutaneous soft tissue difference of transverse diameter as the best measure to distinguish stage I from stage II lymphedema

## CLINICAL RELEVANCE/APPLICATION

MRI can quantitatively assess the severity of primary lower extremity lymphedema, facilitating clinical decision making and improving prognosis.

### W5A-SPPH- Radiomics Based on MRI to Distinguish between Stage I and II Primary Lower Extremity Lymphedema

Participants

MENGKE LIU, BEIJING, China (*Presenter*) Nothing to Disclose

## PURPOSE

A feasible and valid method for detecting and staging LEL would facilitate clinical development of appropriate treatment and management strategies. The present study aims to establish an MRI-based imaging radiomics model and a radiomics-clinical model for primary lower extremity lymphedema (LEL) and to evaluate its role in identifying the clinical stages (stages I-II) of primary LEL.

## METHODS AND MATERIALS

96 patients with primary LEL were retrospectively collected (67 in the training cohort and 29 in the validation cohort) and classified into stage I and II according to the International Society of Lymphology (ISL) clinical staging criteria. Radiomics features were extracted automatically from the region of interest (ROI) manually outlined on the Short Time Inversion Recovery (STIR) sequence images by radiologists applying the Dr. Wise Multimodal Research Platform. Selected radiomics features were retained to construct the radiomics model. Clinical factors that are statistically significant in identifying stages I and II were selected, and a radiomics-clinical model combining imaging radiomics features and significant clinical factors was established. The performance of the two models was evaluated using ROC curves. The clinical usefulness of the models was assessed using decision curve analysis (DCA).

## RESULTS

A total of 1743 radiomics features were extracted, then the features were filtered by F Test, and finally, 20 features were selected to construct the radiomics model. The radiomics-clinical model, which was based on the radiomics signature and 4 clinical factors, showed superior discriminatory efficacy compared with the radiomics model alone (area under the curve (AUC) in the training cohort: 0.997 vs. 0.961, the validation cohort: 0.914 vs. 0.900). The clinical usefulness of radiomics-clinical model was confirmed by DCA.

## CONCLUSION

The MRI-based radiomics model was able to effectively identify the clinical stages I and II of primary LEL. The discrimination performance of the radiomics-clinical model was superior to that of the radiomics model alone.

## CLINICAL RELEVANCE/APPLICATION

A MRI-based radiomics model has the ability to identify the clinical stages of LEL of primary LEL

### W5A-SPPH- The Potential of Deep Learning Image Reconstruction Algorithms to Improve Low Dose Cranio-cerebral CT Image Quality: A Phantom study

Participants

Tingting Cai, Guangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

To compare the image quality of low dose deep learning image reconstruction (DLIR) with that of conventional clinical dose filtered back projection (FBP) in cranio-cerebral CT.

## METHODS AND MATERIALS

The clinical cranio-cerebral protocol (Group A: 120kV 240mA, 34.76mGy) and two low-dose protocols (Group B: 120kV 200mA (29mGy); Group C: 120kV 150mA (21.71mGy)) were applied to Catphan 500/600 body models. Ten consecutive scans were performed on the Revolution APEX CT at all dose levels. The conventional dose group were reconstructed using filtered back projection (FBP), and both low dose groups used DLIR medium-high levels (DLIR-M, DLIR-H) for image reconstruction. The noise power spectrum (NPS), task-based transfer function (TTF) and detectability index ( $d'$ ) were measured. Two radiologists independently recorded low-density insert minimum diameter, spatial resolution line pairs, and use of the Likert 5 points scale (5, excellent; 4, good; 3, measurable and acceptable; 2, identifiable; 1, not acceptable) for subjective evaluation of image quality.

## RESULTS

Compared with the FBP of group A, the noise of NPS in groups B and C decreased significantly ( $p < 0.05$ ), and the noise of NPS of DLIR-H in group B was the lowest; All images of group B and C were shifted toward lower frequencies with respect to FBP (FBP: , , DLIR(M,H) of Group B,C: , ), and the DLIR-M of group C was closest to the texture of FBP image. The the Air inserts had no offset, while those of the Teflon, Acrylic, and LDPE inserts all shifted. Among them, of DLIR-H of Teflon and LDPE in group C were larger than FBP, and of the rest were smaller than or close to FBP images. Compared with FBP, of DLIR-H of the four inserts in groups B and C were all higher, and the  $d'$  of DLIR-H of the four inserts in group B was the best. Two observers agreed that the low-density resolution and subjective score of DLIR-H in group B were better than FBP of group A ( $p < 0.05$ ) and the subjective score of group C was lower than that of group A ( $p < 0.05$ ), but still can achieve more than 4 points. The distinguishable line pairs per centimeter at all three dose levels were 7 lp/mm. The Kappa values of the two observers for the low-density insert diameter and subjective image analysis were 0.541 and 0.754, respectively, with good agreement.

## CONCLUSION

s The DLIR-H algorithm can provide comparable or even better image quality at low dose than that of clinical routine dose FBP.

## CLINICAL RELEVANCE/APPLICATION

DLIR-H algorithm provides parameter selection for clinical low dose craniocerebral scanning.

## W5A-SPPH- White Matter Clustering using Conformal Mapping

13

### PURPOSE

Diffusion Tensor Imaging (DTI) facilitates the delineation of white matter fiber tracts in the brain. Clustering white matter fiber bundles by various methods has been a research focus over the past decade. We propose a deep neural network which requires a novel approach to data normalization, augmentation, and problem formulation.

### METHODS AND MATERIALS

Conformal mapping is a technique used to establish a bijective mapping of one shape into its topologically equivalent target shape; the bijectivity ensures that the mapping is invertible and unique. We used volumetric transformations in which not only the surface of the shape is reshaped into the target shape but every point inside the shape is also transformed. Eleven epilepsy patients without structural brain abnormalities were retrospectively reviewed. Diffusion-weighted imaging was obtained with a multiband spin-echo echo planar imaging sequence on a 3 Tesla MR system (Siemens Vida or Prisma) using a 64-channel head and neck coil. A total of 64 diffusion directions were obtained. Diffusion data were preprocessed, and orientation distribution function was estimated. Whole brain tractography was then created using deterministic tracking. Fiber tracts from the 11 patients are mixed forming the dataset comprising 2469292 fiber tracts. The dataset was divided into training, test, and validation sets in a 3:1:1 ratio. The neural network classifier is based on the VGG 16 architecture and contains two convolution layers with 32 and 64 feature maps followed by two fully connected dense layers. The network uses rectified linear units as the activation function. Fiber tracts with length less than 30 mm or greater than 300 mm are filtered out, and all the fiber tracts are resampled to contain 50 points, flipped in order, and convolved with a 1D Gaussian filter for data augmentation. The fiber tracts are then mapped into a spherical space using the conformal mapping. The neural network is trained with a batch size of 500 fibers, a learning rate of 0.0001, and categorical cross-entropy is minimized using Adam optimizer in 10 epochs.

### RESULTS

The confusion matrix for the classification is shown in figure 1. All accuracies for 26 tracts exceeded 0.890379.

## CONCLUSION

s We presented a deep learning framework for clustering white matter fibers using a volumetric conformal mapping approach and the initial experiments showed promising results.

## CLINICAL RELEVANCE/APPLICATION

We aim to automate this process and further this algorithm such that the deep learning tools can eliminate all the noisy fibers and identify the appropriate anatomical clusters based on whole brain tractography. We also aim to expand this algorithm to identify white matter tracts in the presence of pathologies that can change the anatomy of the tracts.

## W5A-SPPH- Investigation of the Inherent Challenges Associated with Quantitative 90Y PET-CT Imaging towards Improved Dosimetric Accuracy in 90Y SIRT Therapies

2

### PURPOSE

Yttrium-90 (90Y) PET-CT imaging for dose verification following 90Y selective internal radiation therapy (SIRT) has a number of associated dosimetric quantification challenges. SIRT tumours can be irregularly shaped, multi-nodular and have heterogeneous activity distributions. Partial volume effects (PVE) and high background activity due to low number of true coincidences further contribute to degradation of quantification accuracy. Accordingly, the objective of this research is to further investigate the effects of PVE, heterogeneity and background activity in 90Y PET-CT imaging, towards more accurate patient dosimetry for 90Y SIRT therapies.

### METHODS AND MATERIALS

90Y PET-CT imaging datasets were acquired using a Siemens Biograph Horizon PET-CT scanner. 3D-printed non-spherical objects, representative of clinical data and designed using a novel radiomics analysis approach, were employed to assess the effects of PVEs for non-spherical lesions. Recovery Coefficient (RC) curves were generated by filling spherical and non-spherical objects with known 90Y activities, submerged in a water phantom for a range of object-to-background ratios (10:1, 20:1, 25:1, 30:1). The effects of tumour heterogeneity was investigated using novel 3D-printed phantoms, with phantom infills of 0%, 20%, 40% and 60%. 90Y sensitivity measurements and the effects of inherent background activity from the lutetium oxyorthosilicate crystals were investigated using an anthropomorphic thorax phantom, assessing noise levels in the lung and liver fields.

### RESULTS

The effects of heterogeneous distributions and PVE for spherical and non-spherical objects on the quantitative accuracy of 90Y PET-CT imaging will be presented. In addition, results on the implications of background activity on quantitative 90Y imaging will be quantified by means of noise equivalent count rate, background variability and contrast recovery. Correction factors accounting for heterogeneity, PVE, 90Y activity recovery (0.84) and LSO background activity (4 - 8 kBq/ml) will be investigated and presented.

## CONCLUSION

s Inherent background activity, low PET count rate, high random fractions and PVEs at small volumes are some of the inherent challenges associated with quantitative 90Y PET-CT imaging following SIRT therapies. Evaluating and correcting for these limitations is necessary to improve quantification accuracy, and for identifying any mismatch between pre- and post-treatment dosimetry, thus allowing for improvements towards improved personalised dosimetry.

## CLINICAL RELEVANCE/APPLICATION

This research aims to improve the quantitative accuracy of 90Y PET-CT imaging post SIRT therapy to facilitate improved accuracy

in the dosimetry estimation for SIRT therapy patients.

### **W5A-SPPH- Evaluation of Device Less Respiratory Gating Method for PET through Characterization of Motion Blur Spatial Frequency** 3

Participants

Ikuo Kawashita, PhD, Hiroshima, Japan (*Presenter*) Nothing to Disclose

#### **PURPOSE**

We developed a method to evaluate the degree of motion blur in each direction based on the ratio of amplitude spectra of multiple images. The purpose of this study is to evaluate a respiratory gating method for PET that does not require a device, using the proposed method.

#### **METHODS AND MATERIALS**

The PET/CT scanner used in this study was a Cartesion Prime, Canon Medical Systems, and the phantom was a NEMA IEC-body phantom filled with FDG solution activity contrast 1:4 (background: spheres). The phantom was placed on a drive unit that moved in accordance with the input waveform signal taken from a real human respiration of about four seconds per cycle. We used 9 cases of liver tumors with FDG accumulation as clinical examples. Data were obtained at five reconstructions in phantom study, 1. reference: static, 2. auto: data-driven auto-gating for the auto-gated reconstruction, we extracted the 35% of total time frames by comparing the similarity of feature vectors. 3. device-based: device-monitoring with respiratory motion, 4. phase: data-driven-phase-gating, 5. non-gate: no gating with respiratory motion. Using the amplitude spectrum of a reference image without motion as a standard, the reconstruction methods of the comparison target were absolutely evaluated with MTF. The evaluation of clinical cases was compared using the following three types: auto, phase, non-gated. Using the amplitude spectrum of the auto-gated reconstructed image as a standard, the phase-gated and non-gated reconstruction methods were relatively evaluated.

#### **RESULTS**

Auto-gating were closest to the reference data in in phantom study (Fig.1). The MTF results were consistent with the measurement results of the signal diameter. Figure 2 shows the average relative MTF of the 9 clinical cases. The results showed that the auto-gated reconstruction method had a relatively lower impact of respiratory blur compared to the phase-gated and non-gated methods. These results were consistent with the measurement results of tumor diameter.

#### **CONCLUSION**

s The developed image quality evaluation method for motion blur can be used for performance evaluation of respiratory-gated PET reconstruction.

#### **CLINICAL RELEVANCE/APPLICATION**

The image quality of the deviceless Auto-Gating was closest to that of static images than the conventional respiratory gating method.

### **W5A-SPPH- Deep Learning Image Reconstruction Impacts on Robustness of CT Radiomics Features: Opportunity for Minimizing Radiomics Variability** 4

#### **PURPOSE**

To investigate the influence of deep learning image reconstruction (DLIR) on robustness of CT radiomics features.

#### **METHODS AND MATERIALS**

A standardized phantom with sixteen clinical-relevant densities was scanned under single-energy CT (SECT) and dual-energy CT (DECT) modes at standard and half (20 and 10 mGy) dose level. Images of SECT 120 kVp and corresponding DECT 120 kVp-like virtual monochromatic images were generated with six reconstruction algorithms: filtered back-projection (FBP), adaptive statistical iterative reconstruction-Veo at 40% (AV-40) and 100% (AV-100) blending levels, and DLIR algorithm at low (DLIR-L), medium (DLIR-M) and high (DLIR-L) strength levels, resulting twenty-four image sets. 94 radiomic features were extracted via Pyradiomics. Reproducibility of radiomic features was evaluated between SECT and DECT scan modes, between standard and half dose levels, across reconstruction algorithms in reference to FBP images, and across all image sets, using intraclass correlation coefficient (ICC) and concordance correlation coefficient (CCC).

#### **RESULTS**

The average percentage of features with ICC > 0.90 and CCC > 0.90 were 11.35% and 11.17% between SECT and DECT scans. The reproducibility between scan modes did not obviously changed with the increasing strength level of DLIR algorithm. The average percentage of features with ICC > 0.90 and CCC > 0.90 between images acquired at 10 and 20 mGy dose levels were 28.55% and 27.40%. The reproducibility between dose levels increased with the increasing strength level of DLIR algorithm within SECT scans, but DLIR-M images showed highest reproducibility within DECT scans. The average percentage of features with ICC > 0.90 and CCC > 0.90 in reference to FBP images decreased from 27.93% to 17.82%, and from 27.66% to 17.29%, respectively, with the increasing strength level of DLIR. The AV-40 images resulted average percentage of features with ICC > 0.90 and CCC > 0.90 of 26.06% and 25.80% in reference to FBP images, and 18.88% and 18.62% for AV-100 images, respectively. Within SECT scans, DLIR-H images at 10 mGy presented percentage of features with ICC > 0.90 and CCC > 0.90 of 79.78% and 76.60%, respectively, comparing to DLIR-M images at 20 mGy.

#### **CONCLUSION**

s DLIR and IR algorithms potentially alters minable information in images, while DLIR algorithm provides opportunity for minimizing radiomics variability.

#### **CLINICAL RELEVANCE/APPLICATION**

DLIR and IR algorithms potentially alters deeper information hidden in the images, indicating that radiomics models based on images with different reconstruction algorithms must be interpreted with caution. However, DLIR algorithm has potential for minimizing radiomics variability, which opens possibility for generalizable radiomics model.

**W5A-SPPH-** Participants

## 5 Using Fully Synthetic Training Data to Automate Clinical CT-ACR Phantom Analysis

Morgan Daly, BSc, Los Angeles, CA (*Presenter*) Nothing to Disclose

### PURPOSE

We aim to illustrate the feasibility of using a convolutional neural network (CNN) trained solely on simulated input data to perform meaningful clinical medical physics tasks. We demonstrate this by automating detection and alignment of the HU module of the CT-ACR phantom (Gammex 464).

### METHODS AND MATERIALS

All training and validation data was generated on-the-fly using a computational phantom generator that uses four parameters to control phantom placement: x and y position, simulated reconstruction field of view (FOV), and rotation. These were randomly sampled in the ranges: x, y position: [-50 mm, 50 mm], FOV: [200 mm, 510 mm], and rotation: [-50°, 50°]. A ResNet50-based network was trained to predict a feature vector consisting of the x, y position, FOV, and rotation for a given input 256x256 phantom image. The model was evaluated on 5 clinical images of the HU module acquired on a Siemens Force scanner with labels manually calculated by aligning simulated phantoms with the clinical image. Mean absolute error (MAE) between the network-predicted features and manually aligned features were quantified and reported, and a visual assessment was performed.

### RESULTS

The MAE of the features produced by the model on a computational phantom test set (n=100) were:  $x=0.90 \pm 0.6\text{mm}$ ,  $y=0.53 \pm 0.4\text{mm}$ ,  $\text{FOV}=2.81 \pm 1.9\text{mm}$ ,  $\text{rot}=0.84 \pm 0.7$ . The MAE of the transformations produced by the CNN on the set of 5 real ACR phantom scan images:  $x=2.77 \pm 5.0$ ,  $y=9.72 \pm 20.3$ ,  $\text{FOV}=17.78 \pm 24.4$ ,  $\text{rotation}=3.52 \pm 4.2$ . In a visual assessment, the model achieves excellent agreement with clinical scans that are moderately misaligned (the likeliest to occur in routine practice). In one test case with more substantial misalignment (a large FOV) the disagreement between the input and the model prediction was apparent.

### CONCLUSION

The trained network does an acceptable job of predicting the correct parameters to align the HU module of the CT-ACR phantom, which can be used to automate phantom analysis. Methodologically, we have illustrated that CNNs trained on fully-synthetic data can be directly applied to clinical tasks, and additional augmentation of the synthetic data (e.g., noise, table-like objects in frame) could further improve performance. Finally, we hope that interpretable feature outputs will help build confidence in the broader use of clinical AI in medical physics and quantitative imaging.

### CLINICAL RELEVANCE/APPLICATION

These methods could generalize automated analysis to any phantom without the need for image acquisition or manual annotation. Synthetic data as ground truth could aid in training networks for more complex clinical/medical tasks.

## 6 W5A-SPPH- A Comparison Among LowRes, HighRes and Cascaded CNNs for Segmentation of Cardiac CT Images in TAVR Patients

Participants  
James Goldfarb, PhD, (*Presenter*) Nothing to Disclose

### PURPOSE

Cardiac CT is routinely used for pre-planning aortic valve repair. Segmentation of cardiac structures would enable the calculation of several quantitative values (e.g., EF, LVM). The optimal convolutional neural network (CNN) for this task can be limited by hardware memory, compute power, and segmentation speed. We compared the segmentation of cardiac CT images using three CNN architectures to determine which anatomical structures require a larger CNN.

### METHODS AND MATERIALS

We used 56 training and 200 testing contrast CT angiograms in patients with aortic valve disease for TAVR planning. Eleven regions were annotated for training: AscAorta, DescAorta, InfVenaCava, LeftAtrium, RightAtrium, LeftVentricle, RightVentricle, LVMycocardium, and aortic valve leaflets (calcified and non-calcified). We trained three CNN 3DUnet architectures with increasing memory and compute requirements: LowRes, HighRes, and Cascaded. We statistically analyzed the Dice Coefficient (DC), Intersection-over-Union (IoU), and volumes of regions at systole and diastole. Visual assessment of 3D renderings was performed to detect failed segmentations.

### RESULTS

DC and IoU were slightly higher ( $p < 0.001$ ) for the cascaded network compared to the low and high resolution CNNs (DC: 0.93 vs 0.92, 0.92) and (IoU: 0.87 vs 0.86, 0.86). Although the segmentation volume intraclass correlation (ICC) was excellent (0.94-0.99), 10% of the HighRes segmentations had at least one region with a failed segmentation vs 2% of LowRes vs 0% of the cascaded CNN ( $p < 0.001$ ). The cascaded CNN had a small (0.6%+/-0.58%) difference in large structures but a larger difference in smaller calcified structures (18.73%+/-13.8%).

### CONCLUSION

A cascaded CNN performs the best both qualitatively and quantitatively. For segmentation of large structures such as the left ventricle, small segmentation errors do not affect quantitative values. However, for finer segmentation such as aortic valve calcium or calcified leaflets, a cascaded or high-resolution network is necessary.

### CLINICAL RELEVANCE/APPLICATION

For segmentation of large structures such as the left ventricle or left atrium, a LowRes CNN is sufficient. However, if higher resolution structures are also segmented (as is done in an aortic valve calcium score), a cascaded CNN is necessary. This has implications for the required GPU/CPU memory and compute power for timely segmentation, especially when the typical 20 cardiac phases are segmented.

## 7 W5A-SPPH- High Spatial Resolution Diffusion Tensor Imaging Aided by Synthetic-MRI: An Application of Sixfold Multiparameter Quantitative MRI (MP6-qMRI)

Participants

Hernan Jara, PhD, Boston, MA (*Presenter*) Author with royalties, World Scientific Publishing;

## PURPOSE

In diffusion tensor MR imaging (DTI), the spatial resolution of the mean diffusivity (MD) and fractional anisotropy (FA) maps depend on the spatial resolution of the diffusion encoded images ( $b > 0$ ) as well as the  $b_0$  images. We investigate spatial resolution improvements in DTI maps resulting from using high spatial resolution synthetic  $b_0$  images as substitute to the standard  $b_0$  images, which are acquired at lower resolution to shorten scan time.

## METHODS AND MATERIALS

Two healthy volunteers (37yo male, and 59yo male) were scanned with local IRB approval. The modular MP6-qMRI turbo spin echo (TSE) pulse sequence was implemented on a 3T Ingenia Elition X whole body scanner (Philips Healthcare) by concatenating with same pre-scan settings high resolution Triple-TSE and half in plane spatial resolution DTI-TSE modules (Fig. 1A). All modules were implemented without fat suppression and generated 80 contiguous slices. Key scanning parameters were a) Triple-TSE modules (9.5min): TR<sub>long</sub> = 16s, TR<sub>short</sub> = 0.5s, TE<sub>1</sub> = 10ms, TE<sub>2</sub> = 110ms, voxel = 0.47 x 0.47 x 2mm<sup>3</sup> and b) DTI module (11min): TR = 25.4s, TE<sub>eff</sub> = 72ms, voxel = 0.94 x 0.94 x 2mm<sup>3</sup>. The unified MP6-qMRI relaxometry and DTI processing pipeline was programmed in Python (version 3.9.13) with the Anaconda Navigator (version 2.3.2). The primary (nPD-T1-T2) qMRI maps were calculated according to the Bloch equation solution as applicable for the Triple-TSE pulse sequence. DTI maps were calculated according to the Bloch-Torrey equation as in DIPY tensor reconstruction (<https://dipy.org/>).

## RESULTS

For both volunteers, the MP6-qMRI framework yielded high quality MD (Fig. 1B) and FA (Fig. 1C) maps with full head coverage and with imperceptible geometric distortion artifacts. Furthermore, MD and FA maps obtained with calibrated synthetic  $b_0$  had superior spatial resolution providing improved anatomic delineation that is most noticeable for white-to-gray matter differentiation and for improved delineation of the extra cranium.

## CONCLUSION

Added benefits of using turbo spin echo multiparameter qMRI frameworks are the opportunities of reducing magnetic inhomogeneity distortions, and of increasing the spatial resolution of DTI maps (MD and FA) by means of Synthetic MRI. Hence, MP6-qMRI can extend the usefulness of DTI to magnetically inhomogeneous regions such as the extra-cranium and the neck and with higher spatial resolution.

## CLINICAL RELEVANCE/APPLICATION

Use of turbo spin echo based MP6-qMRI and Synthetic MRI can extend clinical applications of diffusion tensor MRI for assessing the extra-cranium and nasal cavity structures with negligible geometric distortions.

## W5A-SPPH- To Biopsy or Not to Biopsy? Feasibility of Predicting Gleason Score as a Pre-biopsy Gatekeeper in Prostate Cancer Patients using Multimodal Patient Features

### PURPOSE

The diagnosis of prostate cancer (PCa) is based on a prostate biopsy. Even though this diagnosis is important for further treatment decision, a biopsy is painful and can result in adverse effects for the patient. In this study, we aim at developing a biopsy gatekeeper by predicting the Gleason score (GS) using a machine learning (ML) classification model. Therefore, results from various diagnostic screening examinations are combined with patient-specific variables to explore the feasibility of a binary ML model to predict GS >6 and thus the need for biopsy in PCa patients.

### METHODS AND MATERIALS

Patients screened in our hospital (n=295) underwent a digital rectal examination (DRE), transrectal ultrasound (TRUS) and a screening magnetic resonance (MR) examination. Preceding the MR examination, prostate-specific antigen (PSA) and prostate health index (PHI) blood tests were acquired on the same day. Patients obtained a TRUS-guided biopsy to detect PCa, as determined by the GS. Various classification models were explored to predict GS <7 and =7 using 7 features: TRUS- and DRE findings, PSA and PHI density results, prostate imaging-reporting and data system (PI-RADS) score, as well as patient-specific variables being age and genetic risk. 28 model architectures are constructed by combining 3 components: (1) a scaler (Robust or Standard); (2) a sampler to balance the dataset (Synthetic Minority Oversampling TEchnique or Adaptive Synthetic) and (3) a classifier (Logistic Regression - LR, Random Forest, K-Nearest Neighbours, Decision Tree, Support Vector Machine - SVM, Gaussian Naive Bayes - GNB, or Gradient Boosting). To minimize bias, a stratified 10-fold cross validation is implemented. Hyperparameter tuning for the 28 model architectures resulted in training 2188 models. All models are trained to maximize the area under the curve (AUC). The classification is done with threshold set to 0.35.

### RESULTS

The AUC for predictions of GS is 0.77 (95% CI 0.67-0.87). 3 features, being PI-RADS, PHI density and age, were revealed as significant predictors for GS ( $p=0.006$ ,  $p=0.001$  and  $p=0.001$  respectively). This finding was confirmed by the selectKBest algorithm selecting the 3 most important features for GS prediction. Repeating the model with these 3 features resulted in LR, SVM and GNB as best classifiers, with AUC respectively 0.81 (95% CI 0.66-0.97), 0.82 (95% CI 0.66-0.98) and 0.84 (95% CI 0.68-1.0).

### CONCLUSION

This study demonstrates the potential of using a ML algorithm to predict the need of prostate biopsy. This way, physicians could opt to eliminate a biopsy which is painful for the patients and could cause adverse effects.

### CLINICAL RELEVANCE/APPLICATION

This study aims at developing a ML model as a pre-biopsy gatekeeper to eliminate unneeded biopsies in PCa.

Participants  
MENGKE LIU, BEIJING, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The staging of primary lower extremity lymphedema (LEL) is difficult and vital in clinical work, and Short time inversion recovery (STIR) sequence of MRI can be used for quantitative assessment of primary lower extremity lymphedema due to its high soft tissue resolution. So we evaluated the value of STIR-based soft tissue area measurements for staging primary lower extremity lymphedema.

#### **METHODS AND MATERIALS**

90 consecutive patients with clinically diagnosed primary lower limb lymphoedema from January 2017 to December 2019 in Beijing Shijitan hospital were enrolled retrospectively. STIR sequence was applied to measure the total, muscle, bone, and subcutaneous areas in the upper 1/3 level of the bilateral lower calf. The difference between the affected and unaffected calf regarding the subcutaneous area was obtained. (Subcutaneous area)/(bone area) and (subcutaneous area)/(muscle area) were calculated. According to the International Society of Lymphology (ISL) clinical staging standard in 2020, all patients were divided into stages I, II and III. Statistical analysis was performed to determine the validity of MRI measurements in staging LEL.

#### **RESULTS**

Clinical stages were I in 33 patients, II in 44 patients, and III in 13 patients. There are significant differences in the difference in subcutaneous area of limbs, subcutaneous/bone and subcutaneous/muscle between stage I and II as well as between stage I and III ( $P < 0.001$ ), but not between stage II and III ( $P = 0.706, 0.329, 0.229$ , respectively). There was a positive correlation between the clinical stage and difference in subcutaneous area of limbs ( $\rho = 0.752, P < 0.001$ ), subcutaneous/bone ( $\rho = 0.747, P < 0.001$ ) and subcutaneous/muscle ( $\rho = 0.709, P < 0.001$ ). For staging primary lower extremity lymphedema, receiver operator characteristic (ROC) curves indicated that difference in subcutaneous area of limbs had the best discrimination ability among parameters [area under the ROC curve (AUC) = 0.950; 95% Confidence Interval (CI): 0.875 - 0.987; sensitivity: 95.45%, specificity: 84.85%], followed by subcutaneous/bone [AUC = 0.930; 95%(CI): 0.848 - 0.975; sensitivity: 77.27%, specificity: 93.94%] and subcutaneous/muscle [AUC = 0.895; 95%(CI): 0.804 - 0.953; sensitivity: 77.27%, specificity: 90.91%].

#### **CONCLUSION**

The measurement of the soft tissue area by STIR may be used as an auxiliary method for staging primary lower extremity lymphedema. For patients with unilateral primary lower extremity lymphedema, the difference in subcutaneous area of limbs could be a specific indicator to distinguish clinical stage I from II.

#### **CLINICAL RELEVANCE/APPLICATION**

STIR enables quantitative assessment of primary lower extremity lymphedema.

#### **W5A-SPRO- Can Serial Brain Metastases MRI Radiomics Kinetics Predict Stereotactic Radiation and Immunotherapy Outcomes?** 1

#### Participants

Hesham Elhalawani, MD, MSc, Boston, MA (*Presenter*) Nothing to Disclose

#### PURPOSE

Radiation necrosis (RN) remains to be the primary dose-limiting toxicity of stereotactic radiosurgery (SRS), especially in combination with immunotherapy (IO). This debilitating adverse event is often confused with tumor regrowth, posing significant diagnostic and therapeutic challenges. This study employed magnetic resonance imaging (MRI) radiomics to quantify sub-acute radiation-induced changes in irradiated BM and their value in predicting treatment response.

#### METHODS AND MATERIALS

Following IRB approval, we queried our single-institution dataset to identify adult patients with brain metastases managed with SRS and IO between 2006 and 2021. We collected patient, disease, and treatment variables. Specifically, per-BM outcomes were categorized as RN (radiographic and/or symptomatic), progressive disease (PD), or neither (NA). All patients had diagnostic pre- and post-SRS contrast-enhanced T1-weighted MRIs. Individual BMs were manually segmented in MIM Software (Beachwood, OH). 1061 hand-crafted radiomic features were computed per lesion using IBEX Software. Feature reduction followed using Spearman's correlation coefficient (0.3 cut-offs). Simple then multiple nominal logistic regressions (SLR and MLR) with Bonferroni correction ensued to model the risk of RN, PD, or NA using JMP software.

#### RESULTS

92 patients with 301 BM of NSCLC, melanoma, and renal cell carcinoma primaries were included. All patients received brain SRS and IO. RN, PD, or NA occurred in 74 (24.6%), 75 (24.9%), and 152 (50.5%) BM, respectively. 39 radiomic features significantly changed post-SRS ( $p < 0.01$ ). Using MLR modeling, we created a 3-feature radiomic RN predictor (ROC AUC 0.71). The model included post-SRS BM surface area, texture (GLCM 3D Homogeneity), and pre-RT BM roundness. A 5-feature radiomic signature could predict RN and PD risk (ROC AUC 0.71) based on pre-SRS GLCM 3D texture feature, 3 post-SRS shape features (surface area, mean breadth, and roundness), in addition to delta-volume.

#### CONCLUSION

s SRS and IO induce changes in BM shape, MRI texture, and signal intensity that radiomics can capture. Pre-SRS, post-SRS, and percent changes of these radiomic feature values could correlate to post-therapy tumor control or radiation necrosis. Pursuing model external validation, combination with clinical variables, and integrating other MRI sequences is imperative before larger-scale adoption of this novel diagnostic approach.

#### CLINICAL RELEVANCE/APPLICATION

The premise of our study is to employ to develop an artificial intelligence-powered MRI radiomic predictor of BM treatment outcomes. These serial 'virtual digital biopsies' could guide cost-effective follow-ups and earlier personalized interventions to improve patients' quality of life.

#### **W5A-SPVA- Fast Imaging of Lenticulostriate Arteries by Combining High-Resolution Black-blood T1-weighted with Variable Flip Angles Compressed Sensitivity Encoding** 1

##### Participants

Yukun Zhang, Dalian, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To visualize and characterize lenticulostriate arteries (LSAs) in a short time on a 3.0T MR scanner, we investigated the feasibility of high-resolution black-blood T1-weighted with variable flip angles (T1w TSE-VFA) accelerated by compressed sensitivity encoding (CS-SENSE) and further identify the optimal acceleration factors (AF) for routine clinical use.

##### METHODS AND MATERIALS

Twenty-five healthy volunteers (13 males, and 12 females, the age ranged from 27 to 68 years, with a median age of 58 years) and 20 patients with cerebrovascular disease (12 males, 8 females, mean age:  $64.3 \pm 8.9$  years) were prospectively enrolled. Volunteers underwent T1w TSE-VFA sequences with different AFs, including conventional sensitivity encoding (SENSE) AF=3 and CS-SENSE AF=3, 4, 5, and 6 (The scanning time was 510s, 480s, 361s, 298s, and 245, respectively) at 3 Tesla. The image quality and the display of LSAs of T1w TSE-VFA protocols were evaluated through objective evaluation (contrast ratio [CR Callosum /WM, CR Brainstem /WM, CR Epencephalon /WM], number of LSAs, total length of LSAs, and average length of LSAs) and subjective evaluation (overall image quality, scores on LSAs). Comparisons were performed among the 5 sequences to select the best AF. All patients underwent both T1w TSE-VFA with optimal AF and digital subtraction angiography (DSA) examination, and the number of LSAs of both was compared.

##### RESULTS

The pair-wise comparisons among CS3, CS4, and SENSE3 showed no statistically significant differences in the objective measurement and subjective evaluation in (all  $P > 0.05$ , Fig.1 and Fig.2). There was no statistically significant difference in the LSA counts on 1 side measured by DSA and CS4 in patients (3, 3 - 3 and 3, 3 - 3,  $P = 0.384$ , Fig.3).

##### CONCLUSION

s CS3 can provide a better LSA display but takes a long time (480s, 6% reduction); CS4 can balance the visualization of LSAs and acquisition time (361s, a 30% reduction) and is recommended for routine clinical application.

##### CLINICAL RELEVANCE/APPLICATION

T1w TSE-VFA accelerated by CS-SENSE can be used as a non-invasive head microvasculature examination in asymptomatic subjects and patients with cerebrovascular disease, which will be an important asset in preventive medicine.

#### **W5A-SPVA- Acceleration of Time-of-flight Magnetic Resonance Angiography by Intelligence-assisted Compressed Sensing** 2

##### Participants

Yukun Zhang, Dalian, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To compare the image quality of time-of-flight magnetic resonance angiography (3D TOF-MRA) accelerated by sensitivity encoding (SENSE), compressed sensing (CS), and intelligence-assisted compressed sensing (ACS) with different acceleration factors (AF) to optimize the sequence

##### METHODS AND MATERIALS

Fourteen healthy volunteers were prospectively recruited and underwent 3D TOF-MRA scans with different AFs, including SENSE AF = 3; CS AF=3; ACS AF = 3, 5, 7, and 9 (The scanning time was 189s, 170s, 165, 150s, 136, and 115, respectively) at 3.0 T. Two radiologists delineated the regions of interest (ROI) for the callosum, right and left middle cerebral artery (MCA), and adjacent white matter on raw images. The signal intensity and standard deviation were recorded for further calculation of the signal to noise ratio (SNR) and contrast to noise ratio (CNR). Meanwhile, the overall image quality of 3D TOF-MRA with different AFs and 9 pre-defined arteries structures (intracranial segment of the bilateral ICAs, the anterior cerebral artery, the MCA, the distal bilateral vertebral arteries, and the basilar artery) were scored using 4-point scale subjective criteria. The difference in measurement data and subjective score between different AFs was analyzed by pairs comparison (LSD-t test).

##### RESULTS

In the objective evaluation (Table 2), ACS7 and ACS9 had significantly lower CNR callosum than SENSE3, CS3, ACS3, and ACS5 ( $P > 0.05$ ); ACS3 was significantly higher than SENSE3 in SNRR-MCA, SNRL-MCA, CNR L-MCA ( $P > 0.05$ ). In the subjective evaluation

(Fig.1 and Table 2), CS3, CS5, and CS9 are different from SENSE3 in overall image quality evaluation ( $P>0.05$ ); and there was no significant difference in the evaluation of arteries structures ( $P<0.05$ ).

#### **CONCLUSION**

s Compared with SENSE and CS, the better imaging quality of craniocerebral arteries could be obtained using 3D TOF MRA based on ACS with a shorter time, especially with AF of 5

#### **CLINICAL RELEVANCE/APPLICATION**

Compared with SENSE and CS, 3D TOF-MRA accelerated by ACS can further shorten the scanning time while maintaining the image quality, which greatly increases the comfort and success rate of MR Scanning

#### **W5B-SPBR- Breast Cancer Risk Models: Observations From a Multi-Site Database of Women Screened for Breast Cancer** 1

##### Participants

Emily F. Conant, MD, Philadelphia, PA (*Presenter*) Research Grant, Hologic, Inc; Advisory Panel, Hologic, Inc; Research Grant, OM1, Inc; Research Grant, iCad, Inc; Advisory Panel, iCad, Inc; Speaker, WebMD LLC

##### PURPOSE

With emerging interest in risk-based screening strategies and known disparities in breast cancer outcomes by race, risk models need to address gaps in risk assessment. To inform questions about the inclusion of characteristics like race in these models, we explored associations between race, breast cancer risk factors (including Gail risk score) and breast cancer detection in a large, real-world cohort.

##### METHODS AND MATERIALS

This retrospective cohort study used electronic medical record, radiology, and tumor registry data from five healthcare organizations. Women 40-79 years old with no history of breast cancer, non-missing race data, and =1 screening exam between 2016-2020, were included. Cancer detection rates (CDR) were calculated per 1,000 screens. Logistic regression models were used to estimate odds ratios (OR) and 95% confidence intervals (CI) for the associations between age, race, breast density and risk status (Gail model) and CDR.

##### RESULTS

The cohort included 1,563,019 screenings (123,371 Asian, 203,412 Black, 56,961 Other, 1,179,274 White). Both Black and White women were on average 58±10 years of age and slightly older than Asian or women of Other race (mean age 54±9 years). Asian women had significantly higher breast density versus other groups (52% mostly heterogeneously dense; 15% extremely dense tissue). Elevated breast cancer risk status varied by race; 16% Asian, 23% Black, 17% Other, 31% White. Overall CDRs (per 1,000 screens) by race were; Asian 4.9 [95% CI 4.5, 5.3]; Black 5.3 [95% CI 5.0, 5.6]; Other 4.2 [95% CI 3.7, 4.7]; White 5.2 [95% CI 5.1, 5.3]. Among women identified as elevated risk, CDRs differed slightly as compared to White women: Asian 6.6 [95% CI 5.5, 7.8] p=0.26; Black 6.7 [95% CI 6.0, 7.5] p=0.05; Other 4.9 [95% CI 3.7, 6.5] p=0.20; White 5.9 [95% CI 5.7, 6.2]. After adjusting for age (p<0.001), density (p<0.001) and risk (p=0.001), no statistically significant association between race and CDR remained (p=0.25) (Figure).

##### CONCLUSION

In a large real-world cohort, we observed meaningful differences in breast cancer risk factors and risk scores by race. Racial differences in cancer detection rates do not persist after adjusting for age, breast density and Gail score. Careful consideration should be given to the use of risk models in the clinical setting. The observed misalignment in risk scores and breast cancer detection rates suggest the potential for insufficient capture of risk factors and the need to better understand the drivers of racial differences in mammography outcomes.

##### CLINICAL RELEVANCE/APPLICATION

It is critical to understand which risk factors may underlie recognized racial disparities in breast cancer burden in order to optimize risk models used to support clinical decision making for screening prioritization.

#### **W5B-SPBR- Diagnostic Performance of Diffuse Optical Spectroscopic Imaging for Breast Cancer According to Clinical Factors** 2

##### Participants

Yeji Kwon, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

Although breast cancer screening programs have reduced the mortality rate of breast cancer patients by about 20%, the sensitivity of mammography decreases to 30-48% in dense breast. On the contrary, there are concerns regarding the potential elevation of false positive rates when ultrasound is employed. It has been suggested that optical imaging could enhance the specificity of breast imaging, but this has not been conclusively established. This study aims to evaluate the impact of clinical factors on the diagnostic performance of diffuse optical spectroscopic imaging/discrete multi-wavelength near-infrared spectrum (DOSI/DMW-NIRS) for breast malignancy.

##### METHODS AND MATERIALS

Our institutional review board granted approval for this investigation, and signed informed consent was obtained. From September 2021 to June 2022. In this study, 85 participants were enrolled, of which 23 participants were excluded. Among the exclusions, 4

participants refused to participate or had unavailable biopsy results, 4 participants had absent raw or chromophore data, and 15 participants were unavailable for analysis due to the subareolar location of the lesion. Total of 62 women with 62 breast lesions (37 malignant, 25 benign) biopsied under US guidance were analyzed. DOSI/DMW-NIRS was used to quantify the chromophores (HbO<sub>2</sub>, HHb, THC, StO<sub>2</sub>, water, lipid, and TOI) of lesions and then the computed chromophore ratios were compared to those of contralateral normal breasts. Lesions were categorized by demographic (age, BMI, bra cup size, and menstrual cycle phase) and sonographic variables (tumor diameter, depth, distance from nipple, vascularity, breast thickness, and BI-RADS category), and areas under the curve (AUCs) were compared between subgroups.

## RESULTS

TOI ratio showed the highest AUC value (0.904, 95% confidence interval: 0.831-0.977), followed by water (0.836, 95% confidence interval: 0.736-0.936) for diagnosing breast malignancy among the seven chromophore values. TOI ratio demonstrated no significant difference in diagnostic performance among all subgroups (p-value>0.05). The diagnostic performance of water ratio differed according to breast thickness (p-value: 0.033) and distance from nipple (p-value: 0.011). The diagnostic performance of THC and HbO<sub>2</sub> differed according to BMI (p-value 0.0119 and 0.0056, respectively) and menstrual cycle (p-values: 0.011 and 0.006, respectively).

## CONCLUSION

s TOI ratio evaluated with DOSI/DMW-NIRS shows strong diagnostic performance regardless of demographic and sonographic parameters.

## CLINICAL RELEVANCE/APPLICATION

TOI ratio evaluated with DOSI/DMW-NIRS has the potential to be generally applied to various clinicoradiologic condition to diagnose breast cancer.

## W5B-SPBR- A Systematic Review and Meta-Analysis of Online Patient Education Materials in Breast Cancer: Is Readability the Only Story

### PURPOSE

Online patient education materials (OPEMs) are an increasingly popular resource for women seeking information about breast cancer. The AMA recommends written patient material to be at or below a 6th grade level to meet the general public's health literacy, but breast cancer readability studies have found reading levels to be much higher than the AMA's recommended level. Metrics such as quality, understandability, and actionability also heavily influence the usability of health information, and thus should be evaluated alongside readability. A systematic review and meta-analysis was conducted to determine: 1) Average readability scores and reporting methodologies of breast cancer readability studies; and 2) Inclusion frequency of additional metrics associated with health literacy.

### METHODS AND MATERIALS

A registered systematic review and meta-analysis was conducted in Ovid MEDLINE, Web of Science, Embase.com, CENTRAL via Ovid, and ClinicalTrials.gov in June 2022 in adherence with the PRISMA 2020 statement. Eligible studies performed readability analyses on English-language breast cancer-related OPEMs. Study characteristics, readability data, and reporting of non-readability health literacy metrics were extracted. Meta-analysis estimates were derived from generalized linear mixed modeling.

### RESULTS

The meta-analysis included 30 studies yielding 4,462 OPEMs. Overall, average readability was 11.81 (95% CI [11.14, 12.49]), with a significant difference (p<0.001) when grouped by OPEM categories. Commercial and government organizations had the highest average readability at 12.2 [11.3, 13.0] and 12.0 [11.3, 12.7], respectively; non-profit organizations had one of the lowest at 11.3 [10.6, 12.0]. Readability also varied by index, with New Fog, Lexile, and FORCAST having the lowest average scores (9.4, 10.4, and 10.7, respectively). Only 57% of studies calculated average readability with more than two indices. Only 60% of studies assessed other OPEM metrics associated with health literacy.

### CONCLUSION

s Average readability of breast cancer OPEMs is almost double the AMA's recommended 6th grade reading level. Readability reporting is currently not standardized - multiple indices should be used and averaged together with an interval estimate to capture a more comprehensive picture of reading grade level. Additional non-readability OPEM metrics are also inconsistently reported and may help convey the usefulness of information presented.

### CLINICAL RELEVANCE/APPLICATION

Beyond readability, the quality, understandability, and actionability of OPEMs are important components to aid shared decision-making and may be critical to increased screening rates and breast cancer awareness.

## W5B-SPBR- Examining the Barriers to Breast Cancer Early Diagnosis in Uganda: A Prospective Study

4

### PURPOSE

Women diagnosed with breast cancer (BRC) in Uganda have a 5-year mortality rate of 50%. Early diagnosis is an appropriate strategy for downstaging disease in low-resource settings, but women face significant barriers to accessing care (e.g., clinical examination, ultrasound, tissue diagnosis); assessing these barriers is a key step in designing successful programs. For the first time, we report findings from a prospective study examining the trajectory of care among Ugandan women with breast symptoms presenting for care.

### METHODS AND MATERIALS

450 symptomatic women attending 5 community health clinics in Uganda were recruited and followed for six months. Participants completed questionnaires at baseline and six months, which collected data on demographics, barriers to care, and provider's recommendations for care (baseline), and actions taken at 6-months (follow-up). Logistic regression and multiple regression models were used to assess the relationship between delay (< or > 90 days) and sociodemographic factors. Differences in adherence to provider recommendations at 6 months were assessed via Pearson X<sup>2</sup> test/Wilcoxon Rank Sum test.

## RESULTS

442 (98.2%) completed follow-up. Breast lumps and pain were the main symptoms. 57.3% waited >90 d before seeking care, of whom 27.9% delayed >1 year. After multivariate analysis, rural setting (OR=13.34) and symptoms at time of presentation (OR=0.30) were significantly associated with delay. At 6 months, 184/442 (41.6%) were referred to either diagnostic imaging or tissue biopsy (+/-) imaging. 137/184 (74.5%) did not adhere to recommendations. Positive initial breast symptoms ( $\chi^2=9.3$ ,  $P=0.01$ ) and older women ( $P=0.002$ ) were more likely to follow provider's recommendations. 22/47 (46.8%) were diagnosed with breast cancer, a diagnostic yield of 46.8%. Main reasons for no action at 6 mo. for the 137 were: resolution of breast symptoms (40.0%), decision to wait for symptoms to resolve (19.2%), provider said that it was nothing to worry about (18.3%), and financial barriers (17.5%), despite 85.6% endorsing full understanding of need for follow-up. We estimated an additional 32 undiagnosed cancers in this group, a BRC rate of 12%.

## CONCLUSION

Low adherence to follow-up recommendations for diagnostic care should be an area of focus for programs to improve BRC outcomes in Uganda.

## CLINICAL RELEVANCE/APPLICATION

To increase effectiveness of diagnosis programs in Uganda, interventions should prioritize breast health education in the community, and removing barriers to accessing diagnostic services.

## W5B-SPBR- Point of Care Breast Cancer Risk Assessment Increases Rates of Supplemental MRI Screening Among Women Undergoing Screening Mammography

Participants

Jocelyn Cheng, South Easton, MA (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of our study was to examine the impact of providing point of care breast cancer risk assessment (CRA) with results provided to patients at the time of annual screening mammography on rates of supplemental screening completion with MRI.

## METHODS AND MATERIALS

We performed a retrospective review of patients who underwent breast imaging from November 2019 through May 2021. We examined the total number of screening mammograms performed one year prior to the cancer risk assessment (CRA) intervention start date ( $n=5,431$ , (epoch 1) 11/1/2019-5/1/2020), the total number of screening mammograms performed in patients who completed CRA for six months after the CRA intervention start date ( $n=1,976$ , (epoch 2) 11/1/2020-5/1/2021), and the total number of patients who underwent screening mammography but did not complete CRA intervention for six months after CRA intervention start date ( $n=4,578$ , (epoch 2) 11/1/2020-5/1/2021). We used an interrupted time series design and analysis with a natural control to evaluate rate of MRI completion before and following integration of the Tyrer-Cuzick CRA screening tool. We identified which patients underwent supplemental screening with MRI during the 12 months following each time period to calculate the change in rate of supplemental screening completion based on intervention. Supplemental imaging rates with MRI was modeled over time between pre- and post-intervention windows using a generalized linear mixed model (GLMM) with sandwich estimation and assuming binary distribution where observations are nested within patients.

## RESULTS

The cohort included 11,985 women who underwent screening mammography during the study period. During epoch 1, no patients received CRA, 0% (0/5,431). During epoch 2, 30% (1,976/6,554) received CRA and 70% (4,578/6,554) did not. Before the implementation of CRA (epoch 1), the rate of MRI was 2.8% (152/5,431). After the implementation of CRA (epoch 2), the rate of MRI among patients who did NOT undergo CRA intervention was 3.2% (144/4,578); for those who did receive CRA, the MRI rate was 6.0% (118/1,976),  $p<.05$ .

## CONCLUSION

Receiving point of breast care risk assessment at time of screening mammography doubled the rate of follow-up screening with MRI as compared to the rate among patients who did not receive the intervention (3.1% to 6.0%,  $p<.05$ ). Our facility reached maximum capacity for MRI screening after implementation of CRA intervention; the increased volume of follow-up screening MRI following introduction of CRA was likely limited by this constraint.

## CLINICAL RELEVANCE/APPLICATION

Study findings will inform practices about supplemental screening yield after implementation of point of care risk assessment.

## W5B-SPBR- Socioeconomic Factors and Health Disparities in Access and Adherence to Breast Imaging Services and Breast Cancer Screening

Participants

Sonali Sharma, Vancouver, BC (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the impact of socioeconomic factors on the access and adherence to breast imaging services and breast cancer screening programs by analyzing data from the Digital Database for Screening Mammography (DDSM) and the National Health Interview Survey (NHIS).

## METHODS AND MATERIALS

We integrated data from the DDSM, which includes 2,620 scanned film mammograms with ground truth information and annotations, and the NHIS, which contains comprehensive health-related data from a nationally representative sample of US households. We combined mammography images and annotations with demographic and socioeconomic information, such as age, race/ethnicity, income, education, and health insurance status. We employed multivariable logistic regression models to examine the influence of socioeconomic factors on breast imaging service utilization and early breast cancer detection

## RESULTS

Our analysis showed that lower-income, lower-educated, and minority women were less likely to access breast imaging services and had a lower likelihood of early breast cancer detection. Regression models revealed that socioeconomic factors, including income, education, and health insurance status, significantly predicted access to breast imaging services and early breast cancer detection after adjusting for relevant covariates such as age and race/ethnicity.

## CONCLUSION

This study underscores the importance of addressing socioeconomic disparities in breast imaging service access and early breast cancer detection using the DDSM and NHIS datasets. Tackling these disparities by developing targeted interventions and policies to promote equitable access to breast imaging services can enhance health equity and patient outcomes.

## CLINICAL RELEVANCE/APPLICATION

Identifying and addressing socioeconomic barriers to breast imaging services can lead to increased early breast cancer detection rates and improved patient outcomes, ultimately reducing health disparities.

## W5B-SPBR- Pushing the Envelope in Breast Conserving Surgery: Is Multiple-wire Localization (3 or more wires) Associated with Increased Risk of Compromised Margins

7

### PURPOSE

In the last two decades there has been a paradigm shift with breast conserving surgery (BCS) being applied to larger and more extensive breast malignancies. The aim of this study is to examine the success of BCS being performed in patients with extensive breast malignancies requiring at least 3 wires for localization, and to assess possible risk factors for failure.

### METHODS AND MATERIALS

We performed a retrospective single center review of 232 patients who underwent BCS between 2010 and 2020 requiring at least 3 wires for localization. The cohort included a control group of 232 single-wire BCS patients chronologically matched with the multiple-wire group. Patients with either invasive malignancy or ductal carcinoma in situ (DCIS) were included in the study. Clinical, radiological and pathological data was collected. Proportions of positive surgical margins, re-lumpectomies and conversion to mastectomy were calculated.

### RESULTS

In the multiple-wire group the patients were younger (mean age 57 vs 63.1,  $P<0.001$ ), had larger tumors (mean size 5.1cm vs 1.2 cm,  $p<0.001$ ), had higher rate calcifications on mammogram (71.9% vs 17.2%,  $P<0.001$ ) and higher rate of DCIS component (72.3% vs 38.4%,  $P<0.001$ ); a higher proportion underwent neoadjuvant treatment (29.9% vs 9.9%,  $P=0.001$ ). Positive surgical margins were higher in the multiple-wire group (13.4% vs 7.3%,  $P=0.03$ ), which lead to higher proportions of re-lumpectomies or conversion to mastectomies (7.3% vs 4.3%,  $P=0.17$ ). On multivariate analysis, patients with positive margins were more likely to have a DCIS component (77.1% vs 52.8% ,  $p=0.006$ ) and positive ER hormonal status (93.5% vs 85.1%,  $p=0.048$ ). The number of wires was not an independent predictor of positive margins. breast density, presence of calcifications on mammogram, type of tumor (unifocal vs multifocal/multicentric), tumor size, surgical specimen volume, undergoing Neoadjuvant treatment, undergoing magnetic resonance imaging and use of oncoplastic techniques did not predict margin status.

### CONCLUSION

BCS requiring 3 or more wires is associated with a higher proportion of positive margins. The increased risk of positive margins appears to be related to type of tumor (DCIS component and ER status) rather than to the number of wires.

### CLINICAL RELEVANCE/APPLICATION

This information may be useful for pretreatment planning of extensive breast malignancies, especially those suitable for BCS.

## W5B-SPBR- Upgrade Rates of Atypical Ductal Hyperplasia, Atypical Lobular Hyperplasia, and Flat Epithelial Atypia at a Community-based Breast Imaging Center

8

### PURPOSE

To review the prevalence of breast malignancy (invasive or noninvasive) at surgical excision in patients who had atypical ductal hyperplasia (ADH), atypical lobular hyperplasia (ALH) and flat epithelial atypia (FEA) on needle core biopsy.

### METHODS AND MATERIALS

A retrospective chart review was performed on patients who had atypical ductal hyperplasia (ADH), atypical lobular hyperplasia (ALH) or flat epithelial atypia (FEA) on breast needle core biopsy at a community-based breast center between 1/1/2011 to 12/31/2022. There was a total of approximately 909 atypical diagnoses on core needle biopsy in 876 patients during this time (ADH, ALH or FEA). Exclusion criteria included co-existing malignancy in the ipsilateral breast, or needle core biopsy pathology demonstrating atypia bordering on DCIS. Data collected included patient demographics, lesion characteristics, and correlation with surgical biopsy or follow-up imaging.

### RESULTS

There was a total of 909 diagnoses of ADH, ALH or FEA in 876 patients on needle core biopsy. The average patient age was 57.8 years. Diagnoses on needle core biopsy were as follows: 651 ADH, 180 ALH, 78 FEA. Collectively, the majority of ADH, ALH and FEA lesions were presented as microcalcifications (69%). Of the ADH lesions, the majority presented as microcalcifications (71%), followed by 16% masses. ALH most frequently presented as microcalcifications (56%), followed by 20% masses. Eighty-three percent of FEA presented as microcalcifications, followed by 6% architectural distortion. All were recommended for open surgical biopsy (OSB)- 46 lesions did not undergo excision. Twenty percent of the atypical lesions that underwent OSB ( $n=173/863$ ) upgraded to malignancy at excision; 31% ( $n=53$ ) invasive carcinoma and 69% ( $n=120$ ) non-invasive. Specifically, 153/651 ADH upgraded (24%), 16/180 ALH upgraded (9%), and 4/78 FEA (5%).

### CONCLUSION

We found that 20% of the atypical lesions evaluated in this review upgraded to carcinoma at excision; most of the upgrades were ADH lesions. While surgical excision of ALH and FEA is controversial, our data suggests that it may be warranted. More research is needed to determine the optimal follow-up protocol for ALH and FEA.

**CLINICAL RELEVANCE/APPLICATION**

ADH, ALH and FEA are some of the high-risk lesions that are frequently recommended for surgical excision when diagnosed on core needle biopsy, though controversy exists.

## Abstract Archives of the RSNA, 2023

W5B-SPCA

### Cardiac Imaging Wednesday Poster Discussions II

#### Sub-Events

#### W5B-SPCA- Deep Learning for Contrast Medium and Radiation Reduction in Coronary CT 1

##### Participants

Giuseppe Tremamunno, MD, Rome, Italy (*Presenter*) Nothing to Disclose

##### PURPOSE

The aim of the study was to evaluate the performance of high-strength deep learning image reconstructions (DLIR-H) in maintaining or improving image quality of coronary CT angiography (CCTA) under the "double low" condition (reduced radiation dose and contrast medium dose), compared with conventional 100kVp - ASiR-V protocol.

##### METHODS AND MATERIALS

In this single-center study, from June to December 2022, clinically indicated CCTA of consecutive patients with BMI < 30 kg/m<sup>2</sup> were prospectively included and randomly assigned (1:1 ratio) into three groups: group A (100 kVp, ASiR-V 50% and iodine delivery rate [IDR] =1.8); group B (80 kVp, DLIR-H, and IDR =1.4), and group C (80 kVp, DLIR-H and IDR =1.2). Radiation and contrast dose, objective image quality (vascular attenuation, image noise, contrast-to noise ratio [CNR], signal-to-noise ratio [SNR]) and subjective image quality were compared among the three groups. To assess the objective image quality, regions of interest were drawn in the left pectoral muscle as a reference, in the ascending aorta and in the main coronary arteries. Subjective image quality was rated using a 4-point Likert scale.

##### RESULTS

144 CCTA were evaluated. Group B and C significantly reduced radiation dose compared to Group A ( $2.16 \pm 0.8$  mSv and  $1.99 \pm 0.6$  mSv, respectively, VS  $3.6 \pm 1$  mSv;  $P < 0.001$ ). Group B and group C outperformed group A in terms of lower contrast media dose, with a decreasing trend from group A to group C ( $57.7 \pm 6.7$  mL,  $51.5 \pm 6.3$  mL, and  $42.9 \pm 3.8$  mL, respectively); all the differences among the groups were statistically significant ( $P < 0.001$ ). Group B and C also achieved significantly higher SNR, CNR, and lower background noise compared to group A (all  $P < 0.001$ ). In terms of subjective image quality, group B obtained the highest score, significantly higher than group A ( $P < 0.001$ ) and group C ( $P < 0.05$ ).

##### CONCLUSION

In non-obese patients, "double low" CCTA protocol coupled with DLIR-H significantly reduces radiation and contrast medium dose while improving image quality, compared to conventional CCTA protocol.

##### CLINICAL RELEVANCE/APPLICATION

The "double low" CCTA protocol coupled with DLIR-H allows us to have excellent image quality while reducing radiation and contrast media burden; therefore, it can be safely implemented in non-obese patients. Further investigations focused on diagnostic accuracy are needed.

#### W5B-SPCA- Basic Verification of Myocardial Extracellular Volume Quantification by Prototype Photon Counting 2 Detector CT

##### Participants

Seitaro Oda, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

This study aimed to investigate the accuracy of myocardial extracellular volume (ECV) quantification by prototype photon counting detector CT (PCD-CT) and the influence of the radiation dose and spectral image settings.

##### METHODS AND MATERIALS

We used a multi-energy CT phantom simulating the blood pool and myocardium. The solid rods representing blood and soft tissue were used as pre-contrast CT. Besides, the solid rods including different iodine concentrations (2 mgI/mL and 4 mgI/mL) were used as post-contrast CT. The tube voltage was set at 120 kVp and three types of tube current (105mAs, 150mAs, 300mAs) applied. Virtual monoenergetic images (VMI) at 50-100 keV were reconstructed. The ECV value was calculated from the CT numbers between pre-contrast and post-contrast. Hematocrit of blood for ECV calculation was fixed at 0.5. We compared the accuracy of ECV values at each monoenergetic level.

##### RESULTS

There was a small but significant difference in ECV values at each keV level in each radiation dose setting. ECV tended to be overestimated at higher keV in all radiation dose settings. There was a significant difference in the variability of ECV values among keV levels in all three radiation dose settings, with higher keV having greater variability. The variation was particularly large in the low dose setting. In all radiation dose settings, the residual values were significantly larger at higher keV levels: the average

residual values at 105mAs, 150mAs and 300mAs settings were 0.5%-6.1%, 0.4%-4.5% and 0.3%-4.9%, respectively. In 150mAs and 300mAs settings, the residual values were smaller at 50keV and 60keV with no significant difference.

## CONCLUSION

When quantifying myocardial ECV with PCD-CT, it was necessary to set appropriate VMI keV and radiation dose settings because the keV levels can cause differences in the quantification value and measurement variation. This PCD-CT system enabled accurate myocardial ECV quantification at 50 and 60 keV in 150mAs and 300mAs settings.

## CLINICAL RELEVANCE/APPLICATION

Accurate myocardial ECV quantification is feasible using PCD-CT with appropriate keV settings.

## W5B-SPCA- Evaluation of Coronary Artery Stents with Ultra-High-resolution Photon-Counting CT: Analysis Of the Optimal Reconstruction Kernel

### PURPOSE

To assess the impact of reconstruction kernel on the image quality of coronary artery stents with ultra-high-resolution photon-counting CT (UHR-PCCT) in a phantom model

### METHODS AND MATERIALS

Six different coronary stents in a coronary phantom were examined at a tube voltage of 120kV. Images were reconstructed using vascular kernels of 11 sharpness levels based on three matrix sizes (matrix size of 512×512 pixels: Bv44, Bv48, Bv56; matrix size of 768×768 pixels: Bv60, Bv64, Bv68; matrix size of 1024×1024 pixels: Bv72, Bv76, Bv80, Bv84 and Bv89), using quantum iterative reconstruction (QIR) at a strength level of 3, and a slice thickness of 0.2 mm. Images with the Bv44 kernel, QIR at a strength level of 3, and a slice thickness of 0.4 mm served as the reference. Image noise and signal-to-noise ratio (SNR) were measured automatically using Python (Version 3.5). The sharpness and the attenuation effects of the stents were objectively evaluated with 10%-90% edge rise distance (ERD), 10%- 90% edge rise slope (ERS) and stent lumen attenuation increase ratio (SAIR). The visible diameter of the coronary stent was measured by the peak-to-peak CT attenuation of stent strut. The overall image quality of the coronary stents was subjectively scored on a 5-point scale (1= poor [poor vessel definition, severe artifacts, diagnostic information impaired], 5= excellent [clear stent strut definition, minimal blooming artifacts from the stent, and diagnostic information sufficient]). Friedman test or Kruskal Wallis test was used to check for differences between the reconstructions as appropriate. The Benjamini-Hochberg procedure was used to adjust P values for multiple comparisons.

### RESULTS

Reconstructions with the Bv44 kernel and a slice thickness of 0.4 mm showed lowest image quality (3[2-3]) and lowest vessel sharpness (ERD:  $0.42 \pm 0.03$  mm; ERS:  $2498.25 \pm 403.83$  HU/mm) (all  $P < 0.05$ ). Considering reconstructions with a slice thickness of 0.2 mm, reconstructions with the Bv72 to the Bv89 kernel had highest image noise and lowest SNR (all  $P < 0.05$ ). Reconstructions with the Bv44 to the Bv56 kernel demonstrated a lower stent sharpness (all  $P < 0.05$ ). No difference was demonstrated among reconstruction kernels in terms of SAIR and the ratio of the visible stent lumen diameter to the true diameter. The overall image quality of coronary stents for reconstructions with the Bv60 to the Bv68 kernel (median score of 5) were favored by the readers.

## CONCLUSION

UHR-PCCT enables the visualization of coronary stents with an excellent image quality and high sharpness. Reconstructions with the Bv60 to the Bv68 kernel may be optimal for evaluation of coronary artery stents.

## CLINICAL RELEVANCE/APPLICATION

UHR-PCCT with the Bv60 to the Bv68 kernel allows improvement of coronary stent evaluation.

## W5B-SPCA- Photon-Counting Detector CT Angiography of the Coronary Arteries: Intra-Individual Comparison of Image Quality to Conventional Energy-integrating Detector CT Angiography

Participants

Daniel Pinos, MD, Charleston, SC (*Presenter*) Nothing to Disclose

### PURPOSE

The aims of this study were to determine the objective and subjective image quality of coronary computed tomography angiography (CCTA) on a clinical dual-source photon-counting detector CT (PCD-CT) and to compare the image quality to conventional dual-source energy-integrating detector CT (EID-CT) in the same patients.

### METHODS AND MATERIALS

Twenty prospectively enrolled patients ( $67.5 \pm 9.0$  years, 28.5 median BMI, 75% male) underwent PCD-CT and EID-CCTA at an average interval of 11 days. Contrast agent protocol and radiation dose were matched between the PCD- and EID-CCTA. Polychromatic images were reconstructed for both EID- and PCD-CT, while virtual monoenergetic images (VMI) were created at 40, 45, 50, 55, 60 and 70 keV for PCD-CT. Contrast-to-noise ratio (CNR) was calculated for each coronary artery by two blinded readers. Stratification analysis of patients was performed according to BMI [high ( $>30$  kg/m<sup>2</sup>) vs low ( $<30$  kg/m<sup>2</sup>)]. For subjective analysis, readers scored image noise, vessel attenuation, vessel sharpness and overall quality using a 1-5 Likert scale.

### RESULTS

Compared with EID-CT, attenuation and image noise of the coronary arteries were higher for all PCD-CT VMI reconstructions (all  $p < 0.008$ ). Coronary artery CNR values from PCD-CT monoenergetic and polychromatic reconstructions were all significantly higher than CNR values from EID-CT (all  $p < 0.008$ ). A proportionally greater increase in CNR of 33.1% was found in high BMI patients averaged over all reconstructions. Subjective scores of image noise, vessel attenuation, vessel sharpness and overall quality were significantly higher for 55, 60, and 70 keV compared to EID-CT (all  $p < 0.05$ ).

## CONCLUSION

The improved objective and subjective image quality of PCD-CCTA compared to EID-CCTA may offer better visualization of the coronary arteries for a wide array of patients, especially those with high BMI.

## CLINICAL RELEVANCE/APPLICATION

The improved image quality of CCTA with PCD has the potential advantages of lower radiation dose, better detection of coronary artery disease, and better visualization in obese patient.

### W5B-SPCA- Deep Learning-Based Myocardial Strain Analysis from Cine MR Image: A Comparative Study of Unet and ResUnet

Participants  
Dayeong An, MSc, Milwaukee, WI (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study is to develop a deep learning (DL)-based network for measuring myocardial regional function from conventional cine magnetic resonance (MRI) images, combining the advantages of cardiac magnetic resonance feature tracking (CMR-FT) and MRI tagging while minimizing their respective limitations in assessing regional cardiac function.

#### METHODS AND MATERIALS

Modified Unet and ResUnet architectures were implemented and trained to handle spatiotemporal data. Deeper layers and dilated convolutional blocks were incorporated to increase the receptive field and improve multi-scale feature learning. A custom loss function was employed for better optimization. Paired cine MR images and myocardial displacement fields generated from corresponding tagged images were acquired at matching locations and timepoints. The dataset comprised 1280 images (64 MRI slices with 20 cine and tagged images per slice). Data were split into training, validation, and test datasets as 80%, 10%, and 10%, respectively. Random flip data augmentation was performed. Radial and circumferential strains at end-systolic were measured using the American Heart Association (AHA) 6-segment model.

#### RESULTS

After 100 epochs, accuracies were 87% for Unet and 86% for ResUnet with losses of 0.6% and 0.7%, respectively. Mean±SD global strains for tagging, Unet, and ResUnet were Err = 15.4±8.4, Ecc = -15.3±8.3; Err = 17.1±10.3, Ecc = -14.7±9.1; and Err = 17.8±10.2, Ecc = -15.6±9.2, respectively. Unet and ResUnet achieved mean squared errors (MSE) of 0.5 and 0.46, peak signal-to-noise ratios (PSNR) of 71.62 and 72.08, structural similarity indices (SSIM) of 91.7 and 92.4, and Pearson correlation coefficients (PCC) of 92.9 and 95.9, respectively, compared to MRI tagging. Paired t-test revealed no statistically significant differences in strains between conventional and Unet methods ( $p>0.05$ ). However, significant differences were observed in radial AHA sectors 2 and 4, and circumferential AHA sector 1 between conventional and ResUnet methods ( $p<0.05$ ).

#### CONCLUSION

The study results demonstrate the feasibility of using deep learning-based networks, particularly the modified Unet architecture adapted for spatiotemporal data analysis, for assessing regional cardiac function in a clinical setting without the need for acquiring MRI tagged images. Potentially, this network can be used to reduce MRI scan time and allow for more adoption of strain imaging for evaluating different cardiovascular diseases.

## CLINICAL RELEVANCE/APPLICATION

The deep learning-based networks adapted for spatiotemporal data analysis provides an efficient and accurate alternative to MRI tagging for assessment of regional cardiac function for early detection of cardiovascular diseases.

### W5B-SPCA- Coronary Artery Calcium Quantification with Super Resolution Deep-learning Reconstruction Algorithm: An Anthropomorphic Phantom Study

Participants  
Shinsuke Shigematsu, Kumamoto, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the impact of a novel super-resolution deep-learning reconstruction (SR-DLR) algorithm on coronary artery calcium (CAC) quantification in comparison with filtered back projection (FBP), hybrid iterative reconstruction (HIR), model-based iterative reconstruction (MBIR), and normal resolution deep-learning reconstruction (NR-DLR) algorithms.

#### METHODS AND MATERIALS

A QRM Thorax phantom with cardiac calcification inserts containing three different amounts of hydroxyapatite with three different diameters was used for this study. The phantom was placed inside a body ring (400×300 mm diameter) and scanned on a 320-row scanner with a tube voltage of 120 kVp. Scanning was performed with six tube currents ranging from 100 to 350 mA in 50 mA increments (CTDIvol: 1.4 to 5.1 mGy). Images were reconstructed using FBP, HIR (AIDR3D), MBIR (FIRST), NR-DLR (AiCE), and SR-DLR (PIQE) at a 3 mm slice thickness. Image noise, contrast-to-noise ratio (CNR), and task-based detectability index of calcifications were quantified. CAC volume and Agatston score were measured semi-automatically; the relative volume measurement error from the nominal CAC volume (360.6 mm<sup>3</sup>) was calculated for each reconstruction at each radiation dose level. Using the Agatston scores obtained at 350 mA as a reference for each reconstruction, the relative measurement errors at lower radiation doses (100-300 mA) were calculated. Using the Agatston scores obtained on 350-mA FBP images as a clinical reference, the relative measurement errors of each reconstruction at each radiation dose were also calculated.

#### RESULTS

SR-DLR yielded the lowest image noise, the highest CNR, and the highest CAC detectability index among all reconstructions at each radiation dose level. The lowest measurement errors in CAC volume relative to nominal volume and the Agatston score relative to reference dose (350 mA) were obtained with SR-DLR at all dose levels. When the Agatston score at 350-mA FBP was used as a reference, SR-DLR showed a systematic underestimation at all radiation doses (relative measurement error < -7.6%).

#### CONCLUSION

SR-DLR may improve image quality and facilitate accurate CAC quantification even at lower radiation doses, but its clinical application requires caution due to the deviation of the Agatston score from the conventional high-dose FBP setting.

## CLINICAL RELEVANCE/APPLICATION

The novel SR-DLR algorithm may yield accurate detection and quantification of CAC due to its excellent noise and spatial resolution characteristics, but the clinical evaluation for potential impact on risk classification and patient management is warranted before routine clinical use.

### Chest Imaging Wednesday Poster Discussions II

#### Sub-Events

#### **W5B-SPCH- Deep Learning-Based Prediction of Left Ventricular Ejection Fraction Using Chest Radiographs: Potential Role in Pre-Screening Individuals in Health Checkup Populations** 1

##### **PURPOSE**

To develop and validate deep learning automatic prediction algorithms (DLLV) for left ventricular ejection fraction (LVEF) from chest radiographs (CRs), and explore its potential role as pre-screening target individuals for echocardiography in health checkup populations.

##### **METHODS AND MATERIALS**

To develop DLLV, patients who received CR and echocardiography at the same day at Seoul National University Hospital (SNUH) between 2016 and 2021 were retrospectively collected. 32,137 CRs from 23,616 patients (12,854 men [54%]; mean age, 69 [IQR, 62-80] years old) were included and randomly split into training (n= 25,709), validation (n= 3,214), internal test (n= 3,214) datasets. LVEF measured on echocardiogram was used as reference standard. ResNet50 was used as backbone convolutional neural network while final layers were adapted to predict LVEF in ranges of [0, 35, 50, 65, 100] (classification branch) and exact LVEF values (regression branch). For external testing, two independent cohorts were collected: 1) 5440 patients (2867 men [53%]; 66 [55-66] years old) who received same day CR and echocardiography at SNUH in 2015 (SNUH cohort) and 2) 28,034 individuals (17252 men [62%]; 56 [50-63] years old) at Healthcare System Gangnam Center between 2015-2021 (HCS health checkup cohort) were retrospectively collected. Prediction performance of DLLV was evaluated using area under the receiver operating characteristic curve (AUROC).

##### **RESULTS**

In internal test dataset, DLLV showed AUROCs of 0.79 (95% CI, 0.78-0.81) and 0.80 (0.79-0.81) in predicting patients with LVEF =35% and =50%, respectively. In SNUH cohort, 8% (459/5440) and 2% (123/5440) of the patients showed LVEF =35% and 50% on same day echocardiogram, and DLLV exhibited AUROC of 0.85 (0.84-0.86) in predicting LVEF =35% and 0.78 (0.77-0.80) in predicting LVEF =50%. In HCS cohort, only 0.2% (62/28,034) of the individuals showed LVEF =50%, and none showed LVEF =35%. DLLV showed AUROC of 0.74 (0.74, 0.75) in detecting those with LVEF =50%. When selective recommendation of echocardiography was assumed depending on DLLV results from CRs (i.e., those with DLLV >5%), DLLV could screen 68% (42/62) of individuals with LVEF =50% by recommending echocardiography for 8655 among 28,034 individuals (70% reduction of examinations). Only 0.1% (20/19,329) showed abnormal LVEF among individuals echocardiography was not recommended by DLLV.

##### **CONCLUSION**

s DLLV exhibited promising performance in predicting patients' LVEF from CRs. In a health checkup cohort, DLLV showed potential in pre-screening individuals who may need echocardiography.

##### **CLINICAL RELEVANCE/APPLICATION**

Selective recommendation of echocardiography using DLLV may enhance chance of opportunistic screening and reduce expense from unnecessary examinations.

#### **W5B-SPCH- Missed Diagnosis on Chest X-Ray: Auditing Large Volumes of Data with the Help of Comprehensive Artificial Intelligence** 2

##### **PURPOSE**

Chest x-rays (CXR) are the most common imaging modality in radiology and also one of the earliest imaging modalities to be developed. Despite many decades of experience in this modality, the diagnostic error rate has remained relatively unchanged. This could partly due to the lack of consistent feedback to radiologists when reporting CXRs. The purpose of the current study was to detect the rate of missed diagnoses on CXRs reported in a busy teaching hospital environment and demonstrate an efficient method of auditing the CXRs.

##### **METHODS AND MATERIALS**

A consecutive cohort of adult (= 18 years) CXRs reported normal within the St. Vincent's Hospital Melbourne Imaging Department were retrospectively collected and de-identified. A commercially available system (Annalise Enterprise CXR) was applied over included studies to identify cases predicted by the AI to contain one or more of 60 findings deemed significant/critical. The discrepancy between original radiology report and AI predictions were reviewed by a radiologist with over 10 years-experience to evaluate the level of agreement between radiologists and the AI-predictions, and the number of missed findings determined through subsequent review.

##### **RESULTS**

A total of 1559 CXRs reported in 2016 were retrospectively collected and de-identified. All of these studies were successfully processed by the AI system. The AI detected significant abnormalities in 169 of the studies. Of these, 97 were confirmed to have

significant missed findings by the reporting radiologist. The most common missed findings were pulmonary nodules (16%), pleural effusions (16%), spinal compression fractures (12%) airspace opacities (11%), acute rib fractures (9%) along with a number of other significant missed findings of hilar lymphadenopathy, pulmonary artery enlargement, bone lesions, interstitial thickening, pulmonary congestion, two shoulder dislocations and an acute clavicle fracture.

## CONCLUSION

The study demonstrates a time-effective means for auditing CXRs in a busy radiology department within a teaching hospital in order to provide constructive feedback to radiologists and trainees. A total of 1559 CXRs were automatically processed by AI allowing the radiologist to review the findings with 97 findings deemed significant out of the 169 studies detected by AI.

## CLINICAL RELEVANCE/APPLICATION

Integration of a comprehensive AI model in a real-world reporting environment has the potential to improve radiologist performance, ultimately improving patient care.

### W5B-SPCH-3 **Assessment of Intensive Care Unit Physician Performance and Perception towards AI Utilizing a Concurrent-Read Endotracheal Tube Detection Algorithm on Portable Chest Radiographs: A Multi-Reader, Multi-Case Study**

Participants

Kaustav Bera, MD, Cleveland, OH (*Presenter*) Nothing to Disclose

## PURPOSE

AI tools to detect and measure endotracheal tubes (ETT) on frontal chest radiograph (CXRs) are primarily used by radiologists. The purpose of this study was to compare the interpretation time and performance improvement of ICU physicians for detection and measurement of ETT without and with concurrent AI assist. We also assessed the perception of the readers towards AI before and after the exercise in the form of multiple choice questionnaire.

## METHODS AND MATERIALS

A fully crossed multi-reader and multi-case reader study was conducted. 34 participating physicians engaged in critical care (16 fellowship-trained attendings; 18 physicians-in-training [15 fellows; 3 residents]) were enrolled and retrospectively interpreted 100 CXRs (50 with ET tube; 50 without) in two reading scenarios (once without and once with AI assist). Readers were also asked to self-record the interpretation times. Interpretations of any given case set with and without AI would be separated by 4 weeks of washout. The physician and AI interpretations were compared to the reference standard measurements by board-certified cardiothoracic radiologist (10 years experience). Sensitivity, specificity, PPV, NPV was used to evaluate performance. Performance and time to interpretation was compared between AI assisted and unassisted scenarios using Fisher's exact test and Wilcoxon rank sum test. A pre- and post-completion survey was also administered and analyzed using the Likert scale.

## RESULTS

We here present preliminary results for the first set before washout. Only completed surveys were taken for analysis (30%). AI had sensitivity, specificity, PPV, NPV and likelihood ratio of .98, .98, .98, .98, 49 ( $p < .001$ ) when compared to reference standard. Mean reader performance in terms of sensitivity, specificity and likelihood ratio were improved from 0.98, 0.91, 15 to 1, 0.97, 20 ( $p < .001$ ). The average interpretation time per case was significantly reduced by approximately 52% (median time 25 secs vs 16.5 secs;  $p < .01$ ). Following the completion of set 1 of the study, 75% of respondents expressed the desire to use AI in their clinical practice. Interestingly 63% of respondents had answered that they had no prior experience with AI at the beginning of the study.

## CONCLUSION

An FDA approved AI tool for detecting and measuring ETT distance on frontal CXRs showed excellent agreement with the ground truth, and significantly improved interpretation times as well as overall performance for ICU physicians across a broad spectrum of experience levels.

## CLINICAL RELEVANCE/APPLICATION

ETT AI tool showed excellent accuracy as well as helped ICU physicians improve their performance and time to interpretation. This paves the way for future prospective studies and ultimately bedside clinical deployment.

### W5B-SPCH-4 **Consecutive Cohort Analysis with Natural Language Processing (NLP) and Multi-finding AI Algorithm for Chest Radiographs: Multidimensional Opportunity for QA/QC**

Participants

Emiliano Garza Frias, MD, Monterrey, NL (*Presenter*) Nothing to Disclose

## PURPOSE

To assess if comprehensive discrepancy analysis of findings between NLP-based radiology reports search and a multi-finding, image-based AI algorithm can help audit quality of chest radiograph (CXR) reporting in community and quaternary healthcare settings.

## METHODS AND MATERIALS

Our IRB-approved, HIPAA-compliant, retrospective study included 3760 consecutive CXRs (PA/AP /or lateral views) from 3760 adult patients (age > 18 years) in two community and quaternary care hospitals. We queried an NLP-based radiology report search engine (Microsoft Nuance) for the presence of following findings: optimal/misplaced/absent lines/tubes (endotracheal tube, esophageal tube, pulmonary arterial and central venous catheters), solitary pulmonary nodule (SPN), pneumonia, simple pneumothorax, tension pneumothorax, pneumomediastinum, pneumoperitoneum, osteopenia, and compression vertebral fractures. Each radiology report (Rad1) was manually reviewed for presence of these findings by at least 1/5 participating physicians. Each CXR was processed with a multi-finding AI algorithm (Annalise.AI) for presence of the same findings. CXRs with discrepant finding between the NLP-Rad1 and the AI was blindly assessed by either one or two thoracic radiologists (Rad2/3) based on the discrepancies to establish the standard of reference. The data were analyzed with descriptive statistics.

## RESULTS

NLP/Rad1 and AI had high true positive and true negative concordance for CXR findings (lowest: 86.7%, 3260/3760; highest 98.8%, 3708/3760). Among the 3760 CXRs, the AI correctly identified false-negative (FNr) and false positive findings (FPr) in radiology reports for simple pneumothorax (FNr 0.4% [13/3760], FPr 0.2% [7/3760]); pneumonia (7.1% [270/3760], 1.2% [44/3760]), SPN (1.6% [60/3760], 1.7%[65/3760]), osteopenia (5.3% [200/3760], 0.2% [8/3760]), and compression fractures (3.1%, [114/3760], 0.2% [8/3760])

## CONCLUSION

Consecutive discrepancy analysis of NLP-based radiology reports search and AI outputs can help identify a substantial proportion of missed and overcalled CXR findings with low false positive or false negative frequencies.

## CLINICAL RELEVANCE/APPLICATION

Our proposed framework of NLP/AI for consecutive discrepancy analysis has broad applications such as a second reader to avoid missed or miscalled findings, and in peer-review and QA/QC efforts.

## W5B-SPCH- Glucose Metabolic Rate from Dynamic 18F-FDG PET/CT Scan to Differentiate Sarcoid Lymph Nodes from Malignant Lesions

5

Participants

Akihiro Inoue, MD, Kawadacho Shinjuku-Ku, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Long-term fasting 18F-Fluorodeoxyglucose positron emission tomography (FDG-PET) has contributed to the diagnosis of active inflammation in cardiac sarcoidosis (CS). In the diagnosis of FDG-PET, an accumulation of active sarcoid lymph nodes is often difficult to differentiate from lymphatic metastasis or lymphoma. In differentiating active sarcoid lymph nodes from malignant lesions, we investigate the potential of the glucose metabolic rate (MRglc, mg/min/100ml) that is a new quantification of glucose metabolic kinetics derived from dynamic FDG-PET scan with a silicon photomultiplier.

## METHODS AND MATERIALS

100 CS patients and 67 cancer-bearing patients who underwent dynamic FDG PET/CT scan with a silicon photomultiplier between March 2021 and December 2022 were enrolled. Mediastinal or hilar lymph nodes with SUVmax  $\geq 3$  in sarcoidosis patients and metastatic or primary lesions with SUVmax  $\geq 3$  in cancer-bearing patients were included in the analysis. MRglc was derived from tissue and plasma blood time-activity concentration curves using the Patlak linearization approach, with data acquired between 30 and 50 min after injection in dynamic FDG-PET/CT. Then, 60 minutes later, a standard scan performed. Active lesion was defined as SUVmax  $>3.0$  on standard whole body image. Use of parametric horizontal-axial image, mean value in VOI (size 1.5cm<sup>3</sup>) was measured.

## RESULTS

Forty-seven lymph node lesions from 25 of 100 CS patients and 39 malignant lesions from 27 of 67 cancer-bearing patients were included in the analysis. SUV and MRglc for sarcoid lymph nodes were significantly lower than those for malignant lesions (SUV, 4.93 $\pm$ 2.09 vs. 5.95 $\pm$ 2.32; MRglc, 2.42 $\pm$ 1.26 vs. 3.57 $\pm$ 1.57;  $p < 0.001$ ). Receiver-operating-characteristic analysis revealed that the ability to discriminate sarcoid lymph nodes and malignant lesions was the area under the curve (AUC) of 0.71, 77% sensitivity, and 60% specificity for SUV, AUC of 0.74, 80% sensitivity, and 66% specificity for MRglc, and AUC of 0.76, 90% sensitivity, and 62% specificity for the ratio of MRglc to SUV, respectively.

## CONCLUSION

MRglc and the ratio of MRglc to SUV are significantly lower for sarcoid lymph nodules than malignant. The use of MRglc improves sarcoid lymph nodes identification over SUV alone.

## CLINICAL RELEVANCE/APPLICATION

The ability to distinguish between sarcoid and metastatic lymph nodes with FDG-PET will lead to accurate staging of malignant tumors.

## W5B-SPCH- Incremental Prognostic Value of Deep learning-based Quantification of Macroangiopathic Aortic Changes for Cardiovascular Mortality in Heavy Smokers

6

Participants

Alexander Rau, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

Macroangiopathic changes of the aorta are a common manifestation of cardiovascular (CV) disease. Currently, maximum diameter is the only prognostic measure used in clinical practice, despite quantification of other macroangiopathic changes (e.g. calcification) is available on computed tomography (CT) imaging. Thus, we applied a deep learning model to automatically quantify macroangiopathic changes of the aorta and investigated their prognostic value for CV mortality in a high-risk population of heavy smokers.

## METHODS AND MATERIALS

We used a deep learning model to automatically segment the aorta on lung screening chest CTs of participants enrolled in the National Lung Screening Trial at baseline and one-year follow-up. The following features were quantified: maximum diameter (cm), volume (deciliter) and calcifications (ml, categorized into tertiles). We assessed the association between (I) baseline features and CV and (II) the change of features within one year and CV mortality via multivariable Cox proportional hazard regression adjusted for traditional CV risk factors including smoking and hypertension. Harrel's c-index was used to compare the predictive value of the features.

## RESULTS

Among 24,770 participants at baseline (mean age 61.4 $\pm$ 5.0 years; 59.2% male) 440 (1.8%) CV deaths occurred over a mean follow-up of 6.3 $\pm$ 1.0 years. In univariate models, C-index of aortic volume and calcifications were significantly higher compared to

diameter (c-index 0.63 and 0.66 vs. 0.61;  $p=0.02$ ) for the prediction of CV mortality. After adjustment for traditional CV risk factors, volume (aHR: 1.04 [1.01-1.08];  $p=0.008$ ) and calcification (aHR: 2.53 [1.87-3.41];  $p<0.001$ ) remained significantly associated with CV mortality whereas the association for diameter was attenuated. In subjects with one year follow-up available ( $n=22,140$  individuals, mean age  $61.4\pm 4.9$  years; 58.3% male with a 1.5% CV), the strongest association was found between an increase in calcifications and CV mortality (aHR highest tertile: of 1.74 [1.32-2.29],  $p<0.001$ ) after multivariable adjustment for traditional CV risk factors.

## CONCLUSION

Deep learning can automatically quantify macroangiopathic changes of the aorta on lung screening chest CTs and identify individuals at high risk of CV mortality beyond traditional risk factors.

## CLINICAL RELEVANCE/APPLICATION

Deep learning-based quantification of macroangiopathic aortic changes can identify individuals at risk of CV mortality beyond traditional risk factors in a high-risk population of heavy smokers. This enables opportunistic risk assessment to improve personalized prevention and treatment strategies.

## W5B-SPCH- Dependent Contrast Layering Sign" on CT: Preliminary Cross Sectional Descriptive Study

7

Participants  
Youssef Mohsen, MD, MS, Iowa City, IA (*Presenter*) Nothing to Disclose

## PURPOSE

CT findings of contrast layering in the dependent part of the central venous system have been reported to be associated with compromised cardiac function and imminent cardiac arrest. To the best of our knowledge, there is no systemic research on this finding and its association with cardiac arrest and mortality. Therefore we studied the radiologic findings of dependent contrast layering in vascular structures on CT and its clinical implications.

## METHODS AND MATERIALS

This single center retrospective study involved a list of 226 patients obtained by searching PACS reports for the keywords "layering of contrast", "pooling of contrast" or "dependent layering of contrast" in contrast enhanced CT chest and CT abdomen performed between Jan 2008 and Jan 2022. Two body radiologists reviewed for the dependent layering of contrast in vascular structures and parenchyma of abdominal organs. Clinical data were investigated from electronic medical records. The frequencies of the radiologic findings in association with clinical data were analyzed.

## RESULTS

Dependent contrast layering in the vascular structures is demonstrated in 21 patients (9.3%, mean age:  $67.4\pm 12.4$ ). Layering of contrast is shown in the IVC ( $n=19$ , 90.4%), hepatic vein ( $n=17$ , 80.9%), liver parenchyma ( $n=7$ , 30.3%), right atrium ( $n=5$ , 23.8%), and other organs ( $n=10$ , 47.6%). Among the 21 patients, 6 patients (28.5%) had cardiac arrest within 24 hours, all of which occurred within 2 hours. 11 patients (52.3%) died during their hospital stay. Layering in the right atrium shows the highest rate of cardiac arrest within 2 hours (4 of 5, 80%) followed by liver parenchyma (5 of 7, 71.4%). Reflux into liver parenchyma shows the highest rate of death during the same hospital stay (4 of 7, 57.1%). The mean number of involved structures per patient is  $3.29\pm 2.0$  (range 1-9). It is higher in patients who died during the same hospital stay ( $4.25\pm 1.15$ ) compared to those who survived ( $3.3\pm 2.02$ ). The mean number of involved structures is similar between the cardiac arrest ( $3.29\pm 1.98$ ) and non-cardiac arrest ( $3.28\pm 2.08$ ) groups. The mean left ventricular ejection fraction (LVEF) was  $38\pm 12\%$  (range 15-67). LVEF was less than 40% in 52% (10 of 19) of patients. The shock index was 0.9 or higher in 66.6% (12 of 18) of patients and its mean was  $1.08\pm 0.50$  (range 0.5-2.6).

## CONCLUSION

The CT findings of dependent contrast layering in the central venous system are related to high rates of imminent cardiac arrest and mortality.

## CLINICAL RELEVANCE/APPLICATION

Radiologists and technicians need to recognize these findings to alert clinicians the risk of cardiac arrest. Our study provides important preliminary data for radiologists and clinicians to recognize the significance of "Dependent contrast layering sign" for clinical decision-making.

## W5B-SPCH- Performance of a Novel Intravascular Tantalum Oxide-based CT Contrast for Enhancement and Conspicuity of Thoracic Vasculature in an Animal Model: Total and Relative Contrast Material Advantage

8

Participants  
Maurice Heimer, MD, Munich, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

To compare a novel intravenous tantalum oxide (TaCZ) nanoparticle CT contrast agent to conventional iodinated (Iopromide) CT contrast agent for thoracic artery and vein visualization in a rabbit model.

## METHODS AND MATERIALS

Five New Zealand White rabbits were serially placed in a human-torso-sized adipose-equivalent encasement and scanned on a clinical CT system (Philips IQon, Best, Netherlands) before and 6, 40, 75, 136, and 240 sec after IV injection of 540 mg element (Ta or I) per kilogram of body weight of TaCZ or Iopromide. Animals were scanned twice, once with each contrast agent. Absolute contrast enhancement of the aortic arch, pulmonary trunk, superior vena cava, and subclavian vein was measured in Hounsfield Units (HU) by averaging three regions of interest drawn in the center of the lumen minus corresponding non-contrast measurements. Randomized imaging series were viewed on a clinical PACS system to rate vascular conspicuity on a 5-point Likert scale (0 = no vascular enhancement; 1 = faintly seen or visible but discontinuous; 2 = adequate contrast of main vessel, not all branches seen; 3 = good contrast of main vessel and depiction of branches; 4 = excellent contrast of main vessel and deep branches).

## RESULTS

Mean vascular enhancement was significantly higher for TaCZ in all examined blood vessels at all time points compared to Iopromide; aortic arch at 6s (263 vs. 217;  $p < 0.01$ ), at 40s (265 vs. 145;  $p < 0.01$ ), at 75s (240 vs. 119;  $p < 0.01$ ), at 136s (217 vs. 93;  $p < 0.01$ ) and at 240s (183 vs. 73;  $p < 0.01$ ), pulmonary artery at 6s (296 vs. 266;  $p < 0.01$ ), at 40s (263 vs. 138;  $p < 0.01$ ), at 75s (246 vs. 102;  $p < 0.01$ ), at 136s (213 vs. 83;  $p < 0.01$ ) and at 240s (174 vs. 64;  $p < 0.01$ ), superior vena cava at 6s (307 vs. 211;  $p < 0.01$ ), at 40s (255 vs. 127;  $p < 0.01$ ), at 75s (239 vs. 96;  $p < 0.01$ ), at 136s (196 vs. 79;  $p < 0.01$ ) and at 240s (169 vs. 49;  $p < 0.01$ ) and the subclavian vein at 6s (280 vs. 225;  $p < 0.01$ ), at 40s (254 vs. 111;  $p < 0.01$ ), at 75s (236 vs. 86;  $p < 0.01$ ), at 136s (205 vs. 67;  $p < 0.01$ ), and at 240s (170 vs. 54;  $p < 0.01$ ). The mean vascular enhancement of TaCZ at a 136s delay provided comparable results to the 6s arterial phase of Iopromide (213 vs. 223;  $p > 0.05$ ). Overall, vascular enhancement correlated well with perceived vascular conspicuity scores for both agents.

## CONCLUSION

s TaCZ provides both an absolute and relative contrast advantage compared to Iopromide for improved visualization of the thoracic arteries and veins across a broad range of timepoints after contrast injection.

## CLINICAL RELEVANCE/APPLICATION

TaCZ gives superior prolonged thoracic vascular enhancement over iodine agents at CT and warrants clinical testing as a means to improve the quality and consistency of CT angiograms and venograms.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

W5B-SPER

### Emergency Radiology Wednesday Poster Discussions II

#### Sub-Events

#### **W5B-SPER-1 Channeling the Neuroradiology Crystal Ball: Predicting Presenting Symptoms Associated with Imaging-Proven Acute Cord Compression in the Emergency Department**

#### Participants

Mercy Mazurek, Boston, MA (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Spinal cord compression (CC) can result from both atraumatic and traumatic causes. CC commonly presents with back pain, urinary incontinence, lower extremity weakness, and malignancy, among others. While the occurrence of these symptoms is high, the prevalence of CC due to both atraumatic and traumatic causes is low. Understanding the clinical symptoms that are associated with CC may better inform the utilization of imaging in the emergency department (ED) to reduce costs and provide efficient care.

#### **METHODS AND MATERIALS**

This retrospective study analyzed patients who underwent our ED's abbreviated survey spine MRI protocol for suspected CC from 2018 to 2022. The survey protocol includes sagittal T2 and short-TI inversion-recovery (STIR), with optional axial T2. Imaging reports were reviewed by a blinded, board-certified neuroradiologist and characterized as positive or negative for CC. Demographic factors and presenting symptoms were extracted from the electronic medical record and compared among patients with imaging-positive acute CC vs negative. Univariate analysis was performed using the student's t-test and chi-squared test. A multivariate logistic regression was performed with stepwise backwards elimination where the variable with the largest P value was removed in a stepwise fashion in each iteration until all variables on the final model had a  $P < .20$ .

#### **RESULTS**

A total of 845 patients (mean age  $57 \pm 19$  years, 45% female) received a survey spine MRI for suspected CC during the study period. Of these, 23% presented with trauma, 55% back pain, 29% lower extremity weakness, 5.7% history of malignancy, 14% urinary incontinence, 6.0% bowel incontinence, 14% neck pain, 20% numbness, 7.3% ataxia, and 6.4% hyperreflexia. There were 725 (85%) and 120 (14%) patients negative and positive for CC, respectively. In the univariate model, trauma, back pain, numbness, ataxia, and hyperreflexia were significantly associated with having a positive study (Table 1). In the multivariate model, trauma, back pain, lower extremity weakness, urinary or bowel incontinence, numbness, ataxia, and hyperreflexia were significantly associated with being positive for acute CC (Table 2).

#### **CONCLUSION**

Presenting symptoms of trauma, back pain, lower extremity weakness, urinary or bowel incontinence, numbness, ataxia, and hyperreflexia were significantly associated with positive CC findings on ED survey spine evaluation in the ED. These results may inform which patients should receive triage priority in the ED.

#### **CLINICAL RELEVANCE/APPLICATION**

Understanding the symptoms associated with acute CC informs efficient utilization of abbreviated, CC-specific survey spine MRI protocols to limit unnecessary imaging studies thereby expediting diagnosis and emergent treatment.

W5B-SPGI

### Gastrointestinal Imaging Wednesday Poster Discussions II

#### Sub-Events

#### W5B-SPGI-1 Preoperative Prediction of Ki-67 Expression in Hepatocellular Carcinoma by Spectral Imaging on Dual-Energy CT

##### PURPOSE

To investigate the value of quantitative spectral parameters measured on a dual-energy CT in preoperative predicting the expression level of Ki-67 in HCC.

##### METHODS AND MATERIALS

91 HCC patients underwent both pathological examination and two-phase contrast-enhanced CT scanning with spectral imaging mode were included in this study. According to Ki-67 expression determined by the Ki-67 positivity rate (Ki-67%), patients were divided into two groups: high expression group (Ki-67% > 20%, n = 51) and low expression group (Ki-67% = 20%, n = 40). CT values on 100 and 140 keV monochromatic energy images (HU100-140keV), normalized effective atomic number (Neff-Z), water density (Dwater), fat density (Dfat) were measured and calculated. The parameters comparison between groups, receiver operation curve for prediction efficacy evaluation were conducted.

##### RESULTS

The Neff-Z, Dfat, HU100-140keV and Dwater in high expression group were significantly higher than those in low expression group (all P < 0.05). In prediction of Ki-67 expression, the AUCs of Neff-Z, Dfat, HU100-140keV and Dwater were 0.650, 0.677, 0.692-0.750, 0.777. The corresponding sensitivities were 0.647, 0.804, 0.529-0.824 and 0.961, respectively. The specificities were 0.600, 0.525, 0.825-0.625 and 0.475, respectively. Dwater showed highest Ki-67 expression prediction performance, with AUC of 0.777. The multi-variable analysis combining spectral CT parameters and morphological characteristics improved the prediction efficiency (AUC=0.814).

##### CONCLUSION

The spectral parameters (Neff-Z, Dfat, HU100-140keV and Dwater) obtained by contrast-enhanced spectral imaging on dual-energy CT can be used to predict Ki-67 expression in HCC, the efficiency would be improved by multi-parameter analysis combining spectral CT parameters and morphologic features.

##### CLINICAL RELEVANCE/APPLICATION

Ki-67 was a significant marker for HCC prognosis and clinical decision, however current method to evaluate Ki-67 always needs surgery, which is detrimental for assessing patients who lost surgery chance. Contrast-enhanced spectral imaging on dual-energy CT provides various parameters to predict cell proliferation in HCC with good performance, shedding lights in clinical diagnosis and therapeutic strategy decision.

#### W5B-SPGI-2 The Added Value of Reduced field-of-view IRIS-DWI Sequence for T2WI Sequence in T Staging of Rectal Cancer

#### W5B-SPGI-3 Impact of MRI after CT on the Therapeutic Decision of Pancreatic Adenocarcinoma

##### PURPOSE

The purpose of this work is to determine the impact of MRI after CT on the therapeutic decision of pancreatic adenocarcinoma.

##### PURPOSE

Oblique axial high-resolution T2WI(HR-T2WI)was the recommended sequence for rectal cancer T staging.We attempted to evaluate the added value of reduced field-of-view (rFOV) IRIS-DWI sequence for T2WI sequence in evaluating T staging of rectal cancer.

##### METHODS AND MATERIALS

All patients underwent rectal MRI examinations in our institution between June 2022 and November 2022 . rFOV IRIS-DWI and oblique axial HR-T2WI images were acquired using a 3.0T MR scanner (Ingenia Elition, Philips, Best, the Netherlands) (Table 1). All patients were evaluated in two rounds by two methods. First, one senior radiologist (Y.K.M.) with more than 7 years of experience in rectal cancer MRI evaluated the T staging based on oblique axial HR-T2WI images and recorded the diagnosis confidence. Second, the same radiologist (Y.K.M.) reevaluated the T staging based on rFOV IRIS-DWI and HR-T2WI images after one-week interval.The diagnosis confidence was also recorded. The radiologist was blind to the detailed pathologic T staging. MedCalc statistical software (version 20.116) was used for data analysis. The accuracy of two diagnosis methods between oblique axial HR-T2WI and T2WI + rFov IRIS were compared by paired t-test. Paired sample t-test was used to compare the diagnosis confidence between the two diagnosis methods. ROC curve was used to evaluate the diagnostic performance for pT3 staging. P < 0.05 indicated the difference was statistically significant.

##### METHODS AND MATERIALS

It's a prospective, cross-sectional and evaluative study over 24 months from January 2020 to December 2021 of patients suspected of having pancreatic cancer.

## RESULTS

A total of 117 cases of patients were included, aged 34-91 years with an average age of  $62 \pm 11$  years and a sex ratio of 1.25. The average diameter is  $43.61 \pm 15.268$  mm. The TDM and MRI assessment of resectability was performed according to NCCN version 1.2020 criteria. 46 patients (i.e. 39.3%) were at the metastasis stage, 36 patients (i.e. 30.8%) resectable, 19 patients (i.e. 16.2%) locally advanced and 16 patients (i.e. 13.7%) borderline resectability. To determine the impact of MRI after CT on the treatment decision, we compared the staging of the resectability of each of the two techniques by referring to surgery for resectability and metastases and to MRI data for characterization of liver damage. The analysis showed that in 15 patients (i.e. 12.8%) the therapeutic approach was changed on MRI after CT.

## RESULTS

Twenty-seven patients with rectal cancer were enrolled in this retrospective study. The average age was  $66.7 \pm 6.9$  years, and there were 15 (56%) males (Table 2). The diagnosis accuracy for pT1-pT2 and pT3 was 58.3% and 73.3% according to oblique axial HR-T2WI. According to the oblique axial HR-T2WI and rFOV IRIS-DWI, 11 patients (91.7%) in 12 pT1-T2 staging patients and 14 patients (93.3%) in 15 pT3 staging patients were accurately diagnosed ( $P < 0.0001$ ) (Table 3). Based on T2WI + rFOV IRIS-DWI imaging showed higher diagnosis confidence, and the diagnosis confidence were 2.9 and 2.37 in all patients ( $P < 0.001$ ). For pT2 and pT3 staging subgroups, the diagnosis confidence based on T2WI + rFOV IRIS-DWI imaging also showed higher confidence (2.8 vs. 2.1,  $P = 0.01$ ; 2.93 vs. 2.53,  $P = 0.009$ , respectively) (Table 4). ROC analysis showed the diagnosis performance based on T2WI + rFOV IRIS-DWI imaging was superior to T2WI sequence. The AUC, sensitivity and specificity were 0.928, 93.3%, 91.7% and 0.658, 73.3%, 58.3%, respectively ( $P = 0.002$ ) (Table 5, Figure 3).

## CONCLUSION

Complementary MRI to CT led to changes in resectability and therapeutic management in a significant proportion of patients with ADCP

## CONCLUSION

rFOV IRIS-DWI combined T2WI imaging provide higher diagnosis confidence and higher diagnosis accuracy for rectal cancer T staging.

## CLINICAL RELEVANCE/APPLICATION

Complementary MRI to CT => changed resectability and therapeutic management

## CLINICAL RELEVANCE/APPLICATION

rFOV IRIS-DWI improved the diagnosis performance in rectal cancer T staging.

## W5B-SPGI-4 Imaging Features Prognostic of Overall Survival in Patients with Advanced Hepatocellular Carcinoma Undergoing Systemic Therapy

Participants

Kathleen Ruchalski, MD, Santa Monica, CA (Presenter) Nothing to Disclose

## PURPOSE

Modified RECIST measures arterial enhancement of liver lesions in hepatocellular carcinoma (HCC), evaluating treatment related alterations in tumor viability not captured by size alone. However mRECIST clinical translation to advanced HCC and ability to predict response to systemic therapy is less well reported. Our objective is to evaluate for imaging features beyond RECIST 1.1 which correlate with overall survival (OS) in advanced HCC.

## METHODS AND MATERIALS

This is a retrospective study of patients with advanced HCC at our institution enrolled in clinical trials for systemic treatment between 2015-2022. Patient characteristics and OS were obtained. Liver tumor imaging features on baseline CT or MRI chest, abdomen pelvis were analyzed. Relationship to overall survival (OS) was assessed by cox regression model and log rank test.

## RESULTS

Of 74 patients, we identified 53 who met our criteria, enrolled in a clinical trial with baseline imaging. There were 40 (75.5%) men and 13 (24.5%) women with a mean age of 66.2 years ( $SD = 9.5$ ). Median OS was 31.5 months. Percent total liver tumor involvement n = (%) included: < 25% n=25 (47.2%), 25-50% n=20 (37.7%), 51-75% n=8 (15.1) patients. Multifocal liver disease and macrovascular invasion were present in 41 (77.4%) and 25 (47.2%) of patients respectively. Individual liver lesions measured on average 41.7mm ( $SD = 28.2$ ) on arterial phase. Lesion margins were characterized as infiltrative (n=14 (13.2%)), irregular (n=19 (17.9%)), well circumscribed (n=60 (56.6%)) and N/O (n=13 (12.3%)). Arterial enhancement patterns were described as central heterogeneous in 41 (38.6%), homogeneous: 24 (22.6%), partial enhancement: 15 (14.2%), rim only: 11 (10.4%) and no enhancement in 15 (14.2%) patients respectively. Multifocal liver disease was associated with significantly increased risk of death ( $p = 0.043$ ). Patients with partially enhancing liver lesion had improved survival compared to those with central heterogeneously enhancing tumor ( $HR = 0.28$ ;  $p = 0.044$ ). Individual liver lesion size ( $p = 0.399$ ), margin ( $p = 0.289$ ) and % liver involvement ( $p = 0.125$ ) did not correlate with OS.

## CONCLUSION

While lesion size was not prognostic, presence of multifocal liver disease and central heterogeneous tumor enhancement were poor prognostic features of OS for advanced HCC.

## CLINICAL RELEVANCE/APPLICATION

Although further investigation is required, reporting imaging findings on multifocal liver disease and arterial enhancement pattern may provide prognostic information for patients with advanced HCC undergoing systemic therapy.

## **W5B-SPGI-5 Participant Study on Predicting Pathological Grade of Rectal Adenocarcinoma based on Extracellular Volume Fraction of CT**

Qingyang Li, Hohhot, China (*Presenter*) Nothing to Disclose

### **PURPOSE**

Objective The purpose of this study was to explore the feasibility of predicting the pathological grade of rectal adenocarcinoma based on extracellular volume fraction (ECV) of enhanced CT.

### **METHODS AND MATERIALS**

Methods From October 2021 to October 2022, enhanced CT scanning was performed in our hospital. 25 cases of high-grade and 71 cases of low-grade rectal adenocarcinoma were confirmed by operation and pathology. According to the histological classification of colorectal adenocarcinoma (non-special type) (according to the 2010 WHO standard), patients were divided into low-grade group and high-level group. The clinicopathological features, routine CT parameters and ECV were compared between the two groups, the ECV of the primary focus was calculated by measuring the CT values of the areas of interest in the non-contrast scan and the balance period. The independent predictors for predicting the pathological grade of rectal adenocarcinoma were screened by binary Logistic regression, and the joint predictors were constructed. The diagnostic efficacy of independent predictors and joint predictors was evaluated by ROC curve.

### **RESULTS**

Results 1. There was no significant difference in gender (0.065), age (0.547) and preoperative CEA (0.343) between the two groups. There was significant difference in the longest diameter of tumor between the two groups ( $P < 0.05$ ). 2. Among the routine CT parameters, there were significant differences in arterial phase ( $P < 0.012$ ), equilibrium phase ( $P < 0.007$ ), S 1 ( $P < 0.001$ ) and S 3 ( $P < 0.006$ ). 3. There was significant difference in ECV between the two groups ( $P < 0.05$ ). 4. Binary Logistic regression analysis showed that ECV and S1 were independent predictors of high-grade rectal adenocarcinoma. 5. ROC curve comparison results: the AUC of ECV is 0.796, with 34.54% as the cutoff value, the sensitivity is 80%, the specificity is 77.46%; the AUC of S1 is 0.714, with 21.1HU as the cutoff value, the sensitivity is 88%, the specificity is 53.52%; the AUC of joint prediction factor Y is 0.869%, with 0.365 as the cutoff value, sensitivity is 76%, specificity is 88.73%.

### **CONCLUSION**

s Conclusion The longest diameter of tumor, CT value of arterial phase, CT value of equilibrium phase, S1, S3 and ECV are the influencing factors to predict the pathological grade of rectal adenocarcinoma. S1 and ECV are the independent factors to predict the pathological grade of rectal adenocarcinoma. S1, ECV and combined predictor Y have certain accuracy in predicting the pathological grade of rectal adenocarcinoma.

### **CLINICAL RELEVANCE/APPLICATION**

Applying ECV to rectal adenocarcinoma further provides a basis for its application in the abdomen.

## **W5B-SPGI-6 Multiparametric MRI Tumor Sub-region Analysis for Predicting Microvascular Invasion in Hepatocellular Carcinoma**

### **PURPOSE**

Microvascular invasion (MVI) is a major prognostic factor for hepatocellular carcinoma (HCC), and preoperative identification of MVI is crucial for determining proper treatment strategies.<sup>1</sup> However, detecting MVI through imaging tests such as CT and MRI is challenging, and histopathological diagnosis is required.<sup>2</sup> This study aims to investigate the feasibility of multiparametric MRI tumor subregion analysis for predicting MVI in HCC patients and evaluate the performance of tumor subregion features.

### **METHODS AND MATERIALS**

42 patients with HCC were included and divided into MVI-positive and MVI-negative groups. MRI examination included T2-weighted, diffusion-weighted imaging, and Gadoxetic acid-enhanced imaging (precontrast, arterial phase, and hepatobiliary phase). K-means clustering algorithm was used to identify three functional clusters based on ADC, wash-in slope, and wash-out slope. Tumor subregion volume fraction was compared between MVI-positive and MVI-negative groups using a Wilcoxon signed-rank test, with a p value of less than 0.05 considered statistically significant.

### **RESULTS**

The identified clusters were: (1) high perfusion cluster with high wash-in and wash-out slope, (2) low tumor aggressiveness cluster with low wash-in, wash-out slope, and low ADC, (3) necrotic cluster with low wash-in, wash-out slope, and high ADC. Tumor subregion analysis showed higher volume fraction of high perfusion and necrotic clusters and lower volume fraction of the low tumor aggressiveness cluster in the MVI-positive group compared to the MVI-negative group, although only the volume fraction of the necrotic area showed a significant difference ( $P = 0.0271$ ). The traditional ADC value of the whole tumor showed no statistical difference between the two groups ( $P > 0.05$ ).

### **CONCLUSION**

s Multiparametric MRI tumor subregion analysis can identify tumor regions with high perfusion, necrosis, and low tumor aggressiveness, which can aid in predicting MVI in HCC patients.

### **CLINICAL RELEVANCE/APPLICATION**

Multiparametric MRI tumor subregion analysis is a promising radiological tool for predicting MVI in HCC, which can lead to the proper treatment strategy for patients with HCC.

## **W5B-SPGI-7 Exosomal Nanoprobe Exo-USIO and its Combination with Gemcitabine for the Treatment of Pancreatic Cancer**

### **PURPOSE**

Pancreatic cancer is a malignant tumor of the digestive system, which has not obtained substantial breakthrough in early diagnosis

as well as chemotherapy in the middle and late stages due to the diagnosis and treatment dilemmas, such as poor blood supply imaging and chemoresistance caused by poor oxygen. In this study, metal nanomases were targeted and delivered to pancreatic cancer tumors by utilizing the properties of exosomes targeted homing and delivery carriers, which improved tumor hypoxia and promoted the therapeutic effect of GEM while accurately imaging tumors.

## **METHODS AND MATERIALS**

Nanozyme ultrasmall iron oxide nanoparticles (USIO NPs) with T1 weighted imaging were loaded into panc-02 cell-derived exosomes using the electroporation method, and the exosomal nanoprobe Exo-USIO was constructed and characterized, and its enzyme like efficacy was determined. The efficacy of Exo-USIO combined with gemcitabine (GEM) to inhibit the proliferation of hypoxic Panc-02 cells was investigated by CCK-8 and flow cytometric apoptosis assays; The effect of the nanoprobe on tumor targeted MR imaging of pancreatic cancer was investigated by tail vein injection of Exo-USIO; Based on tail vein injection of Exo-USIO combined with intraperitoneal injection of GEM, the in vivo therapeutic effect of Exo-USIO combined with gem was investigated.

## **RESULTS**

A series of characterizations have shown the successful preparation of exosomal nanoprobe Exo-USIO with good stability and a peak particle size distribution of approximately 122.5nm. In vitro cell experiments have shown that nanoprobe has strong homing ability, which can improve the efficiency of USIO NPs entering tumor cells, thereby enhancing enzyme like efficiency, catalyzing endogenous H<sub>2</sub>O<sub>2</sub> production of O<sub>2</sub> in cells, and reducing the HIF-1 $\alpha$  protein expression level in hypoxic cells. When the nanoprobe was combined with GEM, the cell inhibition rate and apoptosis rate of the two Exo-USIO concentration groups were higher than those of the USIO NPs group. In tumor bearing mice, the nanoprobe Exo-USIO demonstrated the ability to target MR imaging of tumors and overcome tumor hypoxia in an almost non-toxic manner, achieving good therapeutic effects after combined application of GEM.

## **CONCLUSION**

Exosomal nanoprobe Exo-USIO was successfully fabricated with good enzyme like potency to improve tumor hypoxia, thereby strengthening the therapeutic effect of GEM.

## **CLINICAL RELEVANCE/APPLICATION**

Taken together, syngeneic cell-derived exosomes are effective vehicles for targeted delivery of USIO NPs to pancreatic cancer tumors, and this delivery strategy may provide some guidance for precise diagnosis and treatment of pancreatic cancer.

## **W5B-SPGI-8 Energy Spectral Computed Tomography for Predicting Mutation Status of c-KIT exon 11 in Patients with Gastrointestinal Stromal Tumors**

### **PURPOSE**

This study aims to evaluate the value of quantitative parameters of energy spectrum CT in predicting the mutation status of c-KIT exon 11 in gastrointestinal stromal tumors (GISTs), construct predictive models, and draw nomogram to assist in clinical treatment decision-making.

### **METHODS AND MATERIALS**

61 patients with confirmed GISTs by pathology were retrospectively enrolled. All patients underwent energy spectrum CT preoperatively and c-KIT gene testing. chi-square test, Mann-Whitney U test and independent sample t test were used to compare and analyze the clinical and energy spectrum CT quantitative parameters of patients. The statistically significant parameters in the above univariate analysis were incorporated into Logistic regression, screen independent predictors for predicting the mutation status of c-KIT exon 11. Draw nomogram of clinical + spectral CT quantitative parameters model for predicting the mutation status of c-KIT exon 11, and evaluate the discrimination, calibration, and clinical net benefit of nomogram using C-index, calibration curve, and decision curve analysis.

### **RESULTS**

In our research, 26 were men and 35 were women. The average age of all participants was 59.25 $\pm$ 14.25 years. In the quantitative parameters of energy spectrum CT, the CT values at a single energy level of 40 keV-120 keV (all, P<0.05), energy spectrum curve slope K (P=0.002), iodine concentration (IC) (P=0.002), normalized iodine concentration (NIC) (P=0.004) in the venous phase, and the CT values at a single energy level of 40 keV-60 keV (all, P<0.05), energy spectrum curve slope K (P=0.002), IC (P=0.002), NIC (P=0.004) in the delay phase of c-KIT exon 11 mutant type is lower than c-KIT exon 11 wild type. The C-index of nomogram of the clinical+energy spectrum CT quantitative parameters model was 0.827 (95% CI: 0.723-0.932), the sensitivity and specificity were 72.5% and 81.0%, respectively. The calibration curve showed the predicted values of the models was in good consistency with the actual values (P=0.724). Decision curve analysis showed that nomogram model achieved high clinical net benefits.

### **CONCLUSION**

Age and the quantitative parameters of energy spectrum CT can be used as preliminary evaluation indicators for the mutation status of GISTs c-KIT exon 11. The clinical combined energy spectrum CT quantitative parameters model has high efficiency in predicting the mutation status of GISTs c-KIT exon 11.

### **CLINICAL RELEVANCE/APPLICATION**

The quantitative parameters derived from energy spectrum CT may become a useful, and non-invasive clinical imaging index for predicting the mutation status of GISTs c-KIT exon 11, and can assist in clinical risk stratification and determining treatment plans for patients.

## Abstract Archives of the RSNA, 2023

W5B-SPGU

### Genitourinary Imaging Wednesday Poster Discussions II

#### Sub-Events

#### W5B-SPGU- Deep Learning Prostate MRI Progression Risk Interval Prediction

1

Participants

Christian Roest, MSc, GRONINGEN, Netherlands (*Presenter*) Grant, Siemens AG

#### PURPOSE

MRI follow up is increasingly used to manage patients with low-risk prostate cancer, (PCa) but lacks personalization of follow-up timing. Therefore, We propose a novel AI approach to predict the time to prostate cancer progression.

#### METHODS AND MATERIALS

This retrospective study was performed on a dataset of 875 patients that underwent an MRI of the prostate between 2014 and 2021. Patients received follow-up MRIs and targeted biopsy for all PI-RADS=3 lesions. This study defined progression as the detection of ISUP>1 PCa at follow-up. A novel deep learning model was developed and trained to predict progression-free survival (PFS) based on the MRI and available clinical parameters (PSA, PSA density, prostate volume, and age). Five-fold cross-validation was used to obtain likelihood scores for the three-year risk of progression in each patient. Patients were stratified into high- and low-risk groups based on their predicted likelihood of progression, with an equal number of patients in each group. Kaplan-Meier analyses validated whether the predicted likelihood accurately predicted PFS. Finally, the C-index was calculated to assess the prognostic accuracy of our model.

#### RESULTS

Our AI model's predictions were significantly associated with PFS in the test data ( $p < 0.0001$ ). The C-index was  $0.72 \pm 0.05$ , indicating that our model was a good predictor of PFS. PFS was significantly better in patients predicted to be at low-risk of disease progression, when measured after two years ( $95.3 \pm 0.04\%$  vs  $84.9 \pm 0.02\%$ ,  $p = 0.008$ ), three years ( $92.7 \pm 0.05\%$  vs  $73.3 \pm 0.04\%$ ,  $p = 0.008$ ) and four years ( $87.7 \pm 0.12\%$  vs  $62.8 \pm 0.04\%$ ,  $p = 0.008$ ).

#### CONCLUSION

Our novel AI approach accurately predicted PFS from prostate MRI and clinical information.

#### CLINICAL RELEVANCE/APPLICATION

An improved predictor for the time to progression based on MRI and clinical parameters may improve MRI follow-up protocols by enabling more personalized interval timing and decision making.

#### W5B-SPGU- Detection of Clinically Significant Prostate Cancer in Men with a Negative Initial Round of Targeted Biopsies and Highly Suspicious Multiparametric Magnetic Resonance Findings

2

Participants

Debora Recchimuzzi, MD, Sao Paulo, (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to evaluate the frequency of imaging-pathology discordance and the rate of csPCa detection on repeat TBx.

#### METHODS AND MATERIALS

This single-center, retrospective study of prospectively generated data, included all men who underwent mpMRI and had a PIRADS score 4 or 5 at our institution between Jan/2017 and Nov/2022. The frequency of imaging pathology discordance (PI-RADS score 4 or 5 lesion and no csPCa on TBx) and the rate of csPCa (grade group 2 or higher) detection on a repeat TBx (MRI-TRUS fusion or in-bore biopsy) were determined. Univariate analysis and multiple analysis with logistical regression were used to identify potential parameters associated with true-negative targeted biopsies, including PSA, PSA density, prostate volume as measured by MRI and ADC measurement.

#### RESULTS

Of the 4047 men reviewed, 63% (2581/4047) had PI-RADS 4 or 5 lesions on mpMRI followed by TBx. In 40% (1050/2581) of these men, TBx did not reveal csPCa. Among these 1050 men with discordant imaging-pathology findings, 18% (191/1050) men had a repeat targeted biopsy (MRI-TRUS fusion or MRI guided inbore), and 40 men underwent radical prostatectomy for grade group 1 disease. Repeat TBx identified csPCa in 35% (67/191) of the men who underwent a second TBx. The frequency of csPCa at repeat biopsy was significantly higher for PIRADS 5 (45%; 32/70) compared to PIRADS 4 lesions (28%; 35 of 121) ( $p =$ ).

#### CONCLUSION

A negative targeted biopsy of a highly suspicious lesion on mpMRI must be interpreted with caution and early repeat biopsy should

be considered, particularly in men with PI-RADS 5 lesions.

#### **CLINICAL RELEVANCE/APPLICATION**

Multiple studies have demonstrated that men with highly suspicious (PI-RADS score 4 and 5) prostate lesions at multiparametric MRI (mpMRI) are highly likely to harbor clinically significant prostate cancer (csPCa). The degree of suspicion on multiparametric MRI is the strongest predictor of a positive targeted biopsy with positive rates of 70% to 90% when the MRI findings are highly suspicious for PCa. It is known that prostate biopsies - including targeted biopsies (TBx) - are vulnerable to sampling error. Discordance between histologic and imaging findings may indicate, therefore, that the lesion may not have been sampled adequately, highlighting the importance of a systematic post-biopsy imaging-pathology concordance review.

#### **W5B-SPHN- Quantitative Gland Function Analysis in Dry Mouth Patient using T1, T2 and PD Mapping based on the Multi-dynamic Multi-echo Method**

Participants

Chena Lee, DDS, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### PURPOSE

Dry mouth is a subjective complaint of dryness of intraoral cavity and the primary etiology is the hypofunction of salivary gland. Clinical diagnosis is conducted by collecting patient's whole saliva and evaluate the volume and this is a time consuming cumbersome examination. Thus, the current study aimed to utilize T1, T2 and PD mapping as diagnostic tool for parotid gland dysfunction in dry mouth patients.

#### METHODS AND MATERIALS

Dry mouth (n = 32) and control subjects (n = 30) that underwent magnetic resonance imaging (MRI) from July 2020 to December 2022 were reviewed. The T1, T2, and PD mapping of the parotid gland were evaluated simultaneously based on the multi-dynamic multi-echo (MDME) MR imaging. The values from control and dry mouth group were compared using Mann-Whitney test and receiver operating characteristic (ROC) curve analyses.

#### RESULTS

The mean of T1, T2-relaxation time and PD value of the gland in dry mouth group were 606.90 ms, 91.63 ms, and 82.37 pu, respectively. The mean of T1, T2-relaxation time and PD value of control group were 628.08 ms, 80.69 ms and 91.12 pu. The T2-relaxation time and PD value showed significant difference between the dry mouth and control group while there no significant difference between two groups in T1-relaxation value. The area under the ROC curve (AUC) was 0.8164 and 0.7564 respectively for T2-relaxation time and PD value. The diagnostic performance between T2-relaxation time and PD value were not significantly different (p-value = 0.4851).

#### CONCLUSION

s The T2-relaxation time and PD value can be used as quantitative indicators of dry mouth due to hypofunction of parotid gland and the performance of T2-relaxation time presented higher diagnostic ability. Further study with large population could be leaded to more accurate result.

#### CLINICAL RELEVANCE/APPLICATION

T2 and PD mapping, based on the MDME technique, presented diagnostic ability for detecting parotid gland hypo function and could be utilized as quantitative tool for dry mouth diagnosis in clinic.

#### **W5B-SPHN- From Suspected to Confirmed : Intrathecal Gadolinium-Enhanced MR Cisternography as a Key Diagnostic Modality in CSF Rhinorrhoea**

#### PURPOSE

To establish the role and diagnostic accuracy of Intrathecal gadolinium enhanced MR Cisternography in clinically suspected cases of CSF rhinorrhoea

#### METHODS AND MATERIALS

As of now, a total of 19 consecutive patients with active or suspected CSF rhinorrhea have been included in this study. History of trauma was present in 8 patients (42%), endoscopic surgery in 5 patients (26%), spontaneous in 6 patients (32%). Most of the patients had CT PNS which showed evidence of skull base fractures, defects or erosions. We used mixture of non-ionic iodinated contrast (5 ml of iohexol; Omnipaque 300) with Gadolinium (0.4 ml of gadobutrol; Gadovist) along with normal saline (5 ml of 0.9 % normal saline) for injecting into the intrathecal space. MR sequences were taken approximately 30-40 minutes after the contrast injection. For all patients, hemodynamic studies (heart rate, blood pressure) and evaluation of neurologic status were performed.

#### RESULTS

We observed objective CSF leakage in 11 of 19 patients (58%). The CSF leak was located in the cribriform plate in 7 patients (37%), in the superior wall of the sphenoid sinus/planum sphenoidale in 4 patients (21%), fovea ethmoidalis/roof of ethmoid sinus in 2 patients (11%), through the post-operative sella turcica defect in 1 patient (5%), including multiple defects identified in 4 patients (21%). No objective CSF leakage in spite of bony defect was seen in 4 patients (21%). No bony defect and no objective CSF leakage were seen in 4 patients (21%). Surgical closure of CSF leak was performed in all patients with positive findings on cisternography and the site of leak was confirmed intraoperatively. Post-procedure 6 patients (32%) had mild headache. No other adverse event were noted.

## CONCLUSION

s MR cisternography after the intrathecal administration of gadolinium represents an effective and minimally invasive method for evaluating suspected CSF fistulas along the skull base. It provides multiplanar capabilities and high resolution without risk of radiation exposure and is an excellent approach to depict the anatomy of CSF spaces and CSF fistulas. Furthermore, use of combination of non-ionic iodinated contrast with gadolinium increase the distribution of contrast in subarachnoid space and improve the resolution when compared with just using gadolinium. No significant gross neurologic abnormalities were observed during the initial examination or during follow-up.

## CLINICAL RELEVANCE/APPLICATION

CSF rhinorrhoea is potentially very serious because of the risk of an ascending infection which could produce fulminant meningitis. Exact identification of the location of the CSF fistula is important for proper surgical planning, increases the chances of dural repair and can prevent complications.

## W5B-SPHN- Tracheal Cartilage Calcification and Glucose Metabolism in Aging Adults Assessed by 18F-NaF and 18F-FDG PET/CT

Participants

NilooFaralsadat Motamedi, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study was to examine if 18F-sodium fluoride (18F-NaF) and 18F-fluorodeoxyglucose (FDG) PET/CT can be used to measure physiological calcification and glucose metabolism of the tracheal cartilage, respectively, and whether there was any association with aging.

## METHODS AND MATERIALS

Out of 139 healthy control subjects from the CAMONA study (NCT01724749), a total of 128 subjects in whom tracheal cartilage could be segmented on 18F-NaF-PET/CT (mean age  $48.58 \pm 14.44$  years, 51.56% males) were included in the analysis. Similarly, a total of 119 subjects (mean age  $48.46 \pm 14.34$  years, 54% males) in whom tracheal cartilage could be segmented on FDG-PET/CT were included in the analysis. The PET/CT acquisitions were performed 90 minutes after 18F-NaF administration and 60 minutes after FDG administration. The mean standardized uptake value (SUV<sub>mean</sub>) of both tracers was measured by assigning regions of interest (ROIs) around the cartilage using OsiriX software (Pixmeo SARL, Bernex, Switzerland). To assess the relationship of tracheal calcification and glucose metabolism with aging, Pearson correlation analysis was performed between age and the 18F-NaF and FDG, respectively.

## RESULTS

A statistically insignificant positive correlation was present between age and 18F-NaF SUV<sub>mean</sub> ( $r=0.094$ ,  $p=0.28$ ) (Figure 1). Similarly, there was a statistically insignificant negative correlation observed between age and FDG SUV<sub>mean</sub> ( $r=-0.125$ ,  $p=0.17$ ) (Figure 2).

## CONCLUSION

s 18F-NaF- and FDG-PET/CT can be used to measure physiological calcification and glucose metabolism of the tracheal cartilage. Although the results were statistically insignificant, there was a trend of an increase in physiological calcification and a decrease in glucose metabolism of the tracheal cartilage with aging, as assessed by 18F-NaF- and FDG-PET/CT, respectively. Prospective studies with larger sample sizes and longitudinal in subjects of varying ages are needed to continue investigation into changes in tracheal cartilage calcification and metabolism with aging.

## CLINICAL RELEVANCE/APPLICATION

To assess calcification and glucose metabolism of tracheal cartilage with aging by 18F-NaF and FDG PET/CT, age-related trends were observed, and further studies are needed to confirm clinical significance.

## W5B-SPHN- Relationship between Cochlear Implant Patients' Auditory Outcomes and Insertion Length and Angulation

Participants

Paloma Puyalto, PhD, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

## PURPOSE

??Cochlear implants are transducers that transform the acoustic waves into electrical signals to stimulate the cochlear nerve in patients that suffer unilateral or bilateral, deep or severe, neurosensorial deafness that do not benefit from an auditory prostheses. The main objective of this study was to determine whether a deeper cochlear implant insertion within the cochlea, in terms of length and grade, results in improved auditory performance.

## METHODS AND MATERIALS

After IRB approval a cohort of 46 patients with 50 cochlear implants were prospectively reviewed. A temporal bone HRCT was performed before and after cochlear implantation. Prior and post-implantation audiometric studies and functional clinical variables such as speaking on the phone, listening to music, or time in months needed till auditory rehabilitation was optimal were recorded and correlated to the electrode insertion depth in terms of length and insertion angle grades.

## RESULTS

21 men and 25 women ( 29- 78 y.o) with a 2 to 63 years story of neurosensorial deafness were analyzed. 4-12 electrodes were encountered within the cochlea in HRCT. A median of 88.7% of the cochlea was covered. The insertion angle ranged between 90° and 720° with  $\mu=536^\circ$  and  $s=146.40^\circ$ . ??Two years after implantation, there was a median of 11 (3-12) final functioning electrodes. 76% of patients achieved >70% bisyllabic discrimination at 60 dB, 60% used phones after implantation, 26% listened to music, Less than a year was the median time to finish hearing rehabilitation for 38%, followed by 12 to 24 months for 34% and 24 months for 28%. There was a correlation between the angle of insertion and the length of the inserted implant with a correlation coefficient of 0.846 ( $p<0.01$ ).A statistical correlation between the number of electrodes, length and insertion angle within the cochlea, and

audiometric values, speaking at the phone, or the number of months of rehabilitation after the procedure was found ( $p < 0.01$ ) although the ability to listen to music after cochlear implantation showed no statistical correlation with radiographic variables.

## CONCLUSION

Better auditory outcomes are obtained in terms of audiometric values and functional recovery the deeper the cochlear implants are inserted into the cochlea.

## CLINICAL RELEVANCE/APPLICATION

The cochlear coverage of the implant should be checked using a post-operative HRCT in patients with insufficient auditory results. Since these patients' functional outcomes are suboptimal it will be necessary to intensify and optimize the implant programming strategies in those with fewer than 8 functional electrodes inside the cochlea in post-surgical HRCT, or even to consider early replacement.

## W5B-SPHN- Clinical Application of a 5G-based Telerobotic Ultrasound System for Thyroid Examination on a Rural Island: A Prospective Study

### PURPOSE

To evaluate the feasibility of a 5G-based telerobotic ultrasound (US) system for thyroid examination on a rural island.

### METHODS AND MATERIALS

From September 2020 to March 2021, this prospectively study enrolled a total of 139 patients (average age,  $58.6 \pm 12.7$  years) included 33 males and 106 females, who underwent 5G-based telerobotic thyroid US examination by a tele-doctor at Hospital A and a conventional thyroid US examination at Hospital B 84 km away. The clinical feasibility of 5G-based telerobotic US for thyroid examination were evaluated in terms of safety, duration, US image quality, diagnostic results, and questionnaire survey.

### RESULTS

92.8% of patients had no examination-related complaints. The average duration of the 5G-based telerobotic US examination was similar as that of conventional US examination ( $5.57 \pm 2.20$  min vs.  $5.23 \pm 2.1$  min,  $P = 0.164$ ). The image quality of telerobotic US correlated well with that of conventional US ( $4.63 \pm 0.60$  vs.  $4.65 \pm 0.61$ ,  $P = 0.102$ ). There was no significant difference between two types of US examination methods for the diameter measurement of the thyroid, cervical lymph nodes, and thyroid nodules. Two lymphadenopathies and 20 diffuse thyroid diseases were detected in two types of US methods. 124 thyroid nodules were detected by telerobotic US and 127 thyroid nodules were detected by conventional US. Among them, 122 were the same thyroid nodules. In addition, there were good consistency in the US features (component, echogenicity, shape, and calcification) and ACR TI-RADS category of the same thyroid nodules between telerobotic and conventional US examinations ( $ICC = 0.788-0.863$ ). 85.6% of patients accepted the telerobotic US, and 87.1% were willing to pay extra fee for the telerobotic US.

## CONCLUSION

The 5G-based telerobotic US system can be a routine diagnostic tool for thyroid examination for patients on a rural island.

## CLINICAL RELEVANCE/APPLICATION

This study provided robust evidence that 5G-based telerobotic US is feasible, which can provide qualified thyroid examination to help patients with thyroid diseases on a rural island. It can achieve the same effect as face-to-face and close-range conventional US examination without reducing diagnostic accuracy or increasing related procedural times.

## W5B-SPHN- A New XAI Framework with Feature Explainability for Tumors Decision-making in Ultrasound Data

Participants

Fajin Dong JR, MD, MD, Shenzhen, China (*Presenter*) Nothing to Disclose

### PURPOSE

The value of implementing artificial intelligence (AI) on ultrasound screening for thyroid cancer has been acknowledged, with numerous early studies confirming AI might help physicians acquire more accurate diagnoses. However, the black box nature of AI decision-making process makes it difficult for users to grasp the foundation of AI's prediction. Furthermore, explainability is not only related to AI performance but also responsibility and risk in medical diagnosis. In this paper, we offer Explainer, an intrinsically explainable framework that can categorize images and create heatmaps highlighting the regions where its prediction is based on.

### METHODS AND MATERIALS

This study included 19341 2D ultrasound images (9171 horizontal views and 10170 vertical views) of 7714 thyroid nodules obtained from 7236 individuals from October 2019 to May 2021, with pathological results and physician annotated TI-RADS features are used to train and test the robustness of the proposed framework. Then we conducted a benign-malignant classification study to whether physicians perform better under the assistance of Explainer than diagnose alone or with Gradient-weighted Class Activation Mapping (Grad-CAM).

### RESULTS

Reader studies show that the Explainer can achieve more accurate diagnosis while providing explaining heatmaps and that physicians' performances are improved when assisted by the Explainer. Case study confirms that the Explainer can locate more reasonable and feature-related regions than the Grad-CAM.

## CONCLUSION

The Explainer offers physicians a tool to understand the basis of AI predictions and to evaluate its reliability, which has the potential to unbox the black box of medical imaging AI.

## CLINICAL RELEVANCE/APPLICATION

In the case study comparing heatmaps generated by Explainer and Grad-CAM, Explainer is capable of locating more reasonable and feature-related regions. Evidence proves that in ultrasound images explaining tasks, our method is more detailedly.

## Participants- Diagnosis of Malignancy in Surgery after Radiofrequency Ablation of Benign Thyroid Nodule

Jung Hee Shin, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

### PURPOSE

Nodule regrowth after radiofrequency ablation (RFA) of symptomatic large benign thyroid nodules is sometimes diagnosed as malignancies during surgery. This study aimed to assess the ultrasound (US) characteristics of thyroid nodules later diagnosed as cancer, predictive factors for cancer after RFA, and preventive methods for these cancers to avoid RFA procedure.

### METHODS AND MATERIALS

We reviewed the medical records of 134 consecutive patients with 148 nodules who underwent RFA between 2008 and 2016 for the debulking of symptomatic benign thyroid nodules. We investigated the pre-RFA characteristics of the thyroid nodules, changes at follow-up after RFA, and final surgical pathology.

### RESULTS

Nodule regrowth after RFA for benign nodules was observed in 36 (24.3%) of the 148 nodules. Malignancies were confirmed in seven (19.4%) of the 36 regrown nodules. Of the 22 nodules removed surgically, pre-RFA mean maximal diameter was significantly higher for malignant nodules than for benign nodules ( $3.89 \pm 0.98$  vs  $5.23 \pm 1.52$  cm,  $P = .01$ ). There was no difference in the regrowth interval between benign and malignant nodules ( $P = .19$ ). Volume reduction rate at 12 months was lower for malignant nodules than for benign nodules ( $51.16 \pm 13.81\%$  vs  $73.68 \pm 20.15\%$ ,  $P = .02$ ). Pre-RFA benignity of all seven malignant nodules was confirmed using two ultrasound (US)-guided fine-needle aspirations (FNAs), except for one nodule confirmed using US-guided core needle biopsy (CNB). The regrown malignant nodules were diagnosed as suspicious for follicular neoplasms using CNB. Histological examination of the malignant nodules during surgery after RFA revealed follicular thyroid carcinomas, except for one follicular variant of papillary thyroid carcinoma.

### CONCLUSION

s Symptomatic large thyroid nodules confirmed to be benign prior to RFA should be considered false-negative FNA results. In RFA patients, CNB prevents delay in cancer diagnosis.

### CLINICAL RELEVANCE/APPLICATION

Considering false-negative fine-needle aspiration results in symptomatic large benign thyroid nodules before radiofrequency ablation, core needle biopsies should be included in the revised RFA guidelines to prevent delayed cancer diagnosis.

## Abstract Archives of the RSNA, 2023

W5B-SPIN

### Imaging Informatics Wednesday Poster Discussions II

#### Sub-Events

#### W5B-SPIN-1 Deep Learning-based Survival Prediction using CT and Clinical Data Fusion

##### Participants

Yujin Nam, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

Develop a discrete-time survival model that combines image data and clinical data fusion to increase the accuracy of survival rate prediction through nodules in computed tomography (CT) images for patients with lung cancer.

##### METHODS AND MATERIALS

A total of 1,095 patients with lung cancer from a tertiary hospital in South Korea who underwent curative resections were enrolled. These datasets were divided into 6:2:2 as training, validation, and test set, respectively. CT volumes were cropped to 50×50×50 based on the nodule mask and were set as lung windows (window width, 1000 hounsfield unit (HU); window level, -700 HU). Also, clinical data consisted of Tumor Recur, Age, Sex, Subtype, Size, 7th stage T, 7th staging N, and smoker. Image data was trained with 3D-DenseNet and clinical data was trained with multi-layer perceptron (MLP). The proposed model is an end-to-end model that trains image data and clinical data in parallel. Our model predicted the survival rate by dividing it into 6 intervals using time and event variables. During the training, we used Adam optimization with a batch size of 32, learning rate of 1e-5, and weight decay of 1e-3.

##### RESULTS

Figure 1 depicts several cases of gradient-weighted class activation map (Grad-CAM) results from DenseNet. The model was observed to focus on nodules while performing survival prediction on axial, coronal, and sagittal planes. Figure 2 is a graph expressing the Kaplan-Meier curve that calculates the actual cumulative survival rate and the discrete-survival prediction curves of 6 intervals according to each model (clinical data, image data, fusion data (clinical + image data)). Not only is the survival rate curve of the fusion data closer to the Kaplan-Meier curve but also the fusion data had the highest c-index of 0.742, which was better than the clinical data model's c-index of 0.674 and the image data model's c-index of 0.725.

##### CONCLUSION

Our proposed model of combining image data and clinical data showed better performance than when image and clinical data were used separately.

##### CLINICAL RELEVANCE/APPLICATION

Our model could be helpful in stratifying patients and facilitating the establishment of personalized surveillance strategies or the selection of candidates for adjuvant therapy by predicting their survival rate.

#### W5B-SPIN-2 Deep Learning Based Synthetic Contrast Enhanced T1 Map for Contrast Agent-free Myocardial Extracellular Volume (ECV) Mapping in Cardiac MRI

##### Participants

Sebastian Nowak, PhD, Bonn, Germany (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the utility of generative adversarial networks (GAN) to generate artificial contrast enhanced (CE) T1 maps for creation of synthetic extracellular volume (ECV) maps of the myocardium.

##### METHODS AND MATERIALS

This study includes 1086 cardiac MRI exams with native and CE T1 maps in 3 short axis slices of 986 patients undergoing MRI for various clinical indications between January 2019 and August 2021. Manual myocardium segmentations of 522 slices were used to develop a U-Net for image cropping prior to rigid registration. All registered native and CE T1 map pairs were inspected and excluded if rigid registration failed due to dissimilar contraction phase, resulting in 2074 curated T1 map pairs from 827 patients (age: 48 ± 19 years, 344 female). Of those, 191 native and CE T1 map pairs from 78 patients were defined as hold-out test set with hematocrit available within 48h prior to imaging, allowing for creation of reference 'real' ECV maps. With the remaining cases a U-Net generator was trained with L1 loss and 5-fold cross validation in combination with a PatchGAN discriminator to generate synthetic CE T1 maps from native T1 maps. Note that for ECV calculation, the correct enhancement ratio of blood to myocardium is crucial rather than prediction of exact CE T1 values. Two ECV maps were created for the test set: one using the real and one using the synthetic CE T1 map. The difference between the synthetic and real mean ECV (?ECV) within the myocardium was calculated, and their correlation was quantified with the Pearson correlation coefficient (R). To investigate whether the GAN simply linearly transforms the input native T1 maps, the correlation of the real mean ECV with the mean of the native T1 maps was also compared with the correlation between synthetic and real ECV. Bootstrapping with 1000 resamples were used for calculating 95% confidence

intervals.

## RESULTS

The synthetic mean ECV values in the myocardium showed a high correlation to the real ECV (R: 0.81 [0.74-0.86]), which was significantly higher compared to the correlation of the native T1 and real ECV values (R: 0.61 [0.51-0.69]). A mean  $\Delta$ ECV of  $2.30 \pm 2.04$  % was observed in the hold-out test set.

## CONCLUSION

s Generation of synthetic CE T1 maps from native T1 maps by GANs shows promising results for contrast agent-free estimation of myocardial ECV. The results motivate multicenter studies including more patients with appropriate MRI examination and hematocrit to also investigate direct generation of synthetic ECV without hematocrit and contrast agent use.

## CLINICAL RELEVANCE/APPLICATION

Deep learning based generation of synthetic CE T1 maps from native T1 maps for synthetic ECV calculation might facilitate faster cardiac MRI examinations without the use of gadolinium-based contrast agents.

## W5B-SPIN-3 Identifying Stroke Onset on DWI-FLAIR Mismatch using Deep Learning with Multi-Task Learning: Validation with External Datasets

Participants

Yujin Nam, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

To develop a multi-task learning (MTL) based model with diffusion weighted imaging - fluid attenuated inversion recovery (DWI-FLAIR) mismatch in MRI to predict stroke onset time.

## METHODS AND MATERIALS

A total of 354 stroke patients with DWI and FLAIR from a tertiary hospital in South Korea who had clear stroke onset time were enrolled. The stroke onset times of 3, 4.5, and 6 hours of each patient were predicted with deep learning using MTL. The input image is a combination of apparent diffusion coefficient (ADC), FLAIR, and DWI-b1000 volumes. The training and test sets were composed of 298 and 56 patients, respectively, considering the similar distributions of onset time. Two external datasets consist of 104 and 346 scans with clear onset times from the same hospital with different period and the United States, respectively. A model was trained to perform infarct segmentation and onset time prediction simultaneously by adding an auxiliary classifier to the bottleneck layer of a 3D patch SwinUNETR model. To perform patient-level classification, a voting ensemble on the patch level classifiers was performed. We compared the performances of our model and 3D DenseNet in internal and external validations. Area under curve (AUC), accuracy, specificity, and sensitivity were used as evaluation metrics. During the training, we used Adam optimization with a batch size of 2, learning rate of  $1e-4$ , and weight decay of  $1e-2$ .

## RESULTS

In internal validation, AUCs of 3D DenseNet and our model showed 0.617, 0.690 for onset time classification within 3 hours, 0.632, 0.895 for 4.5 hours, and 0.691, 0.848 for 6 hours, respectively. Sensitivity, specificity, and accuracy within 4.5 hours were 0.879, 0.783, and 0.839, respectively, in our model, 0.667, 0.575, and 0.625, respectively, in 3D DenseNet. In Figure 1, AUCs of two external validations for onset time classification within 4.5 hours were 0.803 and 0.709, respectively. Also, the model focused on infarction of images while performing onset time prediction with gradient-weighted class activation map (Grad-CAM) from its encoder, as indicated in Figure 2.

## CONCLUSION

s This model with on multi-task learning showed better performance for identifying stroke onset time in internal and two external validations, which could lead to its potential use in a real clinical setting.

## CLINICAL RELEVANCE/APPLICATION

Our model has the potential to assist in performing thrombolysis treatment at the appropriate time for stroke patients with an unclear onset time in a real clinical setting by predicting their onset time.

## W5B-SPIN-4 Development and Validation of a CAD System with Reduced False Positives for Bone Metastasis on Chest CT

## PURPOSE

To develop and validate a computer-aided diagnosis (CAD) system using a deep learning (DL) with improved specificity for detecting bone metastasis on chest CT for accurate and efficient workflow in lung cancer screening.

## METHODS AND MATERIALS

In this retrospective study, a CAD system was developed using DL algorithm trained on 3,809 chest CT scans (age  $57.7 \pm 71$ ; women 3,533) obtained from the patients who had various cancer origins (breast: 131, colorectal: 24, lung: 11 and others 34), including 825 with confirmed bone metastasis. The diagnostic performance was evaluated using both internal and external test set of 200 (age  $55.7 \pm 58$ ; women 157; 40 confirmed bone metastasis) and 50 (age  $66.1 \pm 46$ ; women 15; all confirmed bone metastasis) chest CT scans, respectively. The bone metastasis was annotated slice-by-slice indicating whether the lesion exists or not, and the confirmed bone metastasis cases included up to 63 lesions in a single scan. A DL algorithm based on DenseNet-161 was trained with axial slices from CT scans. Each slice was individually assessed whether it contains bone metastasis or not. The axial slices were converted into window level of 800 and window width of 1,500, for better visualization of the bone area. Diagnostic performance was evaluated in a patient-based manner using the maximum prediction value of all slices as the representative prediction value for the patient. For internal test, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated and for external test, only sensitivity was evaluated as positive cases were considered only. Additionally, the performance of subgroups by primary cancer was evaluated.

## RESULTS

The DL based CAD system achieved specificity, sensitivity, PPV, and NPV of 92%, 70%, 92%, and 68% for the internal test, and sensitivity of 86% for the external test in patient-based manner. For the internal test, the specificity of subgroups by primary cancer was 90%, 100%, 88% and 93%, and the sensitivity was 63%, 100%, 100%, and 71% for breast, colorectal, lung and other origins.

## CONCLUSION

s We successfully developed and validated a CAD system with high specificity thus reducing false positive cases for bone metastasis evaluation on chest CT.

## CLINICAL RELEVANCE/APPLICATION

The proposed system can be applied to lung cancer screening, providing a valuable tool for efficient workflow. Further studies are warranted to assess the performance in different clinical settings and malignancies.

## W5B-SPIN-5 Integrating Clinical Data with AI to Optimize Decision-making in Prostate MRI

### Participants

Nadia Moreira Da Silva, Cambridge, United Kingdom (*Presenter*) Employee, Lucida Medical

## PURPOSE

To determine whether combining prostate MRI AI-based decision support outputs, clinical data and PI-RADS scores in a multi-modal predictive model enhances detection of clinically significant prostate cancer.

## METHODS AND MATERIALS

MRI, clinical history, histopathology, and PI-RADS scores were obtained retrospectively from five sites in a multi-vendor, multiple field strength study. After exclusions for AI contraindications including prior treatment and quality issues, model training used data from 352 patients and a held-out test set comprised data from 235 patients (Gleason grade group (GGG)=2, prevalence 34%). Our automated multi-stage AI-based software segments and calculates the volume of prostate whole gland and transition zone (TZ) on MRI, and segments and scores lesions/patients for GGG=2 disease likelihood. Biopsy-verified GGG=2 was used as ground truth, with MRI-negative patients not undergoing biopsy assumed negative. Sensitivity, specificity, and AUC were evaluated at patient level on the held-out test set, with 95% confidence intervals obtained through bootstrapping. Combinations of AI, clinical and PI-RADS data were tested for significant improvement to the AI score and PI-RADS assessment, at pre-determined thresholds equivalent to PI-RADS 3.

## RESULTS

mpMRI PI-RADS scores alone detected GGG=2 with sensitivity 1.00 (95% CI 1.00-1.00), specificity 0.67 (0.61-0.75) and AUC 0.94 (0.91-0.97). GGG=2 was detected by bpMRI AI with sensitivity 0.97 (0.93-1.00), specificity 0.55 (0.47-0.62) and AUC 0.88 (0.84-0.92). Combining AI score and TZ-PSA density (PSAD) improved specificity (sensitivity 0.95 (0.90-0.99), specificity 0.70 (0.63-0.77) and AUC 0.90 (0.85-0.93)). The addition of AI and TZ-PSAD to PI-RADS scores maintained high sensitivity of 0.99 (0.96-1.00), while significantly improving specificity to 0.83 (0.77-0.89, KS p-value<0.001) and AUC to 0.96 (0.93-0.98, DeLong p-value 0.003). TZ volume based PSAD had modest additional benefit compared to whole-prostate PSAD. Other variables offered <5% specificity improvements or non-significant benefits. Findings with bpMRI and mpMRI AI models were similar. Limitations: Most MRI-negative cases did not receive biopsy in this retrospective study.

## CONCLUSION

s The use of PSAD improves the predictive accuracy of prostate MRI AI decision support, with significant improvement in specificity at similar sensitivity. Combining PI-RADS, PSAD and AI offers substantial improvement compared to AI or PI-RADS assessments alone.

## CLINICAL RELEVANCE/APPLICATION

The improved specificity achieved through integrating patient PSAD and radiologists' PI-RADS scores with AI software can potentially reduce false positive cases, further aiding patient selection for biopsy using MRI.

## W5B-SPIN-6 Deep Learning to Predict Fat and Appendicular Skeletal Masses from Chest Radiograph

### Participants

Ki Duk Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

To predict fat and appendicular skeletal muscle (ASM) masses from chest radiograph (CXR), which can be highly beneficial for analyzing the health impacts of body composition.

## METHODS AND MATERIALS

A total of 40,369 CXRs with body composition, including fat and ASM, from a tertiary hospital's health screening center was used. Fat and ASM were acquired using bioelectrical impedance analysis (BIA). The Inception v3 architecture was used to predict body composition, and assessment to determine the impact of demographics, such as age, sex, height, and weight, on the model's performance was conducted. Deep label distribution learning with additional Mean-Variance (MV) loss was used to train the network. Two independent unseen test datasets comprising 1,000 individuals each, which follows normal distribution and uniform distribution of age, from same center were used. The mean average error (MAE) and Pearson's correlation coefficient (r) between BIA and model prediction were evaluated. Correlation analyses and Bland-Altman plots were also presented.

## RESULTS

The age of test dataset was  $56.732 \pm 10.519$  and  $54.421 \pm 19.160$  (range from 20 to 90), respectively for test set of normal distribution and test set of uniform distribution. And the ASM was  $25.839 \pm 5.814$  and  $25.709 \pm 6.152$ , respectively. Sex was sampled evenly for both datasets. In the test set of normal distribution, MAEs of the models without information and without MV loss, without information and with MV loss, with information and without MV loss, and both with information and MV loss for predicting fat were 1.773, 1.673, 1.564, and 1.564, respectively. All model significantly correlated with BIA with decent r scores of 0.805, 0.839, 0.855, and 0.861, respectively ( $P < 0.001$  in all model). In the uniform distribution set, MAEs were 1.945, 1.844, 1.773,

and 1.726 respectively, while r scores were 0.805, 0.849, 0.853, and 0.860, respectively ( $P < 0.001$  in all model). In the normal distribution set, MAEs of each model for ASM were 1.309, 1.181, 1.307, and 1.172 respectively. All model showed decent r scores of 0.927, 0.932, 0.981, and 0.940 ( $P < 0.001$  in all model) with the same order. In the uniform test dataset, MAEs were 1.424, 1.250, 1.376, and 1.278, respectively, while r scores were 0.920, 0.932, 0.930, and 0.932, respectively ( $P < 0.001$  in all model).

## **CONCLUSION**

s deep learning model of CXR can precisely predict fat and muscle masses. Demographics and MV loss can significantly enhance the predicting power of the model

## **CLINICAL RELEVANCE/APPLICATION**

Prediction of fat and ASM from CXR can be applied to a variety of clinical fields, such as sarcopenia assessment, prognosis prediction of cancer patients, precision medicine for optimum drug dose estimation in inpatient settings.

### Interventional Radiology Wednesday Poster Discussions II

#### Sub-Events

#### **W5B-SP1R-1 Long-Term Survival after Percutaneous CT and US guided Microwave Ablation of Pathologically Proven Renal Cell Carcinoma**

##### Participants

Daniel Kim, Los Angeles, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the long-term overall (OS), cancer-specific (CSS), and local tumor progression (LTP)-free survival of patients who underwent percutaneous microwave ablation (MWA) of pathologically proven renal cell carcinoma (RCC).

##### METHODS AND MATERIALS

This IRB-approved, HIPAA compliant study included patients who underwent percutaneous MWA between 2013 and 2017 of biopsy-proven RCCs. All patient demographics, tumor characteristics, procedural technical outcomes, and pre- and post-procedural estimated glomerular filtration rate (eGFR) were evaluated. OS, CSS, and LTP-free survival were calculated and Kaplan-Meier analysis was performed. Complications were classified per the Clavien-Dindo system.  $\chi^2$  test was used for proportions for categorical outcomes excluding repeated measures for patients and a paired t-test for differences in eGFR.

##### RESULTS

The study cohort comprised 86 biopsy-proven RCCs from 81 patients (mean age: 67.6±16.9) and were 62% male. The median follow-up period was 76.8 months (1 to 123 months). The mean tumor size was 2.8cm (0.7cm to 7.0cm) and RCC lesions were more commonly located on the right side (60.5%), anterior (41.9%), lower pole (44.2%), and endophytic (69.8%). Primary and secondary technical success was achieved in 88.4% (76/86) in a single session and 90% (9/10) in two sessions with overall technical success of 100%. The 5-year and 10-year OS, CSS, and LTP-free survival rates were 82.7%, 90.8%, and 84.3% and 75.7%, 84.7%, and 82.9%, respectively. RCC = 4cm ( $p=0.016$ ) was predictive of LTP. There were no significant changes in pre-ablation and 2-3 years post-ablation eGFR (58.5 vs 58.4 mL/min/1.73m<sup>2</sup>,  $p=0.932$ ). There was a 2% overall incidence of complications, all grade I.

##### CONCLUSION

s Percutaneous CT and US guided MWA of biopsy-proven RCC was safe and effective with excellent long-term OS, CSS, and LTP-free outcomes within 10 years from initial treatment.

##### CLINICAL RELEVANCE/APPLICATION

Image-guided ablative therapies are a safe and effective treatment option for renal cell carcinoma with durable long-term survival rates.

#### **W5B-SP1R-2 Long-Term Survival after CT and US Guided Radiofrequency Ablations of T1a and T4 Pathologically Proven Renal Cell Carcinomas**

##### Participants

Daniel Kim, Los Angeles, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

To determine the long-term overall, renal cell carcinoma (RCC)-specific, and progression-free survival of patients who underwent percutaneous radiofrequency ablation (RFA) of pathologically proven RCC.

##### METHODS AND MATERIALS

This IRB-approved, HIPAA compliant study included patients who underwent percutaneous RFA between 2004 and 2015 of their biopsy-proven RCCs. All patient demographics, tumor characteristics, procedural technical outcomes, and pre- and post-procedural estimated glomerular filtration rate (eGFR) were collected. Overall survival (OS), and local tumor progression (LTP)-free survival were calculated by Kaplan-Meier survival curves. In addition, a subcohort analysis of the RCC T1a and T4 was conducted to examine the RCC-specific survival (RSS) rate with Kaplan Meier survival analysis. Complications were classified per the Clavien-Dindo system.  $\chi^2$  test was used for proportions for categorical outcomes and paired t test was used for changes in eGFR.

##### RESULTS

The study cohort comprised 129 biopsy-proven RCCs from 101 patients (mean age: 68.5±12.4). Primary technical success was achieved in 91.5% (118/129) of ablations and secondary technical success was achieved in 90.9% (10/11) of ablations with remaining one lesion requiring three ablations. The median of the follow-up period was 136 months (1 to 230 months) with mean tumor size of 2.3cm (0.5cm to 8.0cm). RCC lesions were more commonly located on the right (52.7%), in the midpole (37.2%), and were endophytic (54.3%). The study cohort comprised the following RCC subtypes: clear cell (69%), epithelial neoplasm (16%), papillary (11%), and chromophobe (5%). There was a slight decrease in preprocedure eGFR relative to 2-3 years postprocedure

eGFR (59.2 vs 55.4 mL/min/1.73m<sup>2</sup>; p=0.003). There were 6 complications mostly grade I-III. The 15-year OS and LTP-free survival rates were 63.6% and 92.2% in 101 patients and 129 lesions. The T1a and T4 subcohorts comprised 65 patients and 32 patients with a 15-year RSS rate of 96.5% and 82.7%.

## CONCLUSION

s Image-guided percutaneous RFA of RCCs was safe with durable 15-year OS rate of 63.6%, LTP-free survival rate of 92.2%, and RSS rate of 96.5% and 82.7% in the T1a and T4 subcohorts.

## CLINICAL RELEVANCE/APPLICATION

Percutaneous CT and US guided radiofrequency ablation was safe with excellent 15-year durable responses in both T1a and T4 subcohorts.

## W5B-SPiR-3 No-touch Radiofrequency Ablation versus Tumor Puncture Microwave Ablation for Small Hepatocellular Carcinoma: Comparison of Treatment Outcomes

Participants

Jae Hyun Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

The aim of this study was to compare the therapeutic outcomes between no-touch (NT) radiofrequency ablation (RFA) and tumor puncture microwave ablation (MWA) for single hepatocellular carcinomas = 4 cm.

## METHODS AND MATERIALS

A total of 335 patients who underwent NT RFA (n=155) or tumor puncture MWA (n=180) for single HCCs = 4 cm were included in this retrospective study. A matched cohort comprising 121 patients from each group was selected after propensity score matching analysis to adjust for potential biases. This study assessed the therapeutic outcomes after ablation including technical success, local tumor progression (LTP), and major complications. Cumulative LTP rates were estimated using the Kaplan-Meier method.

## RESULTS

A total of 242 patients (mean age, 66.2 years ± 9.5 [standard deviation]; 183 men) were evaluated. The technical success rates were 99.2% [120/121] vs. 100% [121/121] in the NT RFA and MWA groups, respectively (P>0.05). The estimated 1- and 2-year cumulative LTP rates in the NT RFA were 2.2% and 3.1%, respectively, and were not significantly different from the 3.0% and 6.0% observed in the MWA group (P=0.279). There was no significant difference in the major complication rate between the NT RFA and MWA groups (1.7% [2/121] vs. 0.8% [1/121], P=1.000).

## CONCLUSION

s Tumor puncture MWA showed comparable therapeutic outcomes including LTP and major complication rates to those of NT RFA in single HCCs (= 4 cm).

## CLINICAL RELEVANCE/APPLICATION

NT RFA and tumor puncture MWA are potentially effective and safe treatment options for small HCCs (= 4 cm).

## W5B-SPiR-4 Perfusion CT for Early Prediction of Treatment Response of Cryoablation in Renal Cell Carcinoma

Participants

Oyunbold Lamid-Ochir, Ulaanbaatar, Mongolia (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate quantitative analysis of perfusion CT (pCT) for assessment of early treatment response after cryoablation in renal tumors.

## METHODS AND MATERIALS

A total 54 patients with renal tumors who had treated by CT-guided percutaneous cryoablation in our institution from June 2014 to August 2016. Twenty-seven patients were selected, who underwent pCT before and after within 1 week, 1, 3, 6 months and 1-year treatment. Perfusion parameters including arterial flow perfusion (AFP) as tumor maximum, minimum, average and average changes and tumor diameter, freezing time, treatment cycles and progression-free-survival were analyzed and compared. The effects of treatment response were evaluated by RECIST standards version 1.1 as a non-responder and responder.

## RESULTS

Twenty-seven patients (22 men, 5 women: age, 68 ± 12 y.o.) evaluated as quantitative analysis with pCT. Five of 27 patients were non-responders, and 22 patients were responder. The mean AFP values were significantly different between non-responder (46.6±25.8) and responder (25.1 ± 6.1) at 1 month after cryoablation (p<0.05). ROC analysis demonstrated that tumor average (AFP) at 1 month had the cut-off of perfusion value (29.95) and area under curve (0.94), with sensitivity and specificity of 100% and 84.2%, respectively (p<0.05). Percent of progression free-survival was 100% (cut-off < 29.95) and 66.7% (cut-off >29.95) for 32 months observation.

## CONCLUSION

s pCT was able to evaluate and predict therapeutic effects of cryoablation at 1 month after treatment. It can offer both morphologic and functional evaluation, providing a quantitative assessment of residual tumor vascularization after treatment.

## CLINICAL RELEVANCE/APPLICATION

pCT can be predicted to responder and non-responder at 1 month after cryoablation and might be earlier than dynamic CE-CT. Also, it can detect minimal focal perfusion changes whether the tumor is shrinking or without tumor volume changes.

## **W5B-SPiR-5 SAR-COOL: Sarcoma Cryoablation Outcomes and Optimization of Life**

Participants

Koustav Pal, MBBS, Houston, TX (*Presenter*) Nothing to Disclose

### **PURPOSE**

To evaluate the local tumor progression-free survival following cryoablation of recurrent or metastatic soft tissue sarcoma (STS) lesions.

### **METHODS AND MATERIALS**

A single-institution retrospective analysis of patients with a histopathological diagnosis of metastatic STS who underwent percutaneous cryoablation (PC) from January 2022 to April 2023 was performed. . Patients with less than 60 days of follow-up and those treated for more than four lesions during one procedure were excluded. Complications were categorized based on the Common Terminology Criteria for Adverse Events (CTCAE) classification system. R software version 4.2.3 was used for analysis. (We aim to further analyze the outcomes of 239 patients with 391 procedures from Jan. 2016 to April 2023)

### **RESULTS**

61 patients who underwent PC for 84 STS lesions met the eligibility criteria. There were 21 different histological subtypes of sarcoma in the study, with the two most common being leiomyosarcoma (20/61) and liposarcoma (16/61). The median size of sarcoma lesions was 2.1 cm (range 0.4 to 13.4). Complete response at six months was achieved in 81% of the treated lesions. Local tumor progression-free survival was 86.1% at 6 months and 77.3% at 1 year. The overall survival was 97.2% at 1 year. Chemotherapy free time for patients was 54.57% at 6 months. The complication rate was 14%, with 56.55% classified as CTCAE grade 3 or higher. Subgroup analysis for leiomyosarcoma vs. liposarcoma demonstrated an overall survival of 100% vs. 90.9% at 12 months, respectively. Local tumor-free progression was 86.7% at 6 months and 86.7% at 12 months for liposarcoma. Leiomyosarcoma demonstrated 91.97% local tumor-free progression at 6 months and 46.4% at 12 months. There was no statistically significant difference between the two groups ( $p=0.37$ ).

### **CONCLUSION**

s PC of STS and its metastases is a safe and effective treatment modality.

### **CLINICAL RELEVANCE/APPLICATION**

Surgical resection is a cornerstone in the management of recurrent or oligometastatic soft tissue sarcoma. Percutaneous cryoablation is a minimally invasive technique that may complement surgical approaches. This study demonstrates that cryoablation can achieve high local control rates with durable responses in this patient population.

## **W5B-SPiR-6 Assessment of Spectral CT Images for Mapping Treatment Volume during CT-guided Thermal Ablations: A Feasibility Study**

Participants

Kuan Zhang, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

### **PURPOSE**

CT-guided thermal tumor ablations suffer from limited visualization of the treatment volume. In this study, we investigated the application of spectral CT to improve the visualization of the treatment zone and quantify the underlying temperature changes.

### **METHODS AND MATERIALS**

Two cryoablation probes (IceFORCE, Boston Scientific) were inserted 2 cm apart through a custom, 3D-printed holder and into a tissue mimicking gel (3% HEC, 0.15% NaCl, and 96.85% DI water). In between the cryo probes, 8 fiber optic temperature sensors (OmniFlex, Neoptix) were inserted through the holder and positioned at 5 mm increments parallel to the CT rotation axis. A 15-minute freeze cycle was performed operating both probes at 100% (VisualICE, Boston Scientific) followed by two consecutive 20-minute thaw cycles. The phantom was scanned every minute during the freeze-thaw cycles (120 kV, 500 mAs, 0.6 pitch, 64x0.625 collimation; Spectral CT7500, Philips Healthcare) and reconstructed with 1mm slice thickness and a soft tissue filter (B). Regions of interest and line profiles were drawn adjacent to the temperature sensors and used to correlate pixel values to temperature for each reconstructed series. Measurements from both conventional CT and electron density images with respect to the measured temperature data were compared to H<sub>2</sub>O density vs temperature curves.

### **RESULTS**

Line profiles for different image results demonstrated similar iceball image contrast. Importantly, increasing CT numbers were observed in the (colder) central region of the iceball compared to its (warmer) periphery. This trend was most visible on electron density images owing to the reduced image noise. Similar conclusions were drawn from line profiles through heated region. Conventional single energy and electron density image data as a function of temperature showed a MSE of 0.605 and 0.259 kg/m<sup>3</sup>, respectively, when compared with the scaled temperature-dependent density curve of ice.

### **CONCLUSION**

s Spectral results offer similar image contrast of the treatment region to conventional images, however with overall reduced image noise iceball conspicuity increases for high monoE and electron density images. In particular, electron density showed a superior level of correlation to measured temperature in both hypo- and hyper-thermal regions. These results demonstrate the feasibility of using spectral CT data to develop in vivo CT thermometry for ablation guidance, indicating promising potential for further research in this area.

### **CLINICAL RELEVANCE/APPLICATION**

CT thermometry obtained from spectral CT images has the potential to enhance both hypo- and hyper-thermal tumor ablation procedures by providing improved visualization of the lethal treatment zone.

Printed on: 04/12/24

W5B-SPMK

### Musculoskeletal Imaging Wednesday Poster Discussions II

#### Sub-Events

#### **W5B-SPMK- The Reference Value of Trabecular Bone Score in Chinese Population: A Single-center Retrospective Study** 1

##### PURPOSE

To investigate the reference value of trabecular bone score (TBS) in Chinese population.

##### METHODS AND MATERIALS

The study included subjects who had at least one dual-energy X-ray absorptiometry (DXA) examination from October 2021 to March 2023. Subjects with age from 30 to 89 years and body mass index (BMI) of 15 - 37 kg/m<sup>2</sup> were included. The exclusion criteria included diseases that may affect the function of bone metabolism. Bone mineral density (BMD) was measured and TBS was calculated based on the DXA images by the TBS iNsite software (version 3.0.0.15). Every ten years was an interval group and BMD and TBS were calculated for each group. Differences in BMD and TBS as well as clinical characteristics (weight, height, age, and BMI) between male and female subjects were compared using a t-test.  $P < 0.05$  was considered significant.

##### RESULTS

The study included a total of 2007 Chinese participants (540 males and 1467 females). The clinical characteristics (weight, height, age, and BMI) were significant different between male and female subjects. For men, the mean BMD value peaked at the age group of 51 to 70 years ( $1.17 \pm 0.09$  g/cm<sup>2</sup>) and decreased until 80 years ( $1.05 \pm 0.19$  g/cm<sup>2</sup> for age of 71 - 80 years) and then again raised ( $1.19 \pm 0.18$  g/cm<sup>2</sup> for age of 81 - 89 years). The TBS value for men peaked at the age of 51 - 60 years ( $1.40 \pm 0.07$  g/cm<sup>2</sup>) and then gradually decreased until the age of 89 years ( $1.37 \pm 0.10$  g/cm<sup>2</sup> for both age group of 61-70 and 71-80 years;  $1.36 \pm 1.20$  g/cm<sup>2</sup> for age group of 81 - 89 years). For women, both BMD and TBS experienced an obvious decrease with age. The BMD and TBS were in general higher in men than in women, with a significant difference after the age of 51 years ( $P < 0.01$  for all groups after the age of 51 years).

##### CONCLUSION

The single-center retrospective study provided the reference value for trabecular bone score at different age in Chinese population. A significantly higher trabecular bone score can be observed in men than in women especially after the age of 51 years.

##### CLINICAL RELEVANCE/APPLICATION

TBS is a novel textural index to measure the gray-level variations in lumbar spine DXA images. It can provide an effective evaluation of trabecular microstructure without a second-time scanning and therefore without extra radiation dose. The availability of TBS reference values can help to further understand the distribution of trabecular bone microstructure in Chinese population. Accordingly, osteoporosis and fracture risk could be better evaluated.

#### **W5B-SPMK- The Next Frontier in Lumbar Spine MR Bone Imaging: Harnessing the Power of Super-Resolution Deep Learning Reconstruction** 2

Participants  
Masamichi Hokamura, Kumamoto, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

This study aims to assess the effectiveness of super-resolution deep-learning-based reconstruction (SR-DLR), which leverages k-space properties, on the image quality of lumbar spine magnetic resonance (MR) bone imaging using a 3D multi-echo in-phase sequence.

##### METHODS AND MATERIALS

In this retrospective study, 29 patients who underwent lumbar spine MRI, including an MR bone imaging sequence, between January and April 2023, were analyzed. Images were reconstructed with and without SR-DLR (Matrix sizes: 960 x 960 and 320 x 320, respectively). The signal-to-noise ratio (SNR) of the vertebral body and spinal canal, along with the contrast and contrast-to-noise ratio (CNR) between the vertebral body and spinal canal, were quantitatively evaluated. Furthermore, the slope at half-peak points of the profile curve drawn across the posterior border of the vertebral body was calculated. Two radiologists independently assessed image noise, contrast, artifacts, sharpness, and overall image quality of both image types using a 4-point scale. Interobserver agreement was evaluated using weighted kappa coefficients, and quantitative and qualitative scores were compared via the Wilcoxon signed-rank test.

##### RESULTS

In this retrospective study, 29 patients who underwent lumbar spine MRI, including an MR bone imaging sequence, between January and April 2023, were analyzed. Images were reconstructed with and without SR-DLR (Matrix sizes: 960 x 960 and 320 x 320, respectively). The signal-to-noise ratio (SNR) of the vertebral body and spinal canal, along with the contrast and contrast-to-noise

ratio (CNR) between the vertebral body and spinal canal, were quantitatively evaluated. Furthermore, the slope at half-peak points of the profile curve drawn across the posterior border of the vertebral body was calculated. Two radiologists independently assessed image noise, contrast, artifacts, sharpness, and overall image quality of both image types using a 4-point scale. Interobserver agreement was evaluated using weighted kappa coefficients, and quantitative and qualitative scores were compared via the Wilcoxon signed-rank test.

## CONCLUSION

s SR-DLR, which is based on k-space properties, has the potential to enhance the image quality of lumbar spine MR bone imaging utilizing a 3D gradient echo in-phase sequence.

## CLINICAL RELEVANCE/APPLICATION

The application of SR-DLR can lead to improvements in lumbar spine MR bone imaging quality.

## W5B-SPMK- Application of Material Decomposition Technique based on Dual-energy CT in the Differential Diagnosis of Acute and Old Thoracolumbar Fracture

3

### PURPOSE

To identify acute and old thoracolumbar vertebral compression fractures by using material decomposition technique based on dual-energy CT (DECT).

### METHODS AND MATERIALS

A total of 12 patients with acute trauma or diagnosed compression fracture who underwent thoracolumbar DECT and MR scanning in Shenzhen Qianhai Shekou Free Trade Zone Hospital from June 2022 to February 2023 were retrospectively collected. 24 cases about vertebral compression fracture was found in DECT and MRI (fat suppressed T2WI). The time about patients took DECT and MRI examination from the first day they get injured to 2 weeks after they got fractured. A total of 16 vertebral bodies' data were collected, including 8 patients with old fractures. All patients had a fracture injury time of more than six months. Water (Iodine), Water (Calcium) and Water (HAP)-based on material decomposition images were reconstructed. The signals of edema area is calculated from water density values and water difference values in three material decomposition images in both area of acute fractured vertebrae and old fractured vertebrae. With reference to bone marrow edema area of fracture based on MRI. A paired T test was used to compare the difference in water density between acute vertebral fracture edema and old compression fractures. A two-factor ANOVA was used to compare the difference in water density values between edematous fractured vertebrae and old compression fractured vertebrae among three material images sets.

### RESULTS

The water density values for Water (Iodine), Water (Calcium) and Water (HAP) images were significant higher in the acute fracture edema vertebral bodies compared to old compression fracture vertebral bodies (1147.6mg/cm<sup>3</sup> Vs 1040.9mg/cm<sup>3</sup>, 1089.4mg/cm<sup>3</sup> Vs 1014.4mg/cm<sup>3</sup> and 996.7mg/cm<sup>3</sup> Vs 972.2mg/cm<sup>3</sup>, respectively, all  $P < 0.001$ ). There was a significant statistical difference in the water difference values between the acute fractured vertebrae and the old compression fractured vertebrae ( $P < 0.001$ ), and with the largest water difference values in the Water (Iodine) image.

## CONCLUSION

s The water density values for Water (Iodine), Water (Calcium) and Water (HAP)-based material decomposition images can distinguish acute thoracolumbar fractures from old compression fractures on dual-energy CT examination. Water (Iodine) images showed the best discrimination.

## CLINICAL RELEVANCE/APPLICATION

The measurement of water density values for material decomposition images based on dual-energy CT, can improve the clarity of diagnosis of acute thoracolumbar fractures and old compression fractures, and also avoid confusion caused by contraindications to MRI examination. This is a valuable aid for both patients and clinical practice.

## W5B-SPMK- Application of Dual-energy CT Single Energy Reconstruction Technique in Acute Fractures of Thoracolumbar Spine with Bone Marrow Edema

4

### PURPOSE

To identify bone marrow edema in acute thoracolumbar fractures by using single-energy reconstruction technique based on dual-energy CT (DECT).

### METHODS AND MATERIALS

A total of 18 patients with acute trauma or diagnosed compression fracture who had thoracolumbar DECT and MR scanning in Shenzhen Qianhai Shekou Free Trade Zone Hospital from June 2022 to February 2023 were retrospectively collected. 20 cases about vertebral compression fracture was found in DECT and MRI (fat suppressed T2WI). The time about patients took DECT and MRI examination from the first day they get injured to 2 weeks after they got fractured. 40KeV images, 70KeV images, 100KeV images, 140KeV images-based on single energy reconstruction technique were reconstructed. On the median sagittal plane of the Water (Ca) pseudo-color image, the fracture bone marrow edema area was identified. According to the edema areas shown by MRI, manually delineated the region of interest. CT values of the edema area of the fractured vertebra and the normal vertebra were recorded at different Single energy. All edema areas of compression fractures were use MRI fat suppressed T2WI sequences as reference. A paired T test was used to compare the difference in CT values between the fractured edema vertebra and the normal vertebra under different single energies. A two-factor ANOVA was used to compare the difference in CT values between oedematous fractured vertebrae and normal vertebrae at four keV sets.

### RESULTS

The CT values of vertebrae with acute fracture edema vertebral bodies compared with normal vertebral bodies measured at 40KeV, 70 KeV, 100 KeV and 140KeV were (691.5Hu Vs 252.9Hu, 319.1Hu Vs 106.1Hu, 222.4Hu Vs 67.9Hu and 183.1Hu Vs 52.5Hu, respectively, all  $P < 0.001$ ). There was a significant statistical difference in the difference in CT values between the acutely fractured vertebrae and the normal vertebrae ( $P < 0.001$ ), and with the greatest difference in CT values in the 40KeV image.

## CONCLUSION

The single energy values of 40KeV, 70 KeV, 100 KeV and 140KeV images can differentiate bone marrow edema from normal vertebral body on acute thoracolumbar fracture dual-energy CT scan. The greatest difference in CT value is at 40KeV. Combined with Water(Ca) material density film, it can provide a more accurate diagnosis of acute thoracolumbar fracture edema.

## CLINICAL RELEVANCE/APPLICATION

The measurement of single-energy reconstruction on dual-energy CT, combined with Water(Ca) material density picture, can improve the clarity of diagnosis of thoracolumbar fractures and bone marrow edema, and also avoid confusion caused by contraindications to MRI examination. This is a valuable aid for both patients and clinical practice.

## W5B-SPMK- Assessing the Combined Efficacy of Radiofrequency Ablation and Kyphoplasty with Radiation Treatment for Painful Spine Metastases

5

### PURPOSE

To compare kyphoplasty ablation with and without radiotherapy for the treatment of patients with painful metastatic neoplastic disease to the spine.

### METHODS AND MATERIALS

Between 3/2019 and 08/2022, 59 kyphoplasty procedures were performed for palliation of metastatic spine disease. 21 patients (36.2%) with metastatic tumor received radiation in addition to kyphoplasty/RF ablation to palliate pain: 9 patients (47.4%) had prior radiation, 2 patients (10.5%) had concurrent, and 10 patients (1.4%) had radiation therapy after. 37 painful metastatic spinal tumors were treated with kyphoplasty ablation without radiation. The primary neoplastic disease was as follows: multiple myeloma (n=17, 28.8%), breast (n=15, 25.4%), lung (n=7, 11.9%), prostate (n=6, 10.2%), lymphoma and colorectal (each n=3, 5.1%), urothelial (n=2, 3.4%), thyroid, pancreas adenocarcinoma, renal cell, and metastatic adenoid cystic (each n=1, 3.3%). Pain relief was evaluated by the visual analogue scale (VAS) score, disability by the Oswestry Disability Index (ODI), performance status by the Karnofsky Performance Status Scale (KPS) score and ECOG score before and within 3-months after the procedure. The highest documented VAS, ODI, KPSS, and ECOG scores pre- and post-procedure were recorded. A P-value < 0.05 was considered statistically significant.

### RESULTS

Technical success was achieved in all patients. Table 1 compares demographics, pre procedural and post procedural pain, disability, and functional scores between the two groups. The median change in VAS, ODI, KPSS, and ECOG scores from baseline to three months was not significantly different between the two groups. There were no major complications.

## CONCLUSION

The study suggests adding radiation therapy to kyphoplasty/RFA for palliation of metastatic neoplastic disease to the spine may not significantly change pain, disability, or performance status scores. Further studies with a larger number of subjects and longer follow-up and prospective design are needed to validate these findings.

## CLINICAL RELEVANCE/APPLICATION

MSK Interventional Radiology - Palliative Spine Intervention

## W5B-SPMK- Symmetry Plane Analysis for Determination of Vertebral Rotation

6

Participants  
Dillon Haughton, BS, Las Cruces, NM (Presenter) Nothing to Disclose

### PURPOSE

Accurate vertebral rotation measurements are crucial in the understanding and treating of spinal pathologies. Many methods exist to aid in determining this metric, with the most common and widely accepted method utilizing axial CT scans being the Aaro-Dahlborn method. This method is simple and accurate but is limited due to errors when used by inexperienced users. It only considers one axial cut through the vertebra limiting its accuracy when the vertebra is rotated in sagittal and coronal planes. We propose a new method using symmetry planes calculated by iterative closest point registration and pairwise assignment of curves, as an alternative to the Aaro-Dahlborn method in determining vertebral rotation. Our method considers the entire vertebra and is an automated method applied post segmentation, which would limit operator error.

### METHODS AND MATERIALS

Our method was coded in python utilizing a Jupyter notebook compatible with 3DSlicer. It was tested on segmented vertebrae from the VERSE2020 opensource dataset. 812 vertebrae with no gross pathology were selected from the VERSE2020 database and processed utilizing our method for feasibility analysis. Out of those 812, 96 vertebrae from 8 randomly selected CT scans were divided up among two medical students who performed measurements utilizing the Aaro-Dahlborn method. Correlation-coefficients and Bland-Altman plots were calculated to determine the alignment between the two methods.

### RESULTS

Out of 812 vertebrae analyzed, 799 had their vertebral rotation successfully calculated using our algorithm (98% success rate). Correlation coefficient was calculated at 87% amongst the 96 vertebrae whose vertebral rotation was determined manually against our method. Bland-Altman plotting showed mean difference of -0.51 degrees, a +2 standard deviation of 2.2 degrees and -2 standard deviation of -3.2 degrees.

## CONCLUSION

Our method had similar accuracy to the Aaro-Dahlborn manual method. Our method was also demonstrated to work with a wide variety of normal vertebrae. This provides a quick and efficient means of determining vertebral rotation and can act as an objective reference due to no post-segmentation user input. As segmentation algorithms for individual vertebrae become more accessible and the process is simple manually, we don't see this as a limiting factor to the utility of our method. An extension of our method can also be applied to determining the rotation of vertebrae in both sagittal and coronal planes, which could greatly contribute to our understanding of vertebral movements.

## CLINICAL RELEVANCE/APPLICATION

Improvement in speed and accuracy of methods of determining vertebral rotation will further our understanding of vertebral movements in pathologies such as back pain and scoliosis.

### W5B-SPMK- How Effective is Radiofrequency Ablation with Kyphoplasty at Decreasing Narcotic and Analgesic Requirements in Painful Spine Metastases 7

#### PURPOSE

To determine the effect of radiofrequency ablation (RF) in conjunction with kyphoplasty on pain relief and analgesic requirements in patients with painful metastatic disease to the spine.

#### METHODS AND MATERIALS

Between 3/2019 and 8/2022, 59 kyphoplasty/RF ablations were performed. The median age was 63 years old (IQR, 55-69) with a male-to-female ratio of 0.97. The primary neoplastic diseases were as follows: multiple myeloma (n=17, 28.8%), breast (n=15, 25.4%), lung (n=7, 11.9%), prostate (n=6, 10.2%), lymphoma and colorectal (each n=3, 5.1%), urothelial (n=2, 3.4%), thyroid, pancreas adenocarcinoma, renal cell, and metastatic adenoid cystic carcinoma (each n=1, 3.3%). Pain relief was evaluated by the highest visual analogue scale (VAS) score before and within 3-months after the procedure. The number of non-opioid and opioid pain medications that were taken before, at 1-mo, and 3-mo after the procedure was recorded. A two-tailed p value < 0.05 was considered statistically significant.

#### RESULTS

Technical success was achieved in all patients. The median VAS score decreased from 10 (IQR, 8-10) to 2 (IQR, 0-4) after the procedure (p < 0.001) and 2 (IQR, 2-3) at 3 months after procedure (p < 0.001). Table 1 demonstrates the number (and percentages) of patients who were taking non-opioid and opioid analgesics before the Kyphoplasty/ablation, and at 1-mo and 3-mo after the procedure. Overall, use of opioid medications decreased at 1-mo and 3-mo after the procedure.

#### CONCLUSION

s RFA in conjunction with kyphoplasty appears to provide meaningful clinical improvement in VAS pain scores and decrease requirements for narcotic medications in patients with metastatic disease to the spine.

## CLINICAL RELEVANCE/APPLICATION

MSK Interventional Radiology - Palliative Spine Intervention

### W5B-SPMK- How Effective is Radiofrequency Ablation with Kyphoplasty at Improving Pain Scores in Burdensome Spinal Metastases 8

#### PURPOSE

To determine the improvement in pain, performance status and disability index, and the safety of radiofrequency ablation (RFA) in conjunction with kyphoplasty for the treatment of painful metastatic neoplastic disease to the spine.

#### METHODS AND MATERIALS

Between 3/2019 and 8/2022, 59 kyphoplasty/RFAs were performed. The median age was 63 (IQR, 55-69) with a M:F ratio of 0.97. There were 11 different primary cancers; multiple myeloma was the most prevalent (n=17, 28.8%). Pain relief was evaluated by the Visual Analog Scale (VAS); performance status by the ECOG and Karnofsky Performance Status Scale (KPS), Disability by the Oswestry Disability Index (ODI). The highest VAS, ECOG, KPS and ODI score pre- and within 3 months post-procedure were recorded. A two-tailed p value < 0.05 was considered statistically significant.

#### RESULTS

Technical success was achieved in all patients. Within 3 months from the procedure, the median VAS score decreased from 10 (IQR, 8-10) to 2 (IQR, 2-3, p < 0.001). The median ECOG performance status score improved from 3 (IQR, 2-3) to 1 (IQR, 1-2) (p < 0.001). The median KPS increased from 50 (IQR, 40-60) to 75 (IQR, 62.5-90) (p < 0.001). The median ODI decreased from 66.5 (IQR, 49.8-80) to 20.5 (IQR, 13-26) (p < 0.001). There were no major complications.

#### CONCLUSION

s RFA in conjunction with kyphoplasty is safe and provides meaningful clinical improvement in VAS, ECOG, KPS, and ODI scores in patients with pain due to metastatic disease to the spine, when measured at post procedure follow-up within 3 months of the procedure.

#### **W5B-SPMS- Value of MRI in the Staging of Klippel-Trenaunay Syndrome Complicated with Lower Extremity Lymphedema** 1

#### Participants

Xingpeng Li, Beijing, China (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the value of MRI in the staging of Klippel-Trenaunay syndrome (KTS) complicated with lower extremity lymphedema.

#### METHODS AND MATERIALS

Thirty-four patients who were diagnosed as KTS complicated with lower extremity lymphedema were recruited in this retrospective study from July of 2011 to November of 2021. Referring to the clinical staging standard of lower extremity lymphedema of the international society of lymphology in 2020, all patients were divided into two groups including stable stage and advanced stage. The MRI indexes of the two groups were recorded and were statistically compared: longitudinal involvement range of lymphedema, thickened parts of skin and subcutaneous soft tissue, signs of subcutaneous soft tissue edema (parallel line sign, grid sign, band sign, honeycomb sign, lymph lake sign, crescent sign and star cloud sign).

#### RESULTS

Compared with stable stage, patients in advanced stage demonstrated older onset age ( $P < 0.05$ ). For imaging features, the proportion of honeycomb sign are higher in advanced stage than stable stage ( $P < 0.05$ ). While no statistical difference was found in the incidence of parallel line sign, grid sign, band sign, lymph lake sign, crescent sign, star cloud sign, skin and subcutaneous soft tissue thickening, range of lymphedema in lower limbs (all  $P > 0.05$ ). The sensitivity, specificity, positive predictive value, negative predictive value and accuracy of honeycomb sign in the diagnosis of advanced lower extremity lymphedema were 55.00%, 92.86%, 91.67%, 59.09% and 70.59%, respectively.

#### CONCLUSION

s MRI is of great value in KTS complicated with lower extremity lymphedema. Honeycomb sign is an important imaging index for the diagnosis of advanced KTS complicated with lower extremity lymphedema.

#### CLINICAL RELEVANCE/APPLICATION

It is necessary to evaluate the severity of edema with MR for KTS complicated with lower extremity lymphedema, which is very important for therapeutic options.

W5B-SPNMMI

### Nuclear Medicine & Molecular Imaging Wednesday Poster Discussions II

#### Sub-Events

#### **W5B-SPNMMI-1 Correlation of FLT PET Findings with Histopathology in the Assessment of Response to Neoadjuvant Chemoradiotherapy in Pancreatic Cancer: Comparison with FDG PET**

##### Participants

Yuka Yamamoto, PhD, Kita-gun, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Although the role of FDG PET has been proposed in pancreatic cancer, a high percentage of patients have diabetes due to pancreatic cancer. Therefore, the rate of false negative results is high due to elevated plasma glucose levels. On the other hand, 3'-deoxy-3'-18F-fluorothymidine (FLT) is being studied to assess tumor proliferating activity. We evaluated the ability of FLT PET to predict the response to neoadjuvant chemoradiotherapy in pancreatic cancer, in comparison with FDG.

##### METHODS AND MATERIALS

FDG and FLT PET/CT studies were performed before and after neoadjuvant chemoradiotherapy in 19 patients with pancreatic cancer. The values of maximum standardized uptake value (SUV<sub>max</sub>) at the primary tumor obtained before and after neoadjuvant chemoradiotherapy are SUV<sub>before</sub> and SUV<sub>after</sub>, respectively. Percent change was calculated according to the following equation:  $(SUV_{before} - SUV_{after}) \times 100 / SUV_{before}$ . In the FDG PET analysis, patients with a blood glucose level of 200 mg/dL or higher at the time of the FDG PET/CT scan were excluded from the analysis. Based on histopathological analysis of the specimens obtained at surgery, the patients were classified as pathologic responders or pathologic non-responders.

##### RESULTS

Nine patients were found to be pathologic responders and 10 pathologic non-responders. Three patients were excluded from before therapy FDG PET analysis due to their high blood glucose levels. The FDG SUV<sub>after</sub> in pathologic responders was significantly lower than that in pathologic non-responders ( $p=0.03$ ). The FLT percent change in pathologic responders was significantly higher than that in pathologic non-responders ( $p=0.028$ ).

##### CONCLUSION

Based on the results of this preliminary study in a small patient sample, FLT PET seems to be as useful as FDG PET for predicting response to neoadjuvant chemoradiotherapy in pancreatic cancer. FLT PET does not require fasting prior to imaging and is not dependent on blood glucose levels, making it a potentially more convenient technique of evaluation in pancreatic cancer.

##### CLINICAL RELEVANCE/APPLICATION

FLT PET does not require fasting prior to imaging and is not dependent on blood glucose levels, making it a potentially more convenient technique of evaluation in pancreatic cancer.

#### **W5B-SPNMMI-2 Textural Indices Extracted from FMISO and FLT PET/CT for Predicting IDH1 Mutation in Newly Diagnosed High-grade Gliomas**

##### Participants

Yuka Yamamoto, PhD, Kita-gun, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Tumor hypoxia and proliferation have been recognized as determinant factors characterizing tumor aggressiveness in high-grade gliomas. To clarify in vivo hypoxia and proliferation in relation to isocitrate dehydrogenase (IDH) mutation, we retrospectively analyzed texture indices extracted from 18F-fluoromisonidazole (FMISO) PET/CT and 3'-deoxy-3'-18F-fluorothymidine (FLT) PET/CT in newly diagnosed high-grade gliomas.

##### METHODS AND MATERIALS

Thirty-three patients with newly diagnosed high-grade (WHO grade III and IV) gliomas were included in this study. They underwent both PET/CT studies with FMISO and FLT before surgery. The maximal standardized uptake value (SUV<sub>max</sub>) and 31 texture indices were measured. Texture indices were extracted from four different matrices computed for each volume of interest: gray-level co-occurrence matrix, gray-level run length matrix, neighborhood gray-level difference matrix, and gray-level zone length matrix. The PET parameters in relation to IDH1 mutation status were statistically analyzed.

##### RESULTS

The value of FMISO SUV<sub>max</sub> and FLT SUV<sub>max</sub> of IDH1-mutant tumors was significantly lower than the corresponding value of IDH1-wildtype tumors. Fifteen of 31 texture indices (Homogeneity, Energy, Contrast, Dissimilarity, Short-run emphasis, Long-run emphasis, Low grey-level run emphasis, High grey-level run emphasis, Short-run low grey-level emphasis, Short-run high grey-level emphasis, Long-run low grey-level emphasis, Run percentage, Low grey-level zone emphasis, High grey-level zone emphasis, and

Short-zone high grey-level emphasis) extracted from both FMISO and FLT PET/CT significantly differed between IDH1-mutant tumors and IDH1-wildtype tumors. In addition, 5 texture indices (Entropy, Short-zone low grey-level emphasis, Long-zone low grey-level emphasis, Zone length non-uniformity, and Zone percentage) extracted from FLT PET/CT significantly differed between IDH1-mutant tumors and IDH1-wildtype tumors. In receiver operating characteristic analysis, Entropy extracted from FLT PET/CT was the best discriminative index for predicting IDH1 mutation status.

#### **CONCLUSION**

s These preliminary results indicate that texture indices extracted from FMISO and FLT PET/CT, especially Entropy extracted from FLT PET/CT, seem to be useful for predicting IDH1 mutation status in patients with newly diagnosed high-grade gliomas.

#### **CLINICAL RELEVANCE/APPLICATION**

Texture indices extracted from FMISO and FLT PET/CT, especially Entropy extracted from FLT PET/CT, seem to be useful for predicting IDH1 mutation status in patients with newly diagnosed high-grade gliomas.

Printed on: 04/12/24

SPNPM-1

#### Enhancing Patient Communication with Chat-GPT in Radiology: Evaluating the Efficacy and Readability of Answers to Common Imaging-related Questions

#### PURPOSE

To assess ChatGPT's accuracy, relevance, and readability in answering common imaging-related questions and examine the effect of a simple prompt on these parameters.

#### METHODS AND MATERIALS

22 imaging-related questions were developed based on previously described categories important to patients: safety, report, procedure, preparation, meaning, and medical staff. Each question was asked three times on the ChatGPT-3.5 platform, both with and without a short prompt which instructed the model to "provide an accurate, and easy-to-understand response that is suited for an average person". Responses were evaluated by four board-certified radiologists for accuracy, consistency and relevance. Readability was assessed by Flesch Kincaid Grade Level (FKGL). Statistical comparisons were performed using chi-square tests, paired student's t-tests.

#### RESULTS

264 answers were assessed for both unprompted and prompted queries, resulting in a total of 528 evaluations. The model demonstrated a high degree of accuracy at 83% (218/264), with no significant difference for prompted responses at 87% (229/264,  $P=.2$ ). 72% (63/88) of answers were consistent across all three repeats, increasing to 86% (76/88) when prompted ( $P=0.02$ ). Essentially no responses were irrelevant, scoring at least partially relevant for 99% (261/264) of both sets of responses. Fewer responses were considered fully relevant at 67% (176/264), though this increased significantly to 80% when prompted (210/264) ( $P=.001$ ). The average FKGL was high at 13.6 [12.9-14.2] and did not significantly change with the prompt (13.0 [12.41-13.60],  $P=.2$ ). None of the responses reached the eighth grade readability level generally recommended for patient-facing materials.

#### CONCLUSION

ChatGPT demonstrates potential for accurate, consistent, and relevant imaging-related question responses. Readability levels exceed recommendations, reflecting currently available patient education materials. Prompts reduced response variability and yielded more targeted information but did not improve readability, possibly due to limitations in deviating from pre-trained knowledge without more detailed prompting.

#### CLINICAL RELEVANCE/APPLICATION

The study demonstrates ChatGPT's potential to increase accessibility to health information and to streamline production of patient-facing educational materials. Addressing readability limitations and employing prompt engineering strategies could optimize ChatGPT for imaging-related patient concerns, but cautious implementation and further research is needed.

W5B-  
SPNPM-2

#### Evaluation of Accuracy, Completeness, and Length of Rads-Lit Outputs: A Novel Patient-Facing Artificial Intelligence Literacy Tool

#### Participants

Rushabh Doshi, MPH, MSc, Cerritos, CA (*Presenter*) Nothing to Disclose

#### PURPOSE

Radiology reports frequently incorporate intricate medical jargon and lengthy text, which can lead to misunderstandings, anxiety, and erroneous interpretation for patients. By leveraging novel natural language processing (NLP) open-source technology, we developed a patient-centric tool aimed at simplifying radiology reports. Here, we test the accuracy, completeness, and length of the outputs from our tool.

#### METHODS AND MATERIALS

We engineered a proof-of-concept patient-facing radiology literacy website by harnessing OpenAI's application programming interface. Our model was specifically configured to optimize the readability of outputs (Flesch-Kincaid Grade Level: 6.68, Gunning Fog: 9.22, Coleman-Liau: 6.16, Automated Readability Index: 8.56). Three radiologists examined 62 radiology reports across modalities such as CT, MRI, X-Ray, PET, and U/S. For each of the 62 reports, the radiologists reviewed the clinical impressions and the corresponding simplified output, and evaluated the output for accuracy, completeness, and extraneous information using single-item Likert-type scales.

#### RESULTS

Two attending radiologists and one radiology resident assessed 62 Rads-Lit outputs using a five-level Likert scale, ranging from 1 (Strongly Disagree, 0-20% agreement) to 5 (Strongly Agree, 80-100% agreement). The evaluations demonstrated that the Rads-Lit outputs were factually accurate, with a median rating of 5 (80-100% agreement), and the first and third quartiles at 4 (60-80%

agreement) and 5 (80-100% agreement), respectively. The outputs were also found to be complete in relation to the original radiologist reports, with a median rating of 5 (80-100% agreement), and the first and third quartiles at 4 (60-80% agreement) and 5 (80-100% agreement), respectively. Furthermore, the radiologists strongly disagreed that the outputs were excessively long or filled with extraneous information, as indicated by median rating, first quartile, and third quartile at 1 (0-20% agreement).

## CONCLUSION

Our tool demonstrates promising results, showing that the Rads-Lit outputs frequently maintained factual accuracy and completeness in relation to the original radiologist reports while avoiding being lengthy or containing extraneous information. These findings suggest that the Rads-Lit tool has the potential to improve patient literacy and activation by enhancing the readability of their radiology reports. Further research is necessary to corroborate these findings and assess the broader impact of Rads-Lit on patient populations.

## CLINICAL RELEVANCE/APPLICATION

This study evaluates the potential of novel NLP technology to improve patient literacy and health outcomes by reducing anxiety and erroneous interpretations in radiology reports.

## W5B-SPNPM-3 Which Procedures Bring in the Most Medicare Reimbursement and RVUs for the Individual Diagnostic Radiologist

Participants

Aditya Khurana, MD, Scottsdale, AZ (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate which specific imaging examinations result in the most wRVUs and reimbursement for individual radiologists serving the US Medicare population.

## METHODS AND MATERIALS

Imaging claims 2013-2020 submitted by diagnostic radiologists were extracted from the CMS POSPUF database outpatient imaging claims made for beneficiaries of US Medicare Part B. These data were merged with year specific CMS professional relative value unit (wRVU) files. The total number of wRVUs as well as standardized Medicare reimbursement produced by each imaging procedure, was calculated for each radiologist. For each radiologist, the imaging examination that resulted in the largest number of wRVUs and reimbursement from 2013 to 2020 was determined. The frequency in which each CPT code produced the most wRVUs or reimbursement for an individual radiologist per year was tallied.

## RESULTS

In 2013, 5992 individual radiologists (20.3% of all radiologists) produced the largest number of imaging exam specific wRVUs interpreting screening mammography (CPT G0202), followed by CT head without contrast (CPT 70450) for 5866 radiologists (19.8%), CT abdomen and pelvis with contrast (CPT 74177) for 4475 radiologists (15.1%), single view chest radiograph (CPT 71010) for 2542 radiologists (8.6%), and CT abdomen and pelvis with and without contrast (CPT 74176) for 1387 radiologists (4.7%). In 2020, 8095 individual radiologists (25.2% of all radiologists) produced the largest number of imaging exam specific wRVUs from CT abdomen and pelvis with contrast (CPT 74177), followed by screening mammography (CPT 77067) for 5932 radiologists (18.5%), CT head without contrast (CPT 70450) for 4691 radiologists (14.6%), single view chest radiograph (CPT 71045) for 2223 radiologists (6.9%), and MRI brain without and with contrast (CPT 70553) for 1318 radiologists (4.1%). For each year evaluated the order of the five CPT codes that most frequently produced the most Medicare reimbursement for individual radiologists was constant. Screening mammography (G0202/77067) was the most frequent highest reimbursed CPT code across diagnostic radiologists, followed by CT abdomen and pelvis with contrast (CPT 74177), CT head without contrast (CPT 70450), single view chest radiograph (CPT 71010), and MRI brain without and with contrast (CPT 70553).

## CONCLUSION

Over time, the same imaging exams have consistently brought in the most reimbursement for the individual radiologist. This study documents the procedures that are likely to be a larger proportion of any radiology practice participating in Medicare.

## CLINICAL RELEVANCE/APPLICATION

This data shows which exams are the most important for a practice to generate revenue to maintain quality services for patients.

Printed on: 04/12/24

### Neuroradiology Wednesday Poster Discussions II

#### Sub-Events

#### **W5B-SPNR- A Preliminary 4D Flow MRI Analysis of Blood Flow Characteristics in Cerebral Veins of Adults** 1

##### Participants

Chihang Dai, MD, Beijing, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate blood flow characteristics in the cerebral veins of adults using 4-dimensional flow magnetic resonance (4D Flow MRI).

##### METHODS AND MATERIALS

A total of 65 volunteers prospectively underwent 4D Flow MRI and 12 volunteers underwent repeated scans during one month in a single center. Velocity, average blood flow rate (Flowavg), and blood flow patterns of cerebral sinuses were evaluated for each volunteer. The mastoid emissary veins, posterior condylar emissary veins, and oblique occipital sinuses were also evaluated.

##### RESULTS

The mean age of volunteers was  $36.31 \pm 11.05$  years old, including 3 (50.8%) females and 32 (49.2%) males. 4D Flow MRI data showed good reproducibility. The velocity and Flowavg of the superior sagittal sinus increased along the direction of flow. Flowavg near torcular herophili were 3.14 times that through the straight sinus. Slight fluctuations were found within a cardiac cycle. A vortex flow pattern was shown in 12.3% of torcular herophili, 7.5% of the transverse-sigmoid junction and 51.3% of jugular bulbs and was associated with increased blood flow velocity/rate in the upstream sinuses. Mastoid emissary veins, posterior condylar emissary veins and oblique occipital sinuses were all drained in the extracranial direction.

##### CONCLUSION

Cerebral veins, including venous sinuses and emissary veins, could be measured visually and quantitatively in vivo by 4D Flow MRI. Cerebral veins' velocity varied with segments and showed slight fluctuations within a cardiac cycle. The analysis of cerebral blood flow in healthy volunteers lays the foundation for the study of cerebral venous system diseases.

##### CLINICAL RELEVANCE/APPLICATION

4D Flow MRI is a reliable method for the evaluation of hemodynamic characteristics of intracranial venous sinuses. Intracranial venous blood flow, including venous sinuses and emissary veins, could be measured visually and quantitatively in vivo. Individual segments of venous sinuses show characteristic changes in velocity and slight fluctuations within a cardiac cycle were observed. The vortex flow pattern is not uncommon in normal individuals and may be related to increased blood flow in upstream sinuses. The mastoid emissary veins, posterior condylar emissary veins, and oblique occipital sinuses were all drained in the extracranial direction. The approaches used during the current study may enable further hemodynamic research into pulsatile tinnitus, idiopathic intracranial hypertension, vascular malformation and sinus thrombosis.

#### **W5B-SPNR- A New Era in Time-of-Flight MR Angiography: Assessing the Impact of High-Resolution Deep Learning Reconstruction on Intracranial MRA Image Quality** 10

##### Participants

Masamichi Hokamura, Kumamoto, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

This study aims to assess the effect of super-resolution deep learning-based reconstruction (SR-DLR), which uses k-space properties, on image quality of intracranial time-of-flight (TOF) magnetic resonance angiography (MRA) at 3T.

##### METHODS AND MATERIALS

This retrospective study involved 35 patients who underwent MRA using a 3T MRI system with SR-DLR based on k-space properties in October and November 2022. We reconstructed MRA with SR-DLR (Matrix =  $1008 \times 1008$ ) and without SR-DLR (Matrix =  $336 \times 336$ ). We measured the SNR, contrast, and CNR in the basilar artery (BA) and the anterior cerebral artery (ACA) and the sharpness of the posterior cerebral artery (PCA) using the slope of the signal intensity profile curve at the half-peak points. Two radiologists evaluated image noise, artifacts, contrast, sharpness, and overall image quality of the two image types using a 4-point scale. We compared quantitative and qualitative scores between images with and without SR-DLR using the Wilcoxon signed-rank test.

##### RESULTS

The SNRs, contrasts, and CNRs were significantly higher in images with SR-DLR than those without SR-DLR ( $p < 0.001$ ). The slope was significantly greater in images with SR-DLR than those without SR-DLR ( $p < 0.001$ ). The qualitative scores in MRAs with SR-DLR were significantly higher than MRAs without SR-DLR ( $p < 0.001$ ).

##### CONCLUSION

s SR-DLR with k-space properties can offer the benefits of increased spatial resolution without the associated drawbacks of longer scan times and reduced SNR and CNR in intracranial MRA.

#### CLINICAL RELEVANCE/APPLICATION

SR-DLR can enhance the image quality of intracranial MRA.

#### W5B-SPNR- 11 **Super-Resolution Deep Learning-Based Reconstruction in Hippocampal MRI: A Volunteer Study Emphasizing Comparison with Actual High-Resolution Images**

Participants

Takeshi Nakaura, MD, (*Presenter*) Nothing to Disclose

#### PURPOSE

The objective of this study is to compare the impact of super-resolution deep learning-based reconstruction (SR-DLR) employing k-space properties and standard-resolution DLR on image quality for thin-slice T2-weighted hippocampal magnetic resonance imaging (MRI).

#### METHODS AND MATERIALS

Thirteen healthy volunteers participated in this study, undergoing standard-resolution (Matrix = 320 x 320) and high-resolution thin-slice T2-weighted hippocampal MRI (Matrix = 960 x 960) on a 3-T MRI system. Standard-resolution MRI was reconstructed with and without DLR (Matrix = 320 x 320) and with SR-DLR (Matrix = 960 x 960), while high-resolution MRI was reconstructed with and without DLR (Matrix = 960 x 960). Signal-to-noise ratio (SNR), and contrast and contrast-to-noise ratio (CNR) between white and grey matter in the hippocampus, as well as the slope of the transparent septum, were measured. Two radiologists were asked to rank the image noise, contrast, artifacts, sharpness, and overall image quality of all five protocols. Results of quantitative and qualitative analyses are presented as the median and interquartile range (IQR), and those between standard-resolution MRI without DLR and other protocols were compared using the Wilcoxon signed-rank test with Holm correction.

#### RESULTS

The SNRs and CNRs were significantly higher in standard-resolution images with SR-DLR (SNR: 21.01 (IQR:18.17, 29.5); CNR: 7.5 (IQR:6.4, 8.37)) than those without SR-DLR (SNR: 17.22 (IQR:14.46, 19.31); CNR: 7.5 (IQR:6.4, 8.37)) ( $p < 0.001$ ). The SNRs and CNRs were significantly lower in real high-resolution MRIs with DLR (SNR: 10.4 (IQR:9.91, 11.06); CNR: 4.84 (IQR:2.99, 5.43)) or without DLR (SNR: 10.4 (IQR:9.91, 11.06); CNR: 2.24 (IQR:1.43, 2.38)) than those in standard-resolution MRIs without DLR ( $p < 0.001$ ). There were no statistically significant differences in contrast in all protocols ( $p > 0.05$ ). The best ranks were assigned for the standard-resolution images with SR-DLR in all qualitative analyses, and these were significantly better than those of the standard-resolution images without DLR in the sharpness and overall image quality ( $p < 0.01$ ).

#### CONCLUSION

s In this volunteer study, the technique of enhancing the resolution of standard-resolution hippocampal MRI using SR-DLR demonstrated the potential to provide higher image quality in a shorter acquisition time compared to real high-resolution hippocampal MRI.

#### CLINICAL RELEVANCE/APPLICATION

SR-DLR in standard-resolution hippocampal MRI improves image quality, including sharpness and overall quality, compared to actual high-resolution images. This technique offers the potential for higher image quality in a shorter acquisition time, enhancing the clinical utility of hippocampal MRI.

#### W5B-SPNR- 12 **AI-based Virtual Synthesis of Methionine PET from Contrast-Enhanced MRI: Development and External Validation Study**

Participants

Hirota Takita, MD, PhD, Osaka, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

To generate synthetic methionine PET images from contrast-enhanced MRI (CE-MRI) through an artificial intelligence (AI)-based image-to-image translation model and to compare its performance for grading and prognosis of gliomas with that of real PET.

#### METHODS AND MATERIALS

An AI-based model to generate synthetic methionine PET images from CE-MRI was developed and validated from patients who underwent both methionine PET and CE-MRI at a university hospital from January 2007 through December 2018 (Institutional set). Pearson correlation coefficients of maximum and mean tumor-to-normal background uptake (T/N<sub>max</sub>, T/N<sub>mean</sub>, respectively) ratios and lesion volume between synthetic and real PET were calculated. Two additional open-source glioma databases of preoperative CE-MRI without methionine PET were the external test set. Using the T/N ratio, the area under the curve of the receiver operating characteristic curve (AUC-ROC) for classifying high- and low-grade gliomas and an overall survival (OS) analysis was evaluated.

#### RESULTS

The institutional set included 362 patients (mean age, 49±19 years; training=294, validation=34, test=34). In the institutional test set, Pearson correlation coefficients were 0.68 (95% CI: 0.47, 0.81), 0.76 (0.59, 0.86), and 0.92 (0.85, 0.95) for T/N<sub>max</sub> ratio, T/N<sub>mean</sub> ratio, and lesion volume, respectively. The external test set included 344 patients with glioma (mean age, 53±15 years; high-grade=269). The AUC-ROC by T/N<sub>max</sub> ratio was 0.81 (95% CI: 0.75, 0.86) and the OS analysis showed a statistically significant difference between high- (two-year survival rate=27%) and low-T/N<sub>max</sub> ratio groups (two-year survival rate=71%;  $P < .001$ ).

#### CONCLUSION

s The AI-based model-generated synthetic methionine PET images strongly correlated with real PET, and showed good performance for glioma grading and prognostication.

## CLINICAL RELEVANCE/APPLICATION

Methionine PET is useful for the management of glioma. But radiation exposure and a lack of molecular imaging facilities limit its use. Since CE-MRIs are generally obtained for patients with suspected brain tumors in routine clinical situations, synthetic methionine PET images can be obtained from CE-MRIs without the aforementioned inconveniences or additional examination.

## W5B-SPNR- Twinkling T2 STAR: Robust Radiomics Features for Reliable Cerebral Microbleeds Classifier 13

Participants

Hiroki Nakajima, RT, Osaka, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Cerebral microbleeds (MBs) have gained attention due to the increased availability of high-field-strength MR systems, as a higher microbleed burden is associated with an increased risk of ischemic stroke and cerebral hemorrhage. We aimed to identify robust Radiomics features between scans in the T2 GRE sequence and evaluate their diagnostic performance using machine learning-based classifiers.

## METHODS AND MATERIALS

We used two cohorts of subjects who underwent T2 GRE imaging in 3T MRI systems. We retrospectively reviewed 20 cases with twice T2 GRE sequences acquired in one examination from 2021 to 2022, and prospectively collected 75 subjects as hold-out test data in 2022. We defined 16x16px regions of interest (ROIs) based on a manual radiologist's annotation of MBs and randomly set up equal numbers of ROIs in other locations. We obtained 91 Radiomics features for these ROIs and measured intra-class coefficients (ICCs) to determine robust features between imaging sessions. Then, we selected seven features with ICCs greater than 0.95 to train and validate a support vector machine (SVM) classifier with the leave-one-out method. Furthermore, a radiologist randomly displayed 16x16px images for the hold-out test group and rated MBs-likeness on a 0-100 continuous variable. We evaluated the diagnostic performance using the area under the ROC curves (AUC) for univariate logistic analysis of each Radiomics feature, SVM classifier, and radiologist.

## RESULTS

For ICC evaluation and modeling, we used 212 MBs (432 total ROIs) and 192 MBs (387 total ROIs) for the test group. Regarding the inter-imaging reproducibility, 9 (10%) features had ICCs less than 0.8, and 26 (29%) had ICCs less than 0.9. Seven of the 32 (35%) features with ICCs greater than 0.95 were used to train SVM. In the test group, SVM's diagnostic performance was 0.96 recall, 0.67 precision, and 0.73 accuracy, with an AUC of 0.88 (0.85-0.92). The AUC for SVM was significantly higher ( $P < .01$ ) than the AUC for each feature alone (0.48-0.85) and not significantly lower than the radiologist's AUC of 0.91 (0.89-0.95) ( $P = .15$ ).

## CONCLUSION

s We identified robust Radiomic features inter-imaging of the T2 GRE sequence and demonstrated that an SVM classifier with these features had a comparable AUC to the radiologist.

## CLINICAL RELEVANCE/APPLICATION

Assessing reproducibility of Radiomics features between two T2 GRE imaging sessions, we identified robust features and developed an SVM classifier to improve cerebral MB detection, potentially reducing stroke and hemorrhage risk.

## W5B-SPNR- Quantitative Multiparametric MRI and Machine Learning based Model to differentiate Progression 14 from Pseudo-progression in Glioblastoma: Towards Precision Neuro-Oncology

Participants

Archith Rajan, Philadelphia, PA (*Presenter*) Nothing to Disclose

## PURPOSE

We hypothesize that radiomic features derived from conventional MRI sequences, diffusion tensor imaging (DTI) and dynamic susceptibility contrast (DSC)-perfusion-weighted imaging (PWI) along with molecular signatures will facilitate accurate distinction of true progression (TP) from pseudoprogression<sup>1,2</sup> (PsP) in glioblastoma (GBM) patients with high accuracy.

## METHODS AND MATERIALS

A cohort of 75 GBM patients exhibiting new/increasing enhancing lesions within 6 months after completion of standard-of-care therapy, were included in this study. These patients were classified as TP (n=55) or PsP (n=20) based on histological features or mRANO criteria<sup>3</sup>. Motion and eddy current corrected DTI derived maps [mean diffusivity (MD), fractional isotropy (FA), coefficient of linear (CL), planar (CP) and spherical anisotropy (CS)] and DSC-PWI derived cerebral blood volume (CBV) map, FLAIR images were co-registered to post-contrast (PC) T1-weighted images. A semiautomatic approach was used to segment contrast-enhancing regions. The median values of DTI metrics and CBV were computed. The CBV values were normalized with contralateral normal brain regions to obtain relative CBV (rCBV). The top 90th percentile rCBV values were also measured (rCBV<sub>90</sub>)<sup>4,5</sup>. O6-methylguanine-DNA-methyltransferase (MGMT) promoter status was noted from all of these patients. To address the issue of imbalanced sample size between TP and PsP, synthetic-minority-oversampling-technique (SMOTE) was applied to augment PsP cases from 20 to 35 resulting in a total sample size of 110. A random forest (RF) algorithm was applied to select the optimized features using a sequential forward feature selection (SFFS) approach. The data were randomly split into training (n=90) and testing (n=20) sets. A 6-fold cross-validation approach was also applied to training dataset. To develop a robust prediction model in distinguishing TP from PsP, several machine learning classifiers were employed. Receiver operating characteristic curve analyses were performed to determine the diagnostic accuracies.

## RESULTS

The best nine diagnostic performances of multiple machine learning algorithms, and feature selection modules are presented in Table 1. RBF support vector machine (SVM) classifier was selected to build the predictive model in distinguishing TP from PsP with a training accuracy of 90.9%, cross-validation accuracy of 85.5% and testing accuracy of 85%.

## CONCLUSION

s Machine learning model using multi-parametric MRI and molecular signatures is a promising approach to differentiate TP from PsP in

GBM patients.

#### **CLINICAL RELEVANCE/APPLICATION**

Multiparametric MRI combined with machine learning could successfully differentiate True Progression from Pseudoprogression in Glioblastomas.

#### **W5B-SPNR- Impact of Radiographic Signs of Advanced and Severe Cerebral Venous Thrombosis on the Efficacy of Endovascular Treatments**

Participants  
Mihir Khunte, Providence, RI (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To study the benefit of endovascular treatment (EVT) with thrombolytics and/or thrombectomy as a treatment option for cerebral venous thrombosis (CVT) in comparison with conservative medical management.

#### **METHODS AND MATERIALS**

The National Inpatient Sample database 2016-2020 was queried to identify adult patients (18 years or older) with CVT. Patient demographics, medical comorbidities, CVT risk factors, and CVT manifestations were identified. The presence of radiographic signs of advanced and severe CVT (venous stroke, cerebral edema, and intracranial hemorrhage) were recorded. Primary and secondary outcomes were good discharge outcomes and in-hospital mortality, respectively.

#### **RESULTS**

17,130 CVT patients were identified; 945 (5.5%) received EVT. EVT patients were more likely to have strokes (35.4% vs. 21.8%,  $p < 0.001$ ), edema (35.4% vs. 20.1%,  $p < 0.001$ ), and hemorrhage (37.6% vs. 19.7%,  $p < 0.001$ ). After multivariable adjustments, EVT for patients without stroke, edema, or hemorrhage was moderately associated with higher odds of good outcomes (OR 1.86 [95%CI 0.98 - 3.53],  $p = 0.059$ ) and resulted in zero deaths. However, with increasing burden of radiographic signs of advanced CVT measured by the cumulative presence of stroke, edema, and hemorrhage, EVT was associated with decreasing odds of good outcomes and increasing odds of in-hospital mortality compared to medical management (interaction  $p = 0.046$  and  $0.029$ , respectively).

#### **CONCLUSION**

s EVT may be beneficial for patients who have not yet developed overt parenchymal manifestations of backpressure changes, and the presence of stroke, edema, and hemorrhage may diminish the comparative effectiveness of EVT over medical management.

#### **CLINICAL RELEVANCE/APPLICATION**

EVT may be beneficial in subset of patients with CVT who lack radiographic signs of advanced and severe CVT such as venous stroke, cerebral edema, and intracranial hemorrhage.

#### **W5B-SPNR- Associations of Quantitative and Qualitative Intracranial Aneurysm Wall Enhancement Indices to Wall Instability and Risk Stratification Scores**

#### **PURPOSE**

The mortality and morbidity among patients with ruptured Intracranial Aneurysms (IAs) remain as high as 50% despite the low incidence of IAs (3-50/100000). The PHASES score was established to quantify IA rupture risk, whereas the ELAPSS score was established to quantify risk of growth in IA size. MR-Vessel Wall Imaging (VWI) has gained popularity in assessing a number neurovascular diseases including IAs. Aneurysm wall enhancement (AWE) is utilized as a marker of wall instability. We evaluate two distinct quantified measures of post-contrast T1-SPACE AWE in conjunction with the PHASES and ELAPSS scores as a sign of wall instability.

#### **METHODS AND MATERIALS**

We conducted an IRB approved study of patients with unruptured IAs scanned using VWI protocol between January 2018 to December 2022. AWE was evaluated qualitatively and quantitatively on T1-SPACE sequences. IA Wall Morphology (IAWM) was evaluated on catheter angiography. Quantified AWE values were obtained using 3-point ROIs on the IA wall and normalized with white matter signal intensity obtained using 10 mm circular ROIs. Percentage change in normalized AWE from pre to post contrast imaging was calculated. Furthermore, a ratio of post-contrast quantified AWE to post-contrast pituitary infundibulum (PI) signal intensity (AWPI ratio) was also calculated. Pearson correlation test, and unpaired t-tests were used to assess statistical correlations in SPSS v28. P-value was set at 0.05.

#### **RESULTS**

We evaluated 271 IAs in 219 patients (Age: 63.31 +/- 13.17, 24-89, 165 female). The mean size of IAs was 5.12mm +/- 3.91 mm, 2-30 and the mean PHASES score was 4.31 +/- 2.73, 0-16. Qualitatively, AWE was seen in 141 (52%) IAs and irregular IAWM in 132 (48.7%). PHASES score showed a moderately strong correlation to AWPI ratio,  $r = 0.439$ , and to percentage increase in AWE,  $r = 0.334$ . ELAPSS score also showed a moderately strong correlation to AWPI ratio,  $r = 0.487$  and percentage increase in AWE,  $r = 0.367$ . AWPI ratio showed as stronger correlation than percentage increase to both PHASES and ELAPSS scores. The mean PHASES and ELAPSS scores for IAs with AWE were 5.36 and 18.48 whereas in IAs without AWE, these scores calculated to be 3.31 and 10.93, respectively, ( $p < 0.001$ )

#### **CONCLUSION**

s Our findings demonstrates a correlation between increased AWPI, Percentage Increase and higher PHASES score, ELAPSS score .

#### **CLINICAL RELEVANCE/APPLICATION**

The results of this finding suggests a possible use of both qualitative and quantitative evaluation of AWE, particularly an increased AWPI ratio as a marker of wall instability. This could be utilized to evaluate the progression of wall instability and to guide therapeutic intervention.

#### Participants 4 **Impact of White Matter Hyperintensities on Structural Connectivity and Cognition in Cognitively Intact Older Adults**

Mohammad Taghvaei, MD, MPH, Philadelphia, PA (*Presenter*) Nothing to Disclose

##### **PURPOSE**

White matter hyperintensities (WMH) on T2-weighted fluid-attenuated inversion recovery (FLAIR) magnetic resonance imaging (MRI) are nearly ubiquitous in aging. Prior studies suggest that both the volume and the spatial distribution of WMH lesions are predictive of cognitive performance decrements. WMH lesion burden has also been associated with both the severity and progression rate of Alzheimer's pathology. We used indirect brain mapping with virtual lesion tractography in older control subjects from the Alzheimer's Disease Neuroimaging Initiative (ADNI) study to test the hypothesis that the extent of specific white matter (WM) tract disconnection due to WMH is associated with corresponding cognitive performance decrements.

##### **METHODS AND MATERIALS**

Demographic information, structural MRI data, PET imaging, neuropsychological test scores, and CSF analysis from 481 cognitively intact ADNI subjects were obtained. WMH lesions mask were extracted from the FLAIR MRI of these subjects and applied as a region of avoidance for fiber tracking in 50 Human Connectome Project (HCP) subjects' diffusion MRI data to estimate tract disconnection caused by each WMH lesion mask for 8 WM pathways. The direct relationship of global WMH lesions burden or tract disconnections with performance in specific cognitive domains, as well as the mediation effect of specific tract disconnection on WMH lesion related cognitive performance decrement in the corresponding domain were assessed.

##### **RESULTS**

Global WMH lesion burden was significantly associated with global cognitive measures ( $p=0.011$ ), episodic memory ( $p=0.015$ ), executive function, and processing speed ( $p=0.018$ ). Further, estimated tract disconnection in the right inferior fronto-occipital fasciculus, right frontal aslant tract, right inferior longitudinal fasciculus, and right superior longitudinal fasciculus disconnection mediated the effect of WMH lesion volume on executive function, the left uncinate fasciculus disconnection mediated the effect of WMH lesion volume on memory, and the right frontal aslant tract disconnection mediated the effect of WMH lesion volume on language.

##### **CONCLUSION**

s Tract-specific disconnections caused by WMH lesions mediate cognitive domain-specific decrements in cognitive performance in cognitively intact older adults.

##### **CLINICAL RELEVANCE/APPLICATION**

The spatial distribution of WMH lesions and the extent of particular WM tracts involvement by them could predict decrement in corresponding cognitive domains.

#### W5B-SPNR- **Transformer-based Unified Tissue and White Matter Hyperintensity Segmentation of UK Biobank Brain Imaging** 5

Participants

James Ruffle, MSc, London, United Kingdom (*Presenter*) Nothing to Disclose

##### **PURPOSE**

The causes and consequences of white matter hyperintensities (WMH), amongst the commonest findings in neuroradiology, remain a subject of intense study. UK Biobank provides the largest research cohort of MRI studies with accompanying WMH labels, with great potential to cast light on this important condition. Unfortunately, many of the lesion labels are spurious, misidentifying healthy choroid plexus, normal ependymal lining, or imaging artefact, leading to reduced accuracy and potential confounding of downstream analytic tasks. Here we derive a substantially improved set of WMH labels through the combination of classical and vision-transformer based segmentation methods.

##### **METHODS AND MATERIALS**

In a cohort of 33241 UK Biobank participants, we develop a pipeline employing classical multi-channel volumetric (T1 and FLAIR) tissue segmentation, brain extraction, and WMH segmentation based on a vision transformer model with a custom tissue-leveraging loss. We quantify segmentation fidelity out-of-sample with conventional metrics, intra-subject stability over time, and a downstream predictive task.

##### **RESULTS**

We obtained out-of-sample Dice scores for brain extraction ( $>0.999$ ), gray matter (0.98), white matter (0.99), cerebrospinal fluid (0.96), and WMH (0.87). At 8 seconds per participant, processing time was significantly faster than conventional tissue segmentation with SPM (218 seconds,  $p<0.0001$ ). No differences in model performance were observed between young or old, and male or female ( $p>0.05$ ), indicating good demographic calibration. WMH segmentation showed significantly greater temporal stability compared with current UK Biobank WMH labels ( $p<0.0001$ ) for a subset of the cohort imaged twice. Age regression based on WMH count was superior compared with the original labels ( $R^2=0.18$  vs 0.14).

##### **CONCLUSION**

s We provide a tissue and WMH segmentation model optimized for UK Biobank data with evidence of fidelity superior to existing labels.

##### **CLINICAL RELEVANCE/APPLICATION**

We make our model and segmentations available through UK Biobank to assist in the study of this important disorder.

#### W5B-SPNR- **Hyperintensities in the Anterior Portion of the Callosal Splenium on FLAIR: A Large Cohort Study** 6

Participants

Sera Kasai, Hirosaki-Shi, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Although hyperintensity in the anterior portion of the callosal splenium on FLAIR (aCS-hyperintensity) is a common finding in elderly adults (Figure), no previous studies with large sample sizes have examined the clinical significance of the aCS-hyperintensity. In this large elderly population study, we aimed to investigate the associations of aCS-hyperintensity with cerebro- and cardiovascular risk factors and cognitive decline. In addition, to illustrate the probable mechanism thereof, we compared the clinical significances of the aCS-hyperintensity with those of the other MRI measurements.

## METHODS AND MATERIALS

This cross-sectional study included 2,110 participants (median age, 69 years; 61.1% females) who underwent 3T MRI. The participants were grouped as 215 with mild cognitive impairment (MCI) and 1,895 cognitively normal older adults (NOAs). Two neuroradiologists evaluated aCS-hyperintensity by using a four-point scale (none, mild, moderate, and severe) (Figure). Periventricular hyperintensities (PVHs) were also rated on a four-point scale according to the Fazekas scale. The total intracranial volume (ICV), total brain volume, choroid plexus volume (CPV), and lateral ventricle volume (LVV) were calculated.

## RESULTS

For the cerebro- and cardiovascular risk factors, the logistic regression analysis showed that diabetes was the main predictor of aCS-hyperintensity after adjusting for potential confounders (age, sex, hypertension, hyperlipidemia, BMI, smoking status, alcohol frequency, and medical history) ( $p < 0.01$ ). On the other hand, PVH was associated with a presence of hypertension ( $p < 0.01$ ). The aCS-hyperintensity rated as "severe" was associated with a presence of MCI. The logistic regression analysis for the imaging factors showed that PVH was significant independent predictor of aCS-hyperintensity ( $p < 0.01$ ). The LVV was also an independent predictor of aCS-hyperintensity when brain volume and PVH grade was added to the analyses ( $p < 0.01$ ).

## CONCLUSION

Cerebral small vessel disease due to diabetes is a major contributor to the development of aCS-hyperintensity. Cerebrospinal fluid clearance failure may also relate to aCS-hyperintensity, which may offer new insights into the pathologic processes underlying MCI.

## CLINICAL RELEVANCE/APPLICATION

Although aCS-hyperintensity is a common finding in elderly adults, its severity may associate with cerebral small vessel disease due to diabetes and MCI presence.

## W5B-SPNR- Radiological and Clinical Characteristics of N2O Related Myeloneuropathy: A Multicenter Study

7

Participants

Paula Heredia Cacha, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

## PURPOSE

The aim of this work is to report the clinical and imaging features of nitrous oxide (N2O) recreational abuse related myeloneuropathy.

## METHODS AND MATERIALS

We conducted a retrospective multicenter study. The inclusion criteria were: (i) neurological symptoms, (ii) history of recreational N2O abuse, (iii) myeloneuropathy on MRI. The exclusion criteria were: (i) other causes of myelopathy (ii) absence of strong temporal association with N2O consumption. Demographic, clinical and laboratory data were collected. Imaging patterns, treatments and patients' outcomes were analyzed.

## RESULTS

We included 40 patients (age:  $24 \pm 4$  years; 18 ?) from 8 tertiary care centers. The study period was from December 2020 to April 2023. A chronic consumption (at least weekly for = 3 months) of N2O was present in 77% of the patients (26/34). All patients (40/40) presented with paresthesia, 36/36 with distal onset. Other main complaints were unsteady gait (38/40; 95%) and limb weakness (23/40; 58%). When measured, homocysteine level was elevated (32/33; 97%), while vitamin B12 level was mostly normal (20/34; 58%). Nerve conduction studies were often altered (23/32; 72%). Typical MRI features of subacute combined degeneration (SCD) of the spinal cord in cervical and upper thoracic cord were often seen (35/40; 86%, fig. 1A). Contrast enhancement of SCD was present in 5/35 of the patients (14%, fig. 1B). In 3 patients, a brain MRI was performed in first place for ataxia and 3D-FLAIR sequence suggested upper cervical abnormalities in its lowest slices (Fig. 1C). Atypical MRI findings (5/40) consisted of (i) cone involvement associated with exclusively lateral columns involvement (1/5, fig. 1D) and (ii) abnormally extensive lesion to lower thoracic cord (4/5; fig. 1F). 20% (7/35) of patients showed cauda equina roots enhancement (Fig. 1E). Patients were treated mainly with vitamin B12 supplementation (36/38; 95%). When follow-up information was present (12/40), recovery was slowly progressive, with persistent paresthesia (10/12; 80%).

## CONCLUSION

N2O-induced myeloneuropathy, mostly due to functional vitamin B12 deficiency, typically appears on MRI as SCD involving the cervical and upper thoracic cord. However, atypical radiological findings exist, and cauda equina roots enhancement is possible, even though not described yet in literature. In addition, cerebral MRI can pinpoint the correct diagnosis when not suspected.

## CLINICAL RELEVANCE/APPLICATION

N2O is a popular recreational drug among young adults. Social awareness on N2O side effects is poor and clinicians lack on information on vitamin B12 deficiency-related myeloneuropathy, a common N2O toxic effect.

## W5B-SPNR- 3D SPACE MRI of the Transverse Ligament in Whiplash Associated Disorder

8

## PURPOSE

To describe the 3D SPACE MRI findings of transverse ligament (TL) in whiplash associated disorder (WAD), and to compare them with nontraumatic group.

## METHODS AND MATERIALS

Cervical spine MRIs were retrospectively analyzed including 46 patients with WAD and 62 patients in the nontraumatic group. Axial

Cervical spine films were retrospectively analyzed including 40 patients with WAD and 62 patients in the nontraumatic group. Axial 2D T2-SPACE images were used for image analysis. The symmetry of lateral atlantodental interval (LADI) and the morphology grade of TL was evaluated by two radiologists, using a four-point scale (0 = homogeneous low SI with normal thickness, 1 = high SI with normal thickness, 2 = reduced thickness, 3 = full-thickness rupture or indistinguishable from surrounding structures). The presence of atlantoaxial instability and the number of cervical levels with degeneration was evaluated.

## RESULTS

Among the WAD patients, 17% showed asymmetric LADI and 39% showed high-grade TL morphology grade (grade 2 or 3). The high-grade TL change group had a significantly higher mean age than the low-grade group. There was no significant difference in WAD stage or grade between the high-grade and low-grade TL change groups. High-grade TL changes were significantly more frequent in the WAD group compared to the nontraumatic group, and the number of degenerative levels was lesser in the WAD group. Logistic regression analysis revealed that a lesser number of degenerative levels and high-grade TL changes were independent predictors for WAD.

## CONCLUSION

s High-grade TL changes were significantly more frequent in the WAD group compared to the nontraumatic group.

## CLINICAL RELEVANCE/APPLICATION

The evaluation of TL using 3D SPACE MRI sequence can be useful in the evaluation and management of the WAD patients.

## W5B-SPNR- Predicting Outcome of the Epidural Blood Patch in Spontaneous Intracranial Hypotension by using an Artificial Intelligent Aided Quantitative MRI Approach

Participants

Jyhwen Chai, MD, PhD, Taichung, Taiwan (*Presenter*) Nothing to Disclose

## PURPOSE

Spontaneous intracranial hypotension (SIH) is a disorder of spinal CSF leakage with uncertain pathogenesis that presents challenges in reliable diagnosis and treatment. Though epidural blood patching (EBP) is commonly used, response rates are variable and predictors are lacking. In this study, we aimed to predict the outcome of EBP treatment in SIH patients using a quantitative MRI approach aided by artificial intelligence (AI).

## METHODS AND MATERIALS

We recruited 30 SIH patients with typical orthostatic headache and characteristic MRI findings of spinal CSF leakages, and 26 healthy volunteers. In addition to brain MRI, we used retrospective ECG-gated cine phase-contrast (PC) sequences to measure fluctuating CSF flow, and a heavy 3D-T2WI of the whole spine to identify CSF leakage and quantify spinal CSF volume. We used YOLO algorithms of AI models for object detection and semantic segmentation of CSF space on spine images, and a pulsatility-based segmentation (PUBS) method combined to measure CSF flow dynamics in the cine PC-MRI.

## RESULTS

Our results showed that SIH patients had significantly lower mean and peak CSF flux at the level of the 2nd cervical spine and a smaller volume of whole spinal CSF compared to healthy volunteers. The optimal cut-off values to distinguish the two groups were 1.00 ml/s and 3.53 ml/s for mean and peak flux, respectively, with the best AUC of 0.821 and 0.833 ( $p < 0.001$ ). The cut-off value of whole spinal CSF volume was 64.9 ml/s with the AUC of 0.694 ( $p < 0.05$ ). Using these two cut-off values of CSF flux, we divided 25 of 30 SIH patients accepting EBP into two groups based on high and low CSF flow dynamics one week after treatment. 25 of 30 SIH patients who underwent EBP were divided into high and low CSF flow dynamics groups. Of the 13 patients with high CSF flow dynamics and much improvement in orthostatic headache, 10 received one EBP and 3 received two. Nine of the 12 patients with low flow dynamics and persistent symptoms required more than two EBPs.

## CONCLUSION

s Our study suggests that CSF flow parameters in the upper cervical spine are more sensitive than spinal CSF volume measurement in detecting early pathophysiological alterations in SIH patients after EBP treatment. AI-aided quantitative MRI has the potential to effectively predict the treatment response of EBP in SIH patients.

## CLINICAL RELEVANCE/APPLICATION

AI-aided quantitative MRI could be an effective tool for predicting the treatment response of epidural blood patching in patients with spontaneous intracranial hypotension (SIH).

Printed on: 04/12/24

W5B-SPOB

### OB/Gynecology and Pediatric Imaging Wednesday Poster Discussions II

#### Sub-Events

#### **W5B-SPOB- The Application of Radiomics in Predicting Intraoperative Massive Bleeding in Cesarean Scar Pregnancy Patients** 1

#### Participants

Feng Gao, Shanghai, China (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop a comprehensive model based on MRI radiomics signatures and independent risk factors for predicting the risk of intraoperative massive bleeding in cesarean scar pregnancy (CSP) patients.

#### METHODS AND MATERIALS

In total, 119 patients with CSP who underwent surgery were retrospectively reviewed. According to surgical records, intraoperative bleeding greater than 100ml was defined as intraoperative massive bleeding. All subjects were randomly separated into the training and testing sets at a ratio of 7:3. The radiomics signatures from the gestational sac (GS) and decidua (DEC) regions were respectively extracted in T2WI. Variance analysis, univariate correlation analysis (cutoff = 0.7), general univariate analysis and Gradient Boosting Decision Tree (GBDT) selection were performed orderly to select features. Seven image geometric features and eight clinical features were recorded and analyzed. Information with statistically significant differences was utilized in conjunction with the selected radiomics features to construct predictive models via the logistic regression model. Models were evaluated through ROC and AUC analysis. Decision curve analysis (DCA) evaluated the clinical usefulness of the constructed models, while Delong's test compared performance differences.

#### RESULTS

Thirty-seven patients suffered intraoperative massive bleeding and 82 patients did not. Five, eight, and nine radiomics features were selected from DEC, GS, and DEC+GS cohort, respectively. Seven features were statistically differently between GS and DEC (all  $p < 0.05$ ), and were included into the model as predictive features. AUCs of test datasets were 0.856, 0.843, and 0.846 for DEC, GS, and DEC+GS, respectively. Calibration curves with H-L test  $p$  values  $> 0.05$  showed good fitness for all three models. Delong's tests revealed no statistical differences among AUCs, indicating similar predictive abilities of the models. DCA showed that blood loss prediction models are beneficial when threshold probability ranges from 0.02 to 0.78.

#### CONCLUSION

A prediction model composed of T2WI-based radiomics features, image geometric features and clinical parameters could be applied to guide the gynecologists assess the risk of intraoperative bleeding in CSP patients before surgery.

#### CLINICAL RELEVANCE/APPLICATION

CSP refers to an ectopic pregnancy in which the GS is implanted into the scar of a previous cesarean section uterine incision. It may cause uncontrollable bleeding, uterine rupture, and even require hysterectomy during surgery. Our combined prediction model can preoperatively, accurately, and noninvasively identify high-risk individuals. For these high-risk individuals, preoperative intervention can be taken to avoid the massive bleeding.

#### **W5B-SPOB- Accelerated Three-dimensional Susceptibility Weighted Imaging of the Whole Spine of Fetus at 3T** 2

#### PURPOSE

The aims of this study were to evaluate the image quality, vertebral visibility and diagnostic performance in suspected fetal vertebral pathologies of three-dimensional (3D) susceptibility weighted imaging (SWI) of the whole spine column at 3T magnetic resonance imaging (MRI) and compared these with those of conventional protocol and ultrasonography (US).

#### METHODS AND MATERIALS

A total of 37 pregnant women (gestation age 22 to 39 weeks, average  $29 \pm 3$  weeks) with suspected fetal vertebral anomalies by ultrasound (US) screening underwent 3.0T MR imaging with 3D SWI, conventional two-dimensional (2D) half-fourier acquisition single-shot turbo spin-echo (HASTE) and 3D true fast imaging with steady-state precession (True FISP). The acquisition time of each protocol was recorded. Signal-to-noise ratios (SNRs) and contrast-to-noise ratios (CNRs) were determined in representative interest regions of fetal thoracic vertebrae and compared among three pulse sequences. Two radiologists rated image quality independently in random order on a 5-point scale. Kappa coefficients were computed to assess inter-observer reliability. Receiver operating characteristic curves were generated, and the area under the curve (AUC) was used to compare the diagnostic performance of each protocol in vertebral deformities.

#### RESULTS

The acquisition time was 15 s for 3D-SWI and 17 s for 3D True FISP, significantly shorter than conventional HASTE (37 s; both  $P < 0.01$ ). Of the three protocols, The SNR was highest on 3D True FISP, while the CNR was highest on 3D SWI. Visualization of all

segments of the whole spine by 3D SWI was comparable with 3D True FISP. In contrast, 3D SWI and 3D True FISP depicted cervical and sacrococcygeal vertebrae better than HASTE. The weighted kappa statistic was 0.70-0.89 to evaluate the image quality of all segments of the whole spine, indicating good to excellent interobserver agreement. 3D SWI had the highest diagnostic performance for detecting fetal vertebral anomalies (AUC = 0.92).

## CONCLUSION

s 3D-SWI is feasible for improved visualization of the whole fetal vertebral column and their congenital malformations with adequate image quality, thereby providing a supplementary method to conventional MR imaging.

## CLINICAL RELEVANCE/APPLICATION

Our preliminary results suggest that 3D-SWI enables superior 3D visualization of 3D sequences take an advantage in display of the overall structure of the spine compared with conventional 2D sequences. A potential use of the 3D sequence is to define the degree of scoliosis or precise localization of deformed vertebrae. 3D sequences could be a useful addition to the routine examination of the fetal vertebrae, facilitating the incorporation of this technique into routine patient studies.

## W5B-SPOB- Doppler Ultrasound Gated Fetal Cardiac MRI in an Unselected Population: A Clinical Feasibility Study 3

### PURPOSE

Doppler ultrasound-based gating of fetal cardiac MRI has shown promising results in late pregnancy but has not been tested in younger fetuses <26 weeks of gestation in a clinical setting yet. The aim was to investigate the feasibility of ultrasound-gated fetal cardiac imaging in clinical routine during whole-body-MRI and the association of image quality with gestational age.

### METHODS AND MATERIALS

We included 23 singleton pregnancies with clinical indication for fetal whole-body-MRI with and without suspected cardiac anomalies. Standard protocols for body and CNS MRI were performed, followed by gated cine-balanced steady state free precession sequences of the fetal heart in three planes (four-chamber-view (4C), short (2S) and long (2L) axis two-chamber-views). Image quality was rated "good" if there was depiction of both atria and ventricles in the four-chamber-view, and of the left atrium and ventricle in the long and short axis two-chamber view without artifacts. In case of displaced planes or artifacts but possible identification of cardiac anatomic structures, image quality was rated as "moderate". If no recognizability was given, images were rated "non diagnostic". Image quality was correlated with gestational week (GW) groups (GW <26, GW 26-31, GW >31).

### RESULTS

We evaluated a total of 69 cardiac MRI sequences in 23 fetuses (70% with and 30% without suspected cardiac anomalies; GW <26: 30.4%, GW 26-31: 30.4%, GW >31: 39.1%; mean: 28+6 GW +/-30.4 days). Overall, image quality was "good" in 31 (45%) of the cardiac sequences and "moderate" in 21 (30%). Seventeen (25%) were "non diagnostic". Differences in image quality were significant between the cardiac planes ( $p=0.013$ ) with best quality of the 2S and poorest quality of the 2L. Highest image quality was found in the youngest fetuses <26 GW ("good" in 57%, "moderate" in 19%, "non diagnostic" in 24%); followed by fetuses >31 GW ("good" in 48%, "moderate" in 41%, "non diagnostic" in 11%) and fetuses between 26 and 31 GW ("good" in 29%, "moderate" in 29%, "non diagnostic" in 43%). There was no significant difference between age groups ( $p=0.158$  for 4C,  $p=0.595$  for 2S,  $p=0.178$  for 2L).

## CONCLUSION

s Doppler ultrasound gated fetal cardiac MRI with diagnostic quality in 75% of cardiac planes is feasible during clinical routine whole-body-MRI already in the second trimester of pregnancy. Image quality is not associated with gestational age.

## CLINICAL RELEVANCE/APPLICATION

Fetal cardiac MRI in the second and third trimester of pregnancy could be included in a whole-body MRI protocol as a complementary imaging method to echocardiography in congenital heart disease when ultrasound conditions are limited.

## W5B-SPOB- Automatic Quantification of Fetal Brain Gyrfication Based on MRI in Control and in Fetuses with Polymicrogyria and Lissencephaly 4

### PURPOSE

Current imaging assessment of fetal brain gyrfication is performed qualitatively and subjectively using both ultrasound and MRI. A few previous studies suggested methods for quantification of fetal gyrfication based on 3D reconstruction of MRI, which requires unique data and is time-consuming. In this study, we aimed to develop an automatic pipeline for gyrfication assessment based on routinely acquired fetal MRI 2D data, quantify normal changes with gestation, and measure differences in fetuses with lissencephaly and polymicrogyria compared with controls (fetuses with normal gyrfication).

### METHODS AND MATERIALS

Coronal T2 weighted MRI data of 162 fetuses retrospectively collected from two clinical sites were included: 134 control fetuses, 12 with lissencephaly, 13 with polymicrogyria, and three suspected with lissencephaly based on ultrasound, yet with normal MRI diagnosis. The developed automatic pipeline included brain detection, brain component segmentation and identification of the right and left hemisphere, and calculating five gyrfication parameters separately for each hemisphere based on the area and ratio between the contours of the cerebrum and its convex hull.

### RESULTS

In control fetuses, all parameters were changed significantly along gestational age ( $p<0.05$ ), providing developmental curves on a wide range of gestation (27-37 weeks). Compared with controls, fetuses with lissencephaly showed significant reductions in all gyrfication parameters ( $p=0.02$ ). Similarly, but less pronounced, significant reductions were detected for fetuses with polymicrogyria in several parameters ( $p=0.001$ ). The three suspected fetuses showed normal gyrfication, supporting MRI diagnosis.

## CONCLUSION

s This study presents a pipeline for automatically quantifying fetal brain gyrfication and provides normal developmental curves from a large cohort. These curves differentiated fetuses with lissencephaly and polymicrogyria significantly, demonstrating lower values. The method may aid radiological assessment and improve the early identification of fetuses with cortical malformation.

**CLINICAL RELEVANCE/APPLICATION**

The method suggested in this study provides a quantitative assessment of fetal brain gyrification, and can aid radiological diagnosis and improve early identification of fetuses with cortical malformation.

### Pediatric Imaging Wednesday Poster Discussions II

#### Sub-Events

#### **W5B-SPPD- Deep-learning Reconstruction for Reducing Slice Thickness and Radiation Dose in Pediatric CT: Matched Pair Comparisons with Standard Dose Thick Slice Iterative Reconstruction**

#### Participants

Ryota Harai, Kumamoto, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

Low-dose and thin-slice image acquisition is desirable for pediatric CT, but increased image noise can compromise image quality and diagnostic confidence. Deep learning reconstruction (DLR) may be a promising technique to simultaneously reduce radiation dose and slice thickness due to its excellent noise reduction performance. This study aimed to compare the image quality between standard-dose, thick-slice (3 mm) hybrid iterative reconstruction (HIR) and low-dose, thin-slice (0.5 mm) deep-learning reconstruction DLR in pediatric CT.

#### METHODS AND MATERIALS

This retrospective study included 76 children (=6 years) who underwent 80-kVp contrast-enhanced CT using standard dose (n=38) and low dose (n=38) protocols on a 320-row scanner. Patient age and body weight were matched between the standard and low dose groups. The standard dose images were reconstructed at a 3 mm slice thickness using the HIR algorithm; the lower dose images were reconstructed at a 0.5 mm slice thickness using the HIR and DLR algorithms. The size-specific dose estimate (SSDE) was compared between groups. For quantitative image analysis, image noise and contrast-to-noise ratio (CNR) at the hepatic parenchyma, abdominal aorta, and portal vein were quantified. For qualitative assessment, noise magnitude, noise texture, edge sharpness, partial volume effect, artifacts, and diagnostic confidence were subjectively rated on a four-point scale.

#### RESULTS

There were no significant differences in age ( $24.1 \pm 23.0$  vs.  $24.2 \pm 23.0$  months,  $p=0.98$ ) and body weight ( $9.9 \pm 4.6$  vs.  $10.2 \pm 5.8$  kg,  $p=0.80$ ) between the standard and low dose groups. The SSDE of the low dose group was 60% lower than that of the standard dose group ( $3.3 \pm 0.9$  vs.  $8.3 \pm 1.6$  mGy,  $p<0.01$ ). DLR considerably reduced the quantitative image noise and improved CNR and subjective image quality of the low dose 0.5 mm images compared to HIR (all,  $p<0.001$ ). Compared to the standard dose 3 mm HIR images, the low dose 0.5 mm DLR images showed significantly lower quantitative image noise ( $p=0.02$ ) and equivalent CNR in all structures analyzed (all,  $p>0.11$ ). The low dose 0.5 mm DLR images achieved superior subjective scores for diagnostic confidence compared to standard-dose 3 mm HIR images ( $p<0.01$ ).

#### CONCLUSION

In pediatric CT, the application of DLR to low-dose thin-slice (0.5 mm) images can yield equivalent or even better subjective and objective quality compared to standard-dose thick-slice (3 mm) HIR images.

#### CLINICAL RELEVANCE/APPLICATION

DLR allows reduction of both radiation dose and slice thickness in pediatric CT without increasing image noise and degrading the subjective image quality compared to the HIR algorithm.

#### **W5B-SPPH- Extending Coronary Calcium Scoring to New Protocols using a Specificity Criterion** 1

Participants

Scott Hsieh, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Coronary calcium is scored today using the Agatston algorithm, which was devised for 3-mm thick slices at 120 kVp. Scanners today offer protocols with thinner slices, better in-plane resolution, lower kVp, different mAs, advanced reconstruction, or new technologies such as multi-energy or photon counting detector CT. A framework is desired to adapt the Agatston algorithm threshold to these variations while maintaining an acceptable false positive rate. We propose to do this directly by imposing a specificity criterion. Because our interest is in detecting smaller calcifications, we do not impose a minimum size criterion.

#### **METHODS AND MATERIALS**

For each scan, we select a series of control regions (2 ml each, matching the volume of the coronary arteries) in a nearby, uniform anatomic area or in an anthropomorphic phantom of matched patient size and protocol. The 95th percentile of the maxima of these control regions is selected as the scoring threshold to ensure a Type I error rate of 5%. An adjustment is made for the mean difference in CT number between the control regions and coronary arteries, if any. We tested this framework on numerical simulations and an anthropomorphic phantom with 10 small calcifications (from 0.4 to 0.8 mm in size) that was scanned with different energy integrating detector CT (EID-CT) or photon counting detector CT (PCD-CT) protocols, all at matched dose.

#### **RESULTS**

In numerical simulations, our framework selected CT thresholds between 74 to 212 HU depending on the dose level and reconstruction kernel used. Higher doses improved sensitivity, but all scans had equivalent specificity. The sharper kernel increased sensitivity for small, bright calcifications but decreased sensitivity for large, less bright calcifications because the threshold increased with sharpness. In the anthropomorphic phantom, with a medium-sharp Qr54 EID-CT with 0.6 mm thick slices, a threshold of 410 HU was selected, and sensitivity was 40%. With a sharper Qr66 kernel, the threshold increased to 1015 HU and the sensitivity fell to 30%. With PCD-CT and a Qr68 kernel, the threshold decreased to 357 HU threshold because of the higher resolution capability of PCD-CT and sensitivity increased to 90%. No false positives were seen in these cases.

#### **CONCLUSION**

A specificity criterion provides a disciplined approach for selecting an Agatston scoring threshold. This allows objective detection of coronary calcium in new protocols and was demonstrated on high resolution protocols from PCD-CT.

#### **CLINICAL RELEVANCE/APPLICATION**

Coronary calcium scoring algorithms must be modified to take advantage of new scanner capabilities. We provide a general framework for making modifications that is especially useful for new, higher resolution CT protocols.

#### **W5B-SPPH- Impact of Deep Learning Reconstruction on Radiation Dose Reduction and Cancer Risk in CT** 10 **Examinations: A Real-World Clinical Analysis**

Participants

Naoki Kobayashi, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The purpose of this study is to estimate the degree to which the introduction of Deep Learning Reconstruction (DLR) into clinical settings may reduce the radiation dose and the risk of radiation-induced cancer from CT examinations, utilizing real-world clinical data.

#### **METHODS AND MATERIALS**

In our institution, we retrospectively collected scanning information for two distinct periods based on the date of DLR implementation: the 12 months immediately prior to the introduction of DLR, when iterative reconstruction (IR) was used for routine CT, and the 12 months following the implementation of DLR, when the routine CT reconstruction was switched to DLR. Inclusion criteria consisted of adult patients (aged 20 to 100 years) who underwent body CT during this period on specific CT units where DLR was introduced. The dose management system, Radimetrics™ (Bayer), was used to collect dose data and to estimate the equivalent dose for each organ and the effective dose for the whole body. From the dose data, we calculated the reduction rate of the average dose upon the implementation of the DLR. Utilizing the R package, "LARisk 1.0.0", we also estimated the lifetime attributable risk (LAR) for each CT examination based on exposure dosage estimates. We summarized the LARs by age, gender, and organ, and evaluated the degree to which the LAR was altered before and after the implementation of DLR. The number of radiation-induced cancers before and after the introduction of DLR was also estimated.

## RESULTS

A total of 6,172 cases prior to and 6,423 cases following the implementation of DLR were incorporated into the analysis. The total effective dose in body CT was significantly lower post-DLR introduction ( $15.8 \pm 10.6$  mSv) compared to pre-DLR introduction ( $27.9 \pm 14.1$  mSv) ( $p < 0.001$ ), amounting to a 43% dose reduction. The decrease in radiation dose resulted in a substantial reduction in the risk of radiation-induced cancer, with particularly notable benefits in a group of relatively young women. The estimated annual incidence of radiation-induced cancers was 0.261% (16.1 out of 6,172) prior to the introduction of DLR and 0.139% (8.9 out of 6,423) following its implementation.

## CONCLUSION

Our single-center study suggests that the implementation of DLR has the possibility to reduce radiation dose and radiation-induced cancers by nearly half in the clinical routine CT compared with the iterative reconstruction.

## CLINICAL RELEVANCE/APPLICATION

This study shows the degree to which the introduction of DLR contributes to a reduction in radiation dose and thus in the incidence of radiation-induced cancer.

## W5B-SPPH- A Fundamental Investigation into the Behavior of Active Collimators in Multi-detector CT Systems 11 under Varying Imaging Conditions

Participants

Ryo Moriwake, BS, Kurashiki, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

This study aims to investigate that the effects with and without active collimator usage on dose profiles in the body axis direction and over-range length when scan conditions are altered.

## METHODS AND MATERIALS

We used a 80-detector row CT scanner. A polymethyl methacrylate (PMMA) phantom with a diameter of 16 cm was placed at the center of the gantry rotation. The high-accuracy Thimble ionization chambers (10X6-0.6CT, Radcal) was inserted in the center of the phantom with a scan length of 10 cm to include scattered radiation. The scan parameters were set as follows: tube voltage of 120 kV, tube current and rotation speed set to 50 mAs, and various combinations of detector rows of  $0.5 \times 80$  mm,  $0.5 \times 64$  mm, and  $1.0 \times 40$  mm were used at three pitch factor levels: High Definition, Standard, and High Speed. Each measurement was performed three times, and the axial dose profiles and over-range lengths were determined for each scan condition.

## RESULTS

The dose profiles in the Z axial direction with and without AC were wider in each scan condition with AC than without AC. The dose profiles in the body axial direction during the change of imaging conditions tended to differ depending on the rotation speed and the number of detector rows. The widest dose profile was observed at high speeds. The over-range length was approximately 18 to 45 mm. The over-range length was particularly large at the combination of 0.5 sec,  $1.0 \times 40$  mm, and high speed.

## CONCLUSION

By comparing the dose profiles with and without AC, the operation of AC was confirmed. It was also confirmed that the operation of the AC depends on the imaging conditions. Overrange lengths ranged from about 18 to 45 mm, The overrange length was particularly large for the combination of 0.5 sec,  $1.0 \times 40$  mm, and high speed.

## CLINICAL RELEVANCE/APPLICATION

The use of active collimator may reduce over-range. Since the over-range varies depending on the scan conditions, it is important to understand the effect of overrange in advance for children with a short scan range. In addition, the use of a semiconductor detector may make it possible to easily determine the effect of over-range.

## W5B-SPPH- Effect of Radiation Dose on CT Attenuation of Photon Counting CT Scanner: A Phantom Study 12

## PURPOSE

NAEOTOM Alpha is the new generation CT scanner (Siemens Healthineers, Forchheim, Germany) which epoch-makingly used the semiconductor material for detector. The new detector system could convert photons directly into electronic signals to improve the utilization of photons and result in a lower noise, a higher resolution and image quality. Compared with the mixed image in dual source system, NAEOTOM Alpha would generate a monoenergetic image of 70keV as the 'standard' image for doctors' diagnosis. In this project, we want to first evaluate the accuracy and change of CT attenuation with different mono-energetic images using a liver nodule phantom.

## METHODS AND MATERIALS

We applied a liver nodule phantom (QRM, Möhrendorf, Germany) consisting of the anthropomorphic abdomen phantom body, the liver and spleen insert in this project. The liver insert contains multiple oval and spherical lesions of different sizes and in two kinds of densities. The phantom was scanned with the standard QuantumPlus protocol on NAEOTOM Alpha in 3 different scanning modes (Spiral, Flash and Sequence). In each mode, the tube voltage was set at 120kV and 140kV. Each scan was performed for 3 times to reduce the errors. All images were reconstructed as SPP image with a kernel of Qr40, slice thickness of 2mm and increment of 2mm and imported into the post-processing workstation (Syngo.Via VB70, Siemens Healthineers, Forchheim, Germany) for measurement. All statistical analysis was performed with Python 3.10.11. The difference between measured results and standard CT attenuation was tested with student T test. A p value smaller than 0.05 was considered as significant.

## RESULTS

As shown in Fig.1, the CT attenuation is close to the standard value when the mono-energy is around 70keV for abdomen region, low-density and high-density lesions, with no significant difference when compared with the standard values. For liver region, for Spiral and Sequence mode, the CT values were close to the standard value when the mono-energy is around or lower than 55keV, while 60keV for Flash mode. For the spleen region, the CT attenuations are close to the standard value when the mono-energy is around 65keV.

## CONCLUSION

s From the result, we could conclude that the CT attenuations of 70keV image are close to the standard value for the abdomen region, low-density and high-density lesions in the liver. However, 65keV image for spleen and 60keV image for liver seem to be closer to standard value. This could help the doctors in clinical routines to decide the parameters.

## CLINICAL RELEVANCE/APPLICATION

To lay the foundation for the further promotion of photon CT to clinical applications.

### W5B-SPPH- Comparison of Non-gated, High-pitch Cardiac CTA in Pediatric Patients under 1 Year of Age: Energy Integrating Detector vs Photon Counting Detector CT

Participants

Scott Bugenhagen, MD, PhD, Saint Louis, MO (*Presenter*) Nothing to Disclose

## PURPOSE

To determine image quality and radiation doses on photon counting detector (PCD) CT compared to conventional energy-integrated detector (EID) CT in under 1 year old congenital heart disease (CHD) patients.

## METHODS AND MATERIALS

This study involved an Institutional-Review-Board (IRB) approved retrospective analysis of CHD patients that underwent clinically indicated CT angiography examinations using dual-source EID-CT (Siemens Healthineers, SOMATOM Force) and dual-source PCD-CT (Siemens Healthineers, NAEOTOM Alpha). All examinations, regardless of detector technologies, were acquired with non-gated, high-pitch technique (3.2) and automated exposure control. All PCD scans used 120kV and 55keV reconstructions, while EID scans used automated kV technology with tube potential of 70 and 80kV. Patient characteristics (age, body mass index, patient weight) as well as dose descriptors including volume CT dose index (CTDIvol), dose length product (DLP), and size-specific dose estimate (SSDE), were recorded and compared. Image quality assessment was based on review of the 4 major coronary arteries and was scored on an 8 point scale: 3 points for right coronary artery (RCA) (1 for origin, 2 for origin + proximal, 3 for origin + proximal + distal), 1 point for left main coronary artery (LMCA) (seen or not seen), and 2 points for the left anterior descending artery (LAD) and left circumflex artery (LCA) arteries (1 for proximal and 2 for proximal + distal). Parametric (t-test) testing was used for statistical evaluation.

## RESULTS

29 and 24 CT examinations were included for EID and PCD, respectively. There were no overall differences in demographic characteristics including mean (standard deviation) patient age [0.137 vs 0.157 years,  $P = 0.844$ ], body mass index [14.2 (+/- 2.5) vs 13.9 (+/- 2/5) kg/m<sup>2</sup>,  $P = 0.5$ ], or patient weight [3.63 vs 3.62 kg,  $P = 0.9$ ]. In comparison with EID CT, PCD CT had significantly lower mean CTDIvol [0.48 vs 0.39 mGy,  $P=0.001$ ]. SSDE [1.005 vs 0.951 mGy,  $P = 0.11$ ] and DLP [7.07 vs 5.66 mGy cm,  $P = 0.06$ ] differences were non-significant. There was negligible difference in image quality (visualization of coronary arteries) ( $P = 0.19$ ).

## CONCLUSION

s Our experience indicates that radiation doses in non-gated high-pitch cardiac PCD-CT in children are similar to or lower than those of current EID-CT, while subjective image quality is maintained.

## CLINICAL RELEVANCE/APPLICATION

Similar to lower doses in non-gated high-pitch cardiac PCD-CT compared to EID-CT supports use of PCD-CT in cardiac imaging in children.

### W5B-SPPH- Correlation of Human Observer Impression of X-ray Fluoroscopy and Angiography Image Quality with Technical Changes to Image Quality

Participants

Jelena Mihailovic, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

## PURPOSE

Perceived angiographic image quality is a combination of image formation technical factors and image processing. No standard methods to measure angiography quality exists due to the combination of spatio-temporal anatomical variability and non-linear image processing. However, methods to assess image quality are needed to optimize radiation dose and image quality in the clinical practice. The purpose of this work was to develop and validate methods to measure observer impression of angiographic image quality.

## METHODS AND MATERIALS

Multi-frame images of the thorax of a euthanized pig were acquired to provide an anatomical background. Detector dose (DD) was varied from 6 to 200 nGy (increments 2x) to provide background with a wide range of quantum SNR. For each DD images with 0.6 and 1.0 mm focal spots (FS) were acquired to assess FS blur. Two stents with/without 0.5 mm separation and a synthetic right coronary artery (RCA) with spherical defects were embedded as test objects into the pig images. Embedded test objects included motion to mimic cardiac function. Quantitative observer (n=14) performance was measured through 2AFC test of whether stents were touching and by observer count of RCA defects. Subjective impressions of quality were measured through visual analog scale (VAS) response to statements assessing small object details, noise impression, and overall image quality. The paired t-test was used to describe significance of observer response changes associated with DD or FS size.

## RESULTS

Proportion of correct responses of stent separation and number of RCA defects reported changed significantly with DD increment in the range 6-100 nGy ( $p<0.05$ ). While there was a trend which favored the 0.6 vs. 1.0 mm FS for these quantitative assessments, this was not significant. VAS measurements changed significantly with both DD increment in the range 24-100 nGy and with FS size for a given DD ( $p<0.05$ ). Quantitative and subjective measurements were highly correlated. The most sensitive measurement was VAS assessment of small object details.

## CONCLUSION

s Compared to quantitative human observer assessment, measurement of subjective impression of image quality demonstrated higher sensitivity for image quality changes associated with quantum SNR and focal spot size. These findings embolden future work to assess quality of fluoroscopy and angiography images using subjective measurements. Our strategy to ensure rigor is systematic, self-conscious study design, data collection, and interpretation.

#### CLINICAL RELEVANCE/APPLICATION

For cardiovascular imaging procedures, defining image quality is complex task because it relates to numerous dynamic variables. Feedback from the end user can lead to more accurate and reproducible measurements.

### W5B-SPPH- Is it Possible to Achieve Consistent Outcomes in CT NSCLC Radiomics? An In-depth Exploration of the Sources of Uncertainties<sup>3</sup>

#### PURPOSE

Radiomics features have been used in machine learning models to quantify tissue characteristics that are not observable by clinicians to aid in the prediction of clinical decisions and outcomes. However, there are still many uncertainties involved in this process which reduce the robustness of results and limit its clinical implementation. We investigate the impact of each component in the radiomics pipeline on predicting clinical outcomes.

#### METHODS AND MATERIALS

A thorough review of over 120 CT lung radiomics studies was conducted to examine current. Patient images were retrospectively retrieved from a GE VCT scanner. The lung nodules were manually delineated using Eclipse to define a region of interest. First-order features were extracted with IBEX and high-order features were extracted using Python. Clinical features were retrieved from the Kentucky Cancer Registry (KCR). The features were organized into five feature sets, Radiomic (low), Radiomic (high), Radiomic (high+low), Clinical, and Radiomic+Clinical. Prediction of 2-year survival was investigated. Cohort size was examined by extracting balanced sub-cohorts of the original cohort to be run in parallel to the original cohort. The included feature selection methods are: ANOVA, LASSO, MI, mRMR, and Relief. The number of selected features used for model training was also established as a variable for examination, ranging from 5 to 25 features. The included predictive models are: SVC, Naïve-Bayes, DT, RF, LR, GBoost, and kNN. Model validation methods were also examined, using 2-, 5-, and 10-fold cross-validation (CV).

#### RESULTS

496 patient image sets are retrieved for use in this analysis. CT datasets are fairly balanced, with 237 patients lt;2 years survival and 259 patients gt;2 years survival. A total of 1419 first-order features, 360 high-order wavelet features, and 9 clinical features are included in the feature sets. Statistical analysis is done using Kruskal-Wallis for within-group analysis and further pairwise testing establishes relative rankings. A total of 17220 AUCs involving all combinations shows certain trends. Overall CT lung cancer radiomic stability favors larger cohort size, Clinical and Radiomic+Clinical feature sets, mRMR feature selection, RF predictive model, and 10-fold CV.

#### CONCLUSION

s Radiomic feature selection and machine learning methods are inter-dependent. Appropriate inclusion of different feature types and choice of feature selection can improve predictive power for clinical outcome.

#### CLINICAL RELEVANCE/APPLICATION

Conducting systematic analysis of each phase of the radiomic workflow may heighten general understanding of uncertainties that contribute to unstable outcomes, thus potentially improving the robustness of future radiomic studies.

### W5B-SPPH- A Data Dashboard Approach to Improving Image Analysis: Survival Prediction of Patients with Bladder Cancer after Cystectomy based on Clinical, Radiomics, and Deep Learning Descriptors<sup>4</sup>

Participants  
Di Sun, MEng, BEng, Ann Arbor, MI (*Presenter*) Nothing to Disclose

#### PURPOSE

To predict the 5-year survival of bladder cancer patients after radical cystectomy by combining clinical, radiomics, and deep learning (DL) descriptors (CRD).

#### METHODS AND MATERIALS

With IRB approval, we collected clinical information and CTU scans from 163 patients with bladder cancer who underwent neoadjuvant chemotherapy followed by radical cystectomy. Five-year survival data were collected. We split the data into three sets: training (55 alive (A); 37 deceased (D)); validation (4 A; 3 D); and test (20 A; 44 D). The clinical information collected included post-surgery pathologic stage, lymphovascular invasion, pathologic node stage, if patients underwent chemotherapy, or adjuvant radiotherapy. The nomogram by Shariat was used to predict the survival of patients. Radiomics and DL descriptors were extracted from CTU images. Each patient had two CTU scans (before and during/after chemotherapy), forming a pre- and post-treatment pair. We used our AI-CALS algorithm to segment the lesions. To train and validate the DL convolution neural network (DL-CNN), hybrid ROIs extracted from the lesion area were used. A total of 182 radiomics features were extracted from the lesions, including grey level, morphological, and texture features from the post-treatment scans (post features) and the percentage difference between pre- and post-treatment features (difference features). Backpropagation neural network was used to classify the radiomics features. The area under receiver operating characteristic curve (AUC) and Kaplan-Meier analysis were used to evaluate the classification performance on the test set.

#### RESULTS

The nomogram model achieved an AUC of  $0.82 \pm 0.06$  on the test set; DL-CNN achieved an AUC of  $0.71 \pm 0.07$ ; and the classification based on radiomics features had an AUC of  $0.73 \pm 0.07$ . By combining all CRD descriptors, we obtained an AUC of  $0.87 \pm 0.05$ . The differences between any pairs of AUCs did not reach significance ( $p > 0.05$ ), which likely relates to sample size. The median survival times by Kaplan-Meier analysis for the two classes (deceased or alive) were 1.2 and 5 years ( $p < 0.001$ ) as estimated by the nomogram model, and 1.6 and 5 years ( $p = 0.007$ ) estimated based on CRD descriptors.

#### CONCLUSION

s While larger data sets are needed, this study demonstrates that combining the radiomics and DL descriptors with clinical information holds promise for improving the prediction of the 5-year survival of bladder cancer patients after radical cystectomy.

#### **CLINICAL RELEVANCE/APPLICATION**

The CRD descriptors has the potential to improve the prediction of the 5-year survival of bladder cancer patients after radical cystectomy. Accurate assessment of 5-year survival offers potential benefits with patient counseling and postoperative surveillance strategies.

#### **W5B-SPPH- Fissure Integrity Scores in Pre-treatment Chest CT Images as a Biomarker for Predicting a Targeted Lobar Collapse with Endobronchial Valve Implantation in Subjects with Emphysema**

5

#### **PURPOSE**

We propose to build an initial endobronchial valve (EBV) prediction model using quantitative CT measurements to evaluate the response of emphysema patients to EBV implantation for a targeted lobe.

#### **METHODS AND MATERIALS**

The study retrospectively collected 127 anonymized pre-treatment EBV CT scans. Selection criteria for the targeted lobe for EBV implantation is based on the highest emphysema density and largest degree of heterogeneous emphysema between the targeted and the ipsilateral adjacent lobe. A fissure integrity score (FIS) is used as a primary quantitative biomarker for the development of the EBV prediction model. Previous work on fissure segmentation and integrity assessment used a deep learning approach that segments pulmonary fissure and quantifies FIS for the right horizontal fissure (RHF), right oblique fissure (ROF), and left oblique fissure (LOF). An FIS is defined as the percentage of complete fissure voxels along the surface of the interlobar region. Fissures are categorized as complete with a FIS of = 90%; otherwise, a fissure is considered incomplete. Separate FIS for the right fissures are calculated based on the targeted lobe for lobar exclusion (i.e., upper lobar boundary for a targeted right upper lobe). Successful EBV placement in a targeted lobe is described as a reduction of = 50% of its total lung capacity (TLC). A reduction of less than 50% of targeted lobe volume reduction (TLVR) does not achieve the desired lobar collapse. Statistical analysis of FIS and EBV volume reduction is applied to assess the significance of fissure completeness and EBV placement.

#### **RESULTS**

FIS and TLVR comparisons are separated by total sample size and targeted lobes. For all targeted lobes, a mean ( $\pm$ SD) FIS of 0.93 ( $\pm$ 0.05) and 0.72 ( $\pm$ 0.26) was attained for successful and unsuccessful TLVR, respectively. Subjects with complete target lobe fissure are likely to experience TLVR by six-fold compared to subjects with incomplete target lobe FIS (Odds Ratio = 6.05, p-value=0.001). All targeted lobes and the right upper lobe achieved a TLVR (p-value < 0.01); the left lobes and right lower lobe did not achieve statistical significance.

#### **CONCLUSION**

s Quantified fissure integrity scores are essential for the foundation of the EBV prediction model, but additional quantitative biomarkers may improve the efficacy for the model.

#### **CLINICAL RELEVANCE/APPLICATION**

The development of a prediction model that will more successfully identify emphysema patients that respond to EBV treatment helps guide treatment decisions for clinicians and manages medical resources.

#### **W5B-SPPH- Practicing Precision Medicine: Using Machine Learning to Predict Time-to-Surgery in Renal Cell Carcinoma under Active Surveillance**

6

Participants

Shiva Singh, MBBS, Bethesda, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Clear cell renal carcinomas (ccRCCs) in VHL patients are typically managed with active surveillance (AS) until the tumor reaches 3 cm, when surgical resection is recommended. While current guidelines suggest annual screening with abdominal imaging, tailoring imaging frequency to each patient's tumor growth rate can reduce unnecessary radiation exposure and metastasis risk. This study aims to use MRI-based machine learning algorithms to predict the time to 3 cm threshold and design personalized imaging protocols for VHL patients.

#### **METHODS AND MATERIALS**

The retrospective study included 40 vHL patients with 68 histopathologically-confirmed ccRCCs (size 1-2 cm) undergoing AS according to institutional protocol. Tumor segmentation was performed on all available pre-operative scans using ITK-SNAP and radiomics features were extracted from co-registered pre-contrast and post-contrast sequences using PyRadiomics. A growth curve was plotted for each tumor, and the time taken for each tumor to grow to 3 cm (T3) from the initial time point was calculated using the respective growth curve's fitted line equation. Based on T3, the tumors were classified into three categories: aggressive (<365 days), moderate (1-3 years), and slow (>3 years). Stacked ensemble technique with random forest and XGBoost were used for training models to predict T3 based on radiomics features. Five-fold cross-validation was used and the model was benchmarked on 100 different combinations (85% train and 15% test) to find the best model which was reported with F1 score, and the area under the curve of the receiver operating characteristic curve (AUC-ROC).

#### **RESULTS**

A total of 40 patients (28 males) with mean age of  $44 \pm 3$  years and mean follow-up of  $2.9 \pm 1$  year were studied. Median volumetric growth rate of 1.8 cm<sup>3</sup> and diametric growth rate of 0.91 cm/year was observed. The best model showed an accuracy of 0.67 and F1-score of 0.67, 0.70 and 0.62 was observed with aggressive, moderate and slow tumor class respectively. AUC of ROC drawn for aggressive, moderate, and slow class were 0.65, 0.71 and 0.76. A Matthews Correlation Coefficient of 0.58 reveals a moderately well predicted analysis.

#### **CONCLUSION**

s The use of MRI-based machine learning algorithms can predict the time to 3 cm threshold and classify tumors into aggressive,

moderate, and slow-growing categories for VHL patients with ccRCCs, providing a personalized imaging protocol. However, moderate accuracy of the model suggests the need for large dataset and external validation to improve the performance.

#### CLINICAL RELEVANCE/APPLICATION

Tailoring imaging frequency based on the predicted time to 3 cm can reduce unnecessary radiation exposure and financial burden for slow-growing tumors as well as enables timely resection of aggressive lesion.

#### W5B-SPPH- Deep Learning-enabled Automatic Sarcopenia Analysis in Abdominal CT: Finding an Association with Cardiovascular Disease in Korean Population

Participants

Sihwan Kim, BSc, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### PURPOSE

Little studies have shown that sarcopenia can increase the risk of cardiovascular disease, we aimed to investigate the association between a sarcopenia and cardiovascular mortality for the Korean population.

#### METHODS AND MATERIALS

Data were retrospectively collected from non-contrast enhanced abdominal CT scans between 2005 and 2017. The number of abdominal CT scans was 641, the CT data is scanned from 352 males (54.9%) and 289 females (45.1%). Among the abdominal CT data, 141 patients (21.9%) had cardiovascular disease (CVD). Mean age of studied data was about 64 yrs (64 for male and 63 for female). The sarcopenia is defined by the sex-specific L3 skeletal muscle area (SMA) threshold referenced as 117.04 cm<sup>2</sup> for male and 71.39 cm<sup>2</sup> for female. The SMA value of L3 vertebra level was calculated using automatic body composition analysis software (ClariMetabo, ClariPi, Seoul, Republic of Korea).

#### RESULTS

In the study data (n = 641), 75 patients (11.7%) had the sarcopenia. The result showed that 46.7% of Sarcopenia group had the CVD, compared to 18.7% in the non-sarcopenia group. The odds ratio for CVD event was 3.79 [95%CI: 2.30-6.26]. However, the correlation was 0.22 (p<0.0001) in the Phi correlation coefficient analysis, indicating a weak positive correlation. Among the sarcopenia patients, the CVD risk was 2.83 [95%CI: 0.79-10.6] times higher in male than in female.

#### CONCLUSION

s Automated analysis of abdominal CT imaging markers based on deep learning showed that patients with sarcopenia are more likely to have the cardiovascular disease compared to normal people in the Korean population.

#### CLINICAL RELEVANCE/APPLICATION

Deep learning-based automatic muscle mass analysis in abdominal CT is expected to contribute to improving human survival by predicting the risk of cardiovascular disease due to the sarcopenia at an early stage.

#### W5B-SPPH- Feasibility of Artificial Intelligence-supported Assessment of Dual-energy Computed Tomography for Measuring Bone Mineral Density: Correlation with Quantitative CT

#### PURPOSE

To evaluate the precision and agreement between BMD measurements performed in DECT-derived hydroxyapatite (HAP) concentration of the L1 vertebra to L3 vertebra and automated, AI-supported assessment of DECT-derived HAP concentrations with European Spine Phantom (ESP) compared with quantitative CT (QCT).

#### METHODS AND MATERIALS

Data acquisitions were performed on Revolution CT (GE Healthcare, Waukesha, WI) at 120kV with 0.8r/s and 100 and 500mA, fast tube voltage switching between high and low energy (140/80kVp) with 0.5r/s and 240 and 365mA using ESP (No. 145, Germany ORM company). Mindways QCT PRO workstation can automatically generate ROIs and analyze BMD. For DECT-derived HAP values, ROI (468.78mm<sup>2</sup>) was set as the median plane of the vertebral body avoiding cortical bone and its pedicle, and the HAP values of the L1, L2, and L3 were measured from the axial-view HAP (Water)-based material decomposition images on a dedicated GE AW 4.7 Workstation. For automated assessment of DECT-derived HAP concentration was performed by a new fully automatic BMD analysis with AI technology: Firstly, using spectral CT images as the original input, process detects, names, segments and recognizes the orientation of the vertebral body within the image; Secondly, system automatically selects the most suitable three vertebrae for evaluation, recognizes their direction and central plane, segments and extracts the three-dimensional structure of the vertebrae based on vertebral body segmentation; Thirdly, system automatically calculates ROIs in trabecular bone; Lastly, system generates personalized bone density reports. Paired t test and Pearson correlation were to determine the differences and association between two measurements.

#### RESULTS

The CTDIvol with QCT were 5.53mGy in 100mA and 27.66mGy in 500mA, whilst DECT were 5.80mGy in 240mA and 9.25mGy in 365mA. QCT-derived BMD values of the L1, L2, and L3 were 53.60±0.27, 106.25±0.11, 202.76±0.23mg/cm<sup>3</sup>, respectively. The DECT-derived HAP-Water values of the L1, L2, and L3 were 45.25±0.42, 89.2±0.86, 180.00±0.15mg/cm<sup>3</sup> with tube current of 240mA, whilst 39.46±0.51, 88.64±0.74, 170.1±0.38mg/cm<sup>3</sup> with tube current of 365mA. The DECT-derived HAP-Water values of the L1, L2, and L3 with AI were 44.2±0.87, 94.73±0.32, 173.22±0.71mg/cm<sup>3</sup> with tube current of 240mA, and 41.23±0.23, 92.03±0.74, 173.79±0.78mg/cm<sup>3</sup> with tube current of 365mA. There was a strong positive correlation between two methods (r=0.91, P<0.0001).

#### CONCLUSION

s The automated, AI-supported assessment of DECT-derived HAP concentration of the three vertebrae is feasible to measure BMD values and potentially aid a help in opportunistic osteoporosis screening in high-risk populations.

#### CLINICAL RELEVANCE/APPLICATION

none

## W5B-SPPH- External Review of High CT Doses: Reasons and Improvements 9

### Participants

William Sensakovic, PhD, Cave Creek, AZ (*Presenter*) Nothing to Disclose

### PURPOSE

To review reasons for high CT dose cases during external review and implement improvements to improve review workflow.

### METHODS AND MATERIALS

An in-house built external CT dose review was clinically implemented in August of 2021. Cases exceeding machine Dose Notification Values are automatically retained for review. For each case a technologist records possible reasons for the high dose and final review, updating of reasons, and sign-off is performed in-system by a qualified medical physicist or a supervisor/team lead with physicist final review. Summary statistics related to number of review cases and the reason for high doses as well as the rate of cases referred for review were calculated.

### RESULTS

A total of 4,212 cases for 3098 unique patients were reviewed across our 21 CTAP sites. Mean CTDIvol was  $62.3 \text{ Gy} \pm 22.9 \text{ Gy}$ . Cases exceeded notification values by  $15.5\% \pm 18.5\%$  on average. 31.2% of cases exceed the notification value by less than 5%. A reason for the high dose was included in 3,994 cases (94.8%). In those that listed a reason for the high dose, 3,678 (92.1%) included large patient size at part or all of the reason for the high doses. Mean BMI of patients in reviewed cases was  $42.5 \pm 10.9$ . BMI data was missing from 791 cases (18.8%). The next most frequent reasons were presence of shoulders (typically in neck scans) at 250 cases (6.3%) and misplacement of arms at 174 cases (4.4%). The presence of implants and casts was mentioned in 68 cases (1.7%) and combo scan across anatomy 46 (1.2%). No other reason exceeded 1% of the cases.

### CONCLUSION

s Most cases only exceed notification values by a small amount and represent only a small risk to the patient. The vast majority of external review cases are due to patient size and are generally considered appropriate. Other major issues include arm placement, combinations studies, and studies across the neck and into the shoulders. Our external review software lists BMI when available to improve physics workflow.

### CLINICAL RELEVANCE/APPLICATION

Physics workflow can be improved in external review by listing indicators of patient size along with other basic demographics to reduce the need for searching for such information. It is important that size indicators are available for systems to pull and autopopulate for external review.

### Vascular Imaging Wednesday Poster Discussions II

#### Sub-Events

#### W5B-SPVA- Association Between Carotid Artery Perivascular Fat Density with Intraplaque Hemorrhage

1

#### PURPOSE

Perivascular inflammation plays a key role in atherosclerosis, but its effects on the composition of carotid atherosclerotic plaques are unknown. Our aim was to investigate the association between perivascular inflammation with intraplaque hemorrhage (IPH) in carotid artery.

#### METHODS AND MATERIALS

Carotid inflammation was assessed by perivascular fat density (PFD) in 72 participants (mean age, 65.1 years, 56 men) who underwent both computed tomography angiography (CTA) and magnetic resonance imaging (MRI) within 2 weeks. Presence of IPH was assessed with MRI. Carotid stenosis, maximum plaque thickness, calcification, and ulceration were evaluated through CTA. The association between PFD and the occurrence of IPH was studied using generalized estimating equations analysis.

#### RESULTS

Of 156 plaques, 72 plaques (46.2%) had IPH. Plaques with IPH show higher PFD than those without ( $-41.4 \pm 3.9$  HU versus  $-55.8 \pm 6.5$  HU;  $P < 0.001$ ). After adjusting for age, calcification, degree of stenosis, maximum plaque thickness, and ulceration, PFD (OR, 1.96; 95% CI, 1.41-2.73;  $P < 0.001$ ) was found to be strongly associated with the presence of IPH.

#### CONCLUSION

Higher PFD is associated with presence of IPH in the carotid artery. These findings may provide novel insights into the pathogenesis of IPH, and thus may serve as a guide in developing a new targeted therapy for IPH.

#### CLINICAL RELEVANCE/APPLICATION

IPH, a compositional characteristic of vulnerable plaques contributes to plaque progression and rupture, thus increasing the risk of cerebrovascular ischemic events. Recently, several studies have shown that the use of antithrombotic treatment is associated with a higher frequency of IPH in the carotid atherosclerotic plaques. These findings seem to contradict current knowledge because antithrombotic treatment is used to reduce the risk from IPH, including subsequent cardiovascular events caused. In the present study, we found the association between IPH and carotid inflammation, providing a theoretical basis for new targeted anti-inflammatory therapy. At present, considerable studies have focused on preventing atherosclerosis by intervening in PVAT. Therefore, PVAT may be emerging as the therapeutic target for IPH.

#### W5B-SPVA- Low-dose 4D Head and Neck Computed Tomography Angiography Conducted via Helical Scans Jointing with ECG-gated Axial Scans: Study in Image Quality

2

#### Participants

Jinhui Zhang, Xiamen, China (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the image quality of low-dose 4D head and neck computed tomography angiography (CTA) conducted via helical scans jointing with ECG-gated axial scans, compared with conventional standard-dose spiral scanning.

#### METHODS AND MATERIALS

This study enrolled 100 patients suspected with Cerebral aneurysm and received head and neck CTA. The patients were divided into two groups according to the scanning methods. Group A ( $n=50$ ) performed helical neck CTA jointing (pitch=0.992: 1) with ECG-gated axial head CTA at 20%-110% R-R interval in sequence, noise index (NI) was set as 8 HU and rotation time was 0.35 s. Group B ( $n=50$ ) received normal conventional helical scanning with pitch of 0.984: 1, NI of 5 HU, rotation time of 5 s. Regions of interest were placed at the bifurcation of internal carotid artery and M1 segment of middle cerebral artery. CT values and SD values of ROIs and muscle or white matter were measured, and SNR and CNR were calculated. The overall image quality was subjectively scored using a 5-scale method. The radiation dose, subjective and objective image evaluation results were compared.

#### RESULTS

Compared with Group B, Group A had a decreased DLP by 34.6% (A vs. B:  $558.92 \pm 57.01$  vs.  $944.88 \pm 86.05$  mGy·cm,  $P < 0.001$ ). For bifurcation of internal carotid artery, the two group images showed no statistical difference in CT values (A vs. B:  $545.58 \pm 93.92$  vs.  $535.66 \pm 71.30$ ), SD ( $11.35 \pm 2.51$  vs.  $10.70 \pm 2.48$ ), SNR [ $48.16$  (20.99) vs.  $49.43$  (21.46)] and CNR ( $62.87 \pm 16.02$  vs.  $66.74 \pm 16.04$ ), with all  $P > 0.05$ . For M1 segment of middle cerebral artery, the two group images also showed no statistical difference in CT values ( $528.68 \pm 124.60$  vs.  $513.32 \pm 71.22$ ), SD [ $14.09$  (4.18) vs.  $11.94$  (3.65)], SNR [ $39.99$  (17.05) vs.  $45.57$  (17.60)] and CNR ( $54.99 \pm 14.56$  vs.  $50.83 \pm 12.76$ ), with all  $P > 0.05$ . Regarding subjective scoring, both the two-group images met diagnostic requirements and the difference was not statistically significant ( $P > 0.05$ ).

#### CONCLUSION

s For head and neck CTA, low-dose helical scans jointing with ECG-gated axial scans showed comparable head and neck artery displays with standard-dose conventional helical scanning.

#### **CLINICAL RELEVANCE/APPLICATION**

Aneurysm is at risk of rupture, and monitoring of its pulsatility with the cardiac cycle shows predictive value, where ECG-gated 4D CTA potentially be helpful. However, 4D scans may increase the risk of radiation doses, in this study, we found that helical combined ECG-gated axial scan with exposure during 20% -110% R-R interval could obtain comparable artery visualization with conventional helical

## Abstract Archives of the RSNA, 2023

BREE

### Breast Imaging Education Exhibits

#### Sub-Events

#### **BREE-1 Pathologic Nipple Discharge: Is Breast MRI a Good Option?**

##### Participants

Valeria Vidales, Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

##### TEACHING POINTS

Pathologic nipple discharge (PND) is unilateral, spontaneous, involves a single duct, and is serous or bloody in appearance. MRI is able to detect the etiology of nipple discharge in 56-61% of cases when initial imaging with mammogram and ultrasound are negative. To describe differential diagnosis and its classification in BIRADS system.

##### TABLE OF CONTENTS/OUTLINE

Description of the anatomy of the nipple and retroareolar Description of different types of lesions that could be found in patients with nipple discharge US, mammographic and RM principal findings and its correlations. Sample cases

#### **BREE-10 Single Duct Abnormalities: Multimodality Imaging and Assessment**

##### Participants

Juliana Sitta, MD, Jackson, MS (*Presenter*) Nothing to Disclose

##### TEACHING POINTS

Ductal abnormalities entail a wide range of pathology that may present clinically or grow silently, ranging from benign to malignant processes. Solitary dilated duct is a rare mammographic finding with controversial clinical significance in the literature. Workup of the solitary dilated duct must include additional mammographic views and ultrasound to assess for additional findings that would raise suspicion for malignancy and provide a biopsy target. Ductal ectasia is the most common benign finding; however, atypical presentations such as peripheral location, wall thickening, and hypoechoic tissue should raise suspicion for secondary obstruction causes. Inspissated secretions can mimic intraductal masses and may be seen in association or secondary to acute and chronic mastitis, ductal ectasia, and intraductal papilloma. Patients with papillomatosis often have associated high-risk lesions and an increased lifetime risk of breast malignancy. MRI is a great adjunct to evaluate nipple discharge, particularly when the initial workup is negative, and to exclude underlying DCIS or invasive ductal carcinoma.

##### TABLE OF CONTENTS/OUTLINE

Review and illustrate ductal anatomy, physiology, and normal findings on multimodality imaging, including mammography, ultrasound, galactogram, and MRI. Illustrate and discuss problem-solving for single duct findings and presentations commonly associated with single duct abnormality with interesting cases from our institution. Analyze the added value of multiple imaging modalities in assessing ductal pathology, including galactogram and MRI.

#### **BREE-100 The Leading Role of Ultrasound in Breast Implant Evaluation in Developing Countries**

##### Participants

Giannina Secco, MD, Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

##### TEACHING POINTS

To illustrate ultrasound findings in breasts with implants and their comparison with those in magnetic resonance imaging. To discuss the advantages and limitations of ultrasound for breast implant evaluation and why it remains a valuable and irreplaceable tool in underdeveloped and developing countries.

##### TABLE OF CONTENTS/OUTLINE

Detecting a broken breast implant is essential due to the potential physical discomfort, cosmetic deformity, and health risks associated with a ruptured implant. Early detection and prompt treatment of a broken implant are crucial to prevent further complications and ensure optimal patient outcomes. Knowledge of a ruptured implant can help patients make informed decisions about implant replacement or removal. In order to acknowledge this, we believe breast implant ultrasound is a preferable choice to MRI for breast implant evaluation in underdeveloped and developing countries. Breast implant ultrasound is more cost-effective, with often portable machines, non-invasive procedure that does not require the use of contrast agents or ionizing radiation, provides real-time imaging, does not require anesthesia and is widely available in many healthcare facilities. Ultrasound imaging can be performed and interpreted quickly, allowing clinicians to make prompt treatment decisions. Furthermore, breast implant ultrasound is safe for patients with pacemakers or other implanted devices, while MRI may not be feasible for these patients. Although ultrasound has its limitations in some cases, it remains a valuable and irreplaceable tool for breast implant evaluation in underdeveloped and developing countries.

#### **BREE-101 Cystic Breast Lesions Assessment and Management: An Educational Approach for Radiology**

## Residents

### Participants

Karina Pesce, PhD, Capital Federal, Argentina (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To recognize the spectrum of cystic breast lesions. To learn tools and tips for the sonographic evaluation of cystic lesions. To understand the importance of distinguishing benign cystic lesions from potentially malignant cystic masses To learn skills in the assessment and management of cystic breast lesions

### TABLE OF CONTENTS/OUTLINE

1-Introduction: Cystic breast lesions are a common finding in breast imaging studies. Accurate characterization and precise management of these lesions are essential to avoid unnecessary biopsies and tests, as well as to timely identify which of these lesions require further diagnostic evaluation. 2- Ultrasound parameters necessary for a correct evaluation of cystic lesions. 3- Tips and tricks in the ultrasound evaluation of cystic lesions. 4- Spectrum of cystic lesions. 5- Ultrasound appearance 6-Radiological appearance of cystic breast lesions on other imaging modalities such as mammography, MRI. 7- Management. 8- Interactive clinical cases for self-evaluation. 9- Conclusions

### **BREE-102 Radiological Signs in Breast Imaging: What Should the Radiology Resident Know?**

### Participants

Karina Pesce, PhD, Capital Federal, Argentina (*Presenter*) Nothing to Disclose

### TEACHING POINTS

1.To know recognize the different radiological signs in breast imaging.2.To learn the importance of accurate identification of the different radiological signs.

### TABLE OF CONTENTS/OUTLINE

Introduction This educational poster reviews the importance of understanding breast radiological signs. Accurate identification of different radiological signs is critical for early diagnosis and effective treatment of various medical conditions, including breast cancer. Furthermore, knowledge of clinical and radiological signs in breast imaging can help prevent diagnostic errors and reduce the number of unnecessary medical tests. Description of the radiological signs in breast imaging. Tips and techniques for identifying these signs are also provided to assist residents in their interpretation of medical images. Interactive clinical cases for self-evaluation. These cases offer residents the opportunity to apply their knowledge and receive immediate feedback, thereby strengthening their diagnostic skills and decision-making abilities. Conclusion: Radiologists residents must be familiar with different radiological signs to accurately interpret medical images and provide an accurate diagnosis.

### **BREE-103 Peer Learning in Breast Imaging: Lessons Learned in Our Institution**

### Participants

Marcela Lauer, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

### TEACHING POINTS

It is estimated that medical diagnostic mistakes contribute to approximately 10% of patients deaths and 17% of adverse events in hospitals. Consequently, optimal patient care is related to recognizing and preventing such errors. Strategies were developed to ensure performance standards in radiology departments, including score-based second-reader peer review systems. However, this type of strategy may be associated with subjectivity, sampling bias, underreporting of errors due to peer relationships and fear of punitive action. It may have emotional impact for radiologists and lead to feelings like anxiety, shame, and humiliation, contributing to a culture of defensiveness. On the other hand, peer learning is an strategy focused on learning and improvement that has gained momentum, as a respectful nonpunitive collaborative culture improves performance in modern radiology practice. The objective of this presentation is to show how we established peer learning in our breast imaging department, the bias that were related to the mistakes we made, how we concluded they could have been avoided and our experience with peer learning as a group. We aim that this presentation may help and encourage other services to implement peer learning in their clinical practice, and also learn from the multimodality imaging cases we provide.

### TABLE OF CONTENTS/OUTLINE

Didactic case-based reviews of breast imaging exams (including mammography, ultrasound and magnetic resonance imaging performed in our service) that were discussed in our peer learning meetings in the last 5 years, with correlation of associated cognitive bias, how the cases could have been better managed and lessons learned that changed our daily practice.

### **BREE-104 Multimodality Surveillance of Breast Implants in Asymptomatic Patients and the Potential Challenges for the Radiologist in Light of the 2022 United States Food and Drug Administration (FDA) Guidelines**

### Participants

Carisa Le-Petross, MD, FRCPC, Houston, TX (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Recently the United States Food and Drug Administration (FDA) implemented changes to breast implant surveillance that radiologists may not be aware of<sup>1,2</sup>. At the end of this exhibit, the participant will: • Be up-to-date on the 2022 FDA guidelines for breast implant screening. • Learn the common signs of implant rupture on ultrasound (US). • Learn the common signs of implant rupture on magnetic resonance imaging (MRI). • Be familiar with implant complications and new technology to minimize some complications<sup>3</sup>. • Be familiar with some key differences between updated FDA guidelines and the imaging recommendations from the American College of Radiology Appropriateness Criteria.

### TABLE OF CONTENTS/OUTLINE

• Discuss the changes in the 2022 FDA guidelines for breast implant screening, especially the addition of US as an alternative to MRI for initial imaging surveillance for silicone implant rupture in asymptomatic patients<sup>1-4</sup>. • Discuss the 2022 FDA guidelines recommendation for the first screening imaging test at 5 years after implantation instead of 2 years after implantation, the lack of

compliance from patients, and background behind this change<sup>1-5</sup>. • Discuss the potential controversies regarding the imaging modality of choice to evaluate for implant rupture via case-based presentation<sup>4</sup>. • Review the imaging signs of implant rupture on different modalities, focusing mainly on US and MRI. Review benefits and/or challenges of new implants, technology such as acellular dermal matrix (ADM), and new generation tissue expanders.

### **BREE-105    Abnormality of the Duct on Breast Ultrasound: Comparison with Multimodality, Correlation with Pathological Findings, and Assessment**

#### **TEACHING POINTS**

The 6th edition of BI-RADS is expected to include nonmass lesions detected on breast ultrasound. In breast imaging, it is important to comprehend lesions such as ductal carcinoma in situ which do not form masses but appear as abnormalities of the ducts. Ultrasound is the best imaging tool for a detailed evaluation of the ducts. Although definitions and terminology for ductal abnormalities may vary in the literature, there is a growing interest among Asian countries regarding ultrasound findings of ductal abnormalities. In this review, we present a method for detecting and evaluating ductal abnormalities based on a detailed comparison with pathological findings. To understand and organize the terminology found in various literature and guidelines, as well as the corresponding findings. To become familiar with normal anatomy and identify findings accurately. To compare expected findings in other modalities with pathological findings. To discuss evidence-based assessment and management plan for each finding.

#### **TABLE OF CONTENTS/OUTLINE**

Normal anatomy    Methods of detection    Terminology    Comparison with multimodality and correlation with pathological findings    Assessment and management plan of each pathological finding    Case studies    The included cases are as follows: Ultrasound findings    Ductal dilatation    Duct dilatation with internal echoes    Duct wall thickening    Irregularity of the ductal caliber    Pathological diagnoses    Duct ectasia    Fibrocystic change    Intraductal papilloma (IDP)    Atypical ductal hyperplasia    Ductal carcinoma in situ (DCIS)    Ductal carcinoma in situ with invasive component    Invasive ductal carcinoma (IDC)

### **BREE-106    A Review of Contrast-Enhanced Mammography in the Evaluation of Suspicious Breast Micro-Calcifications and Our Experience**

Participants

Félix Maimir Quadrado, MD, Madrid, Spain (*Presenter*)    Nothing to Disclose

#### **TEACHING POINTS**

- To outline a potential indication of contrast-enhanced mammography (CEM).- To review the contribution to date of CEM in the evaluation of suspicious breast microcalcifications.- To share and discuss our initial experience using CEM in the evaluation of suspicious breast microcalcifications and their histopathologic results.The interpretation and description of breast microcalcifications have always posed a great challenge to breast radiologists. Due to the intrinsic relation of microcalcifications with different breast lesions, and in the case of suspicious ones with breast carcinomas, CEM has been proposed as a promising technique because of its capability to assess neoangiogenesis. We present an up-to-date revision of CEM in the evaluation of suspicious breast microcalcifications and our center's initial experience.

#### **TABLE OF CONTENTS/OUTLINE**

- Introduction- False-positive cases- False-negative cases- What the recent literature tells us- Our experience

### **BREE-107    Diagnostic Approach and Assessment of Cystic Breast Lesion**

#### **TEACHING POINTS**

1. Cystic masses are common findings on mammography, ultrasonography, and MR imaging and a thorough understanding of their imaging findings and management is important.2. It is important to obtain US images with meticulous technique for accurate classification and assessment of cystic breast lesions. 3. Complex cystic and solid masses may have one or all of the following characteristics: a thick wall ( $\geq 0.5$  mm), thick internal septations, an intracystic mass, and both solid and cystic components. 4. Complex cystic and solid masses are usually assessed as suspicious (BI-RADS category 4) and accompanied by a recommendation for biopsy.

#### **TABLE OF CONTENTS/OUTLINE**

A. Definition of cystic breast lesions 1. Simple cyst 2. Complicated cyst 3. Clustered microcysts 4. Complex cystic and solid mass B. Meticulous technique in evaluating cystic breast lesions on US C. Multimodality imaging findings with important differential diagnosis 1. Simple or complicated cyst vs. Nearly anechoic solid mass on US 2. Inflamed or ruptured cyst vs. Rim enhancing mass on breast MRI D. Imaging-pathologic correlation of complex cystic and solid mass E. Diagnostic approach and BI-RADS assessment of cystic breast lesions F. Management of cystic breast lesions

### **BREE-108    Breast Malignancy: Beyond Breast Carcinoma**

Participants

Alex Gil Ordóñez, MD, Barcelona, Spain (*Presenter*)    Nothing to Disclose

#### **TEACHING POINTS**

- To provide the basis for recognizing morphological and functional imaging findings of non-epithelial and metastatic lesions of the breast (B5d, NHSBSP).- To review the most common B5d lesions through a pictorial review of our cases.- To describe the clinical management of B5d lesions and the role of the radiologist in these cases.

#### **TABLE OF CONTENTS/OUTLINE**

1.Introduction 1.1. NHSBSP classification. 2. B5d lesions through a pictorial review of our cases. 2.1. Metastatic disease. 2.2. Oncohematological disease. 2.3. Sarcomas 3. Imaging features 4. Management 5. ConclusionsThe vast majority of malignant breast neoplasms are breast carcinomas. Nevertheless, some malignant breast lesions present different histologies, which are commonly less suspicious than carcinomas on imaging techniques. Their recognition is essential to an early diagnosis and therapeutic approach.

## **BREE-109 Vague and Nebulous: Non-Mass Ultrasound Lesions**

### **TEACHING POINTS**

(1.) To review descriptors of ultrasound (US) non-mass lesions. (2.) To illustrate US non-mass lesions identified as correlates for breast MRI non-mass enhancement. (3.) To demonstrate methods for locating US non-mass lesions as correlates for breast MRI non-mass enhancement.

### **TABLE OF CONTENTS/OUTLINE**

Introduction: Ultrasound (US) correlates of MRI-detected non-mass enhancement (NME) may have no defined mass-like sonographic margin or shape, or may show subtle disruptions of the background tissue pattern. A new US lexicon term, non-mass lesion (NML), better describes these US findings. Cases: This educational exhibit will show 10 cases of US NML corresponding to MRI NME. We will highlight methods of predicting the US appearance and location of the NML on MRI-directed US by the use of breast architecture, surrounding cysts/masses, and use of the MRI appearance to predict the size and shape of the NML. Histopathologies include breast cancer, radial scar, sclerosing adenosis, fibrocystic change and fat necrosis. Conclusion: The exhibit illustrates subtle US NML correlates to MRI NME. Techniques for successful MRI-directed ultrasound detection of these findings are described. Once correlation is confirmed, US-guided biopsy, which is more expeditious than MRI-guided biopsy, can be performed.

## **BREE-11 Male Breast Lesions: To Infinity and Beyond**

Participants

Camila Guimaraes, PhD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Teaching Points: Male breast disease encompasses both benign and malignant conditions that are hormonally influenced. Gynecomastia and skin lesions are the most common conditions in symptomatic men, referred for a palpable mass, with imaging patterns that can correlate with different histopathological phases. Other benign tumors in male breasts include lipoma, pseudoangiomatous stromal hyperplasia, granular cell tumor, fibromatosis, myofibroblastoma, schwannoma, and hemangioma. The incidence of breast cancer in men is rare but has increased and accounts for 1% of all breast carcinomas, with invasive ductal carcinoma being the most common type in adult males. Other tumors that may occur include papillary carcinoma, invasive lobular carcinoma, adenoid cystic carcinoma, liposarcoma, dermatofibrosarcoma, pleomorphic hyalinizing angiectatic tumor, basal cell carcinoma of the nipple, hematopoietic malignancies, and secondary tumors. Understanding the clinical and imaging characteristics of these tumors is important for their accurate diagnosis and optimal treatment.

### **TABLE OF CONTENTS/OUTLINE**

Table of Contents/Outline: This article examines the clinical, radiological, and pathological characteristics of both benign and malignant tumors of the male breast. Cases of male breast disease were selected from the file of the Breast Radiology group of our hospital showing some of these pathologies: 1. Complicated Cyst; 2. Dermoid Cyst; 3. Myxoid Liposarcoma; 4. Hybernoma.

## **BREE-110 From Words to Images: Applying the Contrast Enhanced Mammography BI-RADS® Lexicon**

Participants

Mitva J. Patel, MD, Columbus, OH (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

The American College of Radiology Breast Imaging Reporting and Data System (ACR BI-RADS®) lexicon is widely used in clinical practice and is a standardized nomenclature used for mammographic reporting. Recently, an extension of the lexicon was developed for the interpretation and reporting of contrast-enhanced mammography (CEM) findings. Adopting the American College of Radiology (ACR) Contrast Enhanced Mammography (CEM) Lexicon is important as standardization reduces inter-observer variability and improves the accuracy and reliability of diagnostic reporting, which ultimately leads to better patient outcomes. Education on this new topic is essential as adoption of the lexicon is critical to assist standardize reporting, improve patient care, and facilitate communication between radiologists and clinicians.

### **TABLE OF CONTENTS/OUTLINE**

I. CEM Lexicon classification for recombined images? A. Background parenchymal enhancement? 1. Level? 2. Symmetry? B. Lesion conspicuity? C. Masses? - Internal enhancement characteristics? D. Non-mass enhancement? - Distribution? E. Enhancing asymmetry? II. Interpretation? A. Findings on low energy images only? B. Areas of enhancement seen on recombined images only? C. Low energy images with associated enhancement on recombined images

## **BREE-111 The Power of Contrast: Contrast Enhanced Mammography in the Diagnostic Clinic**

Participants

Mitva J. Patel, MD, Columbus, OH (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

We hope that by highlighting the practical uses of CEM and its potential to enhance breast cancer detection in the diagnostic clinic, more practices will embrace this powerful technology. Contrast enhanced mammography (CEM) is an imaging technique that combines standard mammography with iodinated contrast to improve breast cancer detection. By highlighting areas of increased vascularity associated with malignancy, CEM has been shown to improve the sensitivity of mammography, particularly in women with dense breast tissue. Despite these well-known benefits, the adoption of CEM in clinical practice has been slow, owing primarily to the difficulties establishing a CEM program and reimbursement. Despite these challenges, we believe the benefits it brings to the diagnostic clinic outweigh the additional effort. CEM may be used to: - resolve equivocal findings on mammography, and to increase confidence prior to stereotactic biopsy for vague areas of architectural distortion. - as a more efficient, accessible alternative to MRI in pre-operative extent of disease and workup of highly suspicious findings identified on screening mammography. We hope that by highlighting the practical uses of CEM and its potential to enhance breast cancer detection in the diagnostic clinic, more practices will embrace this powerful technology.

### **TABLE OF CONTENTS/OUTLINE**

Examples provided will demonstrate how CEM impacted these patients' management and supports the notion that CEM has a place

in the diagnostic clinic as a cost-effective and time-efficient alternative to breast magnetic resonance imaging (MRI) for select patients.

### **BREE-112 Common Enough to Care - Young Women with Breast Cancer: Multidisciplinary Approach and Special Considerations**

#### **TEACHING POINTS**

Breast cancer in young women, widely accepted as women under 40 years of age, has a worse prognosis compared to older patients as young age is an independent predictor of adverse breast-cancer specific outcomes, including morbidity, local and systemic recurrence, and death. Historically, young women have been underrepresented in clinical trials and undergo more aggressive therapy solely based on their young age. As it is important to recognize how these women differ from older patients, the teaching points of this presentation are to: 1. Describe the epidemiology, clinical presentation, and tumor biology of young women with breast cancer. 2. Define imaging guidelines in high-risk populations and in young women after diagnosis of breast cancer. 3. Explain surgical management and surgical risk reducing strategies. 4. Highlight the special considerations unique to young women including the effects of oncology treatment on fertility and lactation and describe fertility preservation techniques.

#### **TABLE OF CONTENTS/OUTLINE**

1. Appearance of breast cancer in young women: Epidemiology and clinical presentation, Tumor biology; 2. Imaging guidelines: Risk factors and assessment, Genetics based or calculated lifetime risk, Diagnosis and staging; 3. Surgical management: Breast conserving vs. mastectomy, Cosmetic options, Risk reducing strategies; 4. Effects of oncology treatment on fertility: Chemotherapy, Hormone therapy; 5. Fertility Preservation Techniques

### **BREE-113 Breast US: A Guide for Beginners**

Participants

Erica E. Francolin Federicci, PhD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Ultrasonographic characterization of mammographic abnormalities and palpable lesions is indicated in the evaluation and management of breast diseases. Although in the United States breast ultrasounds (US) are performed by sonographers, in many countries it is performed by physicians. Considering that breast screening US as an adjunct to mammography will be more widely practiced in the United States, the Breast Imaging-Reporting and Data System (BI-RADS®) provides training and performance guidance as set forth in ACRIN 6666. Because the effective use of the US lexicon relies on excellent sonographic technique and understanding of breast anatomy, the objective of this presentation is to didactically illustrate how the BI-RADS® recommendations should be followed, including the most common findings, pitfalls and how to avoid them.

#### **TABLE OF CONTENTS/OUTLINE**

We used ultrasonographic images (in correlation to mammography and magnetic resonance imaging, when appropriate) from our institution's digital archive, in order to provide a case-based didactic review of the most common findings in breast ultrasounds, including a review of the adequate technical parameters, lexicon and reporting system and tips to avoid common pitfalls, based on the BI-RADS® recommendations.

### **BREE-114 Pseudo-progression During Immunotherapy: A New Challenge for Breast Radiologists**

#### **TEACHING POINTS**

Immunotherapy has emerged as a promising treatment strategy for advanced breast tumors. Immune checkpoint inhibitors (ICI) such as blockades that target programmed death-1 (PD-1), programmed death-ligand 1 (PD-L1) and cytotoxic T-lymphocyte associated antigen (CTLA-4), are one of the most powerful tools in the immunotherapy armamentarium and offer a beneficial immunotherapeutic regimen for patients with breast cancer. The pattern of treatment with immunotherapy is totally different from other therapeutic modalities, thus bringing major challenges to clinicians and radiologists who are not familiar with it. One of these challenges is pseudoprogression, that can be characterized as a transient increase of tumor burden followed by tumor regression. Although rare, it is fundamental for the radiologist to be aware of this condition and to carry out studies in the direction of finding diagnostic tools that are capable of more accurately identify this phenomenon contributing for better patient outcomes. In this didactic exhibit, we will discuss the basis of immunotherapy in breast cancer, demonstrate imaging findings of cases of breast cancer pseudoprogression and discuss the current tools available to identify the possibility of this condition such as biomarkers, imaging techniques and biopsy.

#### **TABLE OF CONTENTS/OUTLINE**

1) Basis of immunotherapy 2) Definition of pseudoprogression 3) Tools used to identify pseudoprogression 3.1) Biomarkers 3.2) Medical imaging 3.3) Biopsy 4) Cases of breast cancer pseudoprogression

### **BREE-115 Contrast-enhanced Mammography in Breast Cancers for Women with Dense Breasts: Accuracy, Value, Controversies and Solutions**

Participants

Bingmei Zhang, Ankang, China (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

The purpose of this exhibit is: 1. To familiarize the reader to what CESM implies as an emerging modality and its implementation for breast imaging. 2. To demonstrate diagnostic accuracy and correlation in lesion size estimation of CEM against DCE-MRI in dense breast patients. 3. To illustrate value of CEM in evaluating BI-RADS 4 microcalcifications including morphology, distribution and neovascularity of microcalcifications. 4. To discuss whether CEM can be an effective imaging tool in pre-surgical planning for women with dense breast parenchyma. 5. To highlight the benefits and deficits of CEM in women with dense breast who are at an increased risk of developing breast cancer.

#### **TABLE OF CONTENTS/OUTLINE**

1. Brief overview about the different approaches in CEM and their features in imaging interpretation (temporal subtraction and dual

energy technique). 2. Cancer evaluation in the dense breast and review of cases, comparing CESM with MRI in the assessment of disease extent in breast carcinomas. 3. Practical application of CEM with illustrated clinical examples in evaluating BI-RADS 4 microcalcifications in dense breast. 4. Is CESM adequate and accurate in pre-surgical planning for women with dense breast. 5. Advantages vs. drawbacks of CEM and potential pitfalls elucidation for high risk screening for women in dense breast. 6. The future applications of CEM in breast evaluation.

### **BREE-116 Preoperative Wire and Wireless Localizations Gone Wrong: How to Get Out of Trouble**

Participants

Sheila Enamandram, MD, MBA, Stanford, CA (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Accurate, thoughtful planning of preoperative image-guided wire or wireless localizations is critical for breast conservation surgery, especially in complex imaging scenarios. Target lesion visualization and localization may require more than one imaging modality and/or a non-routine approach for difficult marker/target localizations. Understanding the differences in size, appearance, and deployment techniques of localization devices is important in accurate placement and retrieval. Targeted markers may be found in unexpected places when not seen in the initial specimen radiograph. Clear communication with surgical colleagues is paramount.

#### **TABLE OF CONTENTS/OUTLINE**

This case-based exhibit will highlight anatomic, procedural, and technical troubleshooting steps in the following scenarios: Biopsy marker, wire, or wireless device migration; Biopsy marker non-visualization; Target not marked at time of initial biopsy; Target obscured or visible on only one imaging modality; Wireless radar reflector malfunction; Alternative imaging modalities needed for localization; Biopsy marker not seen in the specimen and ultimately found in unexpected places; Incomplete retrieval of distal hook wire in the specimen.

### **BREE-12 Nipple Discharge: In the Era of Multimodality Imaging**

#### **TEACHING POINTS**

TEACHING POINTS 1. To remind the different etiologies responsible for nipple discharge 2. To recognize the worrisome signs of a nipple discharge that must lead to further investigation 3. To discuss imaging modalities and management

#### **TABLE OF CONTENTS/OUTLINE**

TABLE OF CONTENTS 1. Clinical history and physical examination 2. Etiologies responsible for nipple discharge a. Extra-mammary causes :- Hyperprolactinemia- Drugs- Others b. Breast lesions :- Benign lesions (infections, galactophoritis, papillomas)- Malignant lesions (intra-ductal, inflammatory) 3. Multimodality imaging approach a. Gold standard of initial evaluation of nipple discharge- Mammography + Ultrasound b. Second level of investigation :- The role of MRI and contrast-enhanced mammography 4. Diagnosis a. Cytology of the nipple discharge b. US guided microbiopsy c. MRI guided core biopsy d. Emerging role of contrast-enhanced guided core biopsy 5. Patient management flowchart a. Follow-up, what? When? b. US guided macrobiopsy, when? c. Surgery

### **BREE-13 Staying Vigilant: Imaging Surveillance and Risk Prediction After Breast Cancer**

Participants

Beatriu Reig, MD, MPH, New York, NY (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Patients with a personal history of breast cancer have 5-20% recurrence rates and are at increased risk of second breast cancers. 2. Risk factors for recurrent or second breast cancer include dense breasts, young age at diagnosis of the first breast cancer, omission of radiation after breast conserving therapy, and hormone receptor negative first breast cancer. 3. Imaging biomarkers such as background parenchymal enhancement are under investigation and may permit personalized risk prediction and guide surveillance recommendations in the future.

#### **TABLE OF CONTENTS/OUTLINE**

1) Introduction (definition, statistics, localized vs metastatic recurrence, early vs late recurrence) 2) Risk factors for recurrence a) Association of molecular subtypes with risk for recurrence b) Effect of neoadjuvant chemotherapy c) Modifiable risk factors (aromatase inhibitor or tamoxifen after ER+ cancer, alcohol consumption, weight) 3) Screening methods for recurrence a) Mammography b) Ultrasound i) Inclusion of the axilla c) MRI i) Abbreviated vs full-protocol d) Contrast-enhanced mammography 4) What should be the imaging interval? 5) Post-mastectomy imaging 6) Risk models for individualized screening a) Clinicopathologic factors b) Imaging biomarkers c) Radiomics and artificial intelligence models

### **BREE-14 Breast Cancer or Not? An Interactive Case-Based Review of FDG-PET/CT Positive Findings in the Breast**

Participants

Emily Yoon, MD, Mineola, NY (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Background Interpretation of lesions with increased FDG uptake in the breast can be challenging due to nonspecific uptake in various benign and malignant processes involving the breasts. Knowledge of this wide spectrum is essential for accurate analysis of FDG-PET/CT in conjunction with a patient's symptomatology. The purpose of this educational exhibit is to illustrate the multi-modality imaging appearance of various benign and malignant processes that demonstrate hypermetabolic activity within the breast on FDG-PET/CT. Teaching Points Differentiate various benign and malignant processes that can result in hypermetabolic lesions in the breast Understand sensitivity and specificity of FDG-PET/CT for breast cancer and metastatic breast lymphadenopathy Conclusion There is a wide range of benign and malignant conditions presenting as hypermetabolic breast lesions on FDG-PET/CT. Knowledge of the various imaging features is important for accurate diagnosis and patient management.

#### **TABLE OF CONTENTS/OUTLINE**

This presentation will be case-based with review of clinical history and imaging findings (mammogram, US, MRI, PET/CT) of patients with FDG-PET positive findings in the breast. Several benign and malignant pathologies will be reviewed, as outlined below.

Teaching points with recent literature review will provide guidance when non-breast cancer pathology should be suspected in cases, while also highlighted when additional dedicated breast imaging is indicated. Breast implant capsule-associated squamous cell carcinoma Reactive lymphadenopathy Metastatic disease Granulomatous mastitis Fat necrosis Inflammatory breast cancer Gynecomastia Infectious/Inflammatory changes

### **BREE-15 The Role of DBT-Guided Biopsy for MRI/CEM Detected Lesions**

Participants

Cesar Urtasun Iriarte I, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

To emphasize the need to correlate MRI/Contrast Enhanced Mammography (CEM) findings with DBT (Digital breast tomosynthesis). To show the advantages of DBT-guided biopsy compared to MRI-guided biopsy. To consider DBT-guided biopsy as an alternative for CEM-detected lesions.

#### **TABLE OF CONTENTS/OUTLINE**

INTRODUCTION: Both MRI and CEM are morphofunctional imaging techniques based on neoangiogenesis. These techniques are more sensitive than pure morphological techniques, such as DM or DBT. ASSESSMENT OF MASS ENHANCEMENTS: Second look US is of choice to evaluate these lesions. ASSESSMENT OF NON-MASS ENHANCEMENTS: These lesions are challenging. Although US plays an important role, in many cases it is inconclusive. DBT correlation is very important, specifically using the craneocaudal (CC) view. This view is easy to compare anatomical structures with both MRI (axial) and CEM. DBT GUIDED BIOPSY: This technique offers several advantages over MRI or CEM guided biopsies: Less time consuming, widely spread technique. Not all the vendors have dedicated units to perform CEM guided biopsies. Once the lesion is located with DBT, the performance of the biopsy is easy. Usually 10G vacuum assisted biopsy devices are used. CONCLUSION: DBT guided biopsy can offer a good alternative for MRI/CEM detected lesions, specially for non-mass enhancements.

### **BREE-16 Male Breast: Common and Rare Conditions**

Participants

Carla Sitges, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Teaching Points: To describe the spectrum of imaging features of benign and malignant lesions of the male breast from a review of pathologically-proved cases. To correlate imaging and pathological findings. To discuss the appropriate imaging workup of male breast cancer.

#### **TABLE OF CONTENTS/OUTLINE**

Introduction Gynecomastia Benign lesions Imaging features on mammography, ultrasound and MRI. Radiologic-pathologic correlation. Malignant lesions Imaging features on mammography, ultrasound and MRI. Radiologic-pathologic correlation. Conclusions

### **BREE-17 Breast Ductal Disease: Multimodality Imaging Detection and Assessment**

#### **TEACHING POINTS**

Review normal ductal anatomy and its imaging features. Review the broad differential of benign and malignant ductal diseases, particularly in the setting of a single dilated duct. Recognize imaging abnormalities of ductal diseases and features associated with malignancy on DBT, US, and MRI. Describe appropriate diagnostic workups and management of ductal diseases.

#### **TABLE OF CONTENTS/OUTLINE**

Breast ductal disease is an important aspect of breast imaging and often poses challenges in diagnosis and management, particularly in the setting of a single dilated duct. Thus, radiologists should be familiar with clinical presentations, diagnostic workup, imaging features, and differentials for ductal abnormalities. Patients may present with nipple discharge, palpable abnormalities, infectious symptoms, lactational issues, or be asymptomatic. Ductal pathologies range from ductal ectasia, periductal mastitis, intraductal papillomas, to ductal carcinoma in situ, invasive ductal carcinoma, and Paget's disease. Radiologists should recognize both normal and abnormal ductal imaging features on DBT (dilated ducts, masses, and/or calcifications), on US (cystic ductal dilation, ductal wall irregularities or arborization, intraductal masses or debris), and on MRI (clustered ring non-mass enhancement, abnormal linear or segmental NME). This educational exhibit will provide a comprehensive case-based review of benign and malignant ductal diseases, their multimodality imaging features, and associated management recommendations.

### **BREE-18 Breast Surgery: Changes and Findings Multimodal Diagnosis**

Participants

Maria Jose Chico, Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Identify the different post-surgical changes of breast surgery. 2. Learn to identify which findings are suspicious and which are not. 3. Understand and integrate the findings in the different imaging modalities. 4. Understand the differential diagnoses

#### **TABLE OF CONTENTS/OUTLINE**

The accurate interpretation of images of the postsurgical breast depends on the availability of high-quality imaging. These changes should be interpreted in conjunction with the clinical and surgical history. They may correspond to benign or suspected changes. It is useful to analyze them in the different imaging modalities to support or rule out a suspected diagnosis. They can appear in the post-surgical period due to both malignant and benign conditions

### **BREE-19 Beyond the Lump: Navigating the Challenges of Cystic Breast Lesions**

Participants

Maria Vitoria Ludwig, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Our educational exhibit is directed to review the assessment and management of cystic breast lesions through the following points: review the pathologies presented as cystic breast lesions; understand how to identify and categorize breast cysts at ultrasonography; comprehend the appropriate management according to the imaging finding, correlating with clinical history and other imaging modalities if available; enlighten biopsy modalities, indication and technique; recognize the importance of subsequent histological analysis.

## TABLE OF CONTENTS/OUTLINE

The subject will be approached in the following sequence: pathologies presented as cystic breast lesions and their malignancy risk; diagnosis, initial evaluation and ultrasound classification of breast cysts, linked with drawing representations of each type of cyst; appropriate risk assessment and management according to the imaging finding considering correlation with clinical history and other imaging modalities, namely mammography and magnetic resonance imaging; how to choose the most suitable biopsy modality and possible pitfalls; correlation of radiological findings with histopathologic analysis, followed by revision of management if required; illustrative cases in the different imaging methods.

## BREE-2 Lipofilling: What Does Breast Radiology Need to Know?

Participants

Karen Caro, PhD, CABA, Argentina (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1.- Describe the imaging characteristics of the lesions in lipofilling  
2.- When should we consider that a lesion after a lipofilling procedure would need histological certification, in relation to the imaging findings?

## TABLE OF CONTENTS/OUTLINE

Currently fat transfer (lipofilling) is used in breast reconstruction. In this paper we will describe its advantages and how it is seen in the different imaging studies (ultrasound, mammography and MRI). It is important to identify which are the usual benign findings in the different methods and what Bi-Rads to assign, in this way we can define those cases in which their histological evaluation should be considered. Describe the advantages and disadvantages of this method in breast remodeling. The importance of recognizing radiological manifestations and the difficulties involved in detecting suspicious lesions. Knowing how to recognize that fat necrosis is a frequent lesion after lipofilling, which should be suspected in order to avoid other more complex studies such as MRI and even biopsies

## BREE-20 Not Every Ductal Ectasia Is Evil: Spectrum of Ductal Lesions

Participants

Raissa Soares, MD, Sao Luis, Brazil (*Presenter*) Nothing to Disclose

## TEACHING POINTS

To review the imaging appearance of normal ductal anatomy; Illustrate imaging findings of ductal ectasias using different techniques, including mammography, ultrasound and magnetic resonance imaging, providing clinical images and histopathology correlation; To discuss the appropriate management of these lesions; Review a case series of benign ductal breast diagnoses from our institute, without associated malignancy;

## TABLE OF CONTENTS/OUTLINE

Identify imaging criteria that may help in the diagnosis of ductal ectasia and, eventually, in its management; Typical multimodality imaging findings (magnetic resonance imaging, ultrasound and mammography) from cases of our radiology department; Diagnostic challenges, main differentials, and key points suspicion of this pathology; Discuss the role of percutaneous biopsy (ultrasound-guided core biopsy and vacuum - assisted biopsy) in the diagnosis of ductal ectasias; Conclusion.

## BREE-21 Understanding the BI-RADS 3 Category

## TEACHING POINTS

By the end of this educational exhibit, learners will: 1. Accurately define BI-RADS 3 and appropriate use cases. 2. Explain BI-RADS 3 radiographic features and diagnostic considerations for mammography, ultrasound, and MRI. 3. Demonstrate proficiency in the assessment process of a BI-RADS 3 lesions, through a case-based review.

## TABLE OF CONTENTS/OUTLINE

1. What is BI-RADS 3? a. Definition b. Appropriate use cases  
2. BI-RADS 3: Mammography a. Imaging features b. Diagnostic considerations  
3. BI-RADS 3: Ultrasound a. Imaging features b. Diagnostic considerations  
4. BI-RADS 3: MRI a. Imaging features b. Diagnostic considerations  
5. Identifying BI-RADS 3 Lesions: Case-Based Walkthrough a. Classic BI-RADS 3 cases b. Special cases

## BREE-22 Back to the Tumor: Navigating Breast Cancer Recurrence Like a Pro

Participants

Vitor Zanetta, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Review the risk and pattern of tumor recurrence according to molecular subtype Provide visual and data-driven insights into expected imaging changes following treatment. Highlight the role that multimodality plays in differentiating expected imaging findings from treatment and imaging findings indicative of recurrence or new breast cancer. Review current follow-up protocols after breast cancer and screening for intermediate risk patients.

## TABLE OF CONTENTS/OUTLINE

Review the influence of breast cancer subtype on the rate, timing and location of tumor recurrence. Expected imaging changes following treatment with visual and data-driven insights: Expected timeline of post-surgical changes. Details in the assessment of local recurrence in breast-conserving surgery and mastectomy. Possible changes in axillary and internal mammary lymph nodes. The

role that multimodality imaging (mammogram, ultrasound, MRI and PET-CT) plays in differentiating recurrence or new breast cancer from post-treatment changes, including: Frequent dilemmas in clinical practice: evaluation of calcifications, distortions, fat necrosis and enhancements in the surgical bed. How to deal with conflicting findings between different imaging methods to avoid unnecessary biopsies without losing sensitivity for early recognition of recurrence. Subtle recurrence and the importance of serial follow-up imaging. Examine the follow-up protocols after breast cancer and screening for intermediate-risk patients from the perspective of personalized medicine.

### **BREE-23 From Flat to Fabulous - A Radiological Guide to Breast Aesthetic Fillers and Biostimulators**

Participants

Heni Skaf, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

To expose, through cases from our institution, manifestations of different breast filling and biostimulator materials in the most diverse imaging methods, such as: free silicone, acrylates (PMMA, PAAG), hyaluronic acid, vitamin D, calcium hydroxyapatite and fat grafting. To familiarize the breast radiologist with the radiological presentation of these materials, avoiding false positives and unnecessary investigations. To discuss the usual topography in which they are injected, as well as possible local and systemic complications of using such materials.

#### **TABLE OF CONTENTS/OUTLINE**

Introduction: The demand for percutaneous aesthetic procedures is rising in medicine, especially in the context of facial harmonization. This also applies to the breast, both for use in cancer patients, with the increase in the incidence and in diagnosis of breast cancer, as well as for purely aesthetic purposes in the breast itself or even due to migration from other injection sites. Imaging findings: on mammography, ultrasonography and magnetic resonance as well as possible complications and usual injection sites of free silicone, acrylates (PMMA, PAAG), hyaluronic acid, vitamin D, calcium hydroxyapatite and fat grafting. For the most part, non-resorbable synthetic biomaterials, fat grafting, as well as resorbable materials used recently, have radiologic representation. Conclusion: The use of aesthetic breast fillers, whether in the oncological context or not, is on the rise. Often, the patient does not have knowledge of what was used, which can limit the clinical decision of the physician. Additionally, recognition of the radiological appearance of different fillers can avoid false positives and unnecessary biopsies.

### **BREE-24 Far Beyond The Axilla, What Else do We Need to See? Tips and Pitfalls of Lymph Nodes**

Participants

Raissa Soares, MD, Sao Luis, Brazil (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Aspects of normal images of axillary and supraclavicular lymph nodes and internal mammary in different methods and mainly in ultrasound; To present imaging cases of normal lymph nodes, as well as differential diagnoses of axillary, supraclavicular and internal mammary lymph node enlargement, from our database; Image-guided procedures; Show the importance of the radiological-pathological correlation.

#### **TABLE OF CONTENTS/OUTLINE**

Review the main spots of mammary drainage; To show imaging cases of normal findings and our histological correlation; To present some differential cases of lymph node pathologies; Discuss the types of lesions and which ones require biopsy; Conclusion.

### **BREE-25 Axillary Lymphadenopathy Induced by COVID-19 Vaccination: What Have We Learned?**

Participants

Miguel Barrio Piqueras I, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- US features of reactive lymph nodes after COVID-19 vaccination in patients with and without previous COVID-19 infection- Nodal reactivity in young and middle-age patients vaccinated with different COVID-19 vaccine protocols- Association between the cortical thickness measurement of reactive post-vaccine lymphadenopathy and an effective humoral response in COVID-19-naïve patients

#### **TABLE OF CONTENTS/OUTLINE**

The COVID-19 pandemic led to the approval of an emerging vaccination program to contain coronavirus dissemination. One of the most commonly reported local side effects of COVID-19 vaccination has been the development of axillary lymphadenopathy. In this poster, we will discuss about this phenomenon: 1. Which ultrasound features should be evaluated? 2. Does nodal response differ if there exists a prior history of COVID-19 infection? 3. Do the ultrasound characteristics of reactive axillary nodes change depending on the administered COVID-19 vaccination? 4. What is the nodal reactivity to the COVID vaccination according to age? 5. How long does reactive lymphadenopathy last? 6. Does cortical thickness of reactive post-vaccine lymph nodes reflect a humoral response? Conclusions- Reactive lymphadenopathy is a common side effect of COVID-19 vaccination- It is generally a harmless and temporary condition- Healthcare providers should be aware of this potential phenomenon to provide an appropriate guidance to patients

### **BREE-26 Cystic Carcinomas: Preventing Misdiagnosis and Lessons Learned**

Participants

Hemal Grover, MD, New York, NY (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Simple cysts: well circumscribed isodense masses on mammogram; well circumscribed anechoic masses on ultrasound with a thin, smooth, imperceptible wall and posterior acoustic enhancement. Complicated cysts meet all criteria for simple cysts except they contain debris/echogenic intracystic contents. Necrotic tumors (rapidly growing) can present as cystic masses. They can be anechoic, demonstrate posterior acoustic enhancement and therefore often misdiagnosed as simple or complicated cysts. However, careful evaluation of the margins is imperative as it can reveal subtle irregularity and raise suspicion for malignancy. Correlation with mammogram (particularly spot compression views) can be helpful to reveal obscured or irregular margins. Cystic carcinomas often

present as palpable masses. These cases should be viewed with a higher index of suspicion before being labeled as BIRADS 2. Real time physician directed ultrasound is recommended along with a bilateral mammogram with spot compression views (including in women 30-35 years old). Family history, genetic mutations and ancestry (eg Ashkenazi Jewish descent) should be considered while evaluating these patients.

#### **TABLE OF CONTENTS/OUTLINE**

Imaging features of simple, complicated and complex cysts. Classification of complex cysts. Clinical history, diagnostic mammogram, ultrasound and MRI findings of authors' cases of cystic carcinomas. Errors of interpretation/misdiagnosis and lessons learnt. Differential Diagnoses.

#### **BREE-27 Granulomatous Mastitis: Imaging Insights into a Benign Mimicker of Breast Infection and Malignancy**

Participants

Sravani Gampala, MD, Syracuse, NY (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Understand the etiology and clinical presentation of granulomatous mastitis. 2. Recognize the imaging findings of granulomatous mastitis across mammography, ultrasound, and MRI. 3. Appreciate the importance of correlating imaging findings with the clinical picture. 4. Acknowledge the consequences of misdiagnosing granulomatous mastitis. 5. Emphasize the role of radiologists in considering granulomatous mastitis as a differential diagnosis. 6. Discuss the importance of a multidisciplinary approach in the accurate diagnosis of granulomatous mastitis.

#### **TABLE OF CONTENTS/OUTLINE**

I. Introduction to Granulomatous Mastitis A. Etiology B. Clinical presentation II. Imaging Modalities A. Mammography 1. Findings 2. Differential diagnosis B. Ultrasound 1. Findings 2. Differential diagnosis C. MRI 1. Findings 2. Differential diagnosis III. Consequences of Misdiagnosis A. Unnecessary studies B. Patient anxiety C. Invasive procedures IV. Radiologist's Role in Diagnosis A. Considering granulomatous mastitis B. Biopsy and pathological challenges V. Multidisciplinary Approach A. Collaboration in diagnosis B. Improved diagnostic accuracy.

#### **BREE-28 More Than Just a Pretty Cyst - Assessment and Management of Cystic Breast Lesions**

Participants

Vivian Ogata, MD, (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- To discuss the ultrasound imaging parameters, from B-mode adjustments, Doppler imaging, to post-processing techniques, to properly evaluate cystic breast lesions.- To present the imaging findings of the listed cystic lesions according to the BI-RADS® lexicon such as: simple cyst, complicated cyst, clustered microcysts and complex solid and cystic masses, illustrating with multimodality imaging.- To discuss each subcategory of cystic lesions, its management and follow-up, illustrating with some challenging radiologic cases.- To habituate general radiologists with these findings in order to improve the diagnostic rate of such mammary lesions, reducing unnecessary biopsies.

#### **TABLE OF CONTENTS/OUTLINE**

- Introduction and epidemiology: breast cystic lesions are a common diagnosis in women and include a wide spectrum of diseases, from a simple apocrine cyst to complex solid cystic carcinomas.- Scanning techniques, ultrasound adjustment, artifacts and post-processing imaging: adjustment of ultrasonographic basic parameters and adequate scanning techniques are essential for an accurate diagnosis. We can also employ Doppler, elastography, as well as use imaging artifacts to our advantage, patient's position changes more recent post-processing techniques (harmonic and spatial compounding imaging) to better characterize cystic lesions.- Cystic lesions subcategories, classification, histological representation and multimodality imaging depiction.- Management and follow-up: adequate ACR BI-RADS® categorization of each subtype of cystic lesion, illustrating with some challenging cases, exploring some related pitfalls and discussing benign and malignant differential diagnosis.

#### **BREE-29 Can Aesthetic Procedures Interfere With Breast Cancer Screening?**

Participants

Leticia Oliveira, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

The incidence of dermatological procedures to modify aesthetics in body contouring, including post-surgical reconstructions, has been increasing every year, especially minimally invasive ones with injectables. Recognizing the imaging findings provoked by these procedures will avoid possible diagnostic pitfalls and allow the radiologist to alert the dermatologist about the possible loss of breast cancer screening caused by some of these previously unregistered procedures. Further, patients should be educated about the hazards associated with improper use of injectables from non-licensed individuals. Patients must be encouraged to seek out licensed physicians who use FDA-approved products for any medical and cosmetic care.

#### **TABLE OF CONTENTS/OUTLINE**

To review literature data on aesthetic dermatological procedures in the breast and axillary region, with cases from our institution, and illustrate with imaging findings found, based on different imaging methods

#### **BREE-3 It's Not the Same As It Was: Multimodal Review of Breast Cancer Recurrence and What the Radiologist Needs to Know**

Participants

Leticia Oliveira, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- Breast cancer is the most common cancer in the female population worldwide and the number of patients underwent conservative surgery is growing; - The annual risk of recurrence disease varies between 2 to 5% in 5-20 years after diagnosis; - Locoregional

recurrence is defined as the detection of lesions in the ipsilateral breast, chest wall or regional lymph node. If the other parts of the body are affected, it becomes a systemic recurrence; - Some factors related to breast cancer recurrence include failure in the first treatment and non-adherence to adjuvant therapy and surgical margins, but could be related to tumor size, aggressive biology of the primary tumor, young patient age at diagnosis and presence of familial or genetic risk factors; - Tumor recurrence may or may not be similar to the primary malignancy and can simulate benign conditions; - Imaging recurrence are variable and this knowledge becomes essential in radiological practice in order to improve the diagnosis and management of the patient.

#### TABLE OF CONTENTS/OUTLINE

- To review the factors associated to breast cancer recurrence and the epidemiology of these cases; - To show the most common findings in breast cancer recurrence using cases of our institution; - To teach how to evaluate the different methods of imaging (mammogram, ultrasound and MRI) in these cases and give tips that may help to differentiate sequelae of treatment from suspect lesion; - Easy-to-use take home messages to facilitate the handling of challenging cases.

#### BREE-30 Demystifying Gynecomastia: A Pictorial Review

Participants

Rocio Cortes Quezada, MEd, Tlalpan, Mexico (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

\*Most male breast masses are benign and the most common reason is gynecomastia. \*Forms of breast imaging in male patients are used for diagnostic purposes. \*Pseudogynecomastia and cancer are the most common differential diagnoses. \*Mammography can show increased glandular tissue and ductal dilatation in cases of gynecomastia. Masses, calcifications or signs suggestive of malignancy can also be visualized. \*Ultrasound can help distinguish true gynecomastia from pseudogynecomastia (accumulation of fatty tissue in the breast region). \* Biopsy is the only method to determine if a breast mass in a man is benign or malignant. • \*Biopsy can be guided by ultrasound or mammography

#### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Definition 3. Epidemiology 4. Clinical presentation 5. Etiology 6. Anatomy and embryology of the male breast 7.Types of gynecomastia 8. Imaging tests of the male breast 9. Imaging findings (mammography, ultrasound) 10. Differential diagnoses 11. Cases: a. Pseudogynecomastia. b. Lipoma. c. Epidermal inclusion cyst of the breast. d. Duct ectasia. e. Fat necrosis f. Invasive ductal carcinoma 12. Conclusions

#### BREE-31 Breast Cancer Surveillance in Patients with Prior History of Breast Cancer: Updates and Controversies

Participants

Sona Chikarmane, MD, Newtonville, MA (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Patients with a prior history of breast cancer (PHBC) are at increased risk of recurrent or second breast cancers. PHBC are also living longer due to improved screening and advances in treatment. Developing optimal screening regimens are critical in detecting breast cancers in these high-risk patients. Expected post-treatment changes include architectural distortion, edema, and skin thickening, which stabilize around two years post-treatment. Multimodality breast imaging surveillance is available, with screening mammography (full field digital mammography or digital breast tomosynthesis), whole breast ultrasound, contrast-enhanced mammography, and breast MRI. The purpose of this educational exhibit will be to review breast cancer surveillance in PHBC, highlighting updates and controversies in screening guidelines.

#### TABLE OF CONTENTS/OUTLINE

1. Review literature on risk of recurrent/second breast cancers in PHBC 2. Discuss optimal mammography screening regimens, including screening vs diagnostic mammography, cadence of screening, and batch vs immediate interpretation. 3. Review the current societal screening guidelines, including mammography and breast MRI. 4. Show multi-modality image-rich cases of recurrent breast cancer versus expected post-treatment changes. 5. Highlight controversies in breast cancer screening guidelines, including age when to stop screening, imaging the reconstructed breast, and compliance with screening.

#### BREE-32 Tales from the Breast: When Breast Problems Have Surprising Origins

Participants

Natalia Lima, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Diseases that affect the breast, but do not originate from it, may include systemic, autoimmune, infectious or even tumoral conditions from other sites. They can cause inflammation in the breast tissue and manifest with pain, skin thickening, ulcerations and masses. It is essential to know each one of them to help the clinical practice of differentiating breast carcinoma from these pathologies.

#### TABLE OF CONTENTS/OUTLINE

Illustrated didactic cases from our Breast Radiology group showing some diseases and their presentation forms that can simulate breast carcinoma. They were classified into subgroups such as: 1. Related to the vasculonervous system (MAV and neurofibromatosis), 2. Systemic disorders (cutaneous lymphoma and congestive heart failure), 3. Metastasis to the breast (melanoma and adrenal cortical carcinoma), 4. Soft Tissue tumors (granular cell tumor and synovial sarcoma), 5. Infectious (tuberculosis and dermatobiosis).

#### BREE-33 Spectrum of Papillary Lesions of the Breast: Multimodality Imaging and Radiologic-Pathologic Correlation

Participants

Janice Thai, MD, Boston, MA (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Papillary lesions represent a heterogeneous group of entities with histologic continuum from benign, atypical to invasive and non

1. Papillary lesions represent a heterogeneous group of entity with histologic continuum from benign, atypical to invasive and non-invasive malignant lesions. 2. To review the multimodality imaging spectrum of papillary lesions. 3. To review the unique histopathologic patterns of lesions with papillary and micropapillary features. 4. To review the clinical management algorithm for different papillary lesions diagnosed on core needle biopsy.

#### TABLE OF CONTENTS/OUTLINE

- Multimodality imaging review of common and uncommon imaging features of papillary lesions.
- Review of classification system according to WHO 5th Edition Breast Tumors (2019)
- Review of histopathology of papillary lesions.
- Review of current evidence-based management algorithm for benign, atypical and malignant papillary lesions.

#### BREE-34 A Guide to Cystic Breast Lesions

Participants

Christina Le, DO, Morristown, NJ (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Breast imaging is often complex and can appear difficult to understand. It is rarely explored in depth throughout medical school training and can be rather limited throughout residency, especially for those pursuing other specialties for fellowship. The purpose of this exhibit is to provide a demystified review of cystic breast lesions. This is meant to supplement a resident's knowledge of breast pathology and present the information in a concise yet comprehensive manner. Throughout the presentation, the pathophysiology and patient presentation of each entity will be discussed. This will be followed by the often variable imaging findings that can be encountered on ultrasound, mammography, and MRI. Annotated pictorial examples are provided to facilitate visualization of the specific lesion characteristics. To conclude, the exhibit will discuss treatment options and the appropriate BIRADS criteria to help standardize the severity of these lesions.

#### TABLE OF CONTENTS/OUTLINE

1. Overview/educational objectives 2. BIRADS categories 3. Simple Cyst 4. Galactocele 5. Fat necrosis/oil cyst 6. Hematoma 7. Abscess 8. Intracystic papilloma 9. Necrotic neoplasm 10. Conclusion 11. References

#### BREE-35 Cryoablation Therapy for Breast Cancer: Procedural Technique and Imaging Review

Participants

Janice Thai, MD, Boston, MA (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. To review the procedural techniques for performing breast cancer cryoablation. 2. To review multimodality post procedural imaging features of cryoablation to identify normal and abnormal findings.

#### TABLE OF CONTENTS/OUTLINE

- Review of proper patient selection in a multidisciplinary approach.
- Review of equipment, device and procedural technique.
- Review of post procedural imaging, including normal and abnormal findings on mammography, ultrasound, and MRI.
- Review of follow-up imaging protocol and strategies for detection of tumor recurrence.

#### BREE-36 Exploding Jelly of the Breast: The Mucocele-Like Lesion (MLL)

#### TEACHING POINTS

<Mucocele-Like Lesions are considered risk injuries (B3a). Mucin in the stroma calcifies over time, showing up as such on mammography. By mammography the type of calcifications is variable. By ultrasound it appears as microcysts, complex cysts or irregular nodules. The treatment depends on the diagnostic biopsy method.>

#### TABLE OF CONTENTS/OUTLINE

<Mucocele-Like Lesions were first described by Rosen in 1986 as a benign lesion "cysts containing mucin, lined by squamous or cuboid epithelium with or without extravasated mucin", currently considered a risk lesion. It is due to mucinous ducts that obstruct their contents, causing rupture with extravasation of the contents into the surrounding stroma, which over time can form calcifications, which are observed by mammography; less commonly, it presents as a mass. By ultrasound they are observed as a cyst with thick, mucin-like content or microcystic conglomerates. The more complex the cystic lesion, the more likely it is to be associated with Ductal Carcinoma In Situ (DCIS). With core needle biopsy, the percentage of diagnostic underestimation is less than 4% if they are lesions without atypia, but amounts to approximately 20% if they are lesions with atypia, so removal by vacuum-assisted biopsy or surgery is preferred.>

#### BREE-37 Rare Tumors of the Breast

#### TEACHING POINTS

Rare tumors of the breast: Metaplastic carcinoma of the breast and Primary signet ring cell carcinoma of the breast. Epidemiology, image presentation of cases, clinical characteristics, imaging findings

#### TABLE OF CONTENTS/OUTLINE

Metaplastic breast carcinoma is a rare type of neoplasm that resembles a high-grade histological carcinoma, presents a high incidence of recurrences, poor prognosis, difficulties at the time of diagnosis, the establishment of therapeutic guidelines, and controversy regarding its nomenclature. The bibliography is very limited and the published descriptive studies have a low number of cases, making it difficult to obtain definitive and extrapolated conclusions, especially when making therapeutic decisions. Primary signet ring cell carcinoma of the breast is a rare tumor of controversial histogenesis, aggressive behavior and unusual metastatic pattern to the gastrointestinal tract and serous surfaces, posing differential diagnosis problems with metastasis of signet ring cell carcinoma of the breast. Other origins, preferably gastrointestinal.

#### BREE-38 AI Advancements in Breast Imaging: Transforming Radiology for Improved Patient Care

Participants

Matteo Mancino, MD, Roma, Italy (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

To explore the basic concepts of deep learning and machine learning in breast imaging. To examine AI-based tools and their applications in detection, diagnosis, and treatment planning for breast cancer. To assess AI performance compared to human experts. To discuss ethical considerations. To investigate AI future trends and developments for breast imaging.

#### TABLE OF CONTENTS/OUTLINE

Introduction: presenting the fundamental principles of deep learning and machine learning in the context of breast imaging. 1. Workload to explore how AI algorithms can positively influence radiologists' workload, also triaging negative mammograms and potentially replacing second readers. 2. AI accuracy to discuss how AI-based solutions contribute to improve diagnostic accuracy in mammography and enable a more precise lesion classification. 3. Cancer-Prediction evaluating the ability of AI algorithms to identify cancer-predictive features in mammograms. 4. AI role in ultrasound and MRI to examine the development and performance of AI-based solutions for detecting and classifying breast lesions in ultrasound and MRI. 5. Ethical considerations Addressing the ethical concerns surrounding AI implementation, including data privacy, algorithm fairness, and potential biases in the development process. 6. Future trends to address the future trends of AI, contemplating the potential integration of AI with other imaging modalities, exploring the role of radiogenomics in breast imaging, and anticipating novel AI advancements.

#### **BREE-39 Multimodal Imaging of Breast Tissue Expanders, Including Associated Complications and MRI Contraindications**

Participants

Almir Bitencourt, MD, PhD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

? To show the types of breast tissue expanders and MRI contraindications. ? To perform a multimodal review of the imaging aspects of breast tissue expanders. ? To illustrate complications associated to breast tissue expanders.

#### TABLE OF CONTENTS/OUTLINE

Breast tissue expanders are temporary devices commonly used in two-stage breast reconstruction surgery. Tissue expanders are gradually filled with saline to stretch the skin and chest tissues to make room for breast reconstruction with a permanent implant. There are different types of breast tissue expanders depending on the number of lumens (one or two), filling (saline and/or silicone) and injection dome (remote or internal). Some types have metallic components that are not suitable for MRI imaging due to the potential for image distortion or dislocation. It is important to recognize the imaging features of breast tissue expanders, to avoid misdiagnosis, since tissue expanders with small filling may mimic implant rupture on imaging. Complications associated with breast tissue expanders are rare and include infection, hematoma, rupture, and displacement.

#### **BREE-4 Code of Con-DUCT: An Algorithmic Approach to Multimodality Assessment and Management of Dilated Mammary Ducts**

Participants

Rajshree Singh, MD, Lansdowne, PA (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

- The ACR BI-RADS® 5th Edition indicates that a SDD has a > 2% likelihood of malignancy, and therefore warrants a suspicious (BI-RADS 4A) assessment. Otherwise, there are few recommendations for evaluation and management of dilated ducts found at breast imaging.
- Further evaluation with MRI and/or tissue sampling may be warranted if ductal dilation (DD) is new or increasing, symptomatic, or associated with worrisome mammographic or ultrasound (US) features.
- We propose an algorithm-based approach to assessing dilated ducts, specifying worrisome features on mammogram and targeted US to guide further workup.
- This approach may potentially reduce radiologists' uncertainty, unnecessary biopsies, missed cancers, and healthcare expenditures.

#### TABLE OF CONTENTS/OUTLINE

1. Ductal anatomy 2. Definition of DD 3. Etiologies of DD 4. DD requiring further evaluation: a. New or interval change b. Patient symptoms and/or clinical findings c. Suspicious mammographic findings 5. Worrisome US findings 6. Proposed algorithm for assessment and management 7. Identification of key findings that help guide diagnostic decisions. 8. Case-based application and examples 9. Role of ductography, US with elastography, and MR

#### **BREE-40 Breast Imaging Disparities in the U.S**

Participants

Dami Olufosoye, BS, MPH, Mount Pleasant, MI (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

This educational exhibit is a call to action for radiologists to identify racial disparities in their own practice. We will review recent studies identifying disparities individuals of color face in breast imaging and discuss successful interventions. 1. Breast cancer is the second leading cause of cancer deaths in women in the US but the leading cause in black women. 2. Black women have less access to screening mammography 3. Black and Hispanic women have lower rates of receiving adequate breast cancer treatment and post-treatment surveillance 4. Black women have increased rates of breast cancer recurrence 5. Imaging disparities based on race and other factors can be identified by radiologists and mitigated with outreach programs

#### TABLE OF CONTENTS/OUTLINE

1 US Epidemiologic breast cancer data 2 Racial disparities in breast cancer screening • Decreased access to mammography centers, advanced imaging equipment, specialized physicians, genetic testing • Additional limitations: § Patient distrust § Provider-patient relationship 3 Racial disparities in diagnostic work-up • Increased time to diagnostic work-up and to biopsy • Later stage at diagnosis 4 Racial disparities after breast cancer diagnosis • Lower rates of receiving adequate breast cancer care and post-treatment surveillance • Lower rates of 5-year breast cancer survival • Higher rates of cancer recurrence 5 How radiologists can help • Identification and mitigation of imaging disparities is part of our professional responsibility to our patients • Examples of successful initiatives

## **BREE-41 Breast Cysts: A Pictorial Exhibit of Benign and Malignant Twists**

Participants

Flavia M. Starling, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Cystic breast lesions are the most common masses found in the female breast of any age group, mainly between 30 and 50 years of age. They are derived from the terminal lobular duct unit as a result of fibrocystic change and may contain isolated liquid or even associated solid component, thus comprising a wide spectrum of variable disease entities, including benign and malignant pathologies. Simple and complicated cysts are usually benign; but on the other hand, complex cystic masses containing mixed cystic and solid components are indeterminate. Therefore, knowing that cysts are common lesions and that up to approximately 31% of complex breast cysts are associated with malignancy, the radiologist must be familiar with the main pathologies and imaging characteristics that includes this category of lesions.

### **TABLE OF CONTENTS/OUTLINE**

- Didactically review the main cystic lesions of the breast and their characteristics through different imaging methods and case-based revision obtained from the digital archive of our institution.
- Take home message
- References

## **BREE-42 Molecular Classification of Breast Cancer: Guide for the Radiologist**

Participants

Sandra Lara, CABA, Argentina (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Breast cancer is a disease that, despite having a histopathological classification, also includes molecular and genetic subtypes, being able to carry out a molecular classification that guides the clinical behavior, prognosis and different radiological characteristics based on the expression of biomarkers (HER2, ER, PR, Ki67), this classification complements the traditional classification and adds a very useful biological approach to disease management. That is why it is important for the radiologist to know and recognize the importance of classification, as well as to identify the most common imaging characteristics in the different diagnostic methods according to each molecular subtype.

### **TABLE OF CONTENTS/OUTLINE**

Introduction· Breast molecular biomarkers· Revision of the classification of molecular subtypes of breast cancer· Imaging characteristics in the different methods according to each molecular subtype· Clinical cases· Conclusions

## **BREE-43 Invasive Lobular Carcinoma (ILC): The Cancer With a Thousand Faces**

Participants

Adriana Alvarez, MD, Santiago De Compostela, Spain (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

The Invasive Lobular Carcinoma (ILC) is the second most common type of invasive breast cancer. The incidence is increasing due to replacement therapy in postmenopausal women and diagnosis advances. There are two histologic variants: classic and pleomorphic. ILC is usually estrogen receptor positive and her2 negative. The loss of desmoplastic cell reaction and the low density of cells in this tumors make the clinical and the mammographic detection difficult. This entity has multiple imaging manifestations, being a challenge for the radiologist. ILC can be bilateral, multifocal or multicentric, with an unique metastatic pattern. Diagnosis is based in clinical and radiological tests. The most common manifestation is an irregular or spiculated mass in mammography and an hypoecic irregular mass with posterior shadowing in US. MRI is the gold standard and it is used in the presence of multifocal, multicentric or bilateral disease as well as in the presence of lymphadenopathies.

### **TABLE OF CONTENTS/OUTLINE**

This educational exhibit presents epidemiological and main ILC features. Tumor presentation and behaviour are explained. A multi-modality review of clinical and radiologic features through clinical cases, as well as pitfalls, are presented and they can help the radiologist in the diagnosis.

## **BREE-44 MRI-Detected US: How to Improve the Detection Rate of Non Mass Lesions Using Breast Anatomical Landmarks**

### **TEACHING POINTS**

Nonmass lesions on US are most often observed when US is used to target mammographic asymmetries, biopsy suspicious calcifications seen on screening mammography, and to biopsy abnormalities on MRI. In a meta-analysis of 2201 lesions, the success rate of targeted US after MRI was 58% (range, 23%-82%) and detection rates varied by lesion type. Nonmass enhancement lesions on MRI are less likely to be detected on targeted US than mass lesions (66% of all masses and 30% of nonmass enhancement lesions were seen). This review introduces a new viewpoint on breast ultrasound anatomy necessary to obtain a close correlation with MRI and describes a target US method with anatomical landmarks based on this viewpoint. 1. Some US images of MRI-detected lesions are more indistinct than surrounding benign lesions and need to be correlated with precision. 2. About effective anatomical landmarks for MRI correlation including surrounding tissues and vascular routes as a new anatomical landmark. 3. Pattern classification of mammary fat and mammary gland distribution for reading anatomic landmarks in MRI correlation. 4. The anatomical mechanism of deformity and how to decipher it on US. Breast deformity during ultrasound examination is not related to breast size, but varies from individual to individual.

### **TABLE OF CONTENTS/OUTLINE**

1. the identification rate of in each literature and its relationship to landmarks used 2. identification rates by anatomical landmarks and MRI images using those landmarks 3. classification of patterns of fat and mammary gland distribution in the breast based on anatomical understanding 4. anatomic mechanisms of breast deformity in MRI and US 5. US techniques considering breast deformity 6. case presentation

## **BREE-45 Unraveling the Enigma of DCIS: A Multimodality Imaging Journey**

Participants  
Giselle Mello, PhD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

-Definition and classification of DCIS-Epidemiology and risk factors-Clinical presentation and symptoms Imaging modalities for DCIS detection and assessment

#### TABLE OF CONTENTS/OUTLINE

-Interpretation of mammography, ultrasound, and MRI in DCIS diagnosis-The role of breast tomosynthesis in DCIS detection-Pathologic correlation and biopsy techniques-Management options: Discuss management options for DCIS, including surgery (lumpectomy or mastectomy), radiation therapy, hormonal therapy, and surveillance.-Discuss emerging imaging technologies for DCIS detection and assessment.-Future directions: Discuss future research directions and areas of innovation in the field of DCIS detection and assessment, such as the use of artificial intelligence and machine learning in radiology, and the development of more personalized approaches.

#### **BREE-46 Unveiling the Mysteries of PASH in Breast Radiology: A Cutting-Edge Approach**

Participants  
Andrea Di Ninno, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Definition and classification of PASH Imaging modalities for PASH detection and characterization Differential diagnosis of PASH with other breast lesions

#### TABLE OF CONTENTS/OUTLINE

Definition and histopathology of PASH Clinical presentation and diagnostic workup of PASH Radiologic features of PASH on mammography, ultrasound, and MRI Differential diagnosis of PASH, including benign and malignant breast lesions Radiologic-pathologic correlation of PASH Management and follow-up of patients with PASH, including surveillance imaging and surgical options Association of PASH with other breast conditions, such as atypical ductal hyperplasia and breast cancer Multi-disciplinary approach to PASH management, involving radiologists, pathologists, and clinicians.

#### **BREE-47 Imaging Review of Mammography and Ultrasound Findings in Uncommon Breast Lesions: A Trainee-Focused Guide**

Participants  
Thurl Hugh Cledera, MD, Taguig, Philippines (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Differentiating uncommon breast lesions from cancerous lesions in the breast is paramount to proper diagnosis, risk stratification, and treatment in patients presenting with a breast mass in imaging. Uncommon breast lesions may vary from those arising in the glandular parenchyma (phyllodes), inflammation (mastitis and abscess), autoimmune (granulomatous mastitis), and metabolic (diabetic mastopathy) etiologies. In centers where resources are limited, knowing the value of mammography and ultrasound findings may help guide biopsy, which in turn provides adequate treatment. At the end of this exhibit, the learner will be able to review the basic findings that are seen in breast lesions on imaging and understand the role of clinical and imaging correlation in the proper identification of these lesions.

#### TABLE OF CONTENTS/OUTLINE

1. Introduction  
2. Brief review of histology of uncommon breast lesions  
3. Basic findings in mammography  
4. Basic findings in ultrasound  
5. Correlating findings in mammography and ultrasound  
6. Cases of uncommon breast lesions  
a. Lactating adenoma  
b. Intraductal papilloma  
c. Mastitis (bacterial)  
d. Granulomatous mastitis  
e. Diabetic mastopathy  
f. Mondor's disease  
g. Paget's disease  
h. Phyllodes tumor  
i. Dermatomyositis  
j. Foreign bodies

#### **BREE-48 Untangling the Mammary Ducts: Decoding the Complexity of Intraductal Pathology**

Participants  
Elsa Cecilia Molina Miranda, MD, Ciudad De Mexico, Mexico (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Mammography: Mammography can show intraductal lesions as grouped calcifications in a linear or branching pattern. Breast ultrasound: Ultrasound can identify intraductal lesions as masses or areas of ductal dilation. Core needle biopsy (CNB): This procedure is used to obtain a tissue sample from the lesion. CNB is performed guided by ultrasound or mammography. Vacuum-assisted biopsy (VAB): This procedure uses a suction device to obtain a tissue sample from the lesion. VAB is performed guided by ultrasound or mammography. Contrast-enhanced mammography: This exam uses a contrast medium to evaluate the vascularity of lesions in the breast, which may suggest the presence of a malignant lesion. Management of intraductal lesions depends on the definitive diagnosis obtained by biopsy. If the lesion is found to be malignant, treatment may include surgery, radiation therapy, and/or chemotherapy. If the lesion is benign, treatment may include observation or surgical removal.

#### TABLE OF CONTENTS/OUTLINE

Table of contents: 1. Objectives 2. Anatomia y fisiopatologia 3. Cases 4. Metodos diagnosticos 5. Approach 6. Conclusions  
Outline: Intraductal breast lesions are those that originate in the breast ducts and can be benign or malignant. These lesions can be detected by diagnostic methods such as mammography, breast ultrasound, core needle biopsy (CNB), vacuum-assisted biopsy (VAB), and contrast-enhanced mammography. The management of intraductal lesions depends on the definitive diagnosis obtained by biopsy, and treatment may include surgery, radiotherapy, and/or chemotherapy for malignant lesions, while benign lesions may be observed or surgically removed.

## **BREE-49 Coming Out of the Bubble: Assessment and Management of Cystic Breast Lesions**

Participants

Bruna Nantes, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

An approach to the evaluation and diagnosis of cystic lesions in the breast, with the aim of helping radiologists in their daily practice. Detail the different types of cystic breast lesions and their differential diagnoses, as well as the appropriate management of these lesions.

### **TABLE OF CONTENTS/OUTLINE**

Brief introduction: the prevalence of cystic breast lesions and the importance of adequate recognition and classification of these lesions. Definition and descriptors: detail the correct definition and description of the different types of cystic lesions. Flowchart on the management of cystic breast lesions. Multiple clinical cases of the different differential diagnoses of each type of cystic breast lesion, that contemplate: - Images from mammography, ultrasound and eventually MRI or CT scan; - Type of biopsy performed (if performed); - Recommendations on approaches to cystic lesions as per BI-RADS; - Recommendations on some special cases of cystic lesions; Conclusion.

## **BREE-5 When Lightning Strikes the Same Place Twice: Detecting Ipsilateral Breast Cancer Recurrence in the Post Operative Breast**

### **TEACHING POINTS**

Illustrate the imaging features suspicious of ipsilateral breast cancer recurrence in patients with prior lumpectomy or mastectomy. Review current literature for recommendations on adjunct imaging surveillance in women with prior history of breast cancer given their increased risk of a second breast cancer. Review imaging mimickers of breast cancer recurrence and discuss management recommendations. Highlight teaching points for each case to increase confidence in making a timely diagnosis.

### **TABLE OF CONTENTS/OUTLINE**

Case base review We will present an image rich exhibit depicting imaging findings in ipsilateral breast cancer recurrence in the post lumpectomy patients who present for annual surveillance mammography or breast MRI, and in patients who present with clinical concerns. Cases will illustrate imaging findings, histopathology and management at the initial diagnosis and at time of recurrence. Examples of imaging mimickers of breast cancer will familiarize the learner with benign conditions in the post-surgical breast. At the end of the exhibit, teaching points will be summarized. Summary: Women with a prior personal history of breast cancer are at an increased breast cancer risk. Cumulative incidence of ipsilateral breast tumor recurrence rate has been reported at 14.3%. The image appearance of the post operative breast can make the detection of breast cancer recurrence more challenging. As a result, radiologists should be familiar with common and uncommon imaging findings of ipsilateral breast cancer recurrence. This presentation will review the current screening recommendations in this setting, expected post operative changes, breast cancer mimics, and the imaging findings of recurrence.

## **BREE-50 New Blossoms on the Old Tree: Advancing Ductography with Digital Breast Tomosynthesis (DBT) or Contrast-enhanced Mammography (CEM)**

Participants

Juan Tao, Wuhan, China (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. Ductography is a useful tool for evaluating pathologic nipple discharge, allowing for identification and localization of intraductal lesions. 2. Ductography combined with DBT or CEM can eliminate masking of small filling defects caused by overlapping ductal branches and improve visualization of the entire ductal tree, enhancing the clarity of diagnosis. 3. Fine-tuning of the procedural steps and optimization of the contrast agent concentration are necessary for the successful implementation of ductography with DBT or CEM. 4. Potential additional risks of radiation exposure associated with combining DBT or CEM should be considered, and measures should be taken to minimize radiation dose to the patient in accordance with established protocols and guidelines for radiation safety in breast imaging.

### **TABLE OF CONTENTS/OUTLINE**

I. The Old Tree: Overview of Ductography and Its Clinical Value in Evaluating PND. II. The New Bloom on the Tree: Clinical Cases Demonstrating the Utility of Ductography combined with DBT or CEM. A. Sharper Sights Case: DBT-Ductography Increased Accuracy of Diagnosis. B. Wider Insights Case: CEM-Ductography Improved Visualization of the Entire Ductal Tree. III. Technical Aspects of Ductography combined with DBT or CEM. IV. Radiation Safety Considerations with Ductography and DBT or CEM. A. Potential Additional Risks of Radiation Exposure. B. Strategies to Minimize Radiation Dose to the Patient. C. Importance of Adherence to Established Protocols and Guidelines for Radiation Safety in Breast Imaging. V. Conclusion. A. Summary of the Key Points Regarding Ductography with DBT or CEM. B. Future Directions and Potential Applications of Ductography with DBT or CEM. VI. References.

## **BREE-51 Genetic Risk Assessment in the Radiology Setting: Our Nationwide Experience in 2023**

Participants

Sean Raj, MD, (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. Review breast cancer risk assessment opportunities 2. Review key high-risk breast care and assessment considerations 3. Highlight key workflow, operational, and regulatory considerations from our practice's experience spanning multiple states on both coasts

### **TABLE OF CONTENTS/OUTLINE**

I. Risk Assessment Guidelines a. Discuss often conflicting recommendation statements suggesting when to begin and which individuals to consider for cancer risk assessment, genetic testing, education/counseling, and modified medical management b. Spotlight recommendations for different demographics c. Examine benefits of supplemental screening II. Higher than average risk:

Breast Screening Considerations a. Mammography sensitivities: general population with breakdown by demographics and women with intermediate risk, high risk, and women with genetic mutations b. ACR/SBI guidelines for those with genetically based [and/or family history and dense breast] increased riskIII. Higher than average risk: Genetic Testing Considerations a. 32% of women qualify for genetic testing: a combination of hereditary and familial risk factors b. Simple multi-gene panel tests and risk assessment workflow can assess germline and polygenic risk for inherited cancer risk factorsIV. Review development of Risk-Assessment ChatBot, Intake and Educational Workflow and discuss our nationwide practice's experience including pearls and pitfalls

## **BREE-52 Vascular Mammary Lesions: Key Features to Make an Accurate Diagnosis and Avoid Unnecessary Biopsies**

Participants

Ladys Camargo, MD, Ciudad Autonoma de Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. Review the normal vascular anatomy of the breast2. Know the most frequent vascular breast lesions3. Know and discuss the diagnostic modalities commonly used for the diagnosis of vascular lesions4. What is the imaging follow-up of vascular lesions?

### **TABLE OF CONTENTS/OUTLINE**

There are various vascular mammary lesions, ranging from chronic systemic processes, congenital malformations, post-traumatic sequelae, benign masses, to malignant tumors. Accurate diagnosis of vascular lesions in breast images is very risky due to overlapping characteristics. This is why radiologists must be aware of the key features in the different diagnostic methods for interpreting images of vascular lesions in order to make an accurate diagnosis and avoid unnecessary biopsies and finally be able to discuss management recommendations and guidance. Outline-Introduction-Vascular anatomy of the breast-Imaging characteristics of the most frequent vascular mammary lesions-Diagnostic methods for the diagnosis of vascular lesions-Discussion of management and monitoring-Clinical cases.-Conclusions.-Bibliography

## **BREE-53 Cyst Breast Lesions: The Good, the Bad and the Ugly**

### **TEACHING POINTS**

Definition of cystic breast lesions and their prevalenceDifferentiation between simple cysts, complicated cysts, and complex cystic lesionsImaging modalities used for the assessment of cystic breast lesions, including mammography, ultrasound, and MRI

### **TABLE OF CONTENTS/OUTLINE**

Symptoms and clinical presentationDiagnostic imaging modalities for cystic breast lesions, including mammography, ultrasound, and MRIImaging features of cystic breast lesionsDifferential diagnosis of cystic breast lesions, including benign and malignant conditionsRole of imaging-guided percutaneous biopsy techniques in the diagnosis of cystic breast lesions, including fine-needle aspiration, core needle biopsy, and vacuum-assisted biopsy, and their advantages and limitations. Discussion of the importance of a multidisciplinary approach in selecting the most appropriate biopsy technique based on lesion characteristics, patient factors, and imaging findings.Follow-up and surveillance after diagnosis and treatment of cystic breast lesions

## **BREE-54 Everything We Need to Know About Papillary Breast Carcinoma**

Participants

Lisett Cruzado-Quiroz, MD, Lima, Peru (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Papillary breast carcinoma is a rare subtype of invasive ductal carcinoma with infiltrative papillary growth representing about 0,5 - 0,7% of all invasive breast cancers. It is usually seen in postmenopausal in their sixth to eight decade of life. Association with carcinoma in situ is uncommon. Typically presents with bloody nipple discharge or/with slow growing palpable tumors, frequently found in the periareolar region. In general, they have better prognosis than ductal carcinoma with a 100% 10 year survival rate following treatment. Lymph node involvement and distant metastases are rare except in the invasive form. Mammography usually shows a solitary round or oval mass with circumscribed margins. Rarely they associate poorly defined margins or spiculation, given the low occurrence of desmoplastic reaction. Ultrasound generally shows a complex mass with solid and cystic components with good sound transmission. MRI may demonstrate heterogeneous lesions with septations, mural nodule and intracystic haemorrhage, the solid components typically show washout kinetics. Intracystic papillary carcinomas can occur in a pure form or may be associated with ductal carcinoma in-situ or invasive ductal carcinoma. The authors will review the clinical manifestation, imaging features and pathology correlation of this rare breast carcinoma.

### **TABLE OF CONTENTS/OUTLINE**

Review of the pathophysiology of papillary breast cancers (histological and molecular aspect).Multimodal review of imaging features of papillary cancers (mammographic, ultrasonographic, and MR findings)To determine the Radiology-Pathology concordance/discordance by reviewing cases.Update on the treatment of papillary breast cancer.

## **BREE-55 Decoding Ductal Pathology: Multimodality Approach to Nipple Discharge and Management of the Solitary Duct**

### **TEACHING POINTS**

1. Identify what differentiates physiologic nipple discharge from pathologic discharge 2. Describe an approach to the diagnostic workup of patients with nipple discharge 3. Discuss the clinical importance of a solitary dilated duct and describe an approach to management in these patients 4. Implement new strategies for biopsy of hard-to-sample intraductal masses under both ultrasound and MRI-guidance

### **TABLE OF CONTENTS/OUTLINE**

Nipple discharge represents 2-5% of medical visits among women and is the third most common breast concern (pain > lump > nipple discharge). As radiologists our primary responsibility in assessment and management of these patients is to distinguish physiologic and pathologic causes of nipple discharge. This presentation will review the prevalence, epidemiology and pathologic subtypes of papillary lesions and other common pathologies resulting in pathologic nipple discharge and provide the reader with a

diagnostic algorithm for management of these patients. Using a multimodality case-based approach, the reader will develop a differential diagnosis and management strategy for imaging findings in patients with nipple discharge, including management of the solitary dilated duct. We provide the reader with important tips and tricks for biopsy of intraductal lesions and solitary dilated ducts under ultrasound and MRI-guidance and address the potential challenges of radiology-pathology concordance in these cases.

### **BREE-56 Uncovering False Positive Lesions Through DBT**

Participants

Giovana D'Avila I, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Teaching Points Screening mammography using DBT is replacing digital mammography as the preferred imaging modality. Recognize that DBT and mammography together minimize the effects of overlapping breast tissue and improves lesion detection and localization. Identify that digital breast tomosynthesis showed lower recall, cancer detection rate, and biopsy rate. The ability to problem solve with DBT images reduces patient anxiety associated with a callback.

#### **TABLE OF CONTENTS/OUTLINE**

Table of contents 1 - Advantages of screening mammography using DBT. 2 - Amorphous calcifications 3 - Left axillary lymphadenopathy 4 - Palpable finding 5 - Solid Mass

### **BREE-57 Ductal Carcinoma in Situ: Beyond First Impressions**

Participants

Hannah L. Chung, MD, Salt Lake City, UT (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

DCIS often co-exist with invasive cancers and 19-36% of DCIS after percutaneous needle biopsy are upstaged to an invasive cancer at surgical excision. Up to 3% of DCIS demonstrate axillary nodal metastases. The morphology of the calcifications are useful in predicting the nuclear grade. DCIS may also manifest as a noncalcified mass, asymmetry or distortion. Sonography demonstrates these findings as a mass, nonmass area or ductal change. MRI demonstrates the extent of DCIS better than other imaging modalities and findings correlate with high grade DCIS. Observed recurrences and lymph node metastases pose challenges to current evaluation and treatments of DCIS.

#### **TABLE OF CONTENTS/OUTLINE**

Table of Contents 1. What is DCIS a. Significance of DCIS b. Biology and evolution of DCIS 2. Clinical Presentation of DCIS a. Asymptomatic b. Nipple discharge c. Paget's disease of the nipple d. Palpable lump 3. Imaging correlates with biology and pathology a. Mammographic i. Calcifications, mass, asymmetry, distortion b. Sonographic i. Nonmass findings 1. hypoechoic areas 2. echogenic foci 3. shadowing, 4. pseudomicrocyst ii. Ductal change c. MRI- MRI is useful to demonstrate extent of disease, exclude invasive disease, and correlates with high grade DCIS. i. nonmass enhancement ii. mass. 4. Special considerations a. Occult invasive cancers or misdiagnosis- Can imaging predict invasion? b. Axillary Staging- Is axillary ultrasound with biopsy and sentinel lymph node necessary? 5. Research: Past, now, and future endeavors a. NSABP, UKANZ, ECOG-ACRIN b. Active surveillance vs standard treatment - COMET, LORIS, LORD c. Advanced imaging techniques and artificial intelligence in both radiology and pathology

### **BREE-58 When Cysts Are Not So Simple: Tips for Complex Cystic Breast Masses Evaluation.**

#### **TEACHING POINTS**

-To review the different entities causing the sonographic appearance of a complex cyst. -To illustrate a series of cases of complex cystic benign and malignant lesions of the breast providing correlation with imaging (US, contrast-enhanced mammography, MRI) and pathology. - To discuss the specific management of those lesions including imaging and interventional procedures. -To emphasize pitfalls, diagnostic difficulties, and differential diagnosis.

#### **TABLE OF CONTENTS/OUTLINE**

Cystic breast lesions are frequently detected on breast ultrasonography. Simple cysts, complicated cysts, and oil cysts do not require further invasive diagnostic procedures. However, malignant entities may present with complex cystic and solid masses. Through sample cases, a variety of imaging and pathology findings from complex cystic lesions with management discussion will be demonstrated. 1. Introduction. US findings and technical pitfalls. 2. Cystic lesions evaluation, useful findings that could be of significant diagnostic value to distinguish between confusing cysts. Classification of cysts and suspicious findings. 3. Work-up of suspicious lesions on US: mammography/contrast-enhanced mammography (CEM) and MRI. Interventional procedures. 4. Typical benign and malignant lesions with their important findings on ultrasonography, contrast-enhanced mammography, and MRI: Benign: complicated/inflammatory cyst, seroma, oil cyst, epidermal inclusion cyst, galactocele, mucocele-like tumor, hematoma, abscess, fat necrosis, fibroadenoma, papilloma, benign Phyllodes tumor. Malignant: malignant Phyllodes tumor, papillary, medullary, colloid, and squamous cell carcinoma, sarcoma.

### **BREE-59 Differentiating Simple Cysts From Complicated Cysts, Complex Cystic and Solid Masses, and Other Cystic Breast Lesions**

Participants

Tara Retson, MD, PhD, San Diego, CA (*Presenter*) Research Consultant, CureMetrix, Inc Stock options, CureMetrix, Inc

#### **TEACHING POINTS**

Cystic diseases of the breast are common, and confusion can occur regarding their appropriate classification and management. Distinguishing between benign cysts/cystic lesions and malignant cyst-like/fluid-containing cancers may be challenging. Specifically, triple negative breast cancers and intracystic papillary carcinomas should not be dismissed as benign/probably benign. Cystic lesions may be diagnosed accurately and managed appropriately using characteristic imaging findings. It is imperative to properly classify lesions as complex cystic and solid masses vs. complicated cysts since their management differs, and the differential of complex cystic and solid masses includes cancer. This educational exhibit will define simple cysts, teach radiologists about cystic lesions that may not be benign, review their imaging appearances, and recommend management options for complicated cysts,

clustered microcysts, and complex cystic and solid breast masses.

#### TABLE OF CONTENTS/OUTLINE

Introduction; Definitions/illustrations of simple cysts, complicated cysts, clustered microcysts and complex cystic and solid masses; Multimodality examples of cystic breast lesions, systematic approach to the characterization of cystic lesions; How to appropriately apply BI-RADS classification and management recommendations of cystic breast lesions; Utilization of a quiz at the end of the exhibit to test yourself on the systematic approach presented.

#### BREE-6 Get Your Ducts in a Row: Imaging and Management Considerations of Ductal Disease of the Breast

Participants

Firouzeh Arjmandi, MD, Dallas, TX (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

-In the imaging evaluation of spontaneous clear and/or bloody nipple discharge, negative diagnostic conventional imaging (mammogram and ultrasound) warrants further evaluation with breast MRI.-Nipple changes on physical exam even in the absence of imaging findings are suspicious. Clinical exam findings should guide next steps in management, and nipple tissue biopsy should be performed by the surgeon in the appropriate clinical setting.-In the setting of a small, subtle intraductal mass seen on diagnostic MRI and not well visualized at time of MR-guided biopsy, targeting the end of a blind-ending solitary duct can help to guide the biopsy.-The combination of findings of a palpable lump, nipple discharge, and nipple inversion, and the presence of associated coarse heterogeneous calcifications raises concern for malignancy, and biopsy should be recommended (despite the presence of more benign appearing rim calcifications).-Treatment of intraductal papillomas without atypia has become more conservative. Upgrade to DCIS or invasive carcinoma is more common in women >50 years, lesions >1 cm, palpable lesions and papillomas >5 cm from the nipple.

#### TABLE OF CONTENTS/OUTLINE

-Overlapping imaging features of benign and malignant calcifications, including high grade versus low grade DCIS-Utility of MRI in the evaluation of extent of disease in intermediate to high grade DCIS-Multimodality imaging and clinical evaluation of pathologic nipple discharge and nipple changes (erythema and scaling)-Imaging assessment and clinical management of a solitary dilated duct and intraductal lesions-Accurate assessment of response to neoadjuvant chemotherapy in the setting of increasing calcifications post therapy

#### BREE-60 Test Your Knowledge: A Case Based Quiz of Contrast Enhanced Mammography BI-RADS Lexicon

Participants

Daniel Sandoval, MD, Ciudad De Mexico, Mexico (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

• To learn the descriptors published in the ACR 2022 BI-RADS supplement for contrast enhanced mammography by reviewing a series of daily case images. • As this supplement has only recently been published, this exhibit is intended to help radiologists become familiar with the terminology and its representation on images, through an interactive and entertaining activity.

#### TABLE OF CONTENTS/OUTLINE

• Background Contrast enhanced mammography lexicon overview (categories, terms, features and definitions) • Illustrated case based quizzeso Case #1: Background parenchymal enhancement - Level: Minimal, Mild, Moderate, Marked. - Symmetry: Symmetric, Asymmetric.o Case #2: Masses - Shape: Oval, Round, Irregular.- Margin: Circumscribed, Irregular, Spiculated. - Internal enhancement characteristics: Homogeneous, Heterogeneous, Rim enhancement. o Case #3: Non mass enhancement - Distribution; Diffuse, Multiple regions, Regional, Focal, Linear, Segmental- Internal enhancement characteristics: Homogeneous, Heterogeneous, Clumped. o Case #4: Enhancing asymmetry - Internal enhancement pattern: Homogeneous, Heterogeneous. o Case #5: Lesion conspicuity - Low - Moderate - High• References

#### BREE-61 Complex Cystic Breast Masses: An MR Imaging Review

Participants

Jie Liu, Wuhan, China (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. To define the concept of complex cystic breast masses. 2. To categorize complex cystic breast masses into three types based on the percentage and spatial distribution of cystic and solid components in the contrast-enhanced MRI. 3. In comparison with US, MRI affords superior visualisation of the proportion and distribution characteristics of solid and cystic components within complex cystic breast masses, which facilitates their differential diagnosis. Moreover, multi-parametric MRI such as T2WI, dynamic contrast-enhanced MRI (DCE-MRI) and diffusion-weighted imaging (DWI) enables the recognition of the presence and distribution characteristics of cystic and solid components, the combination of which can serve as a complementary imaging aid for accurate diagnosis.

#### TABLE OF CONTENTS/OUTLINE

I. Introduction A. Overview of complex cystic breast masses B. Importance of accurate diagnosis II. Complex cystic breast masses A. Definition of complex cystic breast masses B. Etiology of complex cystic breast masses C. Clinical manifestations of complex cystic breast masses III. Categorization of complex cystic breast masses based on MRI features Group A : thick outer wall and/or thick internal septa (> 0.5 mm). Group B: predominantly cystic component(>50%)or intracystic mural nodule. Group C:predominantly solid component and cystic component=50% IV. Comparison of MRI and ultrasound in complex cystic breast masses A. Advantages of MRI over ultrasound B. Limitations of ultrasound C. Diagnostic value of multiparametric MRI in identifying cystic components V. Conclusion A. Summary of key points B. diagnostic flow chart of complex cystic breast masses C. Future directions for research VI. References

#### BREE-62 Trial by Priors: When to Call Back a Stable Mammographic Finding

#### TEACHING POINTS

1. Comparison with multiple prior studies can help identify slowly evolving malignancies. 2. Mammographic findings that warrant further evaluation include increasing number of calcifications or suspicious distributions, evolving asymmetries, architectural distortions, and slow growing or spiculated masses. 3. Early recognition of these suspicious findings allows for appropriate diagnostic workup and improved diagnosis of slow growing malignancies.

#### TABLE OF CONTENTS/OUTLINE

1. Introductory slide. This exhibit hopes to educate breast imagers about stable mammographic findings that require further evaluation. While stability of imaging findings over two years is often suggestive of benignity, comparison with multiple prior imaging studies can allow better evaluation of stability and identify features that are slowly evolving over time. There are also some imaging features that should be further evaluated and sampled regardless of apparent stability. This educational exhibit will discuss several cases of malignancy, highlighting the suspicious imaging features that prompted additional work up. 2. List of teaching points to guide the upcoming case discussion. 3. Anonymized cases demonstrating different examples of slow growing malignancies. Each case will include: Multiple prior studies to demonstrate evolution over time; Explanation of decision making that lead to diagnostic evaluation; Findings on diagnostic imaging; Pathology results after biopsy. 4. Summary slide that reviews the teaching points.

#### BREE-63 Indications and Outcomes of Cryoablation in Breast Malignancies: A Single Institution Case Review

Participants

Sasha Kurumety, MD, Houston, TX (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The goal of this presentation is to educate radiology trainees on the use of cryoablation as a treatment option for breast malignancies, when cryoablation may be appropriate, and expected short and long term outcomes of the procedure. Using a series of cases from our institution, we will describe selection criteria to identify patients that may benefit from this minimally invasive cancer treatment option and demonstrate post treatment imaging findings. After this presentation, learners will be able to describe the utility of cryoablation in treating breast malignancies and mechanisms of action, as well as understand the complications, outcomes, and future directions/ongoing trials for cryoablation.

#### TABLE OF CONTENTS/OUTLINE

Background:- Current FDA approved indications for cryoablation and uses of cryoablation in breast cancer- Ongoing trials: discussion of ICE3, FROST, and home institution trials and preliminary outcomes  
Discussion of mechanism of action:- Direct freezing and cell death, indirect immune response activation- Advantages, disadvantages, and risks/complications of cryoablation  
Cryoablation at our institution:- Qualifying patient and tumor characteristics, preprocedural evaluation- Interdisciplinary decision-making  
Institutional cryoablation cases:- Preprocedural imaging, biopsy pathology results, imaging during procedure, and post cryoablation follow up imaging/pathology  
Future directions: pathway to FDA approval, Medicare coverage, and increasing accessibility.

#### BREE-64 To Treat or Not to Treat: A Review of Papillary Lesions of the Breast

#### TEACHING POINTS

Papillary breast lesions are a heterogeneous group of proliferative changes that occur within the epithelial lining of breast ducts. These lesions have varying presentations, pathological characteristics, and treatment options, requiring careful radiological evaluation for an accurate diagnosis. The spectrum of the lesions includes intraductal papilloma with/without atypia, intraductal papillary carcinoma, encapsulated papillary carcinoma, solid papillary carcinoma, and invasive papillary carcinoma. Radiologists must be aware of these variations to accurately identify, diagnose, and provide appropriate management recommendations. The primary objective of the exhibit is to present a comprehensive pictorial review of papillary breast lesions with radiological pathological images. We will also discuss the steps in the diagnosis and current management recommendations of these lesions. By the end of this exhibit, the audience will have a better understanding of the various papillary lesions and their clinical and imaging presentations, enabling them to provide appropriate radiologic-pathologic correlation and treatment recommendation for patients.

#### TABLE OF CONTENTS/OUTLINE

1) Introduction. 2) Definition of papillary breast lesions. 3) Pictorial review of the spectrum of papillary lesions. 4) Case examples of the spectrum of papillary lesions with pathological correlation. 5) Symptoms presentation of various papillary lesions. 6) Imaging techniques recommendations for diagnosis of papillary lesions. 7) Review of current BI-RADS terms in the description of these abnormalities. 8) Latest management recommendation for papillary lesions within the spectrum. 9) Conclusion/Summary.

#### BREE-65 Case Based Review of the Modern Reconstructed Breast: Benign Imaging Findings and Complications

Participants

Shelby Breit, MD, Durham, KS (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Understand imaging findings associated with modern reconstruction techniques. 2. Recognize uncommon and common benign findings. 3. Discuss complications.

#### TABLE OF CONTENTS/OUTLINE

Reconstruction Methods  
Implants  
Autologous Flaps (AF)  
Imaging after implant reconstruction  
Type: silicone vs saline implant  
Acellular dermal matrix (ADM)  
Benign complications: Rupture, Gel bleed, Abscess/infection, Hematoma, Siliconoma  
Implant associated mesenchymal tumors (fibromatosis)  
Imaging after AF reconstruction  
Type: pedicled, free, perforator flaps  
Venous coupler device  
Benign complications: Fat necrosis/lipografting, Epidermal inclusion cyst

#### BREE-66 Breast MRI: What the Surgeon Wants to Know

#### TEACHING POINTS

As there is increasing need for a multidisciplinary approach to patient care, it is important for the radiologist to understand which MRI findings change clinical management. After this presentation, participants will understand: 1. Indications for breast MRI. 2. Breast cancer staging. 3. Indications for different types of breast cancer treatment, including surgery, radiation, and systemic. 4. Breast MRI findings that change clinical/surgical management. 5. MRI correlates on mammogram and ultrasound.

## TABLE OF CONTENTS/OUTLINE

A. Indications for MRI a. American College of Radiology Practice Parameter b. American Society of Breast Surgeons Consensus Guidelines B. Overview of breast cancer staging C. Surgical management a. Indications b. Mastectomy vs. lumpectomy c. Types of mastectomy D. Radiation a. Indications b. Whole vs. partial breast treatment E. Systemic a. Indications for neoadjuvant chemotherapy b. Types of systemic treatment (chemotherapy, hormone blockade, biologic therapies) F. MRI findings that impact staging and management with multimodality case examples a. Multicentric/multifocal disease b. Nodal involvement (rotter's node, level I, level II, level III, internal mammary chain node) c. Nipple enhancement d. Skin enhancement e. Chest wall involvement f. Cancer in contralateral breast g. Metastatic disease - bone/lung involvement

### BREE-67 The Not So Simple Cyst

#### TEACHING POINTS

Cystic breast lesions are frequently encountered on ultrasound, often incidentally with a broad differential diagnosis including both benign and malignant pathology. Accurate description and classification according to the BI-RADS Lexicon based on ultrasound characteristics are essential for appropriate estimation of risk for malignancy and in turn management guidance. Emphasis on optimal ultrasound techniques, BI-RADS classification based on imaging characteristics, and correlation with example cases will be given with the purpose of helping residents and radiologists feel confident on how to proceed when faced with a cystic breast lesion.

## TABLE OF CONTENTS/OUTLINE

I. Introduction II. Optimal Ultrasound Technique III. BI-RADS classification of cystic lesions 1. Simple cyst 2. Complicated cyst 3. Complex cystic and solid mass (classification of complex masses) IV. Sampling techniques V. Take Away Points

### BREE-68 The Cures Act: Challenges and Benefits in Breast Imaging

#### TEACHING POINTS

The 21st Century Cures Act is a federal law signed in 2016, aiming to remove barriers to health information exchange. The legislation includes a Final Rule, federally enforced as of April 2021, mandating patient access to electronic health information to increase transparency. Part of the mandate prohibits "information blocking," defined as a healthcare practice that is "likely to interfere with access, exchange, or use of electronic health information." For radiology practices, this means that reports are released to patients immediately when finalized. Immediate release allows for increased patient autonomy but reports often include sensitive information, especially in breast imaging, in addition to terminology that might be confusing to patients. Screening and diagnostic reports, previously held for a period of time at many institutions to allow time for direct patient communication, are now immediately released to patients. This educational exhibit reviews the impact of the Cures Act on breast imaging practices, including benefits, challenges, and potential solutions to navigate the legislation.

## TABLE OF CONTENTS/OUTLINE

I. Legislation II. Positive Implications and Challenges III. Evolution of Practice

### BREE-69 How to Start Using Optoacoustic Imaging in Your Breast Practice: A Primer

Participants

Berat Bersu Ozcan, MD, Dallas, TX (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Optoacoustic imaging (OAI) is a novel technique that uses non-ionizing lasers to detect endogenous tissue contrast. Gray scale ultrasound (GUS) is fused with parametric maps of relative light absorption for oxy/deoxyHgb in real-time, enabling simultaneous functional and anatomic imaging. The most frequently tested interpretation schema involves dividing mass into 3 internal and 2 external features. The 3 internal scores include the number of individually resolved vessels and their relative deoxygenation (vessel score), tumor blush, representing volume-averaged vessels too small to resolve individually (blush score), and Hgb amount (hemoglobin score). The 2 external scores reflect the amount and relative oxygenation of hemoglobin and vessel morphology within the boundary zone (bz, immediately surrounding the tumor, analogous to the thick echogenic rim surrounding tumors on GUS images) and the peripheral zone (pz, territory beyond the bz). Combined evaluation of GSUS and OAI features to classify benign and malignant masses have consistently shown to increase significantly (43.0% vs 28.1%,  $p < 0.001$ ) diagnostic specificity with high interreader (7 readers) agreement (mean kappa = 0.55;  $p < 0.001$ ). A study combining decision support tools with 15 fellowship-trained radiologists showed that interreader agreement [intraclass correlation coefficient (ICC) 0.80, 95%CI: 0.78, 9.82] and agreement between reader and decision support tool (95.3% of all reads) was high.

## TABLE OF CONTENTS/OUTLINE

1. Optoacoustic Imaging Principles 2. Equipment Types and Current Status 3. Interpreting Optoacoustic Images: A Comprehensive Guide 4. Understanding system limitations 5. Case Demonstration 6. Test Your Knowledge

### BREE-7 Non-Malignant Papillary Lesions of the Breast: Imaging Features and Management

Participants

Antonio Morales Rosa, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

- To describe the characteristics of non-malignant papillary lesions of the breast (B3) on different imaging techniques: mammography, US and MR. - To review the therapeutic algorithm of papillary B3 lesions of the breast and the role of vacuum assisted excision biopsy (VAE).

## TABLE OF CONTENTS/OUTLINE

1. Introduction 1.1 Intraductal papiloma without atypia. 1.2 Intraductal papiloma with atypia. 2. Imaging features. 2.1 Mammography. 2.2 US. 2.3 MR. 3. Radiopathological correlation. 4. Management of B3 papillary breast lesions. Algorithm. Role of MR. Indications of VAE. 4.1 Follow-up. 4.2 Surgery. 4.3 Vacuum assisted excisional biopsy (VAE). 5. Conclusions

**BREE-70 What You Need to Know About the Pediatric Breast: A Review of the Normal Breast and Diagnostic Approach of Pediatric Breast Disease.**

**TEACHING POINTS**

The purpose of this exhibit is to: Describe the physiologic breast development and its variants from birth to adolescence. Review the optimal imaging modalities for evaluation of breast lesions in children and adolescents. Recognize imaging appearances of benign and malignant lesions that can affect the pediatric breast. Learn the recommendations for follow-up and management of pediatric breast lesions to avoid a delayed diagnosis or unnecessary interventions.

**TABLE OF CONTENTS/OUTLINE**

We review: Utility of the different imaging modalities in the assessment of the pediatric breast. Breast physiologic development from birth to puberty and pathological conditions that can occur. Benign and malignant pediatric breast disease with illustrating cases. Non-mass findings: Asymmetrical breast development, accessory breast tissue, accessory nipple, pseudogynecomastia, gynecomastia, atypical ductal hyperplasia, surgical scar. Benign masses: Simple and complex cysts, retroareolar cyst, epidermal inclusion cyst, fibrocystic changes, mastitis and abscess, hematoma, intramammary lymph node, reactive lymph node to vaccines, fibroadenoma, pseudoangiomatous stroma hyperplasia, sclerosing adenosis, phyllodes tumor and tubular adenoma. Malignant masses: Metastasis and primary breast cancer. Diagnostic approach of pediatric breast disease with follow-up and management algorithm and indications for interventions such as biopsy or surgery.

**BREE-71 Localization for Nonpalpable Breast Lesions. A Pictorial Review of Different Imaging-guided Preoperative Localization Procedures in the Breast and Axilla.**

Participants

Javier Azpeitia Arman, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

-To know the different devices employed for nonpalpable breast lesions localization. -To review the role of imaging techniques (mammogram, US, MR, CT, gamma detector) in the localization of breast lesions for breast conserving surgery. -To understand surgeon needs including technical factors of localization and communication of the relationship of the lesion and the marker. -To become familiar with the localization process, and different tips and tricks for each device.

**TABLE OF CONTENTS/OUTLINE**

Breast-conserving surgery requires multidisciplinary communication and planning between the surgeon and the radiologist. Removal of the lesion with adequate surgical margins and avoiding resection of healthy breast tissue is essential. 1. History of wire localization, radioactive seed, and other non-needle-wire localization techniques 2. Advantages and disadvantages of using seed localization versus needle-wire localization. 3. Wire localization. 4. Non-wire devices: radioactive I125, magnetic, radar, and radiofrequency seeds 5. Technique and pitfalls. Before the procedure: review of the patient's imaging and histopathologic findings. Wire or seed placement. Preoperative detection. Operating room. Recovery. 6. Case examples of potential difficulties and problems and how to overcome them.

**BREE-72 Is it Back? Multimodality Surveillance of Breast Cancer Recurrence: Literature Review and Case Presentation**

Participants

Mohammed Sabawi, MBChB, Iowa City, IA (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

Screening patients with previously treated breast cancer is challenging, because benign post treatment changes can obscure or resemble an underlying recurrence and due to technical limitations in performing a mammography on a treated breast. There are postoperative mammographic findings in a conservatively treated breast which follow expected time course. Any new mammographic finding (new masses, asymmetries or microcalcifications) should raise suspicion for recurrence. Abnormal screening mammogram is the most common presentation of breast cancer recurrence. Margin involvement and lack of radiotherapy and/ or chemotherapy are important prognostic factors of local recurrence. There is no clear guidelines to dictate ipsilateral breast screening after mastectomy and reconstruction with or without implant. Breast MRI is highly sensitive imaging modality to detect local recurrence in certain patient groups. It can be also utilized as problem solving to assess equivocal clinical or mammographic findings.

**TABLE OF CONTENTS/OUTLINE**

Introduction Review of incidence, risk factors, diagnostic performance of multimodality surveillance and presentation of breast cancer recurrence. Review of post breast conserving treatment imaging findings and their time course of evolution. Review of available national guidelines for multimodality surveillance after curative treatment for locoregional breast cancer. Case based review of different and unusual presentations of breast cancer recurrence. Conclusion. References.

**BREE-73 A Review of the Combined Score for Quantitative Shear Wave Elastography (SWE) and Superb Microvascular Image Vascular Index (SMIVI) to Evaluate Breast Masses**

Participants

NA YOUNG LEE, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

**TEACHING POINTS**

1. To differentiate between benign and malignant breast masses, we propose using the combined score of quantitative parameters for shear wave elastography (SWE) and superb microvascular image (SMI) with BI-RADS. We suggest using the combined score for SWE<sub>max</sub>, SWE<sub>ratio</sub>, and SMIVI and demonstrate how it can be used to differentiate between benign and malignant breast masses. 2. We calculated the combined score by adding the BI-RADS score and each quantitative parameter (SWE<sub>max</sub>, SWE<sub>ratio</sub>, and SMIVI). The BI-RADS categories were scored on a scale of 1 to 5 (C3:1, C4a:2, C4b:3, C4c:4, and C5:5), and SWE<sub>max</sub>, SWE<sub>ratio</sub>, and SMIVI were scored as 0 or 1 based on applied cutoff values. The summed score ranged from 1 to 8. We used a cutoff value of 4 for the combined score to discriminate between benign and malignant cases based on the reported AUC values. 3. The combined score of B-mode US and quantitative parameters can improve diagnostic performance and reduce unnecessary breast biopsy.

However, the combined scores should be applied with caution, considering that the quantitative parameters have limitations in assessing small-sized, pure DCIS, or low-grade invasive cancer.

#### TABLE OF CONTENTS/OUTLINE

1. Review the principles of quantitative parameters for SWE (SWE<sub>max</sub>, SWE<sub>ratio</sub>) and SMIVI. 2. Review the appropriate cut off value for quantitative parameters for SWE<sub>max</sub>, SWE<sub>ratio</sub>, and SMIVI and evaluate their diagnostic performance in differentiating between benign and malignant masses. 3. Showcase the various case of combined score and pathology reviews to demonstrate how combined scores are helpful for differential diagnosis of breast masses, and which cases will be carefully applied.

#### **BREE-74 Threading the Needle: The Role of Breast Radiologists in Managing Suspicious Internal Mammary Lymph Nodes**

Participants

Megan Kalambo, MD, Missouri City, TX (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Examine Internal Mammary Lymph Nodes (IMLN) as an important component of breast lymphatic drainage. 2. Review the implications of metastatic IMLN adenopathy in the staging of breast cancer. 3. Provide an overview of IMLN basin anatomy, differential diagnosis of IM adenopathy, and the clinical indications for imaging and sampling. 4. Explain the tools and technical steps necessary for conducting a successful ultrasound biopsy of IMLNs. 5. Recognize ultrasound-guided Fine Needle Aspiration (FNA) biopsy as a feasible percutaneous sampling technique radiologists can use to provide treatment planning assistance to clinical teams.

#### TABLE OF CONTENTS/OUTLINE

Based on our experiences at a tertiary oncologic referral center, we will provide an overview of internal mammary lymph nodes (IMLN) with regard to the anatomical, clinical, imaging and procedural considerations for radiologists. • Overview of IM nodal basin anatomy • Management of indeterminate and suspicious IMLNs • Differential diagnosis of abnormal/indeterminate IMLNs • Incidence and implications of IMLN adenopathy on breast cancer staging • Indications for imaging of IMLN • Multimodality identification of IMLN on Ultrasound, MRI, PET/CT • Biopsy considerations • Indications • Tools • Technical steps • Case-based discussion of IMLNs • Tips for imaging and clinical management of patients with indeterminate/suspicious IMLN.

#### **BREE-75 The State of Breast Imaging in the Caribbean**

Participants

Dami Olufosoye, BS, MPH, Mount Pleasant, MI (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Provide an overview of the current trends in incidence and mortality of breast cancer in the Caribbean 2. Discuss the state of breast services with respect to breast exams and screening 3. Discuss the challenges in breast services including infrastructure and health workforce availability 4. Recognize patient-related barriers 5. Review main points of the global breast cancer initiative and goals for breast imaging in the Caribbean

#### TABLE OF CONTENTS/OUTLINE

• Overview of breast cancer incidence, prevalence, mortality, and stage of diagnosis in the Caribbean compared globally and to the US • State of breast services with respect to breast exams and testing • National guidelines on breast exams and screening • Self-breast exams • Clinical breast exams • Access to mammograms • Discuss the state of breast services pertaining to the infrastructure and health workforce availability • Number of equipment in the region • Type of equipment available: digital mammography vs full film digital mammography vs tomosynthesis • Maintenance/ Audit of equipment • Health workforce: radiologists, oncologists, physicists • Breast treatment services • Barriers surrounding breast cancer • Knowledge deficits • Patient beliefs • 2021 Global Breast Initiative • Key messages • Recommendations for implementing interventions

#### **BREE-76 Breast Lesions Detected on CT: When to Refer for Triple Breast Assessment**

Participants

Sharmeen Jaffer, MD, London, United Kingdom (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

• Incidental breast lesions are a common finding on CT and unnecessary referrals can create a significant burden on the breast clinic. • To evaluate imaging characteristics of incidental breast lesions identified on CT and suggest characteristics which warrant referral to the breast clinic. • To identify imaging characteristics of breast lesion mimics or benign breast lesions; avoiding unnecessary referral to the breast clinic. • To explore the limitations of CT with imaging breast lesions including post-contrast enhancement in benign and malignant lesions.

#### TABLE OF CONTENTS/OUTLINE

• Variability of normal breast glandular tissue on CT including asymmetry and differences in density. • Breast lesions with benign characteristics such as coarse or popcorn calcification or well defined cysts with homogenous fluid attenuation. • Indeterminate breast lesions including intramammary lymph nodes, leiomyomas, papilloma, fat necrosis or lobular fibroadenomas which demonstrate post-contrast enhancement. • Suspicious breast lesions and indicators of malignancy including irregular or speculate margins and global or peripheral contrast enhancement; measured in Hounsfield units (HU). • Mimics of breast malignancy including lymphoedema, post surgical changes or radiotherapy. • Factors that negate an unnecessary referral to breast clinic include: long term stability, lesion previously assessed on mammography/ultrasound/biopsy proven benign lesion.

#### **BREE-77 Multimodality Imaging of Recurrent and Residual Breast Cancer**

#### TEACHING POINTS

After this exhibit, the reader will be able to: 1. Describe the epidemiology and clinical implications of recurrent and residual breast cancer. 2. Demonstrate the importance of a multimodality approach to the detection, workup and diagnosis of recurrent and residual breast cancer. 3. Apply specific strategies to improve early detection to optimize patient outcomes.

## TABLE OF CONTENTS/OUTLINE

Recurrent and residual breast cancer remains a diagnostic challenge with significant clinical implications. Early and accurate detection is critical for optimizing patient outcomes. Using a case-based multi-modality approach, this exhibit will: 1. Review the epidemiology and clinical implications of recurrent and residual breast cancer. 2. Discuss current surveillance recommendations and supporting literature, including the importance of patient anxiety. 3. Review expected post-treatment findings, discussing the advantages and disadvantages of each modality (mammography, ultrasound and MRI). 4. Provide an approach to surveillance imaging and residual disease, with emphasis on the surgical pathology report, surgical margins and the importance of breast biopsy marker clips. 5. Provide tips and tricks to ensure early identification of recurrent/residual disease and avoid post-treatment surveillance pitfalls.

### **BREE-78 From Benign to Malignant: Understanding the Spectrum of Phyllodes Tumors**

Participants

Abel Gonzalez Huete, MD, Madrid, Spain (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. To provide an overview of Phyllodes tumors, including their pathology features, categories and clinical presentation. 2. To discuss the role of the different imaging in the diagnosis of Phyllodes tumors. 3. To review the differential diagnosis of Phyllodes tumors and how to differentiate them from other breast tumors. 4. To highlight the importance of accurate diagnosis in the management of Phyllodes tumors.

## TABLE OF CONTENTS/OUTLINE

1. Introduction: Breast anatomy, Fibroepithelial tumors, Epidemiology, Pathogenesis, Categories of Phyllodes Tumors (Benign, Borderline, and Malignant) 2. Clinical Presentation 3. Pathology 4. Imaging Findings: - Benign Phyllodes tumor (Mammography, Ultrasound and MRI), - Borderline Phyllodes tumor (Mammography, Ultrasound and MRI), - Malignant Phyllodes tumor (Mammography, Ultrasound and MRI). 5. Differential Diagnosis: Fibroadenoma, Primary Sarcoma of the Breast, Periductal Stromal Tumor of the Breast, Other. 6. Benign vs Malignant Phyllodes Tumors: Key Differences 7. Management, Treatment and Prognosis 8. Conclusion 9. References

### **BREE-79 A Sheep in Wolf's Clothing: The Multiple Appearances of Local Breast Cancer Recurrence After Breast Mastectomy**

Participants

Agostina Peralta I, Buenos Aires, Argentina (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

-Discuss the role of the different image modalities in the surveillance of breast cancer recurrence after breast mastectomy.-Recognizing the imaging and the normal anatomic changes depending on the type of breast mastectomy performed.-Illustrate the imagen findings corresponding to a breast cancer recurrence on different image modalities.-Differentiating post-surgical benign findings from a malignant relapse.

## TABLE OF CONTENTS/OUTLINE

Studies have proven that the presence of local recurrence is an independent predictor for survival this is why radiologist should be familiarized to distinguish normal or benign findings after mastectomy from a recurrence. With the main objective of early detection and treatment. -Briefly review the different surveillance recommendations for these patients given by international societies. -Description of the different surgical breast reconstruction techniques used nowadays will be performed. These include the use of prosthetic implants, autologous tissue flaps, skin and fat flaps. -Illustrations will be shown of the expected anatomic changes after mastectomy on different image modalities depending on the surgical technique. -Images showing and differentiating benign findings from a post-surgical local breast cancer recurrence will be portrait.

### **BREE-8 Comparison of Indications, Reading Time, and Work Flow of FDA Approved Supplemental Screening Automated Whole Breast Ultrasound Tomography in Women With Dense Breasts**

Participants

Mary W. Yamashita, MD, South Pasadena, CA (*Presenter*) Research Grant, Delphinus Medical Technologies, Inc; Consultant, Delphinus Medical Technologies, Inc

#### TEACHING POINTS

- Ultrasound as adjunct to screening mammography for women with dense breasts increases cancer detection. - There are new ultrasound technologies available for same day supplemental dense breast screening. - Invenia ABUS from GE and SoftVue Automated Whole Breast Ultrasound Tomography (SV) from Delphinus Medical Technologies are both PMA-approved for screening and diagnostic purposes. - In clinical practice, ABUS is time-consuming and requires significant reading time. - SV offers benefits of same day supplemental screening with mammography and, unlike other ultrasound imaging, only adds 3-4 mins of reading time per case for the radiologist.

## TABLE OF CONTENTS/OUTLINE

1. Why ultrasound is important in screening women with dense breasts 2. Overview of ultrasound technologies available for dense breast screening 3. Comparison of indications for use 4. Benefits and challenges with integrating ultrasound into practice for adjunct screening for women with dense breasts: Workflow 5. Reading time: what makes reading ABUS and HHUS challenging in clinical practice, what are the main drivers of the time it takes for radiologist to interpret images including technique and training, number of images, image quality, and artifacts 6. Overview of SV automated whole breast ultrasound 7. Image sequence and reading protocol for SV 8. Example clinical cases demonstrating SV hanging protocol 9. SV reading time study and results 10. Conclusion

### **BREE-80 Do Not Miss Architectural Distortion!**

Participants

Haydee Ojeda-Fournier, MD, San Diego, CA (*Presenter*) Research Consultant, View Point Medical, Inc; Stock options, CureMetrix, Inc

## TEACHING POINTS

The BI-RADS 5th edition manual defines architectural distortion (AD) as “distortion of the breast parenchyma with no definite mass visible.” AD of the breast is an abnormality found in multimodality breast imaging and occurs with benign and malignant lesions. The most common cause of architectural distortion is a surgical scar. However, 4% of breast cancers present with AD. In addition to being a primary imaging finding, AD may also be an associated finding. In addition, AD is notorious for being a missed mammographic lesion. It is important for radiologists to “train their eyes” to identify AD and to know the differential considerations and pitfalls associated with AD evaluation to avoid potential missed breast cancer. The goals of this educational exhibit are to 1. recognize AD by 2D mammogram, digital breast tomosynthesis (DBT), ultrasound, and MRI, 2. review the differential considerations of AD, and 3. recommend management options and perform radiology-pathology concordance.

## TABLE OF CONTENTS/OUTLINE

Introduction; Definition of AD; Multimodality imaging examples of AD of the breast including mammography, sonography, and MRI; Learn a systematic approach to the characterization of AD; AD and DBT; How to appropriately apply the BI-RADS classification and management recommendations of AD; Challenging cases of AD; Pitfalls in evaluating AD: fat-containing, one view only, not seen at biopsy; Discordance in AD rad-path correlation; Sample cases; Conclusion.

### BREE-81 Non-mass Lesion on Breast Ultrasound: Radiologic-Pathologic Correlation and a Guide to Approach

Participants

Haejung Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Unlike mass, non-mass lesion does not show a three-dimensional structure, so it is more difficult than mass to detect and make an accurate diagnosis on breast ultrasound. For this reason, non-mass lesion evaluation on breast ultrasound often follows the detection of abnormality on other imaging modalities, such as mammography or MRI. This educational exhibit was prepared to increase understanding of non-mass lesions seen on breast ultrasound and to help accurately diagnose benign and malignant non-mass lesions. 1. Review the definition of non-mass lesion on breast ultrasound, 2. Correlate radiologic and pathological findings of benign and malignant non-mass lesions, and 3. Discuss a guide to approach for evaluating non-mass lesions on breast ultrasound.

## TABLE OF CONTENTS/OUTLINE

1. Definition of non-mass lesion on breast ultrasound A. True non-mass lesion vs. Normal variants 2. Correlation between radiologic and pathologic findings of non-mass lesions on US A. Imaging features of non-mass lesions on US B. Pathologic features correlated with benign and malignant non-mass lesions 3. Approach for evaluating non-mass lesion on breast ultrasound

### BREE-82 The Cyst Bang Theory: When to Biopsy

## TEACHING POINTS

1. Explain the epidemiology and pathogenesis of breast cyst. 2. Recognize the characteristics by image of breast cysts. The complex cyst is uncommon, but are suspicious of malignancy and merit biopsy. 3. Recognize criteria that will help identify a complex cyst. 4. Identify intraductal papillary nodule. Benign papillomas constitute 85% and 90%, intracystic papillary carcinomas 6% to 7%. 5. Points to help distinguish real from artifacts (echos) on ultrasonography images. 6. Recognize the most important differences in images between complicated and complex cyst. The true papillary nodules are anchored to the wall and do not move with the postural changes of the patient. 7. Analyze when to suspect malignancy in the breast cysts and categorize them based on the BIRADS.

## TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Epidemiology and pathogenesis 3. What are complex cysts 4. What should birads assign to a complex cyst 5. Review the spectrum of findings (mammography, us and contrast-enhanced mammography) 6. When to decide biopsy, a complex cyst 7. Let's practice (illustrative cases) 8. Conclusions

### BREE-83 Solitary Dilated Duct in the Breast: A Multimodality Pictorial Review

## TEACHING POINTS

Solitary dilated duct is associated with benign and malignant findings and the BI-RADS classification has varied over previous editions. Solitary dilated duct has characteristic imaging features on multiple modalities. Recognizing the imaging features, particularly if new, is important for management.

## TABLE OF CONTENTS/OUTLINE

Background Review of solitary dilated duct and BIRADS classification. Pictorial Review: Cases illustrating benign and malignant lesions with multiple modalities. Case 1: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound. Pathology: Papilloma without atypia. Case 2: History: Presenting with breast pain. Imaging: Mammogram, ultrasound. Pathology: Invasive ductal carcinoma. Case 3: History: 60-year-old female presenting for screening mammogram. Imaging: Mammogram, ultrasound. Pathology: Papilloma without atypia. Case 4: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound, MRI. Pathology: Papilloma with high-risk features. Case 5: History: Presenting for screening mammogram. Imaging: Mammogram, ultrasound. Pathology: Intraductal papilloma. Case 6: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound, ductogram. Pathology: DCIS. Case 7: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound, ductogram, MRI. Pathology: Multifocal DCIS with intraductal papillomatosis. Conclusion Review pearls for solitary dilated duct findings and management.

### BREE-84 MRI Detected Lesion in Women with a Personal History of Breast Cancer, and Then?

Participants

Ga-Eun Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## TEACHING POINTS

• Screening is still important for women with a history of breast cancer, because of high risk for future breast cancer. Breast MRI shows impressive resolution with high sensitivity, but specificity is relatively low. • Second look ultrasound is a well-established

approach for MRI detected lesions, and lesions found on subsequent ultrasound have a high probability of malignancy. However, second look ultrasound has limitations, such as operator dependence and the possibility of false negatives. Follow-up is required, and re-biopsy should be considered in case of image-pathology discordant. • Correlation with mammography can sometimes be helpful. In particular, new or increasing calcifications can be objective evidence for lesion detection and confirmation of biopsy results. • MR-guided biopsy must be considered in lesions with suspicious MRI features but occult on US or mammography.

#### TABLE OF CONTENTS/OUTLINE

<Representative cases of new enhancing lesion on breast MRI>• According to surgical method: op site after BCS, ipsilateral and contralateral breast after BCS, after mastectomy• According to detection modality: second look ultrasound (successful and missed), mammography, MR-guided biopsy for occult lesion• According to biopsy results: recurrence, false positive (benign), false negative (missed)

#### **BREE-85 5 Years of False Negative Review from the Mammography Audit: Observations and Lessons Learned**

Participants

Heather Garrett, MD, Saint Louis, MO (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

-Review of false negative (FN) cases can refine your mammography practice.-Sensitivity of mammography is limited in dense breasts.-BCT changes can make mammography difficult to interpret. ACR recommends annual screening MRI in patients with a prior history of BCT and dense breasts.-Screening MRI is more sensitive than mammography in the detection of breast cancer. High-risk patients should obtain annual mammography and annual screening MRI alternating at 6 month intervals.-Clinical symptoms (palpable breast lump, nipple discharge, skin changes and focal breast pain) should be evaluated using a multi-modality imaging approach.-BIRADS 3 cases are included in the FN review of diagnostic mammography. 0-2% of these cases may be cancers.

#### TABLE OF CONTENTS/OUTLINE

Background: False negative (FN) case review is mandated part of the annual mammography radiologist audit (MQSA/ACR). We are a large academic practice with dedicated breast imagers. We analyzed 135 FN cases from 5 years (2016-2020).Observations: -FN cases tended to be in patients with dense breasts, personal history of breast cancer, prior BCT, elevated life-time risk for breast cancer.-FN cases were mostly detected by presenting clinical symptom or screening MRI.-Some FN cases were women who had been given the assessment of BIRADS 3 in the diagnostic setting.Cases: 5-10 cases to illustrate teaching points.Lessons Learned: Overall, we found that there are many reasons for FN studies, the minority of which involved "missed cancers." Review of FN cases can refine your mammography practice.

#### **BREE-86 Don't Forget About the Nipple: Overview of the Anatomy and Different Lesions Involving the Nipple-areolar Complex**

Participants

Maria Guerra, MD, Monterrey, Mexico (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

To describe the normal anatomy and some anatomic variants of the nipple-areolar complex (NAC).To review imaging anatomy of the NAC by different techniques.To present a pictorial review of commonly known benign and malignant NAC lesions.

#### TABLE OF CONTENTS/OUTLINE

Anatomy of the nipple-areolar complexRetractionInversionImaging anatomy: mammogram, ultrasound, magnetic resonanceDifferent lesions:Dermal lesions: nipple calcifications, Epidermal inclusion cystInflammatory lesions: duct ectasia, retroareolar cyst, periductal mastitis, abscess, Zuska diseaseBenign Tumors: Nipple adenomaMalignant tumors: papilloma, carcinoma, Paget's disease

#### **BREE-87 The Many Faces of Invasive Lobular Carcinoma**

Participants

Miral Patel, MD, (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Invasive lobular carcinoma accounts for 5-15% of all breast cancers. 2. ILC is characterized by the lack of E-cadherin function, which explains the discohesive growth pattern and the subtle findings in imaging. 3. A review of radiologic and pathologic correlation of invasive lobular carcinoma and its morphologic variants can aid radiologists in recognizing patterns in the imaging presentation of invasive lobular carcinoma to facilitate early detection.

#### TABLE OF CONTENTS/OUTLINE

This educational exhibit reviews: 1- Basic review of invasive lobular carcinoma 2- Case based discussion of the radiologic presentation and pathologic correlation of the variants of invasive lobular carcinoma including classic, solid, signet ring cell, and pleomorphic 3- Pattern recognition in the presentation of invasive lobular carcinoma

#### **BREE-88 Breast Cancer Recurrence: Incidence and Imaging Appearance**

Participants

Haydee Ojeda-Fournier, MD, San Diego, CA (*Presenter*) Research Consultant, View Point Medical, Inc;Stock options, CureMetrix, Inc

#### TEACHING POINTS

Locoregional recurrence has been estimated to occur in 5-25% of breast cancer (BC) survivors, defined as the reappearance of the tumor at the surgical site or metastases in the regional lymph nodes. Even after mastectomy, there is a 2-10% reported lifetime risk of recurrence. Recurrence varies by molecular subtypes of BC, triple negative BC at 2-5 years after and other types at 5-15 years after treatment. Mammography remains the primary imaging modality for post-BCT surveillance. Breast MRI has the highest accuracy for differentiating post-surgical scar from recurrence. By the end of this educational exhibit, the learner will: 1. Learn the incidence, risk factors, and clinical presentation of breast cancer recurrence, 2. Review imaging recommendations for patients with a history of breast cancer and those with suspected breast cancer recurrence, 3. Recognize the common imaging appearance of

recurrent breast cancer on multimodality imaging, 4. Distinguish the appearance of recurrent breast cancer from expected post-surgical changes and other differential diagnoses

#### TABLE OF CONTENTS/OUTLINE

Introduction; Incidence and definition of breast cancer recurrence; Expected recurrence rates based on molecular subtypes of BC; Clinical presentation of breast cancer recurrence; Review imaging recommendations for patients with a history of breast cancer; Review diagnostic workup for patients with suspected breast cancer recurrence; Differential considerations of in-breast recurrence and regional nodal recurrence; A pictorial review of multimodality imaging in BC recurrence; Clinical management of recurrent BC; Algorithm for imaging patients with suspected recurrence; Conclusion

#### **BREE-89 AI in Breast Imaging: Current Status and Future Directions**

Participants

Berat Bersu Ozcan, MD, Dallas, TX (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

- Artificial intelligence (AI) in breast imaging is being used for lesion classification, breast density and cancer risk assessment. In screening mammography setting, stand-alone sensitivity of commercially available AI system range 75-85% at radiologists' specificity of 49-79%. This indicates comparable results with radiologist performance (AUC, 0.84 vs 0.81, respectively).
- Beyond screening, a deep learning model trained on uses mammograms and traditional risk factors showed superior performance in predicting 5 year breast cancer risk compared to the Tyrer-Cuzick model. (AUC, 0.70 vs 0.62,  $p < 0.001$ ).
- Model drift is a concept that describes degradation of AI model performance as the data it is used on changes. This raises concerns regarding the performance and reliability of AI models in real-life clinical settings.
- The FDA requires manufacturers of Artificial Intelligence/Machine Learning (AI/ML)-Based Software as a Medical Device (SaMD) to be transparent and monitor the real-world performance of their products to ensure the algorithm meets the standards after deployment.
- In a recent Dutch patient survey most patients (77.8%) did not support stand-alone use of AI in screening interpretation. Furthermore, 41.7% opposed the idea of using AI to select cases for second reading and 17% objected to AI as a second reader.
- The reimbursement for breast imaging AI has not yet been established, and several proposed frameworks are currently under discussion.

#### TABLE OF CONTENTS/OUTLINE

Integrating AI Tools to Breast Imaging Workflow: Opportunities, Challenges and Potential Impact Patient Engagement Ethical and Regulatory Perspectives The Future of AI in Breast Imaging

#### **BREE-9 Navigating Mammary Ducts Pathologies and Anatomy: A Radiological Handbook**

Participants

Giovanna Andreani, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The breast is an apocrine gland that contains different types of tissue: glandular, fibrous or connective, and fatty tissue. The glandular tissue is composed of mammary lobules and ducts, the latter being a tubular structure with the function of carrying the milk produced by the gland to the nipple. There are several pathologies and variations that can affect the mammary duct, ranging from benign alterations such as ductal ectasia or papilloma to even malignant ones (ductal carcinoma in situ or invasive ductal carcinoma, among others). Knowing that the majority of breast cancer arises from the ductal epithelium, it is crucial in the diagnosis and treatment of breast cancer by detecting intraductal lesions at an early stage. The objective of this study is to didactically review the anatomy and embryology of mammary ducts, as well as the main pathologies that affect this very important structure.

#### TABLE OF CONTENTS/OUTLINE

Review of the anatomy and discussion of the radiological findings in the mammary ducts, whether in their normal appearance or pathological changes through the different imaging methods obtained from the digital archive of our institution.

#### **BREE-90 Beyond the Norm: An Exploration of Extramammary Metastases to the Breast**

Participants

Berat Bersu Ozcan, MD, Dallas, TX (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

- Metastases to the breast are rare, comprising 0.5-6.6% of all malignancies in the breast, and typically indicate widely disseminated disease and poor prognosis.
- Lymphoma (17-38.3%), melanoma (8.3-23.4%), lung (8-15%), gynecological carcinomas (8-12.8%), and sarcomas (2%-12%) are the most common primary tumors to metastasize to the breast.
- Imaging features can vary depending on the primary neoplasm and route of dissemination, hematogenous (more common) or lymphatic.
- Typically, metastases present as well-defined masses without calcifications or distortion on mammography and round hypoechoic masses on ultrasound. Hematogenous metastases present as solitary or multiple breast masses located in the skin, subcutaneous tissue, or the breast parenchyma.
- Breast findings should be characterized according to the BI-RADS lexicon and managed according to the most suspicious features. If metastatic disease to the breast is in the differential diagnosis based on patient history and/or clinical presentation, early confirmation of secondary involvement with pre-operative biopsy of breast lesions is crucial to direct appropriate management.
- Breast metastases can be highly vascular, and ultrasound technique should be optimized to not confuse with pseudoaneurysms or aneurysms, which could result in a delay of diagnosis.

#### TABLE OF CONTENTS/OUTLINE

1. Literature review 2. Diagnostic algorithm 3. Key clinical and imaging features 4. The diagnostic and prognostic role of imaging modalities 5. Case demonstration and pathologic correlation

#### **BREE-91 Optimizing DWI for Improved Imaging in Breast Cancer and Beyond**

Participants

Sheida Ebrahimi, MD, La Jolla, CA (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Diffusion weighted imaging (DWI) is an advanced MRI technique that reflects water diffusion in tissues of interest and has been shown predicting pathologic response to neoadjuvant chemotherapy. It assists radiologists in better detecting and characterizing breast lesions. DWI can be challenging due to the breast morphology and introduction of artifacts. This exhibit reviews current state of DWI in breast cancer imaging including the physics of DWI, protocols utilized, advanced DWI techniques, and current indications. Strategies for optimizing DWI to improve image quality, diagnostic accuracy, and clinical utility will also be reviewed. At the end of this educational exhibit, learners will: 1. Recall the fundamentals of DWI and ADC Values; 2. Describe the correlation between ADC values and breast cancer prognostic factors; 3. Understand DWI challenges and limitations, and strategies for enhancing standard DWI; 4. Classify advanced DWI.

## TABLE OF CONTENTS/OUTLINE

1. Introduction: Overview of DWI and its importance in breast cancer; 2. Fundamentals of DWI: Explanation of water diffusion in tissues; ADC values and their significance in DWI; 3. ADC Values and prognostic factors in breast cancer; 4. Benefits and applications of DWI in breast cancer; 5. Quality control and factors influencing repeatability and reproducibility of ADC measure: Techniques to improve the quality of ADC measurements; 6. Comparison of DWI protocols: QIBA recommendations vs. our institute's approach; 7. Technical challenges and limitations of DWI: Techniques to Improve standard DWI; 8. Classification of advanced DWI: Overview of subtypes of advanced DWI, their differences, and advantages; 9. Conclusion.

## BREE-92 **Swipe Left or Right? The Multimodality Imaging Detection and Assessment of the Solitary Dilated Duct**

Participants

Tanya W. Moseley, MD, PhD, Houston, TX (*Presenter*) Consultant, Hologic, Inc; Consultant, Merit Medical Systems, Inc; Owner, TW Moseley, LLC; CEO, TW Moseley, LLC

## TEACHING POINTS

- Review ductal anatomy and the epidemiology of ductal disease.
- Discuss imaging findings of benign and malignant ductal disease.
- Discuss the solitary dilated duct (SDD) and review the BI-RADS® 5th edition's recommendations for classifying and managing ductal lesions.
- Describe the role of imaging in the screening and diagnosing of ductal disease including mammography/tomosynthesis, ultrasound, magnetic resonance imaging, and galactography/ductography.
- Review methods and challenges specific to the sampling of ductal abnormalities.

## TABLE OF CONTENTS/OUTLINE

-Introduction-Anatomy-Benign ductal findings-Malignant ductal findings-Solitary dilated duct (SDD) BI-RADS® 5th edition's recommendation-Imaging's role in screening and diagnosis and the correlation with prognosis-Imaging Techniques to evaluate the ductal anatomy and pathology-Methods to sample ductal abnormalities and tips to overcome the challenges that may be encountered-Conclusion

## BREE-93 **Idiopathic Granulomatous Mastitis: A Case-Based Review**

## TEACHING POINTS

1. Idiopathic granulomatous mastitis (IGM) is estimated to affect 2.4/100,000 women, at median age of 36.5 years, and bilateral involvement in 8.8%. 2. Common symptoms are pain, erythema, palpable lump, and less frequently, fistulous drainage or nipple discharge. 3. The most common ultrasound findings are hypoechoic collection (75.9%) and skin involvement (53.5%). Mammography is often nonspecific, but common findings include focal asymmetry (51.6%), global asymmetry (18.3%), mass (17.2%), abnormal lymph nodes (8.6%). 4. IGM can mimic infectious mastitis or breast cancer on imaging and clinically. 5. Biopsy is usually required to confirm diagnosis and guide management. Often biopsy is necessary to exclude malignancy, especially inflammatory or triple-negative subtypes. Suspected IGM may be tentatively diagnosed by clinically assessing treatment response, but given overlap of imaging features and different treatment for IGM and infectious mastitis, biopsy is often needed. 6. Imaging findings often persist after resolution of clinical symptoms, thus clinical follow-up should be the mainstay for surveillance.

## TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Typical imaging findings on mammography and ultrasound 3. Other entities that mimic IGM 4. Case-based review of biopsy-proven cases using key images with descriptions, treatment and clinical outcome data 5. Biopsy and management considerations

## BREE-94 **Don't Be Fooled: Not Every Late-Onset Peri-Implant Effusion is Seroma! A Case-Based Review of Breast Implant-Associated Anaplastic Large Cell Lymphoma (BIA-ALCL)**

## TEACHING POINTS

We report the case of a female patient, with a history of mastoplasty six years ago, reporting sudden enlargement of the left breast. Imaging exams showed the presence of peri-implant fluid in the same breast, with the analysis of the fluid confirming the BIA-ALCL. Breast Implant-associated Anaplastic Large Cell Lymphoma (BIA-ALCL) is characterized by a late-onset peri-implant effusion, appearing on average 10 years after exposure to breast implants. The pathogenesis is not completely identified, but it is known that cases of BIA-ALCL are related to textured prostheses, with the surface of the prosthesis being the most important factor in inducing the disease. It may present only with the effusion (subtype of effusion) or associated with a peri-implant mass (mass-forming disease). The main associated symptoms are sudden edema secondary to the peri-implant effusion and, in case of mass-forming disease, the presence of a palpable nodule. Multiple imaging methods can be used in the evaluation of patients with suspected BIA-ALCL. However, diagnostic confirmation depends on the analysis of the fluid found. The diagnosis of BIA-ALCL is made with the characterization of morphologically atypical lymphocytes, with CD30 expression and negativity for ALK-1. The differential diagnosis of the effusion subtype is made with late seroma. Distant disease is rare, being a neoplasm with a high potential for cure, if identified in the early stages and when not associated with masses, with a surgical approach as a curative technique, in the case of the subtype of effusion.

## TABLE OF CONTENTS/OUTLINE

Introduction; Definition and Subtypes; Pathogenesis; Symptoms; Image Methods; Diagnosis; Differential diagnoses

## BREE-95 **Cystic Breast Lesions- What to Do When It's Not Simple**

Participants

Laura Harper, MD, Rochester, MN (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Imaging features of benign and malignant cystic lesions may overlap, causing misclassification with the potential to produce diagnostic delay and harm. The purpose of this exhibit is to review ultrasound features of benign and malignant cystic breast masses to guide appropriate characterization and management. The Breast Imaging Reporting and Data System (BIRADS) assessment categories will be reviewed as it pertains to cystic breast masses, including review of appropriate utilization of the BIRADS-3 (probably benign) assessment category. Emphasis will be placed on recognizing suspicious imaging features warranting further evaluation with percutaneous biopsy. Teaching Points: 1. Examine imaging features of various cystic breast masses (Simple cysts, complicated cysts, and complex cystic and solid mass). 2. Discuss overlap of benign and malignant complex cystic and solid masses (ex: hematoma, abscess, cancer). 3. Review appropriate BI-RADS category assessment and management for various cystic lesions

#### TABLE OF CONTENTS/OUTLINE

1. Introduction of the prevalence, clinical presentation and patient factors associated with cystic breast masses 2. Review distinguishing features and BI-RADS category assessments for various cystic masses 3. Multimodality (mammography, contrast-enhanced mammography, ultrasound, and magnetic resonance imaging) case-based review of benign and malignant cystic breast masses 4. Conclusion (summary of key educational points)

#### **BREE-96 Patterns of Breast Cancer Recurrence in the Post-Mastectomy Breast with or without Reconstruction: A Case-Based Review**

Participants

Shannon Lanzo, MD, Stanford, CA (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Women treated for breast cancer with mastectomy with or without reconstruction are at risk of developing loco-regional recurrence along the suture line or within residual tissue. 2. Benign post-operative findings include edema, seroma, hematoma, fat necrosis, post-operative scarring and fibrosis, which evolve over time. 3. Recurrence may be difficult to distinguish from these benign findings. 4. Biopsy is warranted when imaging findings are equivocal.

#### TABLE OF CONTENTS/OUTLINE

1. This case-based exhibit will review the expected post-operative appearance post mastectomy without or with reconstruction using autologous tissue flaps (pedicled or free flap), and/or prosthetic implants. 2. We will illustrate typical imaging features of benign post treatment changes (fat necrosis, fibrosis, edema, skin thickening, etc.) and malignant findings on mammogram, ultrasound, and MRI. 3. We will review appropriate use of combined imaging and biopsy methods when imaging findings are equivocal.

#### **BREE-97 Keep Calm, It's PASH**

Participants

Daniela Martinez del Razo, MD, Mexico City, Mexico (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

In the daily practice of diagnostic imaging in breast cancer, we find various entities that can simulate malignant diseases and it is very interesting to know their spectrum of presentation in the different imaging modalities. There are few breast alterations that have a typical radiological characteristic, there are multiple benign and malignant pathologies with similar findings in which they overlap, for which it is essential that mastologists know and keep in mind the wide range of pathologies, to take advantage of all the tools at your fingertips and make correct diagnosis

#### TABLE OF CONTENTS/OUTLINE

I show various suspicious imaging findings that were shown to be pseudoangiomatous stromal hyperplasia by percutaneous or surgical biopsy

#### **BREE-98 Diagnostic Potential of Photon-Counting Detector Computed Tomography to Evaluate Breast Cancer Patients**

Participants

Misugi Urano, MD, PhD, Nagoya, Japan (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Photon-counting detector computed tomography (PCD-CT) has several advantages over energy-integrating computed tomography (EID-CT). It provides high spatial resolution and improves image contrast, resulting in precise visualization of soft tissue and microstructures while reducing radiation dose. In addition, a simultaneous multi-energy acquisition offers further qualitative and quantitative information in a single scan. These benefits make PCD-CT a valuable tool for systemic staging, preoperative planning, and post-treatment monitoring of breast cancer patients due to its ability to precisely depict the local extent of tumors and the presence of small lesions. This presentation will focus on PCD-CT in initial staging workup, treatment response assessment, or recurrences monitoring in breast cancer patients, comparing to EID-CT, other image modalities, and pathological results. We will also discuss the advantages and pitfalls of PCD-CT.

#### TABLE OF CONTENTS/OUTLINE
