### Breast Imaging Monday Poster Discussions

#### Sub-Events

#### **M2-SPBR-1 Stand-alone Performance of Artificial Intelligence-based Computer-assisted Diagnosis in Screening Automated Breast Ultrasound**

##### Participants

Haejung Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the stand-alone performance of artificial intelligence-based computer-assisted diagnosis (AI-CAD) in screening automated breast ultrasound (ABUS) interpretation and find the factors associated with false-negative and false-positive results.

##### METHODS AND MATERIALS

The ABUS source data of 435 women in a single institution were retrospectively analyzed using AI-CAD system (LUCAS). Three volume data of antero-posterior, medial, and lateral scanning were obtained for each breast. Of total 435 women, 97 were breast cancer patients with screening detected single malignant lesion between October 2019 and June 2020, and 338 were women who underwent screening ABUS between May 2019 and June 2019 and showed negative final diagnosis. We reviewed the results of AI-CAD system in detecting malignant lesion on ABUS and analyzed the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). Also the associated factors with false-negative and false-positive results were analyzed.

##### RESULTS

The sensitivity, specificity, PPV, and NPV of AI-CAD in ABUS interpretation were 0.75 (73 of 97; 95% confidence interval, 0.65 to 0.83), 0.58 (195 of 338; 95% CI, 0.52 to 0.63), 0.34 (73 of 216; 95% CI, 0.30 to 0.37), and 0.89 (195 of 219; 95% CI, 0.85 to 0.92), respectively. The average number of CAD-detected lesion was 1.2 per study (1.8 in patients with cancer, and 1.0 in patients without cancer). True positive lesions were detected in 1.81 of 3 volumes of breast, while false positive lesions were detected in 1.30 of 3 volumes (1.5 in benign lesions and 1.1 in pseudo-lesions). False-negative results in breast cancer were more frequent for isoechoic mass ( $p < 0.001$ ) and mass without echogenic rind ( $p = 0.043$ ). Among 143 patients with false-positive results, 49 (34.3%) had pseudo-lesions. False-positive results were more frequent for dense breasts on mammography ( $p < 0.001$ ), however, the background echotexture of ABUS was not associated with false positive results or pseudo-lesions.

##### CONCLUSION

s AI system showed NPV of 89% for negative interpretation of ABUS. However, radiologists should carefully recheck the results of AI-CAD system to reduce false-positive results and recall rate.

##### CLINICAL RELEVANCE/APPLICATION

By providing information on the stand-alone performance of AI-CAD in screening ABUS interpretation, it helps to correctly understand the advantages and disadvantages of AI-CAD system and apply them to clinical practice.

#### **M2-SPBR-2 A Novel Triage Model for Screening Mammograms Based on a Density AI and a Cancer Detection AI**

##### PURPOSE

To estimate the effectiveness of a triage model for breast cancer screening examinations based on two AI systems: one for breast density assessment and one for cancer detection.

##### METHODS AND MATERIALS

For this retrospective simulation study, a dataset of 2,981 tomosynthesis screening examinations was collected. The dataset included 696 biopsy-proven cancer cases and 2,285 negative screens (verified by a negative follow-up). For each collected screen, the interpretation made by the primary reader was also collected. A two-steps triage model was set up based on two AI systems: one estimating the breast composition, and one detecting and characterizing regions suspicious for malignancy (hereafter referred to as AI-density and AI-detection). The first step was based on density: examinations whose density was assessed as C or D by AI-density were considered as requiring human interpretation. Examinations whose density was assessed as A or B were further processed by AI-detection: those with an AI-detection score lower than a given threshold were considered negative and not worth of reader interpretation, otherwise they were considered as requiring human interpretation. The proposed triage model is based on the French breast screening context where patients with high density breasts systematically undergo both mammography and ultrasound, and autonomous offloading of examinations by AI is mainly applicable to low density breasts. We examined the effect on recall rate and workload reduction keeping constant the cancer detection rate. We used inverse probability weighting to compensate for distribution differences between the used dataset and a typical screening population.

##### RESULTS

AI-density assessed 611 exams (20.5%) as density A, 1,024 (34.35%) exams as density B, 967 exams (32.44%) as density C and 379 exams (12.71%) as density D. Based on AI-detection scores of examinations assigned with densities A and B, 26.43% of

women were considered negative without significantly affecting the cancer detection rate (which remained constant around 5/1000 - 95% CI 4.6/1000 to 5.7/1000). The recall rate decreased from 10.02% (8.74% - 11.29%) to 8.2% (7.07% - 9.32%).

## CONCLUSION

Results have shown that the proposed two-step triage strategy could safely select patients to be removed from radiologists' workload without affecting the cancer detection rate. A prospective study that applies this model has been set up in France and is supposed to start including patients on January 2024.

## CLINICAL RELEVANCE/APPLICATION

Using two AI systems (one for density and one for cancer detection) to triage mammograms could potentially reduce radiologist workload at constant cancer detection rate, and decrease the rate of women recalled back for further examinations.

### M2-SPBR-3 Automated Assessment of Breast Positioning and Image Quality Using Artificial Intelligence for Digital Breast Tomosynthesis (DBT) with Two-Dimensional Synthetic Mammography and Full-Field Digital Mammography (FFDM)

#### PURPOSE

This study aimed to evaluate the accuracy of an artificial intelligence based tool for automated assessment of breast positioning and image quality in DBT, using synthetically reconstructed projection images.

#### METHODS AND MATERIALS

A total of 150 mammography examinations were enrolled in this study. Subjects underwent screening mammography including DBT with 2D-SM and FFDM. The AI-assisted automated assessment tool evaluated the quality of breast positioning in each image set. Nine image quality criteria evaluating the appearance of the nipple, breast rotation, pectoral muscle, inframammary fold, pectoral nipple line, shoulder overlap shadow, abdominal skin, contralateral breast and foreign body were used for craniocaudal and mediolateral-oblique views. Image quality of cases were also evaluated with the standards of Mammography Quality Standards Act (MQSA) as grade "adequate" or "inadequate". The performance of the AI system was evaluated using accuracy, sensitivity, and specificity. The inter-rater agreement and comparison of their findings with those reported by the AI system was calculated using Cohen's kappa coefficient.

#### RESULTS

The AI algorithm demonstrated high accuracy in distinguishing between adequate and inadequate images, with an overall accuracy of 93%, sensitivity of 94% and specificity of 92% for FFDM and an accuracy of 92%, sensitivity of 95 and specificity of 91% for DBT with 2D-SM. In terms of breast positioning, the AUC of poor imaging quality prediction by AI system according to incomplete gland, incomplete pectoralis muscle, over or insufficient exposure was (0.903 vs 0.937 vs 0.982). Overall accuracy of AI system were 0.958 for FFDM and 0.932 for DBT with 2D-SM. Inter-observer agreement for image quality assessment was found to be 0.82 (95% confidence interval [CI]: 0.77-0.87), indicating substantial agreement between radiologists and AI system using 2D-SM images. The kappa coefficients for breast positioning assessment were also calculated and found to be moderate to substantial, with values ranging from 0.57 to 0.83 (95% CI: 0.48-0.67 and 0.78-0.88, respectively).

## CONCLUSION

The results showed a high degree of agreement between the automated and manual assessments, also indicating the performance of the AI tool in assessing breast positioning and image quality in DBT using 2D-SM images was comparable with that in FFDM.

## CLINICAL RELEVANCE/APPLICATION

The study demonstrated the potential of this AI assisted system to improve the efficiency, accuracy, and reliability in DBT screening.

### M2-SPBR-4 TopoTxR: A Topology-based Framework for Breast Parenchyma Characterization on DCE-MRI

#### Participants

Prateek Prasanna, PhD, Stony Brook, NY (*Presenter*) Nothing to Disclose

#### PURPOSE

In order to comprehensively analyze the biology of breast cancer, it is necessary to examine the surrounding breast parenchyma. Automated characterization of breast parenchyma using DCE-MRI is challenging due to the intricacy of the parenchymal tissue structures. Existing quantitative techniques, when combined with deep learning, are unable to accurately represent the complex structures, such as fibroglandular tissue. The fibroglandular tissue may undergo malignant transformation. To better evaluate the subtle structures of the breast, we propose a novel approach, TopoTxR, that incorporates topological features extracted from persistence diagrams as auxiliary information. This enables the convolutional neural network (CNN) to directly focus on the biologically-relevant topological structures.

#### METHODS AND MATERIALS

We train and validate TopoTxR to predict pathological complete response (pCR) using ISPY-1 post-contrast DCE-MRI data. Our study involves 161 patients, with 47 achieving pCR and 114 not. To enhance the performance of the 3D CNN, we integrated a mask-guided attention module that leverages a prepared topology-related mask. This mask approximates the curvilinear tissue-like structures enclosed by tissues and glands in their proximity. While inputting the raw DCE-MRI as the input of the CNN backbone, we applied the topological structure mask to guide the generation of the attention map in the latent space. TopoTxR takes advantage of the noise-free topological structures while retaining other biologically relevant information of the original data. Finally, we employed a classifier to the attention-filtered features for pCR prediction, followed by a custom loss function combined mask guided loss and refined the classification loss to address the sample imbalance problem.

#### RESULTS

TopoTxR utilizes the topological mask as supplementary input combined with the original image and incorporating Focal Loss. It improves pCR prediction significantly compared to previous methods and it also surpasses the state-of-the-art, Densenet-KD, by

3% in accuracy. Our ablation studies show the effectiveness of mask-guided attention modules and Focal Loss, respectively.

## CONCLUSION

Our novel method leverages pre-computed topological biomarkers to enhance the performance of 3D CNN in pCR prediction. This model reasonably integrates both topology and full image information to obtain and evaluate high biological related features.

## CLINICAL RELEVANCE/APPLICATION

Predicting treatment response enables physicians to plan and determine the most effective treatment strategy for their patients prior to disease progression (i.e. immediate surgical intervention in cases where neoadjuvant chemotherapy is predicted to fail).

### M2-SPBR-5 Cloud-Based Machine Learning Platform for the Detection and Localization of Breast Cancer on DCE-MR Scans

Participants

Gavin Jones, Hummelstown, PA (*Presenter*) Nothing to Disclose

Michelle Le, BEng, Allentown, PA (*Presenter*) Nothing to Disclose

## PURPOSE

Breast cancer is the most common cancer diagnosed in US women and is second to lung cancer as a cause of death in women. Machine learning (ML) can play a role in aiding breast radiologists with the detection and localization of tumors on MRI. The aim of this project was to create an ML algorithm using cloud-based software capable of accurately identifying breast cancer on DCE-MRI. The trained algorithm may be used as a radiologist adjunct in the early identification of lesions.

## METHODS AND MATERIALS

Breast cancer MR images were obtained from a publicly available dataset of 922 radiologist-annotated and biopsy-confirmed breast cancer. The provided annotations denoted a 3D bounding box of each tumor. Using these coordinates, multiple 2D slices of the tumor were selected to augment the total number of tumor-containing images to 1267 training and 396 test images. Tumor images were further processed to exploit contrast enhancement data by compiling pre-contrast tumor slices with their corresponding early and late post-contrast slices into a single RGB image. Cloud-based ML software was then used to train the algorithm on the processed 1267 pre-annotated MR images. Following training, the algorithm's accuracy and precision were assessed using the remaining 396 test images. Tumor subgroup analyses were also performed to assess detection performance on classifiers such as ductal and lobular histology and molecular features such as luminal A/B, HER2+/-, ER +/-, PR+/-, and triple-negative carcinomas.

## RESULTS

The trained ML model had 94.3% recall and 89.8% precision when the probability and overlap thresholds were set to 95% and 30% respectively. When tested on the 396 non-annotated validation images, the model localized breast cancer tumors with a recall of 88.6% and an average precision of 86.5% with a confidence interval of 0.95 and an F1 score of 0.89. For the subgroup analyses, HER2 enriched molecular subtype (n=20) had the highest overall average precision (95.5%), recall (95.5%), and F1 (0.95). The lowest-performing subgroup was lobular carcinoma (n=31) with average precision (88.8%), recall (84.4%), and F1 (0.90).

## CONCLUSION

Our study has shown that ML techniques trained on a large set of annotated MR images can produce a highly accurate breast cancer detection and identification tool. The performance of tumor classifiers varies depending on tumor type, receptor status, and molecular subtype.

## CLINICAL RELEVANCE/APPLICATION

An ML tool that can accurately detect and localize breast cancer tumors can improve care by providing women with diagnoses and thus treatment options more quickly. In the future, this ML model can be made accessible within an online tool that will quickly review breast MR slices and determine if there is breast cancer and localize tumors.

### M2-SPBR-6 Artificial Intelligence-Supported Additional Review of Screening Mammography Improves Radiologist Cancer Detection Rate

## PURPOSE

Studies estimate that for every 5 cancers detected by screening mammography, there is 1 false negative. A common method of reducing the false negative rate is "double-reading," where two readers interpret mammograms. However, double-reading is costly, and single-reading is standard practice in the USA. The purpose of this study was to explore the utility of an Artificial Intelligence (AI) supported additional review process (AIAR) where AI identifies the most suspicious exams for selective additional review. The goal is to realize the benefit of decreased false negatives through double-reading while minimizing additional workload.

## METHODS AND MATERIALS

A total of 522,078 digital breast tomosynthesis screening mammograms from March 2021 to August 2022 underwent AIAR at 5 practices in the US. The dataset contained 2,739 screen-caught cancers. In the AIAR process, screening mammograms were assessed using a custom AI algorithm. Exams considered suspicious by the AI algorithm that were not recalled by the interpreting radiologist (i.e. given a BIRADS 1 or 2) were flagged for review by an experienced radiologist. The reviewer could consult with the interpreting radiologist if they thought a recall was warranted, who could decide whether to revise to a BIRADS 0 and recall the patient. Performance metrics, including recall rate (RR), cancer detection rate (CDR), and positive predictive value 1 (PPV1) were computed for 98 individual interpreting radiologists.

## RESULTS

A total of 19,560 exams were flagged by AIAR, and 201 additional cancers were detected. Thus, with AIAR only 4% of exams required an additional review, while yielding an 8% increase in cancer detection. AIAR increased CDR across practices (range 5-21%), while minimally impacting RR (range 1-3%). PPV1 also increased at every practice (range 3-16%), indicating AIAR finds more cancers for each recall. Radiologists with lower pre-AIAR CDRs improved more compared to those with high pre-AIAR CDR (e.g., CDR increase of 0.55 vs 0.35 for radiologists with pre-AIAR CDR of 2-4 vs 4-6). Finally, AIAR could be further improved to identify up to 243 more cancers by standardizing the consult rate to ~5 consults per 100 reviews which would maximize the positive predictive

value of consults at ~35 cancers per 100 consults.

## CONCLUSION

s AIAR increases cancers detected, while minimizing the additional workload required to identify and recall at-risk patients in a large real-world dataset.

## CLINICAL RELEVANCE/APPLICATION

AIAR is a practical means to improve cancer detection in the real-world, and therefore reduce false negatives without incurring substantial additional costs.

## M2-SPBR-7 Sonographic Prediction of Breast Cancer Patients Non-Responding to Neoadjuvant Chemotherapy at Baseline: Comparison of Standard B-mode and a Deep-Learning Model

Participants

Panagiotis Kapetas, MD, PhD, Vienna, Austria (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate whether pre-therapeutic breast ultrasound (US) can serve in the prediction of breast cancer (BC) patients non-responding to neoadjuvant chemotherapy (NAC) and to compare two different models.

## METHODS AND MATERIALS

This retrospective, IRB-approved study included 245 patients with histologically confirmed invasive BC who underwent NAC. The dataset was divided into a training (165 cases) and a validation set (80 cases). A representative B-mode US image of each tumor from the pre-treatment examination was selected. 2 experienced breast fellows independently evaluated the lesions using standard BI-RADS descriptors. Logistic regression was used to identify independent predictors of response to NAC in the training set and create a model. Additionally, a Resnet18-based neural network with Dropout layers to decrease the amount of overfitting was trained to predict the treatment outcome. The performance of both models was evaluated on the validation set using descriptive statistics. Postoperative histology was the standard of reference for treatment response: absence (pathological complete response- pCR) or presence of residual invasive tumor in the breast or axillary lymph nodes.

## RESULTS

145 patients (59.2%) did not achieve a pCR. From the BI-RADS descriptors, oval or round shape, microlobulated or spiculated margin and the presence of calcifications or edema proved to be independent predictors of pCR. A model using these showed an accuracy, sensitivity, specificity, positive and negative predictive value of respectively 65%, 82%, 41%, 67% and 61% for the prediction of non-responders to NAC. Compared to that, the DL-based model achieved an accuracy, sensitivity, specificity, positive and negative predictive value of 72%, 83%, 55%, 74% and 69%.

## CONCLUSION

s Breast US can accurately predict lack of response to NAC for BC patients prior to its initiation. A DL model using images from the baseline US examination demonstrates an increased diagnostic performance as compared to standard B-mode BI-RADS descriptors.

## CLINICAL RELEVANCE/APPLICATION

Pre-therapeutic breast ultrasound offers accurate information, which may aid in the management of breast cancer patients, planned to undergo neoadjuvant chemotherapy.

## M2-SPBR-8 Prediction of Pathologic Response to Neoadjuvant Chemotherapy in Patients with Breast Cancer Based on Artificial Intelligence Techniques

Participants

Ahmed Sharafeldein, Louisville, KY (*Presenter*) Nothing to Disclose

## PURPOSE

The aim is to develop a computer aided diagnosis (CAD) system to accurately predict the response of neoadjuvant chemotherapy on breast cancer patients based on magnetic resonance imaging (MRI). The system aims to predict three possible responses, which are complete response (indicating the complete disappearance of the lesion), partial response (in which the tumor partially disappeared), or no response (suggesting that the tumor did not respond to chemotherapy).

## METHODS AND MATERIALS

The proposed system is composed of four distinct stages. The first stage involves manual delineation of the breast tumor by an experienced radiologist. Secondly, four distinct features are extracted from the manually segmented tumor, namely functional imaging markers, apparent diffusion coefficient (ADC), computed from diffusion-weighted imaging (DWI) using baseline scans and b-500, b-1000, and b-1500 scans, along with texture features, grey level co-occurrence matrix (GLCM) and grey level run length matrix (GLRLM), extracted from T1-weighted, T2-weighted, and STIR models. Thirdly, these features are statistically represented using percentiles, which helps to capture the salient aspects of the data distribution while minimizing the impact of outliers. Finally, the features are combined together and then fed into a gradient boosting classifier.

## RESULTS

To evaluate the effectiveness of the proposed system, a dataset of 110 breast cancer patients was used, with 28 patients showing complete response, 53 with partial response, and 29 with no response. The system's performance is assessed using k=15 cross-validation approach. The findings demonstrated that the proposed system outperforms the accuracy of classifying each feature individually as well as other statistical machine learning classifiers, achieving an impressive accuracy of 85.5 a specificity of 73.5 a sensitivity of 98.5. The results clearly indicate that integrating functional imaging markers and texture markers using majority voting approach significantly enhances the diagnostic system's performance.

## CONCLUSION

s The proposed CAD system accurately predicts the response of neoadjuvant chemotherapy on breast cancer patients by utilizing

various markers related to the pathology. The system's performance is further improved by integrating functional imaging markers and texture markers in a non-invasive manner.

#### **CLINICAL RELEVANCE/APPLICATION**

The motivation behind this objective is to reduce the risk of exposure to neoadjuvant chemotherapy, which can be painful and dangerous. By assessing the response of the impact of chemotherapy exposure, physicians can determine whether chemotherapy is necessary or if the patient should undergo surgery directly.

#### **M2-SPBR-9 Analyzing the Collinearity of Race and Breast Tissue Density in Misclassification of Abnormality in Screening Mammograms**

##### **PURPOSE**

Deep learning techniques have been developed to assist the assessment of potential breast cancer in screening mammograms. Research has shown gaps in model performance within subgroups of some demographic and imaging features in classifying abnormality in mammograms presenting region of interests (ROIs); However, the collinearity between such features is unknown. The purpose of this study was to investigate the collinearity of those demographic and imaging characteristics in association with the performance of deep learning model in classifying abnormality in screening mammograms.

##### **METHODS AND MATERIALS**

We applied a modified ResNet152V2 convolutional neural network structure trained on 39,054 and tested on 13,390 mammogram patches from (REDACTED) dataset. Positive patches are the ROIs annotated by the original interpreting radiologists on BI-RADS 0 images; Negative patches were randomly selected from regions in BI-RADS 0 images avoiding ROIs, and regions in BI-RADS 1 and BI-RADS 2 images. The classification result of test set patches was aggregated to their source images, while only images containing all correctly classified patches were considered as successful prediction. Image-level classification results on 5,723 test images containing ROIs were analyzed by logistic regression models for the association with race and tissue densities, separately and together. Variance inflation factor (VIF) was calculated for race and tissue density.

##### **RESULTS**

VIF between race and density is 1.000005, showing features are moderately, nearly not correlated. Experiment 1 combined three race groups and four densities into 12 subgroups, no significant correlation with image misclassification was found. Experiment 2 had three models built in White, Black and Other races populations separately, we found that only in Black population, BI-RADS densities C ( $p=0.026$ ) and D ( $p=0.012$ ) have significantly higher chance to be misclassified.

##### **CONCLUSION**

The study reveals there is no collinearity issue with race and tissue density in the dataset and deep learning structure that were used.

#### **CLINICAL RELEVANCE/APPLICATION**

This can be used as a guide for future model development.

Printed on: 04/12/24

M2-SPCA

### Cardiac Imaging Monday Poster Discussions

#### Sub-Events

#### **M2-SPCA-1 Construction of a Predictive Model Combining Clinical and CCTA Parameters for the Coronary Collateral Circulation in Patients with Ischemic Heart Disease**

Participants  
Ting Mao, MA, Changsha, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Coronary computed tomographic angiography (CCTA) currently cannot directly assess coronary collateral circulation due to limited spatial and temporal resolution. The aim of this study is to construct a predictive model combining clinical and CCTA parameters for the good coronary collateral circulation (CCC) in patients with ischemic heart disease (IHD).

#### **METHODS AND MATERIALS**

This study is a retrospective analysis of 634 consecutive patients with IHD whose luminal stenosis of at least 70% on coronary angiography (CAG) and underwent CCTA within 2 months prior to CAG. According to the CAG, patients with a Rentrop grade of 2-3 were defined as having good CCC and those with a Rentrop grade of 0-1 as having poor CCC. Finally, 80 patients with good CCC were enrolled, while 80 age- and sex-matched patients with poor CCC were randomly selected as the control group. Complete clinical data were collected and pericoronary fat attenuation index (FAI) and CT-fraction flow reserve (CT-FFR) were measured. CT-FFR measurements included lesion-specific CT-FFR (2 cm distal to the stenosis), vessel-specific CT-FFR (distal-most vessel with diameter of 2 mm) and  $\Delta$ CT-FFR (difference between proximal and distal CT-FFR of the lesion). The correlation and predictive value of these clinical and imaging parameters with good CCC were analyzed.

#### **RESULTS**

The differences in RCA-FAI,  $\Delta$ CT-FFR and lesion-specific CT-FFR in patients with good CCC were statistically significant compared with controls [-78.49 $\pm$ 10.92HU vs. -73.54 $\pm$ 8.92HU, 0.09 (0.06, 0.15) vs. 0.13 (0.10, 0.16), 0.67 (0.62, 0.73) vs. 0.66 (0.59, 0.70), P=0.002, 0.001, 0.027, respectively]; Spearman correlation analysis showed that Beta-blocker use and lesion-specific CT-FFR were positively correlated with good CCC (r=0.282, 0.176, P=0.001, 0.026, respectively), and TG, TG/HDL-C, RCA-FAI, and  $\Delta$ CT-FFR were negatively correlated with good CCC (r=-0.252, -0.245, -0.233, -0.257, P=0.001, 0.002, 0.003, 0.001, respectively). Multifactorial logistic regression analysis showed that Beta-blocker use, RCA-FAI and  $\Delta$ CT-FFR were independent predictors of good CCC. The combined model constructed by these three indicators predicted good CCC with an AUC of 0.747, a sensitivity of 65.00% and a specificity of 80.00%.

#### **CONCLUSION**

The FAI and CT-FFR by CCTA correlated with CCC, and the combined Beta-blocker use, RCA-FAI and  $\Delta$ CT-FFR helped to noninvasively assess the extent of CCC in patients with IHD.

#### **CLINICAL RELEVANCE/APPLICATION**

Good CCC is known to reduce the incidence of major adverse cardiovascular events in patients with IHD. Our study shows that combined CCTA-derived FAI, CT-FFR and clinical indexes may contribute to the non-invasive assessment of CCC in clinical work.

#### **M2-SPCA-2 Lipoprotein(a) Associated with Myocardial Infarction in Patients with Low Attenuation Plaque: A Multicenter Prospective Study**

#### **PURPOSE**

Lipoprotein(a) [Lp(a)] is associated with an increased risk of myocardial infarction (MI). However, the mechanism underlying this association has yet to be fully elucidated. To evaluate whether association between Lp(a) and MI risk is modified by the presence of low-attenuation plaque (LAP) identified by coronary CT angiography (CCTA).

#### **METHODS AND MATERIALS**

Between January 2010 and July 2022, consecutive patients suspected of coronary artery disease who underwent CCTA and Lp(a) measurement were prospectively enrolled from three institutions. High Lp(a) was defined as Lp(a) = 50 mg/dL. The primary endpoint was a composite of time to fatal or nonfatal MI. Multivariable Cox regression analysis was applied to compare survival rates.

#### **RESULTS**

A total of 5607 patients (mean age, 54  $\pm$  11 years) were included. Multivariable logistic regression analysis revealed that elevated Lp(a) levels were independently associated with the presence of LAP at CCTA (adjusted OR=5.21, 95% CI: 4.44 to 6.26, p<0.001). Furthermore, multivariate linear regression analysis indicated that Lp(a) levels were positively associated with LAP volume (standardized  $\beta$ =0.46, p<0.001). During a median follow-up of 8.2 [7.2, 9.3] years, 261 (4.6%) patients experienced MI events. In the overall population, elevated Lp(a) levels were associated with MI occurrence [adjusted hazard ratio (aHR)= 1.91, 95% CI: 1.46 to 2.49, p<0.001]. An Lp(a)-by-LAP interaction was observed (p interaction < 0.001). When stratified by the presence or absence

of LAP, Lp(a) was associated with MI in patients with LAP (aHR= 3.03, 95% CI: 1.92 to 4.76, p<0.001); however, no association was observed among the patients without LAP (aHR=1.12, 95% CI: 0.74 to 1.70, p=0.570). The principal findings remained unchanged in the patients with CT-FFR > 0.8.

## CONCLUSION

Elevated lipoprotein(a) predominantly augmented the risk of myocardial infarction in patients with low-attenuation plaque identified by coronary CT angiography.

## CLINICAL RELEVANCE/APPLICATION

The mechanism underlying the association between lipoprotein(a)[Lp(a)] and myocardial infarction (MI) has yet to be fully elucidated. Our study evaluate whether association between Lp(a) and MI risk is modified by the presence of low-attenuation plaque (LAP) identified by coronary CT angiography. We find that elevation of Lp(a) was exclusively associated with MI in patients with evidence of LAP but not in those without LAP. Our study indicated that Lp(a) is not an equivalent risk factor for MI, which has important implications for risk assessment as well as the use of preventive therapies.

## M2-SPCA-3 Preliminary Investigation of the Right Ventricular Scalloping Index as a Novel CMR-derived Marker for Diagnosing Arrhythmogenic Right Ventricular Cardiomyopathy

### PURPOSE

The cardiac magnetic resonance (CMR) evaluation of right ventricular (RV) morphologic abnormalities in patients with arrhythmogenic right ventricular cardiomyopathy (ARVC) is subjective. Here we aimed to develop a novel index, the right ventricular scalloping index (RVSI), to standardize the measurement of RV free wall scalloping and aid in the imaging diagnosis.

### METHODS AND MATERIALS

We retrospectively included 15 patients with definite ARVC and 45 age- and sex-matched patients with idiopathic right ventricular outflow tract ventricular arrhythmia (RVOT-VA) as controls. The RVSI was measured from cine images on four-chamber view to evaluate its ability to distinguish between ARVC and RVOT-VA patients.

### RESULTS

The RVSI was significantly higher in the ARVC than RVOT-VA group (1.57±0.22 vs. 1.27±0.07, p<0.001). The RVSI demonstrated high intra- and interobserver reliability (intraclass correlation coefficient, 0.94 and 0.93, respectively). A cut-off value of RVSI = 1.38 provided high sensitivity of 86.7% and high specificity of 95.6%. Moderate linear correlations were found between RVSI and RVEF (r=-0.42, p<0.001) as well as between RVSI and RVEDVI (r=0.5, p<0.001). The subgroup analysis revealed a moderate linear correlation between RVSI and RVEDVI (r=0.67, p=0.006) in the ARVC subgroup. In a multivariable analysis, a family history of ARVC or sudden cardiac death (odds ratio, 98.14; 95% confidence interval, 2.34-4116.35; p=0.016) and an RVSI = 1.38 (odds ratio, 145.24; 95% confidence interval, 9.90-2131.10; p<0.001) remained predictive of definite ARVC.

## CONCLUSION

RVSI is a quantitative method with good performance for distinguishing ARVC and RVOT-VA patients.

## CLINICAL RELEVANCE/APPLICATION

ARVC is among the major differential diagnoses to be considered in patients with an initial impression of RVOT-VA, image survey with CMR before ablation is recommended to provide a comprehensive assessment of RV morphology, and RVSI is easy and intuitive to measure.

## M2-SPCA-4 Regional Variation of Left Ventricular Myocardial T2 Mapping Values and Diagnostic Performance for Active Cardiac Sarcoidosis

Participants

Jordan Chamberlin, MD, Charleston, SC (*Presenter*) Nothing to Disclose

### PURPOSE

Myocardial tissue characterization with T2 mapping has been shown to aid in diagnosis of cardiac sarcoidosis, but the regional variation and diagnostic performance has not been well evaluated.

### METHODS AND MATERIALS

2503 patients undergoing 1.5T cardiac MRI from 2017-2022 were queried. 326 patients with biopsy proven extracardiac sarcoidosis were enrolled in this retrospective cohort analysis, of which 110 were found to have complete T2 mapping series. The left ventricle was manually delineated into the 16 corresponding anatomic segments and 7 regions (Basal, mid, apical, anterior, inferior, septal, and lateral) according to the American Heart Association segmentation guidelines. Active cardiac sarcoidosis (aCS) was defined using the 2017 Japanese Circulation Society criteria within 30 days of imaging. Optimal thresholds were calculated using a balanced resampling bootstrapping technique. The optimal thresholds were rounded to the nearest integer for ease of clinical use. Mann-Whitney U Tests were used for comparing continuous distributions.

### RESULTS

37 (33.6%) patients (mean age 57 years, 65.9% males, 63.4% Black) were found to meet aCS criteria. T2 values across all myocardial regions were found to be significantly higher for patients meeting criteria for aCS (P < 0.05). Median regional T2 values in patients with aCS ranged from 48.6 ms (septal) to 50.8 ms (apical) and median regional T2 values in patients without aCS ranged from 47.0 ms (lateral) to 49.5 ms (apical). Utilizing optimized thresholds (>50ms), the septal myocardium was most specific for active disease (specificity = 0.923). The single region most sensitive for active disease involvement was the inferior segments (sensitivity = 0.630). Using a 50 ms positive threshold for each region, the positive predictive value (PPV) increased proportionally with the addition of each positive region (PPV 1 region > 50ms, = 0.42, PPV 5 regions = 0.65, PPV 6 regions = 0.88, PPV 7 regions = 1.00). Correspondingly, using a < 47 ms negative threshold, the negative predictive value for ruling out aCS was highest for three segments < 47 ms (NPV = 0.82).

## CONCLUSION

s T2 mapping values vary significantly across the left ventricular myocardium. The best threshold for active disease was found to be  $> 50$  ms, and the best threshold for ruling out active disease was  $< 47$  ms. Elevated regional T2 mapping (especially in the septal and inferior segments) is highly specific for active disease and shows a proportional relationship of myocardial involvement with diagnostic performance.

#### CLINICAL RELEVANCE/APPLICATION

T2 mapping, with attention to regional variation, can help identify patients with active cardiac sarcoidosis.

#### M2-SPCA-5 Cardiac Magnetic Resonance Feature-tracking Assessment of Whole-heart Myocardial Mechanics: Prognostic Value for Early Outcomes in Non-ischemic Dilated Cardiomyopathy

Participants

Gryte Galnaitiene, MD, Kaunas, Lithuania (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the prognostic value of whole-heart myocardial strain parameters derived from feature tracking (FT) on cardiac magnetic resonance imaging (CMRI) for early outcomes in patients with nonischemic dilated cardiomyopathy (NIDCM).

#### METHODS AND MATERIALS

This was a single-center prospective study involving 97 patients (mean age  $49.5 \pm 10.1$  years; 69.1% males) with NIDCM. We identified the baseline CMRI-derived whole-heart myocardial mechanical parameters: global longitudinal and circumferential strains of the left ventricle (LVGLS and LVGCS, respectively), global longitudinal strain of the right ventricle (RVGLS), peak longitudinal strain of the left atrium (LA strain) and right atrium (RA strain). The volumes of both ventricles and areas of both atria were also assessed. We evaluated the prognostic impact of the mechanical parameters for early outcomes that were: cardiac death, heart transplantation and hospitalization for worsening heart failure (HF) at 1 year after diagnosis of NIDCM. Logistic regression analysis was used to assess the potential predictors of these early outcomes.

#### RESULTS

The patients were divided into two groups according to the presence of early outcomes. The groups did not differ in mean age and males ( $p > 0.05$ ). The early outcomes were established in 32 patients (3 heart transplantations, 9 cardiac death, and 30 hospitalizations for HF worsening). All patients' left ventricular ejection fraction (LVEF) was severely reduced (mean LVEF  $28.9 \pm 8.9\%$ ) and more decreased in the group with early adverse outcomes ( $23.7 \pm 10.1\%$  vs  $32.9 \pm 10.6\%$ ,  $p < 0.001$ ). Both ventricles and atria were more dilated in the group with early adverse outcomes ( $p < 0.05$ ). Patients without early outcomes had higher LVGLS and RVGLS values ( $-8.2 \pm 4.1$  vs  $-11.7 \pm 4.6$  and  $-12.7 \pm 5.3$  vs  $-16.8 \pm 6.5$ , respectively,  $p < 0.05$ ). The similar tendency was noticed in LA strain and RA strain parameters ( $8.4 \pm 5.0$  vs  $14.6 \pm 4.3$  and  $11.5 \pm 6.9$  vs  $17.1 \pm 8.0$ , respectively,  $p < 0.05$ ). Logistic regression analysis showed that LVGLS was an independent predictor of early adverse outcomes in patients with NIDCM after 1 year ( $p = 0.001$ ).

#### CONCLUSION

s LVGLS derived from FT on CMRI can be a significant independent predictor of early adverse outcomes in patients with NIDCM.

#### CLINICAL RELEVANCE/APPLICATION

The mechanics of all parts of the heart in patients with NIDCM were evaluated. It was revealed that LVGLS has an additive prognostic value to predict early adverse outcomes in patients with severely reduced LVEF and NIDCM.

#### M2-SPCA-6 Evaluation of Myocardial Histological Properties by Pharmacokinetic Analysis Using Golden-angle Radial Sparse Parallel Imaging-volumetric Interpolated Breath-hold Examination (GRASP-VIBE)

Participants

Masaru Shiotani, RT, Suita, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

Golden-angle radial sparse parallel imaging-volumetric interpolated breath-hold examination (GRASP-VIBE) is a sequence used for dynamic contrast-enhance (DCE) MRI that is robust to motion and enables to evaluate of tissue dynamic contrast analysis. This study examined the feasibility of myocardial perfusion imaging under free-breathing conditions using the GRASP-VIBE method and the possibility of assessing myocardial properties using pharmacokinetic analysis.

#### METHODS AND MATERIALS

Prior to cardiac contrast-enhanced MRI, written informed consent was obtained from all 60 subjects enrolled in the study. Perfusion imaging was performed using GRASP-VIBE for 100 seconds following bolus injection of contrast agent. 3D-image reconstruction was performed with a temporal resolution of 3.0 seconds with liver gate, a breath correction technique using liver tracking. The reconstructed images were visually evaluated for streak and cardiac motion artifacts using a 5-point scale, and the image set with the best visual quality was chosen for pharmacokinetic analysis. The analysis was conducted using a workstation (Syngo Tissue 4D) and involved placing a region of interest (ROI) in the septum of the left ventricular myocardium and calculating the volume transfer constant (Ktrans) using curve fitting with the Tofts model. The myocardial properties were evaluated by pharmacokinetic analysis for the three groups of hypertrophic cardiomyopathy (HCM), dilated cardiomyopathy (DCM), and normal subjects, as diagnosed from clinical information. ROC analysis determined cutoff values for differentiation of these diseases using Ktrans, and sensitivity and specificity were calculated.

#### RESULTS

Among the participants, 7 were diagnosed as normal, 14 as HCM, and 8 as DCM. The Ktrans was significantly lower in the HCM (0.606,  $p = 0.0104$ ) and DCM (0.694,  $p = 0.0188$ ) groups compared to the normal group (1.299). The area under the curve (AUC) for differentiating HCM from normal myocardium was 0.964, and the sensitivity and specificity were 0.857 and 1.00, respectively, when a cutoff value of 0.816 was used. The AUC for differentiating DCM from normal myocardium was 0.939, and the sensitivity and specificity were 0.875 and 1.00, respectively, when a cutoff value of 0.834 was used.

#### CONCLUSION

s GRASP-VIBE is a promising tool for evaluating myocardial perfusion and has the potential to become a new myocardial histological characterization index using pharmacokinetic analysis.

#### **CLINICAL RELEVANCE/APPLICATION**

GRASP-VIBE can acquire myocardial perfusion images without motion artifacts under free breathing without ECG synchronization. Ktrans might be a new biomarker for assessing myocardial properties.

#### **M2-SPCA-7 Coronary Microvascular Dysfunction in Nonobstructive Hypertrophic Cardiomyopathy: A Cardiac Magnetic Resonance First-pass Perfusion Study**

Participants

Wei Gao, Kunming, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Coronary microvascular dysfunction (CMD) may be associated with adverse cardiovascular outcomes in nonobstructive hypertrophic cardiomyopathy (NOHCM). The aims of this study were to assess CMD in patients with NOHCM using cardiac MR rest first-pass perfusion imaging, and explored significant risk factors for CMD.

#### **METHODS AND MATERIALS**

This was a retrospective cohort study of patients with NOHCM (n=47), obstructive hypertrophic cardiomyopathy (OHCM, n=18), and healthy controls (HCs, n=28). Maximal wall thickness, late gadolinium enhancement (LGE), and perfusion parameters including time to peak (Tpeak), peak signal intensity (SI peak), and up-slope were assessed according to AHA-16 myocardial segments. The ratio between the left ventricular outflow tract (LVOT) and aorta (AO) diameter was measured. Based on the segmental presence or absence of hypertrophy or LGE, segments in HCM were divided into four subgroups: H-LG-, H-LG+, H+LG-, H+LG+, and perfusion parameters were compared.

#### **RESULTS**

The OHCM group had significantly increased Tpeak and reduced up-slope compared with the NOHCM group (both  $P < 0.001$ ). The NOHCM group had significantly prolonged Tpeak and decreased up-slope compared with HCs (Tpeak:  $30.85 \pm 3.35$  vs.  $25.10 \pm 3.69$  s; up-slope:  $18.36 \pm 4.73$  vs.  $23.62 \pm 4.84$ , both  $P < 0.001$ ). The H-LG- segments (n = 217) in the NOHCM group had a longer Tpeak and lower up-slope compared with segments in HCs (n = 448) (Tpeak:  $29.98 \pm 3.64$  vs.  $25.11 \pm 4.11$ s; up-slope:  $18.99 \pm 4.88$  vs.  $23.84 \pm 6.99$ , both  $P < 0.001$ ). In patients with NOHCM, smaller LVOT/AO diameter ratio is closely associated with increased Tpeak (adjusted  $\beta$ :  $-0.501$ ,  $P < 0.001$ ) and decreased up-slope (adjusted  $\beta$ :  $-0.499$ ,  $P = 0.002$ ).

#### **CONCLUSION**

s CMD is highly prevalent in subjects with NOHCM even in the H-LG- segments. In NOHCM, CMD is related to the reduction of LVOT/AO diameter ratio.

#### **CLINICAL RELEVANCE/APPLICATION**

Our results urge that reconsideration of the management decisions in patients with NOHCM, and more attention should be paid to their CMD, leading to a more thoughtful assessment of risk stratification. It also implied that LVOT/AO diameter ratio may be a useful early imaging biomarker that could potentially be used to monitor disease progression and response to treatment outcomes.

M2-SPCH

### Chest Imaging Monday Poster Discussions

#### Sub-Events

#### **M2-SPCH-1 Low-field MRI to Visualize Interstitial Lung Disease Yields High Conformity with CT in Assessing Fibrosis Extent**

Participants

Nadine Bayerl, Erlangen, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The purpose of this study was to assess the feasibility of lung imaging using a 0.55 T MRI for visualization of interstitial lung disease (ILD) compared to high-resolution CT (HRCT) as the current standard of reference.

#### **METHODS AND MATERIALS**

This ongoing prospective clinical trial complied with the Declaration of Helsinki and enrolled 25 consecutive patients so far (mean age  $63 \pm 13$  years; male  $n=15$ ; female  $n=10$ ). Inclusion criteria were confirmed ILD on HRCT and the absence of MRI contraindications. Underlying primary diseases were systemic sclerosis ( $n=16$ ), anti-synthetase syndrome ( $n=3$ ), rheumatoid arthritis ( $n=2$ ), mixed collagenases ( $n=1$ ), systemic lupus erythematosus ( $n=1$ ) and idiopathic pulmonary fibrosis ( $n=2$ ). All patients gave informed written consent. Within the maximum of 30 days, patients underwent conventional HRCT and lung MRI on a 0.55 T scanner. In the latter, two-dimensional turbo-spin-echo (TSE) proton density-weighted sequences (TE/TR=35/2000 milliseconds) with BLADE (periodically rotated overlapping parallel lines with enhanced reconstruction) readout,  $1.25 \times 1.25$  mm<sup>2</sup> in plane-resolution,  $304 \times 304$  matrix and 6 mm slice thickness were acquired in transversal plane for visualization of pulmonary findings. Evaluating the visualization of ILD was performed at five defined levels of the lung by assessing the overall extent of ILD, ground-glass opacity (GGO) and reticulation. Wilcoxon signed-rank tests were performed to evaluate the differences between the paired groups. Significance was assumed for  $p < 0.05$ . Statistical analysis was carried out using GraphPad Prism 9 for macOS, Version 9.4.1 (458).

#### **RESULTS**

Low-field MRI of the lung allowed an assessment of the overall extent of pulmonary fibrosis comparable to CT (MRI, median=10 %, interquartile range IQR=5-40%; CT, median=15%, IQR=5-40%) with no significant differences between the two modalities. In MRI the extent of reticulation was slightly underestimated compared to CT (MRI, median=5%, IQR=5-18%; CT, median=10%, IQR=5-20%), and the extent of GGO was overestimated (MRI, median=5%, IQR=0-20%; CT, median=5%, IQR=0-10%), both reaching significance ( $p < 0.01$ ). The main limitation of this still ongoing study is the small sample size. Our observations will be substantiated in further studies.

#### **CONCLUSION**

Our study indicates that low-field MRI of the lung provides a reliable visualization of overall extent of ILD and could be useful for monitoring in follow-up examinations as a radiation-free alternative to HRCT.

#### **CLINICAL RELEVANCE/APPLICATION**

Patients undergo CT scans up to once a year to monitor the extent of ILD, resulting in repeated radiation exposure. Low-field MRI has the potential to be a promising radiation-free alternative to CT for follow-up.

#### **M2-SPCH-2 Idiopathic and Infection-triggered Acute Exacerbation of Idiopathic Inflammatory Myopathies-associated Interstitial Lung Disease: Clinical, Radiological Features and Prognosis**

#### **PURPOSE**

Acute exacerbation (AE) of idiopathic inflammatory myopathies-associated interstitial lung disease (IIM-ILD) is a life-threatening event. According to the newly proposed diagnostic criteria for the AE of rheumatic disease-associated interstitial lung disease (RD-ILD), infection is regarded as one of the triggers of AE, and AE could be categorised as idiopathic (I-AE) or infection-triggered (IT-AE). In the present study, we aimed to investigate the differences in the clinical, radiological features and prognosis between I-AE and IT-AE of IIM-ILD patients.

#### **METHODS AND MATERIALS**

We retrospectively analysed 69 patients with AE-IIM-ILD (I-AE (34), IT-AE (35)) in our hospital consecutively between January 2014 and December 2020. Infection was identified as confirmation of bacteria, virus, or fungus in samples obtained from the respiratory tract. The outcome was 1-year all-cause mortality.

#### **RESULTS**

I-AE patients showed higher haemoglobin and PaO<sub>2</sub>/FiO<sub>2</sub> ratio than IT-AE patients ( $P < 0.05$ ), and lower pulse, body temperature, white blood cell (WBC) count, neutrophil percentage (NEU), lower C-reaction protein, erythrocyte sedimentation rate, lactate dehydrogenase, hydroxybutyrate dehydrogenase levels, and lower extent of ground-glass opacities (GGO) on HRCT than IT-AE

patients ( $P < 0.05$ ). Multiple logistic regression analysis showed that the combination of NEU and the extent of GGO could help discriminate I-AE from iT-AE patients; the area under the receiver operating characteristic (ROC) curves (AUC) was 0.812 (95%CI 0.711-0.913, Sensitivity 0.714, Specificity 0.735, Accuracy 0.725). There is a significant difference in 1-year all-cause mortality between I-AE and iT-AE patients (mortality: I-AE 17.9%, iT-AE 54.3%; log-rank test,  $P = 0.0023$ ).

## CONCLUSION

s Infection-triggered AE-IIM-ILD suffered a poorer prognosis than the idiopathic AE-IIM-ILD. The combination of NEU and the extent of GGO on HRCT could help differentiate between the two groups.

## CLINICAL RELEVANCE/APPLICATION

Distinguishing infection-triggered AE from idiopathic AE of IIM-ILD is essential in clinical practice for providing appropriate treatment. NEU combined with GGO extent on HRCT could help differentiate idiopathic AE from infection-triggered AE of IIM-ILD. Infection-triggered AE-IIM-ILD suffered a poorer prognosis than the idiopathic AE-IIM-ILD.

## M2-SPCH-3 Role and Accuracy of MRI in Connective Tissue Disease Related Interstitial Lung Disease

### PURPOSE

To determine diagnostic accuracy of MRI with respect to HRCT in connective tissue disease related interstitial lung disease CTD-ILD.

### METHODS AND MATERIALS

Prospective single-center diagnostic study with sample size of 31 patients of CTD-ILD. Patients underwent HRCT chest and MRI chest on a 1.5 T scanner. PFT and 6-minute-walk-test were done. Warrick-scores and extent-scores were calculated for HRCT and MRI. Warrick score is sum of morphology-score extent-score. Morphology score is sum of scores given for presence/absence of various CT findings with maximum score of 5 for subpleural cyst and minimum score of 1 for ground-glass-opacity, 0 for absence. Extent-score is calculated for each morphology based on number of bronchopulmonary-segments involved, 1 for less than 3, 2 for 4 to 6 and 3 for more than 6 segments. Each MRI sequence was scored independently and combined-MRI-score was also calculated.

### RESULTS

MRI showed agreement with HRCT for extent of subpleural-line (50%;  $p=0.0015$ ), honeycombing (46.67%;  $p=0.0004$ ), subpleural-cysts (60%;  $p<0.0001$ ) and ground-glass-opacities (50%;  $p=0.003$ ). Best sequences to look for subpleural-line, honeycombing, subpleural-cyst and ground-glass-opacities were STIR (46.67%;  $p=0.0194$ ), 4-minute postcontrast sequence (61.11%;  $p=0.0290$ ), BTFE (50%;  $p=0.0003$ ). Among combined-scores calculated excluding postcontrast sequences, only 1/31 cases had different score than combined-score derived from all 10 sequences (including postcontrast sequences). Ground-glass-opacities were overestimated by MRI (higher scores in 13; lower scores in 2). Combined-MRI-score showed significant correlation with FEV1( $r=0.3484$ ;  $p=0.05$ ), FEV1/FVC( $r=0.4086$ ;  $p=0.02$ ), MEF50( $r=0.4203$ ;  $p=0.03$ ) post-walk test fatigue score(0.4639;  $p=0.01$ ).

### CONCLUSION

s MRI shows moderate, statistically significant, agreement with HRCT and clinical-parameters in morphological and global assessment of ILD extent in CTD patients. Abbreviated MRI protocol for ILD assessment would be T2, STIR, BTFE in axial planes as these sequences show closest correlation with the CT-scores. Post-contrast sequences didn't contribute significantly to global-score. With evolving MRI technology, shorter scan times and longer lifespan of patients, MRI becomes an attractive radiation-free option for serial follow-up of such patients.

### CLINICAL RELEVANCE/APPLICATION

MRI has the potential to provide a radiation free imaging alternative to CT in follow up of ILD.

## M2-SPCH-4 Prediction Model of Mediastinal Lymph Node Metastasis of Lung Cancer Based on Radiomics Abstract

Participants

Chunyu Gu, Xianyang, China (*Presenter*) Nothing to Disclose

### PURPOSE

Predicting the mediastinal lymph node metastasis of lung cancer based on radiomics construction model, it is an important guide for doctors to develop surgical plans

### METHODS AND MATERIALS

Retrospectively collecting 70 cases of lung cancer patients with enhanced CT imaging and biopsy confirmed by surgery or biopsy. Seventy patients underwent routine CT enhanced scan and magnetic resonance chest scan. Evaluation of mediastinal lymph node metastasis using DWI lymph node high signal as a gold standard in magnetic resonance plain scan, then divided patients into metastatic and non-transfer groups. The patient's aortic phase image was imported into ITK-SNAP to manually delineate the tumor boundary as the region of interest, and then imported into A.K. software for feature extraction, and 396 features were extracted from each tumor. Using LASSO regression to reduce data and establish a predictive model. The receiver operating characteristic curve (ROC) was used to evaluate the diagnostic efficacy of angiography in predicting lymph node metastasis, and the area under the curve (AUC), sensitivity and specificity were calculated.

### RESULTS

There was no statistically significant difference in age and gender between the two groups. LASSO regression data reduction achieves a total of three non-zero coefficient parameters. The area under the ROC curve of the constructed prediction model is 0.844 (95% CI: 0.709-0.980), the sensitivity is 78.6%, and the specificity is 87.5%.

### CONCLUSION

s The construction of mediastinal lymph node metastasis model based on lung cancer imaging pedigree has certain diagnostic efficacy.

### CLINICAL RELEVANCE/APPLICATION

Based on the imaging parameters of lung cancer, it has a good predictive value for lymph node metastasis of lung cancer, which can provide a reference for the clinician's surgical plan and patient prognosis evaluation.

## **M2-SPCH-5 An Explainable Artificial Intelligence to Detect Histopathological UIP Pattern from HRCT Images and Validation of its Ability**

### **Participants**

Ryoko Egashira, MD, PhD, Saga, Japan (*Presenter*) Speakers Bureau, Boehringer Ingelheim GmbH; Speakers Bureau, AstraZeneca PLC; Speakers Bureau, Shionogi & Co, Ltd; Speakers Bureau, KYORIN Holdings, Inc; Speakers Bureau, DAIICHI SANKYO Group; Speakers Bureau, Bayer AG; Speakers Bureau, Otsuka Holdings Co, Ltd;

### **PURPOSE**

To create an explainable artificial intelligence that can predict histopathological UIP pattern from HRCT images by machine learning and to validate its ability

### **METHODS AND MATERIALS**

233 cases of interstitial lung diseases (ILDs) of mixed etiologies with volumetric CT images were retrospectively identified for this study from an archive with pathologically proven ILDs. The cases were divided into CT-training set for CT-imaging features (n=74), pathology-training set for UIP/non-UIP labels (n=61, UIP: non-UIP=34:27), and a test set (n=98, UIP: non-UIP=60:38). CT-training set cases were selected to include a variety of morphologic patterns and etiologic backgrounds. A custom machine learning model was trained to CT-imaging features. CT-feature extractors for 2D patches from volumetric CT images were created using self-supervised learning. The CT patches with similar features were clustered based on the output features and then pulmonologists/radiologist integrated the radiologically synonymous clusters. Using the integrated clusters as labeled data, deep-learning models to classify the CT findings were created by transfer-learning. A UIP/non-UIP classifier model to classify the cases into UIP or non-UIP by distribution of CT findings in each lung zone using Random Forest. The model was validated using leave-one-out cross validation. Unaware of the labels, two board-certified radiologists classified the test-set cases into UIP/non-UIP pattern according to modified Fleischner's UIP criteria. The validation and test set results were presented as an average of UIP/non-UIP classifier output. The performance of the model was compared with the radiologists' performance.

### **RESULTS**

The accuracy and area under curve (AUC) of the model in validation were 71.47%, 0.785, respectively. In the test set, the accuracy, AUC, sensitivity, specificity and F1 score of the model were 78.67%, 0.843, 84.16%, 70%, and 82.88%. The radiologists' accuracy, sensitivity and specificity were 74.49%, 58.3% and 92% in reader A, 68.37%, 48.3% and 92.1% in reader B, respectively.

### **CONCLUSION**

The model's performance in predicting pathological UIP pattern in various ILDs was 78.67% in accuracy and 82.88% in F1 score, which was better than the radiologists' performance using modified UIP criteria. While radiologists' performance was excellent in specificity.

### **CLINICAL RELEVANCE/APPLICATION**

The detection of histopathological UIP pattern is a key to the prediction of progressive pulmonary fibrosis. There are currently no diagnostic HRCT criteria for UIP pattern other than IPF, this predictive model may be useful.

## **M2-SPCH-6 Effect of Contrast Enhancement on Diagnosis of Interstitial Lung Abnormalities in Automatic Quantitative CT Measurement**

### **PURPOSE**

To evaluate the effect of contrast enhancement on the diagnosis of interstitial lung abnormalities (ILA) in automatic quantitative CT measurement

### **METHODS AND MATERIALS**

Patients who underwent preoperative chest CT for lung cancer between April 2017 and December 2020 were retrospectively included. Each examination consisted of a pair of nonenhanced and contrast-enhanced CT scans, and images were analyzed using a commercially available deep learning-based automated quantification software for ILA. According to quantified results based on the definition by the Fleischner Society, patients were divided into normal and ILA groups. The agreement for the diagnosis of ILA was estimated with kappa values. Reproducibility and measurement variability were also estimated using the intra-class correlation coefficient (ICC) and Bland-Altman method.

### **RESULTS**

Of the 1199 included patients (mean age, 62.2 years  $\pm$  10.9 [SD]; 595 females), ILA was identified in 46 (3.8%) and 76 (6.3%) on pre- and post-contrast images, respectively. Pre-contrast and post-contrast CT scans showed substantial agreement (weighted Kappa: 0.67) in the diagnosis of ILA. Of the 46 patients diagnosed with ILA on pre-contrast scans, 42 were also diagnosed with ILA on post-contrast scans. Post-contrast images showed a greater extent of total ILA than pre-contrast images (mean percentage,  $0.99\% \pm 2.2$  vs  $0.63\% \pm 1.6$ ,  $p < 0.0001$ ). Pre- and post-contrast images showed excellent reproducibility for fibrotic ILA (ICC = 0.96), but only fair reproducibility for non-fibrotic ILA (ICC = 0.74). Measurement variability was wider in nonfibrotic ILA than in fibrotic ILA (95% limits of agreement, nonfibrotic: [-2.3, 3.0] vs. fibrotic: [-0.1, 0.1]).

### **CONCLUSION**

Contrast enhancement influenced the quantification of ILA with a tendency to overestimate, especially for nonfibrotic ILA.

### **CLINICAL RELEVANCE/APPLICATION**

Automatic quantitative assessment for ILA on contrast-enhanced CT images may lead to overdiagnosis of ILA; thus care should be taken in the diagnosis of ILA and subsequent visual assessment may be needed.

## **M2-SPCH-7 Quantitative CT-based Regional Lung Function and PFT at Baseline Predict One-Year Change of DLCO**

## in Idiopathic Pulmonary Fibrosis

### PURPOSE

While carbon monoxide lung diffusing capacity (DLCO) test is an important functional measure for idiopathic pulmonary fibrosis (IPF), it is also difficult for patients to conduct. We aimed to predict future DLCO using regional lung function variables computed from quantitative CT (QCT) and baseline pulmonary function test (PFT) variables, via machine learning.

### METHODS AND MATERIALS

Full inspiratory and full expiratory CTs, demographics, and PFT measurements (spirometry and DLCO) at baseline and DLCO at 1-year follow-up visits were prospectively collected of 45 IPF patients (age=71±5, M:F=39:6) at 5 institutions in South Korea (under IRB approval and with subject consent, using a common dose-reduced QCT protocol). 113 multiscale lung structural and functional features were derived from QCT analysis, using VIDA Vision (Coralville, IA) and in-house software. QCT, demographics, and PFT features significantly correlated with percent predicted DLCO (DLCO%pred) after one year ( $p < 0.05$ , Pearson's correlation) were then used to predict DLCO%pred after one year using XGBoost machine learning algorithm. Model performance was evaluated by  $R^2$  and mean absolute error (MAE).

### RESULTS

QCT variables had significant correlations with DLCO. Baseline percent predicted DLCO ( $r=0.76$ ;  $p < 0.001$ ), percent predicted forced expiratory volume in the first second (FEV1%pred) ( $r=0.65$ ;  $p < 0.001$ ) and forced vital capacity (FVC%pred) ( $r=0.64$ ;  $p < 0.001$ ). Among QCT variables, regional ventilation index (RRAVC) at whole lobe and Right lower lobe (RLL) ( $r=-0.35$ ,  $-0.13$ ;  $p=0.03$ ,  $0.04$ ), high attenuation area percent (HAA%) at whole lung, left upper lobe (LUL) and left lower lobe (LLL) ( $r=-0.45$ ,  $-0.40$ ,  $-0.39$ ;  $p=0.04$ ,  $0.02$ ,  $0.03$ ) also contributed in predicting future DLCO score. Normalized tracheal wall thickness (WT\*trachea) was also negatively associated with future DLCO ( $r=-0.3$ ;  $p < 0.03$ ). XGBoost model's performance in  $R$ -squared ( $R^2$ ) and mean absolute error (MAE) were 0.73 and 9.01, implying 73% of the total variation and predictions off by 9.01 units from the actual values. Results suggest association of left lung RRAVC, HAA% and tracheal wall thickening with smaller future DLCO in IPF.

### CONCLUSION

QCT based regional lung structure-function and PFT features can predict DLCO after 1 year via machine learning.

### CLINICAL RELEVANCE/APPLICATION

Predicting DLCO after 1 year via machine learning provide pathophysiological interpretation of regional changes in lung structure and function in IPF.

## M2-SPCH-8 Severe Asthma Patient Treatment Response Evaluation Using Visual and Quantitative Analysis of Chest CT

### Participants

Miji Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

### PURPOSE

Visual and quantitative analysis on chest CT for bronchiectasis(BE) score and mucus impaction(MI) extent in patients with severe asthma investigate the correlation with the patient's treatment response.

### METHODS AND MATERIALS

The 34 asthma patients (mean age; 55.1±12.8 years, male;female=40%;60%) who had undergone initial and 1 year follow up inspiration/expiration CT after treatment. Experienced thoracic radiologists independently determined the change of BE score and MI extent. Using Aview software (Coreline Soft), quantitative air-trapping and airway were analyzed at the initial and 10months follow up CT scan. Clinical parameters considered in patient have FEV1 and FEV1/FVC, sputum and blood eosinophils. For statistical analysis, intraclass correlation coefficient and correlation analysis were used.

### RESULTS

In the intraclass correlation coefficient between the two readers, the bronchiectasis(BE) score showed a reliability of 78% and the mucus impaction showed a reliability of 89%. Table 1 shows the greater the BE score and MI extent, the closer the pattern of obstructive lung disease is derived from both readers. MI extent was positive correlated with eosinophils. In the quantitative analysis, FEV1 and FEV1/FVC showed a positive correlation in the normal lung area, but a negative correlation in the case of functional air-trapping with and without emphysema. Quantitatively, when the counted branch segment increases, the PFT result shows a positive correlation, and the Pi10 and wall area measurements show a negative correlation. According to table 2, changes in BE score and MI extent showed a relatively significant correlation with changes in clinical parameters. Only Pi10 showed a negative correlation with PFT, and quantitative normal lung and functional air-trapping changes did not show any correlation.

### CONCLUSION

In patient with asthma, changes in MI extent with treatment have clinical significance rather than the severity of BE score itself. Visual changes in MI extent after treatment of asthma on CT and quantitatively decreased Pi10 correlated with changes in PFT and eosinophilia.

### CLINICAL RELEVANCE/APPLICATION

Through quantitative analysis of airway and visual analysis of mucoid impaction extent, post-treatment response can be evaluated in patients with severe asthma.

M2-SPER

### Emergency Radiology Monday Poster Discussions

#### Sub-Events

#### M2-SPER-1 **Classification of Acute Superior Mesenteric Artery Occlusion on CT using a 3D Machine Learning Model**

#### PURPOSE

Acute superior mesenteric artery (SMA) occlusion is a life-threatening condition that requires immediate diagnosis and treatment. Although our group has previously developed a machine learning 2D model to identify SMA occlusion by analyzing each CT slice individually, it is sometimes not possible to identify an occlusion on a single CT slice. We hypothesized that we could train a machine learning 3D model to identify SMA occlusion on CT with full volumetric context.

#### METHODS AND MATERIALS

Natural language processing (NLP) of radiology CT reports was used retrospectively to identify studies containing SMA occlusion. An axial image series from each of these studies was annotated by a Board Certified radiologist by segmenting the region of occlusion using an in-house brush tool. These segmentations were converted into 3D bounding boxes; 615 annotated volumes were used as positives, and 618 CT volumes with no SMA occlusion were used as negatives in the training dataset. A RetinaNet 3D model using the Medical Open Network for AI (MONAI) framework was implemented for training. The model was applied to a test dataset consisting of 20 negative studies and 59 studies positive for SMA occlusion. The positive studies were cases where the pathology had been missed by the initial reading radiologist (quality assurance cases). Prior to running the RetinaNet 3D model, a separate CT anatomy classification model was run on each series and only slices with abdominal anatomy were kept, to reduce the total image volume inferred by the RetinaNet 3D model. The highest probability from bounding boxes generated by the RetinaNet 3D model was taken as the overall model result for a study.

#### RESULTS

The highest validation accuracy during training was 0.678, at which point the final model was saved. The model achieved an AUC of 0.837 on the test dataset. At a threshold of 0.88, sensitivity was 63.6% with a specificity of 100%, suggesting that over half of missed SMA occlusion cases at our practice would have been caught had this model been in place.

#### CONCLUSION

An artificial intelligence model was trained to identify SMA occlusion on CT imaging. To our knowledge, this is the first use of a machine learning 3D model to identify SMA occlusion on CT images. This model is currently undergoing iterative retraining with false positives and false negatives from prospective data and will be continually updated in preparation for live clinical deployment.

#### CLINICAL RELEVANCE/APPLICATION

SMA occlusions on CT must be timely diagnosed to improve patient outcome and are sometimes missed by radiologists. A 3D model to identify these cases for both worklist prioritization and quality assurance would be highly relevant to improving patient care.

### Gastrointestinal Imaging Monday Poster Discussions

#### Sub-Events

#### **M2-SPGI-1 A Preliminary Study on the Value of Multi-frequency MR Elastography in Auxiliary Evaluating the Efficacy of Neoadjuvant Chemoradiotherapy for Locally Advanced Rectal Cancer**

#### **PURPOSE**

To investigate the value of multi-frequency magnetic resonance elastography (m-MRE) in auxiliary evaluating the efficacy of neoadjuvant chemoradiotherapy (nCRT) for patients with locally advanced rectal cancer (LARC).

#### **METHODS AND MATERIALS**

From Nov. 2021 to Dec. 2022, 81 patients with rectal cancer were prospectively recruited and after screening by exclusion criteria, 64 patients who underwent radical resection after nCRT were finally enrolled. All patients underwent MRI and rectal elastography examination within 1 week before surgery. Maps of shear-wave speed  $c$  ( $c$ -map) and phase angle of the shear modulus  $f$  ( $f$ -map) were generated and then measured  $c$  and  $f$  values for tumor or rectum wall. According to the collected pathologic ypTN stages and tumor regression grades (TRG), patients were divided into Group1: ypT0-1 (Good response, GR) and ypT2-4 (Poor response, PR) groups, Group2: ypN0 and ypN1-2 groups and Group3: pCR (TRG0) and Non-pCR (TRG1-3) groups. To analyze whether the differences of m-MRE parameters ( $c$ ,  $f$ ,  $c+f$ ) among different groups were statistically significant, and drew ROC curve to analyze the diagnostic efficiency. Compared with T2WI+DWI, to explore whether m-MRE ( $c+f$ ) can show better diagnostic efficacy in distinguishing different groups and to further analyze whether the combination of T2WI+DWI and m-MRE ( $c+f$ ) can achieve higher diagnostic efficacy. To explore whether the combination of T2WI+DWI and m-MRE ( $c+f$ ) could improve the diagnostic accuracy and consistency than that of T2WI+DWI, with pathological results as gold standard.

#### **RESULTS**

Significant differences of  $c$  and  $f$  values were observed in Group 1 and Group 3 ( $P < 0.05$ ), but not in Group 2. m-MRE ( $c$ ,  $f$  and  $c+f$ ) showed good diagnostic efficacy both in Group 1 with AUC values 0.810, 0.736 and 0.853, and Group 3 with AUC values 0.810, 0.736 and 0.853 (all  $P < 0.05$ ). m-MRE ( $c+f$ ) had significantly higher AUC values ( $P < 0.05$ ) than T2WI+DWI in Group 1 and Group 3. Furthermore, the combination of T2WI+DWI and m-MRE ( $c+f$ ) can get higher AUC values ( $P < 0.05$ ) than T2WI+DWI in Group 1 and Group 3 as well. Besides, it could also improve the diagnostic accuracy and consistency than that of T2WI+DWI, with pathological results as gold standard.

#### **CONCLUSION**

m-MRE has a potential auxiliary value in evaluating the efficacy of nCRT for LARC patients.

#### **CLINICAL RELEVANCE/APPLICATION**

Reliable preoperative methods to accurately evaluate tumor regression and identify patients with pCR are significant to LARC patients, which can promote making personalized clinical treatment plans.

#### **M2-SPGI-2 Predicting the Risk of Postoperative Distant Metastasis in Patients with Locally Advanced Rectal Cancer: Using MRI-based Delta-imaging Methods**

#### **PURPOSE**

To predict the risk of postoperative distant metastases in patients with locally advanced rectal cancer by using delta-imaging features extracted from MRI before and after nCRT.

#### **METHODS AND MATERIALS**

A total of 213 patients with locally advanced rectal cancer were retrospectively enrolled in Yunnan Cancer Hospital from January 2016 to June 2019. All patients underwent surgical treatment after nCRT and underwent MRI examination before and after nCRT. All patients were followed up for at least 3 years after surgery, except those with postoperative endpoint events. They were randomly divided into training group and verification group (training group  $n=149$ , verification group  $n=64$ ) in a ratio of 7:3, which were used for feature selection and verification respectively. Tumor lesions were delineated layer by layer on T2-weighted imaging (T2-weighted imaging) before and after nCRT, and 3D-slicer software was used for feature extraction. Delta-image omics features are defined as the difference in image omics features before and after nCRT. Using The least absolute shrinkage and selection operator algorithm (LASSO) for feature reduction and extraction, three delta-image omics models were constructed. It includes the Delta-Imagomics model and the combined Delta-imagomics model based on the absolute and relative variation of imagomics features before and after nCRT. Receiver operating characteristic curve (ROC) was used to evaluate the predictive value of the model for DM.

#### **RESULTS**

A total of 213 patients with LARC were included in this study (42% female and 58% male), with an average age of  $58.50 \pm 12.37$  years and a median follow-up time of 39.8 months. A total of 36 patients (16.9%) developed DM after surgery. 1382 features were extracted from each lesion before and after nCRT. After feature reduction and screening, 7 key features were included in the delta-

imaging model based on absolute and relative changes of imaging features before and after nCRT in the training set. In the training set, the area under ROC curve of the absolute and relative variation Delta-Imaging model and the combined Delta-imaging model were 0.77, 0.74 and 0.82, respectively, and the AUC of the corresponding test set were 0.73, 0.70 and 0.84, respectively.

## CONCLUSION

s The combined prediction model based on delta-imaging features of MRI is helpful to predict the risk of distant metastasis after local advanced rectal cancer surgery, and is better than the pure delta-imaging model of absolute and relative changes.

## CLINICAL RELEVANCE/APPLICATION

To predict the risk of postoperative distant metastases in patients with locally advanced rectal cancer .

## M2-SPGI-3 Machine Learning-based Response Assessment in Patients with Rectal Cancer After Neoadjuvant CCRT: Radiomics Analysis for the Assessment of Tumor Regression Grade Using T2-weighted MR Exam

### PURPOSE

We investigated the machine learning model-based radiomics analysis for the assessment of tumor regression grade using T2-weighted MR images in patients with rectal cancer after neoadjuvant chemotherapy-radiation therapy (CRT).

### METHODS AND MATERIALS

A total of 100 patients with rectal cancer who underwent magnetic resonance (MR) imaging at baseline and after CRT between January 2010 to May 2021 were included. The median age was 64 (31-89) and male was 66% (66/100). All MR scans were acquired with two different 3T scanners (Achieva 3.0T MR system, Philips Healthcare; MAGNETOM Vida, Siemens Healthineers) and included the oblique axial T2-weighted images acquired perpendicular to the long axis of the tumor. Region of interest (ROI) for each cancer lesion was drawn and extracted by a radiologist and 116 radiomics-feature was analyzed using MEDIP software (MEDICAL IP, Seoul, Republic of Korea, medicalip.com/Medip). Treatment responses were evaluated by the radiologist using MR tumor regression grade (mrTRG). Responses were classified into two groups ('good' versus 'poor'); mrTRG 1, 2, and 3 were categorized as 'good', and mrTRG 4 and 5 were categorized as 'poor'. We implemented the 3-principle component analysis (PCA)-ensemble model to predict the response group. Model performance was evaluated by calculating the area under a receiver operating curve (AUROC) for each feature-set, and selected combination of the feature sets.

### RESULTS

Texture-feature based sets and selected combinations were compared with qualitative mrTRG assessment to identify the significant feature sets in predicting the treatment responses. With the volume feature set (3D), the mean volume change was calculated, and overall 38.55% of volume has decreased. In comparison between the two groups, good response group showed lower baseline tumor volume and larger volume loss at post-CRT MR (50.32%) while poor response group showed larger baseline tumor volume and lesser volume loss at post-CRT MR(29.54%). Of all texture-feature sets and selected combinations of the feature sets, volume feature set (3D) combined with histogram-based contrast feature set (1st order) achieved the largest AUC of 0.79 for differentiating good and poor response.

## CONCLUSION

s Machine learning based radiomics analysis using T2-weighted MR imaging demonstrated feasible diagnostic ability for the response assessment in patients with post CRT rectal cancer. This radiomics analysis enables quantification of tumor volume and texture change.

## CLINICAL RELEVANCE/APPLICATION

Machine learning based radiomics analysis represents quantitative assessment of treatment response in post-CRT rectal cancer, and can be a useful assistant for treatment response assessment.

## M2-SPGI-4 Are Systematic Reviews of Diagnostic Tests for Rectal Cancer Trustworthy? A Cross-sectional Study

### PURPOSE

Many systematic reviews (SRs) have evaluated the value of different diagnostic tests for rectal cancer. But the quality of these SRs remains unclear. This study aimed to examine epidemiological characteristics, methodological and reporting quality of SRs of diagnostic tests for rectal cancer, and to explore factors that may affect the quality.

### METHODS AND MATERIALS

PubMed, EMBASE, Cochrane Library, and Chinese Biomedicine Literature were searched to identify SRs evaluating diagnostic tests for rectal cancer. We used AMSTAR to assess the methodological quality and PRISMA-DTA for reporting quality.

### RESULTS

33 SRs were included in our analysis and the number of publications had gradually decreased each year. 33 SRs involved 8 topics and 6 diagnostic tests. The median number of index test was 1 (range: 1-5) and there were 6 index tests, of which MRI (22/33, 66.7%) was the most studied index test. PubMed/Medline (100.0%) was the most frequently searched database. Only 15 (45.5%) SRs reported search strategy. The overall methodological quality was poor. All the SRs were not fully assessed the scientific quality of the included studies, only 33.3% performed a comprehensive literature search, 21.2% used the scientific quality appropriately in formulating conclusions, and 33.3% assessed the publication bias. There were many flaws in reporting quality. None of the SRs presented a structured summary, protocol or registration, only 6.1% provided the results of individual studies, 6.1% conducted additional analyses, 36.4% fully reported limitations, and 21.2% completely reported funding.

## CONCLUSION

s The quality needs to be further improved, especially referring to the performance of comprehensive literature search, assessment of scientific quality of included studies, assessment of publication bias, structured summary, protocol and registration, additional analyses, limitations, and funding.

## CLINICAL RELEVANCE/APPLICATION

There are many deficiencies in the reporting including structured summary, protocol and registration, search, additional analyses, limitations, and funding.

## **M2-SPGI-5 Personalized Weight-Based Dosing of Iodinated Contrast Material: Dose Savings and Effect on Image Quality in Abdominal Computed Tomography (CT)**

### **PURPOSE**

Fixed dosing of iodinated contrast material (CM) (i.e., using the same amount of contrast for all patients or based on weight buckets) is a standard practice among many institutions for abdominal CT. This study aims to investigate effects of personalized weight-based dosing (1.14 mL/kg) of CM on saving of contrast and on image quality of abdominal CT.

### **METHODS AND MATERIALS**

376 patients who underwent abdominal CT at a large urban academic medical center were included in this study. Each patient had at least two CT of abdomen performed within a one-year interval, with one study using a fixed dose of iodine contrast and the other implementing weight-based dosing. Studies were matched by imaging protocol, peak kilovoltage (kVp), and phase of enhancement. The amount of administered contrast for each study was collected. Attenuation of various organs and structures including portal vein, aorta, inferior vena cava, hepatic veins, liver, and spleen was measured. In addition, noise, contrast-to-noise ratio, and subjective image quality were calculated. Values were compared using paired and unpaired t-test. Sub-analysis based on patients' BMI was also performed.

### **RESULTS**

In the fixed-dose protocol, the mean iodine dose was 35 g, compared to 26.2 g and 32.6 g in the weight-based protocol in patients with normal/low weight (BMI = 25) and those with high weight (BMI > 25), respectively. The weight-based protocol also resulted in an average cost reduction of 16.3% with average savings of \$72.58. There were no differences in noise between the two protocols. In patients with high weight, except for the aorta, there were no significant differences in enhancement at the selected ROI between the two contrast protocols. Patients with a normal or low weight with weight-based contrast dosing had lower enhancement ( $p < 0.001$ ), with mean difference in degree of enhancement ranging 7.4-28.1 HU depending on the organ/structure, compared to the studies with a fixed dosing.

### **CONCLUSION**

The results of this study demonstrate that a personalized weight-based CM dosing strategy can result in significant saving of contrast. The saving is more pronounced in patients with lower BMI. In patients with higher BMI, the enhancement of abdominal organs was non-inferior to fixed-dosing CTs. Despite the lower degree of enhancement of structure in low-BMI group, as expected with the lower amount of administered iodine, the difference in degree of enhancement was small with no significant effect on subjective perceived image quality.

### **CLINICAL RELEVANCE/APPLICATION**

These data support that a weight-based contrast protocol can maintain image quality (especially in larger patients) while improving patient safety and reducing healthcare costs.

## **M2-SPGI-6 Deep Learning Image Reconstruction Improves Image Quality at Reduced Dose in Dual-energy Computed Tomography Enterography**

### **PURPOSE**

To demonstrate the clinical advantages of a deep learning image reconstruction (DLIR) in low-dose dual-energy computed tomography enterography (DECTE) by compare images with standard-dose adaptive iterative reconstruction-Veo (ASIR-V) images.

### **METHODS AND MATERIALS**

This was an IRB-approved prospective study. 58 patients undergone DECTE scans. The early-enteric phase scan was acquired using standard-dose (noise index: 8) and datasets were reconstructed 1.25mm slice thickness with 40%ASIR-V. A late-enteric phase low-dose scan (noise index: 12) was added and datasets were reconstructed at 1.25mm slice thickness with ASIR-V 40% and DLIR at two reconstruction strengths (medium, high). Objective parameters including image noise, artifact index, SNR and CNR were measured. Subjective indicators including subjective noise, image contrast, bowel wall sharpness, mesenteric vessel clarity and small structure visibility were assessed by two radiologists blindly. Radiation dose was compared between the early- and late-enteric phases.

### **RESULTS**

The late-enteric phase reduced radiation dose by 50% compared with the early-enteric phase. The DLIR images significantly improved both objective and subjective image quality even with reduced dose. The low-dose 1.25mm DLIR-H images had lowest image noise and highest SNR, CNR values compared with the standard-dose ASIR-V40% images, and significantly higher scores in image contrast, bowel wall sharpness, mesenteric vessel clarity and small structure visibility.

### **CONCLUSION**

DLIR significantly reduces image noise and improves diagnosis confidence in DECTE, compared to conventional ASIR-V 40% images, while providing 50% radiation dose reduction.

### **CLINICAL RELEVANCE/APPLICATION**

Computed tomography enterography is widely used as a first-line imaging study for examining the small bowel to evaluate patients with suspected or known bowel disease. But wide range and multiphase scanning of CTE will increase radiation exposure of patients. Numerous methods have been introduced and applied to limit radiation exposure of patients during a CT scan. However, simply reducing radiation dose will inevitably, increase the image noise and artifacts, which is not conducive to diagnosis. How to reduce the radiation dose while improve the overall image quality is the focus of research in low-dose CTE.

## **M2-SPGI-7 Effect of the Body Water and the Body Composition, Calculated by Bioelectrical Impedance Analysis on Contrast-enhanced Dynamic Computed Tomography Images of the Liver**

Participants

Takanori Masuda, PhD, Okayama, Japan (*Presenter*) Nothing to Disclose

### **PURPOSE**

To improve its diagnosis on contrast-enhanced dynamic CT (CE-DCT) scans, contrast injection protocol must yield stable arterial contrast enhancement. To investigate how the body-water distribution and the body composition, calculated by bioelectrical impedance analysis (BIA), affect aortic and hepatic enhancement on CE-DCT scans.

### **METHODS AND MATERIALS**

This retrospective study was approved by our institutional review board; informed patient consent was waived. Between January 2019 and May 2020, 236 patients with liver cirrhosis underwent CE-DCT before BIA. The CT number (in Hounsfield units, HU) of the abdominal aorta at the celiac artery level on unenhanced scans and during the hepatic arterial phase (HAP) scans was recorded. And, the mean CT number of the hepatic parenchyma of both hepatic lobes at the celiac artery level on unenhanced and portal venous phase (PVP) scans was recorded. We calculated changes in the iodine dose per contrast enhancement (mgI/HU) (IDCE) to evaluate the effect of the patient age and of various constituents of the body composition by performing BIA.

### **RESULTS**

The IDCE of the abdominal aorta during HAP was  $121.5 \pm 32.1$  mgI/HU; it was  $698.7 \pm 211.1$  mgI/HU in the hepatic parenchyma during the PVP. Among the parameters used in our BIA, the total body weight (TBW) was the most important factor affecting the IDCE of the liver abdominal aorta on CE-DCT scans acquired during the HAP ( $r = 0.83$ ). The TBW and the skeletal muscle index most strongly affected the IDCE of the hepatic parenchyma on CE-DCT scans obtained during the PVP ( $r = 0.69$ ).

### **CONCLUSION**

s The TBW had the strongest effect on contrast enhancement. The skeletal muscle index exhibited the strongest correlation with hepatic parenchymal contrast enhancement during the PVP.

### **CLINICAL RELEVANCE/APPLICATION**

We found that many body parameters included in BIA affect IDCE on CE-DCT images. Most exhibited a more than moderate correlation with IDCE of vessels and the hepatic parenchyma. It may be a useful index for machine learning to obtain a stable contrast enhancement on CE-DCT.

## **M2-SPGI-8 Effect of the CT Values for Abdominal Aorta and Liver Parenchyma During Contrast Enhancement Dynamic CT with or without the Splenomegaly**

Participants

Hiroyuki Ikenaga, BS, Kurashiki, Japan (*Presenter*) Nothing to Disclose

### **PURPOSE**

To compare CT (computed tomography) values for abdominal aorta and liver parenchyma during dynamic contrast-enhanced (CE) CT in cirrhotic patients with and without splenomegaly.

### **METHODS AND MATERIALS**

We considered 258 patients (83 males and 46 females for the splenomegaly group, and 83 males and 46 females for the control group) for this study. We measured CT values in the abdominal aorta and hepatic parenchyma during the hepatic arterial (HAP) and portal venous (PVP) phases. The aortic CE at HAP and the hepatic parenchymal CE at PVP were compared between the two groups. For depiction ability, we also calculated the optimal CE rates ( $>280$  HU in the abdominal aorta and  $>50$  HU in the hepatic parenchyma) for each group.

### **RESULTS**

The median and range of the CE for all patients with abdominal aorta and liver parenchyma were 273.0 HU (110.9-477.3 HU) and 54.0 HU (19.9-78.6 HU), respectively, in the Splenomegaly (SM) group and 298.9 HU (158.6-494.0 HU) and 54.0 HU (16.5-78.5 HU), respectively, in the non-SM group. In the SM group, the CE for abdominal aorta decreased during the aortic phase for a dynamic CE CT ( $p < 0.05$ ). For the depiction ability, there were significant differences in the rates of optimal CE between both the groups ( $p < 0.05$ ).

### **CONCLUSION**

s The diagnostic ability and CE for abdominal aorta during the aortic phase exhibited a significant decrease during dynamic CE CT in SM patients.

### **CLINICAL RELEVANCE/APPLICATION**

It is necessary to change the injection rates and contrast materials volume during CE CT depending on the presence or absence of SM.

M2-SPGU

### Genitourinary Imaging Monday Poster Discussions

#### Sub-Events

#### **M2-SPGU-1 Fidelity of Iodine and HU Values in a Renal Phantom using a Novel edge-on-irradiated Si-based Photon-Counting Detector CT**

##### Participants

Fides Schwartz, MD, Durham, NC (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the accuracy of a new edge-on-irradiate silicon-based photon-counting detector CT (Deep Si-PCCT) prototype for quantification of iodine concentration and stability of HU values in moderately and strongly enhancing kidney parenchyma.

##### METHODS AND MATERIALS

A phantom that simulates moderately and strongly enhancing kidney parenchyma (at 180 and 240 HU) inside a small patient (23 cm diameter) was scanned using a novel, Deep Si-PCCT prototype. The simulated kidney parenchyma contains an internal dense water-equivalent rod at 60 HU and a rod of 2.2 mg/mL iodine concentration to simulate a proteinaceous, non-enhancing and a mildly enhancing cystic renal lesion. The rods were positioned in the kidney parenchyma in two separate setups, so each rod was imaged within both levels of kidney enhancement. The accuracy and stability of the iodine quantification and HU values were evaluated with repeated ROI measurements of the same size across consecutive slices along the length of the simulated kidney parenchyma and the internal rods. Images were reconstructed with prototype soft tissue kernel at 2.5mm slice thickness without additional denoising.

##### RESULTS

The Deep Si-PCCT accurately quantified the iodine concentration in the small rod at  $2.1 \pm 0.02$  and  $2.1 \pm 0.04$  mg/mL (Setup 1 and 2, respectively), and the quantification was stable across the length of the internal rod, with both setups. The water equivalent rod was also quantified correctly, showing iodine concentrations within the standard deviation and HU values of  $58 \pm 0.5$  HU and  $60 \pm 0.9$ . The HU values of moderately and strongly enhancing renal parenchyma were stable across the length of the rod and correlated with the know ground-truth values. The figure also shows images of the first patient with cystic renal lesions scanned on the new Deep Si-PCCT at 120 kVp with 400 mAs and 1 second rotation (axial scan), reconstructed with a standard soft tissue kernel.

##### CONCLUSION

The Deep Si-based PCCT is a promising tool for accurate and stable quantification of iodine concentration and measurement of HU values in cystic lesions within moderately and strongly enhancing kidney parenchyma. It has the potential to improve the diagnosis and management of cystic renal lesions.

##### CLINICAL RELEVANCE/APPLICATION

The novel Deep Si-based photon-counting detector CT provides, accurate iodine quantification and HU values in kidney parenchyma and cystic lesions, which is crucial for the classification and management of cystic renal lesions.

#### **M2-SPGU-2 Renal Cyst Pseudoenhancement: Impact of Virtual Monochromatic and Ultra-high-resolution Imaging with Photon-counting Detector CT**

##### Participants

Atsushi Nakamoto, MD, PhD, Suita, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate whether virtual monochromatic and ultra-high-resolution imaging with photon-counting detector CT (PCD-CD) can overcome renal cyst pseudoenhancement.

##### METHODS AND MATERIALS

This retrospective study included 104 renal cysts in 31 patients (20 men and 11 women, age range, 42 to 91 years; mean age, 71.6 years) who underwent abdominal dynamic contrast-enhanced CT with PCD-CT. Cysts less than 3 mm in diameter and greater than 20 mm in diameter were excluded. Unenhanced and portal venous phase images were reconstructed with 512 and 1024 matrices with slice thicknesses of 0.2, 0.4, 1, and 2 mm, respectively. The 0.2-mm-thick images were reconstructed using polychromatic imaging (T3D) because virtual monochromatic imaging is not applicable to the 0.2-mm-thick images. For the other slice thicknesses, 70 keV virtual monochromatic images were reconstructed. In addition, 512-matrix, 1-mm-thick virtual monochromatic images were reconstructed at 50, 60, 80, and 90 keV. CT values were measured by placing regions of interest on the renal cysts and the attenuation increase from unenhanced to portal venous phase was calculated. The attenuation increases in each image were compared and the frequency of pseudoenhancement (an increase of 10 HU or more) was evaluated.

##### RESULTS

There was no significant difference in attenuation increase between the 512 and 1024 matrix images at any slice thickness ( $P > .05$ ). The attenuation increases were significantly higher for the 0.2-mm-thick T3D images and the 2-mm-thick 70 keV images compared to the 0.4-mm and 1-mm-thick 70 keV images ( $P < .001$ ). The attenuation increase was lower at higher keVs, with significant differences among all keVs ( $P < .001$ ). The frequency of pseudoenhancement was lowest for 90 keV images (13/104, 12.5%), followed by 80 keV images and 0.4-mm-thick 70 keV images (18/104, 17.3%). When only cysts with 10 mm or larger in diameter were included, virtual monochromatic images at 70 keV or higher showed no pseudoenhancement.

#### **CONCLUSION**

Virtual monochromatic images with PCD-CT can overcome renal cyst enhancement. Thinner slice thicknesses were useful in reducing pseudoenhancement, although 0.2-mm-thick images had a higher frequency of pseudoenhancement due to their polychromatic nature.

#### **CLINICAL RELEVANCE/APPLICATION**

Virtual monochromatic imaging at 70 keV or higher using photon-counting detector CT shows no pseudoenhancement in renal cysts of 10 mm or larger in diameter and is expected to improve the diagnostic performance of renal masses.

#### M2-SPHN-1 The Prevalence of Malleus-tympanum Synostosis on Ultra-high-resolution CT: A Preliminary Study

##### Participants

Ning Xu, MD, Beijing, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To determine the prevalence of malleus-tympanum synostosis (MTS) in different individuals via 0.1 mm ultra -high-resolution CT (U-HRCT).

##### METHODS AND MATERIALS

This retrospective study evaluated U-HRCT scans with 0.1 mm thickness of 1587 ears from 1122 subjects from October 2020 to March 2022. MTS presented as a bony connection between the malleus and tympanic wall. MTS was detected in subjects with normal ears, subjects with different types of hearing loss (HL), and subjects with various causes of conductive HL. The prevalence of MTS was calculated and statistically compared between subjects with normal ears and with different types of HL, as well as between subjects with various causes of conductive HL. The correlation between MTS and age or gender was calculated using the Mann-Whitney U test.

##### RESULTS

The prevalence of MTS was 2.8% (16/577), 3.4% (12/352), 7.2% (27/374), and 13.7% (39/284) in subjects with normal, mixed HL, sensorineural HL, and conductive HL ears, respectively. MTS was more common in subjects with HL than in subjects with normal ears ( $p < 0.001$ ), and significant differences were shown between mixed and sensorineural HL groups ( $p = 0.023$ ), between mixed and conductive HL groups ( $p < 0.001$ ), and between sensorineural and conductive HL groups ( $p = 0.006$ ). The prevalence of MTS was 83.9% (52/62), 34.8% (23/66), 12.6% (61/483), 7.5% (8/107), and 6.9% (7/102) in subjects with conductive HL with tympanosclerosis, definite middle ear malformations, otitis media, otosclerosis, and middle ear cholesteatoma, respectively. Besides, MTS was found in 18.8% (6/32) of subjects with unexplained conductive HL, 3 of whom were confirmed as having malleus fixation by surgery. No correlation was shown between MTS and age ( $p = 0.41$ ) or gender ( $p = 0.70$ ) in subjects with normal ears.

##### CONCLUSION

MTS is a new sign that can be clearly visualized on an ultra-high-resolution CT with 0.1 mm thickness. The prevalence of MTS was 2.8% and 7.7% in subjects with normal ears and with HL, respectively. It may be asymptomatic, or may be associated with conductive HL.

##### CLINICAL RELEVANCE/APPLICATION

Malleus-tympanum synostosis (MTS) is a new sign that can be clearly visualized on an ultra-high-resolution CT with 0.1 mm thickness. It is not uncommon and may be asymptomatic or may be associated with conductive HL by resulting in malleus fixation. Moreover, MTS may be the cause of some "idiopathic" conductive HL. Otologists can use their understanding of MTS to develop new treatment strategies and improve hearing outcomes.

#### M2-SPHN-2 Comparative Study of the Sensitivity of Ultra-high-resolution CT and High-resolution CT in the Diagnosis of Isolated Fenestral Otosclerosis

##### Participants

Ning Xu, MD, Beijing, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To compare the sensitivity of ultra-high-resolution computed tomography (U-HRCT) and high-resolution computed tomography (HRCT) in the diagnosis of isolated fenestral otosclerosis (IFO).

##### METHODS AND MATERIALS

Eighty-five patients (85 ears) with both clinical and intraoperative diagnosis of IFO were prospectively included between October 2020 and November 2022. Only U-HRCT (0.1mm thickness) was performed for 20 ears, only HRCT (0.67mm thickness) was performed for 45 ears, and both U-HRCT and HRCT were performed for 20 ears. General radiologists and neuroradiologists who were blinded to the clinical and surgical conditions evaluated the images. The sensitivity of U-HRCT and HRCT to detect IFO by the two groups of radiologists were compared.

##### RESULTS

The diagnostic sensitivity of U-HRCT was 100% (40/40 ears) for neuroradiologists and 87.5% (35/40 ears) for general radiologists, which was significantly higher than that of HRCT (89.2% [58/65 ears] for neuroradiologists; 41.5% [27/65 ears] for general radiologists) ( $P = 0.042$  and  $P = 0.000$ , respectively). When evaluated with HRCT, the sensitivity of general radiologists was

significantly lower compared to neuroradiologists ( $P=0.000$ ), while no difference was shown when general radiologists switched to U-HRCT ( $P=0.152$ ). Among the 20 ears that underwent both examinations, 5 ears with  $<1$  mm lesion involving the fissula ante fenestram were shown on U-HRCT, while the sensitivity of HRCT was 40% (2/5 ears) for neuroradiologists, which was significantly lower than that for neuroradiologists to diagnose lesions  $>1$  mm (93.3%, 14/15 ears,  $P=0.032$ ).

## CONCLUSION

s U-HRCT is more sensitive than HRCT in the diagnosis of IFO, and has a significant advantage in the detection of  $<1$  mm lesions.

## CLINICAL RELEVANCE/APPLICATION

U-HRCT has a high spatial resolution scale, which can significantly improve the delineation of IFO lesions and improve the ability of general radiologists to detect this disease. It has the potential to be used for screening of patients with suspected otosclerosis.

## M2-SPHN-3 Feasibility of the mDIXON Method for Estimation the Parotid Gland Fat Fraction in Sjögren's Syndrome

Participants

Changwei Ding, Shenyang, China (*Presenter*) Nothing to Disclose

## PURPOSE

SS characterized by irreversible varying degrees of fat deposition, the objective of this study is to explore the feasibility of estimating fat fraction (FF) in parotid glands with Sjogren's syndrome using the mDIXON method.

## METHODS AND MATERIALS

Conventional MRI and mDIXON-Quant were performed on 62 parotid glands (case group) in 31 SS patients and 62 parotid glands (control group) in 31 healthy volunteers with age and mean body mass index matching. The FF values of the two groups were compared, and the changes of FF values with different degrees of fat deposition were analyzed.

## RESULTS

The FF value of parotid gland in the case group was significantly higher than that in the control group ( $35.7 \pm 15.7$ ,  $28.3 \pm 16.1$ , respectively,  $P=0.008$ ). The FF value in the case group increased gradually from no significant fat deposition in the early stage ( $32.1 \pm 4.8$ ) to significant fat substitution ( $73.0 \pm 4.9$ ).

## CONCLUSION

s The FF values obtained by the mDIXON method are a new method that can quantitatively assess the extent of SS parotid gland lesions.

## CLINICAL RELEVANCE/APPLICATION

mDIXON provides a simple and easy clinical method for quantitative assessment of the extent of SS parotid gland lesions.

## M2-SPHN-4 Performance of 0.55T MRI for Diffusion Weighted Imaging of Parotid Gland: Comparison with 3T MRI

## PURPOSE

To evaluate and compare the imaging quality of parotid in 0.55T and 3T MRI and to explore the application value of 0.55T in clinical practice.

## METHODS AND MATERIALS

Nine healthy volunteers were prospectively recruited and underwent coronal maxillofacial imaging using 0.55T and 3T MRI respectively. The scanning sequence contained T1/T2 TSE and diffusion sequences. Two different DWI sequences were adopted on 3T, one is conventional single-shot EPI, and the other is RESOLVE; while only a SS-EPI sequence was applied on 0.55T. The parameters were presented in supplementary materials. The signal noise ratio (SNR), contrast to noise ratio (CNR), and quantitative degree of the parotid gland deformation were used to evaluate image quality, as well as subjective scores in six aspects. Two radiologists, with 5 and 15 years of diagnostic experience in head and neck imaging respectively, made subjective scores according to the 5-point method on the images with double-blind. The SNRs, CNRs, degrees of deformation and the stability of ADC value were compared under different field strengths and sequences. Graphpad Prism 8.0 software and 3D slicer was used for statistical analysis and image fusion. The quantitative and quality parameters were analyzed with One-way ANOVA and Kruskal-Wallis One-way ANOVA. The correlation Spearman coefficient was used for the inter-observers consistency analysis. Differences were considered statistically significant at  $P<0.05$ .

## RESULTS

The SNR and CNR of images in 0.55T were lower than those in 3T MRI, however no significant differences were found between 0.55T EPI and 3T RESOLVE ( $P>0.05$ ). The deformation degree was the lowest in 0.55T and significant differences were found between 0.55T EPI and 3T EPI ( $P<0.0001$ ) and 3T RESOLVE with  $b=50$  ( $P<0.05$ ) respectively. The stability of ADC value in 0.55T was also relatively better than in 3T MRI. The subjective scores showed that the clarity of boundary of tissue and image quality achieved the best in 3T RESOLVE. However, the deformation degree was the lowest in 0.55T, and no significant differences were found in the clarity of parotid gland between 0.55T and RESOLVE. Additionally, we found the significantly reduced deformation within basis cranii region using coronal maxillofacial imaging in 0.55 T.

## CONCLUSION

s This study demonstrates that 0.55T can significantly reduce image deformation with comparable image quality with 3T RESOLVE, which will be helpful for patients with high field strength contraindications to achieve the normal diagnostic effect.

## CLINICAL RELEVANCE/APPLICATION

The comparable image quality with 3 T and significant image deformation inhibiting in 0.55 T MRI is able to satisfy the diagnostic demand under certain conditions.

## M2-SPHN-5 Characterization of Intratumoral Heterogeneity by using Diffusion-relaxation Correlation Spectrum

## Imaging (DR-CSI) in HNSCC

### PURPOSE

To determine the feasibility of diffusion-relaxation correlation spectrum imaging (DR-CSI) in the characterization of microstructural tissue compartments in HNSCC.

### METHODS AND MATERIALS

Patients suspected with HNSCC who underwent 3-T MRI and surgical resection were prospectively studied. DR-CSI was applied and imaged for primary HNSCC and metastatic lymph nodes in vivo and were co-registered pathological slides. The DR-CSI spectral signal components volume (VA, VB, VC) was identified in accordance with the pathological findings and compared between benign and malignant primary tumors or lymph nodes. A linear model assessed the correlations between (VA, VB, VC) and each component observed in pathological findings. Strength of correlations was evaluated by using Spearman correlation coefficients.

### RESULTS

Totally 32 subjects (mean age, 45 years  $\pm$  5.6) were evaluated in this study; Basically, three pathological components including epithelial, stroma and vascular areas were accordantly matched with DR-CSI spectral signal components (spectral peaks). Different DR-CSI pattern was observed between HNSCC and benign lesions or metastatic and benign lymph nodes. HNSCC exhibited increased VA (HNSCC vs benign,  $0.41 \pm 0.06$  vs  $0.29 \pm 0.06$ ;  $P < 0.01$ ), decreased VC ( $0.13 \pm 0.08$  vs  $0.27 \pm 0.09$ ,  $P < 0.01$ ). High malignancy suggested higher VA (low- vs high malignancy  $0.36 \pm 0.11$  vs  $0.57 \pm 0.13$ ;  $P < 0.05$ ). In addition, metastatic lymph nodes presented decreased Vc (metastatic vs benign,  $0.14 \pm 0.08$  vs  $0.19 \pm 0.18$ ;  $P = 0.04$ ).and increased VB (mtastastic vs benign,  $0.21 \pm 0.08$  vs  $0.14 \pm 0.18$ ;  $P = 0.051$ ).

### CONCLUSION

s Diffusion-relaxation correlation spectrum imaging is feasible to determine the intra-tumoral heterogeneity of HNSCC. The signal components correlate with pathological compartments. Quantitative VA, VB and VC can be applied to determine malignancy and cervical metastasis.

### CLINICAL RELEVANCE/APPLICATION

Microstructural MRI has the potential to improve diagnosis and characterization intra-tumoral heterogeneity. DR-CSI has been approved to quantitatively determine various components within the tumor, which is a promising approach for identify intra-tumoral heterogeneity.

## M2-SPHN-6 Diagnostic Performance of 3D Dixon T1WI Sequence for Assessing Craniofacial Localized Scleroderma

### PURPOSE

To evaluate the soft tissue lesions in craniofacial localized scleroderma using 3D Dixon T1WI sequence.

### METHODS AND MATERIALS

28 patients who were clinically diagnosed as craniofacial localized scleroderma were retrospectively collected. All patients underwent 3D Dixon T1WI sequence examination. 3D Dixon T1WI sequence included in phase, oppo phase, water, fat images. For the assessments of skin and subcutaneous soft tissue, the facial surface was divided into six subunits, including the forehead, temporal, periocular, cheek, nose, and chin. Radiologists recorded the number of craniofacial localized scleroderma which involved in six subunits on 3D Dixon T1WI sequence and on clinical assessment. The diagnostic performance was evaluated by comparing the number on 3D Dixon T1WI sequence and on clinical assessment. The quantitative assessment by measuring the full thickness soft tissue on the affected side of the most severe axial images (including in phase, oppo phase, water, fat images) and the contralateral normal side.

### RESULTS

28 patients which included 15 males and 13 females were collected in this study. On 3D Dixon T1WI sequence and clinical assessment, 75.0% (21/28) vs 75% (21/28), 35.7% (10/28) vs 35.7% (10/28), 60.7% (17/28) vs 67.8% (19/28), 39.3% (11/28) vs 42.8% (12/28), 57.1% (16/28) vs 60.7% (17/28) and 46.4% (13/28) vs 42.8% (12/28) patients of craniofacial localized scleroderma involved in forehead, temporal, periocular, cheek, nose and chin, respectively. There is no significant difference in evaluation of soft tissue lesions between T1W Dixon images and clinical assessment ( $p=0.743$ ). On 3D Dixon T1WI images, the full thickness of forehead ( $2.80 \pm 1.84$  vs  $4.74 \pm 2.94$ ), temporal ( $4.72 \pm 6.58$  vs  $5.96 \pm 8.24$ ), periocular ( $4.26 \pm 3.66$  vs  $4.71 \pm 6.58$ ), cheek ( $4.99 \pm 7.18$  vs  $7.38 \pm 9.45$ ), nose ( $2.22 \pm 2.11$  vs  $3.06 \pm 2.91$ ), and chin ( $3.04 \pm 4.28$  vs  $6.65 \pm 7.87$ ) on the affected side were significantly lower than the contralateral normal side (all  $p < 0.05$ ).

### CONCLUSION

s The range of lesions evaluated by 3D Dixon T1WI sequence was in consistent with clinic, and could add quantitative information about soft tissue lesions in craniofacial localized scleroderma.

### CLINICAL RELEVANCE/APPLICATION

3D Dixon T1WI sequence could evaluate the soft tissue lesions in craniofacial localized scleroderma and provide preprocedural guidance.

## M2-SPHN-7 Improving Metal Artifact Reduction Methods in Dual-Energy CT for Head and Neck CT Examinations: A Clinical Assessment

### PURPOSE

To evaluate the effectiveness of iterative metal artifact reduction (iMAR) technique in reducing dental metallic artifacts during head and neck CT examinations.

### METHODS AND MATERIALS

Thirty patients with dental prosthesis implants were prospectively collected. Siemens single-source dual-energy CT (SOMATOM Definition Edge CT) was used for examination and the original data were reconstructed respectively in iMAR group (Group A) and

conventional iterative reconstruction group (Group B). The CT and SD values of the high density artifacts, low density artifacts, the surrounding soft tissue areas and the same layer of contralateral artifact-free affected areas in the two groups of images were measured respectively. The difference between the two groups was compared by paired t-test. Two senior radiologists used the 5-component table (1~5 points, non-assessable ~ excellent) method to score the metal artifacts removal ability of the two groups. Mann-Whitney U test was used to compare the subjective scores and the consistency of the scores was analyzed by Kappa test.

## **RESULTS**

There was no significant difference in CT values at the opposite side of the same layer without artifacts ( $P>0.05$ ). The CT values in Group A were significantly reduced in the high density artifact area ( $p<0.05$ ), while significantly increased in the low density artifact area ( $p<0.05$ ), and were closer to the CT values in the corresponding anatomical areas at the opposite side of the same layer. In terms of image noise, the SD values in each measurement area of Group A's images were lower than those of Group B and were significantly lower in high density areas and low density areas ( $p<0.05$ ). In terms of subjective score, the results of the two groups of image evaluation were excellent and consistent (Kappa=0.945,  $p<0.05$ ). The subjective score of Group A was significantly higher than that of the control group, and the subjective score was increased by 2.1 (Group A:  $4.23\pm 0.32$ , Group B:  $2.11\pm 0.51$ ;  $P<0.05$ ).

## **CONCLUSION**

s The iMAR technique can significantly reduce metal artifacts around dental implants, correct CT values of surrounding tissues, help to accurately observe tissue structures around implants, improve image quality, and has great clinical application value.

## **CLINICAL RELEVANCE/APPLICATION**

Compared with conventional iterative reconstruction, it is preferable to use the iMAR technique in head and neck CT examinations as it allows better image quality and helps to accurately observe tissue structures around implants.

M2-SPIN

### Imaging Informatics Monday Poster Discussions

#### Sub-Events

#### M2-SPIN-1 Image Perturbation Analysis to Study the Effect of Motion on CT Radiomic Metrics

##### Participants

Hesam Setayesh, Los Angeles, CA (*Presenter*) Nothing to Disclose

Bino Varghese, PhD, Los Angeles, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the robustness of radiomic metrics in simulated clinically observed ranges of organ motion using an anthropomorphic liver CT phantom with 3D-printed texture inserts.

##### METHODS AND MATERIALS

18 Volumetric CT images of the anthropomorphic liver radiomics phantom with 7 texture inserts were obtained under different imaging conditions varying slice thickness (0.625mm, 1.25mm and 2.5mm), dose (13,86 mGy standard, 40 % dose reduction, and 60 % dose reduction), tube voltage (100 kVp and 120 kVp) and reconstruction algorithms (deep learning image reconstruction algorithm and a hybrid iterative reconstruction algorithm ASiR-V50% one at a time). A circular region of interest (ROI) was manually contoured within a centrally placed texture insert of the phantom. 91 radiomic metrics belonging to 6 different texture families were extracted from the ROI using opensource Pyradiomics software. Subsequently, the same 91 radiomics metrics were extracted using the same ROI co-registered on motion perturbed versions of the original CT images. Specifically, 6 motion conditions: rotation by 5 degrees, rotation by 15 degrees, translation by 2 pixels to the right, translation by 3 pixels to the right, rotation 15 degrees plus translation 2 pixels, and rotation 15 degrees plus translation by 3 pixels were considered. Intraclass correlation (ICC) 2-way-mixed with absolute agreement was used to evaluate radiomics robustness under different imaging and motion conditions.

##### RESULTS

In all imaging conditions, translation by 2 or 3 pixels led to the highest number of radiomic metrics with ICC > 0.8 (indicating high robustness). As opposed to translations, rotation of 15 degrees compared to rotation by 5 degrees showed a significant reduction in robust radiomic metrics, under all imaging conditions ( $p < 0.0001$ ). Rotation followed by translation showed an increase in the number of robust metrics compared to rotation alone, possibly due to the overlap between the modified and the original ROI owing to small movements. Also, despite changes in imaging conditions, the trends in robustness were comparable across the different motion conditions.

##### CONCLUSION

Translation motion amplitudes = 3 times the spatial resolution of the image retained the robustness of radiomic metrics on the CT images of anthropomorphic liver phantom. Different radiomic families showed different associations to the simulated motions. However, across different imaging conditions, the trends in robustness were comparable across the different motion conditions.

##### CLINICAL RELEVANCE/APPLICATION

In a clinical situation, understanding the effect of motion and suppressing its effects may support the development of a robust quantitative approach such as radiomics.

#### M2-SPIN-2 Deep Learning is a Promising Tool for Fully Automatic Malignant Lesions Identification and Segmentation in Whole-body [68Ga]Ga-PSMA PET/CT Scans

##### Participants

Joana Castanheira, MD, Lisbon, Portugal (*Presenter*) Nothing to Disclose

##### PURPOSE

This work aims to assess the feasibility and robustness of deep learning-based fully automatic malignant lesion detection and segmentation on whole-body [68Ga]Ga-PSMA PET/CT scans.

##### METHODS AND MATERIALS

A dataset of 122 whole-body [68Ga]Ga-PSMA-11 PET/CT scans from patients with prostate cancer was used as the training set. These scans were acquired on a Philips Gemini TF16 PET/CT scanner. Two nuclear medicine physicians labeled all lesions suspected of malignancy. Then, a self-adaptive Bayesian classifier was used for semiautomatic lesion segmentation [1]. All segmentations were reviewed and manually rectified if necessary. This set (scans and segmentations) was used to train a fully automatic lesion detection and segmentation 3D U-Net, using the nnU-Net framework [2]. The CT scans were used as a second channel to feed the network. For testing, an independent set containing 39 whole-body [68Ga]Ga-PSMA-11 PET/CT scans from prostate cancer patients was randomly selected from our archives. All these scans were performed on a Philips Vereos Digital PET/CT scanner. The gold standard malignant lesions identification and segmentation of the test set were generated as indicated for the training set. The Dice similarity coefficient was used to measure the voxelwise agreement/overlap between the gold standard segmentations and

the ones obtained with the trained network.

## RESULTS

From the 39 test scans included, 32 scans were identified by the physicians as having malignant lesions, and 7 without. The trained network correctly identified all 32 scans with malignant lesions (sensitivity of 100%). From the 7 scans without malignant lesions, the trained network correctly identified 6 (specificity of 86%). Regarding the quality of the segmentation on the 32 scans, the median Dice coefficient was 0.73 (interquartile range [IQR] 0.53-0.82), the sensitivity was 72% (IQR 0.41-0.86), and the predictive positive value was 90% (IQR 0.72-0.99).

## CONCLUSION

The solution herein described and implemented using deep learning achieved very good results, despite the additional difficulty of segmenting scans acquired on a scanner significantly different from the one used to obtain the train scans. Therefore, fully automatic lesion detection and segmentation on [68Ga]Ga-PSMA-11 PET/CT scans using deep learning may be used to help routine clinical work, especially during disease staging and to assess response to therapy. References [1] Constantino et al. J Digit Imaging 2023; [2] Isensee et al. Nature Methods 2021.

## CLINICAL RELEVANCE/APPLICATION

Deep learning-based fully automatic malignant lesions detection and segmentation on [68Ga]Ga-PSMA PET/CT scans is feasible and appears sufficiently robust to be used as an auxiliary tool in the clinics.

## M2-SPIN-3 The CadAIver: Reproducibility Assessment and Novel Normalization Algorithm of Radiomics Features of Vertebral Bone from Different CT Scanners and Protocols

Participants

Riccardo Levi, Pieve Emanuele, Italy (*Presenter*) Nothing to Disclose

## PURPOSE

1. To quantify the effects of different dose protocols, reconstruction algorithms, fields of view and CT scanners on Radiomics features of the lumbar vertebrae in a cadaveric trunk. 2. To develop a novel normalization algorithm to harmonize Radiomics analyses.

## METHODS AND MATERIALS

We performed a total of 96 CT acquisitions of a cadaveric trunk (80-year old male) on 3 different CT scanners from 2 different vendors, using different kV (80 to 140, with 20 kV steps) and mA (250 to 400, with 50 mA steps). Each acquisition was performed using 2 fields of view (500 and 320 mm) and 2 reconstruction kernels (standard and bone). We also performed a Test-Retest protocol on a single scanner to assess repeatability of features. The lumbar vertebrae were segmented using a convolutional neural network (CNN) with nnU-Net structure and Radiomics features were extracted using pyradiomics library. Intra- and Inter-scanner analyses were assessed using either Analysis of Variance Repeated Measurements (parametric test) or Friedman's Test (non-parametric test) and each radiomics feature was tested using a generalized linear model (GLM) to assess the effects of all the above-mentioned CT acquisition parameters. Moreover, the proposed GLM model was successively employed to standardize radiomics features across different acquisitions, and was compared to the Combat algorithm, using a 10-folds cross-validation (CV) evaluating the R2.

## RESULTS

Variation of KV showed the highest feature modification in intra- and inter-scanner analyses, with the First Order features showing the highest variability (up to 94.4% on Scanner 1). Little or no effect was evident upon mA variation. 100% of shape features on all scanners were found significantly dependent on FOV, and 83% of GLSZM were statistically different between reconstruction kernels. The proposed GLM normalization algorithm obtained a mean R2 across CV higher than 0.90 in 21 Radiomics features (19.6%), whereas Combat normalization algorithm obtained a high R2 value in 1 Radiomics feature (0.90%). Moreover, GLM algorithm was statistically superior in 39 Radiomics features in respect to Combat (which was superior in 16 Radiomics features) in terms of R2.

## CONCLUSION

To our knowledge, this study is the first attempt in describing the effects of CT acquisition parameters on Radiomics features in lumbar vertebrae from cadaveric donor. Current and Voltage affect the Radiomics features in different ways. The developed GLM model was superior to Combat in normalizing radiomics features across all the different CT acquisitions.

## CLINICAL RELEVANCE/APPLICATION

CT radiomics features are to be normalized before multi-scanner studies. The complete dataset and GLM normalization model will be publicly available to foster research in Radiomics.

## M2-SPIN-4 Independent Evaluation of the Winning Kits19 Model for Kidney Tumor Segmentation on a Large External Patient Cohort

## PURPOSE

The fully automatic segmentation of kidney tumors on Computed Tomography (CT) can enable significant advantages in clinical practice including increased accuracy of diagnosis and prognostication of patient outcomes. The Kits19 challenge in 2019 set a baseline for kidney tumor segmentation, with the highest scoring model, nnUNet, receiving a Dice score of 0.85. Herein we seek to evaluate this model on an independent dataset of 694 segmented kidney tumors.

## METHODS AND MATERIALS

The nnUNet model trained on 210 Kits19 cases was evaluated on a separate institution-specific dataset of 694 total segmented kidney tumor cases, acquired from a diverse range of partner sites. A separate nnUNet model was trained on 555 of the institutional cases and evaluated on both 139 held out cases from the same institution as well as the 210 Kits19 cases. Unfortunately, the KITS19 90 test cases were not available to evaluate the model trained on institutional data.

## RESULTS

The nnUNet model trained on the 210 KiTS19 cases received a Dice score of 0.64 when evaluated on the institution specific dataset of 555 cases. The nnUNet trained on the 210 KiTS19 cases also received a Dice score of 0.66 on a held-out test set of 139 institutional cases. In addition, an nnUNet model was trained on these 555 institutional cases and received a Dice score of 0.72 when evaluated on the held-out test set of 139 cases from the same institution. The nnUNet model trained on 555 institutional cases received a Dice score of 0.55 when evaluated on the 210 KiTS19 training cases.

## CONCLUSION

s That the KiTS19 nnUNet model performed significantly worse (0.21 and 0.19 Dice score drops) on the institutional dataset was unexpected, but bears significant implications. Likewise, that the institutional nnUNet model performed significantly worse on the KiTS19 dataset (0.17 Dice score drop) despite being trained on a larger pool of data, reinforces a similar concept. Both models tended to do better on independent data derived from their own respective datasets. This highlights the importance of creating large medical machine learning datasets that incorporate data from a broad range of sources that can capture the data heterogeneity present in distinct patient populations and allow for the creation of generalizable machine learning models.

## CLINICAL RELEVANCE/APPLICATION

These results also highlight the value of federated learning in a healthcare setting, which can allow for the incorporation of diverse datasets into model training, while maintaining the privacy of patient and institutional health data. Furthermore, these results raise the question of what the true state-of-the-art Dice score is for kidney tumor segmentation and demonstrate the importance of independent model evaluation prior to potential clinical deployment.

## M2-SPIN-5 Evaluating the Segment Anything Model for MRI Organ Segmentation Using a Simulated Interactive Setup

### PURPOSE

To evaluate the multi-organ segmentation capabilities of the recently released Segment Anything Model (SAM) as an interactive semi-automated annotation tool for organ segmentation in magnetic resonance (MR) images.

### METHODS AND MATERIALS

This retrospective study used the publicly available multi-organ MRI dataset, AMOS22, which contains 60 MRI volumes from multiple institutions. The 15 target organs are: liver, spleen, right kidney, left kidney, gallbladder, esophagus, stomach, aorta, inferior vena cava, pancreas, right adrenal gland, left adrenal gland, duodenum, bladder, and prostate/uterus. We extracted 2D slices from each 3D MRI volume and resized images to 512 by 512 pixels, resulting in a total number of 3609 2D images. We evaluated the SAM in a simulated interactive annotation setup. The initial prompt given to SAM was the ground truth bounding box (bbox) with added random jitter. SAM then outputs an initial segmentation mask. In subsequent iterations, SAM takes point-based prompts, as well as all previous prompts and the current segmentation mask, to generate the next refined segmentation mask. This procedure was repeated for 10 iterations to produce the final segmentation. The magnitude of random jitter for the initial bbox is a scaling factor that's uniformly drawn between [0.5,2] for our experiment. The magnitude of random jitter for subsequent point prompts is a translation  $0.2 * R_{max}$  pixels, where  $R_{max}$  is the shortest distance between the center and the boundary of a false positive/negative region. The segmentation results of target 15 organs were evaluated against the ground truth masks using the Dice similarity coefficient (DSC) on 2D slices.

### RESULTS

The mean±std DSC for 15 organs after the initial bounding box prompt was  $0.777 \pm 0.049$ . The final mean±std DSC after 10 iterative steps was  $0.901 \pm 0.056$ . The best three organs were the right kidney ( $0.954 \pm 0.034$ ), left kidney ( $0.951 \pm 0.028$ ), and spleen ( $0.949 \pm 0.051$ ). The worst three organs were right adrenal gland ( $0.807 \pm 0.113$ ), prostate/uterus ( $0.819 \pm 0.246$ ), and duodenum ( $0.825 \pm 0.156$ ). The mean DSCs increased monotonically with the number of prompts, implying better segmentation results.

## CONCLUSION

s Experimental results demonstrated that after 10 iterations, the SAM model was able to provide reasonable segmentation results for most of the organs in the MR images.

## CLINICAL RELEVANCE/APPLICATION

The SAM model can potentially reduce radiologists' annotation burden for segmenting MR images to just a few mouse clicks.

## M2-SPIN-6 An Automated Quantification Algorithm for Evaluating Total Metabolic Tumor Volume in Patients with FDG-avid Lymphoma using a Deep-learning Model

### Participants

Lale Kostakoglu, MD, MPH, Charlottesville, VA (*Presenter*) Research Consultant, F. Hoffmann-La Roche Ltd

### PURPOSE

Total metabolic tumor volume (TMTV) holds promise as a method for quantifying tumor burden in patients with 18F-fluorodeoxyglucose (FDG)-avid lymphoma, but methodological limitations mean that it is rarely used in clinical practice. We developed a deep-learning (DL) model for automatic lesion segmentation and TMTV quantification from FDG-positron emission tomography/computed tomography (FDG-PET/CT) scans. We aimed to evaluate the model and identify factors influencing its performance in patients with diffuse large B-cell lymphoma (DLBCL) or follicular lymphoma (FL).

### METHODS AND MATERIALS

The DL algorithm (aTMTV) was trained using retrospective trial data from 836 adults with DLBCL. Model testing was performed using an independent retrospective data set including baseline and post-treatment scans from 166 adults with DLBCL and 201 adults with advanced FL collected from two large phase 3 multicenter trials. FDG-PET/CT scans were assessed by expert readers using semiautomated software (mTMTV) and by aTMTV. Pearson's correlation coefficient (r) was used to evaluate aTMTV performance versus mTMTV. Bias was assessed using the slope and intercept from a weighted Deming regression. Lesion detection performance was assessed by sensitivity (the proportion of mTMTV-detected lesions identified by aTMTV) and positive predictive value (PPV; the proportion of aTMTV-detected lesions identified by mTMTV).

### RESULTS

aTMTV quantification highly correlated with mTMTV in the test set (n = 367; r, 0.96 [95% confidence interval (CI): 0.95, 0.96]) for DLBCL and FL. Only moderate bias was detected between aTMTV and mTMTV (slope, 1.06 [95% CI: 1.02, 1.09]; intercept, -0.27 [95% CI: -0.52, -0.03]; mean difference between methods, 0.10 [standard deviation: 1.15]). Agreement between aTMTV and mTMTV was consistent among patients with different demographics and clinical characteristics, and across scans from different PET/CT scanner manufacturers. Overall mean sensitivity and PPV for lesion detection were both > 0.8. Performance was lower for lesions = 10 mL (mean sensitivity, 0.67; mean PPV, 0.72) than for lesions > 10 mL (mean sensitivity and PPV > 0.95).

## CONCLUSION

The model demonstrated good performance and acceptable bias for TMTV measurement in patients with DLBCL or FL. Good generalizability was observed across patient subpopulations and PET/CT scanner manufacturers. Reduced algorithm performance for small lesions (= 10 mL) may be the result of higher variability among readers in the determination of small lesions.

## CLINICAL RELEVANCE/APPLICATION

With further optimization and validation, this model may provide a novel automated approach for lesion segmentation and TMTV quantification to inform the management of patients with FDG-avid lymphoma.

## M2-SPIN-7 Association of Serum Uric Acid with Visceral, Subcutaneous, Hepatic, Pancreatic, Abdominal Wall Muscle Fat and Bone Marrow Adipose Tissue Quantified by Magnetic Resonance Imaging

Participants

Yuhui Liu, Dalian, China (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of our study was to explore the abdominal wall muscle adipose tissue (AMAT) and bone marrow adipose tissue (BMAT) content and ectopic adipose deposition in patients association with Hyperuricemia by MRI fat fraction maps to provide reference for early prevention and disease control according to.

## METHODS AND MATERIALS

A total of 344 participants (160 men and 184 women) who underwent 1.5T or 3.0 T MRI examination of upper abdomen in our hospital from January 2017 to March 2021 were included in our study, including 55 patients in Hyperuricemia group and 189 patients in non-Hyperuricemia group. The MRI images of all patients included the iterative decomposition of water and fat with echo asymmetry at IDEAL-IQ or mDixon Quant sequence, and the image quality met the measurement requirements. The FF and VAT, SAT, AMAT were obtained at the level of the L1 and L2 vertebral bodies by Image J (National Institutes of Health, USA), and the FF and area of BMAT were automatically calculated at the level of the T12 and L1 vertebral bodies by the software where the mean of BMAT were computed. The HFF and PFF were semi-automatically measured by 3D semi-automatic segmentation software (Smart ROI) on the post-processing platform (Intellispace Portal, ISP, Philips, Holland).

## RESULTS

BMI, TG, HFF, VAT area, VAT FF, AMAT area of the Hyperuricemia group were higher than the non-Hyperuricemia group. The difference was statistically significant ( $P < 0.05$ ). However there was no statistically significant difference in SAT area, SAT FF, PFF, AMAT FF and BMAT FF between Hyperuricemia group and the non-Hyperuricemia group ( $P > 0.05$ ) (Table 1) (Fig 1). Continuous SUA was correlated to HFF ( $r = 0.28$ ,  $p < 0.001$ ) and VAT area ( $r = 0.32$ ,  $p < 0.001$ ) and AMAT area ( $r = 0.46$ ,  $p < 0.001$ ) and to a lesser extent to VAT FF ( $r = 0.26$ ,  $p < 0.001$ , compare scatterplots in Fig 2). We found that SAT area, SAT FF, VAT area, VAT FF, HFF, PFF, AMAT area, AMAT FF and BMAT FF were obviously correlated ( $P < 0.05$ ) after adjusting for age, sex and BMI, but the correlation intensity was different (Fig 3).

## CONCLUSION

In this study, we explored the relationship between the occurrence of Hyperuricemia patients and ectopic fat deposition, AMAT and BMAT. We found that in this population-based sample, SUA and hyperuricemia were strongly related to increased storage of HFF, VAT area, VAT FF, AMAT area.

## CLINICAL RELEVANCE/APPLICATION

We found that Hyperuricemia were strongly related to increased storage of HFF, VAT area, VAT FF, AMAT area. by serum uric acid, thus highlighting the different physiological roles of these fat compartments in uric acid metabolism.

M2-SPIR

### Interventional Radiology Monday Poster Discussions

#### Sub-Events

#### M2-SPIR-2 Unilateral Lung Disease Model Developed using Interventional Radiology Technique

##### Participants

Hiroshi Kodama, MD, Nishinomiya, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Standard mouse model of pulmonary fibrosis model has been made by administration of Bleomycin intratracheally or intraperitoneally. The problem of this traditional methods is high mortality rate of more than 50% after Bleomycin administration. Our hypothesis was that unilateral lung disease model established using interventional radiology technique can overcome this limitation, and the feasibility and usefulness of unilateral lung disease was assessed.

##### METHODS AND MATERIALS

After 6-week-old C57BL/6 mice were anesthetized, a 1.7Fr. microcatheter was advanced into trachea using otoscope. Then, 1.0mg/kg of Bleomycin was injected into bilateral lung at trachea (n=13) or unilateral lung (n=14) after advancing the microcatheter to left main bronchus under fluoroscopy. Technical success, %decrease of body weight and survival at day 28 were evaluated. Body weight change and survival were compared between bilateral and unilateral lung disease groups using Mann-Whitney test and log-rank test. Lungs were extracted and evaluated on HE or Masson Trichrome stained specimens.

##### RESULTS

In all mice, bleomycin was successfully injected in bilateral or unilateral lung: Technical success rate was 100%. Body weights decreased 75.7%±14.0% in bilateral lung disease group, and it was significantly improved to 94.1%±11.4% in unilateral lung disease group (p=0.03). Overall survival rate at day 28 was 30.8% and 85.7% in bilateral and unilateral lung disease model, respectively. Survival was significantly better in unilateral lung disease model(p=0.01). On histological evaluation, it is confirmed that collagen deposition was only seen in bleomycin injected lung in unilateral lung disease model.

##### CONCLUSION

Establishing both healthy lung and disease lung in the same individual model using interventional radiology technique was feasible and make it possible to achieve less body weight loss and more favorable survival.

##### CLINICAL RELEVANCE/APPLICATION

Interventional radiology technique helps developing new animal model. Unilateral lung disease mouse model may be useful to analyze the treatment effect to both diseased and normal lung in the same individual.

#### M2-SPIR-3 Fully Automated Dynamic Frame Rate Adjustment in Digital Subtraction Angiography

##### PURPOSE

Digital subtraction angiography (DSA) is a commonly used method for visualizing vasculature throughout the human body. Unfortunately, patient motion can generate artifacts, limiting the diagnostic quality of the images. When motion artifacts are present, image quality can be effectively improved by utilizing higher acquisition frame rates. However, this approach increases radiation dose to both the patient and provider. Moreover, frame rate adjustments are currently performed manually and frequently overlooked. There is a critical need to automatically optimize acquisition frame rates to maximize image quality and limit unnecessary radiation. We aim to develop a fully automated method to adjust frame rates on a series-to-series basis in response to motion artifacts.

##### METHODS AND MATERIALS

DSAs of the cerebral, hepatic, and splenic vasculature were retrospectively collected (n=88 patients, 217 series; frame rate range 1-7 frames per second). The degree of motion artifacts in each DSA was visually scored using a five-grade Likert scale. In addition, image histograms were calculated for each DSA, and the relationship between the standard deviation of pixel intensities and the artifact rating was investigated. A Pearson correlation coefficient with a two-sided p-value was used to quantify the relationship, and the processing time required to analyze each DSA image was recorded.

##### RESULTS

The degree of motion artifacts was strongly associated with the standard deviation of pixel intensities in the image histogram (r = 0.78, p<1x10<sup>-5</sup>). The average processing time required to calculate this metric for a DSA image was 0.008 seconds on a middle-entry PC (Intel Core i5 processor, 8GB RAM).

##### CONCLUSION

The standard deviation of pixel intensities in DSA is significantly associated with the degree of motion artifacts and can be

calculated in less than 0.01 seconds. This relationship can be utilized to adjust acquisition frame rates for DSA in a quantifiable, automated, real-time approach.

#### **CLINICAL RELEVANCE/APPLICATION**

Increasing DSA acquisition frame rates is an effective method to improve image quality when motion artifacts are present, but it also increases the radiation dose. In this study, we present a concept to perform fully automated, real-time frame rate optimizations on a series-to-series basis. This approach will improve image quality when patient motion is present while limiting radiation exposure when high frame rates are unnecessary.

#### **M2-SPIR-4 Impact of a Selective Lens Dose Reduction Protocol in 3D Rotational Angiography on Eye Lens Radiation Exposure in Cerebral Angiography: A Randomized Controlled Trial**

Participants

Jong-Tae Yoon, BS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

There is limited research on the radiation exposure to the eye lens during cerebral angiography. A recent study has reported that a simple adjustment of table height during three-dimensional rotational angiography (3D-RA) can significantly reduce the radiation dose to the lens. This study aims to investigate the radiation dose to the eye lens during cerebral angiography and evaluate the effectiveness of a lens dose reduction protocol for 3D-RA in reducing overall lens dose exposure.

#### **METHODS AND MATERIALS**

A randomized, controlled clinical trial was conducted at a tertiary hospital, with patients undergoing diagnostic cerebral angiography for unruptured intracranial aneurysms. The lens dose reduction protocol in 3D-RA involved raising the table to position the patient's eye lens away from the rotation axis. The radiation dose at the eye lens was estimated by measuring the entrance surface air kerma with photoluminescent glass dosimeter (PLD). The lens doses of 3D-RA and overall examination were analyzed and compared between the two groups. Image quality of the 3D-RA was assessed using quantitative and qualitative methods.

#### **RESULTS**

A total of 20 participants (mean age, 58 years  $\pm$  9.4 [SD]; 12 men [60%]) were enrolled and randomly assigned to either the conventional group or the lens dose group. The lens dose in 3D-RA was significantly lower in the lens dose group compared to the conventional group (median of 1.1 mGy vs 4.5 mGy,  $P < .001$ ). The total dose was significantly lower in the lens dose reduction group (median of 7.5 mGy vs 10.2 mGy,  $P = .003$ ). In the conventional group, 3D-RA accounted for 46% of the total lens dose, while in the lens dose group, its proportion decreased to 16%. No significant differences were observed in the image quality between the groups.

#### **CONCLUSION**

The study demonstrated that the lens dose reduction protocol showed significant reduction in the lens dose of the 3D-RA as well as entire cerebral angiography, without compromising image quality.

#### **CLINICAL RELEVANCE/APPLICATION**

Radiation exposure during neurointerventional procedures is one of the significant issues to consider clinically as lenses have a high radiation sensitivity, and frequent radiation exposure can increase the risk of developing cataracts. Therefore, managing radiation exposure is crucial, and the use of techniques to reduce radiation doses in lenses, as presented in this study, can potentially decrease the likelihood of cataract formation in patients.

#### **M2-SPIR-5 Immunologic Stem Markers of Poorly-differentiated Hepatocellular Carcinoma: Potential Targets for Locoregional NK-cell Based Immunotherapy**

Participants

Jason Chiang, MD, PhD, Los Angeles, CA (*Presenter*) Consultant, Intuitive Surgical, Inc; Equipment support, Johnson & Johnson

#### **PURPOSE**

Poorly differentiated hepatocellular carcinoma (HCC) is hypothesized to contain immunologic markers of cancer stem cells that elevate the risk for recurrence or progression after locoregional therapy. Natural killer (NK) cells are uniquely able to target cancer stem cells via the innate immune pathway. The goal of this study was to identify cancer stem cell immunologic markers of poorly- vs well-differentiated hepatocellular carcinomas that would make them susceptible to NK-cell based therapy. HCC cell lines of poor- and well-differentiated HCCs were then incubated with naïve and activated NK cells to validate their cytotoxicity profile.

#### **METHODS AND MATERIALS**

Two HCC tumor cell lines of different grades of differentiation (SNU-423: poorly differentiated; HepG2: well-differentiated) were used to determine immunologic stem cell phenotype and susceptibility to NK cell-mediated cytotoxicity. Flow cytometry was used to evaluate for surface receptor expression of MHC-I, CD-54, CD-44, and PDL-1 after staining with PE-conjugated antibodies. Isotype control antibodies were used to determine non-specific bindings. Freshly isolated NK cells and IL-2 activated NK cells prior to using 4-hr  $^{51}\text{Cr}$  release assay.

#### **RESULTS**

The poorly differentiated HCC (SNU-423) had significantly higher expression percentage of CD44 ( $P < 0.0001$ ) and much lower expression percentage of MHC-I ( $p = 0.028$ ) and CD-54 ( $P = 0.01$ ), compared to the well-differentiated HCC (HepG2). There was no difference in PDL-1 levels ( $p = 0.70$ ) between the two cell lines. Naïve NK cells and activated NK cells both demonstrated significantly higher targeted killing of the poorly differentiated HCC when compared to the well-differentiated HCC (untreated NK in Snu-423 vs HepG2,  $p = 0.013$ , IL2-treated NK in Snu-423 vs HepG2,  $p < 0.001$ ). Morphologically, poorly differentiated HCCs exhibited smaller size and proliferated faster when compared to well differentiated HCCs.

#### **CONCLUSION**

Poorly-differentiated HCCs demonstrated significantly decreased expression of stem cell markers MHC-I, CD-54, and higher expression of CD-44 when compared to well-differentiated HCC. Poorly-differentiated HCCs were subsequently validated to be more

susceptible to NK cell therapy. Additional studies in in-vivo HCC models are required to confirm stem profile of poorly differentiated HCCs and their utility as a biomarker for successful NK cell targeting.

#### **CLINICAL RELEVANCE/APPLICATION**

NK-cell based therapy can potentially be used to augment conventional locoregional therapy options for early- to intermediate-stage HCC. Advances in NK cell activation and expansion will lend itself well to transarterial directed delivery of immunotherapy.

#### **M2-SPIR-6 Evaluating the Potential of ChatGPT's Competency in Interventional Radiology**

Participants

Hossam Zaki, BS, Providence, RI (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This project investigates ChatGPT's proficiency in Interventional Radiology by evaluating its clinical decision making and performance on a standardized exam.

#### **METHODS AND MATERIALS**

We utilized ChatGPT, an LLM by Open AI trained on general data, as well as GlassAI, an LLM by Glass Health trained on medical text. Using the American College of Radiology (ACR) Appropriateness Criteria's patient presentations and criteria, we prompted ChatGPT to rank the 3 best interventional procedures, devices, or venous access areas. GlassAI was prompted to provide the best interventional procedures only. Each output was scored out of 3, where 3 is "usually appropriate", 2 is "may be appropriate", 1 is "usually not appropriate", and 0 is not listed. Partial scores were given for non-specific answers. We also used a Self-Assessment Module for Vascular and Interventional Radiology from the ACR published in 2011 to feed non-image based multiple choice questions into ChatGPT. A 1 was given for a correct answer, while a 0 was given for an incorrect answer. Clinical scenarios and exam questions were passed into each LLM twice, to account for stochasticity. The score for the board exam questions were averaged across both runs. Statistical significance was determined using a two-sided student's T-test.

#### **RESULTS**

ChatGPT achieved a score of 2.38, 2.32, and 3.00 in selecting interventional procedures, devices, and venous access sites, respectively. GlassAI achieved a score of 3.00 in selecting interventional procedures. The difference between the two scores was found to be statistically significant ( $p < 0.05$ ). The average score for the exam was 74.2%.

#### **CONCLUSION**

This study has demonstrated the potential of LLMs as a valuable tool for IR contexts. Compared to the ACR Appropriateness Criteria, LLMs perform well selecting an interventional procedure when prompted with a specific clinical scenario. GlassAI, a medical-specific model, performed better than ChatGPT, a general model. ChatGPT performed well in predicting interventional devices and venous access sites. ChatGPT performed well on the simulated IR exam.

#### **CLINICAL RELEVANCE/APPLICATION**

Throughout the study, LLMs consistently exhibited a strong ability to comprehend complex medical scenarios and provide accurate, relevant predictions in interventional radiology areas. Moreover, the use of ChatGPT in a test setting demonstrated its proficiency in answering a wide range of questions. By integrating the model into the decision-making process, we can enhance the efficacy of diagnostic and therapeutic interventions while reducing the cognitive burden on clinicians.

M2-SPMK

### Musculoskeletal Imaging Monday Poster Discussions

#### Sub-Events

#### **M2-SPMK-1 Thumb Distal Phalangeal Pseudolesion: Imaging Findings and Associations of an Underappreciated Normal Variant that May Mimic Osteolytic Pathology**

##### Participants

Andrew Helming, MD, Portland, OR (*Presenter*) Nothing to Disclose

##### PURPOSE

In daily practice, we often observe a thumb distal phalangeal lucency on routine radiographs which may prompt cross-sectional imaging for further work-up. We hypothesize this represents a "pseudolesion" similar to those at the proximal humerus, radial tuberosity and femoral neck. To our knowledge, this finding has not been described in peer-reviewed literature. We aim to: 1) Describe imaging features of the thumb distal phalangeal pseudolesion (DPPL), 2) record incidence and frequency across age groups, and 3) evaluate associations with underlying diseases.

##### METHODS AND MATERIALS

IRB approved, retrospective review of 450 radiographic exams from 7/1/2021-7/1/2022. Patients divided into 3 age groups: 0-17, mean 12; 18-65, mean 42; 66+, mean 74.5. Each group of 150 cases had 50 hand, wrist, digit exams. Demographics obtained from electronic medical records and cases reviewed on PACS for: DPPL (Likert scale- 0, not present; 1, possible; 2, definite), view-specific conspicuity, location (distal/proximal, radial/ulnar, palmar/dorsal), size, laterality, osteopenia, osteoarthritis (OA) (modified Kellgren-Lawrence), inflammatory arthropathy, periarticular mineralization, and indication.

##### RESULTS

450 patients, 51% female and 49% male, 51% left and 49% right, DPPL present in 23%. Frequency of DPPL varied with age as follows: 68 (45%) seen in >65, 34 (23%) in 18-65, and 3 (2%) in those <18. DPPL located at proximal palmar aspect of thumb distal phalanx in 100%, 97% at ulnar aspect, 3% radial. 2% of patients had inflammatory arthropathy, 21% osteopenia, and 2% peri-articular mineralization. Positive correlations between DPPL presence and patient age, osteopenia, and presence of osteoarthritis, ( $p < 0.001$ ); severity of OA was not correlated. DPPL was not associated with gender or inflammatory arthropathy, and dubiously associated with periarticular mineralization. DPPL frequently seen on frontal and oblique views, infrequently on lateral views. Average size 6.4 x 4.5 mm (CC x TV). DPPL more common on hand and digit radiographs.

##### CONCLUSION

DPPL is common in patients older than 65 and consistently identified at the proximal, palmar-ulnar aspect of the thumb distal phalanx at wrist, hand, and finger/thumb radiography. DPPL is significantly associated with aging, increasing osteopenia, and osteoarthritis, and is unusual in the pediatric population. Anatomically, DPPL may be attributed to radial and ulnar sided basal tubercles bordering a palmar fossa/concavity which is less discrete prior to skeletal maturation.

##### CLINICAL RELEVANCE/APPLICATION

Increasing radiologist awareness of DPPL as a normal variant at the thumb distal phalanx may decrease overcalls of osteolytic bone disease, eliminating unnecessary work-up and alleviating patient anxiety.

#### **M2-SPMK-2 Peripheral Tear of the TFCC: Diagnostic Accuracy of MR Imaging of the Wrist and Diagnostic Performance of the Primary and Secondary Signs**

##### PURPOSE

The aim of the study was to assess the diagnostic performance value of MRI findings in patients with type 1b triangular fibrocartilage complex (TFCC) tear of the wrist.

##### METHODS AND MATERIALS

In this study, a retrospective enrollment of 78 patients was conducted to examine the diagnostic performance of preoperative MRI examinations in patients with type 1b TFCC tear. Of the enrolled patients, 39 were confirmed to have type 1b TFCC tear through arthroscopy and underwent MRI examination within 180 days before surgery. As the control group, 39 patients were randomly selected from 1157 patients who underwent MRI examination for wrist pain during the same period. Both groups underwent a review of 19 MRI findings by two independent observers, and the correlation between each diagnostic finding and type 1b TFCC tear was assessed using a Chi-square test. The 19 MRI findings comprise 8 primary signs of abnormalities in the distal or proximal lamina, alongside 11 secondary signs suggestive of abnormalities in the surrounding structures.

##### RESULTS

The type 1b TFCC tear group exhibited a significantly greater incidence of 7 primary MRI signs, comprising fiber discontinuity, signal alteration, and retraction of both proximal and distal lamina, as well as scarring of the distal lamina, compared to the control group (all  $p < 0.05$ ). Remarkably, the presence of fiber discontinuity and signal alteration of the distal lamina were higher in the type 1b

TFCC tear group (74.3% vs. 38.5%,  $p=0.003$ , and 87.2% vs. 43.6%,  $p<0.001$ , respectively), as detected by both observers. In contrast, none of the 11 secondary MRI signs were statistically significant.

## CONCLUSION

s MRI assessment of fiber discontinuity and signal alteration in the distal lamina through MRI examination may provide predictive markers for type 1b TFCC tear. These findings highlight the potential value of MRI as a diagnostic tool for this particular condition.

## CLINICAL RELEVANCE/APPLICATION

This study holds the potential to identify the diagnostic accuracy of wrist MR imaging, as well as the diagnostic performance of both primary and secondary signs related to type 1b TFCC tear.

## M2-SPMK-3 Wrist Instability after Sectioning the Different Components of the Scafolunate Ligament and DCSS using a Cadaveric Model and Evaluated by 4DCT

Participants

Badr Sellami, MD, Brussel, Belgium (*Presenter*) Nothing to Disclose

## PURPOSE

To study the effect of sectioning the different components of the SL (scafolunate) ligament-DCSS (dorsal scafolunate septum) in a cadaveric model and assessing dynamic effects with 4DCT.

## METHODS AND MATERIALS

Five fresh frozen cadaveric specimens were imaged with 4DCT while placed in a custom-made wooden frame before and after introduction of different SL-DCSS lesions. The lesions were created arthroscopically and consisted of VSL (ventral), DSL (dorsal), VSL+DSL, VSL+DSL+partial DCSS, and VSL+DSL+complete DCSS. With CT, dynamic acquisitions were obtained in flexion, extension (F-E), and radial and ulnar (R-U) deviation. Relevant bony structures were semi-automatically segmented. Based on this X; Y; Z graphs were created to analyze the movement of the bones.

## RESULTS

With VSL sectioning, no SL diastasis occurred. Dorsal tilt increased with VSL sectioning. With DSL sectioning SL diastasis was seen but only in flexion-extension, and not in ulnar-radial deviation. With sectioning of multiple components SL diastasis was observed in all motions. With VSL, DSL, VSL+ DSL tilting in F-E was not concordant with tilting in R-U deviation. When the DCSS was completely sectioned tilting increased significantly in all motions and SL diastasis was most pronounced.

## CONCLUSION

s 1. SL diastasis does not occur with VSL lesions, however with DSL lesions it can also not be shown on R-U deviation 2. Except for the most severe injury of all structures (SL+ DCSS) the motion in R-U deviation is not concordant with F-E as would be expected. We believe that the extrinsic ligaments restrain the expected motion. 3. The more components are injured the more SL diastasis and tilting increases. 4. The DCSS plays a very important stabilizing role, and SL instability is most severe when it is injured.

## CLINICAL RELEVANCE/APPLICATION

Patterns of abnormal scafolunate motion after section of different components can be analyzed on 4D CT, and could predict the underlying injuries. The DCSS (dorsal scafolunate septum) plays an important stabilizing role.

## M2-SPMK-4 Clinical Importance of the Retinacula, Subsheat, Ligament Attachments and Dynamics of the ECU. An US-MRI Study with Anatomical and Histologic Correlation

## PURPOSE

To perform an US-MR anatomical-histological correlation of the extensor carpi ulnaris retinaculæ, subsheat, and their attachments to the TFC and carpal ligaments. To review MR and US imaging in 7 patients with abnormal subsheat and ulnar sided TFC tears.

## METHODS AND MATERIALS

Five cadaver specimens (fresh frozen, Thiel, embalmed) were dissected and sectioned at the level of the ECU. US was performed prior to dissection at 4 levels (cubital groove, styloid process, subsheat, carpal insertion). In the 2 dissected specimens (one nl TFC, one major TFC tear) dynamic clips during pro-supination were obtained. US imaging was obtained in consensus by 2 experienced MSK radiologists with a 24 Mhz ultrasound probe. Seven cases of abnormal ECU subsheat on MRI and US from 3 institutions were retrospectively reviewed.

## RESULTS

At the cubital level the ECU is only covered by a thin superficial retinaculum, there is no tight bony or ligament attachment and mobility in pro-supination is very significant. The subsheat starts at the styloid process level, where it connects to the styloid insertion of the TFC. The subsheat is actually a sling of ligamentous bands in continuity with other tendons and extrinsic carpal ligaments (band of Barfred, radiolunotriquetral, intercarpal ligament) Dynamic studies showed a sudden click in pro-supination in the specimens with a major TFC tear, in contrast to the specimens with a normal TFC. All studied cases with abnormal subsheat showed ulnar sided TFC tears.

## CONCLUSION

s The ECU retinacula and subsheat are complex, and have not been correctly described in previous anatomical and imaging work. This area is best evaluated on 24 Mhz US as are dynamics of the ECU tendon in pro-supination. There is no subsheat nor tight attachment of the ECU at the cubital level, but tight connections to the extrinsic carpal ligaments distally. In the clinical patients, major abnormality of the subsheat on MR or snapping dislocation of the ECU on US, was associated with ulnar sided TFC tears.

## CLINICAL RELEVANCE/APPLICATION

Understanding the anatomy of the subsheat as described in this work is a requisite to correctly interpret US and MR imaging of

this area. Our findings also shed light on the clinical concept of 'ECU dislocation-abnormal ECU motion'. Although only limited clinical cases were studied, our findings suggest that subsheath abnormalities and 'abnormal ECU motion' are associated with ulnar sided TFC tears.

## **M2-SPMK-5 Open Access AI Tools in Clinical Support Roles - An Example of Shoulder Implant Recognition**

### **PURPOSE**

Uptake of novel artificial intelligence methods into clinical tools is slowed down by multiple factors. One is the lack of access to computing facilities. In this study, we test today's open access resources for performing a musculoskeletal 4-class labeling task.

### **METHODS AND MATERIALS**

The tools we chose are Google-Chrome as browser, Google-Drive as online repository, Google-Colab as running environment. The model was implemented in Python, specifically Google-TensorFlow. The code was run on a deliberately unbalanced dataset with X-ray images containing implants from four different shoulder implant manufacturers. We applied a fine tuning on the Google-EfficientNet, the dataset was enlarged for training by data augmentation.

### **RESULTS**

We show that today's available open access resources are suitable for the intended task. Google-EfficientNet can be trained to perform the class labeling. Accuracy and avoidance of overfitting are improved by the data augmentation.

### **CONCLUSION**

We will make the designed tool available as open access tool on github. Remaining issues today are the data safety and data privacy. Future tools will need to address those if sensitive data is supposed to be processed.

### **CLINICAL RELEVANCE/APPLICATION**

Identification of unknown implants is only one of the many clinical applications. The relevance of our work is to demonstrate a pilot that uses remotely open access tools for AI work. In the future, support tools could be designed to assist a radiologist in his daily clinical routine.

## **M2-SPMK-6 Wavelet Decomposition Synthetic Imaging in Metal Artifact Reduction MRI (Magnetic Resonance Imaging) in Patients With Long Bone Tumor Prosthesis**

### **Participants**

Jiwoo Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose  
Joohee Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

### **PURPOSE**

To identify the optimal metal artifact reduction sequences (MARS) and to explore solutions to overcome the limitation of existing MARS by using wavelet decomposition.

### **METHODS AND MATERIALS**

We assessed a total of 1348 cases of thigh MRI from patients aged  $\geq 18$  years who underwent 3.0T MRI (Philips Healthcare, Best, the Netherlands) at our institution from January 2016 to April 2022. The inclusion criteria were as follows: (1) Bone resection and tumor prosthesis insertion for tumor involvement of the femur (2) MARS were applied to post-operative follow-up MRI; STIR Metal Artifact Reduction for Orthopedic Implants (O-MAR), mDixon O-MAR, STIR O-MAR XD (3) MARS included the coronal T2FS sequence, which allows for viewing the major axis of a long bone tumor prosthesis in a single image and is deemed the most useful for lesion detection (4) Sufficient image quality for assessment. A total of 61 cases (STIR O-MAR: 15 cases, mDixon O-MAR 17 cases, STIR O-MAR XD 29 cases) with MR images were included in the final analysis. To assess the metal related signal changes that can affect the diagnostic performance, MR images were assessed by the following parameters: the distinction of anatomic structures and image quality. (1) For the distinction of anatomic structures, (1.1) bony cortex on the outer layer of the long bone with the tumor prosthesis could be well observed (1.2) the range of the muscles showing artifacts in the anterior compartment of thigh muscles surrounding the femur, (2) Regarding image quality, (2.1) center signal void area and (2.2) total artifact area including geometric image distortion, spatial blurring and image noise. The scores for the four parameters assessed for each MARS were summed up (4-20 points). The scores of three sequences were evaluated using the one-way ANOVA and post hoc Tukey Honestly Significant Difference (HSD) test. Wavelet decomposition was applied to O-MAR XD images: a total of 101 conventional sequence-MARS pairs.

### **RESULTS**

There were no significant difference in OMAR sequence and mDixon O-MAR sequence ( $P=0.378$ ). However, in subsequent images, wavelet decomposition reduced artifacts caused by blurring, a drawback of OMAR-XD, and there were significantly improved image quality and decreased metal artifact reductions in area ( $P<0.001$ ).

### **CONCLUSION**

OMAR or mDIXON OMAR appeared to be more useful than OMAR-XD for assessing 3.0T MRI images of long bone tumor prostheses. Application of the Wavelet decomposition synthetic imaging would aid diagnosis than OMAR-XD in patients with long bone tumor prosthesis.

### **CLINICAL RELEVANCE/APPLICATION**

Efforts to reduce metal artifacts in MRI have been ongoing, but assessing postoperative magnetic resonance imaging (MRI) of patients with a long bone tumor prosthesis is still challenging.

## **M2-SPMK-7 Development of a Fitted Ultrasound Standoff Pad Device**

### **Participants**

Mario Russo, MEng, Cambridge, MA (*Presenter*) Nothing to Disclose

### **PURPOSE**

Ultrasound (US) examinations are ubiquitous diagnostic assessments, reaching nearly 350 scans per 1,000 person-years in the United States. However, US examinations of superficial structures near curved bony prominences, such as the ankle or wrist, can be challenging, often requiring the use of a standoff pad. Unfortunately, a standard standoff pad can be challenging to use due to its bulky size and instability. This is further exacerbated when dynamic maneuvers or procedures are necessary. To address this issue, we have developed initial prototypes of a custom standoff pad adaptor, the FreePad. This exploratory study aims to compare the FreePad to the standard standoff pad and no pad in selected patients undergoing musculoskeletal ultrasound.

## **METHODS AND MATERIALS**

We used an operator-centered iterative design approach to create the FreePad. The Form 3 3D-printer was utilized throughout this process to create and test consecutive prototypes. This study was granted IRB approval and utilized patient informed consent. Included were 12 patients who presented to the outpatient radiology clinic for musculoskeletal ultrasound with a focus on superficial structures near anatomic areas of bony eminences (elbow, wrist, hand, ankle and foot). Each patient was examined under three conditions: 1) using US gel with no standoff pad, 2) with a standard standoff pad, and 3) with the FreePad. Each condition was evaluated for: a) duration of examination in seconds and, on a scale of 1 to 5, b) ease of use, c) quality of images, d) patient comfort, and e) diagnostic confidence. Three staff radiologists assessed the diagnostic confidence independently. The criteria results were evaluated using paired sample t-tests.

## **RESULTS**

The FreePad was easier to use than both US gel and the standoff pad ( $p=0.03$ ,  $p=0.002$ ). While statistically better than US gel across all other conditions, the FreePad compared to a standoff pad trended towards requiring shorter duration (138 vs 169 sec,  $p=0.09$ ), producing higher quality images (4.5 vs 3.9,  $p=0.08$ ), greater diagnostic confidence (4.4 vs 3.8,  $p=0.08$ ), and increased patient comfort (4.8 vs 4.3,  $p=0.06$ ).

## **CONCLUSION**

Use of the FreePad allows for easier scanning of superficial anatomic regions associated with bony eminences. Utilizing a fitted standoff pad device can improve the diagnostic confidence and quality of US images, while significantly enhancing the ease of clinician imaging.

## **CLINICAL RELEVANCE/APPLICATION**

The significantly improved ease of imaging using the FreePad is of everyday benefit to MSK radiologists' diagnostic practice and holds even greater promise for improving US-guided procedures in challenging anatomy.

## **M2-SPMK-8 The Laundry Dilemma: Long or Short Programme to Get Off Calcium Spots**

Participants

David Macia-Suarez, PhD,MD, Santiago de Compostela, Spain (*Presenter*) Nothing to Disclose

## **PURPOSE**

Long-term comparison of two follow up approaches in performing Ultrasound-guided Percutaneous Irrigation of Calcific Tendinopathy (US-PICT) in the shoulder.

## **METHODS AND MATERIALS**

A Cross-sectional study of the evolution of patients undergoing an US-PICT was performed in 2 hospitals, through a Shoulder Pain and Disability Index (SPADI) questionnaire and a clinical survey 5 years after the intervention. The two approaches to assess were: Hospital 1: follow-up by the radiology service a month and a half after the intervention, assessing the need to perform a new US-PICT in case both symptoms and calcification persisted. Hospital 2: the patient was discharged after the intervention, being able to return to the consultation at his own request. In both cases, the same US-PICT (single needle lavage) technique was performed. All patients were informed of their participation in the study and gave their approval through an informed consent document. Authorization was requested and obtained from the regional bioethics committee. At 5 years of the intervention the two approaches were compared using the SPADI questionnaire, a clinical survey and a physical and an US exploration. The SPADI questionnaire consisted of 5 items that assessed pain and 8 items for mobility. The survey consisted of 11 questions that assessed: pain, overall state, mobility and medications compared to before US-PICT. A total of 93 patients were analyzed. 34 from Hospital 1 and 58 from Hospital 2. Statistical analyses were performed using R Statistical Software (v.4.12; Rcore Team 2021), which include a descriptive analysis of the data. Welch test was used in SPADI score means. The Chi-Squared or Fisher test were performed in survey questions.

## **RESULTS**

SPADI Score was statistically significant different in the two centers (Hospital 1:  $2.26 \pm 2.18$ ; Hospital 2:  $4.41 \pm 3.01$ ;  $p$ -value  $<0.001$ ). However, the number of US-PICT was not associated with SPADI Score. Statistically significant differences were found between hospitals in the following aspects of the clinical survey: pain ( $p$ -value = 0.007); mobility compared to healthy ( $p$ -value = 0.001); overall state ( $p$ -value = 0.008). No statistically significant differences were found between the two centers about sex, age, mobility assessment and US features.

## **CONCLUSION**

It seems that closer follow-up of patients (Hospital 1 approach) has better objective (SPADI Score) and subjective (clinical survey) long-term outcomes.

## **CLINICAL RELEVANCE/APPLICATION**

Performing a close and long follow up of patients after US-PICT allows a better outcome and, therefore, a better clinical state.

## **M2-SPMK-9 MRI-guided Retrograde Drilling for Osteochondritis Dissecans of the Talus in Pediatric Patients**

## **PURPOSE**

This study aimed to evaluate the feasibility, effectivity, and safety of MRI-guided percutaneous retrograde drilling in the treatment of osteochondritis dissecans of the talus (OCDT) in pediatric population.

## **METHODS AND MATERIALS**

The retrospective study (2010 - 2019) had 27 consecutive pediatric patients (mean age 13 years) with 30 stable, symptomatic OCDT which were unresponsive to conservative treatment. The OCDT were treated using MRI-guided retrograde drilling. They were graded pre- and post-operatively on a validated 5-grade scale (I - V) based on MRI. The procedure's effectivity was assessed by radiological improvement of the OCDT, and by postprocedural questionnaire that was aimed to evaluate pain (Visual Analogue Scale (VAS) 0 - 10) and performance (scale 0 - 10). Also, an evaluation of procedure-associated symptom alleviation was elicited.

## **RESULTS**

The mean follow-up time was 6.1 (2.4 - 11.4) years. MRI-guided drilling was technically successful in all the cases. No major complications occurred. All the patients were discharged from hospital on the day as the procedure was performed. Mean time interval for follow-up imaging was 4.8 (1 - 12) months. All the OCDT represented grade II - III in pre-operative assessment, and they all remained stable during follow-up. The OCDT grade improved after drilling ( $p = 0.039$ ). Three of grade III OCDT improved to grade I, five of grade III OCDT improved to grade II, and one of grade II OCDT progressed to grade III. The rest of the OCDT remained unchanged. Increased ossification was observed in 39% of the OCDT. The symptoms were significantly alleviated or completely disappeared in 63% of the cases. Preoperative mean VAS and performance was 6.3 (SD 2.0) and 5.2 (SD 2.4), respectively. Both pain (mean change in VAS -3.8, SD 2.6) and performance (mean change 2.6, SD 3.1) were improved significantly ( $p < 0.001$  and  $P = 0.001$ , respectively). Orally administered anti-inflammatory drugs and paracetamol provided satisfactory postprocedural pain relief for 96.7% of the patients.

## **CONCLUSION**

s MRI-guided retrograde drilling of stable OCDT is a feasible, effective, and safe treatment method for pediatric patients.

## **CLINICAL RELEVANCE/APPLICATION**

MRI-guided retrograde drilling of OCDT provides minimally invasive treatment option for patients who are unresponsive to conservative treatment. It is less invasive compared to surgery and is suitable for outpatient care. Additionally, lack of ionizing radiation makes it considerable treatment choice for pediatric patients.

#### M2-SPMS-1 STIR Features of Primary Lower Extremity Lymphedema: A Retrospective Analysis of 228 Patients

##### Participants

MENGKE LIU, BEIJING, China (*Presenter*) Nothing to Disclose

##### PURPOSE

The staging of primary lower extremity lymphedema (LEL) is difficult and vital in clinical work. So we investigated the STIR manifestations of primary lower extremity lymphedema (LEL) in different clinical stages.

##### METHODS AND MATERIALS

A retrospective analysis of 228 patients of primary LEL was conducted, all of which underwent MRI examination using a short-time inversion recovery (STIR) sequence. The affected limb MRI manifestation was observed, and patients were divided into stages I, II, and III based on the 2020 International Society of Lymphology (ISL) clinical staging standards. Two radiologists assessed the following characteristics on STIR: the extent of edema, the frequency of MRI manifestations, including dermal thickening (dermal thickness > 2mm), and the morphology of edema in subcutaneous (grid, honeycomb, parallel-lines, banded, crescent, and lymphatic lake). Parallel-lines were thin, 1-2 mm wide, and parallel to the superficial fascia, not forming a network. Grid signs were multiple intertwined lines, up to 3mm wide, with the largest meridian parallel to the superficial fascia and a width-to-length ratio of less than 2/3. Honeycomb signs represented a further thickening of the grid in more than two directions, with a wall thickness greater than 3mm and a width-to-length ratio greater than 2/3. Band sign is an accumulation of fluid on the fascial surface with a strip-like structure observed at the axial level. Crescent sign is a subfascial accumulation observed at the axial level. Lymphatic lake is a large, structureless area of edema located in the subcutaneous soft tissue.

##### RESULTS

The extent of edema was positively correlated with clinical stage, both longitudinally and transversely. When comparing stages, the incidence of dermal thickening in stages II and III were significantly higher than that in stage I. The incidence of parallel-lines in stage I was significantly higher than that in stages II and III. The incidence of grid in stages I and II was significantly higher than that in stage III. The incidence of honeycomb in stages II and III was significantly higher than that in stage I. The incidence of banded sign in stages I and II was significantly higher than that in stage III. The incidence of lymphatic lake and crescent in stage III was significantly higher than that in stages I and II ( $P < 0.05$ ).

##### CONCLUSION

s STIR manifestations of primary LEL in different stages have certain characteristics, Parallel line sign is a characteristic sign of stage I, and crescentic sign and lymphatic lake are characteristic signs of stage III. MRI can be an effective auxiliary tool for evaluating the severity of primary LEL.

##### CLINICAL RELEVANCE/APPLICATION

STIR can sensitively diagnose lymphedema and assist in clinical staging.

Printed on: 04/12/24

#### **M2-SPNMMI-Virtual Myocardial PET Generated from SPECT-to-PET Translation Model Corrects False High Resting Score in SPECT Due to Photon Attenuation** 1

Participants

Masateru Kawakubo, PhD, Fukuoka, Japan (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Myocardial single photon emission computed tomography (SPECT) is used worldwide for the diagnosis of myocardial ischemia. However, myocardial SPECT with an Anger-type gamma camera has specific artifacts, such as the effect of deep attenuation in the left ventricular inferior wall, that hinder accurate diagnosis. On the other hand, ammonia positron emission tomography (PET) has excellent detector sensitivity and its high-resolution images are considered the gold standard for ischemia diagnosis. We developed an algorithm to generate the virtual PET (vPET) from myocardial SPECT by deep learning network of SPECT-to-PET dataset of the same patient. This research investigates improvement in visual ischemia scoring accuracy of virtual myocardial PET generated by SPECT-to-PET translation (SPT) model.

#### **METHODS AND MATERIALS**

Fifty-four datasets of N-13 ammonia PET and Tc-99m-methoxyisobutylisonitrile SPECT at stress and resting state were retrospectively analyzed. These myocardial base to apical short-axis image dataset from same patient-to-patient were randomly divided into 34 cases of training datasets (2525 images) and 20 cases of test datasets (1762 images). Summed rest scores (SRS) and summed stress score (SSS) derived from vPET with the SPT model, SPECT, and PET in 20 test cases were blindly and independently assessed and compared among them.

#### **RESULTS**

SRS of vPET was not differ from those of PET ( $P > 0.999$ ), but those of SPECT was significantly over-estimated than PET ( $P = 0.002$ ) (vPET vs. SPECT vs. PET =  $0.8 \pm 2.0$  vs.  $1.8 \pm 1.5$  vs.  $0.5 \pm 0.4$ ). There were no differences of SSS among vPET, SPECT, and PET (vPET vs. SPECT vs. PET =  $1.5 \pm 2.2$  vs.  $3.4 \pm 3.0$  vs.  $4.1 \pm 5.6$ ).

#### **CONCLUSION**

Our proposed virtual PET imaging with SPT deep learning model potentially improves visual score based myocardial ischemia diagnosis in SPECT imaging without additional radioisotope injection and the high-cost novel imaging modality. This is the reasonable approach utilizing deep learning because myocardial ischemia diagnosis with standalone SPECT is used worldwide.

#### **CLINICAL RELEVANCE/APPLICATION**

Virtual PET for correcting attenuation artifact in SPECT is applicable as a low-cost and practical clinical tool which provides powerful auxiliary information for myocardial ischemia diagnosis.

#### **M2-SPNMMI-Coronary Artery Bypass Grafting Transiently Improves Myocardial Strain and Myocardial Flow Reserve: An Ammonia PET Study** 2

Participants

Atsushi Yamamoto, MD, PhD, Tokyo, Japan (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Coronary artery bypass grafting (CABG) is associated with better survival and lower rates of major cardiovascular events in the short and long terms. The patency of bypass grafts has been confirmed using coronary CT angiography; however, the effects of CABG on myocardial strain and microcirculatory functions have not been elucidated. We have made it possible to evaluate left ventricular myocardial strain (LVMS), adapting a feature-tracking technique to electrocardiography-gated high-resolution N-13-ammonia positron emission tomography (NH3-PET). The aim of this study was to evaluate the change of LVMS and myocardial flow reserve (MFR) measured by NH3-PET before and after CABG.

#### **METHODS AND MATERIALS**

Between March 2015 and December 2022, 946 consecutive patients were performed resting and stressed NH3-PET because of known or suspected IHD. Patients who underwent NH3-PET before and after CABG (mean interval, 6 months) were enrolled. Patients with a transplanted heart, congenital heart disease, adenosine ineffectiveness, or poor imaging were excluded. LVMS was assessed by a feature-tracking technique on the NH3-PET cine images of horizontal long-axis slices, and the LVMS ratio (LVMSR) was defined as LVMS at stress divided by that at rest. MFR was calculated using a two-compartment model of the time concentration curve for the first two minutes after ammonia injection. LVMSR and MFR before and after CABG were compared by paired t-test. 11 patients who underwent NH3-PET before and after percutaneous coronary intervention (PCI) were analyzed as a comparison group.

## **RESULTS**

16 patients who underwent CABG were retrospectively analyzed. LVMSR in the CABG group showed significant improvement with invasive treatment ( $0.99 \pm 0.13$  vs.  $1.15 \pm 0.21$ ,  $p=0.0013$ ). Global MFR increased significantly from baseline to post CABG ( $1.49 \pm 0.42$  vs.  $1.91 \pm 0.51$ ,  $p<0.0001$ ). On the other hand, there was no significant difference in LVMSR before and after PCI ( $1.01 \pm 0.14$  vs.  $1.00 \pm 0.11$ ,  $p=0.87$ ). No significant improvements in global MFR ( $1.83 \pm 0.65$  vs.  $2.12 \pm 0.77$ ,  $p=0.16$ ) were observed in the PCI group.

## **CONCLUSION**

s CABG transiently improves myocardial strain and MFR significantly. The effect is more pronounced than PCI.

## **CLINICAL RELEVANCE/APPLICATION**

This method can reproducibly assess local function before and after revascularization. Furthermore, it has the advantage of detecting ischemia-related wall motion abnormalities, whereas previously only ischemia was evaluated.

## Abstract Archives of the RSNA, 2023

M2-SPNPM

### Noninterpretive Skills (Beyond Imaging) Monday Poster Discussions

#### Sub-Events

#### M2-SPNPM- **Racial and Ethnic Disparities Among Participants in Uterine Leiomyomas Clinical Studies Evaluating Uterine Fibroid Embolization: A Literature Review** 1

##### PURPOSE

Given the existing racial disparities in utilization of uterine fibroid embolization (UFE) amongst Black and Hispanic women in comparison to surgical intervention, the purpose of this study is to assess the extent of racial and ethnic representation in completed clinical trials for UFE in the United States and to identify specific areas for improvement regarding disparities in fibroid research and care.

##### METHODS AND MATERIALS

A search of PubMed, Embase, and the clinicaltrials.gov database was conducted to identify completed studies on UFE in the US, and information on the number of participants and distribution for each racial and ethnic group (based on OMB definition) was collected.

##### RESULTS

: A total of 20 completed studies were identified, 7 reported race characteristics and 6 reported ethnic characteristics. Two studies compared UFE vs. myomectomy and two compared Embosphere® Microspheres and Embosphere®; particles. White participants were overrepresented in UFE, while in myomectomies predominated black participants. Hispanic or Latino participants were particularly underrepresented in the studies.

##### CONCLUSION

s This study demonstrated the need for race and ethnicity reporting in the scientific literature, racial and ethnic minorities are underrepresented in clinical trials for UFE, indicating potential disparities in access to treatment. The lack of diversity in clinical trial participants may limit the generalizability of study results and perpetuate health inequities. Future efforts should focus on increasing diversity and similar representation in clinical trial participation to ensure that all patients have access to safe and effective treatments for uterine fibroids.

##### CLINICAL RELEVANCE/APPLICATION

It has been demonstrated that UFE has numerous benefits when compared to surgical treatment of fibroids, such as shorter hospital stays and quicker recovery times. Despite this, certain minority groups in the US have yet to fully reap these benefits in comparison to their white counterparts. Black and Hispanic women are both more likely to undergo surgical care, such as hysterectomy, for fibroid treatment. These disparities, combined with the greater number and size of fibroids observed in Black women, lead to health equity concerns. Identifying specific pitfalls in equitable clinical trial design for this condition is critical in the setting of known disparities so that we may enact targeted improvement initiatives.

#### M2-SPNPM- **Radiology Practice Size Distribution Pre- and Post-COVID-19 Pandemic** 2

##### PURPOSE

Prior investigations by Rosenkrantz et. al in 2019 have demonstrated a trend of consolidation of radiology groups in the mid-2010s. However, little is known about changes in radiology practice group size and numbers spanning the COVID-19 pandemic. This study seeks to investigate consolidation trends within radiology practice groups before and after the COVID-19 pandemic.

##### METHODS AND MATERIALS

Data on radiologists and their associated practice affiliations were obtained for 2017 and early 2023 from the Physician Compare national database provided by the Centers for Medicare and Medicaid Services. Calculations of unique radiology practice groups and number of unique associated national provider identifier (NPI) numbers associated with each radiology group were performed using R 4.2.2.

##### RESULTS

The number of unique radiologists nationally increased between 2017 and 2023 from 32060 to 34080. Between 2017 and 2023, the number of radiology practices decreased from 3909 to 3455 unique practice entities. The median number of radiologists per practice remained 6 between 2017 and 2023, but the mean practice size increased from 13.9 to 19.0 unique radiologists, indicating a growing skew towards larger groups. The top 10 groups by size increased from including 2411 unique radiologists in 2017 to 3554 unique radiologists in 2023. The top 10 groups by size in 2023 include 3 groups not previously within the top 100 groups by size; the top ranked group by size in 2023 ranked 39th in size in 2017. The number of unique NPI-Practice group pairs has increased from 54,274 in 2017 to 65,664 in 2023; the average radiologist increased billing from under an average of 1.69 to 1.93 distinct practice entities from 2017 to 2023. Analysis by group size demonstrates relative growth in number of radiology practices with >25 radiologists, with a 119% relative increase in number of groups with 100+ radiologists. Geographic analysis demonstrates a relative increase of proportion of groups located within the western census region of approximately 10%, with relative decreases in the

remaining regions.

## CONCLUSION

s Consolidation of radiology practice groups has continued through the COVID-19 pandemic from 2017 to 2023, with fewer unique practices and higher average number of radiologists per practice. The greatest growth is seen among practices with 100+ radiologists, highlighting the high degree of consolidation in recent years among the largest groups in the US. At least some of this consolidation appears to be due to greater number of distinct practice entities under which radiologists are billing.

## CLINICAL RELEVANCE/APPLICATION

Increasing consolidation of radiology practices was seen between 2017 and early 2023, with the largest growth seen in practices with 100 or more radiologists.

## M2-SPNPM- Reducing Energy Consumption in MRI using Shorter Scan Protocols, Optimized Magnet Cooling Patterns and Deep Learning Sequences: How Low Can We Go

Participants

Saif Afat, MD, Tuebingen, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

This study aimed to investigate energy consumption in MRI scanners and identify strategies for improving energy efficiency in radiology departments and practices. We focused on musculoskeletal MRI and assessed the potential savings achievable through optimizing protocols, incorporating deep learning (DL) accelerated acquisitions, and optimizing the cooling system.

## METHODS AND MATERIALS

Energy consumption measurements were performed on three MRI scanners (1.5T Aera, 1.5T Sola, 3T Skyra) in practices in Munich, Germany, between December 2022 and March 2023. Two levels of energy reduction measures, eco protocols and DL accelerated sequences, were implemented and compared to baseline. Analysis was conducted in R and Python to evaluate the average, median, and standard deviations of sequence scan times and energy consumption.

## RESULTS

Our findings showed significant energy savings by optimizing protocol settings alone, with knee imaging achieving a 21% energy consumption reduction and 22% time reduction. Implementing DL technologies led to a 37% energy consumption reduction and a 46% time reduction compared to baseline. Optimizing the magnet cooling strategy resulted in a 23.2% reduction during off-cycles.

## CONCLUSION

s Implementing energy-saving strategies, including eco protocols, DL accelerated sequences, and optimized magnet cooling, can significantly reduce energy consumption in MRI scanners without compromising image quality or operational efficiency. Radiology departments and practices should consider adopting these strategies to improve energy efficiency and reduce costs.

## CLINICAL RELEVANCE/APPLICATION

Reducing energy consumption in MRI scanners has environmental, financial, and operational implications for radiology departments and practices. Implementing energy-saving strategies can help address the growing demand for medical devices while reducing energy costs and greenhouse gas emissions.

Printed on: 04/12/24

### Neuroradiology Monday Poster Discussions

#### Sub-Events

#### **M2-SPNR-1 Multiscale Principal Gradient Alterations in Subcortical-Cortical Connectome as Potential Biomarkers for Memory Impairments in Major Depressive Disorder**

##### Participants

Qian Zhang, Chengdu, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Major depressive disorder (MDD) is associated with functional abnormalities in subcortical networks, which contribute to clinical symptoms and cognitive impairments. This study introduces a new approach, functional gradient mapping, to identify hierarchical organization in subcortical connectivity patterns and evaluate their relationship with cognitive features.

##### METHODS AND MATERIALS

Resting-state fMRI studies were conducted on 145 never-treated first-episode MDD patients and 145 healthy controls (HCs). The voxel-wise gradient distributions of the subcortical-cortical connectome were mapped, and group-averaged gradient values were compared across all subcortical voxels, three main systems (limbic, thalamic, and basal ganglia), structural subregions, and functional subregions related to specific cortical functional networks. The study also assessed the association between significant gradient alterations and neuropsychological functioning.

##### RESULTS

The principal gradient values were organized along a gradual anterior-posterior axis across subcortical structures in MDD patients, which varied across different subcortical systems and subregions relative to HCs. At the system level, principal gradient values were lower in the thalamic and limbic systems but higher in the basal ganglia (BG) striatal system in the MDD group. Within subcortical functional subfields, MDD patients had lower gradient values in all limbic subregions and higher gradient values in thalamic subregions projecting to the frontoparietal network but lower values in other thalamic-subregions. Higher gradient values were observed in BG subregions projecting to FPN and visual networks, but lower gradient values were observed in BG regions projecting to sensorimotor, default mode (DMN), and ventral attention network (VAN). Notably, altered principal gradient values of the thalamic system and the subregion projecting to DMN were positively associated with episodic memory test performance in MDD patients, while the BG region projecting to VAN was negatively linked.

##### CONCLUSION

s Multiscale principal gradient alterations of the subcortical-cortical connectome reflected hierarchical disorganization underlying functional segregation in MDD. The interactive associations of thalamic and BG gradient alterations were implicated in subcortical functional connectivity disturbance and episodic memory impairments in MDD patients, revealing an internally differentiated and clinically relevant pattern of subcortical gradient dysfunction in MDD.

##### CLINICAL RELEVANCE/APPLICATION

These findings enhanced our understanding of MDD-related hierarchical pathology and presented potential intervention biomarkers for memory improvements in MDD.

#### **M2-SPNR-10 Volume Reduction in Hippocampal Subregions is Associated with Cognitive Impairment in Patients with Cerebral Small Vessel Disease**

##### Participants

Na Wang, Jinan, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Cerebral small vessel disease (CSVD) is a chronic disease that can lead to mental and psychiatric impairment. As a key brain region for memory and learning, the volume change in the hippocampus may play an important role in cognitive impairment in patients with CSVD, but the specific mechanism is still unknown. The purpose of this article is to compare the volume changes in hippocampal subregions in patients with severe CSVD (CSVD-S), patients with mild CSVD (CSVD-M) and healthy controls (HCs) to investigate the influencing factors of cognitive differences in patients with CSVD.

##### METHODS AND MATERIALS

Sixty-seven CSVD-S patients, 150 CSVD-M patients and 98 healthy controls underwent magnetic resonance imaging (MRI) and cognitive tests. FreeSurfer was used to automatically segment the hippocampus from high-resolution MRI and extract the volume data of 19 subregions. One-way analysis of variance was used to compare the volume differences in hippocampal subregions among the three groups, and the correlation between regions of interest (ROIs) and cognitive test results in the CSVD groups was analyzed. In addition, stepwise regression analysis was performed to correlate the ROIs with multiple risk factors in the CSVD groups.

## RESULTS

We found significant differences in the volumes of the presubiculum-body, head of granule cell and molecular layer of the dentate gyrus (GC-ML-DG-head), fimbria and hippocampus amygdala transition area (HATA) among the three groups ( $p < 0.003$ , Bonferroni correction), and the volumes of the CSVD-S group were significantly smaller than those of the HC group ( $p < 0.003$ ). Bivariate correlation analysis showed that these four subregions were correlated with the Stroop color-word test (SCWT), and the GC-ML-DG-head and fimbria were also correlated with the Montreal cognitive assessment (MoCA) ( $p < 0.013$ ) in the CSVD groups. Influencing factors of the four subregions included age, gender, smoking, hyperlipidemia and hypertension. Mediation analysis showed that the average volume of the 4 ROIs partially mediated the relationship between drinking and SCWT scores.

## CONCLUSION

The volume reduction of some hippocampal subregions can aggravate cognitive impairment in patients with CSVD, and the decreased volume of hippocampal subregions was associated with age, gender, smoking, hyperlipidemia and hypertension. The volume of 4 ROIs mediates cognitive function in CSVD patients with drinking.

## CLINICAL RELEVANCE/APPLICATION

Maintaining good living habits and paying more attention to blood pressure and blood lipids can help to reduce the cognitive impairment caused by CSVD.

## M2-SPNR-11 Regional High Iron Deposition on Brain Quantitative Susceptibility Mapping Correlates with Decreased Cognitive Function in End Stage Renal Disease

Participants  
Yuan Li, Dalian, China (*Presenter*) Nothing to Disclose

## PURPOSE

The end-stage renal disease (ESRD) patients usually have increased brain iron depositions. This study aimed to quantitatively evaluate the brain iron deposition in patients with ESRD by threshold method of quantitative susceptibility mapping (QSM), and to analyze the correlation between the iron deposition and cognitive function.

## METHODS AND MATERIALS

Thirty-four ESRD patients and 45 healthy controls (HCs) were prospectively recruited. All subjects were scanned using a 3T MRI to acquire strategically acquired gradient echo (STAGE) sequence. The mean magnetic sensitivity values (MSV) and volume (MSVM, VM) and high iron region (MSVH, VH) of bilateral caudate nucleus (CN), putamen (PUT), globus pallidus (GP), substantia nigra (SN), red nucleus (RN) and dentate nucleus (DN) in both groups were measured manually (Figure 1). All QSM data was compared between groups using analysis of covariance. Neuropsychological examination results were compared between the two groups by two-sample t tests or Mann-Whitney U tests. Partial correlation analysis was used to assess correlations between the MSVH, VH/VM data and cognitive test scores in the ESRD group, with gender, age and education level as covariates. Multiple comparisons of all statistical values were corrected by false discovery rate (FDR). A statistically significant P-value was set at 0.05.

## RESULTS

Compared with HCs, the MSVM of bilateral PUT, DN and right RN were decreased (Table 1), the VM of all gray matter nuclei were decreased, and the MSVH and VH/VM of bilateral CN, PUT, DN and right SN were increased in ESRD patients ( $P < 0.05$ , FDR corrected)(Figure 2). Patients with ESRD had lower MoCA and DSST scores but higher TMT-A, TMT-B, HAMA, HAMD and BDI-II scores (Table 2). The partial correlation analysis showed that the MSVH of the bilateral RN was negatively correlated with orientation scores (left:  $P = 0.002$ ,  $r = -0.568$ ; right:  $P < 0.001$ ,  $r = -0.651$ )(Figure 3).

## CONCLUSION

The iron deposition of gray matter nuclei increased as well as volume decreased in ESRD patients. The MSV in high iron areas can better assess the distribution of iron and is related to the cognitive dysfunction.

## CLINICAL RELEVANCE/APPLICATION

Previous studies were based on the mean MSV of gray matter nuclei in ESRD patients, but since the distribution of iron is uneven, we further divided the gray matter nuclei into high iron area according to the threshold, which can sensitively reflect the abnormal distribution of brain iron and cognitive impairment.

## M2-SPNR-12 Cerebral Blood Flow Changes in Patients with End Stage Renal Disease: A Study Based on Pseudo-continuous Arterial Spin Labeling

Participants  
Yuan Li, Dalian, China (*Presenter*) Nothing to Disclose

## PURPOSE

Patients with end-stage renal disease (ESRD) lead to cerebral hemodynamic instability. This study aimed to quantitatively evaluate the cerebral blood flow (CBF) alteration in patients with ESRD and to analyze the correlation between the CBF with cognitive and clinical indicators.

## METHODS AND MATERIALS

Thirty-five ESRD patients and 46 healthy controls (HCs) were prospectively recruited. All subjects were scanned using a 3T MRI to acquire pseudo-continuous arterial spin labeling (pCASL) sequence. The relative values of cerebral blood flow (rCBF) of the whole brain was measured using SPM8. All CBF data was compared between groups using analysis of covariance. Neuropsychological examination scores and laboratory indexes were compared between the two groups by two-sample t tests or Mann-Whitney U tests. Partial correlation analysis was used to assess correlations between the CBF data, cognitive test scores and blood biochemical test in the ESRD group, with gender, age and education level as covariates. A statistically significant P-value was set at 0.05.

## RESULTS

Compared with the HCs, the ESRD group exhibited lower rCBF in the bilateral thalamus and putamen (Figure 1, Table 1)( $P < 0.05$ , FDR corrected). There were significant differences in the levels of RBC, HB, Cre, eGFR, UA and HCY between the two groups (all  $P < 0.05$ ). Patients with ESRD had lower MoCA and DSST scores but higher TMT-A, HAMA, HAMD and BDI-II scores (Table 3). The partial correlation analysis showed that the rCBF of the bilateral thalamus were positively correlated with HCY (left:  $P = 0.010$ ,  $r = 0.449$ ; right:  $P = 0.005$ ,  $r = 0.486$ ), the rCBF of the left putamen was negatively correlated with the MoCA scores ( $P = 0.010$ ,  $r = -0.447$ ), the rCBF of the right thalamus was negatively correlated with the orientation scores ( $P = 0.016$ ,  $r = -0.421$ ), the rCBF of the left putamen was negatively correlated with the delayed recall scores ( $P = 0.002$ ,  $r = -0.528$ ), and the right putamen was negatively correlated with the attention scores ( $P = 0.047$ ,  $r = -0.353$ )(Figure 2).

## CONCLUSION

The cerebral blood flow in bilateral putamen and thalamus decreased in patients with ESRD, which correlated with HCY level and neurocognitive scores.

## CLINICAL RELEVANCE/APPLICATION

Patients with ESRD have cerebral hemodynamic imbalances and may suffer from a range of complications. So we used arterial-spin labeling MR imaging to non-invasively and quantitatively evaluate cerebral blood flow changes in patients with ESRD, and analysis the correlation between these changes and cognitive impairment.

## M2-SPNR-13 Visceral Abdominal Adipose Tissue and Insulin Resistance Respectively Influence Alzheimer's Disease Amyloid Pathology and Neurodegeneration in Midlife

Participants

Mahsa Dolatshahi, MD, MPH, Khorram Abad, Iran, Islamic Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

Obesity and adiposity at midlife, evidenced by high body mass index (BMI), are increasingly understood as risk factors for Alzheimer's disease (AD). Importantly, visceral fat is known to be associated with insulin resistance and a proinflammatory state, the mechanisms involved in AD pathology. Herein, we aimed to assess the association between brain MRI volumes as well as amyloid and tau uptake with obesity, insulin resistance, and abdominal adipose tissue in the cognitively normal midlife population.

## METHODS AND MATERIALS

A total of 34 middle-aged (age:  $51.27 \pm 6.12$  years, BMI:  $32.28 \pm 6.39$  kg/m<sup>2</sup>), cognitively normal participants, underwent bloodwork, brain, and abdominal MRI, as well as amyloid and tau PET scan. Homeostatic Model Assessment for Insulin Resistance (HOMAIR)  $> 1.9$  was used as a measure of insulin resistance. Visceral and subcutaneous adipose tissue (VAT, SAT) were semi-automatically segmented using VOxel Analysis Suite (Voxa). FreeSurfer 7.1.1 was used for the automatic segmentation of cortical and subcortical brain regions using a probabilistic atlas. Dynamic amyloid imaging was performed with a bolus injection of  $\sim 15$  mCi of [<sup>11</sup>C]PiB, followed by a 60-min scan. A single intravenous bolus of between 7.2-10.8 mCi of AV-1451 was administered. Data from the 30-60 minute, and 80-100 minute post-injection window for PiB and AV-1451 were used for the analysis, respectively. The association of brain volumes and PiB and AV-1451 standardized uptake value ratios (SUVRs) within the default mode network areas with BMI and VAT/SAT ratio were assessed using linear regression models.

## RESULTS

We observed lower right entorhinal white matter volumes in obese participants with insulin resistance compared to metabolically normal non-obese group ( $p=0.004$ ), without any significant difference in PiB or AV-1451 SUVrs. Regression models with sex, age and education as covariates showed a significant positive association between VAT/SAT ratio and left precuneus white matter PiB SUVrs ( $R^2=0.31$ ,  $p=0.005$ ), but no significant associations with AV-1451 SUVrs.

## CONCLUSION

In our midlife obese sample with insulin resistance, there was lower right entorhinal white matter volume, which is involved in relaying information to the hippocampus. We also demonstrated higher early amyloid pathology in AD-signature areas such as the precuneus in mid-life persons with high VAT/SAT ratio, a marker of visceral obesity.

## CLINICAL RELEVANCE/APPLICATION

These findings prompt designing interventions targeted at reducing abdominal visceral fat, obesity, and insulin resistance in midlife to prevent against Alzheimer disease pathology and neurodegeneration.

## M2-SPNR-14 Utility of Quantifying the Glymphatic System Activity using Diffusion Tensor Image Analysis Along the Perivascular Space (DTI-ALPS) in Mild Cognitive Impairment (MCI), Compared to the Cerebrospinal Fluid (CSF) Biomarker

Participants

Hiroto Takahashi, MD, Suita, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Identifying early Alzheimer's disease (AD) would offer better disease management. The cerebrospinal fluid (CSF) biomarker is sensitive to neurodegeneration in dementia. Dysfunction of the glymphatic system has been revealed to be associated with various diseases including AD. We evaluated the activity of the glymphatic system in mild cognitive impairment (MCI) with a diffusion-based technique called diffusion tensor image analysis along the perivascular space (DTI-ALPS) to explore the imaging biomarker for assessing early dementia, while comparing the CSF biomarker level.

## METHODS AND MATERIALS

Sixty-two patients with MCI underwent both CSF measurement and diffusion magnetic resonance imaging at 3T. No hyperintensities in the periventricular white matter were observed in all subjects on T2-weighted images. Based on the CSF p-tau/A $\beta$ 42 ratio value, 33 patients with AD pathology (AD group) were discriminated from 29 patients with non-AD pathology (non-AD group). Diffusivities in the X, Y and Z axes were obtained in the lateral ventricle body plane of all subjects. We assessed the diffusivity along the perivascular spaces, as well as projection fibers and association fibers, respectively in order to acquire the DTI-ALPS index of each hemisphere. The significance of intergroup difference in the DTI-ALPS index was tested using Mann-Whitney's U test. The

performance of the DTI-ALPS index to discriminate the groups was assessed using receiver operating characteristic (ROC) analysis. Correlations between the DTI-ALPS index and each CSF amyloid  $\beta$  (A $\beta$ ) 42, phosphorylated tau (p-tau) and total tau (t-tau) value were assessed in all subjects using Pearson's correlation analysis.

## RESULTS

The DTI-ALPS indices of both hemispheres were higher in the AD group than those of the non-AD group (Right: 1.72/1.59 for AD group/non-AD group; P value was 0.056; Left: 1.61/1.44 for AD group/non-AD group; P value was 0.002, indicating significant intergroup difference). The respective areas under the ROC curve of the DTI-ALPS index of the right/left hemispheres were 0.64/0.73. The DTI-ALPS indices of both hemispheres showed significant correlation with each p-tau value ( $r$ : 0.26/0.28 for right/left) and t-tau value ( $r$ : 0.28/0.31 for right/left), whereas no significant correlation with the CSF A $\beta$  42 value was identified, in all subjects.

## CONCLUSION

Impairment of the glymphatic system was more observed in non-AD pathology than in AD pathology in MCI. The DTI-ALPS index might be useful for discriminating early AD from other dementias as well as for measuring neurodegeneration in MCI.

## CLINICAL RELEVANCE/APPLICATION

Quantifying the activity of the glymphatic system may be a useful biomarker for diagnosing early AD as well as for measuring neurodegeneration in early dementia.

## M2-SPNR-2 Glymphatic System Dysfunction in the Middle-aged and Elderly Chronic Insomnia Patients Evidenced by DTI-ALPS

### PURPOSE

The glymphatic system in the brain, is a highly organized fluid transport pathway for clearing metabolic waste, and this process mainly increases during sleep. Chronic insomnia might result in glymphatic dysfunction and cognitive impairment. The diffusion tensor image analysis along the perivascular space (DTI-ALPS) offers an opportunity for the noninvasive investigation of the glymphatic system in many diseases. Thus, this study focuses on middle-aged and elderly subjects to explore whether DTI-ALPS could be valuable early markers to identify cognitive decline in chronic insomnia, which would be helpful to prevent the progression of cognitive impairment and highlight the importance of early treatment.

### METHODS AND MATERIALS

This study was approved by the institutional ethics committee. We prospectively enrolled 33 patients with chronic insomnia and 20 healthy controls. All participants underwent DTI MRI on a same 3T MRI scanner using 24-channel standard head coil (Ingenia DNA, Philips Medical Systems, Netherlands). DTI was conducted with main parameters as follows: TR/TE = 4472/90 ms, flip angle = 90°, matrix = 240×240, reconstructed voxel size = 2×2×2 mm<sup>3</sup>, 64 noncollinear directions with b value = 1000 s/mm<sup>2</sup>, and acquisition time = 5 minutes. The DTI-ALPS index was calculated from the images (Figure 1). Pearson correlation was used to test the associations between DTI-ALPS with MMSE score. The diagnostic accuracy of DTI-ALPS was evaluated using ROC curve analysis.

### RESULTS

The DTI-ALPS index in chronic insomnia with impaired cognition was significantly lower than that in chronic insomnia with normal cognition and healthy controls (Table 1, Figure 2). Furthermore, the DTI-ALPS index was significantly positively correlated with the MMSE score in chronic insomnia with impaired cognition group ( $r=0.69$ ,  $p=0.002$ , Figure 3). Our results of ROC analysis showed that the DTI-ALPS could distinguish chronic insomnia with impaired cognition group, from normal cognition group with accuracy (area under the curve [AUC]: 0.81, sensitivity: 82.4%, specificity 68.7% (Figure 4).

### CONCLUSION

Our results indicated that non-invasive DTI-ALPS index may be a useful imaging tool to predict cognitive impairment in middle-aged and elderly patients with chronic insomnia. Glymphatic clearance function might play a role in the development of cognitive decline patients in preclinical stage, and it is meaningful to take some measures to prevent disease progression.

### CLINICAL RELEVANCE/APPLICATION

This non-invasive DTI-ALPS index may be a useful imaging marker to predict cognitive impairment in patients with chronic insomnia, and it might be meaningful to use as a reminder to take some measures to prevent disease progression.

## M2-SPNR-3 Evaluate Depression in Parkinson's Disease with a Multi-Flip-Angle and Multi-Echo Gradient Echo Sequence (Multiplex) MRI

### Participants

He Sui, MD, MD, Changchun, China (*Presenter*) Nothing to Disclose

### PURPOSE

Previous multimodal MRI has proven to be a useful imaging approach for both clinical diagnosis and research investigating, however, studies of Parkinson's disease (PD) have focused primarily on motor-related basal ganglia structures and little research has been done on clinical scale indicators. In this experiment, we used multiparametric MRI to detect changes related to non-motor symptoms (NMS) in patients with PD.

### METHODS AND MATERIALS

We included 37 patients with PD diagnosed by two neurologists from August to December 2021 in our hospital in this retrospective study. Hamilton Depression Scale (HAM-D) were used to assess the PD patients. 3D TIWI and Multi-Flip-Angle and Multi-Echo Gradient Echo Sequence (Multiplex) MRI techniques such as T2\*-w, T1-w, PD-mapping and quantitative susceptibility mapping (QSM) were performed using a 3T MR scanner. The regions of interest of the whole brain were depicted according to automatic brain segmentation based on deep learning. The Spearman's rank correlation coefficient was used to analyze the relationship between volume, relaxation value of each brain subregion and NMS related assessment scales

### RESULTS

Among parkinsonian subjects, we found that left paracentral, precuneus on both sides, and right superior temporal gyrus in MTP-QSM, right frontal pole and left lateral occipital gyrus on MTP-T2\* mapping showed correlations with HAMD. Volume of the left superior frontal gyrus, middle frontal gyrus on both sides, left frontal pole, insula on both sides, right middle cingulate gyrus, right entorhinal cortex, right superior temporal gyrus, right middle temporal gyrus and optic chiasm showed negative correlations with HAMD on 3D TIWI images. The indicators in MTP-T1 mapping and PD mapping do not have a clear correlation with HAMD.

## CONCLUSION

There is a certain degree of correlation between Multiplex MRI and some clinical evaluation indicators related to depression of PD, we suggest the fusion of quantitative multiparametric neuroimaging measures as an effective strategy that could generally cope with early diagnosis of PD.

## CLINICAL RELEVANCE/APPLICATION

Quantitative multiparametric neuroimaging measures may serve as an effective strategy for non-invasively characterizing the Parkinson's disease.

## M2-SPNR-4 The Impact of Amyloid Cerebral Small Vascular Disease on Glymphatic Function: A Study Based on Alzheimer's Disease Continuum Participants

### PURPOSE

Glymphatic dysfunction is a crucial pathway for dementia. Alzheimer's Disease (AD) pathologies co-existing with cerebral small vessel disease (CSVD) is the most common pathogenesis for dementia. We hypothesize that AD pathologies and CSVD could be associated with glymphatic dysfunction, contributing to cognitive impairment.

### METHODS AND MATERIALS

Participants completed with amyloid PET, diffusion tensor imaging (DTI) and T2FLAIR sequences were included from the Alzheimer's Disease Neuroimaging Initiative (ADNI). White matter hyperintensities (WMH) as the most common CSVD marker was evaluated from T2FLAIR images and represented the burden of CSVD, amyloid PET was used to assess A $\beta$  aggregation in the brain, and DTI-ALPS calculated from DTI reflected glymphatic function. We used correlation analysis to investigate the relationship between WMH burden/A $\beta$  aggregation and DTI-ALPS and the correlations of DTI-ALPS with cognitive domains. Next, mediation analysis was carried out to explore the mediating effects of DTI-ALPS between WMH burden/ A $\beta$  aggregation and cognitive domains.

### RESULTS

One hundred and thirty-three participants along the AD continuum were included, consisting of 40 CN-, 48 CN+, 26 MCI+, and 19 AD + participants. We found both WMH burden ( $r = -0.432$ ,  $p < 0.001$ ) and whole brain A $\beta$  aggregation ( $r = -0.268$ ,  $p = 0.003$ ) were independently negatively associated with DTI-ALPS. There were no interaction effects of A $\beta$  aggregation and WMH burden on DTI-ALPS ( $\beta = 0.109$ ,  $p = 0.260$ ). DTI-ALPS was positively associated with memory ( $r = 0.470$ ,  $p < 0.001$ ), executive function ( $r = 0.356$ ,  $p < 0.001$ ), visual-spatial function ( $r = 0.241$ ,  $p < 0.040$ ), and language performance ( $r = 0.391$ ,  $p = 0.007$ ). In the mediation analysis, we found that DTI-ALPS mediated the relationship of WMH burden/A $\beta$  with memory, executive and language performance.

### CONCLUSION

Our study provided evidence that both AD pathology (A $\beta$ ) and CSVD were associated with glymphatic dysfunction, which is further related to cognitive impairment.

### CLINICAL RELEVANCE/APPLICATION

Our results may provide a theoretical basis for glymphatic function intervention for treating AD.

## M2-SPNR-5 Discordant Hippocampal Atrophy and Cerebral Hypometabolism in Alzheimer's Disease Subjects with Confirmed $\beta$ amyloid Positivity

### PURPOSE

Hippocampal atrophy on MRI and cerebral hypometabolism on FDG-PET are both widely used biomarkers of Alzheimer's disease (AD). Clinically, hippocampal volumes and FDG-avidity are assessed in comparison to age-matched reference groups, but accuracy of such methods have largely been tested in cohorts without biomarker-confirmed AD. Here, we examined the accuracy of MRI and FDG-PET in amyloid-positive AD, at the single-subject level, and factors that could be associated with structural-metabolic discordance.

### METHODS AND MATERIALS

We included 108 subjects with AD (age 74.5 $\pm$  8.2 years, 59:49 males: females) from the Alzheimer's Disease Neuroimaging Initiative (ADNI), with a positive 18F-florbetapir amyloid PET scan, who underwent FDG-PET and volumetric MRI. 179 amyloid-negative, normal controls (age 75.1 $\pm$  6.9 years, 97:82 males:females) served as the age-matched reference group. Bilateral hippocampal volumes were segmented using Freesurfer v7.1.1, averaged, and normalized by intracranial volume. The same Freesurfer regions were applied to the coregistered FDG-PET and normalized by the pons. A threshold of 1.5 standard deviations below the reference group defined biomarker abnormality (e.g. presence of hippocampal atrophy or cerebral hypometabolism). Two-by-two contingency tables were used to assess concordance/discordance between hippocampal atrophy and hypometabolism. Statistical analyses were performed in STATA 16, and group differences were assessed using the Kruskal-Wallis or Fisher's Exact Tests.

### RESULTS

Hippocampal atrophy correctly classified 40/108 (37%) subjects as AD, whereas precuneus cerebral hypometabolism correctly classified 51/108 (47%) subjects. Structural-metabolic discordance was seen in 47/108 (44%) subjects. Individuals with higher Fazekas scores were less likely to have hippocampal atrophy (OR 0.56,  $p = 0.015$ ) or cerebral hypometabolism (OR 0.62,  $p = 0.04$ ). Older individuals were less likely to have cerebral hypometabolism (OR 0.93,  $p = 0.007$ ). Some subjects without a typical pattern of temporoparietal hypometabolism had significantly decreased FDG avidity in the caudate (5/108) and thalamus (3/108).

### CONCLUSION

Cerebral hypometabolism on FDG-PET and hippocampal atrophy on MRI each detected less than half of the amyloid-confirmed AD

subjects. Discordance was high, suggesting that other factors, including age and microvascular disease, could affect the sensitivity of these biomarkers. Notably, the caudate and thalamus were atypical areas of hypometabolism that warrant further investigation.

#### **CLINICAL RELEVANCE/APPLICATION**

Knowing the limitations of clinically used quantitative AD biomarkers is important for appropriate management.

### **M2-SPNR-6 Defining the Relationship Between Mesial Temporal Atrophy and CSF Biomarkers in Amnesic Mild Cognitive Impairment**

#### **PURPOSE**

The NIA-AA research framework introduced a classification scheme to define and stage the pathologic processes leading to Alzheimer's disease (AD) using three groups of biomarkers: biomarkers of  $\beta$ -amyloid deposition, neurofibrillary tangles deposition, and neurodegeneration. Our aim was to evaluate the differences in mesial temporal atrophy rate among amnesic mild cognitive impairment (MCI) patients with normal CSF biomarkers, CSF biomarkers indicating abnormal  $\beta$ -amyloid deposition (A+), and abnormal CSF biomarkers without  $\beta$ -amyloid deposition.

#### **METHODS AND MATERIALS**

We retrospectively identified 401 elderly patients from the Alzheimer's Disease Neuroimaging Initiative cohort, 243 with a diagnosis of amnesic MCI and 158 cognitively unimpaired (CU). MCI patients were classified into three groups: normal biomarkers (n = 46), Alzheimer's continuum (A+, n = 144), and non-AD pathologic change (all other biomarker profiles, n = 53). Hippocampal (HV) and entorhinal cortex (ERCV) volumes were calculated from brain MRI obtained during the first and second year of study participation. We then evaluated group differences over time using mixed model Analysis of Covariance procedures. Results were considered statistically significant when  $p < 0.05$ .

#### **RESULTS**

HV and ERCV atrophy rates differed among groups of subjects when controlling for age (HV:  $F = 20.45$ ,  $p < 0.001$ ; ERCV:  $F = 11.86$ ,  $p < 0.001$ ). HV atrophy rate was greatest in the MCI A+ group than all other groups. Worse ERCV atrophy rates were observed in the MCI A+ group than CU elderly individuals and MCI subjects with non-AD pathologic change.

#### **CONCLUSION**

Mesial temporal atrophy rate is worse in MCI subjects with abnormal  $\beta$ -amyloid deposition (A+) than other MCI individuals.

#### **CLINICAL RELEVANCE/APPLICATION**

Understanding structural brain differences among patients with different biomarker profiles will enhance the design of clinical trials targeting MCI subjects, especially when MRI markers of neurodegeneration are employed as endpoint.

### **M2-SPNR-7 PET-based A $\beta$ Quantification and Volumetric Comparisons in A $\beta$ classified Patients**

Participants

Priya Santhanam, PhD, Olney, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study aims to identify associations between PET-based quantification of amyloid- $\beta$  (A $\beta$ ) and MR brain volumetrics in patients with or without radiological presence of A $\beta$  plaques.

#### **METHODS AND MATERIALS**

Patients (n=164; mean age=75.1 years) who were clinically identified as having mild cognitive impairment (MCI) and/or Alzheimer's dementia underwent 3T MRI anatomical imaging and PET CT imaging using A $\beta$  binding tracers Amyvid or Vizamy. Neuroradiologist interpretation of PET-imaging allowed patients to be classified as positive (n=89; A $\beta$ +) or negative (n=75; A $\beta$ -) for A $\beta$  presence. NeuroQuant (v3.0) was used to obtain normalized percentile volumes in regions of interest for this patient population (based on previous findings), which were then compared between A $\beta$ + and A $\beta$ - groups. Quantified A $\beta$  tracer in these same regions acquired through newly-available PETQuant (3.0.2) software was also compared between groups. Finally, the statistical association between volumetrics and PET A $\beta$  quantities within regions was assessed via regression modeling.

#### **RESULTS**

PET-based A $\beta$  quantities were significantly higher in A $\beta$ + patients for bilateral amygdala ( $p < 0.001$ ), entorhinal cortex ( $p < 0.001$ ), hippocampus (left:  $p = 0.001$ , right:  $p = 0.002$ ), and parahippocampal regions ( $p < 0.001$ ) as compared to A $\beta$ - patients. Additionally, normalized percentile volumes were significantly lower in the A $\beta$ + group for bilateral amygdala (left:  $p = 0.001$ , right:  $p = 0.005$ ), left hippocampus ( $p = 0.009$ ), and bilateral parahippocampus (left:  $p = 0.003$ , right:  $p = 0.033$ ). A regression model further identified significant associations between A $\beta$  quantity and volumetric percentile in the left entorhinal cortex ( $p = 0.005$ ), bilateral hippocampus (left:  $p = 0.009$ , right:  $p = 0.038$ ), and right parahippocampus ( $p = 0.046$ ).

#### **CONCLUSION**

Decreased volumes and increased A $\beta$  quantities in limbic regions were observed in patients with clinical A $\beta$  positivity. In combination, NeuroQuant and PETQuant metrics provide a useful supplement to radiological examination in patients with MCI or Alzheimer's dementia. Further analysis is needed to determine any predictive value for patient classification and outcomes.

#### **CLINICAL RELEVANCE/APPLICATION**

A $\beta$  classification in patients with MCI or Alzheimer's dementia can be further informed by quantified metrics of volume and A $\beta$  tracer quantities in limbic regions.

### **M2-SPNR-8 The Study of Total Load of Imaging Combined with Cognition on Cerebral Small Vessel Disease in High Altitude Areas**

Participants

Hai Hua Bao, Xining, China (*Presenter*) Nothing to Disclose

## PURPOSE

Cerebral small vessel disease (CSVD) is the most common cerebrovascular disease that can result in disability and cognitive decline in older adults. Owing to the unique environmental conditions, research on cerebral small vessel disease in high altitude areas is limited. The purpose of this study was to investigate whether altitude can affect cognitive function in patients with CSVD, and to evaluate the correlation between total imaging load and cognitive scores.

## METHODS AND MATERIALS

A total of 56 patients with CSVD who were admitted to the Department of Neurology of the Affiliated Hospital of Qinghai University were included in the study, according to the altitude, it is divided into middle altitude group (1500-2500 meters, n=30) and high altitude group (2500-4500 meters, n=26). Use Prisma 3.0 T magnetic resonance to perform head T1WI, T2WI, T2Flair, DWI, SWI and MRA scans, evaluate CSVD imaging markers and calculate the total load (0-4 points, the severity of the disease is proportional to the score). After the scan, the Cambridge Automated Neuropsychological Test Battery (CANTAB) was used to evaluate the cognitive abilities of all patients, including motor screening task (MOT), reaction time (RTI), rapid visual information processing (RVP), paired association learning (PAL), delayed matching to sample (DMS), spatial working memory (SWM), psychomotor speed, sustained attention, memory ability, and executive function were assessed separately. Data analysis was performed using SPSS 25.0 software.

## RESULTS

When the total load score was 0 or 1, The high altitude group performed poorly in the DMS test( $P=0.019$ ) and the RIT test( $P=0.024$ ); When the score was 2, there was statistically significant difference between the two groups in DMS ( $P=0.004$ ); when the score was 3 or 4, there was no statistical difference in the test results between the two groups ( $P>0.05$ ). The CSVD total load score was positively correlated with DMSMLAD, DMSMLS, and MOTML ( $r=0.614, 0.727, 0.448$ , all  $P<0.05$ )

## CONCLUSION

s With the increase in altitude, the memory ability and psychomotor speed of CSVD patients decreased more significantly. In addition, with the aggravation of CSVD, memory ability and psychomotor speed will also decrease.

## CLINICAL RELEVANCE/APPLICATION

Cognitive function decline is more serious in patients with cerebral small vessel disease at high altitude, and it is very important to strengthen early diagnosis and clinical intervention for patients in high altitude areas.

## M2-SPNR-9 Brain Cortical Complexity and Subcortical Morphometrics in T2D with Microvascular Complication

### PURPOSE

To explore the relationship between the change of cerebral gray matter volume and cognitive function in type 2 diabetes patients with microvascular complication (T2D-C), and to analyze how the change of cerebral gray matter volume and cognitive function are causal links through mediators.

### METHODS AND MATERIALS

39 normal controls, 39 type 2 diabetes patients without microvascular complication (T2D), and 39 T2D-C patients were recruited for 3D T1weighted imaging (3D T1WI) scanning and neuropsychological scale testing. Voxel-based morphology (VBM) was used to analyze and compare the differences in gray matter volume and neuropsychological scale among the three groups, then the mean gray matter volume of different brain regions between groups was used for partial correlation analysis with the scores of cognitive assessment scales such as Montreal cognitive assessment (MoCA) and biochemical indicators such as HbA1c.

### RESULTS

With  $p<0.05$  as the test level of statistical difference, the brain regions with the statistical difference in gray matter volume among the three groups were located in the calcarine, thalamus, left putamen, and left precentral gyrus. Compared with T2D group, the volume of gray matter in the thalamus and left putamen in T2D-C group decreased. Partial correlation analysis showed that the thalamic gray matter volume and left putamen in T2D-C patients were negatively correlated with fasting blood glucose, positively correlated with HOMA2-%B, and negatively correlated with TMT-A score. Mediation analysis found that the direct effect of fasting blood glucose on TMT-A was not significant, but the indirect effect was significant, that is, the gray matter volume of the left putamen played a complete intermediary role in the relationship between fasting blood glucose and TMT-A.

### CONCLUSION

s In T2D-C patients, there are extensive areas of reduced gray matter, and the change in gray matter volume is related to cognitive decline.

### CLINICAL RELEVANCE/APPLICATION

Early detection of cognitive impairment in T2D patients and targeted intervention can delay the progression of cognitive decline.

#### Sub-Events

#### **M2-SPPD-1 Diffusion and Perfusion Properties of Fetal Brain and Placenta in Fetuses Affected by Intrauterine Growth Restriction (IUGR): A Preliminary IVIM MRI Study**

##### Participants

Roberta Ninkova, MD, Rome, Italy (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the potential use of Intravoxel Incoherent Motion (IVIM) imaging in the study of microperfusion and microstructural characteristics of fetal brain and placenta in Intrauterine Growth Restriction (IUGR) fetuses, comparing IVIM parameters with those of a healthy control group.

##### METHODS AND MATERIALS

112 pregnancies (30 IUGR; 82 normal) were enrolled. MR examinations were performed at 1.5 T, using a DWI sequence with 10 different b-values (0,10,30,50,75,100,200,400,700,1000 s/mm<sup>2</sup>). For each fetus, specific ROIs were manually placed on fetal and maternal sides of each placenta, and for fetal brain on the following areas: centrum semi-ovale (CSO), frontal and occipital white matter (FWM, OWM), basal ganglia (BG), thalamus (TH), cerebellar hemisphere (CH) and pons. Differences of mean values of perfusion fraction (f), diffusion coefficient (D), and pseudo-diffusion coefficient (D\*) and their correlation with Gestational Age (GA) and Birth Weight (BW) were investigated in both IUGR and control group.

##### RESULTS

We found that in the fetal side of placenta, f allowed to discriminate SGA (Small for Gestational Age) from real FGR (Fetal Growth Restriction) ( $p=0.03$ ), with FGR showing lower values. SGA showed intermediate perfusion pattern in terms of f compared to FGR and healthy controls. A significant positive correlation was found between f and BW in fetal side of IUGR group. Concerning the fetal brain, we found higher D values in supratentorial WM areas compared with the other regions (TH, BG, pons, CH), in both normal and IUGR groups. In particular, higher D values in OWM and pons in IUGR fetuses compared to healthy group. A significant negative correlation between D and GA was found for almost all brain areas in the healthy group and conversely not in the IUGR group.

##### CONCLUSION

Complex interactions between placental and fetal environments ensure normal fetal growth. Impairment of the fetoplacental unit may lead to Intrauterine Growth Restriction (IUGR), which is associated with perinatal morbidity and mortality, and long-term complications, like neurodevelopmental delay. In order to this, the development of new non-invasive examinations, such as fetal MRI, may be helpful in detecting fetal abnormalities and understanding their pathogenesis. Specifically, the IVIM model, may be a novel technique to detect microstructural and microperfusion abnormalities of the placenta and fetal brain that occur in IUGR fetuses.

##### CLINICAL RELEVANCE/APPLICATION

Preliminary results show that IVIM parameters may be potential in vivo biomarkers of IUGR severity, improving prenatal and postnatal diagnosis and management of IUGR fetuses.

#### **M2-SPPD-2 Performance Evaluation of Deep Learning-based Bolus-tracking Technology for Pediatric Abdominal Enhanced CT**

##### Participants

Nan Yang, Tianjin, China (*Presenter*) Nothing to Disclose

##### PURPOSE

The process of bolus-tracking scans before CT angiography usually include monitoring location selection and region-of-interest (ROI) placement to generate a time-density curve (TDC) triggering the CT scan. In this study, we aimed to evaluate the performance of an artificial intelligence-based algorithm, SmartPlan, for the bolus-tracking process in pediatric abdominal enhanced CT examination.

##### METHODS AND MATERIALS

226 pediatric abdominal enhanced CT data were prospectively collected. The monitoring locations for placing ROI by experienced technicians for dynamic contrast-enhancement monitoring in bolus-tracking scans and TDC generated in the ROIs were recorded as the control group; The scout scans and time-resolved images were then imported into the SmartPlan software to automatically determine the monitoring location for placing ROI and to generate TDC, and the results were recorded as the experimental group. There are two steps during the SmartPlan process, monitoring section selection and ROI selection. For the monitoring section selection step, we calculated the accuracy of section selection and defined SmartPlan as accurate if the distance between the section selected by SmartPlan and the section selected by technicians was less than 1cm. For the ROI selection, we calculated the

passing ratio of SmartPlan and defined the passing criteria as ROIs were located inner the aortas.

## **RESULTS**

For the monitoring section selection and ROI selection process in SmartPlan, the accuracy of monitoring section selection was 97.35% with a 95% Confidence Interval [95.24%, 99.44%], and the passing ratio of monitoring ROI selection was 0.962 with 95% Confidence Interval [0.919,1]. There was no difference in the peak value of TDC curves between the experimental and control groups (all  $P > 0.05$ ). Time-consuming was found significantly decreased by  $18.18 \pm 1.17$  seconds in the experimental group compared with that in the control group ( $P < 0.05$ )

## **CONCLUSION**

s The AI-based automatic bolus-tracking technique can efficiently provide good performance on bolus-tracking accuracy of pediatric abdominal enhanced CT with experienced technicians.

## **CLINICAL RELEVANCE/APPLICATION**

The AI-based automatic bolus-tracking technique could simplify the CT scan process of pediatric abdominal enhanced CT by fast and acutely automatically triggering CT scans.

#### Sub-Events

#### M2-SPPH-1 Reliability of CT Numbers on Energy Integrating and Deep Silicon Photon Counting Detector CT with Patient Mispositioning

##### Participants

Aria Salyapongse, BS, Madison, WI (*Presenter*) Nothing to Disclose

##### PURPOSE

In this study we compared the CT number of six clinically relevant materials on an energy-integrating detector (EID) and deep silicon photon-counting (PCD) CT as an effect of mispositioning for different patient sizes.

##### PURPOSE

To investigate the imaging parameters influencing urinary stone detection rate with virtual unenhanced (VUE) images obtained at the excretory phase (EP) in contrast-enhanced dual-energy CT urography (DECTU).

##### METHODS AND MATERIALS

150 urinary stone patients (mean age: 47.51±14.42 years; males vs females: 101 vs 49) who required triphasic DECTU were analyzed. The true unenhanced (TUE) and VUE images at EP (VUE(EP)) were obtained. Per stone detection rates on the above images were recorded. Stone location, size and CT number on the TUE images were recorded and used in univariate and multivariate logistic regression analyses to investigate imaging factors influencing urinary stone detection rate on VUE(EP) images. In addition, five contrast agents were included in the regression analyses. Thresholds for detecting urinary stone on VUE(EP) images were determined using receiver operating characteristics (ROC) analysis.

##### METHODS AND MATERIALS

We performed three sets of dose-matched scans on a patient size-mimicking phantom with five different water-equivalent diameters (WED) (Mercury Phantom, Gammex). The acquisition modes were: (1) 120 kV single-energy (SE) EID CT, (2) 80/140 kV rapid kV-switching dual-energy (DE) EID CT, and (3) 120 kV deep silicon PCD CT at four positions in the bore: (1) isocenter (0 cm), (2) up 4 cm, (3) up 8 cm, (4) and up 12 cm. Average CT number was calculated for air, water, polystyrene, iodine 10 mg/mL, bone, and polyethylene in (1) 120 kV polychromatic EID, (2) 70 keV monochromatic EID, and (3) 70 keV monochromatic deep silicon PCD images. Trends in CT number with WED for each position were assessed by plotting CT numbers against WED. Slopes were compared using t-tests with multiple comparison adjustment to assess whether trends in CT number with WED were decreased for deep silicon PCD CT relative to EID CT. CT number accuracy was assessed by calculating ideal material CT numbers using the U.S. National Institute of Standards and Technology (NIST) XCOM database toolkit.

##### RESULTS

For air, water, iodine, and bone materials, deep silicon PCD CT had the smallest magnitude slope of CT number over WED for all tested positions. Deep silicon PCD CT slopes are flatter compared with SE EID CT and reached statistical significance for iodine ( $p < .001$ ), and bone ( $p < .001$ ) for all positions, and for air ( $p = .008$ ) and water ( $p = .01$ ) at three positions. Deep silicon PCD CT slopes were flatter compared with DE EID CT and reached statistical significance for air ( $p = .005$ ), water ( $p = .04$ ), and bone ( $p < .001$ ) for all positions, and for iodine ( $p = .04$ ) at three positions. The accuracy of deep silicon PCD CT was higher than either SE or DE EID CT for all materials at all positions except for polystyrene at 12 cm, based on relative root mean square error.

##### RESULTS

Three hundred and four stones were detected on TUE images; 217 stones were identified on VUE(EP) images (detection rate, 71.4%). Size (Univariate Multivariate:  $p < 0.001$ ) and CT number (Univariate Multivariate:  $p < 0.001$ ) of the stones were both important factors affecting the detection of stone on the VUE(EP) images (Tab.1). The stone detection rate in the urinary tract was significantly higher than that in the kidney (Univariate Multivariate:  $p < 0.01$ ) (Tab.1 and Fig. 1). However, different contrast agents did not affect the detection rate ( $p = 0.547$ ). The area under ROC curve (AUC) of using size and CT number for detecting stone on the VUE(EP) images was only 0.80 and 0.80, respectively with thresholds for stones with size larger than 3.3 mm and CT number greater than 615 HU being detected. After adding the stone location, the AUC of the three parameters can reach up to 0.88 (Tab.2 and Fig. 2).

##### CONCLUSION

s VUE images at EP in DECTU has a relatively low detection rate for urinary stones. Stone location, size and CT number have significant impact on the stone detection rate using VUE(EP) images.

##### CONCLUSION

s WED contributes more to CT number change than mispositioning. The change in CT number over WED was smallest for deep silicon PCD CT for air, water, and bone at all tested positions. The CT number accuracy was also closest to the ideal CT number on deep silicon PCD CT for all materials at all positions except polystyrene at 12 cm, compared with SE and DE EID CT.

## CLINICAL RELEVANCE/APPLICATION

Accurate and stable CT numbers are important for clinical diagnoses, and use of deep silicon PCD CT provides more stable and accurate CT number over patient size and mispositioning compared with SE and DE EID CT.

## CLINICAL RELEVANCE/APPLICATION

VUE images at EP in DECTU are not suitable for detection of urinary stones. Stone location, size and CT number may have an impact on the stone detection rate.

## M2-SPPH-10 Dual-Energy CT-based Low Energy Virtual Monoenergetic Imaging of the Lower Extremity Runoff in Patients with Diabetes Mellitus: Impact on Image Quality, Vascular Contrast and Diagnostic Accessibility

Participants

Christian Booz, MD, Frankfurt am Main, Germany (*Presenter*) Speaker, Siemens AG

### PURPOSE

To evaluate the impact of low energy virtual monoenergetic imaging (VMI)+ dual-energy CT reconstructions on quantitative and qualitative image quality, vascular contrast and diagnostic assessability of lower extremity arteries in patients with diabetes mellitus.

### METHODS AND MATERIALS

Dual-energy CT angiography scans of lower extremities in patients suffering from diabetes who had undergone clinically indicated dual-energy CT examinations between January 2018 and January 2023 were retrospectively analyzed. Images were reconstructed with standard linear blending (F<sub>0.5</sub>) and low keV VMI+ series were generated from 40 to 100 keV, in an interval of 15 keV. Quantitative analyses included evaluation of vascular CT numbers, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). A total of five CT number measurements per vessel were performed in the superficial and deep femoral artery, the popliteal artery, proximal anterior and posterior tibial artery as well as the fibular artery. Qualitative analyses were performed by three board-certified radiologists independently using five-point scales to evaluate image quality, vascular contrast and diagnostic assessability of lower extremity arteries.

### RESULTS

Our final study cohort consisted of 154 patients (82 males). Mean attenuation, CNR and SNR values were highest in 40 keV VMI+ reconstructions (HU, 1180.41 ± 45.09; SNR, 29.91 ± 0.99; CNR, 28.60 ± 1.03) followed by 55 keV VMI+ reconstructions; all three mean values at these keV levels were significantly higher compared with the remaining VMI+ series and standard F<sub>0.5</sub> images (HU, 251.32 ± 7.13; SNR: 13.22 ± 0.44; CNR: 10.57 ± 0.39) (p<.0001). The qualitative analysis showed highest rating scores for 55 keV VMI+ reconstructions followed by 40 and 70 keV VMI+ series with a significant difference compared to standard F<sub>0.5</sub> images regarding image quality, vascular contrast and diagnostic assessability of lower extremity arteries (p<.0001).

### CONCLUSION

Low keV VMI+ reconstructions at a level of 40-55 keV significantly improve image quality, vascular contrast and the diagnostic assessability of lower extremity arteries in patients with diabetes mellitus compared with standard CT series.

## CLINICAL RELEVANCE/APPLICATION

In patients with diabetes mellitus undergoing dual-energy CT scans of lower extremity arteries, low keV VMI+ CT reconstructions at a level of 40-55 keV should be routinely reconstructed in clinical routine to improve image quality and the diagnostic assessability and to potentially reduce radiation dose and the needed amount of intravenous contrast material in scan protocols in order to protect kidney function.

## M2-SPPH-11 Combining K-edge Filtration and Dual-layer CT for Improved Spectral Performance in Pediatric Diagnostics

### PURPOSE

In pediatric spectral CT, accurate quantitative performance with low radiation doses is imperative. Our study demonstrates the effectiveness of using a combination of a K-edge filter and dual-layer spectral detector to increase the quantification sensitivity of iodine and calcium in pediatric patients.

### METHODS AND MATERIALS

A polychromatic simulation based on a clinical dual-layer spectral CT (Spectral CT 7500, Philips Healthcare) was used to generate incident spectra at tube voltages of 100 and 120 kVp with radiation exposure of 33 mAs. An optimal K-edge filter material and thickness (holmium 0.15 mm) was selected from other potential filters using the Cramer-Rao lower bound of noise in the iodine domain for a single pencil-beam x-ray projection at the central detector. To model the combination of the K-edge filter and dual-layer CT, the input spectra were filtered and linearly scaled to match the patient dose of the non-filtered cases. The spectra were then applied to noiseless photoelectric and Compton scatter basis projections of three pediatric phantoms containing tissue equivalent inserts (iodine 0.5 mg/mL, iodine 2.0 mg/mL, blood, calcium 50 mg/mL). The phantoms ranged in diameter from 10 to 20 cm. Using fan beam geometry, Poisson noise was added, a material decomposition look-up table approach was used, and filtered back projection reconstruction was performed to generate photo/scatter basis images with realistic noise. To estimate spectral sensitivity, noise was measured for each insert in the photoelectric image, and a corresponding noise ratio relative to K-edge filtered simulations was calculated to compare filtered and non-filtered simulations.

### RESULTS

At 100 kVp and across all three phantom sizes, the holmium filter and dual-layer CT combination compared to the non-filtered simulation averaged 11% and 10% improvement in photoelectric noise in iodine 0.5 mg/mL and iodine 2.0 mg/mL inserts, respectively. Average filtered noise improvement at 120 kVp was 3% and 5% for the same rods. For the calcium insert, the maximum relative noise improvement was 17% in the 20 cm phantom at 100 kVp. To match non-filtered patient dose, tube exposure was 93 and 85 mAs for 100 and 120 kVp scans.

## CONCLUSION

s Combined holmium K-edge filtration with dual-layer CT increased iodine and calcium sensitivity in pediatric scans at 100 and 120 kVp with radiation exposures within tube capability. This could lead to increased iodine and calcium quantification accuracy and reduced additional non-contrast scans for pediatric patients.

## CLINICAL RELEVANCE/APPLICATION

The combination of K-edge filtration with dual-layer CT may enhance iodine and calcium quantification accuracy and reduce need for additional non-contrast scans in pediatric diagnostic imaging.

## M2-SPPH-12A Comparative Study of Extracellular Volume Fraction Measured by Spectral CT Between Liver and Pancreas in Patients with Hypertension

### PURPOSE

To investigate the correlation between extracellular volume fraction of liver and pancreas measured by spectral CT iodine maps and hypertension-related indicators and to compare their diagnostic value.

### METHODS AND MATERIALS

166 patients who underwent abdominal spectral CT enhancement scanning were included. They were divided into a normal blood pressure group and a hypertension group according to whether they had hypertension. Then, the hypertension group was further divided into three subgroups according to the systolic and diastolic blood pressure levels. The fECV was calculated by measuring the iodine density (ID) of the liver and abdominal aorta from the iodine maps in equilibrium phase as follows:  $fECV = ID_{\text{hepatic or pancreatic}} \times (100 - Hct) / ID_{\text{abdominal aorta}}$ . One-Way ANOVA analysis was used to compare fECV values among groups. Spearman correlation analysis was used to analyze the correlation between fECV and blood pressure-related indicators, i.e., systolic blood pressure, diastolic blood pressure, pulse pressure. Multiple linear stepwise regression equations were established to obtain the quantitative relationship between fECV and blood pressure-related indicators. ROC curves were used to evaluate the diagnostic performance of hepatic and pancreatic fECV for hypertension.

### RESULTS

The hepatic fECV ( $36.42 \pm 5.20$ ) and pancreatic fECV ( $36.64 \pm 5.46$ ) of patients with hypertension were significantly higher than those patients with normal blood pressure ( $30.17 \pm 4.12$ ,  $33.45 \pm 3.41$ ) and increased with the enhancement of hypertension level. The fECV of liver and pancreas were positively correlated with SBP ( $r=0.57$ ,  $0.42$ ) and DBP ( $r=0.33$ ,  $0.32$ ). Multiple linear regression analysis showed that SBP entered the equation finally ( $\beta=0.105$ , constant= $18.520$ ;  $\beta=0.119$ , constant= $17.528$ ). The AUC for diagnosing hypertension through hepatic fECV was  $0.830$  (SEN  $61.50\%$ , SPE  $88.00\%$ , cut-off value  $34.16\%$ ) and the AUC for diagnosing hypertension through pancreatic fECV was  $0.663$  (SEN  $53.00\%$ , SPE  $94.70\%$ , cut-off value  $37.93\%$ ). Comparing the two AUCs, the accuracy of hepatic fECV was higher than that of pancreatic fECV and the difference was statistically significant ( $P < 0.05$ ).

## CONCLUSION

s The fECV of liver and pancreas measured by spectral CT iodine maps was related to hypertension-related indicators. SBP was an independent risk factor for elevating both hepatic and pancreatic fECV. The hepatic fECV was more helpful for diagnosing hypertension.

## CLINICAL RELEVANCE/APPLICATION

The fECV obtained by dual energy spectral examination is a convenient biomarker to assess the liver and pancreas chronic injury. The fECV derived from spectral CT iodine maps had clinical application values for studying the chronic damage of abdominal organs caused by hypertension.

## M2-SPPH-13A Comparative Study Based on Dual Energy CT and MRI: Grading of Injuries to the Anterior Talofibular Ligament in Ankle

### Participants

Jialiang Guo, Guangzhou, China (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the diagnosis of anterior talofibular ligament (ATFL) injury using ultrafast synchronized KV/mA switching dual energy CT (DECT) and to assess its consistency with MRI grading.

### METHODS AND MATERIALS

Consecutive 41 patients with acute ankle sprain (inversion type) who underwent bilateral ankles scan using DECT (Revolution APEX CT, GE). axial virtual monochromatic image (VMI) at 60 keV with slice thickness of 0.625 mm and material decomposition image (water/HAP) were reconstructed. The MRI (Proton Density Weighted Spectral Attenuated Inversion Recovery, PDW SPAIR) scans were performed on the traumatic ankle joint within two weeks. The width of the injured ATFL was measured on both MRI and VMI images, and the continuity of the ligament and the edema around the ligament were evaluated subjectively. Two radiologists independently evaluated the images and provided grading diagnosis of ATFL injury, and the consistency of DECT and MRI diagnostic grading was assessed using the Kappa test. Paired-sample t-test was used to compare the width of ATFL between DECT and MRI.

### RESULTS

There was no significant difference in the measured widths of ATFL grade I, II, and III injuries measured on DECT and MRI axial PDW SPAIR images (grade I, II, and III, CT:  $2.2 \pm 0.2$ mm,  $3.9 \pm 0.6$ mm,  $5.1 \pm 0.6$ mm; MRI:  $2.3 \pm 0.2$ mm,  $3.9 \pm 0.6$ mm,  $5.1 \pm 0.6$ mm, all  $P > 0.05$ ). The edema within and around the ATFL on the traumatic side can be found in water (HAP) images. In the subjective evaluation of ligament continuity, the agreement between two radiologists is strong ( $K = 0.63$ ). Two radiologists had strong/very strong agreement between the CT diagnostic grading and MRI grading of ATFL injuries ( $K=0.92$ ,  $K=0.78$ ).

## CONCLUSION

s In ankle DECT imaging, grading of ATFL injuries could be performed through the application of VMI image at 60 keV, combined with measurement of the width of ATFL, subjective evaluation of edema within and around the ligament, and ATFL continuity, which has

a good consistency with MRI, providing the possibility of grading ATFL lesions on CT scans.

#### **CLINICAL RELEVANCE/APPLICATION**

Under the condition of VMI imaging at 60 keV, ankle DECT can be used to properly grade ATFL injury by measuring ligament width and subjectively evaluating periligamentous edema and ATFL continuity. This approach showed a good consistency with MRI grading and provided an innovative imaging technique for ankle sprain patients who may not be suitable for MRI examinations.

#### **M2-SPPH-2 Imaging Parameters Affecting Stone Detection using Virtual Unenhanced Images at Excretory Phase in Contrast-enhanced Dual-energy CT Urography**

Participants

Jianying Li, PhD, Beijing, China (*Presenter*) Employee, General Electric Company

#### **M2-SPPH-3 Mobile Photon-counting Detector CT with MD Plus for Neuroimaging of Patients in Intensive Care Unit**

Participants

Junyoung Park, Suwon-Si, Korea, Republic Of (*Presenter*) Employee, Samsung Electronics Co, Ltd

#### **PURPOSE**

The purpose of this study is to evaluate our developed multi-material decomposition method (MD Plus) with mobile PCD-CT for neuroimaging of patients at ICU, and prove the characterization and differentiation of materials between contrast agent and hemorrhage in high-density lesions.

#### **PURPOSE**

To evaluate the performance of self-supervised methods for PCCT image denoising from routine scans, without repeat scans or clean images. These methods include: Noise2Noise (N2N), Noisier2Noise (Nr2N), and Noise2Void (N2V).

#### **METHODS AND MATERIALS**

For clinical images, clean references are difficult to obtain, as noise is always present. Typically, synthetic low-dose images and full-dose images are used as training input and reference, namely Noise2Full-dose (N2Fd), where the inherent noise correlation degrades the result. Alternatively, several self-supervised learning methods have been proposed. N2N is supposed to be equivalent to Noise2Clean (N2C; trained with clean references). For PCCT scans, binomial selection can be used to create the noise independent pairs required in N2N; Nr2N leverages N2Fd which contains residual noise proportional to the synthetic low-dose noise. Thus, it is possible to cancel the residual noise with careful post-processing. To evaluate their performances, we converted clinical images from the KITS21 Challenge to water and Ca density maps and simulated PCCT scans using a 120 kVp spectrum and a realistic energy response. For simplicity, the total counts were used to create a grayscale image. The dataset was split into train (211) / validation (30) / test (59) cases (5 slices from each case). A basic U-Net was trained for 90 epochs, minimizing L2 loss. Dose was split evenly using binomial selection for N2N. N2V was also included in our comparison.

#### **METHODS AND MATERIALS**

For neuroimaging of patients at ICU, the MD Plus was developed and optimized. All CT scans were performed with the FDA 510(k) cleared mobile PCD-CT (OmniTom Elite). For verification of the accuracy of our MD plus algorithm with the mobile PCD-CT, the experiments were conducted using a multi-energy phantom with various exposure conditions and locations of contrast agent. To prove the material characterization of neuroimaging of patients at ICU, our MD plus algorithm was applied to the patients who underwent mobile PCD-CT. The ability of differentiation between iodine and hemorrhage was evaluated.

#### **RESULTS**

All methods reduced the original RMSE of the test set from 27.70 HU. Average RMSE in the test set was 12.37 HU for N2N, which was equivalent to that of N2C (12.38 HU). N2Fd, which violates the independence criterion, had suboptimal results (17.82 HU). Nr2N improved the performance of N2Fd to 13.30 HU. N2V (24.37 HU) had the worst performance since CT images violate its requirement of spatially uncorrelated noise. While Nr2N performed well, we found that the performance relies heavily on the convergence of N2Fd. With a limited amount of training data, the convergence of N2Fd might be incomplete, leading to suboptimal results for Nr2N.

#### **RESULTS**

The results of multi-energy phantom with different exposure showed that there is no critical artifacts on material decomposition maps with various exposure settings. The measured iodine concentrations of each exposure setting were compared to the ground truth. The linear relationships were observed between the measured and true iodine concentrations and the coefficient of determinations ( $R^2$ ) for 5, 10, 15, 20 mA were 0.994, 0.995, 0.996, 0.998 respectively. The results of different contrast demonstrated that the material maps were comparable and the difference ratio was 3.644%. The results of neuro-images of patients at ICU demonstrate the key benefits of our MD plus algorithm with mobile PCD-CT: the regions of intracerebral hemorrhage are clearly visible in material decomposition map. Also, the consistent and repeatable ability to show iodine concentration in material map regardless of different patients was proved.

#### **CONCLUSION**

Among the representative self-supervised learning methods, N2N yields the best performance, approaching that of N2C while only requiring routine scans. Nr2N can effectively improve the performance of N2Fd with proper training and post-processing, but is slightly inferior to N2N. Future work will investigate the applicability of N2N to real data, as well as more sophisticated networks and loss functions.

#### **CONCLUSION**

Our quantitative results of multi-energy phantom verified the accuracy of our MD plus algorithm. In addition, the qualitative results regarding clinical cases of patient at ICU demonstrate that our MD plus algorithm with mobile PCD-CT can separate the contrast agent from the blood accurately. The differentiation of iodine and hemorrhage or acute ischemic stroke can be used in high density lesions after intra-arterial recanalization.

#### **CLINICAL RELEVANCE/APPLICATION**

The accurate results of MD plus algorithm with mobile PCD-CT can lead to simplified clinical imaging protocols and improved workflow for neuroimaging of critical patients with the risks associated with transportation and life-threatening illness.

#### CLINICAL RELEVANCE/APPLICATION

We evaluated representative self-supervised learning methods for PCCT image denoising that can use routine scans to train a denoising network without a clean (noiseless) reference.

#### M2-SPPH-5 Feasibility and Accuracy in Calcium Quantification of the Turbo Flash Mode on a Clinical Photon Counting Detector CT System: A Phantom Study

Participants

Shan Shui Zhou, Shanghai, China (*Presenter*) Nothing to Disclose

#### PURPOSE

The high-pitch scan mode on a first-generation clinical dual-source photon counting detector (PCD) CT system can be used for energy analysis, which is helpful for calcium quantification. However, its performance has not been validated because the high-pitch scan could not obtain the energy spectrum information by the energy-integrating detector dual-source CT. The purpose of this study is to evaluate the feasibility and accuracy of calcium quantification in the high-pitch scan on PCD-CT.

#### PURPOSE

With the beginning of the photon counting CT (PCCT) era, claims are being made that scanning two contrast agents simultaneously is beneficial in terms of dose. Our aim is to quantify the supposed benefit or the possible harm.

#### METHODS AND MATERIALS

A Gammex™ multi-energy CT phantom with three calcium inserts (50, 100, and 300 mg/ml), with and without the elliptical outer layer, was evaluated using a high-pitch (3.2) and regular (0.8) spiral modes on a PCD-CT. Each scan setting was repeated three times with two tube voltages (120 and 140 kVp) and 4 radiation doses (1, 3, 5, and 10 mGy). Calcium maps were generated by adjusting the specific calcium ratio in post-processing and the mean calcium attenuation (CaCT) across three consecutive slices were recorded. Linear regression and Pearson correlation coefficient was implemented for accessing the correlation between CaCT in all scan settings and calcium concentration. The root-mean-squared-error (RSME) was calculated and compared between the high-pitch and regular spiral scans.

#### METHODS AND MATERIALS

PCCT inherently records spectral information. Moreover, the only clinically approved PCCT system, the Naeotom Alpha, is a dual source CT (DSCT): both x-ray tubes can operate at different kV and can utilize different patient-specific prefilters (PSPs), e.g. tin. With PCCT it becomes possible to distinguish more than two materials. Potential applications focus on using two contrast agents, e.g. X=iodine and Y=hafnium. The simultaneous application of two such agents is claimed to be advantageous, e.g. in a way such that the arterial phase of an abdominal acquisition shows X and the venous phase is enhanced by Y. Is this strategy, WXY, with W being the soft tissue, better than two scans W+WX or WX+WY, assuming no patient motion in-between? Or would even three scans, e.g. W+WX+WXY be optimal? To find out, we conducted a study simulating various patient sizes, tube voltages from 70 to 150 kV, four different PSP thicknesses, and all possible bin settings of a photon counting detector to assess the dose-normalized signal-to-noise-ratio (SNRD) of the resulting virtual non-contrast images, and the contrast agent maps of X and Y. No additional noise reduction strategies were applied in order to obtain a fair comparison. Dose penalty (DP) factors are given by the squared ratio of the SNRD values.

#### RESULTS

With just one agent, X=Iodine, doing WX (single source PCCT) instead of W+WX (two scans) yields DP=2.6. Doing WX+WX (DSCT) instead of W+WX yields DP=1.6. With two agents, X=Iodine, Y=Gadolinium, WXY comes with DP=1.5 when compared to WX+WY and with DP=2.0 when compared to W+WXY. Surprisingly, WXY+WXY, which can be realized by a DSCT scan, is only slightly (DP=1.25) outperformed by W+WXY, which requires two separate scans. By far the best performance is obtained by W+WX+WY and by W+WY+WXY (DP=3.2 if doing WXY instead), which, however, require three scans.

#### RESULTS

For all scan settings, the extremely strong correlations between CaCT and calcium concentration were proven by the statistically significant linear regressions (all R-square  $>$  0.99, p  $<$  0.05) and Pearson correlation coefficients (all r  $>$  0.99). The conversion slope ranged from 0.310 to 0.354 mg/mL/HU for the high-pitch scans and from 0.315 to 0.361 mg/mL/HU for the regular spiral scans. The largest RMSE was witnessed in the high-pitch scans of the large phantom at 140 kVp and 1 mGy. The median [interquartile range] RMSE demonstrated similar calcium quantification abilities between the high-pitch and the regular spiral scans (1.25 [0.81; 2.75] versus 0.90 [0.68; 1.50] mg/mL, p = 0.152).

#### CONCLUSION

s For the task of providing contrast agent maps, simultaneous contrast agents always come with a penalty in the order of 1.5 to 3.2 which means that the 1.5- to 3.2-fold patient dose is necessary. If motion between two non-simultaneous scans could be perfectly corrected for, patient dose and thus patient risk could be drastically reduced. In particular, if an unenhanced scan (W) is performed in addition to the enhanced scan(s).

#### CONCLUSION

s The high-pitch scan mode with full spectral information offers feasible and accurate calcium quantification using the dual-source PCD-CT.

#### CLINICAL RELEVANCE/APPLICATION

Accurate calcium quantification by high-pitch scans on PCD-CT even under ultra-low doses could be promising for bone density screening.

#### **CLINICAL RELEVANCE/APPLICATION**

As long as no motion-compensation between scans can be performed, the currently proposed scan strategies are unavoidable. Once motion can be compensated for, scans should be separated into different contrast enhancement schemes.

#### **M2-SPPH-7 Assessing the Blood Supply to Lung Parenchyma Surrounding Different Pathological Types of Lung Carcinoma using Iodine Measurement in Dual-energy Spectral Computed Tomography**

##### **PURPOSE**

The purpose of this study was to investigate the blood supply to lung parenchyma surrounding different pathological types of lung carcinoma using iodine concentration (IC) measurement in dual-energy spectral CT (DEsCT).

##### **METHODS AND MATERIALS**

This study included 47 patients with lung carcinoma (squamous carcinoma, n=18; adenocarcinoma, n=17; small cell carcinoma, n=12), who underwent contrast-enhanced DEsCT before treatment. The IC of the tumor, the ipsilateral lung tissues around tumor and contralateral normal lung tissues were measured in the arterial phase (AP) and venous phase (VP). The IC measurements were further normalized by that of the descending aorta to obtain normalized iodine concentration (NIC). All measurements were repeated by the same radiologist after one month. NIC values were statistically compared among patients with squamous carcinoma, adenocarcinoma and small cell carcinoma using the ANOVA test followed by Scheffe post-hoc correction for multiple comparisons.

##### **RESULTS**

There was significant difference in NIC of ipsilateral lung tissues in AP among adenocarcinoma (0.08), squamous carcinoma (0.07) and small cell carcinoma (0.07) patients. Pairwise comparison indicated that there was a statistical difference between adenocarcinoma and squamous cell carcinoma, while there was no statistical difference between other pairs ( $P < 0.05$ ). In all pathological type tumors, the NIC in AP of ipsilateral lung tissues around tumors were lower than the contralateral, however, the difference was not statistically significant ( $P > 0.05$ ).

##### **CONCLUSION**

s The iodine concentration can be quantitatively measured in DEsCT which can be used as an indicator for the blood supply status to lung parenchyma surrounding tumors.

#### **CLINICAL RELEVANCE/APPLICATION**

To investigate the blood supply to lung parenchyma surrounding different pathological types of lung carcinoma using iodine concentration (IC) measurement in dual-energy spectral CT (DEsCT).

#### **M2-SPPH-8 The Accuracy of Monoenergetic Attenuation at High-pitch Scans using A Dual-source Photon-counting Detector CT: A Phantom Study**

Participants

Le Qin, Shanghai, China (*Presenter*) Nothing to Disclose

##### **PURPOSE**

High-pitch scans performed on a dual-source photon-counting detector CT (PCD-CT) enable reconstructions of virtual monoenergetic imaging at different keV levels. However, the accuracy of monoenergetic attenuation at high-pitch acquisition remains unknown. Thus, the purpose of this study is to evaluate the monoenergetic accuracy of iodine inserts between the regular spiral scan and the high-pitch scan on a first-generation clinical dual-source PCD-CT.

##### **METHODS AND MATERIALS**

The Gammex<sup>TM</sup> multi-energy CT phantom containing iodine inserts of 2, 5, 10 and 15 mg/mL was scanned on a dual-source PCD-CT, with and without the elliptical outer layer. Two pitch levels (3.2 and 0.8), two tube voltages (120 and 140 kVp) and 4 radiation doses (1, 3, 5 and 10 mGy) were alternated, and each scan setting was repeated three times. The image noise in the background and monoenergetic accuracy of the iodine inserts were evaluated at 40, 70, 100 and 140 keV. The median attenuation errors and absolute attenuation bias were further assessed with linear regression to explore the impact of phantom setup and scan parameters.

##### **RESULTS**

The background noise increased with lower keV level and radiation doses. The noise levels between high-pitch and regular spiral scans were evidently different for the large phantom at 40 and 70 keV, especially when radiation dose decreased. In the small phantom, the median attenuation errors at 1, 3, 5 and 10 mGy were 5.5 (1.8; 10.5) [median, (25th percentile; 75th percentile)], 5.9 (1.3; 10.6), 6.0 (2.1; 10.1) and 5.7 (2.6; 13.6) HU, respectively. Similarly, the errors were 3.3 (-2.5; 13.9), 4.1 (-1.6; 11.7), 4.1 (-1.0; 11.2) and 4.6 (-1.0; 12.9) HU in the large phantom. At the worst-case scenario, the attenuation bias exceeded 10 HU in 14.6% (7 of 48 measurements for 4 inserts, 4 keV levels and 3 scan repeats) and 29.2% (14 of 48) for the small and large phantom setups, respectively. The linear regression revealed comparable monoenergetic accuracy between high-pitch and regular spiral scans ( $p = 0.332$ ). Compared to the 70 keV, images at 40 keV and 140 keV were associated with statistically significant (6.6 HU and 1.6 HU, both  $p < 0.001$ ) higher attenuation bias.

##### **CONCLUSION**

s The high-pitch scans exhibited similar monoenergetic accuracy with the regular spiral scans, although the attenuations at 40 keV

and 140 keV still required careful interpretation.

#### **CLINICAL RELEVANCE/APPLICATION**

The monoenergetic images with high-pitch scans enabled by the dual-source PCD-CT provide accurate attenuation and could be quantitative used in conditions requiring fast acquisition such as pulmonary embolism, chest pain triad and ruptured cerebral aneurysm.

#### **M2-SPPH-9 Comparison of Iodine Quantification between High-pitch and Regular Spiral Scans using a Dual-source Photon-counting Detector CT: A Phantom Study**

Participants

Peng Liu, Shanghai, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

With the advent of the dual source photon-counting detector CT (PCD-CT), material decomposition at high pitch could become a clinical reality and potentially exhibit unprecedented diagnostic value. However, its accuracy has not been validated so far. Thus, the purpose of this study is to investigate the accuracy of iodine quantification in a phantom setup and compare the performance between high-pitch and regular spiral scans based on the first-generation clinical PCD-CT.

#### **METHODS AND MATERIALS**

Four inserts with known iodine concentrations (2, 5, 10 and 15 mg/mL) were placed in the removable head section of a Gammex™ multi-energy CT phantom. The phantom, with and without the elliptical outer layer, was scanned using high-pitch (3.2) and regular (0.8) spiral modes on a dual-source PCD-CT. Two tube voltages (120 and 140 kVp) and 4 radiation doses (1, 3, 5 and 10 mGy) were also alternated, and each scan setting was repeated three times. The mean iodine measurements across three consecutive slices were recorded, and the association between the percentage absolute bias (PAB, normalized to the actual reference) and all scan factors was explored using a linear regression analysis.

#### **RESULTS**

A total of 96 acquisitions were performed with both phantom setups and all variations of scan parameters. In the small phantom, the PAB ranged from 1.8% to 5.9% and 1.5% to 3.2% for high-pitch and regular spiral acquisitions, respectively, across different radiation doses and tube voltages. The bias appeared more pronounced in the large phantom (4.4% to 8.5% for high-pitch and 2.5% to 6.8% for regular spiral). The linear regression analysis revealed that scan modes, tube voltages and radiation doses were all statistically irrelevant ( $P > 0.05$ ) to the iodine measurement bias. Compared to the phantom with the outer layer, the small phantom was significantly associated ( $p < 0.001$ ) with 7.2% fewer PAB.

#### **CONCLUSION**

s Iodine density can be accurately and reliably quantified with the high-pitch scan mode, whose ability of material decomposition was only recently brought by the advent of the dual-source PCD-CT.

#### **CLINICAL RELEVANCE/APPLICATION**

High-pitch scans on PCD-CT ensures accurate iodine quantification even in low radiation doses, thus enabling clinical applications which require fast acquisition such as in pediatrics, pulmonary embolism and acute ischemic stroke.

#### **M2-SPRO-1 A CT-based Radiomics Nomogram for Predicting the Progression-free Survival in Small Cell Lung Cancer: A Multicenter Cohort Study**

#### **PURPOSE**

To develop a radiomics nomogram to estimate progression-free survival (PFS) in patients with small cell lung cancer (SCLC) and assess its incremental value to the clinical risk factors for individual PFS estimation.

#### **METHODS AND MATERIALS**

558 patients with pathologically confirmed SCLC were retrospectively recruited from three medical centers. A radiomics signature was generated by using the Pearson correlation analysis, univariate Cox analysis, and multivariate Cox analysis. Patients were classified into the low-risk or high-risk groups based on the optimal cutoff value of the radiomics signature. Association of the radiomics signature with PFS was evaluated. A radiomics nomogram was developed based on the radiomics signature, then its calibration, discrimination, reclassification, and clinical usefulness were evaluated.

#### **RESULTS**

In total, 6 CT radiomics features were finally selected. The radiomics signature was significantly associated with PFS (hazard ratio [HR]: 4.531, 95% confidence interval [CI]: 3.524-5.825,  $p < 0.001$ ). Incorporating the radiomics signature into the radiomics nomogram resulted in better performance for the estimation of PFS (concordance index [C-index]: 0.799, 95% CI: 0.756-0.841) than with the clinical nomogram (C-index: 0.629, 95% CI: 0.586-0.671), as well as high 6-month and 12-month AUCs of 0.885 and 0.846, respectively. Furthermore, the radiomics nomogram also significantly improved the classification accuracy for PFS outcomes, based on the net reclassification improvement (33.7%, 95% CI: 0.216-0.609,  $p < 0.05$ ) and integrated discrimination improvement (22.7%, 95% CI: 0.168-0.278,  $p < 0.05$ ). Decision curve analysis demonstrated that in terms of clinical usefulness, the radiomics nomogram outperformed the clinical nomogram.

#### **CONCLUSION**

A CT-based radiomics nomogram exhibited a promising performance for predicting PFS in patients with SCLC, which could provide valuable information for individualized treatment.

#### **CLINICAL RELEVANCE/APPLICATION**

providing effective support for the implementation of individualized treatment of SCLC.

#### **M2-SPVA-1 "One-stop" Synchronous Dual Imaging for Coronary Artery and Vein on a Dual-layer Spectral Detector CT with Low Contrast Dose: A Primary Study**

##### Participants

Xun Yue, Chengdu, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To explore the feasibility of simultaneous dual imaging of coronary artery and vein system on a dual-layer Spectral detector computed tomography (SDCT).

##### METHODS AND MATERIALS

60 patients with suspected coronary artery disease were prospectively enrolled to undergo coronary CT angiography with a dual-layer spectral detector CT (Spectral CT 7500, Philips Healthcare). The contrast agent was injected at a rate of 4.5ml/s in 3 phases: 9 ml contrast agent and saline 30%:70% mixture, then 0.8ml/kg of contrast agent and finally 30 ml of saline flush. Automatic bolus tracking was used by defining a ROI in ascending aorta, with the scans initiated 8 seconds after the signal attenuation reached a predetermined threshold of 100 HU. 120 kVp polychromatic images with a model-based iterative reconstruction (IMR) were reconstructed. Four monoenergetic levels of images were reconstructed (40 keV, 50 keV, 60 keV, and 70keV). The CT values, noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) on images of each monoenergetic levels were objectively measured at the coronary sinus(CS), the great cardiac vein(GCV), the middle cardiac vein (MCV) and the anterior inter-ventricular vein(AIV) to filter out the best image for vein display. Subjective indicators (contrast, sharpness, subjective noise, and acceptability) of images at each energy were compared on a 5-point scale. The number, morphology and walking of major branches of coronary arteries and veins were observed on VR and slab-MIP images.

##### RESULTS

The display rate of CS, GCV, MCV, AIV, left anterior descending artery(LAD), and left circumflex artery (LCX) is 100%. It was possible to evaluate at least one main vein with adequate caliber and regular course for cardiac re-synchronization therapy (CRT) in 95% (3/60) of these cases. The objective and subjective noise in 40 keV images were worse than 120kVp ( $P<0.05$ ). There is no statistically significant difference in the image noise between 50keV, 60keV, and 70keV compared to 120kVp ( $P>0.05$ ). The SNR, CNR and CT values of 50keV are higher than those of 60keV and 70keV. The contrast, sharpness, and acceptability of 50keV are also better than 60 and 70keV ( $P<0.05$ ).

##### CONCLUSION

s SDCT provides non-invasive evaluation of the coronary artery and venous system, and 50keV monoenergetic images can provide improved coronary vein image quality.

##### CLINICAL RELEVANCE/APPLICATION

The coronary veins is frequently used as an entry route to the heart and treatment modalities for many cardiac diseases and many procedures. But it is difficult, to evaluate the cardiac vein with single-energy CT due to low attenuation. The monoenergetic reconstruction series from cardiac SDCT can significantly reduce high attenuation artifacts by using higher monoenergetic levels.

#### **M2-SPVA-2 Assessment of Diagnostic Efficacy of Photon Counting CT Virtual Mono-Energetic Imaging for Abdominal Aortic and Pelvic Vascular Imaging in Patients Prior to Transcatheter Aortic Valve Replacement (TAVR)**

##### Participants

Leona Alizadeh, MD, Frankfurt, Germany (*Presenter*) Nothing to Disclose

##### PURPOSE

Our study aim was to evaluate the diagnostic efficacy of photon counting CT (PCCT) virtual mono-energetic (VMI)+ imaging for low-keV abdominal and pelvic vascular imaging and TAVR planning.

##### METHODS AND MATERIALS

A total of 125 patients (69 male/ 56 female) underwent PCCT imaging pre-TAVR for assessment of the abdominal aorta and pelvic vessels for transfemoral access planning. Virtual mono-energetic images (40 - 120 keV) were generated in 15 keV steps from the spectral post-processing datasets (SPP). For assessment of quantitative image quality, SNR and CNR were calculated from measurements in the infrarenal aorta, common iliac artery, internal iliac artery, external iliac artery, and common femoral artery. Qualitative IQ, diagnostic significance, and vascular contrast were evaluated in a blinded manner by four experienced radiologists, using a 5-point Likert scale with clinically relevant criteria.

##### RESULTS

The highest mean SNR and CNR values of the VMI+ series were found in 40 keV reconstructions (SNR  $32.5 \pm 9.5$  CNR  $33.3 \pm 9.8$ ), followed by the measurements in the 55 keV VMI+ (SNR  $25.0 \pm 8.0$  CNR  $26.3 \pm 7.8$ )( $p < 0.001$ ). SNR and CNR of 40 keV and 55 keV were significantly higher than all other keV levels including standard 120 kV (SNR  $10.7 \pm 3.0$ ; CNR  $26.2 \pm 9.5$ ) ( $p < 0.001$ ). Accordingly, mean HU-values of 40 keV VMI+ reconstructions were significantly higher at  $1401 \pm 18$ , followed by  $748 \pm 14$  for 55 keV reconstructions ( $p < 0.001$ ). The IQ rating using the Likert scale was higher for the virtual mono-energetic images at 55 keV compared to 40 keV ( $4.6 \pm 1.6$  vs.  $3.9 \pm 1.8$ )( $p < 0.001$ ). The qualitative analysis showed highest rating scores for 55 kV VMI+ reconstructions followed by 40 keV and 70 keV VMI+ series with a significant difference compared to standard 120 kV CT images series regarding image quality, vascular contrast and diagnostic assessability for the femoral access planning( $p < 0.001$ ).

#### **CONCLUSION**

s Our findings suggest that PCCT virtual mono-energetic imaging provides higher SNR and CNR values and better IQ than conventional CT imaging for the abdominal aorta and pelvic vessels at 40 keV. However, for qualitative image quality, 55 keV may be preferred.

#### **CLINICAL RELEVANCE/APPLICATION**

Choice of the right VMI+ reconstruction, allows for use of the diagnostic quality reserve for potential reduction in contrast agent and radiation dose. Further, low-keV VMI+ PCCT reconstructions with enhanced diagnostic quality for TAVR procedure planning may improve patient safety.

M5A-SPBR

### Breast Imaging Monday Poster Discussions I

#### Sub-Events

#### M5A-SPBR-1 Added Value of Contrast-enhanced Digital Mammography (CEDM) in BI-RADS 3 Lesions

##### PURPOSE

The purpose of our study is to evaluate if our cancer detection rate in our institution for BI-RADS 3 lesions was less than 2%, and to assess if our detection rate could be improved by using contrast-enhanced digital mammography (CEDM).

##### METHODS AND MATERIALS

A total of 473 BI-RADS 3 patients depicted on screening mammogram from 2018 to 2020 were collected from our files. All the patients consented to undergo CEDM and biopsy at their next hospital visit. Contrast enhancement intensity categorized as follows: a) Type -1: negative enhancement, b) Type 0: no enhancement c) Type 1: moderate enhancement, d) Type 2: intense enhancement and/or e) Type BE: background enhancement. Pathology results confirmed 473 lesions in total.

##### RESULTS

18 (3,81%) out of the 473 lesions were diagnosed as malignant. The mean age of the patients was 56,22 years. On the contrary, 455 (96,89%) lesions were benign. The mean age of these patients was 51,04. Using CEDM's technique data a total of 5 (1,95%) out of 256 lesions with Type -1 and Type 0 enhancement were diagnosed as malignant and 251 (98,05%) were benign. Additionally, a total of 13 (5,99%) out of 217 lesions with any type of enhancement were proved as malignant and 204 (94,01%) were proved as benign. Negative or no enhancement of a BI-RADS 3 lesion at CEM technique shows 1,95% possibility to be malignant, which is 1,86% better than digital mammography alone.

##### CONCLUSION

Our study confirms CEDM's added value in BI-RADS 3 lesions evaluation, regarding the positive impact on more accurate staging in the first categorization.

##### CLINICAL RELEVANCE/APPLICATION

The use of CEDM on a BI-RADS 3 lesions could potentially predict more accurately benign entities, based on their type of enhancement, and thus play a key role as first line mammography.

#### M5A-SPBR-2 Diagnostic Accuracy of Thoracic Photon-counting Computed Tomography for Locoregional Staging of Breast Cancer: A Prospective Trial

##### Participants

Jakob Neubauer, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

##### PURPOSE

The aim of this study was to demonstrate the feasibility of complementary locoregional staging of breast cancer in thoracic photon-counting CT (PC-CT) and determine diagnostic performance compared to digital mammography (DM) with MRI as the reference standard.

##### METHODS AND MATERIALS

This prospective clinical cohort study included patients with newly diagnosed breast cancer and indication for CT staging of the thorax over a period of 12 months. Patients underwent contrast-enhanced thoracic PC-CT (NAEOTOM Alpha, Siemens Healthineers) and breast MRI in prone position. PC-CT and DM were rated by two independent radiologists regarding the diameter of the largest mass, infiltration of cutis/pectoral muscle/ thoracic wall, number of masses, adjacent DCIS, tumor conspicuity, and diagnostic confidence in a blinded fashion. Reference standard was generated from a consensus reading of MRI by an independent adjudication committee including all histopathological/clinical data. Statistical analysis comprised calculation of Cohen's kappa, Spearman's rho, and pooled measures of diagnostic accuracy.

##### RESULTS

Among 32 enrolled female subjects (mean age 59 [SD 13.0]) diagnostic accuracy for T-classification (TNM8thEd.) was higher for PC-CT compared to DM (0.94 vs. 0.50;  $p < 0.01$ ) and the number of detected tumor masses were more strongly correlated with the reference standard compared to DM (0.72 vs. 0.50;  $p < 0.01$ ). Furthermore, sensitivity and specificity for DCIS were higher in PC-CT compared to DM (0.83 and 0.99 vs. 0.25 and 0.80;  $p < 0.04$ ). Average kappa values for inter-reader reliability were higher for PC-CT than DM (mean 0.88 vs. 0.54, respectively;  $p = 0.01$ ).

##### CONCLUSION

Locoregional breast cancer staging using contrast-enhanced thoracic PC-CT outperformed digital mammography, with significant improvements in diagnostic accuracy for T-classification, number, and pattern of tumor masses.

## CLINICAL RELEVANCE/APPLICATION

Contrast-enhanced thoracic PC-CT might help provide a more accurate locoregional staging for breast cancer compared to digital mammography.

## M5A-SPBR-3 Contrast Enhanced Mammography: Results after 10 Years of Breast Cancer Screening

### PURPOSE

To evaluate the efficacy of contrast-enhanced mammography (CEM) in detecting breast cancer over a ten-year period in women with intermediate breast cancer risk or dense breasts.

### METHODS AND MATERIALS

We conducted a retrospective analysis of all CEM examinations performed for screening purposes at our institution between 2012 and 2023. Demographic data, breast density scores, background enhancement, and BI-RADS scores were extracted using rule-based natural language processing (NLP) techniques. Biopsies performed following CEM examinations and their respective pathology results were also identified. Positive CEM results were defined as BI-RADS 3-5 or 0, while negative results were BI-RADS 1-2. BI-RADS scores of CEM and low-energy images (equivalent to 2D-mammography) were compared with biopsy results and imaging follow-up.

### RESULTS

A total of 5424 CEM screening examinations were performed between the years 2012 and 2023 in 3484 women. The mean age was 54 years, and 18.2% of women (633/3484) had family history of breast cancer. Dense breasts (BI-RADS density score C-D) were observed in 88.3% (3076/3484) of the women, and 34.2% (1193/3484) had background parenchymal enhancement at CEM. A total of 367 biopsies were performed following CEM examinations, and 42 were malignant. CEM detected all cancer cases: sensitivity 100% (42/42), specificity 79.2% (4297/5424), PPV 3.6% (42/1169), NPV 100% (4297/4297). Eight interval cancers were identified during the first-year of follow-up. Of them six with a BI-RADS 0 score at CEM and supplemental MRI recommendation, and two with BI-RADS 3 scores at CEM and six months follow-up. CEM increased the cancer detection rate beyond 2D mammography, with an incremental cancer detection rate of 4/1000 screens.

### CONCLUSION

s CEM increased breast cancer detection rate compared to 2D mammography in women with dense breasts and intermediate breast cancer risk.

## CLINICAL RELEVANCE/APPLICATION

This ten-year screening cohort supports the implementation of CEM for breast cancer screening in specific populations, including women with intermediate breast cancer risk and dense breasts.

## M5A-SPBR-4 Seeing through Contrast: A Dosimetric Comparison of CEM-guided Biopsy and Other Mammography-guided Procedures

### PURPOSE

This study aims to evaluate the average glandular dose (AGD) of contrast-enhanced mammography (CEM) guidance in comparison with other mammography-guided techniques, including digital stereotactic breast biopsy (SBB) and digital breast tomosynthesis (DBT) guidance. Additionally, we investigate the relationship between AGD and compressed breast thickness (CBT) and estimate the percentage dose due to low-energy (LE) and high-energy (HE) images for routine and interventional CEM.

### METHODS AND MATERIALS

We performed a retrospective analysis of 163 anonymized mammography-guided interventions, comprising 43 contrast-enhanced mammography (CEM)-guided interventions, all conducted using the same upright mammography unit. Our assessment focused on the overall average glandular dose (AGD) per image acquisition and modality, as well as its dependence on breast thickness. Additionally, we evaluated the AGD differences between low-energy (LE) and high-energy (HE) acquisitions for both CEM approaches.

### RESULTS

Our study found that the AGD for a single CEM-guided biopsy acquisition (1.48 mGy) was similar to SBB (1.49 mGy) and a single DBT scout (1.55 mGy). The AGD increased with increasing breast thickness for all modalities, with a lower slope for CEM guidance compared to other modalities. Both SBB and CEM require a similar number of images per procedure, while DBT-guided biopsy requires fewer images and offers a lower AGD range. The AGD from a CEM was similar to SBB, even inferior for higher CBT. AGD proportions between LE and HE images are relatively similar for routine and single CEM-guided biopsy image acquisition, with overall dose increase predominantly attributed to LE images across all breast thicknesses.

### CONCLUSION

s Our findings indicate that the radiation dose from CEM guidance during mammography-guided biopsies is within the range commonly achieved for conventional SBB and lower than the values obtained for standard SBB at higher compressed breast thickness. CEM guidance presents great potential to improve the visibility of suspected findings, suggesting it can be a valuable tool for breast interventionism, not only for RC-only findings but also for other indications where increased visibility is required.

## CLINICAL RELEVANCE/APPLICATION

This study provides important dosimetric information on the safety of CEM-guided biopsy, showing that it is a comparable and effective tool for breast interventionism, with similar radiation dose to other established procedures. Our results highlight the potential benefits of CEM-guidance in improving the visibility of suspected findings and increasing diagnostic accuracy in breast imaging.

## M5A-SPBR-5 Uncovering the Unseen: The Potential of CEM for Invasive Lobular Carcinoma Detection

### PURPOSE

Invasive lobular carcinoma (ILC) can be challenging to detect due to its slow-growing nature and subtle appearance. The aim of this study was to determine the lesion conspicuity using contrast-enhanced mammography (CEM) and compare the diagnostic performance of CEM and MRI. We also assessed the correlation of the overall lesion size on imaging with the final histopathological report.

## **METHODS AND MATERIALS**

We retrospectively selected 94 patients with a histopathological diagnosis of ILC who had undergone preoperative CEM between January 2018 and June 2022 at the Hospital del Mar in Barcelona. We collected data on CEM indication, breast density, background parenchymal enhancement (BPE), multicentricity/multifocality, lesion location, lesion findings on low energy (LE) and recombined (RC) images, lesion conspicuity, and lesion size in LE (mm). We also performed a comparative analysis between CEM and MRI for the 59 cases that had both modalities, and verified the agreement between the measurement of lesions in CEM and the sizes in MRI and the final histologic report.

## **RESULTS**

CEM sensitivity in detecting ILC was 98%, and the lesion conspicuity was high in most cases. CEM was not inferior to MRI for ILC evaluation or tumor size assessment, with a positive correlation between CEM and MRI, CEM and histopathology, and MRI and histopathology. The difference between the mean lesion size for CEM and MRI compared to the mean lesion size reported by histopathology was not statically significant.

## **CONCLUSION**

Despite ongoing debate about ILC's perceived weaker enhancement on CEM compared to invasive ductal carcinoma, our results showed that CEM can be a valuable alternative to MRI for ILC evaluation, providing a safe, immediately available, and rapid assessment of tumor extent.

## **CLINICAL RELEVANCE/APPLICATION**

CEM can be a useful alternative to MRI for the preoperative assessment of patients with ILC. It can also help detect potentially larger tumor sizes than initially expected and aid in making appropriate targeting decisions.

## **M5A-SPBR-6 Interobserver Agreement between Breast Imagers using the First Version of the BI-RADS CEM Lexicon**

Participants  
Calogero Zarcaro, MD, Palermo, Italy (*Presenter*) Nothing to Disclose  
Ambra Santonocito, MD, Torino, Italy (*Presenter*) Nothing to Disclose

## **PURPOSE**

The purpose of this study was to assess the interobserver agreement of the CEM lexicon, which has been introduced as a supplement to the 5th edition of the BI-RADS mammography lexicon.

## **METHODS AND MATERIALS**

IRB-approved single center retrospective study. Three breast imaging fellows reviewed 295 lesions in 246 routine clinical breast CEM according to the fifth edition of the BI-RADS lexicon for Mammography and to the first version of the BI-RADS lexicon for CEM. Readers were blinded to patient outcomes, and evaluated breast and lesion features on low energy images (ACR breast density, type of findings, associated architectural distortion), lesion features in recombined images (enhancement findings, lesion conspicuity, mass shape, mass margin, mass internal pattern of enhancement, non-mass distribution, non-mass internal pattern of enhancement, enhancing asymmetry) and also provided a final BI-RADS assessment for both images (MG BI-RADS and CEM BI-RADS assessment). Interobserver agreement was calculated for each evaluated feature using kappa ( $\kappa$ ) statistics.

## **RESULTS**

Interobserver agreement for ACR breast density was substantial ( $\kappa = 0.622$ ). Interobserver agreement was moderate to substantial for breast density and findings assessment on both low-energy and recombined images, especially for type of findings ( $\kappa = 0.644$ ) and for enhancement findings ( $\kappa = 0.700$ ). Regarding mass enhancement, there was moderate agreement for shape ( $\kappa = 0.571$ ) and substantial agreement for margins ( $\kappa = 0.603$ ) and internal enhancement ( $\kappa = 0.648$ ). For non-mass enhancement, there was moderate agreement on distribution ( $\kappa = 0.445$ ) and internal enhancement ( $\kappa = 0.518$ ). However, agreement was only fair for asymmetric enhancement's descriptors (homogeneous vs heterogeneous,  $\kappa = 0.313$ ) and MG and CEM BI-RADS assessment ( $\kappa = 0.379$  and  $\kappa = 0.375$ , respectively).

## **CONCLUSION**

Moderate and substantial interobserver agreement were demonstrated for breast density and findings assessment on both low-energy and recombined images. There was moderate to substantial agreement on most CEM BI-RADS lesion morphology descriptors, while the agreement was only fair for the descriptors of an enhancing asymmetry.

## **CLINICAL RELEVANCE/APPLICATION**

Most of CEM-BIRADS lexicon features allow for an overall high inter-reader agreement, with a lower agreement regarding the descriptors of an enhancing asymmetry and overall BI-RADS assessment.

## **M5A-SPBR-7 Can Contrast-enhanced Mammography (CEM) Categorize More Accurate B3 Lesions and Reduce Unnecessary Surgical Excisions?**

## **PURPOSE**

a) To evaluate the upgrade rates of B3 lesions to malignancy b) To assess if we can get any benefit using CEM to avoid unnecessary open surgical excisions (OSE).

## **METHODS AND MATERIALS**

This is a retrospective analysis of CEM examinations that performed in our institution from 2012-2015. The analysis included a total of 1092 CEM examinations. Contrast enhancement intensity was categorized in four categories as follows: a) "-1": negative

enhancement, b) "0": no enhancement c) "1": enhancement and d) "BPE": background parenchymal enhancement. In addition to the CEM procedures, 776 core needle biopsies (CNB) were performed. The analysis found that 68 patients returned 71 B3 lesions at the pathology result. As a result, an open surgical excision (OSE) was then performed.

## RESULTS

Out of the 71 B3 lesions, 16 (22.54%) were atypical ductal hyperplasia (ADH), 2 (2.82%) were flat epithelial atypia (FEA), 14 (19.72%) were lobular neoplasia (LN), 1 (1.41%) was phyllodes tumor (PT), 33 (46.48%) were papillary lesions (PL) and 5 (7.04%) were radial scars (RS). Using CEM's results these lesions were categorized as follows: 59 (83.1%) lesions had any type of enhancement either "1" or "BPE" and 12 (16.9%) of the lesions had "0" enhancement. None of the lesions had "-1" enhancement. After OSE, 18 (25.35%) lesions upgraded their histological result to a malignancy from which 6 (33.33%) were first categorized as ADH, 1 (1.85%) as FEA, 7 (38.88%) as LN, 1 (1.85%) as PT and 3 (16.66%) as PL. None of the radial scars upgraded their histological result. From these 18 lesions, 17 (94.44%) had any type of enhancement and 1 (5.56%) had no enhancement on CEM.

## CONCLUSION

The findings of this study support the added value of contrast-enhanced mammography (CEM) in the evaluation of B3 lesions, as it can help to categorize these lesions more accurately. Notably, the absence of enhancement in a B3 lesion on CEM has a high negative predictive value, suggesting that it could be a useful tool for reducing the need for open surgical excisions.

## CLINICAL RELEVANCE/APPLICATION

In our institution, the use of CEM could potentially result in a 16.9% reduction in OSE

### **M5A-SPBR-8 Pectoralis Muscle Invasion by Breast Cancer: Can Digital Breast Tomosynthesis Combined with Contrast-enhanced Mammography Improve Diagnostic Confidence**

#### PURPOSE

Pectoralis muscle invasion (PMI) by breast cancer (BC) cannot be confidently diagnosed by mammography. Breast MRI is more effective but has limitations. We evaluated a combination of contrast-enhanced mammography (CEM) and digital breast tomosynthesis (DBT) under the same compression for diagnostic accuracy and reader confidence in predicting PMI.

#### METHODS AND MATERIALS

Prepectoral cancers (defined as masses adjacent to pectoral muscle with no intervening fat plane) were retrospectively identified in patients with DBT/CEM for BC staging at a single institution. 5 radiologists independently reviewed CEM (low energy (LE) and recombined (RC)) and DBT images of the involved breast in craniocaudal (CC) and mediolateral oblique (MLO) projections, then MRI when available, evaluated predefined radiologic signs of PMI for each image, and graded their diagnostic confidence (Table 1). The ground truth was PMI on surgical pathology (SP). For patients with unavailable SP, or in those post neoadjuvant chemotherapy (NAC) with therapy response and no PMI on SP, radiologists' consensus on muscle and/or fascia enhancement on pre-NAC MRI was used as the ground truth. Measures of diagnostic accuracy, mean radiologist confidence and radiologist agreement for each image type/modality were calculated per radiologic sign, per view and per case.

#### RESULTS

Of 145 patients, 9 had prepectoral masses. PMI was present in 3 and absent in 6 cases, with the ground truth based on SP in 3 and on MRI in 6 cases. The range of accuracies for LE was 0.29-0.62 for CC and 0.56-0.67 for MLO. The accuracy of RC was 0.62 for CC and 0.78 for MLO. For CC views the accuracies of LE, RC, and DBT were 0.5, 0.5-0.62, and 0.29-0.5, respectively, with an overall CC DBT/CEM accuracy of 0.62. For MLO views the accuracies of LE, RC, and DBT were 0.67, 0.56-0.78, and 0.67, respectively, with an overall MLO DBT/CEM accuracy of 0.56. Breast MRI had higher per-case diagnostic accuracy than DBT/CEM (1 vs 0.78) with muscle enhancement as the most accurate MRI sign (1.0), followed by fascia enhancement (0.86). On a scale of 1-3, mean radiologist confidence per case was 1.9 for DBT/CEM (1.8-2.3 for LE, 1.6-2.2 for RC, and 2.1-2.4 for DBT) with poor agreement (-0.14); vs 2.7 for MRI with moderate to substantial agreement (0.56-0.6).

#### CONCLUSION

Breast MRI is superior to DBT/CEM in accuracy and radiologist agreement for PMI. RC images improve the accuracy of non-enhanced images but have the lowest radiologist confidence among all modalities. DBT has lowest accuracy but highest confidence. Absence of SP on treatment-naïve BC and use of MRI as a surrogate limits this study.

#### CLINICAL RELEVANCE/APPLICATION

Although RC images marginally improve the accuracy of DBT/CEM for PMI, breast MRI remains the modality of choice for evaluation of prepectoral BC.

### **M5A-SPBR-9 Can the ROI of Enhancement Predict the Histopathology of a Lesion on CESM**

#### PURPOSE

Contrast-enhanced spectral mammography (CESM) is a rapidly emerging technique for the accurate staging of breast cancer. Can the enhancement levels in CESM be used to predict histology of a lesion?

#### METHODS AND MATERIALS

A retrospective analysis of patients undergoing CESM at St Bartholomew's Hospital, between November 2020 and November 2021, was performed. All lesions confirmed by imaging guided histopathology and had CESM enhancement characteristics analysed. The degree of contrast was quantitatively assessed by measuring the region of interest (ROI) difference between the enhancing lesion and background as a ratio, on both craniocaudal (CC) and mediolateral (ML) views. Statistical analysis was performed to determine whether the percentage signal difference between enhancing lesions and background (%RS) correlated to histopathological results. The %RS calculated for the 3 histological results were compared: invasive and non-invasive cancers and benign lesions.

#### RESULTS

138 lesions were detected, consisting of 73 (52.9%) invasive cancers, 32 (23.2%) non-invasive cancers, and 32 (23.9%) benign lesions. Analysis of enhancement indices showed the following mean %RS: Invasive cancers (ML 1.64%, CC 1.51%), Non-invasive

cancers (ML 0.98%, CC 1.02%), Benign lesions (ML 0.75%, CC 0.68%). The enhancement intensity of invasive cancers was significantly higher than that of non-invasive and benign lesions (in both views  $p < 0.01$ ). After the Bonferroni correction, the distribution of %RS in invasive and non-invasive cancers was statistically significant ( $p < 0.01$ , 95%CI -0.01 to 0.003). Similarly for the invasive lesions and benign lesions ( $p < 0.01$ , 95%CI 0.005 to 0.001), while the difference between non-invasive cancer and benign lesions was non statistically significant ( $p = 0.21$ , 95%CI -0.001 to 0.006).

#### **CONCLUSION**

s There is a correlation between the degree of lesion enhancement in CESM among invasive cancers, non-invasive cancers, and benign lesions. Invasive cancers had the stronger enhancement. There is difference in the enhancement between invasive cancer and non-invasive cancers as well as invasive cancers and benign lesions. There is no difference between the non-invasive cancers and benign lesions.

#### **CLINICAL RELEVANCE/APPLICATION**

Quantitative analysis of enhancement levels in CESM is a feasible in the pre-operative assessment of women with breast cancer and can be used to predict histology of a lesion.

M5A-SPCA

### Cardiac Imaging Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPCA-1 Improving Dynamic Evaluation of Myocardial Gadolinium Concentration using Elastic Registration for T1 Mapping with Pharmacokinetics Modeling**

##### Participants

Yasutoshi Ohta, MD, PhD, Suita, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Developing a T1 mapping-based pharmacokinetic method to evaluate myocardial gadolinium concentration over time, and enhancing accuracy by optimizing elastic deformation registration

##### METHODS AND MATERIALS

Thirty-five subjects (66 yrs, IQR 65,76) referred for CMR examination were included in this study. In addition to routine examinations, including cine and LGE, Native T1 and dynamic T1 maps (2, 5, 9, and 15 min after contrast administration) were obtained using the MOLLI sequence. T1 maps were obtained at the base, mid, and apex of the left ventricle, and concentration maps without registration were calculated for each imaging time from the native T1map and the post-contrast T1map. Similarly, the concentration maps with elastic registration (ER) for the native T1 maps were calculated from the post-contrast maps as well. The time after contrast administration was calculated for each image in seconds from DICOM tags. Estimated myocardial concentration maps (mM/l) at each imaging time were generated from the parameters obtained from pharmacokinetic analysis using a two-compartment model for each time series concentration map with and without ER. The model fitting accuracy was evaluated by comparing the residuals with and without ER. Myocardium was extracted from each map, the measured myocardial concentration (MC) and the estimated concentration (EC) at the same post-contrast time of MC, and the mean difference (delta\_mean) and standard deviation (delta\_SD) between the MC and EC were measured. Gadolinium concentration of the blood pool was also evaluated for residuals with and without ER.

##### RESULTS

Analyzable dynamic T1 maps were obtained from all subjects. The fitting residuals in the myocardial contrast medium density analysis improved significantly from 0.746 to 0.822 by applying ER ( $p < 0.001$ ). The fitting residuals for the blood pool improved significantly from 0.848 to 0.875 by applying ER ( $p < 0.001$ ). The delta\_mean with ER was significantly smaller than without ER: 2min; 0.031 vs. 0.026, 5min; -0.026 vs. -0.022, 9min; -0.025 vs. -0.022, 15min; 0.024 vs. 0.019, (without ER vs. with ER, respectively). The delta\_SD was significantly reduced with ER compared to without ER at all imaging times (all; 0.05 vs. 0.03, 2min; 0.05 vs. 0.03, 5min; 0.06 vs. 0.04, 9min; 0.06 vs. 0.04 15min; 0.04 vs. 0.02mM/l) (all,  $p < 0.05$ ).

##### CONCLUSION

Employing elastic deformation registration in dynamic T1 mapping enhanced the accuracy of estimated concentrations derived from myocardial contrast medium pharmacokinetic analysis.

##### CLINICAL RELEVANCE/APPLICATION

The pharmacokinetic approach enables the creation of myocardial gadolinium concentration maps at any given time and the analysis of longitudinal properties such as contrast agent washout in myocardial tissues.

#### **M5A-SPCA-2 Myocardial Tissue Characterization by CMR for the Evaluation of Heart Failure with Preserved Ejection Fraction in Hypertrophic Cardiomyopathy**

##### PURPOSE

This study sought to evaluate the role of myocardial tissue characteristics detected by CMR in the identification of HFpEF in HCM.

##### METHODS AND MATERIALS

In this prospective study, 133 patients with HCM were consecutively enrolled for biomarker testing, echocardiography and CMR including Late gadolinium-enhanced (LGE) imaging and T1 mapping to access tissue characteristics including native T1 values, extracellular volume fraction (ECV) and indexed ECV (iECV).

##### RESULTS

Finally, 75 (56.4%) HCM patients were diagnosed with HFpEF based on the 2019 ESC HFA-PEFF diagnostic algorithm. LGE%, native T1, ECV, and iECV were all significantly greater in HFpEF subjects than in non-HF subjects (all  $p < 0.05$ ). Native T1 value (AUC: 0.723;  $p < 0.001$ ) was a stronger discriminator with the highest sensitivity (80%) than ECV (AUC: 0.622,  $p = 0.016$ ), iECV (AUC: 0.695;  $p < 0.001$ ) and other CMR parameters. In multivariable regression analysis, native T1 (odds ratio [95%confidence interval]: 1.223[1.078-1.388] per 10 ms increased,  $P = 0.002$ ) remained significantly related to the diagnosis of HFpEF-HCM while LGE%, ECV and iECV were not. Native T1, ECV and iECV weakly/moderately correlated with elevated NT-proBNP (? : 0.551, 0.314 and 0.352 respectively; all  $p < 0.05$ ) and lower early diastolic mitral annular velocity (e') (? : -0.381, -0.188 and -0.255 respectively; all

p<0.05).

## CONCLUSION

s Prolonged native T1 and elevated extracellular volume correlated with increased NT-proBNP and impaired diastolic function in HCM patients. Native T1 was a sensitive biomarker that independently associated with the diagnosis of HFpEF-HCM.

## CLINICAL RELEVANCE/APPLICATION

CMR-derived myocardial tissue characteristics, especially native T1 value, could be applied in the clinic even as a supplementary biomarker for discrimination of HFpEF in the HCM cohort. Given that diffuse myocardial remodeling may be a dynamic process, monitoring native T1 might be essential to develop timely interventions to reverse disease progression.

## M5A-SPCA-3 Comparison of Myocardial Lesions by Pharmacokinetic Modeling Concentration Maps Over Time and General One-point LGE

Participants

Yasutoshi Ohta, MD, PhD, Suita, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the feasibility of detecting myocardial lesions earlier than with conventional LGE timing, as well as to assess the temporal characteristics of these changes, utilizing gadolinium density maps generated from a pharmacokinetic model

## METHODS AND MATERIALS

Thirty-five subjects (66 yrs, IQR 65,76) referred for CMR examination were included in this study. In addition to routine examinations, including cine and 10 minutes LGE, native T1 and dynamic T1 maps (2, 5, 9, and 15 min after contrast administration) were obtained using the modified Look-Locker inversion recovery sequence. Pharmacokinetic analysis of myocardial and blood pool gadolinium concentrations was performed using a two-compartment model, and predicted concentration maps (mmol/l) at 5, 7, 10, 15, 20, 25, and 30 minutes after contrast were generated from calculated parameters. In cases with positive LGE, the gadolinium concentration of the LGE lesion and remote myocardium, extracellular volume fraction ECV (ECVles, ECVremo) was calculated at each time point. The contrast ratio between the lesion and the remote myocardium was measured on the density map and LGE images. Changes in these indices at each time point were compared.

## RESULTS

Hyperenhancement was observed in 20 cases in the LGE image. Lesions were detected at the same sites as LGE in all-time concentration maps. Gadolinium concentrations in the LGE area at each time were 0.48, 0.46, 0.41, 0.34, 0.27, 0.22, and 0.19, showing significant changes, respectively. Contrast concentration in remote myocardium was 0.29, 0.27, 0.24, 0.20, 0.16, 0.13, and 0.11, with significant changes each time. Contrast ratios were 0.25, 0.25, 0.26, 0.35, 0.34, 0.33, and 0.32, with significantly higher values after 15 minutes. The contrast ratio of LGE was 0.61. ECVles increased slightly over time to 43%, 45%, 46%, 47%, 47%, 48%, and 50%, but not significantly. ECVremo was 26%, 27%, 27%, 27%, 28%, 29%, and 29%, with no significant difference.

## CONCLUSION

s Though the gadolinium density map was inferior to LGE in contrast, lesions were detected at the same sites as LGE after 5 min. Lesion ECV could also be measured without significant change after 5-30 min.

## CLINICAL RELEVANCE/APPLICATION

The evaluation with density maps can detect lesions as early as LGE after contrast and may allow evaluation of myocardial characteristics using contrast agent kinetic changes in the lesion.

## M5A-SPCA-4 Evaluation of Myocardial Mass Index Effect on Myocardial Function and Adverse Events in Hypertrophic Cardiomyopathic Patients with Normal Left Ventricular Ejection Fraction and Minimal Fibrosis, by Cardiac MRI Strain Analysis: A Prospective Study

Participants

Sanaz Asadian, MD, Tehran, Iran, Islamic Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

HCM patients are at risk of developing adverse cardiac events, so an effective risk stratification tool is desirable, strain value measurements by cardiac MRI are reproducible and can show subclinical myocardial deformity, which makes them a potential imaging marker to predict patient's outcome. We evaluated the pattern myocardial strain changes based on myocardial mass index by cardiac MRI in a group of HCM patients with normal left ventricular ejection fraction (LVEF) and low fibrosis.

## METHODS AND MATERIALS

We evaluated cardiac magnetic resonance (CMR) and clinical data of 70 cases, including 50 HCM (62% male) and 20 healthy (50% male) subjects. HCM cases inclusion criteria were; normal LVEF with a late gadolinium enhancement (LGE) percentage <10%, exclusion criteria were history of hypertension, valvular heart disease, infiltrative cardiac disorders, ischemic heart disease and renal impairment with estimated glomerular filtration rate (eGFR) less than 30mL/min. follow-up time is set to be 3 years, adverse events are defined as sudden cardiac death, aborted cardiopulmonary resuscitation (CPR), hospitalization because of heart failure or serious arrhythmic events. We clarified between-group differences by ANOVA and post hoc tests. Also Univariate, multivariate Cox regression and Kaplan-Meier analyses revealed the strain pattern differences between patient with favorable and unfavorable prognosis. P value <0.05 was considered significant.

## RESULTS

LV global longitudinal, circumferential, and radial strains (GLS, GCS, and GRS) as well as LV myocardial mass index, were different between the control group and HCM cases (P value < 0.05). Even in HCM patients with normal myocardial mass index strain values were significantly lower than control group. A progressive decline in LVGLS, and LVGCS values were noted along with myocardial mass index increase. LVGLS, LVGCS, and LGE percentage predicted adverse events, and LVGCS was the most potent predictor of

adverse events.

## CONCLUSION

s Increase in Myocardial mass index, independently cause myocardial contraction abnormalities evident by LV strains impairment despite normal EF and minimal myocardial scar index. CMR parameters, especially CMR feature tracking strain values, could predict adverse events in our study population.

## CLINICAL RELEVANCE/APPLICATION

HCM can result in adverse cardiac events, but many patients are living an uneventful life, thus a screening method in HCM could optimize preventive approaches, strain measurement by CMR are potential imaging markers in this regard.

## M5A-SPCA-5 Differentiating Cardiac Amyloidosis from Hypertrophic Cardiomyopathy using Myocardial Atrial Strains Derived from Cardiac MRI

### PURPOSE

Cardiac amyloidosis (CA) is a curable disease for which early diagnosis and treatment are vital. T1 mapping or late gadolinium enhancement (LGE) is a reliable method to differentiate amyloidosis from hypertrophic cardiomyopathy (HCM). However, there are several limitations to its usage, such as additional image acquisition, differences in T1 values due to equipment and facility, and the need for contrast materials for LGE. Recently, myocardial atrial and ventricular strains derived from magnetic resonance imaging (MRI) were developed to assess myocardial dysfunction in each chamber. This study aimed to evaluate the feasibility of using cardiac atrial or ventricular myocardial strains derived from MRI to differentiate CA from HCM.

### METHODS AND MATERIALS

A total of 27 patients with CA and 76 patients with HCM underwent cardiac MRI; of these, 27 were identified with matched left ventricular ejection fraction (LVEF). The left ventricular strain (LVS), left atrial strain (LAS), right ventricular strain (RVS), and right atrial strain (RAS) were calculated from 4-chamber cine MRI images using a dedicated workstation. The diagnostic performance of CA for HCM was compared using receiver operating characteristic analysis.

### RESULTS

LAS (CA:9.7%, HCM: 15%), RVS (CA:13.1%, HCM: 16%), and RAS (CA:10.4%, HCM: 20%) were significantly lower in the CA group than in the HCM group ( $P < 0.05$ ), whereas LVS showed no significant difference between the two groups (CA, 11%; HCM, 12.4%) ( $P = 0.21$ ). The areas under the curves were LVS, 0.60; LAS, 0.74; RVS, 0.68; and RAS, 0.82. The RAS and LAS showed significantly higher diagnostic performance than the LVS ( $P < 0.05$ ).

## CONCLUSION

s Myocardial atrial strain derived from MRI can differentiate CA from HCM with high diagnostic performance. Moreover, it reflects the pathophysiological differences between the two.

## CLINICAL RELEVANCE/APPLICATION

The myocardial atrial strain derived from MRI does not require additional image acquisition or contrast administration. This simple and convenient method could be used to diagnose cardiac amyloidosis.

## M5A-SPCA-6 Multimodal Imaging using FDG PET/MR and Adenosine Stress NH3 PET was Used to Study Patients with Hypertrophic Cardiomyopathy

### PURPOSE

Previous studies of FDG PET in HCM are lacking, but this modality can explain the inflammatory process that precedes myocardial fibrosis. The aim of the study was to compare regional inflammation by FDG uptake, fibrosis by LGE MRI, and microvascular dysfunction by adenosine stress NH3 PET in patients with HCM.

### METHODS AND MATERIALS

Between Jan 2016 and Apr 2018, a total of 25 patients were included in the retrospective study. FDG PET and MRI were simultaneously acquired using an integrated PET/MR scanner, and patients were prepared with a low carbohydrate diet to suppress physiologic myocardial uptake. FDG PET and LGE were analyzed using a 17-segment model, and myocardial flow was analyzed using commercial software (4DM) and compared with FDG PET and LGE.

### RESULTS

Four patients were excluded due to improper physiologic myocardial suppression ( $n=1$ ) or combined ischemic heart disease ( $n=3$ ), leaving 21 patients (16 males, age  $59 \pm 15$  years) in the final analysis. All 21 patients showed abnormal FDG uptake ( $6.8 \pm 3.7$  segments) and 20 patients showed LGE ( $5.7 \pm 3.1$  segments). Mean stress myocardial blood flow was  $1.89 \pm 0.59$  mL/min/g. FDG uptake and LGE were observed in hypertrophic myocardium and, in some patients, in non-hypertrophic myocardium. Hypertrophic myocardium showed decreased stress myocardial flow compared with non-hypertrophic myocardium. Increased FDG uptake was related to LGE ( $\rho = 0.805$ ,  $p < 0.001$ ). Of the total 357 segments analyzed, 83.8% showed matched results (102 segments were both positive and 197 segments were both negative). Increased FDG uptake was also related to decreased stress flow ( $\rho = -0.512$ ,  $p = 0.043$ ).

## CONCLUSION

s The study found that evaluation of HCM with FDG PET/MR and stress NH3 PET was useful in evaluating inflammatory changes, fibrosis, and ischemic severity, to explain pathophysiology and to understand disease status. The study also newly found that FDG PET has a correlation with LGE and ischemia, which are known as poor prognostic factors

## CLINICAL RELEVANCE/APPLICATION

The study also newly found that FDG PET has a correlation with LGE and ischemia, which are known as poor prognostic factors

## M5A-SPCA-7 Imaging Features in Female Patients with Wild-type Transthyretin Amyloidosis Cardiomyopathy

Participants

Seitaro Oda, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

## **PURPOSE**

Wild-type transthyretin amyloid cardiomyopathy (ATTRwt-CM) is significantly male-dominated, but there are also female patients. However, sex-related differences in ATTRwt-CM remain unclear. This study aimed to assess imaging features in female patients with ATTRwt-CM.

## **METHODS AND MATERIALS**

We retrospectively analyzed 106 consecutive patients who were diagnosed with ATTRwt-CM and evaluated sex-related differences in the imaging features including cardiac MRI and 99mTc-labeled pyrophosphate scintigraphy (99mTc-PYP).

## **RESULTS**

Twelve patients (11.3%) were female. These female patients were significantly older at diagnosis ( $75.3 \pm 6.3$  years vs.  $80.6 \pm 4.4$  years;  $p < 0.01$ ). Cardiac MRI-measured left ventricular end-systolic volume was significantly lower ( $44.3 \pm 23.8$  ml vs.  $31.1 \pm 29.3$  ml;  $p < 0.05$ ) and the ejection fraction was significantly higher ( $51.6 \pm 14.1$  % vs.  $62.0 \pm 21.0$  %;  $p < 0.05$ ) in female patients. There was no significant gender difference in left ventricular mass ( $138.4 \pm 48.7$  g vs.  $115.0 \pm 75.7$  g;  $p = 0.26$ ). In T1 mapping, there was no significant difference in native T1 ( $1420.3 \pm 54.0$  ms vs.  $1427.3 \pm 77.5$  ms;  $p = 0.76$ ), but extracellular volume fraction (ECV) was significantly lower ( $56.6 \pm 13.3$  % vs.  $49.4 \pm 15.7$  %;  $p < 0.05$ ) in female patients. No significant difference in myocardial T2 value ( $51.0 \pm 4.5$  ms vs.  $51.0 \pm 3.0$  ms;  $p = 0.97$ ). The mean heart-to-contralateral ratio obtained using 99mTc-PYP was significantly lower in female patients ( $1.95 \pm 0.39$  vs.  $1.63 \pm 0.24$ ;  $p < 0.01$ ).

## **CONCLUSION**

Female patients with ATTRwt-CM were predominantly older and had preserved left ventricular ejection fraction, weaker cardiac uptake of the 99mTc-PYP, and lower ECV value compared with male patients. These imaging features may contribute to the underdiagnosis of ATTRwt-CM in female patients.

## **CLINICAL RELEVANCE/APPLICATION**

Female patients with ATTRwt-CM have different imaging features than the male counterparts, and we need to recognize these imaging features to avoid underdiagnosing it.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

M5A-SPCH

### Chest Imaging Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPCH-1 Multimodal Classification Model for Gram-Positive and Gram-Negative Bacterial Pneumonia using Imaging and Clinical Features: Improving Antibiotic Treatment Decisions**

##### Participants

Ru Wen, Chongqing, China (*Presenter*) Nothing to Disclose

##### PURPOSE

This study aimed to develop and validate a classification model that combines imaging features and clinical characteristics to accurately identify patients with Gram-positive and Gram-negative bacterial pneumonia, assisting clinical physicians in empirical antibiotic treatment.

##### METHODS AND MATERIALS

The study included patients with bacterial pneumonia who sought medical care at a tertiary hospital in China between 2010 and 2020. The patients were randomly divided into a training set and a validation set in an 8:2 ratio. The ResNet-18 model was used as the base model, and 512 features were extracted from the maximum lesion layer as deep features. Spearman correlation and mutual information were employed for dimensionality reduction, and the XGBoost model was utilized to construct the imaging model. The GBM model served as the classifier for establishing the clinical model. A logistic regression algorithm was employed to construct an imaging-clinical fusion model based on the individual scores of the imaging model and the clinical model. The classification performance of the clinical model, imaging model, and fusion model was compared using the DeLong test.

##### RESULTS

This study included data from 2423 patients with bacterial pneumonia. Among them, 563 cases were Gram-positive bacterial pneumonia, and 1860 cases were Gram-negative bacterial pneumonia. The imaging model and clinical model had AUCs of 0.719 and 0.827, respectively, in the test set. The fusion model achieved an AUC of 0.884 (95% CI: 0.868-0.898), sensitivity of 0.772, specificity of 0.822, and accuracy of 0.808 in the test set. The Delong test results demonstrated that the performance of the fusion model was slightly higher than that of the individual imaging or clinical models ( $P < 0.05$ ). Nomogram results of the fusion model showed that clinical scores had the highest weight, and the fusion model exhibited good consistency between predicted probability and expected probability. Decision curve analysis (DCA) confirmed that the fusion model performed well in classifying bacterial pneumonia across most threshold probabilities.

##### CONCLUSION

In this study, we integrated multimodal data including imaging, laboratory tests, and clinical signs to classify gram-positive and gram-negative bacterial pneumonia. Our research demonstrates that the fusion of multiple modalities enhances the classification performance of the model.

##### CLINICAL RELEVANCE/APPLICATION

The fusion model we have developed enables accurate classification of bacterial pneumonia in patients based on CT images, laboratory tests, and clinical signs. It holds significant clinical value in avoiding unnecessary antibiotic usage and provides timely information for guiding clinical decisions and improving patient prognosis.

#### **M5A-SPCH-2 Differentiating Imaging Features of Post Lobectomy Right Middle Lobe Torsion**

##### Participants

Farah Tamizuddin, MD, New York, NY (*Presenter*) Nothing to Disclose

##### PURPOSE

To identify differences in imaging features between patients with confirmed right middle lobe (RML) torsion compared to those with suspected RML torsion who did not have torsion.

##### METHODS AND MATERIALS

This retrospective study entailed a search of radiology reports from April 1, 2014 to April 15, 2021, yielding 52 patients with suspected torsion on imaging but ultimately no lobar torsion and 4 with confirmed torsion. This cohort was supplemented by 2 cases identified prior to the search period for a total of 6 confirmed RML torsion cases. Four thoracic radiologists including an adjudicator evaluated chest radiographs (CXRs) and computed tomography (CT) exams for multiple imaging signs and features. A resident measured the angle between the RML bronchus and bronchus intermedius on coronal reformats of any CTs performed to exclude or confirm torsion for these patients. Fisher exact and Mann-Whitney tests were used to identify any significant differences in imaging features ( $P < .05$ ).

##### RESULTS

A confirmed lobar torsion was seen frequently across the patients with confirmed torsion ( $P < .001$ ) compared to non-torsion patients.

A reversed halo sign was more frequently seen in patients with confirmed torsion ( $P=.001$ ) compared to non-torsion patients (83.3% vs. 0% for 3 readers, including the adjudicator). Torsion patients had a higher percentage of ground-glass opacity (GGO) in the affected lobe compared to non-torsion patients (21.7% vs 13.9% for the adjudicator,  $P=.031$ ). The CT Coronal Bronchial Angle between RML bronchus and bronchus intermedius was larger ( $P=.035$ ) in torsion than non-torsion cases ( $121.3^\circ$  vs  $98.3^\circ$ ). A convex fissure towards the adjacent lobe on CT was more frequent in torsion patients (100% vs 27.3% for the adjudicator,  $P=.009$ ) and increased lobe volume on CT ( $P=.001$ ) occurred more often in confirmed torsion.

## CONCLUSION

s A reversed halo sign, greater proportion of GGO in the affected lobe, larger CT Coronal Bronchial Angle, fissural convexity, and larger lobe volume on CT may aid in early recognition of the rare yet highly significant diagnosis of lobar torsion.

## CLINICAL RELEVANCE/APPLICATION

This paper is clinically relevant because RML torsion is a potentially life-threatening diagnosis and awareness of imaging signs and features associated with this diagnosis can aid radiologists in suggesting RML torsion earlier and more accurately, thus expediting patient care and optimizing patient outcomes.

## M5A-SPCH-3 Frogspawn Sign: Special CT Features for the Diagnosis of Pulmonary Lymphatic Reflux Diseases

Participants

Qi Hao, Beijing, China (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study was to evaluate the value and the morphologic characteristics of the so-called "frogspawn sign" on high-resolution CT as the special CT feature for the diagnosis of pulmonary lymphedema and lymphatic dilatation caused by pulmonary lymphatic reflux diseases (PLRD). This sign has not been reported in the literature by our knowledge.

## METHODS AND MATERIALS

We collected 580 patients with clinical and operative proven PLRD in the study, of which 86 cases had frogspawn sign on HRCT and MSCT lymphography. The imaging features of frogspawn sign were retrospectively reviewed by two chest radiologists who reached decisions by consensus. All patients were followed up for HRCT within 3-6 months.

## RESULTS

The frogspawn sign was seen in 86 (15%) of 580 patients with PLRD, which consisted of diffuse inhomogeneous ground-glass opacity (GGO) with superimposed multiple discontinuous small nodules. The diffuse GGO showed bilateral asymmetrical (100%) and peripheral subpleural or peribronchovascular (14/86, 16%) distribution with predominance in the right middle or lower lung zone. The multiple small nodules appeared round-like or tree-in-bud (22/86, 26%) with 3-6mm in size, central or intrapleural distribution and no continuity or fusion between nodules and nodule-pleura. The spatial distance between the nodules is about 2-4mm. A dynamic changes of this sign was showed in all patients with obvious improvement (32/86, 37%) and aggravation (54/86, 64%) on the follow-up CT.

## CONCLUSION

s The frogspawn sign strongly favors a diagnosis of pulmonary lymphedema and lymphatic dilatation caused by PLRD. This sign is very important for judging the degree of lymphedema and the clinical stage.

## CLINICAL RELEVANCE/APPLICATION

Pulmonary lymphatic reflux abnormalities are rare disorders characterized by developmental malformation of the bronchial-mediastinal lymph trunk and/or thoracic duct outlet anomaly. The frogspawn sign consisted of diffuse inhomogeneous ground-glass opacity (GGO) with superimposed multiple discontinuous small nodules and strongly favors a diagnosis of pulmonary lymphedema and lymphatic dilatation caused by PLRD.

## M5A-SPCH-4 Correlation Between Radiomics Features and Ki-67 Expression in Peripheral Lung Cancers

Participants

Wei Wei, Xianyang, China (*Presenter*) Nothing to Disclose

## PURPOSE

To develop CT image feature-based radiomics signatures to estimate the expression level of Ki-67 in peripheral lung cancers.

## METHODS AND MATERIALS

117 peripheral lung cancer patients who underwent contrast-enhanced CT had confirmed histopathologically and tested for Ki-67 expression into 2 levels: low expression ( $n=63$ ) and high expression ( $n=54$ ). Patients were divided into training ( $n=82$ ) and validation cohorts ( $n=35$ ). The arterial phase images were imported into the ITK-SNAP to manually delineate volume of interest (VOI) of the entire-tumor. Each VOI produced 396 radiomics features including Histogram, GLCM, GLSZM, RLM, Form Factor and Haralick. LASSO regression was used for feature screening to generate a radiomics score. Then multivariate logistic regression analysis (MLRA) was used combining clinical information to screen out independent risk factors for predicting Ki-67 expression level. The predictive accuracy of radiomics signatures was quantified by the area under curve (AUC) of a ROC curve in both cohorts. The calibration degree (CD) of the radiomics was evaluated by Hosmer-Lemeshow test. The clinical usefulness of the radiomics signatures was assessed by decision curve analysis (DCA).

## RESULTS

Seven radiomics features with non-zero coefficients were chosen to build a radiomics model that significantly correlated with Ki-67 expression level with an AUC, sensitivity, specificity and CD of 0.844, 93%, 71% and 0.709 in training cohort; and 0.881, 91%, 75% and 0.950 in validation cohort, respectively. There were no significant differences in gender, age and smoke between the high and low Ki-67 expressions ( $P>0.05$ ). Radiomics signatures were considered to be independent predictor of Ki-67 expression level in peripheral lung cancer, and if the threshold probability was between 0.03 and 0.63, using radiomics signatures to predict Ki-67 expression level added more benefit than treating either all or no patients.

## CONCLUSION

s The CT image feature-based radiomics is helpful to predict the expression of Ki-67 in peripheral lung cancers, providing a non-invasive technique for assessing the invasiveness and prognosis for peripheral lung cancers.

## CLINICAL RELEVANCE/APPLICATION

The radiomics that predict Ki-67 expression level can help understand the proliferation characteristics of tumor cells, and promote early diagnosis and individualized treatment.

## M5A-SPCH-5 Exploring the Biological Significance of a Robust Radiomic Biomarker of Tumor Heterogeneity in Advanced Non-small Cell Lung Cancer Patients Treated with First-line Immunotherapy

Participants

Andrew Chen, BS, PhD, Philadelphia, PA (*Presenter*) Nothing to Disclose

## PURPOSE

Tumor PD-L1 expression, the accepted predictive biomarker for pembrolizumab (PEMBRO) immunotherapy, is imperfect. We hypothesize that radiomic features, essentially high-throughput descriptors of tumor heterogeneity, can characterize molecular and histopathological tumor subtypes in vivo, and enable precision therapy selection.

## METHODS AND MATERIALS

After IRB approval, a single-center retrospective analysis of pre-treatment CT for stage 4 NSCLC patients (n=342) treated with 1st-line PEMBRO-based therapy Region of interest (ROI) segmentation was performed with ITK-SNAP. Feature extraction on ROIs was performed with the CaPTk toolkit. OPNested Combat mitigated radiomic feature heterogeneity due to differences in contrast enhancement, kernel resolution, and voxel spacing. Clinical variable categories, age, sex, race, ECOG, BMI, smoking status, and tumor histology, were protected during harmonization to prevent removal. Principal component (PC) analysis reduced harmonized feature dimensionality; the first PC was taken as a radiomic signature for histological subtypes (adenocarcinoma, squamous cell, other) and tumor differentiation, using a linear support vector machine (SVM) classifier. For a subset (n=234), a radiomic signature characterized tumor differentiation subtypes (well, moderate, poor). The statistical significance of the radiomic signature's Spearman correlation coefficient (c) for genomic mutational expression categories (negative, positive, unknown) of NSCLC relevant-genes (EGFR, BRAF, ALK, ROS, MET, HER2) and tumor expression of PDL1 was also assessed.

## RESULTS

The radiomic signature performed patient classification of histological subtype with an accuracy of 81.5% (AUC-0.59), and of tumor differentiation subtypes with an accuracy of 82.3% (AUC-0.62). Statistically significant correlations (p<0.05) were found between the radiomic signature and the following genomic mutational expression categories: ALK (c: 0.88), EGFR (c: 0.87) and ROS (c: 0.62).

## CONCLUSION

s The radiomic signature was shown to have correlations with genes relevant to NSCLC tumor progression and was able to identify tumor subtypes based on their molecular and histopathological characteristics, indicating its biological significance. Our future work involves building a multi-omic predictor (combining radiomic, genomic and clinical information) of progression-free survival to study patient response to PEMBRO-based therapy.

## CLINICAL RELEVANCE/APPLICATION

The radiomic signature correlated significantly with NSCLC-related genes and identified tumor sub-types based on molecular and histological characteristics. These results help us better understand the biological meaning of radiomic descriptors.

## M5A-SPCH-6 Lung Cancer Risk Using Never Smokers' Chest X-Rays: Validation of a Deep Learning-based Model

Participants

Anika Walia, Scottsdale, AZ (*Presenter*) Nothing to Disclose

## PURPOSE

Lung cancer is the most common cause of cancer death. In the United States, 10-20% of lung cancers occur in "never-smokers" - those who never smoked cigarettes or smoked fewer than 100 cigarettes in their lifetime. Centers for Medicare and Medicaid Services (CMS) lung cancer screening criteria do not recommend screening never-smokers; however, never-smokers often present with more advanced lung cancer than those who smoke. In this study, we tested whether a deep learning model CXR-Lung-Risk could identify never-smokers at high risk for lung cancer using chest x-rays (CXRs) from the electronic medical record.

## METHODS AND MATERIALS

The CXR-Lung-Risk model was developed using 147,497 CXRs of 40,643 asymptomatic smokers and never-smokers from the Prostate, Lung, Colorectal, and Ovarian (PLCO) cancer screening trial to predict lung-related mortality risk based on a single CXR image as input. In this study, we externally validated the model in a separate cohort of never-smokers having routine outpatient CXR from 2013-2014. The primary outcome was 6-year incident lung cancer, identified using International Classification of Disease (ICD) codes. Continuous CXR-Lung-Risk scores were converted to low, moderate, and high-risk groups based on externally derived risk thresholds.

## RESULTS

Of 24,333 patients (mean age 63.4 ± 8.21 years; 44.3% male; 18,880 (80.5%) White, 1,789 (7.6%) Black, 789 (3.7%) Hispanic) included in the study, 32% (7774/24,333) were deemed high risk by CXR-Lung-Risk. 2.5% of the total cohort (616/ 24,333) developed lung cancer over 6 years of follow-up. CXR-Lung-Risk groups had a graded association with lung cancer risk, with 1.4% (37/2663) in the low-risk group (CXR-Lung-Risk <45), 2.2% (306/13896) in the moderate-risk group (45 < CXR-Lung-Risk < 55), and 3.5% (273/7774) in the high-risk group (CXR-Lung-Risk > 55). After adjusting for age, sex, race, previous lower respiratory tract infection, and prevalent COPD, there was still a 2.1 (95% CI [1.4,3.1]; p<0.001) times greater risk of developing lung cancer in the high-risk group compared to low risk.

## CONCLUSION

s Using routine CXRs from the EMR, CXR-Lung-Risk identified never-smokers at high risk of lung cancer, a group in which lung cancer rates are increasing.

#### **CLINICAL RELEVANCE/APPLICATION**

CXR-Lung-Risk identified never-smokers at high risk of lung cancer, well above the >1.3% 6-year risk threshold where lung cancer screening CT is recommended by National Comprehensive Cancer Network guidelines.

#### **M5A-SPCH-7 Feasibility of Extracellular Volume Fraction Measurement Derived from the Equilibrium Phase Dual-energy CT for Predicting Pathological Grades of Lung Cancer**

Participants

Hiroaki Nagano, MD, PhD, Kagoshima, Japan (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To assess the diagnostic feasibility of extracellular volume (ECV) fraction measurement using the equilibrium phase dual-energy CT (DECT) for predicting the pathological grade of lung cancer.

#### **METHODS AND MATERIALS**

This study included 110 patients with lung cancer who underwent preoperative DECT examination and surgical resection. These patients were divided into a low-grade group (G1 and G2) and a high-grade group (G3 and G4) based on their histopathological differentiation. Iodine concentration (IC) and effective atomic number (Zeff) were measured using the equilibrium phases DECT, and ECV fraction was calculated based on IC of the lung cancer and the aorta. DECT parameters and ECV fraction were compared between the pathological grade groups using the Mann-Whitney U test. Receiver-operating characteristic (ROC) curve analysis was performed to evaluate the ability of IC, Zeff and ECV fraction to diagnose a high-grade pathological group of lung cancer.

#### **RESULTS**

IC and Zeff during the equilibrium phase and ECV fraction were significantly higher in the low-grade group than in the high-grade group (2.27mg/mL vs. 1.85mg/mL,  $p = 0.006$ ; 8.46 vs. 8.29,  $p = 0.012$ ; 45.2% vs. 35.0%,  $p < 0.001$ ; respectively). The area under the ROC curve values of IC and Zeff during the equilibrium phase and of ECV fraction to differentiate high-grade cancers from low-grade cancers were 0.688 (optimal cutoff, 1.80mg/mL; sensitivity, 60.9%; specificity, 73.6%), 0.672 (optimal cutoff, 8.43; sensitivity, 78.3%; specificity, 51.7%) and 0.750 (optimal cutoff, 30.9%; sensitivity, 47.8%; specificity, 94.3%), respectively.

#### **CONCLUSION**

s IC, Zeff and ECV fraction measurement using DECT can help predict the pathological grade of lung cancers. ECV fraction showed the best diagnostic performance.

#### **CLINICAL RELEVANCE/APPLICATION**

ECV fraction derived from the equilibrium phase dual-energy CT provides useful information to predict the pathological grades of lung cancers.

#### **M5A-SPCH-8 Impact of Duration of Diagnostic Workup on Prognosis for Early Lung Cancer: Validation using the NLST and IASLC Databases**

Participants

Rowena Yip, PhD, MPH, New York, NY (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Impact on prognosis of early stage lung cancer due to time delay for follow-up has been quantified in our previous publication using the I-ELCAP database. Here, our goal is to validate our published findings using two independent databases, the National Lung Screening Trial (NLST) and the International Association for the Study of Lung Cancer (IASLC).

#### **METHODS AND MATERIALS**

Using data collected from the CT arm of the NLST randomized trial (2002-2009) and the IASLC Lung Cancer Staging Project (1999-2010), we determined the size specific 5-year lung cancer (LC)-specific and overall survival rates as surrogates for cure rates. We estimated the change in LC diameter after delays of 90-, 180-, and 365-days using three representative LC volume doubling times (VDTs) of 60(fast), 120(moderate), and 240(slow). We then estimated the decrease in the lung cancer (LC) cure rate resulting from time between CT scans to assess for growth during the diagnostic workup.

#### **RESULTS**

Using the NLST data for a regression model of the 5-year LC survival rates on LC diameter, the estimated LC cure rate of a 4.0 mm LC with fast (60-day) VDT is 97.4%(95% CI: 97.1%-97.8%) initially, but it would decrease to 96.4%(95% CI: 95.9%-96.8%), 94.9%(95% CI: 94.2%-95.6%) and 89.6%(95% CI: 88.2%-89.6%) after delays of 90, 180, and 365 days, respectively. A 20.0 mm LC with the same VDTs has an initial lower LC cure rate of 87.2%(95% CI: 85.5%-88.9%) initially, and decreases more rapidly to 81.9%(95% CI: 79.4%-84.3%), 74.4%(95%CI:70.9%-77.9%) and 47.8%(95% CI: 40.7%-54.8%) after the same delays of 90, 180, and 365 days. Using the IASLC data for a regression model of the 5-year overall survival rates on LC diameter shows a similar trend.

#### **CONCLUSION**

s Although the average tumor size was larger in these two databases, the average change in LC cure rate per unit increase in tumor size was comparable to our previous results. These findings support our earlier research indicating that the interval between scans required to evaluate the growth of lung nodules has a significant impact on prognosis, particularly for fast-growing and larger cancers. To determine the effectiveness of various management protocols, it is essential to quantify the degree of change in prognosis results caused by this delay.

#### **CLINICAL RELEVANCE/APPLICATION**

Timely follow-up is crucial for management of lung nodules. Our study shows that delays in CT scans have a significant impact on prognosis, emphasizing the need to quantify this effect for better management protocols.

## Abstract Archives of the RSNA, 2023

M5A-SPER

### Emergency Radiology Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPER-1 Multicentre Randomised Controlled Trial to Assess the Impact of Online Training on the Diagnostic Performance of Emergency Department Clinicians in Interpreting CT Head Images: The Simulation Training for Emergency Department Imaging 2 (STEDI2) Trial**

#### PURPOSE

Delays in reporting of CT scans can impair patient flow in the Emergency Department (ED). Artificial Intelligence led applications are being evaluated to enable ED physicians to interpret CT Head scans, but their baseline interpretation capability is currently unknown. Here we present preliminary results for a trial to measure the accuracy of ED clinicians in interpreting CT head images, determine the impact of an online training simulation, and estimate potential impacts of clinician-led CT head interpretation on patient flow within the Emergency Department

#### METHODS AND MATERIALS

A multicentre NIHR Portfolio randomised controlled trial (CPMS: 52221, Clinicaltrials.gov: NCT05427838, ISRCTN: 41484, REC reference: 22/HRA/0743) was undertaken across 6 UK hospitals. Emergency medicine clinicians undertook a blinded baseline online assessment of accuracy in interpreting a dataset of 50 CT Head scans. After completing the baseline assessment, participants were offered an online training package on CT head interpretation, then repeated the assessment and recorded interpretation of up to 30 prospective clinical cases with further assessments repeated at 3 and 6 months. Training and assessment were delivered using the online platform [www.raiqc.com](http://www.raiqc.com). The primary outcome was measured changes in reporting accuracy/sensitivity/specificity as calculated in a pooled analysis. Subgroup analyses included diagnostic performance stratified by clinical role, level of seniority, pathological finding. For prospective clinical interpretations times participant and radiology reporting were recorded and compared.

#### RESULTS

From April 2022 until September 2023 206 participants undertook the study. Overall, there was a significant increase in participants' sensitivity (73.3% to 83%) and specificity (65.8% to 89.1%) in detecting the presence of an acute abnormality on the online assessment scans, with a similar increase seen across all pathology subgroups. Overall diagnostic performance for acute abnormality detection remained elevated compared to baseline at six months post training (sensitivity 80.6%, specificity 79.1%).

#### CONCLUSION

Online training can be used to significantly improve ED clinicians' ability to interpret CT Head scans.

#### CLINICAL RELEVANCE/APPLICATION

Our results demonstrate that dedicated online training can significantly improve the image interpretation accuracy of ED clinicians. Provision of a web-based self-directed simulation-based learning platform is a scalable way of delivering this training to departments with a high staff turnover. Further detailed analysis is ongoing and will provide a detailed basis for comparison with other forthcoming interventions such as AI-assisted image interpretation of CT head scans.

#### **M5A-SPER-2 Inter-modality Data Augmentation and Multi-view Reconstructions from CT to Radiography for the Detection of C-Spine Fractures**

#### PURPOSE

Cervical spine fractures are a significant cause of morbidity and mortality worldwide. While ACR appropriateness criteria recommend the use of CT over X-ray, access to imaging can be limited in rural areas. The difference in sensitivity between CT and XR has been shown to be 100% and 63% respectively. Delayed diagnosis of C-spine fractures may lead to adverse outcomes. The goal of this project is to develop a model that can be used in areas where there are significant barriers to acquiring CT C-spines. Our objectives are as follows: To develop a method of reconstructing radiographs from CT to train a convolutional neural network using the reconstructed radiographs to detect C-spine fractures, using single and multiple views To assess the use of reconstructed radiographs as a method of data augmentation To test the model on real radiographs on a model trained on reconstructions.

#### METHODS AND MATERIALS

233 non-contrast CT C-spine studies with fracture labels were collected from a publicly available dataset. The dataset was divided into a training/validation (183) and test set (50). Sagittal, coronal, and oblique Average Intensity Projections (AvIPs) were created at a window width and level of 950/400. The EfficientNet V2-S model with pretrained weights was used as the initial model. A single channel model was trained and tested using sagittal AvIPs. Next, oblique AvIPs were added to the training set and the model re-trained. A multichannel model was trained and tested using sagittal and coronal AvIPs. A training and validation set was created using 5-fold cross validation for training of all models. 188 C-spine radiographs with fracture labels from a publicly available dataset were also used to test the two single channel models. The AUROC was plotted and Youden index used to determine the best threshold for prediction. Accuracy, specificity, and sensitivity were calculated for each model.

#### RESULTS

There is improved AUROC with oblique data augmentation using both AvIPs (from 0.60 to 0.65) and true radiographs (0.77 to 0.70)

There is improved AUROC with oblique data augmentation using both AVIPS (from 0.60 to 0.65) and true radiographs (0.77 to 0.79) as the test set. Sens/Spec of 0.78/0.70 on true radiographs using the augmented model. The multichannel model performed better than the single channel augmented model (AUROC 0.73)

## **CONCLUSION**

s Inter-modality augmentation is possible to create a fair C-spine fracture model using 233 CTs. Multichannel model training can be used to optimize radiograph protocols to detect pathology.

## **CLINICAL RELEVANCE/APPLICATION**

With improvement, an application in rural communities may result in expedited fracture detection. As well, an inter-modality data augmentation technique would assure preservation of labelling and be a valuable tool to enhance datasets.

M5A-SPGI

### Gastrointestinal Imaging Monday Poster Discussions I

#### Sub-Events

#### M5A-SPGI-2 Evaluation of Contrast Enhanced Photon Counting Computed Tomography Performed in the Inpatient Setting

##### Participants

Benjamin Steyer, MD, PhD, Philadelphia, PA (*Presenter*) Nothing to Disclose

##### PURPOSE

Prior work demonstrating the benefits of photon-counting computed tomography (PCCT) has been performed in controlled research or selective outpatient settings. Given high capital costs of this technology, many scanners will serve general purpose, including application in inpatient settings. Here, we evaluate the performance of a clinical PCCT scanner employed in routine inpatient enhanced abdomen and pelvis imaging and directly compare image quality, image contrast and radiation dose to that of a prior state of the art dual energy CT (DECT) scanner.

##### METHODS AND MATERIALS

In this institutional review board-approved retrospective study, we identified patients (n = 35) who had undergone a routine contrast enhanced CT of the abdomen and pelvis on a clinical PCCT scanner (NAEOTOM Alpha, Siemens Healthineers) and who had also undergone a DECT (SOMATOM Force, Siemens Healthineers) within twelve months. The following patient and scan characteristics were recorded: BMI, radiation dose (CTDIvol) and contrast volume. For quantitative comparison, we calculated contrast to noise ratio (CNR) and signal to noise ratio (SNR) for organ parenchyma as well as the great vessels for both PCCT and DECT exams.

##### RESULTS

Average BMI of patients undergoing contrast enhanced PCCT was 25.9 (range: 17.1 to 54.7). Average time between contrast enhanced PCCT and DECT was 42 days (range: 4 to 204 days). We observed a 9% decrease in scan dose (CTDIvol) in PCCT compared to DECT, 8.7 versus 9.8 mGy respectively (p=0.03). Despite reduced dose, calculated CNR and SNR were significantly increased on PCCT versus DECT across all evaluated anatomic structures with the exception of liver, where no significant difference in SNR was observed.

##### CONCLUSION

Our real-world comparison of inpatient contrast enhanced abdomen and pelvis studies on PCCT and DECT indicates decreased radiation exposure (CTDIvol) can be achieved on clinical PCCT with increased quantitative metrics of image quality (CNR and SNR). Future planned analysis will focus on rigorous comparison of qualitative and quantitative metrics of image quality utilizing direct comparison of spectral data from both PCCT and DECT.

##### CLINICAL RELEVANCE/APPLICATION

In routine inpatient application, PCCT can provide quantitatively improved image quality compared to DECT at a reduced radiation dose.

#### M5A-SPGI-3 Low Dose Whole-liver CT Perfusion in Evaluating Residual Viable Tumor Tissue of Hepatocellular Carcinoma after Transcatheter Arterial Chemoembolization

##### PURPOSE

To investigate the value of low dose whole liver CT perfusion (CTP) in evaluating the hemodynamics of residual viable tumor tissue of hepatocellular carcinoma (HCC) treated with transcatheter arterial chemoembolization (TACE).

##### METHODS AND MATERIALS

HCC patients treated with TACE were prospectively collected. All patients underwent low dose whole liver perfusion CT examination 4-6 weeks after TACE. Thirty HCC cases with residual tumor viable tissue were selected. The hepatic arterial fraction (HAF, %), capillary surface permeability (PS, ml/min/100g), blood volume (BV, ml/100g) and time to peak (TTP, s) of necrotic tissue (T1), residual viable tumor tissue (T2) and background liver tissue (T3) were obtained using liver tumor perfusion software. Univariate Wilcoxon signed rank was used for the comparison of the above parameters between T2 and T1, T3 groups.

##### RESULTS

35 HCC lesions with residual viable tumor tissue were found. The HAF, PS and BV of T2 were higher than those of T1 and T3 (P<0.05); there was no significant difference in TTP between T2 and T1 and T3 (P>0.05).

##### CONCLUSION

Low dose whole liver perfusion CT could reflect the hemodynamics of residual viable tumor tissue of HCC treated with TACE.

## CLINICAL RELEVANCE/APPLICATION

It could provide valuable information for the selection of further treatment protocol for HCC patients.

### M5A-SPGI-4 DECT and MRI Indicators for Assessing Iron Overload and the Effectiveness of Iron Overload Therapy in Patients with Primary and Secondary Hemochromatosis

#### PURPOSE

Evaluation of MRI, CT parameters after chelation and hemoexfusion therapy in patients with iron overload, identification of the prognostic value of CT indicators in the assessment of moderate and severe iron overload.

#### METHODS AND MATERIALS

The design of the study is prospective. The study included the liver scans of 43 patients with hereditary hemochromatosis (HH), secondary transfusion-dependent hemochromatosis (TDH) receiving regular hemotransfusions, iron chelators. We evaluated age, frequency of hemotransfusions, chelating drug used. CT was performed on a Dual Energy computer CT scanner Siemens Somatom Definition 128. 27 patients (62.8%) reached repeated CT. MRI was performed on a Siemens Magnetom Espree high-field scanner with a magnetic field induction of 1.5 T.

#### RESULTS

The median age was 34 y.o. [33.00; 53.50] for HH and 52 y.o [36.00; 62.00] for TDH. After therapy in the general group, T2\* values increased by 26%, LIC decreased by 21.2%, DED (dual energy difference)HU 140 and 80 mean by 17.6%, DER (dual energy ratio) HU 140 and 80 mean by 3%, DEI (dual energy index) HU 140 and 80 mean by 92.8%, 80 max by 3%, DEDHU 140 and 80 max by 19%, DERHU 140 and 80 max by 2.5% after therapy. In patients with HH, liver T2\* increased by 4.6 times, LIC decreased by 5.5 times, DEDHU 140 and 80 mean by 35.1%, DERHU 140 and 80 mean by 7.8%, DEIHU 140 and 80 mean by 93.6%, DEDHU 140 and 80 max by 29.3%, DEIHU 140 and 80 max by 21.6%. In patients with TDH, LIC decreased by 18.9%, DEIHU 140 and 80 mean by 92.2%. A value of 80 mean=85.5, 140 mean=71.5, M0.3 mean=76, DEIHU 140 and 80 mean=0.007996 and DEDHU 140 and 80 mean=18.5 predict the probability of severe iron overload.

#### CONCLUSION

s In patients after chelation therapy and hemoexfusion therapy, MRI and CT indicators decrease. The values of CT 80 mean=85.5, 140 mean=71.5, M0.3 mean=76, DEIHU 140 and 80 mean=0.007996, DEDHU 140 and 80 mean=18.5 can predict LIC values of more than 11 mg/g.

## CLINICAL RELEVANCE/APPLICATION

The threshold of hepatic iron overload which can be diagnosed by measuring CT parameters, mainly with dual-energy scanning, was determined.

### M5A-SPGI-5 Shear Wave Elastography and Attenuation Imaging for the Prediction of Risk of Events in Patients with NAFLD

Participants

Yudai Fujiwara, Yahaba-Cho, Shiwa-Gun, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

Common causes of mortality in non-alcoholic fatty liver disease (NAFLD) are cardiovascular events (CVEs), extrahepatic malignancies, and liver-related events (LREs). We aimed to determine the value of fibrosis and steatosis as determined by non-invasive ultrasound-based biomarkers for the prediction of the major events in patients with NAFLD.

#### METHODS AND MATERIALS

During a period 2016-2020, we accumulated a prospective cohort of 279 patients with NAFLD, who underwent shear wave elastography (SWE) together with ultrasound-guided attenuation parameter (UGAP) and liver biopsy within a day, and followed them until December 2022. SWE and UGAP were determined by LOGIQ E9 (GE Healthcare) with a C1-6-D convex probe. The cutoff values of liver stiffness measurements (LSM) by SWE and attenuation coefficient (AC) by UGAP for advanced liver fibrosis stage (F=2) and mild steatosis grade (S=1) were determined by the area under the curve analysis. According to the values, we classified patients into group A (low LSM and low AC), group B (low LSM and high AC), group C (high LSM and high AC), and group D (high LSM and low AC). Cumulative incidence ratio (CIR) of CVE., extrahepatic malignancy or LRE was calculated by Kaplan-Meier analysis and compare among the groups by log-rank test.

#### RESULTS

1) The median LSM values for each stage of liver fibrosis were 6.13 kPa in F0, 6.81 kPa in F1, 8.47 kPa in F3, and 10.23 kPa in F4 ( $p<0.001$ ). The median AC values for each grade of steatosis were 0.42 dB/cm/MHz in S0, 0.55 dB/cm/MHz in S1, 0.68 dB/cm/MHz in S2, and 0.72 dB/cm/MHz in S3, ( $p<0.001$ ). 2) 36 patients experienced one or more events during the observation period with a median of 4.1 years. Diabetes mellitus and AC were found to be independently associated with CIR of CVE (8.76%/5 years among all patients). Similarly, LSM was found to be associated with CIR of LRE (5.01%/5 years). 3) CIR of CVE, extrahepatic malignancy or LRE in groups A, B, C, and D was calculated to be 0.0%, 12.8%, 28.5%, and 46.7%, the values of which were significantly different among the groups ( $p<0.05$ ).

#### CONCLUSION

s A combination of ultrasound-based biomarkers LSM and AC determined by 2D SWE and UGAP may be a help for identifying NAFLD patients at a high risk of subsequent life-threatening events.

## CLINICAL RELEVANCE/APPLICATION

Our prospective cohort study suggested that a combination of SWE and UGAP non-invasively assesses tissue characteristics of NAFLD and contributes to prediction of subsequent major life-threatening events.

### M5A-SPGI-6 Multiparametric Quantitative Ultrasound: Assessment of High-risk Steatohepatitis in Patients with Metabolic Dysfunction-associated Fatty Liver Disease

Participants  
Hong Ding, MD, Shanghai, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Metabolic dysfunction-associated fatty liver disease (MAFLD) affects almost 25% of the adult population worldwide. Early diagnosis and intervention for high-risk steatohepatitis in liver steatosis can prevent disease progression and improve prognosis. Non-invasive detection and quantification are important for the timely management and prevention of the progression of liver steatosis. This study aimed to investigate the clinical value of the predictive model of multiparametric quantitative ultrasound for the non-invasive assessment of high-risk steatohepatitis.

#### **METHODS AND MATERIALS**

The shear wave elastography (SWE), shear wave dispersion (SWD) and attenuation imaging (ATI) examinations were performed on 194 patients with metabolic dysfunction-associated fatty liver disease (MAFLD) who would undergo liver biopsy in Huashan Hospital, Fudan University from June 2021 to September 2022. Based on pathological SAF scoring system, high-risk steatohepatitis is defined as steatohepatitis with greater and clinically significant fibrosis, and a total activity score  $\geq 4$  of steatosis, hepatocyte ballooning and hepatic lobular inflammation. The binary logistic regression was used to identify factors influencing high-risk steatohepatitis. The predictive models were established by using R language. The diagnostic performance for high-risk steatohepatitis was assessed by using the area under curve (AUC), and AUCs were compared by using the Delong test.

#### **RESULTS**

There were 46 cases of high-risk steatohepatitis. Quantitative ultrasound parameters of elastic modulus, dispersion slope and attenuation coefficient, and blood markers including alanine aminotransferase (ALT), aspartate aminotransferase (AST) and high-density lipoprotein cholesterol (HDL-C) were the factors influencing high-risk steatohepatitis (all  $P < 0.05$ ). The AUCs of elastic modulus, dispersion slope, attenuation coefficient, multiparametric ultrasound model, blood markers model and ultrasound combined with blood markers model for diagnosing high-risk steatohepatitis were 0.764, 0.758, 0.634, 0.786, 0.745 and 0.802, respectively. Delong test showed the ultrasound combined with blood markers model had significantly better predictive properties than blood markers model and attenuation coefficient ( $P=0.017$ ,  $P < 0.001$ , respectively).

#### **CONCLUSION**

The combination of multiparametric quantitative ultrasound is useful for the non-invasive diagnosis of high-risk steatohepatitis with positive clinical value.

#### **CLINICAL RELEVANCE/APPLICATION**

This multiparametric quantitative ultrasound is useful for the non-invasive diagnosis of high-risk steatohepatitis.

#### **M5A-SPGI-7 Contrast Enhanced CT Based Radiomics for Predicting Postoperative Re-bleeding in Cirrhotic Patients**

Participants  
Xin Yang, Yangzhou, Jiangsu Province, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To investigate the feasibility of contrast enhanced CT-based radiomics in predicting postoperative esophagogastric variceal re-bleeding (EGVR) after laparoscopic splenectomy and azygoportal disconnection (LSD) in liver cirrhosis patients with portal hypertension.

#### **METHODS AND MATERIALS**

Preoperative contrast-enhanced CT examinations of 182 patients receiving LSD were enrolled. Patients were divided into with and without EGVR groups basing one year follow-up. 145 patients were enrolled randomly into training and validation cohorts in the ratio of 7:3, respectively. 37 patients were used in independent testing group. All radiomic features were extracted from CT images of the portal venous phase. Regions of interest (ROIs) were delineated on liver and spleen at the hilum level, respectively. The liver volumes of interest (VOI) and spleen VOI were automatically extracted. The least absolute shrinkage and selection operator (LASSO) regression was used to obtain optimal features from combined ROIs, as well as combined VOIs features, and incorporated into a logistic regression classifier to construct a model. The EGVR predictive performance of radiomics models was evaluated by the area under receiver-operating characteristic curve (AUC).

#### **RESULTS**

The constructed radiomics models showed good predictive efficacy and outperformed the clinical characteristics models. The best performance of radiomics model was the logistic regression model constructed by 8 features extracted from the ROIs of liver combining with spleen, with AUC of 0.931 and 0.914 for the training and validation group, respectively. An AUC of 0.858 in the independent testing group was obtained.

#### **CONCLUSION**

Contrast enhanced CT-based radiomics model can predict the risk of EGVR after LSD in patient with cirrhotic portal hypertension.

#### **CLINICAL RELEVANCE/APPLICATION**

The rate of esophagogastric vein bleeding in patients with cirrhotic portal hypertension is about 30%, with a 20% increase in mortality after six weeks. A 1 year prospectively study showed that the incidence of EGVR in patients after LSD is 13.4%, which is a lethal complication. Therefore, it is necessary to find a convenient way to predict EGVR, and our study provided a non-invasive way for the prediction of re-bleeding after LSD.

#### **M5A-SPGI-8 Non-invasive Liver Fibrosis Assessment with CT-based Iodine-uptake Parameters and Hepatosplenic Volumetric Indices**

Participants  
Kenichiro Yoshida, Yamaga, Japan (*Presenter*) Nothing to Disclose

## **PURPOSE**

To evaluate the diagnostic performance of iodine uptake parameters and hepatosplenic volumetric indices measured from multiphase hepatic CT to predict liver fibrosis severity in patients who underwent liver resection.

## **METHODS AND MATERIALS**

Ninety-one patients with pathologically proven liver fibrosis who underwent multiphase hepatic CT during the portal-venous phase (PVP) and 3-min delayed phase (DP) were included. The hepatic extracellular volume fraction (ECV) was calculated as  $([1 - \text{hematocrit}] \times [\text{hepatic iodine uptake during DP/aortic iodine uptake during DP}] \times 100)$ . The iodine washout rate (IWR) was calculated as  $([\text{hepatic iodine uptake during PVP} - \text{hepatic iodine uptake during DP}]/\text{hepatic iodine uptake during PVP} \times 100)$ . The liver volume (LV) and spleen volume (SV) normalized to body surface area (LV/BSA and SV/BSA, respectively) were quantified on PVP images using a deep learning algorithm. The correlations between the imaging parameters and the pathologic liver fibrosis stages were assessed using Spearman's correlation coefficient. The areas under the receiver operating characteristic curves (AUCs) to predict liver fibrosis severity were calculated for each imaging parameter. Multivariable logistic regression analysis was performed to identify independent predictors for hepatic cirrhosis, and combined diagnostic performance was assessed.

## **RESULTS**

Patients with F2-4 (n = 37), F3-4 (n =16), and F4 (n = 13) showed higher ECV, lower IWR, and higher SV/BSA than those with F0-1 (n=54), F0-2 (n=75), and F0-3 (n=78), respectively (all p<0.05). The highest correlation with fibrosis stages was attained in IWR (r=-0.593), followed by SV/BSA (r=0.383), ECV (r=0.381), and LV/BSA (r=0.062). The AUC ranges of ECV, IWR, LV/BSA, and SV/BSA for predicting liver fibrosis severity were 0.667-0.717, 0.843-0.882, 0.507-0.560, and 0.685-0.819, respectively. IWR and SV/BSA were independent predictors of cirrhosis, with combined AUCs of 0.881.

## **CONCLUSION**

s IWR and SV/BSA can allow better prediction of liver fibrosis severity compared with ECV and LV/BSA in multiphase hepatic CT.

## **CLINICAL RELEVANCE/APPLICATION**

IWR and SV/BSA may be served as a non-invasive imaging biomarker for predicting liver fibrosis severity on routine multiphase CT.

### Genitourinary Imaging Monday Poster Discussions I

#### Sub-Events

#### M5A-SPGU-1 Feasibility Study of Bone Mineral Metabolism in Chronic Kidney Disease Based on Dual-energy CT

##### Participants

Wei Huang, Xi'an, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the accuracy of dual-energy CT (DECT) in assessing bone mineral metabolism in patients with chronic kidney disease (CKD).

##### METHODS AND MATERIALS

The abdominal dual-energy CT images of 53 patients with CKD were retrospectively analyzed, and the images of T12-L4 vertebral bodies were analyzed by decalcification virtual plain scan technology. The images were processed and analyzed using the virtual non-contrast (VNC) software in the Dual-Energy tab of the Syngo Via CT post-processing workstation. The T12 - L4 vertebral body was measured on the median coronal image, the ROI was manually outlined along the outer edge of the vertebral body, and various measurements automatically given by the software were recorded: CT value of calcium (Contrast media, CM), mixed energy image (Mixing ratio of 0.6) CT value (Regular CT value, rCT), calcium concentration (Calcium density, CaD) and fat content percentage (Fat fraction, FF). Pearson correlation analysis was applied to explore the relation between clinical laboratory testing indicators and these parameters.

##### RESULTS

The contrast media, rCT, CaD in the hemodialysis patients were significantly lower than those in early stage CKD ( $p < 0.01$ ). The CM, rCT and CaD values of vertebral body were negatively correlated with Ca ( $r = 0.486, 0.389, 0.598$ , respectively, all  $p < 0.01$ ). There was no correlation between FF and Ca.

##### CONCLUSION

Dual-energy CT VNCA technique may constitute a valid alternative method for quantifying the mineral content and marrow fat composition of bone in the diagnostic assessments of bone mineral metabolism in chronic kidney disease.

##### CLINICAL RELEVANCE/APPLICATION

Using abdominal dual-energy CT images may additionally evaluate bone abnormalities early in CKD patients.

#### M5A-SPGU-2 Development of a Radiomics Model for CT-based Clear Cell Likelihood Score in Small Solid Renal Masses

##### Participants

Taekmin Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To develop an explainable CT radiomics-based model for diagnosing clear cell renal cell carcinoma (ccRCC) among small ( $\leq 4$  cm) solid renal masses.

##### METHODS AND MATERIALS

This retrospective study included 159 patients (50 women; median age 58 years [IQR 50-65 years]) with pathologically confirmed renal solid masses ( $\leq 4$  cm). Two radiologists independently evaluated mass-to-cortex ratio and heterogeneity score (on a 5-point Likert scale) in corticomedullary phases, and evaluated a five-tiered CT score for diagnosing ccRCC. Interpretable radiomics model was constructed using the CT radiomics features which were associated with mass-to-cortex ratio (first-order statistics of the mass and renal cortex) and heterogeneity score (first-order statistics and texture features of the mass). Diagnostic performance of diagnosing ccRCC were compared between five-tiered CT score and radiomics model.

##### RESULTS

The masses comprised 52.8% of ccRCC (84/159) and 47.2% (75/159) of other histologic diagnoses. The mass-to-cortex ratio and heterogeneity score were significantly higher in ccRCC than in other diagnoses ( $0.87 \pm 0.18$  vs.  $0.58 \pm 0.21$  and  $4.1 \pm 0.9$  vs.  $2.5 \pm 1.1$ , respectively,  $P < 0.001$  for both). CT score = 4 achieved an AUC of 0.851 with sensitivity, specificity, and PPV of 72.6%, 80%, and 80.2%, respectively. The radiomics-based mass-to-cortex ratio and radiomics-based heterogeneity score obtained intraclass correlation coefficient of 0.89 (95% CI 0.85-0.92) and 0.82 (95% CI 0.76-0.86) compared with the original values, respectively. Diagnostic performance of radiomics model for identifying ccRCC obtained AUC of 0.913, which was superior to that of CT score (difference between areas 0.06,  $P = 0.02$ ).

##### CONCLUSION

s The CT-based radiomics algorithm, which was constructed using the features correlated with two key parameters, showed good performance of diagnosing ccRCC in small renal masses.

#### **CLINICAL RELEVANCE/APPLICATION**

CT-based clear cell likelihood score (ccLS) could provide lower cost and greater accessibility for patients, but validation for diagnostic performance and inter-reader agreement are needed. We developed a CT radiomics model for identifying ccRCC, which has a potential to easily apply in clinical practice.

#### **M5A-SPGU-3 Succinate Dehydrogenase-deficient Renal Cell Carcinoma: Characterization of Imaging Features for Precision Diagnosis**

Participants

Aditi Chaurasia, MBBS, Bethesda, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Succinate dehydrogenase-deficient RCC is a rare, newly defined distinct renal cancer subtype under WHO tumor classification, confirmed by immunohistochemistry showing loss of staining of SDHB in tumors. Our aim is to investigate the imaging findings of SDHB-deficient renal tumors to facilitate accurate tumor characterization.

#### **METHODS AND MATERIALS**

The study included 20 SDH-deficient tumors from 16 patients with pathogenic variations in SDHB gene. Cross-sectional and PET imaging scans from this cohort was retrospectively evaluated by two radiologists and one nuclear medicine specialist. Clinical findings such as demographics, family history, extra-renal findings and metastases were recorded. Tumor imaging characteristics on CT and MRI included were laterality, size, homogeneity, morphology, margins, internal content, T1 and T2 signal intensity, enhancement features, and restricted diffusion.

#### **RESULTS**

A total of 16 patients (median age 31 years, IQR 19-41, 8 men) were identified with 68.8% of patients having a known family history of SDHB mutation. 81.3% of lesions were solitary and majority were solid (86.7% on CT, 87.5% on MRI) with well-defined margins in >62.5% of lesions, without evidence of internal fat, calcifications, and vascular invasion. On MRI, 87.5% of lesions had T2 intensity equal or more than cortex but less than CSF, and 100% of lesions demonstrated restricted diffusion. 100% of lesions showed enhancement with degree greater than 75% for most lesions on CT and MRI. On PET, all renal masses showed radiotracer uptake (mean SUVmax 31.9, mean SUVmean 7.1). 43.8% of patients demonstrated extra-renal manifestations and 43.8% distant metastasis.

#### **CONCLUSION**

s SDHB-associated RCC is predominantly noted in young patients with no gender predilection. On imaging, SDH-deficient RCC are frequently unilateral, solitary, and solid with well-defined margins demonstrating avid enhancement with variability in enhancement pattern and showing restricted diffusion.

#### **CLINICAL RELEVANCE/APPLICATION**

The present article is a pilot study to characterize the findings of newly defined SDH-deficient RCC in patients having germline variation in SDHB gene on morphological and PET imaging to aid in early and accurate tumor identification.

M5A-SPHN

### Head & Neck Imaging Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPHN-1 Intravoxel Incoherent Motion Diffusion-weighted Imaging in Nasopharyngeal Cancer: Comparison between Turbo Spin-echo and Echo-planar Imaging Techniques**

##### Participants

Yuan Liu, Wuhan, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To assess the qualitative and quantitative indicators between turbo spin-echo(TSE)-IVIM and echo-planar imaging(EPI)-IVIM in patients with nasopharyngeal cancer.

##### METHODS AND MATERIALS

Thirty patients with nasopharyngeal carcinoma underwent a pre-treatment staging MRI examination (Ingenia 3.0T, Philips Healthcare, the Netherlands). The IVIM images were evaluated subjectively and objectively for anatomical structures (nasopharyngeal lesions, turbinate, spinal cord and temporal pole). Subjective evaluation indicators (five-point scale for susceptibility artifacts, geometric distortion, lesion conspicuity and overall image quality) were compared with Wilcoxon signed rank test. Quantitative indicators were compared with paired t-test of signal-to-noise ratio(SNR), contrast-to-noise ratio (CNR), ADC and IVIM-derived parameters. Bland-Altman and coefficient of variance(CV) was performed to analyse reproducibility and robustness between ADC and IVIM-derived parameters of TSE-IVIM and EPI-IVIM.

##### RESULTS

TSE-IVIM performed significantly better than EPI-IVIM of the qualitative indicators in nasopharyngeal lesions, turbinate and temporal pole (all  $p < 0.001$ ), while no significant difference in spinal cord (table 1). SNR and CNR of TSE-IVIM were significantly lower than EPI-IVIM in spinal cord and temporal lobe, while no significant difference in the nasopharyngeal lesions and turbinate (table 2).  $f$  values of TSE-IVIM showed significant lower than EPI-IVIM in the nasopharyngeal lesions, and ADC and  $D^*$  values of TSE-IVIM showed significant higher than EPI-IVIM in spinal cord (table 3). CV of TSE-IVIM mainly showed lower percentage than EPI-IVIM. Bland-Altman analysis showed wide limits of agreement (LoA) in the nasopharyngeal lesions and turbinate (table 4, figure 1).

##### CONCLUSION

For better image subjective scores and no significant lower SNR and CNR, TSE-IVIM performed better image quality and more stable quantitative indicators in the nasopharyngeal lesions and turbinate area, which were more noticeable for magnetic sensitivity artifacts. For the different  $f$  values and wide LoAs between two sequences in the nasopharyngeal lesions, we recommended to use TSE-IVIM on follow-up of patients with nasopharyngeal lesions.

##### CLINICAL RELEVANCE/APPLICATION

TSE-IVIM provide better image quality and greatly reduce the susceptibility artifacts and geometric distortion in nasopharynx. TSE-IVIM benefit the accuracy and stability for IVIM-derived parameters. We recommend to use TSE-IVIM on follow-up for nasopharyngeal lesions.

#### **M5A-SPHN-2 Feasibility of Using Multi-frequency Magnetic Resonance Elastography for Evaluating the Parotid Glands In Healthy Volunteers**

##### PURPOSE

To assess the feasibility of using multifrequency magnetic resonance elastography (MRE) for evaluating the parotid glands in healthy volunteers.

##### METHODS AND MATERIALS

Six healthy volunteers were divided into two groups. Three volunteers had a passive driver placed on the occiput during scanning (occiput group), while the other three had a passive driver placed on the right face (right face group). Both groups underwent multifrequency MRE (60, 90, 120, and 150 Hz) of parotid gland at 3 Tesla. The image quality of the MRE waveforms, elastograms was evaluated.

##### RESULTS

In the occiput group, the shear wave propagation from the occiput region to the parotid gland was distant, resulting in significant attenuation and interference. The image quality was higher at 60 Hz, but lower at 90 Hz and 120 Hz. Volunteers could not tolerate the scan at 150 Hz and the scan was terminated. In the right face group, the attenuation and interference of the shear wave propagation were smaller. The image quality was high at all frequencies (60, 90, 120, and 150 Hz). However, because the arrival time of the shear wave in the bilateral parotid gland was different, this group was more suitable for observing the right parotid gland.

## CONCLUSION

s The appropriate frequency for the occiput group to evaluate the parotid gland was 60 Hz, while the appropriate frequencies for the right face group were 60 Hz, 90 Hz, 120 Hz, and 150 Hz.

## CLINICAL RELEVANCE/APPLICATION

Multifrequency MRE can be applied to healthy parotid glands, and may be further applied to the study of parotid gland tumors and diffuse lesions such as Sjogren's syndrome in the future.

## M5A-SPHN-3 Validation of a Fluorescent MET-Targeting Probe for Assisting Biopsy in OPMDs

### PURPOSE

The objective of this study is to investigate the use of a topically applied mesenchymal-epithelial transition factor (MET) targeting probe, cMBP-ICG, in conjunction with near-infrared targeted fluorescent imaging (NIRFI) to improve the accuracy of biopsy site selection for oral potentially malignant disorders (OPMDs). This approach aims to reduce the rate of missed detection of intermediate-high grade dysplasia (IHD) and oral squamous cell carcinoma (OSCC).

### METHODS AND MATERIALS

The acute toxicological properties of cMBP-ICG were evaluated in mice. The progression of OPMDs to OSCC was simulated in mice treated with 4-NQO and monitored using MRI and NIRFI. Tongue tissue was evaluated for pathological characteristics and MET expression. The detection rate of IHD was compared between NIRFI-assisted and standard biopsy in mice. An exploratory clinical trial involving six subjects with OPMDs evaluated the consistency between NIRFI-assisted and physician-selected biopsy sites using Cohen's kappa statistic.

### RESULTS

No significant differences were observed in CBC and blood biochemical test results before and after administration of cMBP-ICG. Low-grade dysplasia was present in 62 cases and IHD was present in 34 cases. Carcinoma in situ was present in 21 cases and invasive carcinoma was present in 5 cases. The average signal-to-background ratio and mean fluorescence intensity of neoplasia with higher malignancy than IHD were  $6.3 \pm 2.7$  and  $17.4 \pm 8.9$  arbitrary units, respectively. The mean values of MET-positive area for the four pathological types were  $31.0 \pm 11.9\%$ ,  $57.8 \pm 18.9\%$ ,  $70.4 \pm 13.8\%$ , and  $85.5 \pm 8.4\%$ , respectively. NIRFI-assisted biopsy had a missed detection rate and a detection rate of IHD of  $0.0085 \pm 0.04$  and  $0.66 \pm 0.27$ , respectively, while standard biopsy had a missed detection rate and a detection rate of IHD of  $0.36 \pm 0.2$  and  $0.39 \pm 0.25$ , respectively. There was a statistically significant difference between the two groups ( $P < 0.01$ ). In contrast, there was no statistically significant difference between the two groups in the missed detection rate and detection rate of carcinoma. The OR value related to group assignment was less than 1 for the missed detection rate of IHD and greater than 1 for all detection rates. For the six enrolled patients, NIRFI-assisted biopsy was performed at all sites consistent with experienced clinicians, with a kappa value of 0.39 and a P-value of 0.19.

## CONCLUSION

s Compared to standard biopsy, the use of cMBP-ICG in conjunction with NIRFI may improve the detection of IHD.

## CLINICAL RELEVANCE/APPLICATION

The NIRF probe cMBP-ICG and NIRF imaging system may provide a non-invasive method for biopsy sampling assistance, potentially changing the clinical protocol for OPMDs, and improving the early diagnosis rate of OSCC.

## M5A-SPHN-4 Development and Validation of Deep Learning Based Automated Detection of Cervical Lymphadenopathy in Patients With Lymphoma for Treatment Response Assessment: A Bi-institutional Feasibility Study

Participants  
Ji Su Ko, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

### PURPOSE

To train and evaluate a deep learning (DL) model for the accurate detection and segmentation of abnormal cervical lymph nodes (LN) on head and neck contrast-enhanced CT scans in patients diagnosed with lymphoma and evaluate the clinical utility of the DL model in response assessment.

### METHODS AND MATERIALS

This retrospective study included patients who underwent CT for abnormal cervical LN and lymphoma assessment between January 2021 and July 2022. Patients were grouped into the development ( $n=76$ ), internal test 1 ( $n=27$ ), internal test 2 ( $n=87$ ), and external test ( $n=26$ ) cohorts. A 3D SegResNet model was used to train the CT images. The volume change rates of cervical LN across longitudinal CT scans were compared among patients with different treatment outcomes (Stable, response, and progression). Dice similarity coefficient (DSC) and Bland-Altman plot were used to assess the model's segmentation performance and reliability, respectively.

### RESULTS

No significant differences in baseline clinical characteristics were found across cohorts (age,  $P=0.55$ ; sex,  $P=0.13$ ; diagnoses,  $P=0.06$ ). The mean DSC was  $0.39 \pm 0.2$  with a precision and recall of 60.9% and 57.0%, respectively. Most LN volumes were within the limits of agreement on the Bland-Altman plot. The volume change rates among the three groups differed significantly (progression ( $n=74$ ), 342.2%; response ( $n=8$ ), -79.2%; stable ( $n=5$ ), -8.1%; all  $P < 0.01$ ).

## CONCLUSION

s Our proposed DL segmentation model is reliable for quantifying the cervical LN burden on CT in patients with heterogeneous lymphoma. Longitudinal changes in cervical LN volume, as predicted by the DL model, are useful for treatment response assessment.

## CLINICAL RELEVANCE/APPLICATION

DL-based auto-segmentation model could effectively detect and quantify cervical LN burden in patients with lymphoma across

DL-based auto segmentation model could effectively detect and quantify cervical LN burden in patients with lymphoma across longitudinal CT scans, which could ultimately improve guidance for treatment response assessment.

### **M5A-SPHN-5 Deep Learning Based Multi-Modal Segmentation of Oropharyngeal Squamous Cell Carcinoma on CT and MRI Using Self-Configuring nnU-Net**

Participants

DONGJUN LEE, MD, Anyang, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate deep learning-based segmentation models for oropharyngeal squamous cell carcinoma (OPSCC) using CT and MRI with nnU-Net.

#### **METHODS AND MATERIALS**

This retrospective study included 91 patients with OPSCC. The patients were grouped into development (n=56), test 1 (n=13), and test 2 (n=22) cohorts. In development cohort, OPSCC was manually segmented on CT, MR, and co-registered CT-MR, which served as ground truth. The multimodal and multichannel input images were then trained using a self-configuring nnU-Net framework. For evaluation metrics, dice similarity coefficient (DSC; 1=perfect and 0=no overlap) and mean Hausdorff distance (HD; near 0=good) were calculated for two test cohorts. Pearson's correlation and Bland-Altman analyses were performed between ground truth and prediction volumes. Kruskal-Wallis tests were performed to compare DSC and HD of the three models.

#### **RESULTS**

All three models achieved robust segmentation performances with DSC of 0.64±0.33 (CT), 0.67±0.27 (MR), and 0.65±0.29 (CT-MR) in test cohort 1 and 0.57±0.31 (CT), 0.77±0.08 (MR), and 0.73±0.18 (CT-MR) in test cohort 2. No significant differences were found in DSC among the models. HD of CT-MR (1.57±1.06 mm) and MR models (1.36±0.61 mm) were significantly lower than that of CT model (3.48±5.0 mm) (P=0.037 and P=0.014, respectively). The correlation coefficients between ground truth and prediction volumes for CT, MR, and CT-MR models were 0.88, 0.93, and 0.9, respectively.

#### **CONCLUSION**

The self-configuring nnU-Net framework yielded a reliable and accurate segmentation of OPSCC on CT and MRI. The multimodal CT-MR model showed promising results for the simultaneous segmentation on CT and MRI.

#### **CLINICAL RELEVANCE/APPLICATION**

The multimodal segmentation models trained with the nnU-Net framework provided reliable and accurate segmentations of OPSCC on both CT and MR, which can be applied to facilitate clinical staging, radiation therapy planning, and treatment response assessment.

### **M5A-SPHN-6 Structure-Preserving Image Quality Improvement of Cone Beam CT Using Deep Learning**

Participants

Won-Jin Yi, PhD, MS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The purpose of this study is to increase the image quality and HU accuracy of CBCTs while preserving anatomical structures. We applied contrastive learning-based GAN for unpaired image translation to the quality improvement of CBCT images.

#### **METHODS AND MATERIALS**

We generate CT-like images from CBCT images using a patchwise contrastive learning-based GAN model. Our model is trained on unpaired CT and CBCT datasets of 30 patients with the novel combination of loss, composed of semantic relation consistency loss, spatially correlative loss, and reconstruction loss. We used a customized feature extractor pretrained on our training dataset to calculate the spatially correlative loss. We evaluate the quality of the images generated by our model in terms of Fréchet inception distance (FID), peak signal-to-noise ratio (PSNR), mean absolute error (MAE), and root mean square error (RMSE). Additionally, the structure preservation performance is assessed by the structure score. Furthermore, we performed the ablation study by progressively adding components of the loss to analyze the impact of the various components on the performance.

#### **RESULTS**

The generated CT-like images by our model are significantly superior to those generated by various baseline models in terms of FID, PSNR, MAE, RMSE, and structure score. The spatially correlative loss and the reconstruction loss in our model provided the complementary benefits of preserving the anatomical structures of the input CBCT images and improving the image quality to be similar to CT images.

#### **CONCLUSION**

The generated CT-like images by our model were significantly superior to those generated by various baseline models in terms of FID, PSNR, MAE, RMSE, and structure score. We demonstrate that our model provides complementary benefits of preserving the anatomy of the input CBCT images and improving the image quality to be similar to those of CT images.

#### **CLINICAL RELEVANCE/APPLICATION**

Cone-beam CT (CBCT) is widely used in dental clinics but exhibits limitations in assessing soft tissue pathology because of its lack of contrast resolution and low Hounsfield Units (HU) quantification accuracy. The proposed method considerably enhanced CBCT's quality and HU accuracy while preserving the anatomical structure. We demonstrated that our framework enables detailed visualization of soft tissues and accurate quantification of HU in CBCT. This work could allow for accurate quantification of HU, suggesting the possibility of using CBCT in more clinical situations.

### **M5A-SPHN-7 Quantitative Pharmacokinetic Parameter Ktrans Map Assists in Regional Segmentation of Nasopharyngeal Carcinoma in Dynamic Contrast-enhanced Magnetic Resonance Imaging (DCE-MRI)**

Participants

## **PURPOSE**

Accurate segmentation of nasopharyngeal carcinoma (NPC) lesion areas from dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) facilitates subsequent diagnostic and prognostic workups. Traditionally, anatomical DCE-MRI-based NPC segmentation using deep learning has achieved fair results but still needs further improvement. Hence, we investigate the incremental benefit of incorporating pharmacokinetic parameter maps into anatomical DCE-MR image segmentation tasks by taking advantage of the hemodynamic contrast between NPC and surrounding tissue.

## **METHODS AND MATERIALS**

In this paper, a pharmacokinetic parameter Ktrans map of NPC is used as prior information and combined with anatomical DCE-MRI data to improve the performance of segmentation models. A novel model, multi-input branch residual U-Net (MBRU-Net), which extracts features from both anatomical DCE-MR images and Ktrans maps and fuses them to improve the segmentation performance, is introduced. The effectiveness of the multibranch network is validated by comparing MBRU-Net with deep residual U-Net (ResU-Net) with DCE-MRI + Ktrans data. Additionally, different models (U-Net, segmentation network (SegNet), recurrent residual U-Net (R2U-Net), and ResU-Net) are trained with DCE-MRI and DCE-MRI + Ktrans data separately and compared to validate the effectiveness of multimodal data using the Dice coefficient (Dice).

## **RESULTS**

Our proposed MBRU-Net achieves the best Dice in this study ( $67.39 \pm 15.79\%$ ), higher than ResU-Net's Dice ( $65.57 \pm 17.52$ ) based on DCE-MRI and Ktrans data. U-Net, SegNet, R2U-Net, and ResU-Net achieve better results in terms of segmenting tumor regions with DCE-MRI + Ktrans data than those of the corresponding models with DCE-MRI data alone, where U-Net has the best performance (DCE-MRI + Ktrans: DCE-MRI =  $66.31 \pm 17.80\%$ :  $61.10 \pm 24.14\%$ ).

## **CONCLUSION**

It is beneficial to add a pharmacokinetic parametric (Ktrans) map as prior information to the conventional anatomical MRI-based segmentation task, and multibranch network structures perform better than single-branch network structures in terms of NPC segmentation.

## **CLINICAL RELEVANCE/APPLICATION**

Ktrans map as a priori information is beneficial for the segmentation of NPC on DCE-MRI, which might facilitate diagnostic and prognostic workup.

### Imaging Informatics Monday Poster Discussions I

#### Sub-Events

#### M5A-SPIN-1 Comparison of Human and AI-based Medical and Non-medical Segmentation Algorithms

##### Participants

Matthias Froelich, MD, Mannheim, Germany (*Presenter*) Consultant, Smart Reporting GmbH; Consultant, Guerbet SA

##### PURPOSE

To evaluate the comparative performance of human and AI-based segmentation, especially in the context of novel algorithms, not trained exclusively on (sectional) imaging data.

##### METHODS AND MATERIALS

A challenging CT slice with suboptimal contrast was selected. Manual segmentation was performed by a radiologist using 3D-Slicer. Automated segmentation algorithms (Total Segmentator fast/standard mode, Segment Anything in four settings) were run on the image. No further adjustment of the segmentation was performed. A total of 7 radiologists (3-11 yrs experience), evaluated the segmentations in blinded approach.

##### RESULTS

Human segmentation took 18:23 min, compared to AI-based approaches which took a maximum of 1:12 min. 5 radiologists (62.5%) identified the human segmentation correctly, which was rated best (> 50% very or somewhat closely correct segmentation). For the AI-based approaches, the Total Segmentator Standard Mode was ranked best (at least moderately closely 100%). The results are summarised in the figure attached.

##### CONCLUSION

s AI-based segmentation is significantly faster than human segmentation. In challenging cases with suboptimal contrast, models trained on imaging data exclusively may still be superior to other models.

##### CLINICAL RELEVANCE/APPLICATION

Segmentation is a task that should be performed automatically by AI.

#### M5A-SPIN-2 The Predictive Value of CT Body Composition Indicators Using Fully-Automated AI Tools for Short-term and Long-term Outcomes in Obese Patients Receiving Bariatric Surgery

##### PURPOSE

Computed tomography (CT)-based body composition measures derived from fully automated artificial (AI) intelligence tools are promising for assessing body composition. We aimed to assess the predictive value of CT body composition indicators using fully automated AI tools for short-term and long-term outcomes in obese patients receiving bariatric surgery. Our findings can offer objective recommendations for clinical follow-up, pre- and post-operative interventions.

##### METHODS AND MATERIALS

74 obese patients underwent bariatric surgery were retrospectively analyzed. Patients' skeletal muscle (SMA), subcutaneous fat (SFA) and visceral fat area (VFA) of L3 level were accessed pre- and post-operatively by CT using fully-automated AI segmentation and quantification tools. The clinical variables and perioperative laboratory test data associated with adverse outcomes after surgery were statistically analyzed. %EWL<50% at one year after surgery was considered unsuccessful weight loss. The association of prognostic factors with postoperative complications and body compositions were evaluated by binary univariate and multivariate logistic regression analysis.

##### RESULTS

For obese patients with bariatric surgery, the results of the multivariate model showed that preoperative VFA=284.05 cm<sup>2</sup>(OR: 29.87, 95% CI: 1.42,1386.71, P=0.018) in female patients was an independent risk factor for ICU admission after surgery. Preoperative SFA=748.82 cm<sup>2</sup>(OR: 12.56, 95% CI: 0.81,453.41, P=0.003) in male patients was an independent risk factor for %EWL<50% (unsuccessful weight loss). A sustained decrease in SMA, VFA and SFA was observed during the postoperative period, with the most pronounced drop of approximately 15-50% within 6 months postoperatively (P<0.0001). SFA and VFA continued to decrease long-term after surgery (P<0.0001). SMA was significantly reduced in the short term after surgery and maintained in the long term.

##### CONCLUSION

s CT based body composition using fully automated AI tools can be used to predict short-term and long-term outcomes for obese patients undergoing bariatric surgery. Preoperative VFA in female and preoperative SFA in male are independent risk factors for adverse short-term outcomes. Obese patients can benefit from bariatric surgery, with significant reductions in both muscle and fat

in the short term after surgery. In the long term after surgery, there is a sustained loss in subcutaneous and visceral fat, while skeletal muscle maintained.

#### **CLINICAL RELEVANCE/APPLICATION**

Obese patients can benefit from bariatric surgery. CT based body composition using fully automated AI tools has promising predict value for obese patients undergoing bariatric surgery.

#### **M5A-SPIN-3 Comparative Analysis of Spectral Characteristics of Monoenergetic CT Reconstructions for Different Kidney Stone Types Scanned on Photon-Counting-CT**

Participants

Alexander Hertel, MD, Mannheim, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The aim of this study is to investigate the potential of using the radiomics profile of different monoenergetic reconstructions of photon-counting CT (PCCT) scans to differentiate various types of kidney stones. The study seeks to explore the relationship between radiomics features and the underlying composition of kidney stones, with the ultimate goal of developing a more accurate and non-invasive approach to diagnose and classify kidney stones. The learning objective of this study is to contribute to the development of a more personalized and precise approach to the diagnosis and treatment of kidney stone disease. The learning objective of this study is to contribute to the development of a more personalized and precise approach to the diagnosis and treatment of kidney stone disease.

#### **METHODS AND MATERIALS**

Photon-counting CT (PCCT) is a novel imaging technology that has shown great promise in Radiomics analysis, e.g. due to its high feature stability. In this study, we scanned 150 different types of kidney stones, including Xanthine, Brushite, Carbonateapatite, Cystine, and others, using a PCCT. Monoenergetic reconstructions of the scans were created using the Syngo Via software (version VB60A\_HF02) from Siemens in 30 keV steps from 40 to 190 keV. The stones were semi-automatically segmented using the MITK-Workbench software (v2022.10), and radiomics features were then extracted using a Docker container based on Pyradiomics (Version 3.0.1). Statistical analyses, including cluster analyses and the creation of box plots, were performed using R-Statistics (Version 2023.03.0+386) to explore the potential of radiomics for differentiating between different types of kidney stones.

#### **RESULTS**

In the study it could be shown that especially in the monoenergetic reconstructions with low keV values (40 and 70keV) a differentiation of the different kidney stone types, among other things on the basis of the average HU values, is possible, since these differed significantly depending on the kidney stone type. In contrast, no significant differences were found for the higher keV values.

#### **CONCLUSION**

Radiomics evaluations of monoenergetic reconstructions with low keV values (40 and 70keV) of photon counting CT scans can help differentiate and characterize renal stones noninvasively, potentially optimizing therapy.

#### **CLINICAL RELEVANCE/APPLICATION**

Non invasive differentiation of kidney stones to potentially optimize therapy.

#### **M5A-SPIN-4 Dual-Energy CT-derived Imaging Features: Diagnostic and Prognostic Value of Radiomics Features and Iodine Maps in Patients with Mediastinal Masses**

Participants

Vitali Koch, MD, Frankfurt am Main, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To assess the diagnostic and prognostic value of radiomics features and dual-source dual-energy CT (DECT) based material decomposition in patients with benign and malignant mediastinal masses.

#### **METHODS AND MATERIALS**

This retrospective study included 90 patients (38 males, mean age  $61 \pm 12$  years) with pathologically confirmed mediastinal masses who underwent contrast-enhanced DECT between 10/2014 and 04/2023. All patients were evaluated by two experienced readers regarding conventional radiomics features, as well as DECT-based texture features including attenuation (HU), iodine density (mg/ml), and fat fraction (%). Data comparisons were performed using analysis of variance (ANOVA) and chi-square statistic tests. Cox regression tests and receiver operating characteristic curve analysis were used to predict outcomes and discriminate between benign and malignant mediastinal masses.

#### **RESULTS**

Of the 90 mediastinal masses, 28 (31%) were lymphomas, 6 (7%) were mediastinal tumors, and 9 (10%) were thymic carcinomas. Values differed significantly between benign and malignant mediastinal masses regarding DECT-based texture features ( $p < 0.04$ ) and 30 radiomics features ( $p < 0.03$ ). The area under the curve to differentiate between benign and malignant formations was 0.980 (95% CI, 0.893-1.000;  $p < 0.001$ ) for the combination of DECT imaging parameters and radiomics features, yielding a sensitivity of 100% and specificity of 91%. During a follow-up of 60 months (IQR, 52-60 months), the multiparametric approach including radiomics features, DECT parameters, and clinical parameters showed good prognostic power to predict all-cause mortality (c-index = 0.896 [95% CI, 0.802-0.970],  $p = 0.001$ ).

#### **CONCLUSION**

A multiparametric approach including conventional radiomics features and DECT-based texture features facilitates accurate, non-invasive discrimination between benign and malignant mediastinal masses with high sensitivity and specificity.

#### **CLINICAL RELEVANCE/APPLICATION**

Early detection of malignant masses is of utmost importance to avoid delays in treatment initiation. Combining radiomics features

early detection of malignant masses is of utmost importance to avoid delays in treatment initiation. Combining radiomics features, DECT-derived imaging parameters, and clinical parameters through computational assessment of texture features has the potential to identify masses with an increased risk of malignancy.

## **M5A-SPIN-5 HASKE: A Low-Resource PACS Platform for Improving Diagnostic Imaging Access in Sub-Saharan Africa**

Participants

Udunna Anazodo, PhD, London, ON (*Presenter*) Nothing to Disclose

### **PURPOSE**

The delivery of diagnostic imaging in low-and-middle income countries (LMICs) is challenged by high costs of infrastructure acquisition and shortage of experts, particularly in Sub-Saharan Africa (SSA). One of the main issues accentuating this challenge is the availability of picture archiving and communication systems (PACS) for distribution, archiving and managing of images due to poor availability of quality internet service, high cost of computing infrastructure for hosting and distributing PACS and lack of skilled administrators to effectively maintain the system. Poor access to PACS contributes to poor diagnostic outcomes as the few available radiologists who serve a large population over a vast geographical area, are unable to access images for proper diagnosis. To improve PACS access in resource limited settings, we propose a redistributable PACS platform, HASKE (light in Hausa) accessible to radiologists, physicians, and patients based open-source tools, designed for use in low bandwidth environments and for ease of management.

### **METHODS AND MATERIALS**

HASKE is designed (Figure 1) to provide a low-resource solution for rapid access to images with standard features for 1) onsite and cloud/remote archiving system, 2) integrated zero footprint DICOM viewer, 3) a straightforward DICOM query interface, 4) mobile phone accessibility, and 5) low maintenance requirements for easy management by non-IT health personnel.

### **RESULTS**

The pilot open-source PACS tool is currently in use at three imaging facilities in Nigeria will be scaled up to provide a Health Level 7 (HL7) vendor-neutral PACS platform to ensure ease of integration, especially given the nature of medical device procurement in SSA (third party vs. original equipment manufacturers [OEMs]).

### **CONCLUSION**

The HASKE PACS platform represents a significant step towards improving access to diagnostic imaging in SSA and other resource-limited settings. The platform is designed to overcome prevailing challenges from lost images either through non availability of storage systems or poorly interpreted due to the lack of accessibility to the radiologist. HASKE is designed to help clinicians with limited resources to distribute images better and readily read and share imaging findings to transform disease management in SSA. By utilizing open-source tools, the platform is scalable and affordable, making it accessible to radiologists, physicians, and patients, alike.

### **CLINICAL RELEVANCE/APPLICATION**

While HASKE address the immediate need for diagnostic image data management, it ultimately will enable health equity and inclusion of resource limited settings in imaging data science and artificial intelligence (AI) solutions, where AI is has the greatest potential to improve local health outcomes.

## **M5A-SPIN-6 A Platform for Automatically Extracting Imaging Biomarkers from Ischemic and Hemorrhagic Stroke Patients**

Participants

Rajat Dhar, MD, , (*Presenter*) Nothing to Disclose

### **PURPOSE**

Imaging biomarkers of primary and secondary injury provide critical insights into disease progression and prognosis. Quantifying lesions (infarct or hemorrhage) and associated edema volume can be time-consuming and impractical in large multi-institutional cohorts. We present a cloud-based image repository and computational platform that can archive, analyze, and output multi-dimensional imaging biomarkers from brain CTs of ischemic and hemorrhagic stroke patients.

### **METHODS AND MATERIALS**

The Stroke NeuroImaging Phenotype Repository (SNIPR), based on the XNAT platform, has archived serial imaging from large stroke cohorts from multiple institutions. It allows the implementation of image analysis pipelines wrapped in Docker containers. In this study, we deployed containerized pipelines to analyze lesion and edema volume from both ischemic and hemorrhagic (ICH) stroke cohorts. Scans within each imaging session are first classified (using metadata and a deep learning-based classifier), allowing selection of 'axial brain CT' scans which can be processed (incl. DICOM to NIFTI conversion, brain extraction, and normalization), followed by (U-net-based) segmentation of infarct and hemorrhage lesions as well as peri-hematoma edema (in ICH) and displacement of CSF (for both ischemic stroke and ICH). The ratio of hemispheric CSF volumes was calculated in both groups. Net water uptake (NWU) is calculated in the infarct group as the relative density of infarct vs. Mirrored regions. Resulting segmentation masks are stored, while the biomarker results are stored as CSV files and presented as novel data types that can be viewed on a session, subject, or project level. A superimposed view of the lesion and edema/CSF masks over the NCCT image and a summary of the measurements are also held in a PDF.

### **RESULTS**

The analysis pipelines were implemented on 2649 CT sessions (ischemia:442 and ICH:2207) from three research centers. Axial brain scans could be found in the majority (74%) of sessions. Pipelines were completed in 1407 (71%), with biomarker extraction, including infarct/hemorrhage volumes, CSF ratio, and NWU. The platform can analyze around 1000 images in a week.

### **CONCLUSION**

The study presents a cloud-based image archive and analysis pipeline to calculate biomarkers in axial brain CT. It allows multi-centric collaboration and analyses of thousands of images at a time that would facilitate ongoing stroke research worldwide. The platform will be extended to include more image analysis pipelines useful for stroke research.

## CLINICAL RELEVANCE/APPLICATION

This platform can assist in quantifying infarction, hemorrhage, and edema in large volumes of serial brain CT scans of ischemic and hemorrhagic stroke patients, facilitating stroke research.

## M5A-SPIN-7 Complex Convolutional Neural Networks for Denoising Accelerated Submillimeter Magnetic Susceptibility Brain MRI

Participants

Bryan Quah, MSc, BA, Los Angeles, CA (*Presenter*) Nothing to Disclose

## PURPOSE

Magnetic susceptibility-based imaging using submillimeter isotropic 3D echo-planar imaging (3D-EPI) enables the detection of biomarkers for neurological disorders, such as the central vein sign and paramagnetic rim lesions in multiple sclerosis. Recent developments combining 3D-EPI acquisition with CAIPIRINHA undersampling, have shown to significantly reduce scan times. However, this comes at the cost of a reduced signal-to-noise ratio (SNR) which we address here using a complex denoising deep learning method.

## METHODS AND MATERIALS

3T brain MRI scans from 52 adults scanned at three imaging sites were used. T2\*-weighted magnitude and phase images were acquired at 650  $\mu\text{m}$  isotropic using 3D-EPI without parallel imaging (Acquisition Time, AT:  $\sim 6$  minutes), and with parallel imaging using CAIPIRINHA at different acceleration factors: R=2, (AT:  $\sim 4$  minutes), R=3 (AT:  $\sim 3$  minutes) and R=4 (AT:  $\sim 2$  minutes). The subjects were divided into 2 datasets: a training set (N=41) for the network to learn the denoising task and a testing set (N=11) to evaluate the model performance. The training set consists of data acquired without CAIPIRINHA while the testing set consists of data acquired with CAIPIRINHA at the 3 acceleration factors. We developed a 2-dimensional convolutional neural network to denoise the complex valued data created from the magnitude and phase 3D-EPI images. Our developed network extends the convolution and rectified linear unit operations to the complex domain. Peak signal-to-noise ratio (PSNR) and structural similarity index measure (SSIM) were calculated before and after denoising.

## RESULTS

Upon visual inspection, the denoised magnitude and phase images displayed improved image quality while the visibility of brain features and disease-related biomarkers were preserved. The average PSNR values measured across the cohort were increased after denoising at all acceleration factors (+29% for R=2; +34% for R=3; +41% for R=4). Meanwhile, the SSIM values measured remained high for all acceleration factors (mean  $\pm$  SD:  $0.959 \pm 0.014$  for R=2;  $0.951 \pm 0.021$  for R=3;  $0.942 \pm 0.023$  for R=4).

## CONCLUSION

s We developed a complex denoising deep learning approach to efficiently improve the image quality of accelerated submillimeter magnetic susceptibility brain MRI scans. Even at high acceleration factors (R=3), our method was able to restore the significant loss in SNR while maintaining structural details.

## CLINICAL RELEVANCE/APPLICATION

Our study demonstrates the feasibility of efficiently denoising accelerated magnetic susceptibility brain MRI with complex convolutional neural networks. Our proposed method opens the door for ultra-fast submillimeter SWI and QSM imaging in the clinical setting.

M5A-SPIR

### Interventional Radiology Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPIR-1 Prediction of Response to Treatment and Outcome of Trans-arterial Chemoembolization in Patients with Hepatocellular Carcinoma Using Artificial Intelligence: A Systematic Review Study**

##### Participants

Pedram Keshavarz, MD, Los Angeles, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

This study reviews the efficacy of different AI models for prediction of hepatocellular carcinoma treatment response to transarterial chemoembolization (TACE) including the overall survival (OS).

##### METHODS AND MATERIALS

This systematic review was performed according to Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines. We conducted a literature search in online databases, including Scopus, Medline (PubMed), Web of Science, Embase, and Google Scholar. The random-effect models were utilized to calculate pool sensitivity, specificity, predictive values, summary receiver operator characteristic (ROC), and area under curve (AUC) based on the "Standards for Reporting Diagnostic accuracy studies" (STARD) guidelines.

##### RESULTS

The systematic review cohort included 21 studies with 4,489 patients. The AI algorithm AUC for predicting HCC response to TACE ranged from 0.32-0.97. Radiomics and non-radiomics feature based models had similar pooled AUCs of 0.76 (95%CI: 0.73-0.79) and 0.75 (95%CI: 0.70-0.80), respectively. Compared to the most widely utilized machine learning methods relying on logistic regression, other AI-based methods such as convolutional neural networks (CNN) and support vector machine (SVM) had AUCs of 0.93 (95%CI 0.84-1.00) and 0.79 (95%CI, 0.77-0.81) respectively. Of all predictive feature models, models combining both CT or MR images with clinical features had higher AUCs of 0.78 (CT+clinical, 95%CI 0.74-0.83) and 0.81 (MR+clinical 95%CI 0.78-0.84) respectively, relative to models based on clinical features alone, AUC 0.67 (95%CI 0.53-0.80).

##### CONCLUSION

AI models showed acceptable performance in prediction of treatment response to TACE and post-TACE OS. CNN method utilizing a combination of cross-sectional images findings and clinical characteristics had superior performance compared to sole clinical features.

##### CLINICAL RELEVANCE/APPLICATION

The prediction of post-TACE, HCC treatment response by AI methods was feasible and significant in all studies. Contributing medical data is vital in improving predictions' confidence and stability, while it can significantly enhance accuracy and reduce the burden on the healthcare systems for investigating all the clinical and radiological features to determine the potential TACE responders. Comprehensive studies are required to introduce a highly accurate and reliable AI prediction model and reduce heterogeneity between outcomes.

#### **M5A-SPIR-2 Predicting Survival of Lung Ablation Patients using Deep Learning-Based Automatic Segmentation and Radiomics Analysis**

##### Participants

Hossam Zaki, BS, Providence, RI (*Presenter*) Nothing to Disclose

##### PURPOSE

To identify radiomic features predictive of survival following image-guided thermal ablation (IGTA) of lung tumors segmented using a deep learning approach.

##### METHODS AND MATERIALS

This HIPAA-compliant study was performed with a waiver for informed consent following institutional review board approval. Between January 1, 2004 and July 14, 2022, adult patients who underwent IGTA for primary and metastatic lung tumors were retrospectively identified. Using pre-procedure CT imaging data, lung zones were automatically segmented using a pre-trained U-Net, which was trained on a large dataset that covers significant visual variability and includes tumors in the segmentation. Following this, we used a U-shaped encoder-decoder transformer architecture (UNETR) to segment lung tumors. The model was trained on lung CT scans with tumor annotations. We then applied the pre-trained model to patients who underwent IGTA. Radiomic features were extracted from the lung segmentations. We utilized features related to the shape of the segmentation, including surface area, volume, and diameter. These radiomic features were then used to predict days-to-death of the patients using a Cox proportional hazards model. Death records were extracted from the electronic medical record and/or obituary data.

##### RESULTS

154 consecutive patients were evaluated (median age, 74.6 years; 46.4% Male). Of these patients, 119 experienced the mortality event, with a mean time to death of 3.6 years (minimum 0.6 years; maximum 14.2 years) following the initial IGTA procedure. Median tumor size was 1.8 cm (minimum 0.6 cm; maximum 5.2 cm), and 138 patients (90%) had primary lung cancer. The initial lung tumor segmentation using UNETR achieved a DICE score of .72, indicating a 72% overlap of the predicted segmentation and the ground-truth. The survivability prediction task using radiomic features achieved a c-index of .69, showing a 69% chance the model will correctly predict which subject has a longer survival time out of a random pair. The most predictive features were flatness and diameter along the row, with a c-index of .57 and .55, respectively. Flatness indicates the elongation of the tumor, while diameter indicates the length in a certain axis, both of which relate to tumor growth patterns.

## CONCLUSION

s Radiomic feature analysis of lung tumors following segmentation by transformer-based UNET may predict long-term survival following image-guided thermal ablation of pulmonary malignancies.

## CLINICAL RELEVANCE/APPLICATION

The incorporation of a survival prediction model based on radiomics features extracted from pre-procedure CT imaging by a deep learning algorithm may allow interventional radiologists to modify treatment approaches to optimize outcomes for patients.

## M5A-SPIR-3 Assessing ChatGPT's Proficiency in Generating Differential Diagnoses Based on Transcribed Vascular and Interventional Radiology Findings

Participants

Kenneth Huynh, DO, Orange, CA (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the accuracy and reliability of ChatGPT3.5 and ChatGPT4 in producing a differential diagnosis from transcribed radiological findings of specific vascular and interventional radiology (VIR) cases.

## METHODS AND MATERIALS

A sample of 20 cases specific to VIR imaging were evaluated. Cases were selected from a radiology textbook, from which the answers were used as the gold standard. The case images and history were converted into standardized prompts that contained purely descriptive language of the cases and a query for the most likely diagnosis, top three differential diagnoses, and the corresponding explanations and references from the medical literature. These prompts were fed into the ChatGPT3.5 and ChatGPT4 algorithms. Generated responses were analyzed for accuracy by comparison with the original literature and reliability through manual verification of the generated explanations and citations. The top 1 accuracy and the top 3 accuracy were defined as the percentage of generated responses that matched the original diagnosis and the complete differential provided by the original literature. An additional differential diagnosis score was defined as the proportion of differentials that matched the original literature's answers for each case. Comparisons were made between the results of the two algorithms using a one-tailed two proportion z-test method.

## RESULTS

The top 1 accuracy and top 3 accuracy, for ChatGPT3.5 versus ChatGPT4 were 85.0% compared to 85.0% ( $p = 0.5$ ) and 30.0% compared to 15.0% ( $p = 0.13$ ), respectively. The average differential diagnosis score of ChatGPT3.5 versus ChatGPT4 was 60.0% compared to 56.7% ( $p = 0.42$ ). ChatGPT3.5 and ChatGPT4 hallucinated 48.3% versus 13.4% ( $p < 0.00001$ ) of the references provided and generated 1 false statement versus 0 false statements, respectively.

## CONCLUSION

s The two generations of ChatGPT were able to generate a differential diagnosis for prompts containing descriptive radiological findings. The accuracy of top 1 diagnoses matched the expert literature from which the cases originated with reasonable accuracy, with no statistically significant improvement between the 3.5 to the 4th generation algorithm. However, responses from both algorithms matched the top 3 diagnoses from the expert literature a minority of the time. The well-known hallucination effect was encountered more commonly in the generation of citations than the generation of factual statements, which improved with the newest algorithm.

## CLINICAL RELEVANCE/APPLICATION

ChatGPT and Large Language Models (LLM) have a large potential to impact clinical and educational medicine. Knowledge of the accuracy and erroneous possibilities of these algorithms will provide a better understanding of the limitations of these new tools.

## M5A-SPIR-4 Identification of Inferior Vena Cava (IVC) Filters on CT, X-ray and MRI Radiological Reports with a Natural Language Processing (NLP) Based Tool for Management of Clinical Follow Up

Participants

Yifan Wang, MD, MS, New Haven, CT (*Presenter*) Nothing to Disclose

## PURPOSE

Many patients with IVC filters don't get proper follow up and their filters are not removed even when it is not further needed. Many of the patients who are lost to follow up are undergoing other imaging studies in their lifetime with the presence of an IVC filter gets documented in radiological reports. NLP can assist in discovering those patients with IVC filters and help clinicians in monitoring and clinical follow up. The study aims to measure the effectiveness of an NLP solution in discovering IVC filters in radiological reports and explore the role of AI in improving follow up of patients with IVC filters.

## METHODS AND MATERIALS

Radiological reports of CT, X-ray, and MRI studies from a large academic health system generated between 7/1/2021 and 7/31/2021 were selected for analysis. Follow-up was reviewed up to 20 months after the initial report dates. Radiological reports were analyzed for the presence of mention of an IVC filter using an NLP solution. The NLP positive cases were reviewed to measure: the positive agreement rate of the solution in identifying patients with inferior vena cava (IVC) filter using radiological reports, the number of cases identified that were eligible for IVC removal, the number of cases identified that were eligible for IVC removal and not currently scheduled and the number of IVC removal procedures that resulted from the solution case identification.

## RESULTS

NLP solution classified 225 reports as positive for the presence of an IVC filter. The positive agreement rate was 99.56% (224/225). On secondary review by 4 clinicians, 164 unique cases were identified. 51.2% (84/164) filters were not placed by IR, and 20.1% (33/164) filters were non-retrievable type. 4.3% (7/164) identified cases had IVC filter related major complications. In 20 months follow up 57.3% (94/164) of the identified cases were eligible for removal at time of the scan, however only 12.8% (12/94) of the filters removed and 87.2% (82/94) of the cases had not been followed or scheduled. Particularly, 45 filters had been present for at least 5 years and 30 out of these 45 filters were eligible for removal.

## CONCLUSION

The NLP based solution accurately identified patients with IVC filters using the radiological reports. A significant number of the patients that had IVC filters did not have clinical follow up or their filters removed despite eligibility.

## CLINICAL RELEVANCE/APPLICATION

This is the first report to evaluate the efficacy of IVC filter detection using the commercial product AIDOC. Using radiological reports, NLP has the potential to greatly enhance follow-up management for patients with IVC filters, not only at their home institutions but also for those whose filters were discovered incidentally.

## M5A-SPiR-5 Generative Learned Models for Synthesis of Realistic Soft-Tissue Deformable Motion with Controllable Magnitude in Interventional Cone Beam CT

### Participants

Alejandro Siniaga, PhD, Baltimore, MD (*Presenter*) Research Grant, Siemens AG; Research Grant, Micro-X Ltd; Research Grant, Izotropic Corporation

### PURPOSE

Cone-beam CT (CBCT) is a ubiquitous tool for guidance in interventional radiology, yet susceptible to motion artifacts from a combination of quasi-periodic motion and aperiodic, local, motion. Deep autofocus showed potential for compensation of deformable motion but requires large and diverse datasets of motion-corrupted CBCT, paired with the source motion, for training. Reliable simulation of complex motion remains an open challenge. This work reports a generative model for simulation of realistic deformable motion with controllable magnitude, via observation of unpaired, motion-corrupted data.

### METHODS AND MATERIALS

The generative model receives a motion-free volume as baseline anatomy, and a random perturbation, to synthesize a random, anatomy-aware 4-dimensional motion field. The model implements a variation of the CycleGAN architecture, with spatial transformers coupling the anatomical context to the spatiotemporal motion field. A customized GAN loss was designed to learn an amplitude control code (ACC) yielding controllable motion magnitude, and it was trained in an unsupervised fashion using solely motion-corrupted CBCT volumes. The model was exercised in a proof-of-concept study with (N=144) simulated CBCT including known motion, providing a controlled validation scenario before extension to clinical data. A test set with 594 motion fields was synthesized (9 anatomies, 6 random perturbations, and 11 amplitude control codes).

## RESULTS

Synthetic motion fields showed magnitude in line with the training set with median amplitude of 26 mm vs 32 mm in training (15 mm vs 17 mm IQR). The spatial distributions of synthetic motion agreed with underlying anatomy, with soft-tissue regions showing large motion distortion with a preference towards anterior parts of the anatomy (median 26 mm) and rigid regions around the spine remaining stationary (median 3.6 mm), in agreement with trends in training data. Variation of the ACC resulted in nearly linear increase in motion amplitude in soft-tissue regions with no significant variation of the spatial distribution. Variation of the random perturbation code resulted in different spatial allocation of motion but no change in magnitude for equivalent control codes.

## CONCLUSION

Random synthetic motion with anatomically realistic spatial distribution, amplitude, and direction was achieved with a learned generative model via observation of motion-corrupted CBCT. The proof-of-concept study opens the way to application of the model in clinical scenarios.

## CLINICAL RELEVANCE/APPLICATION

This work presents an unsupervised motion synthesis model able to generate anatomically-realistic motion vector fields, enabling the generation of large training datasets for development of deep autofocus methods.

## M5A-SPiR-6 Evaluating Artificial Intelligence for the Diagnosis of Acute PE

### Participants

Yifan Wang, MD, MS, New Haven, CT (*Presenter*) Nothing to Disclose

### PURPOSE

Pulmonary embolism (PE) is a severe medical condition, with a high mortality rate if left untreated. A pulmonary embolism response team (PERT) is a multidisciplinary group of providers that provide consultation and care to patients with PE. Artificial Intelligence (AI) has the potential to improve the care provided by a PERT team by notifying members of the team immediately about suspected cases and enabling appropriate therapies to occur in a timely fashion by assisting with the rapid coordination of care amongst a PERT. This study aims to evaluate cases identified by an AI solution across a health system. The health system studied is composed of a main campus (hub) that is capable of performing all current PE therapies and multiple other hospitals (spokes) within the system that can provide limited therapies for PE. This study assesses if AI can correctly identify PE cases of a significant risk stratification and those that may benefit from transfer from a spoke hospital to the hub hospital for additional care.

### METHODS AND MATERIALS

A retrospective cohort of patients at 3 spoke hospitals undergoing computed tomography pulmonary angiography (CTPA) between 01/2019 - 12/2020 was analyzed using an AI solution. A positive finding was defined as the AI solution detecting moderate to large central PE thrombi and a right ventricle to left ventricle (RV/LV) ratio greater than 1.3. CT parameters were obtained from

radiological interpretation and data on clinical PERT activation and interventions at each site were obtained by chart review. Metrics measured included the European Society of Cardiology (ESC) PE risk stratification score, PERT consultation, transfer of patients from a spoke-to-hub, and treatment strategy. The findings were compared to historical averages from the hub/main campus.

## **RESULTS**

A total of 43 cases from 3,787 CTPA scans were identified by the algorithm, of which 92.5% (37/40) were intermediate-high or high-risk PE based on the ESC risk stratification. Comparing spoke hospitals to the hub hospital, 55% (22/40) vs 100% (133/133) of the identified cases had a PERT consultation and 22% (9/40) versus 70% (93/133) of identified cases received an advanced therapy (catheter or surgical therapies, systemic thrombolytics or mechanical support). Only 5% (2/40) of the identified cases resulted in a spoke-to-hub transfer.

## **CONCLUSION**

s The use of AI may help optimize the coordination and care of PERT patients by correctly identifying intermediate and high-risk PE cases, those that may require a PERT consultation, and identifying patients who may benefit from transfer to a hub hospital for advanced therapies.

## **CLINICAL RELEVANCE/APPLICATION**

AI may have the ability to assist in detection of acute PE and coordination of care amongst clinicians across a health system.

M5A-SPMK

### Musculoskeletal Imaging Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPMK-1 Quantitative Study of Bone Marrow Edema Due to Acute Fractures with Dual-energy Spectral CT Imaging**

##### Participants

Yanan Zhu, Ankang, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To determine the utility of material density and CT attenuation value measurements in dual-energy spectral imaging for differentiating bone marrow edema due to acute bone fractures from the normal bone marrow.

##### METHODS AND MATERIALS

24 patients who presented with acute fractures from November 2017 to March 2018 underwent dual-energy spectral CT imaging on a 16cm wide-detector CT scanner. The virtual monochromatic images and water-calcium material decomposition (MD) images were reconstructed. The monochromatic CT images with color-coded water-calcium MD image overlay were reviewed by two radiologists to identify bone fractures and the associated bone marrow edema. The CT attenuations and water(calcium) concentrations were measured from the CT images and water(calcium) MD images, respectively for bone marrow edema and normal bone marrow. Receiver operator characteristic (ROC) curve analysis was used to determine the diagnostic accuracies of these measurements.

##### RESULTS

The water(calcium) concentrations ( $1040.28 \pm 33.55 \text{ mg/cm}^3$ ) in the areas with bone marrow edema were significantly higher than in the normal bone marrow ( $1011.11 \pm 45.83 \text{ mg/cm}^3$ ) ( $p < 0.001$ ). The CT attenuation values in the 70keV images were  $210.18 \pm 108.63 \text{ HU}$  and  $133.44 \pm 134.06 \text{ HU}$  in the areas with bone marrow edema and with normal bone marrow, respectively ( $p < 0.001$ ). The Area under the curve (AUC) for ROC analysis using the water(calcium) concentration was 0.771, significantly higher than the value of 0.719 using the CT attenuation measurement ( $p < 0.05$ ).

##### CONCLUSION

The measurement parameters, especially the water(calcium) concentration measurement in bone marrow obtained in the dual-energy spectral CT imaging, have high accuracy in differentiating bone marrow edema from normal bone marrow.

##### CLINICAL RELEVANCE/APPLICATION

Dual-energy spectral CT imaging provided a novel and accurate method to quantitatively evaluate the bone marrow edema due to acute bone fractures.

#### **M5A-SPMK-2 The Use of Monochromatic CT Images Overlaid with Water-calcium Material Decomposition Images in Dual-energy Spectral Imaging for Identifying Bone Marrow Edema Due to Acute Bone**

##### Participants

Yanan Zhu, Ankang, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To determine the utility of identifying bone marrow edema due to acute bone fractures using the monochromatic CT images overlaid with color-coded water-calcium material decomposition (MD) images in dual-energy spectral imaging.

##### METHODS AND MATERIALS

24 patients who presented with acute bone fractures underwent dual-energy spectral imaging on a 16cm wide-detector CT scanner from November 2017 to March 2018. The virtual monochromatic images and water-calcium MD image pairs were reconstructed. The monochromatic CT images overlaid with color-coded water-calcium images were reviewed by two radiologists, and the fractures and associated bone marrow edema were identified. The CT attenuations and water(calcium) concentrations of the areas with bone marrow edema and with normal bone marrow were measured from the CT images and water(calcium) MD images, respectively. These values were compared with paired t-test. Kappa values were calculated between the two readers on the identification of the areas with and without bone marrow edema.

##### RESULTS

There was bone marrow edema associated with every bone fracture and the overlay images had higher confidence and clarity to identify the areas of edema than the CT images alone. The Kappa value was 0.878 between the two readers on the identification of the areas with and without bone marrow edema on color-coded water-calcium images. The water(calcium) concentrations ( $1040.28 \pm 33.55 \text{ mg/cm}^3$ ) in the areas with bone marrow edema were significantly higher than in the normal bone marrow area ( $1011.11 \pm 45.83 \text{ mg/cm}^3$ ) ( $p < 0.001$ ). The CT attenuation values in the 70keV images were  $210.18 \pm 108.63 \text{ HU}$  and  $133.44 \pm 134.06 \text{ HU}$  in the areas with and without bone marrow edema, also had a significant difference between the two areas ( $p < 0.001$ ).

## CONCLUSION

s The monochromatic CT images overlaid with color-coded water-calcium images in dual-energy spectral CT imaging on a 16cm wide-detector CT is sensitive and quantitative to identify the bone marrow edema due to acute bone fracture.

## CLINICAL RELEVANCE/APPLICATION

The monochromatic CT images overlaid with water-calcium images in spectral CT can provide an alternative to MRI for detecting the bone marrow edema due to acute bone fractures.

## M5A-SPMK-3 Evaluation of Radiosynoviorthesis as a Palliative Treatment in Advanced Arthropathies

Participants

Marta Gallego Verdejo, MD, Valladolid, Spain (*Presenter*) Nothing to Disclose

## PURPOSE

Radiosynoviorthesis consists of intra-articular injection of radionuclides to achieve a local therapeutic action in patients with chronic or resistant arthropathies in whom other treatments have failed. This study aims to demonstrate the effectiveness of radiosynoviorthesis in treating chronic synovitis at three levels: clinical, functional, and radiological. Additionally, it will study the safety of the technique.

## METHODS AND MATERIALS

It is a descriptive and retrospective study with a multidisciplinary approach (radiology, radiophysics and nuclear medicine). The current sample consists of 15 patients referred for treatment with radiosynoviorthesis from various hospitals between 2019 and 2022. However, we expect to expand to 30 patients in the coming months, when the controls will be carried out. Each patient is evaluated before and after treatment using a pain visual analog scale (VAS) from 0 (no pain) to 10 (maximum pain) and a functionality scale depending on the treated articulation. Immediately after the puncture, scintigraphy is performed to assess the adequate distribution of the radionuclide in the joint. Also, an ultrasound control is performed before and approximately 3 months after radiosynoviorthesis.

## RESULTS

In preliminary results, the mean VAS score lessened from 7.07 before radiosynoviorthesis to 3.47. Similarly, they show an upgrade in the functional scale from 41.47 % to 70.06 % (values expressed as a percentage of the maximum score for each test). In addition, some patients have exhibited an improvement in synovial hyperemia in the ultrasound control, with a reduction in effusion and synovial thickening. Furthermore, it has been confirmed that it is a safe technique, with a low incidence of complications in the treatments performed.

## CONCLUSION

s Radiosynoviorthesis (RSO) is a good treatment for patients with chronic or resistant pathology of the synovial membrane in whom the first lines of treatment have not been effective. It brings improvements at the clinical and functional levels, with a reduction in ultrasound synovitis signs in some patients. It also has a low complication rate, which makes it an effective and safe alternative in the treatment of chronic arthropathies.

## CLINICAL RELEVANCE/APPLICATION

It is a safe procedure that can bring clinical and functional improvement to patients with limiting arthropathies that can substantially improve their quality of life.

## M5A-SPMK-4 Optimizing US-guided Lavage for Rotator Cuff Calcific Tendinitis: The Effect of Corticosteroids Injection Pre vs. Post-procedure

Participants

Miguel Barrio Piqueras I, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study is to determine whether the pre or post-procedure injection of corticosteroids during US-guided lavage of rotator cuff calcific tendinitis affects the outcome.

## METHODS AND MATERIALS

At our institution, 124 patients with calcific tendinitis of the rotator cuff were treated with US-guided lavage between 2020 and 2021. In 71 patients, a corticosteroid was injected into the subacromial bursa following the lavage (corticosteroid-after group). The remaining 53 patients (corticosteroid-before group) received the injection before undergoing the procedure. Characteristics of calcification were recorded in terms of number, size, location and type according to Gartner and Hayer's classification. Other variables assessed were calcium extracted, number of adverse events and follow-up. Data were analysed using SPSS 25.0 software, and a p-value < 0.05 was considered statistically significant.

## RESULTS

Both groups showed no significant differences regarding sex ( $p = 0.612$ ) or age ( $p = 0.883$ ). The only reported adverse effect was vasovagal syncope in 7 patients (13.2%) in the corticosteroid-before group and 11 patients (15.5%) in the corticosteroid-after group ( $p = 0.721$ ). The percentage of patients in which a significant amount of calcium was extracted was similar in both groups (54.7% vs 54.9%;  $p = 0.981$ ). The type of calcification was the only factor that showed a statistical association with this outcome (68.5% for type 1 and 2 calcifications; 20% for type 3 calcifications;  $p < 0.01$ ). Finally, the number of patients who required further intervention during follow-up was 23 (43.4%) in the corticosteroid-before group and 41 (57.7%) in the corticosteroid-after group ( $p = 0.943$ ).

## CONCLUSION

s Administration timing of corticosteroid injection before or after calcium deposit removal does not impact treatment outcomes or incidence of adverse effects. Both approaches are equally effective, (however, US guidance should always be recommended to ensure accurate placement and prevent potential complications).

## CLINICAL RELEVANCE/APPLICATION

The order in which this procedure is performed has been arbitrary, with no comprehensive study conducted on the optimal approach. Our study suggests that patients exhibit similar tolerance levels regardless of the treatment sequence.

### M5A-SPMK-5 Intra-articular Injections of the Foot: An Evaluation of Physician Ordering Practices of Ketorolac and Kenalog

#### PURPOSE

Intra-articular steroid injections are widely utilized to provide therapeutic relief and diagnostic evaluation of foot pain. Nonsteroidal anti-inflammatory injectants may offer a safer profile and have been shown to provide similar levels of pain relief as steroids. This study sought to evaluate physician preferences for injection agents for intra-articular foot injections.

#### METHODS AND MATERIALS

An IRB-approved retrospective review was performed using radiology data mining system (Nuance mPower) to identify patients who received intra-articular foot injections from 2011-2023 at a single academic institution. Study participants were eligible if they received an image-guided foot injection and divided into two cohorts: 1) injection with Kenalog and 2) injection with ketorolac. Demographics, BMI, diagnosis, site, agent, pre and post pain scores, treatment history, and ordering provider were recorded. The Visual Analogue Scale was used to collect the pain score. The difference between the pre and post pain scores determined the delta pain score. The Mann-Whitney U test was used to compare the delta pain score between the cohorts. Categorical variables were compared using Pearson's chi-square test.

#### RESULTS

Forty one of the 182 injections were with ketorolac. Eighty four percent of the patients were female and the average age was 65.5 years-old. Fifty percent of patients had a BMI =30. Osteoarthritis was the most common diagnosis for Kenalog and ketorolac injections (95% and 51%, respectively,  $p<0.01$ ) while the tarsometatarsal joints were the most common sites for both cohorts (82% and 37%, respectively,  $p<0.01$ ). Out of the four ordering providers identified, Provider 1 ordered ketorolac for 85% of the injections and Provider 2 ordered Kenalog for 91% of the injections ( $p<0.01$ ). Sixty seven percent of patients who received a kenalog injection and 3% of patients who had ketorolac injections required serial injections ( $p<0.01$ ). Twenty one percent of cohort 1 and 34% of cohort 2 underwent surgery after injections ( $p=0.26$ ). The mean delta scores reported for the Kenalog cohort and ketorolac cohort were -4 and -1, respectively ( $p<0.01$ ).

#### CONCLUSION

s There was a clear preference in the type of agent ordered by each provider without a significant difference in post-injection surgical treatment rates. In recent years, there was an increase in usage of ketorolac and for a wider range of injection sites and diagnoses compared to Kenalog. Future studies could quantitate efficacy of intra-articular injections for foot pain by injectant.

## CLINICAL RELEVANCE/APPLICATION

Ketorolac is a low-cost option for diagnostic and therapeutic intra-articular injections of the foot that offers a safety profile comparable to steroids, without significant differences in outcomes.

### M5A-SPMK-6 Quantitative DWI Assessment of Changes in Graft Maturity at 6 and 12 Months after Anterior Cruciate Ligament Reconstruction and Correlation with Clinical Scores

Participants  
Feiyuan Zhang, Shenzhen, China (*Presenter*) Nothing to Disclose

#### PURPOSE

To quantify the status of graft remodeling using DWI functional MRI at 6 and 12 months after anterior cruciate ligament reconstruction (ACLR) and its correlation with the corresponding clinical function score.

#### METHODS AND MATERIALS

Forty-four patients who underwent ACLR between August 2020 and October 2021 and fifteen volunteers were recruited prospectively. Patients underwent 3.0T conventional MRI and DWI scans in 6 and 12 months after ACLR to measure ADC values of the intra-articular segment graft and its three segments (proximal, middle, and distal). IKDC, Lysholm scores were performed at each time point. Differences between 6 and 12 months postoperatively in ADC changes were compared using the Wilcoxon test. Correlation between ADC values of the intra-articular segment of the graft and clinical scores (IKDC, Lysholm score) in 6 and 12 months was analyzed using the Pearson correlation coefficient.

#### RESULTS

ADC values for the overall intra-articular segment of the ACL graft and its three parts (proximal, middle, and distal) decreased significantly from 6 to 12 months ( $P < 0.05$ ). There was no significant correlation between the ADC values of the grafts and the clinical scores (IKDC, Lysholm scores) at 6 and 12 months postoperatively. The ADC values of the distal segment of the intra-articular segment of the graft were higher than those of the middle and proximal segments at 6 months postoperatively ( $P < 0.05$ ), while the ADC values of the three segments in 12 months were similar.

#### CONCLUSION

s The graft continued to mature from 6 months to 12 months after ACLR. The ADC values measured by the graft decreased but were not consistent with clinical function scores, suggesting that DWI and ADC are a finer reflection of changes in graft maturity than clinical scores.

## CLINICAL RELEVANCE/APPLICATION

DWI can indicate the change of graft maturity and guide the recovery time of ACLR patients after surgery.

### M5A-SPMK-7 Metal Suppression Using a New Generation Low-Field MRI; In Vitro Assessment in a Pig Knee Model

#### PURPOSE

To evaluate the artifact size reduction using a metal artifact correction (SEMAC) sequence at 0.55T and 3T in porcine knee specimens with metal hardware compared to standard sequences. This study aims to assess the feasibility of metal suppression on a novel 0.55T system, to optimize the pulse sequence parameters and to compare them with imaging at 3T as standard of reference.

## **METHODS AND MATERIALS**

Steel and titanium screws with 2.2mm diameter were implanted in 12 porcine knee specimens before imaging at 0.55T (Siemens Free.Max) and 3T (Siemens Vida) MRI using turbo spin echo (TSE), view angle tilting (VAT factor 50 and 100), and combined VAT and SEMAC (VAT100+SEMAC) in proton-density (PD) and T2 short TI inversion recovery (STIR) TSE pulse sequences. Sizes of metal artifacts were measured, and the visualization of the bone and cartilage, cruciate ligaments, joint effusion, and growth plate close to the metal artifact as well as the overall image quality, were assessed using a 5-point Likert scale. Wilcoxon-signed-rank tests were performed to determine the differences in image quality between 0.55T and 3T MRI.

## **RESULTS**

The size of the metal artifacts for titanium was smaller in normal PD ( $p=0.002$ ), PD VAT100 ( $p=0.019$ ), PD VAT100+SEMAC ( $p=0.01$ ), and T2 STIR VAT50 ( $p=0.04$ ) at 0.55T MRI compared to 3T MRI. For stainless steel screws, almost all sequences showed smaller artifact sizes using 0.55T compared to 3T MRI ( $p<0.001$  for PD, PDVAT50/100, PD VAT100+SEMAC, T2 STIR VAT50/100, T2 STIR VAT100+SEMAC), only in T2 STIR no difference could be found. Close to stainless steel screws, the visualization of the growth plate and the bone was significantly better at 0.55T MRI in all sequences ( $p<0.001$ ). Results from PD with VAT100 and PD VAT100+SEMAC showed better visualization of growth plates close to the titanium screws at 0.55T MR compared to 3T MRI. For all other sequences, the visualization of the growth plates did not differ close to titanium screws between both systems. PD VAT100+SEMAC, PDVAT100, and standard T2 STIR FSE sequences showed better image quality at 0.55T compared to 3T MRI. For all other sequences (PD, PDVAT50, T2 STIR 50/100, TS VAT100+SEMAC), the image quality did not differ between field strengths.

## **CONCLUSION**

Our results show that imaging of metal hardware using a novel 0.55T MRI system, in particular, if combined with SEMAC techniques, especially by using factor VAT50, is superior compared to 3T MRI. The visualization of anatomical structures at 0.55T MRI is not inferior compared to 3T MRI.

## **CLINICAL RELEVANCE/APPLICATION**

New generation low-field MRI at 0.55T reduces metal artifacts in musculoskeletal imaging, leading to improved visualization of potential hardware complications and thus enhancing patient care.

## **M5A-SPMK-8 Impact of Weight Loss on Knee Joint Synovitis over 48 months and Mediation by Local Subcutaneous Fat: Data from the Osteoarthritis Initiative**

### **Participants**

Maximilian Loeffler, MD, San Francisco, Germany (*Presenter*) Nothing to Disclose

### **PURPOSE**

Synovitis and joint effusion are characteristics of the inflammatory phenotype of osteoarthritis (OA). Weight gain promoted the development of synovitis in a previous study. The purpose of this study was to investigate the effect of weight loss on synovitis progression and to assess whether subcutaneous fat (SCF) around the knee mediates the relationship between weight loss and synovitis progression.

## **METHODS AND MATERIALS**

We included 234 overweight and obese participants (BMI  $\geq 25$  kg/m<sup>2</sup>) from the Osteoarthritis Initiative (OAI) with  $>10\%$  weight loss ( $n=117$ ) or stable overweight ( $<\pm 3\%$  change,  $n=117$ ) over 48 months matched for age and sex. Effusion-synovitis and Hoffa-synovitis using the MRI Osteoarthritis Knee Score (MOAKS) as well as SCF were assessed in unenhanced MRI studies at baseline and 48 months. Average joint-adjacent SCF (ajSCF) was calculated as the arithmetic mean of medial, lateral, and anterior SCF measurements. Odds-ratios (ORs) for synovitis progression over 48 months ( $=1$  score increase) were calculated in logistic regression models adjusting for age, sex, baseline BMI, Physical Activity Scale for the Elderly (PASE), and baseline SCF measurements. Mediation of the effect of weight loss on synovitis progression by a pathway through local SCF change was assessed.

## **RESULTS**

The odds for effusion-synovitis progression decreased with weight loss and ajSCF decrease (OR=0.61 and 0.56 per standard deviation [SD] decrease, 95%-confidence interval [CI] 0.44-0.83 and 0.40-0.79,  $p=0.002$  and 0.001, respectively). In contrast, the odds for Hoffa-synovitis progression increased with weight loss and ajSCF decrease (OR=1.47 and 1.48 per SD decrease, CI 1.05-2.04 and 1.02-2.13,  $p=0.024$  and 0.038, respectively). Decrease in ajSCF mediated 39% of the effect of weight loss on effusion-synovitis progression.

## **CONCLUSION**

Effusion-synovitis progression was slowed by weight loss and decrease in local subcutaneous fat. Hoffa-synovitis characterized by fluid in the infrapatellar fat pad increased at the same time, suggesting a decreasing fat pad rather than active synovitis. Decrease in local subcutaneous fat partially mediated the systemic effect of weight loss on synovitis progression.

## **CLINICAL RELEVANCE/APPLICATION**

Local subcutaneous fat around the knee that can be easily measured in unenhanced MRI influences the progression of effusion-synovitis. Signal alterations in Hoffa's fat pad are non-specific for synovitis and should be interpreted with caution, particularly, in patients with weight loss.

## **M5A-SPMK-9 Outcomes and Surgical Revision of Meniscus Allograft Transplant**

### **PURPOSE**

To evaluate factors influencing outcomes of meniscal allograft transplant as measured by both patient reported outcomes and

complications requiring surgical revision of the meniscus.

## **METHODS AND MATERIALS**

Patients undergoing meniscal allograft transplant between 2002 and 2022 at one institution were reviewed. Patient reported outcomes were measured as symptom and function scores via written survey during clinic visits and surgical revision of the meniscus following transplant was recorded. Surgical revision of the transplanted meniscus included meniscectomy, revision transplant, and joint arthroplasty. Univariate and multivariate analyses were performed to evaluate the effect of various prognostic factors on these two outcome measures.

## **RESULTS**

81 patients were evaluated (median age 25 years, interquartile range 18-34, 44 patients were men). Patients showed a mean improvement in symptom score post-transplant of  $1.26 \pm 1.84$  ( $p < 0.001$ ). Patients without associated non-meniscal knee injuries showed a symptom improvement of  $2.26 \pm 1.66$  compared to  $0.83 \pm 1.87$  for those with these injuries ( $p = 0.006$ ). Interval time from meniscectomy to transplant was shown to have a spearman correlation coefficient of  $-0.293$  (95% CI  $-0.500$  to  $-0.051$ ,  $p = 0.017$ ) for symptom score improvement and  $-0.247$  (95% CI  $-0.462$  to  $-0.002$ ,  $p = 0.047$ ) for function score improvement. On multivariate analysis, age  $< 25$  years at the time of meniscectomy was found to be associated with increased need for post-transplant revision surgery (OR 0.18, 95% CI 0.03 - 0.96,  $p = 0.045$ ), as was post-transplant reinjury (OR 10.39, 95% CI 2.52 - 42.92,  $p = 0.001$ ).

## **CONCLUSION**

Meniscal transplant provides symptomatic improvement for patients, which may be limited by the presence of concomitant non-meniscal injuries and increased time between meniscectomy and transplant. Age  $< 25$  years and reinjury are associated with increased likelihood of revision surgery following transplant, likely due to initial traumatic injury or traumatic reinjury.

## **CLINICAL RELEVANCE/APPLICATION**

Meniscal allograft transplant is an increasingly used option for treating meniscal injury to preserve long term function of the knee. Previous studies have varied in choice of outcome measure, failure criteria, and sample size.

M5A-SPMS

### Multisystem Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPMS-1 Quantitative Assessment of Activity in Idiopathic Inflammatory Myopathy by Magnetic Resonance Image Complication (MAGiC)**

#### Participants

Zhaorong Tian, MD, Yinchuan, China (*Presenter*) Nothing to Disclose

#### PURPOSE

The study explored the feasibility of using Magnetic resonance image compilation (MAGiC) parameters to quantitatively evaluate changes of thigh muscles in idiopathic inflammatory myopathy (IIM), in order to provide a quantitative index for the evaluation of thigh muscle inflammatory activity in IIM. And to investigate the correlation between thigh muscle T1,T2 values and serum creatinine kinase (CK).

#### METHODS AND MATERIALS

Seventy patients with IIM proven by diagnostic criteria were enrolled in the study along with 30 healthy control subjects. According to clinical findings according to the International Myositis Assessment and Clinical Studies Group (IMACS), the 70 patients were divided into an active group (41 cases) and an inactive group (29 cases). All subjects were scanned using a SIGNATM Architect 3.0T MRI scanner by T1WI, FS-T2WI and MAGiC sequence of the thigh muscle. Two radiologists with 10 years of experience in musculoskeletal system diagnosis measured the T1, T2 values of active group, the inactive group, and the healthy control group thigh muscles on the Magic axial image. The T1,T2 values of thigh muscles in the active, inactive, and healthy groups were compared using one-way analysis of variance (ANOVA). Receiver operating characteristic (ROC) curves were used to analyze the diagnostic efficacy of T1,T2 values for activity of idiopathic inflammatory myopathy. A Spearman correlation coefficient model was used to correlate the mean T1,T2 values of thigh muscle with CK.  $P < 0.05$  was considered statistically significant.

#### RESULTS

The T1 values ( $516.11 \pm 82.42$ )ms in the active group of IIM were lower than those in the inactive group ( $794.24 \pm 84.38$ )ms, lower than those in the healthy control group ( $1184.73 \pm 178.23$ )ms, ( $T = -10.693$ ,  $p < 0.001$ ); T2 values of active groups in IIM ( $93.84 \pm 17.15$ )ms, were higher than inactive groups ( $65.07 \pm 9.7$ )ms, higher than those in the healthy control group ( $45.24 \pm 6.7$ )ms, ( $T = -10.013$ ,  $p < 0.001$ ). The areas under the ROC curves (AUCs) of T1,T2 values between the active and inactive groups of IIM,  $0.921$  (95%CI,  $0.846-0.967$ ),  $0.963$  (95%CI,  $0.912-0.993$ ), respectively. The T1,T2 values of thigh muscles in the IIM were positively correlated with CK, and the correlation coefficients ( $r$ ) were  $0.946$ ,  $0.969$  (all  $p < 0.001$ ), respectively.

#### CONCLUSION

MAGiC parameters can be used to quantitatively assess the activity of IIM, but also be used to demonstrate severity of damaged muscles in IIM, and T2 values can serve as a potential biomarker of disease activity. MAGiC provided imaging bases for the clinical diagnosis of IIM.

#### CLINICAL RELEVANCE/APPLICATION

MAGiC parameters can be used to quantitatively assess the activity and severity of damaged muscles of IIM, provided imaging bases for the clinical diagnosis of IIM.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

M5A-SPNMMI

### Nuclear Medicine & Molecular Imaging Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPNMMI-1 Association Between Severity of Heart Failure<Myocardial Amyloid Deposition on 99mTc pyrophosphate Scintigraph<Echocardiography in Patients with Familial Amyloid Polyneuropathy**

##### Participants

Hiroshi Kanaya, Kumamoto, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

We investigated the relationship between heart failure severity and myocardial amyloid deposition in patients with familial amyloid polyneuropathy (FAP) using 99mTc-pyrophosphate (PYP) scintigraphy and echocardiography.

##### METHODS AND MATERIALS

Subjects were 71 cases diagnosed with FAP by histopathological diagnosis and genetic testing. Ejection fraction (EF), brain natriuretic peptide (BNP), and cardiac troponin T (TnT) were used as indexes of severity of heart failure. Echocardiography and PYP scintigraphy were performed within 3 months of the blood test. In PYP scintigraphy, the heart to contralateral (H/CL) ratio was calculated in planar image. Pearson's correlation coefficient was calculated for the relationship between the index of the severity of heart failure and the H/CL ratio, also echocardiogram index such as interventricular septum thickness in diastole (IVSTd), posterior wall thickness in diastole (PLVWd) and the ratio of mitral velocity to early diastolic velocity of the mitral annulus (E/e').

##### RESULTS

IVSTd, E/e' and H/CL ratio had significant correlation with EF ( $r=-0.36$ ,  $p<0.01$ ,  $r=-0.34$ ,  $p=0.01$ ,  $r=-0.31$ ,  $p=0.01$ , respectively). IVSTd, PLVWd, E/e' and H/CL ratio showed significant correlation with BNP ( $r=0.47$ ;  $p<0.01$ ,  $r=0.52$ ;  $p<0.01$ ,  $r=0.43$ ;  $p=0.01$ ,  $r=0.39$ ;  $p<0.01$ , respectively). IVSTd and PLVWd had significant correlation with TnT ( $r=-0.3$ ;  $p=0.02$ ,  $r=-0.46$ ;  $p<0.01$ , respectively). In addition, in patients with H/CL ratio  $> 1.3$ , H/CL ratio was not significantly correlated with any heart failure index.

##### CONCLUSION

s Echocardiographic indices, especially IVSTd, may serve as indices of heart failure, whereas H/CL ratio may not.

##### CLINICAL RELEVANCE/APPLICATION

H/CL ratio on PYP scintigraphy is a useful index for the diagnosis of ATTR-CM, but it may not serve as indices of heart failure.

#### **M5A-SPNMMI-2 Diagnostic Potential of TID Ratio in 13N-Ammonia PET Imaging: Differentiating INOCA from Multivessel CAD**

##### Participants

Midori Fukuyama, MD, Osaka, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Adenosine stress 13N-Ammonia PET (Ammonia PET) is a valuable tool for evaluating both myocardial blood flow reserve (MFR) and cardiac function. It is especially useful for diagnosing multivessel coronary artery disease (Multivessel CAD) by measuring MFR. Ischemia with non-obstructive coronary artery disease (INOCA), one of the chronic coronary syndromes, is increasingly recognized as a risk factor for adverse cardiovascular mortality and outcomes. It is difficult to distinguish between INOCA and Multivessel CAD based on MFR alone because MFR is similarly reduced to less than 2.0 in both. Transient ischemic dilatation (TID) ratio is a useful marker of adverse outcomes on myocardial perfusion imaging in severe and extensive CAD. The usefulness of TID during Ammonia PET in INOCA patients has not been reported. We aimed to evaluate the diagnostic potential of TID ratio and other markers in differentiating INOCA from Multivessel CAD using Ammonia PET.

##### METHODS AND MATERIALS

A retrospective analysis was conducted on 86 patients (47 males, 39 females; median age 73) who underwent rest/ adenosine stress-gated Ammonia PET for known or suspected CAD. Using a commercial-used software program, dynamic scanning measured myocardial blood flow (MBF) and MFR. Patients with global MFR $>2.0$  and no evaluation of epicardial coronary artery within three months before or after Ammonia PET were excluded. Seven INOCA patients and 21 Multivessel CAD patients with more than 50% stenosis were included in the final analysis. TID and LV functions were compared between INOCA and Multivessel CAD.

##### RESULTS

No significant differences were detected in rest MBF and MFR between INOCA and Multivessel CAD (1.16 vs. 0.99, 1.52 vs. 1.70, respectively). Although the left ventricular ejection fraction (LVEF) of both INOCA and Multivessel CAD groups were within the normal range, there was a significant difference in rest/ adenosine stress LVEF (78 vs. 65;  $p = 0.008$ , 75 vs. 61;  $p = 0.015$ ). TID was significantly greater in INOCA than in Multivessel CAD (1.29 vs. 1.11;  $p = 0.026$ ). Based on the ROC analysis for identifying INOCA, a TID threshold of 1.22 could predict INOCA (AUC=0.69, sensitivity 95%, specificity 57%, accuracy 85%).

## **CONCLUSION**

s The TID ratio obtained from adenosine stress Ammonia PET was significantly higher in INOCA patients than in Multivessel CAD patients. Patients with global MFR less than 2.0, TID ratio could be a valuable tool to distinguish INOCA from Multivessel CAD.

## **CLINICAL RELEVANCE/APPLICATION**

Transient ischemic dilatation (TID) in rest/ adenosine stress-gated  $^{13}\text{N}$ -Ammonia PET was more significantly observed in Ischemia with non-obstructive coronary artery disease (INOCA) than in Multivessel CAD. TID ratio can assist in distinguishing INOCA from Multivessel CAD.

M5A-SPNPM

### Noninterpretive Skills (Beyond Imaging) Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPNPM-1 Flipping Education Right Side Up: A Multiyear Assessment of Flipped Classroom Teaching Versus Traditional Didactic Teaching at Two Academic Institutions**

Participants  
Michelle Ho, MD, Seattle, WA (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Traditional radiology education consisting of didactic lectures and workstation readout is associated with poor retention of knowledge. Flipped classroom teaching may be more efficient and effective. At our institution (A), flipped classroom teaching has been used consistently for PGY2 residents on one rotation (FR). While on this rotation, residents are assigned daily teaching topics with pre-recorded lectures followed by in-person discussion of related clinical cases. This forces residents to integrate learned concepts and allows faculty to assess areas of weakness. The purpose of this study is to assess the effectiveness of flipped classroom teaching by comparing resident performance on RadExam for FR compared to other core rotations at Institution A, and to resident performance at another similar institution (B), where flipped classroom is not used.

#### **METHODS AND MATERIALS**

RadExam scores from 5 different PGY2 level core rotations (body imaging, emergency, musculoskeletal, neuro, and thoracic) were collected at both institutions from 7/1/2018 to 4/30/2020. At Institution A, the flipped classroom teaching model has been used consistently for one of the above core rotations (FR). The other rotations are referred to as traditional rotations (TR) 1 through 4. The rotation names are anonymized for privacy per data use requirement. Exam scores at institution A were compared using one-way ANOVA. Exam scores between institutions A and B were compared using factorial ANOVA. Survey scores for residents' perception of educational value and efficient use of time for above rotations at institution A were also compared.

#### **RESULTS**

There was significant difference in resident exam scores between rotations at institution A ( $p=0.005$ ) but no difference between the two institutions ( $p=0.7$ ). Residents at institution A performed better on FR than other rotations except for TR4 (Table and Figure). The perceived educational value of FR was higher compared to TR (4.96 vs 4.85,  $p=0.017$ ). No difference was observed in perception of efficient use of time between FR and TR (4.79 vs 4.66,  $p=0.11$ ).

#### **CONCLUSION**

Flipped classroom teaching is at least as effective as traditional teaching model and it is associated with better resident performance on standardized exams at one institution. It is also associated with higher perceived educational value.

#### **CLINICAL RELEVANCE/APPLICATION**

Flipped classroom teaching may increase efficiency in teaching while minimizing interruptions in clinical work, and may improve overall competency of radiology residents and their morale.

#### **M5A-SPNPM-2 Multicriteria Decision Analysis Comparing Gadolinium Based Contrast Agents for Use in Contrast Enhanced Magnetic Resonance Imaging: A Novel Tool in Benefit Risk Assessment**

Participants  
Robert McDonald, MD, PhD, Rochester, MN (*Presenter*) Consultant, General Electric Company; Research Grant, General Electric Company; Consultant, Bracco Group

#### **PURPOSE**

To compare the benefit-risk balance of all currently available FDA-approved GBCAs using a multicriteria decision analysis (MCDA) model to determine if certain agents provide more favorable benefit-risk balance than others in clinical use.

#### **METHODS AND MATERIALS**

An expert panel developed a MCDA model based on two benefits (relaxivity @ 1.5T and pharmacokinetics) and six safety effects (NSF cases, retained Gd in CNS tissues, and rates of physiologic reactions and mild, moderate, and severe hypersensitivity reactions). After scoring, weighted averages of preference scores for the eight criteria were used to give overall preference values for each GBCA in the MCDA model. The usability of the model was tested using 13 diverse clinical scenarios, 5 of which are detailed below.

#### **RESULTS**

For routine adult patients, and those requiring mitigation of hypersensitivity reactions, preference values were driven by hypersensitivity and physiologic reaction rates: gadodiamide=95, gadopentetate=82, gadobutrol=68, gadoterate=48, gadobenate=34, gadoteridol=4. For patients requiring repeated GBCA doses over a longer timeframe in the detection of

subtle/nascent disease preference values were driven by mitigation of Gd tissue retention and relaxivity: gadobenate=73, gadobutrol=55, gadoterate=38, gadodiamide=31, gadoteridol=30, gadopentetate=24. For patients with severely compromised renal function, preference values were driven by mitigation of NSF risk: gadobenate=82, gadoterate=82, gadobutrol=76, gadoteridol=70, gadodiamide=25, gadopentetate=21. For patients requiring hepatobiliary imaging, preference values were driven by pharmacokinetics and relaxivity: gadoxetate=66, gadobenate=44, gadodiamide=35, gadobutrol=29, gadopentetate=29, gadoterate=21, gadoteridol=6.

## CONCLUSION

s The benefit-risk profiles for all FDA-approved GBCAs were found to be comparable and all had favorable benefit-risk ratios in many common clinical scenarios. However, depending on patient-centered characteristics and clinical needs, the relative ranking of these benefit-risk ratios varied. MCDA results provide insights in the identification of clinical scenarios/situations where use of specific GBCAs is warranted due to greater clinical benefits or diminished risks of undesirable effects. These results demonstrate the complexity and multimodal mechanisms underlying the clinical decision making necessary in diagnostic imaging.

## CLINICAL RELEVANCE/APPLICATION

Decision analysis models are commonly used by regulatory agencies to compare benefits and risks of similar prescribed agents. MCDA models are helpful in making patient-centered decisions about GBCA use and can optimize clinical decision making and health care delivery in radiology.

## M5A- SPNPM-3 Impact Analysis of Primary and Secondary Research in Radiology Journals

Participants

Mohamed Ibrahim, MD, Birmingham, AL (*Presenter*) Nothing to Disclose

## PURPOSE

Primary and secondary studies are considered the two major research categories. In this study, we examined the scientific and social media impact of primary and secondary publication types in papers published radiological journals during 2010-2020

## METHODS AND MATERIALS

PubMed publication type tags were used to filter original articles and systematic review and meta-analysis (SR/MA) articles. Clarivate Web of Science was utilized to obtain a list of all radiology journals from the category "Radiology, Nuclear Medicine and Imaging" in Science Citation Index Expanded (SCIE). Automated approach was developed for programmatic extraction of bibliometric and Altmetric yearly citations of each included article using Dimensions API and Altmetric API with Python. Statistical analysis was performed to compare the citation rates between primary and secondary research articles.

## RESULTS

A total of 96,684 published articles from 2010 to 2020 were identified and their meta-data collected. The mean 2-year citation count following publication year was 5.8 for primary research and 10.2 for SR/MA articles ( $p<0.001$ ). Between 2010 and 2020, the mean number of citations per SR/MA article was 51.3 compared to 30.5 per primary research article ( $p<0.001$ ). Mean Altmetric score was 8.2 in SR/MA compared to 3.7 for primary research articles ( $p<0.001$ ).

## CONCLUSION

s Secondary research studies have been increasing in impact in both academia and social media compared to primary research. Our results highlight the importance and impact of systematic reviews and meta-analysis articles as a scientifically influential study type in radiology.

## CLINICAL RELEVANCE/APPLICATION

The study focuses on the impact and influence of different types of research publications in radiology, and highlights the increasing importance of systematic reviews and meta-analyses as influential types of research publications. The findings suggest that prioritizing secondary research studies in future research agendas may be valuable. The study also demonstrates the potential of bibliometric and Altmetric analysis in evaluating the impact of scientific research publications, which can provide valuable insights into the impact of research on both academia and the wider public. Overall, this study has implications for researchers, clinicians, and policymakers in radiology and can inform the development of research strategies and priorities in this area.

## Abstract Archives of the RSNA, 2023

M5A-SPNR

### Neuroradiology Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPNR-1 Dynamic Functional Connectivity Alterations Associated with Cognitive Impairment in Patients with Type 2 Diabetes**

##### **PURPOSE**

The purpose of this study was to explore the change characteristics and differences of dynamic functional connectivity in type 2 diabetes patients with and without mild cognitive impairment by use of resting state functional magnetic resonance imaging (rs-fMRI).

##### **METHODS AND MATERIALS**

The research consisted of 45 healthy controls (HC) and 102 patients with T2 diabetes (T2). The patients with T2 diabetes were split into two groups based on the presence or absence of mild cognitive impairment, named T2-NC group (n=62) and T2-MCI group (n=40) separately. Thirty-nine components were selected by group independent component analysis (ICA) to construct 7 functional networks. Based on the sliding window method and k-means clustering, changes in dynamic functional connectivity between groups were analyzed and characteristic parameters were compared, while the correlations between characteristic parameters and cognitive performance were evaluated.

##### **RESULTS**

The whole cohort showed four kinds of dFC states: strong local connection state (state 1), extensive interconnection state (state 2), sparse connection state (state 3), and strong connection state (state 4). Compared with the control group, fractional time and mean dwell time of state 2 increased in T2 group, fractional time and mean dwell time decreased in state 4 in T2 group, the number of transitions between state 2 and state 4 reduced in T2 group. The changed dFC characteristics were significantly correlated with cognitive ability. When the statistical efficiency is 0.8 and there are 88 samples in each group, significant differences between T2-NC group and T2-MCI group can be observed.

##### **CONCLUSION**

Our findings indicated that the differences in dFC, which were associated with brain functional impairment due to T2D.

##### **CLINICAL RELEVANCE/APPLICATION**

The differences in dFC might be potential biomarkers for predicting the clinical progression, evaluating the cognitive impairment, and further understanding the pathophysiology of T2D.

#### **M5A-SPNR-10 Temporal and Topological Properties of Dynamic Networks Reflect Disability in Patients with Neuromyelitis Optica Spectrum Disorders**

##### **PURPOSE**

Increasing disability is accrued with each inflammatory attack in neuromyelitis optica spectrum disorders (NMOSD) together with functional network alterations. However, it remains unclear how functional networks relate to clinical disability status in NMOSD. Therefore, our study aims to explore the static strength, time-varying and topological properties within large-scale functional networks, and their associations with disability in NMOSD.

##### **METHODS AND MATERIALS**

A total of 30 NMOSD patients (37.70±11.99 years) and 45 healthy controls (HC, 41.84±11.23 years) were recruited for this retrospective study. All subjects underwent functional MRI and disability assessments. Using independent component analysis, we constructed resting-state networks for subjects, and evaluated between-group differences of static strength, temporal and topological properties of networks using analysis of variance, and their associations with disability by Spearman correlation. Receiver operating characteristic (ROC) curve also was performed to investigate whether abnormal measures could significantly differentiate NMOSD patients from HC.

##### **RESULTS**

Compared to HC, NMOSD patients showed significant alterations in the dynamic networks rather than static ones. Three dynamic states were defined, and State 1 is characterized by overall hypoconnectivity within and between networks. Compared to HC, NMOSD patients showed higher fraction time in State 1 (P<0.001) and more dwell time in it (P<0.001) with lower transitions (P=0.028), and related to higher disability (r=0.421, P=0.029; r=0.461, P=0.031; r=-0.383, P=0.049; respectively). ROC curve analysis indicated the fraction time and dwell time of State 1 could significantly distinguish NMOSD from HC (area under the curve: 0.991-0.996). Moreover, NMOSD patients also exhibited altered small-worldness, decreased degree centrality and clustering coefficients of hub nodes in dynamic networks (P<0.05, false discovery rate corrected). And decreased clustering coefficients of the bilateral precuneus (r=-0.387, P=0.046) and the thalamus (r=0.406, P=0.036) related to clinical disability in NMOSD patients.

##### **CONCLUSION**

s Higher fraction time and more dwell time with less transitions in hypoconnectivity state and decreased clustering coefficients of dynamic networks was observed in NMOSD patients, and associated with higher disability.

#### CLINICAL RELEVANCE/APPLICATION

Our findings indicated altered temporal and topological properties in dynamic networks instead of static ones might better explain disability in NMOSD patients.

### M5A-SPNR- 11 **The Alterations of Glymphatic System Function and Choroid Plexus and Their Correlation with Clinical Features in Relapsing Remitting Multiple Sclerosis Patients**

#### PURPOSE

To investigate the difference in glymphatic system function between relapsing-remitting multiple sclerosis (RRMS) patients versus healthy controls (HCs), and examine the relationship between diffusion along perivascular space (DTI-ALPS) index and choroid plexus (CP) volume or clinical features in RRMS.

#### METHODS AND MATERIALS

The ALPS index, the volume of CP in lateral ventricle and the cortical lesions were derived from magnetic resonance imaging (MRI) in 92 RRMS patients and 40 HCs, 23 of 92 RRMS patients were followed up for an average of 6 months to examine the changes in ALPS index and CP volumes.

#### RESULTS

RRMS patients had lower ALPS-index and higher volume ratio of CP than HCs. Lower ALPS-index was significantly related to higher ratio of CP volume and cortical lesion volume, and longer disease duration. Higher ratio of CP volume was related to higher cortical lesion volume, and lower MoCA scores in MS. But the ALPS index and CP volume didn't have statistical changes after 6 months of follow-up in 23 patients.

#### CONCLUSION

s Our findings demonstrated that the impaired glymphatic system function is involved in the inflammatory processing in MS patients and might help us better understand the pathological mechanism of MS.

#### CLINICAL RELEVANCE/APPLICATION

The DTI-ALPS index may have unique significance for monitoring MS inflammatory reaction.

### M5A-SPNR- 12 **The Diagnostic Value of Dynamic Contrast-enhanced MRI Ktrans in Diagnosing Neuropsychiatric Systemic Lupus Erythematosus**

Participants

Ide Ide, MD, Fukoka, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

Neuropsychiatric systemic lupus erythematosus (NPSLE) is a severe complication of SLE that affects nervous system. Brain MRI findings in SLE often show vascular lesions, but approximately 40% of NPSLE patients have normal MRI findings, which makes diagnosis challenging. The blood-brain barrier (BBB) is crucial for brain microenvironment integrity. However, microvascular disease and neuroinflammatory states can compromise the BBB in NPSLE. Dynamic contrast-enhanced (DCE)-MRI is a promising technique to evaluate BBB permeability, using Ktrans as a flow parameter to measure the volume-transfer constant from intravascular to extravascular extracellular space. An increase in Ktrans indicates compromised BBB integrity. The purpose of this study is to determine whether the Ktrans value is useful for differentiating NPSLE from non-NPSLE.

#### METHODS AND MATERIALS

Forty-seven NPSLE and 55 non-NPSLE patients were recruited. Based on the 1999 ACR classifications, NPSLE patients were classified 43 central nervous system lupus (11 diffuse and 32 focal manifestations) and 4 peripheral nervous system (PNS) lupus. DCE-MRI was performed, and the Ktrans map was obtained for all patients. Regions of interest (ROIs) were set in the cerebral cortex, reflecting small vessel disease, as it is a pathological finding of SLE. Manual ROIs were placed on the frontal, temporal, and occipital cortex with reference to T1-weighted images (Figure 1). Subsequently, the Ktrans value was measured, and the average of three points value was used for group comparison using Welch's t-test. ROC analysis was performed to analyze the diagnostic accuracy of the Ktrans map. All statistics were performed with BellCurve for Excel (Social Survey Research Information Co., Ltd.).

#### RESULTS

The mean value of Ktrans (/min) was significantly larger for NPSLE than for non-NPSLE ( $0.88 \pm 0.56$  vs.  $0.26 \pm 0.46$ ,  $p < 0.001$ ) (Figure 2 and 3). The mean value of Ktrans was  $1.10 \pm 0.41$  for diffuse manifestation,  $0.86 \pm 0.59$  for focal manifestation,  $0.42 \pm 0.43$  for PNS lupus, respectively. The mean value of Ktrans of diffuse manifestation of NPSLE was larger than that of focal manifestation, although there were no significant differences between them due to the small sample size. The ROC analysis showed good diagnostic performance (AUC: 0.832, optimal cut-off points: 0.11 (/min), sensitivity: 71%, specificity: 89%).

#### CONCLUSION

s Our study found that Ktrans value from DCE-MRI can differentiate between NPSLE and non-NPSLE, and suggests that BBB disruption may contribute to NP syndrome development in NPSLE.

#### CLINICAL RELEVANCE/APPLICATION

The Ktrans value derived from DCE-MRI can accurately differentiate between NPSLE and non-NPSLE, indicating that this technique may serve as a new biomarker for SLE.

### M5A-SPNR- 13 **Spinal Cord and Brain Atrophy Patterns in NMOSD and MS are Nonrandom and Clinically Relevant**

Participants

Tiantian Hua, Beijing, China (*Presenter*) Nothing to Disclose

## **PURPOSE**

Silent progressive spinal cord and brain atrophies are common findings in neuromyelitis optica spectrum disorder (NMOSD) and multiple sclerosis (MS), but harbor distinct patterns across brain areas leading to inter- and intra-disease heterogeneity, accounting for different physical disability and cognitive decline.

## **METHODS AND MATERIALS**

This cohort study used data retrospectively collected from eight neurological centers. Totally, 209 patients with NMOSD, 304 patients with relapsing-remitting MS (RRMS), and 1160 healthy controls (HC) were studied. Non-negative matrix factorization (NMF) was used to determine the atrophy patterns of these two diseases, respectively. Then, the weightings across atrophy patterns were obtained for each individual using a linear regression model by regarding the individual atrophy profile as dependent variables and the NMF-derived atrophy patterns as independent variables. Next, we associated the individual weighting across each atrophy pattern with cognitive profiles scores and expanded disability status scale (EDSS) scores to explore the contribution of each atrophy pattern to the disease manifestations. An additional longitudinal cohort were conducted to validate the stability and progression of these NMF-derived atrophy patterns.

## **RESULTS**

Three atrophy patterns were observed in NMOSD: (1) Spinal Cord-Deep Grey Matter (SC-DGM) pattern associated with decreased Brief Visuospatial Memory Test (BVMT), and higher EDSS scores; (2) Frontal-Temporal pattern associated with decreased Mini-Mental State Examination (MMSE) and California Verbal Learning Test (CVLT) scores; and (3) Cerebellum-Brainstem pattern associated with decreased EDSS progression scores. Three atrophy patterns were observed in RRMS: (1) DGM pattern associated with decreased Symbol Digit Modalities Test (SDMT), Paced Auditory Serial Addition Test (PASAT), MMSE, Montreal Cognitive Assessment (MoCA), CVLT and BVMT, and higher EDSS scores; (2) Frontal-Temporal pattern associated with decreased MoCA scores; and (3) Occipital pattern associated with decreased EDSS progression scores. Additionally, the longitudinal cohort validate the stability of atrophy patterns, and formed trajectories of atrophy progression in NMOSD and RRMS.

## **CONCLUSION**

s These findings suggested spinal and brain atrophy patterns in NMOSD and RRMS occurred largely in a non-random manner and developed (at least partly) according to distinct anatomical patterns. Additionally, these offered categorical perspectives that may facilitate clinical trials of stratifying participants.

## **CLINICAL RELEVANCE/APPLICATION**

Atrophy patterns showed stronger associations with cognitive impairment, physical disability, and progression.

## **M5A-SPNR-14 Pseudoaneurysm of the Facial Artery after Tonsillectomy Managed with Endovascular Coiling: A Case Report**

Participants

Subash Phuyal SR, MD,MBBS, Kathmandu, Nepal (*Presenter*) Nothing to Disclose

## **PURPOSE**

Introduction: We present a case of pseudoaneurysm of the facial artery after tonsillectomy managed with successful endovascular coiling.

## **METHODS AND MATERIALS**

Presentation of Case: 41-year-old lady presented with a history of throat pain and 3 episodes of hematemesis on the 3rd, 4th, and 7th postoperative days after tonsillectomy and styloidectomy. She had undergone the operation 20 days back. Neurological examination was normal. Contrast-enhanced computed tomography scan of the neck showed - contrast-filled dilatation of a branch of the right facial artery in the right palatine tonsillar fossa within the operative bed - likely pseudoaneurysm which was managed endovascularly. The patient recovered fully after treatment.

## **RESULTS**

Discussion: Tonsillectomy can have various complications among which one is the pseudoaneurysm of the facial artery which can be managed with coiling in the catheterization laboratory.

## **CONCLUSION**

s Conclusion: Pseudoaneurysm of the facial artery is a rare complication of tonsillectomy. Endovascular treatment of a pseudo aneurysm can be done.

## **CLINICAL RELEVANCE/APPLICATION**

Pseudoaneurysm of the facial artery is a rare complication of tonsillectomy. Endovascular treatment of a pseudo aneurysm can be done.

## **M5A-SPNR-2 Abnormal Functional Network Topology in Autism Spectrum Disorder**

## **PURPOSE**

The topological organization of whole-brain (including cerebrum and cerebellum) functional networks in Autistic Spectrum Disorder (ASD) patients remains unclear. Besides, the cerebellum plays an important role in neural activity and interacts with the cerebrum. So, we aimed to investigate the topological architecture of whole-brain functional networks in ASD patients.

## **METHODS AND MATERIALS**

Resting-state functional MRI was obtained on 40 ASD patients and 40 healthy controls. After constructing whole-brain functional networks by thresholding partial correlation matrices of 116 brain regions, we computed the topological properties (small-world, network efficiency, and nodal centrality) with graph theoretical analysis, comparing topological properties between the two groups,

and analyzed the relationships between parameters showing group difference and Autism Diagnostic Observation Schedule (ADOS) scores.

## RESULTS

Small-world architecture was identified for both groups. ASD patients exhibited decreased nodal centrality absolutely in cerebral areas like superior frontal gyrus (dorsolateral), supplementary motor area, anterior cingulate and paracingulate gyri, median cingulate and paracingulate gyri, cuneus, superior occipital gyrus, precentral gyrus, postcentral gyrus, superior parietal gyrus, supramarginal gyrus. However, the increased nodal centrality mainly in cerebellum regions (including Crus I, Lobule III, VI, VIIb of cerebellar hemisphere and Lobule I, II, III, IV, V of vermis).

## CONCLUSION

s Cerebrum and cerebellum showed opposite functional changes in ASD patients. The increased cerebellum function might be compensation for the decreased cerebral function.

## CLINICAL RELEVANCE/APPLICATION

The topological organization of whole-brain analysis was beneficial to understanding the neural mechanism of ASD.

## M5A-SPNR-3 Advanced Imaging in First Episode Psychosis: A Systematic Review

Participants

Riyad Hanafi, La Madeleine, France (*Presenter*) Nothing to Disclose

## PURPOSE

In addition to ruling out numerous neurological conditions that may have psychiatric manifestations, advanced imaging techniques play a role in identifying imaging biomarkers of psychiatric disorders, selecting patients for optimal treatment, and tracking treatment effects. We performed a systematic review of the literature to determine how advanced imaging in FEP can allow for increasing diagnostic specificity and predicting disease's evolution.

## METHODS AND MATERIALS

PubMed searches were conducted on December 9, 2022, using combinations of the following predetermined search terms: "first episode psychosis" and "advanced imaging" or "functional MRI", or "resting state MRI" or "spectroscopy" or "ASL" or "DTI" or "diffusion imaging", with filters Clinical Trial, Meta-Analysis and Randomized Controlled Trial.

## RESULTS

To date, brain imaging studies have shown grey matter deficits, ventricular enlargement and reduced overall brain volume in FEP. Morphology is commonly assessed using T1-weighted volumetric MRI with automated computerized methods. Patients presenting a FEP show a thinning of certain cortical regions notably involved in emotional processing and higher executive functions. Functional MRI (fMRI) is based on the BOLD (Blood Oxygen Level Dependent) contrast, which uses the paramagnetic properties of deoxygenated hemoglobin, during task-activation or resting-state paradigms. Neuronal activity is associated with changes in oxygen consumption and thus in deoxyhemoglobin concentration. Correlations between BOLD signal time series of distant brain regions reflect their functional interactions, allowing for the identification of different functional resting state networks (RSNs).

## CONCLUSION

s In the routine management of a FEP, brain imaging is mainly used to rule out other conditions. In this indication, structural brain MRI is considered the standard examination. In the near future, advanced sequences, particularly functional imaging studies, may allow improved diagnostic specificity, and play a predictive role, in line with the increasing development of personalized medicine.

## CLINICAL RELEVANCE/APPLICATION

Early treatment of first-episode psychosis (FEP) is one of the major factors that impacts long-term prognosis. Better understanding of FEP pathophysiology, proper patient selection for optimal treatment, and adequate prognostication of disease evolution are real challenges for current research. Besides ruling out some neurological conditions that may have psychiatric manifestations, advanced imaging techniques allow for identifying imaging biomarkers of psychiatric disorders.

## M5A-SPNR-4 MRI Volumetric of Limbic System in Burnout Syndrome and Vigilant Attention in a Population with Nocturnal Shifts

## PURPOSE

To determine association between changes in the sleep pattern, burnout syndrome, vigilant attention deficit with structural alterations of the limbic system.

## METHODS AND MATERIALS

39 Volunteer subjects with night shifts underwent a non-contrast brain MRI using a T1 MPRAGE sequence. Brain images were automatically segmented using the VolBrain software. The Maslach Burnout Inventory Index and the test Psychomotor Vigilante Test (PVT) were used to assess the vigilant attention deficit in all patients. The correlation between the volumetric findings with clinical scales were evaluated using Spearman's test. Non-parametric univariate analysis was performed using the Mann-Whitney U test between the volumetric data and burnout syndrome.

## RESULTS

In subjects with burnout syndrome the hippocampal volume was significantly greater than subjects without burnout syndrome ( $p < 0.01$ ). The response time of the PVT test was lower in the subjects with greater volume of the amygdala ( $r = 0.40$ ,  $p = 0.025$ ). Regarding the precision of the test, an inverse correlation was found between the percentage of failed responses with the volume of the hippocampus ( $r = 0.39$ ,  $p = 0.02$ ) and the volume of the amygdala ( $r = 0.49$ ,  $p < 0.01$ ).

## CONCLUSION

s Burnout syndrome is associated with a decrease in the volume of the hippocampus. Vigilant attention deficit is associated with

changes in the volume of the hippocampus and amygdala.

#### **CLINICAL RELEVANCE/APPLICATION**

The clinical relevance of this work is to use artificial intelligence tools to define brain structural changes on MRI associated with burnout syndrome and vigilance attention that are complementary to clinical evaluation and in the future can will have utility as severity criteria or predictors of complications.

#### **M5A-SPNR-5A Multimodal Imaging Study of Adult-onset Neuronal Intranuclear Inclusion Disease**

##### **PURPOSE**

In this study, we propose to apply diffusion kurtosis imaging (DKI) to study the microstructural changes in patients with Neuronal intranuclear inclusion disease (NIID) and the relationship with cognitive dysfunction. We also analyze the changes in brain functional connections, hoping to provide a new imaging perspective on the neuropathological mechanism and early diagnosis of this disease.

##### **METHODS AND MATERIALS**

Our study retrospectively included 12 patients diagnosed with NIID in the Department of Neurology at \*, as well as 20 healthy control subjects matched for age, gender, and education level during the same period. Neuro-psychological assessments, DKI, and RS-fMRI data were collected in our study. Mean kurtosis (MK), axial kurtosis (AK), radial kurtosis (RK), fractional anisotropy (FA), and mean diffusivity (MD) parameters were obtained, and statistical analysis was performed on each DKI parameter of the subjects. We also analyzed the correlation between the DKI parameter values and neuro-psychological scores in brain regions which show significant differences between NIID patients and healthy controls. Finally, based on the ALL 116 template and independent component analysis, we explored changes in brain network functional connectivity in NIID patients.

##### **RESULTS**

Compared with healthy controls, NIID patients have lower MK and RK values in the thalamus, hippocampus, and left caudate in the gray matter, as well as lower AK values in the thalamus, insula, and left calcarine. In the white matter, FA is reduced in the superior frontal gyrus, corona radiata, corpus callosum splenium, inferior frontal gyrus, and temporal gyrus. While MD is increased in the white matter around the ventricles (FWE-corrected,  $p < 0.05$ ). In NIID patients, there is a positive correlation between the AK value of the left caudate and MoCA results ( $r = 0.770$ ,  $P = 0.015$ ), and a negative correlation between the MD value of the white matter around the ventricles and MoCA results ( $r = -0.678$ ,  $P = 0.045$ ). Additionally, functional connections in multiple brain regions of NIID patients are weakened (NBS correction,  $P_{edge} < 0.05$ ,  $P_{cluster} < 0.05$ , 1000 permutations), with decreased functional connections in the precuneus, angular and frontal\_mid regions of the default mode network (uncorrected,  $P < 0.001$ ,  $cluster > 5$ ).

##### **CONCLUSION**

s NIID patients show changes in the microstructure and functional connections of multiple brain regions. These changes might contribute to the pathological physiology of NIID and serve as potential indicators for monitoring the severity and progression of NIID, which has potential clinical value for early diagnosis.

#### **CLINICAL RELEVANCE/APPLICATION**

We hope to provide a new imaging perspective on the neuropathological mechanism and early diagnosis of this disease.

#### **M5A-SPNR-6 Brain Mechanisms Underlying Emotional Response in Social Pain. Football as a Proxy to Study Fanatism: An fMRI Study**

Participants

Francisco Zamorano, Santiago, Chile (*Presenter*) Nothing to Disclose

##### **PURPOSE**

In this study, we aimed to explore the brain mechanisms underlying positive and negative social stimuli in football fanatics during positive and negative social scenarios and deepen the neural substrate of football-related emotional responses as a proxy of fanatism.

##### **METHODS AND MATERIALS**

Forty-three healthy male volunteers who support Chilean football teams were recruited for this fMRI study. Participants were divided into two groups, 22 supporters of the Colo-Colo team and 21 supporters of the Universidad de Chile team. All participants were presented with a compilation of football matches containing 63 goals, and their brain activity was registered in a Siemens 3T SKYRA, during the visual stimulation of score annotations to rivals and from rivals. We also apply a football supporters' fanatism scale (FSFS) in order to determine the fanatism level for each participant.

##### **RESULTS**

The results demonstrate that the brain activity was different when the goals come or go to the most emblematic rival, which we termed the "emotional delta." In the winning scenarios, subcortical activation was observed, specifically in the ventral striatum, caudate, and lentiform nucleus. These areas are important for the reward dopaminergic circuit, inducing pleasure sensations. The mentalizing network was activated for the losing scenario. This mentalizing network strategy could be involved to mitigate the adverse result's pain. Simultaneously, a deactivation was observed at the dACC, which connects the limbic system with the frontal association regions that command normative behavior, decreasing cognitive control and increasing the probability to fall into disruptive or violent behavior. Both, mentalizing network and dACC correlate with FSFS, negatively and positively respectively.

##### **CONCLUSION**

s Football is an excellent social affiliation model, promoting inclusivity, teamwork, community spirit, social change, and personal achievement. Still, the gregarious component could be the reason behind acts of violence and vandalism. Our study provides new inputs for future research on different fanatism expressions, which is crucial for promoting a more equitable and inclusive society.

#### **CLINICAL RELEVANCE/APPLICATION**

Social affiliation is a crucial requirement for complex social phenomena. Fanaticism is extreme or excessive devotion or enthusiasm

towards a particular cause, belief, or opinion. It often involves blind and unquestioning loyalty to a particular ideology or leader, and a refusal to consider other perspectives or opinions. Fanaticism can lead to intolerance, aggression, and even violence toward those who do not share the same beliefs or views. In this sense, our study proposes a new model for studying complex behaviors like fanaticism.

## **M5A-SPNR-7 Comparison of fMRI Language Laterality With and Without Sedation in Pediatric Epilepsy**

### **PURPOSE**

Functional MRI is an essential component of presurgical language mapping. In clinical settings, young children may be sedated for the MRI with the functional stimuli presented passively. Research has found that sedation changes language activation in healthy adults and children. However, there is limited research comparing sedated and unsedated functional MRI in pediatric epilepsy patients. We compared language activation patterns in children with epilepsy who received sedation for functional MRI to the ones who did not.

### **METHODS AND MATERIALS**

We retrospectively identified the patients with focal epilepsy who underwent presurgical functional MRI including Auditory Descriptive Decision Task at our institution from 2014-2022. Patients were divided into sedated and awake groups, based on their sedation status during functional MRI. Auditory Descriptive Decision Task stimuli were presented passively to the sedated group per clinical protocol. We extracted language activation maps contrasted against a control task (reverse speech) in the Frontal and Temporal language regions and calculated separate language laterality indexes for each region. We considered positive laterality indexes as left dominant, negative laterality indexes as right dominant, and absolute laterality indexes less than 0.2 as bilateral. We defined 2 language patterns: typical (i.e., primarily left-sided) and atypical (Fig 1). Typical pattern required at least one left dominant region (either frontal or temporal) and no right dominant region. We then compared the language patterns between the sedated and awake groups.

### **RESULTS**

Seventy patients met the inclusion criteria, 25 sedated, and 45 awake (Fig 2). Using the Auditory Descriptive Decision Task paradigm, when adjusted for age, handedness, gender, and laterality of lesion in a weighted logistic regression model, the odds of the atypical pattern were 13.2 times higher in the sedated group compared to the awake group (CI: 2.55-68.41, p-value <0.01).

### **CONCLUSION**

Sedation may alter language activation patterns in pediatric epilepsy patients. Language patterns on sedated functional MRI with passive tasks may not represent language networks during wakefulness, sedation may differentially suppress some networks, or require a different task or method of analysis to capture the awake language network.

### **CLINICAL RELEVANCE/APPLICATION**

Given the critical surgical implication of these findings, additional studies are needed to better understand how sedation impacts the functional MRI blood oxygenation level-dependent signal. Consistent with current practice, sedated functional MRI should be interpreted with greater caution and requires additional validation as well as research on post-surgical language outcomes.

## **M5A-SPNR-8 The Individual Functional Connectome in Pediatric Epilepsy Patients - Does it Add to Presurgical fMRI Brain Mapping**

### **PURPOSE**

Speech is a complex brain function underlying an extended functional and structural neural network. fMRI as part of presurgical evaluation allows the investigation of language lateralization and organization. Nevertheless, conventional fMRI maps just represent a small aspect of the language network. In children, language networks may differ substantially from their general linear model (GLM) -based activation maps as generated by task-based fMRI post-processing. In this study, functional connectivity analysis (FCA) of task-based language fMRI data was compared to the general linear model-based analysis in children undergoing presurgical evaluation for drug resistant epilepsy.

### **METHODS AND MATERIALS**

9 patients (5 male, 4 female) between 8 and 16 years with lesional (n=6) and mr-negative epilepsy (n=3), underwent presurgical language evaluation by fMRI. All patients were right-handed. An echo planar imaging (EPI) sequence was used to acquire high temporal resolution (TR=1s) functional images at 3 Tesla. Two task-based fMRI paradigms (verb generation and sentence comprehension) were presented. The CONN-toolbox was used for preprocessing of anatomical and functional data and for creating individual functional connectomes. One experienced pediatric neurologist was blinded to the patients history and reviewed conventionally processed as well as connectome language fMRI data and qualitatively described the activation patterns.

### **RESULTS**

Based on GLM-based analysis, 8 out of 9 patients were determined as left-hemispheric language dominant. One patient had a right-hemispheric language dominance in terms of atypical language representation. In the presurgical fMRI activation analysis 3 out of 9 patients showed contralateral activations in the frontal and temporal lobe. In the FCA in 7 out of 9 patients were found significant connectivities to contralateral frontal and temporal lobes at p-uncorrected <0.05. The FCA also demonstrated significant connectivities (p-uncorrected <0.05) to other cortical brain areas in frontal and temporal lobe in all patients, which were not detected in the activation pattern analysis.

### **CONCLUSION**

In this study it was shown that functional connectomes deliver more information about the language network. In the FCA a more extended bilateral functional network was found in most patients as compared to presurgical created activation patterns.

### **CLINICAL RELEVANCE/APPLICATION**

In order to further understand brain plasticity especially in the presence of brain pathologies, the visualization of functional brain networks and its implementation in clinical setting is essential. Further studies have to show how the information from the FCA can be interpreted in prediction of postoperative speech changes.

## **M5A-SPNR-9 Causal Association Between Body Mass Index and Neuroimaging Features in Adults**

Participants

Han Lv, MD, Beijing, China (*Presenter*) Nothing to Disclose

### **PURPOSE**

High body mass index (BMI) is associated with negative brain health; however, its causal association remains unclear. This study evaluated the effect of high BMI on neuroimaging features in different age groups and to validated the causal relationship.

### **METHODS AND MATERIALS**

This real-world study has been performed based on the KaiLuan Study, a multicenter, long-term follow-up, community-based longitudinal cohort in the adult population since 2006. We modeled the trajectories of BMI during follow-up to evaluate cumulative exposure. Multimodality neuroimaging data have been collected by 3.0T MRI since 2020, which were available for volumetric measurements of the brain structure, white matter hyperintensity (WMH), and skeletonized white matter tract at the voxel-wise level. We performed two-sample Mendelian randomization analysis using genetic data from 681,275 individuals to analyze the causal relationship between BMI and neuroimaging features.

### **RESULTS**

In the real-world study, clinical and neuroimaging data were obtained from 1,074 adults (aged 25-83 years). High BMI was found to be associated with a wide range of negative brain health. For adults <45 years, differences in cerebral parenchyma volume between those with BMI > 26.2 kg/m<sup>2</sup> and those with normal BMI corresponded to 12.0 years (95% CI, 3.0 to 20.0) of brain aging. Volumetric results corresponded to -17.9ml (95% CI, -29.8 to -4.5). Differences in WMH were statistically significant for participants >60 years, with 6.0ml (95% CI, 1.5 to 10.5) increased volume. Genetic analysis of 681,275 individuals further indicated causal relationships among high BMI, decreased volume of the cerebral parenchyma and gray matter, and increased fractional anisotropy in projection fibers, further supporting the causal effect of BMI on brain aging and health.

### **CONCLUSION**

s BMI is causally associated with decreased brain volume and disrupted microstructural integrity in projection fibers. Brain aging is prominent in young adults with high BMI.

### **CLINICAL RELEVANCE/APPLICATION**

Controlling BMI has been suggested throughout life, especially for young adults, for protecting brain health.

M5A-SPOB

### OB/Gynecology Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPOB-1 Proposed New MRI Scoring System of Rectosigmoid Endometriosis: Concise Qualitative Assessment with Pathologic Correlation to Guide Operative Planning**

##### Participants

Hiroaki Takahashi, MD, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

##### PURPOSE

Rectosigmoid endometriosis (RSE) manifests as a broad-spectrum of MRI findings ranging from serosal surface disease to deep bowel involvement, a spectrum which impacts the surgical strategy. We propose a new MRI scoring system for RSE that is beneficial in operative planning based on pathologic depth of invasion as it pertains to MRI.

##### METHODS AND MATERIALS

Patients with RSE treated by rectosigmoid surgery from May 2018 to June 2022 were retrieved. Types of surgery were classified into (1) partial thickness resection, (2) discoid resection, and (3) segmental resection, including low anterior resection and sigmoidectomy. Depth of bowel involvement was extracted from pathology reports. Each pre-treatment MRI was scored based on the mutual agreement of two abdominal radiologists. MRI score was defined as follows: (1) score 0: no evidence of RSE, (2) score 1: minimal tethering involving the serosal surface of the rectosigmoid colon, (3) score 2: indeterminate thickening and/or soft tissue involving the rectosigmoid colon without mushroom cap or submucosal involvement, and (4) score 3: definite mushroom cap sign or definite MRI evidence of submucosal involvement. The contingency of surgical strategy and pathological results between different MRI scores (MRI score 2 versus score 3) was assessed by Fisher's exact test with Freeman-Halton extension.  $P < 0.05$  was considered statically significant.

##### RESULTS

Among 89 enrolled patients (median age: 37 [22-57] year old), 3, 10, 34, and 42 patients had MRI score 0, 1, 2, and 3, respectively. All patients with MRI score 0 and 1 underwent partial thickness shaving. When comparing MRI score 2 to MRI score 3, there was a significant difference in patients requiring partial thickness shaving (53% [18/34] vs 7% [3/42]), discoid resection (18% [6/34] vs 7% [3/42]), and segmental resection (29% [10/34] vs 86% [36/42]) ( $p < 0.001$ ). The depth of bowel involvement was extracted from pathology reports in 13 patients with MRI score 2, and 33 patients with MRI score 3. A higher proportion of patients demonstrated greater depth of invasion with MRI score of 3 compared to MRI score of 2 with higher rates of submucosal invasion (52% [17/33] vs 15% [2/13]) and lower rates of muscularis propria invasion (48% [16/33] vs 62% [8/13]), serosal invasion (0% vs 8% [1/13]), and no invasion (0% vs 15% [2/13]) ( $p = 0.001$ ).

##### CONCLUSION

Our MRI scoring system for RSE has good correlation with the pathological spectrum of bowel invasion and is helpful in operative planning.

##### CLINICAL RELEVANCE/APPLICATION

Our MRI scoring system for rectosigmoid endometriosis is a concise and qualitative scale based on suspected depth of bowel wall invasion and correlates with pathology to best guide operative planning.

#### **M5A-SPOB-2 Contrast-enhanced 3D T1-weighted Image with Compressed Sensing and Fast 3D Wheel Technique on Women's Pelvic MRI: Utility for Improving Quality and Acquisition Time as Compared with Conventional Contrast-enhanced 3D T1-weighted Image**

##### Participants

Takahiro Ueda, MD, PhD, Toyooka, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

To determine the utility of contrast enhanced 3D T1-weighted image with compressed sensing (CS) and wheel encoding order technique (Fast 3D wheel: Fast 3Dw) which is one of the technics for k-space based acceleration technique for improving image quality and acquisition time on women's pelvic MRI as compared with conventional parallel imaging (PI).

##### METHODS AND MATERIALS

24 consecutive female patients with various pelvic diseases underwent contrasted-enhanced 3D T1-weighted image with PI, CS and Fast 3Dw, randomly. Then, all acquisition times were recorded in each patient. For quantitative assessment, SNR of muscle and CR between myometrium and muscle were determined on uterine corpus and cervical level by ROI measurements. For qualitative assessment, two board certified radiologists assessed overall image quality (OIQ), artifact and diagnostic confidence level (DCL) by 5-point scales. Then, each final score was determined as consensus of two readers. To compare the capability for acquisition time reduction, mean acquisition time was compared among all data sets by Tukey's HSD test. To determine quantitative image quality

improvement, SNRs and CRs were compared among all methods by Tukey's HSD test. On qualitative image quality evaluations, inter-observer agreement on each data set was assessed by  $\chi^2$  statistics followed by  $\chi^2$  test. Finally, three indexes among all methods by Wilcoxon signed-rank test.

## RESULTS

Mean acquisition time of CS and Fast 3Dw (CS:  $156.6 \pm 4.8$  sec, Fast 3Dw:  $153.9 \pm 2.7$  sec) were significantly shorter than that of PI (PI:  $313.0 \pm 9.7$  sec,  $p < 0.001$ ). SNR of Fast 3Dw ( $19.3 \pm 0.9$ ) at uterine corpus level were significantly higher than that of PI ( $12.0 \pm 4.2$ ,  $p < 0.05$ ) and CS ( $15.0 \pm 1.4$ ,  $p < 0.05$ ). SNR of Fast 3Dw ( $20.4 \pm 5.5$ ) at uterine cervical level were significantly higher than that of PI ( $15.4 \pm 6.3$ ,  $p < 0.05$ ). There was no significant difference of CR among three methods ( $p > 0.05$ ). All inter-observer agreements were determined as 'moderate' or 'excellent' ( $0.57 < \kappa < 0.83$ ,  $p < 0.0001$ ). OIQs of CS and Fast 3Dw (CS: median 4, IQR 3-4; Fast 3Dw: median 5, IQR 4-5) were significantly higher than that of PI (median 4, IQR 3-4.75,  $p < 0.05$ ). Artifacts of CS and Fast 3Dw (CS: median 2, IQR 2-3; Fast 3Dw: median 1, IQR 1-2) were significantly lower than that of PI (median 2, IQR 1.25-3,  $p < 0.05$ ). There was no significant difference of DCL among three methods ( $p > 0.05$ ).

## CONCLUSION

s CS and Fast 3Dw are considered as useful for image quality improvement with reducing acquisition time on women's pelvic MRI, when compared with conventional PI.

## CLINICAL RELEVANCE/APPLICATION

CS and Fast 3Dw are considered as useful for image quality improvement with reducing acquisition time on women's pelvic MRI, when compared with conventional PI.

## M5A-SPOB-3 Pain-free Survival after Percutaneous Image-guided Cryoablation of Extra Peritoneal Endometriosis

Participants

Milan Najdawi, MD, Montfermeil, France (*Presenter*) Nothing to Disclose

## PURPOSE

To retrospectively evaluate the pain-free survival of percutaneous image-guided cryoablation of symptomatic extraperitoneal endometriosis (EE).

## METHODS AND MATERIALS

From 2017 to 2022, cryoablation of EE was performed in a single institution for 42 consecutive patients (median age: 37 years [interquartile range: 33 - 39.5]) on a total of 47 lesions. Patient and procedural characteristics were reviewed retrospectively. Tolerance and outcomes in terms of pain and patient's satisfaction were evaluated.

## RESULTS

The mean procedure and hospitalization lengths were 73 minutes [48-94] and 1 day [1-1], respectively; including 67% outpatients. The median follow-up was 13.5 months [1.1-37.7] after cryoablation. The median pain-free survival rates were 93.75% [95% CI, 77.25-98.4] at 6 month, and 82.72% [58.8-93.45] after 12 month, respectively. Pain decreased from a median of 8/10 [7-9] on the visual analogue scale to 0/10 [0-1] at the last follow-up ( $P < 0.0001$ ). The median Patient Global Impression of Change score recorded at last follow-up was 1/7 [1 - 2]. Efficacy rate of cryoablation to avoid secondary surgery was 92.8% (39/42) per patient and 93.6% (44/47) per nodule treated. Four patients (9.5%, 4/42) had adverse event in the days following the procedure, one patient (2%) had a severe adverse event.

## CONCLUSION

s Percutaneous cryoablation is safe and effective to significantly reduce pain and obtain local control of extraperitoneal endometriosis.

## CLINICAL RELEVANCE/APPLICATION

Cryoablation provides a minimally invasive alternative to surgery that can achieve local control of the endometriosis and significantly reduce pain. This is important because endometriosis can cause significant pain and can be difficult to treat, often requiring surgery or long-term medical management.

## Abstract Archives of the RSNA, 2023

M5A-SPPD

### Pediatric Imaging Monday Poster Discussions I

#### Sub-Events

#### M5A-SPPD-1 CT Angiography for Acute Pediatric Gastrointestinal Hemorrhage: A Search for Best Practices

##### PURPOSE

Gastrointestinal bleeding (GIB) in children can be a life-threatening emergency. CT angiogram (CTA) is typically the first-line imaging modality to identify a source and direct further management. When evaluating pediatric patients with GIB; however, no guidelines exist to our knowledge for optimal patient selection and scanning protocols. This project sought to better delineate the best protocols for evaluating GIB in the pediatric patients.

##### METHODS AND MATERIALS

Our work meets criteria for quality improvement and did not constitute human subjects research. We retrospectively reviewed CTA exams performed for GIB at a tertiary care pediatric hospital from 1/23/2018 - 9/6/2022. Exams reported as non-diagnostic were excluded. Patient age and sex were recorded. Number of phases, positive studies, follow-up imaging modality and findings, intervention, and final diagnoses were identified. Phase of CTA with the clearest evidence of GIB was determined in consensus by two pediatric radiologists. Data were evaluated using descriptive statistics.

##### RESULTS

88 CTAs were performed for GIB evaluation in 89 patients [60 males (67%), median age 11.9 years (range 9 months to 28 years)] over the evaluation period. Of 88 exams, 24 (27%) were single-phase, 41 (47%) were dual-phase, 18 (20%) were triple-phase, and 5 (6%) included a fourth phase, 35 (40%) were dual energy, and 2 (2%) were nondiagnostic. Active GIB was identified on 18 exams (20%) with all being most conspicuous during the arterial phase. Further imaging occurred 46 times and included repeat CTA (n=5), Meckel's scan (n=14), tagged red blood cell scan (n=12), and angiography (n=15). 3 patients underwent repeat CTA after an initial negative study; 3 patients were found to be bleeding at subsequent angiography. 8 patients (9%) underwent embolization and 8 (9%) went to surgery. In total 20 (23%) occurrences of GIB were diagnosed in this cohort. Etiologies included vascular malformation, enteroenteric anastomoses, pseudoaneurysm, and a Meckel's diverticulum.

##### CONCLUSION

Among the varied CTA protocols, a majority (77%) of GIB cases were identified in the arterial phase. In this small sample size, bleeding was identified by CTA only in 19% of patients but there was a false negative rate of 18.75%. Further investigation of patient characteristics and a larger cohort may help better define which patients are more likely to have positive findings on imaging.

##### CLINICAL RELEVANCE/APPLICATION

Our data helps to further the clinical data available with regard to the optimal protocoling and patient selection for CT angiography to evaluate for acute gastrointestinal hemorrhage in pediatric patients.

#### M5A-SPPD-2 The Feasibility of Portal Vein Flow Quantitation in Pediatric Patients using 4D MRI

##### Participants

Parmede Vakil, MD, PhD, San Francisco, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the feasibility of time-resolved flow-sensitive four-dimensional (4D) Flow MRI for the quantification of portal venous hemodynamics in a clinical pediatric population.

##### METHODS AND MATERIALS

We retrospectively identified patients who received 4D Flow MRI using a 3T scanner at our institution in the past 1 year. Flow was quantified using Arterys Web-based flow analysis software in three pre-defined anatomic regions in the proximal, mid, and distal portal vein. Maximum velocities and flow volumes were tabulated. Inter-observer variability was assessed using Bland-Altman and regression techniques.

##### RESULTS

15 patients (7 male, mean age 9.6 years, range [2, 17]) received 4D Flow MRI as part of the clinical work up of their underlying gastroenterological disease. Portal venous flow averaged 479 mL/min range [180, 1130] across all study participants. On average, portal flow increased from the proximal (453 mL/min) to the mid (480 mL/min) and distal (505 mL/min) portions. Flow rate correlated moderately with age ( $r = 0.5381$ ,  $p = 0.04$ ). Interobserver agreement was excellent with Bland-Altman analysis showing a mean inter-observer difference of 30 mL/min, a 7% difference, which was not significant on 1-tail t-test ( $p = 0.1$ ) or regression analysis ( $r^2 = 0$ ,  $p = 0.87$ ).

##### CONCLUSION

4D Flow MRI assessment of portal venous flow is feasible in a pediatric population with excellent inter-observer agreement and

s 4D Flow MRI assessment of portal venous flow is feasible in a pediatric population with excellent inter-observer agreement and flow measurements that are in line with literature values provided in quantitative portal flow studies in adults. More studies are required to further characterize the clinical utility of this modality.

#### **CLINICAL RELEVANCE/APPLICATION**

4D Flow MRI has the capability of providing both anatomic and functional assessment of portal flow and has been validated against US and 2D Flow MRI in adults; however its feasibility in a pediatric population has not been explored.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

M5A-SPPH

### Physics Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPPH-1 Carotid Artery Assessment in Dual-Source Photon-Counting CT: Impact of Low Energy Virtual Monoenergetic Imaging on Image Quality, Vascular Contrast and Diagnostic Accessibility**

##### Participants

Christian Booz, MD, Frankfurt am Main, Germany (*Presenter*) Speaker, Siemens AG

##### PURPOSE

Preliminary dual-energy CT studies have shown that low energy virtual monoenergetic imaging (VMI)+ reconstructions can provide superior image quality compared to standard 120 kV CTA series. The purpose of this study is to evaluate the impact of low energy VMI+ reconstructions on quantitative and qualitative image quality, vascular contrast and diagnostic assessability of the carotid artery in patients undergoing photon-counting CTA examinations.

##### METHODS AND MATERIALS

A total of 122 patients (67 male) who had undergone dual-source photon-counting CTA scans of the carotid artery were retrospectively analyzed in this study. Standard 120 kV CT images and low keV VMI+ series from 40 to 100 keV with an interval of 15 keV were reconstructed. Quantitative analyses included evaluation of vascular CT numbers, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). CT number measurements were performed in the common, external and internal carotid artery. Qualitative analyses were performed by three board-certified radiologists independently using five-point scales to evaluate image quality, vascular contrast and diagnostic assessability of the carotid artery.

##### RESULTS

Mean attenuation, CNR and SNR values were highest in 40 keV VMI+ reconstructions (HU, 1362 ± 12; CNR, 33 ± 8; SNR, 34 ± 9) followed by 55 keV VMI+ reconstructions (HU, 737 ± 9; CNR, 24 ± 7; SNR, 26 ± 7); all three mean values at these keV levels were significantly higher compared with the remaining VMI+ series and standard 120 kV CT series (HU, 154 ± 7; CNR, 16 ± 4; SNR, 24 ± 6) (p<.0001). The qualitative analysis showed highest rating scores for 55 keV VMI+ reconstructions followed by 40 keV and 70 keV VMI+ series with a significant difference compared to standard 120 kV CT images series regarding image quality, vascular contrast and diagnostic assessability of the carotid artery (p<.0001).

##### CONCLUSION

Low keV VMI+ reconstructions at a level of 40-55 keV significantly improve image quality, vascular contrast and the diagnostic assessability of the carotid artery compared with standard CT series in photon-counting CTA.

##### CLINICAL RELEVANCE/APPLICATION

In patients undergoing photon-counting CTA scans of the carotid artery, low keV VMI+ reconstructions at a level of 40-55 keV should be routinely reconstructed to improve image quality and the diagnostic assessability and to potentially reduce radiation dose and the needed amount of intravenous contrast material in scan protocols in order to protect kidney function.

#### **M5A-SPPH-10 Assessment of Low-dose Chest CT Protocols Prior to Implementation of Lung Cancer Screening Program**

##### PURPOSE

To evaluate low-dose CT (LDCT) chest protocols prior to implementing a pilot lung cancer screening (LCS) program in the Canadian province of Nova Scotia.

##### METHODS AND MATERIALS

Data were collected from five scanners of a university hospital. Each sample included 20 examinations conducted on average-sized adult patients chosen by image measurement of anterior-posterior (AP) thickness. All scanners were from the same manufacturer installed in 2011-2022. Dose modulation options and iterative reconstruction algorithms were implemented on all machines, and two were dual source (DS) scanners. The volume CT dose index (CTDIvol) and dose-length product (DLP) were collected in each study. The size-specific dose estimate (SSDE) was calculated using the conversion factor for each patient's AP diameter, and the effective dose (ED) was estimated using an anatomy-specific conversion factor for the chest. For quantitative analysis of image quality, CT numbers and image noise in Hounsfield Units (HU) were measured in three regions of interest: tracheal bifurcation, peripheral lung parenchyma, and subcutaneous fat. Signal-to-noise ratio (SNR) values were calculated for each region. Descriptive statistics determined the mean, standard deviation, and median values of obtained data. Protocol differences were determined using a single-factor ANOVA test, with a p-value less than 0.05 denoting statistical significance. The correlation between dose and SNR values was assessed using the Pearson correlation coefficient.

##### RESULTS

The survey included 100 patients with an overall median AP thickness of 25.0 cm demonstrating no significant difference between

patient size in each sample ( $p=0.52$ ). Median values of CTDIvol, DLP, and ED ranged from 2.0 to 4.7 mGy, 72.0 to 164 mGy·cm, and 1.0 to 2.3 mSv respectively. The SSDE varied from 2.5 to 5.8 mGy. Differences between the means of the dose distributions from each scanner were statistically significant with higher doses resulting from both DS scanners. A very weak correlation was found between dose and SNR values with the Pearson correlation coefficients of 0.24, -0.09, and -0.15 for trachea, lung, and fat respectively.

## CONCLUSION

Our study demonstrated up to a 2.3-fold difference in dose resulting from the LDCT examination. Only three of five scanners using this protocol comply with screening requirements. Due to iterative reconstruction, quantitative image quality had a very weak correlation with dose suggesting potential for protocol optimization without degradation of image quality.

## CLINICAL RELEVANCE/APPLICATION

Canada currently has no organized LCS, however, some provinces are implementing pilot studies. It is crucial to assess the radiation dose and image quality of LDCT protocols before using them for screening

### M5A-SPPH-11 **Comparison of Photon-Counting-Detector CT and Energy-Integrated-Detector CT for Evaluating Performance Using Tasks Involving Cerebral Small Vessels**

Participants  
Kazuya Ohashi, PhD, RT, Nagoya, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Detectability index ( $d'$ ) and task transfer function (TTF) are used for evaluating image quality of CT systems. TTF is generally measured using a 30 mm diameter cylindrical phantom. However, it has been reported that this task is not ideal for assessing small vessels, such as those with 1 mm diameter. In this study, we measured TTF using an iodine wire phantom to simulate CT angiography of the cerebral vasculature, and calculated  $d'$  to compare the results of a photon-counting CT system (PCD-CT) and an energy-integrating detector CT system (EID-CT).

## METHODS AND MATERIALS

We used a cylindrical water phantom with a diameter of 210 mm to simulate X-ray absorption in an adult head. A wire phantom with a 1-mm diameter, 100-mm length was placed in the water phantom as an object for in-plane TTF measurement. Custom-made iodine wire phantoms, 1 mm in diameter, manufactured by Kyoto Kagaku (Kyoto, Japan), and made of the same material equivalent to diluted iodine with a concentration of 12 mg/ml to simulate the anterior choroidal artery. We evaluated the image quality of small blood vessels in polyenergetic imaging and spectral imaging using this phantom. All images were acquired at 120 kVp and dual energy mode using a PCD-CT (NAEOTOM Alpha, Siemens Healthineers, Erlangen, Germany) and a second generation dual source EID-CT (SOMATOM Definition Flash, Siemens Healthineers, Erlangen, Germany). Virtual monoenergetic images (40 keV at spectral imaging) and polyenergetic image were generated, and noise and contrast-dependent spatial resolution were assessed with noise power spectral (NPS) and TTF, respectively. We also computed the detectability index ( $d'$ ) of simulated small vessels.

## RESULTS

The NPS at 120 kVp was only slightly different between PCD-CT and EID-CT. At 40 keV, PCD-CT had 29 % less noise. The 50 % TTF was 9 % higher for PCD-CT at 120 kVp and 18 % higher at 40 keV. The  $d'$  of PCD-CT was 63 % higher at 120 kVp and 84 % higher at 40 keV.

## CONCLUSION

The phantom used in this study accurately simulates the adult head with contrasted small vessels, enabling the evaluation of both spectral and polyenergetic images. Our measurements using iodine wire phantoms demonstrated the high performance of PCD-CT in cerebral CT angiography.

## CLINICAL RELEVANCE/APPLICATION

Our proposed method for measuring  $d'$  would be effective for clarifying the image quality of cerebral CT angiography.

### M5A-SPPH-12 **Clinical Usefulness of the Latest 256-detector CT Scanner with 3D Anti-scatter System and Multi-material Artifact Reduction Algorithm to Reduce Pseudoenhancement of Renal Cysts in Abdominal Contrast-enhanced CT**

Participants  
Shingo Harashima, Tokyo, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

The latest 256-detector CT scanner (Revolution CT, GE) has been clinically introduced with a focally aligned detector layout and 3D collimator to use 2D grids to reject scatter in the z-direction and angular plates in the third dimension to reduce scatter as well as multi-material artifact reduction (MMAR) algorithm to reduce heel effect and beam-hardening errors in reconstructed images. We assessed clinical usefulness of Revolution CT with the anti-scatter system and MMAR algorithm to reduce pseudoenhancement of renal cysts in abdominal contrast-enhanced CT (CECT).

## METHODS AND MATERIALS

We included 64 simple renal cysts from 30 patients (16 men; mean age,  $68 \pm 10$  years; mean body mass index [BMI],  $24.9 \pm 4.5$  kg/m<sup>2</sup>) who underwent both the noncontrast CT (NCCT) and CECT at 120 kV with Revolution CT and 76 simple renal cysts from other 30 patients (18 men; mean age,  $65 \pm 12$  years; mean BMI,  $23.2 \pm 3.4$  kg/m<sup>2</sup>) with simple renal cysts who underwent both the NCCT and CECT at 120 kV with a conventional CT scanner (Discovery CT, GE). Each patient underwent helical acquisition of both the NCCT and CECT with iodine load of 600 mgI/kg during the nephrographic phase using our routine parameters including noise index of 10-11 HU (mean CTDIvol:  $6.8 \pm 3.1$  mGy for Revolution CT;  $12.3 \pm 3.0$  mGy, Discovery CT). We reconstructed axial images of slice thickness of 1.25 mm; measured the maximum diameter of the largest cyst on the CECT; and identically placed a region of interest within the cyst to measure the mean CT value on both the NCCT and CECT in each patient. Each renal cyst was classified into one of the following three groups based on the maximum diameter: group A, < 10 mm; group B, = 10 mm to < 20 mm; group C, = 20 mm. Degree of pseudoenhancement of each renal cyst was defined as difference of the mean CT value between

CECT and NCCT. Unpaired t test was used to compare the degree of pseudoenhancement between Revolution CT and Discovery CT in the groups A-C.

## RESULTS

The degree of pseudoenhancement was significantly smaller with Revolution CT than with Discovery CT in the group A ( $0.78 \pm 1.66$  HU [n = 22] vs.  $15.96 \pm 5.95$  HU [n = 28]), the group B ( $1.34 \pm 2.39$  HU [n = 22] vs.  $13.38 \pm 6.47$  HU [n = 26]), and the group C ( $0.39 \pm 1.12$  HU [n = 19] vs.  $6.62 \pm 4.05$  HU [n = 23]) (P < 0.001 for all), as shown in Table. Revolution CT better reduced pseudoenhancement of smaller renal cysts.

## CONCLUSION

s Revolution CT with the anti-scatter system and MMAR algorithm is clinically advantageous for significantly reducing pseudoenhancement of renal cysts in abdominal CECT over a conventional CT scanner.

## CLINICAL RELEVANCE/APPLICATION

Revolution CT with 3D anti-scatter system and MMAR algorithm is clinically useful to reduce pseudoenhancement of renal cysts and thus improve differentiation between renal cysts and solid masses in abdominal CECT.

## M5A-SPPH-13 Phantom Study on Radiomic Features in Ultra-High-Resolution CT Imaging: Matrix Size, Radiation Dose, and Reconstruction Algorithms

Participants

Tomoki Maebayashi, Kobe, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

With the advent of ultra-high-resolution (UHR) CT and photon-counting CT systems, 1024-matrix imaging has achieved clinical viability. These images display enhanced spatial resolution compared to conventional 512-matrix images. However, the impact of matrix size, radiation dose, and reconstruction algorithm on radiomic quantification remains unclear. This phantom study aimed to elucidate the effects of imaging parameters on CT radiomic feature quantification.

## METHODS AND MATERIALS

3D-printed cylindrical plastic phantom (19 mm diameter) designed for radiomic analysis was fabricated. The phantom contained an array of cavities filled with varying contrast agent concentrations, generating spatial variation in CT values (6 distinct types). These cylindrical phantoms were integrated into a 30x20 cm CT evaluation phantom (Kyoto Kagaku) and imaged using an UHR scanner (Aquilion Precision; Canon). Radiomic analysis was conducted in two dimensions by placing 2.0 cm<sup>2</sup> circular ROI for each of the six phantoms, evaluating 118 features classified as first-order (n=19), shape (n=24), and texture (n=75). Two comparative analyses were performed: a) super-high-resolution (SHR) mode (0.25 mm thickness, 1024 matrix) versus normal-resolution (NR) mode (0.5 mm thickness, 512 matrix) images, utilizing hybrid iterative reconstruction; b) SHR mode images with three tube currents (150 mA, 290 mA, 580 mA) and three reconstruction algorithms (deep learning, hybrid iterative, filtered back projection). A linear mixed-effects model assessed imaging parameter effects on features. A P-value less than 0.05 divided by 118 for Bonferroni correction was considered significant.

## RESULTS

In 13 (11.0%) of the 118 features, significant disparities arose between measurements from imaging matrices (1024 versus 512 matrix). Neighborhood Gray-Tone Difference Matrix (NGTDM; 20.0%) was primarily affected, followed by Gray-Level Dependence Matrix (GLDM; 14.3%). Examining 1024 matrix images, 35 features (29.7%) exhibited dose-induced measurement alterations. First-order features (73.7%) were most frequently significantly affected, followed by NGTDM (40.0%). No substantial differences were observed in feature measurements related to reconstruction algorithms.

## CONCLUSION

s Significant discrepancies in feature measurements can be discerned when utilizing UHR CT. Approximately 30% of feature measurements using UHR CT images were notably influenced by dose but not by the reconstruction algorithm.

## CLINICAL RELEVANCE/APPLICATION

Radiomic features derived from CT images using a 1024 matrix deviate from those originating from conventional CT, with measurements dependent on radiation dose while remaining largely unaffected by the reconstruction algorithm.

## M5A-SPPH-2 Dual-Source Photon-Counting CTA of the Thorax: Impact of Low Energy Virtual Monoenergetic Imaging on Image Quality, Vascular Contrast and Diagnostic Accessibility

Participants

Christian Booz, MD, Frankfurt am Main, Germany (*Presenter*) Speaker, Siemens AG

## PURPOSE

Preliminary dual-energy CT studies have shown that low energy virtual monoenergetic imaging (VMI)+ reconstructions can provide superior image quality compared to standard 120 kV CTA series. The purpose of this study is to evaluate the impact of low energy VMI+ reconstructions on quantitative and qualitative image quality, vascular contrast and diagnostic assessability of thoracic arteries in patients undergoing photon-counting CTA examinations.

## METHODS AND MATERIALS

A total of 120 patients (66 male) who had undergone dual-source photon-counting CTA scans of the thorax were retrospectively analyzed in this study. Standard 120 kV CT images and low keV VMI+ series from 40 to 100 keV with an interval of 15 keV were reconstructed. Quantitative analyses included evaluation of vascular CT numbers, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). CT number measurements were performed in the ascending and descending aorta, the aortic arch, the common carotid artery, the subclavian artery and the coronaries. Qualitative analyses were performed by three board-certified radiologists independently using five-point scales to evaluate image quality, vascular contrast and diagnostic assessability of thoracic arteries.

## RESULTS

Mean attenuation, CNR and SNR values were highest in 40 keV VMI+ reconstructions (HU, 1205 ± 11; CNR, 29 ± 7; SNR, 30 ± 9) followed by 55 keV VMI+ reconstructions (HU, 679 ± 8; CNR, 23 ± 6; SNR, 24 ± 7); all three mean values at these keV levels were significantly higher compared with the remaining VMI+ series and standard 120 kV CT series (HU, 169 ± 7; CNR, 19 ± 5; SNR, 27 ± 7) ( $p < .0001$ ). The qualitative analysis showed highest rating scores for 55 keV VMI+ reconstructions followed by 40 keV and 70 keV VMI+ series with a significant difference compared to standard 120 kV CT images regarding image quality, vascular contrast and diagnostic assessability of thoracic arteries ( $p < .0001$ ).

## CONCLUSION

Low keV VMI+ reconstructions at a level of 40-55 keV significantly improve image quality, vascular contrast and the diagnostic assessability of the thoracic arteries compared with standard CT series in photon-counting CTA.

## CLINICAL RELEVANCE/APPLICATION

In patients undergoing photon-counting CTA scans of the thorax, low keV VMI+ reconstructions at a level of 40-55 keV should be routinely reconstructed to improve image quality and the diagnostic assessability and to potentially reduce radiation dose and the needed amount of intravenous contrast material in scan protocols in order to protect kidney function.

## M5A-SPPH-4 Usage of DECT Features and Radiomics for Management of Renal Lesions in Patients with Von Hippel-Lindau

### Participants

Mahshid Golagha, MD, Bethesda, MD (*Presenter*) Nothing to Disclose

Shiva Singh, MBBS, Bethesda, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Von Hippel-Lindau syndrome (VHL) is a rare genetic condition that increases the risk of cancer, particularly clear cell renal cell carcinoma (ccRCC). Patients with VHL mutation are usually placed under active surveillance until the tumor reaches a size of 3cm, after which surgery is advised. This study aims to investigate the potential use of dual-energy CT (DECT) and radiomics in predicting time to 3cm in patients with VHL, providing a more accurate and efficient method of monitoring ccRCC lesions.

## METHODS AND MATERIALS

This IRB-approved study comprised 71 adult patients (mean age, 44 ± 13 years, 39 males) with histologically proven ccRCCs in patients with VHL germline mutation who underwent contrast-enhanced DECT of the abdomen during their active surveillance period. A total of 134 lesions which were measured >1cm and <2.5 cm on their baseline DECT studies and had a follow-up study reaching 3cm included in our study. We classified the lesions based on their size on baseline images into small (1-1.5cm), medium (1.5-2cm), and large (2-2.5cm). Within each group, we calculated the median time taken for lesions to reach 3cm, enabling us to classify each lesion as either slow-growing or fast-growing. Deidentified low and high kV series of the venous phase of baseline images were imported and processed on the DECT tumor analysis prototype. We semiautomatically segmented all renal lesions to extract DECT and radiomic features. Using a region of interest on the renal cortex, we normalized the iodine concentrations. Data were analyzed with multiple logistic regression and receiver operator characteristic area under the curve (AUC) as the output.

## RESULTS

In each group, there was no difference in the maximum diameter, volume, and whole area of the lesions growing to 3cm slowly or fast ( $p > 0.3$ ). Normalized iodine concentration was significantly higher in lesions that reached 3cm slower than the others ( $p < 0.001$ ). Although the necrotic volume of the lesions was higher in those that reached 3cm faster, but it was not statistically significant. With multiple logistic regression, the combination of iodine concentration and normalized iodine concentration was the best subset in predicting lesions reaching 3cm fast (AUC: 0.72, 95% CI: 0.71-0.74). Radiomics were not able to predict time to 3cm based on baseline DECT studies.

## CONCLUSION

Quantitative iodine parameters of renal lesions derived from the venous phase of DECT studies show potential in predicting the growth of ccRCC lesions and guiding clinical decision-making in patients with VHL.

## CLINICAL RELEVANCE/APPLICATION

Predicting ccRCC lesion growth in patients with VHL improves care quality, prioritizes monitoring for rapidly growing lesions, and helps minimize unnecessary radiation exposure for slower-growing ones.

## M5A-SPPH-5 Evaluation of an Experimental Tantalum Oxide Contrast Material for Material Separation from Iodine and Gadolinium using DECT and PCCT

### Participants

Yuxin Sun, BS, MSc, San Francisco, CA (*Presenter*) Stockholder, Nextrast, Inc

## PURPOSE

To evaluate material separation of an experimental tantalum oxide nanoparticle contrast agent (TaCZ) from iodine and gadolinium, using clinical DECT and a prototype deep silicon PCCT scanner.

## METHODS AND MATERIALS

Vials of the following concentrations of contrast agents: 2.5, 5.0, 10.0 mg iodine/mL (Ultravist, Bayer); 1.2, 1.9, 2.4, 5.8 mg Gd/mL (Multihance, Bracco); 2.0, 2.5, 4.0, 5.0, 6.0, 8.0, 10.0, 12.0 mg Ta/mL (TaCZ, RPI) were scanned in a water-equivalent CT phantom (MECT Phantom, Gammex) on a clinical fast-kV switching DECT scanner (Revolution CT, GE) and a prototype deep silicon PCCT. Paired iodine and water material decomposition (MD) images were generated for both scanners. Also, PCCT bin images were generated (bin A, 44-52 keV; bin B, 52-60 keV; and bin C, 60-80 keV). ROIs were drawn on 10 slices per vial for all image reconstructions to measure average CT attenuation, iodine and water signals. Slopes of iodine versus material concentration graphs were compared for MD images, and higher to lower bin CT number ratios were compared in the bin images.

## RESULTS

The mean attenuation of 5.0 mg/mL iodine and Ta. and Gd (5.8 mg/mL) at 120 kVp was 129. 130. and 175 HU for DECT. and 119.

130, and 229 HU at 70 keV for PCCT, respectively. Slopes of iodine signal versus elemental concentration for DECT and PCCT are 1.06 and 0.93 for iodine; 0.79 and 0.05 for Gd; and 0.10 and -0.04 for Ta, respectively. For MD iodine maps, a larger slope difference is seen for iodine vs. Ta than for iodine vs. Gd, suggesting better spectral separation of iodine from Ta by DECT and possibly PCCT. At DECT, separation of Ta from Gd appears modest (slope  $\beta = 0.68$ ) but poor for PCCT ( $\beta = 0.08$ ) because both materials are correctly classified as non-iodine by 2-MD. However, in PCCT bin images, Gd signal (K-edge 50.2 keV) is optimized between bins A B with an attenuation ratio of  $\sim 1.38$  between those bins, while Ta signal (K-edge 67.4 keV) is optimized between bins B C with a ratio of  $\sim 1.26$ . Attenuation ratios of other materials, including iodine and water are all = 1.0 for these same bin pairs, indicating promising bin-based material separation of Ta and Gd from iodine and other materials.

## CONCLUSION

s Tantalum provides intense enhancement on par with iodine at 120 kVp. Iodine signal is more readily separated from that of Ta than Gd by DECT material decomposition images, and is slightly more readily separated from that of Ta than Gd by PCCT. When using PCCT bin (non-MD) images, both Gd and Ta signals are readily differentiated from that of iodine, from each other, and from other materials.

## CLINICAL RELEVANCE/APPLICATION

Experimental TaCZ contrast gives a strong "color" signal that should be readily separated from iodine signal by both DECT and PCCT, and from Gd for PCCT, and may enable future multi-color contrast discrimination.

## M5A-SPPH-6 Revisiting Noise Variance-mAs Dependence in Photon Counting Detector CT

### PURPOSE

CT noise variance has long been known to be inversely proportional to tube current-time product (mAs), which is essential in clinical CT protocol optimization. With the introduction of photon counting detector CT (PCD-CT), there is an opportunity to provide low-dose CT imaging with high spatial resolution for various clinical tasks. However, the unique technical aspects of PCD-CT, such as pulse pileup and charge-sharing effects, require a new functional dependence on mAs for noise variance.

### METHODS AND MATERIALS

With the introduction of photon counting detectors (PCDs) in CT imaging, the finite deadtime of the detectors causes the statistical distribution of raw counts to deviate from the ideal Poisson distribution, becoming deadtime-dependent. In this study, a modified Poisson distribution of photon counts for non-paralyzable PCDs was used to derive the post-log sinogram projection data variance. To connect the noise variance of a CT image with the variance of the sinogram data, a cascaded systems analysis was introduced. Additionally, for PCD-CTs with pile-up corrections, a similar analysis was conducted to derive the functional dependence of noise variance on both mAs and deadtime  $t$ . The analytical  $s^2(\text{mAs}, t)$  models were validated by comparing them with simulation results and experimental data obtained from a CdTe-based PCD-CT system.

### RESULTS

In PCD-CTs without pile-up corrections, the traditional noise variance of the CT image on mAs is modified by an additional multiplication factor of  $1/(1 + \beta \text{mAs}t)$  with a numerical constant  $\beta$ . On the other hand, for PCD-CTs with pile-up corrections, the classical noise variance of CT image on mAs is modified by an additional additive factor  $\gamma t$ , where  $\gamma$  is another numerical constant. Compared with simulated PCD-CT noise data with and without pileup corrections, the mean percent errors of the theoretical models are 0.53% (95% limits of agreement: [-8.45%, 9.50%]) and 0.44% (95% limits of agreement: [-8.17%, 9.04%]) respectively. Compared with experimental PCD-CT noise data, the mean percent error of the theoretical model is 0.04% (95% limits of agreement: [-1.30%, 1.38%]).

## CONCLUSION

s In the non-paralyzable counting mode of PCD-CTs, such as those in the existing clinical systems, the dependence of CT image noise on mAs is modified as follows: 1) without pile-up correction,  $s^2$  is altered by a multiplicative factor, and 2) with pulse pile-up correction,  $s^2$  is altered by an additive factor.

## CLINICAL RELEVANCE/APPLICATION

The novel noise variance-mAs relationships allow one to predict the CT noise variance at different mA levels accurately and provide the needed scientific foundation for clinical protocol optimization of PCD-CT.

## M5A-SPPH-7 Optimization and Feasibility of Breast Cancer Imaging with Photon-counting CT: A Phantom Study

### Participants

Richard Ahn, MD, PhD, Dallas, TX (*Presenter*) Nothing to Disclose

### PURPOSE

Contrast enhancement is the most sensitive feature of breast malignancy and forms the basis of cancer detection with either breast MRI or contrast-enhanced mammography. Compared to conventional energy-integrating CT, photon-counting CT (PCCT) offers improved spatial resolution, superior iodine conspicuity, and material differentiation capabilities. The purpose of this study was to evaluate the performance of PCCT for breast cancer imaging using an anthropomorphic phantom.

### METHODS AND MATERIALS

A spectral mammography phantom (Sun Nuclear) containing 2 sets of simulated lesions with 0.2, 0.5, 1.0, 2.0 mg/mL iodine was placed on top of an anthropomorphic chest phantom (QRM GmbH, 35 cm X 25 cm). Additional iodine rods (Sun Nuclear) with matched iodine concentrations were placed in the center of the chest phantom. The phantom was imaged on a clinical PCCT scanner (NAEOTOM Alpha, Siemens) using a chest protocol in both standard (144X0.4 mm) and ultra-high resolution (UHR: 120X0.2 mm) modes. Images were reconstructed using a quantitative kernel (Qr40) with quantum iterative reconstruction algorithm at a strength of 3 (QIR-3) with two field of views (FOVs): a large FOV of 420 mm X 420 mm containing both mammography phantom and chest phantom, and a small FOV of 224 mm X 224 mm only containing the mammography phantom. All reconstructions were performed with two matrix sizes of 512 and 1024. Threshold-low images (T3D), virtual monoenergetic images (VMIs) at 50, 60, and 70 keV, and iodine maps were generated. Circular ROI were drawn within the breast lesions and iodine rods. Normalized root mean square error (nRMSE) in CT number was calculated for ROI in the lesions compared to the reference iodine rods. Contrast to noise ratio (CNR) and linearity were measured. Circularity of the breast lesions was measured using a local threshold model and MATLAB.

## RESULTS

CNR was highest at 50 keV for all iodine concentrations and ranged from 8.2 at 2 mg/mL iodine to 1.0 at 0.2 mg/mL. The nRMSE was similar for all configurations and ranged from 0.5-0.7 HU. CT number linearity was excellent for all configurations ( $R^2=1$ ). Circularity of lesions was highest for the large FOV with standard or UHR mode and a 512 matrix size.

## CONCLUSION

s Standard collimation with large FOV and 512 matrix size was optimal for nRMSE, CNR, and circularity measurements. 50 keV VMIs were optimal for breast lesion evaluation due to increased lesion conspicuity and shape fidelity. These phantom results will guide further protocol development to optimize clinical breast imaging on PCCT.

## CLINICAL RELEVANCE/APPLICATION

PCCT has the potential for improved breast cancer locoregional staging due to greater iodine conspicuity in spectrally derived images and improved resolution compared to prior generations of CT scanners.

## M5A-SPPH-8 Simultaneous Iodine and Bismuth Dual-contrast CT Enterography with Clinical Photon-counting CT: A Feasibility Phantom Study using Low-concentration Samples

### Participants

Afrouz Ataei, PhD, Naples, FL (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate whether low-concentration iodine and bismuth samples can be visually differentiated and accurately quantified using clinical dual-source photon-counting CT (PCCT).

## METHODS AND MATERIALS

Four bismuth-barium solutions (0.7, 1.3, 2.5, and 5.1 mg Bi/mL) were prepared by mixing over-the-counter Pepto-Bismol (10.1 mg Bi/mL, Procter Gamble) with a low-density barium sulfate oral suspension (0.1% w/v, NeuLumEX™, E-Z-EM Canada Inc). The 0.7 mg Bi/mL solution corresponded to 30 mL (one dose) of Pepto-Bismol mixed with 500 mL (one bottle) of oral barium suspension. The four bismuth solutions and three iodine rods (1, 2, and 5 mg I/mL, Sun Nuclear) were inserted into three different multi-energy CT phantoms (20, 33, and 40-cm lateral dimension, Sun Nuclear). Each phantom-sample configuration was scanned on a PCCT system (NAEOTOM Alpha, Siemens) at three kV settings (120 kV: [20, 65 keV]; 140 kV: [20, 70 keV]; Sn140 kV: [20, 80 keV], Sn = 0.6-mm tin filter). Radiation dose levels (CTDIvol) were 3, 8, and 12 mGy, respectively. A custom 3-material decomposition method (iodine/bismuth/water) was used to generate iodine, bismuth, and water maps from the PCCT low- and high-energy bin reconstructed images (Qr44, QIR-3, 2.0/1.0 mm slice thickness/increment) for each data acquisition. Volume conservation was incorporated as a physical constraint for the 3-material decomposition method. The mean bismuth and iodine mass concentrations (mg/mL  $\pm$  standard deviation) were measured by placing a circular ROI of  $\sim 2.2$ -cm<sup>2</sup> on each sample. Linear regression analysis was performed to evaluate the correlation between nominal and measured mg/mL values on the iodine and bismuth maps. The root-mean-square-error (RMSE) for iodine, bismuth, and their combination was computed to assess overall quantification accuracy and was compared across all three kV settings and three phantom sizes.

## RESULTS

All iodine and bismuth samples, including those with the lowest concentrations, were clearly differentiated at all kV settings and phantom sizes. The 140 kV setting (with no additional filter) was found to be the optimal kV across the small, medium, and large phantom sizes, with combined RMSE values of 1.45, 1.91, and 2.00 mg/mL, respectively. Both the iodine and bismuth measured mg/mL values were highly linearly correlated with the nominal mg/mL values ( $R^2>0.99$ ) at the optimal 140 kV setting.

## CONCLUSION

s Iodine and bismuth dual-contrast imaging at low-concentration levels can be accurately performed on a clinical PCCT at routine clinical radiation dose levels.

## CLINICAL RELEVANCE/APPLICATION

Simultaneous imaging and visual segmentation of iodine-enhanced small bowel wall and bismuth containing small bowel lumen may allow for improved diagnosis in CT enterography imaging.

## M5A-SPPH-9 Single-energy Low-kV in Energy-integrating Detector CT Versus Low-keV Virtual Monoenergetic Images in Photon-counting Detector CT for Iodine Imaging

### Participants

Hiroki Kawashima, PhD, RT, Kanazawa, Japan (*Presenter*) Kyoto kagaku, Research collaboration

## PURPOSE

To investigate the performance for iodine imaging of low-keV virtual monoenergetic images (VMIs) in photon-counting detector CT (PCD-CT), compared with those of single energy low-kV images in energy-integrating detector CT (EID-CT), using a Fourier-based assessment.

## METHODS AND MATERIALS

A water-bath phantom with a diameter of 300 mm, which contains two rod-shaped phantoms made of diluted iodine (2 and 12 mg/ml), was scanned using a clinical PCD-CT (SIEMENS, NAEOTOM Alpha) and an EID-CT (SIEMENS, SOMATOM Force) at 15 mGy. A low-kV image was obtained with a tube voltage of 90 kV in EID-CT (EID 90 kV). VMIs at 40 and 64 keV were reconstructed from the scan data obtained with a tube voltage of 120 kV in PCD-CT. The energy level of 40 keV is the lowest keV setting, and 64 keV was the energy level that exhibited the closest CT number to that of EID 90 kV. In PCD-CT, a low energy threshold image with a tube voltage of 90 kV (PCD 90 kV) was also obtained for comparison. The iodine contrast (C) and the task transfer function (TTF) were measured with the rod images; the noise power spectrum (NPS) was measured in the water-only region. The system performance function, including the iodine contrast factor (SPFc2) was defined as  $[C^2 \cdot TTF^2(f)]/NPS(f)$ .

## RESULTS

The SPFc2 of VMI 40 keV was notably higher than that of EID 90 kV as the spatial frequency increased. The ratios of SPFc2 of VMI 40 keV to EID 90 kV were approximately 1.50 and 2.81 at 0.1 and 0.5 mm<sup>-1</sup>, respectively. The SPFc2 of VMI 64 keV was comparable to or somewhat lower than that of EID 90 kV. In comparison between the same tube voltage, PCD images were superior to EID images, which was consistent with the theoretical advantages of PCD. The ratios of SPFc2 of PCD 90 kV to EID 90 kV were approximately 1.28 and 1.58 at 0.1 and 0.5 mm<sup>-1</sup>, respectively.

#### **CONCLUSION**

s VMI 40 keV in PCD-CT had a higher performance for iodine imaging than the low tube voltage techniques (EID 90 kV and PCD 90 kV), whereas the performance degradation might be unavoidable when the iodine contrast equalized (EID 90 kV versus VMI 64 keV).

#### **CLINICAL RELEVANCE/APPLICATION**

This study quantitatively demonstrates that PCD-CT has the potential to provide better image quality than EID-CT in a contrast-enhanced CT scan.

M5A-SPRO

### Radiation Oncology Monday Poster Discussions I

#### Sub-Events

#### M5A-SPRO-1CT Patterns and Clinical Outcomes of Radiation Pneumonitis in Non-small Cell Lung Cancer Patients

#### PURPOSE

To investigate the CT findings of radiation pneumonitis (RP) in non-small cell lung cancer (NSCLC) patients and their relationship with clinical outcomes.

#### METHODS AND MATERIALS

We assessed CT findings and clinical information of 58 patients with NSCLC who underwent radiotherapy as curative treatment. The CT findings were evaluated for the presence and distribution of the parenchymal abnormalities, which were then classified into three patterns: localized pneumonia (LP), cryptogenic organizing pneumonia (COP), and acute interstitial pneumonia (AIP). Radiation technique, gross tumor volume (GTV), radiation (RT) dose, mean lung dose (MLD), and volume of normal lung receiving 20Gy (V20) were also evaluated. Clinical outcome was evaluated on the basis of Common Terminology Criteria for Adverse Events (CTCAE) grade, corticosteroid treatment, admission, and death. Correlations between imaging findings and clinical outcomes were analyzed.

#### RESULTS

Of the total 58 patients, 47 developed RP. Out of 47 patients, 26(55.3%) had symptoms of grade 2 or less, and 2(4.7%) had symptoms of grade 3 or more. RP related death occurred in 11(19.0%) patients. All patients received radiotherapy using the intensity-modulated radiation therapy technique. The mean, median, and range of the radiation-related factors in all patients are as follows; GTV (134.0, 111.5, 6.9-466.4), RT dose (6010.3, 6600.0, 200.0-7000.0), MLD (1437.6, 1465.9, 364.8-2267.5), V20 (24.9, 25.2, 1.1-443.8). The CT findings of RP were ground-glass opacity with reticulation in 46 (97.8%), consolidation in 40 (85.1%), air-bronchogram in 41 (87.2%), traction bronchiectasis in 28 (59.6%), pleural effusion in 19 (40.4%) and necrosis or cavity formation in 4 (8.5%). The most common pattern of RP was LP (n=20, 42.6%) followed by AIP (n=19, 40.4%) and COP (n=8, 17.0%). GTV, MLD and V20 were significantly different between LP, COP, and AIP patterns ( $p<0.05$ ). The presence of underlying pulmonary fibrosis, AIP pattern and CT extent were higher in the patients with higher CTCAE grade than in patients with lower CTCAE grade ( $p<0.05$ ). RT dose, AIP pattern, CT extent were significantly associated with RP-related death ( $p<0.05$ ).

#### CONCLUSION

s RP could be classified into LP, COP and AIP in NSCLC patients and GTV, MLD and V20 were significantly different in each pattern. The underlying pulmonary fibrosis, AIP pattern and high extent of RP were associated with poor clinical outcomes.

#### CLINICAL RELEVANCE/APPLICATION

In NSCLC patients undergoing radiotherapy, RP pattern could be classified into LP, COP and AIP, and GTV, MLD and V20 were significantly different in each pattern. Patients with underlying pulmonary fibrosis or those planned for high RT should be closely followed up to improve patient outcomes.

M5A-SPVA

### Vascular Imaging Monday Poster Discussions I

#### Sub-Events

#### **M5A-SPVA-1 High Resolution MRI Based Radiomics for the Assessment of NIILs after CEA of Patients with Carotid Plaques**

##### **PURPOSE**

This study aimed to assess the occurrence of fresh ipsilateral ischemic lesions in patients with carotid plaques following carotid endarterectomy.

##### **METHODS AND MATERIALS**

We retrospectively collected 115 patients from Renmin Hospital of Wuhan University, all of whom presented with at least 70% carotid luminal stenosis as determined by ultrasound angiography or computerized tomography. Prior to undergoing carotid endarterectomy (CEA), all patients underwent high resolution magnetic resonance imaging (hrMRI) using a 3.0T MR750 system (GE Healthcare, USA) equipped with an 8-channel carotid coil (GE Healthcare, USA). The hrMRI protocol consisted of 2D T1WI FSE, PDWI FSE, and 2D T2WI FSE. The hrMRI images were manually segmented using ITK-SNAP, and radiomics features were extracted using pyradiomics. The occurrence of NIILs was confirmed by DWI following CEA. The patients were randomly divided into training and test groups, and a non-invasive model was built using Lasso and multi-variable logistic regression analysis to predict NIILs.

##### **RESULTS**

Of the total number of patients, 75 were found to have new ipsilateral ischemic lesions (NIILs) following CEA, while 40 did not exhibit any such lesions. Initially, a total of 1175 radiomic features were extracted from T1-weighted images, which were subsequently reduced in dimension to construct a radiomics model to predict NIILs. The area under the curve (AUC) for the radiomics model was 0.864 (95% confidence interval (CI), 0.781-0.947) in the training group and 0.795 (95% CI, 0.646-0.945) in the testing group (Fig. a and b). A clinical model was also built using variables such as sex, age, LDL, HDL, LHR, hypertension, diabetes, IPH (predicted by MRI), and LRNC (predicted by MRI). IPH (OR=42.01) and LRNC (OR=5.11) were incorporated into the clinical model, and a multivariable logistic regression model was constructed by combining radscore, LRNC, and IPH. The model was visualized using a nomogram (Fig. c). The AUC for the combined model was 0.949 (95% CI, 0.906-0.991) in the training group and 0.837 (95% CI, 0.692-0.982) in the testing group. Calibration showed good fitting of the nomogram in both the training and testing groups (Fig. d and e). The nomogram demonstrated the best clinical benefit in the training and testing groups (Fig. f and g).

##### **CONCLUSION**

The findings of this study illustrate that the occurrence of NIILs in patients with carotid plaques after CEA can be predicted non-invasively using a radiomics model and a combined model.

##### **CLINICAL RELEVANCE/APPLICATION**

Compared to traditional hrMRI, the combined model, which incorporates radiomics and clinical variables, not only predicts the occurrence of NIILs but also enables personalized treatment for patients.

#### **M5A-SPVA-2 Imaging of the Aorta in Dual-Source Photon-Counting CT: Impact of Low Energy Virtual Monoenergetic Imaging on Image Quality, Vascular Contrast and Diagnostic Assessability**

##### Participants

Christian Booz, MD, Frankfurt am Main, Germany (*Presenter*) Speaker, Siemens AG

##### **PURPOSE**

Preliminary dual-energy CT studies have shown that low energy virtual monoenergetic imaging (VMI)+ reconstructions can provide superior image quality compared to standard 120 kV CTA series. The purpose of this study is to evaluate the impact of low energy VMI+ reconstructions on quantitative and qualitative image quality, vascular contrast and diagnostic assessability of the aorta in patients undergoing photon-counting CTA examinations.

##### **METHODS AND MATERIALS**

A total of 125 patients (69 male) who had undergone dual-source photon-counting CTA scans of the aorta were retrospectively analyzed in this study. Standard 120 kV CT images and low keV VMI+ series from 40 to 100 keV with an interval of 15 keV were reconstructed. Quantitative analyses included evaluation of vascular CT numbers, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). CT number measurements were performed in the ascending aorta, the aortic arch, the thoracic and infrarenal descending aorta. Qualitative analyses were performed by three board-certified radiologists independently using five-point scales to evaluate image quality, vascular contrast and diagnostic assessability of the aorta.

##### **RESULTS**

Mean attenuation, CNR and SNR values were highest in 40 keV VMI+ reconstructions (HU, 1312 ± 13; CNR, 32 ± 8; SNR, 34 ± 10) followed by 55 keV VMI+ reconstructions (HU, 731 ± 9; CNR, 24 ± 6; SNR, 27 ± 9); all three mean values at these keV levels were

significantly higher compared with the remaining VMI+ series and standard 120 kV CT series (HU,  $160 \pm 8$ ; CNR,  $18 \pm 5$ ; SNR,  $26 \pm 6$ ) ( $p < .0001$ ). The qualitative analysis showed highest rating scores for 55 keV VMI+ reconstructions followed by 40 keV and 70 keV VMI+ series with a significant difference compared to standard 120 kV CT images series regarding image quality, vascular contrast and diagnostic assessability of the aorta ( $p < .0001$ ).

#### **CONCLUSION**

Low keV VMI+ reconstructions at a level of 40-55 keV significantly improve image quality, vascular contrast and the diagnostic assessability of the aorta compared with standard CT series in photon-counting CTA.

#### **CLINICAL RELEVANCE/APPLICATION**

In patients undergoing photon-counting CTA scans of the aorta, low keV VMI+ reconstructions at a level of 40-55 keV should be routinely reconstructed to improve image quality and the diagnostic assessability and to potentially reduce radiation dose and the needed amount of intravenous contrast material in scan protocols in order to protect kidney function.

## Abstract Archives of the RSNA, 2023

M5B-SPBR

### Breast Imaging Monday Poster Discussions II

#### Sub-Events

#### **M5B-SPBR-2 Is Presence of Enhancement on Contrast-enhanced Mammography (CEM) A Diagnostic Biomarker to Determine the Presence of Malignancy in Suspicious Mammographic Calcifications**

Participants  
Leyla Zeitouni, MD, Riyadh, Saudi Arabia (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Aim: Calcifications are a regular finding on screening mammograms and considered a potential early sign of breast cancer. However, the majority of calcifications are benign and stereotactic biopsies could be avoided in a large proportion of cases. We assessed whether the presence of a corresponding enhancement on CEM is diagnostic for the presence of malignancy in mammographic calcifications.

#### **METHODS AND MATERIALS**

Eligible for this retrospective, IRB-approved, single-center study were women recalled due to mammographic BI-RADS 4 calcifications and who received CEM as part of their diagnostic workup between 2020 and 2022 at our institution. CEM protocols followed international recommendations. Two blinded breast fellows (R1, R2) assessed the presence of enhancement corresponding to calcifications on CEM. Reference standard for findings was stereotactic 9G vacuum-assisted breast biopsy or follow up of at least 24 months. For lesions of uncertain malignant potential, surgery was considered. Proportions were compared using the chi-square test.

#### **RESULTS**

69 women with mammographic calcifications (mean age, range) were included. 17 out of 69 cases (25%) were malignant (13 cases were intraductal and 4 were invasive ductal cancers). In the malignant cases, an enhancement was found in 12/17 (71%, R1) and 15/17 (88%, R2) cases. Seven of 52 (13%) [PB1] benign lesions presented enhancement detected by both readers. The higher enhancement rate in malignant compared to benign calcifications was statistically significant ( $p < 0.001$ , respectively). Non enhancing malignant cases were DCIS cases of varying grades. Enhancing benign cases were intraductal papilloma, adenosis and fibrocystic changes with intraductal epithelial proliferation.

#### **CONCLUSION**

Enhancement in CEM is diagnostic for the presence of malignancy in mammographic calcifications. The risk of false negative in the absence of enhancement ranged between 1-3 of 10 malignant cases. Benign calcifications can sometimes show enhancement on CEM.

#### **CLINICAL RELEVANCE/APPLICATION**

CEM identifies pathological enhancement associated with malignant calcification in the majority of the cases, but a significant amount of DCIS may not show enhancement.

#### **M5B-SPBR-3 Performance of Node-RADS Scoring System for a Standardized Assessment of Regional Lymph Nodes in Breast Cancer Patients**

Participants  
Roberto Maroncelli, MD, Guidonia (RM), Italy (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Current cross-sectional imaging modalities exhibit heterogeneous diagnostic performances for the detection of a lymph node invasion (LNI) in breast cancer (BC) patients. Recently, the Node-RADS score was introduced to provide a standardized comprehensive evaluation of LNI, based on a five-item Likert scale accounting for both size and configuration criteria. In the current study, we hypothesized that the Node-RADS score accurately predicts the LNI and tested its diagnostic performance. The secondary objective focuses on assessing the applicability and feasibility of the score among readers.

#### **METHODS AND MATERIALS**

We retrospectively reviewed BC patients treated with mastectomy or QUART and lymph node dissection, from January 2020 to January 2023. Patients receiving preoperative systemic chemotherapy were excluded, therefore we included only patients undergoing lymphadenectomy after sentinel node positivity, who refused neoadjuvant therapy (NT) by self-determination and patients who had contraindications to NT. A logistic regression analysis tested the correlation between the Node-RADS score and LNI both at patient and lymph-node level. The ROC curves and the AUC depicted the overall diagnostic performance. In addition, the sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated for different cut-off values ( $>1$ ,  $>2$ ,  $>3$ ,  $>4$ ).

#### **RESULTS**

Overall, data from 100 patients were collected. Node- RADS assigned on CT scans and CE-MRI images, was found to independently predict the LNI after an adjusted multivariable regression analysis, both at the patient (OR 3.36, 95%CI 1.68-9.40,  $p=0.004$ ) and lymph node (OR 5.18, 95%CI 3.39-8.64,  $p<0.001$ ) levels. Node-RADS exhibited an AUC of 0.85 and 0.90 at the patient and lymph node levels, respectively. With increasing Node-RADS cut-off values, the specificity and PPV increased from 50.0 to 95.3% and from 50.3 to 80.0%, respectively. Conversely, the sensitivity and NPV decreased from 100 to 40.0% and from 100 to 75.3%, respectively. Excellent inter-reader agreement was found in the classification of LN according to the NODE-RADS MRI score.

## CONCLUSION

The current study lays the foundation for the introduction of Node-RADS for the regional lymph-node evaluation in BC patients. Interestingly, the Node-RADS score exhibited a moderate-to-high overall accuracy for the identification of LNI, with the possibility of setting different cut-off values according to specific scenarios.

## CLINICAL RELEVANCE/APPLICATION

Node-RADS has only been validated in prostate and bladder cancer, showing promising results. No previous reports have investigated his role in BC; we want to address this gap. Higher Node-RADS score could be associated with an increased risk of LNI.

## M5B-SPBR-4 Multi-national Validation of A Clinical Image-based AI-risk Model for Individualizing Breast Cancer Screening

### PURPOSE

To investigate the predictive performance of a clinically used image-derived AI-based breast cancer risk model in multiple European screening populations.

### METHODS AND MATERIALS

Four European mammographic screening populations in three countries screened between 2009-2020 for women aged 45-69 was used to perform a nested case-control study. In total, 739 women with incident breast cancers were included together with 7,812 controls matched to cases on year of study-entry. Mammographic features (density, microcalcifications, masses, left-right breast asymmetries of these features) for risk assessment were extracted using AI from full-field digital mammograms. Breast cancer occurrence was assessed after two years of follow-up. Absolute risks of breast cancer were predicted using the risk model from negative mammograms at study-entry. Adjusted Area Under the receiver operating characteristic Curves (aAUC) estimated discriminatory performance and, adjusted risk-ratios estimated the stratification performance of women at high/general risk per the clinical guidelines.

### RESULTS

The overall aAUC of the AI risk model was 0.72 (95%CI 0.70-0.75), range 0.71 (95%CI 0.67-0.75) to 0.74 (95%CI 0.69-0.78) for breast cancers developed in four screening populations. In the 4.6% of women classified at high risk using the NICE guidelines thresholds, cancers were more likely diagnosed after 2 years follow-up, risk-ratio (RR) 6.7 (95%CI 5.6-8.0), compared with the 71% of women classified at general risk by the model. Similar risk-ratios were observed across tertiles of mammographic density. In the high-risk group, 22% of the 2-year future cancers were diagnosed, and 29% of stage 2 and higher cancers,  $p<0.01$ .

## CONCLUSION

The AI risk model showed generalizable discriminatory performances across European populations and, captured ~30% of clinically relevant stage 2 and higher breast cancers in ~5% of high-risk women who were sent home with a negative mammogram. Similar results were seen in fatty and dense breasts. An image-derived AI model is feasible for personalized screening to improve screening outcomes.

## CLINICAL RELEVANCE/APPLICATION

Image-derived AI risk models for breast cancer have shown high discriminatory performances compared with clinical risk models based on family history and lifestyle factors. However, little is known about their generalizability across different screening settings and clinical feasibility.

## M5B-SPBR-5 The Tyrer-Cuzick Risk Model: Is it Effective for All Races?

### PURPOSE

To assess the predictive value of the Tyrer-Cuzick Version 8 (TC8) Risk Model in a diverse group of patients in an urban medical center. TC scores predict a patient's 10 year and lifetime risk of developing breast cancer.

### METHODS AND MATERIALS

A retrospective review of breast imaging patients from multiple clinics within a university hospital system from January 1, 2018-November 1, 2022 was conducted. We collected each patient's most recent lifetime TC8 score, self-reported race and ethnicity (Hispanic/Latina), and cancer status. We excluded patients who did not report race or did not have TC8 scores. The final cohort contained 74,181 total patients. Analyses to explore differences in TC8 scores by race and ethnicity were first conducted on the entire sample, and then on 700 patients with breast cancer. Patients not reporting race or ethnicity were excluded from those analyses. Data was analyzed using two sample unpaired, unequal variance t-tests and  $p<0.05$ .

### RESULTS

In the total sample ( $n=74,181$ ), mean TC8 risk scores were statistically different between all racial groups and the White reference group. The largest differences were between White and Black (2.4 points,  $p<0.0001$ , CI 2.23-2.57) and White and "Other" (2.9 points,  $p<0.0001$ , CI 2.74-3.06). For the breast cancer cohort ( $n=700$ ), Black patients had a mean TC8 score 2.4 points lower than White patients ( $p=0.02$ , CI 0.32-4.4). There was no statistical difference between mean TC8 scores for White vs. Asian or White vs. "Other". Ethnicity did not have a significant impact on TC8 score relationships. For the total group there was a statistical difference between Non-Hispanic (NH)-White and NH-Black (2.7 points,  $p<0.0001$ , CI 2.53-2.87), consistent with the previous race findings. The Hispanic (H)-Black score was statistically higher than H-White score, however the difference was less than one point. For the breast cancer cohort NH-White had a mean TC8 score 2.2 points greater than NH-Black ( $p=0.045$ , CI 0.41-4.3), and there was no statistical difference between H-White and H-Black scores.

## CONCLUSION

s TC8 scores in Black patients were consistently lower suggesting that TC8 may underestimate Black patients' lifetime breast cancer risk.

## CLINICAL RELEVANCE/APPLICATION

The TC8 score is an important tool for predicting breast cancer risk. Currently insurance companies only reimburse MRI screening for patients with TC lifetime risk score >20. It is possible that some of our patients' risk was underestimated. Specifically, in our cohort 468 Black patients had scores between 17-19 narrowly missing the cutoff. If the 2.2-2.7 point difference was considered those patients may have been advised to pursue MRI screening. We hope our results encourage future research on the appropriateness of TC8 cutoffs for Black patients.

## M5B-SPBR-6 Development and Application of a Feature Based Explainable AI Method (XAI) for Trustworthy Breast Cancer Risk Prediction using the Mirai Model

### PURPOSE

The Mirai model (Yala, MIT) is a publicly available deep learning (DL) model predicting 1- to 5-year breast cancer risk from digital mammograms. The model prediction relies on features extracted by an encoder that utilizes a convolutional neural network. We hypothesized that understanding the individual features in terms of their receptive fields offers a route to explainable AI (XAI). The purpose of this study was to retrieve and quantify the features captured in the final layer of the encoder for the short-term risk prediction.

### METHODS AND MATERIALS

The Mirai encoder detects 512 receptive fields in each mammogram and computes one DL feature value for each field. In this study, features were indexed by the order of encoder outputs. Corresponding receptive fields were matched with the annotations in the individual images. Two datasets were used to evaluate localization and discriminatory power of these features for the present lesions: the Cyprus dataset (100 mammograms) with micro-calcification cases and BI-RADS scores, and the CSAW-S dataset (338 mammograms), which is a case collection of malignant masses. Precision scores between the receptive fields and the locations of masses and calcifications were used to identify lesion-specific features with the highest scores. The area under the receiver operating characteristic curve (AUC) for the discriminative power of BI-RADS scores was calculated for the feature values with the highest calcification precision. Other annotated regions studied included the nipple, skin, thick vessels, and axillary lymph nodes.

### RESULTS

A precision score of 0.81 was found between feature (F) 145 and calcification clusters, while the annotated mass regions had a precision score of 0.80 for F 397. The discriminative ability of the calcification-related feature values for the BI-RADS scores resulted in AUCs of 0.91 and 0.88 for distinguishing suspicious (BI-RADS 4,5) cases from normal (BI-RADS 1,2) and benign (BI-RADS 2) cases, respectively. Other potentially relevant regions had the following feature indexes and precision scores: nipple (F 5, 0.31), skin (F 114, 0.60), thick vessels (F 171, 0.21), and axillary lymph nodes (F 166, 0.26).

## CONCLUSION

s This study provides evidence that risk prediction features in the Mirai model focus on early detection of breast lesions in mammograms, despite not being trained with pixel-wise annotation. The findings provide essential insight into the functionality of short-term breast cancer risk prediction models.

## CLINICAL RELEVANCE/APPLICATION

It is possible to extract the main features at the core of a short-term breast cancer risk prediction AI algorithm. Increasing AI trustworthiness should encourage the inclusion of this AI algorithm in the clinical decision-making process.

## M5B-SPBR-7 Mammographic Density Changes after Neoadjuvant Chemotherapy in Triple-negative Breast Cancer: Association with Treatment and Survival Outcome

### PURPOSE

To evaluate the associations between mammographic density changes after neoadjuvant chemotherapy (NAC) and treatment and survival outcomes in triple-negative breast cancer (TNBC).

### METHODS AND MATERIALS

This single center retrospective study evaluated a total of 306 women with TNBC who underwent NAC followed by surgery between 2010 and 2019. Baseline density and density changes after completion of NAC were evaluated both qualitatively and quantitatively. Qualitative breast density (a-d) was evaluated based on the BI-RADS. Quantitative breast density (%) was evaluated using an open-source software (LIBRA) and mediolateral oblique/craniocaudal mammograms of the contralateral breast. Multivariable logistic regression analysis was used to evaluate the association between breast density and pathologic complete response (pCR) according to the menopausal status. Cox proportional hazard regression analysis was used to evaluate the association between breast density and development of (a) contralateral breast cancer and (b) locoregional recurrence and/or distant metastasis.

### RESULTS

Among 306 women, 93 (30%) achieved pCR, and 71 (23%) had contralateral breast density reduction 10% or greater after NAC. For only premenopausal women (n=177), the contralateral breast density reduction 10% or greater was independently associated with pCR (odds ratio, 2.5; P value=.03). On a median follow-up of 54 months, 10 (3%) women developed contralateral breast cancers, and 68 (22%) women developed locoregional recurrences and/or distant metastases. The contralateral breast density reduction 10% or greater was not associated with the development of contralateral breast cancer (Hazard ratio [HR], 1.3; P value =.78) nor the development of locoregional recurrence and/or distant metastasis (HR, 1.1; P value =.79). Family history of breast cancer was independently associated with the development of contralateral breast cancer (HR, 6.2; P value =.005). The presence of lymphovascular invasion (HR, 2.1; P value=.02), invasive cancer 2cm or greater (HR, 3.9; P value <.001), and lymph node metastasis on the surgical specimen (HR, 2.7; P value =.004) were independently associated with the development of locoregional recurrence and/or distant metastasis. Baseline density was not associated with the treatment and survival outcomes.

## CONCLUSION

s For premenopausal women, contralateral breast density reduction 10% or greater after NAC was independently associated with pCR, although it was not translated to improved outcomes.

#### **CLINICAL RELEVANCE/APPLICATION**

The contralateral breast density reduction 10% or greater after NAC was associated with achievement of pCR in premenopausal women, however, the density reduction was not translated to improved outcomes.

### **M5B-SPBR-8 Volumetric Parenchymal Pattern Radiomic Analysis in Digital Breast Tomosynthesis for Breast Cancer Risk Estimation**

#### **PURPOSE**

We evaluate the performance of volumetric parenchymal pattern analysis from digital breast tomosynthesis (DBT) versus digital mammography (DM), accounting for conventional risk factors and breast density for breast cancer risk estimation. The rationale is that 3D parenchymal texture analysis with radiomic features may provide information beyond 2D breast density.

#### **METHODS AND MATERIALS**

We performed a retrospective case-control study in women with concurrent DM and DBT screening (Selenia Dimensions, Hologic Inc.) at our institution from 3/2011-12/2014. Cases were diagnosed with breast cancer within 1-year of screening; controls were confirmed negative or benign at 1-year follow-up, matched on race (Black, White, other/unknown) and age (5-year bins). After exclusions for imaging artifacts, craniocaudal (CC) and mediolateral oblique (MLO) views for 187 cases and 737 controls, in six image formats were assessed: 1) raw DM; 2) processed DM; 3) raw DBT central projection; 4) processed DBT central projection; 5) DBT central reconstructed slice; and 6) 3D DBT reconstructed stack. For cases, we analyzed the breast contralateral to cancer diagnosis and the same breast in matched controls. We extracted 487 radiomic features using a lattice-based approach with the Cancer Imaging Phenomics Toolkit, averaging features for each breast over CC and MLO views. We examined 3 lattice window sizes (6.4, 12.8, and 25.6 mm) and 23 image resampling resolutions (0.075 - 2mm). We performed principal component analysis on the resulting 487 features for each combination of window size and resampled resolution and built conditional logistic regression models to assess the association of the first seven principal components with breast cancer, with models adjusting for age, BMI, and Breast Imaging Reporting and Data System (BI-RADS) density. We calculated the model C-statistic at all window sizes and resolutions (i.e., total of 2304 experimental conditions).

#### **RESULTS**

Radiomic features from 3D reconstructed DBT scans had on average higher C-statistics across all experimental conditions. A model using only age, BMI, and BI-RADS density had a C-statistic of 0.61. Models using radiomic features plus age, BMI, and BI-RADS density had mean C-statistic of 0.68 (IQR 0.68, 0.69) for reconstructed DBT scans; for all other image types, the mean C-statistic ranged from 0.64 to 0.66.

#### **CONCLUSION**

s 3D volumetric breast parenchymal patterns from DBT may improve breast cancer risk estimation beyond markers derived from 2D DM and conventional breast density metrics alone.

#### **CLINICAL RELEVANCE/APPLICATION**

Fully-automated, 3D parenchymal pattern radiomic analysis is feasible in DBT, and our preliminary evaluation suggests that it may improve breast cancer risk assessment beyond 2D DM measures.

### **M5B-SPBR-9 Mammographic Density Assessment: Radiologists, Artificial Intelligence-based Computer-assisted Diagnosis, and Automated Volumetric Measurement**

Participants

Su Min Cho, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate breast density assessment using BI-RADS (Breast Imaging Reporting and Data System) breast density category across readers with different levels of experience, artificial intelligence-based computer-assisted diagnosis (AI-CAD) and automated volumetric density measurement program (Volpara®).

#### **METHODS AND MATERIALS**

A total of 1,015 screening mammography were retrospectively reviewed (56 ± 10 years). Density assessment according to BI-RADS category was performed by four readers with two different levels of experience; experts and general radiologists. Agreements between visually assessed BI-RADS category, AI-CAD (Lunit INSIGHT MMG) and Volpara® were evaluated using weighted kappa statistics.

#### **RESULTS**

Inter-reader agreement between expert and general radiologist was substantial ( $k = 0.65$ ) with a matched rate of 72.8%. The agreement was substantial between the expert or general radiologist and Volpara® ( $k = 0.64 - 0.67$ ) with a matched rate of 72.0% but moderate between expert or general radiologist and AI-CAD ( $k = 0.45 - 0.58$ ) with a matched rate of 56.7 - 67.0%. The agreement between Volpara® and AI-CAD was moderate ( $k = 0.53$ ) with a matched rate of 60.8%.

#### **CONCLUSION**

s Density assessment by AI-CAD showed moderate agreement with those of radiologists, while Volpara® showed substantial agreement with radiologists.

#### **CLINICAL RELEVANCE/APPLICATION**

Volpara® presented better agreement with radiologists than AI-CAD with a better matched rate.

## Abstract Archives of the RSNA, 2023

M5B-SPCA

### Cardiac Imaging Monday Poster Discussions II

#### Sub-Events

#### M5B-SPCA-1 Can Cardiac CT Alternate Cardiac MRI for Myocardial ECV Quantification in Cardiac Amyloidosis?

##### Participants

Hidetaka Hayashi, MD, Kumamoto, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Myocardial extracellular volume (ECV) on CT, a possible alternative to cardiac MRI, has significant practical clinical advantages. However, the consistency between ECVs quantified via CT and MRI in cardiac amyloidosis (CA) has not been fully investigated. Therefore, the current study investigated the application of CT-ECV in CA with MRI-ECV as the reference standard.

##### METHODS AND MATERIALS

We retrospectively evaluated 31 patients with CA who underwent cardiac CT and MRI. Pearson correlation analysis was performed to investigate correlations between CT-ECV and MRI-ECV at each segment. In addition, correlations between ECV and clinical parameters were assessed.

##### RESULTS

There were no significant differences in terms of the mean global ECVs between CT and MRI ( $51.3\% \pm 10.2\%$  vs  $50.0\% \pm 10.5\%$ ). CT-ECV was strongly correlated with MRI-ECV at the septal ( $r=0.88$ ), lateral ( $r=0.80$ ), and global ( $r=0.87$ ) segments. A strong correlation was also observed at the anterior ( $r=0.77$ ) and inferior ( $r=0.79$ ) segments. In both CT and MRI, the ECV had a weak to strong correlation with high-sensitivity cardiac troponin T level, moderate correlation with global longitudinal strain, and inverse correlation with left ventricular ejection fraction. The septal ECV and global ECV had a slightly higher correlation with the clinical parameters.

##### CONCLUSION

Cardiac CT can quantify myocardial ECV and yields results comparable with those obtained using MRI in patients with CA. A significant correlation was also observed between CT-ECV and clinical parameters.

##### CLINICAL RELEVANCE/APPLICATION

CT-ECV can be used as an imaging biomarker and alternative to MRI-ECV in patients with CA.

#### M5B-SPCA-2 Clinical Utility of 'Faded Edge Sign' on the Post-contrast T1 Mapping for Diagnosis of Cardiac Amyloidosis

##### Participants

Eun Ju Chun, MD, PhD, Seongnam-si, Gyeonggi-do, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the frequency and potential clinical utility of the 'faded edge sign' on the post-contrast T1 mapping to identify cardiac amyloidosis (CA) among patients with left ventricular hypertrophy (LVH).

##### METHODS AND MATERIALS

We retrospectively enrolled 222 patients with pathologically confirmed LVH (56 CA, 116 hypertrophic cardiomyopathies [HCM], 50 hypertensive heart disease[HHD]) who underwent cardiac MR. The 'faded edge sign' was defined as the boundary between the myocardium and the left ventricular (LV) cavity was unclear and the LV myocardium/cavity signal intensity ratio was between 0.8 and 1.2 on the post-contrast T1 mapping. In diagnosing CA among patients with LVH, we compared the diagnostic accuracy of additional faded edge sign compared to the characteristic late gadolinium enhancement (LGE) pattern (global subendocardial enhancement), native T1 values, and extracellular volume (ECV).

##### RESULTS

The faded edge sign was noted in 40 of 56 patients with CA (71.4%) and 5 of 116 patients with HCM (4.3%) and none of the HHD patients. Mean native T1 value and ECV was the highest in CA, followed by HCM and HHD ( $1442 \pm 81$  msec vs.  $1320 \pm 58$  msec vs.  $1230 \pm 32$  msec for native T1 value;  $41 \pm 7\%$  vs.  $29 \pm 7\%$  vs.  $23 \pm 2\%$  for ECV;  $p < 0.05$ ). The sensitivity and specificity of faded edge sign for CA was 71.4% and 97.0%, respectively. For the diagnosis of CA, the diagnostic accuracy of the added faded edge sign for the combination of LGE, ECV, and native T1 (AUC 0.931) was higher than that of the combination of LGE+ECV+native T1 (AUC 0.920) or LGE alone (AUC 0.866).

##### CONCLUSION

The 'faded edge sign' on the post-contrast T1 mapping is a simple observation method that is helpful in increasing the ability for

diagnosis of CA.

#### CLINICAL RELEVANCE/APPLICATION

In addition to LGE, native T1 and ECV, post-contrast T1 mapping was also helpful for the diagnosis of CA.

### M5B-SPCA-3 Prediction of Early Death from Anthracycline-induced Cardiotoxicity using CMR Parameters: An Animal Study

Participants

Nayoung Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### PURPOSE

We aimed to compare cardiac magnetic resonance (CMR) parameters between the early death and survival groups of anthracycline-induced cardiotoxicity rat models, and to identify factors that could predict early death.

#### METHODS AND MATERIALS

We generated 38 Sprague-Dawley cardiotoxicity rat models by injecting doxorubicin (1.0 mg/kg) twice weekly for 12 weeks. We conducted CMR biweekly until 12 weeks, including pre-contrast and post-contrast T1 mapping using a saturation recovery Look-Locker sequence and T2 mapping using a spin echo sequence using a 9.4 T Bruker scanner. Biventricular function, left ventricle (LV) mass, native T1, T2, and ECV (extracellular volume fraction) were measured. The CMR parameters and blood troponin I (TnI) were compared between the early death and survival groups using linear mixed regression analysis.

#### RESULTS

Among 38 rats, seven were excluded because of poor image quality or because they died before CMR at two weeks. Seventeen rats died before 12 weeks, so they were assigned to the early death group: 2 rats surviving for 2 weeks, 2 rats for 4 weeks, 3 rats for 6 weeks, and 3 rats for 8 weeks. Fourteen rats survived until the maximum treating period of 12 weeks and were assigned to the survival group. During the treatment, native T1, T2, and ECV increased, and LVEF (left ventricular ejection fraction) decreased in each group. When the two groups were compared, native T1 showed a significant difference at 8th week, with the early death group showing a higher value than survival group (1364.1ms  $\pm$  75.6 vs. 1235.7ms  $\pm$  60.2,  $P = .01$ ). The ECV exhibited significant differences from 6th week (21.7%  $\pm$  2.4 in early death group vs. 18.5%  $\pm$  2.2 in the survival group,  $P = .046$ ) through 8th week (24.5%  $\pm$  2.5 vs. 20.5%  $\pm$  2.3 in survival group;  $P = .022$ ), with the early death group exhibiting significantly higher values. T2 and LVEF showed no significant differences between groups throughout all weeks. TnI levels significantly differed at 8th week (7.5 $\mu$ g/mL vs. 0.02 $\mu$ g/mL,  $P = .002$ ). In the survival group, ECV increased significantly between 4 and 6 weeks ( $P = .044$ ), and LVEF decreased significantly between 8 and 12 weeks ( $P = .001$ ). However, native T1 did not show significant week-by-week differences within the survival group. Within the early death group, LVEF decreased significantly between 2 and 4 weeks ( $P = .04$ ), and native T1 and ECV showed a significant increase between 4 and 6 weeks earlier than the survival group ( $P = .007$  and  $.001$ , respectively).

#### CONCLUSION

We have observed the differences in changing patterns in native T1, ECV, T2, and LVEF over the treatment time between the survival and early death groups.

#### CLINICAL RELEVANCE/APPLICATION

Quantitative measurement of native T1 and ECV with CMR may facilitate the prediction of anthracycline-induced cardiotoxicity.

### M5B-SPCA-5 Diagnostic Yield of Cardiac MRI in Patients with Clinically Suspected Myocarditis after COVID-19 Vaccination

#### PURPOSE

To evaluate cardiac MRI findings in patients with suspected myocarditis following COVID-19 vaccination in relation to clinical presentation and timing of imaging.

#### METHODS AND MATERIALS

Consecutive adult patients who underwent clinically indicated cardiac MRI for evaluation of suspected myocarditis following mRNA-based COVID-19 vaccination at a single center between June 2021-December 2022 were retrospectively evaluated using the revised 2018 Lake Louise Criteria (LLC). Patients were classified into groups based on presence/absence of T1 criteria (late gadolinium enhancement and/or high T1 map values) and T2 criteria (regional T2-hyperintensity and/or high T2 map values). Clinical information including vaccine history and presenting symptoms were extracted from the health record.

#### RESULTS

89 patients were included, 64% male with mean age 34 $\pm$ 13 years; all had received at least one dose of a COVID vaccine (mRNA-1273 in 38% and BNT162b2 in 62%) with median interval between the last dose vaccine dose and cardiac symptoms (chest pain, palpitations or shortness of breath) of 5 days (IQR 1-9). The median interval between last COVID-19 vaccine dose and MRI was 92 days (IQR 31-157). At least one T1 or T2 abnormality on MRI consistent with myocarditis was identified in 42 patients (47%); 25 (28%) met both T1 and T2 criteria on MRI (definite myocarditis); 17 (19%) met T1 criteria but not T2 criteria (possible myocarditis); and 47 (53%) did not meet either T1 or T2 criteria (no myocarditis). None of the patients met T2 criteria but not T1 criteria. The three groups did not differ in age ( $p=0.10$ ), sex ( $p=0.29$ ), vaccine type ( $p=0.24$ ), or left ventricular ejection fraction ( $p=0.53$ ). The interval between last vaccine dose and cardiac MRI was significantly shorter in patients who met both T1 and T2 criteria (28 days, IQR 8-69) compared to those meeting T1 criteria only (110 days, IQR 66-255,  $p<0.001$ ) and those not meeting either T1 or T2 criteria (120 days, IQR 80-252,  $p<0.001$ ). However, the interval between last vaccine dose and MRI did not differ between those meeting T1 criteria only and those not meeting either T1 or T2 criteria ( $p>0.99$ ).

#### CONCLUSION

In a cohort of patients with symptoms concerning for acute myocarditis following COVID-19 vaccination who underwent clinically indicated cardiac MRI, 28% met criteria for definite myocarditis (T1 and T2 abnormal) and 19% met criteria for possible myocarditis (only T1 abnormal). Identification of myocardial edema on cardiac MRI was highly dependent on the timing of imaging after vaccination.

## CLINICAL RELEVANCE/APPLICATION

Cardiac MRI should be performed as soon as possible after symptom onset in patients with suspected acute myocarditis as the likelihood of detecting myocardial edema drops substantially after a few weeks.

## M5B-SPCA-6 Diagnostic Accuracy of Cardiac MRI Versus Nuclear Imaging for Cardiac Amyloidosis: A Systematic Review and Meta-Analysis

Participants

James Roberts, MD,MSc, Vancouver, BC (*Presenter*) Nothing to Disclose

## PURPOSE

There is no consensus regarding the relative diagnostic performance of cardiac MRI and nuclear imaging in cardiac amyloidosis. The purpose of this study was to perform a systematic review and meta-analysis to compare the diagnostic accuracy of cardiac MRI and cardiac nuclear imaging for cardiac amyloidosis.

## METHODS AND MATERIALS

MEDLINE, Ovid Epub, CENTRAL, EMBASE, EMCARE, and Scopus were searched from inception until September 2022. Inclusion criteria included studies that evaluated the diagnostic accuracy of cardiac MRI or cardiac nuclear imaging studies for cardiac amyloidosis in adults. Abstracts and case reports were excluded. Data were independently extracted by two investigators. Summary accuracy metrics were obtained using bivariate random-effects meta-analysis. Meta-regression was used to assess the impact of different covariates. Risk of bias was assessed using the Quality Assessment Tool for Diagnostic Accuracy Studies-2 tool. The study protocol was registered a priori in the International Prospective Register of Systematic Reviews (PROSPERO CRD42022352480).

## RESULTS

Our search strategy yielded 7322 studies. We screened 2785 studies after excluding duplicates and reviewed the full text of 272 studies. Thirty-nine studies were included (3836 patients, 2331 with cardiac amyloid); 18 studies evaluated cardiac MRI (1553 patients, 968 with cardiac amyloidosis) and 24 evaluated cardiac nuclear imaging (2372 patients, 1401 with cardiac amyloidosis). Only 3 evaluated both MRI and nuclear imaging in the same patients. Overall, combined  $^{99m}\text{Tc}$ -scintigraphy bone tracers (including  $^{99m}\text{Tc}$ -DPD,  $^{99m}\text{Tc}$ -PYP, and  $^{99m}\text{Tc}$ -HMDP) had higher specificity than LGE on cardiac MRI (96% vs. 85%,  $p < 0.001$ ), with no difference in sensitivity (95% vs. 91%,  $p = 0.88$ ). When the analysis was restricted to studies with endomyocardial biopsy as the reference standard, there was no difference in specificity between modalities (96% vs. 90%,  $p = 0.56$ ). Covariate analysis demonstrated that sensitivity and specificity for nuclear imaging did not differ significantly by quantitative vs. qualitative evaluation. Thirty-seven studies were at risk of bias. There were insufficient studies to pool data on the diagnostic performance of T1 mapping, ECV and PET.

## CONCLUSION

Nuclear imaging  $^{99m}\text{Tc}$  bone tracers have higher specificity for cardiac amyloidosis than LGE on cardiac MRI, but similar sensitivity. Limitations including risk of bias and few studies with direct comparison necessitate additional study.

## CLINICAL RELEVANCE/APPLICATION

Nuclear imaging  $^{99m}\text{Tc}$  bone tracers are only specific for transthyretin amyloid while MRI detects all types including light chain. Additional studies are needed to determine the relative diagnostic performance in amyloid subtypes.

## Abstract Archives of the RSNA, 2023

M5B-SPCH

### Chest Imaging Monday Poster Discussions II

#### Sub-Events

#### **M5B-SPCH-1 Modeling Risk of Progression to Lung-RADS 4 from a Benign Lung Cancer Screening CT using Imaging and Clinical Data**

##### Participants

Gunvant Chaudhari, MD, San Francisco, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

For patients with benign low-dose chest CTs (LDCTs) with Lung-RADS score = 2, the screening interval is set to one year. To optimize screening intervals, we aim to build a deep learning system to predict risk progression in two years from full volume CT and clinical features.

##### METHODS AND MATERIALS

In this retrospective modeling study, full-volume LDCTs and baseline surveys from the National Lung Screening Trial (NLST) dataset (n=26,722 patients) were accessed to use as training data. A proprietary AI-based system augmented with solid-component segmentations was used to calculate the Lung-RADS 1.1 score for each scan. Baseline LDCTs with Lung-RADS = 2 were selected. For the clinical and demographics data, backward stepwise selection based on p-values was conducted to select the four most predictive features. Then, statistical and deep learning models were trained to predict progression to Lung-RADS 4 in two years. Models were compared based on the AUC-ROC score. To test generalizability, institutional lung screening LDCT and clinical data was collected (n=583 patients). A subset of baseline screenings with corresponding studies in 2 years +/- 4 months were selected. The NLST trained models were evaluated on institutional data.

##### RESULTS

From the NLST dataset, a subset 15,942 baseline LDCT screenings were found to have Lung-RADS = 2, with 1,637 progressing to Lung-RADS 4 (10.3%). Benign Lung-RADS score institutional studies totaled 50 studies, with 7 (14%) progressing to Lung-RADS 4 in two years. After backward stepwise selection on all input features, those that were significantly associated with Lung-RADS 4 progression were average nodule size, largest nodule size, number of nodules, and emphysema diagnosis. Models for predicting progression to Lung-RADS 4 based only on clinical and imaging features had a maximal AUC of 0.667 and 0.750 on the NLST and UCSF holdout data, respectively. Convolutional neural network-based models trained on full volume CTs had an AUC of 0.627 and 0.555 on the NLST and UCSF data, and combined models with clinical features and full-volume CT had a maximal AUC of 0.704 and 0.724.

##### CONCLUSION

This study shows that AI based models can predict future progression to Lung-RADS 4 from clinical features and full-volume CT scan. The full-volume CT based models have limited generalizability to institutional data, likely due to differences in acquisition dates and qualities.

##### CLINICAL RELEVANCE/APPLICATION

Modeling clinical and baseline imaging features that contribute to Lung-RADS 4 progression from a benign baseline LDCT may allow for optimized screening frequency for low-risk patients.

#### **M5B-SPCH-2 AI Assisted Lung Cancer Screening: A Retrospective Multinational Study in the US and Japan**

##### Participants

Atilla Kiraly, PhD, Mountain View, CA (*Presenter*) Former Employee, Siemens AG; Employee, Alphabet Inc

##### PURPOSE

To evaluate the impact of an Artificial Intelligence (AI) assistant for lung cancer screening (LCS) on multinational clinical workflows.

##### METHODS AND MATERIALS

We iteratively developed an AI interface via six user experience reader studies. We then conducted two retrospective randomized multi-reader multi-case studies where 627 (141 cancer positive) cases were each read twice (once with and once without AI assistance) by experienced thoracic radiologists (6 US-based or 6 Japan-based), resulting in a total of 7,524 interpretations. Positive cases were defined as imaging studies within two years before a lung cancer diagnosis. Cases without any subsequent cancer diagnosis for at least two years after the imaging study were defined as negative, and enriched for a spectrum of diverse nodules. The studies measured the readers' level of suspicion (LoS, on a 0-100 scale), country-specific screening system scoring categories, and management recommendations. Evaluation metrics included the area under the receiver operating characteristic curve (AUC) for LoS and sensitivity and specificity for recall recommendations.

##### RESULTS

With AI assistance, the institutional AUC increased 0.20% (70% to 70.2%) (p < 0.001) for the US study and 0.20% (60% to 60.2%)

with AI assistance, the radiologists' AUC increased 2.3% (70% to 72%, p=0.022) for the US study and 2.3% (93% to 96%, p=0.179) for the Japan study. Scoring system specificity for positive screens increased 5.5% (57% to 63%, p<0.001) for the US and 6.7% (23% to 30%, p<0.001) for the Japan study. No significant drop in sensitivity occurred. Specificity increased 5.8% (p<0.001) and 5.4% (p<0.001) in the US-based and Japan-based studies for any actionable recommendations, respectively.

## CONCLUSION

s We demonstrate a rigorous randomized study of an AI assistant into real-world-like clinical workflows. Our PACS-integrated AI interface demonstrated improved LCS specificity in both US and Japan-based reader studies, meriting further study in additional international screening environments.

## CLINICAL RELEVANCE/APPLICATION

We developed a general lung cancer screening AI interface and retrospectively tested it with experienced radiologists on more difficult screening cases under both US-based and Japan-based reading protocols.

### M5B-SPCH-3 Multi-modality Artificial Intelligence Model Based on CT and Haematoxylin and Erosin (HE)-stained Slides Images to Predict PD-L1 Status in NSCLC

## PURPOSE

Programmed death-ligand 1(PD-L1)expression status is the most important biomarker that has been approved in immunotherapy for lung cancer. However, the gold standard of PD-L1 evaluation based on manual assessment by pathologists, which is influenced by the professional knowledge and experience. The aim of this study is to develop and validate a multi-modality artificial intelligence (AI) model to predict the PD-L1 expression status of lung cancer based on eligible computed tomography (CT) images and haematoxylin and eosin (HE)-stained slides.

## METHODS AND MATERIALS

We retrospectively analyzed a PD-L1 expression dataset from 227 consecutive eligible lung cancer patients, including chest CT images and whole slide images (WSI) of haematoxylin and eosin(HE)-stained specimen during the corresponding period. The multi-modality AI model integrates CT radiomics and pathological deep learning based on multi-instance learning. The datasets were divided into training, validation, and testing group in a 4:1:1 ratio (n=151,38,38, respectively). Finally, a separate lung cancer immunotherapy cohort (n=47) was used to evaluate the prognostic value of the multi-modality fusion model.

## RESULTS

The proportion of PD-L1 positive in patients was 55.1%(n=125). The area under the curve (AUC) of fusion model to predict PD-L1 expression status was 0.922, 0.745 and 0.685 in the training, validation and testing group, respectively. The fusion model shows significantly better performance than the single-modality model (AUC=0.781, 0.695, 0.518 for CT radiomics model and AUC=0.93, 0.697, 0.594 for pathological deep learning model in training, validation, testing group, respectively; all p<0.05). Additionally, for the survival cohort, the progression-free survival (PFS) was significantly longer in PD-L1 positive patients predicted by the multi-modality AI model than the negative patients (mean PFS 280 days vs 185 days, p<0.05).

## CONCLUSION

s The multi-modality AI model based on CT and haematoxylin and eosin (HE)-stained slides images can predict the PD-L1 expression status of lung cancer effectively.

## CLINICAL RELEVANCE/APPLICATION

Our AI model can assess the PD-L1 expression status of NSCLC automatically, which can avoid subjective bias in manual evaluation and provide more precise assistance for clinical treatment decisions.

### M5B-SPCH-4 Comparison of Radiologists' Reports and AI for Detecting Ectasia and Aneurysms of the Thoracic Aorta on LDCT for Lung Cancer Screening: A Multicenter, Multivendor Study of 430 Patients

## Participants

Lina Karout, MD, Boston, MA (*Presenter*) Nothing to Disclose

## PURPOSE

We assessed the frequency of inconsistent reporting of thoracic aorta ectasia and aneurysm on unenhanced, low-dose CT for lung cancer screening (LCS) and compared the performance of radiologists' reports with an AI algorithm (AIRC, AI Rad Companion, Siemens) for measuring aortic dimensions.

## METHODS AND MATERIALS

Our IRB-approved and HIPAA-compliant retrospective study included 420 patients (mean age 66±7 years; females: males 157:263) who underwent LCS-LDCT on 10 single and dual-source MDCT scanners at one of the three community and quaternary hospitals. The patients were identified from a commercial radiology report data mining software (mPower, Nuance) with the keywords of "thoracic aorta" "aneurysm" and "ectasia." The negative LDCT-LCS represented consecutive cases over the same period and scanners. We recorded the presence of thoracic aneurysm or ectasia as well as when available the thoracic aorta dimensions from the radiology reports. Separately, thin-section DICOM images (1-1.25mm) were deidentified, exported, and processed with the AIRC to obtain maximum diameter of ascending and descending thoracic aorta. To establish the standard of reference (SOR), a thoracic radiologist independently measured short-axis dimensions of the ascending and descending thoracic aorta. Descriptive statistics and receiver operating characteristics area under the curve were estimated (ROC AUC) with 95% confidence interval.

## RESULTS

Per SOR, 25/420 patients (5.9%) had ascending thoracic aorta aneurysm (≥ 45 mm), 78/420 (18.6%) had aortic ectasia (≥40 <45 mm), and 18/420 (4.3%) had descending thoracic aorta aneurysm (≥35 mm). The respective AUC, sensitivity and specificity of radiology reports were 0.86 (95% CI: 0.75-0.97), 72% and 100% for ascending thoracic aorta aneurysm; 0.66 (95% CI: 0.59-0.74), 35% and 97% for aortic ectasia; and 0.50 (95% CI: 0.36-0.63), 0% and 99% for descending thoracic aneurysm. The corresponding ROC AUCs, sensitivity and specificity for the AI algorithm were 0.99 (95% CI 0.99-1.00), 100% and 99% for ascending thoracic aorta aneurysm; 0.86 (95% CI: 0.81-.091), 82% and 90% for aortic ectasia; and 0.93 (95% CI: 0.87-0.99), 94% and 91% for descending thoracic aneurysm. There was no difference in the performance of AI across different patients'

gender, age groups, as well as scanners and hospitals ( $p>0.1$ ).

## CONCLUSION

s The generalizable AI can improve radiology reporting of ascending and descending thoracic aorta aneurysms on LDCT for lung cancer screening.

## CLINICAL RELEVANCE/APPLICATION

Radiologists' reports on thoracic aorta ectasia and aneurysm are inconsistent on LDCT; AI can help improve and automate aortic dimensions and help improve reporting accuracy.

## M5B-SPCH-5 Clinical and Imaging Factors Associated with Growth of Subsolid Pulmonary Nodule on CT

Participants

Masha Bondarenko, San Francisco, CA (*Presenter*) Nothing to Disclose

## PURPOSE

Growth of part solid nodules are predictive of the nodule becoming cancerous along the adenocarcinoma spectrum. We aimed to investigate the clinical significant features that are predictive for growth of part-solid nodules (PSNs) identified by a commercial algorithm and verified by natural language processing (NLP) of radiology reports.

## METHODS AND MATERIALS

A retrospective study was conducted on patients who underwent chest CT scans between 2015 and 2019 at a single institution. CT scan radiology reports were extracted from mPower to select for patients with subsolid nodules. A commercial algorithm was used on the final dataset to identify nodules with a solid component larger than 6 mm and a non-solid component. The radiology reports were processed using NLP to verify whether the PSNs were growing or not. Clinical and imaging features including age, gender, nodule location, shape, length, margin, lobulation, and pleural traction were evaluated for their predictive value for PSN growth using univariate and multivariate logistic regression analyses.

## RESULTS

A total of 901 PSNs were included in this study, with 148 of those being growing PSNs. On univariate analysis, lobulated margin ( $p<0.01$ ), age ( $p<0.01$ ), and middle lobe ( $p=0.6$ ) were significantly associated with growing PSNs at a significance level of 0.1. On multivariate analysis, middle lobe (Odds Ratio (OR) [95% Confidence Interval (CI)]=0.27 [0.12-0.99],  $p=0.02$ ), age (OR=1.10 [0.98-1.02],  $p<0.001$ ), and lobulated margin (OR=1.53 [2.77-6.50],  $p<0.001$ ) were significant predictors of growing PSNs.

## CONCLUSION

s In patients with PSNs identified by a commercial algorithm and verified by NLP of radiology reports, higher age, no presence in the right middle lobes, and lobulated margin were independent predictors for fast-growing PSNs. These findings could help identify patients who are at high risk of PSN growth and guide appropriate management decisions. The combination of a commercial algorithm and NLP of radiology reports may be a useful tool for identifying PSNs and monitoring their growth.

## CLINICAL RELEVANCE/APPLICATION

By identifying adenocarcinoma spectrum nodules at risk for further growth, clinicians can more precisely identify, monitor, and potentially treat high-risk nodules.

## M5B-SPCH-6 Satellite Modularity as Indicator of Benign Versus Malignant Etiology of Lung Nodules in a Histoplasmosis-endemic Region

## PURPOSE

To evaluate if presence of satellite nodularity can distinguish between benign and malignant lung nodules in histoplasmosis-endemic regions. Additionally, to evaluate any other factors that can add confidence in distinguishing between benign and malignant etiology.

## METHODS AND MATERIALS

An IRB-approved retrospective review was performed of all CT and CTA chest exams from November 2015-2020 containing the phrase "satellite nodule" in the report. Short- and long-axis measurements of both the primary lung nodule and largest satellite nodule were recorded. Data was collected on patient demographics, history of cancer, margins, cavitation, calcification, change in size over time, presence of adjacent bronchovascular bundle nodularity, and tissue diagnosis. Predictive capabilities for demographic and clinical variables were analyzed with logistic regression models to produce odds ratio and area under ROC curve values.

## RESULTS

346 chest CTs were identified, of which 111 were excluded based on primary nodule size outside the range of 0.6 to 3.0 cm ( $n = 46$ ), undecided final pathology ( $n=12$ ), or insufficient follow-up for diagnosis ( $n=53$ ). Benign primary nodule pathology was found in 201 of 235 patients (86%). Bronchovascular bundle nodularity demonstrated the highest odds of benignity (OR 18.4,  $p.01$ ) followed by presence of calcification (OR 10.6,  $pt;.01$ ) as single variables. Spiculated margins (OR 0.06,  $pt;.01$ ) and history of metastatic disease or newly diagnosed cancer (OR 0.15,  $pt;.01$ ) were most associated with malignant diagnosis. Bronchovascular nodularity alone demonstrated poor ability to predict the odds of benignity (AUC 0.66,  $pt;.01$ ) but was increased when combined with margin characteristics (AUC 0.82,  $pt;.01$ ) or patient age (AUC 0.80,  $pt;.01$ ). The multivariable combination of margin characteristics and age demonstrated the largest ability to predict the odds of benignity (AUC 0.84,  $pt;.01$ ).

## CONCLUSION

s Approximately 86% of lung nodules with satellite nodules had benign pathology. Spiculated margins followed by clinical history of either new cancer or known metastatic disease were most associated with malignant diagnosis. Bronchovascular bundle nodularity was most associated with benign etiology, more strongly than presence of calcification. Bronchovascular nodularity combined with smooth primary nodule margins or younger patient age, was an excellent predictor of benign diagnosis, possibly permitting less rigorous follow up imaging or further work up.

## CLINICAL RELEVANCE/APPLICATION

The ability to predict benign etiology of a lung nodule based on the presence of satellite nodularity and bronchovascular bundle nodularity in histoplasmosis endemic regions can direct future follow up recommendations.

## M5B-SPCH-7 Deep Learning Automated Characterization of Lesion Volume and Growth Rates of Histologic Subtypes of Primary Lung Adenocarcinoma

Participants  
Hafsa Babar, MD, San Diego, CA (*Presenter*) Nothing to Disclose

### PURPOSE

CT is the dominant modality for the detection and staging of lung cancer. Nodule size and growth rate are two most predictive imaging biomarkers of likelihood of malignancy. Lesion volume and volume doubling time have been proposed as the most reliable metrics of size and growth rate. Deep learning algorithms allow measurement of both through a combination of automated detection, segmentation, and lesion-level co-registration. We applied these algorithms to measure the growth rates of various histologic subtypes of primary lung adenocarcinoma to determine whether VDTs have discriminative potential in non-invasive nodule assessment.

### METHODS AND MATERIALS

We conducted a retrospective review of biopsy proven lung adenocarcinomas from 2018 to 2021. Clinical and histopathologic data were abstracted from medical records of patients with at least two chest CTs prior to treatment, excluding patients with pulmonary masses (>3 cm) and those with fewer than 14 days between CTs. Images were automatically analyzed using a commercially available DL software (Lung AI, MICA v29.8.2; Arterys, CA) capable of detecting, segmenting, and co-registering pulmonary nodules across multiple CTs. VDTs were calculated for each lesion and stratified across histologic subtypes.

### RESULTS

71 patients with 81 biopsy proven pulmonary adenocarcinoma nodules, satisfied the inclusion criteria [mean age, 68 years (42 females and 29 males)]. Among these, 70 nodules were sub-categorized based on the dominant histopathological pattern: 12 lepidic, 22 acinar, 14 papillary, and 22 solid/micropapillary. Mean nodule size was 16.5 mm (1640 mm<sup>3</sup>) for all lesions. Acinar subtype nodules were the largest on presenting CT (19.3 mm, 2118 mm<sup>3</sup>), followed by lepidic (16.6 mm, 1668 mm<sup>3</sup>), solid/micropapillary (15.7 mm, 1024mm<sup>3</sup>), and papillary (14.4 mm, 1710 mm<sup>3</sup>). The mean overall VDT was 485 days (range: 47 to >1000 days) for all lung adenocarcinomas. Initial VDT was shortest for solid/micropapillary subtypes (210 days), followed by acinar (425 days), papillary (482 days), and lepidic (492 days), (ANOVA: Single Factor, p<0.03). Interestingly, 22/81 (27%) nodules showed volume contraction of at least 50 mm<sup>3</sup> on sequential scans. Amongst these, lepidic (9/22) and acinar (6/22) were the predominant subtypes.

### CONCLUSION

s VDTs varied substantially between histologic subtypes of lung adenocarcinoma. A subset of lesions (mainly lepidic and acinar) contracted between some exams.

## CLINICAL RELEVANCE/APPLICATION

Deep learning algorithms are able to characterize differential growth rates between histological subtypes of primary lung adenocarcinoma, mirroring prior studies with manual linear measurements. They have a potential to non-invasively characterize pulmonary nodules on serial chest CTs.

## M5B-SPCH-8 Prediction of High-grade Histological Subtypes of Stage IA Lung Adenocarcinoma Based on CT Radiomics Model

Participants  
Guojin Zhang, MD, PhD, Sichuan, China (*Presenter*) Nothing to Disclose

### PURPOSE

This study aimed to investigate the value of CT radiomics model in predicting high-grade histological subtypes of stage IA lung adenocarcinoma (LADC).

### METHODS AND MATERIALS

A total of 236 patients with stage IA LADC were included, who were divided into low-grade group (n=112) and high-grade group (n=124) according to the pathological grading system, and randomly divided into training and validation sets according to a ratio of 7:3. Minimum redundancy maximum relevance and least absolute shrinkage and selection operator regression were used to screen the radiomics features. Multivariate logistic regression was used to screen independent predictors from baseline clinical data and traditional CT signs. The radiomics, clinical, and clinical-radiomics models were established, respectively. Receiver operating characteristic curve curves were used to evaluate the model's predictive performance, decision curve analysis (DCA) to evaluate the model's clinical net benefit, and calibration curves to evaluate the model's goodness of fit.

### RESULTS

Eight radiomics features were significantly correlated with the high-grade group of LADC. The clinical-radiomics model combined with baseline clinical data, traditional CT signs, and radiomic features had the best discriminant ability in predicting high-grade histological subtypes of LADC. In the training and validation sets, the areas under the curve were 0.950 (95% CI, 0.919-0.982) and 0.950 (95% CI, 0.910-0.973), respectively. DCA analysis showed that the clinical-radiomics model had better net clinical benefit.

### CONCLUSION

s Clinical characteristics combined with radiomics features were helpful for preoperative noninvasive prediction of high-grade LADC in stage IA.

## CLINICAL RELEVANCE/APPLICATION

The clinical-radiomics model incorporating the radiomics features and clinical risk factors showed excellent performance in predicting high-grade histological subtypes of stage IA LADC, which may help in clinical decision-making for personalized treatment of lung

adenocarcinoma patients.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

M5B-SPER

### Emergency Radiology Monday Poster Discussions II

#### Sub-Events

#### **M5B-SPER-1 The Diagnostic Ability of Postmortem CT for the Cause of Natural Death from Out-of-hospital Cardiac Arrest**

##### Participants

Yu Nakaki, Hiroshima, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Postmortem CT (PMCT) can help to identify the cause of death. Its diagnostic ability has been reported, however, its findings depend on the corpse and the methodology applied. PMCT cannot diagnose cardiac disease, e.g. myocardial infarction, lethal arrhythmia, and pulmonary thromboembolism, consequently its ability to determine the cause of natural death, especially from out-of-hospital cardiac arrest (OHCA) may be lower than expected. To reveal the current issue of PMCT, we investigated the ability of PMCT to identify the cause of natural death from OHCA.

##### METHODS AND MATERIALS

Between January 2018 and December 2022, we enrolled 306 patients with OHCA who were taken to our hospital and performed non-contrast PMCT. Excluded were 94 patients with unnatural death and 6 patients younger than 18 years. Included were 206 patients (121 males, 85 females; median age 79 years, range 18-104 years) who died a natural death from OHCA. The median interval from death to PMCT was 2.5 hours (range 1 - 28 hours). All were scanned on a 16-row multi-detector CT scanner. The scan parameters were 120 kVp and automated exposure control; the preset noise was 11 Hounsfield units. All images were consensually interpreted by two board-certified radiologists and categorized into diagnostic (PMCT alone was sufficient to determine the cause of death), suggestive (the cause of death was suggested but additional information was needed), and non-diagnostic (the cause of death could not be determined on PMCT images).

##### RESULTS

Of 206 PMCT images, 46 (22.3%) were diagnostic, 16 (7.8%) were suggestive, and 144 (69.9%) were non-diagnostic. Aortic dissection (n=15), aortic aneurysm rupture (n=12), cardiac rupture (n=8), subarachnoid hemorrhage (n=6), cerebral hemorrhage (n=4) and visceral aneurysm rupture (n=1) were diagnosable. In the suggestive group were malignant tumors (n=7), gastrointestinal bleeding/occlusion/perforation (n=7), and 2 other causes.

##### CONCLUSION

As PMCT images were diagnostic or suggestive in only 62 of 206 cases (30.1%) of natural death from OHCA, the diagnostic ability of PMCT must be improved.

##### CLINICAL RELEVANCE/APPLICATION

The low diagnostic ability of PMCT for identifying the cause of natural death from OHCA may require the development of contrast-enhanced- and dual-energy PMCT.

#### **M5B-SPER-2 T1 and T2 Signal Appearance of Intracranial Hemorrhage in Post-mortem Magnetic Resonance Imaging**

##### PURPOSE

In forensic medicine, age estimation of intracranial hemorrhage can be crucial. Post-mortem MRI (PMMR) can be used as an alternative to autopsy in certain case constellations. In clinical MRI, age estimation of intracranial hemorrhage is based on differing signal behaviors of T1 and T2 over time as hemoglobin passes through different forms before red cell lysis and breakdown into ferritin and hemosiderin. In PMMR, post-mortem phenomena such as putrefaction, autolysis, temperature decrease, and biochemical degradation processes can influence MR signal appearance, particularly at longer post-mortem intervals. So far, it is unknown, if intracranial hemorrhage of different ages appears with the same T1 and T2 signals known in the living and if post-mortem interval alters signal appearance. Therefore, the purpose of this study was to investigate the PMMR T1 and T2 signal behavior of intracranial hemorrhage of different age stages at different post-mortem intervals and to compare it to the known signal behavior in the living.

##### METHODS AND MATERIALS

N=200 forensic cases (110 male, 90 female, mean age 54 years) with intracranial hemorrhage due to traumatic injury or natural causes were investigated. Post-mortem interval (time from death to imaging) ranged from 12 h to 21 days. 3 Tesla T1 and T2 weighted unenhanced PMMR of the head was conducted before the autopsy. Age estimation of intracranial hemorrhage (hyperacute: < 12 h, acute: 12-48 h, early subacute: 2-7 d, late subacute: 8 d - 1 month, and chronic: > 1 month) was performed based on autopsy and histology findings as well as medical records. Two observers blinded for autopsy results and medical records evaluated the T1 and T2 signal appearance of intracranial hemorrhage in PMMR. Hemorrhage signal appearances were assigned to the corresponding age estimations. PMMR results were compared to known clinical MRI signal behavior in living patients.

## **RESULTS**

The following PMMR T1 and T2 signal appearances were observed for different age stages of intracranial hemorrhage: hyperacute: T1 isointense, T2 hyperintense; acute: T1 isointense to hypointense, T2 hypointense; early subacute: T1 hyperintense, T2 hypointense; late subacute: T1 hyperintense, T2 hyperintense; chronic: T1 hypointense, T2 hypointense. The observed signal appearance did not differ from the known signal appearance of living persons. Longer post-mortem intervals of up to 21 days did not significantly alter signal appearance.

## **CONCLUSION**

s In a post-mortem interval of up to 3 weeks, PMMR T1 and T2 signal behavior of intracranial hemorrhage of different age stages are the same as in the living.

## **CLINICAL RELEVANCE/APPLICATION**

T1 and T2 post-mortem MRI of the head can be used as an alternative to autopsy for age estimation of intracranial hemorrhage.

#### M5B-SPGI-1 Gd-EOB-DTPA MRI-based Severity Classification and Prognosis in Fontan-Associated Liver Disease

##### Participants

Atsushi Yamamoto, MD, PhD, Tokyo, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Fontan procedure for congenital single ventricle improves prognosis in childhood but is not a curative treatment. The prognosis in the long-term period after Fontan procedure is extremely poor compared to other congenital heart diseases. This is due to liver injury caused by elevated central venous pressure, which is a feature of the Fontan circulation, and is now attracting attention as Fontan-associated liver disease (FALD). FALD frequently progresses to cirrhosis and develops hepatocellular carcinoma (HCC) despite the young age of the patient. Gd-EOB-DTPA MRI is an effective tool for detecting HCC, but the features of FALD have not been studied. We propose an Gd-EOB-DTPA MRI-based severity classification of FALD and its association with prognosis, including the development of HCC.

##### METHODS AND MATERIALS

Data of Gd-EOB-DTPA MRI for 44 patients (mean age, 25 years; female, 22) after Fontan procedure between January 2010 to April 2023 was retrospectively analyzed. The hepatocyte phase image at 15 minutes after Gd-EOB-DTPA injection was scored semi-qualitatively using the following four points. 1) The extent of low-signal reticular shadows extending from the subhepatic capsule with "reverse lobulation": 0, 1 or 2 points. 2) Liver marginal irregularity: 0 or 1 point. 3) Decreased liver-spleen signal ratio: 0 or 1 point. 4) Atrophy of entire liver: 0 or 1 point. Based on the summed scores, patients were classified as Grade-1 (0 or 1 point), 2 (2 points), 3 (3 points), or 4 (4 points or higher). The endpoint was a composite outcome consisting of HCC, intractable ascites, and heart failure (HF) hospitalization. The event-free survival was analyzed by Kaplan-Meier and log-rank test.

##### RESULTS

There were 11 Grade-1 patients, 18 Grade-2 patients, 8 Grade-3 patients, 7 Grade-4 patients. During a mean follow-up period of 60 months, the composite outcome occurred in 11 patients (6 cases of HCC, 3 cases of intractable ascites, and 2 cases of HF hospitalization). Nine of the 11 patients (82%) were in Grade-3 and 4 groups. Kaplan-Meier analysis revealed that patients with Grade-3 and 4 had significantly poorer prognosis than those with Grade-1 and 2 ( $p < 0.0001$ ).

##### CONCLUSION

s Gd-EOB-DTPA MRI could classify the severity and predict prognosis of patients with FALD.

##### CLINICAL RELEVANCE/APPLICATION

This method is not as invasive as liver biopsy and has no sampling errors. It is suitable for surveillance of FALD in young subjects.

#### M5B-SPGI-2 Staging Liver Fibrosis in Volunteers and Patients with Nonalcoholic Fatty Liver Disease with Intrinsic Shear Strain Measurement by 4D Phase-contrast MRI

##### PURPOSE

To investigate the diagnostic performance of intrinsic shear strain induced by pressure pulse and cardiac motion, measured by phase-contrast MRI, for the detection and staging of liver fibrosis in volunteers and patients with nonalcoholic fatty liver disease using liver biopsy as the reference standard.

##### METHODS AND MATERIALS

This prospective cross-sectional study was institutional review board approved. The study included volunteers and patients with nonalcoholic fatty liver disease undergoing 3T MRI with a quantitative 4D phase contrast sequence with retrospective cardiac gating. The 3D displacement field during eight phases of the cardiac cycle were measured. Automated motion processing and masking techniques were used to extract the hepatic octahedral shear strain (OSS). The reference standard was fibrosis staging by liver biopsy. One-way ANOVA and receiver operating characteristic analyses were performed for normal categorized and dichotomized groups based on hepatic fibrosis stages, including F0 versus = F1, = F1 versus = F2, = F2 versus = F3, and = F3 versus F4. The area under the receiver operating characteristic curve (AUC) was reported for each dichotomization of fibrosis stages.

##### RESULTS

The study included 11 volunteers and 24 patients. Mean values of OSS decreased with higher fibrosis stage, with a mean of  $0.15 \pm 0.08$  (standard deviation) for F0,  $0.12 \pm 0.01$  for F1,  $0.07 \pm 0.01$  for F2,  $0.07 \pm 0.02$  for F3, and  $0.05 \pm 0.03$  for F4. The cardiac-induced strain measurements demonstrated high accuracy in discriminating NASH patients, with  $p < 0.01$  and F score 8.35 from one-way ANOVA and the area under ROC curves (AUC) of 0.87 for F0 vs. = F1, 0.96 for = F1 vs. = F2, 0.90 for = F2 vs. = F3, and 0.90 for = F3 vs. F4.

## CONCLUSION

s The study demonstrated a significant decrease in the liver's OSS with increasing fibrosis stage.

## CLINICAL RELEVANCE/APPLICATION

The study found that intrinsic shear strain measured by, standard phase-contrast MRI, without the use of any external actuation, has the potential to be a noninvasive diagnostic tool for detection and staging liver fibrosis.

## M5B-SPGI-3 Depiction of Lymphatic Pathway in Fontan Circulation Using Gd-EOB-DTPA Magnetic Resonance Lymphangiography

### PURPOSE

Although postoperative mortality rates in congenital single ventricle patients after the Fontan procedure have dramatically improved, the long-term mortality rates have remained high compared to those in patients with other types of congenital heart disease. In the Fontan circulation, congestive liver and lymphatic congestion caused by elevated central venous pressure become permanent, resulting in cirrhosis, refractory ascites, and protein-losing enteropathy. These complications are considered poor prognostic factors as Fontan-associated liver disease (FALD). Gadolinium ethoxybenzyl diethylenetriamine pentaacetic acid (Gd-EOB-DTPA) MRI is expected to detect hepatocellular carcinoma (HCC) that develops in FALD. We attempt to depict abnormal lymphatic pathway in FALD using Gd-EOB-DTPA MRI and propose a classification of their severity.

### METHODS AND MATERIALS

Fifty-two patients (mean age, 25 years) after Fontan procedure who underwent Gd-EOB-DTPA MRI for evaluation of the FALD were enrolled. MR lymphangiography was scanned using three-dimensional heavily T2-weighted imaging with a 3-tesla scanner 10 minutes after Gd-EOB-DTPA administration. This sequence takes advantage of the T2 shortening effect of Gd-EOB-DTPA to suppress the bile duct and vessel's signals, thereby enhancing the lymphatic pathway. Based on the extent of lymphatic tract involvement in the abdomen, patients were classified into the following three categories; Grade 0: no lymphatic pathway, Grade 1: the presence of lymphatic pathway mainly around the bile duct and liver surface, Grade 2: lymphatic pathway extended from the spine to the inferior vena cava periphery. Refractory ascites, protein-losing enteropathy, development of HCC, and hospitalization for heart failure were used as composite outcomes and contrasted with lymphangiographic findings.

### RESULTS

In MR lymphangiography, 20 patients were Grade 0, 17 were Grade 1, and 15 were Grade 2. 16 patients had composite outcomes, including 10 with HCC, 4 with refractory ascites, and 2 with heart failure hospitalization. Grade 0 patients had no events (0/20), whereas Grade 1 and Grade 2 patients had the adverse events in 53% (9/17) and 47% (7/15) of patients, respectively.

### CONCLUSION

s A novel technique, MR lymphangiography with Gd-EOB-DTPA, demonstrates the localization and extent of the abnormal lymphatic pathways in Fontan circulation. The lymphangiographic grade is associated with the adverse events in FALD.

## CLINICAL RELEVANCE/APPLICATION

This MR lymphangiography can be added as one of Gd-EOB-DTPA contrast protocol and does not extend the overall examination time.

## M5B-SPGI-4 A Rules-Based Algorithm for Extracting Structured Clinical Data from Liver CT Free-Text Radiology Reports

### PURPOSE

A large proportion of patients throughout the world have undiagnosed liver disease. Given the abundance of data found in radiology reports, they represent an untapped source to study patients with liver disease. Oftentimes it may be arduous to manually sift through patient-level data. As such, validated methods to study these patients and associated radiology reports are needed. Here we present a rules-based algorithm that determines the presence or absence of liver pathologies from unstructured radiology reports for CT liver scans.

### METHODS AND MATERIALS

Three common diagnosis of liver pathologies were selected for this study, namely focal liver lesions, steatosis and cirrhosis. A data dictionary was created to identify phrases that describe these diagnoses in a radiology report. Data mining and dictionary generation was done by a gastroenterologist treating these liver conditions for more than 20 years at the James A Haley VA Hospital. A random subset of liver CT reports (n = 100) of patients with a liver-related complaint were extracted and split into training and testing sets (65 and 35 patients, respectively). Ground truth values for the presence or absence of three liver pathologies were manually annotated, specifically for focal liver lesions, cirrhosis, and steatosis. A rules-based algorithm was leveraged using the two phase sentence analysis for radiology label extraction (SARLE) method: (1) remove phrases and handle negations and (2) link remaining terms to liver pathologies. The algorithm's performance was assessed using accuracy, sensitivity, and specificity.

### RESULTS

On the test set, the algorithm had an average accuracy across all 3 pathologies of 99.25% (95% CI: 98.76% to 99.65%), sensitivity of 84.21% (68.75% to 93.98%), and specificity of 99.68% (95% CI: 99.25% to 99.89%). Across the 100 patients, the reports of 90 patients were perfectly extracted for all 3 attributes.

### CONCLUSION

s We demonstrate high performance of a rules-based algorithm to extract tabular data information from free text reports of liver CT scans. Our tool performed well in identifying patients with focal liver lesions, steatosis, and cirrhosis, as benchmarked by an expert gastroenterologist.

## CLINICAL RELEVANCE/APPLICATION

This tool may be useful in developing new machine learning approaches to predict outcomes in liver and other abdominal conditions.

Additionally this method may serve as a first step towards identifying the natural language used in radiology reports for future machine learning implementations.

### **M5B-SPGI-5 Staging of Liver Fibrosis Assessed by Quantification of Hepatic Extracellular Volume Obtained by Dual-energy CT Would be Easier-to-Access than Previous**

Participants

Kumi Ozaki, MD, PhD, Hamamatsu, Japan (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To assess the validity of 3-min equilibrium-phase CT images compared to 5-min equilibrium-phase images in the quantification of hepatic extracellular volume fraction (ECV) obtained by dual-energy CT.

#### **METHODS AND MATERIALS**

A total of 80 patients (45 men and 35 women, mean age, 69.3 + 10.4 years) who underwent both 3- and 5-min equilibrium-phase CT images to assess the focal liver lesions, that were suspected of hepatic hemangioma or intrahepatic cholangiocarcinoma between January 2020 and July 2022. The iodine densities of the hepatic parenchyma and aorta were measured and ECV was calculated. Comparisons of value of ECV of each phase, and the relation with fibrosis-4 index (Fib4) and albumin-bilirubin (ALBI) grade were then statistically analyzed.

#### **RESULTS**

There was no significant difference in value of ECV of 3- and 5-min equilibrium-phase CT images ( $p = 0.056$ ). ECV of 3- and 5-min showed a strong or moderate correlation with ALBI grade (Spearman's  $\rho$ ; 0.763, 0.724, respectively). The correlation with Fib4 was similar to each ECV (Spearman's  $\rho$ ; 0.537, 0.571, respectively).

#### **CONCLUSION**

s ECV value and the correlation with ALBI grade and Fib4 were not significantly different, and ECV of 3-min equilibrium-phase CT images is clinically acceptable.

#### **CLINICAL RELEVANCE/APPLICATION**

Validity of ECV of 3-min equilibrium-phase CT image can facilitate the prevalence of staging of liver fibrosis assessed by ECV because it can be obtained within routine dynamic contrast examination.

### **M5B-SPGI-6 Establishing the Evaluation Model for Liver Cirrhosis Based on CT Radiomics Characteristics of Different Liver Segments**

#### **PURPOSE**

To evaluate the performance of evaluating liver cirrhosis by radiomics characteristics of different liver segments in contrast-enhanced CT portal vein phase images.

#### **METHODS AND MATERIALS**

154 cases with clinically confirmed liver cirrhosis were included in the study group and 150 cases with normal liver findings in the control group. All patients underwent enhanced liver CT on a GE discovery CT 750 HD. The portal phase CT images were selected for analysis, and two radiologists used a commercial radiomics software (Shukun Radiomics V94) to outline different liver segments on the slice of portal vein left branch into four regions of interest (ROI): S1, S2/3, S4 and S7/8; Intraclass correlation coefficient was calculated to test the inter-group consistency. Patients were randomly divided into training set and testing set at a ratio of 7:3, the radiomics characteristics (first-order features, shape features and texture features) of each ROI were extracted. After dimensionality reduction, the radiomics features with the most predictive performance were selected to establish the evaluation model of liver cirrhosis. The area under curve (AUC) was used to evaluate the performance of the model.

#### **RESULTS**

The two radiologists had good consistency ( $ICC > 0.75$ ). Five, 6, 6 and 6 radiomics features were used for modeling of liver segment S1, S2/3, and S4 and S7/8, respectively. The AUC, accuracy, sensitivity and specificity were 0.948, 0.931, 0.955 and 0.908 in the training set; and 0.928, 0.896, 0.912 and 0.879 in the testing set, respectively for S1; 0.958, 0.924, 0.955 and 0.892 in the training set; and 0.957, 0.881, 0.912 and 0.848 in the testing set, respectively for S2. 0.974, 0.924, 0.940 and 0.908 in the training set; and 0.964, 0.910, 0.941 and 0.879 in the testing set, respectively for S4, and 0.948, 0.908, 0.909 and 0.908 in the training set; and 0.955, 0.910, 0.941 and 0.879 in the testing set, respectively for S7/8

#### **CONCLUSION**

s Good evaluation models of liver cirrhosis may be established using different liver segments, and the model established in the left medial segment gives the highest AUC.

#### **CLINICAL RELEVANCE/APPLICATION**

Good evaluation models of liver cirrhosis may be established using different liver segments, and the model established in the left medial segment gives the highest AUC.

### **M5B-SPGI-7 Prediction of Lymph Node Metastasis of Progressive Gastric Adenocarcinoma Nodes with a Short-Axis Diameter of $\geq 6$ mm**

#### **PURPOSE**

To explore the value of the features of lymph nodes (LN) with a short-axis diameter = 6 mm in prediction of lymph node metastasis (LNM) in advanced gastric adenocarcinoma (GAC) based on dual-energy CT (DECT) radiomics.

#### **METHODS AND MATERIALS**

Data of patients with GAC who underwent radical gastrectomy and LN dissection were retrospectively analyzed. To ensure the

correspondence between imaging and pathology, metastatic LNs were only selected from pN3 patients, nonmetastatic LNs were selected from pN0 patients, and the short-axis diameters of the enrolled LNs were all =6 mm. The traditional features of LNs were recorded, including short-axis diameter, long-axis diameter, long-to-short axis ratio, position, shape, density, edge and the degree of enhancement, and univariate and multivariate logistic regression analyses were used to establish a clinical model. Radiomics features at the maximum level of LNs were extracted in venous phase equivalent 120 kV linear fusion images and iodine maps. Intra-class correlation coefficients and the Boruta algorithm were used to screen significant features, and random forest was used to build a radiomics model. The traditional features with statistical significance in univariate analysis and radiomics scores (Rad-score) were included in multivariate logistic regression analysis to construct a combined model. ROC curve and DeLong test were used to evaluate and compare the diagnostic performance of the models. DCA was used to evaluate the clinical benefits of the models.

## RESULTS

This study included 114 metastatic LNs from 45 pN3 patients and 65 nonmetastatic LNs from 28 pN0 patients. The samples were divided into a training set (n=125) and a validation set (n=54) at a ratio of 7:3. Long-axis diameter and LN shape were independent predictors of LNM and were used to establish the clinical model. 27 screened radiomics features were used to build the radiomics model. LN shape and Rad-score were independent predictors of LNM and were used to construct the combined model. Both the radiomics model (AUC of 0.986 and 0.984) and the combined model (AUC of 0.970 and 0.977) outperformed the clinical model (AUC of 0.772 and 0.820) in predicting LNM in both the training and validation sets. DCA showed superior clinical benefits from the radiomics and combined models.

## CONCLUSION

The models based on LNs DECT radiomics features, or combined traditional features have high diagnostic performance in determining the nature of each LN with a short-axis diameter of =6 mm in advanced GAC.

## CLINICAL RELEVANCE/APPLICATION

The models have important clinical value in the preoperative judgment of N staging, individualized treatment plans and prognosis of patients.

## M5B-SPGI-8 The Spectral Parameters Measured by Fast kVp Switching Dual-Energy CT: The Association with Ki-67 Expression in Hepatocellular Carcinoma

### PURPOSE

To investigate the correlation between spectral parameters obtained from contrast-enhanced spectral CT scanning and Ki-67 expression in hepatocellular carcinoma (HCC).

### METHODS AND MATERIALS

91 HCC patients with hepatitis complicated underwent both pathological examination and two-phase contrast-enhanced CT scanning with spectral imaging mode were included in this study. Then water- and fat-based material decomposition images as well as virtual monochromatic images acquired at energies ranging from 100 to 140 keV were reconstructed. Region of interest (ROI) was placed on the lesion, and water and fat density ( $D_{water}$ ,  $D_{fat}$ ), CT values at monochromatic energy images (HU100-140keV), as well as effective atomic number were measured. The effective atomic number for lesions was normalized by those for aorta to derive normalized atomic number (Neff-Z). Ki-67 expression level was determined by Ki-67 positivity rate according to immunohistochemistry analysis. Pearson coefficient was used to analyze the correlation between spectral parameters and Ki-67 positivity.

### RESULTS

The Neff-Z, HU100-140keV, water and fat density were positively and fairly correlated with the Ki-67 expression, and correlation coefficient  $r$  (P value), were 0.324 (P = 0.002), 0.252-0.358 (P = 0.016-0.001), 0.415 (P <0.001) and 0.293 (P = 0.005), respectively. Particularly,  $D_{water}$  showed strongest correlation with Ki-67 expression. Additionally, the correlation between CT value and Ki-67 was enhanced gradually with the increase of monochromatic energy (100keV to 140keV).

### CONCLUSION

Conclusion: The Neff-Z, HU100-140keV, water and fat density obtained from spectral scanning on dual-energy CT exhibited positive and fair correlation with Ki-67 expression.

### CLINICAL RELEVANCE/APPLICATION

Ki-67 was a significant marker for HCC prognosis and clinical decision, however current method to evaluate Ki-67 always needs surgery, which is detrimental for assessing patients who lost surgery chance. Spectral scanning on Dual energy CT provides a new noninvasive method and various parameters to evaluate Ki-67 (indicative of proliferative activity) expression in HCC, which is valuable for clinical diagnosis and treatment.

## Abstract Archives of the RSNA, 2023

M5B-SPGU

### Genitourinary Imaging Monday Poster Discussions II

#### Sub-Events

#### **M5B-SPGU-1 The Additional Value of Pseudocapsule for Clear Cell Likelihood Score v2.0 in Predicting Small Renal Masses: A Multicenter Retrospective Study**

##### Participants

Yuwei Hao, Beijing, China (*Presenter*) Nothing to Disclose

##### PURPOSE

This study aims to explore the additional value of pseudocapsule for clear cell likelihood score v2.0 (ccLS v2.0) in diagnosing small renal masses (SRM) and develop a modified clear cell likelihood score (m-ccLS) for predicting malignancy.

##### METHODS AND MATERIALS

In this study, clinical data and MR images of patients with pathologically confirmed solid SRM were retrospectively collected from three academic medical centers between January 1, 2019 and December 31, 2021. All patients were divided into a training group (n = 235), an internal validation group (n = 60), and an external validation group (n = 57). Two junior radiologists independently evaluated whether SRM had pseudocapsule, other MRI features and the ccLS scores according to ccLS v2.0, respectively. Disagreements were resolved by two senior radiologists who reached an agreement. The risk prediction value of pseudocapsules and the ccLS scores in ccRCC and malignant tumors were analyzed using the logistic regression model. M-ccLS was established and calibration curves were drawn to evaluate the consistency of m-ccLS predictions with pathological findings. The diagnostic performance of m-ccLS and ccLS v2.0 was evaluated by drawing ROC and the percentage of ccRCC and malignant tumors in each score was compared using ccLS v2.0 and m-ccLS. The net reclassification index (NRI) and integrated discrimination improvement (IDI) were calculated.

##### RESULTS

352 patients (248 males, 104 females; mean age, 54±12 years) with 358 renal masses were identified. The evaluation results of SRM revealed that pseudocapsule had the additional value for ccLS v2.0 evaluation of ccRCC and malignant tumors ( $P < 0.001$ ). M-ccLS showed a good interobserver agreement in predicting ccRCC and malignant tumors ( $P > 0.05$ ). The diagnostic performance of m-ccLS for ccRCC was comparable to ccLS v2.0 ( $P > 0.05$ ). Compared with ccLS v2.0, the AUC of m-ccLS for diagnosing malignant tumors increased from 0.772 (95%CI: 0.714-0.824), 0.801 (95%CI: 0.680-0.892) and 0.645 (95%CI: 0.507-0.767) to 0.848 (95%CI: 0.796-0.891), 0.887 (95%CI: 0.781-0.953) and 0.716 (95%CI: 0.581-0.827) among three groups, respectively. M-ccLS could achieve the prediction of benign and malignant tumors (the percentage of malignant tumors in m-ccLS 1-5 scores was 19.5%, 31.5%, 72.5%, 91.1%, and 100.0%, respectively). Among three groups, the NRI and IDI of m-ccLS were higher than those of ccLS v2.0.

##### CONCLUSION

Pseudocapsule had the additional value for ccLS v2.0 in the diagnosis of SRM. M-ccLS has great diagnostic performance and improvement for ccRCC and malignant tumors and could predict benign and malignant tumors of SRM.

##### CLINICAL RELEVANCE/APPLICATION

M-ccLS may prove to be a valuable tool for the future non-invasive evaluation of renal tumors.

#### **M5B-SPGU-2 CT-based Potential Predictor for CKD-free Survival after Partial Nephrectomy in Patients with Small RCC**

##### Participants

Seong Min Ahn, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate prognostic utility of 3D remaining functional parenchyma (RFP) extracting post-operative kidney CT in predicting chronic kidney disease (CKD)-free survival after partial nephrectomy (PN) in patients with small RCC.

##### METHODS AND MATERIALS

A retrospective analysis was carried out of 331 patients who underwent PN for clear cell RCC (less than 5cm) between September 2006 and September 2020. In order to construct a predictive model for CKD-free survival probability after PN, multivariable Cox regression analysis was carried out adding 3D volume of RFP extracting from the post-operative kidney CT to clinical parameters proven to have an impact on postoperative renal function such as eGFR, age, or perioperative variables.

##### RESULTS

The median age was 53 years, median tumor size was 3.4 cm. A total of 18 patients (5.4%) developed new-onset CKD at a median follow up of 35 months. The CKD-free survival rates at 1, 3, 5 and 7 year were 97.5%, 97.2%, 96.1% and 94.5%, respectively. On

univariable Cox regression analysis, age (hazard ratio 1.097,  $P = 0.0001$ ), Charlson Comorbidity Index (hazard ratio 1.728,  $P = 0.0001$ ), hypertension (hazard ratio 4.792,  $P = 0.0017$ ) and Furhmann\_grade (hazard ratio 2.828,  $P = 0.0086$ ) were independent predictors for new-onset CKD. The C-index for CKD-free survival prediction with clinical parameters along was 0.8358. The addition of 3D RFP improved the C-index to 0.8525 ( $p = 0.0405$ ).

## CONCLUSION

s Addition of 3D RFP values to standard clinical factors improves CKD-free survival prediction after PN in patients with small RCC. Using this model, RFP could be a reliable method for preoperative prediction of prognosis in PN.

## CLINICAL RELEVANCE/APPLICATION

The revised prediction model adding 3D imaging parameters might have an important role in partial nephrectomy decision-making and follow-up plan after surgery in patient with RCC.

## M5B-SPGU-3 Automatic Segmentation of Renal Tumors: A Novel Visualization Approach

### Participants

Sophie Bachanek, Gottingen, Germany (*Presenter*) Nothing to Disclose

Sophie Bachanek, MD, Gottingen, Germany (*Presenter*) Nothing to Disclose

Johannes Uhlig, Goettingen, Germany (*Presenter*) Speaker, Bayer AG; Research Grant, Siemens AG

## PURPOSE

To establish an automatic segmentation algorithm and visualisation method for solid renal tumors that utilizes CT-studies acquired in clinical practice and multireader input.

## METHODS AND MATERIALS

Renal tumor patients diagnosed 2018-2021 were retrospectively assessed. Inclusion criteria were CT-imaging of renal tumors in corticomedullary or nephrogenic contrast media (CM/NG) phase. Patients with cystic or infiltrative renal tumors and age <18 years were excluded. Manual segmentation of the tumors was performed on all axial CT slices and used for training of a convolutional neural network (UNET). In an independent validation dataset, the accuracy of the UNETs predictions of renal tumor contours was compared to manual segmentations (quantified by DICE score).

## RESULTS

$n=394/n=350$  patients in CM/NG phases were included (median age 66 years; 35% female; median tumor diameter 5.4cm). CT-studies from >20 radiological imaging centers were included with different imaging protocols and slice thickness. The UNET was trained on  $n=316$  CM/  $n=294$  NG contrast phase patients ( $n=7019$  /  $n=6859$  CT images). In the independent validation dataset ( $n=78$  /  $n=56$  patients with 1713 / 1298 CT images), the UNET achieved a DICE score of 0.88 and 0.90 for the corticomedullary and nephrogenic CM phase, respectively. The UNET predictions were visualized using a tile-based approach with color-coding and contour-lines that could be overlaid on CT-images to depict varying levels of prediction confidence.

## CONCLUSION

s A UNET yields a robust automatic delineation of renal tumors on CT-images acquired in clinical routine, irrespective of the contrast media phase. Color-coding and contour-lines can be overlaid on original CT-images to provide visual feedback of UNET segmentations and confidence levels.

## CLINICAL RELEVANCE/APPLICATION

Automatic renal tumor segmentation using UNETs robustly performs on heterogeneous clinical CT data. Color-coding provides an explainable approach to model predictions and might improve acceptance in clinical practice.

M5B-SPHN

### Head & Neck Imaging Monday Poster Discussions II

#### Sub-Events

#### **M5B-SPHN-1 Prediction of Cervical Lymph Node Metastasis in Thyroid Cancer Based on CT Imageomics and Deep Learning**

##### **PURPOSE**

The aim of this study is to explore the feasibility and accuracy of using CT imageomics analysis combined with deep learning technology to predict cervical lymph node metastasis in thyroid cancer patients, and to provide reliable reference for clinical treatment.

##### **METHODS AND MATERIALS**

A retrospective analysis of CT image data was performed on 112 thyroid cancer patients with confirmed cervical lymph node metastasis who underwent surgery in our hospital from April 2021 to March 2023. First, the corresponding lymph nodes that were confirmed by pathology were identified on the CT images, and a convolutional neural network (CNN) was used to perform image segmentation and extract 59 features including morphological, texture, and histogram statistical features. Then, feature selection methods were applied to screen out the features with significant differences in lymph node metastasis. Finally, a logistic regression model was used for prediction modeling and its accuracy and generalization ability were evaluated.

##### **RESULTS**

Through feature selection, we selected four optimal features, including angular second moment, entropy, area, and variance. In the test set, after cross-validation and ROC curve analysis, the logistic regression model had an accuracy of 88.2%, sensitivity of 84.0%, specificity of 92.4%, and AUC of 0.913 for predicting cervical lymph node metastasis in thyroid cancer.

##### **CONCLUSION**

This study demonstrates that CT imageomics and deep learning technology can be used to predict lymph node metastasis in thyroid cancer. The optimal features extracted can effectively distinguish between thyroid cancer patients with and without lymph node metastasis.

##### **CLINICAL RELEVANCE/APPLICATION**

The logistic regression model has high accuracy and generalization ability, and can be used as a reliable clinical decision support tool to help doctors formulate better treatment plans and improve treatment outcomes. In the future, we will further expand the sample size, improve algorithm performance, and develop an automated lymph node metastasis prediction system based on CT imageomics and deep learning technology.

#### **M5B-SPHN-2 Evaluation and Survival Prediction for A Novel Fully Automatic System for Lymph Node Segmentation and Counting in Nasopharyngeal Carcinoma Using Multimodal MRI**

##### **PURPOSE**

The accurate segmentation and counting of lymph nodes (LNs) is essential for the structured reporting and prognostic diagnosis of nasopharyngeal carcinoma. As such, developing a fully automatic system for accurate LNs segmentation and counting in nasopharyngeal carcinoma patients is of great clinical significance for the accurate prognostic analysis of this disease.

##### **METHODS AND MATERIALS**

First, we proposed a multimodal LNs segmentation model based on T1-weighted, contrast-enhanced T1-weighted, and T2-weighted MRI images, which named NPCnet. We then developed a fully automatic algorithm for LNs counting and combined it with the segmentation model to create a comprehensive system called the Fully Automatic Lymph Node Counting System (AMLNC). The accuracy and practical value of our system were evaluated by comparing its performance metrics (Interclass Correlation Coefficient (ICC) and Bland-Altman plot) with those of detailed MRI assessment (gold standard) and automatic counting using manual delineation (MDAC). Finally, we analyzed the relationship between the LNs count and the prognostic outcomes of the patients, such as Overall Survival (OS), Progression-free Survival (PFS), and Distant Metastasis-free Survival (DMFS).

##### **RESULTS**

We retrospectively analyzed the data of 995 patients and divided them into training and validation datasets at a ratio of 7:3 for constructing the segmentation model. The mean DICE similarity coefficient in the validation set of 298 cases was 0.771. We selected 20 cases randomly for manual repeat delineation, and there was no statistically significant difference in the mean DICE between automatic segmentation and manual delineation (0.785 vs 0.806,  $p = 0.068$ ). The median (IQR) LNs counts for the gold standard, AMLNC, and MDAC were 3 (2-4.074), 4 (2-4.581), and 4 (2-5.513), respectively. The ICC showed that the AMLNC had good repeatability (0.778 (Gold vs AMLNC), 0.638 (Gold vs MDAC), and 0.739 (AMLNC vs MDAC)). Furthermore, we selected 40 cases randomly for manual reading repeatedly, and the ICC still showed that the AMLNC system had good repeatability (0.805 (Gold vs AMLNC), 0.663 (Gold vs manual MDAC), and 0.672 (Gold vs Gold repeatedly)). The Bland-Altman plot displayed good agreement between the AMLNC and the gold standard. We divided all patients into low (1-4 positive LNs), moderate (5-9), and high (>9) risk

groups, and the K-M plots showed a great discriminating ability for OS, PFS, and DMFS using AMLNC

## CONCLUSION

s The AMLNC System in this study demonstrates good repeatability and reliability in its results and clinical survival prediction ability

## CLINICAL RELEVANCE/APPLICATION

The AMLNC System can be directly used for structured reporting and survival prognosis analysis of nasopharyngeal carcinoma

## M5B-SPHN-3MRI Radiomics Approach with Deep Transfer Learning for Distinguishing Sinonasal Malignancies: A Preliminary Study Based on Different Machine Learning Algorithms

Participants

Naier Lin, MS, Shanghai, China (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the diagnostic performance of MRI hand-crafted (HC) radiomics features combined with deep transfer learning (DTL) features in distinguishing between sinonasal squamous cell carcinoma (SCC), adenoid cystic carcinoma (ACC) and non-Hodgkin's lymphoma (NHL) .

## METHODS AND MATERIALS

This retrospective analysis consisted of 50 patients with sinonasal SCC, 42 patients with NHL and 40 patients with ACC. Patients were allocated to training and testing cohorts randomly at a ratio of 8:2. HC radiomics features and DTL features were extracted from T2-weighted image (T2WI), apparent diffusion coefficient (ADC) and contrast-enhanced T1-weighted image (CE-T1WI). A ResNet50 convolutional neural network (CNN) pretrained model was used for DTL features extracting. The least absolute shrinkage and selection operator (LASSO) regression was applied for feature selection and radiomic signature (radscore) construction. The classification performance for detection of sinonasal SCC, ACC and NHL was compared between seven machine learning (ML) algorithms.

## RESULTS

The radscore included 24 HC radiomics features and 8 DTL features. Algorithm of SVM showed the best performance with the highest accuracy (92.6%) in the testing cohort. ROC analysis indicated that the macro-average AUC and micro-average AUC values of SVM were 0.98 and 0.99. AUCs for diagnosis of ACC, NHL, SCC were 0.99, 0.97 and 1.00, respectively. Besides, KNN and XGBoost algorithms also provided better results with both the macro-average and micro-average AUC values > 0.90.

## CONCLUSION

s Three-MRI sequence-based HC radiomics features and DTL features combined with SVM model improved differentiation between sinonasal SCC, NHL and ACC.

## CLINICAL RELEVANCE/APPLICATION

The tumor biological behaviors and therapeutic schedules of SCC, ACC and NHL are different. As a noninvasive and convenient method, the MRI radiomics approach with deep transfer learning represented an opportunity to advance precise prediction for the type of sinonasal malignancies preoperatively and assist in making appropriate treatment and improving the prognosis.

## M5B-SPHN-4Radiomics Analysis for the Prediction of Locoregional Recurrence of Locally Advanced Oropharyngeal Cancer and Hypopharyngeal Cancer

## PURPOSE

By radiomic analysis of the postcontrast CT images, this study aimed to predict locoregional recurrence (LR) of locally advanced oropharyngeal cancer (OPC) and hypopharyngeal cancer (HPC), that carry high LR rate >50% and poor overall survival rate <50%.

## METHODS AND MATERIALS

From two independent cohorts, this retrospective study enrolled 194 patients with stage III-IV OPC or HPC according to the 7th edition of the American Joint Committee on Cancer. These patients were randomly split into a training cohort with 153 cases (80%) and a testing cohort with 39 cases (20%). Only the primary tumor mass was segmented manually for the radiomic analysis. Radiomic features were extracted using PyRadiomics, and then the support vector machine (SVM) was used to build the radiomic model with a 5-fold cross-validation process in the training dataset. For each case, a radiomics score was generated to indicate the probability of LR.

## RESULTS

Within a follow-up period of 2 years, there were 94 patients with LR assigned in the progression group and 98 patients without LR assigned in the stable group. There was no significant difference in clinical TNM staging, treatment strategies, and common risk factors between these two groups. For the training dataset, the radiomics model to predict LR showed 83.7% accuracy and 0.832 (95% CI: 0.72, 0.87) area under the ROC curve (AUC). For the test dataset, the accuracy and AUC slightly declined to 79.5% and 0.770 (95% CI: 0.64, 0.80), respectively. The sensitivity/specificity of the training and test dataset for LR prediction were 77.6%/89.6%, and 66.7%/90.5%, respectively.

## CONCLUSION

s The proposed image-based radiomic approach could provide a reliable prediction model of LR in locally advanced OPC and HPC with high accuracy and specificity. Early identification of those prone to post-treatment recurrence would be helpful for appropriate adjustments to treatment strategies and posttreatment surveillance.

## CLINICAL RELEVANCE/APPLICATION

For locally advanced oropharyngeal and hypopharyngeal cancers with high recurrence rates and poor prognoses, we demonstrated that an image-based radiomic model might potentially identify those prone to post-treatment recurrence with high accuracy and high specificity. Pending the future validation in a large cohort, it is expected to provide an opportunity to make appropriate

adjustments to the treatment choices (concurrent chemoradiation therapy vs. surgery with adjuvant treatment), post-treatment imaging interval (6 weeks vs. 12 weeks), chemoradiotherapy treatment protocols, and the patient's rehabilitation plan, psychological support, and social care resource allocation.

## **M5B-SPHN-5 Assessment of a Commercially Available Artificial Intelligence Algorithm for Risk Stratification of Thyroid Nodules: Diagnostic Performance at a Tertiary Academic Center**

### **PURPOSE**

To evaluate the diagnostic performance of a commercially available, artificial intelligence-based software platform for risk stratification of thyroid nodules on ultrasound (US). This tool was recently FDA approved and no external validation studies have been published to date evaluating its clinical performance.

### **METHODS AND MATERIALS**

This retrospective study included all thyroid US examinations containing thyroid nodules over a 1-year period at a large academic medical center. Nodules were included if they had a ground truth diagnosis by: a) surgical pathology, b) fine needle aspiration, or c) three-year follow up US showing stability. The cohort included 650 nodules from 348 patients. An FDA-approved, AI-based software tool (Koios DS Thyroid, Koios Medical) was applied to the images for each nodule. The Koios algorithm generates two primary outputs: 1) ACR TI-RADS nodule descriptors with TI-RADS score and follow up recommendation, and 2) an optional AI adaptor score which can adjust the risk assessment and recommendation based on the overall AI analysis of the images. Four different groups were compared: 1) AI software with AI adaptor enabled, 2) AI software without the AI adaptor, 3) clinical radiology reports (using ACR TI-RADS), and 4) radiology reports combined with AI adaptor score. Diagnostic performance of the final recommendations (FNA or no FNA) was determined based on the ground truth, and comparison between the four groups was made using sensitivity, specificity, and AUROC analysis.

### **RESULTS**

Diagnostic performance of the AI algorithm with the AI adaptor tool enabled was similar to the performance of the clinical radiologists (AUC 0.70 for both). The algorithm + adaptor had improved specificity compared to radiologists (0.63 vs 0.43) but decreased sensitivity (0.69 vs 0.81). Without the AI adaptor enabled, performance of the algorithm was slightly worse (AUC 0.65), while the best performance was seen when the radiology interpretation was combined with the AI adaptor (AUC 0.76). When combined with the AI adaptor, radiologist specificity improved from 0.43 to 0.53, resulting in 17% fewer FNA recommendations, with unchanged sensitivity (0.81).

### **CONCLUSION**

The Koios DS algorithm demonstrated standalone performance similar to that of radiologists, though with lower sensitivity and higher specificity. Performance was best when radiologist interpretations were combined with the AI adaptor component, which led to improved specificity and a reduction in unnecessary FNA recommendations.

### **CLINICAL RELEVANCE/APPLICATION**

AI software can improve thyroid US diagnostic performance and reduce unnecessary procedures. Workflow may also be improved through automated generation of TI-RADS scores, though performance is highest with human input.

## **M5B-SPHN-7 FaBoA: Computed Tomography-based Facial Bone Fracture Analysis Solution**

### **PURPOSE**

Facial bone fractures must be diagnosed and treated as early as possible to avoid complications and sequelae. Computed Tomography (CT) images are essential for accurate diagnosis and treatment planning, but analyzing these images is time-consuming and requires specialized expertise. While many classification and object detection studies have been conducted to address these issues, their limitations have hindered their widespread clinical use. The ability of classification-based studies to pinpoint the exact location of fractures is limited, while object detection-based research is challenging due to the ambiguity of the shape of a fracture. To address these challenges, we propose a deep learning-based facial bone fracture diagnosis system named FaBoA.

### **METHODS AND MATERIALS**

FaBoA was trained on a dataset of 6,294 CT scans with facial bone fractures acquired from January 2009 to March 2020. Experienced expertise manually annotated facial fractures with bounding boxes on all the datasets. Our deep learning model was evaluated on an additional 346 CT scans. We used deep learning-based object detection for the initial detection and class activation-based weakly-supervised segmentation for pixel-wise fine-grained localization.

### **RESULTS**

FaBoA achieved sensitivity and specificity were 100% and 84.2%, respectively, for nasal bone fractures. The sensitivity and specificity of all types of facial bone fractures were 81.3% and 70.5%, respectively. Furthermore, FaBoA can visualize fine-grained 3D fractures using the localization technique.

### **CONCLUSION**

FaBoA is a reliable and accurate CT-based facial bone fracture analysis solution that has the potential to assist radiologists in the diagnosis and treatment of facial bone fractures, leading to better patient outcomes. The combination of object detection and class-activation-based localization enables FaBoA to accurately detect and classify bone fractures with high sensitivity and specificity. In addition, FaBoA includes not only the diagnosis model but also a user-friendly interface that allows doctors to interact with the solution and access the analysis results easily. FaBoA can also be integrated into radiology workflows to enhance efficiency and reduce interpretation variability. The dataset used in this study, which spans over a decade of CT scans with facial bone fractures, provides a representative sample of real-world clinical cases and enhances the generalizability of the FaBoA model.

### **CLINICAL RELEVANCE/APPLICATION**

FaBoA's AI engine and user-friendly interface have the potential to assist in diagnosis, treatment planning, postoperative assessment, and monitoring of facial bone fractures, leading to better patient outcomes and workflow efficiency.

## Abstract Archives of the RSNA, 2023

M5B-SPIN

### Imaging Informatics Monday Poster Discussions II

#### Sub-Events

#### M5B-SPIN-1 Scaling Temporal and Volumetric Datasets for Tumor Localization Without Per-Pixel Annotations

##### Participants

Zongwei Zhou, PhD, Baltimore, MD (*Presenter*) Nothing to Disclose

##### PURPOSE

To examine whether AI trained using simple annotation strategies can achieve comparable or superior performance to that trained using per-pixel annotations in the context of computer-aided tumor detection.

##### METHODS AND MATERIALS

Two large-scale datasets were retrospectively collected for this study: SUN-SEG consists of 1,106 colonoscopy video clips for polyp detection, in which 49,136 frames are with polyps and 158,690 frames are without polyps. The video clips were split into training (507), validation (126), and test (473) sets. JHH contains 2,426 subjects collected and annotated at Johns Hopkins University for pancreatic tumor detection, where each subject was scanned by contrast-enhanced CT. We randomly split CT scans into training (1,683), validation (420), and test (323) sets. Tumors in both datasets were annotated on a per-pixel basis. We develop a new annotation strategy, simplifying the tumor annotation process to drag and drop (DragDrop). Furthermore, we designed a watershed-based weakly supervised learning method to leverage the DragDrop annotations and accommodate the high-dimensional temporal and volumetric data. Finally, we assessed Sensitivity, Specificity, Precision, and F1-score for tumor detection at both lesion and patient levels.

##### RESULTS

Given a certain annotation budget, our proposed DragDrop strategy improves the sensitivity, specificity, precision, and F1-score at the lesion-level for polyp detection when compared to per-pixel annotation, with improvements from 68% to 71%, 58% to 67%, 43% to 51%, and 54% to 59%, respectively. The patient-level results improve from 75% to 80%, 69% to 79%, 54% to 64%, and 62% to 66%, respectively. For pancreatic tumor detection, the results improve from 61% to 71%, 33% to 42%, 42% to 57%, and 52% to 61%, respectively. The patient-level results improve from 76% to 88%, 70% to 64%, 75% to 74%, and 61% to 73%, respectively. More importantly, for minority patients aged between 75 to 80 and 80 to 85, who only account for 7% and 3% of the JHH test set, our DragDrop improves lesion-level precision from 42% to 61%, and 45% to 60% and improves lesion-level F1-score from 55% to 72% and 59% to 75%.

##### CONCLUSION

Our proposed strategy reduced 87% and 99% annotation efforts for polyp and pancreatic tumor detection, respectively, and achieved a significantly better tumor detection rate than per-pixel annotations given an annotation budget.

##### CLINICAL RELEVANCE/APPLICATION

Simpler annotations demonstrate their advantages in scaling up datasets for tumor localization in comparison with per-pixel annotations. This not only improves accuracy and generalizability but also allows for better representation of underrepresented groups and identifying rare diseases that may be more prevalent in specific populations.

#### M5B-SPIN-2 Early Prediction of Motor Abnormalities in Very Preterm Infants Using MRI Radiomic Data with a Collaborative Self-Supervised Transformer Model

##### PURPOSE

To develop a collaborative self-supervised learning (Co-SSL) deep learning model for predicting motor abnormalities in preterm infants using MRI radiomic data without large-scale annotated images.

##### METHODS AND MATERIALS

Very preterm infants (gestational age  $\leq 32$  weeks) were enrolled in our institute, and axial T2-weighted MR images were collected on a 3T Philips Ingenia scanner. We processed T2 images using the Developing Human Connectome Project pipeline into 87 regions of interest (ROIs) and the PyRadiomics pipeline to extract 100 radiomic features for each ROI, resulting in a large radiomic feature map ( $87 \times 100$ ) for each subject. We assessed the motor abnormalities using Bayley III Motor score and dichotomized the infants into low-risk (score  $> 85$ ) vs. high-risk (score  $\leq 85$ ) groups. We developed a Co-SSL Transformer model for motor abnormalities prediction. Typical self-supervised learning (SSL) defines a pretext task to pretrain a model without using labels, then fine-tunes the model for the downstream real task. In contrast, our Co-SSL strategy uses two collaborative pretext tasks to jointly pretrain the model. Specifically, we first conducted data augmentation on  $N$  original subjects by randomly masking radiomic features of ROIs from radiomic feature maps, generating  $M$  augmented subjects. We defined two collaborative pretext tasks 1) Reconstruction- to reconstruct the masked radiomic features using the observable ones for all  $M$  subjects, and 2) Discrimination- to cluster  $M$  augmented subjects into  $N$  groups according to  $N$  original subjects. Using these two collaborative tasks, we pretrained a Transformer neural network to learn latent features without human labeling, and then fine-tuned this model for our motor

abnormality prediction. Performance was assessed by 5-fold cross-validation.

## RESULTS

A total of 362 subjects were included in this study, out of which only 318 have Bayley III motor scores at 2 years corrected age. Our Co-SSL Transformer achieved a mean (standard deviation [SD]) accuracy of 76.3 (5.1)% and AUC of 0.73 (0.05), outperforming the supervised Transformer [accuracy = 66.6 (5.3)%, AUC=0.64 (0.05)], SimCLR [accuracy=67.3 (5.2)%, AUC=0.65 (0.07)], and Invariant [accuracy=68.3 (4.4)%, AUC=0.67 (0.08)].

## CONCLUSION

We showed that the proposed model outperformed peer self-supervised ones for early risk stratification of developing motor abnormalities assessed at 2 years corrected age.

## CLINICAL RELEVANCE/APPLICATION

Very preterm infants are especially at increased risk of developing motor abnormalities compared to infants who were term born. Our AI strategy enables the early diagnosis of motor abnormalities using brain MRI radiomics without large-scale annotated datasets.

## M5B-SPIN-3 Quantum Kernel Methods Can Improve Binary Classification of COVID-19 Pneumonia on Chest Radiographs

Participants

John Mayfield, MD, MS, Lithia, FL (*Presenter*) Nothing to Disclose

## PURPOSE

Chest radiography has continued to serve as the workhorse of initial screening and surveillance of patients diagnosed with COVID-19, however, the nonspecific and variable patterns of pneumonia limited diagnostic accuracy as a predictor of disease. Increasingly complex and robust datasets such as COVIDx CXR3 provide enriched training environments for machine learning (ML) models to help clarify diagnosis. However, the stochastic nature of the disease may benefit from emerging technologies that combine ML with quantum computing (QC), known as Quantum machine learning (QML). Here, we evaluate a Quantum Projected Kernel (QPK) method and compare its performance against classical ML methods.

## METHODS AND MATERIALS

8,000 chest radiographs were randomly selected from the COVIDx-CXR3 database and split 80:20 training:validation set as well as a hold-out testing set of 400 cases. The images underwent dimensionality reduction using UMAP and were encoded into a 11-qubit circuit. Google Cirq's Density Matrix simulator was utilized with realistic noise simulation that is based upon Google's Rainbow quantum processor. Kernel density matrices were optimized in a complex Hilbert space to provide greater separation between classes and then subsequently projected into spatial coordinate space. This processed data was then passed through a linear dense classifier layer where accuracy, f1-score, precision, recall, and sensitivity/specificity were calculated for cross-validation and hold-out testing sets.

## RESULTS

The model demonstrated an accuracy of 94% [95% CI: 87-95%] with an AUC of 0.94 [95% CI: 82-95%] and f1-score of 0.92. Performance on the holdout testing set yielded 84% accuracy, AUC of 0.83, with an f1-score of 0.84, precision of 81%, recall of 86%, and sensitivity and specificity of 87% and 81%, respectively.

## CONCLUSION

QPK methods demonstrated promising performance on a diverse database that generalized well to a hold-out testing set. However, further optimization and evaluations are required to assess its performance.

## CLINICAL RELEVANCE/APPLICATION

QML can provide a quantum advantage to the data to potentially improve robustness compared to classical architectures alone. Given the improved accessibility to cloud-based quantum machines, such approaches may increase productivity and reliability of classification strategies, easing the reliance on larger, more complex models.

## M5B-SPIN-4 Joint Self-supervised and Supervised Contrastive Learning for Multimodal Brain MRI at Term: Towards Predicting Motor Impairments in Infants Born Preterm

Participants

Zhiyuan Li, BS, MS, Oxford, OH (*Presenter*) Nothing to Disclose

## PURPOSE

To develop a joint self-supervised and supervised contrastive learning model using multimodal brain MRI at term-equivalent age to predict later motor impairments in infants born preterm.

## METHODS AND MATERIALS

Data acquisition and pre-processing. This IRB approved study involves a multisite cohort of 297 preterm infants born before 33 weeks gestational age. T2-weighted structural MRI (sMRI), diffusion tensor imaging (DTI), resting-state functional MRI (fMRI), and clinical non-imaging data were collected for each subject. We preprocessed each subject using the Developing Human Connectome Project (dHCP) pipeline to segment the whole brain image into 87 regions of interest (ROIs) for the first three modalities. We further extracted radiomic features, structural connectome, and functional connectome from sMRI, DTI, and fMRI, respectively. Individual subjects underwent motor ability assessment using the Bayley-III Motor subtest at 2 years corrected age. We categorized infants into two groups based on their Motor score (range 40-160): high risk of (scores  $\leq$ 85) or low risk of motor impairments (scores  $>$ 85). Joint self-supervised and supervised contrastive learning. Our proposed model is shown in Figure 1. We first designed 5 feature extractors to extract feature embeddings from structural connectome, functional connectome, radiomic features, sMRI images, and clinical non-imaging features, respectively. Next, we pretrained all feature extractors by two pretext contrastive learning tasks, in which the first task was to learn the cross-modality-complementary features by clustering the feature types of an individual patient, and the second task was to learn cross-subject-similarity features by clustering the patient with the same class label.

Finally, we fine-tuned the pre-trained network to solve the real task (i.e., risk stratification of motor impairments) in a supervised manner. We evaluated our model using 10-fold cross-validation.

## RESULTS

Our model achieved an AUC of 0.73, outperforming the Siamese network (AUC=0.65) and Triplet network (AUC=0.68) models. In addition, our model also achieved better prediction performance than the single-modality models, such as the models using DTI (AUC=0.71) or fMRI (AUC=0.70).

## CONCLUSION

We proposed a novel joint self-supervised and supervised contrastive learning model to predict later motor impairments in very preterm infants using multimodal MRI data. The results showed that our proposed model outperformed peer and single modality models, demonstrating the effectiveness of the designed approach.

## CLINICAL RELEVANCE/APPLICATION

The proposed model can facilitate deep learning-based applications for multimodal MRI data.

## M5B-SPIN-5 Towards Patient Consumable Radiology Reports - Improving Content Signal-to-Noise Ratio (SNR) While Converting Medical Jargon to Plain English via GPT-4

### PURPOSE

With the increasing complexity of imaging modalities and the trend toward higher-level structured reporting, radiology reports have become equally as complex and lengthier by default; becoming nearly incomprehensible to the average person (patient). Additionally, there are ongoing efforts to produce patient-consumable radiology reporting. However, we believe that improving radiologist report structure and content is a necessary first step to having consistently structured reports for clinician ease of reading. More concise reports with predictable fields in anatomically oriented top-down logical order more effectively convey meaning. We listed and further removed well-known unnecessary words (noise) common in radiologist reports that do not help convey meaning resulting in an easier-to-read objective report (signal). This was followed by prompting the resultant higher Signal-to-Noise Ratio (SNR) phrases to read in plain English.

### METHODS AND MATERIALS

We first prompted GPT 4.0 (Generative Pretraining Transformer) to common radiologist phraseology that consistently slashed report length in half while maintaining content. Removed commonly used unnecessary words including: there is, of the, within the, visualized, measures, approximately, the patient, at this time. Second, we prompted GPT to convert the higher SNR report text to active voice plain English understanding defined by established doctrine, e.g., SEC (Security and Exchange Commission Rule).

### RESULTS

Report content SNR was doubled (total words cut in half) following the removal of unnecessary words while maintaining meaning for physicians in a more inviting/easier-to-read structured format. Following prompting for improved SNR to read in plain English, the report content was explained in a manner for general public understanding. Example GPT input (37 words): "Nonobstructive renal calculus within the left kidney collecting system measuring approximately 0.4 to 0.5 cm in cross-sectional diameter. This renal calculus was present on prior CT, though it has enlarged compared to the previous study". Example GPT output (17 words): "Enlarged non-obstructive kidney stone in left collecting system measuring 0.4-0.5 cm, previously seen on CT." GPT plain English: This report shows that there is a small stone in your left kidney that is not causing a blockage. The stone is growing and has gotten a bit bigger since your last scan.

### CONCLUSION

We show that GPT-4 can significantly increase the SNR of the radiology report for both physicians and for patients.

### CLINICAL RELEVANCE/APPLICATION

Improving report content SNR leveraging GPT helps referring physicians radiologists report readability further converting to plain English completes radiology's service to our patients.

## M5B-SPIN-6 Quantifying the Technical Challenges and DICOM Metadata Variability in Stroke Machine Learning Data Curation

Participants  
Peter Kamel, MD, Baltimore, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Data curation is a challenging and often rate-limiting task in machine learning algorithm development. This is compounded by heterogeneity of DICOM metadata labeling and storage conventions, which often makes data curation require extensive preprocessing and manual cleaning. The purpose of this study was to quantify the variability in DICOM metadata labeling conventions and analyze the largest factors limiting data curation for the use case of machine learning on stroke CTs and MRIs.

### METHODS AND MATERIALS

We evaluated data curation on a set of stroke MRI-CT pairs consisting of DWI sequences from MRI and associated dual energy CT head with 120 kV and 190 keV virtual monochromatic images. From an initial list of 946 patients, we used DICOM queries to find the studies of interest, identify the b1000 DWI images and thick resolution axial 120 kV and 190 keV images, download the images from the PACS, anonymize them, and convert them to NIFTI file format for machine learning. During each step of the process, errors and limitations of data curation were recorded, characterized, and quantified.

### RESULTS

In the 946 MRI examinations we found 1,122 unique Series Descriptions, of which over 20 were used to identify the DWI sequence, due to varying labeling and storage conventions (Figure 1a). Multiple methods of encoding were used to store the DWI sequence b-value, requiring multiple iterations and regular expression matching to extract the necessary MRI images. Of the initial 946 MRI examination, 24 (2.5%) were missing the appropriate series or unretrievable from the PACS, 2 (0.2%) contained improper or absent

b-value encoding, and 32 (3.4%) contained slice increment, geometric, or orientation inconsistencies that prevented image conversion to NIFTI. Similar challenges were encountered with head CT preprocessing and download which contained 18 unique Series Descriptions for the thick-slice axial images. The final yield of MRI-CT pairs that would be useful for our use case was 815, reflecting an approximately 13.8% data loss from the initial list (Figure 1b).

## **CONCLUSION**

Technical challenges in DICOM metadata variability pose a significant limitation to machine learning dataset curation. Even with extensive manual correcting, a loss of 10-15% can be expected from an initial list to a curated dataset due to technical factors, which do not include scan or clinical limitations on examinations. Such limitations in dataset curation should be considered at the outset of any machine learning project and accounted for during study design.

## **CLINICAL RELEVANCE/APPLICATION**

Machine learning data curation poses significant technical challenges, which need to be accounted for when estimating the yield of an initial data set.

## **M5B-SPIN-7 Mr**

### **PURPOSE**

The purpose of this study is to introduce two approaches that leverage multi-armed bandit algorithms to select the most appropriate participants for each round of training in Federated Learning (FL) for brain tumor segmentation. FL is a machine learning approach that enables collaborative training of a model without sharing data. Developing accurate and reliable machine learning models for brain tumor segmentation in federated settings is crucial, and collaborator selection plays a significant role in achieving this goal. However, choosing the most appropriate collaborators for each round of training in Federated Learning (FL) is a challenge. Hence, Reinforcement Learning (RL) algorithms have potential to tackle this challenge.

### **METHODS AND MATERIALS**

We use RL to evaluate the estimated performance of each collaborator and select the most promising candidates for collaboration. We employ a markov decision process for reward-based selection of collaborators. We measure the estimated performance of each collaborator and the overall performance of the model. Segmentation accuracy and convergence scores are the evaluation metrics used to assess model performances in the OpenFL platform.

### **RESULTS**

The two proposed approaches (epsilon-greedy and upper confidence bound) effectively select the most promising collaborators for each round of training in FL for brain tumor segmentation. The results show that our approach induces participation of the best candidates leading to better segmentation results. The selected collaborators based on the RL approach showed a higher estimated performance than random selection or the batch-wise collaborator selection. Results indicate a positive correlation between selecting the most appropriate collaborators and the overall performance of the model.

## **CONCLUSION**

The proposed multi-armed bandit algorithms effectively select the most promising collaborators for each round of training in FL for brain tumor segmentation. The reward-based selection process encourages the participation of the best candidates, leading to better segmentation results and a generalizable model.

## **CLINICAL RELEVANCE/APPLICATION**

Accurate and reliable machine learning models are essential in clinical settings for early diagnosis and treatment planning. However, after GDPR and HIPAA laws, data privacy concerns limit data sharing, making federated learning a viable approach. This study can lead to better diagnosis and treatment planning for brain tumor patients.

M5B-SP1R

### Interventional Radiology Monday Poster Discussions II

#### Sub-Events

#### **M5B-SP1R-1 Prophylactic Internal Iliac Artery Balloon Occlusion in Placenta Accreta Spectrum: Evaluating Efficacy, Risks, and Clinical Implications**

#### **PURPOSE**

This study aimed to assess the efficacy and risks of prophylactic internal iliac artery balloon occlusion (IIABO) in managing placenta accreta spectrum (PAS) disorders and to discuss the clinical implications of this technique.

#### **METHODS AND MATERIALS**

We conducted a retrospective analysis of 623 confirmed PAS cases, including placenta accreta, increta, and percreta, between December 2013 and December 2022. Patients were divided into two groups based on whether they received prophylactic IIABO (Balloon Group, n=310) or not (No Balloon Group, n=313). The diagnosis of PAS was based on ultrasonography and verified by MRI when needed. Clinical management, surgical outcomes, complications, and hospitalization-related outcomes were compared between the groups using independent sample t-test, Mann-Whitney U test, or Fisher's exact test, as appropriate.

#### **RESULTS**

Among 623 confirmed PAS cases, patients were divided into Balloon (n=310) and No Balloon (n=313) groups. The Balloon Group had lower intraoperative bleeding and transfusion, with a significant difference in placenta percreta cases (P=0.03), and shorter operation duration for placenta percreta (P=0.02). No significant differences were observed in demographics, placenta removal, hysterectomy, or obstetric complications between the groups. Balloon Group had higher rates of arterial injury, thrombosis, and lower extremity ischemia (without statistical differences), as well as higher hospitalization costs (P=0.01). Balloon blocking time significantly increased from PA to PI and then to PP (P=0.03).

#### **CONCLUSION**

s Prophylactic IIABO can be beneficial in reducing intraoperative bleeding and operation duration in selected PAS cases, particularly placenta percreta. However, the increased vascular complications and costs must be weighed carefully. Further studies should focus on optimizing patient selection and minimizing complications.

#### **CLINICAL RELEVANCE/APPLICATION**

This study sheds light on the potential benefits and risks of prophylactic internal iliac artery balloon occlusion (IIABO) in managing placenta accreta spectrum (PAS) disorders. While IIABO may be advantageous in specific cases, such as placenta percreta, clinicians must carefully evaluate the associated risks and costs. Future research should focus on refining patient selection and mitigating complications to improve the safety and effectiveness of IIABO in clinical practice.

#### **M5B-SP1R-2 Time-driven Activity-based Cost Analysis of Uterine Artery embolization**

#### **PURPOSE**

Time-driven activity-based costing (TDABC) is the most accurate costing methodology in healthcare. The aim of this study was to increase cost transparency and uncover potential areas for savings in outpatient uterine artery embolization (UAE) for using TDABC methodology.

#### **METHODS AND MATERIALS**

We retrospectively reviewed 109 patients who underwent outpatient UAE for fibroids or adenomyosis at a large urban tertiary academic center between January 2020 and December 2022. A process map defined the steps of UAE during a procedure day. Utilization times were captured from electronic health record timestamps and staff interviews using validated techniques. Capacity cost rates were estimated using a combination of institutional data, regional surveys, and manufacturer proxy prices. Costs were calculated using TDABC methodology for personnel, equipment, and consumables. Consumables were further sub-categorized into standard items, vascular devices (eg, needles, sheaths, catheters, wires), embolic agents (trisacryl gelatin particles and/or gelfoam), medications, and other (eg, contrast, closure devices).

#### **RESULTS**

The mean total cost of UAE was \$4,529 (SD=\$936), the greatest contributor of which was consumables (66%; \$2980 [\$799]), followed by personnel (30%; \$1372 [\$265]) and equipment (4%; \$177 [\$42]). Within consumables, embolic agents accounted for the greatest proportion of costs, accounting for 42% (\$1268 [\$771]), followed by vascular devices (33%; \$980 [\$151]). The cost of embolic agents was highly variable, largely driven by the number of vials (range 1-19) of trisacryl gelatin particles used.

#### **CONCLUSION**

s Consumables accounted for the majority of the total cost of UAE, largely driven by the cost of embolic agents and vascular devices. It is unlikely that improved efficiency in room or personnel time will lead to cost-savings for UAE.

## CLINICAL RELEVANCE/APPLICATION

Understanding true procedural costs and addressing the high cost of consumable equipment in interventional radiology remains an important obstacle in improving the cost-effectiveness of IR procedures.

### M5B-SPIR-4 The Cost of an Interventional Radiology Fellow: Time-driven Activity-based Cost Analysis of Uterine Artery Embolization for Symptomatic Uterine Fibroids

#### PURPOSE

Academic teaching hospitals garner many benefits for undertaking the training of residents and fellows; however, the cost of trainees in the context of clinical care is not well-captured. The aim of this study was to investigate differences in utilization time and total costs between attending alone and attending/fellow cases in patients receiving outpatient uterine artery embolization (UAE) for symptomatic uterine fibroids using time-driven activity-based costing (TDABC) methodology.

#### METHODS AND MATERIALS

We retrospectively reviewed 109 patients who underwent outpatient UAE for fibroids or adenomyosis at a large urban tertiary academic center between January 2020 and December 2022. Using a process map to capture all steps of a single procedure, we gathered utilization times, including pre-procedure care, room time, intra-procedure time, and post-procedure care, from electronic health record timestamps and staff interviews. Capacity cost rates were estimated using validated techniques. Costs were calculated using TDABC methodology for personnel, equipment, and consumables. We analyzed differences in time utilization and costs between procedures performed by an IR attending only (AO) versus an IR attending and IR fellow (AF) using two-sample t-tests, additionally stratifying by time period (July-December vs January-June) to account for trainee experience.

#### RESULTS

Of 109 total cases, 23 (21%) were performed by an attending alone. AO cases had significantly shorter room times (AO vs AF: 141 vs 156 min,  $p=.042$ ) and intra-procedure times (94 vs 110 min,  $p=.009$ ); there were no differences in pre- or post-procedure care times. The mean total cost of AO cases was 12% (\$539) cheaper than AF cases (\$4,103 vs 4,642;  $p=.003$ ). In both AO and AF cases, the greatest contributor of total costs were consumables (70% and 65%, respectively), followed by personnel (27% and 30%). Intra-procedure times were significantly lower for AO cases during July-December (88 vs 114 min,  $p=.024$ ) but not during January-June (99 vs 106 min,  $p=.48$ ).

#### CONCLUSION

The presence of an IR fellow is associated with significantly longer room and intra-procedure times, as well as higher total costs in outpatient UAE. These differences are likely attributable to trainee inexperience during the first half of the fellowship year.

## CLINICAL RELEVANCE/APPLICATION

Cost of procedures varies depending on practice setting, as well as the presence and experience of a clinical trainee. Understanding true costs is important in determining cost-effectiveness of interventional radiology procedures in different environments.

### M5B-SPIR-5 The Evolving Role of IR in the Management of Cholecystitis

#### PURPOSE

(Please review this as an educational exhibit if possible- sorry for the inconvenience!) Teaching Points  
1. Introduce various innovative interventional radiology (IR) management options for cholecystitis and its complications that impact clinical outcomes  
2. Review the success of traditional interventions of cholecystitis by IR  
3. Present a successful example of a standardized multidisciplinary approach for the management of cholecystostomy drains  
4. Demonstrate successful approaches of management of cholecystitis and its complications through the use of novel IR techniques  
5. Review high-impact studies regarding IR management of cholecystitis including new, innovative interventions

#### METHODS AND MATERIALS

Table of Contents  
1. Introduction, including epidemiology of cholecystitis and current traditional surgical management options  
2. Traditional role of IR in the management of non-operative cholecystitis  
3. Review of existing high-impact studies regarding success of percutaneous cholecystostomy drains  
4. Indication, technique, and complications of percutaneous cholecystostomy drain  
5. Standardized management of percutaneous cholecystostomy drains used at our center  
6. Novel roles for IR in management of cholecystitis  
7. Indication, technique, and successful cases of percutaneous stone extraction, electrohydraulic lithotripsy (EHL), and laser lithotripsy  
8. Indication, technique, and successful case of gallbladder cryoablation for chronic cholecystitis  
9. Review of a high-impact studies regarding novel IR techniques: percutaneous cystic duct interventions for non-operative cholecystitis and percutaneous stone extraction  
10. Conclusion and summary

### M5B-SPIR-6 Prediction of the Benefits of DEB-TACE and Molecular Targeted Sequential Therapy in Advanced Hepatocellular Carcinoma using a Radiological-Clinical Nomogram: A Multi-Institutional Study

#### PURPOSE

To explore the value of a radiological-clinical (Rad-Clinical) model in predicting the clinical efficacy on advanced hepatocellular carcinoma (HCC) after drug eluting beads transcatheter arterial chemoembolization (DEB-TACE), to optimize the targeted sequential treatment.

## METHODS AND MATERIALS

A total of 202 patients with advanced HCC who received DEB-TACE treatment in 17 institutions from June 2018 to December 2022 were retrospectively analyzed (training cohort: n=105; internal validation cohort: n=45; external validation cohort: n=52). Progression-free-survival (PFS) related radiomics were computationally extracted from HCC to build a radiological signature (Rad-signature) with least absolute shrinkage and selection operator regression. A Rad-Clinical model for postoperative PFS was further built according to Rad-signature and clinical variables by Cox regression analysis. It was presented as a nomogram and evaluated by receiver operating characteristic curves, calibration curves, and decision curve analysis. And further evaluate the application value of Rad-Clinical model in clinical stages and targeted sequential therapy.

## RESULTS

Tumor size, Barcelona Clinic Liver Cancer(BCLC) stage, and Radiomics score(Rad-score) were independent risk factors that affect PFS after DEB-TACE treatment for advanced HCC with the Rad-Clinical model being the best model for predicting PFS in these patients (hazard ratio: 2.08; 95% confidence interval: 1.56-2.78;  $P<0.001$ ). Based on this model, low-risk patients had higher PFS than high-risk patients in BCLC-B and C stages ( $P=0.021$ ). Targeted sequential therapy for patients with high and low-risk HCC in BCLC-B stage exhibited significant benefits ( $P=0.018$ ,  $P=0.012$ ), but no significant benefit for patients with high-risk HCC in BCLC-C stage ( $P=0.052$ ).

## CONCLUSION

s The Rad-Clinical model may be favorable for predicting PFS in patients with advanced HCC treated with DEB-TACE and for selecting patients who may benefit from targeted sequential therapy.

## CLINICAL RELEVANCE/APPLICATION

With regard to advanced HCC, we have established several prognostic models or scoring systems to predict survival after TACE . However, the accurate prognosis for HCC patients is not only related to age, lesion size, vascular invasion, treatment methods, lesion number, but also related to the internal features of the lesion .In this study, we investigated the clinical risk factors and CT radiomics features in association with the prognosis of patients with advanced HCC treated with DEB-TACE, and then established and validated a model for predicting postoperative progression-free-survival (PFS). By means of this model, we further identified which patient population could benefit from targeted therapy.

## M5B-SPiR-7 Bacterial Community Analysis of Pyogenic Liver Abscess With or Without Gas Formation by 16S rDNA Sequencing

### PURPOSE

Gas formation is an important feature of pyogenic liver abscess (PLA). The potential relationship between gas formation bacterial composition in PLA remains unclear. The present study attempts to compare bacterial composition between gas-forming PLA (GFPLA) non-gas-forming PLA (non-GFPLA) to identify factors associated with gas formation in PLA .

### METHODS AND MATERIALS

Clinical data from 331 patients with PLA was collected retrospectively, 16S rDNA sequencing was performed to analyze the bacterial composition of pus samples from 60 consecutive PLA patients. Patients were divided into GFPLA non-GFPLA groups according to the presence or absence of gas on computed tomography (CT). Univariate multivariate logistic analyses were used to identify factors associated with gas formation in PLA.

### RESULTS

Rates of extrahepatic migratory infection (EMI), intensive care unit (ICU) admission mortality were significantly higher in the GFPLA group. 16S rDNA sequencing showed no differences in bacterial community richness diversity between the two groups. Linear discriminant analysis effect size (LEfSe) revealed a higher abundance of Enterococcus faecium Enterobacter cloacae in the GFPLA group. However, the presence of Enterococcus faecium Enterobacter cloacae was not associated with the gas formation on multivariate regression analysis. Only the history of digestive system cancer was independently associated with gas formation in PLA .

### CONCLUSION

s No relationship was observed between gas formation bacterial composition in PLA; only the history of digestive system cancer was independently associated with PLA gas formation.

### CLINICAL RELEVANCE/APPLICATION

An increased understanding of the mechanisms underlying PLA gas formation may provide new insights into the clinical phenomenon that patients with gas-forming pyogenic liver abscess (GFPLA) tend to have more severe symptoms increased mortality compared to patients with non-gas-forming PLA (non-GFPLA).

M5B-SPMK

### Musculoskeletal Imaging Monday Poster Discussions II

#### Sub-Events

#### M5B-SPMK-1A Preliminary Study of MRI T2 Mapping Imaging of Knee Cartilage in Type 2 Diabetic

##### PURPOSE

To preliminarily explore the effect of type 2 diabetes mellitus (T2DM) on articular cartilage of knee osteoarthritis (OA) based on MRI T2 mapping sequence.

##### METHODS AND MATERIALS

A total of 52 participants were recruited for MRI T2 mapping sequences. The subjects were divided into experimental group and control group. The experimental group was classified as group A of type 2 diabetic osteoarthritis (T2DM OA), with 32 patients and a total of 61 knees; and the control group was classified as group B of non-diabetic osteoarthritis (NDM OA), with 20 persons and a total of 34 knees. Group A was divided into severe group (Ax1) and mild group (Ax2) according to whether there were diabetes-related complications and basal insulin therapy. According to the course of the disease, = 10 years are classified as Ay1 and > 10 years are classified as Ay2 group. Each subject's cartilage was divided into four regions of interest according to the medial and medial femoral condyle and the medial and medial tibial condyle. The cartilage T2 value for each region of interest is defined as the average of the optimal cartilage display level and the most significant lesion level for each region of interest. The optimal cartilage display layer is selected at the middle level of the articular cartilage on this side; and the most significant lesion area level is selected, from the most serious grade of cartilage lesions. The cartilage T2 value of each region of interest is measured twice and averaged calculated.

##### RESULTS

(1) Compared with the NDM OA group, the T2 value of cartilage in the T2DM OA group was generally increased in the early cartilage grading group. (2) The T2 values of knee cartilage in the severe diabetes group were generally greater than those in the mild group, and the T2 values in the medial femoral condyle and the medial tibial condyle were statistically different ( $p < 0.05$ ). (3) When graded according to the course of the disease, the T2 value of cartilage in the Ay2 group was greater than that in the Ay1 group, and the T2 value of the medial tibial condyle cartilage was statistically different ( $p < 0.05$ ).

##### CONCLUSION

The sequence of MRI T2 mapping is able to help assess knee OA by detecting the T2 value of the knee cartilage. Type 2 diabetes has an impact on knee cartilage degeneration, and the course of diabetes and the condition of blood glucose control are correlated with the degree of knee cartilage degeneration.

##### CLINICAL RELEVANCE/APPLICATION

T2 mapping sequence was used to evaluate the quantitative effect of type 2 diabetes on articular cartilage of knee OA, and to provide evidence for early clinical intervention of T2DM OA.

#### M5B-SPMK-2DISH: The Role of Peripheral Involvement

##### Participants

Celia Cantolla, MD, Santander, Spain (*Presenter*) Nothing to Disclose

Ana Berasategui Criado, MD, Santander, Spain (*Presenter*) Nothing to Disclose

##### PURPOSE

Diffuse idiopathic skeletal hyperostosis (DISH) predominantly affects the axial skeleton. However, it can also affect peripheral joints, even prior to spinal involvement. In this study we aim to assess the frequency, distribution and precocity of lower limb joint involvement in these patients.

##### METHODS AND MATERIALS

We reviewed chest CT scans of 200 patients, from January 1, 2023 to April 31, 2023, dividing them into two groups: first group of 100 patients aged between 50 and 70 years, and second group of 100 patients older than 70 years. We selected patients with DISH following the criteria of Arlet and Mazière. We then reviewed all previous imaging tests (simple x-Ray, CT and MRI) of the lower extremities stored in our PACS for findings characteristic of DISH and their time of onset.

##### RESULTS

We detected 19 DISH patients in the first group (18 men and 1 woman) and 34 in the second (26 men and 8 women). Knee involvement is frequent. Thus, of the 19 patients in the first group, 30% had previous imaging of this joint, and 66% of the cases showed involvement. Of the 34 patients with DISH in the second group, 38% had previous images of the knee, and 53% of them were affected by their disease. In addition, knee involvement was present prior to axial skeletal involvement in 42% of the cases, all of them male. In all patients with knee involvement, the extensor apparatus involvement was in the form of "gull wings".

##### CONCLUSION

s The involvement of the joints of the lower limb joints in DISH disease is frequent and with typical characteristics that allow the diagnosis to be suspected in the absence of imaging studies of the axial skeleton. In a not negligible percentage of cases, peripheral involvement precedes axial involvement, especially in males. Earlier involvement of the axial skeleton is associated with a higher percentage of peripheral joint involvement.

#### **CLINICAL RELEVANCE/APPLICATION**

We should familiarize ourselves with the characteristics of peripheral involvement in DISH that may even precede spinal disease, as early diagnosis is important for treatment and suspicion of complications.

### **M5B-SPMK-3 Opportunistic CT-derived Analysis of Fat and Muscle Tissue Composition Predicts Mortality in Patients with Cardiogenic Shock**

Participants

Babak Salam, Bonn, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Estimation of prognosis in patients presenting with cardiogenic shock (CS) is important to guide clinical decision making. Patients with CS frequently undergo computed tomography (CT) on admission. Aim of this study was to investigate the predictive value of opportunistic CT-derived body composition analysis in CS patients.

#### **METHODS AND MATERIALS**

Amount and density of fat and muscle tissue were quantified from single-slice CT images at the level of the intervertebral disc space L3/L4 in 152 patients with CS. Multivariable Cox regression and Kaplan-Meier survival analyses were performed to determine the predictive value of opportunistically CT-derived parameters of body composition and compare them with established clinical parameters for risk stratification. The primary endpoint was defined as 30-day mortality.

#### **RESULTS**

Within the 30-day follow-up, 90/152 (59.2 %) patients died. On univariable analyses, patient age and lactate as clinical prognosticators, as well as skeletal muscle (SM) area, visceral adipose tissue (VAT) area, area of fat tissue in muscle, and inter-muscle fat fraction as imaging biomarkers, were associated with 30-day mortality. On multivariable analyses, lactate (HR 1.10 (CI:1.04-1.17);  $p=0.002$ ) and patient age (HR 1.04 (CI:1.01-1.07),  $p=0.017$ ), as well as visceral adipose tissue (VAT) area (HR 1.004 (CI:1.002-1.007);  $p=0.001$ ) and skeletal muscle (SM) area (HR 0.987 (CI:0.975-0.999);  $p=0.043$ ) remained as independent predictors of 30-day mortality. Kaplan-Meier survival analyses showed significantly increased 30-day mortality in patients with higher VAT area ( $p=0.015$ ) and lower SM area ( $p=0.035$ ).

#### **CONCLUSION**

s CT-derived VAT and SM area are independent predictors of dismal outcomes in CS-patients and have the potential to become a new imaging biomarker, which is available from clinical CT.

#### **CLINICAL RELEVANCE/APPLICATION**

In this study we propose the use of VAT area and SM area, representing objective measures of patient clinical status, as promising imaging biomarkers for the outcome of patients with CS. The potentially outstanding value of VAT area and SM area is underscored by the fact that, unlike most CS risk scores, they can be rapidly and easily determined using available diagnostic imaging.

### **M5B-SPMK-4 Quantitative Diagnostic Value of CTP on Microcirculatory Perfusion of Lower Extremity Soft Tissues in Diabetic Patients**

#### **PURPOSE**

To quantitatively assess the lower extremity soft tissue perfusion characteristics in patients with unilateral diabetic foot using CTP technique and to initially identify quantitative imaging indicators that can predict lower extremity hemodynamic changes in patients with diabetic foot.

#### **METHODS AND MATERIALS**

A total of 45 patients with unilateral diabetic foot symptoms were included, and the normal side of the limb was included as its own control as the control group and the affected side as the affected foot group. The data were imported into syngo.via workstation for post-processing and analysis to obtain perfusion parameter values, including Blood Flow (BF), Blood Volume (BV), Mean Transit Time (MTT), Time to Peak (TTP), Permeability Surface (PS), and peak residual function of the pulse. Blood Volume (BV), Mean Transit Time (MTT), Time to Peak (TTP), Permeability Surface (PS), Time to Max (T<sub>max</sub>), and permeability (flow extraction, FED)

#### **RESULTS**

There were no statistically significant values of each parameter compared between the two groups of gastrocnemius control and affected foot; there were differences between the BV and FED groups of tibialis anterior control and affected foot groups with perfusion values of BV ( $0.68\pm 0.61$ )/mL and ( $0.44\pm 0.46$ )/mL, respectively, and FED ( $3.56\pm 2.92$ )/(mL/100mL/min) and ( $2.00\pm 2.55$ )/(mL/100mL/min). The differences in BF, BV and FED values were statistically significant between the two groups in the lesser extensor muscles, with perfusion values of BF ( $15.1\pm 17.5$ )/(mL/min) and ( $5.93\pm 5.95$ )/(mL/min), BV ( $1.09\pm 1.27$ )/mL and ( $0.40\pm 0.41$ )/mL, and FED ( $4.67\pm 4.99$ )/(mL/100 mL/min) and ( $1.70\pm 1.89$ )/(mL/100mL/min).

#### **CONCLUSION**

s CTP perfusion imaging of the lower extremity can be used as a reference technique for the initial assessment of the soft tissue perfusion characteristics of the lower extremity in patients with diabetic foot, and some quantitative CTP parameter values of the anterior tibial and lesser adductor muscles can provide some reference basis for the early clinical assessment of the microcirculatory characteristics of the diabetic foot.

#### **CLINICAL RELEVANCE/APPLICATION**

CTP perfusion imaging of the lower extremity can be used as a reference technique for the initial assessment of the soft tissue perfusion characteristics of the lower extremity in patients with diabetic foot.

## **M5B-SPMK-5 The Association Between Change of Muscle Quality and Mortality in Patients with Septic Shock**

Participants

Jiyeon Ha, MD, PhD, (*Presenter*) Nothing to Disclose

### **PURPOSE**

To investigate the prognostic significance of myosteatorsis in septic shock patients undergoing protocolized bundle therapy in the emergency department.

### **METHODS AND MATERIALS**

We conducted a retrospective single center study based on prospectively collected registry of septic shock in adult patients between May 2016 and May 2020. Patients who conducted computed tomography (CT) scan on ED visit day and have prior CT more than 180 days ago were enrolled in this study. Myosteatorsis was defined as sum of low attenuation muscle (LAMA) which represents low quality muscles with fatty infiltration and intermuscular adipose tissue (IMAT) based on CT density of muscle area. Myosteatorsis area difference was calculated between the ED visit day and the prior visit day. An example of body composition measurement is shown in Figure 1. Multivariate logistic regression model was used to evaluate odds ratios (ORs) and 95% confidence intervals (CIs) for 28-day mortality.

### **RESULTS**

Of the 569 enrolled patients, the 28-day survival rate was 40.7% and myosteatorsis area was increased in ED visit day compared with the prior visit day in both non-survival and survival group. But the area was more increased in non-survival group (11.5 cm<sup>2</sup> vs. 22.2 cm<sup>2</sup>,  $p < 0.01$ ). Normal attenuation muscle area was more decreased (-20.0 cm<sup>2</sup> vs. -27.6 cm<sup>2</sup>,  $p < 0.01$ ) and LAMA was more increased (10.9 cm<sup>2</sup> vs. 18.8 cm<sup>2</sup>,  $p < 0.01$ ) in non-survival group. The multivariate analysis showed that the decreased SFA and increased myosteatorsis area were independent risk factor for 28-day mortality of septic shock.

### **CONCLUSION**

s Myosteatorsis area which implies the low quality muscle area was increased in non-survival group of septic shock. Our results revealed the trend of myosteatorsis could be better indicator of septic shock prognosis compared with the single measurement of body composition.

### **CLINICAL RELEVANCE/APPLICATION**

The results of the study suggest that monitoring the trend of myosteatorsis could offer valuable insights into the prognosis of septic shock and guide clinical decision-making to enhance patient management.

## **M5B-SPMK-6 Utilization of AI-aided Osteosarcopenia Measurement on Opportunistic Abdominal CT Scans to Evaluate the Impact of Gastrectomy on Bone Mineral Density**

Participants

Hyunseung Lee, MD, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

Jimi Huh, MD, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

### **PURPOSE**

Osteosarcopenia is the co-existence of osteoporosis and sarcopenia, which is closely related with survival outcome in patients with major diseases and elderly patients. In patients treated with gastrectomy, osteoporosis and sarcopenia commonly occurred, but not evaluated routinely in clinical practice. Thus, we applied AI-aided osteosarcopenia measurement methods in opportunistic abdominal CT scans for evaluation of bone mineral density and skeletal muscle area (SMA) in patients treated with gastrectomy.

### **METHODS AND MATERIALS**

In fifty two gastric cancer patients (mean age,  $56.2 \pm 11.3$  years) treated with curative gastrectomy, preoperative and 1-year postoperative abdominal CT scans were analyzed for the SMA and BMD. Deep-learning AI techniques were applied to automatically select the L3 vertebrae level, measure the SMA, and place ROI for trabecular attenuation value. Nutritional risk index (NRI) was also calculated based on laboratory results.

### **RESULTS**

Between preoperative CT and postoperative CT, all patients showed a decrease in the SMA ( $123 \pm 30$  cm<sup>2</sup> vs.  $113 \pm 28$  cm<sup>2</sup>,  $p=0.08$ ) and the trabecular attenuation values ( $137 \pm 31$  HU vs.  $125 \pm 25$  HU,  $p=0.03$ ). The NRI ( $100 \pm 8$  vs.  $92 \pm 12$ ,  $p<0.001$ ), body weight ( $63 \pm 10$  kg vs.  $57 \pm 9$ ,  $p=0.002$ ) and BMI ( $23 \pm 3$  vs.  $21 \pm 3$ ,  $p=0.001$ ) were also decreased. During the 5-year follow-up record, two patients were identified to show osteoporotic vertebral compression fractures. Both patients showed both osteoporosis and sarcopenia.

### **CONCLUSION**

s We found that the significant loss of bone mineral density and skeletal muscle mass occurred in patients treated with gastrectomy through AI-aided measurement techniques on opportunistic CT scans.

### **CLINICAL RELEVANCE/APPLICATION**

AI-aided measurement of bone mineral density and skeletal muscle area simultaneously is greatly helpful to evaluate osteoporosis and sarcopenia in clinical practice using opportunistic CT scans.

## **M5B-SPMK-7 Revolutionizing Bariatric Surgery Outcomes: A Radiomics-Based Model to Unveil the Prognostic Power of Preoperative Skeletal Muscle Analysis on Abdominal CT for Metabolic Syndrome Remission**

### **PURPOSE**

To develop and assess the performance of a CT radiomics-based machine learning predictive model to determine if preoperative skeletal muscle characteristics can predict the remission of metabolic syndrome following bariatric surgery.

### **METHODS AND MATERIALS**

Our study population included 79 morbidly obese patients who underwent bariatric surgery and had abdominal and pelvic CT scans preoperatively and one year postoperatively between January 2019 and October 2020. An experienced musculoskeletal radiologist with eight years of experience, unaware of the patients' clinical information, manually outlined regions of interest encompassing the total abdominal muscle area (including psoas, paraspinal, quadratus lumborum, rectus abdominis, transverse abdominis, and internal and external obliques) on every slice throughout the entire extent of the third lumbar vertebra (L3). We extracted radiomics features from preoperative CT images of skeletal muscle and developed a framework for optimal feature selection. To develop our predictive models, we randomly split the complete dataset into 70% for model development and 30% for model validation. To enhance predictive performance, we employed normalization, standardization, and a random search with 5 repeated 5-fold cross-validation for optimization. We utilized three popular algorithms: logistic regression (LR), random forest (RF), and support vector machine (SVM).

## RESULTS

Feature selection based on absolute correlation (COR) resulted in 43 features with Least Absolute Shrinkage and Selection Operator (LASSO), 35 with Elastic-Net (EN) and 10 with Random Forest (RF). In the cross-validation method, the logistic regression (LR) model achieved the best performance using the COR and RF combination, with train area under the curve (AUC) of 0.774 and test AUC of 0.800. The RF model attained train AUC of 1.000 and test AUC of 0.675 with the COR and RF combination. The SVM model secured train AUC of 0.819 and test AUC of 0.783 using the VIF and RF combination.

## CONCLUSION

In conclusion, our study demonstrates that the CT radiomics-based machine learning predictive models effectively utilize preoperative skeletal muscle analysis to predict the remission of metabolic syndrome after bariatric surgery. Among the models examined, the logistic regression model with the COR and RF combination yielded the best performance.

## CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of radiomics and machine learning approaches in personalized preoperative evaluation and prediction of post-bariatric surgery outcomes, ultimately contributing to the advancement of precision medicine in obesity treatment.

## M5B-SPMK-8 Deep Learning to Quantify Altered Muscle Status and its Association with Survival in Lung Cancer Screening Eligible Individuals

Participants

Johannes Beat Kessler, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

Skeletal muscle (SM) has been described as an important prognostic factor in patients with cancer or cardiovascular disease. However, its prognostic value in asymptomatic screening eligible individuals at increased risk is not routinely determined on performed CT scans due to limited resources. Thus, we used a 3D deep learning model for fully automatic quantification of SM on routine chest CT and explored its association with survival in heavy smokers participating in a lung cancer screening trial.

## METHODS AND MATERIALS

A 3D deep learning model was used to estimate SM volume (SMVol) and SM attenuation (SMHU), a known measure of muscle quality, on non-contrast enhanced lung screening chest CTs of 26,144 participants of the National Lung Screening Trial at baseline and on the 1-year follow-up scan (n=52,228). The primary outcome was all-cause mortality. Secondary outcomes were lung cancer and cardiovascular mortality. The association between SMVol and SMHU and outcomes was assessed via multivariable Cox proportional hazards regression at baseline. In addition, the association between muscle wasting (decrease in SMVol or SMHU [= 20%]) between the baseline and 1-year follow-up scan and mortality was determined.

## RESULTS

A total of 1,839 (7%) deaths occurred over a median follow-up of 6.5 years among the 26,144 participants (age 61.4±5.0 years; 40.9% female). At baseline, multivariable Cox regression revealed an independent association between SMVol, SMHU and all-cause mortality after adjustment for age, sex, BMI, race, pack years, smoking status, prevalent diabetes or hypertension, prior myocardial infarction, prior stroke (SMVol: HR: 0.43, 95% CI [0.21-0.88]; p=0.02; SMHU: HR: 0.62, 95% CI [0.57-0.67]; p<0.001). Individuals with a decrease in SMVol or SMHU >20% within one year had a significantly worse survival than those with stable SM measures (HR adjusted for the same risk factors. SMVol: HR 2.10, 95% CI [1.91-2.31], p<0.001; SMHU: HR 1.78, 95% CI [1.62-1.95], p<0.001). Similar results were obtained for the prediction of lung cancer and cardiovascular mortality.

## CONCLUSION

Altered muscle status is an independent predictor of survival in a high-risk population of heavy smokers participating in a lung cancer screening trial. Deep learning allows for opportunistic assessment of this currently unused but prognostically relevant information with the potential to guide decision-making and improve personalized prevention.

## CLINICAL RELEVANCE/APPLICATION

Deep learning-based opportunistic screening of altered muscle status can identify individuals at increased risk of mortality beyond traditional risk factors in a screening setting. Implementation of such methods may provide a solution to inform risk assessment and improve patient management.

## M5B-SPMK-9 Ability of Radiofrequency Echographic Multi Spectrometry to Identify Bone Fragility in Subjects with Osteogenesis Imperfecta

Participants

Carla Caffarelli, Siena, Italy (*Presenter*) Nothing to Disclose

## PURPOSE

Osteogenesis imperfecta (OI) is a heterogeneous group of heritable bone disease characterized by bone fragility, reduced bone mineral density (BMD), joint laxity, easy bruising, and variable short stature. This study aimed to evaluate the usefulness of the new Radiofrequency Echographic Multi Spectrometry (REMS) technique in the assessment of bone status in subjects with OI.

## **METHODS AND MATERIALS**

In a cohort of 35 subjects ( $39.5 \pm 21.2$  years) with OI and in 30 healthy controls we measured BMD at the lumbar spine (LS-BMD), at femoral neck (FN-BMD) and total hip (TH-BMD) using a dual-energy X-ray absorptiometry device; TBS was calculated using TBS iNsite software. Moreover, REMS scans were also carried out at the same axial sites. Moreover, in OI subjects the presence of prior fractures was reported.

## **RESULTS**

A total of 85.7% of patients presented with a fracture history. The most common fracture sites were extremity long bones (femur, tibia-fibula and radius-ulna) (70.0%) and at vertebral site (54.3%). BMD evaluated by DXA and REMS technique at all measurement sites were all significantly ( $p < 0.01$ ) lower in subjects suffering from OI than in controls. Dividing OI patients on the bases of Silence classification, no differences between the BMD-LS values carried out with the DXA technique between OI type I group and OI Type III and IV group. On the contrary, the OI Type III and IV group presented significantly lower values of both TBS and BMD-LS by REMS with respect to patients OI type I ( $p < 0.05$ ) [figure 1]. TBS value presented significant correlations with both BMD-LS by DXA and BMD-LS by REMS technique, however, the better correlation was observed between TBS values and BMD-LS by REMS.

## **CONCLUSION**

This preliminary study has shown that REMS appears to be an accurate non-ionizing technology able to assess the bone status in subjects with OI. The attractiveness of the use of REMS for bone measurements in OI patients lies in its lack of ionizing radiation, its ease of use and the portability. In fact, the REMS device can be used directly on patient's bed, and this could represent an excellent method for assessing the bone status even in OI subjects with a recent fracture.

## **CLINICAL RELEVANCE/APPLICATION**

This is the first study that has evaluated the usefulness of REMS technology in adult patients with osteogenesis imperfecta. • Finding of a significant correlation between REMS and TBS • REMS could become an important tool able to assess the risk of fragility fractures so helping to overcome the limitations of DXA.

M5B-SPMS

### Multisystem Monday Poster Discussions II

#### Sub-Events

#### **M5B-SPMS-1 Detection and Characterization of Urinary Stone Using Virtual Non-contrast Images Derived from Two Dual-energy CT Scanners: A Phantom Study**

#### **PURPOSE**

To assess the feasibility of virtual non-contrast images derived from dual-energy CT (DECT) for urinary stone detection and measurement at different iodine solutions and radiation doses

#### **METHODS AND MATERIALS**

Twenty-four urinary calcified stones (average size: 1.7-5.8mm) were placed in a custom-made cylindrical phantom filled with water and iodine contrast mixture at different degrees of concentration (0, 7, 13, 22, 30 and 57 mg/mL; CT attenuation value: 0, 200, 350, 600, 800 and 1500HU at 120kVp). Thirty-six scans with three radiation doses (CTDIvol) of 5, 10 and 15mGy at the above six iodine concentrations were performed with rapid tube voltage switching DECT (rsDECT) and dual-layer detector-based CT (dIDECT). True non-contrast images (TNC) and virtual non-contrast images (VNC) were reconstructed. Detection rate and measurement of urinary stones were assessed by two radiologists and statistically compared. Stone detection confidence was also assessed using 4-point grading scale (4: detectable; 3: iodine contrast agents and stones are distinguishable; 2: iodine contrast agents and stones are indistinguishable; 1: not detectable). Stones were considered detected only when the score was greater than 2 points. Size (length and width) and CT attenuation value were performed on the coronal image showing the maximal stone diameter.

#### **RESULTS**

Most stones were detected on both TNC and VNC images at different iodine concentrations (rsDECT: 91.7%-100%; dIDECT: 95.8%-100%) with detection confidence greater than 2 except VNC1500HU images (rsDECT: 8.3%-20.8%; dIDECT: 33.3%-45.8%) (Tab.1, Fig. 1). There was no statistically significant difference in stone detection rates among different radiation doses. Stone size and attenuation value on VNC images at different iodine concentrations were significantly lower than those of TNC images except the stone width on rsDECT (Tab.2 and 3). As the radiation dose increased, the measurement difference decreased on the VNC images from rsDECT, while not found on the dIDECT (Fig.2).

#### **CONCLUSION**

s VNC images from the two dual-energy CT enabled reliable detection for urinary stone at moderate iodine concentrations (<30mg/mL) with less dependent on radiation dose. Stone size and CT value measurements were underestimated on VNC images.

#### **CLINICAL RELEVANCE/APPLICATION**

VNC images at different iodine concentrations and radiation doses are feasible to detect and measure urinary stones except higher iodine concentration. It should be noted that stone size and CT value measurements on VNC images were underestimated.

M5B-SPNMMI

### Nuclear Medicine & Molecular Imaging Monday Poster Discussions II

#### Sub-Events

#### M5B-SPNMMI-1 **Deep Learning Reconstruction Enables High SNR at Low Counts in SiPM-based PET/CT Imaging**

##### PURPOSE

AiCE-i (Advanced intelligent Clear-IQ Engine-integrated) is an image reconstruction technique designed using deep learning for the Cartesion Prime SiPM-based PET/CT device from Canon. AiCE-i is a denoising reconstruction technique that effectively reduces noise without compromising contrast, leading to stable, high signal-to-noise ratio (SNR) images even with fewer counts contributing to image generation. In this study, we evaluated the relationship between counts and PET image SNR using clinical images with both the conventional method and the new deep learning reconstruction technique.

##### METHODS AND MATERIALS

We analyzed the relationship between liver SNR and counts (True+Scatter) in clinical images of 54 patients who underwent 18F-FDG PET/CT imaging using a SiPM-based PET/CT scanner, Cartesion Prime. The average weight of the patients was 62.5±12.5 kg. All cases underwent at least 4 hours of fasting before PET/CT, and after injection of 233.3±51.1 MBq of 18F-FDG, patients were instructed to rest quietly for 60 minutes. The injected dose per body weight was 3.6±0.3 MBq/kg. Data acquisition started 60±7 minutes after administration, and list-mode acquisition was performed for 5 minutes/bed at the position that included the liver the most (27 cm/bed), followed by 30sec/bed reconstruction from 30 to 300 seconds. The 3D-OSEM method with subset 12, iteration 3, time-of-flight (+), PSF correction (+), and reconstruction using Clear Adaptive Low-Noise Method (CaLM) and AiCE-i were performed. The obtained data were divided into two groups: CaLM and AiCE-i, and statistical analysis was performed using the Kruskal-Wallis test. In the case of significant differences in the multiple comparisons test (Dunn-Bonferroni) for three or more samples, the test was performed. P-values less than 0.05 were considered statistically significant in all analyses.

##### RESULTS

To achieve liver SNR of 10 or higher, which is recommended by the Japanese Society of Nuclear Medicine, a data acquisition time of 120 seconds using CaLM and 30 seconds using AiCE-i was required. In addition, with CaLM, liver SNR increased with increasing counts from 30 to 300 seconds (5.5-16.4,  $r_s=0.98$ ), whereas with AiCE-i, approximately constant liver SNR was obtained from 30 to 300 seconds, which did not correlate with counts (13-16,  $r_s=0.005$ ).

##### CONCLUSION

s Using the deep learning reconstruction technique AiCE-i in SiPM-based PET/CT enables stable high liver SNR even with lower counts contributing to image generation, compared to conventional methods.

##### CLINICAL RELEVANCE/APPLICATION

Deep learning reconstruction in SiPM-based PET/CT improves spatial resolution and contrast, allowing high SNR images at low counts, reducing patient burden and radiation exposure.

#### M5B-SPNMMI-2 **Tolerability of Lutetium-177-PSMA-617 in Men with Prostate Cancer and Baseline Cytopenia**

##### PURPOSE

Results from the VISION trial (NCT03511664) led to the approval of lutetium-177 (177Lu)-PSMA-617 for the treatment of metastatic castration-resistant prostate cancer (mCRPC). This trial excluded patients with baseline cytopenias, thus safety in this frequently encountered patient population is unknown. We aimed to use real-world data to describe the tolerability of radioligand therapy in those with poorer bone marrow reserve.

##### METHODS AND MATERIALS

We retrospectively reviewed the records of all patients, who received a first dose of 177Lu-PSMA-617 at Mayo Clinic in the interval of April 26, 2022, to December 1, 2022. Patients were categorized as having poor marrow reserve on the basis of pre-treatment hematologic parameters, including: (1) an anemia cohort with hemoglobin (Hg) less than 9 g/dL, (2) a thrombocytopenia cohort with platelets (Plt) less than 100 x 10<sup>9</sup>/L, (3) a leukopenia cohort with white blood cell count (WBC) less than 2.5 x 10<sup>9</sup>/L, and (4) a multiple cytopenia cohort. These were exclusionary parameters from the VISION trial. Longitudinal laboratory data and clinical outcomes were collected and analyzed using descriptive statistics.

##### RESULTS

At data cutoff, 273 patients had received one or more doses of 177Lu, including 33 (12%) with at least one baseline cytopenia prior to their first cycle of treatment. In total, there were 25 (76%) patients with anemia, 4 (12%) with thrombocytopenia, 2 (6%) with leukopenia, and 2 (6%) with multiple cytopenias at baseline. The median number of cycles received thus far is 4, including 21 (64%) who are still receiving therapy and 12 (36%) who have permanently discontinued treatment. Median longitudinal changes in blood counts for the anemia cohort are presented in Table 1. Reasons for treatment discontinuation include: toxicity (n=5), disease progression (n=4), or death (n=8). Among the 9 patients who stopped 177Lu for toxicity or disease progression, 5 subsequently also died. Dose reductions or treatment delays for worsening myelosuppression were utilized in 8 (24%) and 8 (24%) patients,

respectively. Transfusions of packed red blood cells or platelets were required for 26 (78%) patients. A total of 16 (48%) received care in the emergency department or were hospitalized.

#### **CONCLUSION**

s Treatment discontinuation for toxicity was rare among men with mCRPC and baseline cytopenias, while receiving <sup>177</sup>Lu; however, these patients have an overall poor prognosis.

#### **CLINICAL RELEVANCE/APPLICATION**

Patients with initial cytopenia have been excluded originally from the Vision trial and in our study, we found that this group of patients can safely receive <sup>177</sup>-PSMA Lutetium.

M5B-SPNPM

### Noninterpretive Skills (Beyond Imaging) Monday Poster Discussions II

#### Sub-Events

**M5B-SPNPM-1** **Determining the Utility of Augmented Reality Coupled with Diagnostic Medical Sonography: A Potential Workflow Improvement**

#### PURPOSE

To systematically investigate the advantages and challenges related to the workflow implementation of augmented reality (AR) technology, specifically using the Microsoft HoloLens version 2 (HL2) (MediView LLC), paired with a portable ultrasound (US) equipment system.

#### METHODS AND MATERIALS

After obtaining IRB approval, multiple data collection methods were employed to assess the utility of AR for US applications. A diverse sample of US users, ranging in experience levels, were invited to participate in a video training session, a hands-on demonstration, and remote instruction while wearing the HL2, connected to a portable US system. The duration of participants' tasks was recorded, both with and without the AR platform. Participants' postures and positions were evaluated using the Rapid Upper Limb Assessment (RULA)<sup>1</sup>, which assesses ergonomic risk factors linked to body positioning and muscle usage. Subjects also completed the System Usability Scale (SUS) (IBM, Armonk, New York), a reliable tool for measuring usability consisting of a 10-item questionnaire. Lastly, participants were invited to share qualitative feedback regarding the AR system evaluation.

#### RESULTS

A total of 12 US users provided data during their individual sessions, with and without AR. The time spent on simulated work, both with and without the products, remained consistent, as a group. The RULA scores for the group indicated a lower (better) upper extremity sub-score and a statistically significant lower neck sub-score ( $p < 0.05$ ) when using AR. This suggests a reduced risk of repetitive stress injury when using AR compared to a traditional US examination. Post-test data revealed positive SUS scores, reflecting favorably on both the product and the education and training provided. Participants consistently expressed interest in having access to additional post-processing ultrasound equipment system controls while using the HL2 (i.e., overall gain, power, etc.). Qualitative exit interviews highlighted participants' enthusiasm for incorporating AR systems into their respective clinical workflow.

#### CONCLUSION

s Although larger studies are necessary to validate these initial findings, this cohort identified numerous opportunities for integrating the AR platforms such as the HL2 and portable ultrasound systems. Preliminary evidence suggests that AR usage may offer occupational health benefits when the workflow includes providing ultrasound guidance.

#### CLINICAL RELEVANCE/APPLICATION

Implementation of AR systems for US, have the potential to decrease repetitive stress injuries related to ergonomics in the workplace thereby increasing the productivity and longevity of clinical staff.

**M5B-SPNPM-2** **Online Search Trends Correlation with Imaging Volumes for Screening Mammography and Low-Dose Chest CT: A Multicenter Retrospective Five Year Study of 800,000 Examinations**

Participants  
Emiliano Garza Frias, MD, Monterrey, NL (*Presenter*) Nothing to Disclose

#### PURPOSE

Public awareness of disease and screening programs increases participation in cancer prevention programs. We assessed the correlation between the online search trends and the volume of clinical requests and scheduling for breast and lung cancer screening with mammography and low-dose CT (LDCT) in multicenter settings of a predominantly urban population.

#### METHODS AND MATERIALS

We first obtained the search interest for the terms "lung cancer" and "lung cancer screening," "breast cancer," and "breast cancer screening" from Google Trends data for the entire United States in the last five years (1st Jan 2018 to 31st Dec 2022). Google trends data are displayed as a linear graph on a scale of 0 to 100, where 100 is the peak popularity, and 0 means insufficient data. The weekly trend data were exported to Microsoft Excel. Next, we queried our radiology report search and analytic engine (Nuance mPower) to obtain data on physician orders for mammography and LDCT examinations per week over the same five years. We then performed a Pearson correlation between the weekly Google trends data and the ordered and performed mammography and LDCT.

#### RESULTS

Over the 260-week study duration, 779,366 mammograms and 43,035 LDCT were performed across the 17 sites. There was a significant correlation between the Google trends for "breast cancer screening" and "lung cancer screening" with the corresponding volume of the ordered ( $r=0.48-0.55$ ) and performed ( $r=0.43-0.55$ ) mammograms and LDCT exams. Upon omission of word

"screening," the Google trends for "lung cancer" and "breast cancer" had a much weaker correlation with the volumes of ordered ( $r = -0.07-0.37$ ) and performed ( $r = -0.06-0.23$ ) mammograms and LDCT examinations. Google search spikes during cancer awareness weeks had a stronger correlation with imaging volume surges in breast cancer than for lung cancer.

#### **CONCLUSION**

s Increased interest in "screening" for breast and lung cancer, as reflected in Google trends data, correlates with an increase in the utilization of screening mammography and LDCT.

#### **CLINICAL RELEVANCE/APPLICATION**

Concerted and sustained online efforts aimed at screening awareness can help enhance the utilization of screening exams and help reduce mortality associated with lung and breast cancer.

#### **M5B- SPNPM-3**      **Formal Wellness Training of Academic Radiology Leaders Improves Work-Life Conflict**

Participants

Jay R. Parikh, MD, FRCPC, West University Place, TX (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To investigate the effect of formal leadership training of academic radiology leaders within an academic center on their own burnout and professional fulfillment.

#### **METHODS AND MATERIALS**

The study cohort were academic radiology leaders within one of the largest academic organizations of academic radiologists within the United States. All academic radiology leaders within the organization were electronically mailed a weblink to a confidential IRB-approved survey in April 2021. The survey included validated questions from the Stanford Professional Fulfillment Index (PFI), values alignment, teamwork, overload, and work family conflict. Academic leaders were invited in May 2021 to participate in instructor-led formal training on leading wellness focusing on 5 core leadership skills - emotional intelligence, self-care, resilience support, demonstrating care, and managing burnout. An identical follow-up survey was electronically mailed 6 months after initial training in November 2021.

#### **RESULTS**

The overall response rate of academic radiology leaders was 59 % (19/32). For both measures, there was acceptable internal consistency (Cronbach's  $\alpha = 0.63$  for work exhaustion and  $\alpha = 0.90$  for fulfillment). There was statistically significant improvement in work family conflict (3.32 vs 2.86;  $p=0.04$ ). No statistically significant differences were identified for fulfillment, work exhaustion, alignment, work overload and teamwork scores after training.

#### **CONCLUSION**

s Formal instruction in leading wellness improved work-life conflict for academic radiology leaders. There was no significant change in burnout, fulfillment nor organizational alignment of the leaders.

#### **CLINICAL RELEVANCE/APPLICATION**

Formal instruction in leading wellness raised awareness and improved work-life conflict in academic radiology leaders.

#### M5B-SPNR-1 Terson Syndrome in Association with Sub-arachnoid Hemorrhage: A Case Report

##### PURPOSE

Introduction: We present a case of Terson Syndrome in a patient with diffuse sub arachnoid hemorrhage

##### METHODS AND MATERIALS

Presentation of Case: 48-year-old lady presented with a history of loss of consciousness. Neurological examination was normal. Fundus examination showed vitreous hemorrhage on both eyes two days after admission. Digital Subtraction Angiography was performed. Aneurysm of the V4 segment of the left vertebral artery was noted. Flow Diverter placement was done. Patient complained of bloaters in eye with loss in visual acuity, ophthalmoscopic examination showed vitreous hemorrhage defined as terson syndrome. The visual acuity gradually improved and was normal after 21 days.

##### RESULTS

Discussion: Terson syndrome can present clinically with loss of visual acuity and bloaters in patient with sub arachnoid hemorrhage.

##### CONCLUSION

s Conclusion: Patient with terson syndrome have improvement in vision gradually within weeks and mostly resolves with fourth to five weeks.

##### CLINICAL RELEVANCE/APPLICATION

Patient with terson syndrome have improvement in vision gradually within weeks and mostly resolves with fourth to five weeks.

#### M5B-SPNR-10 Advanced MRI Techniques in the Diagnosis of Amyotrophic Lateral Sclerosis (ALS): Morphometry, DTI, ASL Perfusion and BOLD Connectivity

##### Participants

Jose Manuel Hidalgo Gomez De Travededo, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

##### PURPOSE

Amyotrophic lateral sclerosis (ALS) is a chronic and progressive neurodegenerative disease characterized by damage to the upper and lower motor neuron, whose diagnosis is currently based on clinical criteria. This study aims to analyze structural and functional MRI parameters in ALS patients to define imaging biomarkers.

##### METHODS AND MATERIALS

An observational cross-sectional study was conducted with a sample of 71 subjects; 34 patients diagnosed with ALS according to El Escorial criteria and 37 age and gender-matched healthy subjects. All participants underwent a basal 3T-MRI including 3D T1WI morphometric sequences, Susceptibility Weighted Imaging (SWI), Diffusion Tensor Imaging (DTI), perfusion Arterial Spin Labeling (ASL) and functional MRI (BOLD), as well as a neuropsychological evaluation. Patients underwent a second MRI and neuropsychological assessment six months later. Post-processing analysis was performed using FreeSurfer, MRTrix, TBSS, BASIL and CONN toolbox software.

##### RESULTS

Morphometric analysis demonstrated greater cortical atrophy in ALS patients, highlighting rolandic regions with left predominance, bilateral amygdala and cerebellum. An association between atrophy and some clinical phenotypes, including cognitive impairment, was found. Greater iron deposition in the rolandic cortex of the patients was quantified by SWI. DTI analysis identified widespread white matter damage in ALS patients, with decreased fractional anisotropy and increased mean diffusivity, in anterior temporal lobe and left frontal lobe. Asymmetric left predominantly disruption of the proximal corticospinal tract (CST), left superior longitudinal fasciculus and frontal aslant tract damage were also notified. Functional connectivity showed foci of motor network impairment in superior and middle frontal gyri and left fusiform gyrus. At six-month reassessment, patients showed an asymmetric progression of the atrophy in rolandic cortex, predominantly right, and cingulate gyrus; further disruption of white matter tracts in frontal and temporal lobes, corpus callosum and CST; and small areas of increased connectivity in motor network and DMN.

##### CONCLUSION

s Advanced MRI techniques permit the identification of structural and functional damage in the brain of ALS patients and demonstrate progression of the atrophy over time. Involvement of motor and extra-motor areas was objectified, supporting the relationship between this condition and the group of frontotemporal dementias.

##### CLINICAL RELEVANCE/APPLICATION

ALS is a rare and fatal disease whose diagnosis, based on clinical parameters, is often delayed. Imaging biomarkers through

advanced MRI techniques could improve diagnostic accuracy and positively impact healthcare practice.

## **M5B-SPNR-11 Prediction of Conversion to Parkinson's Disease in Individuals with Prodromal Symptoms through a Machine Learning Model using MRI**

### **PURPOSE**

Prodromal Parkinson's disease (PD) is the phase during which progressive neurodegenerative pathology is initiated, but motor features necessary for the diagnosis of PD are not yet manifested. Such preclinical nature of prodromal PD leads to the notion that prodromal PD could be considered as being somewhere in between healthy and PD. In this study, we tested the notion by classifying individuals with prodromal PD into those close to healthy and PD respectively and checking plausibility of such distinction.

### **METHODS AND MATERIALS**

From the Parkinson's Progression Markers Initiative (<https://www.ppmi-info.org/>), 75 healthy individuals (59.9±11.3 years, 26 women), 132 individuals with PD (60.7±9.2 years, 44 women), and 66 individuals with prodromal PD (62.3±7.6 years, 31 women) for whom structural and diffusion-weighted MRI data were available at the baseline were included. A machine learning model for distinguishing healthy and PD was constructed using the random forests method based on brain structural features in terms of cortical thickness in 62 grey matter regions and fractional anisotropy in 48 white matter regions. The constructed model was externally tested for additional individuals (83 healthy individuals and 130 individuals with PD). Individuals with prodromal PD were divided into healthy-like and PD-like ones by making predictions with the model, while development of PD at follow-ups was assessed for them.

### **RESULTS**

For individuals with prodromal PD, motor symptoms as assessed with the Unified Parkinson's Disease Rating Scale Part III was significantly lower than individual with PD. In classifying healthy and PD, the machine learning model showed adequately high performance in cross-validation (accuracy = 91.3%) and external validation (accuracy = 93.8% for healthy individuals and 86.7% for individuals with PD). When the model was applied to individuals with prodromal PD, 40 were classified as PD-like ones while the other 26 were classified as healthy-like ones. Of 26 individuals with prodromal PD who were classified as PD-like ones, 8 (30.8%) converted to PD, while none of those who were classified as healthy-like ones were found to develop PD later ( $p = 0.018$  in Fisher's exact test).

### **CONCLUSION**

The externally validated machine learning model for classifying healthy and PD could be used to distinguish healthy-like and PD-like ones among individuals with prodromal PD. Occurrence of all PD converters in PD-like ones suggests that individuals with prodromal PD could be differently positioned on the course of PD development according to their individual risks.

### **CLINICAL RELEVANCE/APPLICATION**

Distinguishing PD-like ones from healthy-like ones among individuals with prodromal PD may help to assess the risk of developing PD.

## **M5B-SPNR-12 Quantitative Parameter Mapping of Brain Structure and Components in Parkinson's Disease and Progressive Supranuclear Palsy**

Participants

Yuki Matsumoto, PhD, Tokushima, Japan (*Presenter*) Nothing to Disclose

### **PURPOSE**

Our aim was to simultaneously evaluate changes in brain structure and components, depending on the level of dopamine receptor cells, in Parkinson's disease (PD) and progressive supranuclear palsy (PSP) using the quantitative parameter mapping (QPM) technique. Additionally, we investigated whether there were differences in the quantitative values of proton density, T1, T2\*, and quantitative susceptibility mapping (QSM) between PD and PSP patients.

### **METHODS AND MATERIALS**

A total of 44 patients with PD and PSP Richardson syndrome (PSP-RS), all of whom provided informed consent, underwent a 3T MRI brain scan (FUJIFILM Healthcare Corporation) and ioflupane [<sup>123</sup>I] SPECT (DaTscan, SIEMENS Healthcare). In this study, the quantitative values of proton density, T1, T2\*, and QSM images were generated. Additionally a synthetic T1-weighted (T1w) image was computed from the T1 map. FreeSurfer was used to estimate the brain volume, cortical thickness, and local gyrification index (LGI) in each region from the synthetic T1w data of these patients. Furthermore, regions of the left and right substantia nigra and red nucleus were determined by drawing a region of interest (ROI) for each patient. The parcellated results were then compared to the average specific binding ratio (SBR) adjusted by age, or the asymmetry index (AI) in the striatum using Pearson correlation coefficients ( $r$ ). Subsequently, the mean proton density, T1, T2\*, and QSM values of each brain region were measured using the parcellated results so as to investigate the relationship between the average SBR and the mean quantitative values. Finally, the standardized mean difference (SMD) was calculated. For SMD calculations, patients with a SBR<4.5 were included to determine differences between PD and PSP patients.

### **RESULTS**

We observed significant positive or negative correlations between the average SBR, cortical thickness, segmented volume, and mean quantitative values (refer to figure). Notably, the right amygdala exhibited the strongest correlation ( $r=0.54$ ), with a volume decrease observed depending on the average SBR. Our results were consistent with previous findings in cases when the correlation was strong.

### **CONCLUSION**

Our findings suggested that QPM can simultaneously evaluate changes in brain structure and components related to dopamine receptor cell levels. Moreover, QPM may prove to be a valuable tool for differentiating between PD from PSP in future research.

### **CLINICAL RELEVANCE/APPLICATION**

QPM has the ability to simultaneously detect changes in brain structure and components based on dopamine receptor cell levels, all

within a short scan time. This makes it a valuable tool that may have clinical applications.

### **M5B-SPNR- 13 Cortical and Subcortical Morphological Alterations in Parkinson's Disease Patients with Depression**

Participants  
Mingrui Qu, Dalian, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

We aimed to explore the alteration pattern of cortical thickness and subcortical volume in Parkinson's disease (PD) with depression and their correlation with the severity of the depressive symptom.

#### **METHODS AND MATERIALS**

PD patients with depression (PDD) (n=42), PD patients without depression (PDND) (n=26) and healthy controls (HC) (n=33) were studied. All subjects underwent a 3D-T1 sequence. FreeSurfer was used to derive measures of cortical thickness and deep grey matter nuclei volume. The FreeSurfer's QDEC was used for cortical thickness analysis and correlation analysis. Multiple comparisons were corrected with Monte Carlo Simulations set at  $P < 0.05$ . ANOVA was applied to compare the subcortical grey matter nuclei volume differences. Age, gender and education were included as covariates.

#### **RESULTS**

The demographic and clinical data are summarized in Table 1. PDD group showed decreased cortical thickness compared to HC in the bilateral superior frontal gyrus, left middle temporal gyrus, right superior temporal gyrus, right insula, and right bankssts. A lower cortical thickness was observed in PDND group compared to HC in the left superior frontal gyrus, right rostral anterior cingulate and right superior temporal gyrus. PDD group only showed decreased cortical thickness in the right superior temporal gyrus compared to PDND group (Figure 1, Table 2). Cortical thinning correlated with higher HAMD scores in the middle temporal gyrus (Figure 2). In subcortical nuclei, PDD group showed significantly reduced volumes in bilateral hippocampus ( $p < 0.001$ ), bilateral amygdala ( $p = 0.008$ ), left thalamus ( $p < 0.001$ ) and right nucleus accumbens ( $p < 0.001$ ) compared to HC. PDD group showed significantly reduced volumes in left thalamus ( $p = 0.008$ ) and right nucleus accumbens ( $p = 0.001$ ) compared to PDND group. However, the volume of bilateral caudate and putamen ( $p < 0.01$ ) increased significantly compared with HC in the two PD groups (Figure 3).

#### **CONCLUSION**

s Depression has an impact on subcortical nuclei volume and cortical thickness in PD patients. Alterations were found in the frontotemporal regions, thalamus, nucleus accumbens and limbic brain region. Interestingly, this study indicated the volumes of bilateral putamen and caudate increased in the PD group; the effect may be due to a compensatory response to impaired cerebral function in early PD.

#### **CLINICAL RELEVANCE/APPLICATION**

We explored the alteration pattern of cortical thickness and subcortical nuclei volumes in PDD. Our study implies the distinct effects of the frontotemporal regions, thalamus, nucleus accumbens and limbic brain region on emotional regulation in PD patients. Our results may guide the discovery of neuroimaging markers and underlying mechanisms related to emotional disorders in PD.

### **M5B-SPNR- 14 Advanced MRI Neuroimaging Biomarkers in Alzheimer's Disease and Their Association with Liquid Biopsy**

Participants  
Jose Manuel Hidalgo Gomez De Travecedo, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Alzheimer's disease (AD) is the most frequent cause of age-related dementia, but it is only suspected when clinical cognitive decline appears and, by then, neural damage is already irreversible. The aim of this study is to define MRI biomarkers to improve diagnostic accuracy and to investigate their relationship with the recently described technique of liquid biopsy (LB).

#### **METHODS AND MATERIALS**

An observational cross-sectional study was conducted with a sample of 150 subjects; 59 patients diagnosed with "dementia due to probable AD" according to NIA-AA criteria and 91 age- and gender-matched healthy subjects. Both groups were drawn from the cohort of a previous neuroepigenetic investigation (iBEAS) carried out in our institution. Participants underwent a 3T MRI including T1WI morphometric sequences, diffusion tensor imaging (DTI) and Arterial Spin Labeling (ASL) perfusion assessment. Post-processing analysis was performed using FreeSurfer, TBSS and BASIL software. iBEAS group had previously identified in LB a series of differentially methylated genes in patients with AD that were proposed as potential biomarkers. In the current project, its association with the alterations detected in MRI was investigated.

#### **RESULTS**

Morphometric analysis showed a marked cortical atrophy in AD patients, highlighting gray matter loss in medial temporal lobe and thalamus. In addition, certain relationships were demonstrated between clinical and epidemiological variables such as age, sex, time of evolution and score on the Mini Mental State Evaluation and atrophy. DTI revealed damage in corpus callosum and fornix, fronto-parieto-temporal deep white matter and parahippocampal gyri. ASL showed hypoperfusion in dorsolateral prefrontal cortex, inferior parietal and temporal lobe and posterior cingulate/precuneus. In the analysis of the results of the liquid biopsy, patients with differentially methylated ISR-2 and TREM-2 genes presented foci of cortical atrophy in the left frontal, right temporal, and bilateral parietal lobes; and in the lower region of the left cerebellar hemisphere respectively. DTI analysis showed greater disruption of white matter tracts in patients with differentially methylated APOE E4, IRS-2 and TREM-2.

#### **CONCLUSION**

s Advanced MRI permits the identification of structural and perfusion brain damage in AD. The association between differential methylation of some genes studied by LB and the pattern of brain atrophy could open the door to the development of new biomarkers of the disease.

#### **CLINICAL RELEVANCE/APPLICATION**

AD is a frequent condition whose current diagnosis is mainly clinical and in most cases delayed. Advanced MRI biomarkers and liquid

biopsy could improve diagnostic accuracy and positively impact healthcare practice.

## **M5B-SPNR-2 Assessment of MRI Vulnerability of the Magnetically Programmable Shunt Valve**

### **PURPOSE**

Hydrocephalus is a condition characterized by accumulation of cerebrospinal fluid (CSF) within the cerebral ventricles which, if left untreated, may exert pressure on the brain, potentially causing brain damage and death. Surgical treatment with a ventricular shunt for drainage of excess CSF is the standard of practice for diagnosed patients. Modern shunts typically contain a programmable valve which controls CSF drainage rate based on symptomatic response. Magnetically programmable valves are important clinically because they allow for noninvasive changes to shunt settings. However, there is concern for unintended changes in setting due to external magnetic sources, such as 3T magnetic resonance imaging (MRI). We aimed to systematically evaluate the resistance of this valve to changes in setting within the MRI environment in a single-center cohort.

### **METHODS AND MATERIALS**

Patients who underwent shunt placement for hydrocephalus between 2016 and 2019 at a single institution were retrospectively included. Demographics, shunt type, shunt valve settings, and dates of shunt valve radiograph and MRI imaging were abstracted from the electronic medical record. Patients were included if they received a Codman Certas shunt and had received an MRI at any point following surgery.

### **RESULTS**

Forty-two patients who received an MRI after shunt placement were included for review of pre- and post-MRI shunt valve radiograph. Average age was 60.7 years (range: 18-85) and 24 patients (57%) were female. One patient (2.4%) with normal pressure hydrocephalus, who resided at a skilled nursing facility, experienced an unintentional change in their shunt valve setting. Four days following 3T MRI for suspicion of stroke, the patient presented to the emergency department (ED) for postural headaches and projectile emesis, symptoms consistent with over-drainage. Shunt valve radiograph demonstrated a decrease in valve setting compared to most recent radiograph prior to MRI. Between MRI and ED presentation, the patient had not seen another neurosurgical provider. After resetting the valve to the appropriate setting, symptoms resolved.

### **CONCLUSION**

In a single-center retrospective cohort of hydrocephalus patients with programmable valves, only 1 of 42 patients had a change in their shunt dial settings potentially related to 3T MRI. Even given the low frequency of this event, shunt valve radiography before and after receiving an MRI is important to ensure that dial setting remain unchanged. Future prospective studies should investigate these effects further as additional advances in MRI-compatible programmable valve technology emerge.

### **CLINICAL RELEVANCE/APPLICATION**

While changes were seen at a low rate (~2%), diligent surveillance of shunt settings after MRI is important.

## **M5B-SPNR-3 The Accero-Rex-Stent - A Giant Stent For Giant Aneurysms**

Participants  
Hermann Kraehling, MD, Muenster, Germany (*Presenter*) Nothing to Disclose

### **PURPOSE**

Until now, the treatment of giant fusiform aneurysms of the posterior circulation has been a disease that is difficult or impossible to treat, mostly due to the lack of availability of a large-format stent. In this multicentre study, we report on the world's first five clinical deployments of the Accero-Rex-Stents (Acandis) for the treatment of fusiform giant aneurysms.

### **METHODS AND MATERIALS**

The Accero-Rex-Stents are self-expanding, braided, fully radiopaque Nitinol stents. They are available in three different sizes (diameter 7 - 10 mm, length 30 - 60 mm) and intended for implantation in vessels with diameters of 5.5 - 10 mm. The stents were implanted in aneurysm of the posterior circulation.

### **RESULTS**

Five patients with large fusiform aneurysms of the posterior circulation were treated endovascularly using the Accero-Rex-Stents. There were no major technical complications peri- and post-intervention and the implanted stents showed proper contrast perfusion in all follow-up examinations. A significant remodelling and reduction in the size of the stent-covered aneurysms was already seen in the short-term post-interventional course, no major clinical complications occurred.

### **CONCLUSION**

The Accero-Rex-Stents were used safely in five patients for the treatment of fusiform aneurysms of the posterior circulation without any technical complications. The treatment options of giant fusiform aneurysms are extended by the Accero-Rex-Stents.

### **CLINICAL RELEVANCE/APPLICATION**

The treatment options of giant fusiform aneurysms are extended by the Accero-Rex-Stents.

## **M5B-SPNR-4 Determining the Functional Outcome of Patients Presenting with a Large Volume Stroke without Endovascular Intervention to a Level 1 Stroke Center: Single Center Retrospective Review**

### **PURPOSE**

Several lines of evidence demonstrate the effectiveness of endovascular treatment (EVT) for large volume stroke (LVS) as defined by low Alberta Stroke Program Early CT Score (ASPECTS) of less than 6 in decreasing severe disability and death. Despite this, there remains hesitancy to offer EVT in these cases. The modified Rankin Score (mRS) is a validated 7 point scale used to measure degree of disability. We aim to determine the clinical outcome of patients with a LVS who do not undergo EVT utilizing the mRS.

### **METHODS AND MATERIALS**

2485 CT angiograms of head and neck. and CT Head examinations performed between 2018-2021 were obtained from the picture

Time of angiograms or those and nearly one of those examinations performed between 2000-2005 were obtained from the picture archiving and communication system (PACS). Cases presenting with ASPECTS<6 as assigned by a neuroradiologist were identified. Functional outcomes was obtained utilizing the mRS for those patients who did not undergo EVT. Premorbid mRS as defined by degree of disability prior to the acute presenting event and outcome mRS as defined by degree of disability on discharge were collected. All patients with a documented outcome mRS were included in the analysis. Patients were excluded if presenting ASPECTS was >=6, if stroke symptoms were attributable to etiology other than large vessel or tandem occlusion, if metastatic lesions were noted on presentation, if the patient underwent EVT or if the studies had been duplicated. As a further subgroup analysis cases excluded who underwent EVT were also analyzed.

## RESULTS

From the 2485 examinations, 62 had a baseline ASPECTS<6; 34 cases met exclusion criteria. 28 cases were available for analysis [premorbid mRS (n): 0=(11), 1=(3), 3=(4), 4=(6), 5=(2), ?=(2); age range: 28-93; 10 male, 18 female]. All patients progressed from premorbid mRS to an outcome mRS of 5 (n=6/28, 21%) or 6 (n=22/28, 79%). Subgroup analysis of cases which underwent EVT identified 12 cases [premorbid mRS (n): 0 =(7), 1=(2), 3=(3); age range: 45-90; 9 male, 3 female]. 1/11 cases were technically unsuccessful. Of the 10 successful cases, 6 had outcome mRS of 0-3 (60%) and 4 had outcome mRS of 5-6 (40%). 5/10 (50%) of cases returned to premorbid mRS.

## CONCLUSION

s Patients presenting with a large volume stroke will progress to being bedridden or dead irrespective of premorbid functional status without endovascular intervention. Although our analysis of cases who underwent EVT is underpowered, it corroborates current evidence demonstrating that patients presenting with a LVS can have good outcomes and return to premorbid baseline in technically successful cases.

## CLINICAL RELEVANCE/APPLICATION

To better understand the clinical ramifications of not offering endovascular treatment in the setting of large volume stroke.

## M5B-SPNR-5A Systematic Search and Analysis of Diagnostic Reference Levels (DRLs) in Interventional Neuroradiology (INR)

### PURPOSE

The purpose of this study was to identify whether DRLs for diagnostic and interventional neuroradiology have been previously published and whether any guidelines specify optimal or maximum safe doses for various INR procedures. DRLs are crucial in standardizing practice and may potentially reduce radiation doses during such interventions. In general, INR procedures tend to be associated with high radiation doses both to the patient and operators.

### METHODS AND MATERIALS

An extensive electronic search of the literature was performed using 3 different databases, namely Scopus, Web of Science, and PubMed, without language restrictions. Four main keywords were identified for this search as follows: Dose Area Product (DAP), Fluoroscopy Time (FT), Cumulative Air Kerma (CAK) and Diagnostic Reference Levels (DRLs). The keywords and various synonyms were integrated using the Boolean operators "OR" and "AND". A reference management software was used to import the search results from the 3 databases and the results were scanned for duplicates. Strict inclusion and exclusion criteria were developed, and the abstracts were scanned to check whether the studies met the inclusion criteria. All exclusion and inclusion decisions were documented via the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA).

### RESULTS

The included studies were categorised into 4 main groups: - namely 'Cerebral Angiography', 'Aneurysm Coiling', 'Stroke (Thrombectomy)' and 'AVM/AVF Embolization'. The 3rd Quartile Values for DAP, Air Kerma, Fluoroscopy Time and Image Frames from each of the included studies recorded and tabulated for the 4 categories. Analysis of these values were then performed and screened for significant differences. The authors also sought to identify potential reasons for such discrepancies within the included studies.

### CONCLUSION

s To date, few studies have published data regarding DRLs in INR procedures. Guidelines are necessary both for quality control and to reduce procedural radiation doses to "as low as reasonably achievable" as per the "ALARA" principle. This analysis has gathered all the available literature on the matter and may help in future development of standard acceptable doses in INR.

### CLINICAL RELEVANCE/APPLICATION

Identification and analysis of DRLs in INR procedures is essential for subsequent development of recommended radiation doses. Adherence to such recommendations may reduce radiation exposure to "as low as reasonably achievable".

## M5B-SPNR-7 Selective Aberrant Alterations in Structural-functional Coupling of Large-scale Brain Networks with Progressive Supranuclear Palsy

### PURPOSE

We combined functional and structural connectivity to investigate both global and modular-specific topology changes in the brain following progressive supranuclear palsy (PSP). We also hypothesized that the disruption of connections may lead to structural-functional (S-F) connectivity alterations.

### METHODS AND MATERIALS

In our study, 51 PSP and 101 healthy control (HC) subjects were enrolled. These participants underwent 3D-T1WI, rs-fMRI, DTI and neuropsychological assessment. Furthermore, two weighted adjacency matrices, representing the structural and functional connectome, were created using the same cortical parcellation. S-F coupling was determined to use the spearman rank correlation. Then, the intramodular and intermodular connectivity strengths were computed and the graph-theoretic method was used to calculate network topology metric. Finally, we make correlations between clinical scales and S-F coupling.

### RESULTS

For structural connectivity network (SCN). compared with HCs. the intramodular structural connectome of PSP in subcortical cortex

(SC) decreased significantly. The intermodular SCN between SC and the sensorimotor network (SMN) decreased, while the connections between SC and limbic network increased (FDR  $q < 0.001$ ). The characteristic path length ( $L_p$ ) was significantly increased. At the nodal level, these alterations were in SMN, dorsal attention network (DAN), ventral attention network (VAN), frontoparietal network, default mode network (DMN) and SC. For functional connectivity network (FCN), the intramodular functional connectome of PSP in DMN decreased significantly. As the intermodular FCN, DAN-DMN, DAN-SMN, DAN-VAN and DAN-VN decreased (FDR  $q < 0.001$ ). At the global level, the normalized clustering coefficient ( $\gamma$ ), small worldness ( $s$ ) and  $L_p$  were significantly increased and normalized characteristic path length ( $L_p$ ) was decreased. Both PSP and HC groups showed significant correlations in regional S-F connectivity ( $P < 0.05$ ). Besides, we compared regional S-F coupling between PSP and HC by two-sample T-test. We found that PSP increased significantly in visual network (VN), VAN and DMN. Finally, there is no association between S-F coupling and clinical variables.

## CONCLUSION

The S-F coupling features in PSP are aberrant. These results could contribute to better comprehending the relationships between structural and functional underlying the motor impairments in PSP.

## CLINICAL RELEVANCE/APPLICATION

Our study discovered increased S-F coupling in PSP, which would indicate the additional breakdown of coherence between brain function and structural connections after brain damage. These findings suggest that functional reorganization occurs along indirect anatomical pathways in PSP.

## M5B-SPNR-8 Development and Validation of a Deep Learning-based Automatic Brainstem Segmentation and Multi-class Classification Algorithm for Parkinsonian Syndromes using 3D T1-Weighted Images

Participants

Seongken Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

To develop and validate a deep learning-based automatic brainstem segmentation and multi-class classification algorithm for parkinsonian syndromes.

## METHODS AND MATERIALS

The model was developed using 3D T1-weighted brain MR images from subjects that were either cognitively normal or had progressive supranuclear palsy, multiple system atrophy of the cerebellar variant, or Parkinson's disease. We used 2D U-NET for architecture and a multi-view ensemble strategy. The final output was inferred using ensemble probabilities. To assess our segmentation performance using Dice similarity coefficient (DSC), we compared segmentation masks with manual labels in both training and external datasets. We evaluated classification performance based on the regional volumetric measurements obtained from segmentation. The multi-class performance was evaluated using five-fold cross-validation. Three classification models based on support vector machine (SVM), random forest, and XGBoost were trained. We adopted the area under the receiver operating characteristic curve (AUROC) as a representative value of classification performance.

## RESULTS

In total, 300, 513, 82 eligible patients were recruited as training, internal, and external dataset, respectively. Our model achieved DSC scores of 0.969 and 0.996 in the training and external datasets, respectively, when compared to the manually labeled ground truth masks for the brainstem region. The multi-class classification algorithm using SVM showed higher differentiation performance than the two other approaches. The AUROCs for SVM were  $0.937 \pm 0.022$  ( $\pm$  standard deviation) and 0.914 for internal and external validation, respectively.

## CONCLUSION

We developed and validated a deep learning model using 3D T1-weighted brain MR images which may allow for fast and accurate differentiation of parkinsonian syndromes.

## CLINICAL RELEVANCE/APPLICATION

Considering the widespread availability of T1-weighted brain MRI, this automated brainstem segmentation algorithm might be a promising and widely applicable method for the differentiation of parkinsonian syndromes in the clinical practice.

## M5B-SPNR-9 Alterations in T1, Proton Density and T2\* Properties of Deep Brain Nuclei in Parkinson's Disease Patients Measured by Synthetic MRI

## PURPOSE

Combined application of T1, proton density and T2\* map for the differential diagnosis of Parkinson disease (PD) from health controls with the Strategically Acquired Gradient Echo (STAGE) technique.

## METHODS AND MATERIALS

41 PD patients and 38 volunteers as the control group were prospectively enrolled. Brain MRI examinations, including STAGE, were performed at 3T (Ingenia CX, Philips Healthcare, the Netherlands). T1, proton density and T2\* maps were obtained after post-processing. The nuclei included in this study were caudate nucleus (CN), putamen (PUT), globus pallidus (GP), thalamus (THU), red nucleus (RN), black nucleus (SN) and dentate nucleus (DN). The regions of interest (ROIs) to cover these structures were manually drawn on T1, proton density and T2\* maps by two researchers using SPIN (Signal Processing in NMR, SpinTech, Inc., Bingham Farms, MI, United States), and the mean value within each ROI was measured and recorded. Statistical analysis was performed using SPSS20.0 software, and the normal distribution was tested in each group. Data in accordance with normal distribution were expressed as means  $\pm$  standard deviation, while the others expressed by median (upper and lower quartiles). Independent sample t-test or Mann-Whitney U test (not in accordance with normal distribution) were used to compare the mean values of T1, proton density and T2\* between PD and control group in both hemispheres, and the differences between the left and right were tested by independent sample t-test or Mann-Whitney U test. A P-value  $< 0.05$  was considered statistically significant.

## RESULTS

Compared to the control group, the T1 values of the CN, GP, DN and the proton density values of the CN, PUT, THU, DN were

Compared to the control group, the T1 values of the CN, GP, RN and the proton density values of the CN, PUT, THU, RN were significantly reduced in the PD group, while the T1 values of the DN was increased. ( $P < 0.05$ ) (Table 4-5, Figure 1-2). Meanwhile the T2\* value of the SN was significantly reduced and the THU was increased in PD patients. ( $P < 0.05$ ) (Table 6, Figure 3). In control group, the T1 values of the right THU and DN and the proton density value of the right DN were significantly lower than when compared to their counterparts in the left. There was no difference in the T1 proton density and T2\* values between the affected side and the healthy side in the PD group. ( $P < 0.05$ ) (Table 1-3, 7-9)

#### **CONCLUSION**

In summary, we found the alterations of T1, proton density and T2\* values may reflect the microstructural changes of deep brain nuclei.

#### **CLINICAL RELEVANCE/APPLICATION**

Combined application of T1, proton density and T2\* map for the differential diagnosis of Parkinson disease (PD) from health controls is potentially promising and valuable methods in clinical application.

M5B-SPOB

### OB/Gynecology Monday Poster Discussions II

#### Sub-Events

#### **M5B-SPOB-1 Automatic Detection and Segmentation of Ovarian Epithelial Tumor using a Multitask Model in CT Images**

##### Participants

Jing Ren, MD, Beijing, China (*Presenter*) Nothing to Disclose

##### PURPOSE

It is of great importance to identify the location and boundary of the ovarian tumors on medical images. The study aimed to develop and validate a multitask model utilizing the 3D nnU-Net framework in multicentric datasets, which can simultaneously complete the tasks of ovarian tumor detection and segmentation.

##### METHODS AND MATERIALS

Multiphase contrast-enhanced CT images from 748 patients who were histologically diagnosed with ovarian epithelial tumors between January 2016 and September 2022 were obtained from two medical centers. The internal dataset from center A consisted of a training set (n=405) and a testing set (n=135), and the external dataset contained 208 patients from center B. The manual annotations of the primary ovarian tumors by two professional radiologists were served as the ground truth of the datasets. The multitask model utilizing the 3D nnU-Net framework was trained for 500 epochs with a loss function that combined binary cross entropy loss and Dice loss. The training procedure involved the 5-fold cross-validation method, and the ensemble prediction was utilized. The segmentation performance was evaluated using the Dice similarity coefficients (DSCs), 95% Hausdorff distance (HD95), and Average Surface Distance (ASD). To evaluate the detection performance of the model, the recall and precision metrics were calculated.

##### RESULTS

The proposed multitask model exhibited good segmentation performance both in the internal and external testing sets, with average DSCs of 91.2% and 85.1%, respectively. The HD95 and ASD of the model were  $17.79 \pm 35.24$  and  $2.86 \pm 7.27$  in the internal testing set, and  $20.99 \pm 31.41$  and  $4.73 \pm 11.73$  in the external testing set. For the task of ovarian tumor detection, the model showed good performance (recall = 95.3% and precision = 72.9%) in the internal dataset, and promising result (recall = 88.7% and precision = 63.4%) in the external dataset.

##### CONCLUSION

The proposed multitask model shows promising in the automatic detection and segmentation of ovarian epithelial tumors.

##### CLINICAL RELEVANCE/APPLICATION

Our proposed multitask model can automatically and accurately complete the tasks of ovarian tumor detection and segmentation, thus avoiding time-consuming and labor-intensive manual operations.

#### **M5B-SPOB-2 Don't Forget about the Teens! Does Adenomyosis Also Affect Young Girls**

##### Participants

Ana Luiza Di Mango, MD, Rio de Janeiro, Brazil (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the difference in prevalence and pattern of adenomyosis between adolescents and reproductive-age adults patients.

##### METHODS AND MATERIALS

In a retrospective study, we evaluated the findings of dedicated pelvic magnetic resonance imaging (MRI) with a medical request of endometriosis/pelvic pain in 192 female patients, of which 96 were adolescents (aged between 11-19 years) and others 96 were reproductive-age adults. Two radiologists independently evaluated the exams. Adenomyosis was defined as the ectopic presence of endometrium as a punctuate high-intensity T2-weighted signal in the junctional zone (JZ) seen in MRI.

##### RESULTS

The prevalence of adenomyosis in adolescents patients was 8.3% (n=8) and in adult patients was 23% (n=22). Superficial adenomyosis was the most prevalent pattern in adolescent patients, with seven cases (87.5%), while only one case (12.5%) had deep adenomyosis with uterine cavity distortion. In adult patients, the most prevalent pattern of adenomyosis involvement was also superficial (n=11, 50%), followed by deep adenomyosis with uterine cavity distortion (n=8, 36.4%) and deep involvement without cavity distortion (n=3, 13.6%).

##### CONCLUSION

Adenomyosis, like in adults patients, is one of the manifestations of endometriosis in adolescents patients, with a difference in

prevalence of 14.7% in our study. The most common pattern of involvement in both groups was superficial.

#### **CLINICAL RELEVANCE/APPLICATION**

The presence of pelvic pain and/or hypermenorrhea in adolescents patients should raise the suspicion of endometriosis, which despite being more common in adult patients, also affects the first group. Early suspicion and diagnosis of adenomyosis can reduce long-term morbidity.

M5B-SPPD

### Pediatric Imaging Monday Poster Discussions II

#### Sub-Events

#### **M5B-SPPD-1 Clinical Value of Virtual Unenhanced CT Images for Children with Hepatic Tumors: CT Measurement and Lesion Detection**

##### **PURPOSE**

To access the feasibility of multi-material decomposition based virtual unenhanced images (VUE) replacing true non-contrast (TNC) images in the CT follow-up of children with hepatic tumor

##### **METHODS AND MATERIALS**

This study retrospectively collected 24 children with hepatic tumor who received conventional non-contrast CT scan and sequential dual phase contrast-enhanced spectral CT scans. VUEs were generated at artery phase [VUE(A)] and portal vein phase [VUE(PV)]. Regions of interest were placed on liver parenchyma and tumor site, CT values were measured. The consistency of CT measurement on two-group images were assessed by Pearson analysis and Bland-Altman method. The detection rate of liver tumor lesions was also evaluated with pathologic examination and CT follow-up as standard reference.

##### **RESULTS**

The 24 children contained 10 with hepatoblastoma, 6 with hemangioma, 5 with focal nodular hyperplasia, 2 with hepatic metastases from neuroblastoma and 1 with lymphomatosis. Including 12 showing hypovascular and 12 cases showing hypervascular. The CT<sub>liver</sub> among three-group images shown no statistical difference (both  $P > 0.05$ ), while CT<sub>tumor</sub> were higher in VUEs than TNC ( $P < 0.05$ ). The CT<sub>liver</sub> and CT<sub>tumor</sub> between VUE(A) and VUE(PV) images exhibited strong positive correlation ( $r_{liver} = 0.878$ ,  $r_{tumor} = 0.972$ ,  $p < 0.001$ ). The CT<sub>liver</sub> showed strong correlations between TNC and VUEs [ $r_{VUE(A)} = 0.787$ ,  $r_{VUE(PV)} = 0.802$ ,  $p < 0.001$ ]. For CT<sub>tumor</sub>, VUE(PV) showed moderate correlation [ $r_{VUE(PV)} = 0.497$ ,  $p = 0.014$ ] while VUE(A) showed no correlation ( $r_{VUE(A)} = 0.394$ ,  $p = 0.057$ ) with TNC, however for hypervascular tumors the CT<sub>tumor</sub> had strong correlation between VUE(A) and TNC ( $r = 0.749$ ,  $p = 0.005$ ). Bland-Altman analysis displayed that the VUE(A) had 6 cases and VUE(PV) had 7 cases where the CT<sub>tumor</sub> bias to TNC larger than 10 HU, therein most had hypervascular lesions. For lesion detection, there were total of 111 lesions, TNC, VUE(A) and VUE(PV) had detection rates of 68.47%, 57.66% and 83.78%, respectively.

##### **CONCLUSION**

For CT follow-up of children with hepatic tumor, VUE(PV) could replace TNC, VUE(PV) had good correlation with TNC in CT<sub>liver</sub> and CT<sub>tumor</sub>, and VUE(PV) improved tumor lesion display and internal structure announcement.

##### **CLINICAL RELEVANCE/APPLICATION**

Patients with hepatic tumors need long-term CT follow-up, but children are sensitive to X-ray exposure, excessive radiation may affect growth and development. The CT values measured on the VUE(PV) generated from the enhanced spectral CT data are correlated with that on TNC, and VUE(PV) can improve the lesion detection, so VUE(PV) could replace TNC and reduce the radiation dose of one unenhanced CT scan in the follow-up of children with hepatic tumors.

#### **M5B-SPPD-2A Comparative Analysis of Clinical and MRI Characteristics of Atypical Teratoid Rhabdoid Tumors and Medulloblastomas of the Posterior Fossa in Pediatric Patients**

##### **PURPOSE**

Atypical teratoid rhabdoid tumor (AT/RT) typically presents at a younger age and had a poorer prognosis compared to medulloblastoma. Notwithstanding, these two neoplasms share a considerable degree of neuroimaging overlap and are nearly indistinguishable on MRI. The aim of our study was to discriminate between AT/RT and medulloblastoma through retrospective analysis of their clinical and MRI features, with the ultimate goal of improving treatment strategies and prognostic assessment.

##### **METHODS AND MATERIALS**

Between 2005 and 2022, a total of 16 patients with histopathologically confirmed AT/RT and 58 patients diagnosed with medulloblastoma were retrospectively enrolled from our institution. We evaluated their clinical data and MRI findings, including lesion signals, intratumoral morphologies, and peritumoral/distal involvement.

##### **RESULTS**

The age of children diagnosed with AT/RT was younger than that of children with medulloblastoma ( $2.8 \pm 4.9$  [0-17] vs.  $6.6 \pm 4.0$  [0-18],  $P < 0.001$ ), and the overall survival rate was lower (21.4% vs. 66.7%,  $P = 0.005$ ). With regards to lesion signals on MRI, AT/RT exhibited a lower ADC<sub>min</sub> (cutoff value =  $544.7 \times 10^{-6}$  mm<sup>2</sup>/s, area under the curve [AUC] = 0.845,  $P < 0.001$ ), a lower ADC ratio (cutoff value = 0.705, AUC = 0.860,  $P < 0.001$ ), and a higher DWI ratio (cutoff value = 1.595, AUC = 0.802,  $P < 0.001$ ) than medulloblastoma. In respect to the intratumoral morphologies, the manifestation of the "tumor central vein sign" was found to be predominantly limited to medulloblastoma while being absent in cases of AT/RT (24/58 [41.4%] vs 1/16 [6.3%],  $P = 0.008$ ). For the peritumoral invasion detected on T2WI, AT/RT demonstrated a greater propensity for invasion of the brainstem ( $P < 0.001$ ) and middle cerebellar peduncle ( $P < 0.001$ ) compared to medulloblastoma.

## **CONCLUSION**

s MRI findings that include a lower ADC value, greater peritumoral invasion, and the absence of a "tumor central vein sign" have shown promise in distinguishing AT/RT from medulloblastoma. These discernible MRI features, coupled with the comparatively younger age of AT/RT patients, may account for the inferior prognoses observed in this patient population.

## **CLINICAL RELEVANCE/APPLICATION**

AT/RT can be distinguished from medulloblastoma based on specific MRI findings, such as a lower ADC value, greater peritumoral invasion, and the absence of the "tumor central vein sign." A combination of these MRI features and the patient's age can improve the accuracy of a pretreatment diagnosis of AT/RT versus medulloblastoma. This improved diagnostic accuracy can help guide treatment strategies and aid in prognostic assessment.

M5B-SPPH

### Physics Monday Poster Discussions II

#### Sub-Events

#### **M5B-SPPH-1 Feasibility Study of Coronary CT Angiography in Patients with Different Heart Rates under Free Breathing State**

#### **PURPOSE**

To explore the diagnostic value of different heart rates for patients with coronary CT angiography (CCTA) under free-breathing scanning in coronary heart disease.

#### **METHODS AND MATERIALS**

Forty-five patients with suspected coronary atherosclerotic heart disease undergoing CCTA examination were collected in our hospital. According to the real-time monitoring of the heart rate of the scanned patients, they are divided into 3 groups, group A: low heart rate group (heart rate =69 beats/min), group B: medium heart rate group (heart rate 70~80 beats/min), group C: high heart rate group (heart rate =81 times/min), 15 cases in each group. All patients used 256-slice wide-body detector CT (Revolution CT, GE Healthcare) for prospective ECG-gated coronary scans. Transfer the reconstructed image to GE AW 4.7 workstation. Two physicians with experience in cardiovascular CT diagnosis used the blind method to score subjectively and objectively the original images of the three groups of coronary artery imaging, and compared the radiometric measurements of each group. The subjective evaluation adopts the coronary segmentation method of the American Heart Association (AHA), and each segment is scored in 4 grades. Objective image quality evaluation places region of interest on the muscles of the anterior chest wall, the aortic root, the main left coronary artery, the proximal left anterior descending artery, the proximal left circumflex artery, and the root of the right coronary artery. Calculate the signal-to-noise ratio and contrast-to-noise ratio. SPSS 23.0 software was used, and one-way ANOVA analysis was used for comparison among multiple groups.

#### **RESULTS**

The subjective RCA scores of the three groups of image quality were  $3.36 \pm 0.61$ ,  $3.02 \pm 0.69$ ,  $2.90 \pm 0.64$ , respectively; LAD were  $3.35 \pm 0.60$ ,  $3.02 \pm 0.69$ ,  $2.92 \pm 0.62$ ; LCX was  $3.30 \pm 0.59$ ,  $2.97 \pm 0.55$ ,  $2.62 \pm 0.75$ , the difference was statistically significant ( $p$  were 0.000, 0.006, 0.001). The effective radiation dose ED of the three groups of patients was  $9.40 \pm 1.38$ ,  $7.39 \pm 0.96$ ,  $6.28 \pm 1.38$ , and the difference was statistically significant ( $p=0.000$ ).

#### **CONCLUSION**

Heart rate is an important factor affecting the quality of patients' coronary CTA images. Although the image quality of patients with different heart rates under free breathing decreases slightly with the increase of heart rate, it can meet the needs of diagnosis and also reduce the radiation dose received by patients with high heart rates.

#### **CLINICAL RELEVANCE/APPLICATION**

Although the image quality of patients with different heart rates under free breathing decreases slightly with the increase of heart rate, it can meet the needs of diagnosis and also reduce the radiation dose received by patients with high heart rates.

#### **M5B-SPPH-10 CT Number Reliability on Energy Integrating and Deep Silicon Photon Counting Detector CT with Patient Size**

#### Participants

Aria Salyapongse, BS, Madison, WI (*Presenter*) Nothing to Disclose

#### **PURPOSE**

In this study we compared the CT number of six clinically relevant materials on an energy-integrating detector (EID) and a prototype deep silicon photon-counting detector (PCD) CT as an effect of patient size.

#### **METHODS AND MATERIALS**

We performed three sets of dose-matched scans on a patient size-mimicking phantom (Mercury Phantom, Gammex), (1) 120 kV single-energy (SE) EID CT, (2) 80/140 kV rapid kV-switching dual-energy (DE) EID CT, and (3) 120 kV deep silicon PCD CT. Average CT number was calculated for air, water, polystyrene, iodine 10 mg/mL, bone, and polyethylene in (1) 120 kV polychromatic EID, (2) 70 keV monochromatic EID, and (3) 70 keV monochromatic deep silicon PCD image volumes. Trends in CT number with patient size were assessed by plotting CT numbers against phantom water equivalent diameter (WED). Slopes were compared using t-tests with multiple comparison adjustment to assess whether trends in CT number with WED were decreased for deep silicon PCD CT relative to EID CT. CT number accuracy was assessed by calculating ideal material CT numbers using the U.S. National Institute of Standards and Technology (NIST) XCOM database toolkit.

#### **RESULTS**

For all tested materials, deep silicon PCD CT had the smallest magnitude slope of CT number over WED. Deep silicon PCD CT slopes compared with SE EID CT and DE EID CT reached statistical significance for air ( $p = .03$ ,  $p = .007$ ), water ( $p = .02$ ,  $p = .03$ ), iodine

10 mg/mL ( $p < .001$ ,  $p = .04$ ), and bone ( $p < .001$ ,  $p < .001$ ). The accuracy of deep silicon PCD CT was higher than either SE or DE EID CT for all materials based on relative root mean square error. All materials except air had negative slopes for CT number with WED. The slopes for iodine and bone were smallest for deep silicon PCD CT, then DE EID CT, followed by SE EID CT: 20.3, 34.7, 81.5 HU/cm for iodine and 46.9, 113.1, and 186.6 HU/cm for bone, respectively.

## CONCLUSION

The change in CT number over WED was smallest for deep silicon PCD CT for air, water, iodine 10 mg/mL, and bone. The CT number accuracy was closest to the ideal CT number on deep silicon PCD CT for all materials compared with SE and DE EID CT.

## CLINICAL RELEVANCE/APPLICATION

Myriad characterizations in clinical radiology rely on accurate and stable CT numbers, use of deep silicon PCD CT could provide more consistent and accurate CT number over patient size and therefore better classification of tissue in clinical radiology.

## M5B-SPPH- 11 Assessing the Efficacy of Multiple Additive Processing in Contrast Enhancement Boost CT Technique for the Diagnosis of Hypervascular Hepatocellular Carcinoma

Participants

Shinji Yabe, MD, PhD, Kobe, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

For accurate diagnosis of hepatocellular carcinoma (HCC) in contrast-enhanced CT (CE-CT), providing better tumor-to-liver contrast is desirable. Recently, it has been demonstrated that a post-processing technique (CE-boost; Canon Medical Systems) can enhance the degree of contrast in CE-CT and facilitate HCC detection. In this technique, an iodine image can be obtained by subtracting the precontrast from the contrast phase image and is added to the contrast phase image with a non-rigid registration and denoising procedure. Despite the potential for further contrast enhancement via an additional additive process, the efficacy of this process remains unexplored. This study aimed to investigate the usefulness of the CE-boost technique with multiple additive processing for the evaluation of hypervascular HCC.

## METHODS AND MATERIALS

This retrospective study included 21 patients (age,  $74 \pm 8$  years; 13 men) with 31 hypervascular HCCs who underwent multiphase CE-CT. In this study, the late arterial phase (LAP) and portal venous phase (PVP) images were used to evaluate hypervascular HCCs. In the LAP, three types of CE-boost images were created by one to three times additive processing (LAP A1, LAP A2, and LAP A3, respectively). Similarly, three types of CE-boost images were created in the PVP (PVP A1, PVP A2, and PVP A3). Tumor-to-liver contrast-to-noise ratios (CNRs) were calculated in the LAP and PVP and were compared among CE-CT and CE-boost images using the Wilcoxon signed-rank test with Bonferroni correction. Also, the presence or absence of artifacts caused by the CE-boost technique was evaluated using a 3-point scale (1= non-diagnostic, 2= slight artifact, and 3= almost no artifact).

## RESULTS

The mean size of lesions was  $18.8 \pm 15.5$  mm (range, 8-93 mm). The tumor-to-liver CNR was significantly higher in CE-boost (LAP A3) images ( $7.0 \pm 3.9$ ) than in LAP ( $2.9 \pm 1.9$ ), CE-boost (LAP A1) ( $4.3 \pm 2.5$ ), and CE-boost (LAP A2) images ( $5.8 \pm 3.9$ ) (P<0.01 for all). On the other hand, there were no significant differences in tumor-to-liver CNR among CE-CT and CE-boost images in the PVP (P<0.99 for all). Artifacts due to the CE-boost technique were not noticeable in all CE-boost images and were rated 3.

## CONCLUSION

The CE-boost technique with multiple additive processing can increase the conspicuity of arterial phase hyperenhancement of hypervascular HCC by improving the tumor-to-liver CNR. In contrast, improvements in tumor-to-liver CNR were not observed in the PVP for washout assessment of hypervascular HCC.

## CLINICAL RELEVANCE/APPLICATION

CE-boost with multiple additive processing can improve the degree of contrast effect of CE-CT effectively. This technique is especially beneficial in the detection of focal liver lesions that show arterial phase hyperenhancement.

## M5B-SPPH- 12 Low-dose Cerebral Perfusion CT Reconstruction Based on Voxel-level TAC Correction (VTC)

## PURPOSE

To propose a low-dose cerebral perfusion CT (PCT) image reconstruction method and promote the application of PCT imaging in clinical cerebrovascular diseases (CVD) diagnosis.

## METHODS AND MATERIALS

A regularized least-squares method with high interpretability based on voxel-level time-attenuation curve (TAC) correction (VTC) is proposed in this study for low-dose PCT image reconstruction. The theory of third-order Hermite interpolation (THI) is applied to voxel-level TAC correction during dynamic images reconstruction. Clinical PCT imaging data is involved for the evaluation of the proposed VTC method, with peak signal-to-noise ratio (PSNR) and structural similarity (SSIM) being the quantitative indexes for imaging performance measurements. Based on the reconstructed PCT images, hemodynamic maps, including cerebral blood flow (CBF), cerebral blood volume (CBV) and mean transition time (MTT), are calculated to validate its ability to restore hemodynamic parameters.

## RESULTS

Indicated by the PSNR and SSIM values of the low-dose PCT images reconstructed by different methods, the proposed VTC method for low-dose PCT imaging has better performance than several state-of-the-art dynamic CT imaging methods, including the PICCS, ndiNLM, PIDT and NL-T-RPCA methods. Meanwhile, VTC provides the most accurate hemodynamic maps (CBF, CBV and MTT) among all the compared methods.

## CONCLUSION

The proposed VTC method is capable to reconstruct PCT image with satisfactory image quality under a low-dose PCT scan protocol.

## CLINICAL RELEVANCE/APPLICATION

The VTC method remarkably reduced the necessary radiational dose for PCT scan. This meaningful for promoting the application of PCT technique in the clinical diagnosis of CVD.

## M5B-SPPH- Photo-realistic Virtual Endoscopy Images for CT Colonography

13

### PURPOSE

Algorithms introducing photo-realism to the volume rendering (VR) have been investigated since early 2010s; as a result, some applications for photo-realistic VR (PRVR) have been clinically available. However, there are no applications for photo-realistic virtual endoscopy (PRVE) used for the CT colonography (CTC). An image-based deep-learning technique was proposed for CTC; however, CT-number information is ignored in it and it focused on a different reality. The purpose of this study was to investigate methodologies to achieve the PRVE for CTC and compare images between PRVE and a conventional VE.

### METHODS AND MATERIALS

To achieve photo-realistic rendering in VE, the rendering calculation of PRVR was modified to suit to a typical viewing field of VE. Unlike the conventional VR for CT, the photo-realistic rendering reflects the CT-number gradient with small fractions in the shading. Thus, the PRVE improves spatial resolution and is less sensitive to the image noise similarly to PRVR. Exploiting this feature, we reconstructed CT images with a high-resolution kernel to improve shape reproducibility of lesions. For the conventional VE (VEc), a standard kernel for abdomen was used. The following parameters were not altered from routine ones: a slice thickness of 1.0 mm, a table position increment of 0.5 mm, and a CT dose index of  $\sim 3.8$  mGy. The averaged rendering time per frame (RT) was measured for consecutive 100 renderings. One radiologist visually evaluated the superiority of PRVE over VEc using a five-point scale (1: worse, 2: somewhat worse, 3: equal, 4: somewhat better, 5: better) for image sharpness, artifact, lesion conspicuity, and gross morphology of ten clinical cases.

### RESULTS

The RTs of PRVE and VEc were 0.032 and 0.015 s, respectively. The average scores of visual comparisons for image sharpness, artifact, lesion conspicuity, and gross morphology were 5.0, 3.8, 4.1, and 5.0, respectively. The lesions were rendered more clearly with PRVE than with VEc, thanks to the photo-reality enhanced by the high-resolution kernel. Since the CT-number is reflected in the shading more in PRVE than in VEc, residual stools with tagging were able to be easily recognized in the PRVE images.

### CONCLUSION

s The PRVE for CTC exhibited high-quality VE images with better visual evaluations compared to the conventional VE. The PRVE would be effective visualization method for CTC.

## CLINICAL RELEVANCE/APPLICATION

The PRVE can render lesions in CTC more clearly compared to the VEc. Moreover, it was effective in the fecal tagging because the CT number is more reflected in the PRVE rendering than in VEc rendering.

## M5B-SPPH-2 Advancing Optimization Strategies for Oncological Abdominal CT Scanning: The i-Violin EU Project Approach Applied to Photon Counting CT

Participants

Gizem Yegin, MSc, Leuven, Belgium (*Presenter*) Nothing to Disclose

### PURPOSE

To propose CT optimization curves to improve oncological imaging of chest-abdomen CT as worked out in the i-violin EU4Health supported multicenter project for CT Guideline development.

### METHODS AND MATERIALS

An anthropomorphic abdominal phantom with an extension ring (PTW, Germany) and a length of 17cm was scanned on a Siemens Naeotom Alpha photon-counting CT scanner (Siemens-healthineers, Germany). The phantom contains an in-house designed cylindrical insert placed in the center of it. The first half of the insert contains a collection of low-contrast spheres with sizes of 4, 6, and 8mm diameter (15 of each size) while the second half was background only to provide signal-free segments. CT acquisitions were performed with a large range of scanning parameters and reconstruction settings: tube voltage, CTDI, bowtie filter, reconstruction kernel, iterative reconstruction strength, field of view, matrix size, and slice thickness. An anthropomorphic channelized Hotelling model observer was used to predict the human detectability of the spherical targets. From the percentages of correctly detected spheres of the 3 diameters, the threshold diameter (Dtr) at 62.5% correct was determined via logistic regression (GraphPad Prism, USA), and the 95% CI were estimated via bootstrapping. Optimization curves were realized with all Dtr values for specific parameters, each obtained from all scans with these parameter values.

### RESULTS

The results of most CT scan parameter combinations were as expected. As an example, a doubled CTDI value corresponds to a significantly lower Dtr ( $p < 0.001$ ). The results allow to compare the relative impact of the CTDI to other parameters. The switch to a smaller field of view, different slice thickness, bowtie filter, and iterative reconstruction strength did not lead to a significantly different low-contrast image quality ( $p > 0.07$ ). The change to 1024x1024 matrix size from 512x512 gave a significant performance increase ( $p = 0.001$ ). Interestingly, despite the use of the same CTDI, for the phantom with an extension ring, the 120 kVp scan outperformed the 90 kVp scan, while this effect was inverted without the ring.

### CONCLUSION

s From this systematic task-based comparison focused on soft tissue performance, it becomes possible to assess the effects of various parameters quantitatively. When completed with reference levels typically used by multiple centers, this approach may facilitate the development of practical guidelines to optimize CT scan protocols.

## CLINICAL RELEVANCE/APPLICATION

Quantitative and graphical representations of the Dtr values for the different conditions provide a fast approach to measures and parameter settings that would lead to improved soft tissue detection thresholds in abdominal oncological CT.

## **M5B-SPPH-3 Evaluation of Low-contrast Detectability of Abdominal Protocols in Clinical Photon-counting CT**

### **PURPOSE**

Accurate and clear representation of anatomy is essential in the assessment of pathology in clinical computed tomography (CT). With the introduction of photon-counting CT (PCCT) and more advanced iterative reconstruction (IR) algorithms into clinical practice, there is potential to improve low-contrast detectability in clinical CT protocols. Therefore, this work aimed to assess IR image quality to optimize low-contrast detectability and reduce radiation dose in a clinical abdominal CT protocol.

### **METHODS AND MATERIALS**

Data were acquired on a clinical PCCT scanner, Siemens NAEOTOM Alpha. Low contrast detectability was investigated in the CTP 515 low contrast module of the Catphan 600 phantom, which was surrounded by a fat ring to simulate an abdomen and resulted in a water equivalent diameter of 298-mm. Supra-slice contrast rods with a nominal 1.0 % contrast and diameters of 4, 6 and 9 mm were used. A factory abdominal protocol was adjusted to acquire virtual monoenergetic images (VMI) with four tube voltages and two quantum IR (QIR) strengths. VMI were produced at the mean energy of the applied spectrum. The noise power spectrum and task transfer function of each scan protocol was quantified; and detectability index and accuracy for each protocol was also determined using model (in-house non-prewhitening matched filter, NPW) and human observers (in-house 4-alternative forced choice, 4-AFC, scoring with standard deviation, SD), respectively.

### **RESULTS**

Preliminary studies with a NPW model observer show that lower doses can be achieved without sacrificing low-contrast detectability of various target sizes when QIR strength is increased in clinical abdominal protocols. For a 6-mm 1% contrast target, detectability may be matched, regardless of tube potential setting, between a protocol using a CT DIvol of 10 mGy and QIR 2; and another protocol using CT DIvol of 5 mGy and QIR 4. Additionally, 4-AFC human observer studies confirm that detectability is relatively unchanged with different tube potential settings when VMI energy levels are selected to match the mean energy of the applied spectrum. For a 6-mm 1% contrast target imaged with a CT DIvol of 10 mGy and QIR 4, tube potential settings of 70, 90, 120, and 140 kVp yielded 4-AFC detective accuracy scores of  $68.3 \pm 2.6\%$ ,  $65.1 \pm 2.7\%$ ,  $63.7 \pm 2.7\%$  and  $60.6 \pm 2.7\%$ , respectively.

### **CONCLUSION**

Lower doses can be achieved without sacrificing diagnostic capability and low-contrast detectability in clinical PCCT abdominal protocols when QIR strength is increased and appropriate VMI energies are selected.

### **CLINICAL RELEVANCE/APPLICATION**

Comparing various settings in clinical abdominal protocols, this work investigates avenues for optimizing low-contrast detectability in PCCT while also reducing radiation doses.

## **M5B-SPPH-4 Contrast-enhancement Boost Technique on Abdominal-enhanced CT Improves Image Quality of Adamkiewicz Artery**

Participants  
Huiqing Zhou, Jinan, China (*Presenter*) Nothing to Disclose

### **PURPOSE**

To evaluate the contrast-enhancement boost (CE-Boost) technique on improvement of the image quality of adamkiewicz artery.

### **METHODS AND MATERIALS**

109 patients who underwent abdominal-enhanced CT in Aquilion ONE Genesis were retrospectively collected. Images of arterial phase were postprocessed with CE-Boost technique. The arterial phase images (group A) and CE-Boost images (group B) were transferred to vitrea workstation to evaluate the objective and subjective image quality. The CT value and image noise (SD) of descending aorta and erector spinae muscle were measured, and signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. Subjective image quality was analyzed by using a five-point scale to score image quality of adamkiewicz artery.

### **RESULTS**

The CT value, SNR, CNR of descending aorta in group A and group B were  $406.2 \pm 104.9$  HU,  $46.1 \pm 13.9$ ,  $46.8 \pm 18.7$  and  $588.9 \pm 157.2$  HU,  $104.6 \pm 48.4$ ,  $120.6 \pm 52.2$ , respectively (all  $P < 0.01$ ). In group A, adamkiewicz artery were observed in 82 patients and observation rate was 75.2% (82/109). In group B, adamkiewicz artery were observed in 97 patients and observation rate was 88.9% (97/109). The image scores of group A (82 cases) and group B (97 cases) were 2 (1.5, 3) and 3 (2, 4), respectively ( $P < 0.01$ ).

### **CONCLUSION**

CE-Boost technique can improve the image quality of adamkiewicz artery.

### **CLINICAL RELEVANCE/APPLICATION**

CE-Boost technology can improve the visualization of adamkiewicz artery, which is beneficial for understanding spinal cord blood supply and improving the therapeutic effect of diseases of the thoracic aorta and abdominal aorta.

## **M5B-SPPH-5 Comparison of Imaging Methods for Ultra-high-resolution CT to Delineate Very Small Vessels: Low Tube Voltage Imaging vs. Small Focal Spot Imaging**

### **PURPOSE**

Imaging techniques with high contrast and spatial resolution are necessary to delineate such as Adamkiewicz. Low-tube-voltage imaging is effective in achieving high contrast, and small-focus imaging is effective in achieving high spatial resolution. Low-tube-voltage imaging requires the use of a large tube current, whereas small-focus imaging is limited by the tube current, which makes it difficult to achieve both low-tube-voltage and small-focus imaging. This study aimed to clarify whether low-tube-voltage imaging or small-focus imaging is superior for delineating blood vessels smaller than 1 mm.

### **METHODS AND MATERIALS**

In this study, we used an ultra-high-resolution CT (Aquilion Precision, Canon, Japan) to scan simulated vessel phantoms (DSA2, Kyoto Kagaku, Japan) with diameters of 1, 0.75, 0.5, and 0.25 mm as well as deep learning reconstruction. The imaging conditions were 80 kVp, large focus (0.8 mm × 1.3 mm) and CTDIvol 16.4 mGy for low-tube-voltage imaging and 120 kVp, small focus (0.4 mm × 0.5 mm) and CTDIvol 16 mGy and 29.6 mGy for small-focus imaging. The simulated vessel phantom was filled with a diluted contrast medium to achieve a contrast of approximately 500 HU (high contrast) and 300 HU (low contrast) against the background at 120 kVp. The peak CT values of the simulated vessels and SD of the background were measured for image evaluation, and the signal-to-noise ratio (SNR) was calculated.

## RESULTS

The SNR of the 1 mm simulated vessel with high contrast dilution contrast media was  $27.75 \pm 0.43$  at low kVp;  $17.74 \pm 0.35$  at small focus 16 mGy;  $22.78 \pm 0.29$  at 29.6 mGy; and  $19.96 \pm 0.45$ ,  $13.16 \pm 0.36$ , and  $22.83 \pm 0.43$  at 0.75 mm, respectively. The values were  $9.07 \pm 0.27$ ,  $7.78 \pm 0.15$  and  $10.75 \pm 0.32$  for 0.5 mm and  $5.52 \pm 0.12$ ,  $6.16 \pm 0.14$ , and  $6.96 \pm 0.13$  for 0.25 mm, respectively. The SNRs of 1 mm simulated vessels with low-contrast diluent were  $19.18 \pm 0.41$  for low kVp;  $12.82 \pm 0.28$  for small focus 16 mGy;  $16.21 \pm 0.27$  for 29.6 mGy; and  $13.3 \pm 0.31$ ,  $8.9 \pm 0.19$ , and  $12.45 \pm 0.26$  for 0.75 mm, respectively. The values were  $7.66 \pm 0.28$ ,  $6.8 \pm 0.23$ , and  $8.41 \pm 0.27$  for 0.5 mm and  $5.52 \pm 0.12$ ,  $6.16 \pm 0.14$ , and  $6.96 \pm 0.13$  for 0.25 mm, respectively.

## CONCLUSION

In microvascular imaging, low-tube-voltage imaging is effective when a sufficient contrast cannot be obtained, whereas small-focus imaging is effective when a large imaging dose is required.

## CLINICAL RELEVANCE/APPLICATION

In ultra-high-resolution CT, if the patient is large, rapid injection of a high-density contrast agent and small-focus imaging at 120 kVp can be used to ensure depiction of very small vessels, although the dose will increase. If the patient is small, Low-tube-voltage imaging can be used to ensure the depiction of very small vessels without increased invasiveness of rapid injection of high-density contrast medium.

## M5B-SPPH-6 Radiology Professional Preferences for CT Radiation Dose and Image Quality Monitoring

### PURPOSE

Existing radiation dose monitoring systems (RDMSs) primarily focus on radiation dose. The purpose of this work was to assess how image quality metrics can be incorporated into these systems taking into consideration the preference of different radiology professionals.

### METHODS AND MATERIALS

A new RDMS was designed to incorporate image quality assessment alongside radiation dose for clinical performance monitoring in CT. The study investigated how such data should be visualized for effective utilization by radiology professionals. To achieve this, a set of key questions was formulated and answered using various charts, illustrating trends, variations, outliers, comparisons, and inconsistencies in radiation dose and image quality data as oriented by the question. Fifteen such charts were then systematically evaluated by 12 experienced radiology professionals of four radiologists, four technologists/radiographers, and four medical physicists, with a combined professional experience of over 130 years. A Likert scale (very useful = 10, useful = 8, moderately useful = 6, slightly useful = 4, and not useful = 0) was used to assess the usefulness of the charts. To provide additional insights on potential improvements, free-text fields were also enabled. The data were analyzed in terms of average score and deviation per group as well as their individual insights.

### RESULTS

The system interface overall received an overall average score of 7.8 out of 10.0. Among the 15 charts, the one comparing scanner radiation output with literature and regulatory standards (i.e., diagnostic reference level and achievable dose across patient body habitus), showed the highest variation in scores among professional subgroups. In contrast, the chart representing scanners workload received similar scores across the subgroups. Specific visualizations resonated differently with each professional group, leading to 58 unique suggestions to better inform performance monitoring.

### CONCLUSION

The study highlighted the importance of including image quality in performance monitoring, regardless of the professional subgroups' preferences. However, we found strong differences across radiology professionals as to what they wish to see visualized.

### CLINICAL RELEVANCE/APPLICATION

A comprehensive monitoring system that integrates radiation dose with image quality assessment should be tailored to different radiology professionals' roles and responsibilities for best clinical practice in radiology.

## M5B-SPPH-7 Impact of X-Ray Tube on Image Quality and Conspicuity of Pancreatic Ductal Adenocarcinoma in Pancreatic Protocol Dual-Energy CT

Participants

Tetsuro Kaga, MD, PhD, Gifu, Japan (*Presenter*) Nothing to Disclose

### PURPOSE

To compare the image quality and conspicuity of pancreatic ductal adenocarcinoma (PDAC) in dual-energy pancreatic protocol CT between two x-ray tubes mounted in Revolution CT Apex.

### METHODS AND MATERIALS

Between January 2019 and March 2022, 80 patients underwent dual-energy pancreatic protocol CT using either Performix HDw (old x-ray tube; Group A, n = 41) or Quantix 160 (new x-ray tube; Group B, n = 39) mounted in Revolution CT Apex, respectively. All data were reconstructed at 70- and 40-keV and with medium-strength level of deep-learning image reconstruction. The two groups were compared in terms of CT dose-index volume (CTDIvol), CT numbers of the abdominal aorta, pancreas and PDAC, background noise, and qualitative scores for image noise, overall image quality, and conspicuity of PDAC.

## RESULTS

The CTDI<sub>vol</sub> was lower in Group B than in Group A (9.2 mGy vs. 7.9 mGy;  $P < .001$ ). The median CT numbers of all anatomical structures at 70- and 40-keV were comparable between two groups ( $P = .06-.78$ ). The background noise at 70- (14 HU vs. 12 HU;  $P = .046$ ) and 40-keV (30 HU vs. 26 HU;  $P < .001$ ) were lower in Group B than in Group A. Qualitative scores for image noise and overall image quality at 70- and 40-keV and conspicuity of PDAC at 40-keV were higher in Group B than in Group A ( $P < .001-.045$ ).

## CONCLUSION

In dual-energy pancreatic protocol CT, Revolution CT Apex with Quantix 160 improved qualitative image quality and reduced radiation dose.

## CLINICAL RELEVANCE/APPLICATION

Even when using the same Revolution CT Apex, the latest x-ray tube of Quantix 160 has clinical impact on the image quality and conspicuity of PDAC.

## M5B-SPPH-8 New Generation Wide Detector Spectral CT: What is the Optimal Monochromatic Energy Level for Diagnosing Iliac Vein Compression Syndrome

### PURPOSE

To determine the optimal monochromatic energy level for iliac vein compression syndrome (IVCS) assessment in dual-energy spectral CT imaging and demonstrate its advantages by comparing with the 120kVp-like images.

### METHODS AND MATERIALS

18 patients (56% female, 51±15y) with suspected IVCS underwent CT venography with spectral imaging mode on a new generation wide detector CT (Revolution CT, GE Healthcare). Scans started at 130s after 85-95 ml (370mgI/ml) was injected at 4.0ml/s speed followed by 40 ml saline. Monochromatic images (every 5 keV from 40 to 70 keV) and 120kVp-like images at 1.25mm were reconstructed and independently assessed by two radiologists both quantitatively and qualitatively. CT attenuation and standard deviation (SD) were measured in regions of interest (40±2mm<sup>2</sup>) in the following locations: bilateral common iliac artery and vein, psoas muscle and subcutaneous fat. The SD value for subcutaneous fat was used to represent image noise and to calculate contrast-to-noise ratio (CNR) for the arteries and veins. The data were analyzed using SPSS 22.0.

### RESULTS

CT attenuation and CNR values increased monotonically as energy level decreased with the monochromatic images at 40keV having the highest CT attenuation and CNR vein (6.26±1.08), CNR artery (7.32±1.45). However, the image noise at 40keV was also the highest (Fig1), shifting the highest subjective image quality score to 55keV (4.82±0.49,  $p < 0.05$ ). Reader 1 chose 55 keV in 61% cases, 50 in 33%, 60 in 6%. Reader 2 selected 55 keV in 50% cases, 50 in 33%, 60 in 17%. The monochromatic images improved both the quantitative and qualitative image quality over the 120kVp-like images (all  $p < 0.001$ ).

### CONCLUSION

Low energy (50-55keV) monochromatic images in spectral CT improves image quality for IVCS compared with 120kVp-like images.

### CLINICAL RELEVANCE/APPLICATION

Spectral CT images at the optimal energy level may be used to improve image quality for the assessment of iliac vein compression syndrome.

M5B-SPRO

### Radiation Oncology Monday Poster Discussions II

#### Sub-Events

#### M5B-SPRO-1 Prediction of EGFR Mutations in Non-small Cell Lung Cancer Based on Hybrid Radiomics

##### PURPOSE

This study aimed to predict EGFR gene mutations in non-small cell lung cancer patients based on deep learning and radiomics using CT and clinical characteristics.

##### METHODS AND MATERIALS

A total of 1,917 patients with non-small cell lung cancer were selected as the final study population, who underwent contrast-enhanced CT scans and EGFR gene testing before treatment. Clinical characteristics included gender, family history, height, and weight. The region of interest was segmented from CT images to extract radiomics features and obtain tumor images. The tumor images were used as input data for a CNN model to extract 512 image features, and combined with radiomics features and clinical data to predict EGFR gene mutations. The generalization performance of the model was evaluated using external institutional data.

##### RESULTS

AUROC was used as the performance evaluation metric. The model using tumor images and radiomics features as input data showed an AUROC of 0.67. The model using tumor images, radiomics features, and clinical data showed an AUROC of 0.72.

##### CONCLUSION

This study provides a convenient and non-invasive method for predicting EGFR gene mutations. EGFR gene mutations play a very important role as one of the factors that increase the risk of recurrence in non-small cell lung cancer patients, and can also be used to determine treatment strategies. Therefore, further research is needed to improve the accuracy of the model and address issues related to data collection in the future.

##### CLINICAL RELEVANCE/APPLICATION

EGFR gene mutation is the most commonly observed gene mutation in non-small cell lung cancer patients. EGFR is a signal transduction protein that regulates cell growth and division. When the DNA sequence inside the gene is mutated, the signal transduction pathway works abnormally, causing cancer cells to rapidly proliferate or form tumors. Existing gene mutation tests can only observe a part of the tumor, not the entire tumor, and thus cannot determine the heterogeneity of the entire tumor. In addition, there are technical difficulties and high costs associated with conventional methods, so a non-invasive and convenient test method must be developed to overcome these limitations.

M5B-SPVA

### Vascular Imaging Monday Poster Discussions II

#### Sub-Events

#### **M5B-SPVA-1 Benefit of Photon-counting CT for Lower Extremity CTA Compared to Conventional Energy-integrating Detector CT**

##### Participants

Safa Hoodeshenas, MD, Rochester, MN (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the impact of photon-counting detector (PCD) CT on radiologist confidence and visualization of below-knee arteries at lower extremity CT angiography (CTA) compared to conventional energy-integrating detector (EID) CT.

##### METHODS AND MATERIALS

Patients who underwent clinically-indicated lower extremity CTA performed on a commercial PCD CT system (NAETOM Alpha, Siemens), as well as a prior or subsequent lower extremity CTA performed with EID CT were included. PCD-CTA included 0.6 mm slices with sharp kernel (Bv68), whereas EID CTA included 2 mm slices using routine kernel (Bv44), per clinical protocols. Two radiologists independently reviewed the anonymized and randomized CTA exams in separate reading sessions, with each patient's images appearing once per reading session. Readers estimated maximum stenosis grade for each of 7 below-knee arterial segments (popliteal to dorsalis pedis and plantar arteries), noting confidence in stenosis grading (0-100%). Visualization of small vessels was evaluated by counting the number of fibular perforators and grading visualization of fibular perforators, dorsalis pedis and plantar arteries on a 5-point Likert scale (1=worst, 5=best). Image quality metrics (i.e., sharpness, enhancement, and overall image quality) were assessed per patient.

##### RESULTS

25 patients (mean age  $68 \pm 10$  years; M: F=18: 7) underwent CTA runoff using PCD-CT (mean contrast volume:  $120 \pm 14$  cc) and EID-CT (mean contrast volume:  $114 \pm 16$  cc). For both readers, confidence in stenosis grading was significantly higher in PCD-CT for all evaluated arterial segments (e.g., popliteal artery  $92.9 \pm 6$  vs.  $77.3 \pm 14.7$ ;  $p < 0.001$ ; dorsalis pedis artery  $90.6 \pm 6.4$  vs.  $67 \pm 19.5$ ;  $p < 0.001$ ). The number of visualized fibular perforators was significantly higher with PCD-CT ( $8.1 \pm 3$  vs.  $5.4 \pm 2$ ;  $p < 0.001$ ). Visualization of small vessels was rated significantly higher with PCD-CT for all the evaluated small vessels (e.g., plantar arteries:  $4.5 \pm 0.8$  vs.  $3.1 \pm 0.8$ ,  $p < 0.001$ ; fibular perforators,  $p < 0.001$ ; dorsalis pedis,  $p < 0.001$ ). PCD-CT had significantly greater arterial sharpness ( $4.7 \pm 0.5$  vs.  $2.7 \pm 0.9$ ;  $p < 0.001$ ), arterial enhancement ( $4.3 \pm 0.6$  vs.  $3.4 \pm 0.7$ ;  $P < 0.001$ ), and overall image quality ( $4.6 \pm 0.6$  vs.  $3.3 \pm 0.8$ ;  $P < 0.001$ ).

##### CONCLUSION

Lower extremity CTA runoff with PCD-CT and 0.6 mm slices resulted in significantly increased reader confidence in small vessel stenosis grading, a higher number and improved visualization of small arteries, and greater arterial sharpness and enhancement.

##### CLINICAL RELEVANCE/APPLICATION

Thin-slice PCD-CT improved visualization of small calcified below-the-knee vessels, with greater reader confidence and higher number of visualized small vessels.

#### **M5B-SPVA-2 Short Segment Linear Flaps" of the Abdominal Aorta are Not Dissections: Discovery of their Origin via Retrospective Imaging Review**

##### Participants

Amar Shah, MD, Phoenix, AZ (*Presenter*) Nothing to Disclose

##### PURPOSE

Linear filling defects of the abdominal aorta are often referred to as focal aortic dissection or flaps in radiology reports, triggering concern amongst clinicians for acute aortic syndrome. However, these "flaps" are highly unlikely to represent true intimal dissection flaps given their short segment and often incidental discovery. This retrospective study aims to determine the etiology of linear filling defects of the abdominal aorta utilizing prior contrast-enhanced (CE) imaging.

##### METHODS AND MATERIALS

An IRB-approved, HIPAA compliant retrospective study was performed. Abdomen/pelvis CT reports finalized Jan 2021 through Dec 2022 from two sites of an academic medical center were queried for the terms "focal dissection," "dissection flap," "linear filling defect," and "linear flap". Duplicate patients were removed. Exclusions based on reports were vessel other than abdominal aorta, thoracoabdominal dissection, no prior CE imaging, and less than 6 months between exams. On imaging review, cases with no change in appearance between exams were excluded. Cases were excluded if medical record review indicated femoral catheter access between imaging exam dates. Imaging review of more recent exam included presence of flap, flap calcification, and qualitative assessment of aortic caliber at the level of flap. Prior exam assessment included evaluation of aortic caliber and aortic

findings at the location of subsequent flap.

## **RESULTS**

Report query yielded 865 reports and 702 unique patients. After initial exclusion, the imaging of 70 patients was reviewed, of which 40 were excluded for lack of change in imaging appearance of the linear filling defect. 10 patients were excluded for femoral access, yielding a final population of 20 patients. There was a median of 70 months between imaging exams (range 14-230). All aortas were atherosclerotic and 75% (n=15) were ectatic or aneurysmal at the level of flap; on the older exam only 5 aortas were ectatic or aneurysmal. Of 20 cases, mural thrombus or partially ulcerated mural thrombus was present at the flap site in 17, thrombosed PAU in 1, and no corresponding findings in 2.

## **CONCLUSION**

s Short segment linear filling defects within the abdominal aorta correspond to sites of prior mural thrombus. Mural thrombus has ulcerated or resorbed, leaving behind the luminal surface of the thrombus. Therefore, short segmental filling defects within the abdominal aorta should not be referred to as a dissection flap but rather a remnant of ulcerated and resorbed mural thrombus.

## **CLINICAL RELEVANCE/APPLICATION**

Linear filling defects of the abdominal aorta are often reported as focal dissections, but this incorrectly describes their pathophysiology. These filling defects are the remnant surface of ulcerated/resorbed mural thrombus.

R2-SPBR

### Breast Imaging Thursday Poster Discussions

#### Sub-Events

#### R2-SPBR-1 The Value of Dual-Energy CT Quantitative Parameters in Predicting the Nature of Breast Space-Occupying Lesions

Participants  
Minghui Wei, Nanning, China (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the value of parameter of dual energy CT in predicting breast space occupation lesions.

#### METHODS AND MATERIALS

66 patients with breast space occupation lesions confirmed by pathology who tested by enhancing arterial and venous dual energy CT scan of breast in our hospital from Jan 2023 to Mar 2023 were collected, which were 42 cases of invasion breast cancer and 24 cases of fibroadenoma. To obtain the iodine map, use the virtual plain scan program. Then, use the single energy spectrum program to obtain the energy spectrum curve of the lesion. Record the CT value of the lesion at both 40 keV and 70 keV. Finally, calculate the slope of the energy spectrum curve ( $\alpha = (CT_{40keV} - CT_{70keV}) / (70 - 40)$ ). The study utilized the rank sum test to compare quantitative parameters on two-phase images between benign and malignant groups, and also used the Spearman rank sum test to analyze the correlation between quantitative parameters and breast space-occupying lesions.

#### RESULTS

During the arterial phase, the IC of the lesions in the malignant and benign groups were 0.700 (0.4, 0.9) and 0.100 (-0.3, 0.5 mg/mL), and the  $\alpha$  values were 0.995 (0.5, 1.4) and 0.330 (-0.4, 0.9). During the venous phase, the IC of the lesions in the malignant and benign groups were 1.800 (1.4, 2.6) and 1.000 (0.3, 1.6) mg/mL, respectively. Additionally, the  $\alpha$  values were 3.265 (2.6, 4.6) and 1.415 (0.3, 3.0) for the malignant and benign groups, respectively. In both arterial and venous phases, there were significant statistical variations in IC and  $\alpha$  values between the two types of pathological lesions ( $P < 0.05$ ). The IC and  $\alpha$  values of arterial and venous phase lesions exhibit weak to moderate correlation with the pathological types of breast space-occupying lesions.

#### CONCLUSION

The dual-energy CT iodine map and the slope of the energy spectrum curve are effective in distinguishing between benign and malignant breast space-occupying lesions. They also show a strong correlation with pathological types and provide quantitative information for differential diagnosis. These methods offer a valuable means of analysis for breast space-occupying lesions of different pathological types.

#### CLINICAL RELEVANCE/APPLICATION

The dual-energy CT iodine map and the slope of the energy spectrum curve are effective in distinguishing between benign and malignant breast space-occupying lesions.

#### R2-SPBR-2 Multiparametric MRI Assessment of Primary Tumor for Predicting Axillary Tumor Burden in Women with Invasive Breast Cancer

Participants  
Jin You Kim, MD, PhD, Busan, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess whether multiparametric MRI features of a primary tumor are associated with axillary lymph node tumor burden in women with invasive breast cancer.

#### METHODS AND MATERIALS

This retrospective study evaluated women with invasive breast cancer who underwent 3-T multiparametric breast MRI including diffusion-weighted imaging (DWI) between 2019 and 2020. Two radiologists independently evaluated peritumoral edema and intratumoral necrosis on T2-weighted imaging (T2WI) and measured the mean, minimum, and maximum apparent diffusion coefficient (ADC) values by manually placing regions of interest within the breast tumors. Quantitative kinetic features of breast cancer assessed with computer-aided diagnosis (CAD) and clinical-pathologic characteristics were analyzed. Uni- and multivariable logistic regression was performed to identify predictors of axillary lymph node metastasis or high axillary nodal burden ( $\geq 3$  positive nodes).

#### RESULTS

A total of 242 women (mean age, 54.4 years; age range, 29-86 years) were evaluated. Eighty-three (34.3%) had axillary lymph node metastasis and 39 (16.1%) had high axillary nodal burden by surgical pathologic analysis. On multivariate analysis, predictors of axillary lymph node metastasis were peritumoral edema (Odds ratio [OR]: 4.54; 95% confidence interval [CI]: 2.32, 8.87;  $P <$

.001), maximum ADC value ( $= 1.207 \times 10^{-3} \text{mm}^2/\text{s}$ ) (OR: 2.60; 95% CI: 1.33, 5.10;  $P = .005$ ), lymphovascular invasion (OR: 5.20; 95% CI: 2.61, 10.35;  $P < .001$ ), and larger tumor size ( $> 2\text{cm}$ ) (OR: 3.17; 95% CI: 1.59, 6.29;  $P < .001$ ). Predictors of high axillary nodal burden were peritumoral edema (OR: 7.39; 95% CI: 2.72, 20.02;  $P = .001$ ), maximum ADC value ( $= 1.045 \times 10^{-3} \text{mm}^2/\text{s}$ ) (OR: 9.74; 95% CI: 3.26, 29.07;  $P < .001$ ), lymphovascular invasion (OR: 8.38; 95% CI: 2.95, 23.75;  $P = .001$ ), and larger tumor size ( $> 2\text{cm}$ ) (OR: 6.08; 95% CI: 1.77, 20.91;  $P = .004$ ). CAD-derived kinetic features of breast cancer did not associate with axillary nodal status. In the subgroup analysis of 192 early-stage breast cancer patients, peritumoral edema (OR: 17.12; 95% CI: 2.02, 144.90;  $P = .009$ ) and lymphovascular invasion (OR: 4.65; 95% CI: 1.01, 21.51;  $P = .049$ ) maintained significance for predicting high axillary nodal burden.

## CONCLUSION

s Peritumoral edema on T2WI and maximum ADC value of breast cancer on DWI could be helpful for predicting axillary lymph node tumor burden in women with invasive breast cancer.

## CLINICAL RELEVANCE/APPLICATION

Multiparametric MRI assessment of primary tumor using T2WI and DWI might have predictive value for assessing axillary tumor burden in women with invasive breast cancer.

## R2-SPBR-3 A Radiomic-Clinical Model of Contrast-Enhanced Mammography for Biopsy Outcome Prediction on BI-RADS 4A/4B Patients

### PURPOSE

In the US over 1 million biopsies are performed annually, with 9.6% diagnostic exams given BI-RADS =4A, most of which are rated as BI-RADS 4A/B. Contrast enhanced mammography (CEM) may improve lesion classification. BI-RADS 4A and 4B patients are particularly challenging for biopsy outcome prediction. The goal of the study is to build machine learning quantitative analysis of CEM to improve breast biopsy outcome prediction.

### METHODS AND MATERIALS

With HIPAA-compliance and IRB-approval, 292 patients (aged 30-86) with 332 included BI-RADS =4A lesions (78 cancers (49 IDC, 14 ILC, 15 DCIS) and 254 benign) underwent pre-biopsy CEM. An experienced radiologist produced Initial BI-RADS based on mammography, tomosynthesis and/or ultrasound, and then CEM-adjusted BI-RADS after CEM interpretation. Logistic regression models for outcome prediction were built using radiomic features of segmented lesions in CEM and four CEM-assessed qualitative clinical descriptors (enhancement, strength of enhancement, kinetics, and background parenchymal enhancement). The area under the receiver operating characteristic curve (AUC) measured model performance. PPV conditioned at 100% sensitivity assessed performance on BI-RADS 4A/B lesions.

### RESULTS

AUC for radiomics was 0.87, clinical descriptors 0.89, and combination 0.92. PPV3 for clinical BI-RADS 4A lesions is 6.9% and model 17.6%. PPV3 of CEM BI-RADS 4A is 5.1% and model 9.1%. PPV3 of clinical BI-RADS 4B is 15.3% and model 25.0%. PPV3 of CEM BI-RADS 4B is 35.9% and model 45.7%. Compared to the radiologist, the model increased 153% (or 63%) and 78% (or 30%) of the PPV for initial clinical BI-RADS 4A (or 4B) patients and CEM-adjusted 4A (or 4B) patients.

## CONCLUSION

s Machine learning models of tumor radiomics and clinical descriptors of CEM can substantially increase biopsy outcome prediction accuracy, particularly for the 4A and 4B patients. For 4B patients, the collaboration of radiologists (producing CEM BI-RADS) and our model can largely reduce false positives with a PPV of 45.7%.

## CLINICAL RELEVANCE/APPLICATION

Machine learning analysis and radiologists' clinical assessment of CEM can improve biopsy outcome prediction and their collaboration can gain the highest benefits for the 4A/4B patients.

## R2-SPBR-4 Kinetic Features on DCE-MRI Rather than Glycolytic Phenotype on 18F-FDG PET/CT Predict Recurrence Free Survival in Patients with ER-positive/HER2-negative Early Breast Cancer

### PURPOSE

Estrogen receptor (ER)-positive/human epidermal growth factor receptor 2 (HER2)-negative subtype of breast cancer is known to show low F-18 fluorodeoxyglucose ([18F]FDG) uptake on positron emission tomography/computed tomography (PET/CT). The purpose of this study was to evaluate prognostic value of preoperative dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) compared to [18F]FDG PET/CT in patients with ER-positive/HER2-negative early breast cancer.

### METHODS AND MATERIALS

We analyzed data from 145 consecutive women with breast cancer who underwent [18F]FDG PET/CT for initial staging and subsequent surgery between 2008 and 2015. Among them, a total of 118 patients had preoperative DCE-MRI. The clinicopathological variables, computer-aided diagnosis (CAD)-generated kinetic features, apparent diffusion coefficient, and maximum standardized uptake value (SUVmax) were assessed for the risks of recurrence. Hazard ratios (HRs) were estimated from Cox proportional hazards regressions. Recurrence free survival (RFS) curves were estimated using the Kaplan-Meier method and differences in each risk layer were assessed using the log-rank test.

### RESULTS

During the follow up ( $82.25 \pm 22.91$  months), 16 (11.0%) patients experienced recurrence. Peak enhancement (PE)  $>210\%$  (HR 10.70; 95% CI: 1.36-84.51;  $p=0.025$ ), Ki-67  $>6\%$  (HR 5.06; 95% CI: 1.15-22.27;  $p=0.032$ ) and SUVmax  $>6.75$  (HR 4.50; 95% CI: 1.64-12.39;  $p=0.004$ ) were significant factors for RFS on the univariate analysis. On the multivariate analysis, PE  $>210\%$  (HR 9.23; 95% CI: 1.16-73.29;  $p=0.036$ ) was the only significant prognostic factor. On the Kaplan-Meier survival analysis, patients with tumors showing PE  $>210\%$  at preoperative MRI had a significantly poorer 5-year RFS compared to those with PE  $\leq 210\%$  (83.7% and 98.1%, respectively,  $p=0.010$ ).

## CONCLUSION

s In patients with early-stage ER-positive/HER2-negative breast cancer, high PE at preoperative DCE-MRI was more effective than [18F]FDG uptake on PET/CT for predicting RFS.

#### **CLINICAL RELEVANCE/APPLICATION**

CAD-generated kinetic information that can be obtained automatically from preoperative breast MRI in routine clinical practice could help stratify which early-stage ER-positive HER2-negative breast cancer to treated with adjuvant chemotherapy.

### **R2-SPBR-5 An Innovative Technique using Discrete Multi-Wavelength Near Infra-Red Spectroscopy Diffuse Optical Imaging to Differentiate Breast Lesions in Fast Scans: A Feasibility Study**

Participants

Min Jung Kim, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To investigate the potential role of newly developed diffuse optical spectroscopic imaging (DOSI) device using discrete multi-wavelength near-infrared spectrum (DMW-NIRS) in fast scans to differentiate breast lesions.

#### **METHODS AND MATERIALS**

The protocol for DOSI using DMW-NIRS in fast scans was approved by the Institutional Review Boards of Severance Hospital; all participants provided informed consent. A total of 62 consecutive women (range, 29-80 years; mean, 49.9 years) with 62 breast lesions (37 malignant, 25 benign) that were biopsied under US guidance were included. A handheld probe consisting of 5 pairs of light-emitting diodes and photodiodes was used, with the lesion location marked according to conventional US findings. Light absorption and scattering were measured with 8 NIR wavelengths. Lesion to normal ratios (L/Ns) of quantitative chromophores (HbO<sub>2</sub>, HHb, THC, StO<sub>2</sub>, Water, Lipid, and TOI) that were calculated in comparison to the contralateral normal breast tissue were assessed. L/Ns of chromophores were compared between the malignancy and benign. Diagnostic performance was calculated for each L/N of chromophores. Subgroup analysis was performed for Breast Imaging Reporting And Data System (BI-RADS) category 4A lesions.

#### **RESULTS**

All L/Ns of chromophores showed significant differences between malignant and benign groups (all  $p < 0.05$ ). Area under receiver operating characteristic curve (AUROC)s of L/Ns of chromophores ranged 0.710-0.901 (all  $p < 0.05$ ), with TOIL/N showing the highest AUROC (0.901; 95% CI: 0.825-0.976). Accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of TOIL/N were 83.9%, 86.5%, 80.0%, 86.5%, and 80.0%, respectively. In subgroup analysis for BI-RADS category 4A lesions, all L/Ns of chromophores, except for Lipid, showed significant differences between malignant and benign groups ( $p < 0.05$ ). AUROC of L/Ns of chromophores ranged 0.710-0.902 (all  $p$  except for Lipid  $< 0.05$ ), and TOIL/N showed the highest AUROC (0.902; 95% CI: 0.788-1.000). Accuracy, sensitivity, specificity, PPV, and NPV of TOIL/N were 90.6%, 100.0%, 82.4%, 83.3%, and 100.0%, respectively.

#### **CONCLUSION**

s L/Ns of chromophores measured by the newly developed DOSI using DMW-NIRS in fast scans showed promise as an adjunct to BI-RADS categorization for distinguishing breast cancers from benign lesions. This new technique also demonstrated similar performance even in subgroup that included only low suspicious lesions.

#### **CLINICAL RELEVANCE/APPLICATION**

New DOSI technique using DMW-NIRS could be a quick, safe, and noninvasive supplemental method to increase diagnostic accuracy. However, it is essential to validate our results with larger patient cohort.

### **R2-SPBR-6 Comparison of Radiomics-Based Machine-Learning Classifiers for Pretreatment Prediction of Pathologic Complete Response to Neoadjuvant Therapy in Breast Cancer**

#### **PURPOSE**

In recent years, machine learning (ML) classifiers have gradually been used to establish high-performance predictive models for pathological complete response (pCR) in breast cancer after neoadjuvant therapy (NAT). However, few studies have compared the effectiveness of different ML classifiers. This study investigated the ability of radiomics models based on pre- and post-contrast first-phase T1 weighted images (T1WI) to predict breast cancer pCR after NAT and compared the performance of different ML classifiers.

#### **METHODS AND MATERIALS**

In this retrospective study, 300 patients from the Duke-Breast-Cancer-MRI dataset who underwent neoadjuvant therapy (NAT) were included, including pCR ( $n=76$ ) and non-pCR ( $n=224$ ) cases. These patients were randomly divided into training and validation groups at a ratio of 8:2. Radiomics features were extracted from pre- and post-contrast first-phase T1WI images of each patient. The radiomics model was built using features selected through the Spearman correlation analysis and the LASSO algorithm after normalization. SVM, RF, extraTrees, DT, KNN, XGBoost, LightGBM were used as classifiers. ROC curves were used to assess the predictive performance of the radiomics models.

#### **RESULTS**

Out of the seven classifiers used, the LightGBM classifier performed best in predicting breast cancer pCR, with an AUC of 0.813 in the validation group (95% CI: 0.697-0.928, accuracy 78.3%, sensitivity 46.7%, specificity 100.0%). During subgroup analysis, RF achieved the highest AUC in pCR prediction in luminal breast cancers (0.859, 95% CI: 0.710-1.000, accuracy 85.9%, sensitivity 68.8%, and specificity 83.3%), and DT yielded the highest AUC in pCR prediction in triple negative (TN) breast cancers (0.909, 95% CI: 0.790-1.000, accuracy 88.2%, specificity 81.8%, accuracy 100%).

#### **CONCLUSION**

s Overall, the LightGBM-based radiomics model demonstrated superior performance in predicting breast cancer pCR, while RF and DT displayed promising results in predicting pCR for luminal and TN breast cancers, respectively, during subgroup analysis.

## CLINICAL RELEVANCE/APPLICATION

pCR after neoadjuvant therapy (NAT) in breast cancer strongly correlates with overall survival. Over the past few years, the value of radiomics in predicting pCR in breast cancer has attracted significant attention, and machine learning algorithms have become a research hotspot. It is widely acknowledged that high-performance machine learning algorithms are essential for establishing radiomics models. Therefore, in our study, we extracted radiomics features based on pre- and first post-contrast T1WI and used seven machine learning classifiers to build prediction models, respectively, and compared their prediction performance.

## R2-SPBR-7 Evaluating Mammography Positioning Quality on Digital Screening Mammograms in Large Urban Health Systems - Same as Film?

Participants

Laurie Margolies, MD, New York, NY (*Presenter*) Stock options, Nuevozen Corporation Medical Advisory Board, Screenpoint Medical

### PURPOSE

Mammography positioning quality (MPQ) is critical to detection of breast cancer. Approximately 90% of poor-quality screening mammography images are due to poor positioning. The most common errors on film screen mammography (FSM) reported in the medical literature are inadequate pectoralis major muscle, sagging and poor visualization of posterior tissue. Understanding how positioning errors present themselves on digital mammograms can help tailor quality improvement initiatives. The purpose of this study was to examine MPQ, as defined by American College of Radiology (ACR) criteria, of digital screening mammograms at two US health systems.

### METHODS AND MATERIALS

Data from two US health systems was collected as part of an international multi-center mammography positioning quality research collaboration (MAMMO.IQ Study). MPQ errors, including exaggeration, portion cut off, posterior tissue missing, nipple not in profile, too high on image receptor (IR), inadequate pectoralis length, sagging, and posterior nipple line (PNL) length difference, were evaluated using artificial intelligence MPQ algorithms applied to screening mammograms acquired between December 2019 and April 2021; associated proportions and rankings of the positioning errors were computed. A total of 221,427 and 318,929 digital mammography images were processed from two health systems. The study was approved by research ethics at the participating sites.

### RESULTS

175,591 and 290,503 MPQ errors were identified respectively at the centers. The rank order of the eight MPQ errors was nearly identical for the two centers (Wilcoxon Rank Sum Test,  $p=0.645$ ). The three most common MPQ errors, PNL on CC view not within 1 cm of that on MLO view, inadequate pectoralis major muscle, and excessive exaggeration on CC view, accounted for 66% and 72.0% of all MPQ errors at the centers respectively; only inadequate pectoralis major muscle is amongst the reported most common errors on FSM. The two least common errors, breast positioned too high on IR and sagging, accounted for 10.4% and 7.0% of all MPQ errors at the centers respectively.

### CONCLUSION

s MPQ errors on digital mammograms were similarly distributed at the centers, but did not align with the pre-digital era reported findings on film screen mammograms.

## CLINICAL RELEVANCE/APPLICATION

Knowledge of common MPQ errors can inform technologist teaching efforts. MPQ errors may be affected by equipment used. MPQ assessments may be more reliable by AI than by humans.

## R2-SPBR-8 Using Artificial Intelligence to Triage Screening Mammograms after Breast-conserving Therapy

Participants

Jeaneun Park, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

### PURPOSE

This study aims to evaluate the clinical usefulness of artificial intelligence (AI) for triaging of screening mammograms after Breast-conserving therapy (BCT).

### METHODS AND MATERIALS

The consecutive mammograms from January to May 2021, conducted in patients who underwent BCT were included. Mammograms were analyzed by dividing into ipsilateral and contralateral breast. Triage was performed in the following three methods. One method was to classify exams as no recall (BI-RADS C1, C2) and recall (C0, C3, C4 or C5) based on the original report by expert radiologists. The commercially available AI for mammography was used for the others. If AI did not detect any abnormality, it was assigned as a no recall, and otherwise as a recall (Standalone AI-triage). For cases classified as recall by AI, one radiologist classified them as recall or no recall in consideration of mammography findings (Decision referral AI-triage). We analyzed cancer detection rate (CDR), recall rate and sensitivity for each method.

### RESULTS

A total of 1190 patients (mean age 56.6 years) were included in the study, with 1221 cases of the ipsilateral and 1135 cases of contralateral breast. In ipsilateral breast, the CDR, recall rate and sensitivity of the original report were 6.5/1000, 3.4%, and 80%. Standalone AI-triage was able to reduce the workload by 77%, while maintaining the same level of CDR and sensitivity. Decision referral AI-triage lowered the recall rate to 2.8%. The CDR, recall rate and sensitivity of the original report were 1.7/1000, 1.9%, and 66.7% in contralateral breast. About 90% of workload could be reduced in standalone AI-triage. In decision referral AI-triage, the CDR, recall rate and sensitivity for were 2.5/1000, 2.0% and 100%.

### CONCLUSION

s AI-based triage can contribute to reducing the radiologist's workload without harming sensitivity in the screening mammograms of BCT patients. However, sufficient experience of radiologists is essential to interpret false-positive results, especially in ipsilateral breast after BCT.

## **CLINICAL RELEVANCE/APPLICATION**

The population undergoing screening after surgery is accumulating, as the number of breast cancer patients increases worldwide. Also, the personal history of breast cancer itself is a sustained long-term risk for future breast cancer. This study investigated the clinical usefulness of AI-based triage to maintain quality even in the screening of patients who underwent BCT, while reducing the radiologist's workload.

R2-SPCA

### Cardiac Imaging Thursday Poster Discussions

#### Sub-Events

#### **R2-SPCA-1 Impact of Diabetes Mellitus on Left Ventricular Deformation in Restrictive Cardiomyopathy Patients Assessed by Cardiac Magnetic Resonance Imaging**

##### Participants

Yue Gao, MD, Chengdu, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Diabetes mellitus (DM) is considered a major risk factor for cardiovascular events and increases the risk of worse long-term outcomes in patients with restrictive cardiomyopathy (RCM). We aimed to investigate the impact of comorbid DM on LV deformation in RCM individuals.

##### METHODS AND MATERIALS

Seventy-four RCM patients without DM [RCM (DM-)], 33 with DM [RCM (DM+)], and 75 age- and sex-matched controls who underwent CMR scanning were included. We exclude patients with congenital heart disease and heart failure secondary to other cardiomyopathies or diseases. LV geometry, function, and LV global strains, including peak strain in the radial, circumferential, and longitudinal directions were measured. We evaluated the type of LGE in each RCM patient, which was divided into no-LGE (type 1), local LGE (type 2), and diffuse LGE (type 3). The determinants of reduced LV myocardial strain for all RCM patients were assessed using multivariable linear regression analyses.

##### RESULTS

Compared with normal controls, both RCM (DM-) and RCM (DM+) patients exhibited increased LV end-diastolic and end-systolic volume index and decreased LV ejection fraction. LV global strains progressively declined from the normal controls to two RCM groups. RCM subgroup analysis showed that LV global longitudinal PS was worse in RCM (DM+) group than in RCM (DM-) group ( $p = 0.014$ ). DM was an independent determinant of reduced LV global longitudinal PS in patients with RCM ( $\beta = -0.208$ ,  $p = 0.018$ ). The LGE type was independently associated with a decreased global longitudinal PS ( $\beta = 0.411$ ,  $p < 0.01$ ) in RCM patients.

##### CONCLUSION

DM has an additive deleterious effect on LV function and deformation in RCM patients. The LGE type and DM were found to be associated with reduced LV global longitudinal strain.

##### CLINICAL RELEVANCE/APPLICATION

Diabetes mellitus can aggravate the left ventricular global strain damage in patients with restrictive cardiomyopathy without heart failure, so the control of diabetes mellitus should be strengthened

#### **R2-SPCA-2 Could Coronary Artery Calcium Score be a Reliable Predictor of Coronary Artery Stenosis in Women?**

##### Participants

Yuval Liberman, MD, Boston, MA (*Presenter*) Nothing to Disclose

##### PURPOSE

Coronary Artery Calcium Score (CACS) has been widely used to predict coronary artery disease (CAD) risk in both men and women. However, due to physiological differences between these two groups, more studies are needed to assess CACS thresholds for suspected CAD in women. This study aims to evaluate the predictability of CACS for determining CAD with  $\geq 50\%$  stenosis in women and to explore the impact of age and CACS threshold selection on its predictive performance.

##### METHODS AND MATERIALS

The study was approved by the hospital IRB. We reviewed all female patients who underwent CCTA for coronary artery disease (CAD) assessment (including CACS) between 01/01/2006 - 12/31/22 in tertiary medical center. CACS was assessed according to Agatston score. SCAS was identified qualitatively on CCTA as  $\geq 50\%$  stenosis using multiplanar curved reconstructions. Correlation between CACS and SCAS was assessed with Pearson correlation. Various CACS cutoff values were used to check the sensitivity and specificity of CACS as predictor for SCAS. Age information was used for multivariate analysis of the accuracy of CACS in predicting SCAS.

##### RESULTS

1378 consecutive female patients ( $62.4 \pm 11.7$  y.o average, min 21, max 93) were included. Average CACS was 194.1 (min 0, max 4130). 381 of the patients had SCAS (27%). Continuous CACS demonstrated a correlation of 0.501 with SCAS. CACS threshold of 100 provided sensitivity of 68.9% and specificity of 88.8%. Increasing the threshold to 400 and 1000 resulted in higher sensitivity (87.3% and 94.8%, respectively) but lower specificity (81.3% and 76.3%, respectively). Optimal performance was achieved with a CACS threshold of 77, providing a sensitivity of 65.5% and specificity of 90.1%. Taking into consideration age and pre/post

menopausal age did not statistically improve the results

## CONCLUSION

s Our study demonstrates the potential of CACS as a non-invasive tool for predicting  $\geq 50\%$  coronary stenosis in women. Optimal performance is achieved with a CACS threshold of 77. Further research is needed to identify additional factors that can enhance the predictability of CACS for stenosis in women.

## CLINICAL RELEVANCE/APPLICATION

Utilizing CACS in women more accurately.

### R2-SPCA-3 Coronary Artery Calcium Score (CACS) vs. CAD-RADS Predictability of Positive Cardiac Catheterization in Pre-Solid Organ Transplant Patients: A Comparative Analysis

Participants

Yuval Liberman, MD, Boston, MA (*Presenter*) Nothing to Disclose

## PURPOSE

The accurate prediction of significant coronary artery stenosis (SCAS) is crucial in the pre-solid organ transplant evaluation process. This study aims to compare the predictability of Coronary Artery Calcium Score (CACS) and CCTA in determining the presence of SCAS ( $\geq 50\%$ ) in pre-solid organ transplant patients, as detected by cardiac catheterization (Cath).

## METHODS AND MATERIALS

This study was IRB approved. All pre-solid organ transplant patients who underwent CCTA for coronary artery disease (CAD) assessment (including CACS) and were sent to Cath between 01/01/2018 - 12/31/22 were reviewed. CACS was assessed according to Agatston score. SCAS was identified as  $\geq 50\%$  stenosis on CCTA. Similarly, Cath was identified as positive if there was a finding of  $\geq 50\%$  stenosis. Correlation between CACS and Cath was assessed, as well as between CCTA and Cath. CCTA and Various CACS cutoff values were used to create predictors for a positive Cath, which were checked for their sensitivity and specificity.

## RESULTS

We analyzed data from 72 pre-solid organ transplant patients who underwent CCTA, CACS, and cardiac catheterization (57 males and 15 females). These patients had an average CACS of 709 (min 0, max 7675) and average CCTA of 2.2. The patients had an average age of  $58.2 \pm 9.8$  (min 37, max 71). Our results showed that CACS had a correlation of 0.35 with positive Cath, while CCTA demonstrated a correlation of 0.31. Using CCTA as a binary predictor of positive Cath resulted in a sensitivity of 46% and specificity of 100%. In contrast, CACS yielded a maximum sensitivity of 83.3% (specificity of 68.3%, threshold 2920) and a maximum specificity of 83.3% (sensitivity of 42%, threshold 45).

## CONCLUSION

s The findings suggest that CACS is a better screening tool for eliminating patients without significant stenosis due to its higher specificity, whereas CCTA serves as a better diagnostic tool due to its higher sensitivity. However, it should be noted that both tools demonstrated only moderate correlations with positive catheterization findings, indicating the need for further research to optimize their performance in this patient population.

## CLINICAL RELEVANCE/APPLICATION

how predictive is calcium score in comparison to ccta of stenosis identified in cath (the gold standard)

### R2-SPCA-4 Improving Spatial Resolution at Coronary CT Angiography on Photon-counting Detector CT: A Structured Phantom Study

Participants

Zhou Yu, Vernon Hills, IL (*Presenter*) Employee, Canon Medical Systems Corporation  
Keiichi Nomura, PhD, Kashiwa, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

The photon-counting detector CT (PCD-CT) features a semiconductor detector. Due to electrical noise cancellation, its high-density detector element yields high-resolution- and low-noise images. We developed a photon-counting detector CT scanner whose detector is made of CdZnTe. Here we evaluate the spatial resolution of PCD-CT using a structured phantom that simulates coronary CT angiographs (CCTA).

## METHODS AND MATERIALS

Our structured phantom for CCTA (Fig.1) uses a 3D printer (KEYENCE Agilista-3200). The vessels were filled with iodine contrast medium diluted to 20 mgI/ml; one simulated coronary artery harbored 70% of one simulated stenotic lesion, another a stent graft (Medtronic, BeStent, 3.0 mm  $\times$  15 mm). We scanned the phantom on a prototype PCD-CT scanner (Canon Medical Systems) in high-resolution mode. The detector element density was approximately three times that of a conventional CT system. The slice thickness was about 0.2 mm, the tube voltage was 120 kV, and the tube current was 250 mA. For comparison, a conventional energy integrating detector CT (EID-CT; Aquilion ONE GENESIS, Canon Medical Systems) was used; the structured phantom was scanned with a scan protocol that resulted in similar radiation exposure. All images were reconstructed with hybrid iterative reconstruction. To evaluate the image quality of the phantom we measured the noise power spectrum (NPS) as a metric of the noise characteristics and the task-based modulation transfer function (MTF) as a metric of the spatial resolution.

## RESULTS

The radiation doses (CTDIvol) were approximately 9.5 mGy. The image noise on PCD-CT scans was almost twice as high as on EID-CT scans (SD: 26.8 v.s. 13.8 HU, Fig. 2 left); the spatial resolution was higher with PCD-CT (10%MTF: 1.05 v.s. 0.75 cy/mm, Fig. 2 right) than EID-CT. Comparison of the images shown in Figs. 3 and 4 confirmed the high spatial resolution on PCD-CT images.

## CONCLUSION

s The high-resolution mode on our PCD-CT scanner yields images of fine structures. It is suitable for examining fine structures

because it significantly improves spatial resolution, its cost is increased noise.

#### **CLINICAL RELEVANCE/APPLICATION**

The high-resolution mode of PCD-CT may facilitate a more precise stenosis evaluation and the assessment of the patency of coronary stent grafts at CCTA.

### **R2-SPCA-5 Comparative Study of One-stop CTA Scan Delay Protocol in TAVI/TAVR Patients**

#### **PURPOSE**

To compare the effect of preoperative CTA examination using bolus testing or bolus tracking delay protocol on image quality in patients with transcatheter aortic valve implantation (TAVI)/transcatheter aortic valve replacement (TAVR).

#### **METHODS AND MATERIALS**

A total of 43 patients with TAVI/TAVR in our hospital were randomly divided into two groups, and performed preoperative one-stop CTA examination using bolus testing and bolus tracking, respectively. After scanning, the CT value and SD value of the aortic root sinus (C1), the proximal left and right coronary arteries (C2, C3), the ascending aorta (A1), the abdominal aorta on the renal artery level (A2), the left and right femoral arteries (A3, A4), and the paraspinal muscles of the same layer were measured, and the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) of the corresponding parts were then calculated. All the parameters were compared both in subjective and objective aspects.

#### **RESULTS**

There was no significant difference in image quality between the two groups in the aortic root sinus (C1), the proximal left and right coronary arteries (C2, C3), and the ascending aorta (A1) ( $P > 0.05$ ). Significant differences were detected in the abdominal aorta at the renal artery level (A2) and the left and right femoral artery levels (A3, A4) ( $P < 0.05$ ) in terms of image quality.

#### **CONCLUSION**

Compared with bolus tracking, the preoperative one-stop CTA examination using bolus testing in TAVI/TAVR patients showed better image quality in the aortic artery below the renal artery level and the femoral artery.

#### **CLINICAL RELEVANCE/APPLICATION**

the preoperative one-stop CTA examination using bolus testing in TAVI/TAVR patients showed better image quality in the aortic artery below the renal artery level and the femoral artery.

### **R2-SPCA-6 Deep Learning Image Reconstruction Algorithm and Second-generation Motion Correction Algorithm Improve Dosage Saving and Diagnostic Performance of Coronary CT Angiography with Patients after Percutaneous Coronary**

#### **PURPOSE**

To investigate the image quality and diagnostic value of low-dose coronary CT angiography (CCTA) with deep learning image reconstruction algorithm (DLIR) and second-generation motion correction algorithm (SSF2) compared with conventional-dose CCTA with high-definition (HD) mode assisted by adaptive statistical iterative reconstruction Veo algorithm (ASIR-V) and first-generation motion correction algorithm (SSF) in coronary in-stent restenosis (ISR).

#### **METHODS AND MATERIALS**

A total of 105 patients after Percutaneous coronary intervention (PCI) who received CCTA and invasive coronary angiography (ICA) were prospectively collected and randomly divided into two groups: 60 patients in 100kVp low-dose group (LD group) reconstructed with high-grade DLIR (DLIR-H) and second-generation motion correction algorithm (SSF2), and 45 patients in 120kVp conventional-dose group reconstructed with high-definition mode (HD group) assisted by ASIR-V 50% and first-generation motion correction algorithm (SSF1). Radiation dose and contrast media dose, objective image quality including CT value, image noise (SD), signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) for vessels, as well as subjective image quality parameters with Likert 5-level scoring method were assessed. Moreover, based on the ICA results, we compared the diagnostic performance of these two groups at patient level and stent level.

#### **RESULTS**

With 58.2% radiation dose reduction and 22.5% contrast media reduction, 100kVp LD group assisted with DLIR and SSF2 could achieved even better objective and subjective image quality scores than the 120kVp HD group assisted with HD mode assisted with ASIR-V 50% and SSF. To be specific, SD in AO, LM, LAD, LCX and RCA in LD group was significantly lower than those in HD group (all  $p < 0.05$ ). SNR and CNR in all vessels in LD group were significantly higher than those in HD group (all  $p < 0.05$ ). The subjective image quality scores of the LD group were better than those of the HD group (all  $P < 0.001$ ). The sensitivity, specificity and accuracy of LD group and HD group for diagnosing coronary ISR were 100.0%, 92.1%, 94.2% and 100.0%, 77.9% and 83.8%, respectively, and the number of false positive cases in the DLIR group decreased by 19.2%.

#### **CONCLUSION**

Compared with conventional-dose CCTA with HD mode assisted by ASIR-V and SSF1, 58.2% dose reduction and 22.5% contrast media reduction CCTA with DLIR and SSF2 could further improve the image quality and diagnostic performance in coronary ISR.

#### **CLINICAL RELEVANCE/APPLICATION**

It can effectively reduce the radiation dose while improving the quality of CCTA images, and has a high diagnostic efficiency for ISR, which has good clinical application value.

## Abstract Archives of the RSNA, 2023

R2-SPCH

### Chest Imaging Thursday Poster Discussions

#### Sub-Events

#### **R2-SPCH-1 AI-based Diagnosis of Incidental Pulmonary Embolism (PE) on Contrast-enhanced CT Images: A Multi-center Study**

##### Participants

Roshan Fahimi, MD, Cambridge, MA (*Presenter*) Nothing to Disclose

##### PURPOSE

Unsuspected, incidental PE on routine, contrast-enhanced chest CT can be overlooked and missed. We performed a standalone, multicenter, external validation study of an AI algorithm for detecting incidental PE on routine contrast-enhanced chest CT.

##### METHODS AND MATERIALS

Our IRB approved study included 432 patients from four hospitals (two quaternary and two community hospitals) with a mean age of  $56 \pm 12$  years and a female-to-male ratio of 248:184. We used a radiology reports database search engine (Nuance mPower) to identify routine contrast-enhanced CT examinations with and without incidental PE. CT images with section thickness  $<1.5$  mm were deidentified and exported from Visage PACS. All CT exams were processed with an AI algorithm (Cina, Compose, Avicenna Inc.) for triage (CE and FDA cleared) and detection of incidental PE on routine contrast enhanced chest CT. We assessed the model performance the area under the curve (AUC) of the receiver operating characteristic (ROC) curve and calculated sensitivity and specificity with SPSS (IBM).

##### RESULTS

The AI algorithm had an overall AUC of 0.86 (95%CI 0.94-0.78) and accuracy of 0.88 for diagnosing incidental PE on routine chest CT. When stratified by sex, the AUC was 0.83 (95%CI 0.95-0.71) for females and 0.92 (95%CI 0.99-0.83) for males. There were no significant inter-institutional variations in model performance across the four sites ( $p>0.1$ ). When stratified by age, the AUC was 0.85 (95%CI 0.98-0.72) for patients  $\leq 60$  years and 0.89 (95%CI 0.98-0.80) for  $> 60$  years, with specificities of 0.91 and 0.93 and sensitivities of 0.80 and 0.87. There were no significant differences among scanners from two main vendors in terms of model AUC, sensitivity, and specificity (GE: 0.85 [95%CI 0.70-0.99], 0.75, 0.96; Siemens: 0.88 [95%CI 0.78-0.98], 0.85, 0.92) ( $p>0.1$ ).

##### CONCLUSION

The assessed AI algorithm was generalizable across different imaging sites, patients gender, age, and scanner vendors for detection of incidental PE on routine contrast-enhanced chest CT.

##### CLINICAL RELEVANCE/APPLICATION

The assessed AI algorithm can help detect incidental PE on routine contrast-enhanced chest CT examination.

#### **R2-SPCH-2 Three-dimensional Growth Mapping in Subacute Type B Aortic Dissection Predicts Long-term Outcomes**

##### Participants

Prabhvir Marway, BA, MBChir, Ann Arbor, MI, MI (*Presenter*) Nothing to Disclose

##### PURPOSE

Aneurysmal degeneration of the false lumen (FL) is a common complication of Type B aortic dissection (TBAD) often requiring surgical repair. Prophylactic endovascular repair (TEVAR) can prevent FL aneurysm, but early identification of high-risk patients is challenging. Subacute FL growth may predict late adverse events (LAE) but detecting small changes (1-3 mm) is hampered by measurement error. Vascular deformation mapping (VDM) is an emerging CT analysis technique that provides highly accurate 3D maps of aortic growth using routine clinical CTs. We hypothesized that early identification of FL growth by VDM within 3 months post-TBAD can more accurately identify patients at risk of LAE versus standard CT measurements.

##### METHODS AND MATERIALS

We performed a retrospective study (2005-2018) of adult patients with acute, uncomplicated TBAD, with high-quality CT angiograms (CTA) pre-discharge and at 1-3 months post-discharge. Exclusions included: Prior repair of the descending aorta; poor FL enhancement OR complete FL thrombosis. VDM analysis used a multi-step deformable image registration process after semi-automated segmentation. Quantitative growth data from the descending thoracic aorta was extracted from VDM, and 90th percentile radial values were used for analysis. Standard CT measures were collected by expert raters: maximal diameter; proximal tear size; tear distance from the left subclavian artery (LSC). LAE were defined as aneurysmal growth of the dissected aorta  $>55$ mm, rupture, and surgical repair of TBAD.

##### RESULTS

Among the 33 patients analyzed, 22 (66%) had LAE. There was no significant difference in follow-up period ( $6.3 \pm 2.7$  vs.  $6.3 \pm 4.0$

years,  $p = 0.99$ ), or time between scans ( $45 \pm 17$  vs.  $46 \pm 29$  days,  $p = 0.88$ ). Based on clinically reported measurements (chart review), there were no significant predictors of LAE by anatomic metrics: maximal diameter ( $42.8 \pm 7.4$  vs.  $39.4 \pm 6.2$ mm,  $p = 0.20$ ), change in maximal TBAD diameter by clinical measurements between scans ( $3.3 \pm 4.2$  vs.  $2.2 \pm 5.3$ mm,  $p = 0.54$ ), and LSC to proximal tear distance ( $51.8 \pm 62.9$  vs.  $41.6 \pm 76.8$ mm,  $p = 0.70$ ). However, VDM identified higher growth in the LAE group compared to the no AE group ( $3.7 \pm 2.8$ mm vs  $1.0 \pm 0.8$ mm,  $p = 0.006$ ). Most (68%) patients in the LAE group had a maximum baseline diameter of = 40mm, compared to 45% in the no AE group ( $p = 0.20$ ).

## CONCLUSION

s 3D growth mapping (VDM) using routine CTA images can detect subacute FL growth that is largely missed by clinical CT diameter measurements. Small growth (>2 mm) 1-3 months post-TBAD can identify patients at high risk of late adverse events.

## CLINICAL RELEVANCE/APPLICATION

Even small aortic growth (>2 mm) can be mapped over a short CT interval using an image analysis technique called VDM, identifying TBAD patients at high risk of late adverse events.

## R2-SPCH-3 A Preliminary Study on the Reduction of Radiation Dose in CT Pulmonary Arterial Imaging with the Combination of the Dual-energy Spectral and ASIR-V Presets for Scan Technique

### PURPOSE

To explore the feasibility of reducing radiation dose in dual-energy spectral CT pulmonary artery imaging by using the ASIR-V presets for scan option.

### METHODS AND MATERIALS

44 patients for dual-energy spectral CT pulmonary artery imaging (CTPA) were prospectively divided into 2 groups. Group A (n=18) used the spectral CT imaging mode without the ASIR-V preset (0%), while Group B (n=26) used the spectral CT imaging mode with ASIR-V 50% preset for scanning. Both groups used a contrast agent with iodine concentration of 350mg/ml, with a dosage of 15-20ml and a flow rate of 4-4.5ml/s. Images at the 60keV were reconstructed by default using ASIR-V at 50% for reconstruction and used for analysis. Using the independent samples t-test to compare pulmonary CT value and image background noise, the signal-to-noise ratio (SNR), contrast to noise ratio (CNR), Volume CT dose index (CTDIvol), Dose length product (DLP) and the effective dose and effective dose (ED) between group A and group B. Two senior physicians evaluated the subjective image quality for the two groups, and the Mann-Whitney U test was used to compare the differences in subjective scores between the two groups.

### RESULTS

There was no difference in the gender, age, height, weight and BMI of the two groups ( $P > 0.05$ , table 1). There was no significant difference for the CT values and the SD values of the 60keV monochromatic images between the two groups ( $P > 0.05$ , table 2). However, the CTDI, DLP and ED values in group A were significantly higher than those of group B, with statistically significant difference ( $P < 0.05$ , table 2). For the subjective evaluation: the image noise of group A was higher, and the score was slightly lower than in group B, but the difference was not statistically significant.

## CONCLUSION

s Dual-energy spectral CT with ASIR-V preset for scan can achieve image quality comparable to that of the routine spectral imaging protocol in CTPA with the added benefit of reducing dose requirement.

## CLINICAL RELEVANCE/APPLICATION

The use of energy spectrum combined with Pre-ASIR-V iterative reconstruction technology can reduce the radiation dose received by every CTPA patient and ensure the safety of patients.

## R2-SPCH-4 Real-world Performance of an AI-based Algorithm for Pulmonary Embolism Detection at Several Emergency Departments

Participants

Sarah Quenet, MD, La Ciotat, France (*Presenter*) Employee, Avicenna.ai

### PURPOSE

The integration of artificial intelligence (AI) in clinical routine allows accurate diagnosis and may ultimately improve patients' outcome of life-threatening conditions such as pulmonary embolism (PE). However, the accuracy needs to be constantly evaluated. This study aims to analyze the real-world performance of an FDA-cleared and CE-marked AI-based software designed to detect PE on chest computed tomography angiograms (CTAs) at a large emergency teleradiology network.

### METHODS AND MATERIALS

CTAs from patients admitted to several emergency departments (ED) from June 2022 to March 2023 and received by a teleradiology company (Telediag, Lyon, France) for clinical interpretation were retrospectively analyzed. CINA-PE v1.0.3 (Avicenna.AI, La Ciotat, France), an AI-powered algorithm designed to flag acute suspected PEs up to the segmental level, was already integrated into the clinical workflow. Only the scans automatically processed by the device were included in the study. A board-certified senior thoracic radiologist, not blinded to any clinical information, randomly reviewed 5% of the CTAs and their radiological reports, as part of the company's quality control program. The AI-device results were compared to the expert's interpretation, defined as the ground truth. The sensitivity, specificity, PPV and NPV were calculated. Furthermore, the potential causes of false positives (FP) and false negatives (FN) were analyzed.

### RESULTS

A total of 295 scans (mean age:  $66.9$  yo  $\pm 18.5$  [SD]; 47.1% male) from 58 ED were reviewed. Among the 34 exams identified as positive for PE by the expert, the device correctly identified 29, yielding a sensitivity of 85.3% [95% CI: 68.9% - 95.1%]. Similarly, 250 out of 261 were correctly identified as negative for PE (specificity of 95.8% [95% CI: 92.6% - 97.9%]). The PPV and NPV were 72.5% and 98.1%, respectively. All the missed PEs (5 FN) were located at the segmental level. The 11 FP had confounding conditions such as bronchiolitis (n=3), pulmonary edema (n=1), lymphadenopathy (n=1), fibrosis (n=1), vena cava artifacts (n=1), overlapping pulmonary vein and artery (n=1), pleuritis (n=1) and unknown (n=2). In addition, the dataset included 2 PEs at the

subsegmental level that were considered as negative cases because the algorithm is not intended to detect them.

## CONCLUSION

s The AI-based algorithm, tested on real-world data from several ED, demonstrated high accuracy for PE detection. These results suggest that the integration of AI into daily practice may help optimize the clinical workflow providing a faster and accurate diagnosis.

## CLINICAL RELEVANCE/APPLICATION

This study provides insight into the high performance of an AI-based algorithm in real clinical routine, tested on heterogeneous data from several clinical sites.

## R2-SPCH-5 Unenhanced MR Angiography and V/Q Scan for the Detection of Pulmonary Embolism: Systematic Review and Meta-analysis

Participants  
Stephan Altmayer, PhD, Stanford, CA (*Presenter*) Nothing to Disclose

## PURPOSE

Our purpose was to conduct an updated meta-analysis to compare the diagnostic performance of unenhanced magnetic resonance angiography (MRA) and ventilation/perfusion (V/Q) scintigraphy in the diagnosis of acute pulmonary embolism (PE).

## METHODS AND MATERIALS

Systematic searches of PubMed, Embase, Scopus, BVS, Web of Science, and Cochrane databases were conducted through April 2023. The inclusion criteria of our study required the evaluation of the performance of unenhanced MRA and V/Q scintigraphy for the detection of acute pulmonary embolism using computed tomography pulmonary angiography (CTPA) as the reference standard. We excluded studies in which CTPA was performed more than 30 days after the MRA or V/Q scan.

## RESULTS

A total of 1695 studies were identified through systematic searches, with seven studies meeting inclusion criteria. The results showed that unenhanced MRA had a pooled sensitivity of 0.87 (95% CI 0.82 - 0.91) and specificity of 0.96 (95% CI 0.93 - 0.98), with no statistically significant heterogeneity. The pooled summary receiver operating characteristic (SROC) curve for unenhanced MRA yielded an AUC of 0.92 (95% CI 0.85 - 0.96). On the other hand, V/Q scanning had a pooled sensitivity of 0.81 (95% CI 0.76 - 0.85) and specificity of 0.84 (95% CI 0.74 - 0.91), with statistically significant heterogeneity for both sensitivity and specificity. The selected studies were assessed using the revised QUADAS-2 tool, and all studies were considered to have a relatively low risk of bias.

## CONCLUSION

s Unenhanced MRA has a comparable if not superior diagnostic accuracy compared to V/Q perfusion scan for the detection of pulmonary embolism.

## CLINICAL RELEVANCE/APPLICATION

Unenhanced MRA for at least similar if not superior diagnostic performance compared to V/Q scan without the need for contrast agents, exposure to radiation, and contraindication in patients with known lung parenchymal abnormality.

## R2-SPCH-6 CT-defined Low-skeletal Muscle Mass and Muscle Density are Related with Mortality in Acute Pulmonary Embolism: A Multicenter Analysis

## PURPOSE

Computed tomography (CT) defined muscle mass can be used as a surrogate parameter for sarcopenia. The present study used thoracic CT to assess pectoralis muscle area and density as an imaging biomarker for prognosis of 30-day mortality in patients with acute pulmonary embolism (PE)

## METHODS AND MATERIALS

The clinical database was retrospectively screened for patients with thoracic CT in 3 centers. Pectoralis musculature was measured on axial slices of the thoracic CT at the level of T4 of contrast enhanced pulmonary angiography CT. Skeletal muscle area (SMA), skeletal muscle index (SMI), muscle density and gauge were calculated.

## RESULTS

Overall, 981 patients (440 female, 44.9%) with a mean age of  $63.5 \pm 15.9$  years were included into the study and 144 patients (14.6%) died within the 30-days period. Every pectoral muscle value was higher in survivors compared to non-survivors (exemplarily for SMI  $9.9 \pm 3.5$  cm<sup>2</sup>/m<sup>2</sup> versus  $7.8 \pm 2.6$  cm<sup>2</sup>/m<sup>2</sup>,  $p < 0.001$ ). Moreover, 91 patients were defined as hemodynamically instable (9.3%). Comparable, every pectoral muscle parameter was higher in patients with hemodynamically stable course compared to instable course. Different muscle variables are related to 30-day mortality: SMA, OR = 0.94 (95%CI = (0.92; 0.96),  $p < 0.001$ ); SMI, OR = 0.78 (95%CI = (0.72; 0.84),  $p < 0.001$ ); muscle density, OR = 0.96 (95%CI = (0.94; 0.97),  $p < 0.001$ ); muscle gauge OR = 0.96 (95%CI = (0.94; 0.99),  $p < 0.001$ ). SMI and muscle density were independently associated with 30-days mortality: SMI, OR = 0.81 (95%CI = (0.75; 0.88),  $p < 0.001$ ); muscle density: OR = 0.96 (95%CI = (0.95; 0.98),  $p < 0.001$ ).

## CONCLUSION

s Parameters of the pectoralis musculature are associated with 30-day mortality in patients with acute PE. These findings should lead to an independent validation study and ultimately to the inclusion into clinical routine as a prognostic factor.

## CLINICAL RELEVANCE/APPLICATION

Pectoralis muscle is a potential important imaging biomarker, which can be easily quantified in clinical routine. There was an association with 30-day mortality in patients with acute PE.

## R2-SPCH-7 PURPOSE

## Improved Quantification and Prognostication of Lung Disease on CT in Pulmonary Hypertension by Combining the Strengths of Deep Learning and Radiologists: A Retrospective Multicentre Study with External Validation

Gold standard for Computed Tomography (CT) lung disease quantification is visual assessment by specialist radiologists. Due to overlapping characteristics, distinguishing between Idiopathic Pulmonary Arterial Hypertension (IPAH) and PH associated with Lung Disease (PH-LD) is challenging in patients with 'mild' lung disease. A new IPAH lung disease sub-phenotype has been recently identified. Accurate diagnosis is vital, as therapeutic agents are only indicated in IPAH. CT imaging is routinely performed, but its prognostic impact is not well understood. This retrospective multicentre study deploys an artificial intelligence (AI) model to quantify the prognostic value of CT lung parenchymal patterns in a combined approach with radiological reporting.

### METHODS AND MATERIALS

521 consecutive IPAH and PH-CLD patients with incident CT imaging between 2001-19 were included from the ASPIRE registry. A DenseNet121 and nnU-net AI model with AUC 0.94 on external testing quantified the percentage of normal lung, ground glass, ground glass with reticulation (GGR), emphysema, honeycombing and fibrosis. Fibrosis severity was scored by sub-specialist radiologists. Multivariate cox regression adjusting for age, sex, WHO function class, pulmonary vascular resistance (PVR) and diffusing capacity of carbon monoxide (DLCO) was performed. Findings were externally validated in 246 patients.

### RESULTS

AI quantified fibrosis was a significant predictor independent of age, sex, WHO FC, PVR and DLCO in the internal (HR 1.01 per one percentage point,  $p=0.043$ ) and external (HR 1.03,  $p=0.006$ ) cohorts. In sub-group of patients scored by radiologists as having 'no' fibrosis, AI identified minor (1%) fibrosis, which was of prognostic (HR 1.03,  $p=0.004$ ) significance. Adding AI quantified fibrosis to a predictive model of radiologically scored disease and patient demographics significantly improved its predictive strength (c-index 0.763 vs 0.742,  $p=0.038$ ).

### CONCLUSION

AI quantified parenchymal patterns are prognostic markers for survival, independent of age, sex, WHO function class, disease severity (PVR) and DLCO. This is the largest AI study in this domain and first with external validation (246 patients, 33 centres, 37 scanners). AI is sensitive to minor lung disease, and when used in combination with radiological reporting, provides additional predictive value. These findings have implications for phenotyping, radiological reporting, and therapeutic decisions.

### CLINICAL RELEVANCE/APPLICATION

This study demonstrates the strength of combining radiological reporting and automated quantitative AI models together to improve patient outcomes. This approach will aid in identifying PH phenotypes and identify new phenotypes based on lung disease severity.

## R2-SPCH-8 Artificial Intelligence Algorithms for Incidental Pulmonary Embolism Detection: A Systematic Review and Meta-analysis

### PURPOSE

In patients with suspected pulmonary embolism (PE) who undergo chest CT angiogram (CTA), the efficacy of artificial intelligence (AI) algorithms for PE detection has been well established. However, less is known about the use of AI algorithms for detection of incidental PE on imaging ordered for reasons other than suspected PE. The purpose of this study is to evaluate the use of AI algorithms for detection of incidental PE.

### METHODS AND MATERIALS

We performed a comprehensive literature search using PubMed, Embase, and Web of Science databases from inception to 2/25/2023, for all studies that assess an AI algorithm for detection of incidental PE. Pooled sensitivity, specificity, and the corresponding 95% CI were calculated using the random effect model. Heterogeneity was assessed using the Higgins I<sup>2</sup> index.

### RESULTS

A total of four studies, including 19,440 CT scans were included in the analysis. The pooled sensitivity of the artificial intelligence algorithms for the detection of incidental PE was 0.839 (95% CI:0.637-0.939, I<sup>2</sup>: 88.23%) and the pooled specificity was 0.999 (95% CI: 0.996-1.000, I<sup>2</sup>: 82.51%).

### CONCLUSION

Our meta-analysis demonstrated that AI algorithms can detect incidental PEs on CT scans with good sensitivity and excellent specificity. Such algorithms can potentially be used as screening tools or second readers for detection of PEs on non-CTA imaging. Further large-scale studies are necessary to validate our findings.

### CLINICAL RELEVANCE/APPLICATION

More hospitals are now implementing artificial intelligence and deep learning algorithms to their imaging protocols. It is important to present the overall usefulness of such algorithms as we have done in this study.

#### R2-SPER-1 Dual-Energy CT for Suspected Scaphoid Fractures: Evaluation of a Clinical Implementation

##### Participants

Felix Muller, MD, Herlev, Denmark (*Presenter*) Employee, Siemens AG

##### PURPOSE

In December 2020 we changed the workup of patients with radiographically occult but clinically suspected scaphoid fractures from MRI to dual-energy CT (DECT) using virtual non-calcium images (VNCA). Previous studies have shown similar diagnostic accuracy for MRI and DECT, but we still wanted to investigate if this would lead to overlooked injuries. We also tested a previously proposed threshold level for detection of traumatic bone marrow edema on VNCA images.

##### METHODS AND MATERIALS

Patients were eligible for inclusion if they had received a DECT scan of the wrist with a clinical suspicion of a scaphoid fracture after a radiograph during the first 6 month of implementation. We excluded patients with known scaphoid or other fractures. All patients were scanned on a second or third generation dual-source CT scanner with a tube voltage combination of 80 kV / 140kV or 80kV / 150kV with use of tin filtration. VNCA images were available to the reading on-call radiologists. Definite or possible radius or scaphoid fractures as noted in the radiological report were recorded. We then audited the electronic health record and PACS for any follow up visit or radiological imaging of the wrist for a period of 12 months after the trauma for identification of scaphoid fractures, other fractures or soft tissue injury. Patient with scaphoid or radius fractures were selected for quantitative image analysis compared to patients without as a control group. Areas in the VNCA image above -40HU were color-coded for the automatic detection of fracture associated bone marrow edema.

##### RESULTS

Of 322 identified patients 87 were excluded. Of the 235 included patients (214 adults, 21 Children) 8.5% (20/235) had a scaphoid, 17% (40/235) a radius, and 19.1% (45/235) other fractures. We found no patients with overlooked scaphoid fractures during the follow-up period. Three patients presented with a new wrist trauma and were diagnosed with an avulsion from the scaphoid, a radius fracture and a scapholunate dissociation. Two patients were diagnosed with ulnar collateral ligament injury on clinical follow-up examination. VNCA cutoff of -40HU had a sensitivity and specificity of 100% (95% CI 83%-100%) and 96% (95% CI 79%-100%) for radius fracture and 100% (95% CI 59%-100%) and 92% (95% CI 78%-98%) for scaphoid fracture detection.

##### CONCLUSION

We find no evidence that a DECT based scaphoid fracture workup leads to overlooked scaphoid fracture. VNCA values above -40HU were highly sensitive and specific for the detection of fracture associated bone marrow edema.

##### CLINICAL RELEVANCE/APPLICATION

Implementation of DECT based scaphoid fracture detection is safe and quantitative assessment of virtual non-calcium images can assist radiologists in the detection of radiographically occult fractures.

Printed on: 04/12/24

### Gastrointestinal Imaging Thursday Poster Discussions

#### Sub-Events

#### R2-SPGI-1 Comparison of Split Bolus Dual Energy CT and Multiphase Dual Energy CT in Assessing Vascular Invasion in Patients with Biliary Malignancies: A Randomized Study

#### PURPOSE

To compare image quality, definition of vascular invasion and radiation dose of split bolus dual energy CT (DECT) with multiphase DECT in biliary malignancies.

#### METHODS AND MATERIALS

This prospective single centre approved study included 88 patients of gallbladder cancer and hilar cholangiocarcinoma randomized into two groups and scanned on rapid-switching DECT scanner. Patients in group 1 (n=43, mean age: 54.6 years, 12 men) were scanned with multiphase protocol (MPP; arterial, venous, delayed phases in DECT) and those in group 2 (n=45, mean age: 52.6 years, 20 men) with split bolus protocol (SBP; split-bolus, delayed phases in DECT). For both groups, virtual monoenergetic images (VMI) were generated at 50 and 70 keV. Mean attenuation, contrast to noise ratio (CNR) and signal to noise ratio (SNR) of tumor, liver and hepatic vessels were assessed in each phase and VMI and were compared between the two groups along with dose length product and volumetric CT dose index. Two readers independently assessed subjective image quality and vascular invasion (5 point Likert scale) in each phase (MPP and SBP) and inter-reader agreement was compared within groups. Mann Whitney U-test and kappa statistics were used for comparison and  $p < .05$  was considered significant.

#### RESULTS

Arterial phase of group 1 had significantly higher attenuation, CNR and SNR of arteries compared to SBP (for both 50 and 70 keV) of group 2 ( $p < .001$ ). However, venous phase of group 1 had significantly poorer attenuation, CNR and SNR for arteries compared to SBP (both VMI) ( $p < .001$ ). Quantitative parameters for veins and tumor between venous phase (group 1) and SBP (group 2) were comparable. Good-to-strong inter-reader agreement ( $k=0.45$  to  $0.75$ ) for image quality for both protocols was observed. For hepatic arterial invasion, SBP had significantly higher inter-reader agreement ( $k=0.71$ ) compared to arterial phase of MPP ( $p < .001$ ). For arterial invasion, 32% and 24% of images of group 1 could not be assessed by reader 1 and 2 respectively, compared to 8% and 6%, respectively in group 2 ( $p < .001$ ). Venous invasion was comparable between the two readers. 50 and 70 KeV VMI were comparable for staging of vascular invasion for both readers. MPP had 37% higher radiation dose than SBP ( $p < .001$ ).

#### CONCLUSION

Image quality of SBP is non-inferior to MPP for biliary malignancies. However, SBP showed significantly better inter-observer agreement for arterial invasion indicating better assessment of vascular involvement with significantly lower radiation dose.

#### CLINICAL RELEVANCE/APPLICATION

Biliary malignancies are better defined in venous phase in which arteries are indistinct, making arterial invasion assessment tough. SBP overcomes this by clearly depicting arteries and tumor in same phase for confident assessment.

#### R2-SPGI-3 Sarcopenia During Neoadjuvant Chemotherapy and its Effect on Survival in Gastroesophageal Adenocarcinomas

#### Participants

Clarissa Hosse, Berlin, Germany (*Presenter*) Nothing to Disclose

#### PURPOSE

Gastroesophageal adenocarcinomas are one of the most prevalent types of cancer worldwide and their incidence has been increasing over the last few decades. Despite advances in treatment, the survival rate remains low, with less than 30% of patients surviving beyond five years. Patients suffer from dysphagia, weight loss and often present with sarcopenia, a progressive muscle loss associated with both age and cancer. Sarcopenia has been gaining attention as a prognostic factor in cancer, mainly focusing on surgical patients. Its prognostic power for patients who receive multimodal treatment, however, remains unclear. This study aimed to investigate the effect of changes in muscle mass on patients with gastroesophageal adenocarcinomas who received neoadjuvant chemotherapy before surgical resection. The study focused on overall survival (OS), disease-free survival (DFS), and length of stay (LOS) after curative resection as the endpoints.

#### METHODS AND MATERIALS

We collected retrospective data from 146 patients treated between 2010 and 2020. We used a fully automatic "AI body composition analysis software" to measure the lumbar skeletal muscle index (LSMI) on CT scans taken before and after neoadjuvant chemotherapy to evaluate sarcopenia. We defined sarcopenia as  $LSMI < 38.5 \text{ cm}^2/\text{m}^2$  (female) and  $< 52.4 \text{ cm}^2/\text{m}^2$  (male). The primary outcome was OS, and the secondary outcomes were DFS and LOS after curative resection. We conducted Kaplan-Meier analyses for survival and tested with Log-Rank.

#### RESULTS

The median OS was 82.13 months (95% CI [64.22 - 10.05]), with 32 recorded deaths (21.9%). The median skeletal muscle loss during neoadjuvant chemotherapy was 2.79%. Although any loss of skeletal muscle during neoadjuvant chemotherapy indicated worse OS, it did not reach statistical significance ( $p = 0.068$ ). LSMI-loss significantly correlated with worse DFS ( $p = 0.028$ ) with a mean of 77.06 months (95% CI [63.03 - 91.09]) without and 47.40 months (95% CI [37.92 - 56.89]) with loss of skeletal muscle mass. It also correlated with LOS ( $p = 0.026$ ) with a median of 12 days (95% CI [11.19 - 12.81]) without and 14 days (95% CI [12.86 - 15.14]) with loss of skeletal muscle mass.

## CONCLUSION

Patients with gastroesophageal adenocarcinomas undergoing neoadjuvant chemotherapy before surgery are at risk of skeletal muscle loss associated with adverse outcomes. While further studies are needed, loss of skeletal muscle mass during treatment, rather than sarcopenia at any timepoint, has the potential to become a prognostic marker and target for interventions.

## CLINICAL RELEVANCE/APPLICATION

Using AI body composition analysis techniques to find individual prognostic markers for patients with cancer

### R2-SPGI-4 Assessment of Predictive Efficacy of Microvascular Invasion in Hepatocellular Carcinoma Based on Preoperative Clinical Variables and Radiological Findings

#### PURPOSE

Microvascular invasion (MVI) is one of the most important risk factors for poor prognosis in hepatocellular carcinoma (HCC) patients, but there remains a lack of reliable and effective noninvasive preoperative prediction methods. Therefore, we aimed to analyze preoperative clinical data and MRI features in HCC patients and construct a clinical-radiological model to predict MVI in HCC.

#### METHODS AND MATERIALS

One hundred and sixty-one patients with pathologically confirmed HCC in our hospital were retrospectively recruited from January 2017 to May 2022 and randomly divided into training and validation sets at a ratio of 7:3 (training set: validation set = 112:49). The patients' preoperative clinical data and MRI features were collected. Independent predictors of MVI were explored by univariable and multivariable logistic regression analysis in the training set. The best variables combination was enrolled into the clinical-radiological model for predicting MVI by the Akaike Information Criterion (AIC). Furthermore, the model was validated in the validation set, and the performance of the model was evaluated by the area under the receiver operating characteristic curve (AUC).

#### RESULTS

Univariable logistic regression analysis showed that elevated alpha fetoprotein (AFP) levels, maximum tumor diameter, non-smooth tumor margin, arterial hyperenhancement, nonperipheral washout, peritumoral arterial enhancement, peritumoral hypointensity on hepatobiliary phase, mosaic sign, intratumoral hemorrhage and intratumoral necrosis were predictors of MVI ( $P < 0.05$ ). Multivariable logistic regression analysis revealed non-smooth tumor margin (OR = 4.036, 95%CI = 1.419-12.25,  $P = 0.01$ ) and peritumoral hypointensity on hepatobiliary phase (OR = 3.217, 95%CI = 1.102-10.038,  $P = 0.036$ ) were independent predictors of MVI. Finally, non-smooth tumor margin, peritumoral hypointensity on hepatobiliary phase, AFP > 400 ng/mL, peritumoral arterial enhancement, and intratumoral necrosis were included into the clinical-radiological model for predicting MVI. The AUC (95% CI) of the model were 0.824 (0.748-0.900) on the training set and 0.754 (0.619-0.890) on the validation set.

## CONCLUSION

The clinical-radiological model based on preoperative clinical data and imaging features showed a good predictive performance for MVI.

## CLINICAL RELEVANCE/APPLICATION

We hope to provide non-invasive imaging biomarkers for the prediction of MVI for hepatocellular carcinoma through the clinical-radiological model based on preoperative clinical data and imaging features.

### R2-SPGI-5 A Fusion Model of Clinical-radiological-radiomics to Predict Microvascular Invasion of Hepatocellular Carcinoma

#### PURPOSE

To construct a fusion model of clinical-radiological-radiomics in predicting MVI of HCC, and find its independent risk factors.

#### METHODS AND MATERIALS

The radiomics score of the optimal model was classified into binary data named radiomics signatures (Radiomics signature, RS) based on the appropriate cut-offs corresponding to maximal Youden index, and the variables in the clinical-radiological model and RS were included into a multivariable logistic regression analysis to construct a clinical-radiological-radiomics fusion model, which was visualized by a nomogram. The performance of the fusion model was evaluated by using receiver operating characteristic analysis, calibration curves, HL goodness-of-fit test and decision curves. Furthermore, univariable and multivariable logistic regression analysis for the included variables were used to find independent risk factors for MVI.

#### RESULTS

The AUC (95% CI) for the fusion model was 0.875 (0.81-0.941) and 0.82 (0.704-0.936) on the training and validation sets, respectively, which was higher than that of the clinical-radiological model (DeLong test,  $P = 0.040$  for the training set and  $P = 0.036$  for the validation set). The calibration curve showed a good agreement for the fusion model (HL goodness-of-fit test  $P$ -value > 0.05), and the decision curves indicated that the model had good clinical application value. Multivariable logistic regression analysis showed that RS and peritumoral hypointensity on hepatobiliary phase were independent risk factors for MVI, with odds ratio of 7.111 and 2.986 respectively.

## CONCLUSION

The clinical-radiological-radiomics fusion model can provide individualized risk assessment of MVI in HCC patients and help to develop individualized preoperative treatment strategies; RS and peritumoral hypointensity on hepatobiliary phase were independent

risk factors for MVI.

#### **CLINICAL RELEVANCE/APPLICATION**

We hope to provide non-invasive imaging biomarkers and provide individualized risk assessment for the prediction of MVI for hepatocellular carcinoma through the clinical-radiological-radiomics fusion model.

#### **R2-SPGI-6 CT Radiomics to Predict Prognosis of Gastric Cancer Treated with PD-1/PD-L1 Inhibitor Therapy**

##### **PURPOSE**

To develop and validate personalized radiomics prediction models and assess their predictive efficacy.

##### **METHODS AND MATERIALS**

293 gastric adenocarcinoma patients treated with PD-1/PD-L1 inhibitor therapy at our institution were retrospectively collected and randomized divided into a training set of 206 patients and a validation set of 87 patients. All patients had baseline CT enhanced images and complete follow-up information. Overall survival (OS) and progression free survival (PFS) was regarded as endpoint events, and radiomics features were extracted and screened based on the region of interest (ROI) of tumor and peritumor. Then, LASSO-COX was applied to establish the tumor, peritumor and tumor+peritumor radiomics signature. In training set, the multivariate COX regression was used to constructed the clinical model and the radiomics models, and their prognostic predictive performance were assessed. The risk of patients was stratified using the median predictive value of the optimal radiomics prediction model. Kaplan Meier analysis and Log rank test were used to estimate and compare OS and PFS between low-risk and high-risk patients.

##### **RESULTS**

206 patients had a median OS of 11.0 (6.8-16.9) months and a median PFS of 7.5 (4.1-13.5) months in training set. A tumor+peritumor radiomics model based on distant metastasis, tumor location, CA125, CA199 and tumor+peritumor radiomics signature was developed to predict OS in gastric cancer patients receiving PD-1/PD-L1 inhibitor therapy, and the radiomics model for predicting PFS included age, the thickest diameter of tumor, CA125 and tumor+peritumor radiomics signature. The radiomics model had a good performance in predicting OS and PFS, with a C-index of 0.746 (95% CI: 0.720, 0.772) and 0.726 (95%CI:0.705, 0.746). The patients in high-risk group had a worse prognosis. Time-dependent ROC curves showed the area under the curve (AUC) for predicting 1-year and 2-year OS were 0.828 and 0.873 and AUC for predicting 0.5-year and 1-year PFS were 0.686 and 0.762. Calibration curves showed a high agreement in predicting OS and PFS. DCA showed the tumor+peritumor radiomics model achieve clinical benefit within a large threshold, particularly in predicting the 1-year OS and 0.5-year PFS (threshold probability >20%) for gastric patients receiving PD-1/PD-L1 inhibitor therapy.

##### **CONCLUSION**

The radiomics model based on CT enhanced images had an excellent performance in predicting prognosis of gastric cancer treated with PD-1/PD-L1 inhibitor therapy.

#### **CLINICAL RELEVANCE/APPLICATION**

The radiomics prediction model had a significant clinical application value and is expected to directly screen the clinical benefit populations.

#### **R2-SPGI-7 Evaluation of Programmed Cell Death Ligand 1 Expression in Gastric Cancer by Enhanced CT Parameters**

##### **PURPOSE**

We aimed to explore the correlation between enhanced CT imaging features and programmed cell death ligand-1(PD-L1) expression status in gastric cancer and to evaluate the predictive value of imaging parameters for immunotherapy biomarkers.

##### **METHODS AND MATERIALS**

Patients with gastric adenocarcinoma who underwent abdominal CT three stage enhanced scan and PD-L1 immunohistochemical testing before treatment were retrospectively examined. All diagnoses were confirmed by pathology. According to the expression status of PD-L1, they were divided into positive group(CPS $\geq$ 5) and negative group(CPS<5). Baseline CT imaging features were collected. CT value were collected in the unenhanced(U), arterial(A), venous(V), and delayed(D)phases to further calculate the arterial attenuation and venous attenuation with arterial enhancement fraction(AEF). Diagnostic performances of the different variables were evaluated using receiver operating characteristic(ROC) curve.

##### **RESULTS**

A total of 67patients with gastric adenocarcinoma were included in the study. On abdominal enhancement CT images, the probability of maximum lymph node short diameter>1cm and peak of lesion enhancement occurring in the arterial phase were statistically significant between the two group(p<0.05); Moreover, the AEF was significantly higher in the positive group than in the negative group(p<0.05). And the ROC curve analysis showed that the AEF exhibited a high evaluation efficacy [AUC: 0.724(95%CI: 0.602~0.826)]. The combined model had the best diagnostic efficacy[AUC: 0.786(95%CI: 0.669~0.877), sensitivity: 58.33%; specificity: 88.37%].

##### **CONCLUSION**

There is a correlation between CT imaging features and PD-L1 expression status in gastric cancer, and AEF may help to assess high PD-L1 expression and help to select patients suitable for immunotherapy.

#### **CLINICAL RELEVANCE/APPLICATION**

To explore the value of CT imaging features in evaluating biomarkers for immunotherapy of gastric.

#### **R2-SPGI-8 MRI-traceable Nanoparticles for Integrin Targeted Liver Fibrosis Detection**

Participants

Qihui Hu JR, MD, Hangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

To timely detection and intervention of liver fibrosis are crucial for preventing the progression of the liver disease, we designed an integrin  $\beta 3$  targeted nano-platform (cRGD-PLGA/IONP) based on iron oxide nanoparticles (IONPs) for the detection and grading of liver fibrosis.

## METHODS AND MATERIALS

Preparation of cRGD-PLGA/IONP. The PLGA microcapsules were prepared by the double emulsion process, where superparamagnetic IONPs were introduced into the reaction. cRGD-PLGA/IONP were subsequently characterized by a series of methods. Animal models. C57BL/6 mice received an intraperitoneal injection of 20% CCl<sub>4</sub> (1  $\mu$ g/g) twice weekly for 0, 3, 7, or 11 weeks. MRI protocol. C57BL/6 mice were imaged on a 3.0 T MRI system with animal coils. MR imaging (Discovery 750w, GE Healthcare) was performed at different time points after cRGD-PLGA/IONP, IONP and PBS i.v. injection. Scanning with T2WI and T2 mapping sequences. The T2 and R2 values in various areas of the mice livers at different time points after cRGD-PLGA/IOFA administration were measured and calculated to assess the contrast enhancement.

## RESULTS

Liver fibrosis induction. Immunofluorescence and Sirius staining confirmed the increased protein expression of integrin  $\beta 3$  subunit in aHSCs and the fibrogenic marker  $\alpha$ -SMA with the time of CCl<sub>4</sub> administration, which indicates the animal model was established successfully (Figure 1). cRGD-PLGA/IONP for MRI detection of liver fibrosis. cRGD-PLGA/IONP group demonstrated a contrast enhancement in R2 to 33.9 s<sup>-1</sup> ( $R_2 \sim 4.7$  s<sup>-1</sup>, an approximate 16.2% increase in the liver area) in the early-stage fibrotic liver (Ishak 1). Compared with the control group (Ishak 0), the significantly increased signal ( $R_2$ ) of mice (Ishak 3 and Ishak 5) injected with cRGD-PLGA/IONP were 12.4 (42.5%) and 37.4 (127.9%), and the R2 values were nearly 1.4 and 2.3 times than that of the control group, respectively. (Figure 2a, b). The Fe concentration in mice liver of cRGD-PLGA/IONP group was measured by the inductively coupled plasma-mass spectroscopy. Figure 2c showed that the levels of Fe content in the mice liver were basically consistent with the changes in MRI liver signal values. In contrast, the IONP group did not result in significant signal enhancement at different time points. These results illustrated that cRGD-PLGA/IONP was a highly efficient MRI agent for liver fibrosis diagnosis.

## CONCLUSION

In conclusion, cRGD-PLGA/IONP could perform MRI visualization detection and grading.

## CLINICAL RELEVANCE/APPLICATION

Liver fibrosis is the critical stage in developing chronic liver disease (CLD), from simple and reversible injury to irreversible cirrhosis. A novel contrast agent-enhanced MRI detection is a potential new method for diagnosing liver fibrosis.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

R2-SPGU

### Genitourinary Imaging Thursday Poster Discussions

#### Sub-Events

#### R2-SPGU-1 Development and Validation of a Predictive Model Based on Clinical and mpMRI Findings to Reduce Additional Systematic Prostate Biopsy

##### PURPOSE

To develop and validate a predictive model based on clinical features and multiparametric magnetic resonance imaging (mpMRI) to reduce unnecessary systematic biopsies (SB) in biopsy-naïve patients with suspected prostate cancer (PCa).

##### METHODS AND MATERIALS

274 patients who underwent combined cognitive MRI-targeted biopsy (MRTB) with SB were retrospectively enrolled, and temporally be split into development (n = 201) and validation cohorts (n = 73). Multivariable logistic regression analyses were used to determine independent predictors of clinically significant PCa (csPCa) on cognitive MRTB, and the clinical, MRI and combined models were established respectively. Area under the receiver operating characteristic curve (AUC), calibration plots and decision curve analyses were assessed.

##### RESULTS

Prostate imaging data and reporting system (PI-RADS) score, index lesion (IL) on the peripheral zone, age and prostate specific antigen density (PSAD) were independently predictors and included in the combined model. The combined model achieved the best discrimination (AUC: 0.88) as compared to both MRI model incorporated by PI-RADS score, IL level and zone (AUC: 0.86), and clinical model incorporated by age and PSAD (AUC: 0.70). The combined model also showed good calibration and enabled great net benefit on internal and external validation. Applying the combined model as a reference for performing MRTB alone with a cutoff of 60% would reduce 43.8% of additional SB, whilst missing 2.9% csPCa.

##### CONCLUSION

s The combined model based on clinical and mpMRI findings improved csPCa prediction and might be useful in making a decision about which patient could safely avoid unnecessary SB in addition to MRTB in biopsy-naïve patients.

##### CLINICAL RELEVANCE/APPLICATION

• Age, PSAD, PI-RADS score and index lesion on the peripheral zone were independently predictors of detecting csPCa by cognitive MRTB. • The combined model that incorporated clinical and mpMRI findings achieved best discrimination in predicting csPCa, with satisfactory calibration and net benefit in biopsy naïve patients. • Using the combined model with a cutoff of 60% as an indication of performing MRTB alone would reduce 43.8% of unnecessary SBs, whilst missing 2.9% csPCa.

#### R2-SPGU-2 Readout Segmented Diffusion Weighted Imaging Sequence of Clinical Application in Prostate Cancer and Benign Prostatic Hyperplasia in High b Value

##### Participants

Yang Yang, MMed, Xianyang City, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the readout segmented diffusion weighted imaging sequence (Rs-EPI) ultra high b value used in the diagnosis of prostate cancer and benign prostatic hyperplasia.

##### METHODS AND MATERIALS

37 patients with prostate disease who underwent MR diffusion weighted imaging were enrolled in this study. MR diffusion weighted images were acquired before surgery or biopsy. All data were collected on a MAGNETOM Skyra 3.0T MR scanner (Siemens AG, Erlangen, Germany) with the b value of 0,1000,2000,3000 s/mm<sup>2</sup>. The patients were identified with either prostate cancer (15 cases) or prostate hyperplasia (22 cases) according to pathological results. All images were analyzed by two experienced radiologists blinded to the final result, the signal strength were measured in DWI at the region with higher signal than that in background. The efficacy of parameters for differentiation of prostate cancer was investigated using receiver operating characteristic (ROC) curve.

##### RESULTS

For all the 15 cases of prostate cancer, the signal strength values were significantly higher than those in prostate hyperplasia patients. Overall DW-MRI sensitivity and specificity for tumor detection were 80% and 63.6% with the b value of 1000 s/mm<sup>2</sup>; and they were 93.3% and 68.2% with the b value of 2000s/mm<sup>2</sup>, and 93.3% and 72.7% with the b value of 3000 s/mm<sup>2</sup>. Both the sensitivity and specificity were higher by using ultra-high b value as 3000 s/mm<sup>2</sup>.

##### CONCLUSION

s Rs-EPI with ultra high b value (1000,2000,3000 s/mm<sup>2</sup>) with satisfactory sensitivity and specificity can be used as an important

auxiliary method in the diagnosis of prostate cancer and prostate hyperplasia.

**CLINICAL RELEVANCE/APPLICATION**

Rs-EPI with ultra high b value (1000,2000,3000 s/mm<sup>2</sup>) with satisfactory sensitivity and specificity can be used as an important auxiliary method in the diagnosis of prostate cancer and prostate hyperplasia.

### Head & Neck Imaging Thursday Poster Discussions

#### Sub-Events

#### R2-SPHN-1 **Ultrasound Radiomics Models Based on Multimodal Imaging Feature Fusion of Papillary Thyroid Carcinoma for Predicting Central Lymph Node Metastasis**

##### PURPOSE

This retrospective study aimed to establish ultrasound radiomics models to predict central lymph node metastasis (CLNM) based on preoperative multimodal ultrasound imaging features fusion of primary papillary thyroid carcinoma (PTC).

##### METHODS AND MATERIALS

In total, 498 cases of unifocal PTC were randomly divided into two sets which comprised 348 cases (training set) and 150 cases (testing set). In addition, the independent testing set contained 120 cases of PTC at different times. The presence or absence of CLNM in all the studied cases was confirmed with postoperative pathology. The following steps were used to build models: the regions of interest were segmented in multimodal ultrasound images which contained PTC primary tumors, multimodal (grayscale, color Doppler, strain elastography) ultrasound image features were then extracted by the deep learning residual neural network with 50-layer (ResNet50) network, followed by feature selection and fusion; subsequently, classification was performed using three classical classifiers—adaptive boosting (AB), linear discriminant analysis (LDA), and support vector machine (SVM). Model performances were analyzed in terms of areas under curve (AUC), accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV).

##### RESULTS

The unimodal (grayscale) models (Unimodal-AB, Unimodal-LDA, and Unimodal-SVM) yielded AUCs equal to 0.764, 0.816, and 0.877 (testing set) and 0.724, 0.754, and 0.806 (independent testing set). The multimodal models (Multimodal-AB, Multimodal-LDA, and Multimodal-SVM) yielded AUCs equal to 0.852, 0.865, and 0.910 (testing set) and 0.743, 0.762, and 0.851 (independent testing set). The Multimodal-SVM model achieved the best predictive performance than the other five models ( $P < 0.05$ ) in the testing and the independent testing sets. When the Multimodal-SVM model was applied to the cN0 subgroup cases ( $n = 396$ ) in the main cohort (training and testing sets), the prediction model achieved an AUC of 0.920; in the cN0 subgroup cases ( $n = 100$ ) in the validation cohort (independent testing set), it achieved an AUC of 0.828.

##### CONCLUSION

The ultrasound radiomics model only based on the multimodal ultrasound image of PTC primary tumors have high clinical value in predicting CLNM and can provide a reference for treatment decisions.

##### CLINICAL RELEVANCE/APPLICATION

The ultrasound radiomics model only based on the multimodal ultrasound image of PTC primary tumors have high clinical value in predicting CLNM and can provide a reference for treatment decisions.

#### R2-SPHN-2 **The Effects of Improved Position on Image Quality of CT Scanning of Thyroid**

##### PURPOSE

In this study, we explore the effect of the Improved Swimmer's position on computed tomography (CT) image quality of thyroid, on the radiation dose to patients and the detection rate of thyroid micronodules on CT, using GE Revolution Energy Spectrum CT.

##### METHODS AND MATERIALS

Thyroid examinations with spectral CT were compared for Traditional position group (TDN); Swimmer's position group (SWIM) and Improved Swimmer's position group (I-SWIM). We used subjective grades and objective SNRs and CNRs indicators to assess image quality. Potential confounders, such as Body Mass Index (BMI) and the effective diameter of the neck, were assessed. Patients' radiation exposure was measured by the volume CT dose index (CTDIvol), dose-length product (DLP), and the effective dose of the neck (EDN) and thyroid (EDT). We also evaluate the micronodules detection rate on CT images.

##### RESULTS

Subjective and objective evaluation of thyroid CT image quality were significantly improved in the I-SWIM group compared with SWIM group and TDN group ( $p < 0.001$ ). Although there was no statistically significant difference ( $p = 0.109$ ) in BMI, effective neck diameter and radiation dose received between the groups ( $P > 0.05$ ), there was no significant increase in radiation exposure in the modified swimming position group. There was a significant promotion in micronodules detection of thyroid in the I-SWIM group versus SWIM group and TDN group ( $p < 0.001$ ).

##### CONCLUSION

Based on spectral CT, I-SWIM position improved the image quality of thyroid CT without increasing the radiation exposure of the patients, and increased the detection rate of thyroid micronodules on CT.

## CLINICAL RELEVANCE/APPLICATION

Based on spectral CT, I-SWIM position improved the image quality of thyroid CT without increasing the radiation exposure of the patients, and increased the detection rate of thyroid micronodules on CT.

### R2-SPHN-3 Medium-Term Study Results of Ultrasound-Guided Radiofrequency Ablation for Thyroid Follicular Neoplasm with Low SUV in PET/CT

#### PURPOSE

To evaluate the long-term results of radiofrequency ablation (RFA) of thyroid nodule with cytology of follicular neoplasm with low standard uptake value (SUV) in a positron emission tomography (PET/CT) study.

#### METHODS AND MATERIALS

From January 2018 to January 2021, 40 patients were diagnosed with follicular neoplasm. All patients received ultrasound, fine needle aspiration (FNA) or core needle biopsy (CNB) prior to the treatment. A PET/CT scan was performed in 33 patients prior to treatment. Under local anesthesia, RFA was performed with the use of an RF generator and an 18-gauge internally cooled electrode. Volume changes in nodules on follow-up ultrasonography (US), changes in symptomatic and cosmetic scores, and complications arising during or after RFA were evaluated. Six to twelve months after RFA, all patients received FNA to reevaluate the neoplasm status.

#### RESULTS

Significant volume reductions during follow-up between values prior to RFA and 6 months after RFA ( $7.31 \pm 12.83 \text{ cm}^3$ ,  $p < 0.001$ ) were demonstrated. The respective mean volume reduction ratios at the 6-month and final follow-up were 71.5% and 81.45%. The mean follow-up time was  $2.38 \pm 0.9$  years. One patient presented with vocal cord palsy and another patient presented with ptosis, both of whom recovered after RFA. No post-procedural hypothyroidism occurred in the RFA patients. Pre-RFA thyroglobulin level was significantly positively correlated with the SUVmax value of PET/CT ( $p = 0.001$ ).

#### CONCLUSION

RFA is a safe and effective treatment for patients with low-risk follicular neoplasm (SUVmax value  $\leq 5$ ) in long-term follow-up. It is a viable alternative treatment for patients not suitable or willing to undergo surgery.

## CLINICAL RELEVANCE/APPLICATION

RFA is a safe and effective treatment option for patients with thyroid follicular neoplasm, specifically those with low SUVmax on PET/CT studies. This treatment can provide significant volume reductions in the nodule and improve symptomatic and cosmetic scores. Additionally, RFA may be a viable alternative to surgery for patients who are not suitable or willing to undergo surgery. Clinicians could consider using RFA as a treatment option in patients with low-risk follicular neoplasm, as it has been demonstrated to have minimal complications and no post-procedural hypothyroidism. Furthermore, clinicians could consider performing PET/CT studies in patients with thyroid nodules to assess their SUVmax value, as it can be a useful predictor of the malignancy rate of thyroid nodule.

### R2-SPHN-4 The Value of Radiomics Models Based on DWI and ADC for Predicting Benign and Malignant Thyroid Nodules

Participants  
Qian Yang, Shenzhen, China (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the value of radiomics features extracted from DWI and ADC in differentiating benign and malignant thyroid nodules.

#### METHODS AND MATERIALS

The clinical and imaging data of 140 thyroid patients with 148 pathology-confirmed thyroid nodules in our hospital were analyzed retrospectively, including 50 benign nodules and 98 malignant nodules. All patients underwent thyroid magnetic resonance DWI examination. Based on the delineated region of interest (ROI), radiomics features were extracted from DWI and ADC images. Student-t test, the Least Absolute Shrinkage and Selection Operator (LASSO) algorithm and correlation analysis were sequentially used for feature selection. Four classifiers of k-nearest neighbor (KNN), support vector machine (SVM), random forest (RF) and logistic regression (LR) were used for modeling (DWI model, ADC model and combined model). The receiver operating characteristic (ROC) analysis with area under curve (AUC) was used to evaluate the efficacy of radiomics model in predicting benign and malignant thyroid nodules.

#### RESULTS

After feature selection, 10 DWI features and 18 ADC features were used to build models. Among the three radiomics models built with the same classifiers, combined model outperformed either DWI model or ADC model for all classifiers, except for RF models in which ADC model (AUC=0.825) outperformed combined model (AUC=0.809). Among the combined models, LR model (AUC=0.885) was superior to the other three models (SVM: AUC=0.867; KNN: AUC=0.846; RF: AUC=0.809).

#### CONCLUSION

The radiomics model based on DWI and ADC image is helpful to differentiate benign and malignant thyroid nodules.

## CLINICAL RELEVANCE/APPLICATION

The results of this study will help the diagnosis of benign and malignant thyroid nodules and provide clinical assistance.

### R2-SPHN-5 Development and Validation of Radiomics Model Based on Ultrasound Images to Predict Malignancy in Bethesda Category III and IV Thyroid Nodules

#### PURPOSE

This study aimed to predict malignancy in thyroid nodules with initial fine-needle aspiration (FNA) results of Bethesda category III

and IV using a machine learning algorithm.

## **METHODS AND MATERIALS**

A total of 266 thyroid nodules (= 1 cm) were included from January 2017 to May 2022 retrospectively. The initial FNA results were Bethesda category III or IV and subsequent pathological diagnoses were obtained. All subjects were divided into a training set and a test set randomly at a ratio of 7:3. One senior and one junior radiologist independently and blindly reviewed the images of the test set and evaluate the nodule features based on the American College of Radiology (ACR) Thyroid Imaging Reporting and Data System (TI-RADS). For each nodule, two grayscale ultrasonography images including one transverse and one longitudinal were selected and segmented. Then radiomics features were extracted and selected using a machine learning algorithm to develop a radiomics model. Univariate and multivariate logistic regression analyses were used to select clinical independent predictors which were used to develop the clinical-radiomics combined model. The receiver operating characteristic (ROC) curves of the radiomics model and combined model were plotted. The AUCs were calculated and compared using DeLong's test.

## **RESULTS**

Among the final set, 226 cases were Bethesda III nodules with a malignant rate of 39.4%; 40 cases were Bethesda IV nodules with a malignant rate of 50.0%. The variables included in the clinical-radiomics combined model were nodule size, suspected cervical lymph node metastasis and radiomics probability. In both the training and test sets, the AUC of the combined model was higher than that of the radiomics model (training, 0.823 vs 0.751,  $P = 0.003$ ; test, 0.800 vs 0.749,  $P = 0.040$ ). In the test set, the AUC of the combined model was significantly higher than that of the junior radiologist (0.800 vs 0.658,  $P = 0.029$ ) and no significant difference compared to senior radiologist (0.800 vs 0.760,  $P = 0.550$ ). Moreover, the specificity of the combined model (66.7%) was higher than that of the junior radiologist (44.4%) and senior radiologist (62.2%). There was no significant difference between the AUC of the radiomics model and two radiologists ( $P > 0.05$ ).

## **CONCLUSION**

The radiomics model and clinical-radiomics combined model based on grayscale ultrasound images can effectively predict malignancy in Bethesda category III and IV thyroid nodules. The diagnostic performance of the combined model is comparable to that of the senior radiologist and better than that of the junior radiologist.

## **CLINICAL RELEVANCE/APPLICATION**

Machine learning algorithm may help in more accurate identification of malignancy in Bethesda category III and IV thyroid nodules for further evaluation.

## **R2-SPHN-6 "Unlocking the Secrets of F-18-FDG PET/CT Thyroid Incidentalomas". A Comprehensive Analysis of Ultrasound and Pathology in a Leading Mexico City Hospital**

### **PURPOSE**

Study the prevalence of focal and diffuse thyroid incidentalomas detected by 18-FDG PET/CT. Investigate the relation between SUVmax, ultrasound features, and histopathology to estimate the risk of malignancy in these patients. Estimate a cut-off point of SUVmax to suspect malignancy.

### **METHODS AND MATERIALS**

We retrospectively reviewed the reports of 3958 patients in whom 18-FDG-PET/CT scans were performed. Studies in which the presence of thyroid incidentaloma were analyzed. SUVmax and Total lesion glycolysis (3D slicer) values were obtained prospectively. Ultrasound was also prospectively reviewed if available, Fine Needle Aspiration (FNA) and histopathology data were collected. Statistical analysis was made with SPSS 25.

### **RESULTS**

The prevalence of thyroid incidentaloma in FDG-PET/CT was 3.2% (130 patients), 98 (2.53%) had focal uptake, and 32 (0.82%) diffuse uptake. 43 patients with focal uptake underwent further workup. The prevalence of focal uptakes was higher in women than in men (33.7% vs 66.3%, OR 1.54, CI 95% 1.0132 - 2.3644). Nodules were classified as benign (N=14) and malignant (N=14) by pathology. The median SUVmax of focal uptakes was 4.50 (1.66-56.24). Malignant lesions had higher SUVmax than Benign (8.25 vs 4.49,  $p = 0.049$ ). In ultrasound analysis (n=43), nodules with the following features had higher SUVmax and malignancy rates: Hypoechoic ( $p = 0.004$ , SUVmax: 7.28), taller-than-wide ( $p = 0.003$ , SUVmax: 8.84), lobulated or irregular margins ( $p = 0.000008$ , SUVmax: 8.84), punctate echogenic foci ( $p = 0.039$ , SUVmax: 10.23) and presence of adenopathy ( $p = 0.037$ , SUVmax: 12.16). A significant difference in SUVmax values among ATA classification was found ( $H = 19.27$ ,  $df = 4$ ,  $p = 0.0007$ ). Benign nodules had lower SUVmax values (2.46, 1.86-3.05), while high suspicion nodules had higher SUVmax values (11.62, 4.46-56.24). A cut-off value of 4.880 g/ml SUVmax was used to determine malignancy with a sensitivity of 81% and specificity of 77%.

### **CONCLUSION**

Higher SUVmax in PET/CT were consistent with ultrasound features of suspicion and the rate of malignancy. SUVmax values are significantly different among nodules classified according to the ATA guidelines, with benign and low suspicion nodules having lower SUVmax values and high suspicion nodules having higher SUVmax values. A cut-off value of 4.880 g/ml has good sensitivity, and specificity (81% and 77%, respectively). This suggests that SUVmax may be a useful metric for distinguishing between benign and malignant lesions in PET-CT imaging.

### **CLINICAL RELEVANCE/APPLICATION**

Up to 3% of PET-CT scans showed a thyroid incidentaloma. It is important to determine which nodules are more likely to be malignant. This study shows SUVmax has a good correlation with ultrasound and pathology for determining malignancy.

## **R2-SPHN-7 Preoperative Localization of Previously Occult Parathyroid Adenomas using Dynamic, Contrast Enhanced Parathyroid MR Imaging**

Participants  
Jacob Musiol, MD, San Antonio, TX (Presenter) Nothing to Disclose

### **PURPOSE**

Common techniques for preoperative localization of parathyroid adenomas include nuclear medicine parathyroid sestamibi scans with

Common techniques for preoperative localization of parathyroid adenomas include nuclear medicine parathyroid sestamibi scans with or without SPECT or SPECT-CT, ultrasound, and 4D parathyroid CT with differing levels of success. While not widely utilized, dynamic contrast enhanced parathyroid MRI has also been previously shown to demonstrate parathyroid adenomas with increased sensitivity and specificity when compared to dynamic parathyroid CT. Our interest in dynamic parathyroid MRI began when a patient presented with clinical hyperparathyroidism but occult prior imaging. We tailored a protocol on our clinical use 3 Tesla Siemens magnet using previously published parameters. We subsequently scanned six patients for evaluation of parathyroid adenoma.

## **METHODS AND MATERIALS**

Our patient selection included six patients imaged over 18 months with biochemical hyperparathyroidism and elevated serum parathyroid hormone values, but negative prior imaging. Using a clinical Siemens 3T magnet, we performed T1 axial, T2 axial, T2 fat saturated coronal, T1 coronal, T1 axial VIBE pre contrast, and T1 axial VIBE post contrast dynamic sequences. After the administration of gadolinium-based contrast, 11 axial dynamic contrast series were obtained at 11.5 second intervals for a total imaging sequence time of 2 minutes 7 seconds. Additional T1 VIBE post contrast subtraction images were created. All images were submitted to the AGFA PACS, and clinical interpretation was performed by a board certified neuroradiologist.

## **RESULTS**

We utilized our protocol to image six patients, all with positive findings on MRI. The lesions identified as positive demonstrated T2 hyperintensity and intense arterial enhancement within the first 30 seconds of contrast injection, followed by delayed washout. The patients were taken to surgery with accurate surgical localization. All six had pathology-proven parathyroid adenomas. The smallest lesion measured 6 mm and the largest lesion measured 14 mm.

## **CONCLUSION**

While not widely utilized, dynamic parathyroid MR imaging is a helpful resource for localizing parathyroid adenomas with high sensitivity and specificity. While other modalities such as nuclear medicine parathyroid sestamibi scans or 4D parathyroid CT are more widely available, implementing this dynamic post contrast technique in clinical practice can assist surgeons in preoperative localization, as well as decrease the incidence of exploratory surgery of the neck.

## **CLINICAL RELEVANCE/APPLICATION**

Dynamic parathyroid MRI can be readily and easily integrated into routine outpatient imaging protocols for evaluation of parathyroid adenoma. Utilization can improve preoperative surgical localization and improve patient outcomes.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

R2-SPIN

### Imaging Informatics Thursday Poster Discussions

#### Sub-Events

#### **R2-SPIN-1 Prediction on Lateral Cephalograms of Post Orthognathic Surgery using Graph Convolutional Neural Network and Diffusion Model**

##### Participants

JiHeon Jeong, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To generate lateral cephalogram of post orthognathic surgery based on pre-operation lateral cephalogram using a graph convolutional neural net (GCN) and a diffusion model

##### METHODS AND MATERIALS

Among a dataset from nine university hospitals with different types of cephalography machines and radiation exposure protocols, 800 pairs of pre- (T0) and post- (T1) surgery with 12-bit deep grayscale images were selected and registered based on the sella and nasion points. And the dataset was divided into a training set of 700 pairs and a test set of 100 pairs. Landmarks were measured on each image at 41 points using a pre-trained model with an average error of  $0.80 \pm 0.79$  mm. First, a model was trained to predict the movement predictions of each landmark in T1 image by embedding the T0 image and its landmarks using CNN and graph GCN, respectively. To generate T1 images, we used various prompts, including the movement of landmarks based on surgical planning. To ensure more realistic and detailed generation quality using various prompts, an autoencoder using not only a labeled dataset of T0 and T1 but also an unlabeled cephalogram dataset was trained. A diffusion model for image generation in the encoding space was trained with various prompts as conditioning factors. Specifically, T0, and T0's landmarks, and movement predictions were used as prompts.

##### RESULTS

The distances between the landmark points on the images generated by the diffusion model and the T1 images were measured for 100 test images, both with and without various prompts. The diffusion model without prompts had an average error of approximately  $2.33\text{mm} \pm 6.16\text{mm}$  across 30 landmark points, while the diffusion model with prompts had an average error of  $1.76\text{mm} \pm 1.45\text{mm}$ , which was statistically significant based on paired t-test results ( $p < 0.001$ ).

##### CONCLUSION

A diffusion model was trained to generate T1 cephalogram based on T0 images of orthognathic surgery using graph CNN and diffusion model, which lead to better prediction of post-operational cephalogram.

##### CLINICAL RELEVANCE/APPLICATION

This generative model could be used to predict surgical result based on surgery planning and pre-operative cephalogram with landmarks. Therefore, based on this, among various surgical planning options of orthognathic surgery, better outcome could be selected.

#### **R2-SPIN-2 Artificial Intelligence (AI) Software for Automated Fracture Detection in Emergency Department: 2-month Experience**

##### Participants

Francesco Pucciarelli, MD, Rome, Italy (*Presenter*) Nothing to Disclose

##### PURPOSE

Computer-aided detection tools are routinely used in clinical practice. In recent years, artificial intelligence (AI) is playing an increasing role in medical imaging, aiming at speeding up the workflow and improving human diagnostic performances. The purpose of this study is to evaluate the reliability of an AI software trained to detect fractures on radiographs and to compare its accuracy to radiologists.

##### METHODS AND MATERIALS

This retrospective study included radiographs of patients admitted for trauma to the emergency department of our hospital from May 19 2022 to July 19 2022. Radiographs of each patient were analyzed for the presence of fracture by both radiologists and AI software. For discordant cases a radiologist with 25 years of experience in emergency radiology was considered the ground truth and, when available, CT. Statistical analysis was performed with a dedicated software and accuracy of both radiologist and AI software was collected.

##### RESULTS

Final population consisted of 981 patients, comprising 1360 anatomical districts and 3367 X-ray projections. Concordance between radiologists and AI software was 88.8% (871/981) and discordance was 11.2% (110/981). In discordant cases false positive (FP)

were 30 for radiologists vs 76 for AI software; true negative (TN) were 76 vs 30, respectively; true positive (TP) were 3 vs 1 respectively; false negative (FN) were 1 vs 3 respectively. Accuracy was 0.96 for radiologists and 0.91 for AI software (sensitivity 0.99 vs 0.99 and specificity 0.96 vs 0.91 respectively). Positive predictive value (PPV) was 0.92 for radiologist vs 0.81 for AI software; negative predictive value (NPV) was equal (0.99). FP for AI software were mainly due to image artifacts, external devices, and immature bone in pediatric patients.

## CONCLUSION

Radiologists and AI software showed the same sensitivity on fracture detection with a slightly higher specificity for radiologists. NPV was equal. We can conclude that the use of AI software has shown good reliability in ruling out fractures on radiographs.

## CLINICAL RELEVANCE/APPLICATION

This AI software could be applied to clinical routine to improve the radiologist's confidence in ruling out fractures in the emergency department.

## R2-SPIN-3 Using Deep Learning to Augment Radiologist Interpretation of Brain MRIs for Alzheimer's Disease

### PURPOSE

Modern machine learning approaches are being developed to assist radiologists in evaluating MRIs for Alzheimer's disease (AD) detection. We sought to determine if a deep learning model can augment neuroradiologist evaluations of MRIs for AD assessment.

### METHODS AND MATERIALS

We developed a multimodal deep learning framework for dementia assessment that combines MRIs and non-imaging data including demographics, past medical history, neuropsychological testing, and functional assessments [1]. The model was trained on 4,822 participants from the National Alzheimer's Coordinating Center dataset. A subset of cases clinically diagnosed with dementia (n=50) was evaluated by seven neuroradiologists who were asked to differentiate between persons with AD and those with non-Alzheimer's dementia (nADD) using MRI scans and demographic information. We evaluated the model performance against the radiologist assessments and constructed a consensus opinion from the expert ratings and model predictions. [1] Qiu et. al., Nat Commun. 2022 Jun 20;13(1):3404. doi: 10.1038/s41467-022-31037-5

### RESULTS

Our results showed that combining the radiologist assessments with predictions from our model yielded greater accuracy, sensitivity, specificity, and Matthews correlation coefficient (MCC) in differentiating persons with AD from those with nADD than the assessments made by the neuroradiologists alone. The consensus methods used in this study resulted in an improvement in accuracy from 58% to 64%, in sensitivity from 58% to 64%, in specificity from 60% to 72%, and an increase in the MCC from 0.16 to 0.28.

## CONCLUSION

Incorporating machine learning model assessments into the consensus radiologist interpretation improved the reliability of AD diagnosis based on brain MRIs, age, and gender.

## CLINICAL RELEVANCE/APPLICATION

AI-augmented radiologist assessment can improve the diagnostic accuracy of AD diagnosis, leading to more precise and timely treatment, potentially improving patient outcomes.

## R2-SPIN-4 Joint Generative and Mixture Data Augmentation for Metastatic Focal Liver Lesion Classification in Abdominal CT Images

### PURPOSE

Generative data augmentation (DA) using generative adversarial network (GAN) has been successful in improving the learning efficiency of medical image analysis tasks where training data is limited. However, it is prone to mode collapse, where the GAN generates a limited variety of patterns due to inadequate learning of the training data pattern. To overcome this limitation, we propose a novel data augmentation approach that combines generative DA with MixUp-based mixture DA to diversify the pattern of synthetic data. We evaluate the effectiveness of this approach on the classification of metastatic focal liver lesions (FLLs) in abdominal CT images.

### METHODS AND MATERIALS

Our dataset consists of CT scans from 502 colorectal cancer patients, including 1,290 FLL images with 676 cysts, 130 hemangiomas, and 484 metastases. First, we generated synthetic images by training a StyleGAN model on real training images. We then created new training images by performing MixUp-based linear combinations between synthetic and real training images. The VGG-16 network is then trained using these training images to classify FLLs. To validate the effectiveness of our approach, we compared the accuracy, sensitivity, and specificity of classification results, and analyzed the t-SNE feature distribution to determine whether our approach mitigates mode collapse in generative DA.

### RESULTS

Generative DA achieved a marginal improvement over the affine DA-based baseline, with 73.2% accuracy compared to 72.3%. Our proposed method achieved 80.8% accuracy and demonstrated a significant enhancement in the sensitivity of cyst and metastasis. In the t-SNE feature distribution, synthetic images generated by generative DA were concentrated around specific locations due to mode collapse, while training images of our method were distributed across the entire class. This outcome confirms that our method can mitigate mode collapse by diversifying the pattern of synthetic images.

## CONCLUSION

We proposed a novel DA method that combines generative DA with mixture DA to address mode collapse, a major limitation in generative DA. We confirmed that our method diversifies the pattern of synthetic images created by generative DA, mitigating the mode collapse phenomenon and enhancing classification performance in the classification of FLLs in CT images. (This work was supported by the National Research Foundation of Korea Grant funded by the Korea government (No. RS-2023-00207947))

## CLINICAL RELEVANCE/APPLICATION

Our approach can be applied to a wide range of medical image analysis tasks in which training data is scarce or mode collapse arises during generative DA.

### R2-SPIN-5 Development of Accurate Automated Organ Segmentation in Pediatric CT Scans: Impacts of Model Pretraining

Participants

Panagiotis Korfiatis, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

## PURPOSE

To develop a deep learning-based segmentation model for pediatric patients with CT imaging.

## METHODS AND MATERIALS

This study utilized two publicly available datasets: a pediatric dataset with imaging of 359 patients ranging from 5 days to 16 years old, with varying imaging parameters, and a dataset of adult patients consisting of 1204 scans, with annotations of 104 structures. The pediatric dataset comprised 29 organs. In this study we focused on 20 organs. The nnUNet model was trained utilizing the following approach: First, a model was trained using the adult dataset. Then, the weights of the adult model were used to initialize the weights of the pediatric model. The training/validation dataset was comprised of 325 scans, while 34 patients were used for testing. The default nnUNet augmentations were applied in this model excluding mirroring. Finally, the ensemble of the five models from the 5-fold training process was obtained as the final model (Figure 1, supplement).

## RESULTS

Training the model with weight initialization led to performance improvements especially in smaller structures (Figure 1, supplement). The performance of the pretrained nnUNet ranges from 0.57 to 0.97 with the performance of the model being better in larger structures. Smaller structures like the adrenal glands and more complex anatomical structures like the small intestine benefit when pretrained models are utilized.

## CONCLUSION

Leveraging pretrained models to facilitate model training for populations where large datasets that are not widely available can further improve segmentation performance. More advanced training techniques like self-supervised training or data-centric training should also be investigated.

## CLINICAL RELEVANCE/APPLICATION

Image segmentation is the fundamental step in many downstream clinical applications such as quantification and treatment planning, and less attention has been given to solving this problem in pediatric populations.

### R2-SPIN-6 Detection of Progression to Clinically Significant Prostate Cancer Using End-to-End Deep Learning in Sequential MRI

Participants

Christian Roest, MSc, GRONINGEN, Netherlands (*Presenter*) Grant, Siemens AG

## PURPOSE

Reading sequential prostate MRI is a difficult task for radiologists. Deep learning (DL) may help detect progression. We explored end-to-end deep learning to compare two sequential MRI scans in detecting progression to clinically significant prostate cancer.

## METHODS AND MATERIALS

This retrospective study included 714 patients with at least two consecutive biparametric MRI scans of the prostate between 2014 and 2021 (875 follow-up scans). We recorded all PIRADS reported prostate cancer lesions. PI-RADS=3 lesions received MRI-targeted biopsy, and lesions with histopathological grade of ISUP=2 were considered clinically significant (csPCa). All patients were negative for csPCa at the first MRI. Three separate end-to-end DL segmentation approaches were subsequently tested to detect csPCa: 1) a single, current MRI model; 2) a sequential model comparing prior and current MRI 3) model 2 extended with clinical parameters (PSA, PSA density, age, prostate volume). Maximum detected per lesion likelihood in the heatmap was considered the patient-level likelihood for csPCa progression. Receiver-operating characteristic (ROC) curve analysis was used to compare the three DL models at patient level. Lesion level performance was evaluated using free-ROC (FROC) analysis by comparing the area-under-the-FROC-curve (AUFROC) between 0.1 and 2.5 false-positives per patient. Explainable AI was used to create saliency maps, ranking the importance assigned by the model to information in the sequential MRI input. Differences in AUROC and AUFROC were evaluated using DeLong's and bootstrap tests, respectively.

## RESULTS

The sequential model outperformed the single-scan baseline at lesion-level (AUFROC: 1.45 [1.29–1.61] vs 1.56 [CI 1.40–1.72],  $p < 0.05$ ) and patient-level (AUROC: 72.9% [CI 68.7–77.2%] vs 75.7% [CI 71.6–79.9%],  $p = 0.008$ ). Including differential clinical parameters further improved patient-level performance to 76.1% AUROC (CI 71.6–80.6%). Saliency maps showed significantly higher importance for temporal high b-value sequences, compared to T2W and ADC ( $p < 0.0001$ ).

## CONCLUSION

Our proposed end-to-end deep learning model can accurately detect progression to csPCa using sequential MRI.

## CLINICAL RELEVANCE/APPLICATION

Active surveillance is crucial in prostate MRI, and an accurate artificial intelligence tool for detecting progression to clinically significant disease may help to prevent unnecessary biopsies.

## Abstract Archives of the RSNA, 2023

R2-SPIR

### Interventional Radiology Thursday Poster Discussions

#### Sub-Events

#### R2-SPIR-1 **STING Pathway Activation and Antitumor Immunity Induction by an Injectable Hydrogel Loaded Lysed OK-432 and DOX for Incomplete Radiofrequency Ablated Liver Cancer**

##### PURPOSE

To investigate the efficacy and mechanism of an injectable hydrogel loaded lysed OK-432 and doxorubicin for incomplete radiofrequency ablated (inRFA) liver cancer.

##### METHODS AND MATERIALS

RADA16-I (R) peptide was dissolved in a mixture of doxorubicin (D) and lyOK-432 (O) to develop a ROD hydrogel. The characteristics of ROD hydrogel were evaluated. Tumor necrosis and mice survival were measured after different treatments. Immune cells and cytokines were measured, and the cGAS/STING/IFN-I signaling pathway in dendritic cells (DC) was evaluated in vitro and in vivo.

##### RESULTS

LyOK-432 was more effective than OK-432 in promoting DC maturation and activating the IFN-I pathway. ROD was an injectable hydrogel for the effective loading of doxorubicin and lyOK-432, and presented controlled-release property. ROD treatment achieved the highest tumor necrosis rate ( $P < 0.001$ ) and significantly longer survival time ( $P < 0.001$ ) than other therapies. The ROD group also displayed the highest rates of DCs, CD4+ T cells and CD8+ T cells ( $P < 0.001$ ), the lowest level of Treg cells ( $P < 0.001$ ), and significantly higher expression levels of IFN- $\gamma$  and TNF- $\alpha$  ( $P < 0.001$ ) than the other groups. Moreover, the expression levels of pSTING, pIRF3, and IFN- $\beta$  in DCs were obviously higher after treatment with lyOK-432 combined with doxorubicin than after monotherapy. The surviving mice in the ROD group showed inhibition of rechallenged subcutaneous tumor growth.

##### CONCLUSION

The novel ROD peptide hydrogel was effective for the treatment of liver cancer previously treated with inRFA.

##### CLINICAL RELEVANCE/APPLICATION

This modality probably leads to a progression in the eradication of larger liver cancer in clinical practice.

#### R2-SPIR-2 **GNMT and MMP12 Expression Determines Transarterial Chemoembolization in Hepatocellular Carcinoma**

##### PURPOSE

Transarterial chemoembolization (TACE) is a first-line treatment for patients with intermediate hepatocellular carcinoma (HCC). It is crucial to accurately identify patients who are effective for TACE and explore their related mechanisms. Our purpose is to determine the key molecular characteristics and related pathways that affect TACE efficacy.

##### METHODS AND MATERIALS

Based on microarray datasets and high-throughput sequencing dataset, a TACE-effectiveness model was constructed using logistic regression. Based on external data validation, its accuracy was verified by Kaplan-Meier survival analysis, Principal Component Analysis (PCA), and immunohistochemistry was used to verify the expression level of signature genes. Kyoto Encyclopedia of Genes and Genomes (KEGG) analysis and Cibersort x were used to investigate related mechanisms.

##### RESULTS

Three independent cohorts were used, among which GSE104580 was randomly divided into a training set and a validation set at a ratio of 6:4. TACE-effectiveness model was constructed including GNMT and MMP12 through the training set. Our model can effectively distinguish TACE efficient and inefficient patients in the validation set and GSE14520. The OS and DFS of TACE efficient patients were significantly higher than those of TACE inefficient patients. Immunohistochemistry results showed that GNMT was highly expressed in TACE efficient patients, while MMP12 was lowly expressed in TACE efficient patients ( $p < 0.05$ ). MMP12 and GNMT may determine the TACE effectiveness by affecting the metabolic pathway and HIF-1 $\alpha$  signaling pathway.

##### CONCLUSION

Our research provides a model that can accurately evaluate the effectiveness of TACE, and MMP12 and GNMT may determine the TACE effectiveness by affecting the metabolic pathway and HIF-1 $\alpha$  signaling pathway.

##### CLINICAL RELEVANCE/APPLICATION

Our study provides a basis for individualized accurate medical care for patients with HCC, and provides a novel idea and direction for exploring the mechanism of TACE.

## **R2-SPIR-3 Transarterial Chemoembolization Combined With Apatinib Plus PD-1 Inhibitors for Hepatocellular Carcinoma With Portal Vein Tumor Thrombus: A Multicenter Retrospective Study**

### **PURPOSE**

The aim of this study was to compare transarterial chemoembolization (TACE) combined with apatinib and PD-1 inhibitor (TACE-AP) with TACE combined with apatinib alone (TACE-A) in the treatment of hepatocellular carcinoma (HCC) with portal vein tumor thrombus (PVTT) and to explore the prognostic factors affecting the survival of patients.

### **METHODS AND MATERIALS**

This retrospective study analyzed data of patients with HCC with PVTT who were treated with TACE-AP or TACE-A between January 2018 and June 2021. The primary end points of the study were progression-free survival (PFS) and overall survival (OS), and the secondary end points were objective response rate (ORR) and adverse events (AEs). Propensity score matching (PSM) and inverse probability weighting (IPTW) analyses were used to reduce patient selection bias, and Cox regression analysis was used to analyze prognostic factors affecting patient survival.

### **RESULTS**

Sixty-nine and 40 patients were included in the TACE-A and TACE-AP groups, respectively. After PSM and IPTW analyses, the median PFS and median OS in the TACE-AP group were significantly higher than those in the TACE-A group (PFS: after PSM, 6.9 vs 4.0 months,  $P < 0.001$ , after IPTW, 6.5 vs 5.1 months,  $P < 0.001$ ; OS: after PSM, 14.6 vs 8.5 months  $P < 0.001$ , after IPTW, 16.1 vs 10.5 months,  $P < 0.001$ ). After PSM and IPTW analyses, the tumor ORR in the TACE-AP group was significantly higher than that in the TACE-A group (PSM, 53.6% vs 17.9%,  $P = 0.005$ ; IPTW, 52.5% vs 28.6%,  $P = 0.013$ ). All treatment-related AEs were observed to be tolerated. Multivariate Cox regression analysis showed that the main prognostic factors affecting the survival of patients were tumor number, PVTT type, alpha-fetoprotein, and treatment mode.

### **CONCLUSION**

In the treatment of patients with HCC with PVTT, TACE-AP significantly improved PFS, OS, and ORR, and the AEs were safe and controllable.

### **CLINICAL RELEVANCE/APPLICATION**

The study's findings may have clinical relevance in the treatment of HCC patients with PVTT, as it suggests a potential treatment option that could improve patient outcomes. Clinicians treating HCC patients with PVTT may consider the use of TACE-AP, as it may lead to better survival rates and improved objective response rates. Additionally, the findings may inform future research on potential treatment strategies for HCC patients with PVTT, and the prognostic factors identified in the study may aid in patient selection and treatment planning.

## **R2-SPIR-4 Efficacy, Mechanism Safety of Melatonin-loaded on Thermosensitive Nanogels for Rabbit VX2 Tumor Embolization: A Novel Design**

### **PURPOSE**

To explore the efficacy, mechanism and safety of melatonin loaded on p(N-isopropyl-acrylamide-co-butyl methacrylate) (PIB-M) in the treatment of rabbit VX2 tumors.

### **METHODS AND MATERIALS**

In this study, PIB-M was used for tumor embolism. Two types of human hepatoma cell lines (HepG2 and LM3 cells) were used to explore the mechanism by which melatonin prevents the growth and metastasis of cancer cells in vitro. High-performance liquid chromatography was used for pharmacokinetic analysis. A VX2 rabbit tumor model was used to evaluate the efficacy, mechanism and safety of PIB-M in vivo.

### **RESULTS**

We found that under hypoxic condition, melatonin could inhibit tumor cell proliferation and migration by targeting hypoxia inducible factor-1 $\alpha$  (HIF-1 $\alpha$ ) and vascular endothelial growth factor A (VEGF-A) in vitro. The results of pharmacokinetics in vivo showed that a high concentration of melatonin in the PIB-M group could be maintained in tumor tissue for 72 hours after embolization. In vivo, PIB-M inhibited tumor growth and metastasis in rabbit VX2 tumors by targeting related angiogenic proteins and vascular permeability proteins. The liver and kidney functions were most damaged on the first day but recovered to normal on the seventh day after embolization in the PIB-M group.

### **CONCLUSION**

PIB-M can effectively inhibit the growth and metastasis of tumor after treatment, and it is safe. This novel method may open avenues for reduced tumor growth and metastasis after embolism, which may be used for treatment for other solid tumors and clinical translation.

### **CLINICAL RELEVANCE/APPLICATION**

The conclusion of this study may provide a theoretical basis for the use of melatonin in interventional therapy for liver cancer.

## **R2-SPIR-5 Impact of Acute Kidney Injury After Radiofrequency Ablation for Patients with T1a Renal Cell Carcinoma**

### **PURPOSE**

To investigate the association between acute kidney injury (AKI) and renal function 1 year after RFA, and whether this relationship is affected by the duration of AKI.

### **METHODS AND MATERIALS**

We analyzed the data of 393 patients treated by RFA for a single T1aN0M0 renal cell carcinoma. Three outcomes of interest have been defined as follows: (1) recovery of at least 90% of baseline function 1 year after RFA, (2) percentage change of 1-year renal function compared with baseline function, and (3) chronic kidney disease upstaging. AKI was defined according to the RIFLE

criteria. The association between AKI and each endpoint of interest was investigated using a regression model after adjusting for common predictors of renal function.

## RESULTS

Total 58 patients (14%) experienced AKI after RFA. The rate of patients recovering 90% of baseline function was lower in the AKI group (20% vs. 51%), while the proportion of patients who had CKD upstaging was significantly higher (40% vs 19%;  $P < 0.0001$ ). At multivariable analysis, AKI was associated with worse renal function 1 year after RFA, regardless of the outcome of interest (all  $p < 0.0001$ ). Longer AKI increases the risk of functional deterioration, especially after the 3rd day of injury. The risk of CKD upstaging for an average patient who had 1-3 versus = 4th day of AKI was 26% (95% CI: 20-32%) versus 67% (95% CI: 45-68%; absolute risk increase of 11%; 95% CI: 7-22%).

## CONCLUSION

s AKI negatively affects long-term functional recovery after RFA.

## CLINICAL RELEVANCE/APPLICATION

Monitoring of renal function after RFA for RCC is important for patient management. Through this study, it can be helpful for patient management by identifying the correlation between AKI and changes in renal function after RFA for RCC.

## R2-SPIR-6 Impact of Clinical Evident Portal Hypertension on Hepatocellular Carcinoma with Transarterial Chemoembolization (CHANCE-CHESS 2301): A Multicenter Cohort Study

Participants

Zhicheng Jin, MD, Nanjing, China (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the impact of clinically evident portal hypertension (CEPH) on the prognosis of hepatocellular carcinoma (HCC) patients treated with transarterial chemoembolization (TACE).

## METHODS AND MATERIALS

A total of 1614 consecutive HCC patients treated with TACE were retrospectively collected from 10 tertiary centers between June 2006 and December 2019. CEPH was defined when at least one following factor was present: 1) esophageal/gastric varices on upper endoscopy or CT imaging, 2) ascites requiring diuretic treatment, 3) splenomegaly (largest diameter on CT  $> 12$  cm) with a low platelet count ( $< 100,000/\text{mm}^3$ ). Overall survival (OS) as the study endpoint was analyzed by Kaplan-Meier and Cox regression. Propensity score matching analysis was used to match patients for predetermined prognostic factors. During the following up, portal hypertension-related adverse events were described.

## RESULTS

Among 1614 patients, 504 (31.2%) were affected by CEPH. Most patients were male (1339, 83.0%) with predominantly etiology of HBV (1167, 72.3%). Before matching, the median OS in CEPH group was 24.5 months (95% confidence interval [CI]: 21.7-28.8) versus 27.3 months (95%CI: 24.9-31.4) (adjusted hazard ratio [HR], 1.22,  $p = 0.011$ ). After matching, 413 pairs were included. The median OS was also significantly lower in CEPH group (23.4 months [95%CI: 21.6-28.8] vs. 31.7 months [95%CI: 28.0-39.3]; adjusted HR, 1.24,  $p = 0.022$ ). Subgroup analysis showed that CEPH group had a trend that persisted on lower OS compared to non-CEPH group. Patients with  $\geq 2$  CEPH factors had a significantly worse prognosis than patients with 0 or 1 CEPH factor ( $p < 0.001$ ). Among them, 25.2%, 5.8%, and 5% of patients developed ascites progression/occurrence, hepatic encephalopathy, and esophageal/gastric variceal bleeding, respectively.

## CONCLUSION

s The presence of CEPH, especially  $\geq 2$  CEPH risk factors, was significantly associated with poor outcomes and should be taken into consideration when managing HCC patients who underwent TACE.

## CLINICAL RELEVANCE/APPLICATION

The large-sample, real-world study highlights the importance of portal hypertension management by identifying morbidity rate and prognostic impact on clinical decision-making and trial design in HCC patients treated with TACE.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

R2-SPMK

### Musculoskeletal Imaging Thursday Poster Discussions

#### Sub-Events

#### R2-SPMK-1 **Assessing the Efficacy of Radiofrequency Ablation and Kyphoplasty for Alleviating Painful Spine Metastases: A Study Using VAS Pain Scale**

##### PURPOSE

To determine the efficacy of pain improvement of radiofrequency ablation (RFA) in conjunction with kyphoplasty in treatment of patients with painful metastatic neoplastic disease to the spine.

##### METHODS AND MATERIALS

Between 3/2019 and 8/2022, a total of 59 kyphoplasty/RFA procedures were performed. The median age of the cohort was 65 years old (range, 41-86) with male-to-female ratio of 0.97. The primary neoplastic disease was as follows: multiple myeloma (n=17, 28.8%), breast cancer (n=15, 25.4%), lung cancer (n=7, 11.9%), prostate cancer (n=6, 10.2%), lymphoma and colorectal cancer (each n=3, 5.1%), urothelial carcinoma (n=2, 3.4%), thyroid cancer, pancreas adenocarcinoma, renal cell carcinoma, and metastatic adenoid cystic carcinoma (each n=1, 3.3%). Pain relief was evaluated by the visual analogue scale (VAS) score before and within 3-months after the procedure. The highest documented VAS pre- and post-procedure was recorded. A P value < 0.05 was considered statistically significant.

##### RESULTS

Technical success was achieved in all patients. The median follow-up was 15 days (IQR, 14-52.5) after the procedure. The median VAS score decreased from 10 (IQR, 8-10) to 2 (IQR, 2-3) within 3 months after procedure ( $p < 0.001$ ). There were no major complications.

##### CONCLUSION

s RFA in conjunction with kyphoplasty is safe and provides meaningful clinical improvement in VAS pain scores when measured within 3 months of the procedure.

##### CLINICAL RELEVANCE/APPLICATION

MSK Interventional Radiology - Palliative Spine Intervention

#### R2-SPMK-2 **Accuracy of GE Revolution CT and Philips iQon CT Energy Spectrum Scanning in Measuring Lumbar Bone Density**

##### PURPOSE

In this study, the European spine phantom (ESP) was used to investigate the accuracy of GE Revolution CT and Philips iQon CT in measuring human lumbar vertebra bone density

##### METHODS AND MATERIALS

The ESP (QRM GmbH, Moehrendorf, Germany) used in this study consists of epoxy resin and three hydroxyapatite (HAP) at densities of 50 mg/cm<sup>3</sup> (osteoporosis), 102 mg/cm<sup>3</sup> (osteopenia) and 197 mg/cm<sup>3</sup> (normal), They were labeled as the first, second, and third lumbar vertebrae (L1), respectively. The energy spectrum scanning of the body mold was performed by Revolution CT and iQon CT. The scanning parameters of Revolution CT were 140/80kVp instantaneous switching of high and low voltage, tube current was 230mA, tube speed was 0.8s /r, and pitch was fixed at 0.984:1. iQon CT scanning parameters: tube voltage 120kVp, tube current: automatic milliampere technology, tube speed 0.75 s/r, pitch 0.801:1. The BMD values of ESP L1-3 vertebra were measured, and the linear regression equations between the two CT measurements and the real values were calculated. The differences between the two linear regressions were analyzed by MedCalc.

##### RESULTS

There was no significant difference between the measured values and the real values between the two machines ( $P > 0.05$ ). The linear regression equation of Revolution CT was  $y = 1.0365x - 2.593$ , and the linear regression equation of iQon CT was  $y = 1.0193x - 1.528$ . There was no significant difference in slope and intercept ( $P > 0.05$ ).

##### CONCLUSION

s Under the optimal scanning parameters of Revolution CT and iQon CT, the two machines can measure lumbar bone density with good consistency.

##### CLINICAL RELEVANCE/APPLICATION

iQon CT, like Revolution CT, can also accurately measure lumbar bone density.

#### R2-SPMK-3 **Preoperative Imaging Features of Bone Cement Leakage After Percutaneous Vertebroplasty in**

## Kummell's Disease

### PURPOSE

To investigate the preoperative imaging features of bone cement leakage after percutaneous vertebroplasty for Kummell's disease.

### METHODS AND MATERIALS

The clinical, imaging, treatment and follow-up data of patients with Kummell's disease vertebral compression fracture and percutaneous bone cement filled vertebroplasty from January 2016 to January 2022 were analyzed retrospectively. According to whether there was bone cement leakage in postoperative follow-up, they were divided into two groups. The continuous variable data were compared by independent sample t-test or Mann-Whitney U nonparametric rank sum test, and the classified variable data were compared by chi square or Fisher exact chi square; Finally, binary logistic regression was used to explore the independent risk factors of bone cement leakage.

### RESULTS

A total of 67 cases were included (mean age  $69.63 \pm 9.11$  years, 13 males and 54 females). The injured vertebrae of Kummell's disease were mainly in the thoracolumbar (T5, T6, T7 and T10 were all 1, T8:3, T11:8, T12:19, L1:16, L2:12, L3:1 and L4:4). 38 cases (57%) of bone cement leakage occurred within one month after follow-up, including 24 cases (63%) of intervertebral disc leakage, 11 cases (29%) of soft tissue leakage, 1 case (2.6%) of intravascular leakage, 1 case of intraspinal leakage and 1 case (2.6%) of mixed leakage. The following signs were statistically different between the leakage group and the non leakage group: the degree of X-ray vertebral compression ( $\chi^2=6.278, P=0.043$ ), CT Intravertebral Vacuum Clefts ( $\chi^2=4.899, P=0.025$ ), vertebral cortical discontinuity ( $\chi^2=4.540, P=0.030$ ). Binary logistic regression showed that CT Intravertebral Vacuum Clefts was an independent predictor of bone cement leakage (Odds ratio,  $OR=3.069, P=0.029$ ).

### CONCLUSION

The Intravertebral Vacuum Clefts is related to the leakage of bone cement after percutaneous vertebroplasty, which can be used to guide the choice of treatment before operation.

### CLINICAL RELEVANCE/APPLICATION

The Intravertebral Vacuum Clefts is related to the leakage of bone cement after percutaneous vertebroplasty, which can be used to guide the choice of treatment before operation. The Intravertebral Vacuum Clefts is the preoperative imaging features of bone cement leakage after percutaneous vertebroplasty for Kummell's disease.

## R2-SPMK-4 Trabecular Bone Score as an Assessment Tool to Identify the Risk of Vertebral Fractures in SAPHO Syndrome

### PURPOSE

To investigate the clinical utility of TBS evaluation for vertebral fracture (VF) risk assessment in SAPHO patients compared with BMD assessment.

### METHODS AND MATERIALS

Seventy SAPHO patients [mean age 50.1 (10.7) years, 81% women] were enrolled in this cross-sectional study. TBS and BMD were assessed using dual-energy X-ray absorptiometry. VF of spine were evaluated using whole-spine CT. We compared BMD and TBS results regarding to the presence/absence of VF.

### RESULTS

Patients with VF had significantly lower BMD, T-score and Z-score of lumbar spine (LS) and TBS values and more frequently presented median-high fracture risk in TBS and abnormal BMD at the three evaluated sites than without. Univariate logistic regression analyses identified lower TBS value ( $<1.23$ ), abnormal BMD of the LS, femoral neck (FN) and total hip (TH) were associated with VF [odds ratio (95% CI): 22.9 (6.1, 85.7), 7.6 (2.4, 23.5), 7.6 (2.4, 23.5), and 10.1 (3.0, 33.8), respectively]. For predicting VF in SAPHO patients. TBS showed the greatest AUC in the ROC curve, with a value of 0.920 compared with 0.777, 0.690 and 0.652 for LS, FN and TH BMD, respectively.

### CONCLUSION

TBS has a better discriminatory value than BMD for prediction of VF in SAPHO patients.

### CLINICAL RELEVANCE/APPLICATION

TBS may, therefore, be a useful clinical tool to identify the risk of VF in SAPHO patients.

## R2-SPMK-5 Deep Learning Reconstructed T2-weighted Dixon Imaging of the Spine: Impact on Acquisition Time and Image Quality

### Participants

Thierno Diallo, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

Zeynep Berkarda, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the image quality and impact on acquisition time of a novel deep learning based T2 Dixon sequence (T2DL) of the spine.

### METHODS AND MATERIALS

This prospective, single center study included  $n=44$  consecutive patients with a clinical indication for lumbar MRI at our university radiology department between September 2022 and March 2023. MRI examinations were performed on 1.5-T and 3-T scanners using dedicated spine coils (MAGNETOM Aera and Vida; Siemens Healthcare, Erlangen, Germany). The MR study protocol consisted of our standard clinical protocol, including a T2 standard Dixon sequence (T2std) and the additional T2DL. T2DL acquisition used a conventional sampling pattern with a higher parallel acceleration factor. The individual contrasts acquired for Dixon water-fat separation were then reconstructed using a dedicated research application. After reconstruction of the contrast images from k-

space data, a conventional water-fat separation was performed to provide derived water images. Two readers with 6 and 4 years of experience in interpreting MSK imaging, respectively, analyzed the images in a randomized fashion. Overall image quality (OIQ), banding artifacts, artifacts, sharpness, noise, and diagnostic confidence were analyzed using a 5-point Likert scale (from 1 = non-diagnostic to 5 = excellent image quality).

## RESULTS

Forty-four patients (median age 61,5 years, [IQR: 35.3,67.5], male sex: 39%) were prospectively included. 31 examinations were performed on 1.5-T and 13 examinations on 3-T-scanners. A sequence was successfully acquired in all patients. The total acquisition time of T2DL was 93 seconds at 1.5-T and 86 seconds at 3-T, compared to 235 seconds, and 257 seconds, respectively for T2std (reduction of acquisition time: 60.4% at 1.5-T, and 66.5% at 3-T;  $p < 0.01$ ). OIQ was rated equal for both sequences (mean T2DL 4.66,  $\pm 0.61$ , and T2std 4.61  $\pm 0.72$ ;  $p = 0.59$ ). T2DL showed reduced noise levels compared to T2std (4.93,  $\pm 0.26$  versus 3.84,  $\pm 0.37$ ;  $p < 0.01$ ). In addition, sharpness was rated to be higher in T2DL (4.84,  $\pm 0.37$  versus 3.95,  $\pm 0.53$ ;  $p = 0.01$ ). Although T2DL displayed significantly more banding artifacts (4.25,  $\pm 0.92$  versus 4.91,  $\pm 0.29$ ;  $p < 0.01$ ), no impact on readers diagnostic confidence between sequences was noted (T2std: 4.7,  $\pm 0.63$ , and T2DL: 4.8,  $\pm 0.48$ ;  $p = 0.61$ ). Inter-reader agreement ranged from fair (? for noise: 0.3) to substantial (? for OIQ: 0.8).

## CONCLUSION

s T2DL is feasible with image quality comparable to the reference standard while substantially reducing the acquisition time.

## CLINICAL RELEVANCE/APPLICATION

T2DL may replace standard imaging, while significantly reducing time and cost in MRI of the spine. Further interchangeability analyses seem reasonable to assess the diagnostic performance of the new sequence.

## R2-SPMK-6 Diagnostic Delay in Patients with Osteoid Osteoma

### Participants

Florian Gassert, MD, BSc, Muenchen, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the diagnostic delay in patients with osteoid osteoma and to analyze influencing factors.

## METHODS AND MATERIALS

All patients treated for osteoid osteoma at our tertiary referral center between December 1997 and February 2021 were retrospectively identified (n=302). The diagnosis was verified by an expert panel of radiologists and orthopedic surgeons. Exclusion criteria were post-interventional recurrence, missing data on symptom onset, and if no pretherapeutic CT images were available. Clinical parameters were retrieved from the local clinical information system. CT and MR images were assessed by a senior specialist in musculoskeletal radiology.

## RESULTS

After all exclusions, we studied 162 patients (mean age, 24  $\pm$  11 years, 115 men). The average diagnostic delay was 419  $\pm$  485 days (median: 275 days; range: 21 - 4503 days). Gender, patient age, presence of nocturnal pain, positive Aspirin test, extent of bone sclerosis, and location of the tumor within bone and relative to joints did not influence diagnostic delay ( $p > .05$ ). It was, however, positively correlated with nidus size ( $r = 0.26$ ;  $p < .001$ ), and shorter with affection of long tubular bones compared to all other sites ( $p=.04$ ). If osteoid osteoma was included in the initial differential diagnoses, diagnostic delay was also shorter ( $p = .007$ ).

## CONCLUSION

s The diagnostic delay in patients with osteoid osteoma is independent from demographics, clinical parameters and most imaging parameters.

## CLINICAL RELEVANCE/APPLICATION

A long average delay of more than one year suggests low awareness of the disease among physicians. Patients with unclear imaging findings should thus be referred to a specialized musculoskeletal center or an expert in the field should be consulted timely.

## R2-SPMK-7 Differentiation of Bone Metastases from Benign Red Marrow Depositions: Concerns of Conventional MR Imaging

### Participants

Jisu Lim, MD, Busan, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

To differentiate bone metastases (BMs) from benign red marrow depositions (BRMs) by qualitative and quantitative analyses of T1-weighted imaging (T1w) and fat-suppressed T2-weighted imaging (T2 FS) and to compare the diagnostic performance of normal muscle and normal bone marrow as internal standards on T2 FS in differentiating BMs and BRMs

## METHODS AND MATERIALS

Seventy-five lesions, including 38 BMs and 37 BRMs, were assessed with T1w and T2 FS. Two radiologists independently evaluated MR images by qualitative (signal intensity [SI] of lesions compared to that of normal muscle [NM] or normal bone marrow [NBM]) and quantitative (parameters of the ROIs in the lesions, including T1 ratio [ratio of T1 SI of lesion to that of NM], T2FMu ratio [ratio of T2 FS SI of lesion to that of NM], and T2FMa ratio [ratio of T2 FS SI of lesion to that of NBM]) analyses. Qualitative and quantitative characteristics of BMs and BRMs were compared. To evaluate the diagnostic utilities of quantitative parameters, ROC curves were analyzed.

## RESULTS

Hyperintensity relative to NM or NBM on T2 FS was more frequent in BMs than in BRMs (100% vs 59.5%~78.4%, respectively;  $p=0.001$ ) but also was present in more than half of BRMs. All quantitative parameters showed a significant difference between BMs

and BRMs (T1 ratio, 1.075 vs. 1.227 [p=0.002]; T2FMu ratio, 2.094 vs. 1.282 [p<0.001]; T2FMa ratio, 3.232 vs. 1.810 [p<0.001]). The ROC AUCs of T2FMu and T2FMa ratios were clinically useful (0.781 and 0.841, respectively) and didn't demonstrate statistically significant differences.

## CONCLUSION

s The quantitative analysis of T2 FS can be useful in differentiating BMs from BRMs, regardless of whether the reference was NM or NBM.

## CLINICAL RELEVANCE/APPLICATION

Quantitative analysis of conventional T2 FS without additional scanning could be used to differentiate bone metastases from benign red marrow depositions, regardless of whether the comparison reference was normal muscle or normal bone marrow.

## R2-SPMK-8 Can Material Density Imaging Improve Detection of Healthy-appearing Bone Metastases at Contrast-enhanced Dual-energy CT?

Participants

Hitoshi Takeuchi, MD, Fuchu, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Because CT is an imaging modality of choice for oncologic assessment but not sufficiently sensitive to detect bone metastases, sensitive detection of bone metastases by material density imaging is expected at body contrast-enhanced dual-energy CT (ceDECT). We assessed usefulness of water/hydroxyapatite (W/H-DI) and iodine/water density imaging (I/W-DI) to improve detection of healthy-appearing bone metastases at body ceDECT.

## METHODS AND MATERIALS

From September 2022 through March 2023, two experienced radiologists by consensus included 41 bone metastases that appeared healthy without definite sclerotic/lytic changes or mass formation on virtual monochromatic imaging (VMI) at 70 keV but were diagnosed by MRI, bone scintigraphy/SPECT, and/or FDG-PET/CT from four patients who underwent body ceDECT during the venous phase using a 256-detector DECT scanner (Revolution CT, GE). We reconstructed VMI at 70 keV, W/H-DI, and I/W-DI of slice thickness of 1.25 mm with a deep-learning reconstruction algorithm (TrueFidelity, GE) to place regions of interest within each healthy-appearing bone metastasis and its corresponding non-metastatic area with anatomical symmetry (for a vertebral metastasis, a non-metastatic area in only a little more cranial/caudal vertebra) as reference to measure mean CT value, W/H density, and I/W density, respectively. Paired t test was used to compare the mean CT value, W/H density, and I/W density between the healthy-appearing bone metastases and the reference areas. Receiver operating characteristic (ROC) analysis was adopted to assess diagnostic performance of these parameters to detect healthy-appearing bone metastases.

## RESULTS

W/H density was significantly higher ( $985.3 \pm 10.9$  mg/mL vs.  $962.9 \pm 10.6$  mg/mL;  $P < 0.001$ ) and I/W density was significantly lower in the metastases than in the reference areas ( $3.4 \pm 1.4$  mg/mL vs.  $3.8 \pm 1.3$  mg/mL;  $P < 0.001$ ), whereas CT value at 70 keV was comparable ( $151.3 \pm 62.8$  HU vs.  $149.1 \pm 60.7$  HU;  $P = 0.429$ ). Area under the ROC curve improved from CT value at 70 keV (0.513) to I/W density (0.595) to W/H density (0.951).

## CONCLUSION

s Material density imaging, particularly W/H-DI, can improve detection of healthy-appearing bone metastases at body ceDECT.

## CLINICAL RELEVANCE/APPLICATION

As a comprehensive oncologic study, ceDECT with improved detectability of bone metastases by W/H-DI can reduce radiation exposure and/or medical cost and improve patient management by omitting unnecessary further examinations.

R2-SPNMMI

### Nuclear Medicine & Molecular Imaging Thursday Poster Discussions

#### Sub-Events

#### **R2-SPNMMI- Functional Imaging Metrics in Patients with Metastatic Paraganglioma/pheochromocytoma Treated with Lu-177-dotatate: A Single-center Experience**<sup>1</sup>

Participants

Ridvan Demirci, MD, Seattle, WA (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Paragangliomas and pheochromocytomas are rare neuroendocrine tumors for which there is no standard of care for patients that develop metastatic disease. Radioligand therapy in neuroendocrine tumors shows promising results in disease control with minimal adverse events. This study describes our observations of changes in functional imaging metrics relative to time to progression (TTP) with Lu-177-dotatate treatment in patients with metastatic paraganglioma/pheochromocytoma (mPara/Pheo).

#### **METHODS AND MATERIALS**

Of nine patients with mPara/Pheo treated with four cycles of Lu-177-dotatate, eight patients had both pre-and post-treatment dotatate PET and were included in the image analysis. Total tumor volume (mL, TV) was determined by thresholding all tumor sites with uptake above blood pool activity measured from the left ventricle. SUV<sub>mean</sub> of the TV and ratio of SUV<sub>mean</sub> TV to liver (SUV<sub>mean</sub> T:L ratio) were also measured, and changes between these parameters on pre and post imaging were calculated. Progression was defined as presence of new lesions on post-treatment dotatate PET or by RECIST in those with RECIST measurable disease. TTP was calculated from the date of the 1st cycle.

#### **RESULTS**

Median age in the cohort was 52 [range 33 to 83], 4 female, with 0 - 1 lines of prior therapy. Median TTP for all patients was 19 [range 4 to 26]. Patients were then divided into two groups, those with progressive disease (N=2, PD) and those with stable disease or partial response (N=6, SD), on initial re-staging scans after the 4th cycle. Median values of TTP were 5 months [range 4 to 6] and 20.5 months [range 13 to 26], respectively. In the two patients in the PD group, TV increased by 103% and 235% from the pre-treatment scan and SUV<sub>mean</sub> T:L ratio decreased by 8% and 35%. Median change in TV in the SD group was -7.5% [range -43% to +25%]. Two had increased TV, and the remaining four had decreased TV in their post-treatment scans compared to pre-treatment scans. Median SUV<sub>mean</sub> T:L ratio change was -14.5% [range -52% to +53%].

#### **CONCLUSION**

Functional imaging metrics, particularly tumor volume, may have predictive power for clinical outcomes in metastatic paraganglioma/pheochromocytoma. Further studies with a larger patient population and correlation with other clinical and biochemical parameters are needed to confirm these results.

#### **CLINICAL RELEVANCE/APPLICATION**

Functional imaging metrics may serve as an independent biomarker of response in patients with metastatic paraganglioma/pheochromocytoma.

#### **R2-SPNMMI- The Usefulness of FDG-PET Indexes Including Heterogeneity Parameters in the Prediction of Initial Chemo-radiotherapeutic Effect in Oropharyngeal Cancer**<sup>2</sup>

#### **PURPOSE**

FDG-PET parameters were useful for prediction for the treatment response in various tumors. However, few reports have been analyzed regarding predictivity of FDG-PET indexes particularly heterogeneity indexes for the initial treatment response to chemoradiotherapy in oropharyngeal cancers. The study was done to analyze the predictive capability of various FDG-PET indexes, including heterogeneity parameters such as Entropy, Kurtosis and Skewness for the initial treatment response to chemoradiotherapy.

#### **METHODS AND MATERIALS**

Sixty-six patients with oropharyngeal cancer were analyzed. Forty patients showed CMR after the initial chemo-radiotherapy. Average age was 63.4, the gender ratio was male 51 and female 15. The case number of each stage were 12 in stage II, 39 in stage III and 15 in stage IV respectively. After the initial therapy, complete remission (CMR) was 48 and partial remission (PMR) was 18 cases based on PERCIST criteria using FDG-PET. The group comparison was done between CMR and PMR group regarding SUV<sub>max</sub>, SUV<sub>peak</sub>, metabolic tumor volume (MTV) and total lesion glycolysis (TLG). In addition, the values of heterogeneity indexes such as Entropy, Kurtosis and Skewness were also compared. Then under the best cut-off level, the value of positive predictive values (PPV) for CMR were compared among these parameters.

#### **RESULTS**

Both MTV and TLG values showed significantly lower values in CMR group compared with those in PMR group (9.1 vs. 18.7ml, and

71.9 vs. 157.5g). Other parameters did not show any statistical significance. In the cases with lower TLG (<70g) at baseline, the rate of CMR cases was 100%. Similarly, the cases with lower MTV (<10ml) at base line showed CMR response in 90%. The value of PPV (%) in CMR to the chemo-radiotherapy under the best cut-off values were 100% in TLG, 90% in MTV, 85.7% in SUVmax, 80% in SUVpeak, 69.2% in Entropy, 76.9% in Kurtosis, and 63.6% in Skewness.

#### **CONCLUSION**

s In the prediction of therapeutic response for oropharyngeal cancer, both TLG and MTV were excellent parameters. Among, heterogeneity indexes, Kurtosis seemed to be promising parameter for predicting chemo-radio therapeutic response.

#### **CLINICAL RELEVANCE/APPLICATION**

In the prediction of chemoradiotherapy for oropharyngeal cancer, the heterogenetic index in particular kurtosis preferably checked in addition to TLG and MTV.

## Abstract Archives of the RSNA, 2023

R2-SPNPM

### Noninterpretive Skills (Beyond Imaging) Thursday Poster Discussions

#### Sub-Events

#### R2-SPNPM-1 Prevalence and Impact of Workplace Sexual Harassment Among Medical Sonographers in the United States

Participants  
Sue Yi, PhD,BS, Verona, WI (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the prevalence and impact of workplace sexual harassment experienced by sonographers in the USA with a national survey including both quantitative and qualitative data.

#### METHODS AND MATERIALS

A survey was adapted from multiple existing well validated instruments and distributed anonymously to a convenience sample of medical sonographers via email contacts and sonographer-specific social media pages. Survey data were analyzed to determine respondent demographics, the prevalence of sexual harassment in the last two years, the type and severity of harassment experienced, demographics of perpetrators, personal and institutional responses to such experiences, and the impact of sexual harassment on sonographer physical and mental health and job satisfaction.

#### RESULTS

220 sonographers (82.7% female) participated in the survey. The majority (45%) were aged between 18 and 34 years, and 81% identified as white. The majority (87%) reported experiencing at least one incident of harassment within the last two years. Female respondents experienced higher harassment rates (76%) compared to male respondents (50%,  $p=0.02$ ). The most common forms of harassment were verbal, including suggestive or sexist jokes (69%) and offensive sexist remarks (61%). Perpetrators were predominantly male (78%) and most commonly patients (89%) or their friends/family members (46%). The majority of respondents either ignored the harassing behavior (70%) or treated it like a joke (50%), with only a minority (12%) officially reporting incidents. Of those who reported, 44% were unsatisfied with their institution's response. Among respondents, 34% reported negative impacts of workplace sexual harassment, such as anxiety, depression, sleep loss, or adverse workplace consequences.

#### CONCLUSION

Sexual harassment experienced by sonographers in the workplace is commonplace, and often leads to negative health and career outcomes. Female sonographers are significantly more likely to experience harassment compared to male sonographers, and in a profession where 90% of sonographers are female, it is critical to find systemic methods to prevent harassment behavior and support victims of sexual harassment in the workplace.

#### CLINICAL RELEVANCE/APPLICATION

Sexual harassment is prevalent among sonographers, harming their physical and mental health. Strong institutional policies are critical to curb harassment and lessen its impact.

#### R2-SPNPM-2 The Shift From Hospital Based Imaging To The Office Setting: A Medicare Analysis from 2013 to 2020

Participants  
Aditya Khurana, MD, Scottsdale, AZ (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate trends in productivity for diagnostic radiologists serving the Medicare population, by practice setting.

#### METHODS AND MATERIALS

All imaging interpretation claims from 2013 to 2020 were extracted from the CMS POSPUF Database for Medicare Part B, a national social insurance program providing health insurance for outpatient services for Americans over 65 yrs and disabled. Claims data were merged with CMS data files to determine the year specific total professional component (wRVU) value for each procedure. These values were aggregated for each individual radiologist and stratified by "Place of Service." "Place of service" has two possible values: "Facility" includes hospital affiliated sites, emergency room, or ambulatory surgery center, while "Non-facility" includes private offices and urgent care facilities. Market share of services was defined as the proportion of wRVUs from a given setting divided by wRVUs performed in both settings. Claims were assigned to a US Census region.

#### RESULTS

In 2013, there were 52,179,386 total imaging wRVUs, 63,276,990 (+21.3%) in 2019, and 53,907,670 (-14.8%) in 2020. Facility (hospital) settings accounted for 42,607,520 wRVUs in 2013, 48,578,010 (+14.0%) in 2019, and 40,957,510 (-15.7%) in 2020. Facility market was 81.7% in 2013, 76.8% in 2019, and 76.0% in 2020. Non-facility (office) services accounted for 9,571,866 wRVUs in 2013, 14,698,980 in 2019 (+53.6%), and 12,950,160 (-11.9%). Non-facility market share was 18.3% in 2013, 23.2% in

2019, and 24.0% in 2020. By US region, 2020 total outpatient imaging wRVUs and CAGRs were: South 4,928,295 (+28.1% from 2013), Northeast 3,228,274 (+44.2%), West 2,791,136 (+31.9%), and Midwest 2,002,454 (+46.1%). 2020 wRVU market share of non-facility services by US region was: Northeast 30.5% (+8.7% from 2013), West 29.1% (+3.4%), South 23.6% (+5.5%), and Midwest 15.5% (+4.5%).

## **CONCLUSION**

s In the Medicare population, the rate of growth of office based imaging wRVUs outpaced growth of hospital settings by 39.4% from 2013 to 2020. Office market share grew by 5.7% nationally, and by 3.4% - 8.7% across US regions. These findings document a shift toward office settings, which are often less subject to peer review, validation, or regulation than are hospital settings. This shift follows several legislative, regulatory and payer efforts to steer patients toward lower cost settings. Further research is advised to ensure appropriate imaging utilization and consistent high quality patient care is provided in non-facility settings.

## **CLINICAL RELEVANCE/APPLICATION**

Outpatient imaging services for the US Medicare population have shifted from hospital based to office settings, which are often less expensive, yet also less regulated.

## **R2-SPNPM-3 The ACR Learning Network Mammography Positioning Improvement Collaborative: Facilitating Local Performance Improvement through Shared Learning**

Participants

Sarah Pittman, MD, FRCPC, Stanford, CA (*Presenter*) Nothing to Disclose

## **PURPOSE**

To establish and maintain consistent excellent performance in mammography positioning at multiple sites simultaneously by utilizing a structured quality improvement (QI) program within a learning network framework that enables participating sites to develop and implement locally-successful strategies while sharing with and learning from other sites.

## **METHODS AND MATERIALS**

The Mammography Positioning Improvement Collaborative is led by a physician leader and administrative leader, supported by learning facilitators and an advisory committee comprised of national experts and thought leaders. Sites enter the collaborative by first participating in a structured QI training and project execution program. Sites were selected on the basis of strength of local leadership support, intra-organizational relationships, access to data and analytic support, and experience with QI initiatives. During the QI program, participating sites went through a process of organizing their teams, developing goals, gathering data, evaluating their current state, understanding root causes of problems, and developing and testing solutions. A common process map and an image quality scoring system were established. The impact of the interventions implemented at each site was assessed by tracking the percentage of screening mammograms meeting overall passing criteria over time.

## **RESULTS**

Six organizations were selected to participate in the first cohort of the collaborative, beginning with participation in the QI program. Run charts from the six sites show that interventions developed and implemented at each site during the program resulted in improvement in the percentage of screening mammograms meeting overall passing criteria, with five of six sites meeting or exceeding the target mean performance of 85% by the end of the QI program. Anticipated variability in progress is observed between sites.

## **CONCLUSION**

s Using a structured QI program within a learning network framework, five of six sites participating in the first cohort of the Mammography Positioning Improvement Collaborative increased the percentage of screening mammograms meeting overall passing criteria from a collaborative mean of 59% to greater than 85%.

## **CLINICAL RELEVANCE/APPLICATION**

Suboptimal mammography positioning can lead to undetected breast cancer on mammograms. A structured QI program within a learning network framework can facilitate improvement in mammography positioning at multiple sites simultaneously.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

R2-SPNR

### Neuroradiology Thursday Poster Discussions

#### Sub-Events

#### R2-SPNR-1 **White Matter Lesion Asymmetry: An Indicator of Amyloid PET Positivity in Mild Cognitive Impairment Patients**

Participants

Hye Weon Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### PURPOSE

Assessing amyloid-positivity in mild cognitive impairment (MCI) patients is crucial as it may indicate a higher risk of developing dementia. This study aims to investigate whether the asymmetry of white matter lesions (WML) on T2-fluid attenuated inversion recovery (FLAIR) magnetic resonance imaging (MRI), assessed through artificial intelligence (AI) based hyperintensity segmentation, could potentially serve as an indicator for amyloid positron emission tomography (PET) positivity in patients with MCI.

#### METHODS AND MATERIALS

In this retrospective cohort study, MCI patients who visited a clinical site in South Korea were enrolled. The participants underwent a comprehensive evaluation, including clinical and neuropsychological assessments, brain MRI, and [18F]-Flutemetamol amyloid PET. Our study utilized in-house AI based software for segmenting and separating WML into left and right hemispheres. Using the processed segmentation, we measured individual WML differences through volumetric assessment.

#### RESULTS

A total of 122 subjects were enrolled in the study, with 53 in the amyloid-negative group and 69 in the amyloid-positive group based on amyloid-PET positivity. The two groups were comparable, with no significant differences in age ( $p=0.189$ ), sex ( $p=0.057$ ), education years ( $p=0.411$ ), and MMSE scores ( $p=0.861$ ). However, the amyloid-positive group showed a significantly higher frequency of having an e4 allele of APOE genotype ( $p=0.033$ ) and Clinical Dementia Rating scale ( $p=0.024$ ). The average WML volume differences between hemispheres were significant in the amyloid-negative group ( $p=0.02$ ) but not in the amyloid-positive group ( $p=0.2$ ). Both groups had a larger WML volume in the right hemisphere, which did not differ significantly between the groups.

#### CONCLUSION

Our study results indicate that it is crucial to evaluate the asymmetry of WML rather than the total hyperintensity lesion load in MCI patients, especially in those without amyloid pathology. Therefore, WML asymmetry could be a potential indicator of amyloid positivity in MCI patients.

#### CLINICAL RELEVANCE/APPLICATION

The WML asymmetry could be utilized as an indicator for amyloid PET positivity in MCI patients.

#### R2-SPNR-10 **Impact of an AI Software on the Diagnostic Performance of Radiologists for the Detection of Cerebral Aneurysms on Time of Flight MR-Angiography**

#### PURPOSE

To evaluate the impact of an AI based software trained to detect cerebral aneurysms on Time-of-Flight MR-Angiographies on the diagnostic performance and reading times of multiple readers with different amounts of experience in diagnostic neuroimaging.

#### METHODS AND MATERIALS

A dataset of 186 MRI studies was evaluated by the different readers for the presence and localization of cerebral aneurysms. First, the reading was done with the support of an AI based software. After a washout period of six weeks, the reading was repeated without the support of the AI software. To document the findings and to measure the reading times, a standardized report was used. The results were compared to the consensus reading of two neuroradiological specialists as a reference standard and sensitivity on patient level and lesion level, specificity on patient level, and false positives per case were calculated.

#### RESULTS

According to the reference standard, there were 54 aneurysms present in the dataset. Six readers took part in the reading with no experience (three medical students), two years experience (resident in neuroradiology), six years experience (fellow neurointerventional radiologist) and twelve years experience (neuroradiology specialist), respectively. Sensitivities on lesion level ranged from 66.7% - 87.0% with AI and 57.7% - 87.0% without AI, sensitivities on patient level ranged from 63.4% - 81.8% with AI and 52.3% - 75.0% without AI. Specificities ranged from 93.7% - 97.2% with AI and 89.4% - 98.6% without AI. False positive findings per case ranged from 0.03 - 0.12 with AI and 0.02 - 0.17 without AI. The differences in diagnostic performance did not reach the level of statistical significance. 4 out of 6 readers showed significantly shorter reading times with the use of AI, while the remaining two readers showed a significant increase in reading times.

#### CONCLUSION

s In our retrospective study, we found equivocal results for the diagnostic performance of six different readers for the detection of cerebral aneurysms with and without the use of an AI software. Although we found a tendency towards a better diagnostic performance, these differences were not statistically significant. The majority of readers showed a significant decrease of reading times, but the radiologist and one medical student showed a significant increase of reading times.

#### **CLINICAL RELEVANCE/APPLICATION**

AI softwares for the detection of pathologies in neuroimaging are increasingly used in the clinical routine. There is a chance that the use of the softwares may improve readers' performances, but radiologists must be aware that with the use of additional softwares, there is a risk of slowing down established workflows without a significant increase in diagnostic performance.

### **R2-SPNR-11 Sensitivity and Specificity of Ischemia Detection on Brain MRIs using a Commercially Available Deep Learning Algorithm in Patients with Suspected Stroke from a Non-comprehensive Stroke Center**

#### **PURPOSE**

Several deep learning artificial intelligence (AI) products exist to detect intracerebral pathology in magnetic resonance imaging (MRI). We set out to estimate the ability of a commercially available CE-approved AI product to detect acute brain ischemia on MRI, compared to an experienced Neuroradiologist.

#### **METHODS AND MATERIALS**

We retrospectively included patients from January 2020 based on the following criteria: Age = 18 years, brain MRI due to suspicion of stroke, with onset of symptoms within four weeks prior to the scan. The Neuroradiologist reinterpreted the MRI scans and subclassified ischemic lesions, serving as the reference test. Scans were excluded if artifacts hampered interpretation, or if sequences were missing. The patients were scanned by one of four different MRI models from the same vendor. The first 3/4 of the patients were included consecutively and the remaining patients were included in an enriched manner to increase the size of subgroups of less frequent ischemic lesions. The index test was a CE-approved AI product.

#### **RESULTS**

The final analysis cohort comprised 995 patients (mean age 69 years, 53% female). A case-based analysis for detecting acute or subacute ischemic lesions showed a sensitivity of 89% (95% CI: 85%-91%) and specificity of 90% (95% CI: 87%-92%). In the consecutive cohort only, consisting of 767 patients, we found a sensitivity of 86% (95% CI: 80-90%) and a specificity of 90% (95% CI: 87-92%). The consecutive and enriched cohorts did not differ significantly in sensitivity, nor was there a significant difference in sensitivity or specificity based on sex or age. However, specificity was significantly reduced in cases with DWI artifacts as opposed to those without (77% vs. 91%,  $p < 0.01$ ). Sensitivity increased significantly with lesion size, for fragmented lesions, and for lesions with signs of hemorrhagic transformation. Furthermore, sensitivity varied with the radiological age of the ischemic lesions. For lesions located in multiple anatomical subgroups, sensitivity was 97% (95%CI 94%-99%), while it was 82% (95%CI 77%-87%) for lesions located within one anatomical subgroup, which was significantly different ( $p < 0.001$ ).

#### **CONCLUSION**

s The AI product exhibits high sensitivity and specificity in detecting acute ischemic lesions on MRI compared to an experienced Neuroradiologist at our non-comprehensive stroke center. However, upon clinical application of this AI tool, awareness of the reduced sensitivity for detecting smaller ischemic lesions is required.

#### **CLINICAL RELEVANCE/APPLICATION**

Validating AI products that analyze brain scans is essential before clinical application as they can impact patient diagnostics. AI models often decrease accuracy in clinical settings, highlighting the need for validation studies.

### **R2-SPNR-12 Diagnostic Performance of ChatGPT from Patient History and Imaging Findings in Neuroradiology**

#### **PURPOSE**

To evaluate the diagnostic performance and utility of Generative Pre-trained Transformer (GPT)-4 based ChatGPT in neuroradiology.

#### **METHODS AND MATERIALS**

We collected 80 consecutive "Case of the Week" cases in the American Journal of Neuroradiology between October 2021 and April 2023. ChatGPT was provided with patient history and imaging findings for each case and asked to provide a diagnosis. The generated diagnoses were compared with the ground truth to evaluate ChatGPT's diagnostic accuracy rate. Each case was categorized by anatomical location (brain, spine, and head neck). Brain cases were further divided into two groups: the central nervous system (CNS) tumor group and the non-CNS tumor group. The Fisher's exact tests were conducted to compare the diagnostic accuracy rates among the three anatomical locations, as well as between the CNS tumor and the non-CNS tumor groups.

#### **RESULTS**

ChatGPT's overall diagnostic accuracy rate was 43% (34/80). When categorized by anatomical location, the diagnostic accuracy rates were 40% (24/60) in brain cases, 60% (6/10) in spine cases, and 40% (4/10) in head neck cases. There was no significant difference in the diagnostic accuracy rates among the three anatomical locations ( $p = 0.56$ ). When comparing the CNS tumor and non-CNS tumor groups, the diagnostic accuracy rates were 8% (1/13) in the CNS tumor group, and 49% (23/47) in the non-CNS tumor group. The diagnostic accuracy rate was significantly lower for the CNS tumor group compared to the non-CNS tumor groups ( $p < 0.01$ ).

#### **CONCLUSION**

s This study demonstrates the potential of ChatGPT's diagnostic performance and utility in neuroradiology. ChatGPT can be used without considering anatomical locations in neuroradiology. ChatGPT's diagnostic accuracy may vary depending on the etiology of the diseases, and its diagnostic accuracy is significantly lower in CNS tumors compared to other diseases. Radiologists should understand the potential advantages and limitations of ChatGPT as a diagnostic tool and decision support system.

#### **CLINICAL RELEVANCE/APPLICATION**

The integration of ChatGPT into neuroradiology practice has the potential to revolutionize the field. improve diagnostic accuracy.

The integration of enhanced image reconstruction, provides not only the potential to revolutionize the field, improve diagnostic accuracy, and ultimately improve patient outcomes.

## **R2-SPNR-13 Improved Differentiation of Cavernous Malformation and Acute intraparenchymal Hemorrhage on CT using AI Algorithm**

Participants

Hwangseon Ju, Gyeonggi-Do, Seongnam-Si, Bundang-Gu,, Korea, Republic Of (*Presenter*) Nothing to Disclose

### **PURPOSE**

The aim of this study was to evaluate the utility of an artificial intelligence (AI) algorithm in differentiating between cavernous malformation (CM) and acute intraparenchymal hemorrhage (AIH) on brain computed tomography (CT) images, as the differentiation between these two conditions can be challenging on brain CT and may lead to unnecessary additional studies in clinical practice.

### **METHODS AND MATERIALS**

A retrospective, multi-reader, randomized study was conducted to validate the performance of the AI algorithm (SK Inc. CC Medical Insight + Brain Hemorrhage), a commercial software product, in differentiating AIH from CM on brain CT images. CT images of CM and AIH smaller than 3 cm were collected from the electronic database search. The diagnostic performance of the AI algorithm for differentiating CM and AIH was evaluated using the area under the receiver operating characteristics curve (AUC). Six blinded reviewers, including two neuroradiologists, two radiology residents, and two emergency department physicians, evaluated CT images from 288 patients (CM, n = 173; AIH, n = 115) with and without AI assistance, and the diagnostic performance was compared.

### **RESULTS**

The overall AUCs for AI standalone performance in the dataset were 0.93 and 0.92 for slice-wise and patient-wise analyses, respectively. The best diagnostic performance was achieved with a cut-off level of 97.75 % and 97.95 %, sensitivity of 97.1 % and 94.2 %, and specificity of 73.0 % and 73.0 % in slice-wise and patient-wise analyses, respectively. Brain CT interpretation by the reviewers with AI assistance resulted in significantly higher diagnostic accuracy than that without AI assistance (86.92 % vs. 79.86 %,  $p < 0.0001$ ). Radiology residents and emergency department physicians showed significant improvement in the diagnostic accuracy for brain CT interpretation with AI assistance compared to that without AI assistance (84.21 % vs 75.35 %, 80.73 % vs. 72.57 %; respectively, all  $p < 0.05$ ). Neuroradiologists showed a trend of higher diagnostic accuracy with AI assistance in the brain CT interpretation, but with no statistically significant difference (95.83 % vs. 91.67 %).

### **CONCLUSION**

The use of AI algorithm can enhance the differentiation of AIH from CM in brain CT interpretation for non-experts in neuroradiology.

### **CLINICAL RELEVANCE/APPLICATION**

The AI algorithm can aid in the proper diagnosis and management of patients who present with a hyperdense lesion on brain CT in clinical practice.

## **R2-SPNR-14 Battle of the Brains: Exploring the Accuracy of Artificial Intelligence in Detecting Brain Bleeds on CT Scans**

Participants

Victor Tang, MBBS, BSc, Melbourne, Australia (*Presenter*) Nothing to Disclose

### **PURPOSE**

Artificial intelligence (AI) has the potential to improve the accuracy and speed of diagnosis of acute intracranial haemorrhage (ICH) which can enhance daily radiology practice and reduce diagnostic errors. As the number of commercial AI algorithms increase, radiology departments are met with a choice of which companies to partner with. This study aimed to compare the performance of two different AI algorithms in detection of ICH on CT scans.

### **METHODS AND MATERIALS**

All technically adequate non-contrast CT brain studies collected over one month were second-read independently by a neuroradiologist to establish a ground truth for the presence of ICH. Two AI algorithms (1 and 2) were then utilized to review these CT studies and assess them for the presence of ICH. The outputs of the AI algorithms were then compared to the ground truth in order to evaluate their diagnostic accuracy and to compare their performance. Repeat CT brains performed on the same patient were included within the study.

### **RESULTS**

A total of 1241 brain CT scans were performed within the study period, with 1058 scans marked as negative and 183 scans marked as positive for ICH (14% incidence) by the neuroradiologist. The sensitivity and specificity for Algorithm 1 was 86.3% and 97.2%, respectively. Stratifying by location (emergency [ED], inpatient [IP], outpatient [OP]), the sensitivity was 82.6% (ED), 91.1% (IP), 53.8% (OP), the specificity was 97.1% (ED), 97.3% (IP), 91.7% (OP). The sensitivity and specificity for Algorithm 2 was 88.5% and 96.7%, respectively. Stratifying by location, the sensitivity was 87.0% (ED), 91.1% (IP), 69.2% (OP), the specificity was 96.7% (All), 97.2% (ED), 96.0% (IP), 94.4% (OP). Statistical analysis of the data was conducted using a McNemar test. No statistically significant differences between the two algorithms were found at a significance level of 0.05; all cases P-value: 0.913, ED P-value: 1, IP P-value: 0.458, OP P-value: 0.453

### **CONCLUSION**

Both algorithms demonstrate high diagnostic accuracy with no significant difference. The drop in OP sensitivity could be due to the low sample size (power = .80). AI 2 did provide a differential output for ICH subtypes, however this was not evaluated in this study. Nonetheless, other features of the AI, such as detection of pathologies other than ICH, user interface and cost, will carry more weight in determining which AI solutions to integrate into the departmental workflow.

### **CLINICAL RELEVANCE/APPLICATION**

The growing number of commercial AI algorithms presents radiology departments with an opportunity of selecting a partner

The growing number of commercial radiomics products, regulatory requirements, and opportunities for creating a profitable company, in order to enhance daily practice and reduce diagnostic errors.

## **R2-SPNR-2 Automatic Brain MRI Segmentation Quality Control for More Reliable Study Outcomes**

### **PURPOSE**

Large-scale (>10,000) retrospective observational studies of quantitative regional brain volume assessment from magnetic resonance imaging (MRI) require automated segmentations (SEG). Segmentation errors on standard clinical data are frequent and hamper results. We seek to mitigate this with automated reliability quantification.

### **METHODS AND MATERIALS**

All 35,818 consecutive 3D T1 brain MRI scans acquired for clinical purposes on 24,261 patients in 11 hospitals in the Capital Region of Denmark during 2019 and 2020 were harvested after regulatory waiving of consent. All MRIs were processed and segmented in anatomical brain regions using FAST-AID Brain [DOI:10.48550/arXiv.2208.14360]. A random subset of 4,887 MRIs was manually categorized by a neurologist as with no, minor, and major SEG failure. We fine-tuned a pre-trained 3D residual convolutional neural network (3DResNet) [DOI:10.1038/s41467-019-13163-9] on 3,910 brain MRIs excluding minor SEG failure to predict the SEG failure probability. We compared various scan exclusion (SE) methods, including no SE, manual SE based on major SEG failure (MM1), and manual SE based on any SEG failure (MM2). To examine the automatic approach, we excluded equally many scans with the highest predicted SEG failure probability matching MM1 and MM2, resulting in AM1 and AM2, respectively. We assessed male-female separation using Cohen's d (CD) across age groups for intracranial volume (ICV), hippocampus, cerebellum, and ventricles and computed the minimum sample size per group (MSS) to obtain a power of 0.8 with an alpha of 0.05.

### **RESULTS**

On the test set containing no and major SEG failures, we achieved a ROC-AUC of 0.98 and a PR-AUC of 0.99, with a specificity of 0.93 and an accuracy of 0.94 at the 95% sensitivity level. For ICV, both manual and automatic SE methods showed similar separation, with a higher CD for most age groups compared to no SE. Both approaches resulted in a larger average CD for all examined brain regions. The required MSS was significantly reduced, up to five times, compared to no SE.

### **CONCLUSION**

Employing a machine learning-based approach for predicting SEG failure probability effectively improves the power of retrospective clinical studies focusing on quantitative regional brain volume assessment. The automatic SE method led to a larger average CD for all examined brain regions and substantially reduced the required MSS, ultimately contributing to more reliable conclusions and improved power in retrospective observational studies.

### **CLINICAL RELEVANCE/APPLICATION**

Accurate and reliable quantitative regional brain volumes from MRI are critical for large-scale retrospective observational studies of neurological disorders. We automate quality assurance to increase power and insight.

## **R2-SPNR-3 Advancing the Use of IA in Clinical Practice: Preliminary Outcomes of a Retrospective Clinical Validation Analysis of an AI Volumetric Segmentation Model**

Participants  
Rafael Loureiro, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

### **PURPOSE**

The use of Artificial Intelligence (AI) in radiology presents a potential remedy to the escalating volume of medical exams and the insufficient number of specialists. Nonetheless, most AI applications in radiology have not undergone rigorous clinical validation trials. Such validation is essential to reveal any unforeseen downstream implications of implementing AI models in clinical practice, including sociodemographical factors that could affect the model's performance. Additionally, most volumetric brain segmentation tools were originally designed for Magnetic Resonance Imaging (MRI), which is more expensive, time-consuming, and limited in availability compared to Computed Tomography (CT). To tackle such challenges, we evaluated the reliability and accuracy of an AI model in the volumetric segmentation of the intracranial region and lateral ventricles task, using a retrospective dataset comprised of real-world head CT exams stored in our institution's PACS.

### **METHODS AND MATERIALS**

The model is based on an efficient, lightweight U-Net architecture and performs concurrent segmentation in head 3D images of brain and lateral ventricles. For model development, 559 real-world CT images from neonates to adults were used and included typical and atypical cases besides different scanner models, and acquisition settings. For retrospective clinical validation, 167 anonymized exams from February 2021 were chosen. Intracranial and ventricular ground-truth (GT) binary masks were generated using simpleITK and 3D Slicer, respectively and were approved by board-certified neuroradiologists with at least 6 years of experience. Both generation and validation of GT masks were done remotely by using a 3D Slicer Docker web application and a dashboard based on Trame framework. Project approved by the institutional Ethics Committee.

### **RESULTS**

Comparison between GT and AI model's masks showed positive results with a mean Hausdorff distance metric and a mean Jaccard similarity index of 10,11 and 0,97, for the intracranial masks, and 13,20 and 0,65 for the ventricle masks, respectively. Intracranial volumes were more homogenous than the ventricles volumes.

### **CONCLUSION**

The proposed model demonstrated favorable outcomes by using a pipeline that does not require software installation or data download. Future efforts will focus on advancing the model to a prospective stage by conducting external clinical validation using multicentric real-world data.

### **CLINICAL RELEVANCE/APPLICATION**

The model can accurately and efficiently segment CT exams, according to clinical retrospective results. In the future, it might help diagnose patients with greater precision and effectiveness, especially in resource-limited settings.

## **R2-SPNR-4 An Experimental Study of Newborn Pigs Based on MRI Histological Analysis: Pathological Control for Predicting Brain Edema Gradation in HIE**

### **PURPOSE**

Hypoxic-ischemic encephalopathy is one of the causes of death and severe disability in clinical children. Cerebral edema is the main pathological change affecting the clinical prognosis of HIE. Because the pathology of HIE cannot be obtained, clinical experience is commonly used to determine. Noninvasive and rapid prediction of the degree of cerebral edema is essential for clinical decision-making. To solve the clinical problem, we performed pathological studies by simulating clinical children through HIE animals. According to the pathological changes of brain tissue, the MRI images were divided into mild edema group and severe edema group, so that the microscopic pathological changes corresponded to the abnormal signals of macroscopic images. Then the microscopic pathological changes were associated with the omics model, and finally the omics model with pathological validation was realized to predict the HIE brain edema grade.

### **METHODS AND MATERIALS**

The HIE model was established by sealing both common carotid arteries and hypoxia in 54 newborn Yorkshire breeding pigs. T2WI and DWI scans were performed at 1 h, 3 h, 6 h, 9 h, 12 h, 16 h, 22 h, and 24 h. At the end of scanning at each time point, a group of neonatal pigs were taken for pathological examination of brain tissue. It provides a biological basis for omics research and explores the biological significance of image-omics. Each sequence manually delineated ROI in the region of interest to extract omics features, and three methods of dimensionality reduction screening features were used to establish the model. The combination of sequences and classifiers with better efficacy was assessed with ROC curves, K-Fold cross-validation, etc.

### **RESULTS**

Based on the sequence DWI, T2WI, ADC and their combination, the classifiers with better model efficacy were LR, LR, KNN and SVM, and the AUCs were 0.89, 0.86, 0.80 and 0.84, respectively. LR model has the best performance among different classifiers. In the combined sequence and classifier power: the LR classifier training set AUC was 0.88; the validation set AUC was 0.89. Logistic regression classifiers based on DWI images had the best predictive model diagnostic efficacy. Gray level dependent matrix class features and homogeneity class features were found to have more important potential for differentiating brain edema.

### **CONCLUSION**

s 1. The logistic regression model based on DWI sequences was effective in identifying HIE brain edema in neonatal pigs. 2. The gray-scale dependent matrix and homogeneity correlation features have the potential to be used as imaging biomarkers to reflect the degree of HIE edema.

### **CLINICAL RELEVANCE/APPLICATION**

To provide a non-invasive histological prediction model with pathobiological significance for children with clinical HIE.

## **R2-SPNR-5 Deep Learning-based CT to MRI Image Synthesis with Contrastive Loss**

### **Participants**

Seungyu Kim, Yongin-Si, Korea, Republic Of (*Presenter*) Nothing to Disclose

### **PURPOSE**

Magnetic Resonance Imaging (MRI) is an essential imaging modality in clinical radiology. However, conventional Positron Emission Tomography (PET) quantitative analysis requires MR images, and it is challenging to utilize PET images alone. Recently, deep learning-based generative models have been widely applied in the medical field, yet attempts to synthesize MRI images from CT scans, which possess higher resolution, are scarce. Moreover, as PET-CT devices are more commonly used than PET-MRI, patients often require multiple scans, leading to increased time and cost. In this study, we introduce a deep learning model utilizing contrastive loss to obtain MRI images from CT scans and demonstrate the feasibility of replacing conventional MRI with synthesized MRI for PET quantitative analysis with 18F-Fluorbetaben (FBB) PET imaging.

### **METHODS AND MATERIALS**

We used data from 150 patients with brain CT and T1 MRI scans. Among them, 114 were used for training and the remaining 36 for validation. The CT and MRI scans were co-registered using SPM12 and subsequently used for image translation training. We employed a 2D-based Generative Adversarial Network (GAN) model, utilizing four models: pix2pix, cycle-GAN, Dual Contrastive Learning GAN (DCLGAN) and Contrastive Unpaired Translation (CUT). We extracted slices from CT scans, trained the deep learning models to synthesize MRI slices from 256x256 CT slices, and combined the synthesized slices to generate MRI images.

### **RESULTS**

We assessed the performance using the Peak Signal-to-Noise Ratio (PSNR), Root Mean Square Error (RMSE), and Structural Similarity Index Measure (SSIM). DCLGAN showed the best performance with a PSNR of 24.13, RMSE of 0.1038, and SSIM of 0.8590. Qualitative evaluation also revealed that DCLGAN accurately predicted structures like basal ganglia and cerebellum, challenging to discern in CT scans. Moreover, we retrospectively compared SUVR evaluation using original MRI and synthesized MRI from 142 patients' FBB-PET scans, obtaining an Intraclass Correlation Coefficient (ICC) of 0.9561, indicating a strong correlation between them.

### **CONCLUSION**

s Our deep learning model demonstrates the ability to generate high-quality MRI images from CT scans, capturing intricate structures that are difficult to identify in CT images. This research highlights the potential of our approach as a valuable tool when MRI is inaccessible, ensuring continued advancements in medical imaging analysis.

### **CLINICAL RELEVANCE/APPLICATION**

Our deep learning model generates high-quality MRI images from CT scans, providing a time- and cost-effective alternative for clinical quantitative analysis, such as SUVR, when MRI is inaccessible.

## **R2-SPNR-7 Improved Multimodal Diagnosis of Alzheimer's Disease through MRI and PET Image Fusion**

### **PURPOSE**

Alzheimer's Disease (AD) is a degenerative neurological disorder commonly seen in the ageing population and there is currently no universally accepted atomic diagnostic technique. Previous studies have shown that multimodal analysis can be of great benefit in the diagnosis of AD. In this work, we present two novel multimodal diagnostic models for early detection of AD that utilize fused images from Magnetic Resonance Imaging (MRI) and Positron Emission Tomography (PET): the 2D dynamic image analysis model and the 3D image analysis model. These models have the potential to improve diagnostic accuracy and facilitate early detection of AD, allowing for timely interventions and better patient outcomes.

### **METHODS AND MATERIALS**

Our study utilized a dataset of 394 paired MRI and PET scans from the Alzheimer's Disease Neuroimaging Initiative (ADNI), which included 120 AD, 154 MCI, and 120 Normal Control (NC) scans. We performed multimodal fusion of paired images to create 3D images containing structural and functional information about the brain. We trained two deep learning models for AD diagnosis: a traditional 3D ResNet-18 model and a novel 2D dynamic image analysis model.

### **RESULTS**

Based on our experiments, we found that both models performed similarly well in more challenging tasks such as differentiating between AD and MCI (85.75% for the 2D model vs 85.66% for the 3D model) and distinguishing between AD, MCI, and NC (86.88% for the 2D model vs 86.20% for the 3D model). However, the 3D image analysis model showed higher accuracy in relatively simpler tasks such as distinguishing between AD and NC (96.11% for the 3D model vs 99.44% for the 2D model) and between MCI and NC (93.47% for the 3D model vs 98.80% for the 2D model).

### **CONCLUSION**

In this study, we have developed two advanced multimodal diagnostic models that offer efficient and accurate early Computer Aided Diagnosis (CAD) of AD and have experimentally demonstrated their effectiveness. Our models outperform existing multimodal diagnostic models using PET images and MRI images as input, in terms of decision-based fusion and image fusion. The proposed models have the potential to assist in early detection and diagnosis of AD, ultimately improving patient outcomes.

### **CLINICAL RELEVANCE/APPLICATION**

Our models have significant clinical relevance as they can aid in the early detection and diagnosis of AD, leading to improved patient outcomes. Although the 2D and 3D models perform similarly in some tasks, we recommend the 2D model due to its faster processing time. Our automated approaches have the potential to enhance healthcare professionals' performance and save costs.

## **R2-SPNR-8 Improved Neurovascular Imaging using Advanced Intelligent Clear-IQ Engine (AiCE)**

### **PURPOSE**

To evaluate the effects of deep-learning image reconstruction on image quality and diagnostic confidence of ultra-high-resolution computed tomography (UHRCT).

### **METHODS AND MATERIALS**

In this single-center study, 100 consecutive patients with acute neurological symptoms underwent CT imaging including cranial computed tomography (CCT) and computed tomography angiography (CTA) using an ultra-high resolution CT scanner. CTA images were reconstructed with normal resolution mode (NR-CTA, matrix 512 x 512, slice thickness 0.5 mm) and ultra-high resolution mode (UHR-CTA, matrix 1024 x 1024, slice thickness 0.25 mm) using iterative reconstruction. Additionally, a deep-learning reconstruction algorithm (advanced intelligent clear-IQ engine, AiCE); specifically trained for ultra-high resolution CT-angiography of the brain was utilized to generate a further UHR-CTA datasets (DL-UHR-CTA, matrix 1024 x 1024, slice thickness 0.25 mm). Image quality for all three reconstructions was evaluated visually by two blinded radiologists using a 4-point Likert-scale. Therefore, general (overall image quality, contrast in general, artifacts, diagnostic confidence and image noise) and vessel specific (assessability of proximal, intermediate and subcortical vessels as well as perforators) criteria were assessed. The quantitative features including slope, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), noise, entropy and co-occurrence matrix (COOC) were examined and compared using an in-house tool.

### **RESULTS**

Qualitative analysis revealed highest scores for DL-UHR-CTA, followed by UHR-CTA and NR-CTA, whereas DL-UHR-CTA yielded excellent results for all qualitative parameters and was significantly superior to UHR-CTA and NR-CTA (all  $p < 0.001$ ). The quantitative analysis was in line with the qualitative findings with significantly superior results for DL-UHR-CTA (slope:  $p < 0.01$ , SNR/CNR:  $p = 0.004$ , entropy  $p < 0.01$ , COOC:  $p < 0.01$ ).

### **CONCLUSION**

Deep-Learning image reconstruction significantly improves image quality of ultra-high resolution neurovascular CT-angiography allowing for higher diagnostic confidence, potentially improving the detection of subtle but oftentimes-significant pathologies.

### **CLINICAL RELEVANCE/APPLICATION**

Deep-learning image reconstruction improves the quality of UHR-CTA images, leading to higher diagnostic confidence and potentially aiding in the detection of subtle but clinically significant pathologies.

## **R2-SPNR-9 Prediction Model of Vascular Cognitive Impairment Based on MRI White Matter Hyperintensities Radiomics Features in the Elderly Patients with CSVD**

Participants  
Wei Wang, Xuzhou, China (*Presenter*) Nothing to Disclose

### **PURPOSE**

To establish a prediction model of vascular cognitive impairment (VCI) based on white matter hyperintensities (WMH) radiomics feature, in order to guide people at risk of VCI to carry out early intervention and delay the occurrence of VCI or dementia.

## **METHODS AND MATERIALS**

MRI data of 57 patients with VCI and 169 patients with no cognitive impairment (NCI) were retrospectively analyzed. Patients were randomly divided into training set (n=159) and test set (n=67) in a ratio of 7:3. The images were standardized and WMHs were segmented automatically by using the lesion prediction algorithm in the SPM software package. Two radiologists determined whether there was any error, and if there was any error, ITK-SNAP software was imported for manual delineation. Then features were extracted from the segmented WMHs to select the best image morphological features to build the model. Clinical data and conventional MRI signs were incorporated into the study to build a clinical model, and then the radiomics model was combined with clinical model. The receiver operating characteristic (ROC) curve was plotted and the decision curve analysis (DCA) was performed to evaluate the diagnostic efficacy and clinical application value of each model.

## **RESULTS**

8 radiomics features were extracted from WMH, and the WMH radiomics model, clinical model and combined model were established respectively. The area under the ROC curve (AUC) of the training sets of the three models were as follows: WMH radiomics model was 0.74(95%CI: 0.66-0.83), clinical model was 0.88(95%CI: 0.81-0.94), combined model was 0.90 (95%CI: 0.84-0.96), The AUC in the test set was 0.75(95%CI:0.62-0.87), 0.81(95%CI: 0.68-0.95) and 0.85 (95%CI: 0.74-0.96), respectively. The combined model has better diagnostic efficacy and a higher clinical net return as assessed by DCA.

## **CONCLUSION**

s The diagnostic efficacy of WMH radiomics combined with clinical model was better than that of WMH radiomics or clinical model. It could provide more sensitive and reliable markers for the early prediction and diagnosis of VCI.

## **CLINICAL RELEVANCE/APPLICATION**

The model combined WMH radiomics and clinical data had potential clinical application and could provide more sensitive and reliable markers for the early prediction and diagnosis of VCI.

### Pediatric Imaging Thursday Poster Discussions

#### Sub-Events

#### R2-SPPD-1 Absorbed Doses in Ovaries During Pediatric Hip Radiography: To Stop Routine Gonadal Shielding and Move Forward

#### Participants

Kosuke Matsubara, PhD, Kanazawa, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

The National Council on Radiation Protection and Measurements (NCRP) stated that discontinuing routine use of gonad shield is based on our best scientific understanding. To provide data that contributes to our scientific understanding, we evaluated the difference in ovarian dose between the presence and absence of gonad shield and the difference in ovarian dose depending on the shield size and the depth of the positions of the ovaries.

#### METHODS AND MATERIALS

Twenty-five sensitivity-corrected fluorescent glass dosimeters were placed on the cross section at the level of the femoral head of a 1-year-old pediatric phantom to measure absorbed doses with and without a 2-mm-thick lead gonad shield. They were arranged within a depth of 3-9 cm from the body surface and 0-3 cm to the left and right of the body midline. The imaging conditions were as follows: a tube voltage of 50 kV, tube current-time product of 6.3 mAs, a field size of 7×10 cm, and the source-to-image receptor distance of 100 cm. The ovaries were assumed to be 6 cm depth from the body surface and 1.5 cm to the left and right of the body midline. In the Monte Carlo simulation, a voxel phantom was built from CT images of the 1-year-old pediatric phantom, and the absorbed doses in the ovaries were calculated when changing the area covered by the shield to large, medium, and small and when changing the depth of the ovaries to 3-9 cm.

#### RESULTS

Although the gonad shield blocks almost 100% of the primary X-rays, significant values of absorbed doses were observed in the area covered by the shield. There was a tendency for the dose reduction rate to decrease from 75.5-81.6% to 52.8-66.7% at positions covered by the shield with increasing depth from the body surface from 3 to 9 cm. The dose reduction rate ranged from 2.3% to 23.1% at positions not covered by the shield. The average dose reduction rates obtained from measurements and simulations at the assumed positions of the ovaries were 66.2% for measurements and 72.7% for simulations. In the simulation, the dose reduction rate was 80.0-80.1% when the ovaries were completely covered by the shield (large size), but it was 72.4-73.1% and 53.6-55.3% when the ovaries were partially uncovered (medium size) and completely uncovered (small size), respectively.

#### CONCLUSION

When using a gonadal shield, ovarian dose is affected by how deep the ovaries are located from the body surface and whether the locations of ovaries are covered by the shield. Ovarian doses were far below the thresholds for temporary and permanent infertility even without shielding.

#### CLINICAL RELEVANCE/APPLICATION

This study reveals that gonadal shielding does not eliminate a significant number of scattered X-rays produced in the unshielded irradiated areas, supporting the abolition of gonadal shielding in medical practice.

#### R2-SPPH-1 Skin Dose Estimation Reduces Need for Patient Follow-up

##### Participants

William Sensakovic, PhD, Cave Creek, AZ (*Presenter*) Nothing to Disclose

##### PURPOSE

Determine how reference point air kerma and estimated skin dose are related. Further, determine how use of estimated skin dose could impact patient follow-up.

##### METHODS AND MATERIALS

Reference point air kerma ( $K_{air}$ ) and other demographic information was recorded from 629 patients (669 cases) with  $K_{air}$  above 2Gy. An in-house skin dose ( $D_{skin}$ ) estimation system (DIT Platform) was applied to each case. Dose differences between  $K_{air}$  and  $D_{skin}$  were recorded and summary statistics calculated. Trends against demographics were investigated. Percentage of cases brought below accepted dose thresholds related to skin damage and patient follow-up were determined.

##### RESULTS

Median  $D_{skin}$  estimates were 39.6% lower than  $K_{air}$  [24.9% 25th percentile, 51.1% 75th percentile]. Least squares linear trendline set  $D_{skin}$  as 63.2% of  $K_{air}$  with a  $R^2$  of 0.9. No trend was seen between patient weight and any dose metric. Similarly, difference between  $D_{skin}$  and  $K_{air}$  were not dependent on patient weight. 82.6% of  $K_{air}$  cases between 2 and 3 Gy fell below the erythema limit (2Gy). 40.7% of  $K_{air}$  cases between 3-4 Gy cases, 17.1% of  $K_{air}$  cases between 4-5Gy cases, and 5.6% of  $K_{air}$  cases between 5-6 Gy cases had  $D_{skin} < 2$  Gy. 91.7% of  $K_{air}$  cases between 5-6 Gy cases fell below 5 Gy which is a patient follow-up threshold suggested by several professional societies.

##### CONCLUSION

$K_{air}$  substantially overestimates  $D_{skin}$  in clinical cases. The estimates reduced the number of patients needing follow-up due to possible tissue reactions. When discussing possible skin reactions with patients and physicians the improved estimate reduced the need to discuss more severe skin reactions.

##### CLINICAL RELEVANCE/APPLICATION

The use of skin dose estimation software can decrease the need for patient follow-up and reduce the kinds of possible skin reactions that need to be discussed with patients and referring physicians.

#### R2-SPPH-10 Experimental Study of using Low-Dose CT Scan with Novel Deep Learning and Conventional Iterative Reconstruction for Image quality: A Phantom Study

##### PURPOSE

To investigate effect between low-dose CT scan combined with DLIR and conventional ASiR-V for image resolution and noise using Japanese Industry Standards Phantom (JIS Phantom) on GE Revolution APEX.

##### METHODS AND MATERIALS

No GSI scanning experiments were performed on JIS phantom based on GE APEX. The image spatial/density resolution parts of the phantom were selected for the comparative study of different reconstruction algorithms. The scan tube voltage was 120kV, the speed was 0.5s, the detector width was 80mm, the helical pitch was 0.992, and the layer thickness was 0.625mm. For control group (A), 11.5 (CTDIvol,mGy) was used as the conventional dose scan with 30%ASiR-V reconstruction; For low dose group (B), 4.22 (CTDIvol,mGy) was used. Reconstruction was performed using with different ASiR-V weights (30%,90%) and different DLIR levels (L, M, H). For the image spatial resolution/density resolution parts of the body model, AdvancedWorkstation 4.7(GE Healthcare) were used for objective assessment (SD) and subjective scoring (5-point scale for noise and resolution, respectively, with 1 being the worst, 5 being the best, and 3 or more being used for diagnosis) with  $P < 0.05$  considered as statistically significant difference.

##### RESULTS

The SD of the control group A (ASiR-V30%) with conventional dose was  $(14.98 \pm 1.48)$  HU, and the subjective scores of image spatial/density resolution parts were 3 and 3, respectively, and the noise was 2. The SD of the different groups were  $(25.21 \pm 2.42, 13.76 \pm 1.36)$  HU for ASiR-V 30%, 90% ,and  $(21.33 \pm 2.05, 17.74 \pm 1.81$  and  $13.84 \pm 1.57)$  HU for DLIR L, M, H, respectively, with significant differences between the groups ( $p < 0.05$ ). The image spatial resolution score of (2,1) for ASiR-V, and (2, 2 and 3) for DLIR; The image density resolution score of (1,1) for ASiR-V, and (2, 2 and 3) for DLIR; The subjective scores of noise of (2,3) for ASiR-V, (2, 3 and 4) for DLIR. From the subjective results, the image resolution decreased with increasing weight of ASiR-V but increased with increasing DLIR level in low-dose scans. Subjective and objective assessments both showed that noise decreased with increasing weight of ASiR-V or DLIR level, but the noise reduction effect of DLIR was more significant than that of ASiR-V.

## CONCLUSION

The application of DLIR in the non-spectral scan of Revolution APEX was able to improve the image quality (noise and resolution) of the low dose scan to achieve the image quality of the conventional dose scan.

## CLINICAL RELEVANCE/APPLICATION

The images reconstructed with new DLIR algorithm are more advantageous than those obtained by conventional ASIR and FBP. Especially for those low-dose scanning, DLIR can offer good image quality while reducing radiation dose, providing a broader application scenario for low-dose scanning.

## R2-SPPH-11 Image Quality Assessment of Deep Learning Image Reconstruction Combined with Low Radiation Dose in Abdominal CT: A Phantom Study

### PURPOSE

To compare the image quality of deep learning image reconstruction (DLIR) at low and ultra-low dose with filtered back projection (FBP) at clinical dose in abdominal CT.

### METHODS AND MATERIALS

Ten consecutive scans of Catphan 500/600 phantom were performed on Revolution Apex CT using a clinical dose (20.7mGy), low dose (12.29 mGy), ultra-low dose (6.19 mGy). The acquired images were reconstructed with FBP in the clinical dose group, and reconstructed with medium, high strength DLIR algorithms (DLIR-M, DLIR-H) in the ultra-low dose and low-dose groups. The noise (SD), contrast noise ratio (CNR), low density insert diameter, spatial resolution line pair, noise power spectrum (NPS) and task transfer function (TTF) were measured. Image quality was assessed independently by two radiologists using a 5-point scale. One-way analysis of variance and K-W test were used for statistics. Kappa test was used to assess consistency.

### RESULTS

The values of SD and CNR of DLIR-H images in low-dose and ultra-low dose groups were better than FBP images in the clinical dose group (all  $P < 0.01$ ). Low density inserts diameter and the number of spatial resolution line pair of DLIR-H images in the low-dose group were equivalent to those of FBP images ( $P > 0.05$ ) in the clinical dose group. Compared to the FBP images of the clinical dose group, the image texture of DLIR-M and DLIR-H in the low-dose group and ultra-low dose group were almost unchanged, and the NPS noise of the DLIR-H group in the low-dose group was the lowest (FBP of the clinical dose group:  $f_{peak} = 0.28 \pm 0.01 \text{ mm}^{-1}$ ,  $f_{ave} = 0.32 \text{ mm}^{-1}$ ,  $NPS_{noise} = 4.44 \pm 0.05 \text{ HU}$ ; DLIR(M,H) of the low-dose group:  $f_{peak} = 0.28 \pm 0.01 \text{ mm}^{-1}$ ,  $f_{ave} = 0.29 \text{ mm}^{-1}$ ,  $NPS_{noise} = 3.88 \pm 0.04 \text{ HU}$ ; DLIR(M,H) of the ultra-low dose group:  $f_{peak} = 0.27 \text{ mm}^{-1}$ ,  $f_{ave} = 0.29 \text{ mm}^{-1}$ ,  $NPS_{noise} = 5 \text{ HU}$ ); The TTF10% of low contrast target in low-dose and ultra-low dose groups were higher than that of FBP the clinical dose group, while TTF50% were lower in both groups. The subjective score of image quality of DLIR in the ultra-low dose and low-dose groups were not statistically different from that of FBP images in the clinical group ( $P > 0.05$ ). The subjective scores of the two doctors showed good consistency (Kappa = 0.72).

## CONCLUSION

The DLIR algorithm hardly impacts the image texture, especially the contrast and spatial resolution of the low-dose group are comparable or even better than those of the clinical dose FBP image, and the potential reduction of radiation dose can reach 40%~70%, which provides theoretical basis and scanning parameter selection for clinical abdominal CT imaging.

## CLINICAL RELEVANCE/APPLICATION

Low-dose DLIR can reduce radiation dose and provide theoretical basis and scan parameter selection for clinical abdominal CT imaging.

## R2-SPPH-12 Improving Head CT Image Quality under Low-Dose Scanning Conditions using Deep Learning Image Reconstruction Algorithms

Participants  
Chunyu Chen, Guangzhou, China (Presenter) Nothing to Disclose

### PURPOSE

To explore the potential of deep learning image reconstruction (DLIR) algorithm for improving image quality under low dose scanning conditions

### METHODS AND MATERIALS

22 inpatients requiring cranial CT reexamination who underwent routine low-dose brain CT scan (120kV200mA) were recruited. All images were reconstructed using filtered backprojection (FBP), ASIR-V at 50% strength (50%ASIR-V), DLIR at low, medium, and high level (DLIR-L, DLIR-M, DLIR-H). The CT values and noise (SD, standard deviation of CT values) of the gray matter (GM) and white matter (WM) at the basal ganglia and centrum semiovale levels were measured at different algorithm groups. The signal-to-noise ratio (SNR) of GM and WM, contrast-to-noise ratio (CNR) between GM and WM, and artifact index (AI) at posterior fossa were calculated. Two radiologists individually performed subjective evaluation of image noise, lesion clarity, overall image quality, and image artifacts using 1-5 scoring system. The consistency between two radiologists was analyzed. The objective and subjective measurements were compared at four algorithm groups.

### RESULTS

There were no significant differences in the CT values among the different algorithm groups (all  $p > 0.05$ ). In the DLIR groups, as the level of DLIR increased, the SD of GM and WM in the basal ganglia and centrum semiovale, as well as AI, gradually decreased, and while the SNR and CNR gradually increased, compared to FBP and 50% ASIR-V. There were significant statistical differences among the five algorithm groups, with the best performance observed in DLIR-H. (FBP vs DLIR-H, in basal ganglia, SDGM:  $9.45 \pm 2.41$ ,  $3.56 \pm 0.90$ ; SNRGM:  $4.42 \pm 1.27$ ,  $11.47 \pm 2.79$ ; CNR:  $1.23 \pm 0.51$ ,  $2.89 \pm 1.12$  AI:  $9.79 \pm 3.69$ ,  $7.22 \pm 2.30$ ; all  $p < 0.01$ ). The subjective evaluation scores in terms of image noise, overall image quality clarity of the lesion, and image artifacts gradually in DLIR (M, H) were higher compare with FBP and 50%ASIR-V, with a significant statistical difference among five algorithm groups (Radiologist1, FBP vs DLIR-H, image noise:  $2.09 \pm 0.53$ ,  $4.14 \pm 0.35$ ; over image quality:  $2.18 \pm 0.40$ ,  $4.00 \pm 0.00$ ; clarity of the lesion:  $2.55 \pm 0.67$ ,  $4.00 \pm 0.31$ ; Image artifacts:  $2.18 \pm 0.59$ ,  $4.05 \pm 0.49$ ; all  $p < 0.01$ ). Two radiologists showed a good consistency

(ICC:0.48-0.75,  $p < 0.01$ ).

## CONCLUSION

Under low-dose scanning conditions, compared with FBP and 50% ASIR-V, the deep learning optimization scheme has better performance in reducing image noise and artifacts, and subjectively evaluates DLIR-M and DLIR-H as the best post-processing image quality.

## CLINICAL RELEVANCE/APPLICATION

Compared with FBP and 50% ASIR-V, deep learning image reconstruction algorithms can better improve the quality of head CT images.

## R2-SPPH-2 Impact of Model Shape on Peak Skin Dose Estimates

Participants

William Sensakovic, PhD, Cave Creek, AZ (*Presenter*) Nothing to Disclose

## PURPOSE

To determine the impact of patient model shape on peak skin dose calculation

## METHODS AND MATERIALS

100 different human models randomly selected from the Civilian American and European Surface Anthropometry Resource dataset were used as input to a previously validated peak skin dose estimation system. Models were scaled to be the same approximate height as the default stylized phantom. Other Patient dimensions were scaled accordingly. The original phantom had craniocaudal, mediolateral, and anteroposterior dimensions of 173 cm, 39 cm, and 20 cm. The scaled patient models had dimensions of 173 cm,  $89 \pm 7.6$  cm, and  $34.5 \pm 3.4$  cm, respectively. Two positions were chosen for the phantoms: 1) patient models most posterior point aligned with default model's most posterior point and 2) patient model center of mass aligned with default model's center of mass. Beam data from 111 scans with reference point air kerma greater than 2 Gy ( $3.3 \text{ Gy} \pm 2 \text{ Gy}$ ) were applied to each patient model. Summary statistics and skin dose maps were calculated.

## RESULTS

When the posterior of the patient models was aligned with the default model the peak skin dose was  $16\% \pm 0.3\%$  larger than using the default model. When the patient model center of mass was aligned with the default model center of mass the peak skin dose was  $19\% \pm 0.3\%$  larger than the default model.

## CONCLUSION

Patient model substantially impacts final peak skin dose estimates. future work is will refine the existing meshes to better represent a realistic patient on the table.

## CLINICAL RELEVANCE/APPLICATION

Dose estimation software should implement an array of patient models to better approximate the patient on the table to improve peak skin dose estimation.

## R2-SPPH-3 Fetal Organ Dose Estimates from the Exposure of Pregnant Women in Fluoroscopy Procedures

Participants

Seth Streitmatter, PhD, Salt Lake City, UT (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the dependence of fetal organ dose on gestational age (GA), beam size and angulation in common fluoroscopy procedures and interventions a pregnant patient may undergo.

## METHODS AND MATERIALS

Hybrid computational phantoms of pregnant woman at four GAs (10w, 20w, 30w, 38w) were used to assess fetal organ doses by simulating common beam quality (70 kVp, 6.83 mm Al), field size (19 x 19 cm) and projections (LAO 25 CAU 25, LAO 25 CRA 25) used in interventional cardiac procedures. The beam geometry data created for the adult female phantom using NCIRF (National Cancer Institute dosimetry system for Radiography and Fluoroscopy), was translated for dose calculations in MCNP6, a general-purpose Monte Carlo code, and fetal organ doses were assessed.

## RESULTS

The major organs that the ICRP has assigned tissue weighting factors to were assessed. As the GA increases and the fetus gets closer to the treatment field, the brain (and other fetal organs that are inferior with respect to the mother's thorax) doses decreases (up to 0.39x), while organs that are superior or distributed throughout the fetus (e.g., bone, skin) show increased dose (up to 4.25x). More dramatically, dose increases as the beam becomes more caudally angulated and the fetus is closer to the beam or partially in it; all fetal organ doses were significantly higher for the LAO 25 CAU 25 scenario (up to 5.19x). Bone shows the largest relative increase in dose for GA 10w - 38w in both scenarios. Figure 1 illustrates the dependence of the doses on GA and beam angulation, normalized to organ dose to dose area product (DAP),  $\text{mGy}/\text{mGy}\cdot\text{cm}^2$ .

## CONCLUSION

For fluoroscopy cases, specifically cardiac/thoracic interventions, differences in GA and beam angulation can have a dramatic effect on fetal organ doses. Using the methods described here provides a higher level of accuracy for fetal organ dose estimates and the interplay between different potential exposure scenarios for pregnant patients than using the older, simple geometric phantoms and the uterus as a surrogate for fetal dose.

## CLINICAL RELEVANCE/APPLICATION

Examinations that involve an unpredictable duration of fluoroscopy have "substantial risk" potential. The capability to compute more accurate fetal organ doses can provide the patient with more relevant fetal risk assessment.

## **R2-SPPH-4 Evaluation of Different Peak Skin Dose Calculators Using an OSL Dosimeter Array in a Hybrid CT/Angiography Suite**

### **PURPOSE**

Fluoroscopically-guided interventional (FGI) procedures can result in high skin doses, potentially in the range where effects such as erythema could occur. Thus, it may be necessary to accurately determine the peak skin dose (PSD) so physicians can predict possible effects and inform the patient. The accuracy of three PSD calculators was evaluated using direct entrance skin dose measurements from optically stimulated luminescent dosimeters (OSLDs).

### **METHODS AND MATERIALS**

An array of 286 OSLDs was used to measure entrance skin dose on patients (n=12) undergoing FGI procedures. A previously validated method was used to separate the OSLD dose into CT and fluoroscopy skin dose for patients who were scanned with CT during their procedure. The OSLD with the highest fluoroscopy skin dose was used as the measured PSD. Additionally, an in-house PSD calculator was used to determine the PSD based on information from each patient's RDSR and room-specific correction factors. The PSD values reported from an independent commercial dose tracking software were recorded for each patient. The PSD values from a vendor/system-specific dose tracking software were recorded for each patient.

### **RESULTS**

The measured fluoroscopy PSD ranged from 189 mGy to 8,095 mGy for the 12 patients. The results show good agreement between the measured PSD and the PSD from the in-house PSD calculator. The mean percent error was -2% with mean absolute percent error of 10%. There was no statistical difference between the two PSD values ( $p = 0.445$ ). The independent commercial dose tracking software had a mean percent error of -16% with a mean absolute percent error of 21%. There was no statistical difference between the two PSD values ( $p = 0.054$ ). The vendor/system-specific dose tracking software showed the worst agreement between the measured PSD and displayed PSD. The mean percent error was -37% with a mean absolute percent error of 37%. There is a statistically significant difference between the measured PSD and the displayed PSD ( $p = 0.005$ ).

### **CONCLUSION**

The in-house PSD calculator that considers parameters from each patient exam and used room-specific correction factors had the best agreement with the measured PSD. The in-house PSD can provide physicians with a relatively more accurate PSD compared to the commercial and vendor dose tracking software.

### **CLINICAL RELEVANCE/APPLICATION**

Providing interventional radiologists with an accurate PSD estimation can help them better predict possible skin effects and potentially reduce effects by modifying exam parameters.

## **R2-SPPH-5 The Feasibility of High-Pitch Spectral CT Monochromatic Imaging in Combination with ASIR-V Technology: A Phantom Study**

### **PURPOSE**

To analyse the influence of high-pitch spectral CT monochromatic imaging in combination with pro-adaptive statistical iterative reconstruction-V(ASIR-V) technology on image quality and radiation dose.

### **METHODS AND MATERIALS**

A chest phantom was scanned on a revolution energy spectrum CT scanner separately using 0.5s rotation time, 0.992 helical pitch and 0.5s rotation time, 1.531 helical pitch. 70KeV monochromatic images were separately reconstructed at slice thickness of 5mm, meanwhile, the 40% pro-ASIR-V was applied to 70 keV high-pitch monochromatic image. Images of lung window and mediastinal window were separately reconstructed by standard algorithm and sharp algorithm. A total of three sets of images were obtained: routine-pitch/0%ASIR-V group, high-pitch/0%ASIR-V group and high-pitch/40%ASIR-V group. The CT dose index volume (CTDIvol), dose-length product (DLP) and effective dose (ED) were recorded. Standard deviation (SD) of pulmonary parenchyma, soft tissues of chest wall and heart were measured. Subjective image quality of lung window and mediastinal window were assessed by two radiologists in a double blinded and randomized manner using five-point scale (from 5=good image quality, almost no artifacts, clear anatomic details, easy to distinguish to 1=poor image quality, obvious artifacts, indistinct anatomic details, unable to distinguish). The differences between groups for MSD, radiation dose and mean subjective score were done with one-way ANOVA. The interobserver variation between two radiologists were assessed by the kappa statistic.  $P < 0.05$  was considered statistically significant.

### **RESULTS**

There was moderate agreement between the two radiologists in rating of subjective image quality ( $K=0.571$ ). Results indicated that the image quality of high-pitch spectral CT monochromatic imaging in combination with 40% pro-ASIR-V were better than routine-pitch or high-pitch in combination with 0%ASIR-V. Effective doses of the routine-pitch group and high-pitch group were 6.84mSv and 5.31mSv. The radiation dose reduction for high-pitch group was 22.37% in comparison with routine-pitch group.

### **CONCLUSION**

The use of high-pitch spectral CT monochromatic imaging in combination with pro-ASIR-V resulted in wonderful diagnostic images with lower radiation dose.

### **CLINICAL RELEVANCE/APPLICATION**

High-pitch spectral CT monochromatic imaging in combination with ASIR-V may acquire high image quality and low radiation dose.

## **R2-SPPH-6 The Impact of Different Noise Index (NI) on Image Quality of Three-low" Chest CTA**

### **PURPOSE**

To investigate the effect of low tube voltage, low contrast agent dosage and low contrast agent flow rate combined with different NI on the image quality of chest CTA.

### **METHODS AND MATERIALS**

This study was randomly divided into two groups: group A (n=20) and group B (n=20). Patients in group A were performed prospective "three-low" chest CTA with following parameters: 100kVp, contrast volume 45ml, contrast flow rate 3.0ml/s, and NI = 12, 14, 16, 18 for subgroup A1, A2, A3 and A4. Group B was control group with routine scanning parameters: 120kVp, contrast volume 60ml, contrast flow rate 4.0ml/s, NI=10. The other scanning sets were same. CT values and SD of the ascending aorta, aortic arch, descending aorta and the same layer of chest wall fat were measured. Then the CNR were calculated. The effective dose (ED = DLP \* 0.014) were also recorded. The subjective image quality of five groups were scored independently by two senior radiologists according to the 5-point system (Five points is the highest and one point is the lowest). More than three points meet the diagnostic criteria.

## RESULTS

The CT values of experimental group A1, A2, A3, A4 and control group B were  $346.1 \pm 22.1$ ,  $340.7 \pm 13.9$ ,  $344.0 \pm 14.8$ ,  $342.7 \pm 11.8$  and  $406.5 \pm 8.1$  HU, respectively. There were statistical significance between groups A and B ( $P < 0.05$ ) and no statistical significance between group A ( $P > 0.05$ ). The CNR of experimental group A1, A2, A3, A4 and control group B were  $12.9 \pm 2.5$ ,  $15.3 \pm 2.8$ ,  $17.9 \pm 4.1$ ,  $20.0 \pm 2.9$  and  $9.99 \pm 0.99$ , respectively. There was statistical significance between groups ( $P < 0.05$ ). The CNR of experimental group A1, A2, A3, A4 and control group B were  $42.2 \pm 8.3$ ,  $36.1 \pm 5.9$ ,  $32.3 \pm 3.5$ ,  $24.9 \pm 2.8$  and  $53.3 \pm 6.2$ , respectively. There was statistical significance between groups ( $F = 69.6$ ,  $P < 0.05$ ). The effective dose (ED) were  $2.5 \pm 0.24$ ,  $1.41 \pm 0.26$ ,  $1.15 \pm 0.4$ ,  $0.93 \pm 0.08$  and  $5.0 \pm 0.32$ , respectively. The effective dose of each group was statistically significant ( $F = 1076$ ,  $P < 0.01$ ). In subjective statistics, the image scores of experimental group A1, A2, A3, A4 and control group B were  $5.0 \pm 0$ ,  $4.98 \pm 0.14$ ,  $4.17 \pm 0.38$ ,  $3.61 \pm 0.49$  and  $2.63 \pm 0.49$ , respectively. The result from two senior radiologists were high consistency ( $\kappa = 0.65$ ). Only the subjective score of B4 did not meet the diagnostic requirements, and the lowest radiation dose of B3 group was about 77% lower than that of the control group.

## CONCLUSION

Three low combined with high NI index can reduce the risk of contrast injection and the radiation dose of patients at the same time.

## CLINICAL RELEVANCE/APPLICATION

To reduce the risk of contrast injection and the radiation dose of patients

## R2-SPPH-7 A Study Related to the Optimal Phase Selection of Virtual Scanning of Spectral Enhanced CT Instead of Conventional Scanning

Participants

Qi Hao, Beijing, China (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the optimal phase selection of virtual non-contrast (VNC) technique instead of conventional true non-contrast (TNC) for spectral enhanced CT scanning.

## METHODS AND MATERIALS

Fifty-seven patients with energy-spectrum-enhanced CT scans of the abdomen were collected, 23 males and 24 females with a mean age of  $55 \pm 12$  years. A spectral CT (Revolution, GE Healthcare, USA) scanner was used, with conventional (non-energy spectral) scanning mode for conventional scanning and gemstone spectral imaging (GSI) abdominal scanning mode for enhanced scanning. The CT scan used spectral mode. The CT values and SD values of the water were measured, and the signal-to-noise ratio (SNR) was calculated. The virtual scanning images were obtained by virtual non-contrast (VNC) technique, and the CT values and SD values of the liver in each phase, and the signal-to-noise ratio (SNR) was calculated. All statistical tests were performed using SPSS version 26.0, and one-way ANOVA was used to compare the differences between CT values, signal-to-noise ratio (SNR), and CT Dose Index (CTDI) of the liver after virtual scanning of the three phases of the spectral enhanced scanning images. For all tests, the level of statistical significance was set at  $P < 0.05$ .

## RESULTS

The SD and SNR of the liver after virtual scanning processing of the three phases of the spectral enhanced scanning were statistically significant ( $P < 0.05$ ) compared with those of the conventional scanning. The differences were statistically significant ( $P < 0.05$ ) when comparing the SD values and SNR of the liver between the virtual scanning of the three phases of spectral enhanced scanning. There were significant differences ( $P < 0.05$ ) in the SD values and SNR of the liver between the virtual scanning of the arterial phase and the virtual scanning of the venous and delayed phases, and there were no significant differences ( $P > 0.05$ ) in the SD values and SNR of the liver of the virtual scanning of the venous and delayed phases.

## CONCLUSION

The image quality of spectral CT virtual scanning was higher than conventional true scanning, the lowest CT Dose Index (CTDI) was in the delayed phase, while the virtual scanning image quality in the delayed phase was better than the virtual scanning image quality in the arterial phase, and they are no difference significantly between the image quality in the portal phase and delayed phase.

## CLINICAL RELEVANCE/APPLICATION

Spectral CT abdominal enhancement virtual scanning allows for the selection of delayed-period virtual scanning images instead of true scanning, this can reduce the number of scans, decrease radiation dose, and improve image quality.

## R2-SPPH-8 Silver (Ag) X-ray Spectrum Modulation Filter vs. Copper (Cu) X-ray Spectrum Modulation Filter: Capability of Low-Dose CT for Lung Cancer Screening at In Vitro and In Vivo Studies

Participants

Yoshiharu Ohno, MD, PhD, (*Presenter*) Research Grant, Canon Medical Systems Corporation; Research Grant, Daiichi Sankyo Co, Ltd; Research Grant, Ministry of Education, Culture, Sports, Science and Technology

## PURPOSE

To compare the capability of low-dose CT for lung cancer screening between newly developed silver (Ag) and traditionally applied

To compare the efficacy of low-dose CT for lung cancer screening between newly developed silver (Ag) and traditional copper (Cu) x-ray beam spectral modulation filters at in vitro and in vivo studies.

## **METHODS AND MATERIALS**

A chest CT phantom including simulated ground-glass and part-solid nodules was scanned with a 320-detector row CT with Ag and Cu filters at 0.6, 1.6 and 2.5 mGys and reconstructed with hybrid-type iterative reconstruction (IR) method at in vitro study. Then, 95 patients who underwent low-dose CT lung cancer screening with Ag and Cu filters at same radiation dose level (i.e. 1.6mGy) as well as standard-dose CT examination within 3 months were retrospectively included to in vivo study. At in vivo study, the same reconstruction method was applied. At in vitro study, SNR at each nodule were determined by region of interest (ROI) measurements at all protocols. At each simulated nodule, the probability of nodule was assessed with 5-point visual score by two board-certified chest radiologists. All final scores were determined as consensus of two readers. At in vivo study, SNR of normal lung parenchyma was also determined by ROI measurement at each low-dose CT. Then, the probability of nodule equal to or more than 4 mm in long-axis diameter was also assessed with 5-point scale by same board-certified chest radiologists. Student's t-test was performed to compare SNR of CT data between Ag and Cu filters at in vitro and in vivo studies. At in vitro study, ROC analyses were performed to compare nodule detection capability between Ag and Cu filters on each radiation dose data. At in vivo study, JAFROC analysis was performed to compare nodule detection capability between Ag and Cu filters. Finally, averaged sensitivity (SE) and false-positive/case (FP/case) were compared by McNemar's test and Wilcoxon's signed rank test.

## **RESULTS**

At in vitro studies, SNR and AUC of Ag filter were significantly higher than those of Cu filter at each radiation dose ( $p < 0.05$ ). At in vivo study, SNR of Ag filter was significantly higher than that of Cu filter ( $p < 0.05$ ). There were no significant differences of averaged figure of merit (FOM) and FP/case of between Ag (FOM=0.92, FP/case=0.24/case) and Cu (FOM=0.91,  $p > 0.05$ ; FP/case=0.24/case,  $p > 0.05$ ) filters. However, averaged sensitivity of low-dose CT with Ag filter (SE=0.88) was significantly higher than that with Cu filter (SE=0.79,  $p < 0.001$ ).

## **CONCLUSION**

s Ag filter can significantly improve image quality and nodule detection capability than Cu filter on low-dose CT screening at in vitro and in vivo studies.

## **CLINICAL RELEVANCE/APPLICATION**

Ag filter can significantly improve image quality and nodule detection capability than Cu filter on low-dose CT screening at in vitro and in vivo studies.

## **R2-SPPH-9 Effects of Different Tube Voltages and Different Levels of Hybrid Iterative Reconstruction on the Detection and Characterization of Pulmonary Nodules in Ultra-low-dose Chest CT**

Participants

Yue Yao, Xi'an, China (*Presenter*) Nothing to Disclose

## **PURPOSE**

To explore the effects of different tube voltages combined with adaptive statistical iterative reconstruction (ASIR-V) algorithms on the detection and characterization of pulmonary nodules by an artificial intelligence software in ultra-low dose chest CT

## **METHODS AND MATERIALS**

An anthropomorphic thorax phantom containing 12 spherical simulated nodules served as the reference standard (Diameter: 12, 10, 8, 5 mm; CT value: -800, -630, 100 HU) was scanned at different dose levels with combinations of kVp and tube current: Group A (70kV/30mA:0.11mSv, 100kV/10mA:0.10mSv), Group B (70kV/100mA:0.34mSv, 100kV/30mA:0.32mSv), and Group C (70kV/150mA:0.53, 100kV/50mA:0.51mSv). Scans were repeated 5 times. Four different weights of ASIR-V (0%=FBP, 30%, 50%, 70%) were used to generate images. All images were automatically analyzed using a commercially available artificial intelligence software (Intelligent 4D Imaging System for Chest CT 5.5, YITU Healthcare) and long diameter, short diameter, location and nature of each nodule, and CT and SD values of muscle under each group of conditions were obtained. The detection rate (DR), deformation coefficient (DC) and size measurement deviation percentage (SP) of pulmonary nodules were calculated and compared between groups. The image quality and noise of each group were compared.

## **RESULTS**

Under the same ASIR-V weight, the image noise of 70kV was in general lower than that of 100kV group; and noise gradually decreased with the increase of reconstruction weight. Under the same dose level, there was no significant difference in DR of nodules between different kV ( $p > 0.05$ ); and DR values in the 70kV group were slightly higher than 100kV at 50%ASIR-V and 70%ASIR-V in Group A, 50%ASIR-V in Group B and 70%ASIR-V in Group C. Higher percentages ASIR-V and 100kV in general had better (lower) DC and SP.

## **CONCLUSION**

s Detection rates were similar between 70kV and 100kV scans. 70kV had better noise performance under the same ASIR-V percentage, while 100kV and higher ASIR-V percentages were better in preserving the forms of nodules.

## **CLINICAL RELEVANCE/APPLICATION**

Under ultra-low radiation dose chest CT, High weight IR is better to balance between nodule detection rate and shape deformation.

R2-SPRO

### Radiation Oncology Thursday Poster Discussions

#### Sub-Events

#### R2-SPRO-1 Auto-contouring of Brain Metastases for Stereotactic Radiosurgery

#### PURPOSE

Brain metastases (BMs) are a common complication of cancer and the most common type of brain tumor. Stereotactic radiosurgery (SRS) is a well-established treatment option which allows for the delivery of highly focused radiation allowing for improved sparing of healthy brain tissue when compared to whole-brain radiotherapy leading to better cognitive outcomes after treatment. Highly focused treatments such as SRS require very precise BMs identification and definition. In this study, we train and evaluate the nnUNet's ability to automatically identify and contour BMs for use in radiotherapy planning and treatment assessment.

#### METHODS AND MATERIALS

Post-contrast T1-weighted (T1w+C) MR scans and planning records from 784 SRS patients previously treated at our institution using Gamma Knife SRS were used in this study. Physician-drawn BMs contours were extracted for each patient treatment. T1w+C scans were acquired on the same day of treatment using Philips Ingenia 1.5T scanner using an axial 3D fast spin echo sequence using 1mm slice spacing and  $0.449 \times 0.449 - 1 \times 1$  pixel spacing. This dataset was split into training ( $n=759$ ) and final testing ( $n=25$ ) cohorts. We then trained the nnUNet (Isensee, F., et al. Nature methods, 2021) on 2 NVIDIA TITAN RTX 24GB GPU using 5-fold cross validation with 1000 epochs in each fold. The nnUNet is a self-configuring model that has demonstrated high performance in various automatic contouring tasks. Auto-contouring performance was evaluated using Dice similarity coefficient (DSC) and voxel-wise precision and recall.

#### RESULTS

The 25 test cases had 78 BMs defined by the treating physician at the time of treatment (average volume of  $9.91 \pm 15.28$  cm<sup>3</sup>). 75.6% (59/78) of BMs (average volume of  $8.89 \pm 12.07$  cm<sup>3</sup>) were detected by the trained model resulting in an average DSC of 0.84 ( $\pm 0.11$ ), and voxel-wise precision and recall of 0.87 and 0.85, respectively. The nnUNet did not detect 19 physician-defined BMs (24.4%) (average volume  $1.82 \pm 5.74$  cm<sup>3</sup>) and identified 43 BMs which were not defined at the time of treatment (average volume  $0.98 \pm 3.22$  cm<sup>3</sup>).

#### CONCLUSION

Overall, the trained model shows promise in automatically detecting and contouring BMs. However, the current approach is less accurate in identifying smaller BM volumes. Further work is needed to improve automatic identification and contouring performance for these smaller lesions.

#### CLINICAL RELEVANCE/APPLICATION

Accurate detection and definition of brain metastasis volumes through automated solutions could help standardization of delivered treatments across radiation oncology practices. Furthermore, automation of this process could improve treatment assessment on post-treatment imaging.

#### R2-SPVA-1 Evaluation and Comparison of CT Angiography Image Quality Acquired with Single-Energy Metal Artifact Reduction Algorithm and Deep Learning Reconstruction in Patients after Endovascular Aortic Repair

#### PURPOSE

To assess and compare the image quality of hybrid iterative reconstruction (HIR), deep learning reconstruction (DLR), combination of HIR and single-energy metal artifact reduction (SEMAR) algorithm (HIR+SEMAR), and combination of DLR and SEMAR algorithm (DLR+SEMAR) for computed tomography angiography (CTA) examinations in patients after abdominal aortic (AA) endovascular aortic repair (EVAR).

#### METHODS AND MATERIALS

CTA images of 27 patients (mean age  $\pm$  standard deviation, 68.7  $\pm$  8.8 years, 23 male) were reconstructed using HIR, DLR, HIR+SEMAR, and DLR+SEMAR. CT attenuation, image noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) were measured in muscle, liver, AA distant to stents (region 1 of interest, ROI 1), AA near stents and artifacts (ROI 2), AA near stents but not artifacts (ROI 3), mural thrombus with artifacts, and mural thrombus without artifacts. Data were expressed as median (interquartile distribution) for non-normally distributed data. The subjective visual scores (1 for worst -5 for best) of images were obtained for the following: overall image quality and visibility of surrounding organs, vessels outside the scaffold, and stent thrombosis. These parameters were compared among above four methods.

#### RESULTS

HIR+SEMAR or DLR+SEMAR provided higher Hounsfield unit (HU) values in images with artifacts, while there is no statistically significant attenuation in images without artifacts among four methods. The image noise in HU of images with artifacts was significantly lower in HIR+SEMAR or DLR+SEMAR than in HIR and DLR ( $p < 0.001$ ), while the image noise in HU of images without artifacts was significantly lower in the DLR or DLR+SEMAR group than in the HIR and HIR+SEMAR groups ( $p < 0.0001$ ). For images with stents, SNR and CNR were significantly higher in the HIR+SEMAR [6.110 (4.5, 7.9)] or DLR+SEMAR [6.010 (4.7, 10.5)] group than in the HIR [3.080 (1.9, 4.0)] and DLR [2.860 (1.8, 4.6)] groups (SNR of ROI 2, respectively,  $p < 0.001$ ). But the SNR of liver and muscle were significantly higher in the DLR or DLR+SEMAR group than in the HIR and HIR+SEMAR groups ( $p < 0.0001$ ). The subjective visual scores in the DLR+SEMAR were the highest compared those in the images reconstructed with HIR, DLR and HIR+SEMAR ( $p < 0.0001$ ).

#### CONCLUSION

Compared to HIR, DLR, and HIR+SEMAR, DLR+SEMAR provides superior image quality in terms of quantitative and qualitative parameters, not only markedly reducing metal artifacts but also improving reliably attenuation of soft tissues.

#### CLINICAL RELEVANCE/APPLICATION

The combination of DLR and SEMAR algorithm technique significantly improving CTA image quality not only in the images with metal artifacts but also in those without metal artifacts in patients after EVAR, beneficial for postoperative surveillance.

#### R2-SPVA-2 Ultra-High-Resolution Photon-Counting Detector CT Angiography of the Lower Limbs

#### Participants

Dirk Graafen, MD, PhD, Mainz, Germany (*Presenter*) Nothing to Disclose

#### PURPOSE

Peripheral arterial disease frequently affects the lower limbs, and heavy calcifications may reduce the accuracy of CT-angiography. Photon-counting detector (PCD) CT offers improved image quality for CT angiography, recently demonstrated for coronary artery evaluation. However, no previous study investigated the potential of PCD-CT angiography for the assessment of the lower limbs. Therefore, the aim of this study was to identify the optimal reconstruction parameters for ultra-high-resolution (UHR) PCD-CT angiography of the lower limbs in a phantom and patient study.

#### METHODS AND MATERIALS

Silicone pipes with five different inner diameters (1 to 5 mm) were filled with different iodine concentrations (0, 4.63, 9.25, 18.5, and 37.0 mg I/cm<sup>3</sup>) and scanned in a water container using six different radiation doses (CTDI = 1, 2, 3, 4, 10, and 30 mGy). Virtual monoenergetic images at 55 keV were reconstructed with 0.4 mm isotropic resolution using the quantitative kernels with all ten available sharpness levels (Qr36 to Qr76) combined with the three highest levels of Quantum iterative reconstruction (QIR-2 to QIR-4). Noise levels and sharpness (maximal slope values at the pipe walls) were determined for all reconstructions. Additionally, clinical CT angiographies of 20 patients were reconstructed with a normal (Qr-44), sharp (Qr-60), and ultra-sharp (Qr-72) kernel at QIR2-4. Three raters performed a qualitative analysis of these images with a 5-point Likert scale assessing noise, delineation of plaques and vessel walls, and overall image quality.

## **RESULTS**

Increase kernel sharpness led to higher image noise, e.g., for 4 mGy CTDI and QIR-2, noise level was 11 HU for Qr36, 45 HU for Qr60, and 141 HU for Qr76. Maximum slope values increase relevantly until a sharpness level of 60, while higher sharpness levels only yield small additional improvements. QIR clearly decreases noise with higher levels without reducing the maximum slope. Qualitative analysis of the clinical images confirmed these findings. Worse noise scores were given for higher sharpness levels, while no improvement in the delineation of plaques and vessel walls was found between the sharp and ultra-sharp kernel. The sharp kernel (Qr-60) with the highest QIR level (QIR-4) yielded the best overall quality.

## **CONCLUSION**

s Reconstruction kernels with optimized sharpness level in combination with the highest QIR level yield the best image quality for UHR-PCD-CT angiography of the lower limbs, which is Qr60 for 0.4 mm isotropic voxels with edge lengths of 0.4 mm.

## **CLINICAL RELEVANCE/APPLICATION**

Using UHR-PCD-CT angiography with optimized reconstruction parameters might improve diagnostic accuracy and confidence in peripheral artery disease of the lower limbs.

R5A-SPBR

### Breast Imaging Thursday Poster Discussions I

#### Sub-Events

#### **R5A-SPBR-1 Optimizing Double Reading in Screening Mammography through Pairing Strategies Explored by Modelled Radiologists' Assessments**

##### **PURPOSE**

Radiologists' performance characteristics vary, yet the pairing of radiologists for the double reading of screening mammography is done randomly or out of convenience. No attempts have been made to prospectively optimise the pairing of radiologists for improved screening performance. We aim to investigate whether the optimal set of pairs of radiologists can be achieved by using modelled radiologist performance characteristics for pairing.

##### **METHODS AND MATERIALS**

Our retrospective study was performed with datasets from breast cancer screening programs in Sweden (2008-2015), England (2012-2014), and Norway (2004-2018). Logistic regression models with reader and case effects, for positive and negative screening examinations separately, were used to model radiologists' screening assessments. Screening programs with different pairing strategies, including the pairing of readers with 1) opposite or 2) similar true-positive rates (TPR) and/or false-positive rates (FPR), were simulated. Group performances of the different pairing strategies were compared against those of the random pairing strategies, with positive assessments defined by either reader flagging a case as abnormal. Bootstrap resampling (n=1,000) was used to obtain 95% confidence intervals.

##### **RESULTS**

The final study sample consisted of 3,191,955 screening examinations, 936,621 from Sweden, 435,281 from England, and 1,820,053 from Norway. The logistic-regression models adequately predicted individual (Pearson correlations > 0.95) reader performance. Within the simulations, pairing similar readers reduced what they were similar in and pairing opposite readers increased what they were opposite in. The pairing strategies involving readers with similar FPR resulted in significantly lower FPR outcomes (Sweden: 4.50%, England: 5.51%, Norway: 8.03%), compared to the random pairing strategies (Sweden: 4.74%, England: 5.76%, Norway: 8.30%), while the TPR did not change significantly. All other pairing strategies performed equally or worse than random pairing.

##### **CONCLUSION**

There was no pairing strategy that increased TPR and at the same time decreased FPR. However, according to our pairing rule, pairing readers with similar FPR performance characteristics may result in a reduced FPR with no significant reduction in TPR. Pairing readers with similar FPR characteristics may be helpful to reduce the number of examinations sent to consensus or arbitration. Additional studies are needed to explore the effect of consensus and arbitration.

##### **CLINICAL RELEVANCE/APPLICATION**

Pairing readers with similar FPR might result in reduced FPR while not significantly reducing TPR, potentially reducing workload. Future studies are needed to explore what happens after consensus/arbitration.

#### **R5A-SPBR-2 Comparison of Contrast-Enhanced Spectral Mammography and Digital Mammography in Detecting Breast Cancer: A Systematic Review and Meta-Analysis**

##### Participants

Mostafa Shehata, MD, Houston, TX (*Presenter*) Nothing to Disclose

##### **PURPOSE**

To evaluate and compare the diagnostic accuracy of digital mammography (DM) and contrast-enhanced spectral mammography (CESM) in breast cancer detection, through a systematic review and meta-analysis.

##### **METHODS AND MATERIALS**

A comprehensive literature search was conducted using PubMed, Web of Science, Scopus, and Google Scholar up to February 15, 2023. Bivariate modeling was employed to obtain pooled diagnostic accuracy metrics (sensitivity, specificity, DOR, PPV, and NPV) of CESM and DM. Summary ROC curves were used for comparison.

##### **RESULTS**

The systematic review incorporated twenty-four studies based on our eligibility criteria. However, we excluded four studies from the meta-analysis due to incomplete contingency tables. The meta-analysis ultimately included twenty studies, consisting of 3830 breast lesions. Among these, 17 studies focused on diagnostic purposes, two were dedicated to screening and one study aimed at preoperative assessment. For breast cancer detection, CESM demonstrated significantly higher sensitivity (0.948, 95% CI: 0.917-0.968) and better specificity (0.732, 95% CI: 0.626-0.816) than DM (sensitivity: 0.815, 95% CI: 0.731-0.877; specificity: 0.576, 95% CI: 0.415-0.723). The diagnostic odds ratio for CESM (50.4, 95% CI: 35.5-69.5) was notably superior to DM (6.12, 95% CI: 3.4-10.2).

## CONCLUSION

s CESM exhibits superior diagnostic performance compared to DM in breast cancer detection. Clinicians should consider CESM as an alternative or complementary imaging modality to DM.

## CLINICAL RELEVANCE/APPLICATION

CESM offers improved diagnostic accuracy in breast cancer diagnosis of patients retrieved from screening, making it a valuable alternative or complement to DM in specific clinical situations, including dense breast tissue and inconclusive imaging cases, while considering its drawbacks.

### **R5A-SPBR-3 Long-term Effects of a Breast Cancer Screening Programme on Breast Cancer Incidence and Mortality: Results from a Cohort of 2.6 Million Women**

Participants

Amanda Dibden, London, United Kingdom (*Presenter*) Nothing to Disclose

Robert A. Smith, PhD, Atlanta, GA (*Presenter*) Nothing to Disclose

## PURPOSE

Population-wide mammography screening programmes have been in operation for over 30 years with the aim of reducing breast cancer mortality by diagnosing cancers at an early stage when treatment is more likely to be effective. Whilst there have been many studies assessing the short to medium term effectiveness of these programmes, there have been few assessing long-term effectiveness. The objective of this study was to assess whether the national programme in England and Wales was achieving its aim to reduce mortality, with long-term follow-up for estimation of overdiagnosis associated with routine mammography screening

## METHODS AND MATERIALS

An established cohort of 2,669,328 women aged 49 to 64 years at study entry and resident in England and Wales was studied. All women were as yet uninvited to screening upon study entry, with screening status changing on invitation and attendance. Women were followed for invasive and ductal carcinoma in situ breast cancer diagnosis and breast cancer death, with a maximum follow-up of nearly 33 years. Poisson regression was used to assess the effect of invitation and attendance to screening on breast cancer incidence and mortality, and overdiagnosis in relation to the NHS Breast Screening Programme in England and Wales.

## RESULTS

Invitation to screening was associated with a 28% reduction in breast cancer mortality after adjustment for age and time (RR: 0.72; 95% CI: 0.71 - 0.74). The reduction in mortality associated with screening attendance was slightly greater at 29% after adjustment for age, time and self-selection bias (RR: 0.71; 95% CI: 0.68 - 0.73). There was a 4% excess of breast cancer diagnoses associated with being screened (RR: 1.04; 95% CI: 1.02 - 1.07) after adjustment and with at least 10 years follow-up post-screening.

## CONCLUSION

s These results suggest that screening continues to be effective in reducing mortality from breast cancer many years after the cessation of screening and that the level of overdiagnosis associated with long-term screening is low. Work is ongoing to assess the association between screening for breast cancer and death from other causes than breast cancer.

## CLINICAL RELEVANCE/APPLICATION

There is ongoing debate as to whether breast cancer screening causes more harm than good, the main harm being overdiagnosis. This study demonstrates the long-term benefit of screening with a minimal amount of overdiagnosis.

### **R5A-SPBR-4 Opening Doors to Early Detection: The Critical Relationship between Readability and Breast Cancer Screening Attendance**

Participants

Sonali Sharma, Vancouver, BC (*Presenter*) Nothing to Disclose

## PURPOSE

Low health literacy remains a barrier to accessing effective care. The AMA and NIH recommend that health information be written at the sixth and eighth grade reading levels. This study aimed to evaluate the readability, quality, and accuracy of online health information for breast imaging and screening in Canada and ACR Breast Imaging Centers of Excellence websites in the USA, and to examine the relationship between readability and screening attendance.

## METHODS AND MATERIALS

Breast imaging websites in Canadian provinces and territories, and ACR Breast Imaging Centers of Excellence websites in the USA were searched. Readability was assessed using Flesch-Kincaid Reading Ease Index, Flesch-Kincaid Grade Level, and Gunning-Fog Score. The DISCERN instrument measured the quality and accuracy of the online health information. Breast cancer screening attendance rates in the US and Canada and the relationship between website readability was examined.

## RESULTS

Of the 500 websites analyzed, mean readability scores corresponded to a 12th-grade reading level. The websites were considered below-average quality with a DISCERN score of 41.05. A negative correlation was found between website readability and screening attendance, indicating that as readability increased, attendance decreased.

## CONCLUSION

s Online health information regarding breast imaging and screening programs in Canada and ACR Breast Imaging Centers of Excellence websites in the USA is written at a level far greater than most adults' reading level and at below-average quality. The negative correlation between readability and screening attendance emphasizes the need for improved readability and quality of websites, potentially leading to higher screening program attendance and better patient outcomes.

## CLINICAL RELEVANCE/APPLICATION

Low health literacy and readability contribute to reduced screening participation, crucial for early breast cancer detection. By prioritizing high-quality and easily understandable patient materials, healthcare providers and organizations can potentially mitigate low screening attendance, improving patient outcomes and healthcare cost-effectiveness.

### **R5A-SPBR-5 Optimizing Lesion Detection in Digital Breast Tomosynthesis: A Phantom Study Investigating Angular Range Across Varied Breast Density and Thickness**

Participants

Hee Jeong Kim, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To determine the optimal angular range (AR) for digital breast tomosynthesis (DBT) systems that provides the highest detectability of breast lesions across various breast densities and thicknesses.

#### **METHODS AND MATERIALS**

The Modular DBT phantom (Model 165SI; Gammex Inc, WI, USA) composed of tissue-equivalent adipose and glandular modules and a module embedded with test objects of speckles, masses, and fibers was used to generate ten modular combinations simulating different breast thicknesses and densities, as well as different lesion locations. A prototype DBT system (KERI, Gyeonggi-do, Korea) with a W/Al target/filter combination operating at ARs of  $\pm 7.5^\circ$  ( $AR\pm 7.5^\circ$ ),  $12.5^\circ$  ( $AR\pm 12.5^\circ$ ),  $\pm 19^\circ$  ( $AR\pm 19^\circ$ ), and  $\pm 25^\circ$  ( $AR\pm 25^\circ$ ) was used to acquire 11 low-dose projection images of each combination. Image datasets were acquired three times under the same conditions. Three blinded radiologists independently assessed lesion detectability on the reconstructed images according to the 2018 ACR Digital Mammography Quality Control Manual. Their scores were averaged and compared using linear mixed models with combination and reader as random intercepts.

#### **RESULTS**

The  $AR\pm 12.5^\circ$  provided the highest overall lesion detectability across all breast combinations. Speckles were best detected with  $AR\pm 7.5^\circ$  or  $AR\pm 12.5^\circ$  in all breast combinations, with no significant difference between them. However, speckle detectability was significantly lower when using the  $AR\pm 19^\circ$  or  $AR\pm 25^\circ$  ( $P = .014$  for thin fatty,  $0.026$  for thick fatty, and  $< .001$  for dense breasts). The optimal AR for mass detection was  $AR\pm 19^\circ$  for thin breasts and  $AR\pm 25^\circ$  for thick breasts. Specifically, for thin fatty breasts,  $AR\pm 19^\circ$  significantly outperformed the other ranges ( $P = .042$ ), while for thick dense breasts,  $AR\pm 25^\circ$  significantly outperformed the others ( $P = .025$ ). Although the optimal AR for fiber detectability varied among the breast combinations,  $AR\pm 25^\circ$  provided the lowest detectability among the four ARs in all combinations ( $P = .013$  for thin fatty,  $.026$  for thin dense and thick fatty,  $.004$  for thick dense breasts).

#### **CONCLUSION**

The optimal AR for overall lesion detectability was the  $AR\pm 12.5^\circ$  in all breast densities and thicknesses. However, for speckle and mass detection, narrower and wider ARs may be necessary, respectively.

#### **CLINICAL RELEVANCE/APPLICATION**

While current DBT systems generally employ a single AR, using various ARs may enhance the lesion detectability for patients with different breast densities and thicknesses, as well as different lesion types of interest.

### **R5A-SPBR-6 Diagnosis of Lesions Presenting as Architectural Distortion on DBT: Malignancy Rate Related to Accompanied Features, Ultrasound Findings, and BI-RADS Density**

Participants

Jiejie Zhou, PhD, MD, Wenzhou, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Accurate diagnosis of architectural distortion (AD) on DBT is challenging, and usually ultrasound (US) is performed to provide additional information. This study aims to: (1) compare the diagnosis in cases associated with nodular density and microcalcifications; (2) compare the diagnosis in cases with and without corresponding suspicious findings on US; (3) evaluate the malignancy rate in cases with different BI-RADS density backgrounds.

#### **METHODS AND MATERIALS**

A total of 471 cases were included, 265 malignant and 206 benign, which were all pathologically confirmed. The DBT images were reviewed to identify the suspicious areas showing architectural distortion, and to determine whether the lesion was accompanied by nodular density or microcalcifications. The US reports were reviewed to determine whether there were suspicious findings corresponding to the detected AD. The malignancy rate in each DBT BI-RADS category, with or without accompanied nodule density, microcalcifications, US findings, and in different density backgrounds were analyzed.

#### **RESULTS**

Malignant rate in DBT BI-RADS 5, 4C, 4B, 4A, and 2-3 groups were 100%, 86%, 57%, 37%, and 19%, respectively (Table 1). For cases accompanied by nodular density, microcalcifications, and without any features, the malignancy rate was 91%, 69% and 38%, respectively. Of 471 cases, 315 showed the corresponding abnormality on US, and the malignancy rate was 72%. In 156 cases without corresponding US findings, the malignancy rate was much lower at 24% ( $P < 0.00001$ , Table 2). The malignancy rate in patients who had BI-RADS density category A+B was significantly higher (48/64, 75%) than in those who had category C+D (217/407, 53%,  $p=0.0011$ ). When using DBT BI-RADS =4A as the cutoff, 252/265 (95%) malignancies were correctly diagnosed by DBT, and 13 cases were misdiagnosed; but 9 of them could be correctly diagnosed by the supplement US. In the benign group, 54/206 (26%) were correctly diagnosed as DBT BI-RADS 2 or 3. When US was considered, 35 false positive lesions showed US BI-RADS 2-3 and they might be spared of biopsy.

#### **CONCLUSION**

AD lesions on DBT accompanied by nodule density had a higher malignant rate than those with microcalcifications, and the malignant rate was the lowest for those without any accompanied features. Cases with corresponding US abnormalities had a much higher malignancy rate than those without. Lastly, AD detected in fatty breasts had a higher malignancy rate, presumably due to the more clearly revealed features in a clean background.

## CLINICAL RELEVANCE/APPLICATION

Diagnosis of lesions presenting as architectural distortion on DBT can be improved with more understanding of associated features and tissue backgrounds, as well as the corresponding findings by using the supplementary ultrasound.

### R5A-SPBR-7 Diagnosis of Architectural Distortion on Digital Breast Tomosynthesis Using Radiomics and Deep Learning

Participants

Yang Zhang, PhD, New Brunswick, NJ (*Presenter*) Nothing to Disclose

## PURPOSE

The objective of this study is to develop diagnostic models for patients showing architectural distortion in Digital Breast Tomosynthesis (DBT) images using two Artificial Intelligence (AI) techniques: radiomics and deep learning.

## METHODS AND MATERIALS

A retrospective review identified a total of 506 cases. The initial 298 cases were utilized for training, while the remaining 208 cases were allocated for independent testing. The training set includes 175 malignant and 123 benign cases. The architectural distortion areas on craniocaudal (CC) and mediolateral oblique (MLO) views were manually defined as for radiomics analysis. Features were extracted using PyRadiomics, followed by the application of the support vector machine (SVM) to select significant features and construct the classification model. Deep learning employed the ResNet50 algorithm, producing binary outputs for malignancy and benignity. The Gradient-weighted Class Activation Mapping (Grad-CAM) method was used to identify suspicious regions. Malignancy probabilities were utilized to create ROC curves. The model was further applied to a testing dataset consisting of 208 cases, including 122 malignant cases and 96 benign cases for independent testing.

## RESULTS

The radiomics model, created using combined CC+MLO features, resulted in an AUC of 0.82, sensitivity of 0.78, specificity of 0.68, and accuracy of 0.74. Using only CC features, the AUC was 0.77. The deep-learning model generated an AUC of 0.61, significantly lower than all radiomics models ( $p < 0.01$ ), likely due to the utilization of the entire image as input. The Grad-CAM method effectively localized architectural distortion areas. In the testing dataset, the radiomics model, built using combined CC+MLO features, yielded an AUC of 0.8, sensitivity of 0.82, specificity of 0.76, and accuracy of 0.74. When only CC features were used, the AUC was 0.74. The deep-learning model generated an AUC of 0.57.

## CONCLUSION

Radiomics models demonstrate satisfactory diagnostic accuracy, and high specificity within the benign group can help prevent unnecessary biopsies. Deep learning can be employed to localize architectural distortion areas, potentially offering an automated method for ROI delineation. The validation results on the testing dataset further confirm the reliability of the radiomics model in real-world scenarios.

## CLINICAL RELEVANCE/APPLICATION

This study demonstrates the promising potential of radiomics models in accurately diagnosing architectural distortion in DBT. Additionally, the study suggests that deep learning can effectively localize areas of architectural distortion, which could aid in the development of a fully automated computer-aided diagnosis system for breast cancer.

### R5A-SPBR-8 How Long Does It Take to Read a Mammogram? Investigating the Reading Time of Digital Breast Tomosynthesis Compared to 2D Mammography

## PURPOSE

Digital breast tomosynthesis (DBT) can increase cancer detection and reduce recall rates compared to 2D full-field digital mammography (FFDM) alone. We analysed DBT reading times in a national screening program, compared to FFDM, to investigate the impact of DBT implementation on reading times in double reading, high-volume breast screening programmes.

## METHODS AND MATERIALS

Reading time data were recorded as part of the PROSPECTS Trial, a prospective randomised trial comparing DBT plus FFDM or synthetic 2D mammography (S2D) to FFDM alone, in the UK National Health Service (NHS) breast screening programme, from January 2019 to February 2023. The time to report DBT+FFDM or DBT+S2D and FFDM alone was calculated per case and reading times were compared between modalities. Reporting times were also compared between readers from different professional groups - radiologists and radiographers (i.e. technologists); and with years of DBT reading. The effect of experience using DBT in the screening setting on reporting time was investigated.

## RESULTS

Following exclusions, 48 readers reported 1,242 FFDM clinics (34,210 FFDM cases) and 973 DBT clinics (13,983 DBT cases). DBT reading time was doubled compared to FFDM ( $2.09 \pm 0.64$  minutes vs.  $0.98 \pm 0.30$  minutes, respectively;  $p < .001$ ), and DBT+S2D reading was longer than DBT+FFDM ( $2.24 \pm 0.62$  minutes vs.  $2.04 \pm 0.46$  minutes, respectively;  $p = .006$ ). No significant difference was identified in reporting time between radiologists and radiographer readers ( $2.06 \pm 0.71$  minutes vs.  $2.14 \pm 0.46$  minutes, respectively;  $p = .71$ ). Readers with five or more years of experience reading DBT were quicker at reading DBT than those with less than five years' experience ( $1.86 \pm 0.56$  minutes vs.  $2.37 \pm 0.65$  minutes;  $p = .008$ ), and DBT reading time significantly improved after 6-months of accrued screening experience ( $p = .01$ ).

## CONCLUSION

DBT reading required greater time compared to FFDM, yet relatively short exposure with DBT in the screening setting (6-months) improved reporting time.

## CLINICAL RELEVANCE/APPLICATION

In double reading, high-volume breast screening programmes, caution needs to be exercised when considering DBT as a standard screening tool to prevent overwhelming screening workloads in high-volume screening programmes.

## Abstract Archives of the RSNA, 2023

R5A-SPCA

### Cardiac Imaging Thursday Poster Discussions I

#### Sub-Events

#### **R5A-SPCA-1 Ultra-High Spatial Resolution of Photon Counting Detector Coronary CT Angiographies Minimize Overestimation Bias Compared to Invasive Reference**

Participants  
Moritz Halfmann, MD, Mainz, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Ultra-high resolution coronary CT angiographies (UHR-CCTA) from Photon counting detector (PCD)-CT have recently been proven feasible in a patient population. However, data comparing it to quantitative coronary angiography as the clinical reference standard for stenosis assessment, is still missing. Therefore, it was the aim of the study to compare stenosis measurements of UHR-CCTA to QCA.

#### **METHODS AND MATERIALS**

For this retrospective study, the institutional database was searched for patients who had undergone UHR-CCTA for the assessment of coronary artery disease (CAD) and had a clinically indicated coronary angiography within 30 days from CCTA. Exclusion criteria were the chronic total occlusion (CTO) of a coronary artery as well as the presence of coronary stents prior to CCTA. This resulted in a total of 39 patients with 83 coronary stenoses. CCTA images were reconstructed with slice thicknesses of 0.6, 0.4 and 0.2 (UHR) mm using the vascular reconstruction kernels Bv44 (0.6/0.4mm) or Bv64 (0.2mm). Stenoses were assessed on all slice thicknesses by two cardiovascular radiologists and on QCA by two cardiologists. Measurements were compared using univariate analysis of variance with post-hoc testing and Bland-Altman plots.

#### **RESULTS**

Mean degrees of coronary stenosis continuously decreased with decreasing slice thicknesses ( $61.3 \pm 13.7\%$  vs.  $53.8 \pm 15.4\%$  vs.  $46.4 \pm 14.8\%$ , all  $p=0.001$ ). Both the 0.6 and the 0.4mm reconstructions showed significant differences between UHR-CCTA and QCA ( $44.1 \pm 15.1\%$ ,  $p<0.001$  and  $p=0.004$  respectively), while the 0.2mm reconstructions did not ( $p=0.428$ ). Bland Altman analysis revealed significant bias between 0.6mm (mean bias 17.6, limits of agreement -14.6 to 48.8) and 0.4mm (9.8, -24.0 to 43.6) reconstructions and QCA, respectively. UHR-CCTA reconstructions did not show a significant bias (2.1, -27.2 to 31.4) but the spread was broader than for QCA.

#### **CONCLUSION**

UHR-CCTA reconstructions minimized overestimation bias of coronary stenosis measurements in comparison to the clinical reference standard of QCA.

#### **CLINICAL RELEVANCE/APPLICATION**

Reduced overestimation bias from UHR-CCTA reconstructions can obviate the need for unnecessary referral for follow-up imaging including invasive coronary angiography.

#### **R5A-SPCA-2 Deep learning-based Acceleration of Compressed Sensing for Non-contrast-enhanced Coronary MR Angiography in Patients with Suspected Coronary Artery Disease**

#### **PURPOSE**

The clinical application of coronary MR angiography (MRA) remains limited due to its long acquisition time and often unsatisfactory image quality. A compressed sensing artificial intelligence (CSAI) framework was recently introduced to overcome these limitations, but its feasibility in coronary MRA is unknown. Therefore, this study aims to evaluate the diagnostic performance of non-contrast-enhanced coronary MRA with CSAI in patients with suspected coronary artery disease (CAD).

#### **METHODS AND MATERIALS**

64 consecutive patients (mean age  $\pm$  standard deviation [SD]:  $59 \pm 10$  years, 48.4% females) with suspected CAD were enrolled in this study. The 3.0-T balanced steady-state free precession sequence were performed. Three observers evaluated the image quality for 15 coronary segments of the right and left coronary arteries using a 5-point scoring system (1=not visible; 5=excellent). Image scores  $\geq 3$  were considered diagnostic. Furthermore, detection of CAD with  $\geq 50\%$  stenosis was evaluated in comparison to reference standard coronary computed tomography angiography (CTA). Mean acquisition times for CSAI-based coronary MRA were measured. For each patient, vessel and segment, sensitivity, specificity, and diagnostic accuracy of CSAI-based coronary MRA for detecting CAD with  $\geq 50\%$  stenosis according to coronary CTA were calculated. Intra-class correlation coefficients (ICCs) were used to assess the interobserver agreement.

#### **RESULTS**

The mean MR acquisition time  $\pm$ SD was  $8.1 \pm 2.4$  min. Twenty-five (39.1%) patients had CAD with  $\geq 50\%$  stenosis on coronary CTA and 29 (45.3%) patients on MRA. A total of 885 segments on the CTA images and 818/885 (92.4%) coronary MRA segments were

diagnostic (Image score =3). The sensitivity, specificity, and diagnostic accuracy were as follows: per patient (92.0%, 84.6%, and 87.5%), per vessel (82.9%, 93.4%, and 91.1%), and per segment (77.6%, 98.2%, and 96.6%), respectively. The ICCs for image quality and stenosis assessment were 0.76-0.99, 0.66-1.00, respectively.

## CONCLUSION

The image quality and diagnostic performance of coronary MRA with CSAI may show good results in comparison to coronary CTA in patients with suspected CAD.

## CLINICAL RELEVANCE/APPLICATION

The non-invasive and radiation-free CSAI framework could be a promising tool for rapid screening and comprehensive examination of the coronary vasculature in patients with suspected CAD.

## R5A-SPCA-3 Virtual Monoenergetic Reconstructions from Photon-Counting Detector CT Influence Coronary Stenosis Quantification: Comparison Between Coronary CT, Coronary and Invasive Coronary Angiography

Participants

Elias Wolf, Mainz, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the influence of virtual monoenergetic image (VMI) reconstructions on the accuracy of coronary artery stenosis measurements on a clinical dual-source photon-counting detector computed tomography (PCD-CT) system in a dynamic phantom, and in a patient cohort with invasive correlation.

## METHODS AND MATERIALS

A rod phantom with two custom-built vessels (4mm diameter) and two different stenoses grades (50% and 25%) was mounted into an anthropomorphic thorax phantom and heartbeats were simulated with 10 different beats per minute (bpm), between 50 bpm and 80 bpm. In addition, 33 patients (26 (78.8%) male, mean age  $71.3 \pm 9.0$  years) who underwent coronary CT angiography (CCTA) and invasive coronary angiography as part of their clinical work-up for suspected coronary artery disease were retrospectively identified from the clinical database. A total of 9 different VMI levels from 40-140 keV were reconstructed with a slice thickness of 0.4 mm, Qr40 Kernel, and QIR strength level of 3 on a PCD-CT system. Reconstruction parameters for the phantom were matched with those of the clinical patient cohort. Percent diameter stenosis (PDS) measurements were compared to either the manufacturers data sheet (phantom) or quantitative coronary angiography (QCA) measurements (clinical cohort) as a ground truth.

## RESULTS

Variation of VMI reconstructions lead to significantly different stenosis measurements in the phantom and patients (e.g., mean PDS in patients:  $68.3\% \pm 9.6$  at 40 keV vs  $53.0\% \pm 9.7$  at 140 keV,  $p < 0.0001$ ). Across the entire range of artificial heart ranges, the phantom study indicated 100 keV (bias: -0.4%, limit of agreement (LoA): -4.5/3.7) for the 50% and 90 keV (bias: 1.4%, LoA, -1.9/4.8) for the 25% stenosis as an ideal VMI level with the least deviation to the reference stenoses. The tissue quality of the plaque (calcified, mixed, or soft) determined the ideal VMI level in the study group. For the in-vivo comparison to QCA as reference, 100 keV (bias: 17.2%, LoA, -1.2/35.7) for calcified, 140 keV (bias: 5.0%, LoA, -24.5/34.4) for mixed and 40 keV (bias: -0.5%, LoA, -21.5/20.5) for soft plaques led to the best agreements.

## CONCLUSION

VMI reconstructions have the potential to improve the accuracy of coronary CT angiography (CCTA) for the quantification of different stenoses types.

## CLINICAL RELEVANCE/APPLICATION

VMI reconstructions can help overcome current limitations of CCTA due to calcium blooming thereby help reduce bias in stenosis quantification compared to QCA.

## R5A-SPCA-4 Diagnostic Performance of Detecting Specific Ischemia in Patients with Intermediate Coronary Stenosis: CT-derived Fractional Flow Reserve versus CT Myocardial Perfusion Imaging

Participants

Zhao-Qian Wang, Dalian, China (*Presenter*) Nothing to Disclose

## PURPOSE

To compare the diagnostic accuracy of CTFFR with myocardial perfusion imaging (CTMPI) for detecting the specific ischemia of intermediate coronary stenosis (50% - 70%), using FFR as reference standard

## METHODS AND MATERIALS

Between April 2019 and March 2022, the intermediate coronary arteries stenosis confirmed by ICA quantitative analysis and FFR were prospectively enrolled. All participants underwent coronary computed tomography angiography (CCTA) + CTMPI and ICA + FFR within 10 days. CTFFR and  $\Delta$ CTFFR (the difference between proximal and distal of stenosis) value of coronary artery stenosis was calculated. Myocardial blood flow (MBF) and relative MBF (rMBF) were measured. FFR = 0.80 was used as the reference standard for myocardial ischemia, and ROC curve was used to assess the diagnostic performance of CTFFR,  $\Delta$ CTFFR, CTMPI (MBF) and CTMPI (rMBF) for detecting the specific ischemia of intermediate coronary artery stenosis.

## RESULTS

A total of 37 coronary arteries (27 left anterior descending, 5 left circumflex and 5 right coronary arteries) in 35 patients had intermediate stenosis ( $65.20\% \pm 8.40\%$ ). Among them, the FFR = 0.80 was 29, and the FFR > 0.80 was 8. On a per-vessel basis, the sensitivity, specificity, NPV, PPV and accuracy of CTFFR for detecting specific ischemia of intermediate coronary artery stenosis were 89.66%, 87.50%, 70.00%, 96.30% and 89.19%. The optimal cut-off value of  $\Delta$ CTFFR was 0.04. The sensitivity, specificity, NPV, PPV and accuracy of  $\Delta$ CTFFR were 96.55%, 62.5%, 83.33%, 90.32% and 89.19%, respectively. The optimal cut-off value of MBF was 115.15 mL·100 mL<sup>-1</sup>·min<sup>-1</sup>. The sensitivity, specificity, NPV, PPV and accuracy of CTMPI (MBF) were 75.86%,

75.00%, 46.15%, 91.67% and 75.68%, respectively. The optimal cut-off value of rMBF was 0.736. The sensitivity, specificity, NPV, PPV and accuracy of CTMPI (rMBF) were 96.55%, 75.00%, 85.71%, 93.33% and 91.89%, respectively.

## CONCLUSION

The diagnostic performance of CTFFR and CTMPI for detecting specific ischemia in patients with intermediate coronary stenosis is comparable. For investigating specific ischemia in patients with intermediate coronary stenosis from CCTA, CTFFR should be the preferred method because of its unique advantage, and CTMPI can be chosen if CTFFR is not applicable for various reasons.

## CLINICAL RELEVANCE/APPLICATION

diagnostic performance of CTFFR and CTMPI for detecting specific ischemia in patients with intermediate coronary stenosis

### R5A-SPCA-5 Diagnostic Accuracy of CTFFR in Detecting Hemodynamic Significance of Coronary Stenosis and its Incremental Value to CCTA

Participants

Zhao-Qian Wang, Dalian, China (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the diagnostic performance of fractional flow reserve derived from coronary computed tomography angiography (CTFFR) based on machine learning to detect the hemodynamic significance of coronary stenosis, using fractional flow reserve (FFR) as reference standard.

## METHODS AND MATERIALS

From April 2019 to January 2022, patients with suspected coronary heart disease who underwent coronary artery CT angiography (CCTA) and ICA+FFR within 14 days were enrolled retrospectively. FFR = 0.80 was used as the diagnostic criterion of myocardial ischemia to evaluate the diagnostic performance of CTFFR, ?CTFFR (the difference between proximal and distal of stenosis) and combined with CCTA to evaluate specific ischemia of coronary stenosis.

## RESULTS

The 77 stenosis of 77 coronary arteries in 64 patients, 50 had FFR = 0.80 and 27 had FFR > 0.80. Taking FFR = 0.80 as a positive event, the area under the curve (AUC) of specific stenosis ischemia detected by CCTA, CTFFR, ?CTFFR, CCTA + CTFFR and CCTA + ?CTFFR were 0.694, 0.766, 0.791, 0.806 and 0.836, respectively. (1) The diagnostic performance of CTFFR or ?CTFFR for detecting specific stenosis ischemia was slightly higher than that of CCTA, but the difference was not statistically significant ( $P > 0.05$ ). On a per-vessel basis, the sensitivity, specificity, NPV, PPV and accuracy of CTFFR and ?CTFFR were 94.00%, 59.26%, 84.21%, 81.03%, 81.82% and 86.00%, 59.26%, 69.57%, 79.63% and 76.62%, respectively. CTFFR or ?CTFFR correctly diagnosed 5 (31.25%) of the 16 false positive CCTA stenosis. (2) The diagnostic performance of CCTA + CTFFR or CCTA + ?CTFFR was higher than CCTA ( $P = 0.008, P = 0.002$ ). On a per-vessel basis, the sensitivity, specificity, NPV, PPV and accuracy of CCTA + CTFFR were 92.00%, 66.67%, 81.82%, 83.64% and 83.12% respectively. The sensitivity, specificity, NPV, PPV and accuracy of CCTA + ?CTFFR were 88.00%, 66.67%, 75.00%, 83.02% and 80.52%, respectively. (3) There are 15 stenosis in gray area (0.75 - 0.80) of FFR. Two stenosis of CTFFR was higher than 0.80 and the five stenosis of CTFFR was less than 0.75. Eight stenosis of CTFFR was between 0.75 and 0.80. Two stenosis of ?CTFFR was less than 0.05, and thirteen stenosis of ?CTFFR was higher than 0.05.

## CONCLUSION

The specificity in CTFFR is better than CCTA and it can reduce the false positive cases of CCTA by about 1/3. The diagnostic performance of ?CTFFR is comparable to CTFFR. The addition of CTFFR or ?CTFFR has incremental value in the specificity of CCTA alone in the diagnosis of specific stenosis ischemia, but the high false positive rate caused by its moderate specificity (66.67%) may still have some limitations in avoiding ICA including FFR

## CLINICAL RELEVANCE/APPLICATION

detecting hemodynamic significance of coronary stenosis

### R5A-SPCA-6 Quantification and Detection of Calcium Using Multimodal Fusion Approach

Participants

Paddy Raghav, MS, Seattle, WA (*Presenter*) Nothing to Disclose

## PURPOSE

Calcium detection and quantification from computed tomography (CT) scans of the heart is an important tool for the early diagnosis of coronary artery disease (CAD). However, manual identification of calcium can be time-consuming and subject to inter- and intra-observer variability. The majority of current clinical solutions to identify and quantify coronary artery calcium score are semi-automatic and are developed for unenhanced ECG-gated Cardiac CT scan. The proposed method uses a multimodal fusion-based approach, is automatic and precisely quantifies and classifies calcium in different arteries.

## METHODS AND MATERIALS

We developed a multimodal fusion-based approach that utilizes both Cardiac CT and Chest CT. The core of it is an in-house developed segmentation model that segments heart and calcium. One major challenge we faced was due to the variability in scan resolution, orientation, and heart size across different patients. To address this, we normalized the scans to fit a scaled coordinate system. To detect calcium deposits, an intensity threshold was applied to filter out the areas of the scan with higher calcium density, followed by connected-components labeling to identify the connected regions of calcium. To classify calcium deposits based on their location within the heart, a likelihood model based on spatial features and location was built. This helped to determine the probability that a given calcium deposit belongs to a specific region of the heart.

## RESULTS

The solution was tested on 200 cardiac patients and 1000 chest patients. The Pearson correlation coefficient between the reference actual and the computed predictive scores on the test set show a high level of correlation (0.84;  $p < 0.001$ ) and high limits of agreement in Bland-Altman plot. The proposed method correctly classifies the risk group in 75.2% of the cases and classifies the subjects in the same group. For the presence/absence of coronary artery calcifications, the deep learning model

achieved a sensitivity of 90 % and a specificity of 94 %.

#### **CONCLUSION**

s Fully automated deep learning-based calcium quantification on cardiac-CTs shows good correlation compared to reference standards. Automating this process may reduce evaluation time and potentially optimize clinical calcium scoring.

#### **CLINICAL RELEVANCE/APPLICATION**

AI-powered calcium detection has the potential to improve the accuracy, efficiency, and consistency of heart disease diagnosis, ultimately leading to better patient outcomes. By analyzing data from multiple imaging modalities, AI algorithms can identify patterns and correlations that may be missed by a single imaging modality. This can help clinicians to identify patients at high risk for future cardiovascular events and take preventative measures to reduce that risk.

### Chest Imaging Thursday Poster Discussions I

#### Sub-Events

#### **R5A-SPCH-1 Positional Effects on Cardiopulmonary Function Measured by 4D-Flow and 3D-cine MRI with Blanket-Like Coil**

##### Participants

Ryogo Enoki, RT, Suita Osaka, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Hemodynamic changes caused by positional changes are known in patients with heart failure or pregnant women, but clinically applicable noninvasive testing methods have not been well established. This study aims to assess the feasibility of assessing cardiac function and collecting normal values for pulmonary blood flow measurements by changing body position.

##### METHODS AND MATERIALS

CMR imaging was performed on 10 healthy volunteers who gave consent for imaging using a 3T MRI and a blanket-like coil; 3D cine was performed using the Hyperkat acceleration in the horizontal section, and 4D flow using Hyperkat was performed to measure the flow of the mediastinal region. These images were taken in the supine, right lateral recumbent, and left lateral recumbent positions. A questionnaire was obtained from the participants regarding imaging in different positions. The left and right ventricular volume parameters (end-diastolic volume, end-systolic volume, and ejection fraction) were then calculated from the 3D cine. 4D flow data were used to measure the flow volume (ml/heartbeat) of the Aorta, main pulmonary artery (PA), right PA, left PA, SVC, and IVC, respectively. Differences in each flow volume between body positions were compared.

##### RESULTS

Positional changes did not significantly alter right or left ventricular volumetric parameters. Flow volume did not change with position in Aorta (74 ml, 76 ml, 75 ml) and main PA (81 ml, 71 ml, 83 ml). Right PA (36 ml, 42 ml, 27 ml) increased in the right lateral position and significantly decreased in the left lateral position compared with the supine position ( $P=0.09$ ,  $0.02$ , respectively). Left PA (32 ml, 21 ml, 44 ml) significantly decreased in the right lateral position and significantly increased in the left lateral position ( $p=0.02$ ,  $0.01$ , respectively). Blood flow in SVC (21 ml, 24 ml, 19 ml) and IVC (42 ml, 33 ml, 39 ml) was not significantly different by position. The proportion of right/left distribution of pulmonary flow was 0.53 in the supine position, 0.67 in the right recumbent position, and 0.39 in the left recumbent position, showing significant differences between positions ( $p<0.01$ ). The total imaging time for cine and 4D flow was approximately 30 minutes, including positional changes.

##### CONCLUSION

4D flow and cine imaging with a blanket-like coil had clinically applicable imaging times. Cardiac function in healthy volunteers did not differ by positioning, but the left or right pulmonary blood flow increased on the gravity side.

##### CLINICAL RELEVANCE/APPLICATION

The measurement of hemodynamic changes due to positional differences can be performed noninvasively, enabling the evaluation of pathological conditions such as heart failure patients.

#### **R5A-SPCH-2 Radiologist and Surgical Agreement in Classification of Chronic Thromboembolic Pulmonary Hypertension (CTEPH)**

##### Participants

Lewis Hahn, MD, San Diego, CA (*Presenter*) Nothing to Disclose

##### PURPOSE

Determine agreement between radiologists (rads) and surgeons in localizing level of disease in CTEPH and determine factors that affect agreement.

##### METHODS AND MATERIALS

6 rads (3 local and 3 external) localized CTEPH level on CTPA on consecutive patients who underwent pulmonary thromboendarterectomy (PTE) surgery at a leading CTEPH surgical center from 1/7/21-10/22/22. Rads graded the level of most proximal disease in the left and right PAs using a locally developed surgical level classification: level 1= disease in main PA; level 2= disease distal to level 1 to segmental ostia; level 3=segmental disease; level 4=subsegmental disease; level 0=no disease. 10 cases were used for training. The time between CTPA and surgery, minimum slice thickness of CTPA, and number of positive CTEPH cases each radiologist read/year was recorded. Excluded patients (number in parenthesis) included those w/o CTPA study (30), time between CTPA and surgery was >180 days (110), slice thickness was >3mm (2), study was not CTPA protocol (4), path diagnosis of PA sarcoma (4), presence of acute PE (4), patients <18 y/o (3). Surgical notes were reviewed to determine surgical level of disease. Weighted kappa and multivariate analysis were performed.

##### RESULTS

330 patients had PTE over 22 months. After 157 exclusions +10 training cases, rads reviewed 163 CTPAs. Agreement was substantial ( $\kappa=0.62-0.77$ ) between all rads except for moderate agreement between rads 2 and 4 and rads 4 and 5. Agreement between reader 1 and surgical level was substantial ( $\kappa=0.724$ ) and moderate for readers 2-6 ( $\kappa$  range 0.49-0.58). Agreement was significantly better with less time between CTPA and PTE ( $p=0.006$ ) with  $<50\%$  agreement when CTPA  $>118$  days old. Agreement between rads and surgery for proximal (level 1+2) disease did not change with slice thickness. There was a significant drop with distal (level 3+4) disease in studies with slice thickness  $\geq 1\text{mm}$  ( $\kappa$  range 0.06-0.327) vs thickness  $<1\text{mm}$  ( $\kappa$  range 0.34-0.6) ( $p=0.03$ ). No difference was seen between rads agreement and CTEPH level or laterality. Reader experience was marginally correlated with surgical agreement.

## CONCLUSION

Using this CTEPH surgical classification system, agreement between rads was substantial and was moderate to substantial between rads and surgeons. Slice thickness  $<1\text{mm}$  must be used to accurately localize segmental and subsegmental disease. Agreement decreased as time between CTPA and surgery increased.

## CLINICAL RELEVANCE/APPLICATION

There is a high level of agreement between rads and surgeons for grading CTEPH. Slice thickness  $<1\text{mm}$  should be used as experienced surgeons can treat distal disease. Given evolution of disease, patients with studies  $>4$  months old could undergo repeat CTPA prior to PTE to more accurately localize disease for surgeons.

## R5A-SPCH-3 Monitoring Changes in Lung Perfusion of Patients with Acute Pulmonary Embolism under Therapy Using Free Breathing Arterial-spin Labeling (ASL-)MRI: Preliminary Results of an Ongoing Study

### PURPOSE

Organ perfusion can be imaged non-invasively with ASL-MRI. The aim of this study was to evaluate changes of lung perfusion in patients with acute pulmonary embolism (PE) under therapy using ASL-MRI.

### METHODS AND MATERIALS

Between 11/2020 and 12/2022, 15 patients (median/min/max 55/24/90 y/o, 9f) with PE before and after treatment initiation (min/max/mean/median 5/243/165/174 days in-between) were examined by ASL-MRI under free breathing in a prospective study. The study was approved by the local ethic committee and all patients gave written informed consent. Initially, patients were treated with heparin ( $n=9$ ), alteplase and heparin ( $n=1$ ) or oral anticoagulation ( $n=5$ ). One patient additionally underwent catheter-directed embolectomy. After the initial therapy patients were treated with Rivaroxaban ( $n=5$ ), Apixaban ( $n=8$ ) or low molecular weight heparin ( $n=2$ ). The examinations were performed on a 1.5T MRI. Pulmonary perfusion was assessed using free-breathing ECG-triggered pseudo-continuous ASL-MRI. The pulmonary trunk was labeled during systole, and images were acquired during diastole of the subsequent cardiac cycle. Additionally, multisection coronal, balanced steady-state-free-precession imaging was carried out. The proportion of perfusion deficit caused by pulmonary embolism was categorized for each lung lobe: I) 0-25 %, II) 26-50 %, III) 51-75 %, IV)  $>75$  %

### RESULTS

Before treatment, perfusion deficits caused by PE were found in all patients in 59 lobes: I)  $n=5$ , II)  $n=10$ , III)  $n=17$ , IV)  $n=27$ . At follow-up imaging, perfusion deficits were found in 25 lobes of 8 patients: I)  $n=7$ , II)  $n=8$ , III)  $n=6$ , IV)  $n=4$ . Improved lung perfusion was seen in all patients. Perfusion deficits resolved completely in 7/15 patients.

### CONCLUSION

This is the first study using ASL-MRI to evaluate changes of lung perfusion during and after therapy of patients with PE. After therapy, improvements of lung perfusion were seen in all patients. However, in some patients, persistent perfusion deficits could be observed.

### CLINICAL RELEVANCE/APPLICATION

The clinical relevance of these findings needs to be evaluated in future studies. Nonetheless, ASL-MRI might be useful to monitor non-invasively the treatment effects in patients with PE.

## R5A-SPCH-4 Assessment of Missed Incidental Pulmonary Embolisms on Chest CT with an AI-algorithm

### Participants

Vera Inka Josephin Graeve, MD, Gerlafingen, Switzerland (*Presenter*) Nothing to Disclose

Tician Schnitzler, MD, Aarau, Switzerland (*Presenter*) Nothing to Disclose

### PURPOSE

Pulmonary embolism (PE) is the third most frequent cause of cardiovascular related death and occurs in 1 of 1000 patients in the European population. In symptomatic patients a CT angiography reveals a detection rate of more than 95%, while the diagnostic performance for occlusions of pulmonary arteries massively decreases in CT scans, performed due to other reasons than suspected PE. A recent study estimates, that radiologists diagnose nearly as much of those incidental pulmonary embolisms (iPE) than they miss. The aim of this study was a retrospective assessment of iPE missed by radiologists on chest CT with an artificial intelligence (AI) algorithm including prevalence, anatomic distribution pattern and daytime of diagnosis of the CT scans.

### METHODS AND MATERIALS

This IRB approved, retrospective single center study included 1965 chest CT scans acquired during venous or arterial contrast, performed due to other reasons than suspected PE, analyzed by an FDA-approved AI algorithm for diagnosing iPE (Aidoc Medical). The appearance of iPEs, their location and the studytime were retrieved from the radiological reports and compared to all positive findings of the AI algorithm, verified by an experienced radiologist, serving as the gold standard. For statistical analysis SPSS was used (Version 28, 2021).

### RESULTS

Of the 1966 cases 63 suspicious iPEs were displayed by the AI of which 42 were true iPEs (Sensitivity 95%, Specificity 99%). Prevalence of iPE was 2,4%, while half of the positive cases were missed by radiologists (PPV: 66%; NPV: 99%). In nearly 76%

(16/21) the retrospectively identified missed iPEs were allocated in the right lower lobe, while the non-missed iPEs showed a nonspecific distribution affecting all lung segments. Most of the reports which missed an iPE were generated between 1:00 and 5:00pm (57%).

## CONCLUSION

s Nearly 50% of cases with iPE were missed by radiologists, which indicates the need for a robust AI solution. Secondly, this study can pave the way for a better understanding of iPEs with regard to their anatomic distribution pattern and different external influences in order to prevent future misdiagnosis.

## CLINICAL RELEVANCE/APPLICATION

This study illustrates the poor diagnostic performance of radiologists diagnosing iPEs, focussing on their anatomic distribution and additional external influences that may cause misdiagnosis.

## R5A-SPCH-5 Effects of Model-based Iterative Reconstruction Algorithm and Contrast Enhancement Boost Postprocessing Technique on the Pulmonary CT Angiography: A Evaluation of Image Quality for Obese Patients

### PURPOSE

To evaluate whether model-based iterative reconstruction [forward projected model-based IR solution (FIRST)] algorithm and contrast-enhancement-boost (CE-Boost) technique can improve the image quality in pulmonary CT angiography (CTA) for obese patients.

### METHODS AND MATERIALS

This prospective study was conducted on 100 consecutive patients who underwent pulmonary CTA for suspected pulmonary embolism (PE). Patients whose body mass index (BMI) exceeded 25 (group 1) were performed with conventional hybrid iterative reconstruction [adaptive iterative dose reduction 3D (AIDR 3D)], FIRST, and CE-Boost. Non-obese patients (BMI<25, group 2) was subjected to AIDR 3D, considering as reference standard. CT numbers, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and image noise were quantitatively assessed by pulmonary arteries. Two chest radiologists independently reviewed the CT images (5, best; 1, worst) by four subjective characteristics including noise, visibility of pulmonary artery, overall image quality and diagnostic confidence. The Mann-Whitney U test and Independent Samples t-test were used for statistical analysis.

### RESULTS

Group 1 FIRST images had significantly lower image noise compared with group 2 AIDR 3D images ( $p<0.05$ ), while group 1 CE-Boost and AIDR 3D images were inferior to group 2 AIDR 3D images regarding to image noise. Both CE-Boost images and FIRST images showed higher SNR and CNR than group 2 AIDR 3D images (all  $p<0.05$ ). When compared with group 2 AIDR 3D, group 1 AIDR 3D exhibits lower subjective scores, whereas group 1 FIRST and CE-Boost had markedly higher scores (all  $p<0.05$ ). A major increase in diagnostic confidence was observed after the addition of FIRST or CE-Boost (all  $p<0.05$ ).

## CONCLUSION

s The postprocessing technique CE-Boost and FIRST reconstruction algorithm can both improve overall image quality and diagnostic confidence of pulmonary CTA in obese patients.

## CLINICAL RELEVANCE/APPLICATION

High-quality pulmonary CTA image provided by CE-Boost or FIRST enables a better visualization of the main pulmonary artery and its branch vessels. This may enable early diagnosis of PE and reduce exposure dose in obese patients.

## R5A-SPCH-6 Efficacy of Lung Dynamic CT Perfusion in Patients with Pulmonary Hypertension

Participants

Takuya Yokota, Bunkyo Hongo 3-1-3, Japan (*Presenter*) Nothing to Disclose

### PURPOSE

We developed lung dynamic CT perfusion (LCTP) that can evaluate absolute lung blood flow. The purpose of this study was to investigate the incremental diagnostic value of LCTP over CT pulmonary angiography (CTPA) for detecting perfusion defect with perfusion scintigraphy.

### METHODS AND MATERIALS

This retrospective single-center study included 23 patients (mean age, 61 years  $\pm$  16 [SD]; 15 women) who were suspected of pulmonary hypertension underwent LCTP and perfusion scintigraphy from January 2021 to March 2023. LCTP data was obtained by electrocardiogram-gated axial scan targeted at systolic phase using a 320-row CT. The acquisition was performed separately in the upper and the lower lung fields, and these data were combined for analysis. Deconvolution method was used to calculate the blood flow of the lungs using a workstation. The phase in which the pulmonary artery was most contrasted during LCTP scan was selected to reconstruct CTPA. Six regions of interest were placed in each lobe to calculate quantitative perfusion ratio. Diagnostic performance of CTPA and CTPA plus quantitative perfusion ratio was compared to detect perfusion defect with perfusion scintigraphy. The analysis was performed for each lobe (right upper, right middle, right lower, left upper, left lingula, and left lower lobe).

### RESULTS

Of the 138 lobes, 86 lobes (62%) showed perfusion defects on scintigraphy. Adding LCTP to CTPA increased sensitivity from 29.1% (95% CI: 20, 40%) to 95.3% (95% CI: 89, 99%;  $p<0.001$ ) and accuracy from 54.3% (95% CI: 46, 63%) to 92.7% (95% CI: 87, 96%;  $p<0.001$ ) while maintaining specificity (96.2% [95% CI: 87, 100%] vs. 88% [95% CI: 77, 96%];  $p=0.13$ ). The area under the receiver operating characteristics curve increased from 0.63 (95% CI: 0.57, 0.68) to 0.96 (95% CI: 0.94, 0.99;  $p<0.001$ ) when LCTP was included. The mean radiation dose and contrast medium amount was 5.1 mSv  $\pm$  1.3 and 78 ml  $\pm$  15, respectively.

## CONCLUSION

s Adding LCTP to CTPA improves the diagnostic performance to detect perfusion defect in perfusion scintigraphy by increasing

sensitivity.

#### **CLINICAL RELEVANCE/APPLICATION**

Quantitative evaluation of pulmonary blood flow using dynamic lung CT perfusion enables accurate diagnosis compared to CT pulmonary angiography alone with acceptable radiation and contrast medium dose.

#### **R5A-SPCH-7 The Effects of Age on Lung Structure Parameters in Healthy People by Low-dose Computed Tomography**

Participants

Anqi Liu, MD, Beijing, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This article mainly focuses on the associations of lung structure parameters in healthy people with age. We quantified these changes by indicators derived from LDCT such as lung volumes, pulmonary vascular volumes and fractal dimensions, artery diameters, etc.

#### **METHODS AND MATERIALS**

1500 participants aged 20-69 years (mean age, 45±14 years; 51.4% men) with normal chest imaging manifestations were included in this study. The MPAd (main pulmonary artery diameter) at the bifurcation of the pulmonary artery and the AAd (ascending aorta diameter) at the same level in cross section were measured. We calculated the ratio PA by dividing MPAd by AAd. The lung volumes and pulmonary vascular volumes (small, middle, large vessels/arteries/veins) were computed by 3-dimensional(3D) reconstructions using LDCT images of the study population, and vessel fractal dimensions, normalized lung volumes (divided by body surface area) and normalized pulmonary vascular volumes (divided by total lung volume) were calculated.

#### **RESULTS**

We chose the young group (20-44-year-old group) as a reference, the MPAd of middle-aged group (45-59-year-old group,  $\beta=1.040$ ,  $p<0.001$ ) and old group (60-69-year-old group,  $\beta=1.778$ ,  $p<0.001$ ) increased compared to the young group after being adjusted for bias, so did AAd. Increasing total and right lung volumes were associated with age-based groups, the same phenomenon was observed when normalized by BSA, but the left lung volume ( $\beta=0.036$ ,  $p=0.215$ ) and normalized left lung volume ( $\beta=0.010$ ,  $p=0.546$ ) did not show statistically significant increase between the old and young groups. We found statistical differences ( $P<0.05$ ) of vascular volumes between the 3 age-based groups, but there was no association of vascular volumes in the 3 groups after adjustment. The normalized pulmonary vascular volumes except normalized pulmonary large artery and venous volumes presented lower levels comparing the middle-aged and old groups with young group. Vessel fractal dimensions have no associations with age. The 90th percentile cutoff values of MPAd were 27.63, 28.80 and 29.60mm, AAd were 32.28, 37.11 and 40.06mm, ratio PA were 0.97, 0.90, 0.86 for young group, middle-aged group and old group respectively.

#### **CONCLUSION**

s MPAd, AAd, total and right lung volumes increased when compared the old and middle-aged people to young people, while the normalized pulmonary vascular volumes except normalized pulmonary large artery and venous volumes presented lower levels comparing the old and middle-aged people with young people.

#### **CLINICAL RELEVANCE/APPLICATION**

Changes in LDCT-related lung structure parameters with age may provide normal reference values for healthy people in different age stage, which can also be potential markers of lung aging.

R5A-SPER

### Emergency Radiology Thursday Poster Discussions I

#### Sub-Events

#### **R5A-SPER-1 Necessity of Whole Body CT in Trauma Patients After Vehicle Accidents - Predictive Parameters for a Negative CT Examination**

#### Participants

Daniel Ginzburg, Bonn, Germany (*Presenter*) Nothing to Disclose

#### PURPOSE

To rule out serious findings in trauma patients, immediate CT imaging poses a major aspect in the Advanced Trauma Life Support scheme. In order to assess the necessity for whole body CT in patients after a vehicle accident a detailed analysis of this patient group is required. We aimed to identify patients after vehicle accidents that do not benefit from CT imaging in regard to the chest and abdomen.

#### METHODS AND MATERIALS

In this retrospective study, all patients that received a trauma CT in our emergency department after vehicle accidents between 03/2017 and 08/2019 were evaluated regarding trauma mechanisms as well as initial clinical assessment including the extended Focused assessment with sonography for Trauma (eFAST). Inclusion criteria were: vehicle accident, CT scan of the chest and abdomen and GCS = 13.

#### RESULTS

348/2525 patients (13.8 %) met the inclusion criteria. 151/348 patients (43.4 %) had an unremarkable physical examination according the ATLS scheme and a negative eFAST exam. 90/151 patients (59.6 %) had no injuries on CT, while the remaining 61 patients (40.4%) had only minor to moderate trunk injuries (Abbreviated injury scale - AIS < 3) not necessarily requiring CT evaluation (e.g. non-dislocated rib or sternal fractures). None of these patients required surgery, and apart from adjusted pain treatment, no changes were made to the therapeutic regimen based on the CT results. Of 197/348 (56.6%) patients with abnormal findings on physical examination and/or eFAST, 75 (38.1%) had severe trunk injuries (AIS = 3) requiring immediate clinical intervention on subsequent CT; 103 patients (52.3%) had mild/medium injuries (AIS < 3) and 19 patients (9.6%) had no trauma-related injuries.

#### CONCLUSION

While CT examinations remain an essential diagnostic pillar for the assessment of severely injured trauma patients, the indication for performing such examinations in patients with a GCS = 13 without abnormalities on physical examination or eFAST could be approached in a more individualized way. These patients rarely benefit from a trauma CT scan in terms of adjusting their treatment regimen.

#### CLINICAL RELEVANCE/APPLICATION

With vehicle accidents being one of the most frequent causes of death especially in younger patients below the age of 45 the correct diagnostics and treatment of this patient group is of major clinical significance.

## Abstract Archives of the RSNA, 2023

R5A-SPGI

### Gastrointestinal Imaging Thursday Poster Discussions I

#### Sub-Events

#### **R5A-SPGI-1 Pancreatic Volume Changes in Patients with Immunotherapy-induced Acute Pancreatitis and Diabetes Mellitus Type 3c**

##### Participants

Hiroaki Takahashi, MD, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

##### PURPOSE

Immune check-point inhibitors (ICI) therapy causes immune-related pancreatic injury (irPI) resulting in acute pancreatitis (AP) or glandular dysfunction including insulin-requiring diabetes mellitus type 3c (DM-3c). We investigated the chronological pancreatic volume changes in patients with ICI-associated AP and DM-3c.

##### METHODS AND MATERIALS

Patients treated with ICI therapy (pembrolizumab, ipilimumab or nivolumab) who developed ICI-associated AP or DM-3c from 2015 to 2019 at 3 centers in our network were included. CT or PET/CT examinations in each of following periods were reviewed: (1) Pre-treatment scans (prior to ICI administration), (2) pre-diagnostic scans (after ICI administration and prior to irPI diagnosis), (3) early post-diagnostic scans (0-90 days after irPI diagnosis), (4) midterm post-diagnostic scans (91-360 days after irPI diagnosis), and (5) late post-diagnostic scans (>360 days after irPI diagnosis). Each exam was anonymized and segmented by an experienced abdominal radiologist. The mean pancreatic volume was used as the representative value if multiple examinations were performed in each period. Normalized pancreatic volume (NPV) is calculated by the ratio of pancreatic volume in each period to that in the pre-diagnostic scan. Mann-Whitney U test was used to compute NPV statistical differences with  $P < 0.05$  considered statically significant.

##### RESULTS

Among 30 enrolled patients (12 males, 18 females, mean age: 63 [37-90] year-old), 21 patients developed AP and 9 patients developed DM-3c. No patient had concurrent AP and DM-3c diagnosis. The median duration from ICI administration to irPI diagnosis was 131 days (12-715 days) in patients with AP and 146 days (28-685 days) in patients with DM-3c. NPV (pre-treatment; pre-diagnostic; early post-diagnostic; midterm post-diagnostic; late post-diagnostic) was 1.05 (n=14, p=0.53); 1 (n = 21); 1.22 (n=19, p=0.41); 0.71 (n=12, p=0.04); 0.53 (n=5, p=0.14) in patients with AP and 0.80 (n=7, p=0.20); 1 (n=9); 0.71 (n=8, p=0.01); 0.62 (n=8, p < 0.001); 0.73 (n=5, p=0.01) in patients with DM-3c.

##### CONCLUSION

The pancreas shows increase in volume after ICI administration in patients with AP and DM-3c, but at different timing. Increase is seen prior to DM-3c diagnosis, and within 0-90 days after AP diagnosis. Pancreas volume decreases in 91- days after the diagnosis of DM-3c or AP and persists after 1 year. The degree of pancreatic atrophy is more severe in AP than DM-3c.

##### CLINICAL RELEVANCE/APPLICATION

CT pancreatic volumetry is a useful tool to assess irPI. Pancreatic volume loss could suggest previous irPI events. Pancreatic volume increase could suggest the future risk of ICI-associated DM-3c and recent AP events.

#### **R5A-SPGI-2 Time Dependency and Risk Factors of Splanchnic Vein Thrombosis Development in the Early Phase of Acute Pancreatitis: A Systematic Review and Meta-analysis**

##### PURPOSE

Splanchnic vein thrombosis (SVT) is a local complication of acute pancreatitis (AP) that may lead to subsequent complications such as portal hypertension, gastrointestinal bleeding, and mesenteric ischemia. Our aim was to analyze the temporal progression and contributing risk factors of SVT occurrence during the early phase of AP.

##### METHODS AND MATERIALS

We conducted a systematic search in four medical databases (Embase, MEDLINE via PubMed, Scopus, and CENTRAL) on October 27, 2022. Inclusion criteria were studies using appropriate radiological modalities to identify SVT in adult patients with AP, present data on early phase AP, and offer accurate information on the imaging timing. Exclusion criteria were studies with patients having malignant disease or recent surgical history. We used a random effects model, we calculated SVT-affected patient proportions, with 95% confidence intervals (CI), and conducted subgroup analyses. The study protocol was prospectively registered in the PROSPERO database.

##### RESULTS

Our analysis included 14 studies encompassing 1,951 patients. We found that the proportion of patients who developed SVT during the early phase of AP (within 12 days post-symptom onset) was 0.13 (CI 0.08-0.22). SVT incidence was lowest at 0.05 (CI 0.02-0.15) within 0-3 days, increasing almost five-fold to 0.23 (CI 0.1-0.46) between 3-11 days. Factors influencing SVT occurrence

included etiology (alcoholic 0.31 (CI 0.13-0.58), biliary 0.12 (CI 0.04-0.3),  $p=0.03$ ), and pancreatic necrosis (absent 0.09 (CI 0.06-0.15), under 50% 0.29 (CI 0.22-0.37), over 50% 0.46 (CI 0.36-0.56),  $p=0.01$ ). The proportions of distinct venous combinations affected by thrombosis included splenic vein (SV) 0.48 (CI 0.35-0.61), portal vein (PV) 0.28 (CI 0.18-0.42), superior mesenteric vein (SMV) 0.14 (CI 0.08-0.25), SV and PV 0.09 (CI 0.05-0.19), SV and SMV 0.06 (CI 0.02-0.14), PV and SMV 0.13 (CI 0.06-0.27), all three veins 0.1 (CI 0.05-0.19),  $p=0.01$ .

## CONCLUSION

One in six patients develops SVT in the early phase of AP. Alcoholic etiology and pancreatic necrosis increase the risk of SVT. In addition, this risk seems to increase with the duration of AP. The affected veins, in descending order, are the SV, PV, SMV, and combinations thereof.

## CLINICAL RELEVANCE/APPLICATION

Imaging should target high-risk patients and take into account the time-dependent nature of SVT incidence. Furthermore, when reporting, radiologists should have an increased suspicion of SVT if they observe pancreatic necrosis.

## R5A-SPGI-4 Preoperative Assessment of Peripheral Vascular Invasion of Pancreatic Ductal Adenocarcinoma Based on High-resolution MRI

### Participants

Xiaoqi Zhou, Guangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

Preoperative imaging determination of vascular invasion is important for surgical resectability of pancreatic ductal adenocarcinoma (PDAC). The purpose of this study is to compare diagnostic accuracy of PDAC vascular invasion between high-resolution MRI (HR-MRI), conventional MRI (non-HR-MRI) and CT, and clarify the applicable diagnostic criteria for MRI and CT.

## METHODS AND MATERIALS

Pathologically proved PDAC with preoperative HR-MRI (79 cases, 58 with CT) and non-HR-MRI (77 cases, 59 with CT) from 2014 to 2022 were retrospectively collected. Vascular invasion was confirmed by surgical exploration and pathology. The degree of tumor-vascular contact, vessel narrowing and contour irregularity were reviewed respectively. Diagnostic criteria 1 (C1) is the presence of all three characteristics, and criteria 2 (C2) if any one of them is present. The diagnosis efficacy of different examination methods and different criteria was evaluated and compared.

## RESULTS

HR-MRI showed satisfying performance in assessing vascular invasion (AUC: 0.87-0.92), especially better sensitivity (0.79-0.86 vs 0.40-0.79) compared with non-HR-MRI and CT. HR-MRI was superior to non-HR-MRI, but evenly matched to C2 assessed CT. C2 was superior to C1 in CT evaluation (0.85 vs 0.79,  $P=0.03$ ). C1 was superior to C2 in venous assessment by HR-MRI (0.90 vs 0.87,  $P=0.04$ ) and arterial assessment by non-HR-MRI (0.69 vs 0.68,  $P=0.04$ ). Combining C1 assessed HR-MRI and C2 assessed CT yielded the best performance, significantly better than CT alone (0.96 vs 0.86,  $P=0.04$ ).

## CONCLUSION

HR-MRI can provide more accurate assessment of PDAC vascular invasion than conventional MRI. C1 may be more applicable to MRI assessment, while C2 may be more applicable to CT. The combination of HR-MRI and CT outperformed CT alone and should be the recommended preoperative examination option.

## CLINICAL RELEVANCE/APPLICATION

HR-MRI provides vital information for the assessment of PDAC vascular invasion and may contribute to the operative decision making. Combined C1 assessed HR-MRI and C2 assessed CT showed the best efficacy and is the preferred preoperative examination option for PDAC.

## R5A-SPGI-5 Multivariate Quantitative Ultrasound Approach for the Assessment of Hepatic Steatosis in Chronic Liver Disease

## PURPOSE

There is a need for a non-invasive, widely available, and highly accurate tool for assessing hepatic steatosis considering the global increase in the incidence of non-alcoholic fatty liver disease. This study focused on the acoustic properties of the integrated backscatter coefficient (IBSC) and signal-to-noise ratio (SNR) in addition to the ultrasound-guided attenuation parameter (UGAP). We attempted to construct a highly accurate model for the prediction of  $\geq 5\%$  steatosis in chronic liver disease (CLD) using a multivariate quantitative ultrasound approach.

## METHODS AND MATERIALS

This prospective multicenter study enrolled 582 patients with CLD between February 2020 and April 2021, who were grouped into steatosis ( $n=364$ ) and non-steatosis ( $n=218$ ) groups using magnetic resonance imaging proton density fat fraction (MRI-PDFF) values as a reference. Four models were created to compute the prediction equation for steatosis: Model 1 (UGAP alone), Model 2 (UGAP + IBSC), Model 3 (UGAP + SNR), and Model 4 (UGAP + IBSC + SNR). Receiver operating characteristic (ROC) analysis, category-free net reclassification improvement (cf-NRI), and integrated discrimination improvement (IDI) were used to examine the optimal model.

## RESULTS

The areas under the ROC curve for steatosis diagnosis in Models 1, 2, 3, and 4 were 0.923, 0.931, 0.953, and 0.959, respectively. Internal validation using the bootstrap method yielded a C-index of 0.923, 0.930, 0.952, and 0.958, respectively; Models 3 and 4 demonstrated statistically significant discriminative power over the other models ( $p<0.001$ ) (95% confidence interval: 0.431-0.753,  $p<0.001$ ). The cf-NRI and IDI were 0.592 (95% confidence interval: 0.431-0.753,  $p<0.001$ ) and 0.019 (95% confidence interval: 0.005-0.031,  $p<0.01$ ), indicating higher discriminative performance of Model 4 compared to Model 3.

## CONCLUSION

s The multivariate quantitative ultrasound approach focused on the acoustic properties of UGAP, IBSC, and SNR is a promising method for assessing  $\approx 5\%$  steatosis in CLD.

#### CLINICAL RELEVANCE/APPLICATION

We developed a predictive formula using multiple quantitative ultrasound parameters to diagnose  $\approx 5\%$  steatosis in CLD with high discrimination and calibration power. The three quantitative ultrasound parameters, namely ultrasound-guided attenuation parameter, integrated backscatter coefficient, and signal-to-noise ratio, strongly correlated with steatosis in CLD. The procedure also demonstrated the potential to diagnose and quantify hepatic steatosis, with an AUROC of 0.959 (95% confidence interval: 0.944, 0.973) using the multiple quantitative ultrasound model.

#### R5A-SPGI-6 Diagnostic Accuracy of Computed Tomography (CT) for Detection of Hepatic Steatosis: A Systematic Review and Meta-analysis

Participants

Maryam Haghshomar, MD, MA, Chicago, IL (*Presenter*) Nothing to Disclose

#### PURPOSE

CT is a widely accessible imaging method and has an important role for opportunistic diagnosis of fatty liver. Its accuracy and performance however have been inconsistent in various studies and no clear criteria have been established by the societies. Our objective is to conduct a comprehensive review and meta-analysis to assess the diagnostic accuracy of CT in detection of steatosis.

#### METHODS AND MATERIALS

We searched through PUBMED, Embase, and Scopus databases between September 1977 to March 2023. We included studies evaluating diagnostic accuracy, such as sensitivity or specificity, cross-tabulations, or correlations of noncontrast CT (NCCT), contrast-enhanced (CECT), and dual-energy CT (DECT) in detecting fatty liver using either biopsy, proton-density fat fraction, or standard imaging as the reference standard.

#### RESULTS

Thirty-six (4432 participants) studies were included. CT is a reliable method for detecting mild and moderate/severe fatty liver, with sensitivity/specificity of 80.2%/90% for NCCT, 82.3%/96.1%, for CECT, and 83.2%/90% for DECT. Additionally, the area under the curve of diagnostic accuracy for NCCT, CECT, and DECT were 0.891, 0.901, and 0.917, respectively. Stratifying by multiple clinically relevant characteristics did not eliminate the statistical heterogeneity. The heterogeneity was most prominent for DECT and CECT. The threshold range for diagnosing fatty liver was a liver attenuation  $< 38.5$ -58 HU, a liver minus spleen attenuation of  $< -19$  to  $-10.1$  HU, and a liver-to-spleen attenuation ratio  $< 0.89$  to 1.2.

#### CONCLUSION

s NCCT, CECT, and DECT are reliable methods for screening fatty liver in clinical settings. They can detect mild/moderate to severe fatty liver with high reliability and accuracy. It is important to remain cautious when interpreting these findings as there was significant heterogeneity observed, particularly for DECT and CECT.

#### CLINICAL RELEVANCE/APPLICATION

CT is a major modality for opportunistic detection of hepatic steatosis. Results of this meta-analysis explores the performance of CT for this task and discuss the threshold values for diagnosis of steatosis.

#### R5A-SPGI-7 The Application Value of FLIS Combined with T2\* Mapping in Preoperative Liver Function Assessment of sHCC

#### PURPOSE

Using the 15 minutes indocyanine green retention rate (ICG R-15) as the reference standard, the diagnostic value of FLIS combined with T2\* mapping for preoperative assessment of liver reserve function in sHCC were compared with T1 mapping.

#### METHODS AND MATERIALS

A retrospective analysis was conducted on 60 patients with sHCC who had preoperative imaging findings from July 2020 to March 2023. All patients underwent Gd-EOB-DTPA-enhanced MRI, including pre-injection (T1-pre) mapping, post-injection (T1-post) 20 min mapping, and T2\* mapping. The ROIs were selected at the same location and measurements were taken to calculate R2\* values, pre-injection (T1-pre), post-injection (T1-20 min) T1 relaxation times and calculated the T1 relaxation time reduction rate (T1-pre - T1-20 min/ T1-pre). Three features of the hepatobiliary phase were assessed: normal liver parenchyma, biliary system and portal vein signal intensity, and FLIS was calculated. All patients underwent a ICG retention test and were divided into three groups (29 patients in group 1  $< 10\%$ , 19 patients in group 2 10%-20% and 12 patients in group 3  $\approx 20\%$ ). The differences between the normal liver R2\* values, FLIS and T1 relaxation time reduction rates between the three groups were statistically analysed.

#### RESULTS

he reduction rates of T1 relaxation time, R2\* values, FLIS between the 3 groups were (76.56 $\pm$ 1.00)%, (62.12 $\pm$  (1.25)%, (53.19 $\pm$ 2.25)% vs (39.75 $\pm$ 2.57) Hz, (45.39 $\pm$ 1.83) Hz, (55.41 $\pm$ 2.34) Hz vs (4.90 $\pm$ 0.90), (3.68 $\pm$ 0.82) (1.58 $\pm$ 0.79), the differences were statistically significant (P $<$ 0.01), R2\* values were negatively correlated with liver function grade, FLIS and T1 relaxation time reduction rate were positively correlated with liver function grade, Spearman's correlation coefficient Rs were -0.921, 0.821, 0.981. The area under the R2\* value, FLIS and T1 relaxation time reduction rate ROC were 0.883, 0.825 and 0.914 between group 1 and 2, and 0.867, 0.8 and 0.869 between groups 2 and 3. The T1 relaxation time reduction rate was the most efficient diagnostic between the 3 groups, followed by R2\* value and FLIS respectively, and the combined diagnostic efficacy of the two increased (0.945, 0.935).

#### CONCLUSION

s The FLIS and T2\* mapping can accurately assess the liver reserve function of patients with sHCC preoperatively, and their combined diagnostic efficacy is higher than the T1 relaxation time reduction rate.

#### CLINICAL RELEVANCE/APPLICATION

The combined diagnostic efficacy of FLIS and T2\* mapping is higher than the T1 relaxation time reduction rate. And it can shorten scanning time.

## **R5A-SPGI-8 Quantitative liver function analysis using T1 mapping on gadoxetic acid-enhanced MR imaging; the application of Dixon-based fat correction in look-locker inversion recovery sequence**

Participants

Ye Rin Hwang, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

### **PURPOSE**

To investigate the role of T1 map-derived quantitative imaging parameters for the assessment of liver function, and the impact of fat correction of T1 mapping on gadoxetic acid-enhanced MR imaging

### **METHODS AND MATERIALS**

A total of 228 patients with normal liver, chronic liver disease and liver cirrhosis who underwent 3T gadoxetic acid-enhanced MR including Dixon-based fat corrected look-locker inversion recovery (LLIR) sequence were included. Two readers measured pre- and postcontrast T1 relaxation times (preT1 and postT1) on conventional and water map T1 in two sessions with 2-week interval. The averaged preT1, postT1 values, changes between pre- and postcontrast T1 liver ( $\Delta T1$ ), and adjusted postcontrast T1 liver ( $\text{postcontrast T1}_{\text{liver}} - \text{T1}_{\text{spleen}} / \text{T1}_{\text{spleen}}$ ) for both conventional T1 and water map T1, were analyzed for assessment of clinical indices of liver function and hepatic enhancement grade on hepatobiliary phase (HBP). Liver fat fraction (FF) was calculated on MR-based proton density fat fraction (PDFF) map and correlation of T1 map-derived parameters with fat fraction were assessed. With the FF cut-off 6.4%, T1 map-derived parameters were compared between fatty liver and non-fatty liver groups. Multivariate linear regression (MLR) analyses were performed to determine significant variables for T1 value. Reproducibility of T1 values were also assessed.

### **RESULTS**

The inter-reader and intra-reader reproducibility showed near-perfect agreement (ICC 0.929-0.999). 68 subjects were included in fatty liver (FL) group (29.8%, 68/228; mean FF for FL group  $10.77\% \pm 4.92$  vs. non-fatty liver (NFL) group  $2.75\% \pm 1.33$ ). The water map preT1 was lower than preT1 in FL group, and showed significant difference between FL group and NFL group ( $669.4 \pm 274.21$  vs.  $760.67 \pm 207.05$ ,  $p = 0.015$ ). The correlation of preT1 ( $r = 0.232$ ,  $p = 0.0005$ ) and  $\Delta T1$  ( $r = 0.263$ ,  $p = 0.0001$ ) with FF were significant, however water map preT1 ( $r = -0.109$ ,  $p = 0.106$ ) and water map  $\Delta T1$  ( $r = 0.039$ ,  $p = 0.569$ ) showed no correlation with FF. With MLR analysis, albumin, total bilirubin, HBP enhancement grade, FF and R2\* value were significantly associated with T1 map-derived parameters (preT1, postT1,  $\Delta T1$ , and adjusted postT1). For the same T1 map-derived parameters measured on water map, the effect of FF was eliminated while HBP enhancement grade, albumin, and R2\* value were persistently significant factors.

### **CONCLUSION**

T1 mapping on water map using Dixon-based fat corrected LLIR sequence can estimate liver function effectively free from the influence of hepatic steatosis.

### **CLINICAL RELEVANCE/APPLICATION**

With the fat corrected water map T1, T1 mapping of liver can be a useful and noninvasive imaging biomarker for the assessment of liver function regardless of hepatic steatosis.

## Abstract Archives of the RSNA, 2023

R5A-SPGU

### Genitourinary Imaging Thursday Poster Discussions I

#### Sub-Events

#### **R5A-SPGU-1 Comparing the Diagnostic Performance of Biparametric with Multiparametric MRI using PI-RADS version 2.1 for Clinically Significant Prostate Cancer**

##### **PURPOSE**

To compare the diagnostic performance of multiparametric MRI (mpMRI) with biparametric MRI (bpMRI) for clinically significant prostate cancer (csPCa) based on the Prostate Imaging Reporting and Data System (PI-RADS) version 2.1.

##### **METHODS AND MATERIALS**

1939 patients underwent prostate MRI from January 2019 to December 2021. This study finally enrolled 597 patients with 616 lesions who underwent mp-MRI (T2WI, DWI and DCE) before MRI/transrectal ultrasound fusion-targeted biopsy. All lesions were classified as 249 lesions in peripheral zone (PZ) with 81 csPCa and 367 lesions in transition zone (TZ) with 67 csPCa. We scored the lesions on the image according to the site of targeted biopsy using the PI-RADS v2.1 standard with blinding to PSA value and pathology results. There were four weeks in between reading sessions for bpMRI and mpMRI. On bpMRI, the overall category of lesions in PZ was determined solely based on the DWI category. The overall category of lesion in TZ was the same between bpMRI and mpMRI. A Student's t-test and a Mann-Whitney U test were employed to compare continuous variables. When using a cutoff of PI-RADS category =4, the ROC curves for bpMRI and mpMRI in the diagnosis of csPCa were drawn to calculate AUC values.

##### **RESULTS**

Patients with csPCa had higher PSA levels and PSAD values, but lower prostate volumes, and being older, compared to those with non-csPCa ( $P < 0.001$ ). The AUCs of bpMRI and mpMRI in PZ for the diagnosis of csPCa were 0.901 and 0.891, respectively ( $P > 0.05$ ). However, mpMRI had higher sensitivity (93.8%) but lower specificity (76.2%) compared to bpMRI (sensitivity: 74.1%; specificity: 89.9%). The same trend was observed in PZ+TZ lesions. In PZ, significantly fewer lesions were assigned to category 3 in mpMRI than in bpMRI due to some lesions with category 3 in bpMRI were up-scored to category 4 in mpMRI. For PZ, if biopsy had been performed in patients with PI-RADS categories 4 and 5, mpMRI detected 39 additional patients who needed biopsy compared to bpMRI and identified 16 cases of csPCa.

##### **CONCLUSION**

Both bpMRI and mpMRI using PI-RADS v2.1 exhibited similar diagnostic performance in diagnosing csPCa, yet mpMRI might decrease the probability of missing csPCa cases.

##### **CLINICAL RELEVANCE/APPLICATION**

Compared to mpMRI, bpMRI offers several advantages including contrast-free imaging, shorter scanning time, and lower costs. However, the application value of bpMRI in diverse clinical scenarios needs to be further researched. Our study demonstrated that mpMRI had the advantage of reducing the probability of missing csPCa cases.

#### **R5A-SPGU-2 Combined Real-time Elastography and Contrast-enhanced Ultrasound for the Detection of Clinically Significant Prostate Cancer**

##### Participants

Yunkai Zhu, Shanghai, China (*Presenter*) Nothing to Disclose

##### **PURPOSE**

To investigate the diagnostic performance of combined real-time elastography (RTE) and contrast enhanced ultrasound (CEUS) for the detection of clinically significant prostate cancer (csPCa).

##### **METHODS AND MATERIALS**

This prospective study was approved by the local ethics committee. Between November 2019 and December 2022, 286 patients scheduled for prostate biopsy underwent RTE and CEUS evaluation before biopsy procedure. Men with suspicious lesions on RTE (defined as reproducible stiffness lesion) or CEUS (defined as increased focal contrast enhancement) underwent targeted biopsy (TB) in conjunction with systematic biopsy (SB). Men with negative RTE and CEUS underwent SB alone. The primary outcome was the detection of csPCa (Grade Group = 2) in correlation with the biopsy results.

##### **RESULTS**

Among the 286 patients (median age, 67 years) enrolled in this study, mpUS identified suspicious lesion(s) in 204 patients. The biopsy histopathology confirmed the diagnosis of prostate cancer in 146 patients, including 110 patients with csPCa. The csPCa detection rate was 28% (80/286) for CEUS-TB, 26% (74/286) for RTE-TB and 25% (72/286) for SB ( $P = 0.73$ ). The combination of CEUS-TB and RTE-TB could achieve a csPCa detection rate of 34% (101/286), significant higher than that of SB ( $P = 0.02$ )

##### **CONCLUSION**

Combined CEUS-TB and RTE-TB could achieve a csPCa detection rate of 34% (101/286), significant higher than that of SB ( $P = 0.02$ )

s Combined CEUS-IB and RTE-IB could achieved significantly higher csPCa detection rate than SB alone.

**CLINICAL RELEVANCE/APPLICATION**

Combined CEUS-TB and RTE-TB could improve csPCa detection than either individual US and SB alone.

Yun-Lin Huang, MD, Shanghai, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the potential added values of dynamic contrast-enhanced ultrasound (DCE-US) for the diagnosis of small solid thyroid nodules.

##### METHODS AND MATERIALS

This bi-center prospective study was approved by the institutional review board and it was performed between January 2020 and October 2020. B-mode ultrasound and contrast-enhanced ultrasound (CEUS) images were obtained for solid thyroid nodules (= 1.0 cm) confirmed by pathological results. The CEUS time-intensity curves (TICs) of thyroid nodules and surrounding parenchyma were created by VueBox® software (Bracco, Italy). The quantitative parameters of CEUS were analyzed after curve fitting. The weighted kappa statistic (?) was performed to assess the interobserver agreement and consistency between the diagnosis of CEUS and DCE-US. The diagnostic performance of CEUS and DCE-US was evaluated and compared.

##### RESULTS

Totally, 79 thyroid nodules in 79 consecutive patients (55 women; median age: 41 years) were enrolled; 70.9 % (56/79) were malignant and 29.1 % (23/79) were benign nodules. Hypoenhancement during the arterial phase of CEUS was associated with malignant nodules ( $P < 0.001$ ), with an AUC of 0.705, sensitivity of 71.4 %, and specificity of 69.6 %. The peak enhancement (PE), wash-in rate (WiR), and wash-out rate (WoR) of quantitative parameters of DCE-US in malignancies were significantly lower than those in benign nodules ( $P < 0.05$ ). For detecting malignant small solid thyroid nodules (= 1.0 cm), the AUCs of PE, WiR, and WoR were 0.642 (sensitivity 65.2 %, specificity 67.9 %), 0.643 (sensitivity 43.5 %, specificity 91.1 %), and 0.667 (sensitivity 69.6 %, specificity 69.6 %), respectively. Comparing the quantitative parameters between small solid thyroid nodules and surrounding normal thyroid parenchyma, the PE, wash-in area under the curve, WiR, wash-in perfusion index, wash-out AUC, wash-in and wash-out AUC, and WoR of the nodules were significantly lower than those of normal thyroid tissue ( $P < 0.05$ ). A total of 20.3 % (16/79) nodules showed isoenhancement during the arterial phase of CEUS, and the median PE ratio of surrounding tissue and thyroid nodules was 1.70 (IQR 1.33 - 1.89).

##### CONCLUSION

s DCE-US using VueBox® perfusion analysis could provide added values for differential diagnosis of small solid thyroid nodules. VueBox® is a helpful tool for the evaluation of dynamic microvascularization of lesions.

##### CLINICAL RELEVANCE/APPLICATION

This bi-center prospective study highlights the practicality of DCE-US using VueBox® perfusion analysis for the evaluation of dynamic microvascularization of thyroid nodules and differential diagnosis of small solid thyroid nodules.

#### **R5A-SPHN-2 The Value of Deep Learning Reconstruction Algorithms Combined with Organ Dose Modulation Techniques to Improve Thyroid CT Scan Image Quality and Reduce Radiation Dose**

##### Participants

Lv Ren-feng LV, Dalian, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Study the deep learning reconstruction (DLIR) algorithm combined with organ dose modulation(ODM) technology to improve the quality of thyroid CT scan images and reduce the radiation dose value.

##### METHODS AND MATERIALS

Using APEX CT, 36 patients with thyroid examination in our hospital were scanned and divided into non-ODM (N-ODM) and ODM groups according to whether the ODM technique was used or not, with 18 cases in each group. According to the different reconstruction algorithms, the two groups respectively reconstructed 2.5 mm images using adaptive statistical iterative reconstruction (ASIR-V, 30%) and deep learning reconstruction (DLIR). Scan start position is 14cm below the plane of the thyroid cartilage, the ODM area contains a fixed length of 5 cm of the thyroid. At the level of maximum thyroid display in the transectional position, the CT values and noise (SD) of the thyroid and muscle in the same layer were recorded, the contrast noise ratio (CNR) and radiation dose (ED) were calculated, the image quality was evaluated subjectively by two imaging physicians using a 5-point scale.

##### RESULTS

There was no statistical difference in CT values of thyroid and muscle tissue in the four groups ( $P > 0.05$ ). The SD, CNR and image quality subjective scores of the N-ODM-DLIR and ODM-DLIR groups were better than the N-ODM-ASIR and ODM-ASIR groups (all  $P < 0.05$ ), the overall image noise of DLIR group is significantly better than that of ASIR group, which can provide a clear image of the neck hierarchy. The radiation dose reduction was about 23% in the ODM group compared to the N-ODM group ( $2.20 \pm 0.07$  vs.  $2.89 \pm 0.04$ ,  $t = 35.04$ ,  $P < 0.05$ ).

## CONCLUSION

s In thyroid CT scans, using the DLIR reconstruction algorithm can significantly improve the image quality, combined with the ODM technique effectively reduces the radiation dose.

## CLINICAL RELEVANCE/APPLICATION

During thyroid scan, because the thickness of the X-axis of the human neck and shoulder is much greater than the Y-axis, the adaptive statistical iterative reconstruction algorithm can not improve the noise of the lower neck scan image well, while the DLIR algorithm can effectively suppress the noise. The thyroid is a highly sensitive tissue organ, ODM technology can conduct low-dose imaging of thyroid area in the process of scanning, combined with DLIR algorithm can improve the image quality.

## R5A-SPHN-3 Value of Radiomics Model Based on T1-weighted, T2-weighted, and Enhanced T1-weighted MRI in Differentiating Benign and Malignant Thyroid Nodules

Participants

Pin He, Shenzhen, China (*Presenter*) Nothing to Disclose

## PURPOSE

To explore the application value of radiomics model based on T1-weighted, T2-weighted and enhanced T1-weighted MRI (T1WI, T2WI, and enhanced T1WI) in differentiating benign and malignant Thyroid Nodules.

## METHODS AND MATERIALS

The clinical and MR imaging data of 127 patients with 135 thyroid nodules (benign: malignant = 37: 98) confirmed by pathology from January 2019 to December 2022 were retrospectively collected and analyzed in our hospital. These patients were randomly divided into a training group and test group according to 7:3 ratio. All patients underwent T1WI, T2WI and enhanced-T1WI before operation. Based on the manually segmented entire thyroid lesions as the regions of interest (ROI), radiomics features were extracted from T1WI, T2WI, and enhanced-T1WI, respectively. Student-t test, the Least Absolute Shrinkage and Selection Operator (LASSO) algorithm and correlation analysis were sequentially used for feature selection. Four classifiers, i.e., k-nearest neighbor (KNN), support vector machine (SVM), random forest (RF) and logistic regression (LR) were used for building three models (T1WI model, T2WI model, enhanced-T1WI model and combined model). The effectiveness of the model in differentiating benign and malignant thyroid nodules was validated by a receiver operating characteristic (ROC) curve.

## RESULTS

After feature selection, 7, 10 and 5 features from T1WI, T2WI, and enhanced-T1WI were selected to build models. Among the four radiomics models built with the same classifier, LR classifier-based model outperforms other three classifiers-based T1WI model, T2WI model, enhanced T1WI model and combined model. In the test group, LR-based T2WI radiomics model achieved an AUC of 79.1% with the sensitivity and specificity of 76.3% and 98.6%, respectively. Combined model achieved an AUC of 79.7% with the sensitivity and specificity of 79.8% and 89.8%, respectively.

## CONCLUSION

s Radiomics method based on T2WI has certain significance on the malignancy differentiation of thyroid nodules.

## CLINICAL RELEVANCE/APPLICATION

Different benign and malignant Thyroid Nodules require different treatment strategies and have a different prognosis; thus, the noninvasive differentiation of thyroid Nodules before surgery is of great importance. Radiomics models based on structural MRI has good performance in differentiating malignant and benign thyroid nodules, especially radiomics model based on T2WI.

## R5A-SPHN-4 Evaluation of Ultrasound Characteristics of Two Topical Hemostatic Agents after Thyroid Surgery

Participants

Vincenzo Dolcetti, Rome, Italy (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of the study is to describe the ultrasound appearance of topical hemostatics after thyroidectomy, in order to recognize their main features to avoid diagnostic errors and pitfalls.

## METHODS AND MATERIALS

We enrolled 84 patients who underwent hemithyroidectomy or total thyroidectomy and treated with two types of topical hemostats, 49 with an absorbable hemostat of oxidized regenerated cellulose (Oxitemp®) and 35 with a fibrin glue-based hemostat (Tisseel®). All patients were examined with B-mode ultrasound to evaluate post-surgical changes and the presence or absence of residual swab at the level of the thyroid lodge in each patient. A regression analysis was performed for positive cases correlating the size of the residual swab with the time elapsed since surgery

## RESULTS

In 39 patients of the first group (approximately 80%) was detected a haemostatic residue which could potentially be confused with a native gland residue, or with cancer recurrence in oncological patients. No residue was detected in patients in the second group. The main ultrasound characteristics of the swab were analyzed and arranged according to predefined patterns, providing suggestions to recognize it and avoid wrong diagnoses. A part of the group of patients with tampon residue was re-evaluated after 6-12 months, ensuring that the swab remained for months after the maximum resorption time declared by the manufacturer. The regression analysis showed a weak not statistically significant correlation between time elapsed from surgery and the size of the residue.

## CONCLUSION

s Since the two materials showed the same efficacy in post surgical hemostasis, the fibrin glue pad is more favorable in the ultrasound follow-up because it creates reduced surgical outcomes.

## CLINICAL RELEVANCE/APPLICATION

It is important to know and recognize the ultrasound characteristics of oxidized cellulose based hemostats in order to reduce the number of diagnostic errors and the inappropriate diagnostic investigations.

## R5A-SPHN-5 To Explore the Application Value of Spectral CT in the Identification of Benign and Malignant Thyroid Nodules

### PURPOSE

To explore the value of spectral CT in the differential diagnosis of benign and malignant thyroid nodules through the analysis of spectral CT data and the pathological results.

### METHODS AND MATERIALS

Retrospective analysis was performed on 31 patients with pathological confirmation of surgery and enhanced thyroid spectrum CT examination in our hospital from May 2022 to March 2023, with a total of 37 nodules. According to the pathological results, the nodules were divided into two groups, there were 13 nodules in the benign group and 24 nodules in the malignant group. The iodine concentration (IC) in the arterial and venous phases of nodules and that in the artery of the same layer were measured on the iodine concentration diagram, and the standardized iodine concentration (NIC) was calculated,  $NIC = \text{nodule IC} / \text{IC in the artery of the same layer}$ , using GSI viewer software. In addition, the effective atomic number (Z) of the nodules at the arterial and venous stages was measured on the 45 keV single energy map. Independent sample t-tests were performed for the obtained energy spectrum parameters IC, NIC, and Z, Draw the subject's operating characteristic curve (ROI) and calculate the area under the curve (AUC).

### RESULTS

The IC of malignant nodules in arterial and venous stages was  $25.99 \pm 15.19$ ,  $20.95 \pm 6.92$ , lower than that of benign nodules  $42.65 \pm 10.13$ ,  $32.17 \pm 13.17$ , which were statistically significant ( $P < 0.05$ ). The NIC and Z values of benign and malignant nodules in arterial phase were not significant ( $P > 0.05$ ), while the NIC and Z values of venous phase were  $0.94 \pm 0.26$  and  $0.62 \pm 0.16$ , and Z values were  $9.21 \pm 0.51$  and  $8.84 \pm 0.26$ , which were statistically significant ( $P < 0.05$ ). The area under the receiver operating characteristic curve (AUC) of IC, NIC and Z-value in arterial and venous phases were 0.859, 0.782, 0.853, 0.736, respectively, and the corresponding cutoff values were 34.92, 25.09, 0.72, 9.00, respectively.

## CONCLUSION

s The IC value, NIC value and Z value of kinetic and venous stage of spectral CT have good clinical value in the differential diagnosis of benign and malignant thyroid nodules, and can effectively identify benign and malignant thyroid nodules.

## CLINICAL RELEVANCE/APPLICATION

An effective method to distinguish benign and malignant thyroid gland can be provided by using CT enhancement of thyroid spectrum and quantitative parameter analysis.

## R5A-SPHN-6 Utility of Repeat FNA for Benign Thyroid Nodules

### PURPOSE

For a large portion of patients with suspicious thyroid nodules, fine-needle aspiration (FNA) yields a benign diagnosis. There is a paucity of data to help determine which of these patients require a repeat FNA. The primary aim of this study is to evaluate the incidence of malignancy from repeat FNA of thyroid nodules in patients with initially benign pathology. Additionally, we assess if there are any demographic indicators or image features that may predict a need for repeat biopsy.

### METHODS AND MATERIALS

We retroactively identified patients who underwent more than one thyroid FNA at our institution between May 2010 and September 2022. From this cohort, we found 383 patients who underwent a total of 791 biopsies. Of these, 110 nodules had a cytopathologic diagnosis of Benign Follicular Nodule (BFN) based on the Bethesda System at the time of initial FNA. 38 of the 110 had a corresponding second biopsy of the same nodule on a later date. Demographic variables and pertinent risk factors were recorded. Associated TI-RADS descriptors, TI-RADS score, and size of the nodules were documented for each biopsy when available.

### RESULTS

Of the 38 biopsies that were initially benign and underwent repeat biopsy, 36 were confirmed as benign (94.7%) on repeat biopsy. One nodule had a non-diagnostic sample on repeat biopsy and was lost to follow-up (2.6%). Only one nodule was ultimately diagnosed as malignant (2.6%). The mean age (SD) at time of first biopsy was 51.2 (16.1) years. Initial cytopathology from repeat FNA identified 30 BFN (79%), 6 atypical follicular cells of undetermined significance (AFCUS) (15.8%), 1 follicular neoplasm (2.6%) and 1 nondiagnostic (2.6%). Of the six biopsies that were classified as AFCUS, three underwent Afirma genomic sequencing and were determined to be benign (50%). One of the three AFCUS nodules that did not undergo Afirma was surgically removed and identified as a micropapillary thyroid carcinoma. The nodule that was classified as a follicular neoplasm on repeat FNA was diagnosed as an adenomatous hyperplastic nodule on surgical pathologic examination. The mean time (SD) between first and second FNA was 69.6 (40.6) months. Mean increase in nodule size was 0.46 cm between initial and repeat biopsy.

## CONCLUSION

s In this retrospective study of patients who underwent a repeat FNA of thyroid nodule initially categorized as benign on initial FNA, only 1 of 38 patients (2.6%) was found to have malignant pathology on final diagnosis. The single nodule with initial benign cytology subsequently found to be malignant had no interval increase in size.

## CLINICAL RELEVANCE/APPLICATION

Our data suggest a low risk of malignancy for thyroid nodules biopsied based on TI-RADS recommendations, suggesting that re-

biopsy of nodules with benign cytology is likely unnecessary.

R5A-SPIN

### Imaging Informatics Thursday Poster Discussions I

#### Sub-Events

#### R5A-SPIN-1 A New Automatic AI Tool for MR Urography Functional Analysis in Children

##### PURPOSE

Magnetic resonance urography (MRU) is a technique used to evaluate urinary tract abnormalities in children, with the advantage of being noninvasive and allowing both morphologic and functional assessments. Currently, MRU analysis is usually performed with semiautomated software that typically requires manual segmentation of the kidney and pelvis and other time-consuming interactions. In recent years, artificial intelligence (AI) techniques have been used in various domains to solve segmentation, classification, diagnosis tasks. In this work, we propose a deep learning-based approach to automate the functional analysis of the MRU. The proposed approach is integrated into a commercial web viewer (DicomVision) so that it can be used easily included into the clinical routine.

##### METHODS AND MATERIALS

The developed pipeline first employs an Attention U-Net for automatic segmentation of the kidneys and pelvis on morphological MR and then an image registration process to align the segmentations on functional MR. Morphological and functional MR scans are navigable and analyzable on the web viewer along with the automatic segmentations provided by the pipeline. The web viewer allows the automatic segmentations to be edited manually if necessary. Finally, functional analysis is automatically performed by considering the entire 3D anatomy of the kidneys and pelvis, thus assessing the functioning of the renal system in its entirety. The results produced by the analysis, that include excretion curves and split renal functions (with volumetric, area under the curve (AUC), and Rutland Patlack methods) together with derived parameters, are presented in an automatically generated report within the web viewer.

##### RESULTS

The automatic segmentation of morphological MR has been tested on 107 patients using cross validation, achieving a Dice Score of  $0.87 \pm 0.15$  and  $0.91 \pm 0.11$  for left and right kidney, and a Dice Score of  $0.75 \pm 0.24$  and  $0.71 \pm 0.25$  for the left and right pelvis respectively. The registration process, used to align the morphologic segmentations on functional MRU scans, produced functional segmentations that did not require manual retouching in 74% of cases.

##### CONCLUSION

Our analyses demonstrate that the automated web viewer enables rapid and comprehensive analysis of children's MRUs. In particular, the use of such software reduces the time required for segmentation and enables functional analysis on the entire 3D anatomical structure of the kidneys and pelvis.

##### CLINICAL RELEVANCE/APPLICATION

This AI tool for MRU performs faster and better for functional evaluation of SRF and opens the door assessment of new quantitative parameters for obstructive and non-obstructive pathologies which can be useful for surgical planning.

#### R5A-SPIN-2 Generative Adversarial Networks for Brain MRI Synthesis: Impact of Training Set Size on Clinical Applications

##### Participants

Gian Marco Conte, MD, PhD, Rochester, MN (*Presenter*) Nothing to Disclose

##### PURPOSE

To test the impact of training set size on generative adversarial networks (GANs) trained to synthesize brain MRI sequences.

##### METHODS AND MATERIALS

We previously trained two GANs to generate pre-contrast T1 from post-contrast T1 (T1 model) and FLAIR from T2 (FLAIR model) sequences (baseline models). The reference models were trained on 135 from the BraTS 2017 dataset. Here, we trained the same models using 1251 subjects from the BraTS 2021 dataset using the same architecture and hyperparameters from the original model: a batch size of 1, learning rate  $2 \times 10^{-4}$ , Adam optimizer, cross-entropy, and L1 loss. We trained two versions of the updated models: one stopped at an early checkpoint (early models) and one after 50 epochs (late models). We tested all models on a dataset of newly diagnosed 487 IDH-wt gliomas (Fig.1 A, B). The generated T1 and FLAIR sequences were compared with the original MRIs using the structural similarity index (SSI) and mean squared error (MSE). To assess the practical impact of using synthetic data, we simulated scenarios where either the T1, FLAIR, or both were missing and used their synthetic version as inputs of a segmentation model (HD-GLIO) with the original post-contrast T1 and T2. We compared the segmentations obtained in all scenarios using the dice similarity coefficient (DSC) for the contrast-enhancing area, non-enhancing area, and the whole lesion (Fig. 1B, C). We used Friedman and Dunn's test to compare the DSC scores and correct for multiple comparisons.

##### RESULTS

The median SSI on the test set for the generated T1 were .957, .947, and .947 and the median MSE were .006, .014, and .008 for

the baseline, early, and late models. For the generated FLAIR, the median SSI were .924, .908, and .915 and the median MSE were .016, .016, and .019 for the baseline, early, and late models. The range DSC on the test set for the baseline, early and late models were .655 - .953, .420 - .952, and .610 - .952 (Fig. 1D). Overall, the baseline and late models did not show any statistically significant differences in DSC, but both performed significantly better than the early models.

## CONCLUSION

s Generative models trained on a relatively small cohort performed similarly to those trained on a cohort 10 times larger. Overall, synthesizing FLAIR is more challenging than T1; consequently, segmentation of the contrast-enhancing areas is more robust to the use of synthetic data.

## CLINICAL RELEVANCE/APPLICATION

Incomplete MRI exams reduce the possibility of applying AI models in practice. We show that GANs can generate missing MRIs with relatively low data, making them a viable option for rare diseases or institutions with limited computing resources.

## R5A-SPIN-3 Clinical Validation Study of Machine Learning Algorithms for Liver Transplant Planning Including Vessel Segmentation

### PURPOSE

Accurate volumetric measurements have been shown to improve the outcome of liver transplant operations for both donor and recipient. [1] Preparation involves the segmentation of the donor liver in order to ensure acceptable tissue volume to support a good outcome for both the donor and the recipient. Ideally, vasculature would be excluded from these measurements however this process can take up to 1 hour for a highly trained specialist. A reliable, automated machine learning model was developed in order to significantly reduce the time required for generating this vital data.

### METHODS AND MATERIALS

Materials: 35 retrospective liver donor venous phase CT images were collected from historical records in order to train the initial model. Three rounds of evaluation were performed by three separate readers with 10 patients each round. Between rounds the model was re-trained with all previous results. The final model had a total training set of 64 images. Methods: A 3D CNN (NVIDIA Clara segresnet [2, 4-5]) was trained using 44 retrospective cases. Training labels for the right lobe, left lobe and vessels were extracted from venous phase CT images using the EDDA [3] software package by an expert analyst. The model performance was compared to segmentations performed by two readers, one novice to liver segmentation and the other a highly trained specialist in liver segmentation. All 3 results were uploaded to an XNAT [6] server for review. Clinicians performed a blinded review of all 3 segmentations for quality using the OHIF plugin [7].

### RESULTS

The final model was trained using a total of 44 retrospective and 20 prospective clinical cases showing mean dice scores of 0.96 for the right lobe, 0.930 for the left lobe, and 0.725 for the vessels. Three metrics commonly used in liver transplant planning including graft weight to recipient weight ratio (GWRW), future liver remnant (FLR), and graft volume to standard liver volume ratio (GVSTL) were calculated and compared between the ML result and the expert assuming the right lobe as the graft. The median difference between the expert and ML for GWRW was 2% with a mean of 4.5%  $\pm$  0.1%, for FLR the median difference was 7% with an average of 12%  $\pm$  0.2%, and for GVSTL the median difference was 6% with an average of 8%  $\pm$  0.2%.

## CONCLUSION

s The presented machine learning model for liver donor segmentation was able to efficiently provide accurate estimates for liver volumetrics in order to support surgical planning.

## CLINICAL RELEVANCE/APPLICATION

Accurate volumetrics are critical for predicting outcome in liver donor transplant cases. A CNN was trained to quickly and automatically segment the right and left lobes excluding vessels for liver donor transplant surgery planning.

## R5A-SPIN-4 Evaluating ChatGPT as an Adjunct for Radiologic Decision-Making

### PURPOSE

To evaluate ChatGPT's capacity for clinical decision support in radiology via the identification of appropriate imaging services for two important clinical presentations: breast cancer screening and breast pain.

### METHODS AND MATERIALS

We compared ChatGPT's responses to the American College of Radiology (ACR) Appropriateness Criteria for breast pain and breast cancer screening. Our prompt formats included an open-ended (OE) format, where ChatGPT was asked to provide the single most appropriate imaging procedure, and a select all that apply (SATA) format, where ChatGPT was given a list of imaging modalities to assess. Scoring criteria evaluated whether proposed imaging modalities were in accordance with ACR guidelines. Three replicate entries were conducted for each prompt, and the average of these was used to determine final scores.

### RESULTS

ChatGPT achieved an average OE score of 1.83 (out of 2) and a SATA average percentage correct of 88.9% for breast cancer screening prompts, and an average OE score of 1.125 (out of 2) and a SATA average percentage correct of 58.3% for breast pain prompts.

## CONCLUSION

s ChatGPT achieves moderate accuracy in identifying appropriateness of common imaging modalities for breast cancer screening and breast pain. Our results demonstrate the feasibility of using ChatGPT for radiologic decision making.

## CLINICAL RELEVANCE/APPLICATION

Our pilot study of the use of ChatGPT in radiology demonstrates the potential to improve clinical workflows and responsible use of radiology services. Potential use cases include triage and imaging resource allocation.

## **R5A-SPIN-5 Modified Turing Test Unveiled: AI-Generated Radiology Editorials Compete with Human Expertise**

Participants

Burak Ozkara, MD, Houston, TX (*Presenter*) Nothing to Disclose

### **PURPOSE**

The aim of this study was to assess the performance of AI-generated editorials in comparison to human-written editorials in the field of radiology, examining various dimensions including ease of comprehension, English proficiency, technical knowledge and expertise, persuasiveness and convincingness of arguments, and consistency of content.

### **METHODS AND MATERIALS**

16 human-written editorials were collected from eight radiology journals, including AJNR, Radiology, AJR, Academic Radiology, Journal of Neurointerventional Surgery, Stroke, JACR, and Clinical Neuroradiology, with two editorials authored by the same person from each journal. GPT-4.0 was used to generate corresponding AI-written editorials based on the topics provided. A total of 32 editorials were reviewed by five different reviewers, four of whom were editorial board members of AJNR, and one was an editor at The Neuroradiology Journal. The reviewers scored the texts using a 1-5 scale for the aforementioned dimensions. They were blinded to the origin of the texts, and the AI-generated and human-written editorials were presented in separate batches, ensuring that the counterparts were not assessed within the same batch. The Mann-Whitney U test was employed to compare the performance of the texts, and Fleiss's kappa was used to assess inter-rater reliability.

### **RESULTS**

The analysis revealed no statistically significant differences between AI-generated and human-written editorials in any of the assessed dimensions. In terms of ease of comprehension, English proficiency, technical knowledge and expertise, persuasiveness and convincingness of arguments, and consistency of content, AI-generated texts performed similarly to human-written texts. Fleiss's kappa results indicated low inter-rater agreement in scoring the editorials based on the provided scoring criteria. Reviewers' accuracies in identifying AI-generated vs. human-written texts were 14/32, 27/32, 25/32, 30/32, and 7/32, respectively.

### **CONCLUSION**

s AI-generated editorials, as exemplified by GPT-4.0, demonstrate comparable performance to human-written editorials. Reviewers had a hard time differentiating the texts highlighting the challenge faced by even expert reviewers in differentiating the editorials. These findings suggest that AI-generated texts may be on par with human-written texts in terms of the evaluated qualities.

### **CLINICAL RELEVANCE/APPLICATION**

The use of AI-generated content in radiology journals could potentially augment editorial writing, enhance the efficiency of content generation, and contribute to the growing body of literature in the field. Further research and development of AI systems may lead to improved capabilities and applications within the radiology community and beyond.

## **R5A-SPIN-6 Data Mining with Natural Language Processing on Radiology Chest X-Ray Reports**

Participants

Michael Welsh, BS, Philadelphia, PA (*Presenter*) Nothing to Disclose

### **PURPOSE**

Radiology reports are a rich source of diagnostic information. Structured reports particularly lend themselves to data mining and artificial intelligence (AI). However, even structured reporting templates demonstrate inconsistent formatting and large variability in terminology, which hinders large-scale text analysis. We developed an AI system, based on natural language processing (NLP) methods, that extracts the fields from reports and can be used to identify relevant features on an image, such as an endotracheal tube.

### **METHODS AND MATERIALS**

In this retrospective, IRB-approved study, 1492 pediatric chest radiographs with corresponding radiology reports were obtained at our institution from 2014 to 2019. Two pediatric radiologists labeled the 1492 images based on the presence/absence of metallic hardware, endotracheal tubes, tracheostomy tubes, and the number of lines and tubes, documented in the database software REDCap. Patient demographics were directly extracted from the DICOM header information. The labeled images were then used to train an AI system (train/valid/test splits of 60%/20%/20%), using NLP and supervised machine learning algorithms (scikit-learn v1.1.3) to automatically parse text data and predict the presence of hardware.

### **RESULTS**

The AI system was able to determine the presence of metallic hardware, tubes, and the number of lines and tubes using only a few sections of the report (notably the "history", "impression", and "finding" sections). The balanced accuracy of the system is more than 90% (type-I error of 5% and power of 80%) in most classification tasks by using the appropriate fields.

### **CONCLUSION**

s We utilized NLP to reliably and automatically label images for the presence of lines and tubes, using radiology reports. The proposed system can be adapted for other external devices and has significant utility for identifying objects on the image, with important implications for image quality and patient safety.

### **CLINICAL RELEVANCE/APPLICATION**

The proposed system uses radiology reports to identify labeled structures on clinical images. This reduces time-consuming annotation efforts for radiology research and accelerates AI development.

R5A-SP1R

### Interventional Radiology Thursday Poster Discussions I

#### Sub-Events

#### R5A-SP1R-1 Intra-arterial CT Perfusion is Feasible During Liver-directed Therapy Procedures

##### Participants

Rajesh P. Shah, MD, (*Presenter*) Research support, Merit Medical Systems, Inc; Consultant, Intuitive Surgical, Inc; Consultant, F. Hoffmann-La Roche Ltd; Research support, Lucence Health; Consultant, Histosonics, Inc; Consultant, Artio Medical, Inc

##### PURPOSE

To determine feasibility and baseline statistics of intra-arterial CT perfusion during Interventional Radiology (IR) liver-directed therapy procedures.

##### METHODS AND MATERIALS

This was a prospective observational study approved by the local institutional review board. Nine patients undergoing intra-arterial therapy (IAT) for hepatocellular carcinoma (HCC) without treatment in the prior year were enrolled. Subjects underwent injection of a 50% dilution of Iohexol 300 mgI/mL from either the celiac artery at 3 mL/sec for a total volume of 24 mL for conventional hepatic arterial anatomy, or from the superior mesenteric artery (SMA) for replaced anatomy at a rate of 5 mL/sec for a total volume of 40 mL to account for flow into mesenteric vessels. Perfusion scanning was performed continuously for 11 sec, then every 2 sec to a total scan time of 40 sec to capture arterial, portal venous, and washout phases at 100 kV and 60 mA. Radiation dose was recorded. A region of interest (ROI) was drawn on the common hepatic artery, portal vein, spleen (celiac injection) or small bowel (SMA injection), and non-tumor liver by a single Radiologist. Arterial blood flow (AF), portal venous blood flow (PVF), and perfusion index (PI) were calculated from an ROI drawn on a single index tumor 1.5 cm or larger in size without prior treatment. Descriptive statistics were calculated. The Wilcoxon Rank-Sum test was used to determine the significance of peripheral vs. central tumor and any prior treatment (more than 1 year prior) on perfusion values. Analysis of Variance was used to determine impact of tumor segment on perfusion values. A p-value < 0.05 was considered significant. A Pearson Correlation coefficient was calculated to determine impact of tumor size.

##### RESULTS

All 9 patients successfully underwent perfusion CT. Celiac artery injection occurred in 7 patients, while 2 patients had injection via SMA. Median (IQR) radiation dose was 525.3 (524.4-528.6) mGy·cm. Mean (Range) index tumor diameter was 2.46 (1.5-4.5) cm. Index tumors were distributed in segments 2, 5, 7, and 8 (2 subjects each) as well as segment 4 tumor in 1 subject. Three tumors were central while 6 were peripheral. Median (IQR) AF, PVF, and PI were 509.9 (389.6-524), 291.1 (71-859.4), 58.3 (41.9-87.6) mL/min/100 mL, respectively. Treatment more than 1 year prior, tumor segment, and peripheral location of tumor were not significant for perfusion values ( $p > 0.05$ ). Higher AF was strongly correlated with larger tumor ( $r = 0.6$ ).

##### CONCLUSION

s Intra-arterial perfusion CT is feasible during IAT for HCC. A wide range of AF and PVF is seen in HCC and these values can provide a baseline for evaluating dosing of IAT such as radioembolization.

##### CLINICAL RELEVANCE/APPLICATION

CT perfusion of HCC is feasible and may help better personalize IR treatments.

#### R5A-SP1R-2 A Surprising Effect of Metformin Plus Transarterial Chemoembolization on Hepatocellular Carcinoma Patients with Type II Diabetes

##### PURPOSE

Diabetes is common in the patients with hepatocellular carcinoma (HCC) and can lead to poor prognosis for these patients. Metformin is a hypoglycemic drug with anti-tumor effects. Whether metformin can have a positive effect on HCC patients receiving interventional embolization (transarterial chemoembolization, TACE) is still unclear. The study was conducted to explore the effect of metformin plus TACE on HCC patients with type II diabetes.

##### METHODS AND MATERIALS

From January 2014 to June 2021, 385 consecutive HCC patients with type II diabetes from three medical centers were retrospectively reviewed. All of them received TACE, and 216 patients received metformin. Propensity Score Matching (PSM) was used to reduce selective bias. Competing risk model was used to reduce the influence of deaths caused by other factors (not cancer) on the results.

##### RESULTS

The median overall survival (mOS) (35 months, 95%CI: 28-44 months vs 20 months, 95%CI: 16-24 months;  $P < 0.001$ ) and median progression-free survival (mPFS) (11 months, 95%CI: 10-14 months vs 8 months, 95%CI: 6-11 months;  $P < 0.001$ ) for patients with metformin were longer than those without metformin before PSM. Similar results were presented after PSM. The multivariate

regression analysis presented that metformin could reduce mortality risk of patients (HR: 0.56, 95%CI: 0.44-0.71;  $P < 0.001$ ) and tumor progression risk (HR: 0.67, 95%CI: 0.53-0.84;  $P < 0.001$ ) before PSM. The subgroup analysis showed that patients with BCLC stage A, BCLC stage B, BCLC stage C, Child-Pugh A and Child-Pugh B who received metformin could receive survival benefits from metformin. After excluding the influence of deaths caused by other factors (such as heart disease, diabetes, etc), metformin could still reduce mortality risk of patients and tumor progression risk. The adverse events evaluation was based on the NCI-CTCAE 5.0. The results showed metformin did not increase severe adverse events (grade III or grade IV).

## CONCLUSION

s Metformin might bring survival benefits for HCC patients with type II diabetes who received TACE. Metformin could achieve the effect of "killing two birds with one stone" for these patients.

## CLINICAL RELEVANCE/APPLICATION

Metformin has been proved to have anti-cancer effects in preliminary studies. However, there are few clinical studies on metformin against cancer. We included 385 patients from three medical centers to conduct the study to explore the effect of metformin on hepatocellular carcinoma patients with TACE. Our results presented metformin could prolong the survival of patients, which could provide new evidence for clinical decision for HCC patients with type II diabetes.

## R5A-SPiR-3 Relaxin Synergizes with Transarterial Chemoembolization in Immunity for Treating Rabbit VX2 Liver Cancer

### PURPOSE

To investigate the effect of relaxin on the TGF- $\beta$ /Smad2 pathway and immune cells in the tumor microenvironment, and the therapeutic effect of liver cancer after combined with transarterial chemoembolization (TACE).

### METHODS AND MATERIALS

HepG2 cells were adopted to evaluate the protein expression of TGF- $\beta$ , Smad2/pSmad2, and HIF-1 $\alpha$  after relaxin administration by western blotting and immunofluorescence staining. The expression of TGF- $\beta$  and HIF-1 $\alpha$  was also evaluated in the rabbit VX2 liver cancer model after treatment with relaxin combined with TACE (RLX+TACE), TACE, and normal saline, respectively. PD-L1 protein and immune cells of CD8+ T, Treg, and MDSCs were measured by immunohistochemical or immunofluorescent staining. A TGF- $\beta$  inhibitor (1D11) and dexamethasone were used to further clarify the role of immunity. The tumor-killing effect and survival time of rabbits were evaluated.

### RESULTS

Relaxin inhibited the TGF- $\beta$ /Smad2 pathway in vitro. Relaxin significantly suppressed the expression of TGF- $\beta$ , HIF-1 $\alpha$ , and PD-L1 in tumor tissues in the RLX+TACE group compared to TACE alone ( $p=0.011$ ,  $<0.001$ ,  $<0.001$ , respectively). The density of CD8+ T cells was significantly increased ( $p < 0.001$ ), while that of Treg cells and MDSCs were significantly decreased ( $p < 0.001$  and  $< 0.001$ , respectively) in the combination group. The management of 1D11 and dexamethasone improved and inhibited immune cells in tumor tissues, respectively. RLX+TACE treatment achieved a significantly higher tumor necrosis rate and prolonged rabbit survival time ( $p=0.004$  and  $<0.001$ , respectively).

### CONCLUSION

s RLX+TACE improved the therapeutic efficacy in liver cancer by mitigating the immunosuppressive tumor microenvironment.

### CLINICAL RELEVANCE/APPLICATION

This combination treatment provided a novel strategy for mitigating the tumor immunological microenvironment after TACE, and also effectively improving the treatment efficacy of TACE for clinical practice.

## R5A-SPiR-4 Management of Hepatocellular Carcinoma with Portal Vein Tumor Thrombus, Transcatheter Arterial Chemoembolization with Tyrosine Kinase Inhibitors, PD-1 Inhibitors, and Iodine-125 Seed Implantation

### PURPOSE

To retrospectively investigate the safety and efficacy of transcatheter arterial chemoembolization (TACE) with tyrosine kinase inhibitors (TKIs), PD-1 inhibitors, and iodine-125 seed implantation in the treatment of hepatocellular carcinoma (HCC) with portal vein tumor thrombus (PVTT).

### METHODS AND MATERIALS

A retrospective study was conducted on 62 HCC patients with PVTT from Jan 2018 and Aug 2021, who were classified into two groups. In group A, TACE with TKIs, PD-1 inhibitors, and iodine-125 seed implantation was performed, and in group B, TACE with TKIs, PD-1 inhibitors without iodine-125 seed implantation was performed. The blood count, biochemical indexes, coagulation function, complete response, partial response, stable disease, progressive disease, objective response rate, disease control rate were compared three, six and twelve months after the combination treatment. Overall survival and progression-free survival were compared in two groups.

### RESULTS

Overall survival, progression-free survival and disease control rate in group A were significantly greater than those in group B (median overall survival: 19.8 months vs 12.3 months,  $p=0.04$ , median progression-free survival: 11.57 months vs 5.13 months,  $p=0.01$ , disease control rate: 84.2% vs 58.3%,  $p=0.023$  at six months, and 50.0% vs 20.8%,  $p=0.022$  at twelve months). The univariable and multivariable analysis showed that the age, extrahepatic metastasis and treatment method were associated with the survival of those patients.

### CONCLUSION

s TACE with TKIs, ICI, and iodine-125 seed implantation seems to be safe, and effective in the treatment of HCC with PVTT. The age, extrahepatic metastasis and treatment method could be the prognostic factors.

### CLINICAL RELEVANCE/APPLICATION

First: Transcatheter arterial chemoembolization (TACE), TKIs, and PD-1 inhibitors, with iodine-125 seed implantation was found to be safe and effective as treatment for hepatocellular carcinoma with portal vein tumor thrombus. Second: TACE with TKIs, PD-1, and iodine-125 seed implantation showed association with a higher median overall survival, progression-free survival, and disease control rate than the treatment without iodine-125 seed implantation. Third: Age and extrahepatic metastasis showed association with poor prognosis and survival, but combining TACE, TKIs, and PD-1 inhibitors with iodine-125 seed implantation showed potential as a therapeutic regimen for patients with HCC and PVTT.

### **R5A-SPIR-5 Development of PLGA-loaded Ticagrelor Magnetic Microspheres: Towards Prevention of Post PCI Thrombosis**

#### **PURPOSE**

After percutaneous coronary intervention (PCI), dual antiplatelet therapy (DAPT) was required to prevent thrombosis. Systemic DAPT may increase the bleeding risk, especially in populations at high risk of bleeding. Moreover, patients who require non-cardiac surgery during DAPT, have to make decision between postpone surgery and discontinue medication. The aim of this study was to develop PLGA-Fe<sub>3</sub>O<sub>4</sub>-Ticagrelor microspheres (PFTm), which were local infused to aortic wall for local antiplatelet therapy.

#### **METHODS AND MATERIALS**

We designed and prepared PLGA loaded with ticagrelor magnetic microspheres by improved emulsified solvent evaporation method. For in vitro study, the morphology, relaxation rate, drug release rate, encapsulation efficiency, and biocompatibility of PFTm were evaluated. For animal experiment, twenty Japanese rabbits were divided into four groups, including local PFTm therapy group, systemic PFTm therapy group, non-therapy control group, and healthy control group. The last two groups shared one group of animals. The first three groups underwent balloon injury for the abdominal aorta. The first group received balloon PFTm infusion immediately after the injury, while the second group received intravenous PFTm. The other two groups did not receive treatment. MR T2WI was performed pre-operation and post-operation at day0, day2 and day3 to detect PFTm distribution. Then, the targeted aorta was harvest for pathological.

#### **RESULTS**

The characterization of PFTm showed that it was spherical. The size of the PFTm was  $930.5 \pm 134$  nm, with SPAN=0.35. The overall size of the PFTm was uniform. The drug encapsulation efficiency of the PFTm was  $82\% \pm 2\%$ , the release rate of ticagrelor from the microspheres reached 90% within 96 hours. The  $r_2$  of the PFTm was  $332.0 \text{ mm}^{-1} \text{ s}^{-1}$ . The PFTm were nontoxic for the cells by CCK-8. Twenty rabbits (3~4kg) were used. All rabbits were successfully established aorta injury model, in which the first two animals in the local PFTm therapy group were found intramural hematoma during PFTm infusion, resulting in animal death. The results of animal experiments showed that PFTm was infused into aortic wall with no thrombus detected in the local PFTm therapy group. The thrombosis area in the systemic PFTm therapy group was significantly smaller than that in the non-therapy control group ( $0.37 \pm 0.04 \text{ mm}^2$  vs  $0.58 \pm 0.03 \text{ mm}^2$ ,  $P < 0.0001$ ).

#### **CONCLUSION**

s PFTm was successfully developed, which can effectively inhibit thrombosis. This study provides a new concept of local infusion for prevention of thrombosis after PCI.

#### **CLINICAL RELEVANCE/APPLICATION**

The study validated new concept for local antiplatelet therapy after PCI, which may decrease systemic risk of bleeding and provide chance for non-cardiac surgery during anticoagulation therapy.

### **R5A-SPIR-6 Single vs Double Lumen Ports Placements: Infection and Complication Rates**

#### **PURPOSE**

Port-a-cath (subcutaneous port) placements are implanted intravascular ports that allow for easy venous access. With the rise in port placements performed by Interventional Radiologists (IR), it is important to determine whether there are differences in infection and complication rates between double and single lumen ports.

#### **METHODS AND MATERIALS**

We retrospectively analyzed 1582 port placements and removals during a 2-year period (April 2019-March 2021) at the University of Miami(UM) Health System. Patients were grouped by single and double lumen port subgroups and information on infection (bacteremia/port site infection), malfunctions (fibrin sheath, thrombosis, catheter malposition, extravasation), wound dehiscence, and hematoma rates were collected. Chi-square and Fisher t-test analyses were performed on the data in IBM SPSS 2022.

#### **RESULTS**

On average, patient age was 58.7 years, BMI 27 kg/m<sup>2</sup>, with 616 port placements in males (38.9%) and 966 in females (61.1%). We identified 684 single lumen (43.2%) and 898 double lumen port placements (56.8%). Double lumen ports sustained bacteremia at a significantly higher rate than single lumen ports (3.5% vs 1.2%,  $p = 0.005$ ), with the most common causes of bacteremia being *S. Aureus* (65%), *E. Faecalis* (16.1%), and *E. Coli* (12.9%). Moreover, double lumen ports experienced significantly higher rates of fibrin sheath (2.5% vs 0.4%,  $p = 0.002$ ), catheter tip malposition (1.3% vs 0%,  $p = 0.002$ ), and thrombosis (1.2% vs 0%,  $p = 0.007$ ) compared to single lumen ports. Furthermore, double lumen ports encountered more wound dehiscence ( $n = 8$  vs 2), port site infections ( $n = 12$  vs 5), extravasation ( $n = 4$  vs 1), and hematoma ( $n = 4$  vs 1) compared to single lumen ports, although these differences were not statistically significant.

#### **CONCLUSION**

s This study found significantly higher rates of infectious complications and malfunctions of double lumen ports compared to single lumen ports, suggesting that structural differences inherent to double lumen ports may be conducive to bacterial growth and catheter malfunction.

#### **CLINICAL RELEVANCE/APPLICATION**

These results indicate that oncologists and their IR colleagues may consider placing single lumen ports if clinically feasible, however future studies are still needed to determine clinical significance. Limitations of this study include retrospective nature and potential loss of patient follow-up.

## Abstract Archives of the RSNA, 2023

R5A-SPMK

### Musculoskeletal Imaging Thursday Poster Discussions I

#### Sub-Events

#### **R5A-SPMK-1 Dual Energy CT-derived Effective Atomic Number and Electron Density for Differentiation of Bone Tumors: Initial Experience**

##### Participants

Tomohito Hasegawa, Kagoshima, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

To determine whether dual-energy CT parameters including electron density (ED) and effective atomic number (Zeff) could be quantitative imaging markers for differentiating benign from malignant bone tumors.

##### METHODS AND MATERIALS

Fifty-eight patients (34 males and 24 females, age range from 9 to 86 years) with histopathologically proven osteolytic bone tumor who underwent spectral detector CT scan were included in this retrospective study. Images of the conventional CT value (CTconv, HU), electron density relative to water (ED, %), and Zeff (AU) were obtained. Regions-of-interest were manually placed on the largest cross-section of tumor avoiding calcification to obtain the mean parametric values. Histopathologically, the tumors were divided into two groups: benign and intermediate malignant tumor (n=14), malignant tumor (n=44). Mann-Whitney U test was used to compare the DECT parameters between two groups. ROC curve analysis was used to assess the discriminative abilities of the DECT parameters.

##### RESULTS

The mean Zeff of benign and intermediate malignant tumors was significantly higher than that of malignant tumors ( $7.47\pm 0.11$  vs  $7.38\pm 0.12$ ,  $p=0.011$ ), whereas the mean CTconv and ED showed no significant difference between the two groups ( $44.28\pm 7.00$  vs  $41.89\pm 11.92$ ,  $p=0.490$  and  $103.54\%\pm 0.66$  vs  $103.60\%\pm 0.92$ ,  $p=0.637$ ). The AUC for Zeff was 0.727, with a sensitivity of 72.73%, specificity of 64.29% and accuracy of 70.69% (cut off,  $< 7.44$ ).

##### CONCLUSION

The mean Zeff may be helpful in differentiating benign and intermediate malignant bone tumors from malignant tumors. Their difference in Zeff may reflect differences in elemental composition which are inaccessible with conventional CT.

##### CLINICAL RELEVANCE/APPLICATION

The mean Zeff may be helpful in differentiating benign and intermediate malignant bone tumors from malignant tumors.

#### **R5A-SPMK-2 A New Approach to Detect Rib Metastases Using Deep Learning with Hounsfield Unit-augmentation**

##### PURPOSE

With the recent developments of cancer treatments, the number of patients with bone metastases is increasing. CT can well define cortical destruction in bone metastases due to its high spatial resolution. However, detection of bone metastases on CT is challenging for radiologist because of the three types of metastases (osteoblastic, osteolytic, and mixed) to evaluate. Hounsfield Unit (HU)-augmentation, using multiple HU windows in the HU normalization is available for deep learning (DL) algorithm. Thus, HU-augmentation using the appropriate CT values for the three types of bone metastases has the potential to improve detection accuracy. This study aimed to investigate whether the accuracy of the DL algorithm for detecting rib metastases on CT can be improved by HU-augmentation method.

##### METHODS AND MATERIALS

All images of bone metastases were obtained retrospectively from the clinical databases of a single institution between April 2011 and September 2019. Delayed phase axial images of contrast-enhanced CT with soft tissue kernel reconstruction were used. Both training and validation datasets, ground truth labels were established using bounding boxes by two radiologists. After manually extracting thoracic region from the torso CT, faster region-based convolutional neural network is utilized for rib metastasis detection. HU augmentation was performed with three HU windows; osteoblastic (WW 700 HU/WL 450 HU), osteolytic (WW 900 HU/WL 200 HU), and mixed (WW 1300 HU/WL 80 HU), in both training and testing phase. Training and evaluation of DL were performed by 5-fold cross validation. The mean Average Precision (mAP), F-measure, precision, and recall were calculated and compared with and without HU-augmentation.

##### RESULTS

A total of 4218 positive slice images in 159 patients with rib metastases (mean age,  $62\pm 11$  years; 78 male) were used for model development and test. Primary lesion of 159 patients were following; 47 were breast, 46 were lungs, 17 were prostate, and 49 were other origins. The mAP and F-measure with HU-augmentation were 0.609 and 0.591, compared with 0.553 and 0.571 without HU-augmentation. The precision and recall with HU-augmentation were 0.741 and 0.492, compared with 0.667 and 0.503 without HU-augmentation.

## CONCLUSION

s HU-augmentation improved DL algorithm to detect rib metastases on CT.

## CLINICAL RELEVANCE/APPLICATION

This study reveals that HU-augmentation using the appropriate CT values for the three types of bone metastases (osteoblastic, osteolytic, and mixed) improves the detection accuracy of rib metastases.

## R5A-SPMK-3 Retrospective Validation of the Birmingham Atypical Cartilage Tumor Imaging Protocol (BACTIP) in a Single US Tertiary Care Center

Participants

Sonja Oppen, DO, Pittsburgh, PA (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study is to retrospectively validate the Birmingham Atypical Cartilage Tumor Imaging Protocol (BACTIP) in a US tertiary care center. This study will provide the necessary groundwork for prospective validation in real-time patients.

## METHODS AND MATERIALS

Institutional review board approval was obtained. A keyword search within our institutional PACS for the words chondroid, enchondroma and chondrosarcoma in the text of MRI reports from 2014 - 2022. Lesions in the proximal humerus, distal femur, and proximal tibia of adults were included in the study. Lesions were categorized into 1 of 7 BACTIP categories based on size and presence/absence of endosteal scalloping. Rate of malignancy for each BACTIP category was calculated and based on follow up protocol, evaluation of delayed diagnosis was recorded.

## RESULTS

The PACS keyword search resulted in 305 patients that met inclusion criteria. Preliminary results are below: Of these 305 MRI exams, 75% had no additional MRI exams and clinically presumed benign enchondromas. The remaining 25% of patients had 1 or more follow up MRI exam(s). The length of time between MRI exams varied widely from 2 months to 8 years. BACTIP Type IA (47% of lesions, 2% biopsy rate), IB (20%, 3%), IC (10%, 18%), IIA (6%, 0%), IIB (4%, 28%), IIC (11%, 32%), and III (2%, 100%), respectively. Biopsy rate increased with BACTIP category. Type IA and IB lesions had a malignancy rate of 0%. Malignancy rate for type IC was 33%, and 50% for IIB. Type IIC lesions had a 50% malignancy rate. Type III has a biopsy rate of 100% and malignancy rate of 75%. Malignancy rate increased with BACTIP category.

## CONCLUSION

s Retrospective validation of the BACTIP in a single US tertiary care center showed similar results to those reported by Davies et al in 2019. There were no cases where the application of BACTIP would have led to a delayed diagnosis. The BACTIP would serve as a conservative and appropriate imaging follow-up guideline for patients with central cartilage tumors around the shoulder and knee joint.

## CLINICAL RELEVANCE/APPLICATION

Central cartilage tumors are common incidental lesions around knee and shoulder joints. Differentiation of low grade chondroid lesions, such as enchondroma from low grade chondrosarcoma, is often difficult even on MRI given pathologic and radiologic similarities. The BACTIP was introduced in UK literature in 2019 and provides a guide to initial assessment, diagnosis, and imaging follow-up plan for incidental indeterminate central cartilage tumors (Fig 1). This imaging protocol was retrospectively validated in an article published by Davies et al in 2019. However, this protocol has not been widely accepted and has not been validated in the US population.

## R5A-SPMK-4 Iodine Quantification in Bone Marrow Using Photon-counting Detector CT: A Phantom Study

## PURPOSE

Detecting intertrabecular bone metastases, which replace bone marrow without destroying the bony structures, is a challenging task to diagnose on CT. Photon-counting detector CT (PCD-CT) enables a simultaneous multi-energy acquisition that offers further qualitative and quantitative information in a single scan. This study aimed to investigate the accuracy of iodine quantification using a PCD-CT and to assess the feasibility of measuring iodine concentrations in the tissue that has penetrated into the bone.

## METHODS AND MATERIALS

A bone marrow phantom was constructed using cellulated calcium sulfate plaster that was impregnated with iodinated contrast medium at various concentrations (0, 0.75, 1.5, 3, 6, 12, 24, 48, and 96 mgI/mL). Images were acquired using a PCD-CT scanner (NAEOTOM Alfa, SIEMENS, Germany) with a detector size of 0.2 mm and a tube voltage of 120 kVp. The acquired images were reconstructed with a 1-mm thickness using a Qr40 kernel. The CT numbers and calculated iodine quantification values were measured by placing circular regions-of-interest (ROIs, approximately 10 cm<sup>2</sup>) on the iodine maps and quantification maps, respectively, at the top, middle, and bottom of each phantom. Statistical analysis was performed using a two-way ANOVA. P-values less than 0.05 considered as statistically significant.

## RESULTS

The CT values (mean ± SD) for each ROI on the iodine maps of the phantom were as follows: 553 ± 24, 532 ± 20, 504 ± 24, 587 ± 23, 554 ± 14, 708 ± 20, 738 ± 4.4, 1130 ± 17, and 1450 ± 200 H.U. at iodine concentrations of 0, 0.75, 1.5, 3, 6, 12, 24, 48, and 96 mgI/mL, respectively. The quantified iodine values for the phantom were 16.4±0.90, 16.2±1.1, 16.3±0.82, 17.1±0.57, 19.3±0.49, 22.3±0.54, 26.5±0.047, 36.6±0.12, and 49.9±3.6mg/mL, respectively. There were significant differences in either CT values on the iodine maps or quantified iodine values between phantoms with iodine concentrations greater than or equal to 6 mg/mL (P < 0.05). However, there were no differences between phantoms with other iodine concentrations.

## CONCLUSION

s There was a correlation between iodine concentrations and both the CT values on the iodine map and the iodine quantification values in higher iodine solutions, but no clear difference was observed in lower iodine solutions when compared to the iodine quantification values in the water-impregnated bone phantom. The iodine value was overestimated in the phantom without iodine,

and appropriate correction would be necessary when applied to clinical cases.

#### **CLINICAL RELEVANCE/APPLICATION**

PCD-CT has the potential to detect intertrabecular bone metastases that may not be visible on conventional CT scans and evaluate their vascularity.

#### **R5A-SPMK-5 Is Semi-automatic Segmentation with Quantitative Analysis of Whole-body DWI-MRI Images a Feasible Parameter for Assessing Treatment Response in Multiple Myeloma Patients?**

Participants

Miguel Barrio Piqueras I, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To study the feasibility of quantitative whole-body diffusion-weighted MRI (DWI) analysis using a semi-automatic segmentation technique for the assessment of treatment response in patients with multiple myeloma.

#### **METHODS AND MATERIALS**

34 patients with multiple myeloma underwent whole-body MRI at our center. Images were acquired and reported according to MY-RADs (Myeloma Response Assessment and Diagnosis System) guidelines. Patients were classified as responders or non-responders according to their MRI- Response Assessment Category (RAC) and the response category given following the International Myeloma Working Group (IMWG) criteria, considering the latter one as the gold standard. Quantitative analysis of DWI images of each MRI was performed after semi-automated segmentation. Data analysis was performed with SPSS 25.0 software (Chi-square and Student's t-tests). Two-tailed p-values were used for all statistical evaluations and a p-value < 0.05 was considered statistically significant.

#### **RESULTS**

13 patients (38.2%) did not respond to treatment according to IMWG response criteria. They showed no statistically significant differences in total diffusion volume (tDV: 240.82 cm<sup>3</sup> vs. 196.08 cm<sup>3</sup>; p = 0.507) or mean global apparent diffusion coefficient (gADC: 694.92 x 10<sup>-6</sup> mm<sup>2</sup>/s vs. 779.4 x 10<sup>-6</sup> mm<sup>2</sup>/s; p = 0.123) in quantitative analysis of DWI before and after treatment, respectively. Among the remaining 21 responding patients (61.8%), tDV significantly decreased (214.93 cm<sup>3</sup> vs 111.41 cm<sup>3</sup>; p = 0.01) and gADC significantly increased (738.82 x 10<sup>-6</sup> mm<sup>2</sup>/s vs 1126.29 x 10<sup>-6</sup> mm<sup>2</sup>/s; p = 0.002) after treatment. Furthermore, the percentage of high ADC values (=1400 x 10<sup>-6</sup> mm<sup>2</sup>/s) of tDV was higher in responder patients after treatment (36.57 %) than in non-responders (7.8 %), with significant differences (p < 0.001).

#### **CONCLUSION**

s Total diffusion volume (tDV) and global apparent diffusion coefficient (gADC) may be feasible parameters for assessing treatment response in patients with multiple myeloma.

#### **CLINICAL RELEVANCE/APPLICATION**

The utilization of novel imaging techniques for the follow-up and monitoring of multiple myeloma treatment represents a rapidly expanding field, which has the potential to provide dependable data and enhance the precision of radiological reports.

#### **R5A-SPMK-6 Measurement of Tumor Total Diffusion Volume (tDV) of Metastatic Bone Lesions from Prostate Cancer Using Whole-Body MRI(WB-MRI)-Evaluation for Therapeutic Effect**

#### **PURPOSE**

To measure the total diffusion tumor volume (tDV) of metastatic bone lesions from prostate cancer using whole body MRI(WB-MRI) including whole body diffusion weighted images (DWI) and to research the correlation for serum PSA level and to assess the reliability and reproducibility of our diagnostic methods.

#### **METHODS AND MATERIALS**

Nine cases of prostate cancer during various treatment in which WB-MRI was performed twice were retrospectively evaluated. In all patients, serum PSA was measured at the same time of MRI examinations. 3.0T MR scanners were used (Siemens Prisma). The pulse sequences were 1. axial direction of DWI of the level from lower neck and bottom of pelvis. 2. Sagittal direction of T1WI and STIR of total spine 3. Coronal direction of in phase and out of phase of T1WI. In all cases, two radiologists measured tDVs using BD-score (PixSpace. Inc.) which had been developed for calculating ADC value of the lesions and their volume correspond to the tumor automatically by defining the threshold of ADC value. In this study, the threshold was defined as 1.8mm<sup>2</sup>/S. We calculated tDV variation (?tDV) and serum PSA variation (?PSA) before and after therapy in each patient, and examined the relation of ?tDV and ?PSA with Spearman's rank correlation coefficient (rs). Also, the bias between the data of the data of two radiologists was assessed calculating the cross-correlation coefficient.

#### **RESULTS**

In the data of both radiologists, ?tDV and ?PSA were positive correlated strongly by Spearman's rank correlation coefficient (radiologists 1 r=0.99, p=0.000002, radiologist 2 r=0.88, p=0.002). The cross-correlation coefficient of two radiologists was 0.98 (p=0.000002).

#### **CONCLUSION**

s tDV was proved to be a reliable mark for evaluating the grade of bone metastases from prostate cancer. Using BD score for calculating tDV showed less dispersion between the readers.

#### **CLINICAL RELEVANCE/APPLICATION**

Calculating the disease volume rapidly from WBMRI returns to earth.

## **R5A-SPMK-7 Dynamic Contrast Enhanced MRI Assessment of the Chemotherapy Response of Osteosarcoma: A Machine Learning Data Analysis**

### **PURPOSE**

Accurately assessing the response to preoperative chemotherapy of osteosarcoma(OS) is vital in determining the most effective treatment plan and predicting outcomes. The study aims to perform machine learning data analysis to assess the response of OS to preoperative chemotherapy.

### **METHODS AND MATERIALS**

We recruited 20 patients (M/F=15/ 5, ages 9 to 41 years old, average 20 years) with histologically confirmed conventional OS within 2 years. After waivers of Informed Consent, MR imaging examinations were conducted after chemotherapy and before surgery. The 3D dynamic contrast enhancement (DCE) MR imaging features included: 1) for tumor permeability (Ktrans, Kep, Ve, Vp, area under the curve (AUC), and area of tumor region of interest (ROI) and 2)for tumor perfusion (relative enhancement, maximum enhancement, maximum relative enhancement, T0, time to peak, wash-in rate, wash-out rate, brevity of enhancement, AUC, and area of tumor ROI).We used machine learning data analysis techniques in Python programming language, involving clustering analysis, feature importance analysis, regression modeling (correlation heatmap), and classification modeling (decision tree plot). Precision, recall (sensitivity), F1 score, and accuracy were automatically calculated to predict the grade of tumor necrosis, lung metastasis, soft tissue/bone metastasis, and tumor recurrence.

### **RESULTS**

The feature importance analysis revealed that age, area, Ktrans, auc, Rel Enhancement, Max Enhancement, Wash Out Rate, mean ADC were the top features. Correlation heatmaps showed age was highly correlated with necrosis (rate) (coefficient 0.81), auc showed a strong correlation with Max Enhancement, Max Rel Enhancement, and Rel Enhancement (coefficient 0.89, 0.86, 0.81, respectively).Our results demonstrated high precision, recall (sensitivity), F1 score, and accuracy for predicting grading necrosis (0.80-1.00, 0.67-1.00, 0.73-1.00, and 0.91-1.00, respectively), lung metastasis (0.89-1.00, 0.89-1.00, 0.89-1.00, and 0.94-1.00, respectively), soft tissue/bone metastasis (0.90-1.00, 0.90-1.00, 0.90-1.00, and 0.94-1.00, respectively), and tumor recurrence (0.82-1.00, 0.90-1.00, 0.83-1.00, and 0.91-1.00, respectively).

### **CONCLUSION**

s Our preliminary results demonstrate the feasibility of our imaging technique combined with machine learning data analysis for advanced radiomics analysis, MR imaging assessment of chemotherapy response, histopathological correlation, and prediction of patient outcomes

### **CLINICAL RELEVANCE/APPLICATION**

The study shows that the imaging technique combined with machine learning data analysis is feasible in advanced radiomics analysis, establishing an imaging model for MR imaging assessment of chemotherapy response.

## **R5A-SPMK-8 Diagnostic Performance of Magnetic Resonance Imaging for Detecting Meniscal Ramp Lesions in Patients with Anterior Cruciate Ligament Tears. A Meta-analysis**

### **PURPOSE**

The clinical importance of meniscal ramp lesions in patients with anterior cruciate ligament (ACL) tear has emerged as a major issue. However, the diagnostic accuracy of magnetic resonance imaging (MRI) for detecting ramp lesions has a wide range. This meta-analysis was aim to meta-analyze the diagnostic performance of MRI for diagnosing ramp lesion in patients with ACL tear

### **METHODS AND MATERIALS**

Literature search of PubMed, EMBASE, and the Cochrane Library was performed based on the Preferred Reporting Items for Systematic Reviews and Meta-analyses guidelines. Diagnostic performance studies using MRI as the index test and arthroscopy as the reference standard for ramp lesion were included. Bivariate and hierarchical summary receiver operating characteristic modeling was used to evaluate the diagnostic performance. We performed meta-regression analyses for potential sources of heterogeneity.

### **RESULTS**

Nine studies from eight articles (883 patients with ACL tear) were included. The summary sensitivity, summary specificity, and area under the hierarchical summary receiver operating characteristic (AUC) for ramp lesion were 0.71 (95% confidence interval [CI], 0.59-0.81) and 0.94 (95% CI, 0.88-0.97), and 0.90 (95% CI, 0.87-0.92), respectively. Among the potential covariates, magnet strength ( $P<0.01$ ), patients' knee position ( $P=0.04$ ), and MRI interpreter ( $P=0.04$ ) were associated with heterogeneity in terms of sensitivity, whereas, magnet strength ( $P=0.03$ ) was associated with heterogeneity in terms of specificity.

### **CONCLUSION**

s MRI demonstrated moderate sensitivity and excellent specificity for diagnosing ramp lesion. For increase sensitivity, use of 3T MRI with the patients' knee in the neutral position (about 30° flexion), and the involvement of musculoskeletal radiologist for MRI interpretation may be needed.

### **CLINICAL RELEVANCE/APPLICATION**

We recommend routine arthroscopic assessment for the presence of ramp lesion, although it was not suspected on MRI.

## Abstract Archives of the RSNA, 2023

R5A-SPMS

### Multisystem Thursday Poster Discussions I

#### Sub-Events

#### R5A-SPMS-1 Functional and Structural Brain Alterations in Patients Recovered from COVID-19 with Anosmia

Participants

Francisco Zamorano, Santiago, Chile (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate functional and morphological brain alterations in recovered COVID-19 patients.

#### METHODS AND MATERIALS

72 recovered COVID-19 patients (33 females, mean age 42, range [18-66]; 38 with anosmia during infection; 29 hospitalized because of respiratory symptoms) were asked to resolve a Reversal Learning Task (RLT) while their brain activity was measured with fMRI. Images were acquired with a 3T Siemens Skyra scanner. Neuropsychological alterations were assessed with Addenbrooke II and INECO tests. In the RLT, the participants had to choose between two options that were presented with different probabilities of obtaining reinforcement (0.8 vs 0.2 and 0.7 vs 0.3). Through trial and error, participants were able to learn the most advantageous option. After a certain number of repetitions, the probabilities associated with each option could be reversed, and the subject had to learn the new association. Behavior was modeled using a Rescorla-Wagner learning algorithm and Cumulative Prospect Theory. This model uses a learning rate that updates the subjective probability of being rewarded and a multiplicative approach to calculate the expected utility of each option. Brain activity associated with the decision-making period was analyzed with FSL in regard to the expected utility, controlled by reaction time as a proxy of difficulty. Cortical thickness was analyzed with Freesurfer using HCP pipeline and SurfStat from Matlab.

#### RESULTS

There was a decrease of activity in several prefrontal and subcortical regions in those patients that had anosmia, regardless of the severity of respiratory symptoms. There was cortical thinning in the left superior frontal gyrus in those patients that had anosmia, regardless of the severity of respiratory symptoms. This indicates that recovered COVID-19 patients that presented anosmia during the infection have functional and structural brain alterations.

#### CONCLUSION

Our results suggest that anosmia can be used as a marker of brain alterations in patients recovered from COVID-19. It could be important to follow the track of these patients in order to investigate possible long term consequences of COVID-19 on the nervous system.

#### CLINICAL RELEVANCE/APPLICATION

While COVID-19 primarily affects the respiratory system, the brain can also be involved. Increasing evidence indicates that recovered patients present neuropsychiatric alterations and thinning of certain cerebral cortex areas, especially those connected to the primary olfactory cortex. Given this background it is highly relevant to evaluate the possibility of alterations at the brain level in recovered COVID-19 patients, which, as we find, seem to extend to other regions.

R5A-SPNMMI

### Nuclear Medicine & Molecular Imaging Thursday Poster Discussions I

#### Sub-Events

**R5A-SPNMMI-1** **First Application of Novel Human Granzyme B Imaging Agent in a Humanized Melanoma Mouse Model Treated with Immune Checkpoint Inhibitor Therapy**

#### PURPOSE

We have previously shown that granzyme B (GZB) PET imaging can determine treatment response in cancer immunotherapy. This study evaluates whether a novel human granzyme B imaging agent CYT-200 (Cytosite) labeled with 68Ga can be used as a reliable, non-invasive biomarker of intra-tumoral GZB levels and efficacy immune checkpoint inhibitor therapy in vivo.

#### METHODS AND MATERIALS

All animal studies were approved and conducted according to the IACUC guidelines. Naïve NSG mice received human untransduced T cells intravenously for immune reconstitution 14 days prior to subcutaneous implantation of human melanoma cells (G361) into the left shoulders. Mice received three intraperitoneal doses of pembrolizumab (200 µg) and anti-CTLA-4 (100 µg) combined, administered in three days intervals, starting from when the tumors reached 336±38 mm<sup>3</sup>. PET imaging was performed prior to treatment initiation (baseline), such as on days 4, 7, and 14 after the first treatment dose. Tumor-bearing mice were injected with 4.6±0.30 MBq of CYT-200 labeled with 68Ga 60±5 min prior to PET image acquisition. Intra-tumoral T-cell activity was measured by tumor-to-blood ratio (TBR), calculated by the standard uptake values (SUVs) of the tumors normalized against the heart blood pool. Treatment response was assessed by tumor growth measurements over 30 days after tumor implantation.

#### RESULTS

PET imaging on day 4 after treatment initiation showed the highest TBR compared to the baseline (3.08±0.98 vs. 1.22±0.48) with a gradual decrease of the TBRs on day 7 (2.76±1.85) and 14 (1.91±0.23). A combination of pembrolizumab and anti-CTLA-4 therapy decreased tumor size on days 4 and 7 after treatment initiation (336±38 mm<sup>3</sup> vs. 154±31 mm<sup>3</sup> and 131±129 mm<sup>3</sup>, respectively). However, tumor growth resumed 12 days after treatment initiation (181±112 mm<sup>3</sup>), correlating with the reduced T-cell activity shown by declining CYT-200 PET uptake values.

#### CONCLUSION

These preliminary results demonstrate that the novel human granzyme B PET imaging agent CYT-200 labeled with 68Ga can detect intra-tumoral T-cell activity associated with tumor-killing following immune checkpoint inhibitor therapy in a humanized mouse model for melanoma.

#### CLINICAL RELEVANCE/APPLICATION

Granzyme B PET imaging is a tool for monitoring response to immunotherapy in melanoma patients, which could lead to more effective treatment decisions and improved patient outcomes.

**R5A-SPNMMI-2** **Incidental Detection of Focal F-18 FDG Uptake in the Prostate of Oncologic Patients with Application of Logistic Classification**

#### PURPOSE

Although prostate cancer has been refocused in the field of nuclear medicine with the advent of FDA-approved PSMA-targeted PET imaging radiopharmaceuticals, however, F-18 FDG still remains the most used drug in oncologic PET imaging. This retrospective study was to assess the incidentally observed focal prostate F-18 FDG uptake in non-prostate cancer patients, and to apply Logistic classification to improve the diagnostic accuracy.

#### METHODS AND MATERIALS

The reports of F-18 FDG PET/CT performed in non-prostate male cancer patients at our hospital were retrospectively reviewed to identify unexpectedly observed suspicious focal prostate uptake. Among them, those with final histopathological reports of the corresponding FDG uptake sites were included in this study. The focal uptakes were classified as malignant or benign according to the histopathological reports. SUV parameters such as SUV<sub>max</sub>, SUV<sub>peak</sub>, MTV of each focal uptake was measured, and compared between malignant and benign lesions. Logistic classification was applied to the SUV parameters using R software to improve the diagnostic accuracy. Statistical significance was set at  $p < 0.05$ .

#### RESULTS

About half of the focal uptakes were malignant. Among the calculated FDG parameters, maximum SUV differentiated malignant from benign lesions with the best accuracy. Application of Logistic classification didn't improve the diagnostic accuracy.

#### CONCLUSION

About half of the incidental focal prostate F-18 FDG uptake was proved to be malignant. This finding could justify the application of PET imaging to cancer patients and subjects at high risk of developing cancer. A further study with a larger number of subjects and more dedicated machine Learning algorithms might be warranted.

#### **CLINICAL RELEVANCE/APPLICATION**

Authors investigated the clinical significance of incidental prostate FDG uptake and the usefulness of application of machine Learning algorithm such as Logistic classification in the diagnostic accuracy.

R5A-SPNPM

### Noninterpretive Skills (Beyond Imaging) Thursday Poster Discussions I

#### Sub-Events

#### R5A-SPNPM-Sterile Gown and Drape, and Bouffant Cap for Thyroid FNA: Preventing Infections or Producing Unnecessary Medical Waste<sup>1</sup>

##### PURPOSE

Ultrasound-guided fine needle aspiration is a very low-risk procedure. Despite this, there remains great variability with extensive protective equipment use. Given the inherent monetary and environmental costs of protective equipment, this study aims to assess the difference in infection rate when conducted with full versus limited (without bouffant/cap, sterile gown, and full body sterile drape) protective equipment use.

##### METHODS AND MATERIALS

A total of 310 consecutive patients were retrospectively reviewed for thyroid fine needle aspirations at the main hospital and outpatient clinic site from December 1, 2020 to May 15, 2022. The hospital site operated with full protective equipment (bouffant, sterile gown, sterile gloves, and full body sterile drape), and the outpatient site operated with limited (sterile gloves, limited sterile paper drape) protective equipment. Two patients were excluded as no procedure was performed. Review for signs of infection within 30 days of procedure was performed using medical records blindly to the degree of protective equipment utilization. Descriptive statistics and confidence intervals were provided to compare the two groups.

##### RESULTS

No infections were identified in either group, with 0/230 (0%, 95CI% 0 - 2%) in the full protective equipment group vs. 0/78 (0%, 95CI% 0 - 6%) in the limited protective equipment group. There was no statistically significant difference in infection rate between full and limited protective equipment use in thyroid fine needle aspiration (FNA) in the included 308 procedures with 95% confidence interval of -6% - 2%. Two patients out of 230 (0.9%) in the full protective equipment group developed mild allergic reaction to topical antiseptic. The 78 procedures with limited protective equipment represents a saving of at least 70,590 grams of carbon dioxide equivalents compared to full protective equipment procedures.

##### CONCLUSION

Decreasing the extent of protective equipment does not impact the infection rate for thyroid FNA. Given the inherent costs involved in the procurement and waste of protective equipment, reducing protective equipment use is warranted to reduce both the monetary and environmental impacts of waste.

##### CLINICAL RELEVANCE/APPLICATION

Using limited protective equipment (sterile gloves and limited drape) for thyroid FNA does not increase infection rate as compared to full protective set, while saving significant grams of carbon dioxide equivalents.

#### R5A-SPNPM-Dual Energy CT: Less is More<sup>2</sup>

Participants

Caterina Di Manna, MD, Rome, Italy (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the reduction of iodinated contrast agent and radiation dose using Dual Source Dual Energy CT, maintaining the same image quality.

##### METHODS AND MATERIALS

This single-center randomized prospective study enrolled 121 oncologic patients who underwent the first CT exam acquired with a single energy (SE) 128-slice CT (LightSpeed VCT) and the subsequent using a Dual Source Dual Energy CT (Somatom Force) (DSDECT). In the first exam, was administered a dose of contrast agent (CA) (Iomeron 350) of 0.7mg of iodine per kg of lean body mass (LBM). In the second exam with DSDECT the dose of CA was reduced to 0.5mg of iodine per kg of LBM. The mean value of CA administered to patients were compared between the two exams. The difference in radiation dose between the two exams was considered as secondary outcome. Quantitative image analysis was performed considering enhancement of porta, liver parenchima and aorta, and noise metrics. Image quality was evaluated considering visual perception of enhancement, noise, and artifacts based on a 5-point Likert scale.

##### RESULTS

The mean CA dose administered to patients in the first exam (SE) was 105.4ml ( $\pm 13.19$ ), with a mean iodine dose of 36.91g ( $\pm 4.62$ ); in the second control (DE), an average of 81.23ml of CA ( $\pm 14.68$ ) was administered, with an average iodine dose of 28.53g ( $\pm 5.20$ ). Qualitative analysis demonstrated comparable image quality in scans with DECT. Our study also demonstrated a reduction in the average radiation dose delivered to the patient by 36% using DECT.

##### CONCLUSION

s Our study confirms the advantages of DSDECT in the follow-up of oncologic patients. Using DSDECT it is possible to reduce the amount of iodinated CA by 30% and radiation dose by 36% maintaining the same image quality.

#### **CLINICAL RELEVANCE/APPLICATION**

Dual Energy CT is a promising technique to evaluate oncologic patients using a reduced amount of contrast media and radiation dose. These advantages are crucial in patients which, due to their pathology, frequently undergo a follow-up CT scans.

## Abstract Archives of the RSNA, 2023

R5A-SPNR

### Neuroradiology Thursday Poster Discussions I

#### Sub-Events

#### **R5A-SPNR-1 Prediction of Future Dementia for MCI Patients from Neuroimaging and Other Multimodal Data Using a Novel Machine Learning Framework**

##### **PURPOSE**

Prediction of future dementia for patients with mild cognitive impairment (MCI) is a significant clinical goal, so that the identified cases can benefit from available treatments. Currently, the clinical standard for diagnosing dementia utilizes neuroradiological findings from multimodal imaging modalities such as MRI and PET scans, as well as cognitive tests and biomarkers like tau and amyloid uptake levels in cerebrospinal fluid. However, efficiently and objectively analyzing these complex and disparate data can be difficult in clinical settings, contributing to high rates of underdiagnosis or misdiagnosis of dementia at early stages. Machine learning (ML) offers a potentially more efficient and objective methodology to predict future dementia for MCI patients from these multimodal data.

##### **METHODS AND MATERIALS**

We recently developed Ensemble Integration (EI), an ML framework designed to advance predictive modeling from multimodal data by leveraging complementarity among the data modalities (Li et al, Bioinformatics Advances, 2022). In this work, we assessed EI's ability to predict the future development of dementia among MCI patients using processed T1-weighted MRI imaging and other multimodal data from The Alzheimer's Disease Prediction of Longitudinal Evolution (TADPOLE) challenge (Marinescu et al, Predictive Intelligence in Medicine, 2019). Specifically, we developed an EI-based predictive model of dementia from data of 672 MCI patients collected at their first visit (baseline), and rigorously evaluated this model and benchmark methods from two separate test sets.

##### **RESULTS**

For predicting the future development of dementia among MCI patients, the EI-based model performed better on the two test sets (AUROC=0.77/0.78, sensitivity=0.71/0.75, specificity=0.74/0.75) than commonly used XGBoost (AUROC=0.66/0.67, sensitivity=0.59/0.63, specificity=0.73/0.71) and deep learning (AUROC=0.63/0.64, sensitivity=0.78/0.62, specificity=0.41/0.55) approaches. Among the most predictive features in this EI model were MRI-derived measurements of the white matter volume of the thalamus, a region associated with dementia (Aggleton et al, Brain, 2016; Ryan et al, Brain, 2013).

##### **CONCLUSION**

EI is an effective framework for predicting if an MCI patient will develop dementia in the future from neuroimaging and other multimodal data collected at baseline. EI identified several neuroimaging features associated with progression to dementia that may have gone unidentified using traditional statistical methods.

##### **CLINICAL RELEVANCE/APPLICATION**

By integrating neuroimaging and other multimodal data using an effective method like Ensemble Integration, it is possible to accurately predict the development of future dementia among MCI patients.

#### **R5A-SPNR-11 Performance of Dual-Layer Spectral Detector CT in Identifying Early Ischemic Changes in Acute Ischemic Stroke Patients**

##### **PURPOSE**

This study aims to evaluate the efficacy of spectral imaging using computed tomography (CT) equipped with a dual-layer detector for diagnosing acute ischemic stroke.

##### **METHODS AND MATERIALS**

We retrospectively analyzed CT spectral images of 26 regions in 15 patients diagnosed with acute ischemic stroke. We performed non-contrast brain CT using dual-layer detector CT non-contrast brain MRI on the same day. We compared the conventional CT values, relative electron density (ED), effective atomic number (Zeff) of the ischemic stroke region the contralateral normal region. We used the Mann-Whitney U test to compare each imaging parameter in the ischemic region the normal region. Receiver operating characteristic (ROC) analysis was conducted to determine the area under the ROC curve (AUC) for the differentiation of acute ischemic stroke.

##### **RESULTS**

The CT value (28.2±3.93 HU vs. 33.4±2.34 HU, P<0.001) the ED (102.43±0.411 vs. 102.95±0.170, P<0.001) showed a significant difference between the ischemic stroke region the contralateral normal region. There was no significant difference in Zeff (7.357±0.0465 vs. 7.365±0.0365, P=0.47). The AUC for the diagnosis of acute ischemic stroke using conventional CT, ED, and Zeff were 0.846, 0.904, and 0.615, respectively. With an optimal threshold of ED of 102.65, the sensitivity, specificity, PPV, NPV, and accuracy of differentiation of acute ischemic stroke were 80.8%, 100%, 100%, 83.9%, and 90.4%, respectively.

##### **CONCLUSION**

s Our results suggest that electron density images derived from dual-layer detector CT can improve the detection of acute ischemic stroke compared to conventional non-contrast CT imaging.

#### **CLINICAL RELEVANCE/APPLICATION**

Improved discrimination of early ischemic changes region with electron density images, as compared to conventional images, is expected to lead to easier CT diagnosis of acute ischemic stroke.

#### **R5A-SPNR- Neuroimaging Features of Peripheral Neuropathy with Positive Antinodal or Paranodal Antibodies** 12

##### **PURPOSE**

To investigate the magnetic resonance neurography (MRN) characteristics of Autoimmune neuropathy (AN).

##### **METHODS AND MATERIALS**

18 AN patients with MRN examination from Hospital were collected, 2 were excluded due to unqualified images. The enrolled 16 patients included 12 with anti-NF155 IgG4 antibody positive, 1 with anti-Caspr1 antibody positive, and 3 with anti-CNTN1 antibody positive. 6 patients (4 anti-NF155 IgG4 positive, and 2 anti-CNTN1 positive) underwent follow-up MRN examination. The control groups included 18 patients with the MRN examination of the normal peripheral nerve. The basic imaging features of MRN were analyzed in baseline AN group, including the contrast enhancement of the spinal roots of post-ganglion and pre-ganglion, cauda equina. The "Sleeve sign" were also analyzed. Then, the nerve root cross-sectional area (CSA) were measured in all groups. The Kruskal-Wallis H test was used to compare the demographic differences (i.e., genders and ages) among the 3 groups. The Wilcoxon rank sum test was used to compare the CSA between the AN groups and the control groups, the follow-up and baseline groups. Pearson (or Spearman rank) correlation test was used to detect the correlations between the CSA and different clinical parameters.

##### **RESULTS**

There was no significant difference in genders ( $P=0.620$ ), disease duration ( $P=0.277$ ), cranial nerve ( $P=0.790$ ), and tremor ( $P=0.233$ ) among the three groups. Imaging features of the baseline AN patients were as follows: preganglionic nerve enhancement (90.9%), postganglionic nerve enhancement (72.7%), cauda equina enhancement (100%), The CSA of the L3-S1 (both sides) nerve roots were larger in the AN groups than in the control groups (all  $P < 0.05$ ). There was no significant difference in the CSA of nerve roots between the baseline groups and the follow-up groups. There was positive correlation between the Hughes score after treatment and the CSA of the nerve root L5L ( $r=0.88, P=0.02$ ), S1L ( $r=0.90, P=0.014$ ), L4L ( $r=0.88, P=0.021$ ), L3R ( $r=0.95, P=0.003$ ), S1R ( $r=0.92, P=0.01$ ). Spearman rank correlation analysis showed a weak positive correlation between the Hughes score of different value and the CSA of the nerve root L5L ( $r=0.093, P=0.018$ ), L3R ( $r=0.093, P=0.008$ ), S1R ( $r=0.91, P=0.008$ ) and L4L ( $r=0.83, P=0.039$ ).

##### **CONCLUSION**

s The MRN features can differentiate AN and the normal group very well. While, the features did not correlate well with the treatment effect, which needs further studies to find better imaging biomarkers to evaluate the treatment accurately.

#### **CLINICAL RELEVANCE/APPLICATION**

There are differences in MRN between AN patients and normal patients, which are correlated with clinical scores, MRN is a potential imaging biomarker for accurate diagnosis and prognosis evaluation of AN patients.

#### **R5A-SPNR- Neurotransmitters Release in the Brain Extracellular Space Following Neuronal Excitation can be** 13 **Tracked by Tracer-based MRI**

##### **PURPOSE**

The interstitial fluid (ISF) within the brain extracellular space (ECS) is a direct microscopic environment in which brain cells survive and function, however, the dynamic modulatory processes that occur in the ECS upon stimulation, as well as their underlying mechanisms, have not been elucidated. Given the potentially important capacity of tracer-based magnetic resonance imaging (MRI) in visualizing the drainage of ISF in brain ECS and analyzing the diffusion characteristics of ECS in the deep brain, it is pertinent to explore the underlying biophysical mechanisms.

##### **METHODS AND MATERIALS**

In the present study, by using an algorithm-optimized tracer-based MRI and DECS-Mapping techniques, we quantitatively measured the dynamic biophysical parameters of the brain ECS structure and ISF drainage in the thalamus following neuronal excitation in an electric pain stimulation rat model. Immunofluorescence assays and western blot were used to confirm the morphological basis for structural changes in ECS. Additionally, the release and distribution of neurotransmitters were mapped at different time-points following pain stimuli by using mass spectrometry imaging (MSI). The same examinations were performed in an aquaporin-4 (AQP4) gene knockout rat model to explore the roles of AQP4 in regulating ECS structure and ISF drainage.

##### **RESULTS**

Significantly decreased diffusion coefficient (DECS) and volume fraction ( $\alpha$ ) of the brain ECS were found in the thalamus caused by neuronal excitation, accompanied with the slowdown of ISF drainage. The morphological basis for structural changes in ECS was local spatial deformation of astrocyte foot processes. An AQP4 knockout rats model was used in which the changes of the ECS structure were reversed and found that the slowed DECS and ISF drainage persisted. Meanwhile, the dynamic changes of DECS were found to be synchronized with the release and elimination processes for neurotransmitters following neuronal excitation.

##### **CONCLUSION**

s In conclusion, tracer-based MRI represents a promising technique to reflect neuronal activity, the down-regulation of ISF drainage following neuronal excitation is caused by the restricted diffusion in the brain ECS, and DECS might be used to track the neurotransmitters release following neuronal activities in the deep brain.

#### **CLINICAL RELEVANCE/APPLICATION**

Tracer-based MRI represents a promising technique to reflect neuronal activity. Brain ECS and ISF drainage within it will become a new target for monitoring neural network excitation, which will open up new research avenues for understanding the physiology and

pathology of central nervous system diseases.

## **R5A-SPNR-2 Investigating ChatGPT's Capability to Generate Differential Diagnoses from Transcribed Radiological Findings in Neurological Imaging**

Participants

Shawn Sun, MD, MS, Anaheim, CA (*Presenter*) Nothing to Disclose

### **PURPOSE**

To assess the accuracy and reliability of ChatGPT3.5 and ChatGPT4 in producing a differential diagnosis from transcribed radiological findings of neuroradiology cases.

### **METHODS AND MATERIALS**

A sample of 32 neuroradiology cases were selected from a radiology textbook, from which the answers were used as the gold standard. The case images and history were converted into standardized prompts that contained purely descriptive language of the cases and a query for the most likely diagnosis, top three differential diagnoses, and the corresponding explanations and references from the medical literature. These prompts were fed into the ChatGPT3.5 and ChatGPT4 algorithms. Generated responses were analyzed for accuracy by comparison with the original literature and reliability through manual verification of the generated explanations and citations. The top 1 accuracy and the top 3 accuracy were defined as the percentage of generated responses that matched the original diagnosis and the complete differential provided by the original literature. An additional differential diagnosis score was defined as the proportion of differentials that matched the original literature's answers for each case. Comparisons were made between the results of the two algorithms using a one-tailed two proportion z-test method.

### **RESULTS**

The top 1 accuracy and top 3 accuracy, for ChatGPT3.5 versus ChatGPT4 were 37.5% compared to 56.3% ( $p=0.065$ ) and 9.4% compared to 15.6% ( $p = 0.23$ ), respectively. The average differential diagnosis score of ChatGPT3.5 versus ChatGPT4 was 44.3% compared to 52.5% ( $p=0.25$ ). ChatGPT3.5 and ChatGPT4 hallucinated 36.5% versus 12.2% ( $p=0.012$ ) of the references provided and generated 7 total false statements versus 3 total false statements, respectively.

### **CONCLUSION**

s The ChatGPT algorithms were able to produce a differential diagnosis for prompts containing descriptive radiological findings. The responses matched the expert literature from which the cases originated a minority of the time, though a non-statistically significant improvement was made in the accuracy categories from 3.5 to the 4th generation algorithm. The renowned hallucination effect appeared more frequently in generated citations compared to algorithm-produced statements, with both showing improvement in the latest generation.

### **CLINICAL RELEVANCE/APPLICATION**

ChatGPT and Large Language Models (LLM) hold significant potential to influence both clinical and educational aspects of medicine. Familiarity with the precision and potential errors of these algorithms can offer a deeper insight into the constraints of these emerging tools.

## **R5A-SPNR-3 Deep-Learning Augmented Contrast Enhancement Improves the Detection of Cerebral Vessel Occlusions in CT-Angiography of Acute Stroke Patients**

Participants

Sebastian Steinmetz, MD, Mainz, Germany (*Presenter*) Nothing to Disclose

### **PURPOSE**

To examine the impact of deep-learning augmented contrast enhancement on diagnostic performance of poorly contrasted computed tomography angiography (CTA) in acute stroke.

### **METHODS AND MATERIALS**

This retrospective single center study included patients with suspected ischemic stroke who underwent comprehensive CT imaging including cranial computed tomography (CCT), whole brain volume perfusion CT (VPCT) and computed tomography angiography (CTA) and had poorly contrasted CTA (defined as  $<350\text{HU}$  in the proximal MCA) between 01/2021 and 12/2022. 58/102 patients had vascular occlusion with correlate in perfusion. All CTA datasets were reconstructed conventionally using iterative reconstruction (conventional CTA, cCTA) and additionally using an AI-powered Augmented Contrast Enhancing tool (ClariACE, ClariPi, Seoul South Korea), which is a pre-trained deep learning model allowing selective boosting of contrast agent components in CT images (enhanced CTA, eCTA). The quantitative features including slope, signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), noise, entropy and density values were examined by software and were calculated standardized and compared. Datasets were then evaluated by two blinded radiologists, who applied 4-point-Likert-scales to general and vessel specific measures of both cCTA and eCTA datasets (overall image quality, overall contrast, artifacts, diagnostic confidence, image noise, assessability of proximal, intermediate and subcortical vessels). Furthermore, readers evaluated both datasets for presence / absence of cerebral vessel occlusions with VPCT serving as reference standard for calculating sensitivity and specificity.

### **RESULTS**

This study included 102 patients (mean age= $67.69\pm 13.18\text{y}$ ; 32 women). Objective image evaluation revealed an increase in iodine contrast by ca. 100%. eCTA revealed significantly higher subjective contrast, diagnostic confidence and overall image quality ( $p<.001$ ). Both readers achieved significantly improved sensitivity with eCTA as compared to cCTA (Reader 1: 55/58 [95%; 95%-CI: 85.62% to 98.92%] vs. 48/58 [83%; 95%-CI: 70.57% to 91.41%]; Reader 2: 53/58 [91%; 95%-CI: 81.02.% to 97.14%] vs. 46/58 [79%; 95%-CI: 66.65% to 88.83%]). Reader 1 yielded no false positive findings on cCTA or eCTA (specificity 44/44 [100%; 95%-CI: 91.96% to 100%]), reader 2 yielded no false positive findings on cCTA and 1 false positive on eCTA (reader 2: 43/44 [98%; 95%-CI: 87.98% to 99.94%]).

### **CONCLUSION**

s Deep-learning augmented contrast enhancements significantly increases image quality and diagnostic performance of poorly contrasted CTA.

## CLINICAL RELEVANCE/APPLICATION

Enabling faster and more accurate care for stroke patients.

## R5A-SPNR-4 Use of a Computer-based Program to Classify Injuries from the Upper Cervical Spine According to AO Spine Classification

Participants

David Timaran Montenegro, MD, Houston, TX (*Presenter*) Nothing to Disclose

### PURPOSE

AO classification is a detailed, laborious, and challenging standardized assessment to describe imaging findings of UCST. To improve efficiency reducing assessment time, a computerized program was developed to determine AO Classification from standardized imaging report system from Cervical Spine Imaging CT and MRI called, PAUCI: Program for Analysis of Upper Cervical Injury.

### METHODS AND MATERIALS

The computer program utilizes a series of 44 dichotomic questions based on the presence or absence of imaging findings. Initially, registration of lesions was performed retrospectively by two neuroradiologist after consensus was achieved. Then, the database was reviewed by PAUCI and a third blinded neuroradiologist to determine AO classification. Statistical analysis included calculation of agreement coefficients between the neuroradiologist assessment and AO classification according to anatomic level and severity type of injuries.

### RESULTS

Initially, 170 subjects with UCST were included in our study and registered in the database. All patients showed lesions in the upper cervical spine on CT or MRI. Among them, 70 subjects were randomized to be assessed by the third blinded evaluator and PAUCI. Second-order agreement coefficients indicated that PAUCI and the neuroradiologist demonstrated a statistically significant degree of agreement regarding AO injury level (Level I: AC2 0.886, Level II: AC2 0.874, Level III: 0.675;  $\Pr > |Z|$  (p value) <0.0001 for all). There was also significant agreement regarding AO injury severity at each level (Type A: 0.980; Type B: 0.864 Type C: 0.639;  $\Pr > |Z|$  <0.001 for Type A and B and 0.0064 for Type C).

### CONCLUSION

s AO classification for the upper cervical spine injury determined by PAUCI and neuroradiologist demonstrated a statistically significant degree of agreement. Stronger agreement was identified with lesions occurring at the anatomic Level I. More modest agreement was found with lesions at Level III with severity type C. PAUCI represents an opportunity to determine AO classification efficiently and accurately from cervical spine imaging in cases of upper cervical spine injury.

## CLINICAL RELEVANCE/APPLICATION

Detailed description of imaging findings in patients with upper cervical spine trauma using a standardized system is needed to assess prognosis and outcomes. Currently, AO spine is a reliable classification system. Main limitations include difficulty and time consumption in busy real life practice. Computerized systems can help to expedite the process to classify lesions.

## R5A-SPNR-5 Correlation of Brain Stiffness Measured Using Virtual MR Elastography Based on DWI with Enlarged Perivascular Space

Participants

Miran Han, MD, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

### PURPOSE

Enlarged perivascular spaces (EPVS) have been known to be associated with various degenerative disease. However, since they were also frequently observed in healthy population, it is not clear how severe EPVS burden can be considered pathologic. Therefore, we investigated the relationship EPVS and brain stiffness which is also considered as biomarker of neurodegenerative disease, using the virtual magnetic resonance elastography (vMRE). That is a non-invasive and novel technique based on diffusion weighted imaging (DWI)

### METHODS AND MATERIALS

We retrospectively reviewed healthy adults who performed MR imaging for routine medical examination from March 2021 to June 2022. EPVS were rated on visual grading [grade 0, 1, 2, 3, 4 for 0, 1-10, 11-20, 21-40, >40 EPVS at centrum semiovale (CSO) and basal ganglia (BG) of either hemisphere]. We excluded patients who had high SI at white mater (> Fazekas scale 1), EPVS at BG > grade 1, hypertension, cardiovascular disease, and diabetes to minimize the effect of confounding factors. We randomly selected age matched patients according EPVS grade at CSO. Shifted apparent diffusion coefficient was calculated from DWI ( $b=200$  and  $1500\text{sec/mm}^2$ ) and converted to DWI-based virtual shear modulus ( $\mu$ ). Brain stiffness was measured in centrum semiovale area, but also in whole brain. Multiple comparison test were performed for evaluating relationship between EPVS grade and brain stiffness.

### RESULTS

Finally 248 patients (50 patient for grade 0, 1, 2, 3 and 48 patients for 4, 107 female, 141 male) were included. There were no differences in brain volume between EPSV groups ( $P = 0.109$ ), the virtual shear modulus ( $\mu$ ) decreased not only in CSO but also in whole brain, as the EPSV grade increased ( $P < 0.001$ ). In post hoc analysis, there is no significant differences of brain stiffness between G0 and G1 ( $P = 0.939$  for CSO,  $P = 0.984$  for total brain), G2 and G3 ( $P = 0.893$  for CSO,  $P = 0.418$  for total brain). When the EPVS was re-graded as normal (G0-1), mild (G2-3) and high (G4), the change of brain stiffness parameters were significant according to EPSV grade (Normal vs Mild,  $P = 0.001$ ; Mild vs High,  $P = 0.015$  for CSO and  $P = 0.001$ ;  $P = 0.016$  for total brain).

### CONCLUSION

s The higher degree of EPVS at CSO presented lower value of brain stiffness parameter. The rating system of EPVS needs to be revised in consideration of clinical impact.

## CLINICAL RELEVANCE/APPLICATION

The enlarged perivascular space showed negative correlation with brain stiffness measured using virtual MR elastography, new

rating system of EPVS based on brain stiffness could be suggested.

### **R5A-SPNR-6 Harmonized Tract Based Spatial Statistics (TBSS) with Multiple Diffusion Models of the Alzheimer's Disease Connectome Project (ADCP)**

Participants

John Roberts, BS, MADISON, WI (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Alzheimer's Disease (AD) has been mainly thought of as a disease involving gray matter changes. Gray matter atrophy is observed primarily in fronto-temporal regions, but less is known about the disruptions to white matter. This study investigates disruptions to white matter in the AD continuum (cognitive unimpaired (CU) or healthy controls (HCs); cognitive impaired (CI) - Mild Cognitive Impairment (MCI) and AD) using diffusion tensor imaging (DTI) and multi-tissue neurite and orientation dispersion and density imaging (mtNODDI) models of the multi-shell connectome diffusion MRI (ms-dMRI) data from the Alzheimer's Disease Connectome Project (ADCP).

#### **METHODS AND MATERIALS**

Data from 121 participants (Cognitive Unimpaired (26 M, 43 F) mean age 67 +/- 7.2; Cognitive Impaired (31 M, 21 F) mean age 73.2 +/- 8.8) in the ADCP with ms-dMRI were pre-processed using DESIGNER processing guidelines using tools implemented in FSL, ANTS, and MRtrix3. TBSS pre-processing was performed, and parametric ComBat data harmonization was applied to the skeletonized data for the DTI and mtNODDI parameters. The effects of cognitive impairment on these parameters were statistically evaluated using permutation testing and threshold free cluster enhancement with family wise error corrected threshold of  $p < 0.05$ , controlling for age and sex.

#### **RESULTS**

Analysis of DTI and NODDI measures revealed significant differences in mtCSF (partial volume fraction of cerebrospinal fluid), mtODI (orientation dispersion index of neurites), and mtVFEXTRA (partial volume fraction of extracellular free water) between CI and CU individuals. Specifically, CI individuals had higher mtVFEXTRA (1 cluster) and mtODI (6 clusters), and lower mtCSF (1 cluster) and mtODI (1 cluster) than CU individuals. All results are statistically significant with family-wise error corrected p-values with an a level of 0.05.

#### **CONCLUSION**

s Cognitively impaired individuals were found to have decreased axonal coherence in the brainstem and surrounding cerebellar regions as well as in frontal lobe sub gyral white matter, suggesting increased neurodegeneration in these regions. Conversely, cognitively impaired individuals were found to have reduced extracellular fluid in cerebral white matter and decreased tissue complexity in the gray matter of the posterior corona radiata. Further research is needed to replicate and extend these findings and investigate potential confounding factors.

#### **CLINICAL RELEVANCE/APPLICATION**

Neurite complexity tends to decrease in the posterior white matter and increase in the brainstem and sub gyral frontal white matter in cognitively impaired individuals on the AD continuum.

### **R5A-SPNR-7 Pretreatment MR-Based Radiomics in Patients With Glioblastoma: A Systematic Review and Meta-Analysis of Prognostic Endpoints**

Participants

Su Jeong Yang, MD, Incheon, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Recent studies have shown promise of MR-based radiomics in predicting the survival of patients with untreated glioblastoma. This study aimed to comprehensively collate evidence to assess the prognostic value of radiomics in glioblastoma.

#### **METHODS AND MATERIALS**

PubMed-MEDLINE, Embase, and Web of Science were searched to find original articles investigating the prognostic value of MR-based radiomics in glioblastoma published up to March 6, 2022. Concordance indexes (C-indexes) and Cox proportional hazards ratios (HRs) of overall survival (OS) and progression-free survival (PFS) were pooled via random-effects modeling. For studies aimed at classifying long-term and short-term PFS, a hierarchical regression model was used to calculate pooled sensitivity and specificity. Between-study heterogeneity was assessed using the Higgin inconsistency index (I<sup>2</sup>). Subgroup regression analysis was performed to find potential factors contributing to heterogeneity. Publication bias was assessed via funnel plots and the Egger test.

#### **RESULTS**

Among 596 abstracts, 17 studies were included. Respective pooled C-indexes and HRs for OS were 0.65 (95% confidence interval [CI], 0.58-0.72) and 2.88 (95% CI, 2.28-3.64), whereas those for PFS were 0.61 (95% CI, 0.55-0.66) and 2.78 (95% CI, 1.91-4.03). Among 4 studies that predicted short-term PFS, the pooled sensitivity and specificity were 0.77 (95% CI, 0.58-0.89) and 0.60 (95% CI, 0.45-0.73), respectively. There was a substantial between-study heterogeneity among studies with the survival endpoint of OS C-index (n=9, I<sup>2</sup>=83.8%). Publication bias was not observed overall.

#### **CONCLUSION**

s Pretreatment MR-based radiomics provided modest prognostic value in both OS and PFS in patients with glioblastoma.

#### **CLINICAL RELEVANCE/APPLICATION**

Pretreatment MR-based radiomics provided modest prognostic value in patients with glioblastoma with pooled C-indexes for overall survival and progression-free survival as 0.65 and 0.61, respectively.

### **R5A-SPNR-8 Imaging Findings of IIH: The Value of MRI in Predicting the Presence of Disease**

Participants

## PURPOSE

Idiopathic intracranial hypertension (IIH) is a condition characterized by an increase in cerebrospinal fluid (CSF) with a lack of identifiable structural cause or etiology. This condition is expected to rise in incidence along with an increase in obesity in the coming years. Brain imaging has been successfully used to identify this disease with specific findings prompting further evaluation. We believe that MR imaging findings can predict the presence of IIH and we attempted to reproduce and reinforce existing knowledge in the literature.

## METHODS AND MATERIALS

This study was a retrospective data analysis of MRI imaging reports completed during the calendar year 2020 at John Peter Smith hospital. Any MRI report including the phrase "Idiopathic intracranial hypertension" was reviewed and patients with a lumbar puncture confirming the diagnosis of IIH were included. The study sample was 64 IIH cases and 41 normal MRI brains as a control. All cases were deidentified and randomized. These MRI studies were reviewed by three different neuroradiologists who were blinded to the diagnoses. The presence or absence of four imaging findings was noted—empty pituitary sella, posterior globe flattening, bilateral transverse sinus stenosis, and enlarged optic nerve sheaths. Inter-rater reliability (IRR) was analyzed as well as Odds Ratios for each finding using a generalized linear mixed model.

## RESULTS

Our results demonstrated substantial and almost perfect agreement amongst radiologists when identifying empty pituitary sella, enlarged optic nerve sheaths, and posterior globe flattening (IRR value >0.6). However, there was only moderate agreement amongst radiologists when assessing bilateral transverse sinus stenosis (? value 0.569). Odds ratios for each imaging finding were statistically significant (p value <.0001). Posterior globe flattening had the highest odds ratio and was never seen in controls.

## CONCLUSION

Our results reinforce existing evidence that specific MR imaging findings can predict the presence of IIH. A limitation to this study was the lack of vascular imaging such as MR Venography, which is likely responsible for the low IRR in identifying bilateral transverse sinus stenosis. A future study could look at CT or MR venography alone or combined with these findings to predict the presence of IIH.

## CLINICAL RELEVANCE/APPLICATION

As the incidence of IIH increases in the population, it is increasingly important to recognize MR findings which predict the presence of this disease. In addition, vascular imaging should be included in the diagnostic workup of IIH.

## R5A-SPNR-9 Reduction of Injected Volume of Intravenous Contrast Media for Brain CT: Problem or Opportunity

Participants

Goni Merhav, Haifa, Israel (*Presenter*) Nothing to Disclose

## PURPOSE

This study investigates whether reducing the volume of intravenous iodinated contrast material injected during brain computed tomography (CT) provides reliable and accurate enhanced imaging without compromising diagnostic accuracy.

## METHODS AND MATERIALS

In this prospective IRB approved study of 102 consecutive patients all of whom received informed consent, enhanced brain CT was done for indications such as headache and dizziness. 47 patients then received a reduced dose of 60 ml of Omnipaque 350 iv, while the control group of 55 patients received the usual 80 cc of Omnipaque 350 iv as suggested on the package insert. All CTs were done on a Siemens Somatom Definition Flash scanner or Siemens Somatom AS 64 with the same parameters: 100kV, 300-400 mA, 3 mm slice thickness, 12/3200 window width, data collection diameter 500. Three neuroradiologists blinded to the amount of injected contrast material rated the CT scans for image quality and lesion detection using a 5-point Likert scale. Readings were controlled for age and gender. Visibility of six anatomic structures was recorded by each reader. Inter-rater reliability was tested using intra class correlation (ICC, two-way random effect model, single rater, agreement) based on the 95% confidence interval of ICC estimates. Multiple linear regression was used to predict overall diagnostic accuracy.

## RESULTS

Readers' ratings had a high intra class correlation coefficient (ICC) value of 0.873 (CI 95% 0.831-0.908). No significant demographic or clinical differences were noted between the two groups. The 80cc group had significantly higher enhancement ratings compared to the 60cc group for six anatomical structures. However the mean difference scores between the study group and the control group for the six items were less than 0.5 (p<0.001).

## CONCLUSION

The rankings of the raters for both the test and control groups did not differ significantly. Therefore, the overall diagnostic quality did not show a clinically significant difference between the two groups. The potential advantages of reduced contrast volume include shortened scan duration, lower radiation exposure, lower risk of adverse effects such as contrast induced nephropathy or cardiac failure, and cost minimization. Conservation of iodinated contrast media is a timely concern given the recent global shortage of iodinated contrast material in the year 2022.

## CLINICAL RELEVANCE/APPLICATION

Reduced IV contrast volume for brain CT yields accurate IV imaging, may reduce adverse effects (nephropathy or cardiac failure), is cost minimizing, has shorter scan times, and mitigates future supply chain contrast shortages.

## Abstract Archives of the RSNA, 2023

R5A-SPPD

### Pediatric Imaging Thursday Poster Discussions I

#### Sub-Events

#### **R5A-SPPD-1 Developing an Evidenced-Based Pediatric Pituitary Magnetic Resonance Imaging Protocol: How We Did It**

#### Participants

Michael Nance, MD, PhD, Atlanta, GA (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To develop a protocol to facilitate appropriate intravenous contrast use based on various pediatric pituitary imaging indications.

#### **METHODS AND MATERIALS**

A retrospective review of pediatric pituitary MRI protocols at Children's Healthcare of Atlanta was performed from July 2021 to June 2022 using the Empower database and review of patient records. Information for ordering specialty, imaging indication, and MRI protocol including the use of Gadolinium (Gd) were obtained. A comprehensive systematic and manual literature search was performed. PubMed MESH search criteria: (pediatrics OR child) AND magnetic resonance imaging AND (sella OR pituitary OR hypophysis), and patient age from newborn (birth-1 month) to adolescent (13-18 years). Included articles informed the magnetic resonance imaging technique for: precocious puberty, hypopituitarism, septo-optic dysplasia, Sellar mass, diabetes insipidus and pituitary adenoma. The systematic search resulted in 1,778 citations which yielded 57 articles after screening inclusion/exclusion criteria. Manual search contributed an additional 18 articles.

#### **RESULTS**

From July 2021 to June 2022, a total of 375 studies were performed (235 female, 140 male) with an age range of 6 weeks to 20 years (mean 10.7 years). The most frequent imaging indications were growth hormone deficiency (GHD) (44.1%) followed by precocious puberty (33.2%). Other indications included adenoma (13.1%) and pituitary mass (9.6%). Ordering provider specialty was predominantly endocrinology (70.9%). A total of 284 studies were ordered with Gd (75%). Based on indication, there was substantial institutional variance in the use of Gd. Adenoma (96% with Gd), GHD (59% with Gd), mass (75% with Gd), and precocious puberty (90% with Gd). Preliminary review of the literature also showed variation with included references describing Gd use in 93.3% (28/30) for pituitary mass, 50% (13/26) for hypopituitary/GHD, and 80% (4/5) for precocious puberty.

#### **CONCLUSION**

Standardized pediatric pituitary imaging protocols are not widely available potentially causing variance in the diagnostic efficacy. We demonstrate that there is substantial intra-institutional variance in the use of Gd based on pediatric pituitary imaging indication at a single institution quaternary children's hospital. We developed imaging protocol recommendations for each pituitary imaging indication based on our literature review. This will be presented to our endocrinologists for review and modifications to meet our local practice demands.

#### **CLINICAL RELEVANCE/APPLICATION**

We developed an institutional evidenced based pediatric pituitary imaging protocol to inform the appropriate use of Gd contrast for diagnostic efficacy.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

R5A-SPPH

### Physics Thursday Poster Discussions I

#### Sub-Events

#### **R5A-SPPH-1 Comparison of Scan Protocols with Different Automatic Exposure Control Software Using Water Equivalent Diameter Calculated from CT Images**

##### Participants

Hsiang-Chi Kuo, PhD, New York, NY (*Presenter*) Nothing to Disclose

##### PURPOSE

This study evaluated the patient dose and size difference when translating clinical scan protocols from one CT scanner to a new PETCT scanner with different automatic exposure control (AEC) software.

##### METHODS AND MATERIALS

Reference clinical protocols were built on a Philips big bore scanner (P) using 3D DOM version of Dose Right (DR) for AEC with different DR levels at various anatomical sites. These protocols were translated to a new Siemens Biograph V600 PETCT scanner (S) which utilizing CareDose 4D as AEC to modulate mAs in different strength from very weak to very strong with different Quality Reference mAs (Q. RefmAs). The average CareDose strength was applied. The RefmAs of the RT protocols from S were used with minor edits. An anthropomorphic phantom, wrapped with 0 and 5 cm bolus, was scanned using thorax and abdomen protocols at S and P scanners. The cross-sectional size of the phantom on the CT image was calculated as the water equivalent diameter (wED) based on the method described in AAPM TG 220 report. The CTDIvol for each slice was extracted from the DICOM header. The wED, and the CTDIvol data from each scanned protocol were statistically analyzed using the Spearman coefficient to determine the correlation. 85 patient scans on both scanners were compared to the CTDIvol as a function of wED across scanners and anatomical locations.

##### RESULTS

In phantom images' analysis, the P scanner using DR showed a higher correlation to wED ( $>0.83$  vs.  $<0.8$ ) than the S scanner, which applied RefmAs. Comparing the statistical results among protocols from both scanners, the subgroup of the scans from the same scanner (DR=17 vs. DR=21 vs. DR=25; Thorax Q. RefmAs=160 vs. Abdomen Q. RefmAs=250) showed a strong correlation (0.98). The scan results from different scanners (S vs. P) showed a weaker ( $<0.83$ ) correlation. Comparing patient scans, the images of the S scanner demonstrated a significantly higher exposure variance with wED and a sharper CTDIvol increase at wED between 25-30 cm resulting in a higher scanning dose with the pre-estimated patient size larger than  $\sim 28$  cm. P scanner had a maximum exposure limit so that CTDIvol could be kept below 27.6 mGy in the body site. S scanner did not limit maximum exposure from software such that the CTDIvol exposure could be more than 40 mGy, and in the case when scanned with the hand positioned on the chest, the CTDIvol could be more than 60 mGy.

##### CONCLUSION

This study highlights that assessing CTDI vs. wED can be a practical approach to evaluating clinical scan protocols for different AEC software and scan protocols.

##### CLINICAL RELEVANCE/APPLICATION

Translating CT scan protocols.

#### **R5A-SPPH-10 Patient-specific Analysis of Organ Doses and Image Quality in Abdominal Single Energy and Dual Energy CT Examinations**

##### Participants

Keisuke Fujii, PhD, Nagoya, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

The aims of this study are to evaluate organ doses for individual patients in abdominal CT examinations with conventional 120 kV single energy CT (SECT) and 80/135 kV dual energy CT (DECT), and to compare organ doses and image quality of the CT images in DECT scans with them in SECT scans.

##### METHODS AND MATERIALS

Monte Carlo (MC) simulations for each voxelized phantom of 40 adult normal weight and overweight patients undergoing abdominal CT examinations with Aquilion Precision as a SECT scanner and Aquilion ONE / PRISM Edition as a DECT scanner (Canon Medical Systems) were performed by inputting the CT images, descriptions of each CT scanner, and scanning parameters including our estimated tube current modulation profiles into MC simulation software ImpactMC (Advanced Breast CT, GmbH). Region of interests (ROI) of seven radiosensitive organs (thyroid, lung, esophagus, breast, liver, stomach, and bladder) were set on the simulated dose distribution images, and organ doses for each organ were calculated as average doses within each organ ROI. Next, we evaluated image quality of abdominal CT images from SECT scans and 70 keV virtual monochromatic images (VMI) images from DECT scans,

which were reconstructed with deep learning reconstruction algorithms. We set ROIs on liver region of plain SECT and VMI images, applied moving average filters in the ROI, and evaluated apparent noise (which showed the correlation with the subjective recognition of image noise on CT images) from standard deviation of the mean CT values for each filter size. Image contrast was calculated as differences between CT values of aorta at the early phase and those of liver region on plain SECT and VMI images, and contrast-to-noise ratio (CNR) was also calculated as the ratio of the contrast and apparent noise of each image.

## RESULTS

Organ doses for liver and stomach within scan range of normal and overweight patients in abdominal SECT scans were 22-32 mGy while the organ doses for the patients in abdominal DECT scans were 16-21 mGy. Apparent noise of the VMI images obtained from DECT scans was approximately 30% lower than that of SECT images, and contrast of the VMI images was approximately 30% higher than that of SECT images. From these results, CNR of the VMI images was approximately 2 times higher than that of SECT images.

## CONCLUSION

s DECT examinations allows for the reduction of organ doses for organs within scan range by approximately 30% compared to conventional SECT examinations, and VMI images obtained from DECT scans also provides higher signal detectability than SECT images.

## CLINICAL RELEVANCE/APPLICATION

DECT examinations can be performed with lower radiation doses than conventional SECT examinations, and VMI images obtained from DECT scans can provide higher signal detectability than SECT images.

## R5A-SPPH- Ultra-low Dose CT Imaging with a Denoising AI model in Body Composition Analysis

11

Participants

Hooney Min, MD, MS, Seongnam-si, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

Body composition analysis (BCA) is a crucial clinical application. CT is regarded as the gold standard for BCA, but DEXA is more common due to lower radiation exposure. This study evaluated the feasibility of using an ultra-low dose CT protocol with a denoising AI model to reduce radiation exposure without compromising reliability.

## METHODS AND MATERIALS

A prospective study of 100 subjects (26 males and 74 females, aged 23-62 years, mean BMI:  $23.2 \pm 3.25$  kg/m<sup>2</sup>) was conducted. Participants underwent a standard dose CT scan (120 mAs, 120 kVp, 0.066 mSv) and were randomly assigned a second CT scan with varying doses: 1) standard dose: 0.066 mSv, 2) half dose: 0.034 mSv, 3) quarter dose: 0.018 mSv, 4) ultra-low dose: 0.007 mSv. All effective doses included a scout view, obtained with a tin filter. Ultra-low dose CT used 10mAs, the lowest achievable on CT. CT scans captured a single 5 mm slice thickness axial image at the third lumbar spine. Standard dose CT scans were reconstructed using the Filtered Back Projection (FBP) method. Low dose CT images were reconstructed using the FBP method and a denoising AI model. CT scans were segmented using a commercially available software to obtain areas relevant to BCA (muscle, subcutaneous fat, and visceral fat). Intraclass correlation was used to compare BCA area values from low dose CT images to that of standard dose CTs. Muscle area was further divided into normal attenuation muscle (NAM) and low attenuation muscle (LAM). Wilcoxon signed rank test was used to compare NAM and LAM values from low dose CT images to that of standard dose CTs.

## RESULTS

Body composition parameters (muscle, subcutaneous fat, and visceral fat) from low dose CT scans (even without denoising) demonstrated high agreement with standard-dose CT scans, with intraclass correlation coefficients exceeding 0.95. Total muscle area was uniform across doses, but when divided into NAM and LAM, NAM was underestimated and LAM was overestimated as CT dose became lower. NAM and LAM values differed significantly in low-dose CTs compared to standard-dose CTs. The denoising AI model decreased the differences in NAM and LAM area at half-dose CTs ( $p > 0.05$ ).

## CONCLUSION

s Ultra-low dose CT provided accurate BCA without added radiation exposure, even without AI denoising. A denoising AI model enhanced the accuracy in differentiating LAM and NAM in low dose CT scans.

## CLINICAL RELEVANCE/APPLICATION

Ultra-low dose CT imaging (0.007 mSv) offers accurate and safe BCA with a lower effective dose than a single DEXA scan (0.013 mSv), suggesting better BCA without additional radiation exposure.

## R5A-SPPH- Improved Detectability of Low Contrast Objects with Deep Learning-based Denoising on Legacy CT Machine: A 10-Reader Phantom study

12

## PURPOSE

This study aims to assess the detectability of low-contrast objects through a human reader test by comparing denoised images obtained from a legacy CT machine with those acquired from a recent CT machine. Additionally, the study compares the low contrast detectability of the original and denoised images obtained from the legacy CT machine.

## METHODS AND MATERIALS

A Catphan® low-contrast phantom module was used for evaluation, with an added soft tissue-mimicking ring, resulting in a total phantom diameter of 30 cm (simulating adult body size). Images were acquired using a legacy CT machine (Philips Brilliance 64) set to 12mGy and a recent CT machine (Siemens Force) set to 32mGy. The images were reconstructed using the Filtered Back Projection (FBP) method. A vendor-agnostic deep learning-based denoising model was employed to process the images from the legacy CT machine. Based on the sample size calculation using a non-inferiority test with a non-inferiority margin of 0.05 in the area under the curve (AUC), 10 human readers and 100 images were required for each setting (denoised and original 12mGy images on legacy CT, and original 32mGy images on recent CT), resulting in a total of 300 images being tested. Of the 100 images, 50 were set to include a 15 mm object with a contrast of 10 HU, and 50 were set to not include. Ten radiologists with varying years of

experience evaluated the images using a 5-point Likert scale for the presence of the object, and AUC values were calculated for each setting. A non-inferiority test was performed to compare denoised images with images obtained from the recent CT. An additional superiority test was performed between denoised and original FBP images acquired from the legacy CT.

## RESULTS

The AUC for the original FBP image from the legacy CT was 0.895, while the denoised image from the same machine had an AUC of 0.988. The recent CT had an AUC of 0.993. The low-contrast detectability of denoised FBP images from the legacy CT was found to be non-inferior to the FBP images obtained from the recent CT ( $p < 0.01$ ). Furthermore, denoised FBP images exhibited superior low-contrast detectability compared to the original FBP images acquired from the legacy CT ( $p < 0.01$ ).

## CONCLUSION

The deep learning-based denoising model significantly improved low-contrast detectability on legacy CT and was non-inferior to images obtained from recent CT.

## CLINICAL RELEVANCE/APPLICATION

The application of this vendor-agnostic denoising model may offer a potential solution to improve the detectability of low-contrast objects in clinical settings that still use legacy CT machines.

## R5A-SPPH-2 Agreement of Size-specific Dose Prediction and Site-specific Diagnostic Reference Level in Adult Abdominal CT Examinations

### PURPOSE

CT doses range across population can be predicted prospectively with size-specific phantoms or reviewed in dose monitoring software, but the agreement between the two methods lack large population confirmation<sup>1</sup>. We aimed to compare predicted size-specific dose to reported values across multiple vendors in our hospital system, and also, to develop strategies to convert between size-specific prediction with Mercury phantom and retrospective site-specific local diagnostic reference level.

### METHODS AND MATERIALS

The overall study design was illustrated (Fig a). Diagnostic reference levels across academic hospitals ( $n=9$ ) and community sites ( $n=13$ ) in the past 3 years were quantified with quantile summary of CTDIvol for different BMI groups ( $n>30$  per group), using de-identified meta-data from dose monitoring software (DoseTrack, Sectra, Fig b), retrospectively. Patient sizes (water equivalent diameter,  $D_w$ ) in Mercury 4.0 phantom were converted to BMI with a reported equation<sup>2</sup>, with an assumed error of 10%. The phantom was scanned using clinical abdomen protocols with identical tube current modulation settings (reference mAs, DRI or CareDose Index,  $n=11$ ). Phantom CTDIvol and  $D_w$  were calculated with imQuest<sup>3</sup>. The distributions of CTDIvol for different patient sizes from DoseTrack were compared with phantom-acquired CTDIvol data.

### RESULTS

Retrospective DRLs across hospitals (academic vs community) and vendors (Philips vs Siemens) were shown (Fig c,d), generally agree within BMI groups. Phantom scans with same protocols had lower CTDIvol across all patient sizes compared to local DRL. For Siemens, considerable agreement of median CTDIvol between predicted and reported was identified ( $3.4 \pm 1.8\%$  for academic,  $5.3 \pm 1.8\%$  for community). For Philips, maximum CTDIvol predicted was close to DRL reported median CTDIvol ( $9.1 \pm 5.7\%$  for academic,  $6.9 \pm 5.4\%$  for community).

### CONCLUSION

Size-specific CTDIvol estimated with Mercury phantom has considerable agreement with actual dose range of respective BMI population, with conversion of BMI and  $D_w$ . It is feasible to use size-specific phantom to estimate retrospective site-specific dose distribution, with proper optimization for different vendors and protocols.

### CLINICAL RELEVANCE/APPLICATION

Estimating CT dose range prospectively is crucial for imaging protocol optimization. Our findings suggest it is feasible to predict population patient-size-specific CTDIvol for tube-current modulated protocols using size-specific phantom.

## R5A-SPPH-3 Application of Deep Learning Image Reconstruction Algorithm to Reduce Radiation Dose in Brain CT Perfusion

Participants

Fang Wang, Yinchuan, China (*Presenter*) Nothing to Disclose

### PURPOSE

To improve the improvement of deep learning image reconstruction (DLIR) algorithm in CT perfusion (CTP) in suspected acute stroke.

### METHODS AND MATERIALS

Patients with suspected acute ischemic stroke were selected for CTP imaging. Scanning tube voltage was 80 kV and low dose current was set at 50 mA. Image reconstruction of low-dose scan data was performed using hybrid iterative reconstruction-40% (ASiR-V) and DLIR intensity (medium and high), respectively. Perfusion parameters were reconstructed for three sequential images: cerebral blood flow (CBF), brain volume (CBV) and mean passage time (MTT). Comparing the differences in parameter means and correlation of the 3 sequences. Objective evaluation and subjective evaluation (integral system) Image quality: objective evaluation mainly measures the CT value and noise of the lateral ventricle and middle cerebral artery during the peak period, calculates the signal-to-noise ratio (SNR) and contrast noise ratio (CNR); measurement data are expressed in the form of "median  $\pm$  quartile", and the objective score of the peak images of the three groups are compared. Differences between groups were compared by Friedman test and pairwise comparisons by Wilcoxon signed rank test with bonferroni correction, and  $P < 0.05$  was considered statistically significant.

### RESULTS

40% CBF and CBV differences for sir-v, DLIR-M in frontal, temporal, occipital and basal ganglia ( $36.5 \pm 12.3$  vs  $30.2 \pm 7.8$  vs  $33.6 \pm 9.4$ ,  $p < 0.001$ ) ( $2.5 \pm 0.4$  vs  $1.8 \pm 0.3$  vs  $2.1 \pm 0.5$ ,  $p < 0.001$ ), And the mean CBF and CBV in order from large to small: 40% Air-v >

DLIR-H> DLIR-M, Pairwise comparisons were statistically different ( $P < 0.05$ ). The three perfusion parameters of the DLIR sequence were correlated with 40% AIDS-v ( $P < 0.05$ ), and the CBF and CBV values (R values) for the 40% AR-v were higher (0.84,0.66) than the DLIR-M sequence (0.50,0.61). SD values in DLIR-M and DLIR-H arteries were lower than 40% Asia-v ( $P < 0.001$ ), with the highest SNR and CNR in the DLIR-H sequence ( $p < 0.001$ ).

## CONCLUSION

s DLIR-H can significantly improve the peak period image quality of low-dose cerebral CTP arteries, and the reconstructed perfusion parameters are better correlated with 40% Asia-v.

## CLINICAL RELEVANCE/APPLICATION

The DLIR reconstruction algorithm can improve the image quality of arterial vessels during the peak period without affecting the accuracy of perfusion parameters, and further validate that the reconstruction algorithm of DLIR-H is more suitable for intracranial vessels.

## R5A-SPPH-4 A Comparative Study on the Image Quality of Part-Solid Nodules in the Lung: Virtual Non-Contrast Imaging on Venous Phase Based on Dual Energy CT vs. True Non-Contrast Imaging Based on Single Energy

Participants

Jingjing Hong, Guangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

This study explored the feasibility of using virtual non-contrast (VNC) images obtained from ultrafast synchronized KV/mA switching dual energy CT (DECT) in both pulmonary arterial and venous phase to evaluate part-solid nodules (PSN) in the lung, and compared their performance with true non-contrast (TNC) images.

## METHODS AND MATERIALS

46 Cases of Partial Solid Nodules with lung enhanced CT examination who underwent TNC scan and enhanced DECT scan (arterial and venous), and VNC images were reconstructed from DECT. The CT values, and standard deviation (SD) of the PSN and Ipsilateral erector spinae muscle (ESM), as well as diameter of lesion, were measured in VNC and TNC images. The signal-noise-ratio (SNR,  $CTSN/SDSN$ ) and ontrast-noise-ratio [CNR,  $(CTESM - CTPSN) / SDESM$ ] of PSN were calculated. Record the effective radiation dose in TNC and VNC mode. Two experienced radiologists subjectively assessed the IQ(image quality)of VNC and TNC images using a 5-point scale (1, poor; 2, fair; 3, moderate; 4, good; 5, excellent). Non-parametric test was used to compare the subjective and objective image parameters and effective radiation dose of images in different scanning phases. The Kappa test was used to assess consistency of subjective score between groups.

## RESULTS

There were no significant differences in The diameter , CT value, SD, SNR and CNR between TNC and VNC images in arterial/venous phase( $P > 0.05$ ). The TNC ( $4.79 \pm 0.33$ ) had the highest the subjective score, followed by VNC images ( $4.04 \pm 0.26$ ) in venous phase, with significant differences observed among the three groups ( $P = 0.015$ ), however, all scores were up to diagnosis requirements. The consistency of subjective scores between radiologists was strong ( $K = 0.72 \sim 0.73$ ). The effective radiation dose of VNC mode [ $(10.74 \pm 0.93)$  mSv] was lower than that of conventional mode [ $(15.21 \pm 1.89)$  mSv] ( $P < 0.001$ ), about 30% reduction.

## CONCLUSION

s Visual non-contrast on ultrafast synchronized KV/mA switching dual energy CT in venous phase can provide similar image quality to TNC, but the radiation dose is significantly reduced.

## CLINICAL RELEVANCE/APPLICATION

The ultrafast synchronized KV/mA switching dual energy enhanced venous phase VN technique can largely replace the conventional images, providing comparable image quality for patients with lung disease and significantly reducing patient radiation dose.

## R5A-SPPH-5 Clinical Value of Deep Learning Image Reconstruction in the Diagnosis of Pulmonary Nodule in Ultra-low Dose Chest CT

Participants

Zheng Zhijuan, Guangzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

To compare the image quality, lung nodule detectability and accuracy of quantitative analysis of deep learning image reconstruction (DLIR) and adaptive statistical iterative reconstruction-Veo (ASIR-V) in Ultra-low dose (ULD) CT for helping large-scale lung cancer screening in clinical.

## METHODS AND MATERIALS

102 patients required lung examination who underwent simultaneously non-contrast ULD CT and standard chest CT scan were included in this prospective study. Standard chest CT was reference standard using ASIR-V at 50% strength (50%ASIR-V). They are divided into two groups: ULD CT scanning were divided into two groups: ULD-CT (UL-A group,  $n = 46$ , 100 kVp and 50mA) using 50%ASIR-V and DLIR at high level (DLIR-H); ULD-CT (UL-B group,  $n = 56$ , 100 kVp and 30 mA) using 50%ASIR-V and DLIR-H. Radiologists detected and measured nodules. The size, maximum layer area, volume, maximum floor area, 3D long diameter, CT value and standard deviation (SD) of nodules were measured. The signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were to calculate. Two experienced radiologists were subjectively scored image quality and special morphological signs of partial pulmonary nodules using a 5-point method. The Difference between ULD and reference images were compared.

## RESULTS

304 nodules in 294 (96.71%) for UL-A group (50%ASIR-V and DLIR-H), 297 nodules in 280 (94.28%) for UL-B group (50%ASIR-V and DLIR-H) were detected. The detection rate of solid nodules of 99.59%, pure ground glass nodules of 84.48%, and partial solid nodules of 100% for UL-A group, and the detection rate of solid nodules of 97.19%, pure ground glass nodules of 78.26% and

partial solid nodules of 100% for UL-B group, respectively, with the same performance observed at different nodule types between 50%ASIR and DLIR. There were no differences in the size, CT value, SD, total volume, maximum layer area, and 3D long diameter of pure ground glass nodules and solid nodules and SNR in low-dose and standard-dose images for UL-A and UL-B group ( $p>0.05$ ). The DLIR-H images had significantly higher CNR of nodules, lower lung tissue noise than ASIR-V% images for UL-A and UL-B group (all  $P < 0.001$ ). There was no difference in the subjective score of overall image quality between ASIR-V and DLIR-H for UL-A and UL-B group ( $p>0.05$ ).

## CONCLUSION

s Compared with ASIR-V, DLIR-H can significantly improve image quality. The lung lesion measurements in ULD CT scan images based on DLIR reconstruction have high correlation and low difference with CT images of standard dose.

## CLINICAL RELEVANCE/APPLICATION

DLIR can reduce the noise of CT images and provide high image quality. Low-dose chest CT combined with DLIR is conducive to the wide clinical application under the condition of greatly reducing radiation dose.

## R5A-SPPH-6 Impact of the Third Generation and Deep Learning Iterative Reconstructions on Spatial Resolution with Dual energy CT-Dependency on Contrast and Dose

Participants  
Jimmy Zhou, PhD, Los Angeles, CA (*Presenter*) Nothing to Disclose

## PURPOSE

The effects of third generation and deep learning iterative reconstruction (ASIR-V and DLIR) are non-linear. The degree of the impact may depend on the lesion contrast and radiation dose. The objective of this study was to quantify this impact in the context of spatial resolution versus noise reduction.

## METHODS AND MATERIALS

An anthropomorphic liver phantom was used. The liver contains various lesions of different contrast and shapes. The phantom was scanned using a GE Revolution CT at the dual-energy mode with CTDIvol of 14 mGy and 5.6 mGy (slice thickness 2.5 mm). ASIR-V from 0 to 100% and DLIR low, medium, and high were applied to images reconstructed using 70 keV. Thin rectangular regions of interest (ROI of 3 pixels width) were drawn across the boundary of the selected lesions and the horizontal profiles were obtained. The average slopes of the profiles were used as a metric delineating the lesion edge sharpness (a surrogate for spatial resolution). Meanwhile, the contrast-to-noise ratio (CNR) and noise suppression ratio (NSR), defined as the noise divided by noise at ASIR-V 0 of each lesion were also measured at both doses. For each lesion, the normalized edge sharpness was defined as the profile slope divided by the slope at ASIR-V 0 and CTDIvol of 14 mGy.

## RESULTS

The lesion edge sharpness was found significantly reduced at low dose (5.6 mGy). The application of ASIR-V and DLIR further reduced the sharpness albeit improving CNR, but DLIR enhanced the sharpness as compared with higher ASIR-V fractions (above 70%) with improved NSR. Furthermore, the effect of ASIR-V and DLIR depends on the contrast itself: the lower the contrast is, the more blurred the edge is. For the contrast higher than 70 HU, the edge blurring is much less. In addition, the noise suppression was also contrast dependent with the biggest suppression at lowest contrast.

## CONCLUSION

s The degree of spatial resolution loss was found to be dependent on the lesion contrast and radiation dose for a given ASIR-V fraction or DLIR strength. The noise suppression also increases as the contrast decreases. DLIR enhances the sharpness as compared with higher ASIR-V fractions (above 70%) with improved NSR.

## CLINICAL RELEVANCE/APPLICATION

Assist adequate use of iterative reconstructions for low contrast lesions

## R5A-SPPH-7 Assessment of Semi-automatic Whole-body Fat Quantification Using Ultra Low Dose CT Using Iterative and Artificial Intelligence-based Reconstruction in an In-vivo Swine Model: An Intra Individual Analysis

Participants  
Josephine Berger, Tuebingen, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the stability of semi-automatic body fat quantification in real low-dose swine CT scans using iterative and AI-based reconstruction.

## METHODS AND MATERIALS

Ten sedated swines received CT scans with fixed tube voltage and tube-current on the same 3rd generation dual-source scanner. Consecutive scans with reduced mAs to 50%, 25%, 10%, and 5% were performed. All scans were reconstructed using iterative reconstruction strength 2 (IR2) and a novel AI-based reconstruction algorithm (AIR), resulting in 10 datasets per swine. 100% IR2 served as the reference standard. Whole-body fat tissue volume was measured using threshold-based semi-automated segmentation (-200 HU to -40 HU). Total body fat volume, mean HU values and noise (standard deviation of HU) were extracted and compared via adequately corrected mixed-effects analysis.

## RESULTS

The volumetric segmentations were stable down to 25% ( $p=0.104$ ) using IR2 and down to 5% with AIR. Compared to the reference standard, mixed effects analysis showed stable CT values in both groups down to 10% mAs but significant HU bias at 5% IR2 ( $p<0.001$ ), while AIR results were still stable ( $p=0.136$ ). Both datasets had significantly increased image noise at lower radiation doses. Interestingly, 25% AIR produced similar noise to 100% IR2.

## CONCLUSION

s Body fat volume analysis is possible down to 25% radiation dose using conventional iterative reconstruction, although there is significantly higher image noise. AI-based reconstruction mitigates this limitation at the same dose level by enabling comparable noise levels to 100% IR2. Furthermore, AI-based reconstruction preserves CT values and volumetric results better than iterative reconstruction at only 5% mAs.

#### **CLINICAL RELEVANCE/APPLICATION**

In conclusion, our study strongly suggests that by employing AI-based reconstruction, accurate semi-automated quantification of adipose tissue volume can be accomplished with minimal radiation exposure to the patient, thus further empowering CT as a valuable tool in body composition analysis.

#### **R5A-SPPH-8 Impact of the Tube Start Angle on Patient Dose in Single and Dual Source Spiral CT**

Participants  
Edith Baader, Heidelberg, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To determine the radiation dose in single source CT (SSCT) and dual source CT (DSCT) scans as a function of tube start angle and spiral pitch value to identify the dose reduction potential by selecting the optimal start angle.

#### **METHODS AND MATERIALS**

Previous studies have shown that dose to certain radiosensitive organs in spiral CT scans could substantially be reduced by optimizing the tube start angle [MedPhys 36: 5654-5664, 2009][MedPhys 38(6):3177-85, 2011]. This applies particularly to small peripheral organs. This study investigates the impact of the tube start angle on the effective dose as a measure of the overall radiation risk. Furthermore, in addition to SSCT systems with constant tube current (noTCM) as in the previous studies, also today's standard tube current modulation minimizing the mAs-product (mAsTCM) and DSCT systems were considered. Using Monte Carlo simulations, dose values for different tube positions with an angular increment of 10° and a longitudinal increment of 5 mm were simulated in the thorax region of six adult patients based on clinical CT data. The thorax region was chosen as short scan times and thus high pitch values are particularly relevant in this body region; in total, dose simulations were performed over a scan range of 35 cm with a collimation of 38.4 mm. From the resulting dose distributions, organ doses and effective dose were determined as a function of tube angle and longitudinal position. Using these per view dose data, the individual organ doses, as well as the total effective dose, were determined for spiral scans with (mAsTCM) and without (noTCM) tube current modulation with pitch values ranging from p=0.5 to 1.5 for SSCT and up to p=3.0 for DSCT. The dose reduction of the optimal start angle relative to the worst start angle in terms of dose was determined.

#### **RESULTS**

Dose reductions for single organs are highly organ-specific. While the tube start angle affects the lung dose less than 5%, higher variations occur e.g. for the dose to the thyroid gland and the stomach. The impact of mAsTCM depends on the organ and the pitch value; however, the dose reductions are in the same order of magnitude. For the effective dose, dose reductions of up to 7% for SSCT and up to 20% for DSCT can be achieved in particular for high pitch values when selecting the optimal start angle for the simulated patients.

#### **CONCLUSION**

s Variation of the tube start angle in spiral scans exhibit substantial differences in radiation dose for high pitch values. Vendors should provide a method to automatically select the optimal scan start angle to minimize patient risk.

#### **CLINICAL RELEVANCE/APPLICATION**

By controlling the start angle in spiral scans, radiation dose to various organs and effective dose and thus patient risk can be significantly reduced.

#### **R5A-SPPH-9 Fetal Doses in the Most Frequent Diagnostic Radiology Procedures in a Pregnant Patient: Results of In-phantom Measurements**

#### **PURPOSE**

Emergencies during pregnancy do happen! Cardio/cerebrovascular, urologic, GI emergencies and trauma can be singled out. The medical team may be in doubt when choosing proper diagnostic imaging that uses ionizing radiation, potentially causing a delay in diagnosis and treatment. The purpose of this research was to experimentally measure the dose to the fetus during diagnostic imaging and fluoroscopy-guided minimally invasive procedure on a newly developed, anthropomorphic phantom of a pregnant female.

#### **METHODS AND MATERIALS**

A Tena phantom, representing a pregnant female in 2nd trimester, was scanned with imaging modalities that use ionizing radiation (Figure 1). Appropriate protocols for probable clinical emergencies in pregnant females were used: NC CT and CTA in stroke protocol, DSA in ischemic stroke endovascular treatment, PA CTA, trauma CT, abdomen/pelvis NC CT, abdominal radiography and fluoroscopy in nephrostomy placement. RPL dosimeters were placed in the fetal head and body, placenta and adjacent structures of interest, and experimental measurements were performed.

#### **RESULTS**

The highest measured doses in the fetal head and body were recorded in the trauma CT and abdomen/pelvis NC CT. 34,7 mGy and 23,7 mGy were measured in the head, and 32,5 mGy and 19,6 mGy in the body. In all other scanning protocols, the dose to the fetal head and body did not exceed 2 mGy.

#### **CONCLUSION**

s For most imaging scenarios, measured fetal doses were below 2 mGy except in scanning protocols where the fetus was in the field of direct ionizing radiation. The highest measured dose to the fetal head of 34,7 mGy in the performed WBCT was below 50 mGy and well below the 100 mGy recommended by the ICRP above which the deterministic effects on the developing fetus rise. The measured fetal doses for all clinical scenarios are consistent with published data. It should be kept in mind that the fetus in a developed phantom is with its head faced cranially. As fetuses in 2nd trimester are freely movable in the uterus, in a different

position, measured doses could be even lower. The research has limitations as it can be seen as a case report. Patient-specific physical phantoms and computational models are time-consuming and matching anthropomorphic physical phantoms to the size and location of the fetus within the maternal body is almost impossible. This is the reason why faster methods are used for fetal dose estimation in clinical practice. Such methods usually use typical doses from references or use one of a number of available dosimetry software.

#### **CLINICAL RELEVANCE/APPLICATION**

Although there have been guidelines that state how it is possible to carry out imaging diagnostics based on ionizing radiation in pregnant women, their application may still cause anxiety to some radiologists.

R5A-SPVA

### Vascular Imaging Thursday Poster Discussions I

#### Sub-Events

#### **R5A-SPVA-1 The Application Value of Black Blood Imaging Based on CT Flexible Subtraction Technology in Carotid Artery**

##### **PURPOSE**

The CT black blood images may potentially offer more insightful information. In this study, we utilized MR vessel wall imaging of carotid arteries as a gold standard to investigate the improvement effect of carotid soft plaque image quality in CT black blood images.

##### **METHODS AND MATERIALS**

After carotid artery CT angiography (CTA) examination, the images underwent reverse flexible contrast enhancement and CE-BOOST technology to achieve CT black blood. The study was divided into four groups, with Group A being the cervical artery CTA examination group, Group B being the CTA delayed scan group, Group C being the CT black blood group with image reconstruction after 4 minutes and 30 seconds of delay, and Group D being the MR vascular wall imaging group. The subjective evaluation score was 5 points, analyzing multiple dimensions such as the lumen display's clarity, the vessel wall's sharpness, and the presence of plaques. The objective scoring was conducted on the neck artery CTA images, CTA delayed scanning group, and CT black-blood group. The evaluation was based on the SD value of the cervical artery plaque lesion adjacent to the sternocleidomastoid muscle,  $CNR=CT_{lumen}-CT_{sternocleidomastoid\ muscle}/SD_{sternocleidomastoid\ muscle}$ , and  $SNR=CT_{lumen}/SD_{lumen}$ . We conducted the one-way ANOVA, the non-parametric test and Kappa analysis for subjective evaluation score, with  $p<0.05$  indicating a statistically significant difference.

##### **RESULTS**

The study included a total of 20 patients, of whom 12 were male and 8 were female, with an average age of 63 years. The differences in BMI (23.3 vs. 23.5 vs. 24.0) were not statistically significant ( $p<0.05$ ). Objective scoring: in the comparison between groups A, B, and C, group A showed advantages in CNR ( $88.64\pm 30.14$  vs.  $3.74\pm 3.85$  vs.  $-50.25\pm 15.44$ ,  $p=0.000$ ) and in SNR ( $61.27\pm 27.60$  vs.  $6.99\pm 3.91$  vs.  $-19.50\pm 6.91$ ,  $p=0.000$ ); there was no statistically significant difference in SD values ( $5.29\pm 1.34$  vs.  $5.28\pm 2.36$  vs.  $3.96\pm 1.24$ ,  $p=0.487$ ). Subjective scoring: group D > group C > group A > group B, (4.8 vs. 4.3 vs. 4 vs. 3.6,  $p=0.025$ ).

##### **CONCLUSION**

Flexible contrast-enhanced cervical artery CT black blood imaging has a high diagnostic value with a transparent vessel wall and plaque morphology display. Its diagnostic value is superior to conventional CTA scans. Therefore, we recommend adding a delayed scan with flexible contrast-enhanced CT black blood imaging during cervical artery CTA scanning.

##### **CLINICAL RELEVANCE/APPLICATION**

The CT black-blood imaging technology of the carotid arteries enables clear visualization of the anatomy and structure of the vessel wall, overcoming the limitations of traditional carotid CTA. Compared with MR vascular wall imaging, CT black-blood imaging of the carotid arteries also has good diagnostic value.

#### **R5A-SPVA-2 Performance of an Artificial Intelligence Algorithm for Quantifying the Maximum Thoracic Aortic Diameter in Patients with Aortic Pathologies**

Participants

Nicola Fink, MD, Munich, Germany (*Presenter*) Nothing to Disclose

##### **PURPOSE**

Given the high mortality associated with acute aortic events, early detection and appropriate monitoring of aortic dilatation and aneurysm are crucial. However, accurate follow-up CT measurements remain tedious and time-consuming. In this context, artificial intelligence (AI) reduces missed findings and inter-/intra-reader variability. However, most studies evaluated this at predefined landmarks only, which may not necessarily correspond to the largest diameter. This study aimed to assess the performance of a deep neural network (DNN)-based algorithm in quantifying aortic diameters at the most dilated location in a heterogeneous population.

##### **METHODS AND MATERIALS**

A total of 100 patients (67.2 [56.0-73.4] years; 60.0% male) with thoracic aortic dilatation/aneurysm were scanned according to institutional CT protocols. Nearly two third of the included patients ( $n=62$ ) had pathologic findings of the thoracic aorta due to prior repair ( $n=29$  surgical;  $n=17$  endovascular;  $n=10$  both) and/or aortic dissection ( $n=42$ ). Segmentation and measurements of the thoracic ascending (AA) and descending Aorta (DA) were performed on non- and contrast-enhanced CT scans using a combination of multiple DNN models which were previously trained on 1582 CT datasets. All measurements were compared to manual measurements performed by two radiologists, overall as well as in the following subgroups: 1) AA vs. DA; 2) non-obese vs. obese patients ( $BMI=30\text{kg}/\text{m}^2$ ); 3) patients without vs. with aortic repair; 4) patients without vs. with aortic dissection.

## RESULTS

Mean AI-based automated and manual diameters significantly differed (non-contrast: 40.9mm [37.3-48.2] vs. 42.9mm [38.9-50.0],  $p<0.001$ ; contrast-enhanced: 40.9mm [37.3-48.2] vs. 40.3mm [36.6-46.9],  $p<0.01$ ) but showed excellent correlation and agreement ( $r>0.85$ ;  $ICC>0.9$ ). Depending on the subgroup, automated and manual values were similar in the AA but significantly different in the DA ( $p<0.001$ ), similar in obese but significantly different in non-obese patients ( $p<0.01$ ), and similar in patient without aortic repair or dissection but significantly different in patients with such pathological conditions of the aorta ( $p<0.001$ ). However, in all subgroups automated diameters showed strong correlation and excellent agreement with corresponding manual values ( $r>0.84$ ;  $ICC>0.9$ ).

## CONCLUSION

s This DNN-based algorithm enables accurate automated assessment of the largest aortic diameter in a heterogenous patient population with various aortic pathologies.

## CLINICAL RELEVANCE/APPLICATION

By showing high agreement with manual measurements, this algorithm offers the possibility to support radiologists in clinical practice, thus increasing efficiency, with good results even in a heterogenous population.

### Breast Imaging Thursday Poster Discussions II

#### Sub-Events

#### **R5B-SPBR-1 Comparison of Advanced Breast Cancers by Ethnicity: Digital Breast Tomosynthesis versus Digital Mammography**

##### Participants

Liane E. Philpotts, MD, Madison, CT (*Presenter*) Nothing to Disclose

##### PURPOSE

Increasing early detection of nonlethal breast cancers is the main function of screening. Advanced cancers - characterized by larger size, lymph node involvement, or aggressive molecular subtypes - are those that carry a worse prognosis. Our prior data demonstrated a significant decrease in the rate of advanced cancers with digital breast tomosynthesis (DBT) screening compared with 2D full-field digital mammography (DM). The purpose of this study was to examine how the rate of advanced cancers varied with patient race/ethnicity.

##### METHODS AND MATERIALS

Our detailed database of 1407 breast cancers (142 DM, 1265 DBT) was analyzed over 13 years (DM 2008-2011, DBT 2011-2021) of screening with DBT was analyzed. Advanced cancers were defined by TMIST criteria (invasive cancers >2cm, HER2+ or triple negative cancers >1cm, one or more positive axillary lymph nodes, distant organ spread). The rates of advanced compared with non-advanced cancers were assessed by patient race/ethnicity. Statistical analysis was performed using unpaired T-tests and Chi Square with  $p < 0.05$  considered significant.

##### RESULTS

Of 1265 DBT cancers, race/ethnicity data was available in 1246 (98.5%) and was as follows: 935 (75%) White, 177 (14%) Black, 73 (6%) Hispanic, 28 (2%) Asian, 33 (3%) other. Of 968 invasive cancers, the ethnicity data was available in 952 (98.3%): 732 (77%) White, 129 (14%) Black, 45 (5%) Hispanic, 18 (2%) Asian, 28 (3%) other. Of the 968 invasive cancers, 316 (32.6%) were considered advanced. The rate of advanced to non-advanced invasive cancers was not significantly different by ethnic group, although it trended higher among Black and Asian patients: White 230/732 (31.4%), Black 47/129 (36.4%), Hispanic 14/45 (31.1%), Asian 7/18 (38.9%), Other 8/28 (28.6%). Similarly for the DM cohort, no significant differences were noted in the rates of advanced cancers between ethnic groups: White 23/58 (39%), Black 9/15 (60%), Hispanic 3/9 (33%), Asian 1/3 (33%), other 7/14 (50%). However, when comparing the rates between DBT and DM, significant reduction was noted in the White and Black groups: White 31.1% vs 39% and Black 36.4% vs 60%, DBT vs DM respectively ( $p < 0.07$ ).

##### CONCLUSION

s With DBT, advanced cancers rates varied slightly among ethnic groups but overall was not significantly different. However, when compared to DM screening, advanced cancers were significantly reduced in the White and Black populations.

##### CLINICAL RELEVANCE/APPLICATION

Screening with DBT helps reduce advanced cancers, particularly in the White and Black/African American populations.

#### **R5B-SPBR-2 Ultrasound-based Radiomics for Early Predicting Response to Neoadjuvant Chemotherapy in Patients with Breast Cancer: A Systematic Review with Meta-analysis**

##### PURPOSE

This study aimed to evaluate the diagnostic accuracy of ultrasound imaging (US)-based radiomics for early prediction of response to neoadjuvant chemotherapy (NAC) in breast cancer patients.

##### METHODS AND MATERIALS

We systematically searched PubMed, Embase, Cochrane Library, and Web of Science databases up to 1 January 2023 for eligible studies. The methodological quality of the included studies was assessed using the Diagnostic Accuracy Study Quality Assessment 2 (QUADAS-2) and Radiomics Quality Score (RQS) tools. We performed meta-analyses to summarize the diagnostic efficacy of US-based radiomics on response to NAC in breast cancer patients.

##### RESULTS

Eight studies proved eligible. Eligible studies had an average RQS score of 12.88 (35.8% of the total score), with RQS score ranging from 8 to 19. Most studies demonstrated the unclear or low risk of bias in the domains of QUADAS-2. In the meta-analyses, the pooled sensitivity, specificity, positive likelihood ratio, negative likelihood ratio, and diagnostic odds ratio were 0.87 (95% CI: 0.81 - 0.92), 0.78 (95% CI: 0.72 - 0.83), 4.02 (95% CI: 3.18 - 5.08), 0.16 (95% CI: 0.10 - 0.25), and 25.17 (95% CI: 15.10 - 41.95), respectively. Results from subgroup analyses showed that prospective studies appeared to have better sensitivity than retrospective studies. Sensitivity analyses showed similar results to our primary analyses.

## CONCLUSION

s US-based radiomics could be considered an important adjuvant method to evaluate the response of breast cancer to NAC. However, more multicenter prospective studies are needed to further validate our conclusions and explore better radiomics algorithm models.

## CLINICAL RELEVANCE/APPLICATION

Our results suggested that US-based radiomics can be used as an important adjuvant method to evaluate the response of breast cancer to NAC, based on its good diagnostic performance.

## R5B-SPBR-3 Breast Ultrasound Optimization Training for Radiology Residents Utilizing an Interactive Online Module

### PURPOSE

The primary goal of the project was to create an interactive online learning module to teach breast ultrasound optimization to radiology residents and then assess whether the learning module was effective at teaching these concepts to radiology residents.

### METHODS AND MATERIALS

An on-line interactive module teaching concepts of breast ultrasound optimization was created by the lead author utilizing Articulate Storyline 3 Software. The on-line module included navigational toolbars, clickable parameters, and real breast ultrasound examples illustrating concepts of breast ultrasound optimization. Residents were assigned an anonymous study identification number. Participating radiology residents first filled out an on-line questionnaire asking them to rate their subjective breast ultrasound optimization knowledge. They then completed an on-line pre-test consisting of 24 multiple choice questions. Then, participants engaged in the interactive online training module. After completing the online training module, participants completed an online post-test (same questions as the pre-test). They also then completed a questionnaire rating new subjective breast ultrasound optimization knowledge and a questionnaire rating the effectiveness of the training module.

### RESULTS

Overall pre-test mean test scores were 54.4 +/- 4.4% and overall post-test mean scores were 78.9 +/- 3.4%. The mean score significantly improved between the pre-test and post-test by 24.4% (95% CI: [14.2%, 34.6%], P=0.0002). The mean subjective knowledge score significantly improved between the pre-test and post-test by 1.4 (95% CI: [0.9,1.9], P less than 0.0001). Subjective satisfaction with the effectiveness of the module was high: 4.4 +/- 0.2 out of 5.

## CONCLUSION

s This study suggested that an interactive online module could be effective at teaching concepts of breast ultrasound optimization to radiology residents and that learners found it to be a useful activity.

## CLINICAL RELEVANCE/APPLICATION

A breast ultrasound must be properly optimized to avoid errors in interpretation and management. Therefore, radiologists who perform breast ultrasound exams must be proficient at recognizing suboptimal images and be familiar with techniques used to optimize the breast ultrasound image. However, there is no formal program to teach these skills to radiology residents at our institution. In addition, it can be difficult to cover all of the detailed concepts of breast ultrasound optimization during a busy clinical day when scanning time and faculty teaching time can be limited. Online interactive modules can be helpful to teach such concepts allowing flexibility of learning.

## R5B-SPBR-5 Comparison of Automated Breast Ultrasound and Hand-held Breast Ultrasound in Preoperative Evaluation of Early-stage Breast Cancer: A Multicenter Prospective Study

### Participants

Ji Soo Choi, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

### PURPOSE

To compare automatic breast ultrasound (ABUS) and hand-held breast ultrasound (HHUS) as an adjunct to full-field digital mammography (FFDM) for the preoperative evaluation of local tumor extent in women with newly diagnosed early-stage breast cancers

### METHODS AND MATERIALS

This multicenter prospective study included consecutive women with early-stage breast cancers (clinical Tis, T1-2/N0) treated by surgery who had undergone ABUS and HHUS adjunct to FFDM for preoperative local tumor staging between Oct 2019 and Apr 2021. Radiologists independently sought the index cancer and additional ipsilateral and contralateral cancers using ABUS plus FFDM (ABUS/DM) or HHUS plus FFDM (HHUS/DM). Pathologic diagnoses of all suspected lesions were used as reference standards. Sensitivity and specificity obtained for ABUS/DM and HHUS/DM were compared. Noninferiority of ABUS/DM was assessed in sensitivity at a margin of 5%.

### RESULTS

A total of 659 women (mean age, 50.5 years  $\pm$  9 [SD]) were included in the study. Seventy-nine women (12.0%, 79/659) exhibited additional cancers: 64 additional ipsilateral cancers (51 multifocal and 13 multicentric) and 15 contralateral cancers. For index cancers, both ABUS/DM and HHUS/DM showed sensitivities of 100%. ABUS/DM showed non-inferior sensitivity to HHUS/DM for additional ipsilateral cancers (71.9% [46/64] vs. 75.0% [48/64]; P=0.617) and higher sensitivity than HHUS/DM for contralateral cancers (86.7% [13/15] vs. 60.0% [9/15]; P=0.046). Specificities were not significantly different between ABUS/DM and HHUS/DM for both additional ipsilateral cancers (97.7% [581/595] vs. 97.0% [577/595]; P=0.317) and contralateral cancers (97.8% [630/644] vs. 98.3% [633/644]; P=0.467).

## CONCLUSION

s ABUS/DM showed non-inferior sensitivity to HHUS/DM with similar specificity in diagnosing additional ipsilateral and contralateral breast cancers in women with early-stage breast cancers Thus, ABUS may be used as an alternative to HHUS as a preoperative staging tool for early-stage breast cancer.

## CLINICAL RELEVANCE/APPLICATION

There is limited literature on ABUS for preoperative evaluation of newly diagnosed breast cancer patients. ABUS may be used as an alternative to HHUS as a preoperative staging tool for early-stage breast cancer, for whom preoperative axillary US is not essential.

### R5B-SPBR-6 Using Artificial Intelligence To Assess The Risk Of Malignancy In Breast Lesions Identified On Second-Look Ultrasound

#### Participants

Almir Bitencourt, MD, PhD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

Rachel Cruz, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the results of an artificial intelligence (AI) algorithm-based software for predicting the risk of malignancy in breast lesions identified on second-look ultrasound.

#### METHODS AND MATERIALS

This was a retrospective and single-center study, approved by the Institutional Review Board, which evaluated 628 second-look ultrasound examinations performed between January and December 2022 at a reference cancer center. 486 cases were excluded because they did not have had prior magnetic resonance imaging (MRI) or biopsy performed in the same institution, or because no corresponding lesion was found on second-look ultrasound. MRI and ultrasound features were classified according to the BI-RADS lexicon criteria. Subsequently, the images were analyzed using Koios DS Breast software (Koios Medical, USA). The software results were divided into: benign or probably benign (BIRADS 2/3), low or intermediate suspicion (BIRADS 4A/4B), high suspicion or probably malignant (BIRADS 4C/5). The histopathological result was considered the gold standard.

#### RESULTS

164 lesions from 142 patients were included. The mean age of the patients was 48 years (21-78 years) and the mean mass size on ultrasound was 17 mm (3-70 mm). At MRI, 25 lesions (15.2%) were classified as BIRADS 3, 120 (78.0%) as BIRADS 4, and 11 (6.7%) as BIRADS 5. At ultrasound, there were 93 masses (56.1%) and 72 non-mass findings (43.9%), of which 15 lesions (9.1%) were classified as BIRADS 3, 141 (86.0%) as BIRADS 4, and 8 (4.9%) as BIRADS 5. Analysis using the software classified 23 lesions (14.0%) as BIRADS 2/3, 113 (68.9%) as BIRADS 4A/4B, and 28 (17.1%) as BIRADS 4C/5. Core needle biopsy was performed in 129 (78.7%) and vacuum-assisted biopsy in 35 (21.3%), which yielded 131 (79.9%) benign histologic findings (24 with associated atypia) and 33 (20.1%) malignant results. None of the lesions classified as BIRADS 2/3 using the software were malignant, while 2 lesions classified as BIRADS 3 on MRI and 1 lesion classified as BIRADS 3 on ultrasound were malignant. The predictive positive value (PPV) of lesions classified as BIRADS 4A/4B and BIRADS 4C/5 by the software were 17.7% and 46.4%, respectively.

#### CONCLUSION

The AI software demonstrated high sensitivity to predict the risk of malignancy in lesions identified on second-look ultrasound, contributing to a more accurate indication of percutaneous biopsies. It can be used to avoid unnecessary biopsies in lesions classified as benign or probably benign (BIRADS 2/3).

## CLINICAL RELEVANCE/APPLICATION

AI can be used to predict the risk of malignancy in lesions identified on second-look ultrasound, and to avoid unnecessary biopsies.

### R5B-SPBR-7 Multimodal Artificial Intelligence (AI) in Diagnostic Imaging: Added Value of Breast Ultrasound (US) in Symptomatic Patients

#### Participants

Beatriu Reig, MD, MPH, New York, NY (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to explore the accuracy of US alone, full-field digital mammography (FFDM) and/or digital breast tomosynthesis (DBT) alone, and multimodal AI in the diagnostic evaluation of the symptomatic patient.

#### METHODS AND MATERIALS

In this retrospective and IRB-approved study, our IRB-approved multimodal AI system included full-field digital mammography (FFDM), digital breast tomosynthesis (DBT) and hand-held breast ultrasound (US) examinations performed 2010-2020, with 1,964,416 exams in 324,978 patients. We used a patient-based training/validation/testing split of 60%/10%/30%. Our test set consisted of 1371 women (1490 exams) who underwent both diagnostic FFDM or FFDM/DBT with targeted ultrasound for a symptomatic indication (pain, palpable area of concern, nipple discharge). Accuracy of the AI system was evaluated for malignancy for DBT/FFDM alone, US alone, and multimodal AI by calculating AUROC, sensitivity, specificity, PPV and NPV. Cancer types (pathology-confirmed within 120 days of the imaging) detected by DBT/FFDM alone, US alone, and multimodal AI were compared. We dichotomized AI's probabilistic predictions into biopsy vs. no biopsy decisions by matching the clinical biopsy rates. Specificity was therefore standardized across categories.

#### RESULTS

Of 1,371 patients who underwent same day diagnostic FFDM/DBT and US (average age 54.4, standard deviation 11.63), the AI model AUROC for breast cancer detection was 0.956 for multimodal AI, 0.864 for FFDM/DBT only, and 0.944 for US only. Sensitivity was 89.2% (58/65 cancers) for multimodal, 60% (39/65) for FFDM/DBT only, and 84.6% (55/65) for US only. 61.6% (845/1371) of women had dense breasts. For women with dense breasts, AUROC was 0.98 for multimodal, 0.848 for FFDM/DBT only, and 0.963 for US only, with sensitivity of 92.7% (38/41), 58.5% (24/41) and 92.7% (38/41). For women with non-dense breasts, AUROC was 0.919 for multimodal, 0.895 for FFDM/DBT only, and 0.900 for US only, with sensitivity of 83.3% (20/24), 62.5% (15/24) and 70.8% (17/24). 4.61% (3/65) cancers were in women under 40. For women under 40, multimodal AUC=0.982, FFDM/DBT AUC=0.894, US=0.994.

#### CONCLUSION

A multimodal AI system showed higher performance for breast cancer detection in symptomatic diagnostic evaluations than

FFDM/DBT or US models, including women with both dense and non-dense breasts. An US-only model outperformed other models for women < 40.

#### **CLINICAL RELEVANCE/APPLICATION**

Diagnostic workup in symptomatic patients often requires both mammography and ultrasound. Use of multimodal AI in the diagnostic breast cancer setting improves cancer detection regardless of breast density.

### **R5B-SPBR-8 Comparison of Screening Recall Rates When Automated Breast Ultrasound is Coupled or Uncoupled with Screening Mammogram**

#### **PURPOSE**

To compare the screening recall rates (RR) for women with dense breast tissue who underwent automated breast ultrasound (ABUS) either as a coupled exam following same day screening mammogram or at a future date within the one-year screening interval.

#### **METHODS AND MATERIALS**

This single-institution retrospective review included women aged 35-90 with heterogeneously dense or extremely dense breast tissue who had a screening mammogram from June 2016 to June 2021 and an ABUS within the one-year screening interval. The RR for patients who underwent screening mammogram coupled with ABUS on the same day were compared to the RR for those who had screening mammogram followed by ABUS 1-364 days later. Cancer detection rates (CDR) between the two groups were also compared.

#### **RESULTS**

A total of 5,813 screening mammograms were performed on patients who met inclusion criteria. The study population RR was 2.5% (147/5,813) for mammogram and 4.3% (249/5,813) for ABUS, with a CDR of 5.3/1,000 (31/ 5,813). Of the 5,813 patients, same day ABUS was performed on 3,347 (58%) and 2,466 (42%) underwent ABUS 1-364 days following mammogram. The combined RR for the coupled screening mammogram and ABUS group was 5.9% (196/3,347) with 3.1% (105/3,347) RR on mammogram, 3.4% (114/3,347) RR on ABUS, and CDR of 4.2/1,000 (14/3,347). For mammogram and ABUS performed independently, the mammogram RR was 1.7% (42/2466) and the ABUS RR was 5.5% (135/2466), with a CDR of 6.9/1,000 (17/2,466). There was a statistically significant difference in the combined RR of coupled mammogram and ABUS compared to mammogram performed independent of ABUS ( $p<0.0001$ ), between coupled and uncoupled mammogram ( $p=0.0008$ ), and between coupled and uncoupled ABUS ( $p=0.0002$ ). There was no statistically significant difference in CDR between the coupled and uncoupled groups ( $p=0.2223$ ).

#### **CONCLUSION**

s Mammogram and ABUS interpreted as a same day, coupled exam increases both the individual mammogram RR and the combined mammogram/ABUS RR. Conversely, the ABUS RR is lower when ABUS is interpreted as a coupled exam compared to ABUS uncoupled from mammography. There is no statistically significant difference in CDR when ABUS is coupled or uncoupled with screening mammogram.

#### **CLINICAL RELEVANCE/APPLICATION**

This study supports scheduling of ABUS according to patient preference or optimal practice workflow as there is no overall screening outcomes benefit to preferential scheduling of ABUS as a coupled or uncoupled exam.

## Abstract Archives of the RSNA, 2023

R5B-SPCA

### Cardiac Imaging Thursday Poster Discussions II

#### Sub-Events

#### **R5B-SPCA-1 Simultaneous Single-breathhold Cardiac T1, T2, T2\*, and Fat Fraction Mapping with Rosette MR Fingerprinting**

##### Participants

Evan Cummings, Ann Arbor, MI (*Presenter*) Nothing to Disclose

##### PURPOSE

In this work, we present a method for mapping cardiac T1, T2, T2\*, and fat fraction during a single breathhold acquisition. Quantitative MRI can be used to diagnose and evaluate a wide range of cardiac pathologies: T1 mapping for myocarditis, myocardial infarction, and myocardial amyloidosis<sup>1</sup>; T2 mapping for myocardial edema injury<sup>1</sup>; T2\* mapping for iron deposition<sup>2</sup>; and fat fraction mapping to determine fat content of the myocardium<sup>3</sup>. MR Fingerprinting (MRF) is a method for rapidly measuring multiple tissue properties, including T1 and T2<sup>4,5</sup>. MRF data can be collected along a rosette trajectory<sup>6</sup>, a multi-echo trajectory which has previously been used in cardiac applications to map T2\*<sup>7</sup> and fat fraction<sup>8</sup>. In this work, MRF with the rosette trajectory is extended to enable T1, T2, T2\*, and fat fraction mapping in a single breathhold.

##### METHODS AND MATERIALS

A healthy volunteer was scanned on a 1.5T MAGNETOM Sola (Siemens Healthineers, Erlangen, Germany) using a breathheld 15 heartbeat ECG-triggered sequence with the following parameters: TR=20.41 ms, TE=0.84 ms, variable flip angles up to 20°, 1.6x1.6x8mm voxel size, 300x300 mm<sup>2</sup> FOV, with multiple inversion and T2 preparation pulses. Data were acquired with a 23 lobe rosette with an 18.5 ms readout and 0.8 ms echo spacing. Images were reconstructed using an iterative approach with a cluster-based sparsity regularizer. T1 and T2 values were mapped using pattern matching<sup>4</sup>, T2\* values were calculated by fitting decay curves along the rosette echo images<sup>7</sup>, and fat fraction was extracted using Hierarchical IDEAL<sup>9</sup>. The technique was validated in phantoms for accuracy. Volunteer reference T1, T2, and T2\* maps were collected using Siemens Myomaps sequences.

##### RESULTS

Mean myocardial measurements were: T1= 1137±102 ms, T2= 44.5±7.8 ms, T2\*= 22.4±5.0 ms, PDFF= 3.6±3.7%. Rosette MRF T1 values are higher than published MOLLI T1 values<sup>10</sup>, and T2 values are lower than published T2-prep bSSFP values<sup>11</sup>, similar to prior MRF studies<sup>5,8</sup>. T2\* and PDFF values agree with published literature<sup>3,4</sup>.

##### CONCLUSION

s Rosette MRF can be used to simultaneously map T1, T2, T2\*, and fat fraction in the heart in a single-breathhold acquisition. References: 1. Messroghli DR et al. JCMR 2017 2. Triadyaksa P et al. JMRI 2020 3. Ng ACT et al. Circ Cardiovasc Imaging 2018 4. Ma D et al. Nature 2013 5. Hamilton J et al. MRM 2017 6. Noll D IEEE Trans Med Imaging 1997 7. Bush AM et al. JMRI 2020 8. Liu Y et al. Front Cardiovasc Med 2022 9. Tsao J Jiang Y. MRM 2013 10. Dabir D et al. JCMR 2014 11. Hanson CA et al. Radiology 2020

##### CLINICAL RELEVANCE/APPLICATION

We present a method for mapping cardiac T1, T2, T2\*, and fat fraction in a single breathhold acquisition with the aim of reducing patient scan times while providing comprehensive quantitative information for myocardial assessment.

#### **R5B-SPCA-2 To Investigate the Enhancement Effect Between High and Low Concentration Contrast Medium in Coronary Computed Tomography Angiography (CCTA).**

##### PURPOSE

To investigate the enhancement effect between high and low concentration contrast medium in coronary computed tomography angiography (CCTA)

##### METHODS AND MATERIALS

A total of 163 patients suspected of coronary disease (CAD) were randomly assigned into two groups with different contrast concentrations, 25mgI/kg/s injection rate for 10s. A high concentration contrast medium (Iomeprol, 400mgI/ml) was used in group A (n=85), while a lower concentration one (Iohexol, 350mgI/ml,) was used in group B (n=78). All patients were scanned with free breathing with a fixed tube voltage of 100 kVp, smart mA with tube current range from 320 to 720 mA. 50% adaptive statistical iterative reconstruction (ASIR-V50%) was used for the pre-scan dose adjustment and post-scan reconstruction. All CT images were reviewed in randomized order by two experienced radiologists blinded to scan and contrast protocol. Both quantitative measurements including CT value, standard deviation (SD), signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR) and subjective scores (1-5) were obtained and compared between the two groups.

##### RESULTS

There was no significant difference in gender, age, body mass index (BMI), heart rate and radiation dose between the 2 groups (all P value >0.05). Both quantitative measurements (CT value, SD,SNR and CNR) and subjective scores were also similar between the

two groups ( $P>0.05$ ). However, there were statistically significant difference in contrast medium dosage and flow rate between the two groups ( $P$  value was 0.000 and 0.001, respectively). The low concentration contrast medium group had statistically higher in contrast medium dosage and flow rate than the high concentration contrast medium group [ $43.34\pm 8.35$  vs  $49.01\pm 8.50$ ml;  $4.2\pm 0.7$  vs  $4.6\pm 0.5$ ] ( $P$  value was 0.000 and 0.001, respectively).

## CONCLUSION

Under the premise of maintaining the same contrast agent injection scheme, there is no significant difference in image quality and radiation dose between high and low contrast agents with different concentrations, but under the condition of constant total iodine, high concentration contrast agent can achieve a relatively low injection rate.

## CLINICAL RELEVANCE/APPLICATION

High concentration contrast agent but with low injection rate can be applied in coronary computed tomography angiography.

## R5B-SPCA-3 Zero-Contrast Imaging for the Assessment of Transcatheter Aortic Valve Implantation in Candidates with Renal Dysfunction

Participants

Paula Terra Amaral, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

## PURPOSE

Candidates for transcatheter aortic valve implantation (TAVI) are currently evaluated using computed tomography angiography and invasive cardiac catheterization as an essential part of case selection and pre-procedure interventional planning. However, both imaging methods utilize iodinated agents, which may cause contrast-induced nephropathy, particularly in patients with baseline renal dysfunction. This study aimed to describe a zero-contrast imaging protocol for pre-TAVI evaluation in patients with advanced renal impairment.

## METHODS AND MATERIALS

The pre-TAVI zero-contrast scheme consisted of the following multi-modality combinations: 1) gadolinium-free magnetic resonance imaging (three-dimensional navigator-echo with electrocardiogram-gated steady-state free-precession series); 2) iodinated-free multislice computed tomography electrocardiogram-gated; 3) lower limb arterial duplex scan ultrasound; and 4) transesophageal echocardiography. Ultimately, TAVI was performed for those deemed good candidates, and contrast was allowed during the intervention; however, operators were strongly advised to utilize the least volume possible of iodinated agents. This pilot survey included ten patients with symptomatic aortic stenosis and renal dysfunction who underwent zero-contrast multi-modality imaging.

## RESULTS

All the patients ultimately underwent TAVI. The intervention was successful in all cases, without moderate residual aortic regurgitation, prosthesis embolization, annulus rupture, major vascular complications, stroke, or death during index hospitalization. The creatinine clearance remained stable throughout the observation period (baseline:  $26.85 \pm 12.55$  ml/min; after multi-modality imaging:  $26.76 \pm 11.51$  ml/min; post-TAVI at discharge:  $29.84 \pm 13.98$  ml/min;  $p=0.3$  all).

## CONCLUSION

The proposed contrast-free imaging protocol appears to be a promising clinical tool for pre-TAVI evaluation in patients with severe renal dysfunction.

## CLINICAL RELEVANCE/APPLICATION

Chronic renal dysfunction is common in individuals with aortic stenosis and is often challenging for the evaluation of TAVI candidates. The occurrence of acute kidney injury (AKI) following pre-TAVI evaluation using methods based on angiographic contrast has been largely underreported, but everyday practice and common sense indicate that it is a major clinical issue. In this context, we developed a zero-contrast diagnostic routine for patients with severe aortic stenosis and renal dysfunction who are considered for TAVI.

## R5B-SPCA-4 Feasibility, Image Quality and Radiation Dose Evaluation of Coronary CT Angiography (CCTA) in Patients with Arrhythmia by Using the 16cm Wide Detector CT

## PURPOSE

To investigate the feasibility, image quality and radiation dose of a 16cm wide detector CT for coronary CT angiography (CCTA) within single cardiac cycle in patients with arrhythmia.

## METHODS AND MATERIALS

A total of 70 patients with suspected coronary heart disease underwent CCTA were divided into two groups for analysis: Group A ( $n=35$ , arrhythmia) and Group B ( $n=35$ , sinus rhythm). All examinations were performed under free breathing on a 16cm wide detector CT (GE Healthcare) by using the SmartPhase technique for scanning and reconstruction and SSF technique for coronary artery motion correction. Both groups used the same contrast dose rate of 25 mgI/kg/s. CT value and standard deviation in aortic sinus (AS), right coronary artery, left anterior descending, left circumflex and pericardial fat were measured. Contrast-to-noise ratio for vessels was calculated. Two experienced Radiologists independently reviewed the image quality by using a 5-point scale [1] (1: nondiagnostic and 5: excellent). Image quality and radiation dose of the two groups were compared. The Mann-Whitney test and independent sample t test were used for statistical analysis,  $P<0.05$  was considered statistically significant.

## RESULTS

There was no difference in contrast dose, radiation dose, quantitative and qualitative image quality [1] between the two patient groups (all  $p>0.05$ ). The arrhythmia group had statistically higher heart rate and higher heart variation than the sinus rhythm group [ $84.77\pm 35.02$  vs.  $67.80\pm 12.53$  beats/min] ( $P=0.009$ ). The effective radiation dose in the arrhythmia group [ $(2.86\pm 1.07)$  mSv] was higher than that in the sinus rhythm group [ $(2.22\pm 0.64)$  mSv] which was statistically significant ( $P=0.004$ ).

## CONCLUSION

CCTA is feasible in arrhythmia patients by using 16cm wide detector CT providing good image quality, but requires slightly higher

radiation dose compared with that of sinus rhythm patients.

#### **CLINICAL RELEVANCE/APPLICATION**

CCTA is feasible in atrial fibrillation patients using a new generation 256-MDCT providing good image quality and low radiation dose in this challenging population

#### **R5B-SPCA-5 A Comparative Study of Inner Diameter of Measured on CCTA Images Reconstructed by Different Algorithms Using High-definition Scanning Mode on a 512-slice CT**

##### **PURPOSE**

To explore the differences between two reconstruction algorithms in inner diameter measurement of right coronary arteries, in coronary computed tomography angiography (CCTA) with high-definition mode.

##### **METHODS AND MATERIALS**

37 patients underwent CCTA at high-definition mode on a 512-slice CT (Revolution CT, GE Healthcare) were collected in this study. 100kV and auto mA control were used for scanning. Images were reconstructed by ASIR-V60% at both conventional reconstruction function Stand mode and high-definition reconstruction function HD Stand mode. The inner diameters of proximal, middle and distal right coronary artery were measured on the reconstructed images. T-test was used to compare the differences between images reconstructed with two modes.

##### **RESULTS**

The inner diameters were (Stand vs. HD-Stand:  $2.93 \pm 0.66$  vs.  $3.02 \pm 0.66$  mm) for proximal right coronary artery, ( $2.67 \pm 0.57$  vs.  $2.75 \pm 0.59$  mm) for middle right coronary artery, respectively. Results showed statistical differences between Stand and HD-Stand images in the measurement of proximal and middle right coronary artery ( $P < 0.05$ ), and the inner diameters measured on HD-Stand images were higher than those on Stand images. The inner diameters were (Stand vs. HD-Stand:  $2.29 \pm 0.46$  vs.  $2.33 \pm 0.48$  mm) for distal right coronary artery, with no significant difference ( $P > 0.05$ ).

##### **CONCLUSION**

s On a 512-slice CT, HD-Stand images can display the lumen of proximal and middle right coronary artery more accurately than Stand images.

#### **CLINICAL RELEVANCE/APPLICATION**

HD-Stand images can display the lumen of coronary artery more accurately, showing greater values in evaluation of coronary artery stenosis.

#### **R5B-SPCA-6 Improved Detection of Subendocardial Infarction using Synthetic Double Inversion Late Gadolinium Enhancement**

Participants

Jong Eun Lee, MD, Gwangju, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### **PURPOSE**

A novel imaging technique called Synthetic double inversion LGE using T1 mapping has been developed. This study aimed to increase the conspicuity of the enhanced region in patients with MI, particularly those with subendocardial infarction by nulling the signal of normal myocardium and blood cavity.

##### **METHODS AND MATERIALS**

To validate the proposed method, phantom experiment was conducted using a commercial phantom (T1 MES) that mimics nine different T1 values of myocardium and blood pre- and post- enhanced at 1.5T and 3T environment. Synthetic LGE that is generated using the post T1 map allows for the nulling of signal intensity from single tissue with a specific T1 value, depending on the inversion time (TI). The proposed method employs two numerical inversion pulses, which null 2 types of tissues. For the evaluation of our method, 30 cases of MRI study from patients with subendocardial infarction were retrospectively collected, which included T1 maps and LGE images. We generated synthetic LGE for each patient using mathematical equation and nullified the signal from normal myocardium and blood cavity. This can increase contrast with infarct myocardium in MI patients as intended in this study.

##### **RESULTS**

In the phantom experiment, proposed method generated a synthetic LGE that accurately nullified the signal from the regions corresponding to the two selected T1 values. This result demonstrated the effectiveness of our approach. In the in-vivo experiment, the result showed significantly higher contrast compared to conventional LGE. The proposed method demonstrated significantly higher contrast ratios for remote/enhanced and blood/enhanced regions, with values of  $2.59 \times 10^{-5}$  and  $2.07 \times 10^{-5}$ , respectively, compared to conventional LGE with values of 0.06 and 0.91. This represents an increase in contrast of over 400-fold for blood cavity and 23-fold for remote regions compared to conventional LGE.

##### **CONCLUSION**

s Using synthetic double inversion LGE, contrast enhancement was observed in subendocardial infarction, with improved conspicuity compared to conventional LGE. This technique nulling healthy myocardium and blood cavity can improve detection of myocardial infarction.

#### **CLINICAL RELEVANCE/APPLICATION**

This study proposes a new imaging technique, Synthetic double inversion LGE, to overcome the challenges in identifying subendocardial infarction using conventional LGE. This technique has shown promising results in nulling normal myocardium and blood cavity, which can improve the contrast with infarct myocardium in MI patients.

R5B-SPCH

### Chest Imaging Thursday Poster Discussions II

#### Sub-Events

#### **R5B-SPCH-1 Free-Breathing Ultra-High-Pitch Pulmonary Angiography by Means of Photon-Counting Detector CT for Diagnosis of Acute Pulmonary Embolism**

##### Participants

Pauline Pannenbecker, MD, BA, Wurzburg, Germany (*Presenter*) Nothing to Disclose

##### PURPOSE

To assess image quality (IQ) and required radiation dose of an ultra-high-pitch CT pulmonary angiography (CTPA) protocol with a low contrast medium (CM) dose in free-breathing technique for diagnosis of acute pulmonary embolism (PE) using a clinical photon-counting detector (PCD) CT scanner in comparison to a matched conventional energy-integrating detector (EID) based Single-Energy CTPA protocol.

##### METHODS AND MATERIALS

51 CTPAs performed on a clinical PCD CT (Naeotom Alpha, Siemens Healthcare GmbH) were prospectively compared to 51 CTPAs performed on a 3rd generation Dual-Source EID CT (Somatom Force, Siemens Healthcare GmbH). All CTPAs were acquired with an ultra-high-pitch CTPA scan protocol in free-breathing technique (matched parameters: 40ml CM, flow rate 4ml/sec, pitch 3.2) at 140 kV (PCD) and 70-100 kV (EID). Based on spectral CTPAs acquired on the PCD scanner, iodine-distribution maps were reconstructed. As ultra-high-pitch EID CTPA could only be performed in Single-Energy mode due to technical limitations, reconstruction of iodine-maps was not possible in this subgroup. For evaluation of objective IQ, CT attenuation within pulmonary arteries, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were compared. To assess subjective IQ, three readers rated CTPAs (at 60 keV using virtual monoenergetic imaging for PCD and at standard reconstruction for EID) and iodine-maps based on a four-point scale. For radiation dose analysis, effective dose (ED), CTDI<sub>vol</sub>, dose length product, and size-specific dose estimates were compared.

##### RESULTS

CT attenuation was higher within all pulmonary vessels in the PCD-group (all  $p < 0.05$ ). While CNR and SNR were higher in the lobar pulmonary arteries in PCD CTPAs ( $p < 0.05$ ), they were similar within the pulmonary trunk ( $p > 0.05$ ). Subjective IQ of PCD scans was rated best by all three reviewers (excellent or good IQ in 96.1% of PCD CTPAs vs. 50.9% of EID CTPAs, ICC = 0.795). All evaluated radiation dose parameters were lower in the PCD group, as is exemplified with a mean ED of 1.33 ( $\pm 0.47$ ) mSv vs. 1.80 ( $\pm 0.82$ ) mSv (PCD vs. EID; all  $p < 0.05$ ).

##### CONCLUSION

Ultra-high-pitch CTPA acquisition in free-breathing technique with PCD CT allows for superior objective and subjective image quality with reduced radiation dose, while providing full spectral assessability. Moreover, in this protocol setting, PCD CTPA enables reconstruction of color-coded iodine-distribution maps, offering additional functional information compared to matched ultra-high-pitch EID CTPA.

##### CLINICAL RELEVANCE/APPLICATION

In PCD CT, pulmonary arteries can be fully spectrally assessed despite ultra-high-pitch settings, overcoming the need for breath-holds in the context of pulmonary embolism where dys- and tachypnea are common symptoms.

#### **R5B-SPCH-2 Prediction of the Treatment of Pulmonary Embolism using CT Texture Analysis**

##### Participants

Ki Yeol K. Lee, MD, PhD, Ansan, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the utility of computed tomography texture analysis (CTTA) parameters in predicting the treatment outcome in pulmonary thromboembolism (PTE).

##### METHODS AND MATERIALS

We evaluated 88 patients diagnosed with PTE on whom chest computed tomography (CT) for detecting PTE was performed. Texture analysis was performed on the acute PTE detected on chest CT. Using the software, the groups in which PTE disappeared and remained after treatment were compared. The mean, standard deviation (SD), entropy, mean of positive pixels (MPP), skewness, and kurtosis of parameters on the spatial scaling factor (SSF) 2-6 were compared between the groups. The gray-level co-occurrence matrix (GLCM) texture features were used for SSF 0 images.

##### RESULTS

PTE disappeared after treatment in 51 patients, whereas it remained in 37 patients. Entropy was significantly different in SSF

3,4,5,6 ( $p < 0.05$ ). The mean and MPP on SSF 0 and the SD on SSF 4,5,6 were also significantly different ( $p < 0.05$ ). Other parameters, such as the mean, standard deviation, MPP, skewness, and kurtosis, on other SSFs were not significantly different. Among the GLCM parameters, several parameters such as joint energy and entropy, perimeter, area, and long and short axis were significantly different ( $p < 0.05$ ).

## CONCLUSION

s CTTA allows the prediction of whether the PTE will dissolve or remain after treatment. The mean and MPP on non-filtered images, entropy, and SD values on highly filtered SSFs had the best performance in predicting the anticoagulation treatment effects. The results suggest that several parameters of GLCM texture features can be used to predict anticoagulation treatment effects.

## CLINICAL RELEVANCE/APPLICATION

CTTA can be used to predict whether PTE will dissolve or remain in the patient after treatment.

## R5B-SPCH-3 Impact of an AI Based Triage and Prioritization Solution for Incidental Pulmonary Embolism Findings on Contrast CT in an Outpatient Setting

### Participants

Seyedali Nabipoorashrafi, MD, MD, Seattle, WA (*Presenter*) Nothing to Disclose

### PURPOSE

To measure the impact of a computer aided triage and prioritization AI solution for patients with incidental pulmonary embolism (iPE) undergoing CT scan of the chest and/or abdomen.

### METHODS AND MATERIALS

Cases from a large academic health system were collected from the outpatient setting between April 2022 and April 2023. A wait time metric was calculated for AI-notified cases with suspected positive iPE findings and compared to negative non-AI-notified cases. Wait time was defined as the difference between the time of study acquisition completion to the time a radiologist opens the case for dictation. The median wait times were calculated for the AI-notified and non-AI-notified cases. A Mood's median test was used to test for statistical significance.

### RESULTS

A total of 28,914 CT contrast examinations that included the lungs (12,564 chest/abdo/pelvis and 16,350 chest only) were collected. The AI solution provided suspected positive prioritization notifications (AI-notified) on 269 cases (87 chest/abdo/pelvis and 182 chest only). The median wait time was 86 minutes (AI-notified) compared to 242 minutes (non-AI-notified). The observed median wait time reduction was 64.4% (156 minutes,  $p$ -value $<0.001$ ). The median wait time was 76 minutes (AI-notified) compared to 461 minutes (non-AI-notified) and 87 minutes (AI-notified) compared to 172 minutes (non-AI-notified) for chest/abdo/pelvis and chest only cases respectively. The chest/abdo/pelvis subcohort had the largest observed median wait time reduction (83.5%, 385 minutes,  $p$ -value $<0.001$ ) compared to chest only cases (50.6%, 85 minutes,  $p$ -value: 0.009).

## CONCLUSION

s A computer aided triage and prioritization AI solution decreased wait times for contrast CT examinations with suspected iPE potentially saving hours of diagnosis delays in the outpatient setting.

## CLINICAL RELEVANCE/APPLICATION

Using an AI solution to prioritize radiologist interpretation of CT scans with iPE findings decreases wait time. Time saved has the potential to prioritize diagnosis and facilitate earlier treatment initiation.

## R5B-SPCH-4 Feasibility Study Of DLIR Algorithm Combined With Low Contrast Dose In CTPA Imaging

### Participants

Yanbing Yang, Yinchuan, China (*Presenter*) Nothing to Disclose

### PURPOSE

To explore the feasibility of DLIR algorithm combined with low contrast dose in CTPA imaging.

### METHODS AND MATERIALS

Retrospective analysis was performed on 30 patients who underwent CTPA examination in our hospital, the scanning tube voltage was 70kVp and the dosage of contrast agent was 35ml. The original data were reconstructed with different algorithms and levels, including FBP algorithm, adaptive statistical iterative reconstruction (50% ASIR-V) and DLIR (DLIR-L, DLIR-M, DLIR-H). Mean CT values (CT1) of pulmonary trunk, right upper lobe trunk, right medial lower lobe basal segment, venous CT values of right medial lower lobe basal segment, CT value (CT2) of erector muscle at pulmonary trunk level and corresponding noise (SD) of different algorithms and horizontal reconstruction images were measured; CT value difference between arterial and venous of right medial lower lobe basal segment = CT value of artery - CT value of vein of right medial lower lobe basal segment, SNR = CT1/SD, CNR = CT1 - CT2/SD. 4 points were used to score the images subjectively. One-way analysis of variance and Kruskal-Wallis Test were used to compare the subjective evaluation and objective evaluation of different algorithms and horizontal reconstruction images.

### RESULTS

There were no statistically significant differences between the mean CT values of pulmonary artery trunk, right upper lobe trunk, right medial lower lobe basal segment and CT value difference between arterial and venous of right medial lower lobe basal segment in FBP, ASIR-V and DLIR reconstructed images ( $P > 0.05$ ). The noise of FBP, 50% ASIR-V and DLIR (L, M, H) images decreased successively, with statistical significance ( $P < 0.001$ ), and the noise of DLIR-H images decreased by 60% compared with that of FBP images. The SNR and CNR of FBP, 50% ASIR-V and DLIR (L, M, H) images increased successively with statistical significance ( $P < 0.001$ ), compared with FBP images, SNR and CNR of DLIR-H images increased by 151.0% and 150.4%. DLIR-M and DLIR-H had the highest subjective score with the highest proportion of 4 points, while FBP had the lowest subjective score with no 4 points, 50% ASIR-V image had the middle subjective score, 50% ASIR-V, DLIR-L and DLIR-H had statistical significance compared with FBP subjective score ( $P < 0.05$ ).

## CONCLUSION

s In CTPA imaging, DLIR algorithm under 35ml contrast agent can further reduce image noise, improve image quality and diagnostic confidence.

## CLINICAL RELEVANCE/APPLICATION

There is no doubt about the harm of contrast agents, especially for special populations such as renal failure and children. Since CTPA images obtained by DLIR combined with a small amount of contrast agents can meet clinical needs, it can be used as a routine clinical examination method.

## R5B-SPCH-5 Impact of the Recent Global Iodinated Contrast Agent Shortage on Observed Positivity Rate for Pulmonary Embolism in CT Pulmonary Angiograms at a Major US Healthcare System

Participants

Axel Wismueller, MD, PhD, Pittsford, NY (*Presenter*) Nothing to Disclose

## PURPOSE

To quantitatively track the impact of the recent global shortage of iodinated contrast agents on observed Pulmonary Embolism (PE) positivity rate in CT Pulmonary Angiogram (CTPA) exams using AI-based image analysis at a major US healthcare system.

## METHODS AND MATERIALS

Using software of a commercial AI-based image analysis vendor (Aidoc Medical, Tel Aviv, Israel), we analyzed daily volumes and PE positivity rates for a total of 2,407 Computed Tomography Pulmonary Angiogram (CTPA) exams before and during the recent contrast agent shortage (both comprising 04/01/2022 through 07/01/2022). For comparison with a non-contrast CT exam type, we analyzed daily volumes and positivity rates for Intracranial Hemorrhage (ICH) on 10,843 non-contrast head CT exams during the same time period. Specifically, we compared two observational periods, namely (i) a pre-shortage control period from 04/14/22 through 05/05/2022, and (ii) a contrast shortage period from 05/21/2022 through 06/11/2022. Percentage change metrics of case volumes and positivity rates for PE and ICH were calculated, where we report relative changes with regard to a baseline measurement period from 04/01/2022 through 04/14/2022. The two observational periods were compared for statistically significant differences using Welch's unequal variances t-test.

## RESULTS

Case volumes of contrast-enhanced CTPA exams dropped from baseline during the contrast agent shortage period by  $42.88\% \pm 20.22\%$  while PE positivity rates increased by  $47.8\% \pm 13.7\%$ , where statistical differences between observational periods were highly significant ( $p < 10^{-4}$ ). For comparison, non-contrast head CT volumes dropped by only  $7.55\% \pm 2.98\%$ , and ICH positivity rates increased by only  $12.5\% \pm 1.87\%$ , with no significant difference between pre-shortage and shortage observational periods ( $p > 0.05$ ).

## CONCLUSION

s Our results suggest a significant increase of PE positivity rate in CTPA exams at significantly decreased CTPA total exam volumes during the observed global contrast agent shortage period, while non-contrast head CT exam volumes and ICH positivity rates remained essentially stable. Our observations can be explained by more restrictive ordering patterns for CTPA studies during the acute contrast agent shortage period, limiting access to such exams only to patients with high clinical pre-test probability.

## CLINICAL RELEVANCE/APPLICATION

Using AI-based image analysis can quantify effects of unexpected healthcare challenges on critical radiology findings, such as for pulmonary embolism during the observed global contrast agent shortage.

## R5B-SPCH-6 Diagnostic Ability for the Presence and Severity of Pulmonary Hypertension on Super-high-resolution Non-enhanced Chest Computed Tomography

Participants

Yukihiro Nagatani, MD, Otsu, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the detectability of pulmonary hypertension (PH) and the predictability of its severity by cross-sectional vessel area (CSA) on super-high-resolution (SHR) non-enhanced chest computed tomography (CT)

## METHODS AND MATERIALS

Thirty patients including 11 patients diagnosed as PH, 9 patients with connective tissue disease (CTD) associated interstitial pneumonia (CTD-IP) without PH and 10 age-matched controls, underwent UHR non-enhanced chest CT. Mean pulmonary arterial pressure (PAP) were measured at right heart catheterization performed within 1 month of the chest CT examination date for the 11 PH patients. Image data were obtained using iterative reconstruction algorithm with normal-resolution simulation (NRsim) mode (512×512 matrix size, 0.5-mm slice thickness), and using deep-learning-based reconstruction algorithm with SHR mode (1024×1024 matrix size, 0.25-mm slice thickness). By using binary images with the optimal threshold of -720 HU at three predefined trans-axial levels including aortic arch, tracheal bifurcation and right proximal pulmonary vein, average vessel dimension (AVD) and the percentage of the total CSA for the lung field area (%CSA) for dimensions of less than 0.5, 0.5 to 1, 1 to 2 and 2 to 5 mm<sup>2</sup> were quantified for CT data both at NRsim and SHR mode. AVD and %CSA were compared among PH, CTD-IP and age-matched controls with Kruskal-Wallis test, and correlated with mean PAP for PH with Spearman's rank coefficient.

## RESULTS

On CT images at SHR mode, AVD for dimensions of less than 0.5 mm<sup>2</sup> for PH ( $0.226 \pm 0.008$  mm<sup>2</sup>) were smaller as compared with those for CTD-IP ( $0.239 \pm 0.008$  mm<sup>2</sup>) and age-matched controls ( $0.245 \pm 0.004$  mm<sup>2</sup>). ( $p < 0.01$ ) AVD for dimensions of 1 to 2 mm<sup>2</sup> correlated negatively with mean PAP ( $r = -0.67$ ,  $p = 0.048$ ). In contrast, on CT images at NRsim mode, although %CSA for dimensions of less than 0.5 mm<sup>2</sup> correlated positively with mean PAP ( $r = 0.71$ ,  $p = 0.032$ ), the %CSA for PH ( $0.61 \pm 0.38\%$ ) was larger than that for CTD-IP ( $0.53 \pm 0.30\%$ ) and comparable to that for age-matched controls ( $0.60 \pm 0.25\%$ ).

## CONCLUSION

s AVD for dimensions of less than 2 mm<sup>2</sup> at SHR mode on non-enhanced chest CT images has the potential to indicate the presence and severity of PH.

#### **CLINICAL RELEVANCE/APPLICATION**

Quantification of pulmonary smaller peripheral vessels of less than 2 mm<sup>2</sup> depicted at SHR mode may be useful for direct assessment of peripheral arterial remodeling in PH.

### **R5B-SPCH-7 Dual-Layer Dual-Energy CT-Derived Pulmonary Perfusion for the Differentiation of Acute Pulmonary Embolism and Chronic Thromboembolic Pulmonary Hypertension**

Participants

Roman Gertz, MD, Cologne, Germany (*Presenter*) Institutional research contract, Koninklijke Philips NV

#### **PURPOSE**

To assess the ability of dual-layer dual-energy computed tomography (dIDECT)-derived pulmonary perfusion maps to differentiate between acute pulmonary embolism (PE) and chronic thromboembolic pulmonary hypertension (CTEPH).

#### **METHODS AND MATERIALS**

57 patients with acute PE, 52 patients with CTEPH and 22 controls, all of whom underwent CT pulmonary angiography on a dIDECT were included in this retrospective study. Normal and malperfused areas of lung parenchyma were semiautomatically contoured using iodine density overlay maps (IDOs). First order histogram features of normal and malperfused lung tissue were extracted. Iodine density (ID) was normalized to the mean pulmonary artery (MPA) and the left atrium (LA). Group differences were analyzed using the t-test and the Mann-Whitney U test. The data was split into training and validation sets to assess the diagnostic accuracy of the derived histogram features using the area under the receiver operating characteristic curve (AUC).

#### **RESULTS**

In acute PE, normal perfused lung areas revealed a higher mean and peak iodine uptake normalized to the MPA than in CTEPH (both  $p < 0.001$ ). After normalizing mean ID in perfusion defects to the LA, patients with acute PE revealed a reduced average perfusion (ID<sub>mean,LA</sub>) compared to both CTEPH patients and controls ( $p < 0.001$  for both). ID<sub>mean,LA</sub> allowed for a differentiation between acute PE and CTEPH with moderate accuracy (AUC: 0.72, sensitivity 74%, specificity 64%), resulting in a PPV and NPV for CTEPH of 64% and 70%.

#### **CONCLUSION**

s dIDECT enables quantification and characterization of pulmonary perfusion patterns in acute PE and CTEPH, enabling the differentiation between the two diseases.

#### **CLINICAL RELEVANCE/APPLICATION**

The identified parameters yield the potential to enable more timely identification of patients with chronic thromboembolic pulmonary hypertension.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

R5B-SPER

### Emergency Radiology Thursday Poster Discussions II

#### Sub-Events

#### R5B-SPER-1 Disentangling the Knot: Our Experience with Ultrasound Assisted Manual Testicular Detorsion in the Radiology Department

#### PURPOSE

Testicular torsion (TT) is an emergency. Prompt diagnosis and management are key to preserve the testicle. Our objective is to show our experience with intravaginal TT sonographic diagnosis and ultrasound (US) assisted manual detorsion (MD).

#### METHODS AND MATERIALS

A prospective, randomized, controlled trial over an 8-year period with a total of 108 patients diagnosed with TT. Mean age was 14 years, age range 1-48 years. US was performed in 106 patients (98%). Testicular flow was absent in 73 (69%), diminished in 27 (25%), normal in 6 (6%). Torsion of the cord was documented in 103 patients (97,2%) and not demonstrated in 3 (2,8%). In the first group of 59 patients, 57 underwent surgery following sonographic diagnosis of TT and 2 went directly to surgery. In the second group, 49 patients underwent US assisted MD attempt immediately after sonographic TT confirmation and posterior surgery. MD is attempted following US TT confirmation, explaining the procedure and obtaining consent. It is performed with US assistance and without sedation or analgesia thus enabling clinical monitoring and expediting the procedure. US assisted MD was performed by 14 staff radiologist, 1 pediatric surgeon and 8 radiology residents under staff supervision.

#### RESULTS

In the first group, testicular echotexture was preserved in 33 (58%) and altered in 24 (42%). 15 orchiectomies were performed (25,4%) and 44 (76,4%) testicles were fixated including 4 that showed later atrophy (9%). 1 of the patients that did not undergo US exam turned out to be a false positive. 4 underwent spontaneous detorsion while performing the US. 2 patients had inguinal torsion. 1 patient with Asperger syndrome barely cooperated with the diagnostic US exam. In the second group, testicular echotexture was preserved in 44 (89,8%) and altered in 5 (10,2%). MD achieved testicular reperfusion and symptoms relief in 42 patients (85,7% success rate). 1 orchiectomy was performed (2%) and 48 testicles were fixated including 2 that showed later atrophy (4%). There were no complications related to US assisted MD.

#### CONCLUSION

US confirms the diagnosis of TT, evaluates pre-detorsion testicular viability, assists MD and verifies restoration of testicular flow. MD is a non-invasive, simple, feasible, quick, safe and effective maneuver that improves testicular viability by immediately restoring testicular flow if successful, relieves patient's symptoms and improves his comfort and facilitates posterior surgery.

#### CLINICAL RELEVANCE/APPLICATION

Sonographic diagnosis of TT and US assisted MD adds value to the radiologist role in this emergency clinical setting performing a medical act that is both diagnostic and therapeutic.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

R5B-SPGI

### Gastrointestinal Imaging Thursday Poster Discussions II

#### Sub-Events

#### **R5B-SPGI-1 Measurement of Spleen Volume Using CT Images with Deep Learning Segmentation: Definition of Normal Spleen and Splenomegaly**

##### **PURPOSE**

To develop and evaluate a fully automated algorithm for segmenting the spleen and to establish thresholds for splenomegaly from CT.

##### **METHODS AND MATERIALS**

The dataset used to develop this deep learning software on Python consisted of anonymized non-contrast CT images of the abdomen of 138 patients provided by PSP Inc. These 138 images were divided into a training set, a validation set, and a test set. A Bayesian 3D U-Net was trained on the labeled spleen data. The initial study cohort consisted of generally healthy, asymptomatic adult outpatients who were potential renal donors, liver donors, scheduled to undergo CT colonography or abdominal CT for physical examination between April 2011 and April 2022, at a single medical center. A subanalysis was conducted prior to the clinical study. One hundred and twenty patients were randomly selected from the clinical study population. Multiple regression analysis was used to evaluate the relationship between demographic and clinical data and spleen capacity data.

##### **RESULTS**

The final sample consisted of 2554 asymptomatic adult outpatients (mean age  $\pm$  standard deviation, 65.0  $\pm$  15.3 years, including 1736 men and 821 women). The mean height  $\pm$  standard deviation of the patients was 162.1  $\pm$  9.4 cm, and the mean weight of the patients was 62.3  $\pm$  13.7 kg. The deep learning tool was used to successfully segment the spleen in all scans. The mean standardized spleen volume  $\pm$  standard deviation was 123.2  $\pm$  59.2 mL, showing a normal distribution. Patient weight was the major determinant of spleen volume and demonstrated a linear relationship. From this result, a linear weight-based upper limit of normal spleen threshold volume was derived: splenomegaly = 1.87  $\times$  weight (kg) + 124.67 mL. In the subset of 100 patients, the median difference in spleen volume between the deep learning tool and the manual method was 2.3%: mean Dice score was 0.95 (0.72-0.97).

##### **CONCLUSION**

s Weight-based thresholds for objective normal spleen and splenomegaly were derived from a spleen volume database using CT images, based on deep learning.

##### **CLINICAL RELEVANCE/APPLICATION**

Splenomegaly is defined as an abnormal enlargement of the spleen resulting from various clinical conditions such as infections, hematologic diseases, congestion, autoimmune diseases or tumors. Splenomegaly is often a diagnostic entry point for various background diseases, and accurate detection of splenomegaly is clinically important. The purpose of our study is to establish the normal distribution of splenic volume in healthy adults using automated organ segmentation techniques on abdominal CT images. Furthermore, this data will be used to establish a potential threshold for splenomegaly.

#### **R5B-SPGI-2 Imaging Practices and Clinical Outcomes Following Suboptimal Visualization Score on Hepatocellular Carcinoma Ultrasound Screening**

##### **PURPOSE**

The Ultrasound Liver Imaging Reporting and Data Systems (US LI-RADS) provides standardized terminology and reporting of ultrasound (US) screening for hepatocellular carcinoma (HCC). However, limited data exists on the clinical relevance of US LI-RADS suboptimal visualization scores of B/C. The aim of this study is to identify predictors of suboptimal visualization on HCC US screening and investigate follow-up imaging practices and clinical outcomes.

##### **METHODS AND MATERIALS**

Retrospective analysis was performed on patients who underwent initial HCC US screening from 2017-2021. Clinical factors, including demographics, body mass index (BMI), laboratory findings, hepatitis/cirrhosis status, surgical pathology, initial US and follow-up imaging, diagnosis of HCC/cirrhosis, and liver transplant, were collected. Multivariable analysis was performed to determine predictors for suboptimal (B/C) visualization on HCC US screening. Chi-square test and independent t-test were performed to compare follow-up imaging practices and clinical outcomes between scores of A and B/C. Only patients with US LI-RADS visualization scores were included.

##### **RESULTS**

Of 396 patients, 56% (221/396) had a score of A, while 44% (175/396) had suboptimal scores of B/C. Multivariable analysis revealed that BMI (OR:1.05, 95% CI:1.01-1.09,  $p=0.01$ , per 1 score increase) and cirrhosis (OR:2.64, 95% CI:1.11-6.27,  $p=0.027$ ) predicted suboptimal visualization. Further analysis showed that 42.53% (94/221) of the patients with a score of A had follow-up imaging, compared to 45.71% (80/175) with scores of B/C. The mean time to follow-up imaging was not significantly different.

However, US was more frequently performed in patients with a score of A (65.96% vs. 43.75%,  $p=0.003$ ), while CT was performed more frequently among patients with scores of B/C (23.40% vs. 38.75%,  $p=0.028$ ). Clinically, liver transplant was more common within one year from initial US among patients with scores of B/C (13.75% vs. 9.57%,  $p=0.0284$ ), while subsequent diagnosis of HCC/cirrhosis after the initial US was not significantly different.

## CONCLUSION

Our findings suggest that patients with suboptimal visualization scores of B/C on initial HCC US screening were followed at similar intervals as those with a score of A. However, patients with scores of B/C underwent CT follow-up and liver transplant more frequently than those with a score of A. This study highlights the need for establishing recommendations for imaging and clinical management following suboptimal visualization on HCC US screening.

## CLINICAL RELEVANCE/APPLICATION

Suboptimal visualization scores on initial HCC US screening impact follow-up imaging and clinical outcomes, and thus standardized recommendations are warranted for optimal care.

## R5B-SPGI-3 Effect of Liver Fibrosis on the Correlation between US-ATI and MRI-PDFF

Participants

Riwa Kishimoto, MD, PhD, (*Presenter*) Nothing to Disclose

## PURPOSE

With the increasing number of liver diseases caused by obesity and metabolic syndrome, the assessment of fatty liver by ultrasound attenuation imaging (ATI) is widely used clinically. It has been reported that ATI correlates well with MRI-derived proton density fat fraction (PDFF). On the other hand, the influence of liver fibrosis on ATI has been discussed. In the present study, we investigated whether the degree of fibrosis affects the correlation between ATI and MRI-PDFF when divided into high and low fibrosis groups using shear wave speed (SWS) and Fib-4 index.

## METHODS AND MATERIALS

Seventy-four patients with ultrasound (US) and MR examinations performed within two weeks were included. Canon Medical Systems Aplio i800 with an i8CX1 probe was used, and SWS and ATI were obtained simultaneously using an advanced SWE application. After at least 4 hours of fasting, five measurements were taken with a right intercostal procedure avoiding large blood vessels at neutral breathing during a breath hold. MRI was performed using a Philips Achieva 1.5T, and the m-Dixon method was used. ROI of about 10 mm diameter was placed in the center of the right lobe, same as US. The correlation between ATI value and MRI-PDFF was investigated. To evaluate the effect of fibrosis, the patients were divided into two groups using SWS and Fib-4 index, which is considered highly likely to be associated with fibrosis: those with SWS = 1.6 m/s and those with SWS <1.6 m/s, and those with Fib-4 index = 2.67 and < 2.67. The analysis of covariance (ANCOVA) was performed.

## RESULTS

Fifty-five patients were included, excluding those due to low reliability whose interquartile range (IQR)/median of SWS and ATI was over 0.3. The correlation between ATI value and MRI-PDFF of the liver was good,  $R=0.74$ . In a study in which the patients were divided by SWS and Fib-4 index, the correlation coefficients were similar: 0.78 for the high SWS group and 0.74 for the low SWS group, and 0.74 for the high Fib-4 index group and 0.77 for the low Fib-4 index group, respectively. The degree of liver fibrosis did not significantly affect the correlation between ATI and MRI-PDFF using ANCOVA.

## CONCLUSION

We hypothesized that the correlation between ATI and MRI-PDFF would be worse in cases with liver fibrosis, but no difference was found in the study divided into high and low fibrosis groups using SWS and Fib-4 index. The correlation was good in both groups with  $R > 0.7$ , and fibrosis had no confounding effect.

## CLINICAL RELEVANCE/APPLICATION

The degree of liver fibrosis did not significantly affect the correlation between ATI and MRI-PDFF.

## R5B-SPGI-4 Shear Wave Elastography Assessment of the Spleen Before and After Transjugular Intrahepatic Portosystemic Shunt (TIPS)

Participants

Robert Turner, Olathe, KS (*Presenter*) Nothing to Disclose

## PURPOSE

Transjugular intrahepatic portosystemic shunt (TIPS) creation is an effective intervention to minimize complications of portal hypertension. However, periodic surveillance of TIPS is required to detect asymptomatic shunt stenosis or occlusion. Spleen shear wave elastography (SWE) has previously been shown to correlation with portal pressure, therefore it may be a surrogate marker for surveillance of TIPS patency. The goal of this study was to evaluate the changes in splenic stiffness using SWE immediately before and after TIPS placement, to determine how acute changes in portal pressure effect the spleen.

## METHODS AND MATERIALS

This prospective cohort study included adult patients with portal hypertension who underwent nonemergent TIPS creation at a single institution from 10/31/2017 - 5/20/2021. Individuals were excluded if they had a prior splenectomy. Patients were evaluated with spleen SWE immediately before and after TIPS placement. Spleen length was measured by ultrasound in each individual during the pre-TIPS scan. Paired t-test analysis was performed to compare median splenic stiffness before and after the procedure and spleen length between patient groups.

## RESULTS

Thirty patients were enrolled with a mean age of 58 years ( $SD=14.8$ ). There was a decrease in median spleen shear wave velocity (SSWV) in 70% of patients following TIPS creation ( $p=0.03$ , binomial 95% CI=54% - 86%). The average decrease in SSWV after TIPS creation was 0.21 m/sec ( $p=0.01$ , 95% CI=0.38 - 0.05). Spleen length trended higher in patients who showed a decrease in SSWV (mean=16.2 cm,  $SD=2.99$ ) compared to those who had an increase in SSWV (mean=15.3 cm,  $SD=2.51$ ), though this

difference was not statistically significant ( $p=0.43$ ).

## CONCLUSION

s There was a statistically significant decrease in SSWV immediately after TIPS placement, indicating that spleen stiffness is acutely affected by changes in portal pressure. Spleen SWE may be a useful tool in longitudinal surveillance of TIPS patency, using the patient as a self-control.

## CLINICAL RELEVANCE/APPLICATION

Spleen shear wave elastography may be a complementary, non-invasive tool for monitoring TIPS patency and portal hypertension complications.

## R5B-SPGI-5 US-LIRADS: Outcomes of Category 1B and 1C Examinations on Multiphase CT/MRI

### PURPOSE

The purpose of this study is to evaluate the outcomes of ultrasound (US) LI-RADS category US-1B and US-1C examinations performed for hepatocellular carcinoma (HCC) screening and surveillance on the basis of subsequently performed multiphase MRI or CT.

### METHODS AND MATERIALS

In this retrospective analysis, 211 patients at high risk for HCC (127 men and 84 women; mean  $[\pm\text{SD}]$  age, 59.8  $\pm$  13.1 years) underwent screening liver US between June 2019 and September 2022 and were assigned US-1B (111 patients) or US-1C (100 patients) on a prospective clinical basis using the US-LIRADS algorithm. The results of follow-up imaging studies were analyzed.

### RESULTS

US visualization scores were assigned as B (52.6% [111/211]) and C (47.4% [100/211]). The most common reasons for US-1B and 1C visualization scores included overlying bowel gas (52.6% [111/211]), parenchymal heterogeneity/echogenicity (26.5% [56/211]), and body habitus/poor acoustic window (10.0% [21/211]). Follow-up US for ongoing HCC screening was available for 57.8% (122/211) of patients. On follow-up US, 98.4% of patients remained US-LIRADS category 1 (120/122), 0.8% were category 2 (1/122), and 0.8% were category 3 (1/122). Subsequently-performed multiphase contrast-enhanced MRI or CT was available for 38.3% (81/211) of patients including 43.0% (43/100) of 1B patients and 34.2% (38/111) of 1C patients with a time interval between screening US and CT/MR of 287.9  $\pm$  265.5 days. Multiphase CT or MRI results for patients with US-1B and US-1C visualization scores included no abnormality at CT or MRI (70.3% [57/81]), a benign lesion (6.2% [5/81]), a LI-RADS category 3 (LR-3) observation (16.0% [13/81]), a LI-RADS category 4 or 5 (LR-4 or LR-5) observation (5.0% [4/81]), and an LR-M observation (2.5% [2/81]). Within the US-1B cohort, an LR-4 or LR-5 observation was seen in 4.6% (2/43) and an LR-M observation was seen in 2.3% (1/43). In the US-1C cohort, an LR-4 or LR-5 observation was seen in 2.6% (1/38) and an LR-M observation was seen in 5.3% (2/38). The incidence of probable or definite HCC on CT/MR for US-1B or US-1C examinations was 5.0% (4/81) and for any malignancy was 7.4% (6/81).

## CONCLUSION

s In the HCC screening population, approximately 5% of US-1B and US-1C examinations have probable or definite HCC and 7.4% have malignant findings on multiphase CT or MR. Despite this, only 38.3% of patients with US-1B or US-1C examinations underwent multiphase CT or MRI, meaning that the majority of clinical providers are currently opting for continued ultrasound surveillance despite limited liver visualization.

## CLINICAL RELEVANCE/APPLICATION

Patients in the HCC screening population with US-1B or US-1C examinations due to suboptimal liver visualization may benefit from further evaluation with multiphase CT or MRI.

## R5B-SPGI-6 Repeatability and Reproducibility of Multi-parametric Ultrasound in Liver Assessment

### Participants

Reinhard I. Kubale, MD, Homburg/Saar, Germany (*Presenter*) Research Consultant, Siemens AG

### PURPOSE

Quantitative ultrasound-based techniques, such as ultrasound derived fat fraction (UDFF) and point shear wave elastography (pSWE), have become promising noninvasive tools for evaluating liver fibrosis and steatosis. However, the repeatability and reproducibility of these techniques remain critical factors for their broader clinical adoption. This study aims to assess the sonographer reproducibility and measurement repeatability of UDFF and pSWE in liver assessment within a cohort of 31 subjects.

### METHODS AND MATERIALS

Three experienced sonographers performed five acquisitions each on the subjects' livers using the Siemens Sequoia ultrasound system. The intraclass correlation coefficients (ICCs) and Bland-Altman analysis were employed to evaluate the repeatability within each sonographer and the reproducibility across the sonographers for both UDFF and pSWE measurements.

### RESULTS

The results demonstrated good sonographer reproducibility and measurement repeatability for both UDFF and pSWE. The ICC for UDFF repeatability ranged from 0.97 (95% CI: 0.95-0.98) to 0.99 (95% CI: 0.98-1.0), while the ICC for pSWE repeatability ranged from 0.94 (95% CI: 0.89-0.97) to 0.96 (95% CI: 0.93-0.98). Additionally, the ICC for sonographer reproducibility was 0.93 (95% CI: 0.88-0.96) for UDFF and 0.62 (95% CI: 0.43-0.77) for pSWE. Bland-Altman analysis revealed a mean difference of 0 % for UDFF and 0 m/s for pSWE, indicating no bias between the sonographers, and the limits of agreement were within  $\pm 3.51\%$  for UDFF and  $\pm 0.2$  m/s for pSWE, demonstrating acceptable agreement.

## CONCLUSION

s These findings support the repeatability and reproducibility of UDFF and pSWE measurements in liver assessment, highlighting their potential as reliable tools for noninvasive liver fibrosis and steatosis evaluation. Further research is warranted to optimize measurement protocols and investigate their performance in various clinical settings.

## **CLINICAL RELEVANCE/APPLICATION**

This study demonstrates that ultrasound-derived fat fraction (UDFF) and point shear wave elastography (pSWE) show good repeatability and reproducibility for assessing liver fibrosis and steatosis, making them promising noninvasive tools in clinical settings. The high intraclass correlation coefficients and Bland-Altman analysis results support their reliability across different sonographers, highlighting the potential for these techniques to be adopted more widely in liver assessment. Future research should focus on optimizing measurement protocols and evaluating their performance across various clinical contexts to further solidify their clinical utility.

## **R5B-SPGI-7 Ultrasound Point Shear Wave Elastography is Feasible Across All Ages to Evaluate for Sinusoidal Obstruction Syndrome after Hematopoietic Stem Cell Transplantation**

### **PURPOSE**

Veno-occlusive disease or sinusoidal obstruction syndrome (VOD/SOS) is a known potential complication of HCT and usually involves the liver. Hepatic VOD is characterized by damage to blood vessels in the liver and surrounding liver cells, with significant associated morbidity. Ultrasound point shear wave elastography (PSWE) is an imaging technique that has high sensitivity and specificity in detecting tissue stiffness, which is hypothesized to increase in VOD/SOS. A prospective, observational pilot study was performed to evaluate the feasibility and value of shear wave elastography (SWE) in the diagnosis of hepatic VOD/SOS after hematopoietic cell transplantation (HCT).

### **METHODS AND MATERIALS**

Pediatric and adult patients undergoing autologous or allogeneic HCT at a single academic institution, and who received myeloablative conditioning were consented to participate in this study. Pre-transplant liver and other organ evaluation was performed. Post-transplant evaluation and SWE imaging was performed on all subjects at day +5, day +10, day +14, day +21, day +100.

### **RESULTS**

A total of 42 patients were enrolled in the study, of which 62% were males with median age of 15 years (range: 1-50 years). Underlying malignancy was the primary indication for HCT in 73% of patients.; 95% underwent an allogeneic HCT with a median age of participation of 15 years (range: 1-50 years). No patients were diagnosed with VOD and there was no statistical significance in the median liver stiffness before and after engraftment (1.4 (1.1-2.6) vs. 1.4 (1.2-2) m/sec; p=0.81). Trends were observed by ultrasound during the course of observation including hepatic enlargement, gallbladder wall thickening and sludge, alterations in portal and hepatic venous flow, and the development of ascites, all despite the lack of VOD diagnosis.

### **CONCLUSION**

s PSWE is feasible in children and adults to assess the flow dynamics in hepatic and portal vasculature. Further studies need to be performed to evaluate its utility in diagnosis of VOD/SOS and assessing the therapeutic response.

## **CLINICAL RELEVANCE/APPLICATION**

Performing point shear wave elastography is feasible across all ages. Though there were no VOD/SOS cases, this study successfully demonstrates the radiologic changes in hepato-portal venous flow changes and organ changes after HSCT.

R5B-SPGU

### Genitourinary Imaging Thursday Poster Discussions II

#### Sub-Events

#### **R5B-SPGU-1 Estimation of Renal Function Using Iodine Maps in Dual-energy Spectral Computed Tomography Urography: A Feasibility and Accuracy Study**

##### Participants

Shigeng Wang, Dalian, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To explore the feasibility of measuring glomerular filtration rate (GFR) using iodine maps in dual-energy spectral computed tomography urography (DEsCTU).

##### METHODS AND MATERIALS

One hundred and eighty patients with renal tumors referred for DEsCTU were prospectively enrolled. The DEsCTU protocol included non-contrast, nephrographic, and excretory phase imaging. The CT-derived GFR was calculated separately using the above 3-phase iodine maps (CT-GFRiodine) and 120 kVp-like images (CT-GFR120kvp). CT-GFRiodine and CT-GFR120kvp were compared with estimated GFR (eGFR) using paired t-test, correlation analysis, and Bland-Altman plots. The receiver operating characteristic (ROC) curves were used to test the renal function diagnostic performance with CT-GFR120kvp and CT-GFRiodine.

##### RESULTS

There were 100 patients with normal renal function and 80 patients with decreased renal function. The difference between eGFR ( $91.71 \pm 14.17 \text{ ml} \cdot \text{min}^{-1} \cdot 1.73 \text{m}^{-2}$ ) as reference standard and CT-GFRiodine ( $93.42 \pm 14.04 \text{ ml} \cdot \text{min}^{-1} \cdot 1.73 \text{m}^{-2}$ ) was not statistically significant, showing excellent correlation ( $r=0.88$ ,  $P<0.001$ ) and agreement ( $\pm 15.65 \text{ ml} \cdot \text{min}^{-1} \cdot 1.73 \text{m}^{-2}$ ,  $P=0.091$ ). The correlation between eGFR and CT-GFR120kvp ( $84.71 \pm 21.76 \text{ ml} \cdot \text{min}^{-1} \cdot 1.73 \text{m}^{-2}$ ) was poor ( $r=0.58$ ,  $P<0.001$ ), and the agreement was poor ( $\pm 45.75 \text{ ml} \cdot \text{min}^{-1} \cdot 1.73 \text{m}^{-2}$ ,  $P=0.004$ ). The CT-GFRiodine had the largest area under the curve (AUC) for distinguishing between normal and decreased renal function (AUC=0.974).

##### CONCLUSION

s The GFR can be calculated accurately using iodine maps in DEsCTU.

##### CLINICAL RELEVANCE/APPLICATION

This study explored the potential information of iodine maps in DEsCTU and demonstrated that DEsCT could be a non-invasive and reliable one-stop-shop imaging technique for evaluating both the urinary tract morphology and renal function, thereby providing more quantitative parameters for clinical practice and bringing more benefits to patients.

#### **R5B-SPGU-2 AI-based Urinary Calculi Detection, Localization, and Quantification on Abdomen-pelvis CT: A Multicenter, International Internal Testing and External Validation Study**

##### Participants

Parisa Kaviani, MD, Boston, MA (*Presenter*) Nothing to Disclose

##### PURPOSE

Detection and localization of urinary calculi have a crucial role in patient management and in choosing the best course of therapy. Therefore, we performed a multicenter, international study to assess the performance of an AI algorithm for urinary calculi detection, localization, and quantification on abdomen-pelvis CT.

##### METHODS AND MATERIALS

Our retrospective IRB-approved study included 980 patients (mean age  $60 \pm 14$  years; M:F 509:471) who underwent non-contrast abdomen-pelvis CT for the evaluation of suspected urinary calculi at one of the 8 hospitals (4 sites in India,  $n=451$  patients; 4 in the US,  $n=529$  patients). The training ( $n>1000$  CT) and internal testing data ( $n=451$  CT) belonged to the Indian sites while the US sites contributed data for the external model validation. Patients with surgical clips, stent, and metal related artifacts were excluded. All CT exams were reviewed by one of the three radiologists from India and US, and separately processed with Urologiq AI algorithm (Biocliq Technologies PVY LTD, India) to obtain information on the size of urinary calculi ( $n=451$ ) as well as to determine the urinary calculi presence and location, and hydronephrosis/hydronephroureter presence/severity ( $n=980$ ). Deidentified DICOM images were imported to a secure platform CARING Analytics platform (CARPL) for ground truthing. The sensitivity, specificity, and area under the curve of receiver operating characteristics (ROC-AUC) were estimated to assess the AI model performance.

##### RESULTS

Our AI algorithm was able to detect the presence of urinary calculi with sensitivities, specificities, and AUCs of 97.3%, 94.2%, 0.958 (internal testing data) and 100%, 100%, 0.958 (external validation set), respectively. Likewise, the AI model differentiated the location of the renal calculi with sensitivities, specificities, and AUCs of 100%, 69.2%-99.6%, and 0.700 - 0.996 (internal

testing data) and 92.9%-100%, 75.5%-100%, and 0.79-1 (external validation data) at different locations including (renal, ureteric, bladder levels), respectively. There was a strong correlation of 0.941-0.963 between AI and radiologist measured stone dimensions ( $p < 0.001$ ) with a <5% differences between the two measures.

#### **CONCLUSION**

s The assessed AI algorithm was generalizable and accurate for detection, localization, and quantification of urinary calculi in both internal testing and external validation sites.

#### **CLINICAL RELEVANCE/APPLICATION**

The assessed AI model can help improve reporting accuracy and efficiency of abdominal-pelvis CT examinations for kidney stones.

### Head & Neck Imaging Thursday Poster Discussions II

#### Sub-Events

#### **R5B-SPHN-1 New Strategies in the Diagnosis of Thyroid Nodule: TI-RADS Risk Stratification Systems Versus Computer Aided Diagnosis Software**

##### Participants

Vincenzo Dolcetti, Rome, Italy (*Presenter*) Nothing to Disclose

##### PURPOSE

To compare thyroid nodules evaluation of a expert radiologist (based on ACR-TIRADS classification) to the CAD System S-Detect, in a cohort of patients who performed FNAC.

##### METHODS AND MATERIALS

140 patients with an age range of 34 to 78 years with one and no more than three thyroid nodules were enrolled prospectively. The B-mode ultrasound evaluation of the nodule was integrated by a CAD System S-detect evaluation on each patient, and the two were put in comparison with cytology as gold standard. The exclusion criteria were the presence of cystic or mixed predominantly cystic (fluid >50%) lesions, and nodules smaller than 5 mm. All nodules were characterized in terms of size, shape, margins, composition, echogenicity, presence of calcifications or punctate echogenic foci and extrathyroidal extension. Afterward, the S-Detect software was used to automatically determine the shape, composition, echogenicity, and margins of the same nodule.

##### RESULTS

At the cytological examination, 102 benign and 38 malignant nodules were identified. At the B mode evaluation, 99 benign nodules (TIRADS 2/3) and 41 malignant nodules (TIRADS 4/5) were identified with a sensitivity of 98%, a specificity of 93%, a positive predictive value of 97% and a negative predictive value of 97%. The S-Detect software identified 97 benign and 43 malignant nodules, with a sensitivity of 97%, a specificity of 92%, a PPV of 95%, a NPV of 95%. A high agreement (>95%) was therefore demonstrated between the evaluation of thyroid nodules performed by the radiologist at the B-mode US using the ACR-TIRADS classification system and the automatic CAD classification provided by the S-Detect software.

##### CONCLUSION

s ACR-TIRADS shows high agreement with the S-Detect and both show high agreement with cytology results.

##### CLINICAL RELEVANCE/APPLICATION

S-Detect is a viable tool for the characterization of thyroid nodules and it has a potential role as a teaching or support tool for the less experienced operators.

#### **R5B-SPHN-2 Preoperative Diagnosis of Cervical Lymph Node Metastasis in Patients with Thyroid Cancer: Integrative Analysis of CT Imaging Features Based on US**

##### PURPOSE

Ultrasound (US) is widely used as a primary imaging modality for the evaluation of cervical lymph node (LN) metastasis in thyroid cancer, but its diagnostic accuracy is limited. Computer tomography (CT) is often employed as a complementary modality, but there is no clear consensus on how to integrate the findings from the two modalities. We conducted a study to evaluate the concordance between suspicious imaging features observed on US and CT and to determine the clinical significance of concordant and discordant cases.

##### METHODS AND MATERIALS

This retrospective study included consecutive thyroid cancer patients who underwent US, CT examinations, and LN biopsy before surgery between December 2006 and June 2015. We analyzed US and CT images of LNs based on the lexicons of the Korean Society of Thyroid Radiology risk stratification system on a node-by-node basis. The concordance rate was calculated by matching US hyperechogenicity/abnormal vascularity with CT strong/ heterogeneous enhancement, US cystic changes vs. CT cystic changes, and US echogenic foci with CT calcifications. The malignancy rate of LNs was further compared according to the presence of specific suspicious features on US with their concordance with CT features.

##### RESULTS

A total of 277 cervical LNs (228 patients, mean age  $47.4 \pm 13.6$  years, female 73.2%) were analyzed, with 53.1% of them were metastatic. The positive concordance rate of suspicious features between US and CT were generally high (US hyperechogenicity vs. CT strong/heterogeneous enhancement, 89.1%; US abnormal vascularity vs. CT strong/heterogeneous enhancement, 86.4%; US cystic changes vs. CT cystic change, 70.6%; US large echogenic foci vs. CT macrocalcification, 87.0%), except for punctate echogenic foci (PEF) (vs. CT microcalcification, 6.5%). Positive concordant cases of US hyperechogenicity/abnormal vascularity showed higher malignancy risk (93.5%) than that of discordant cases (41.2%,  $P < .001$ ). The presence of cystic change or EF on US indicated a high risk of malignancy (82.6-95.8%), irrespective of presence of corresponding CT features.

## CONCLUSION

s Suspicious imaging features of cervical LNs observed on US and CT were generally concordant, except for PEF. Heterogeneous or strong enhancement features of CT reinforces the diagnostic significance of hyperechogenicity or abnormal vascularity on US. However, when cystic changes or echogenic foci are observed on US, malignancy should be suspected regardless of CT findings.

## CLINICAL RELEVANCE/APPLICATION

An integrative evaluation of the suspicious features with both US and CT can enhance the diagnostic ability for detecting cervical lymph node metastasis in thyroid cancer patients.

### **R5B-SPHN-3 Evaluating the Diagnostic Performance of a Deep Learning Model for Detecting Thyroid Nodule Malignancy: An Expert Evaluation Study**

Participants

Sanaz Vahdati, MD, Rochester, MN (*Presenter*) Nothing to Disclose

## PURPOSE

Thyroid cancer is the most common endocrine malignancy. Ultrasound is the primary imaging modality for evaluating thyroid nodules. Based on the radiologist's assessment, further management, including fine needle aspiration, which is an invasive and costly procedure, may be requested. Thyroid nodule assessment relies on the expertise of radiologists and is subjective to an intrareader agreement. In recent years many deep-learning applications have been developed for thyroid nodule characterization. However, the evaluation of the deep learning model's performance in real-world radiology settings has been limited. In the current work, we aim to evaluate the performance of our previously developed model for thyroid nodule classification into benign and malignant with a radiologist using the American College of Radiology Thyroid Imaging Reporting and Data Systems scoring (TIRAD).

## METHODS AND MATERIALS

The proposed model was trained on the ultrasound images of thyroid nodules from 983 patients with confirmed diagnostic reports from 2008 to 2018. 81 cases were held out as a testing set, and the rest of the data was used for training purposes. One radiologist with more than ten years of experience in ultrasound imaging evaluated the same images of the test set based on the TIRAD scoring system. The radiologist's thyroid nodule evaluation was recorded while the radiologist was blinded regarding the model's prediction and final pathological diagnosis of the patients.

## RESULTS

The whole pipeline from the developed model reached an AUROC of 0.84 (CI 95%: 0.75-0.91) with sensitivity and specificity of 84% and 63%, respectively. The TIRAD evaluation of the test set had a sensitivity of 76% and specificity of 34% which was comparably lower than the model's prediction (p-value=0.003). A comparison of our model's performance with ground truth and the TIRAD score based on an expert radiologist's evaluation was analyzed. In 28% of the cases, the model predicted benign nodules as benign with TIRAD >3 reports from an expert radiologist. In 19% of cases, our model predicted benign nodules with TIRAD =3 as benign, and in 33% of cases, our model predicted malignant nodules correctly with the TIRAD >3. In addition, our model predicted no nodule as malignant, while the nodule had a benign biopsy report with a TIRAD =3.

## CONCLUSION

s We demonstrate the potential diagnostic performance of the deep learning model by comparison of its predictions with TIRAD scores from an expert radiologist.

## CLINICAL RELEVANCE/APPLICATION

Thyroid nodule assessment in ultrasound is subjective to inter and intra-reader agreement. Our deep learning model can provide further assistance to radiologists for thyroid nodule evaluation.

### **R5B-SPHN-4 Real-World Costs Associated with Incidental Thyroid Nodule Workup at an Academic Medical Center**

Participants

Brandon Fields, MD, San Francisco, IL (*Presenter*) Nothing to Disclose

## PURPOSE

Incidental thyroid nodules (ITN) are a frequent finding on cross-sectional imaging, occurring in up to 18% of CT neck studies with a malignancy rate of up to 11% in the reported literature. The rising incidence of thyroid cancer in the United States, due largely to low-risk papillary thyroid cancers detected as ITNs, has been termed an "epidemic of overdiagnosis". ITN workup, including thyroid ultrasound, labs, and biopsy, may therefore cause resource burden on the healthcare system with questionable clinical benefit. The purpose of our study was to prospectively quantify the cumulative financial burden of ITN workup within a single hospital system using real-world data.

## METHODS AND MATERIALS

Starting in August 2022, all ITNs discovered on CT and MR studies that include the neck at a single hospital system were flagged using a key phrase within the radiology report. The patient's age, nodule size, nodule characteristics, and results of any further tests including thyroid labs, thyroid ultrasound, ultrasound-guided fine needle aspiration, and thyroidectomy, were recorded. The cost of thyroid labs, thyroid ultrasound, ultrasound-guided fine needle aspiration, and thyroidectomy was estimated using national 2023 Medicare reimbursement rates for each test.

## RESULTS

From August 2022 to April 2023, ITNs were found on imaging studies including the neck of 355 patients. The overall incidence of thyroid nodules in a representative selection of studies was 4.0%. Further workup was recommended in 130 of 355 patients based on American College of Radiology guidelines. Fifty of 130 patients underwent laboratory testing with TSH, total T4, free T4, and/or free T3 assays. Thus far, 28 ultrasounds and six fine needle aspiration biopsies have been performed. Of the six biopsies, only one showed malignancy and that patient has not yet undergone surgical workup. One patient underwent right partial thyroidectomy for an indeterminate ultrasound result; final surgical pathology was benign and the patient is currently euthyroid. The total cost of thyroid nodule workup thus far has been \$5,780.96 for one malignancy diagnosed. Assuming the patient with diagnosed malignancy

in our cohort undergoes a partial thyroidectomy and remains euthyroid, the total cost for one malignancy diagnosed and treated will be \$6,499.37.

#### **CONCLUSION**

s In this single center prospective cohort study, the total cost of thyroid nodule workup from August 2022 to April 2023 was \$5,780 for one malignancy diagnosed, and \$6,499 for one malignancy diagnosed and treated.

#### **CLINICAL RELEVANCE/APPLICATION**

Incidental thyroid nodule (ITN) workups cause financial burden on a healthcare system with questionable clinical benefit. Quantifying this financial burden is an important step toward cost-effective healthcare.

## Abstract Archives of the RSNA, 2023

R5B-SPIN

### Imaging Informatics Thursday Poster Discussions II

#### Sub-Events

#### R5B-SPIN-1 Using a Large Language Model for Identifying Findings in Chest X-ray Reports

##### Participants

Pritam Mukherjee, PhD, Bethesda, MD (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate Vicuna-13B, a publicly available large language model (LLM), on the task of identifying chest x-ray reports that are positive for a set of findings.

##### METHODS AND MATERIALS

This retrospective study used 25,596 chest x-ray reports from 2797 patients (M: 1,557 (56%), median age: 47, IQR: [32, 58]), corresponding to the test set of the publicly available NIH Chest X-Ray dataset. For the 13 Chexpert findings (atelectasis, cardiomegaly, consolidation, edema, enlarged cardiomeastinum, fracture, lung lesion, lung opacity, pleural effusion, pleural other, pneumonia, pneumothorax, and support devices) we considered the following multi-label binary classification task: the class label for a finding is True if the report contains a positive mention of the finding, and False otherwise. The LLM we chose is Vicuna-13B, a finetuned version of the LLaMA foundation model. We used a rule-based interactive prompting strategy, where each step is a natural language question in English. To avoid randomness in outputs, we set the "temperature" hyperparameter to 0. Since "gold label" radiologist annotations for the large dataset were not available, our primary goal was to assess the agreement of Vicuna's outputs with two popular and state-of-the-art labelers - a rule-based NLP tool Chexpert, and a deep learning model ChexBert - using the Fleiss' kappa statistic performed in a pairwise manner. A subset of 100 reports was manually annotated by a senior radiologist with more than 25 years of experience according to the Chexpert labeling rules. Receiver operating characteristics (ROC) analysis was performed using the radiologist annotations as the reference to assess the reliability of Chexpert, ChexBert and Vicuna.

##### RESULTS

Chexpert and ChexBert showed very high agreement with one another with a kappa value of 0.84 for the NIH dataset. Vicuna showed moderate agreement, with kappa values of 0.54 (P <.001) vs Chexpert and 0.56 (P <.001) vs ChexBert. When compared to radiologist annotations for 100 reports, Vicuna outperformed ChexBert on 4/11 findings (atelectasis, consolidation, enlarged cardiomeastinum, and pleural other), and Chexpert on 5/11 findings (atelectasis, cardiomegaly, enlarged cardiomeastinum, and pleural other); the mean AUROC over 13 labels was 0.85 for all models.

##### CONCLUSION

s LLMs such as Vicuna present promising alternatives to custom-built NLP or deep learning tools for analyzing radiology reports. Vicuna showed satisfactory performance on our task - without any additional training or finetuning.

##### CLINICAL RELEVANCE/APPLICATION

Vicuna can be run locally without risking patient privacy and can accurately determine the presence or absence of findings in reports without the need for any training or custom NLP rules.

#### R5B-SPIN-2 Performance Evaluation and Return on Investment Estimation of a High-Sensitivity Normal-Abnormal Chest X-ray Classifier for Enhanced Clinical Workflow

##### Participants

Eduardo Farina, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

Vasanth Venugopal, MD, New Delhi, India (*Presenter*) Officer, CARPL.AI Inc

##### PURPOSE

To evaluate the performance of a high-sensitivity normal-abnormal chest X-ray classifier, in improving the clinical workflow through efficient batching of normal and abnormal cases.

##### METHODS AND MATERIALS

The IRB-approved study used an enriched retrospective dataset consisting of 2405 normal cases and 2356 abnormal cases. The abnormal cases included clinically significant findings including but not limited to consolidation, nodule, cavitation, pleural effusion, pneumothorax, pneumoperitoneum, cardiomegaly, and rib fractures. These studies were evaluated using ChestLink by Oxipit.ai to classify the chest X-rays into normal and abnormal categories. The algorithm was orchestrated and the inferencing results were analyzed on the CARPL.AI platform.

##### RESULTS

The AI classifier identified 1859 normal and 2902 abnormal cases, with 12 false negatives and 568 false positives. The calculated

sensitivity (recall or true positive rate) of ChestLink is 99.49%, and its specificity (true negative rate) is 76.38%. The positive predictive value (PPV) is 80.77%, while the negative predictive value (NPV) is 99.35%. In the existing workflow with a 30% time reduction for normal cases, the ROI is 26.4%. In the auto-batch workflow, where radiologists take 10 seconds to approve normal cases, the return on Investment (ROI) increases to 180.6%.

## CONCLUSION

s AI solutions can effectively improve the clinical workflow by batching normal and abnormal cases, allowing for the prioritization of abnormal cases for radiologists' review. This minimizes the time spent on normal cases and ensures faster diagnosis and treatment of patients with chest abnormalities. The low false-negative rate further emphasizes its potential to reduce missed abnormal cases, leading to improved patient outcomes. It also demonstrates a positive ROI in both scenarios, significantly improving the efficiency of radiology departments, especially in the auto-batch workflow.

## CLINICAL RELEVANCE/APPLICATION

Implementing ChestLink can lead to faster diagnosis and reporting for patients, while reducing radiologists' workload by optimizing their time spent on normal cases. The auto-batch workflow further enhances these benefits, making it a valuable solution for radiology departments seeking to increase productivity and efficiency.

## R5B-SPIN-3 Development and Clinical Validation of a Radiological Impression Summarization System with Large Language Models

### PURPOSE

To develop and clinically validate a large language model that automatically generates impressions to summarize radiology reports.

### METHODS AND MATERIALS

This retrospective model development study included 204,540 consecutively collected CT, MRI, US, and PET radiology reports from January 2021 to December 2021 from a single academic institution. We devised a text summarization task using a T5 large language model pretrained on the C4 dataset to generate the impression section from the clinical history, comparison, and findings sections of the radiology reports. Repetitive, non-informative phrases such as "No wet reading was provided for this report" and "The above findings have been communicated to the referring physician" were removed from the reports to improve model performance. The Recall-Oriented Understudy for Gisting Evaluation (ROUGE) score, a standard metric for measuring the quality of summaries, was used to evaluate model performance, and a five-reader performance study was conducted to validate clinical utility derived from impression generation. For each of sixty reports, readers were presented with either the report or model-generated impressions and were asked to edit the impression. Impressions were rated for their clinical accuracy, grammatical accuracy, stylistic quality, with the edit distance between their edited impression and the original impression, and time taken to edit also recorded.

### RESULTS

On a UCSF general test dataset composed of 19,710 reports, the model achieved average ROUGE-1, ROUGE-2, and ROUGE-L scores of 54.05, 36.94, and 46.92. For the reader performance study, the model achieved mean ratings of 3.6/4, 3.9/4, and 3.4/4 for clinical accuracy, grammatical accuracy, and stylistic quality respectively and a mean edit distance and edit time of 11.75 words and 18.79 seconds respectively, of a similar performance to the radiologist baseline. The reader performance study demonstrated a moderate level of interexpert agreement (ICC: 0.57).

## CONCLUSION

s Using the clinical history and findings section of a radiology report, large language models can automatically generate radiological impressions with clinical accuracy, stylistic quality, and grammatical accuracy.

## CLINICAL RELEVANCE/APPLICATION

We demonstrate that a large language model can be used to automatically generate excellent quality radiologic impressions, which could potentially improve report quality and workflow efficiency.

## R5B-SPIN-4 Evaluation of A Natural Language Processing Model for Automated Protocolling of CT/MRI Requisitions

Participants

Jia Cheng Yao, MD, Hamilton, ON (*Presenter*) Nothing to Disclose

### PURPOSE

Assess the accuracy of a natural language processing (NLP) model for automatically protocolling CT and MRI requisitions.

### METHODS AND MATERIALS

Image requisitions of all CT/MRIs performed between January 2018-September 2022 at our institution were extracted from the Electronic Medical Record. A total of 234,193 records were obtained containing study requisition text, patient location (outpatient, emergency, inpatient), WTIS triage priority (P1-P4) and selected protocol. Studies were excluded if they did not include a priority or standardized protocol, or were for an interventional radiology procedure (n = 10,150). A total of 224,043 studies were included, with 569 unique protocols (140 CT and 429 MRI). Studies were stratified by triage priority, then randomly split into training, validation and test datasets based on a 80-10-10% split. Data was pre-processed (lower casing, punctuation removal, stop-word removal, lemmatization) using standard techniques. Two independent pre-trained Bidirectional Encoder Representations from Transformers (BERT) models for study protocol and triage priority were fine-tuned using the training dataset based on the optimal hyperparameters (batch size = 10, learning-rate 3e-4) for 5 epochs. Results were analyzed for precision/recall and accuracy, with sub-analysis based on patient location and imaging modality.

### RESULTS

For study protocol, weighted-mean F1-score, precision and recall were 0.813, 0.848 and 0.792, respectively. Overall accuracy was 0.848 (Top-3 accuracy 0.960, Top-5 accuracy 0.973). Stratified by location, accuracy for outpatient (OP), emergency department (ED), and inpatient (IP) studies were 0.832, 0.987 and 0.856, respectively. Accuracy for CT and MRI were 0.899 and 0.762, respectively. Micro-averaged one-vs-rest (OvR) area under the curve (AUC) was 0.998. For study protocol, weighted-mean F1-

score, precision and recall were 0.847, 0.845 and 0.849, respectively. Priority 1 studies demonstrated high F1, precision and recall, 0.952, 0.948 and 0.956, respectively. Overall accuracy was 0.849 (Top-2 accuracy 0.982). Stratified by location, accuracy for OP, ED, and IP studies were 0.832, 0.987 and 0.856, respectively. Accuracy for CT and MRI were 0.831 and 0.881, respectively. Micro-averaged OVR AUC was 0.974.

## CONCLUSION

s Natural language processing models are a feasible solution for automated protocolling of CT/MRI requisitions.

## CLINICAL RELEVANCE/APPLICATION

Applications include workflow optimization, protocol suggestion and study flagging. Given a relative lack of protocol standardization, automated methods also provide opportunities for standardization between institutions and radiologists.

## R5B-SPIN-5 Lifelike Pixel Print Phantoms for Clinical Evaluation of a Deep Learning CT Reconstruction Algorithm

Participants

Jessica Im, BEng, (*Presenter*) Nothing to Disclose

## PURPOSE

Deep learning CT reconstruction (DLR) has become increasingly popular as a method of improving image quality and reducing radiation exposure. Due to their nonlinear nature, these algorithms exhibit object-dependent resolution and noise performance. Therefore, traditional phantoms, which lack tissue morphology, in combination with image quality metrics, such as contrast-to-noise ratio (CNR), have become inadequate indicators of clinical imaging performance. In this study, we propose to utilize lifelike 3D-printed PixelPrint lung phantoms to evaluate DLR performance over a wide range of radiation doses.

## METHODS AND MATERIALS

A lung phantom generated from a patient chest CT with ground glass opacities (GGO) was fabricated using PixelPrint technology. The phantom was scanned with a conventional CT (Incisive CT, Philips Healthcare) at five radiation dose levels (CTDIvol 4.4, 5.6, 9.8, 14.4, 17.0 mGy). At each radiation dose, three scans were acquired, and each was reconstructed with filtered back projection (FBP), iterative reconstruction at one level (iDose4, Level 3), and AI-enabled DLR (Precise Image (PI)) at five levels (Sharper, Sharp, Standard, Smooth, Smoother). Noise and CNR were calculated for each radiation dose and reconstruction technique. With FBP at 17.0 mGy as the reference, structural similarity index measure (SSIM), multi-scale SSIM (MS SSIM), root mean square error (RMSE), and standard deviation (SD) of difference images were also calculated. A two-sample t-test with Bonferroni post hoc test was then performed to evaluate the performance of each dose and reconstruction combination in comparison to the reference for each metric.

## RESULTS

The PixelPrint phantom produced clinically realistic images. iDose4 and DLR demonstrated superior performance at lower radiation doses compared to FBP across all metrics. To match or exceed the performance of the reference for every metric, iDose4 and varying levels of DLR required 9.8 mGy and between 4.4 and 9.8 mGy, respectively. These doses corresponded to dose reductions of 42% for iDose4 and 42% to 75% for DLR.

## CONCLUSION

s DLR has been shown to reduce radiation dose compared to FBP without compromising diagnostic image quality, surpassing the dose reduction achieved through iterative reconstruction. PixelPrint phantoms offer a valuable option for evaluating non-linear and object-dependent reconstruction algorithms, including various flavors of DLR.

## CLINICAL RELEVANCE/APPLICATION

The use of PixelPrint in evaluating novel CT technologies offers a more realistic testing environment compared to traditional phantoms. This, in turn, promotes the translation of new technologies, such as DLR, into clinical practice.

## R5B-SPIN-6 Evaluation of Segmentation Performance using Multiple Reference Standards for Accurate Orbital Bone Modeling in Cranio-maxillofacial Surgery: Based on MSDA-Net Deep Learning Segmentation

Participants

Min Jin Lee, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

Accurate segmentation and modeling of orbital bone on facial CT images are essential for creating customized bone templates in craniomaxillofacial surgery. This study proposes MSDA-Net, a segmentation algorithm that considers varying characteristics of orbital bone in terms of intensity and thickness, and evaluates its performance using reference standards generated through manual labeling by observers and label combination methods.

## METHODS AND MATERIALS

A dataset of 355 facial CT images was divided into 228 training, 56 validation, and 71 test sets. MSDA-Net includes multiscale hierarchy module that considers various bone thicknesses and dual-attention module that focuses on meaningful features of thin bone. Three reference standards were obtained from observers, including a neurosurgeon with over 15 years of experience and two senior medical students. Three additional reference standards were generated using label combination methods, such as label fusion, majority voting, and the STAPLE algorithm. Segmentation performance was evaluated using six reference standards, with the evaluation ROI divided into three regions: whole orbital bone, medial wall, and orbital floor.

## RESULTS

The proposed method outperformed with a DSC of over 89.75% for whole orbital bone and DSCs of 74.38% and 81.42% for the medial wall and orbital floor, respectively. However, differences in reference standards generated by observers and label combination methods resulted in varying levels of precision and recall. Observer 1 tended to generate thick labels, resulting in high precision, while Observers 2 and 3 produced relatively thin labels, leading to high recall values. Label fusion tended to generate thick labels, resulting in high precision, while majority voting and STAPLE generated similar reference standards with high recall. No significant difference in all segmentation measurements was observed between majority voting and STAPLE using the reference

standards.

## **CONCLUSION**

s MSDA-Net provides accurate segmentation results by considering varying thickness and intensity of the orbital bone. Our study emphasizes the importance of using multiple reference standards to evaluate segmentation algorithms for structures prone to inter-observer variability. (This research was supported by a grant from the Korea Health Technology RD Project through the Korea Health Industry Development Institute, funded by the Ministry of Health Welfare (HI22C1496))

## **CLINICAL RELEVANCE/APPLICATION**

Our study can assist in creating customized implants and surgical guides for reconstructing fractured or defective bones and establish reference standards for evaluating automatic segmentation algorithms.

## **R5B-SPIN-7 Evaluating the Reliability of ChatGPT as a Tool for Imaging Test Referral: A Comparative Study with a Clinical Decision Support System**

Participants

Mor Saban, PhD, Tel Aviv, Israel (*Presenter*) Nothing to Disclose

## **PURPOSE**

The purpose of this study is to investigate the feasibility of using Chat Generative Pre-trained Transformer (ChatGPT) to provide accurate imaging referrals for clinical use, as compared to the existing ESR iGuide system. With the continuous evolution and advancement of technology, Artificial Intelligence (AI) is increasingly being used to make diagnosis and decisions, including suggesting the most appropriate imaging referrals. This study aims to explore whether ChatGPT can provide equally or more accurate imaging referrals compared to the ESR iGuide. By evaluating the accuracy and effectiveness of ChatGPT, this study can contribute to the development of AI-based tools for clinical decision-making and potentially improve patient outcomes.

## **METHODS AND MATERIALS**

A comparative study was conducted in a tertiary hospital. Data was collected from 97 consecutive cases that were admitted to the emergency department with abdominal complaints. We compared the imaging test referral recommendations suggested by the ESR iGuide and the ChatGPT and analyzed cases of disagreement. In addition, we selected cases where ChatGPT recommended a Chest Abdominal Pelvis (CAP) CT (n=66), and asked four specialists to grade the appropriateness of the referral.

## **RESULTS**

ChatGPT recommendations were consistent with the recommendations provided by the ESR iGuide. No statistical differences were found between the appropriateness of referrals by age or gender. Using a sub-analysis CAP cases, high agreement between ChatGPT and the specialists was found. Cases of disagreement (12.4%) were further analyzed and presented themes of vague recommendations such as "it would be advisable" and "this would help to rule out".

## **CONCLUSION**

s ChatGPT's ability to guide the selection of appropriate tests may be comparable to some degree with the ESR iGuide. Features such as the clinical, ethical, and regulatory implications are still warranted and need to be addressed prior to clinical implementation. Further studies are needed to confirm these findings.

## **CLINICAL RELEVANCE/APPLICATION**

The article explores the potential of using advanced language models, such as ChatGPT, in healthcare as a CDS for selecting appropriate imaging tests. Using ChatGPT can improve the efficiency of the decision-making process

## Abstract Archives of the RSNA, 2023

R5B-SPIR

### Interventional Radiology Thursday Poster Discussions II

#### Sub-Events

#### **R5B-SPIR-1 Image-guided Intratumoral Radiofrequency Hyperthermia-Enhanced Herpes Simplex Virus Thymidine Kinase Gene Therapy of Non-Small Cell Lung Cancer: The Underlying Molecular Mechanisms**

#### **PURPOSE**

To validate the feasibility of image-guided interventional radiofrequency hyperthermia (RFH)-enhanced direct suicide gene therapy of orthotopic non-small cell lung cancer (NSCLC) and the underlying molecular mechanisms.

#### **METHODS AND MATERIALS**

This study included (a) in vitro experiments to prove the principle of the concept of "RFH-enhanced killing efficacy of Herpes Simplex Virus Thymidine Kinase (HSV-TK) /ganciclovir (GCV) gene therapy" on NSCLC cells, which was confirmed by confocal microscopy, MTS assay and apoptosis analysis; (b) in vivo experiments to validate the feasibility of the new interventional oncology technique, "image-guided intratumoral RFH-enhanced local HSV-TK/GCV gene therapy of NSCLC " by using a multifunctional perfusion-thermal RFH electrode for the rat models of orthotopic lung cancer; and (c) to investigate the related biomolecular mechanisms through three potential pathways, including apoptosis, heat shock protein and immunomodulatory. Both in-vitro and in-vivo experiments were divided into four study groups (n=6/group) with different treatments: (1) combination therapy of RFH+ HSV-TK/GCV; (2) RFH alone at 42°C for 30?min; (3) gene therapy with HSV-TK/GCV; and (4) control with saline.

#### **RESULTS**

In in-vitro experiments, bioluminescence optical imaging of cells confirmed that the relative photon signal intensity in the combination therapy group was significantly lower than those in the other three groups ( $p<0.001$ ). Confocal microscopy and MTS assay also demonstrated significant decrease in cell viability in combination therapy group, compared with other three groups ( $p<0.001$ ). Flow cytometry showed remarkably increased apoptosis in the combination therapy group ( $p<0.01$ ). In in-vivo experiments, follow-up bioluminescence imaging demonstrates a significantly lower relative photon signal intensity of tumors in the combination therapy group than in the other groups ( $p<0.05$ ). Immunohistochemical staining revealed the significantly decreased expression of Bcl-2 ( $p<0.01$ ), and significantly increased expression of Bax ( $p<0.05$ ) and Caspase-3 ( $p<0.01$ ) in the combination therapy group. Immunohistochemical staining also displayed the up-regulation of HSP-70 ( $p<0.01$ ), IL-2 ( $p<0.01$ ) and CD94 ( $p<0.01$ ) in combination therapy.

#### **CONCLUSION**

s This study validated the feasibility of image-guided interventional RFH-enhanced direct suicide gene therapy of orthotopic NSCLC, which is activated through the mechanisms of augmenting Bax/Bcl-2/caspase-3-dependent apoptosis and the HSP-70/IL-2 dependent anti-tumor immunity regulation pathway.

#### **CLINICAL RELEVANCE/APPLICATION**

This study has established ground works for developing a new interventional oncology therapy to effectively manage NSCLC.

#### **R5B-SPIR-2 Delayed Sequelae Following Intranodal Lymphangiogram and Thoracic Duct Embolization**

#### Participants

Alexey Gurevich, MD, Philadelphia, PA (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Over the last decade, intranodal lymphangiography replaced pedal lymphangiography as guidance for thoracic duct embolization (TDE). The long-term effects of intranodal TDE are yet to be elucidated. This study serves the purpose of determining potential delayed sequelae after technically successful intranodal TDE in traumatic and non-traumatic cases.

#### **METHODS AND MATERIALS**

Internal IR QA database (Hi-IQ) was reviewed to identify patients referred for TDE. Between January 2011 and December 2019, 172 patients underwent technically successful intranodal lymphangiogram and TDE to treat isolated chylothorax and plastic bronchitis. The patients were contacted and interviewed for the development of lower extremity edema, diarrhea, abdominal swelling, persistent weight loss, shortness of breath, and development of any other symptoms the patient felt may be temporally related to TDE. Patients were asked to rate their overall health on a scale of 1 to 10 (with 10 being the best) at the time of the interview. Patients who could not be reached were analyzed using electronic medical records (EMR).

#### **RESULTS**

42/177 (20.3%) patients were deceased due to causes unrelated to TDE or did not meet the criteria of minimum 24 months follow-up. 88/130 patients (67.7%, 55M and 43F, 54.6±16.7 years) were assessed with 61/88 (69.3%) patients being available for direct interviews and 27/88 (30.7%) having sufficient clinical information in the EMR. Average follow-up time was 69.4±22.4 months (ranging 25 to 137m). 60/61 (98.3%) patients reported improvement in their lymphatic-related symptoms. Of those who reported

improvement, self-reported health assessment averaged a 9.1 out of 10. 2/88 (2.3%) patients were identified to report one or multiple symptoms that could be related to TDE, such as post-embolization chyluria in patient #1, and abdominal pain with constipation in patient #2. No patients reported diarrhea, shortness of breath, weight loss, or lower extremity swelling that could be directly related to TDE.

## CONCLUSION

s Intranodal TDE is not only effective, but also a safe procedure for treatment of pulmonary lymphatic flow disorders with a reported long-term sequela of 2.3%. Abdominal pain and aberrant lymphatic collaterals may be related to intranodal lymphangiography and TDE, and should be included in routine informed consent.

## CLINICAL RELEVANCE/APPLICATION

This paper demonstrates the long-term safety of TDE. Clinicians should be confident in applying this technique in patients with traumatic and non-traumatic intrathoracic lymphatic leaks.

## R5B-SP1R-3 Outcomes of Percutaneous Transluminal Angioplasty and/or Stenting (PTAS) as Treatment for Transplant Renal Artery Stenosis (TRAS)

Participants

Dhane Stomp, MD,BS, Miami, FL (*Presenter*) Nothing to Disclose

## PURPOSE

The objective of this study was to investigate the efficacy of percutaneous transluminal angioplasty and/or stenting (PTAS) for treatment of transplant renal artery stenosis (TRAS).

## METHODS AND MATERIALS

This single-center, retrospective study analyzed a total of 91 patients with TRAS (median age = 61; 62.46% male and 37.36% female) who underwent 114 PTAS procedures between August 2013 and March 2020. We manually measured renal artery stenosis diameters from pre- and post-intervention angiographic images in the picture archiving and communication system (PACS) for each procedure. Technical success was defined as the ability to successfully dilate the stenosis with angioplasty and/or stent without significant residual stenosis. Baseline and post-intervention peak systolic velocities (PSV) [cm/s] and serum creatinine levels [mg/dL] at regular intervals for at least 24 months were recorded. Baseline and post-intervention results were compared using a two-sided paired samples T-test, with statistical significance defined by a p-value < 0.05.

## RESULTS

Regardless of intervention type, primary technical success was notably high (96.70%). The most performed procedure was stenting (75.44%). Angioplasty alone resulted in a higher reintervention rate compared to stenting (44.44% vs. 20.55%; p = 0.037). Serum creatinine was measured for a median of 12 months; PSV was measured for a median of 6 months. There was a statistically significant reduction in PSV up to 12 months (mean reduction 233 cm/s; p < 0.001). There was also a significant reduction in creatinine from baseline to nadir (mean reduction 0.84 mg/dL; p < 0.001), achieved at a median of 4 months. The reduction in PSV did not correlate with the reduction in creatinine (Pearson correlation coefficient = 0.33; p = 0.79). Fourteen (12.28%) procedural complications occurred, including six minor (e.g., perinephric hematoma, puncture site hematoma, stent kinking) and eight major complications (e.g., dissection, pseudoaneurysm, thromboembolism). Four deaths occurred during the study period, none of which were attributed to study interventions (SIR adverse event class E-F).

## CONCLUSION

s PTAS is an effective, safe treatment for TRAS with a high rate of technical success. A higher reintervention rate was seen with angioplasty alone compared to stenting. Following PTAS, there was a statistically significant reduction in both PSV at 12 months and serum creatinine to nadir. No permanent adverse sequelae or death resulted from any procedure.

## CLINICAL RELEVANCE/APPLICATION

Percutaneous transluminal angioplasty and/or stenting (PTAS) may serve as a safe, effective treatment option for patients with transplant renal artery stenosis (TRAS), which is procedurally and clinically applicable.

## R5B-SP1R-4 New Method of Knee OA Treatment with Intra Genicular Artery Injection of Mesenchymal Stem Cells

## PURPOSE

The aim of this study was to evaluate the role of intra-arterial mesenchymal cell injection in the management of knee osteoarthritis.

## METHODS AND MATERIALS

After IRB and the ethics committee's approval, 30 patients with moderate knee osteoarthritis (OA) were treated. All patients had an MRI prior the procedure confirming the OA. After accessing the contralateral femoral artery, the genicular artery leading to the vascular blush was catheterized. The solution of mesenchymal stem cells (70 million allogenic cells) was then injected in the vessel. All the patients were admitted for one day following the procedure. MRI of the knee is planned in all patients at one month. WOMAC scores were obtained before and weekly after the intervention.

## RESULTS

Technical success rate was 100%. 30 patients have completed clinical, and imaging follow up at one month. They were divided to four age groups and their womac score results recorded in 4 weeks as described below: A) Womac Score for age >55 (n=16) : "32.63" reduced to "7.69" B) Womac Score for age <=55 (n=14): "25.14" reduced to "3.36" C) Womac Score for weight >70 (n=17): "27.76 reduced to 5.47" D) Womac Score for weight <=70 (n=13): "30.92 reduced to 5.92" The average WOMAC score before the intervention, was about (25.14 - 32.63), and it dropped to about (7.69 - 3.36) on one month. This reduction on mean WOMAC numbers is statistically significant. Patient symptoms improved significantly. MRIs of the knee have demonstrated a significant regeneration of the affected cartilage and the subchondral lesions.

## CONCLUSION

s This preliminary study is promising demonstrating that intra-Genicular artery injection of mesenchymal Stem Cells not only

improves clinical symptoms, but also results in early cartilage regeneration. In addition to pain improvement and cartilage regeneration, MRI Pictures demonstrate that in some patients subchondral changes improved significantly

#### **CLINICAL RELEVANCE/APPLICATION**

new method to pain management for OA patients.

### **R5B-SP1R-5 All-payor Utilization of Arterial and Venous Thrombectomy for VTE in the United States**

#### **PURPOSE**

An estimated one million venous thromboembolism (VTE) events occur annually in the U.S. and the use of thrombectomy to treat VTE is becoming increasingly common. Here, we assess utilization trends of arterial and venous thrombectomy to treat VTE for commercial and Medicare beneficiaries between 2017 and 2021.

#### **METHODS AND MATERIALS**

A claims search was performed through the Standard Analytical File (SAF) and claims clearinghouse databases to collect utilization data for arterial and venous thrombectomy across commercial and Medicare payers between January 2017 and December 2021 using Common Procedural Terminology (CPT codes). Thrombectomy CPT codes (37184-37188) were cross-referenced against ICD-10 codes for venous thromboembolism (VTE). Cross-referencing with COVID-19 ICD-10 codes was performed for 2020 and 2021 data. Claim counts and percentages were tabulated, and p-values calculated using chi square in GraphPad Prism.

#### **RESULTS**

Between January 2017 to December 2021, 79,925 claims for arterial and venous thrombectomy to treat VTE were identified. There was a 125% 5-year increase in total claims. Although there were significantly more venous thrombectomy (VT) claims than arterial thrombectomy (AT) (64,258 vs. 15,667,  $p < 0.001$ ), a greater 5-year increase in AT claims was observed compared to VT (5.5- vs. 1.8-fold). AT was more often billed through commercial insurers (62.1%) than Medicare (37.9%) ( $p < 0.001$ ) with the opposite true of VT (53.2% Medicare, 46.8% commercial,  $p < 0.001$ ). Interventional Radiology (IR) performed significantly more AT and VT procedures across all payers from 2017 to 2021 (IR: 46.7%, all cardiology: 23.1%, all surgery: 4.2%, vascular surgery: 25.9%,  $p < 0.001$ ). However, cardiology subspecialties saw a greater rise in AT and VT across all payers from 2017 to 2021 compared to IR (AT: 6.6- vs. 6.0-fold, VT: 2.6- vs. 1.5-fold). The Midwest and Southeast had the highest utilization of AT and VT regardless of payer. In COVID-19 patients, AT claims in 2021 were 3-fold higher than in 2020 (393 vs. 135 claims,  $p < 0.001$ ) irrespective of payer. Top ICD-10 codes associated with AT and VT were "pulmonary embolism without acute cor pulmonale" (61% of AT) and "embolism/thrombosis of iliac/femoral/popliteal veins" (49% of VT), respectively.

#### **CONCLUSION**

From 2017 to 2021, the number of claims for arterial or venous thrombectomy to treat VTE across all payers increased significantly. While a majority of these were VT, a greater rise in the number of AT claims was observed. IR performed more AT and VT procedures than any other specialty over this 5-year period.

#### **CLINICAL RELEVANCE/APPLICATION**

The use of thrombectomy to treat VTE is growing rapidly. Nonetheless, it remains a small percentage of total VTEs occurring nationally each year.

### **R5B-SP1R-6 The Benefit of Filtered Blood Reperfusion in Suction Thrombectomy of Submassive Pulmonary Embolism**

Participants

Ryan Bitar, MD, New Haven, CT (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Catheter-directed suction thrombectomy has emerged as a major tool for reducing right heart strain in the management high-intermediate risk pulmonary embolism (PE); however, suction thrombectomy presents a potential concern for significant blood loss during clot aspiration. The purpose of this study is to assess the benefit and safety of utilizing a blood reperfusion filtration device (BRFD) during thrombectomy which is able to filter and return aspirated blood in an attempt to minimize blood loss.

#### **METHODS AND MATERIALS**

A single-institution retrospective cohort study was conducted on patients who underwent suction thrombectomy from 2018-2022. Patients were categorized into cohorts based on the use versus nonuse of a BRFD. Inclusion criteria involved adult patients with submassive PE (either imaging and/or biomarkers indicative of right heart strain) who underwent suction thrombectomy. Patients with massive PE, preceding cardiac arrest, or contraindication to anti-coagulation were excluded. Critical data points included age, gender, pre-procedural vitals and labs, procedural change in pulmonary arterial pressure (PAP), immediate post-procedural vitals and labs, admission length, blood transfusions, and 30-day post-procedural complications.

#### **RESULTS**

50 patients were recruited for each cohort. No significant difference in patient demographics, preprocedural vitals or labs, pre-procedural PAP, or thrombectomy-related decrease in PAP was observed. Post-procedural decrease in heart rate was -12.4 bpm in the non-BRFD cohort versus -20.6 bpm in the BRFD cohort ( $p = 0.039$ ). 24-hour post-procedural complete blood count demonstrated a significantly increased drop in hemoglobin in the non-BRFD cohort (-2.54g/dL) in comparison to the BRFD cohort (-1.54g/dL) ( $p = 0.00004$ ). Of note 24-hour post-procedural platelets, white blood cells, creatinine, and potassium did not demonstrate a significant change between the two cohorts. 20% of the non-BRFD cohort and 4% of the BRFD cohort required blood transfusions ( $p = 0.028$ ). No significant difference was observed in days of admission or number of complications between the two cohorts.

#### **CONCLUSION**

The results of this study indicate that using a BRFD is a safe means of minimizing blood loss during suction thrombectomy, as evidenced by an attenuated drop in hemoglobin and a reduction in blood transfusions. Of note, the study poses limitations intrinsic to that of a low-power single-institution retrospective cohort study.

#### **CLINICAL RELEVANCE/APPLICATION**

Employment of a BRFD during suction thrombectomy should be considered as a beneficial tool for decreasing the risk of post-procedural anemia and the need for potential transfusions, improving patient energy/recovery and sparing precious blood products.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

R5B-SPMK

### Musculoskeletal Imaging Thursday Poster Discussions II

#### Sub-Events

#### **R5B-SPMK-1 Are Isolated Ulnar Fractures a True Marker for Intimate Partner Violence?**

##### **PURPOSE**

What is the prevalence of confirmed or high risk for intimate partner violence (IPV) among adult women with isolated ulnar shaft fractures within a large integrated health system? Are there injury or sociodemographic characteristics associated with IPV in patients with isolated ulnar fractures?

##### **METHODS AND MATERIALS**

Adult women, age 18 to 65, with ulnar fractures from 2016 through 2021 were identified through electronic health record (EHR) query. Patients were categorized into two groups, one with isolated ulnar fractures and another with fractures of both the radius and ulna. Sociodemographic and clinical data, referral data, reported mechanism of injury and IPV documentation were collected. IPV stratification into four groups: confirmed IPV, high risk for IPV, low risk for IPV and not IPV based on ICD 9/10, internal IPV diagnosis codes and clinical chart review. Radiographs of isolated ulnar fracture group were evaluated for fracture side, location, pattern and displacement.

##### **RESULTS**

29% of 148 patients with isolated ulnar fractures were high risk or confirmed IPV, compared to 10% of the 147 patients who had non-isolated ulnar fractures ( $p < .01$ ). 95% of patients had formal documentation of screening within their EHR and 9% at time of fracture presentation. Within isolated ulna fracture group, confirmed or high-risk for IPV was associated with reported mechanism of injury of assault (37% versus 1%;  $P < .01$ ) but not other injury characteristics. Confirmed or high-risk for IPV was associated with previously reported IPV correlates of alcohol abuse history (30% versus 15%,  $p = .04$ ), depression history (42% versus 15%,  $p < .01$ ), and anxiety history (42% versus 22%,  $p = .01$ ). Increased number of prior documented emergency visits (median 2.0; interquartile range 0.0-6.0 versus median 0.0; interquartile range 0.0-1.0;  $p < .01$ ) was also associated with confirmed or high-risk for IPV.

##### **CONCLUSION**

Prevalence of confirmed or high-risk IPV in isolated ulnar fracture patients was significantly higher than those with non-isolated ulnar fractures. Frequent emergency department visits, alcohol abuse history and psychiatric history would favor IPV etiology.

##### **CLINICAL RELEVANCE/APPLICATION**

IPV is a global public health emergency which is challenging to diagnose. Prior research reported up to a third of 62 adult female patients with isolated ulnar fractures at three Level 1 trauma centers in urban setting may be associated with IPV. We found that 29% of adult female patients with this fracture identified in outpatient, urgent care, and emergency settings across a large multicenter health system had confirmed or were high risk for IPV. Our research supports isolated ulnar fracture as a true marker for IPV and highlights the importance of IPV screening at time of fracture evaluation.

#### **R5B-SPMK-2 Association Between Pelvic Bone CT-Derived Body Composition and Patient Outcomes in Older Adults With Proximal Femur Fracture**

##### **PURPOSE**

To investigate the association between pelvic bone computed tomography (CT)-derived body composition and patient outcomes in older adult patients who underwent surgery for proximal femur fractures.

##### **METHODS AND MATERIALS**

We retrospectively identified consecutive patients aged  $\geq 65$  years who underwent pelvic bone CT and subsequent surgery for proximal femur fractures between July 2018 and September 2021. Eight CT metrics were calculated from the cross-sectional area and attenuation of the subcutaneous fat and muscle, including the thigh subcutaneous fat (TSF) index, TSF attenuation, thigh muscle (TM) index, TM attenuation, gluteus maximus (GM) index, GM attenuation, gluteus medius and minimus (Gmm) index, and Gmm attenuation. The patients were dichotomized using the median value of each metric. Multivariable Cox regression and logistic regression models were used to determine the association between CT metrics with overall survival (OS) and postsurgical intensive care unit (ICU) admission, respectively.

##### **RESULTS**

A total of 372 patients (median age, 80.5 years; interquartile range, 76.0-85.0 years; 285 females) were included. TSF attenuation above the median (adjusted hazard ratio [HR], 2.39; 95% confidence interval [CI], 1.41-4.05), GM index below the median (adjusted HR, 2.63; 95% CI, 1.33-5.26), and Gmm index below the median (adjusted HR, 2.33; 95% CI, 1.12-4.55) were independently associated with shorter OS. TSF index (adjusted odds ratio [OR], 6.67; 95% CI, 3.13-14.29), GM index (adjusted OR, 3.45; 95% CI, 1.49-7.69), GM attenuation (adjusted OR, 2.33; 95% CI, 1.02-5.56), Gmm index (adjusted OR, 2.70; 95% CI, 1.22-5.88), and Gmm attenuation (adjusted OR, 2.22; 95% CI, 1.01-5.00) below the median were independently associated with ICU admission.

## CONCLUSION

s In older adult patients who underwent surgery for proximal femur fracture, low muscle indices of the GM and gluteus medius/minimus obtained from their cross-sectional areas on preoperative pelvic bone CT were significant prognostic markers for predicting high mortality and postsurgical ICU admission.

## CLINICAL RELEVANCE/APPLICATION

CT metrics of the gluteus muscle group and subcutaneous fat can be utilized as risk stratification factors in elderly patients with proximal femur fractures.

## R5B-SPMK-3 Stewart-Treves Syndrome with Lymphedema of Limbs in 21 Cases: CT and MRI Manifestations

Participants

Qi Hao, Beijing, China (*Presenter*) Nothing to Disclose

## PURPOSE

Stewart-Treves syndrome (STS) is a secondary angiosarcoma based on chronic lymphedema after mastectomy and lymphadenectomy. This study is to analysis retrospectively the CT and MRI manifestations of STS in 21cases.

## METHODS AND MATERIALS

From June 2006 to March 2021, 21 patients with STS in our hospital were collected, including 17 females and 4 males, aged from 35 month to 81 years (median age 65). All patients underwent CT scan and MRI or MRL. Follow up for 2-10 years, 15 cases died (71.4%) and 6 cases (28.6%) had poor prognosis.

## RESULTS

Among the 21 patients, 18 lesions occurred in the upper limb (12 cases in right) and 3 cases in the lower limb. The size of lesions ranged from 3 to 15 cm, 8 cases were round-like and 13 cases were irregular in shape, with clear or irregular margin in 15 cases and fuzzy in 6. All lesions were located in subcutaneous connective tissue and involved the skin and adjacent muscle tissue were involved in 10 cases. On plain CT scan, the lesions showed soft tissue density (CT value = 18-46 Hu) and showed homogeneous or heterogeneous mild to moderate enhancement (CT value = 45-68 Hu) enhanced CT with necrosis and liquefaction in only 2 cases. MRI showed low signal on T1WI, high or mixed signal on T2WI and high signal on DWI. There were extensive changes of chronic lymphedema around all the lesions and ipsilateral axillary lymph node enlargement in 16 cases with the size of 1-2.6cm.

## CONCLUSION

s The main feature of Stewart Treves syndrome is a growing soft tissue mass in the area of chronic lymphedema. The CT and MRI are important methods for accurate diagnosis, staging and grading evaluation of secondary angiosarcoma based on chronic lymphedema.

## CLINICAL RELEVANCE/APPLICATION

Multimodality image are important methods for accurate diagnosis of the three subtypes of STS.

## R5B-SPMK-4 Prediction of Histopathological Subtypes of Dermatofibrosarcoma Protuberans Based on MRI Radiomics Machine Learning Model

## PURPOSE

To establish a diagnostic model for classic DFSP and FS-DFSP image information to explore the feasibility of predicting DFSP histological subtypes.

## METHODS AND MATERIALS

53 DFSPs were retrospectively included in this study: 9 subjects with FS-DFSP and 44 subjects with classic DFSP. Their T1WI and FS-T2WI images constituted the primary dataset used to train multiple machine learning algorithms for constructing DFSP histological subtype prediction model. The subjects were randomly divided into training group and testing group. The training group was used for machine learning and the testing group was used to evaluate the training model. All patients were scanned using a 3.0T MR scanner. ROIs were manually delineated by open-source software on each slice of the T1WI and FS-T2WI images by one musculoskeletal radiologist with 5 years of professional experience, and each ROI segmentation was tested by another radiologist with 10 years of experience. LASSO was used to select features from preoperative imaging data. The prediction models of RF and KNN classifiers were constructed on T1WI and FS-T2WI respectively by using the extracted imaging features. The prognostic performance was assessed in training cohort and testing cohort by means of AUC, sensitivity, specificity and accuracy.

## RESULTS

15 imaging features were selected by using LASSO algorithm. The AUC of RF based on T1WI was 0.902; sensitivity, 91.2%; specificity, 89.2%; and accuracy, 90.4%. The AUC of RF based on FS-T2WI was 0.913; sensitivity, 90.7%; specificity, 91.1%; and accuracy, 88.9%. The AUC of KNN based on T1WI was 0.798; sensitivity, 88.7%; specificity, 89.7%; and accuracy, 80.1%. The AUC of KNN based on FS-T2WI was 0.815; sensitivity, 83.5%; specificity, 86.3%; and accuracy, 82.1%.

## CONCLUSION

s This study puts forward for the first time the application of radiomics to distinguish the histopathological subtypes of DFSP, which provides a new and effective assistant diagnostic method for recognizing DFSP variants. The non-invasive machine learning method based on T1WI and FS-T2WI imaging is potential prognostic tool by distinguishing different levels of DFSP pathological subtypes before operation to improve the treatment strategy.

## CLINICAL RELEVANCE/APPLICATION

DFSP is a rare low to intermediate grade soft tissue sarcoma of skin, but the FS-DFSP is a clearly malignant pathological subtype. The identification of malignant pathological subtypes by radiomics plays an important role preoperatively. The non-invasive machine learning method based on T1WI and FS-T2WI imaging is potential prognostic tool by distinguishing different levels of DFSP pathological subtypes before operation in this study to provide a new idea for the diagnosis and treatment of DFSP.

## **R5B-SPMK-5 Radiomics Signature on Magnetic Resonance Imaging: A Feasible Imaging Biomarker for Prediction of the Histopathological Grade of Soft Tissue Sarcomas**

### **PURPOSE**

Radiomics analysis is more comprehensive and reliable to better provide the features of tumor characteristics and heterogeneity. It is important to identify the pathologic grade of soft tissue sarcomas before receiving treatment. Thus, we aimed to build a radiomics signature on the basis of magnetic resonance imaging and evaluate its ability for preoperatively identifying the grade of Soft tissue sarcoma (STS).

### **METHODS AND MATERIALS**

99 patients (55 low grade STS and 44 high grade STS) were at random segmented into a training cohort (39 low grade STS and 31 high grade STS) and a validation cohort (16 low grade STS and 13 high grade STS) with a portion of 7:3. T2 with fat saturation and T1 with fat saturation and gadolinium contrast images were used to extract radiomics features. Radiomics signature was developed by the least absolute shrinkage and selection operator (LASSO) logistic regression model. The receiver that operated characteristics curve (ROC) analysis was used to assess radiomics signature's prediction performance.

### **RESULTS**

A radiomics was developed by 8 radiomics features achieved favorable predictive efficacy. High-grade STS showed higher radiomics score than low-grade STS in both groups. An excellent prediction performance was indicated by the radiomics signature in both groups. The training cohorts and validation cohorts had an area under curves (AUCs) of 0.888 and 0.861, respectively.

### **CONCLUSION**

A radiomics signature on the basis of MRI images could help identification the grade of STS, which could help guide clinical treatment strategies

### **CLINICAL RELEVANCE/APPLICATION**

In this study, we build a radiomics signature on the basis of magnetic resonance imaging and evaluate its ability for preoperatively identifying the grade of Soft tissue sarcoma (STS). We found that the radiomics signature on the basis of MRI images could help identification the grade of STS, which could help guide clinical treatment strategies.

## **R5B-SPMK-6 Shear Wave Elastography in Benign vs Malignant Fatty Tumors**

Participants

Ilyan Mezinskiy Kushnerev, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

### **PURPOSE**

Lipomas are the most frequent soft tissue tumors of the general population, but they are not always easy to differentiate from liposarcomas. The goal of the study was to assess if shear wave elastography (SWE) could help differentiate malignant and benign iso/hyperechoic lipomatous lesions.

### **METHODS AND MATERIALS**

We retrospectively review patients with fatty lesions that underwent percutaneous core needle biopsy in a University Hospital during 2021. All patients underwent ultrasonography followed by SWE to measure elasticity in kPa before biopsy. We compared benign and malignant tumors. The biopsy findings and, in some cases, the surgical-specimen histology were used as gold-standard.

### **RESULTS**

We included 27 patients with lipomatous lesions, 22 with benign (16 lipomas, 3 spindle cell lipomas and 3 hibernomas) and 5 with malignant tumours (well differentiated liposarcomas). Malignant fatty lesions had significantly higher mean (19.07 (6.1-53.6) vs 46.86 (20.6-78.8);  $p=0.006$ ), max (74.4 (36.2-102.7) vs 33.69 (6.4-110.4);  $p=0.013$ ) and Standard Deviation (16.86 (9.8-24.3) vs 7.6 (0.5-25.2)  $p=0.008$ ) elasticity values compared to benign ones. Differences between benign subgroups do not achieve statistical significance.

### **CONCLUSION**

SWE had good specificity and sensitivity for separating benign from malignant soft-tissue lipomatous masses, while differentiation between benign subgroups was not possible. Malignant lesions were stiffer and had more heterogeneous elasticity values than their benign counterparts.

### **CLINICAL RELEVANCE/APPLICATION**

The primary objective of this study is to enhance the comfort of patients by reducing the time taken to arrive at a diagnosis and minimizing the need for unnecessary biopsies. This is a critical consideration because biopsies can be invasive, uncomfortable, and carry a risk of complications. Moreover, unnecessary biopsies can result in increased healthcare costs and undue stress for patients. By increasing the speed and accuracy of diagnosis, SWE has the potential to significantly improve patient outcomes and reduce healthcare costs.

## **R5B-SPMK-7 Feasibility of Dual-layer Spectral CT Histogram Analyses for Differentiation Between Benign and Malignant Myxoid Soft Tissue Tumors: A Preliminary Study**

Participants

Masanori Nakajo, MD, Kagoshima, Japan (*Presenter*) Nothing to Disclose

### **PURPOSE**

To evaluate the usefulness of electron density (ED) and effective atomic number (Zeff) for differentiation between benign and malignant myxoid soft tissue tumors.

### **METHODS AND MATERIALS**

Twenty-two consecutive patients (mean age 60.5 years) with pathologically proven soft tissue tumors including 11 benign myxoid

Twenty-two consecutive patients (mean age 60.5 years) with pathologically proven soft tissue tumors including 11 benign myxoid soft tissue tumors (BMSTTs) and 11 malignant myxoid soft tissue tumors (MMSTTs) were retrospectively analyzed. For all patients, preoperative dual-energy CT examination was performed using a dual-layer spectral detector CT scanner between February 2018 and March 2023. ROIs were drawn to fill the solid parts within each tumor avoiding calcified areas, and placed onto exactly the same locations in the images of Zeff, ED and conventional CT (120 KeV, CTconv). The histogram indices (the mean, skewness, kurtosis and 10th, 25th, 50th, 75th, and 90th percentiles) of the CTconv, Zeff, and ED values were compared between BMSTTs and MMSTTs using the Mann-Whitney U test. ROC curve analysis was carried out to assess the ability of each index to differentiate MMSTTs from BMSTTs. Sensitivity and specificity were calculated with a threshold criterion that would maximize the average of sensitivity and specificity by the largest Youden's index.

## RESULTS

The skewness of ED was significantly lower in MMSTTs ( $-0.11 \pm 1.32$ ) than in BMSTTs ( $0.73 \pm 0.49$ ) ( $P = 0.013$ ), while no significant difference was shown in any other parameters. The area under the ROC curve for diagnosing MMSTTs was 0.81 for ED skewness. With a cut-off value of 0.62, the sensitivity and specificity to predict MMSTTs were 90.91% and 72.73%.

## CONCLUSION

The skewness of ED may be useful in differentiating MMSTT from BMSTT.

## CLINICAL RELEVANCE/APPLICATION

Histogram analysis of dual-energy CT parameters, especially skewness of electron density may be useful in differentiating malignant from benign myxoid soft tissue tumors.

## R5B-SPMK-8 The Diagnostic Role of Ultrasound in Merkel Cell Carcinoma: Our Experience

Participants

Elena Julian Gomez, MD, Santander, Spain (*Presenter*) Nothing to Disclose

## PURPOSE

Merkel cell carcinoma (MCC) is a rare and very aggressive type of skin cancer (<1% of all cutaneous malignancies), predominantly affecting old and/or immunosuppressed patients. Our purpose is to describe and illustrate the main sonographic features of this tumor.

## METHODS AND MATERIALS

We retrospectively reviewed the images of MCC diagnosed in our institution during the last 10 years. We evaluated the demographic and clinical characteristics of the patients, the gray-scale and color Doppler sonographic findings of the lesions, and the locoregional lymph node involvement.

## RESULTS

Ultrasound images of 8 patients were available, 6 women and 2 men with ages between 69 and 94 years. All but one of the tumors were in photoexposed areas. 7 patients debuted with a fast-growing nodular dermal lesion. In those 7 patients who clinically showed a cutaneous nodule, ultrasonographically the tumors were dermohypodermal, hypoechoic, non-encapsulated, with infiltrative margins through the relatively homogeneous subcutaneous septa, and with extensive vascularization that respects the architecture of the cutaneous plexuses. In 4 of the tumors, there was a "sandwich" pattern with an area of elongated dermal involvement and a parallel zone deep in the subcutaneous cellular tissue connected by infiltrated interlobular septa. Locoregional adenopathies and in-transit metastases were detected in almost half of the patients at the time of diagnosis.

## CONCLUSION

Ultrasound is the imaging test of choice in the evaluation of cutaneous and superficial tumors. Despite its rarity, the presence of a dermohypodermal tumor with infiltrating borders through the lobular septa, high vascularization, relatively respected architecture and particularly, the appearance of a "sandwich" pattern, should make us include MCC in the differential diagnosis and force us to study on the spot the locoregional adenopathies and possible in-transit metastases.

## CLINICAL RELEVANCE/APPLICATION

Recognizing the sonographic findings described above is of great importance to suggest the diagnosis of this rare entity, as well as to perform the locoregional extension study in the same exploration. All this means a considerable clinical benefit, since it allows an early management of this condition.

R5B-SPNMMI

### Nuclear Medicine & Molecular Imaging Thursday Poster Discussions II

#### Sub-Events

#### **R5B-SPNMMI-1**    **Dynamic Multi-phase 18F-NaF PET/MRI in Pediatrics**

Participants

Kip Guja, MD, PhD, Stanford, CA (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Skeletal imaging with 18F-NaF offers improved imaging characteristics and biodistribution compared to conventional bone scintigraphy with 99mTc methylene diphosphonate (MDP) and hydroxydiphosphonate (HDP) but is typically acquired in a single delayed phase. Early blood pool phase imaging plays a vital role in pediatric skeletal scintigraphy due to its ability to reveal evidence of hyperemia, inflammation, marrow infiltration, and soft tissue abnormalities. Here we report an initial pilot study combining the superior imaging characteristics of NaF PET and the increased sensitivity of blood pool phase imaging by performing dynamic multiphase 18F-NaF PET/MRI in pediatric patients.

#### **METHODS AND MATERIALS**

Dynamic PET images were acquired in a single bed position focused on the area of clinical concern using fast list-mode starting just after injection of the radiopharmaceutical for a duration of 10 minutes. This was followed by standard delayed phase acquisition for the second portion of the exam. Dynamic blood pool phase images were reconstructed at 2.5 minutes per frame for a total of 10 minutes. Additional static blood pool phase images were reconstructed using the entire first 10 minutes of the exam. For the MRI component of the dynamic phase, zero echo time (ZTE) proton-density weighted MRI images were acquired.

#### **RESULTS**

In this prospective pilot study, a total of eight 18F-NaF PET/MRI examinations were performed on seven pediatric patients, ranging from 5 years old to 20 years old. Four of the exams were performed with traditional single delayed phase imaging only and four were acquired with dynamic and static early blood pool phase imaging in addition to the standard whole body delayed phase. Diagnoses included osteomyelitis, mastoiditis, CRMO, and one indeterminate lesion with subsequently improved after conservative therapy with NSAIDs.

#### **CONCLUSION**

s Dynamic early blood pool phase 18F-NaF pediatric PET/MRI can improve imaging evaluation of children with skeletal complaints by combining the superior imaging characteristics of 18F-NaF PET with the added sensitivity of blood pool phase images and superior contrast with reduced radiation exposure of MRI. Further studies in larger cohorts of pediatric patients with a variety of skeletal pathologies are needed.

#### **CLINICAL RELEVANCE/APPLICATION**

Skeletal scintigraphy is one of the most common indications for pediatric radionuclide imaging. Combining the strengths of 18F-NaF PET with dynamic early blood pool imaging in PET/MRI offers unique and important benefits in evaluating children with skeletal complaints.

#### **R5B-SPNPM-Increased Adverse Iodine Contrast Agent Reactions and Resistance to Epinephrine in the Setting of Beta-blocker Therapy: A Multi-Institutional Analysis of 209,482 Patients** 1

##### Participants

Brittany Dang, BA, Galveston, TX (*Presenter*) Nothing to Disclose

##### PURPOSE

Adverse allergic reactions to iodine contrast agents are not common but can result in urticaria, nausea, vomiting, and potentially anaphylaxis. Beta-blockers, however, are a widely used class of medications that have been associated with an increased risk and severity of anaphylactic reactions. The purpose of this research is to investigate the relationship between beta blockers and adverse iodinated contrast agent reactions and response to epinephrine.

##### METHODS AND MATERIALS

The TriNetX research network provides access to de-identified medical record information for more than 111 million patients in 76 large healthcare organizations and was used for this study. Two patient cohorts were created. Beta-blocker utilization was identified by any of the following medication names and codes: acebutolol (149), atenolol (1202), bisoprolol (19484), metoprolol (6918), nadolol (7226), nebivolol (31555), and propranolol (8787). Contrast exposure was identified by ioxilan (27793), iopromide (27781), ioversol (27792), iopamidol (5966), and iohexol (5956). Both cohorts had exposure to one of the contrast agents at the time of a CT of the chest (CPT code 71260). One group was simultaneously on treatment with a beta blocker, while the other group was excluded from them. The cohorts were balanced for age, race, gender, and ethnicity by propensity score matching via the greedy nearest neighbor algorithm, resulting in 104,741 patients in each arm. They were then evaluated for subsequent ICD-10 code for "adverse effect of diagnostic agents" (T50.8X5), and medication codes for "use of epinephrine" (3992), and "use of glucagon" (4832).

##### RESULTS

Patients on beta blockers were 2.3 times more likely to have an adverse reaction to iodinated contrast agents (RR 2.3, 95% CI (1.65,3.29), p-value <0.0001). They were also 50% more likely to require treatment with epinephrine (RR 1.49, 95% CI (1.43,1.56), p-value <0.0001) and 2.6 times more likely to require treatment with glucagon (RR 2.6, 95% CI (2.43,2.7), p-value <0.0001).

##### CONCLUSION

The results from this large global data set support the idea that beta blockers increase the risk of allergic reactions to substances such as iodinated contrast agents and are associated with a reduced response to epinephrine. With the increasing use of beta blockers and iodine contrast agents, awareness of the potential adverse reactions and resistance to epinephrine is important.

##### CLINICAL RELEVANCE/APPLICATION

The current research is significant because understanding the increased risk of adverse reactions to iodine contrast agents and resistance to epinephrine in the setting of beta blockers will lead to improved safety of evaluation and treatment for patients requiring radiologic imaging with contrast.

#### **R5B-SPNPM-How Many "Lives" Does a Radiologist Save in a Career? A Modeling Analysis and Estimation** 2

##### Participants

Alexander Kuehne, MD, Clear Lake, MN (*Presenter*) Nothing to Disclose

##### PURPOSE

Medical imaging has unquestionably revolutionized medical care over the past century. Due to radiologists playing a supportive role in the care of a large number of patients, our total impact is difficult to quantify. The purpose of this analysis is to estimate the total value, in Quality Adjusted Life Years (QALYs) and average "lives" saved during the course of a usual career in radiology.

##### METHODS AND MATERIALS

We use figures from recent literature to calculate a point estimate as well as plausible ranges for the value of radiologic work over the course of a usual career. Input parameters include the average of a career (30 years), studies read per year (9671-12,669), annual work RVUs (9,264), total/work RVU ratio (1.97), cost per RVU (\$32.41), cost-effectiveness and willingness-to-pay for QALYs in the US (50-200K/QALY), average age of the US population (39), and remaining QALYs for the average person (~35). Deterministic and probabilistic sensitivity analyses were performed to assess plausible ranges and the sensitivity of health utility impact from the career in radiology. Results are reported in 2021 US Dollars.

##### RESULTS

The average radiologist is expected to provide health services with estimated value of \$18 million during the course of their career,

reporting on the order of 300K-400K examinations (impacting at most as many patients). When the average cost-effectiveness of imaging is \$50,000/QALY, a radiologist is expected to provide 355 QALYs during a career or "save" the equivalent QALYs remaining in ~10 average lives. A pessimistic estimation, based on a higher proportion of low-value care (lower cost-effectiveness), could reduce the health utility impact by approximately 75%. Deterministic and probabilistic sensitivity analyses recapitulate the major findings, and emphasize that the health utility consequences of radiologic practice is highly dependent on the cost-effectiveness of imaging.

#### **CONCLUSION**

s Radiologists provide a large volume of clinical care during the course of a career, impacting hundreds of thousands of patients. The total sum of our impact however, is highly sensitivity to health system variables, most importantly, the cost-effectiveness of radiologic imaging. Efforts to advance both value-based care could have an outsized effect on the utility of radiologic practice as a whole.

#### **CLINICAL RELEVANCE/APPLICATION**

Due to radiologists playing a supportive role in the care of a large number of patients, our total impact is difficult to quantify. Further knowledge and analysis of various system wide factors and, the sensitivity of radiology to these variables, can raise awareness of our overall impact on the US health system and potentially point towards ways of further value-basis analysis of radiologic imaging cares.

R5B-SPNR

### Neuroradiology Thursday Poster Discussions II

#### Sub-Events

#### R5B-SPNR-1 Independent Component Analysis vs. Block Design: A Comparison of Methods for Sedated Language Mapping in Pediatric Epilepsy

##### PURPOSE

Passive task-based fMRI under anesthesia is done for presurgical language mapping in pediatric epilepsy patients who cannot complete an awake study. In our previous study, using standard block design task paradigm-based analysis methods, we observed more atypical language patterns in task fMRI under anesthesia compared to wakefulness. We hypothesize that due to the effect sedation has on the brain, unconstrained data driven methods of analyses may be more likely to reveal the language network.

##### METHODS AND MATERIALS

We retrospectively identified patients with focal epilepsy who underwent presurgical functional MRI under anesthesia, including Auditory Descriptive Decision Task paradigm at our institution from 2014-2022. We used two methods to extract language activation maps: 1) paradigm-based block design general linear model (GLM), and 2) data-driven independent component analysis (ICA). A laterality index (LI) was calculated separately in the Frontal and Temporal language regions of interest (ROI). We considered positive laterality indexes as left dominant, negative laterality indexes as right dominant, and absolute laterality indexes less than 0.2 as bilateral. We defined 2 language patterns: typical (i.e., primarily left-sided) and atypical (Fig 1a).

##### RESULTS

Twenty-four patients, mean age 7 years old (SD=3.2), 36% female, met the inclusion criteria and were analyzed. Figure 1 (b-d) shows LI distribution in each ROI based on the analysis method. The language pattern of 16% of the patients is categorized as typical with GLM, compared to 69% with ICA. There is a significant positive correlation between the Frontal and Temporal LI with the ICA (pearson  $r = 0.44$ ,  $P=0.03$ ) compared to GLM (pearson  $r = 0.3$ ,  $P=0.15$ ). There is a significant negative correlation of Temporal LI between the two methods. This is manifested as more left-dominant (typical) patterns with ICA. There is no correlation between the Frontal LIs between the two methods.

##### CONCLUSION

In this fMRI dataset under anesthesia, ICA analysis demonstrates a stronger expected correlation of the frontal and temporal laterality indexes. ICA may be a useful analysis method for sedated scans. However, the possibility of an increased typical pattern with ICA needs further analysis with larger samples.

##### CLINICAL RELEVANCE/APPLICATION

Prior research indicates that anesthesia impacts bold signal of Frontal brain regions disproportionately when compared to Temporal brain regions, which exhibit more robust signal under sedation. The presurgical pattern derived from passive task-based fMRI under anesthesia requires caution in interpretation and further data driven analysis method may improve accuracy of language pattern assignment.

#### R5B-SPNR-10 Deep Learning Enhances Reliability of Dynamic Contrast-Enhanced MRI in Diffuse Gliomas: Bypassing Post-processing and Providing Uncertainty Maps

##### PURPOSE

To propose a deep learning-based probabilistic model for directly estimating and reliably generating pharmacokinetic (PK) parameter maps from dynamic contrast-enhanced (DCE)-MRI, bypassing the limitations of low reliability due to irreproducible arterial input functions (AIFs), and incorporating uncertainty maps.

##### METHODS AND MATERIALS

From Apr 2010 to Feb 2018, we retrospectively enrolled 341 consecutive patients (mean age, 55±15 years; 202 (59.2%) male) with adult-type diffuse gliomas, who underwent preoperative DCE-MRI. We developed a neural network model combining a temporal convolutional network and a probabilistic U-net to estimate PK maps directly without using the AIF. Structural Similarity Index Measure (SSIM) between generated and ground truth (GT) maps was calculated for quantitative validation of map generation. The reliability of the PK parametric maps was evaluated by comparing the intraclass correlation coefficient (ICC) of two Ktrans, Vp, and Ve measurement, averaged for tumor subregions-of-interest, obtained twice independently, using: 1) conventional PK map generation using commercial software; 2) generated PK maps from the neural network model. For clinical validation, Area Under the Receiver Operating Characteristic Curve (AUROC) was obtained for differentiating WHO grade (low- vs high-grade) and IDH mutation.

##### RESULTS

Generated Ktrans, Vp, Ve maps showed high SSIM (0.949±0.02, 0.746±0.021, 0.745±0.023) compared to the GT maps, respectively. The ICC of PK maps was significantly higher in generated PK maps compared to the conventional approach: 0.984 vs 0.119,  $p<0.001$  for ktrans, 0.994 vs 0.465,  $p<0.001$  for Ve, 0.984 vs 0.563,  $p<0.001$  for Vp. In the IDH-mutation prediction and

glioma grading, PK values of enhancing tumor portion obtained from generated and GT maps was comparable in AUROC: 1) Ktrms, 0.844 vs 0.836 ( $p=0.78$ ); Vp, 0.846 vs 0.846 ( $p=0.97$ ); and Ve, 0.837 vs 0.826 ( $p=0.76$ ) for IDH prediction; and 2) Ktrms, 0.892 vs 0.872 ( $p=0.58$ ); Vp, 0.908 vs 0.875 ( $p=0.51$ ); and Ve, 0.910 vs 0.863 ( $p=0.39$ ) for glioma grading.

## CONCLUSION

s PK maps generated from DCE-MRI using a deep learning-based probabilistic model showed improved reliability without compromising diagnostic performance in glioma grading.

## CLINICAL RELEVANCE/APPLICATION

Quick generation of PK maps from DCE-MRI bypassing post-processing using deep-learning with improved reliability may accelerate the application of DCE-MRI to clinical practice, benefiting treatment response monitoring in diffuse gliomas.

## R5B-SPNR- 11 Correlations of Computational Modeling of Interstitial Fluid Pressure and Velocity with IDH1 Expression and Ki-67 Level in Glioblastoma

Participants

Jianan Zhou, Nanjing, China (*Presenter*) Nothing to Disclose

## PURPOSE

The immunohistochemistry features of glioblastoma have important influence on its occurrence and prognosis. This study aimed to explore correlation of computational modeling of interstitial fluid pressure (IFP) and velocity (IFV) based on dynamic contrast enhanced (DCE)-MRI with IDH1 expression and Ki-67 level in glioblastoma.

## METHODS AND MATERIALS

Patients diagnosed as glioblastoma between 2020 and 2021 were included. All patients underwent examination before surgery in a 3.0T MR scanner (uMR770, United Imaging Healthcare). DCE-MRI (transverse T1-weighted spoiled gradient-echo sequence, 100 time-points, temporal resolution 2.5s) were performed before, during and after the injection of contrast agent (gadodiamide injection, 0.2mL/kg, 3.5mL/s). IDH1 expression and Ki-67 level were evaluated by immunohistochemistry of tumor samples after surgery. The permeability parameters were calculated from extended-Tofts model. Volume-of-interests were delineated manually including the whole tumor on late DCE images. The partial differential equation of IFP and IFV was formulated from the continuity equation and solved in MATLAB. All modeling parameters were decided according to foreknowledge from previous studies. Spearman's test was used to assess the relationship between IFP and IFV indicators (mean, standard deviation, kurtosis, skewness) and immunohistochemistry markers. Significance criteria was  $P<0.05$  for all statistic results.

## RESULTS

Thirty-four patients were included (mean age  $57.2\pm 10.4$ , 17 females). IFP and IFV mappings were obtained for each patient. The IDH1 expression was negatively correlated with IFPmean ( $P=0.031$ ,  $r=-0.382$ ), IFPkurtosis ( $P=0.031$ ,  $r=-0.383$ ) and IFVmean ( $P=0.038$ ,  $r=-0.369$ ) and positively correlated with the IFPskewness ( $P=0.023$ ,  $r=0.402$ ). Ki-67 level was negatively correlated with IFVkurtosis ( $P=0.042$ ,  $r=-0.351$ ). No significance was found in other statistic results.

## CONCLUSION

s Computational modeling of IFP and IFV based on DCE-MRI has significant correlation with IDH1 expression and Ki-67 level of glioblastoma.

## CLINICAL RELEVANCE/APPLICATION

This study found that computational modeled IFP were associated with the expression of IDH1 in glioblastoma. IFP is closely associated with tumor permeability, and could be affected by the microvascular properties within the tumor. Compared with IDH mutant, IDH wild-type glioma has faster tumor cell proliferation, richer neovascularization and higher permeability. Ki-67 reflects the proliferation of tumor cells and can be used to distinguish low-grade glioma from high-grade glioma. Therefore, IFP indicators have potential significance in predicting the molecular classification, tumor recurrence and prognosis of glioma.

## R5B-SPNR- 12 Usefulness of Perfusion Imaging with Super-selective pCASL for Meningioma

Participants

Takashi Katsube, Izumo, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

Identification of meningioma's feeding arteries and brain invasion is important for transcatheter arterial tumor embolization (TAE) or tumor resection. Super-selective pseudo-continuous arterial spin labeling (SS-ASL) is capable of selectively labeling the major arteries in the neck and noninvasively assessing the perfusion area of that artery. The purpose of this study is to investigate whether SS-ASL can identify the feeding arteries of meningioma and determine the presence or absence of meningioma brain invasion.

## METHODS AND MATERIALS

The subjects were 19 patients (18 women and a man, mean age 64.6) who had SS-ASL of MRI and angiography and were pathologically diagnosed meningioma. The average major axis of the tumors on MRI is 37.7mm (15-58 mm). SS-ASL was selectively labeled for an external carotid artery, an internal carotid artery, or bilateral vertebral arteries, respectively, and two to five SS-ASL images were taken in each case, with different arteries selected depending on the localization of the tumor. Two observers separately identified the feeding arteries of meningioma by SS-ASL and compared them to angiography to assess their accuracy. Also, increased perfusion in the region of the tumor bordering the brain parenchyma on SS-ASL with selected internal carotid or vertebral arteries was considered as having brain invasion, and the findings was compared with surgical and pathological findings. The image quality of SS-ASL was evaluated on a 4-point scale (grade 1-4).

## RESULTS

One case in which the feeding artery could not be clearly identified on angiography was deleted, resulting in 18 cases being evaluated. In 16 cases (88.9%) for observer 1 and 15 cases (83.3%) for observer 2, the feeding arteries noted on SS-ASL were consistent with the angiographic findings. Surgery and pathology were able to correctly determine the presence or absence of brain

invasion of meningioma in 14 cases, with 3 cases showing brain invasion. And 10 cases (71.4%) were correctly evaluated by SS-ASL. All 7 cases judged as no brain invasion by SS-ASL had no brain invasion. A total of 61 SS-ASL images were obtained in 18 cases. The images graded 3 or 4, which can be judged as good, were 55 (90.2%) for observer 1 and 52 (85.2%) for observer 2.

## CONCLUSION

SS-ASL is expected as a non-invasive method for estimating the feeding arteries of meningioma and may be useful for surgical information and TAE decisions.

## CLINICAL RELEVANCE/APPLICATION

SS-ASL can noninvasively assess blood flow in intracranial lesions. The ability to identify the distribution of blood flow in meningioma with SS-ASL provides useful information for angiography and surgery.

## R5B-SPNR- Spinal CSF Outflow using Spin Labeling MRI

13

Participants

Mitsue Miyazaki, PhD, La Jolla, CA (*Presenter*) Nothing to Disclose

## PURPOSE

In comparison to the brain, the mechanisms of intrinsic CSF spinal outflow are ones that remain to be unclear. The purpose of this research work is to investigate the location of CSF spinal outflow using novel MRI non-contrast, spin-labelling of endogenous CSF.

## METHODS AND MATERIALS

Seven healthy subjects were imaged using a clinical 3 Tesla MR imager with a 16-channel spine coil. Coronal T2-weighted 2D fluid attenuated inversion recovery (FLAIR) and coronal T2-weighted 3D centric ky-kz single-shot FSE (cSSFSE) were used to locate the lumbar regions of the spinal canal, while axial T2-weighted imaging was used to locate a spin-labeling, time-spatial labeling inversion pulse (Time-SLIP). To prevent blood contamination, an effective TE (TE<sub>eff</sub>) of 300 ms was used in the Time-SLIP experiments.

## RESULTS

Using non-invasive, non-contrast techniques, we demonstrate both proximal to distal and cranial to caudal flow gradients, with the highest level of CSF flow along the L3 and L4 nerve roots. Interestingly, the slowest outflow was in ROI 1 and 2 (L1) which also demonstrating overall increased Time - to - Peak (TTP) relative to L2-4.

## CONCLUSION

Our work is the first to validate the use of non-invasive, non-contrast MR techniques to identify and quantify intrinsic CSF spinal outflow metrics. Our quantitative results demonstrate high CSF outflow along the lumbar nerve roots as the first direct visualization of dispersed CSF egress from the nerve root sheaths into the adjacent paraspinous space.

## CLINICAL RELEVANCE/APPLICATION

New avenue for spinal CSF flow study, with implications for intrathecal drug design/delivery, identifying flow abnormalities related to CSF issues, and as biomarker for neuropathy/radiculopathy.

## R5B-SPNR-2 Does Resting-state fMRI have the Potential for Presurgical Functional Mapping?

## PURPOSE

In research, the potential of resting state has been explored for several decades, however, task-based functional MRI (tb-fMRI) is the status quo for presurgical planning where eloquent functional networks of the brain such as language and movement are mapped. But, reliable tb-fMRI mapping requires task compliance whereas resting-state fMRI (rs-fMRI), which utilizes the inherent synchronisation of fMRI BOLD signals between brain areas, enables this mapping even in sleep/anaesthesia conditions. Further, several functional networks can be mapped at once. To leverage the capabilities of rs-fMRI in clinical settings, a comparison of the two is crucial. The purpose of this study was to compare rs-fMRI and tb-fMRI.

## METHODS AND MATERIALS

The raw rs-fMRI data and partially pre-processed tb-fMRI data (n=75 language, n=80 motor) from a healthy cohort were obtained from HCP dataset. After relevant pre-processing steps including artefact correction, skull-stripping, and denoising. Independent component analysis was performed on the rs-fMRI time series using standardized reproducible pipelines in Python. The components were compared with functional atlases - Schaefer (sensory-motor) and SENSEAAS (language) using Dice coefficients, and the component with the largest coefficient was chosen for subsequent analyses. For tb-fMRI, cluster-based z-statistic maps were generated at a significance level of p=0.05 using a threshold of z = 3.69 using the FSL toolbox. Following this, four metrics were computed- sensitivity and specificity of rs-fMRI with respect to tb-fMRI (masked with an average of both to avoid null voxels), concordance of lateralization (left, right, bilateral) between rs-fMRI and tb-fMRI, the distance between the centre of mass (COM) of peak clusters in rs-fMRI and tb-fMRI, and product of group-averaged tb-fMRI and rs-fMRI maps.

## RESULTS

The tb-fMRI produced more lateralized activations than rs-fMRI. The concordance between the lateralization side indicated by rs-fMRI to that by tb-fMRI was 36 % for the language network.

## CONCLUSION

The sensitivity and specificity values were in an acceptable range. The distance between rs-fMRI and tb-fMRI COMs as well as lateralisation concordance were similar to previous studies on tumours. The product of rs-fMRI and tb-fMRI maps indicate good topographic concordance. Taken together, the results reflect that rs-fMRI is comparable to tb-fMRI but doesn't have a very high concordance, likely reflecting the unique activations captured by rs-fMRI.

## CLINICAL RELEVANCE/APPLICATION

Pre-surgical planning based on rs-fMRI can be used for patients non-compliant with tb-fMRI such as comatose, paralyzed, cognitively challenged, claustrophobic, etc.

## **R5B-SPNR-3 ABC/2 and Ice Cream Cone Method for Volumetric Assessment of Vestibular Schwannomas: Reliability of These Methods**

### **PURPOSE**

Vestibular schwannomas are three-dimensional tumors that cannot be accurately assessed with linear measurements or simple volume calculations. Volumetric analysis, using software that segments images, provides a more robust tool for measuring tumor volume, growth rate, and volumetric change. However, this software is not widely accessible and can be time-consuming. As a result, volume-estimating formulas such as ABC/2 and ice cream cone have become popular. This study aimed to evaluate the accuracy of volume estimation using these formulas compared to manual segmentation, using magnetic resonance imaging (MRI).

### **METHODS AND MATERIALS**

The study analyzed 46 cases of unilateral vestibular schwannomas confirmed by pathology and examined using MRI. Volumetric analysis was conducted using a 3-D, T1-weighted, magnetization-prepared rapid gradient echo (MPRAGE) sequence with manual image segmentation. Two-dimensional metrics were used to calculate tumor volume using ABC/2 ( $AP \times ML \times CC / 2$ ) and ice cream cone formulas. The largest anteroposterior (AP) and craniocaudal (CC) dimensions were compared for each tumor. Differences greater than 10% between these dimensions were used to assess the difference between the lesions. Unpaired t-tests were used to analyze the results, with significance set at  $p < 0.05$ .

### **RESULTS**

Of the 46 patients, 34 (74%) had intracanalicular and cisternal components, while 10 (22%) had only intracanalicular component. The comparison of volume estimation was done on a subgroup of 31 patients. The mean tumor volumes obtained by manual segmentation, ABC/2, and ice cream cone methods were 1244.41 ( $\pm 982.35$ ) mm<sup>3</sup>, 1557.23 ( $\pm 1484.05$ ) mm<sup>3</sup>, and 1043.64 ( $\pm 891.13$ ) mm<sup>3</sup>, respectively. There was no statistically significant difference between ABC/2 and manual segmentation ( $p=0.16$ ), ice cream cone and manual segmentation ( $p=0.20$ ), and ABC/2 and ice cream cone ( $p=0.52$ ) measurements. Of the tumors, 26 (57%) had longer AP dimensions, while 6 (13%) had longer CC dimensions.

### **CONCLUSION**

s Linear measurement applications such as the ABC/2 and ice cream cone methods can serve as substitutes for calculating tumor volumes, given their ease of use and accessibility. However, the ABC/2 formula tends to overestimate the tumor volume, while the ice cream cone formula tends to underestimate it. Furthermore, while the majority of vestibular schwannomas are ovoid, 13% of tumors grow predominantly in a CC fashion, which may result in preferential trigeminal nerve involvement.

### **CLINICAL RELEVANCE/APPLICATION**

The ABC/2 and ice cream cone formulas are reliable and time-efficient alternatives to manual segmentation for accurately estimating the volume of vestibular schwannomas.

## **R5B-SPNR-4 Applying ChatGPT to Predict Imaging Modalities Given Neuroradiological Patient Presentation**

Participants

Lleayem Nazario-Johnson, BS, North Providence, RI (*Presenter*) Nothing to Disclose

### **PURPOSE**

The aim of this project is to explore the ability of large language models (LLMs) to predict the best neuroradiologic imaging modality given specific clinical presentations. In addition, we seek to determine if LLMs can outperform an experienced neuroradiologist in this regard.

### **METHODS AND MATERIALS**

We utilized ChatGPT, an LLM built by Open AI that is trained on general data, as well as GlassAI, an LLM built by Glass Health that is trained on medical text. We prompted ChatGPT to rank the three best neuroimaging modalities, while taking the best responses from GlassAI and the neuroradiologist. We compared the responses to the American College of Radiology (ACR) Appropriateness Criteria for 147 conditions under the Neurologic Panel. Clinical scenarios were passed into each LLM twice, to account for stochasticity. Each output was scored out of 3, where 3 is "usually appropriate", 2 is "may be appropriate", 1 is "usually not appropriate", and 0 is not listed. Partial scores were given for non-specific answers. Scores were averaged across neurological topics. Statistical significance was determined using a two-sided student's T-test.

### **RESULTS**

ChatGPT achieved a score of 1.75 with a standard deviation of .81, while GlassAI achieved a score of 1.83 with a standard deviation of .81 across all neurological clinical scenarios. The difference between them was not found to be statistically significant ( $p > .05$ ). The neuroradiologist achieved a score of 2.19, with the difference of the scores being statistically significant when compared to LLMs ( $p < .05$ ). ChatGPT was also found to be the more inconsistent of the two LLMs, with the score difference between both outputs being statistically significant ( $p < .01$ ). It was also found that the score between different ranks outputted by ChatGPT was statistically significant ( $p < .001$  for each).

### **CONCLUSION**

s LLMs perform well selecting an appropriate neuroradiologic imaging procedure when prompted with a specific clinical scenario. ChatGPT, a general model, performed the same as GlassAI, a medical-specific model, suggesting that with medical text training, ChatGPT could significantly improve its function in this application. LLMs did not outperform an experienced neuroradiologist, indicating the need for their continued improvement in the medical context.

### **CLINICAL RELEVANCE/APPLICATION**

LLMs such as ChatGPT and GlassAI are able to comprehensively analyze large volumes of patient data and provide practitioners with accurate and reliable recommendations. This ability can improve diagnostic accuracy, reduce unnecessary testing and radiation exposure, and ultimately improve patient outcomes. Though LLMs do not yet outperform a neuroradiologist, our investigation indicates a proof of concept for their clinical implementation.

## **R5B-SPNR-5 Photon-counting Detector CT Could Visualize Brachial Plexus: A New Method to Evaluate Nervous**

## System

### Participants

Masahiro Nakashima, MD, PhD, Nagoya, Japan (*Presenter*) Nothing to Disclose

### PURPOSE

MRI is widely used to evaluate brachial plexus, however, it is often difficult to visualize it because of field inhomogeneity and anatomical complexity. Recent advent of photon-counting detector CT (PCD-CT) could provide the higher spatial resolution with better tissue characterization. The purpose of this study was to investigate the optimal reconstruction function of the PCD-CT to maximize the quality of imaging for it.

### METHODS AND MATERIALS

This retrospective study included patients who underwent neck PCD-CT for screening between March 1 and April 3, 2023 in our institution. Patients with radiological abnormalities, such as masses and postoperative cervical spine, were excluded. To evaluate the appropriate reconstruction function (kernel), the signal-to-noise ratio (SNR) was quantitatively compared in eight different kernels for each patient while other parameters, including matrix size (512×512mm), degree of iterative reconstruction (QIR2), and slice thickness (0.4mm), were fixed. Radiation dose levels were CTDIvol 11.0-13.8mGy. The kernels of quantitative regular (Qr) series from Qr40 to Qr72 (Qr40, Qr44, Qr48, Qr56, Qr60, Qr64, Qr68, and Qr72), the standard kernel for quantitative evaluation, were used. The SNR was measured on a reconstructed 1mm-thick coronal section image by setting six regions of interest (ROIs) with 3 mm<sup>2</sup> on each of the bilateral C5-C7 nerves, and the average and standard deviations (SDs) of the SNRs were calculated. All the ROIs within each subject were copied and pasted to the images with different kernels to ensure locational accuracy. The SNR was measured by a board-certified neuroradiologist with 8 years of experience. Statistical analyses were performed with the Friedman test, and the Wilcoxon signed-rank test.

### RESULTS

Ten subjects (5 males and 5 females; median 73 [range65-78]years) were evaluated. The SNR (mean±SD) was 3.39±1.30, 2.93±0.96, 2.66±0.95, 2.05±0.72, 1.74±0.59, 1.44±0.48, 1.14±0.37, 1.14±0.37, for Qr40, Qr44, Qr48, Qr56, Qr60, Qr64, Qr68, and Qr72, respectively. The SNRs exhibited a constant decrease with each increase in the Qr number. The SNRs were significantly different ( $P<0.05$ ) between any of the two groups, except for Qr68 vs Qr72. The kernel with the smaller Qr number demonstrated a better SNR in the evaluation of the brachial plexus.

### CONCLUSION

On PCD-CT, the kernel with a smaller Qr number was more suitable to evaluate the brachial plexus. Qr40, in particular, was found to have the highest SNR and was seemed to be clinically useful.

### CLINICAL RELEVANCE/APPLICATION

While MRI has been the mainstay for the evaluation of the brachial plexus, the heterogeneity of magnetic fields hampers image evaluation. PCD-CT, with its improved tissue resolution, may help in the assessment of the brachial plexus.

## R5B-SPNR-6 Large-scale Granger Causality (IsGC) for Identifying Autism Spectrum Disorder Patients Using Functional MRI - A Multivariate Brain Connectivity Analysis

### Participants

Axel Wismueller, MD, PhD, Pittsford, NY (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study is to create and test a new machine-learning approach for identifying individuals with Autism Spectrum Disorder (ASD). This approach uses large-scale Granger Causality (IsGC) to analyze differences in connectivity seen in resting-state functional MRI (rsfMRI).

### METHODS AND MATERIALS

We have selected a subset of 59 rsfMRI data sets from ASD patients and healthy controls from the Olin Institute of Living at Hartford Hospital. This subset is part of the publicly available preprocessed Autism Brain Imaging Data Exchange II (ABIDE II) data repository and specifically represents the Longitudinal Sample. To calculate directed functional connectivity between brain regions, we used the large-scale Granger Causality (IsGC) algorithm. This algorithm has recently been developed and leverages dimensionality reduction for causal modeling in high-dimensional fMRI time series. We applied a 100-iteration cross-validation approach with a 90%/10% train/test ratio. During the feature selection process, Kendall's tau rank correlation was used, followed by support vector machine classification. To evaluate the diagnostic accuracy of IsGC in classifying ASD patients and normal controls, we compared its performance with both a deconfounding partial correlation and the current clinical fMRI analysis standard of cross-correlation (CC). We reported accuracy, area under the ROC curve (AUC), and f1-score to quantitatively evaluate the performance of IsGC.

### RESULTS

The IsGC rsfMRI analysis method demonstrated superior performance compared to both the partial correlation and clinical standard CC techniques in classifying ASD patients from healthy subjects. With an accuracy/AUC/f1 score of 97.9%/1.0/96.4% for IsGC, 75.4%/0.79/60.5% for partial correlation, and 80.1%/0.85/66.8% for CC, respectively, it is suggested that the IsGC rsfMRI analysis method is a favored choice for accurate classification.

### CONCLUSION

Our results demonstrate that IsGC significantly enhances the diagnostic accuracy of identifying patients with ASD from rsfMRI neuroimaging. Based on our findings, we conclude that IsGC is better equipped to capture disease-related changes in brain network connectivity in ASD patients compared to both conventional CC analysis and partial correlation.

### CLINICAL RELEVANCE/APPLICATION

The IsGC method successfully classifies Autism Spectrum Disorder (ASD) patients and controls through identifying key changes in fMRI connectivity, clearly demonstrating its potential usefulness as a novel diagnostic imaging biomarker for neurologic disease.

## **R5B-SPNR-7 Adaptive Changes of Hypoxia Exposure in Normal Adults at High Altitude and Comparison of Brain Structure and Function between Insomnia and Non Insomnia by f-MRI**

Participants

Mingguang Yang, Chongqing, China (*Presenter*) Nothing to Disclose

### **PURPOSE**

To observe the brain adaptation changes in normal adults after exposure to hypoxia at high altitude and the differences in brain structure and function in patients with secondary insomnia

### **METHODS AND MATERIALS**

26 subjects of aid workers in Tibet were prospectively enrolled, and high-resolution three-dimensional T1-weighted structural images and resting state functional magnetic resonance imaging (rs-fMRI) were collected. MRI scans were taken as baseline data before admission to Tibet. Six months after emigration to Tibet, 26 subjects were divided into insomnia group (8 cases) and non-insomnia group (18 cases) according to Pittsburgh Sleep Quality Index (PSQI), and MRI scanning was performed again. Based on voxel morphology (VBM), local consistency (ReHo), low-frequency amplitude ratio (fALFF), and degree center (DC), 26 subjects were analyzed before and after entering Tibet, and the insomnia and non insomnia groups were analyzed respectively.

### **RESULTS**

Compared with the pre Tibet group, the gray matter volume (GMV) atrophy of 26 subjects in the post Tibet group was located in the middle frontal gyrus, parahippocampal gyrus and right parietal inferior marginal angular gyrus, with significant differences ( $P<0.01$ ). The ReHo value between pre Tibet and post Tibet groups were statistically significant ( $P<0.01$ ). The brain area with increased ReHo value was located in the right cerebellar hemisphere. The fALFF values between the pre Tibet and post Tibet groups were statistically significant ( $P<0.01$ ). The brain regions with increased fALFF values were located in the left lingual gyrus, the left middle temporal gyrus, and the cortex around the left talate fissure; The fALFF value between the insomnia group and the non insomnia group was statistically significant ( $P<0.01$ ). The brain area with increased fALFF value was located in the left posterior cingulate gyrus. The DC value between the insomnia group and the non insomnia group was statistically significant ( $P<0.01$ ). The brain area with reduced DC value was located in the left orbital superior frontal gyrus.

### **CONCLUSION**

The structure and function of several brain regions were changed in normal adults after migrating to high altitude and secondary insomnia.

### **CLINICAL RELEVANCE/APPLICATION**

In this study, people exposed to low oxygen in high altitude areas were tracked, and the brain function and morphology were compared with insomnia and non-insomnia after migration to high altitude areas and before and after their own migration, and multiple brain regions with abnormal brain structure and function were found

## **R5B-SPNR-8 Brain Image Reconstruction using Deep Learning CT Image Quality**

### **PURPOSE**

To compare the image quality of brain computed tomography (CT) images reconstructed with deep learning-based image reconstruction, Advanced intelligent Clear-IQ Engine (AiCE), and Iterative Reconstructions (AIDR3D)

### **METHODS AND MATERIALS**

150 consecutive patients underwent unenhanced brain CT scans with the following acquisition parameters: 120 kV, 50 mAs, slice thickness 0.5 mm, rotation time 1.5 sec, field of view, 250 mm; matrix, 512 × 512. Each dataset was reconstructed with AIDR3D and AiCE at 1 mm thickness and 1 mm increment. All images were evaluated using a dedicated PACS system. Image quality on a 4-point scale (excellent, good, sufficient, poor quality), gray matter-white matter differentiation, and anatomical detail (based on the visualization of basal ganglia, internal and external capsule) were independently assessed by two experienced readers. Interobserver agreement was assessed. Posterior fossa artifact index, the contrast to noise ratio (CNR) basal ganglia and the background image noise were evaluated.

### **RESULTS**

No significant difference was observed in image quality ( $p=0.06$ ). The gray matter-white matter differentiation was higher in AiCE reconstructions ( $p=0.003$ ), as well as the anatomical detail ( $p=0.04$ ). Image noise and artifact index of the posterior cranial fossa were significantly lower in images reconstructed with AiCE ( $p=0.003$ , and  $=0.005$ ) respectively. CNR was higher in deep learning based reconstruction ( $p=0.004$ ).

### **CONCLUSION**

In brain CT, deep learning based reconstructions allow significant reduction of noise and artifacts and better subjective image quality compared with iterative reconstructions.

### **CLINICAL RELEVANCE/APPLICATION**

Deep learning based reconstructions improve image quality when compared to iterative reconstruction: this fact may allow the reduction of CT acquisition parameters and radiation exposure in CT protocols.

## **R5B-SPNR-9 Reduction of Posterior Fossa Artifacts using Spectral Monoenergetic CT Images**

### **PURPOSE**

The radiological evaluation of the posterior fossa in conventional brain computed tomography (CT) is often interfered by beam hardening artifacts. Dual energy CT has been increasingly evaluated regarding for example reduction of metal artifacts and general image quality. Artifact reduction that could improve the assessment of the posterior fossa would be of great value since the symptoms of pathology may be non-specific such as headache, nausea, vertigo and ataxia. Patients could receive suboptimal level of care or incorrect treatment if not correctly diagnosed or while awaiting further work-up. The purpose of this study was to evaluate posterior fossa artifacts in virtual monoenergetic images (VMIs) compared to conventional CT images.

## **METHODS AND MATERIALS**

We included consecutive exams from adult (over 18 years) patients at our center who had undergone non-contrast spectral brain CT and whose exam was assessed as normal (e.g. no findings of ischemia, expansivities or hemorrhages). Regions of interest (ROIs) were drawn in predefined areas in posterior fossa grey matter (GM) and white matter (WM), in the interpetrous part of pons and in reference supratentorial GM and WM. Mean Hounsfield values and standard deviation (SD, considered image noise) were noted for the conventional images (CIs) and retrieved in spectral diagrams for monoenergetic series at 40-200 keV. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. The SD of the ROI in interpetrous pons was considered PFAI (posterior fossa artifact index). Visual assessment was performed by independent review by neuroradiologists blinded to reconstruction details.

## **RESULTS**

In the objective part of the study 188 patients were included and of them, forty consecutive patients were included in the subjective part. SNR was significantly higher compared to CIs in VMIs at 50 keV and higher for all measure points and CNR was higher in VMIs from 40 to 80 keV compared to CIs (Figure 1). Compared to CIs, mean image noise was lower for cerebellar WM in VMIs at and above 50 keV and for cerebellar GM the noise values were significantly lower in VMIs at and above 60 keV. The PFAI was significantly lower in VMIs above 50 keV compared to in CIs. VMIs at 60 keV received the highest visual assessment scores regarding overall image quality and artifact severity (higher scores indicating less artifacts) in the interpetrous pons.

## **CONCLUSION**

s Our results indicate that VMIs may improve objective and subjective image quality and artifact severity in the posterior fossa.

## **CLINICAL RELEVANCE/APPLICATION**

CT is the most used neuroradiological imaging modality in clinical routine care. Improving the diagnostic strengths of the images regarding posterior fossa pathology could have a direct impact for the patient outcome.

#### **R5B-SPPH-1 Clinical Comparison of Commercial Dosimetry Software Platforms for Y-90 Radioembolization Treatment**

##### Participants

Judy James, PHD, Maywood, IL (*Presenter*) Nothing to Disclose

##### PURPOSE

Patient dosimetry is an evolving field for therapy procedures in Nuclear Medicine. Post imaging dosimetry verification is gaining importance to validate prescribed dose with delivered dose in tumor and normal tissues. In Yttrium-90 (Y-90) radioembolization, specific targeted amounts of Y-90 radiation (Gy) is prescribed to preferentially destroy the cancerous cells. Different approaches to clinical dosimetry in NM have been proposed, with planar and SPECT images. Aim of this study was to compare clinically available dosimetry softwares to evaluate patient liver tumor dose following Y90 Treatment and the associated challenges with the software calculations.

##### METHODS AND MATERIALS

Dosimetry analysis was performed on a patient that received Y-90 treatment to the right anterior lobe with a prescribed dose of 301 Gy. The lung shunt fraction was at 2.7%. SPECT/CT was acquired following Y-90 administration on two separate gamma cameras: GE CZT and Philips Bright view (BV) and quantitative SPECT images were reconstructed. Following the required segmentations of the liver and tumor, the maximum absorbed dose to the hottest area of the tumor was obtained and compared using 3 dosimetry software platforms: 1) MIM Y90 Sure Plan™, 2) HERMES Voxel dosimetry™ and 3) Simplicity™.

##### RESULTS

Variability was observed in steps leading to computation and calculation of the absorbed radiation dose. The three platforms required a post Y-90 reconstructed SPECT, CT, and the administered dose. In addition, the needs for a) MIM lung shunt fraction (LSF), b) HERMES: duration between administration and scan time; c) Simplicity a pre Y-90 planning CT or MR and LSF. Segmentation and contouring workflow variability was also observed. MIM has a streamlined workflow for contouring and calculating the maximum dose compared to HERMES and Simplicity. Maximum reported doses were: a) MIM: 522.4 Gy with 95% of tumor: 496.28 Gy (CZT) and 196.04 Gy with 95% of tumor: 186.24 Gy (BV); b) HERMES: 184.27 Gy (CZT) and 200.44 Gy (BV); c) Simplicity: 433.7 Gy (CZT) and 574.2 Gy (BV), where the true prescribed dose was 301 Gy. The doses computed by the three software had >20% deviation from the actual prescribed dose.

##### CONCLUSION

Initial results of a dosimetry software comparison provided evidence that variability exists in the calculation of absorbed dose estimates on SPECT/CT images.

##### CLINICAL RELEVANCE/APPLICATION

Absorbed dose calculation in Y-90 radioembolization treatments are feasible clinically. However, dosimetry still faces challenges of standardization among different calculation platforms, imaging scanners, dose calculation models, and target area segmentation.

#### **R5B-SPPH- 10 Radiation Effect Measurement in Brain Tumor using MR-based Conductivity Imaging**

##### Participants

Hyun Chul Kim, MD, Gwangju, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

The ionizing radiation produces ions inside the human body that can kill cancerous tissues by damaging DNA directly or creating charged particles that damage DNA. MR-based electrical conductivity imaging is a sensitive technique for evaluating the response of normal tissues immediately after irradiation, but it is necessary to verify responses of cancer tissues to become a reliable tool for evaluating therapeutic effects in clinical practice. In this study, we used MR-based electrical conductivity imaging to evaluate the responses of irradiated and non-irradiated tissues during the peri-irradiation period in mouse brain tumors.

##### METHODS AND MATERIALS

For intracranial tumors, C6 glioma cells were injected into the right caudate-putamen of 14 Balb/c nude mice for in vivo imaging. Tumor growth was confirmed on MR images using a 9.4T MRI 2 weeks after tumor cell inoculation. The mice were divided into an irradiated group (n = 7) and a non-irradiated group (n = 7). In the irradiated group, the mean dose rate was 0.98 Gy/min, and the field size was 5 × 30 cm under a Co-60 gamma-ray irradiation unit. Imaging experiments were performed before and at 0, 1, 2, 3, 7, and 10 days after irradiation in both groups. For electrical conductivity imaging, a multi-echo spin-echo pulse sequence was applied to obtain a B1 map, which was used to calculate high-frequency conductivity images.

##### RESULTS

Figure 1 shows full time-course MR and electrical conductivity images of tumor with and without irradiation. Morphology of tumor region in MR images showed a similar pattern over time in both groups. However, conductivity images showed clear contrast changes between the two groups over time. In line graphs, the percentage change of the normal region with irradiation increased by 27.2% up to 2 days and then decreased to 12.4%. The change of the normal region without irradiation was not observed. Meanwhile, the change of the tumor region with irradiation increased by 61.1% up to 3 days and then decreased to 52.9%. The change of the tumor region without irradiation was not observed until 3 days after irradiation, but increased to 23.2% at 10 days after.

## CONCLUSION

Conductivity image provides information on cellularity and amounts of electrolytes in tissues, it shows potential as a tool for quantifying therapeutic effects of radiation on tumor.

## CLINICAL RELEVANCE/APPLICATION

The goal of radiation therapy in cancers is to maximize suppression of local tumors and minimize side effects on normal tissue. MR-based electrical conductivity imaging showed potential as a tool with high sensitivity for measuring and evaluating tissue response after irradiation.

## R5B-SPPH- 11 **Catalyzing International Collaboration between Cancer Radiotherapy Centers at Established Institutions and Those Located in Low and Middle Income Countries via Film Dosimetry**

Participants

Achidi Fomujong, Douala, AL (*Presenter*) Nothing to Disclose

## PURPOSE

Cancer remains one of the leading causes of death worldwide, but an even more disturbing fact is the striking disparity of cancer burden among rich and so called low-and-middle-income countries (LMICs). In a recent publication of the global cancer statistics 2020, there were 10 million cancer related deaths worldwide of which 70% were in LMICs. Any collaboration no matter how small to reduce this disparity is certainly welcome news. One such collaboration area is in Quality Assurance using film dosimetry. Film's unique qualities such as tissue equivalence, high spatial resolution, near energy independence and comparatively a less expensive dosimeter ought to make it the preferred and widely used in radiotherapy centers in LMICs. This however is not always the case as other factors that often maybe taken for granted in advanced radiotherapy centers remain a challenge in LMICs. We explored the unique qualities of film dosimetry that can make it possible for one Institution to benefit from another's protocols via collaboration.

## METHODS AND MATERIALS

For simplicity, two Institutions were considered in this work. We used a single batch of films (EBT-XD) and established a calibration protocol, including scan protocols and calibration curve using radiotherapy delivery system at Institution A. We then proceeded and performed patient specific QA for patients treated on system A (PSQA-A-A). Films from the same batch were then sent to a remote center for PSQA on radiotherapy delivery system B. Irradiations were done at Institution B and then returned to Institution A for processing and analysis (PSQA-B-A). The following points were taken into consideration throughout the process (a) A reference film was irradiated to a known dose on the same system irradiating the PSQA film. (b) For calibration, we utilized the one scan protocol and maintained the same scan orientation of the calibration, PSQA and reference films.

## RESULTS

Gamma index analysis using a dose threshold of 10% and 3%/2mm criteria showed a gamma passing rate of 99.8% and 100% for the PSQA-A-A and PSQA-B-A respectively.

## CONCLUSION

This work demonstrates that one could use established film dosimetry protocols in one Institution, eg an advanced radiotherapy center and apply with similar accuracies to irradiations performed at another institution, eg a center located in LMIC which thus encourages collaboration between the two for worldwide patient benefits.

## CLINICAL RELEVANCE/APPLICATION

We show how advances in film dosimetry now make it possible to use well established film calibration protocols at one Institution to impact care at another less privileged institution thus catalyzing international collaboration.

## R5B-SPPH- 12 **Evaluation of the Feasibility of Injectable Lipiodol and Tissue Glue Fiducial Markers for CyberKnife Tracking**

## PURPOSE

To evaluate combinations of lipiodol and tissue glue using phantom and rabbit models, for feasibility in computed tomography (CT) image quality and image recognition of the Cyberknife system.

## METHODS AND MATERIALS

The gold and lipiodol fiducial markers were inserted into tissue-equivalent phantom. CT was performed to assess images in terms of contrast to noise ratio (CNR), signal to noise ratio (SNR), and streak index (SI). To investigate the performance of combination of lipiodol and tissue glue, a study is conducted in the spine phantom which was placed in such a way that the lipiodol fiducial marker was overlapped with the bone in TLS. CT values, deformation, displacement, and diffusion of lipiodol fiducial markers were evaluated one week after injected into the livers of six rabbit models. Tracking accuracy of the gold fiducial markers and the lipiodol fiducial markers were analyzed and compared.

## RESULTS

The phantom show that the fiducial markers in each group could be seen clearly visible on the CT scans. Compared to lipiodol fiducial markers, gold fiducial markers had a greater SI and poorer CNR and SNR. Groups of lipiodol fiducial markers overlapped with the spine can be identified and successfully tracked. Both the pairing tolerance and uncertainty values did not exceed the systematic threshold. There were no adverse reactions such as rupture, necrosis and infection were observed in the injection site. Over the course of a week, the volume of lipiodol glue fiducial marker decreased by 30% while CT value stayed above 1000 HU. The

registration translation deviation of gold fiducial markers tracking was lower than that of lipiodol glue fiducial markers tracking in supero-inferior, left-right and antero-posterior directions ( $Z=-2.276$ ,  $-10.226$ ,  $Z=-6.378$ ,  $P < 0.05$ ).

## CONCLUSION

s Fiducial markers composed of a combination of lipiodol and tissue glue were well visualized in a phantom on CT and produce less artifact than the gold fiducials. Lipiodol fiducial markers were successfully recognized and tracked using the Cyberknife Xsight-Lung tracking system in rabbit models.

## CLINICAL RELEVANCE/APPLICATION

Compared with solid markers, combinations of lipiodol and tissue glue possess the following advantages: ? it can be injected through the liver via a thinner needle, reducing the risk of pain and complications during puncture. ? The corresponding volume can be injected according to the size of the tumor, especially the tracking method combined with Cyberknife only needs one injection, which can reduce the number of punctures and simplify the process. ? The visibility of the markers on the imaging device can be adjusted by changing the ratio of lipiodol to tissue glue.

## R5B-SPPH-2 Clinical and Radiation Risk Across One Million Patients in Computed Tomography: Influence of Age, Size, and Race

Participants  
Francesco Ria, DMP, Durham, NC (*Presenter*) Metis Health Analytics

## PURPOSE

We recently developed a mathematical model to balance radiation risk and clinical risk, namely the risk of misdiagnosis due to insufficient image quality. In this work, we applied this model to a population of one million CT imaging cases to evaluate the risk stratification with different ages, sexes, and races.

## METHODS AND MATERIALS

The demographics were informed by literature and census information simulating a clinical liver cancer population. The Total Risk (TR) was calculated as the linear combination of radiation risk and clinical risk. The model included factors for the radiation burden for different age and sex; the prevalence of the disease; the false positive rate; the expected life-expectancy loss for an incorrect diagnosis for different ages, sex, and race; and a typical false positive rate of 5%. It was assumed that each case received an average radiologist interpretative performance of 0.75 AUC for a hypothetical lesion without any changes in radiation dose beyond routine practice. We further, for each patient, simulated 2,000 imaging conditions with CTDIvol varying from 0.1 and 200 mGy with 0.1 mGy increments. Per each CTDIvol value, the anticipated AUC was calculated by applying the established asymptotic relationships between CTDIvol and image quality. The AUC distribution was then used to calculate the theoretical minimum total risk (TRmin) per each patient.

## RESULTS

For the routine practice, the median theoretical total risk was estimated to be 0.058 deaths per 100 patients (range: 0.002 - 0.154) comprising of the median radiation risk of 0.009 (range: 0.001 - 0.069), and of the median clinical risk of 0.049 (range:  $7.0 \times 10^{-5}$  - 0.094). Considering the varying scanner output conditions, the median TRmin was 0.054 deaths per 100 patients for White male patients, 0.054 for Blacks, 0.057 for Hispanics, and 0.065 for Asians. For female patients, the median TRmin values were 0.049, 0.056, 0.054, and 0.061 deaths per 100 patients, respectively.

## CONCLUSION

s For each demographic condition, the clinical risk was found to largely outweigh the radiation risk by at least 500%. Total risk showed different stratifications with patient age and race.

## CLINICAL RELEVANCE/APPLICATION

To optimize CT conditions for specific patients and/or population, both radiation risk and clinical risks should be accounted together with demographic information. We demonstrated a methodology that allows a complete depiction of total risk in CT, considering radiation and clinical risks at comparable units, and patient demographic.

## R5B-SPPH-3 Attenuation Correction for Total-body Positron Emission Tomography by Exploiting Anatomical Priors

Participants  
Wenbo Li, Shenzhen, China (*Presenter*) Nothing to Disclose

## PURPOSE

During positron emission tomography (PET) scanning, additional computed tomography (CT) imaging is utilized to provide attenuation coefficient maps to achieve more precise quantification on PET images. However, this not only exposes patients to extra doses of ionizing radiation but also makes attenuation correction (AC) difficult for PET/MR or PET-only scanners. Recently, many efforts have been applied to address this issue but the majority of these methods have been implemented on specific anatomical tissue, ignoring the structural differences among various human body sites.

## METHODS AND MATERIALS

Experiments were performed on total-body scans of 20 patients that contained paired NAC PET and AC PET images of different sites, including the head and neck, chest, abdomen, pelvis, and extremities. Considering the anatomical disparities, we utilized the cycle-consistent generative adversarial network (Cycle GAN) as a foundation and modified its discriminator to differentiate between the authenticity of the input and its corresponding anatomy. In addition, the training process included the integration of a discriminative loss that relied on anatomical structures to enhance the quality of the generated AC PET images.

## RESULTS

The results showed that our method yielded superior quantification outcomes with a peak signal-to-noise ratio (PSNR) of  $38.02 \pm 5.52$  dB and a structural similarity index (SSIM) of  $0.96 \pm 0.05$ . Compared to nonattenuation-corrected PET (NAC PET) images ( $33.30 \pm 12.35$  dB,  $0.84 \pm 0.52$ ), our method resulted in a 14% increase in both PSNR and SSIM, indicating its effectiveness in converting NAC PET images into AC PET images.

## CONCLUSION

Our work accounts for differences in the anatomy of various human body sites and applies this information as a priori knowledge in the generation of AC PET images from NAC PET images. By incorporating prior factors, we achieved remarkable quantitative results, as evidenced by significant improvements in both PSNR and SSIM metrics compared to NAC PET images in different body sites.

## CLINICAL RELEVANCE/APPLICATION

Considering anatomical prior information, our work utilizes deep learning techniques to generate AC PET images directly from NAC PET images, bypassing the PET reconstruction step, which facilitates attenuation correction of PET images in PET/MR or PET-alone scanners.

## R5B-SPPH-4 Performance Evaluation of a Super Resolution Deep Learning Reconstruction Algorithm for Chest CT

Participants

Patrik Rogalla, MD, MBA, Toronto, ON (*Presenter*) Institutional Research Grant, Canon Medical Systems Corporation; Institutional Research Grant, KA Imaging

## PURPOSE

To evaluate the effect of Super Resolution Deep Learning Reconstruction (SR-DLR) using 1024 matrix on image quality in chest CT compared to standard-of-care reconstruction methods.

## METHODS AND MATERIALS

A DCNN-based Super Resolution Deep Learning Reconstruction (SR-DLR) model was developed for lung imaging. For training, standard-dose image data acquired using an ultra-high resolution CT scanner (Canon Aquilion Precision) served as target and low-dose image data from the normal resolution mode served as input. Projection data from 31 standard-of-care CT acquisitions (Canon Aquilion ONE PRISM) of the chest were reconstructed with 3 different methods: Hybrid iterative reconstruction (AIDR-3D for lung and body) at 512 matrix (series I), deep learning reconstruction (AiCE, lung and body algorithm) at 512 matrix (series II), and SR-DLR (lung algorithm) at 1024 matrix (series III), all at 3 mm slice thickness with 2.5 mm spacing. Images were also reconstructed using SR-DLR at 1024 matrix and 0.5 mm slice thickness (series IV). All 4 series, synchronized and without annotation, were reviewed in both window settings by 3 chest radiologists blinded to technical details on a 4K monitor with a 4x2 hanging protocol for the following categories on a scale of 1-5: lung resolution; soft tissue contrast; noise texture/level (lung, tissue), artifact (lung, tissue); overall image quality (lung, tissue). Forced ranking of the overall diagnostic confidence was also recorded (1 = highest, 4 = lowest). Image noise (SD) was measured in tissue and air.

## RESULTS

P values refer to series I vs III and I vs IV. The mean rating of series I-IV was 3.1/3.7/4.2/4.7 for lung resolution (both  $p < 0.001$ ); 3.2/4.1/4.1/3.5 for tissue contrast ( $p < 0.001$ ,  $p = 0.002$ ); 3.0/3.8/4.4/4.7 for lung noise (both  $p < 0.001$ ); 3.0/4.2/4.2/3.5 for tissue noise (both  $p < 0.001$ ); 4.3/4.3/4.4/4.4 for lung artifacts ( $p = 0.06$ ,  $p = 0.03$ ); 4.2/4.4/4.3/4.2 for tissue artifacts ( $p = 0.25$ ,  $p = 0.79$ ); 3.1/3.8/4.3/4.7 for overall image quality lung (both  $p < 0.001$ ) and 3.1/4.1/4.0/3.5 for overall image quality tissue (both  $p < 0.001$ ); the mean overall diagnostic confidence ranking was 3.9/2.8/2.1/1.1 for lung (both  $p < 0.001$ ) and 3.5/1.8/1.9/2.7 (both  $p < 0.001$ ) for tissue, respectively. For series I vs IV, mean image noise in tissue was 17.4/17.5 HU ( $p = 0.97$ ) and 45.9/12.5 in air ( $p < 0.001$ ).

## CONCLUSION

The SR-DLR using a 1024 matrix provides superior clinical image quality in chest CT; SR-DLR thin slices are overall preferred for lung parenchyma. SR-DLR holds promise to eliminate the need for separate reconstructions for the lung parenchyma and soft tissues.

## CLINICAL RELEVANCE/APPLICATION

The SR-DLR outperforms current clinical standard-of-care reconstructions and may contribute to improving the diagnostic value of chest CT

## R5B-SPPH-5 K-RCPS: Uncertainty Quantification for Diffusion Models via Conformal Prediction and Conformal Risk Control in CT Denoising

Participants

Jacopo Teneggi, Baltimore, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Diffusion models can generate varied and high-quality samples. It is paramount to estimate the uncertainty of these models when used for inverse problems in medical imaging (e.g., CT denoising). We propose a novel uncertainty quantification procedure to construct pixel-wise intervals that provably contain future samples as well as the ground-truth image while minimizing the mean interval length.

## METHODS AND MATERIALS

A diffusion denoising model was trained and validated on the AbdomenCT-1K dataset comprising 1,112 CT scans (170,000 images) from 12 different medical centers. Uncertainty quantification was carried out on random subsets of 640 images not shown during training. Every image in the subset was perturbed with isotropic Gaussian noise ( $\text{std} = 0.4$ ) and the diffusion model was used to reconstruct 128 noiseless samples (81,920 total images). We compute the pixel-wise calibrated quantiles over the samples to guarantee that with probability at least 80% every pixel in a new sample from the diffusion model on the same noisy observation will be contained in its respective interval. We then conformalize the intervals such that with probability greater than 90% no more than 5% of the pixel in the ground-truth high-quality image will fall outside of the intervals on future, unseen noisy observations. We propose a novel convex optimization extension of the original Risk Controlling Prediction Sets (RCPS) procedure, K-RCPS, that provably minimizes the mean interval length. We compare with existing uncertainty quantification approaches in terms of guarantees provided and mean interval length over 20 draws of the 640 images.

## RESULTS

K-RCPS provides the shortest mean interval length (0.1391  $\pm$  0.0025) compared to quantile regression (0.3522  $\pm$  0.0085), naïve

(i.e., not calibrated) empirical quantiles (0.1401 +- 0.0024), and the existing RCPS procedure (0.1614 +- 0.0020). K-RCPS is currently the only high-dimensional uncertainty quantification approach that guarantees both coverage of future samples on the same noisy observation and risk control on future observations.

## CONCLUSION

s Conformal prediction and conformal risk control can be deployed for diffusion models in CT denoising to construct uncertainty intervals that provide finite-sample and distribution-free guarantees on the generated noiseless images. K-RCPS provably minimizes the mean interval length, and it consistently outperforms existing methods.

## CLINICAL RELEVANCE/APPLICATION

Statistically valid uncertainty quantification techniques build radiologists' confidence in diffusion models used for inverse problems in medical imaging.

## R5B-SPPH-6 Comparing Machine Learning Algorithms for Predictive Radiomic Features of Tumor Response after Pancreatic SBRT

### PURPOSE

Pancreatic cancer is a debilitating malignancy with a short life expectancy. While pancreatic SBRT has shown robust tumor control, identifying patients that respond to SBRT remains challenging. The aim of this study was to compare ML algorithms for prediction of pancreatic tumor response utilizing radiomic features extracted from MR-guided SBRT set-up imaging. We also evaluated whether static radiomic features (e.g. obtained at first SBRT fraction) differed in this predictive potential compared to delta radiomic features (e.g. net change in features between SBRT fractions 1-2 and 1-3)

### METHODS AND MATERIALS

58 pancreatic cancer patients treated with MR-guided SBRT at our institution were analyzed. Gross tumor volumes were delineated on daily set-up MRIs prior to each fraction. Patients were treated to the pancreas at a dose of 35-50 Gy in 5 fractions. Tumor response was defined using TRG-CAP for patients who underwent resection. For patients who remained unresectable post-SBRT, tumor response was determined with RECIST v.1.1 criteria on imaging at 1-3 months. MRI scans were normalized in signal intensity and 39 texture features were extracted. Features were ranked by predictive importance using RF, LASSO, and MRMR algorithms. Top 1-4 importance features from each model were analyzed using logistic regression to determine predictive performance. Logistic regression was used to obtain the area under the curve (AUC) and the Akaike information criterion (AIC) in order to compare models.

### RESULTS

For the static feature model, an MRMR algorithm of the top 2 importance features outperformed other approaches (AUC: 0.656; AIC: 55.12). For the first delta radiomics model (fractions 1-2), an RF model of the top 3 importance features demonstrated the best performance (AUC: 0.681; AIC: 52.1). For the second delta radiomics model (fractions 1-3), LASSO - using the top importance feature only - demonstrated the best performance (AUC: 0.603; AIC: 53.76).

## CONCLUSION

s Leveraging an RF algorithm to rank delta radiomic features from SBRT fractions 1-2 demonstrated the best prediction of pancreatic tumor response.

## CLINICAL RELEVANCE/APPLICATION

Radiomic features of pancreatic tumors may contain predictive information about local control following MR-guided SBRT. These features could be used to personalize adaptive approaches to SBRT by identifying non-responders prior to completion of treatment.

## R5B-SPPH-7 Technical Performance Comparison of Super Resolution Deep Learning Reconstruction Algorithm on a Wide Area, Conventional Energy-Integrating Detector vs Conventional Reconstruction Algorithms on a Photon-Counting Computed Tomography System

Participants

Kirsten Lee Boedeker, PhD, Los Angeles, CA (*Presenter*) Employee, Canon Medical Systems Corporation

### PURPOSE

The purpose of this work is to systematically compare fundamental image quality between data reconstructed with a Super Resolution Deep Learning Reconstruction (SR-DLR) algorithm acquired on a wide volume, energy-integrating detector (EID) Computed Tomography (CT) system vs data reconstructed with Hybrid Iterative Reconstruction (HIR), as well as Filtered Backprojection (FBP), acquired on a Photon-Counting CT System (PCCT) in standard resolution mode.

### METHODS AND MATERIALS

A Catphan<sup>TM</sup> embedded in a 25-35cm body ellipse was scanned at six dose levels from 1.9mGy-19.7mGy on a wide volume EID as well as on a CZT-based PCCT in standard resolution mode (Canon Medical Systems Corporation, Otawara, Japan). Images generated from the EID system were reconstructed with FBP and an SR-DLR for cardiac to a 512 matrix and 1024 matrix. Two clinically realistic fields of view (FOV), 180mm and 360mm, were evaluated. Counting images from the PCCT were generated based on total counts registered over five energy bins and reconstructed with HIR cardiac kernels. Resolution was assessed via task-dependent Modulation Transfer Function (MTF) for three contrast levels. Noise was assessed by measuring the standard deviation (SD) and Noise Power Spectrum (NPS). Noise Equivalent Quanta (NEQ) and Low Contrast Detectability (LCD) were also assessed.

### RESULTS

For FBP, PCCT exceeded the spatial resolution of EID. However, the spatial resolution for SR-DLR with both a 512 and 1024 matrix on the EID system exceeded that of both conventional reconstruction algorithms on PCCT for all contrasts, by up to 5lp/cm at the 10% of the MTF, except at the lowest dose/contrast combinations. For FBP, PCCT decreased noise at low dose relative to EID. SR-DLR had lower noise magnitude, by 20-45%, than FBP and HIR on PCCT for all conditions. Both HIR on PCCT and SR-DLR on EID have noise shifted to lower frequencies, although with 1024 matrix the higher frequency content increases. NEQ is significantly greater for SR DLR for all conditions, leading to better LCD.

## CONCLUSION

s While PCCT provides benefit over EID when reconstructed with equivalent reconstruction algorithms, SR-DLR improves EID image quality above that of PCCT in standard resolution mode with HIR and FBP.

## CLINICAL RELEVANCE/APPLICATION

SR-DLR using both 512 and 1024 matrix sizes leads to significant image quality benefits in spatial resolution and noise relative to conventional reconstruction algorithms on EID CT and PCCT.

## R5B-SPPH-8 Evaluation of Regularized Model-Based Cone-Beam Computed Tomography Image Reconstruction for Image-Guided Radiation Therapy: A Phantom Study

Participants

Shih-Chi Lin, MS, New York, NY (*Presenter*) Nothing to Disclose

## PURPOSE

This study investigates the potential improvement in Cone-Beam Computed Tomography (CBCT) image quality for adaptive image-guided radiotherapy (IGRT) planning using regularized model-based image reconstruction methods. We evaluate maximum likelihood proximity gradient algorithms using higher-order total variation (PGA-ML-HOTV) and tight framelets (TF) regularization to improve CBCT image quality over conventional image reconstruction methods.

## METHODS AND MATERIALS

The Tomographic Iterative GPU-based Reconstruction toolbox (TIGRE) was used for projection processing, code development, and image reconstruction. The filtered back-projection algorithm (FDK), with scatter correction and a ramp filter, was used as the baseline (BL) due to the similarity to the vendors' algorithm. PGA-ML (HOTV/TF) and row-action maximum likelihood algorithm (RAMLA; for comparison) were implemented using a Poisson noise model without scatter correction. These reconstructions were initialized with an FDK and a uniform image using 50, 100, 150, and 200 iterations. A Catphan phantom was scanned using CBCT Head Protocol on a Varian TrueBeam LINAC. Image quality was evaluated using the square root of the area under the 2D noise power spectrum curve (NPS<sub>2D</sub>), contrast (?HU), contrast-to-noise ratio (CNR), target transfer function value at 50% and 10% (TTF-50 and -10), and a model observer with eye filter detectability index (DI) of the -138 HU, 12.2-mm diameter polystyrene plug.

## RESULTS

PGA-ML performances with HOTV and TF were indistinguishable. The highest performance improvement over BL was seen using PGA-ML with 150 iterations initialized with FDK. In this case, NPS<sub>2D</sub>, ?HU, TTF, CNR, and DI improved by 15%, 12%, 51-52%, 4%, and 21%, respectively. It was noted that there is a trade-off in image quality with this method. Specifically, images initialized with a uniform image and 200 iterations had better NPS<sub>2D</sub>, CNR, and DI by 56-57%, 82-83%, and 111-112%, respectively. When initializing with an FDK image, ?HU decreased by 12%, but CNR increased (4%) due to lower noise. ?HU declined with increased iterations. ?HU and TTF improved with increasing iterations with a uniform image, while NPS<sub>2D</sub> and DI worsened, outperforming FDK. CNR increased initially but decreased beyond 150 iterations due to increased noise.

## CONCLUSION

s The study demonstrates that regularized model-based image reconstruction methods can provide better image quality than FDK with optimized iteration and penalty settings and thus enhance target delineation during adaptive IGRT. Task-based performance assessment of these methods is necessary to enable integration into CBCT-based adaptive radiotherapy.

## CLINICAL RELEVANCE/APPLICATION

CBCT quality is important for CBCT-based adaptive IGRT planning.

## R5B-SPPH-9 Is the 120 KVp-like Image Synthesized from Dual-energy CT Equivalent to the Conventional 120 KVp Single-energy CT Image: From the Perspective of Dose Calculation of Photon Radiotherapy

Participants

Bo Yang, Peking, China (*Presenter*) Nothing to Disclose

## PURPOSE

Due to the difference of Hounsfield Unit (HU) characteristic of most dual-energy CT (DECT) oriented images and 120KVp Single-Energy CT (SECT) images, specific CT value to Electric Density (CT-ED) calibration curve are needed for DECT-based dose calculation in photon Radiotherapy (RT), which may hamper the widely use and cover the potential of DECT in RT. To simplify and promote the DECT application in photon RT, the equivalent between the 120 KVp-like image synthesized from DECT and 120KVp SECT image is evaluated via phantom in terms of dosimetry.

## METHODS AND MATERIALS

On the one side, to evaluate equivalent with 120KVp SECT images in dosimetry, 120 KVp-like images combined with the specific CT-ED calibration curve were used to calculate dose. On the other side, due to similarity of HU value between 120 KVp SECT images and 120 KVp-like DECT images, the 120KVp-like dose was calculated via conventional CT-ED curve directly. In detail, CIRS 062M tissue characterization phantom, stuffed with nine rod-shaped tissue substitute inserts, was scanned by DECT and SECT sequentially in the same situation. The specific 120 KVp-like CT-ED calibration curve was established by fitting the measured HU value and ground-truth ED ((FIG.1 (d))). In addition, A VMAT treatment plan with prescribed dose 7000 cGy was optimized based on the SECT image of a head and neck phantom. Finally, by Dose Volume Histogram (DVH) (FIG.2) and gamma pass rate, the recalculated dose distributions of 120 KVp-like image via the specific or conventional CT-ED curve were compared with the dose of 120KVp SECT image, respectively.

## RESULTS

With the specific 120 KVp-like CT-ED curve, the PTV D95 of 120 KVp-like DECT image and 120 KVp SECT image was 7155.4cGy and 7164.9cGy, respectively. The gamma pass rate is 99.5% (3mm,3%), 99.1%(2mm,2%), which represents that the difference between these two dose distributions is acceptable. With the conventional 120 KVp CT-ED curve, the PTV D95 of 120 KVp-like DECT is 7168.9 and is close to that of 120 KVp SECT (D95= 7155.4). The gamma pass rate of dose distribution between 120 KVp-

like DECT and 120 KVp SECT is 100% (3mm,3%), 99.5%(2mm,2%).

#### **CONCLUSION**

s Whatever using specific 120 KVp-like or conventional 120 KVp CT-ED calibration curve, the dose discrepancy between 120 KVp-like DECT image and 120 KVp SECT image is clinical acceptable. And 120 KVp-like image is equivalent with 120 KVp image from the prospective of dose distribution.

#### R5B-SPVA-1 Correlation Between Plaque Characteristics, Serological Indexes and Coronary CTA Flow Reserve Fraction in Patients with Coronary Artery Disease

##### PURPOSE

To study the correlation between coronary CT angiography (Computer tomography angiography, CTA) fractional flow reserve (Fractional flow reserve, CT-FFR) and plaque characteristics, serological indexes in patients with coronary artery disease.

##### METHODS AND MATERIALS

A total of 91 patients with coronary artery disease who underwent coronary CTA examination in the Central Hospital Affiliated to Shandong First Medical University from March 2022 to February 2023 were selected. According to CT-FFR value, patients were divided into non-myocardial ischemia group (CT-FFR value > 0.80, n=58) and myocardial ischemia group (CT-FFR value =0.80, n=33). The CT-FFR value, plaque characteristics parameters (plaque length, minimum lumen area, total plaque volume, lipid plaque volume, fibrous plaque volume, calcified plaque volume), serological indicators (low density lipoprotein cholesterol (LDL-C), high density lipoprotein cholesterol (HDL-C), homocysteine (Hcy), high-sensitivity C-reactive protein (hs-CRP), apolipoprotein A (ApoA), matrix metalloproteinases (MMP-2, MMP-9)], and the correlation analysis was performed.

##### RESULTS

There were no significant differences in fibrous plaque volume, calcified plaque volume and minimal lumen area between the two groups ( $P > 0.05$ ). The plaque length, total plaque volume, lipid plaque volume and serum levels of the serum LDL-C, MMP-2, MMP-9, Hcy and hs-CRP were significantly lower, while serum levels of HDL-C and ApoA were significantly higher in CAD patients without myocardial ischemia than those in CAD patients with myocardial ischemia ( $P < 0.05$ ). The CT-FFR value was negatively correlated with plaque length, total plaque volume, lipid plaque volume, the serum LDL-C, MMP-2, MMP-9, Hcy and hs-CRP, and positively correlated with the serum HDL-C and ApoA.

##### CONCLUSION

The decrease of CT-FFR value in patients with coronary heart disease is closely related to metabolic disorders, glucose and lipid deposition, plaque enlargement and decreased stability, complement system activation, inflammatory mediators release, and endothelial cell injury.

##### CLINICAL RELEVANCE/APPLICATION

By exploring the correlation between plaque characteristics and serological indicators in patients with different CT-FFR values, the mechanism of plaque formation and progression was further understood, providing guiding value for clinical treatment and prognosis of coronary atherosclerotic heart disease.

#### R5B-SPVA-2 Spectral CT Monochromatic Imaging With Metal Artifact Reductions In Assessment Of Stent Lumen In Portal Venography After TIPS: A Retrospective Study

##### Participants

Xingpeng Li, Beijing, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To investigate the clinical value of spectral CT monochromatic imaging with metal artifact reductions in assessment of stent lumen in portal venography after transjugular intrahepatic portosystemic shunt (TIPS).

##### METHODS AND MATERIALS

Twenty-seven patients with TIPS for portal hypertension were performed spectral CT portal venography (CTPV) in our study. All raw data were reconstructed as 120 kVp-like imaging, and 6 groups of monochromatic imaging from 45 keV to 70 keV with 5 keV as an interval, respectively. Four slices CTPV images were evaluated, including main portal vein, proximal, middle and distant level of stent. Objective indexes for portal vein and stent included artifact index (AI), signal intensity (SI), standard deviation (SD), signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). Subjective indexes were assessed by two radiologists with 5-point scale separately. Patients with portal vein thromboses were recorded, and statistical analyses were analyzed.

##### RESULTS

According to Child-Pugh staging in all 27 patients, 3 were classified into grade A, 14 were grade B, and 10 were grade C. For objective indexes in portal vein and stent lumen, all SI, SNR and CNR decreased with the increase of keV (all  $P < 0.01$ ), and 45 keV demonstrates the highest SI, SD, SNR and CNR. The enhancement of portal vein and stent lumen were higher than 200 HU only in 45, 50, 55 and 60 keV, and there is no statistical significance for all indexes between 70 keV and 120 kVp-like group (all  $P > 0.05$ ). With MARs technique, AI decreased significantly for all 45 to 70 keV images. For subjective indexes, 60 keV group manifested best image quality scores and diagnostic confidence among all 7 groups. 1 stent thrombosis was detected in TIPS stent by CTPV,

including 7 patients with portal vein cavernous transformation.

#### **CONCLUSION**

s Combined with subjective and objective assessments of image quality, spectral CT monochromatic imaging at 60 keV with MARs technique increased SI, SNR, CNR in assessment of TIPS stent lumen and portal vein for liver cirrhosis, which is feasible in evaluation of stent lumen and portal vein after TIPS.

#### **CLINICAL RELEVANCE/APPLICATION**

Spectral CT monochromatic imaging at 60 keV with MARs technique demonstrated feasibility in evaluation of stent lumen and portal vein after TIPS.

### Breast Imaging Sunday Poster Discussions I

#### Sub-Events

#### S3A-SPBR-1 Performance of an Artificial Intelligence System on Screening Breast Tomosynthesis Cases

Participants

Roger S. Yang, MD, Warren, NJ (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the performance of artificial intelligence (AI) on screening tomosynthesis mammograms

#### METHODS AND MATERIALS

This retrospective study included 28,278 DBT screening exams and the subsequent BIRADS 0 workups, consecutively collected from February to July 2022 from multiple outpatient imaging centers within a private practice. The screening exams (Hologic) were evaluated by 36 MQSA radiologists and scored according to the Breast Imaging Reporting and Data Classification System (BIRADS). BIRADS 0 cases were recalled for additional evaluation and potential biopsy. All DBT screening exams were analyzed by an AI system (Transpara 1.7.1, ScreenPoint Medical), which assigned an exam score between 1-10 indicating an increasing likelihood of malignancy. The positive predictive value (PPV) of radiologists and the performance of the AI system were evaluated.

#### RESULTS

Out of 28,278 screening exams, 4170 exams were labeled as BIRADS 0, resulting in a recall rate of 14.75%. Of the 4,170 patients recalled, 3,531 returned to one of our facilities for diagnostic imaging. There were 581 diagnostic exams labeled as BIRADS 4-5 and recommended for biopsy. Biopsy results were available for 335 cases at the time of analysis, revealing 70 biopsy-proven cancers. A BIRADS-0 rating corresponded to a PPV of 3.4%. A BIRADS 4-5 rating based on DBT and subsequent workup yielded a PPV of 20.9%. AI identified 92.9% of cancers (65/70) with an exam score between 8 and 10, 84.3% of cancers (59/70) were flagged with the highest AI score of 10.

#### CONCLUSION

s AI score 8-10 has a strong predictive value for cancer. This system can be used to aid radiologists when evaluating screening mammograms.

#### CLINICAL RELEVANCE/APPLICATION

An AI tool that reliably indicates the probability of malignancy on the initial mammogram could serve as clinical decision support reducing biopsy and recall rates and increasing cancer detection rates.

#### S3A-SPBR-2 Improving Video-Based Ultrasound Diagnostic Performance for Breast Cancer to Expert-Level Using Deep Learning: A Retrospective, Multicenter, Diagnostic Study

Participants

Fajin Dong JR, MD, MD, Shenzhen, China (*Presenter*) Nothing to Disclose

#### PURPOSE

we aim to propose and validate a new automated deep learning framework based on standard video recordings of ultrasound examination.

#### METHODS AND MATERIALS

We designed a video-based framework for breast screening cineclips and integrated three classic AI models, DenseNet121, MobileNet, and Xception as backbones. For comparison, image-based framework is also constructed using the same three backbones with physician selected images, since image-based diagnosis is the current standard practice. In total, 3907 patients from two major medical centers were enrolled between July 2015 and January 2022. Both images and videos of the patients are utilized to train and evaluate models, including retrospective real-world data and prospective test data. Cineclip model tests, image model tests, and reader studies with human experts are performed on both retrospective and prospective data.

#### RESULTS

The accuracy of cineclip models is 87.40 to 92.59%, exceeding the accuracy of 76.00 to 85.60% achieved by all physicians with 7 to 10 years of experience in reader studies. In both real-world and prospective tests, cineclip models surpass image models among all evaluation metrics, including accuracy (87.40-92.59% vs. 80.80-85.83%), sensitivity (86.00-93.33% vs. 80.00-91.07%), specificity (83.10-92.00% vs. 78.87-86.67%), F1 (0.876-0.927 vs. 0.807-0.861) and AUROC (Area under Receiver Operating Characteristic Curve, 0.926-0.962 vs. 0.843-0.936). The difference in AUROC between cineclip models and image models with DenseNet121 and Xception backbone is statistically significant in real-world test under significance level ( $p=0.049$  for DenseNet backbone, and  $p=0.008$  for Xception backbone).

## CONCLUSION

s Cineclip models can achieve higher accuracy along with better robustness than image-based models, outperforming human experts. Our video-based AI framework might better aid breast cancer diagnosis and alleviate the scarcity of experienced physicians.

## CLINICAL RELEVANCE/APPLICATION

Ultrasound is one of the most widely used methods for breast cancer screening. However, its popularity is prohibited by its high operator dependence and the scarcity of skilled ultrasound specialists. This study can reduce the skill requirement and inter-operator variations.

### **S3A-SPBR-3 Deep Learning-Based MRI Model to Predict Pathologic Complete Response After Neoadjuvant Chemotherapy in HER2-Positive and Triple-Negative Breast Cancer**

Participants

Sooyeon Kim, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

There are limited studies on the prediction of pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC) using deep learning technique. We aimed to develop a deep learning-based MRI model to predict pCR in women with human epidermal growth factor receptor 2 (HER2)-positive or triple-negative breast cancers.

## METHODS AND MATERIALS

In this IRB-approved single center retrospective study, a total of 852 women (mean age±standard deviation, 51±10 years old) with HER2-positive or triple negative breast cancer who underwent NAC followed by surgery between 2017 and 2021 were included. They were divided into a training set (n=724) and a validation set (n=128) in a ratio of 8.5:1.5. Post-NAC dynamic contrast-enhanced (DCE)-MRI data (subtraction images of the 1st, 3rd, and 5th dynamic phase) and clinical data (age, clinical T stage, clinical N stage, estrogen receptor, progesterone receptor, HER2, Ki-67, histologic grade, histologic type, and initial MRI size) were collected. pCR was defined as the absence of both invasive and in-situ residuals in the breast in the surgical specimen. For each woman, tumor bed or residual enhancing lesions on post-NAC MRI were annotated using the three rectangular region-of-interests for the initial, intermediate (center), and endpoints, respectively. After pre-processing, the deep learning models were developed using 3D ResNet 50 architecture, 5-fold cross validation, and Python 3.6. Clinical data model, each phase model of DCE-MRI, and the combined model were developed, and each performance was evaluated using an area under the receiver operating characteristics curve (AUC). DeLong method was used to compare AUCs.

## RESULTS

The AUCs of the 1st, 3rd, and 5th dynamic MRI model were 0.63, 0.70, and 0.67, respectively. Compared to the 3rd dynamic MRI model with the highest AUC value of 0.70, the combined MRI model obtained from all dynamic images showed a lower AUC value of 0.66 albeit without statistical significance (0.70 vs 0.66, P=0.09). The AUC of the clinical data model was 0.57. The combined model of the clinical data and all dynamic MR images showed an AUC value of 0.65, which was significantly lower than that of the 3rd dynamic MRI model (0.65 vs 0.70, P=0.02).

## CONCLUSION

s The deep learning model based on the 3rd dynamic phase of DCE-MRI showed the best performance in predicting pCR in women with HER2-positive or triple-negative breast cancers.

## CLINICAL RELEVANCE/APPLICATION

Our deep-learning based MRI model demonstrates the potential to predict pCR in women with HER2-positive or triple-negative breast cancer. This information, after careful validation in further studies, can be utilized in a prospective trial to omit breast cancer surgery for women with a high possibility of pCR.

### **S3A-SPBR-4 Combining with Convolution Neural Network and Graph Convolution Network for Predicting Axillary Lymph Node Metastasis in Breast Cancer Based on DCE-MRI: A Multicenter Study**

## PURPOSE

This study aims to develop a deep learning model combining convolution neural network (CNN) and graph convolution network (GCN) based on dynamic contrast-enhanced (DCE)-MRI for predicting axillary nodal status in breast cancer as well as to explore the biological mechanism by employing gene analysis of RNA-sequencing data.

## METHODS AND MATERIALS

A total of 935 patients with breast cancer who underwent preoperative DCE-MRI from four institutes were retrospectively analyzed. 742, 83 and 110 patients were grouped into the training, internal test and independent external test sets, respectively. The regions of interest of the breast lesions were cropped manually by two radiologists. Three conventional CNNs, namely, 3D ResNet, 3D-Xception and HRNet (high-resolution Net) were used as the backbone architecture for axillary lymph node (ALN) metastasis identification based on the tumor, ALN, and combined tumor-ALN regions on the images. The feature maps obtained by CNNs are globally pooled and fused with the spatial structure features obtained by high resolution GCN. RNA-sequencing data from 11 patients were used to explore the underlying biological basis of the AI prediction. To select the most powerful CNN or CNN-GCN model for ALN-metastasis prediction, the performance of three CNN models and three CNN-GCN models was compared with area under the receiver operating characteristic (ROC) curve (AUC), accuracy, sensitivity and specificity. The performance of these models was compared with radiomics models, the Memorial Sloan-Kettering Cancer Center (MSKCC) model, and three radiologists.

## RESULTS

The optimal HRNet-GCN\_tumor+ALN model, achieved an AUC of 0.873 in the internal test cohort, as well as an AUC of 0.870 in the external test cohort, which was better than the best performing radiomics model (logistic regression, AUC: 0.790) and MSKCC model (AUC: 0.752). Additionally, with the assistance of HRNet-GCN\_tumor+ALN, the radiologists' performance was improved (external test cohort, P < 0.05). In the biological basis exploration, the high-risk group was associated with the downregulation of pathways mediating tumor proliferation and the promotion of anti-tumor immune cell infiltration in the microenvironment.

## CONCLUSION

s The proposed GCN-CNN fusion deep learning model could effectively predict ALN status preoperatively in breast cancer patients.

## CLINICAL RELEVANCE/APPLICATION

This study successfully demonstrated a CNN-GCN model base on DCE-MRI, which could non-invasively and preoperatively predict ALN metastasis of breast cancer with high accuracy. This model may assist and guide for radiologists to make more precise evaluation of ALN status.

### S3A-SPBR-5 Patient Race Impacts the Screening Mammogram False Positive Rate of a Commercially Available AI Algorithm

Participants

Derek Nguyen, MD, Durham, NC (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate a commercially available AI algorithm's ability to accurately interpret negative screening mammograms and the impact of patient demographics on its performance.

## METHODS AND MATERIALS

This retrospective cohort study identified 27,681 negative screening tomosynthesis mammograms from our academic institution from 1/1/16 to 12/31/19. All patients had two years of follow up without a diagnosis of atypia or malignancy. Patients with prior breast surgery or implant augmentation were excluded. A subset of unique patients was randomly selected to provide a broad distribution of race/ethnicity. This final cohort was interpreted by an FDA approved, commercially available AI algorithm (ProFound AI 3.0, iCAD, Inc) which was trained prior to the study using an enriched multi-vendor screening population dataset from at least 20 institutions. The algorithm generated case and risk scores for each mammogram. Per vendor, case scores > 49 (range 0-100) have a high certainty for malignancy and risk scores > 0.8 (range 0-1) are at high-risk for developing a malignancy on the subsequent screening mammogram (1-year cancer risk). Patient demographics (age, race/ethnicity, and breast density) were compared with case and risk scores using bivariate and multivariate logistic regression.

## RESULTS

4855 unique patients (median age: 54 years [46-63]) were included. The false positive rate for case and risk scores was 17% (816/4855) and 5% (240/4855), respectively. Every patient demographic was significantly associated with patients' case and risk scores on bivariate analysis,  $p < 0.001$ . On multivariate analysis, Black patients were significantly more likely (OR: 1.45, 95% CI 1.19-1.77) to have case scores > 49 compared to White patients. Asian patients were significantly less likely (OR: 0.68, 95% CI 0.54-0.86) to have case scores > 49 when compared to White patients. Breast density did not influence case scores after adjusting for age and race. On multivariate analysis, only Black patients were significantly more likely (OR: 1.46, 95% CI 1.05-2.03) to have risk scores > 0.8 compared to White patients. Increased breast density was associated with risk scores > 0.8 (fatty - reference; scattered - OR: 1.99, 95% CI 1.33-3.05; heterogeneous - OR: 2.00, 95% CI 1.25-3.55; extremely - OR: 2.80, 95% CI 1.26-5.84).

## CONCLUSION

s Patient race influenced the performance of a commercially available AI algorithm analyzing negative screening mammograms. False positive rates for suspicious case and risk scores were 17% and 5%, respectively.

## CLINICAL RELEVANCE/APPLICATION

Radiologists should be aware that the performance of FDA approved, commercially available AI software will vary by patient demographics and efforts to train on diverse datasets are needed.

### S3A-SPBR-6 AI for Diffusion-Weighted Breast MRI

Participants

Dimitrios Bounias, MSc, Heidelberg, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

Diffusion-weighted imaging (DWI) is a rapidly emerging MRI technique in oncologic breast imaging that requires no contrast agent administration, rendering it an attractive potential future supplement or even alternative to mammography and dynamic contrast-enhanced MRI. Artificial intelligence (AI) has the potential to assist radiological decisions on this emerging MR technique, facilitating a quicker adoption into clinical routine. In this work, we utilized nnDetection, a state-of-the-art self-configuring Retina U-Net based object detection model, with certain breast cancer-specific extensions to create a robust model trained on a large dataset of unenhanced breast MRI acquisitions.

## METHODS AND MATERIALS

The IRB approved study included  $n=818$  patients. Histopathologically proven malignant lesions accounted for  $n=618$  lesions in  $n=268$  patients. All patients underwent a clinically indicated multiparametric breast 3T MRI examination, including a multi-b-value DWI acquisition (50,750,1500). The nnDetection AI model was trained with the following extensions: (i) Apparent Diffusion Coefficient (ADC) as additional input, (ii) random bias field, random spike, and random ghosting augmentations, (iii) a size-balanced data loader to ensure that the fewer large lesions were given an equal chance to be picked in a mini-batch and (iv) replacement of the loss function with a size-adjusted focal loss, that increases as false positive predictions get smaller or as true positive predictions get larger. This adapted loss function prioritizes finding the primary lesion while disincentivizing small indeterminate false positives. The Area Under the Receiver Operating Characteristic (AUROC) was used as the metric for patient-level performance in 5-fold cross-validation.

## RESULTS

The nnDetection AI model was able to achieve an AUROC of 0.88 using only the abbreviated unenhanced DWI MRI acquisition, and compares favorably against multireader performance metrics reported for mammography ((i)0.81, (ii) 0.87, (iii) 0.81). The model was also able to achieve 0.70 FROC (Free-response Receiver Operating Characteristic) for primary lesions, indicating a relevant localization ability.

## CONCLUSION

s This study shows that AI has the ability to complement the assessment of breast MRI in abbreviated unenhanced examinations based on DWI, even before radiologists are involved in the diagnostic process.

## CLINICAL RELEVANCE/APPLICATION

This work supports personalization in breast cancer screening by enabling radiologists to use advanced imaging techniques such as abbreviated diffusion-weighted imaging (DWI), potentially supplementing the diagnostic toolbox.

### S3A-SPBR-7 Risk-aware AI for Lesion Detection and Characterization in Breast MRI

Participants

Dimitrios Bounias, MSc, Heidelberg, Germany (*Presenter*) Nothing to Disclose

## PURPOSE

AI methods for medical object detection revolve around discovering and rating structures of potential relevance to the patient. Performance is commonly calculated with Free-response Receiver Operating Characteristic (FROC) analysis, which calculates sensitivity at predefined thresholds of false positives (FPs) per case. FROC weighs all lesions equally, but in practice not all lesions might be considered as having identical instantaneous impact for the further clinical pathway of a patient, revealing a risk imbalance. Here we describe the development and evaluation of such a risk-aware model for breast cancer using diffusion-weighted imaging (DWI) MR acquisitions.

## METHODS AND MATERIALS

For this IRB approved study we used a dataset with n=818 women undergoing clinically indicated 3T breast MRI including multi-b-value DWI (50,750,1500), containing n=618 histopathologically verified malignant lesions in n=268 patients. The risk function was calculated using reported 15-year breast cancer mortality based on lesion size, from a multi-year study involving n=819,647 patients from Sopik et al, 2018. A risk-adjusted adaptation of FROC (raFROC) is proposed, where true positive predictions and ground truth samples are weighted by the associated risk. FPs are weighted by 1-risk, due to the desire to minimize unneeded biopsies and the lower value of low risk lesions. To accommodate for the metric, we also propose a risk-adjusted focal loss (raFocal) that applies similar weighting. A focal loss and a raFocal model were trained using 5-fold cross validation. Evaluation took place using traditional methods and raFROC.

## RESULTS

The risk-aware (raFocal) model improved both the AUROC (Area Under the Receiver Operating Characteristic curve) and AP (Average Precision) patient-level performance (AUROC/AP 0.86/0.77) compared to the standard "focal" model (0.84/0.70). The proposed raFROC portrays a difference (focal 0.60, raFocal 0.65) between the models across all FP thresholds, being able to better mirror patient-level improvement. In contrast, a lesser difference was present for regular FROC (focal 0.50, raFocal 0.52), appearing only in lower thresholds.

## CONCLUSION

s This work showcases a first step for risk-aware AI model training and validation in medical object detection. Accounting for clinical risk and outcome is very important in medical diagnosis, as it allows balancing the trade off between FP findings and missing pathologies, significantly influencing the clinical outcome of the individual patient.

## CLINICAL RELEVANCE/APPLICATION

This work showcases how to incorporate risk into the training and evaluation of object detection models for breast cancer screening, which previously considered all lesions equal, bringing AI closer to clinical needs.

### S3A-SPBR-8 Chat GPT: How Far Has It Gone Yet?

Participants

Marcela Lumar, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

## PURPOSE

Chat GPT is an artificial intelligence (AI) language model trained on a dataset of human language, making it capable of understanding and generating complex sentences and paragraphs, including medical literature. The objective of this study is to analyze Chat GPT's accuracy and reproducibility in answering questions about breast radiology.

## METHODS AND MATERIALS

Questions were gathered from nationally regarded professional societies, as well as elaborated from breast radiologists with over 15 years of experience. We formulated 10 questions that were answered by medical residents (12 from the 1st/2nd year and 12 from the 3rd/4th year) and 12 professionals specialized in breast imaging. All questions had only one correct answer. The alternatives included the options of "more than one alternative is correct" and "all alternatives are incorrect", for the cases in which Chat GPT could not provide one correct answer for the question. Reproducibility was determined by asking the model each question ten times from at least 5 different devices in at least 3 different locations.

## RESULTS

The mean average of the residents in the 1st and 2nd years was 40% of correct answers, for 3rd and 4th years residents it was 60%, for breast imaging specialists it was 80% and the average of correct responses by Chat GPT-4 was 45%, and varied from 30% to 60% correct answers. Chat-GPT did not demonstrate an increasing or decreasing pattern of number of correct answers thought time that would allow us to infer that it was learning through the questions. Concerning reproducibility, Chat GPT answered the same item in all 10 attempts for only 4 questions.

## CONCLUSION

s ChatGPT could provide accurate responses in 45% of questions related to breast imaging, which is more than a 1st or 2nd year radiology resident but less than a 3rd or 4th year resident. Although it is expected that it will evolve over time, we could not state that in our study. We encourage future studies to further examine how trustworthy are the information provide by it and to analyse

if this technology will continue evolving over time, as we hope this technology may improve education for medical doctors, and even patient's outcomes and quality of life.

#### **CLINICAL RELEVANCE/APPLICATION**

ChatGPT is an AI language model launched in November 2022, trained on a dataset covering a broad range of topics, including the medical literature. Discussion regarding the potential of ChatGPT in all fields of academia is ongoing, and its applicability is under investigation. Although there is one study that tests how Chat GPT would answer questions about screening breast cancer recommendations (Haver et. al), there are currently no studies examining Chat GPT's applicability as a learning tool for professionals consult.

#### **S3A-SPBR-9 Preliminary Interim Analysis of AI-STREAM (Artificial Intelligence for Breast Cancer Screening in Mammography): A Prospective Multicenter Study Design in Korea Using AI-based CADe/x**

Participants

Yun Woo Chang, MD, PhD, (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study is to compare the diagnostic accuracy of radiologists with and without the use of AI-based CADe/x in mammography reading for breast cancer screening of Korean women with average breast cancer risk.

#### **METHODS AND MATERIALS**

Total of 24,601 participants were enrolled between February 2021 and December 2022 at six study sites in Korea. The mammograms were read by breast imaging radiologist (BR) without using AI-based CADe/x through single reading, and results were recorded on the study platform (BEST image). Then, the radiologists reviewed the mammograms with the assistance of AI-based CADe/x and recorded the results on the study platform based on the radiologist's decision after considering both with and without AI-based CADe/x. These BR were experts in breast imaging at an academic hospital for over ten years. If a recall was required, further diagnostic workup was conducted to confirm the cancer detected on screening. In the simulation study, the same participants' mammograms were read by general radiologists (GR) in the same setting of the reading process, without and with use of AI-based CADe/x. GR are radiologists not specializing in breast imaging. The diagnostic accuracy of GR and BR, with or without the use of AI-based CADe/x was compared with AI-based CADe/x for mammography reading for breast cancer screening.

#### **RESULTS**

By the end of patient enrollment, breast cancer was confirmed in 131 patients. GR without AI found 86 cancers, GR with AI found 110 cancers, BR without AI found 110 cancers, and BR with AI found 124 cancers. When a 10% cutoff was applied to AI, it detected 118 cancers. Stand-alone AI-based CADe/x detected significantly higher cancer detection than GR without AI. AI detected slightly more cancer than BR without AI or GR with AI, but there was no statistical significance. BR with AI had the highest cancer detection rate compared with AI stand-alone, BR without AI, or GR with AI, but there was no statistical significance. There was no difference between GR and AI in the recall, but recall in BR was significantly lower.

#### **CONCLUSION**

s AI-based CAD e/x could be helpful for radiologists with less experience in mammography reading. BR with AI had the highest accuracy in cancer detection and a lower recall rate compared with other situations. This is a preliminary interim analysis of the prospective study as cancer registry data will be available at least 26 months after the year of interest.

#### **CLINICAL RELEVANCE/APPLICATION**

This prospective multicenter cohort study aims to generate real-world evidence to compare the diagnostic accuracy of radiologists with and without AI-based CADe/x in mammography reading for breast cancer screening.

S3A-SPCA

### Cardiac Imaging Sunday Poster Discussions I

#### Sub-Events

#### **S3A-SPCA-1 Total Cardiac Volume Segmentation Model for Pediatric Heart Transplant Donors and Patients using Transfer Learning**

##### Participants

Elanchezian Somasundaram, PhD, MS, Cincinnati, OH (*Presenter*) Nothing to Disclose

##### PURPOSE

To develop an optimized model to predict total cardiac volumes (TCV) in donors and pediatric heart transplant patients using transfer learning techniques on pretrained models predicting individual heart segments.

##### METHODS AND MATERIALS

An internal, clinical chest computed tomography (CT) dataset (n=275), consisting of non-contrast and contrast-enhanced exams, was included for the study. 251 exams were used for model training while 27 were retained for model testing. TCV was segmented as part of clinical workflow using Mimics (Materialize NV, Leuven, Belgium). Additionally, heart chamber segments from a large public dataset (n= 866) curated by the University Hospital Radiology Department (Basel, Switzerland) was included for transfer learning. A dynamic U-net (DynUNET) architecture within the MONAI framework was first pre-trained on the public dataset for 100 epochs, using a 0.8/0.2 split for training/validation respectively, and then trained on the internal TCV dataset. Another DynUNET model was trained only on the internal TCV dataset. Experiment tracking and hyper-parameter search tools were used to find the training parameters that produced the best validation dice score. Both models were tested on the internal test dataset (n=27) as well as 20 adult, chest CT scans from multiple institutions, shared by UNOS (United Network for Organ Sharing) through a formal research agreement. UNOS exams were segmented for TCV using 3D Slicer. Relative volume error (RVE) and Dice coefficients (DSC) were calculated for model performance evaluation and comparison.

##### RESULTS

The most optimal DynUNET model trained with pre-trained weights had an initial learning rate of 0.0005 with an exponential learning rate scheduler and an Adam optimizer. The mean ( $\pm$  standard deviation) RVE and DSC was 3.3 ( $\pm$  3.0%) and 0.95 ( $\pm$  0.02) respectively for the internal dataset and 6.9 ( $\pm$  10%) and 0.90 ( $\pm$  0.10) respectively for the UNOS dataset. The most optimal DynUNET model trained only on the internal TCV dataset had an initial learning rate of 0.003 using a cosine learning rate scheduler and Adam optimizer. The mean ( $\pm$  standard deviation) RVE and DSC was 5.3 ( $\pm$  5.5%) and 0.93 ( $\pm$  0.02) respectively for the internal dataset and 11 ( $\pm$  16%) and 0.87 ( $\pm$  0.15) for the UNOS dataset.

##### CONCLUSION

s Transfer learning using pre-trained weights from a large public dataset improved model performance for prediction of TCV in an internal clinical dataset as well as a set from UNOS, where exams span various institutions, scanner manufacturers, and protocols.

##### CLINICAL RELEVANCE/APPLICATION

Total cardiac volume (TCV) is an important metric for recipient-donor organ matching for organ transplantation. A clinically deployable, optimized deep learning TCV segmentation model is useful for such organ size matching.

#### **S3A-SPCA-2 Comparison of Prognostic Value Between CAD-RADS 1.0 and CAD-RADS 2.0 Evaluated by Convolutional Neural Networks Based CCTA**

##### Participants

Zengfa Huang, Wuhan, China (*Presenter*) Nothing to Disclose

##### PURPOSE

The aim of the present study was to investigate the prognostic value of the novel coronary artery disease reporting and data system (CAD-RADS) 2.0 compared with CAD-RADS 1.0 in patients with suspected CAD evaluated by convolutional neural networks (CNN) based coronary computed tomography angiography (CCTA).

##### METHODS AND MATERIALS

A total of 2131 consecutive inpatients with suspected CAD were evaluated by CCTA for CAD-RADS 1.0 and CAD-RADS 2.0 classifications. Kaplan-Meier and multivariate Cox models were used to estimate major adverse cardiovascular events (MACE) inclusive of all-cause mortality or myocardial infarction (MI). The C-statistic was used to assess the discriminatory ability of the two classifications.

##### RESULTS

In total, 94 (5.2%) MACE occurred over the median follow-up of 45.25 months (interquartile range 43.53 to 46.63 months). The annualized MACE rate was 0.014 (95% CI: 0.011-0.017). Kaplan-Meier survival curves indicated that the Coronary Artery Disease

Reporting and Data System (CAD-RADS) classification, segment involvement score (SIS) grade, and Computed Tomography Fractional Flow Reserve (CT-FFR) classification were all significantly associated with the increase in the cumulative MACE (all  $P < 0.001$ ). CAD-RADS classification, SIS grade, and CT-FFR classification were significantly associated with endpoint in univariate and multivariate Cox analysis. CAD-RADS 2.0 showed a further incremental increase in the prognostic value in predicting MACE (c-statistic 0.702, 95% CI: 0.641-0.763,  $P = 0.047$ ), compared with CAD-RADS 1.0.

## CONCLUSION

The novel CAD-RADS 2.0 evaluated by CNN-based CCTA showed higher prognostic value of MACE than CAD-RADS 1.0 in patients with suspected CAD.

## CLINICAL RELEVANCE/APPLICATION

The novel CAD-RADS 2.0 evaluated by CNN-based CCTA showed good performance for predicting major adverse cardiac events (MACE) in patients with suspected CAD and may serve as a non-invasive imaging marker for risk stratification in future clinical practice.

### S3A-SPCA-3 Diagnostic Utility of Artificial Intelligence in Detecting Coronary Artery Disease on CT Coronary Calcium Score Using Manual Calcium Scoring as Reference Standard- A Meta-Analysis

#### PURPOSE

The amount of coronary artery calcification is said to be a strong and independent predictor of coronary heart disease events. Calcium scoring is a non-invasive procedure wherein calcifications within the coronary arteries are quantified and this is interpreted by trained radiologists. However, this is known to be tedious and time-consuming. Artificial intelligence (AI) is now being used as an adjunct tool in cardiovascular imaging. "Machine learning or deep-learning algorithm is a subset of AI that utilizes algorithms to combine voluminous data comprising clinical information and coronary anatomical variables for optimal prediction of major adverse cardiac events" (Wang, 2019). The aim of this study is to determine the accuracy of AI in detecting coronary artery disease on CT coronary calcium score using manual counting as reference standard.

#### METHODS AND MATERIALS

We searched PUBMED, Google Scholar for studies on AI in detecting CT coronary calcium using manual counting as the reference standard. Pooled sensitivity, specificity, positive and negative likelihood ratios were calculated. Two investigators (ISB and SRL) independently extracted the data.

#### RESULTS

Out of 45 articles, three (3) were included in the study. A total of 769 calcium score procedures were included in the analysis. Overall pooled sensitivity of 0.952 (CI=95%, 0.926-0.970), pooled specificity of 0.949 (CI=95%, 0.921-0.970), positive likelihood ratio of 12.1 (CI=95%, 2.304-63.636) and negative likelihood ratio of 0.055 (CI=95%, 0.036-0.084).

#### CONCLUSION

Deep learning A.I. on coronary artery calcium score can be used to detect coronary artery disease. Further study to compare utility of machine learning with deep learning using manual counting as reference standard.

#### CLINICAL RELEVANCE/APPLICATION

Artificial intelligence is now used in a myriad of applications not only in medicine but also in daily life. AI has a potential to improve the workflow in radiology through automation of CT coronary calcium score determination, a task which is known to be time-consuming. If A.I. may be used in the clinical setting, more people may be screened for coronary artery disease in a given amount of time. This may also help in improving the efficiency of radiologists.

### S3A-SPCA-4 Accuracy of Machine Learning Algorithms for Calcium Scores on Chest Computed Tomography: A Systematic Review and Meta-analysis

Participants

Pedro Pereira, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the diagnostic accuracy of artificial intelligence (AI) algorithms for quantifying coronary artery calcium (CAC) on chest computed tomography (CT) images.

#### METHODS AND MATERIALS

PubMed, EMBASE, and Cochrane Central databases were systematically searched for studies published up to April 1st. Studies were included if they compared ML-derived calcium score categories (Agatston score) with expert manual analysis in gated and non-gated studies. The main outcome was the percentage of agreement between automatic and manual analyses of the Agatston score categories. We also calculated the rates of the underestimated and overestimated categories using automatic analysis. Heterogeneity was examined using  $I^2$  statistics. A random effects model was used to perform the meta-analysis. The study protocol was registered a priori in the International Prospective Register of Systematic Reviews (Prospero Protocol CRD42023407318).

#### RESULTS

A total of 23 studies comprising 9788 subjects with gated CT and 4967 with non-gated CT were included. The mean age of the sample was 58.9 years. The percentage of Agatston score agreement between automatic and manual analyses for gated studies was 93.1% (95% CI, 90.8-94.8%). Automatic analysis overestimated the Agatston category by 4.2% (95% CI, 2.8-6.2%) and underestimated it by 2.3% (95% CI, 1.8-2.9%). The percentage agreement for non-gated studies was 79.8% (95%CI, 68.0-88.0%). Automatic models overestimated or underestimated the Agatston category by 10% (95%CI, 4.7-20.0%) and 5% (95%CI, 2.1-11.1%), respectively. Significant heterogeneity was observed in the analyzed outcomes ( $I^2 > 50\%$ ).

#### CONCLUSION

Our findings demonstrate a high degree of agreement in calcium score analysis using machine learning algorithms, particularly in gated studies.

## CLINICAL RELEVANCE/APPLICATION

The use of AI algorithms could improve CT interpretation workflow, offering automatic quantification coronary calcium with high accuracy to both cardiac-gated and non-cardiac-gated chest CTs.

### S3A-SPCA-5 Deep Learning-Based Measurement of Left Atrial Volume on Calcium Scoring CT: Observations in the Dallas Heart Study

Participants

Fernando U. Kay, MD, PhD, Farmers Branch, TX (*Presenter*) Research Grant, Edwards Lifesciences Corporation

## PURPOSE

Coronary calcium scoring CT (CAC-CT) imaging data is currently underutilized. Left atrial (LA) enlargement is associated with atrial arrhythmias and stroke. In this study, we aimed to evaluate the accuracy of an AI-based segmentation algorithm for estimating LA volumes on CAC-CT and compare the results with other clinical variables in the Dallas Heart Study phase 2 (DHS2).

## METHODS AND MATERIALS

Participants with both CAC-CT and cardiac MRI (CMRI) were eligible for inclusion. We developed a 3D Unet Deep Learning model using a semi-supervised approach with nested cross-validation. A cardiac imager created reference cardiac chamber segmentation on CAC-CT for 70 randomly selected participants, using epicardial margins. This initial model generated synthetic segmentations in 1,931 additional scans, which were utilized for model refinement. LA volume was derived using Pyradiomics. In 749 participants, maximum LA volume was independently assessed on CMRI via the biplane method. Clinical variables were collected for analysis. We included a subset of 735 participants without prior events for a Kaplan-Meier analysis of incident atrial fibrillation, stroke, or transient ischemic attack.

## RESULTS

The segmentation model achieved a Dice score of  $0.93 \pm 0.01$  (mean  $\pm$  SD) when compared to manual segmentation. The cohort consisted of 445 females and 304 males with a median age of 50 years (IQR: 43 - 57). The intraclass correlation coefficient between CAC-CT-derived LA volume and maximum LA volume on CMRI was 0.67 (95% CI: 0.63 - 0.71). CAC-CT LA volume had an AUC curve of 0.82 (95% CI: 0.78 - 0.86) for detecting participants in the 4th quartile of maximum LA volume on CMRI. In multivariable linear analysis, CAC-CT LA volume indexed to BSA was significantly associated with male sex (Beta coefficient: 1.6\*\*), age (0.3\*\*\*), smoking habit (-0.7\*), and hypertension (2.9\*\*\*) (P: \* $<0.1$ , \*\* $<0.05$ , \*\*\* $<0.01$ ). The 4th percentile of indexed LA volume on CAC-CT was associated with incident composite events (N = 15) during follow-up when compared to the 1st-3rd percentiles (P = 0.01).

## CONCLUSION

s We developed a segmentation model capable of extracting LA volume from CAC-CT, demonstrating moderate correlation with LA maximum values derived from CMRI. This CAC-CT biomarker was significantly associated with clinical variables, including incident atrial fibrillation and cerebrovascular events in the DHS2.

## CLINICAL RELEVANCE/APPLICATION

AI-derived segmentation algorithms have the potential to enhance the extraction of LA volume from CAC-CT, enabling more comprehensive risk stratification beyond traditional calcium scoring.

### S3A-SPCA-7 Right Ventricular Strain and Abnormal Muscle Formation on Cardiac CT: To Identify Pulmonary Hypertension in Repaired Tetralogy of Fallot

## PURPOSE

In the long-term period of repaired tetralogy of Fallot (TOF), right ventricular (RV) volume augmentation due to pulmonary regurgitation is frequent, and right heart failure due to its aggravation is prognostic. Transcatheter pulmonary valve implantation (TPVI) is becoming increasingly popular as a minimally invasive treatment, but it must be carefully indicated in cases of RV pressure overload. We used multi-phase cardiac CT to assess RV volumetry, strain, and morphology to identify pulmonary hypertension in patients with repaired TOF scheduled for TPVI.

## METHODS AND MATERIALS

Forty-four patients with repaired TOF scheduled for TPVI were enrolled to undergo cardiac CT, MRI, and right heart catheterization. Pulmonary hypertension (PH) was defined as a mean pulmonary artery pressure of 25 mmHg or greater by right heart catheterization. CT-RV strain was calculated using ECG-gated CT data with motion coherence image processing. The association of PH with RV strain and abnormal muscle bundles in the right ventricular outflow tract on cardiac CT was evaluated. Additionally, RV volumetry was compared between cardiac cine MRI and CT.

## RESULTS

Eleven of the 44 patients had PH. CT-RV strain was significantly lower patients with PH than those without PH ( $-8.7 \pm 1.6$  % vs.  $-11.3 \pm 2.33$  %;  $p < 0.001$ ). Receiver-operating-characteristic curve analysis revealed that with optimal RV strain  $-10.4$  %, patients with PH can be diagnosed with an area under the curve 0.97, sensitivity 100%, and specificity 89%. The frequency of formation of abnormal muscle bundles in the RV outflow tract was significantly greater in patients with PH (7/11, 64%) than in patients without PH (11/33, 35%). RV volumes calculated from CT and MRI showed a strong positive correlation, but CT tended to increase volume more than MRI (RV-EDVi: CT vs. MRI,  $176.2 \pm 47.9$  ml/m<sup>2</sup> vs.  $147.0 \pm 42.1$  ml/m<sup>2</sup>; Pearson  $r = 0.90$ ; RV-ESVi: CT vs. MR:  $98.7 \pm 36.9$  ml/m<sup>2</sup> vs.  $79.8 \pm 28.4$  ml/m<sup>2</sup>; Pearson  $r = 0.91$ ).

## CONCLUSION

s The reduction of RV strain and the presence of abnormal muscle bundles in the RV outflow tract obtained from multi-phase CT indicate PH in repaired TOF and should make one cautious about the indication for TPVI.

## CLINICAL RELEVANCE/APPLICATION

Cardiac CT provides not only accurate anatomical information from the RV to the pulmonary artery, but also noninvasive evaluation of pulmonary hypertension.

## Abstract Archives of the RSNA, 2023

S3A-SPCH

### Chest Imaging Sunday Poster Discussions I

#### Sub-Events

#### S3A-SPCH-1 Assessment of Solitary Pulmonary Nodules Using Dual-layer Spectral Detector Computed Tomography

##### PURPOSE

With lung cancer being the most common malignancy diagnosed worldwide, differentiating between malignant solitary pulmonary nodules (SPNs) and other lung diseases remained a substantial challenge. The aim of this study was to examine the usefulness of Dual-layer Spectral Detector Computed Tomography in solitary pulmonary nodule (SPN) assessment.

##### METHODS AND MATERIALS

Between September 2021 and December 2022, dual-layer spectral images of 71 patients confirmed by pathology were retrospectively analyzed in the venous phase. Patients were classified into the malignant group and the benign group. The iodine concentration (IC) values of the SPN, normalized IC of the SPN to aorta/pulmonary artery/pulmonary vein (NICa/NICpa/NICpv), CT values of 40 keV (HU40keV) and 80keV (HU80keV) monochromatic images, and the slope of spectral HU curve were calculated and compared between the benign and malignant groups. ROC curve analysis was performed to assess the diagnostic performance of the above parameters.

##### RESULTS

IC, NICpa, HU40keV, and slope HU had significantly higher values in the malignant group than in the benign group (all  $P < 0.05$  in Mann-Whitney U test). Iodine density (AUC = 0.78) of 1.74 mg/ml yielded a sensitivity of 95% and a specificity of 57%. Slope HU (AUC = 0.79) of 2.9 yielded a sensitivity of 95% and a specificity of 57%.

##### CONCLUSION

Both virtual monochromatic images and iodine concentration maps prove to be highly useful in differentiating benign and malignant pulmonary nodules.

##### CLINICAL RELEVANCE/APPLICATION

Dual-layer Spectral Detector Computed Tomography can help to differentiate benign from malignant SPNs.

#### S3A-SPCH-2 Value of Dual-Layer Detector Spectral CT in Predicting Lymph Node Metastasis of Non-Small Cell Lung Cancer

##### PURPOSE

To explore the potential value of dual-layer spectral detector computed tomography (SDCT) quantitative parameters combined with morphological characteristics and tumour markers for predicting lymph node metastasis (LNM) in non-small cell lung cancer (NSCLC).

##### METHODS AND MATERIALS

Patients presenting with solid solitary pulmonary nodules (SPN) (8 mm < diameter = 30 mm) with pathologically confirmed NSCLC were enrolled. The Mann-Whitney U test and independent sample t-test were used to analyse the differences in multiple SDCT quantitative parameters between the non-LNM and LNM groups. The diagnostic efficacy of the corresponding parameters in predicting LNM in NSCLC was evaluated by plotting the receiver operating characteristic (ROC) curve. To determine the independent predictive factors for LNM of NSCLC, we analysed statistically significant clinical data, tumour indicators, SDCT morphological signs of cancer lesions, and SDCT quantitative parameters using multivariate logistic regression. The best multi-parameter regression prediction model was established. Inter-observer repeatability was assessed using the intraclass correlation coefficient (ICC) and the Bland-Altman plot.

##### RESULTS

There were no significant differences in age, sex, or smoking history between the non-LNM and LNM groups. Between both groups, the lesion size and vascular convergence sign significantly differed ( $P < 0.05$ ), and there were no significant differences in six tumour markers. SDCT quantitative parameters (SAR40keV, SAR70keV, ?40keV, ?70keV, CER40keV, CER70keV, NEF40keV, NEF70keV, ?, NIC, and NZeff) in the non-LNM group were significantly higher than those in the LNM group ( $P < 0.05$ ). ROC analysis showed that CER40keV, NIC, and CER70keV had higher diagnostic efficiencies for predicting LNM. Multivariate logistic regression analysis showed that size, ?, and NIC were independent predictive factors for LNM. The combination of size + ? + NIC had the highest diagnostic efficiency (AUC=0.892). This study's inter-observer repeatability of the SDCT quantitative and derived quantitative parameters was good (ICC: 0.801-0.935).

##### CONCLUSION

SDCT quantitative parameters combined with clinical data have potential value for predicting LNM in NSCLC. The size + ? + NIC combined parameter model can further improve the prediction efficiency of LNM.

##### CLINICAL RELEVANCE/APPLICATION

This study explored the importance of SDCT quantitative parameters and their derivatives, combined with morphological information of the lesion and clinical data of patients in predicting LNM in NSCLC. We believe that our study makes a significant contribution to the literature because it provides a new technique for predicting LNM in patients with NSCLC.

### **S3A-SPCH-3 Combination of Clinical and Spectral CT Parameters for Predicting Lymphovascular Invasion in N0 Stage Non-small Cell Lung Cancer**

#### **PURPOSE**

To investigate the predictive value of spectral CT quantitative parameters for lymphovascular invasion in N0 stage non-small cell lung cancer, a diagnostic model was constructed and visualized as a nomogram to assist clinical preoperative treatment decisions.

#### **METHODS AND MATERIALS**

107 patients with N0 stage non-small cell lung cancer underwent spectral CT before surgery and were divided into two groups: positive group and negative group. Clinical baseline characteristics included age, gender, biochemical markers, serum tumor markers and Immunohistochemical markers. Imaging features included lobe location, tumor boundary, lobulation sign, spiculation, bubblelike lucency, air bronchogram, vascular convergence and pleural retraction. A radiologist delineated the regions of interest on the layer of maximum tumor diameter and the nearest upper and lower layers in axial enhanced images and calculated the average value. Monoenergetic CT value, effective atomic number (Eff-Z), iodine concentration (IC) of tumor and artery were acquired to calculate normalized iodine concentration (NIC,  $NIC = IC_{tumor} / IC_{artery}$ ).  $\chi^2$  test, t-test and U test were used for calculated differences between groups. Then, least absolute shrinkage and selection operator (LASSO) regression and multivariate logistic regression were used to select the most discriminating features, build a predictive model and visualize the model as a nomogram. ROC curves, calibration curves and decision curves analysis (DCA) were used to evaluate prediction performance and clinical utility.

#### **RESULTS**

41 patients had lymphovascular invasion in 107 N0 stage non-small cell lung cancer patients. The gender, TIF-1 and lymphocyte count differed between the two groups ( $P < 0.05$ ). After feature selection, the six variables included 70keV, 90keV and Eff-Z in the dual phase were screened by LASSO regression to construct the nomogram. The AUC of the clinical-spectral CT model were 0.93 (95%CI: 0.88~0.98). The sensitivity and specificity were 0.89 and 0.88, respectively. The model showed good calibration, and the DCA demonstrated that the model has a higher net benefit than the best single variable.

#### **CONCLUSION**

There were differences in gender, TIF-1 and lymphocyte count and spectral CT parameters in lymphovascular invasion status. The nomogram based on Clinical characteristics and 70keV, 90keV and Eff-Z in the dual phase is helpful for the preoperative determination of lymphovascular invasion status in non-small cell lung cancer.

#### **CLINICAL RELEVANCE/APPLICATION**

The nomogram is helpful for the preoperative determination of lymphovascular invasion status in N0 stage non-small cell lung cancer, which can assist in clinical preoperative decision-making and patient risk stratification.

### **S3A-SPCH-4 A Comparative Study on the Image Quality of Part-solid Nodules in the Lung Between Visual Non-contrast on Venous Phase Based on Ultrafast Synchronized KV/mA Switching Dual Energy CT and True Non-contrast**

Participants

Jingjing Hong, Guangzhou, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study explored the feasibility of using virtual non-contrast (VNC) images obtained from ultrafast synchronized KV/mA switching dual energy CT (DECT) in both pulmonary arterial and venous phase to evaluate part-solid nodules (PSN) in the lung, and compared their performance with true non-contrast (TNC) images.

#### **METHODS AND MATERIALS**

46 Cases of Partial Solid Nodules with lung enhanced CT examination who underwent TNC scan and enhanced DECT scan (arterial and venous), and VNC images were reconstructed from DECT. The CT values, and standard deviation (SD) of the PSN and Ipsilateral erector spinae muscle (ESM), as well as diameter of lesion, were measured in VNC and TNC images. The signal-noise-ratio (SNR,  $CTSN/SDSN$ ) and on-contrast-noise-ratio [CNR,  $(CTESM - CTPSN) / SDESMS$ ] of PSN were calculated. Record the effective radiation dose in TNC and VNC mode. Two experienced radiologists subjectively assessed the IQ(image quality)of VNC and TNC images using a 5-point scale (1, poor; 2, fair; 3, moderate; 4, good; 5, excellent). Non-parametric test was used to compare the subjective and objective image parameters and effective radiation dose of images in different scanning phases. The Kappa test was used to assess consistency of subjective score between groups.

#### **RESULTS**

There were no significant differences in The diameter, CT value, SD, SNR and CNR between TNC and VNC images in arterial/venous phase ( $P > 0.05$ ). The TNC ( $4.79 \pm 0.33$ ) had the highest the subjective score, followed by VNC images ( $4.04 \pm 0.26$ ) in venous phase, with significant differences observed among the three groups ( $P = 0.015$ ), however, all scores were up to diagnosis requirements. The consistency of subjective scores between radiologists was strong ( $K = 0.72 \sim 0.73$ ). The effective radiation dose of VNC mode [ $10.74 \pm 0.93$  mSv] was lower than that of conventional mode [ $15.21 \pm 1.89$  mSv] ( $P < 0.001$ ), about 30% reduction.

#### **CONCLUSION**

Visual non-contrast on ultrafast synchronized KV/mA switching dual energy CT in venous phase can provide similar image quality to TNC, but the radiation dose is significantly reduced.

#### **CLINICAL RELEVANCE/APPLICATION**

The ultrafast synchronized KV/mA switching dual energy enhanced venous phase VN technique can largely replace the conventional images, providing comparable image quality for patients with lung disease and significantly reducing patient radiation dose.

### **S3A-SPCH-5 Quantitative Lung and Lobar Perfusion from Dual-source, Dual-energy CTPA in Chronic Thromboembolic Pulmonary Hypertension and Acute Pulmonary Embolism**

#### **PURPOSE**

To investigate the differences in quantitative lung and lobar perfusion metrics between patients with chronic thromboembolic pulmonary hypertension (CTEPH) and acute pulmonary embolism (PE).

#### **METHODS AND MATERIALS**

Under IRB approval, 162 adult patients (>21 years) diagnosed with acute PE or CTEPH were scanned clinically using dual-source, dual-energy CT (Siemens SOMATOM Flash) pulmonary angiography (DE-CTPA) between 2019 and 2023. De-identified, thin-section DE-CTPA images from 81 PE patients (M:F 45:36; median age 69 years [60; 76]) and 81 CTEPH patients (M:F 46:35; median age 71 [61; 78]) were processed using the automated, machine-learning based eXamine DE Lung Isolation software (Siemens Healthineers) to obtain quantitative lung and lobar perfusion data. Clinical data was retrieved from electronic patient journals. Statistical analysis was performed using R (RStudio) with Mann-Whitney U test (individual perfusion parameters), PERMANOVA (for multivariate comparison) and multiple logistic regression (for correlation between perfusion parameters and clinical data and biomarkers).

#### **RESULTS**

Whole lung blood volume was lower ( $p < 0.001$ ) in PE patients (median 3399 mL [2554, 4284]) than in CTEPH patients (median 4094 mL [3397, 4818]). The same was observed at single lung and lobar level (figure 1A). The multivariate comparison encompassing all perfusion variables (figure 1A-C) showed a difference between the two groups ( $F = 6.15$ ,  $Pr > (F) = 0.004$ ) after testing for homogeneity of variance. We found poor correlation ( $r < 0.3$ ) between perfusion parameters and right heart catheterization parameters, 6-minute walking distance, and tricuspid annular plane systolic excursion (TAPSE) in CTEPH patients as well as with TAPSE, mean arterial blood pressure, and saturation in PE patients. In CTEPH, right upper lobe contrast uptake (CU), left upper lobe volume and CU, and left and lower lobe contrast concentration (CC) predicted whether patients had high ( $> 4$  L/min) cardiac output (CO) ( $p = 0.01 - 0.03$ ).

#### **CONCLUSION**

Lung and lobar perfusion are lower in patients with acute PE than patients with CTEPH as highlighted by differences in DECT-derived pulmonary blood volume parameters. This might be explained by the differences between an acute, decompensated disease phenotype and a chronic, compensated disease phenotype. Perfusion parameters correlate poorly with hemodynamic and clinical parameters in both diseases, but might predict severity.

#### **CLINICAL RELEVANCE/APPLICATION**

Fully automatic estimation of quantitative pulmonary perfusion from dual-source, dual-energy CTPA can help assess differences in patients CTEPH and PE.

### **S3A-SPCH-6 Application Value of Spectral CT Multi-Parameter Imaging in the Detection of Emboli and Assessment of Thrombus Burden in Acute Pulmonary Embolism**

#### **Participants**

Weimeng Cao, Zheng Zhou, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study aims to investigate the efficacy of spectral CT multi-parameter (Spectral Based Image) imaging compared to regular CT (rCT) imaging in the detection of emboli and assessment of thrombus burden in acute pulmonary embolism (PE).

#### **METHODS AND MATERIALS**

102 suspected pulmonary embolism (PE) patients who underwent dual-layer spectral CT (DLCT) pulmonary angiography (CTPA) were prospectively enrolled. Spectral data were reconstructed into conventional images (CI), iodine density maps (ID), effective atomic number (Zeff) maps, and ID-Zeff fusion maps (ID-Zeff). The detection rate of acute PE in each group was evaluated, and the diagnostic efficiency for PE was assessed using receiver operating characteristic (ROC) curves and area under the curve (AUC) for each type of image. The diagnostic efficiency for PE was evaluated separately in pulmonary lobes and main pulmonary arteries, pulmonary segmental arteries, and subsegmental pulmonary arteries. In diagnosed acute PE patients, the total number of thrombi and the number of thrombi detected in three level of pulmonary artery were counted, and the thrombus burden was compared among groups using the Qanadli (Q) score. Independent sample t-tests and chi-square tests were used for quantitative and qualitative data, respectively.

#### **RESULTS**

Among the 102 suspected PE patients, a total of 63 cases were diagnosed based on imaging, laboratory tests, and clinical data. Among them, the CI, ID, Zeff, and ID-Zeff respectively diagnosed 53, 55, 60, and 60 cases. The ID-Zeff image (AUC: 0.989, sensitivity: 97%, specificity: 100%) significantly improved the detection rate of PE compared to the CI image (AUC: 0.892, sensitivity: 84%, specificity: 94%). The total number of thrombi detected by the CI image and each spectral image group in each three level of pulmonary artery were as follows: CI (172, 25, 75, 72), ID (217, 25, 82, 100), Zeff (222, 25, 85, 112), and ID-Z-eff (230, 25, 85, 120). The Q scores for each spectral image group were as follows: CI (15.64±5.28), ID (19.25±6.42), Zeff (19.87±6.86), and ID-Zeff (20.46±6.6). The Q scores in each spectral image group were statistically significant compared to the CI group ( $p < 0.001$ ).

#### **CONCLUSION**

DLCT multi-parameter ID-Zeff maps exhibit better detection rates and thrombus detecting efficacy in PE compared to CI images, especially in subsegmental PE. Additionally, the ID-Zeff map provides more accurate Q scores.

#### **CLINICAL RELEVANCE/APPLICATION**

ID-Zeff imaging can use the wedge-shaped perfusion defect region to detect subsegmental and micro thrombi, significantly improving the detection efficacy of peripheral micro emboli in PE. This provides more accurate imaging data for the precise assessment of thrombus burden, risk stratification, and prognosis prediction.

## **S3A-SPCH-7 CT-based Automated Measure of Vertebral Fracture Associates with COPD Severity, Sex and Age in Smokers**

### **PURPOSE**

Osteoporosis is a major comorbidity of chronic obstructive pulmonary disease (COPD) contributing to high prevalence of vertebral compression fractures (VCF). Alteration in spine morphology due to VCF reduces rib-cage mobility and chest space, hinders lung expansion and function, and adversely impacts mobility, quality of life, and clinical outcomes. This retrospective study examines the association of VCF with COPD severity, sex, and age using a CT-based automated method.

### **METHODS AND MATERIALS**

Twelve thoracic and the first lumbar vertebrae were automatically segmented and labeled from chest CT scans using a previously validated deep learning-based method. Following the Genant's principle, an automated VCF assessment method was developed and applied to individual vertebral volume. Inspiratory or total lung capacity chest CT scans from the Iowa cohort of the Genetic Epidemiology of COPD (COPDGene) study at baseline visits were used. Four COPD severity groups were defined—(1) preserved lung function (GOLD 0), (2) mild COPD (PRISm and GOLD 1), (3) moderate COPD (GOLD 2), and (4) severe COPD (GOLD 3 and 4). A generalized linear model of the VCF count with age, sex, height, weight, smoking history, and COPD severity was developed.

### **RESULTS**

Study participants (n=1221; age (mean±SD): 59.29±8.98 years; 581 female) in the preserved lung function and mild, moderate, and severe COPD groups had 0.61±1.27, 0.66±1.37, 0.85±1.53, and 1.03±1.75 VCF counts, respectively. As compared to the preserved lung function group, moderate and severe COPD were associated with significantly higher VCF counts (p=0.047 and p=0.00048, respectively), while the observed higher VCF counts in mild COPD were not significant (p=0.084). Females (p<0.0001) were associated with lower VCF counts. Aging was positively correlated with the VCF count (p<0.0001).

### **CONCLUSION**

s A CT-based automated measure of VCF is presented, and its association with COPD severity, sex, and age is demonstrated. Automation of the CT-based method will facilitate its application to nationwide repositories chest CT scans exploring associations of demographic, lifestyle, and clinical factors on osteoporosis and VCF and their impacts in COPD and other lung diseases.

### **CLINICAL RELEVANCE/APPLICATION**

The new method offers CT-based automated quantification of VCF, which may be useful to investigate the osteoporosis comorbidity in COPD and its impact on lung function and clinical outcomes.

## **S3A-SPCH-8 Deep Neural Network to Detect Emphysema on Chest Radiographs.**

Participants  
Sewoo Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

### **PURPOSE**

Chronic obstructive lung disease (COPD) remains underdiagnosed globally, and chest radiographs are typically obtained for patients with respiratory symptoms. This study aimed to develop a deep neural network to detect emphysema on chest radiographs.

### **METHODS AND MATERIALS**

We retrospectively collected chest radiographs and CT scans between 2009 and 2020 from patients with emphysema, as identified in CT reports, at a single tertiary referral center for the model development. The emphysema index was calculated from the CT scans and dichotomized at a cutoff of 10% to determine the presence of CT-defined emphysema. A U-Net-based deep neural network was trained to predict CT-defined emphysema on chest radiographs. Chest radiographs were processed to generate three-channel images, consisting of a native chest radiograph, a segmented lung image, and a pulmonary vessel map. Lung segmentation and pulmonary vessel map extraction guided the model to focus on anatomical structures relevant to emphysema pathophysiology. The diagnostic performance of the model was evaluated using the area under the receiver operating characteristic curve (AUC) in the temporally separated internal test set and two external test sets. The prognostic value of model-defined emphysema on chest radiographs for overall survival was assessed using a Cox proportional hazards model in an independent internal set of patients with COPD.

### **RESULTS**

A total of 2,579 chest radiographs and 11,284 chest computed tomography (CT) scans from 9,192 adult patients were included in the training. The deep neural network achieved AUCs of 0.90, 0.90, and 0.87 in the internal test set (n=184), external test set 1 (n=491) and external test set 2 (n=559), respectively. In an independent internal set (n=4,919), survival analysis demonstrated that the presence of emphysema, as predicted by the deep learning model, was associated with worse overall survival on multivariable analysis (adjusted hazard ratio: 1.3; 95% confidence interval: 1.2-1.5; P < .01).

### **CONCLUSION**

s The deep neural network accurately detected emphysema presence on chest radiographs.

### **CLINICAL RELEVANCE/APPLICATION**

The deep neural network can help overcome the global underdiagnosis of COPD using chest radiographs.

S3A-SPER

### Emergency Radiology Sunday Poster Discussions I

#### Sub-Events

#### S3A-SPER-1 Detection of Pooled Intracavitary Torso Hemorrhage on CT with Deep Learning

##### Participants

Nathan Sarkar, BS, Baltimore, MD (*Presenter*) Nothing to Disclose

##### PURPOSE

Internal hemorrhage caused by traumatic injury is a potentially life-threatening condition requiring rapid treatment. Hemorrhage accounts for 30-40% of all trauma-related deaths, and approximately 50,000 people die from trauma-related hemorrhage in the US annually. WBCT reports are time consuming, and automated algorithms that detect hemorrhage could be used for early notification, however to our knowledge, no such methods have been described. We develop and test DL algorithms for detection of three forms of pooled hemorrhage at CT- hemothorax, hemoperitoneum, and pelvic hematoma.

##### METHODS AND MATERIALS

Three datasets of patients with hemothorax (n=77), hemoperitoneum (n=150), and pelvic hematoma (n=253) served as positive cases for each feature and 373 negative WBCT scans were used as controls in three separate experiments using a ResNeXt-101 architecture with fully connected layer pre-trained on ImageNet. Positive slices were identified using existing label masks. All scans were resampled to a uniform slice thickness of 1.5 mm, and pre-processed using an abdominal/mediastinal window [HU -175, 250]. Data augmentation was performed using rotation, translation, scaling, and shear transformations. 3 consecutive slices were used as input. Training, validation, and testing was conducted using a 70:10:20 split of the data. Models were trained on an NVIDIA Titan RTX graphics card with 24GB memory. Decision thresholds were optimized for high sensitivity for this screening task. If a single slice was determined to be positive for a given feature, the patient was predicted to be positive. Performance was measured using standard accuracy metrics. Grad-CAM saliency maps were used for explainability.

##### RESULTS

Patient level accuracies in the test sets were as follows: 1. For pelvic hematoma (test n=125 CTs), accuracy, precision (PPV), recall (sensitivity), and NPV were 97%, 93%, 100%, and 100%, respectively. 2. For hemoperitoneum (n=105), these were 97%, 97%, 93%, and 97%, and 3. For hemothorax (n=90), these were 99%, 94%, 100%, and 100%. Hemoperitoneum was the only feature with false negatives and both occurred at low segmented volumes (18 and 23 mL). Saliency maps showed that attention corresponded with areas of pooled blood.

##### CONCLUSION

Our models were highly accurate and could be used to accelerate the activation of life-saving treatment protocols in patients at risk for exsanguination.

##### CLINICAL RELEVANCE/APPLICATION

In future work, these classification algorithms can be scaled to larger datasets and included in a pipeline with segmentation algorithms to serve combined early notification (CADt) and precision medicine (CADx) purposes, thus reducing time to diagnosis and assisting with surgical decision-making in positive patients.

S3A-SPGI

### Gastrointestinal Imaging Sunday Poster Discussions I

#### Sub-Events

#### S3A-SPGI-1 Predictive Value of a Radiomics Nomogram Model Based on Contrast-enhanced Computed Tomography for KIT Exon 9 Gene Mutation in Gastrointestinal Stromal Tumors

##### PURPOSE

To establish and validate a radiomics nomogram model for predicting the KIT exon 9 mutation status of gastrointestinal stromal tumors (GISTs) before surgery.

##### METHODS AND MATERIALS

All imaging and clinicopathological data of 87 patients diagnosed with pathologically confirmed GISTs were retrospectively collected and randomly assigned to the training set ( $n = 60$ ) and test set ( $n = 27$ ) at a ratio of 7:3. Based on contrast-enhanced CT (CE-CT) arterial and venous period images, the region of interest (ROI) of the tumors were manually drawn layer by layer, and the radiomics features were extracted. The ICC (intra-class correlation coefficient) was used to test the consistency between observers and least absolute shrinkage and selection operator regression (LASSO) was used to further screen the features. The nomogram of integrated radiomics score (Rad-Score) and clinical risk factors (extra-gastric location and distant metastasis) was drawn on the basis of multivariate logistic regression. The area under the receiver operating characteristic curve (AUC) and the correction curve were used to evaluate the predictive efficiency of the nomogram, and the clinical benefits that the decision curve evaluation model might bring to patients.

##### RESULTS

The AUC, sensitivity, specificity, and accuracy in the nomogram model were 0.902 (95% confidence interval [CI]: 0.798-0.964), 85.7%, 86.9%, and 91.7% for the training group, and 0.907 (95% CI: 0.732-0.984), 77.8%, 94.4%, and 88.9% for the test group.

##### CONCLUSION

The radiomics nomogram model based on CE-CT can effectively predict the KIT exon 9 mutation status of GISTs and may be used for selective gene analysis in the future, which is of great significance for the accurate treatment of GISTs.

##### CLINICAL RELEVANCE/APPLICATION

Our models show that radiomics has great potential for predicting GIST gene mutations, which may enable clinicians to optimize clinical decisions in patients with GIST.

#### S3A-SPGI-2 The Artificial Intelligence Iterative Reconstruction Improves the Contrast Resolution in CT Imaging of Gastric Tumor

##### Participants

Jiaqi Chen, Zhengzhou, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To quantify the improvement on contrast resolution of the tumor infiltration on gastric wall with an artificial intelligence iterative reconstruction (AIIR) algorithm in CT imaging of gastric cancer.

##### METHODS AND MATERIALS

The contrast-enhanced CT data of 48 patients who were diagnosed with gastric cancer was retrospectively collected. The AIIR was performed in addition to the original hybrid iterative reconstruction (HIR). Contrast-to-noise ratio (CNR) was calculated for the tumor using the normal gastric wall as background. The contrast resolution between the normal gastric wall and the tumor was subjectively assessed with 5-point Likert scoring method by two radiologists (1: poor; 5: excellent). Additionally, the differentiation of layers of gastric wall was scored, where score 5 is the clear visualization and differentiation, and score 1 is non-distinguishable.

##### RESULTS

AIIR images have significantly higher CNR than HIR images ( $5.55 \pm 0.91$  vs.  $1.65 \pm 2.31$ ,  $p < 0.001$ ). Superior contrast resolution was observed on AIIR images comparing with HIR images ( $4.78 \pm 0.42$  vs.  $3.97 \pm 0.65$ ,  $p < 0.001$ ). AIIR images exhibited excellent differentiation of layers of gastric wall than HIR images ( $4.44 \pm 0.55$  vs.  $3.51 \pm 0.56$ ,  $p < 0.001$ ).

##### CONCLUSION

The AIIR provides better contrast resolution of the tumor and differentiation of layers of gastric wall in CT imaging.

##### CLINICAL RELEVANCE/APPLICATION

The artificial intelligence reconstruction algorithm has the potential in improving the accuracy of staging and prognosis for patients with gastric cancer.

### **S3A-SPGI-3 Identification of Macrotrabecular-massive Hepatocellular Carcinoma (MTM-HCC) using Gadoteric Acid-enhanced MRI and User-friendly Radiomics Analysis Suite**

Participants

Jongjin Yoon, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Radiomics analysis is often challenging for radiologists due to time-consuming pre-processing, tumor segmentation, and complex analysis. The purpose of this study was to attempt to develop a radiomics model for identifying macrotrabecular-massive HCCs (MTM-HCCs) using radiomics analysis suite that provides semi-automatic segmentation and user-friendly analysis tools, and to compare the model's performance to that of conventional radiomics analysis.

#### **METHODS AND MATERIALS**

We enrolled 3 independent cohorts from 2 tertiary care centers. The 3 cohorts consisted of a total of 464 patients who underwent gadoteric acid-enhanced MRI and surgical resection for treatment-naïve single HCCs between December 2007 and December 2014. Independent review of histopathology by two pathologists was performed for each cohort. The arterial phase images were semi-automatically segmented by reviewer 1 (faculty radiologist) in training set, and by reviewer 1, reviewer 2 (resident radiologist), and reviewer 3 (research assistant) in validation cohorts. Inter-observer agreement was evaluated using intraclass correlation coefficient (ICC). A commercial radiomics suite (syngo.via, Siemens Healthineers) was used to calculate and analyze 1,234 radiomics features. Additionally, the same radiomics features were analyzed using conventional radiomics analysis method. Area under a receiver operating characteristic curve (AUROC) was the performance metric.

#### **RESULTS**

ICC values in internal and external validation sets mostly exhibited excellent agreement. The training cohort AUROC for the radiomics suite random forest model was 0.72 for reviewer 1. The internal validation cohort AUROC values were 0.63, 0.71, and 0.73, while external validation set values were 0.72, 0.75, and 0.73 for reviewer 1, 2, and 3, respectively. The radiomics suite model demonstrated comparable or superior AUROC values compared to conventional techniques. In the pooled internal and external validation cohort (n=250), the predicted MTM-HCC by radiomics suite was significantly associated with frequent early recurrence and extrahepatic metastasis, and poor overall survival for all reviewers (P<0.05 for all)

#### **CONCLUSION**

s We developed radiomics models to classify histopathologic subtypes of HCCs using a user-friendly radiomics suite. The models' diagnostic performance was comparable to conventional methods and consistent across varying user experience levels. The model showed potential in predicting prognostic factors in a pooled validation cohort.

#### **CLINICAL RELEVANCE/APPLICATION**

This simple, user-friendly approach of developing radiomics models is expected to make radiomics more accessible to radiologists and facilitate real-world application.

### **S3A-SPGI-4 Preoperatively and Non-Invasively Predict the Malignancy of Rectal Cancer with Diffusion Weighted Imaging and Machine Learning**

Participants

Hui Liu, Shijiazhuang, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study aims to integrate different biological insights obtained from various DWI techniques, including cellular density, vascularity, and structural heterogeneity, with multiple machine learning classifiers to preoperatively grade rectal cancer.

#### **METHODS AND MATERIALS**

In this prospective study, 85 patients were enrolled, and DWI examinations were performed on a 3.0 T scanner. The DWI protocol included b values of 0, 20, 50, 80, 100, 200, 400, 600, 800, 1500, and 2000 s/mm<sup>2</sup>. Different DWI parameters, such as ADC, D, Dp, f, Dapp, and Kapp, were calculated to quantify the biological insights. Four machine learning classifiers, namely logistic regression, Random Forest, Support Vector Machine, and K nearest neighbor, were constructed using the metrics. Predictive power was evaluated using ROC analysis with 5-fold cross-validation.

#### **RESULTS**

The different DWI-derived biological inspirations were significantly correlated with each other (p < 0.05), indicating a close association between changes in cellularity, vascularity, and structural heterogeneity during the metastasis of rectal cancer. The study highlights the importance of integrating multiple DWI-derived biological inspirations for comprehensive characterization of rectal cancer. The machine learning classifiers constructed using different DWI-derived parameters, representing cellular density (ADC, D, Dapp), vascularity (f), and structural heterogeneity (Kapp), demonstrated excellent predictive power for grading rectal cancer (AUCs: 0.811 (SVM), 0.807 (RF), 0.902 (LG), 0.819 (KNN)).

#### **CONCLUSION**

s Integrating different DWI-derived biological insights using machine learning classifiers holds great potential for noninvasive and accurate grading of rectal cancer.

#### **CLINICAL RELEVANCE/APPLICATION**

Integrating different DWI-derived biological insights can comprehensively characterize tumors from different perspectives, which could aid in the diagnosis and evaluation of therapeutic efficacy.

### **S3A-SPGI-5 Deep Learning of Two- Dimensional Shear Wave Elastography for Assessment of Clinically Significant Portal Hypertension**

Participants

## **PURPOSE**

We aimed to make a deep-learning model of 2D-shear wave elastography (SWE) images to detect clinically significant portal hypertension (CSPH) [DL-CSPH] using long short-term memory (LSTM) architecture, and to compare the diagnostic performance with conventional diagnostic method.

## **METHODS AND MATERIALS**

A retrospective study was conducted using 2D-SWE image data collected in a single center, and the subject were divided into training (n=168) and test (n=113) sets. CSPH was diagnosed by hepatic venous pressure gradient measurement. With the training set, the DL-CSPH model using convolution neural network (CNN) and long short-term memory (LSTM) architecture of the 2D-SWE measurement image was derived. Especially, sequential order of liver stiffness (LS) measurement was applied into the LSTM model and compared with the LSTM model with random selection. As a conventional diagnostic method, the cut-off value of LS was calculated via a receiver operating curve analysis in the training set and applied the cut-off value in the test set.

## **RESULTS**

In the prediction of CSPH using the deep-learning model, the LSTM model with sequential order showed better performance than the CNN model (sensitivity: 94.3% VS 85.7%, specificity: 86.1% VS 79.1%, accuracy: 91.2% VS 83.2%, AUC: 0.824 VS 0.902). The difference in AUC value was statistically significant. (P=0.03) Although the DL-CSPH model in sequential order performed better in predicting CSPH compared to the LS or APRI cutoff values, this difference was not statistically significant (P=0.53, 0.19, respectively). However, the DL-CSPH model in sequential order exhibited a significant improvement over FIB4 in predicting CSPH (P=0.01).

## **CONCLUSION**

s DL-CSPH model in sequential order demonstrates excellent overall performance in predicting CSPH.

## **CLINICAL RELEVANCE/APPLICATION**

The DL-CSPH model has practical value as it enables non-invasive, automated monitoring of portal pressure in patients with chronic liver disease in a robust and reproducible manner.

### **S3A-SPGI-6 Identification of a Radiomic Signature to Predict the Risk of Hepatocellular Carcinoma in Cirrhotic Patients**

#### **Participants**

Olimpia Bazzini, Parma, Italy (*Presenter*) Nothing to Disclose

## **PURPOSE**

Patients with cirrhosis are at increased risk of Hepatocellular Carcinoma (HCC); currently, clinical and radiological scores for an accurate early prediction of the development of HCC are lacking. The study aims to assess if radiomics can assist in accurately identifying cirrhotic patients at risk of HCC.

## **METHODS AND MATERIALS**

98 patients (M:F=64:34; mean age 67 years  $\pm$ 9,81) were included in this retrospective monocentric study. Two groups were identified: group (a) with 49 patients (M:F=31:18; mean age 67,4 years  $\pm$ 9,12) who had a baseline CT with radiological signs of cirrhosis, without evidence of HCC in follow-up CT (LI-RADS 1-3); group (b) with 49 patients (M:F=33:16; mean age 67,5 years  $\pm$ 10,5) who had a baseline CT with radiological signs of cirrhosis and evidence of HCC in one follow-up CT scan (LI-RADS 4/5). Four radiologists (3 years of experience) provided complete liver segmentations, manually drawing volumes of interest (VOI) on non-enhanced baseline CT scans. 851 radiomic features (RF) were extracted from each VOI. Redundant RF (Spearman correlation coefficient = 0.99) were removed. The dataset was split into train:test set (70%:30%). Decision Tree classification algorithm and a 3-fold cross-validation were performed on train dataset to explore different cost complexity parameters to set the best pruning. The final model was validated on the test set in terms of accuracy, sensibility, sensitivity, precision, areas under the receiver operating characteristic (ROC) curve and under the precision-recall curve (PRC).

## **RESULTS**

The tree-based model included the "wavelet-LLH\_glcM\_DifferenceAverage" RF, classifying patients as positive when higher than 0.97. The final model predicted the risk of developing HCC with an accuracy, sensitivity, specificity and precision of 0.73, 0.93, 0.56, and 0.65, respectively. Areas under ROC curve and PRC were 0.74 and 0.81.

## **CONCLUSION**

s A radiomic model identified a RF for stratification of cirrhotic patients at risk of developing HCC, showing high sensitivity. To increase the specificity of the model, we aim to integrate this radiomic approach with clinical and radiological parameters.

## **CLINICAL RELEVANCE/APPLICATION**

Radiomics can non-invasively predict the development of HCC in cirrhotic patients and may assist clinicians in creating a tailored monitoring path for each patient.

### **S3A-SPGI-7 Added Value of Diffusion-weighted MR Imaging in the Diagnosis of Cholangiocarcinoma Recurrence**

## **PURPOSE**

To evaluate the added value of magnetic resonance (MR) imaging including diffusion-weighted imaging (DWI) in the diagnostic performance of contrast-enhanced computed tomography (CECT) for diagnosis of cholangiocarcinoma recurrence.

## **METHODS AND MATERIALS**

Thirty-three consecutive patients who underwent follow-up CECT and MR imaging after cholangiocarcinoma resection were included: 20 with recurrence and 13 without recurrence. Two observers independently reviewed CECT and subsequently reviewed

combined CECT and MR imaging including DWI (b value, 1000 s/mm<sup>2</sup>). A five-point scale rating for the likelihood of cholangiocarcinoma recurrence was assessed. Both observers reviewed each image set twice. Diagnostic performance (receiver operating characteristic [ROC] curve analysis), accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were evaluated. To evaluate the intra-observer and inter-observer agreement with regard to the correct diagnosis of recurrence, kappa statistics were used.

## RESULTS

For both observers, diagnostic performance (area under curve [AUC] of ROC) improved after additional review of MR imaging including DWI; AUC improved from 0.614 to 0.918 ( $P < 0.01$ ) in the first reading session of Observer A, and from 0.820 to 0.928 ( $P = 0.20$ ) in the second reading session of Observer A, from 0.566 to 0.858 ( $P < 0.01$ ) in the first reading session of Observer B, from 0.753 to 0.930 ( $P < 0.01$ ) in the second reading session of Observer B. Diagnostic accuracy, sensitivity, specificity, PPV, and NPV were higher than CECT alone in the first reading session of Observer A and both reading sessions of Observer B. Intra-observer agreement of confidence levels improved after the addition of MR imaging: kappa value improved from 0.423 to 0.636 for Observer A, from 0.199 to 0.479 for Observer B. Inter-observer agreement of confidence levels also improved after the addition of MR images: kappa value improved from 0.093 to 0.230 for the first reading session, from 0.140 to 0.460 for the second reading session.

## CONCLUSION

The addition of MR imaging including DWI to CECT, improves the detection of cholangiocarcinoma recurrence when compared with CECT alone.

## CLINICAL RELEVANCE/APPLICATION

The addition of MR imaging including DWI to CECT, helps to detect early-stage resectable recurrence lesions of cholangiocarcinoma.

## S3A-SPGI-8 To Predict Hepatic Decompensation Status using Computed Tomography-Based Radiomics Signature with the Body Composition Model

Participants

Yashbir Singh, PhD, MEng, Rochester, MN (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study was to investigate the potential value of computational radiomics in predicting hepatic decompensation using body-composition model in the patients with Primary Sclerosing Cholangitis (PSC), a chronic cholestatic liver disease that can lead to hepatic decompensation.

## METHODS AND MATERIALS

A total of 220 patients diagnosed with PSC and with an available abdomen CT acquired during the portal venous phase were included in the study. We used an in-house developed U-Net model that assesses body composition using the subcutaneous adipose tissue (SAT), skeletal muscle (SKM), visceral adipose tissue (VAT), and intermuscular adipose tissue (IMAT). The PyRadiomics library was used to extract radiomic features on the region of interest (ROI) created by the body composition model. Out of 100 radiomics features, 23 features were identified to be significant using statistical analysis (t-test). We aimed to develop a classification model using radiomics features based on a traditional machine learning approach (random forest classification).

## RESULTS

The machine learning model achieved a prediction accuracy of 97% in the validation set, which was evaluated in terms of the AUC. This study is a first step in this proof-of-concept application of combining Radiomics Signature and the Body Composition Model with imaging data and the model was designed to predict short-term outcomes.

## CONCLUSION

The study revealed the potential for prognostic features for hepatic decompensation patients in PSC and provided hidden information that may help in discovering new differentiating imaging features. This methodological approach may also have the potential for detecting other PSC-related complications such as cholangiocarcinoma and applications in other chronic liver diseases such as non-alcoholic fatty liver disease.

## CLINICAL RELEVANCE/APPLICATION

The use of radiomics with Body composition model in predicting hepatic decompensation in PSC patients may aid in early detection and intervention. The approach may also be useful in detecting other complications associated with PSC and other chronic liver diseases, thereby contributing to better clinical management and improved patient outcomes.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

S3A-SPGU

### Genitourinary Imaging Sunday Poster Discussions I

#### Sub-Events

#### S3A-SPGU-1 Prediction of Bladder Cancer Based on Biparametric MRI Radiomics: Comparison with Traditional MRI

##### PURPOSE

To compare biparametric (bp) MRI radiomics signatures and traditional MRI model for the preoperative prediction of bladder cancer (BCa) grade.

##### METHODS AND MATERIALS

This retrospective study included 255 consecutive patients with pathologically confirmed 113 low-grade and 142 high-grade BCa who underwent preoperative MRI, including T2-weighted imaging (T2WI) and apparent diffusion coefficient (ADC). The traditional MRI nomogram model was developed using univariate and multivariate logistic regression by the mean apparent diffusion coefficient (mADC), vesical imaging reporting and data system (VI-RADS) scoring, tumor size and number of tumors. Volumes of interest were manually drawn on T2WI and ADC maps by two radiologists. Using ANOVA, correlation and LASSO methods to select features. Then, a logistic regression (LR) classifier was used to develop the radiomics signatures in the training set and assessed in the validation set. Receiver operating characteristic (ROC) analysis was used to compare the diagnostic abilities of the radiomics and traditional MRI models by the DeLong test. Finally, decision curve analysis (DCA) was performed by estimating the clinical usefulness of the two models in both the training and validation sets.

##### RESULTS

The areas under the ROC curves (AUCs) of the traditional MRI model were 0.841 in the training cohort and 0.806 in the validation cohort. The AUCs of the three groups of radiomics model [ADC, T2WI, bp-MRI (ADC and T2WI)]-based logistic regression analysis algorithms were 0.888, 0.875 and 0.899 in the training cohort and 0.863, 0.805 and 0.867 in the validation cohort, respectively. The combined radiomics model achieved higher AUCs than the traditional MRI model and was compared using the DeLong test ( $P = 0.026$  and  $0.023$  in the training and validation cohorts, respectively). DCA indicated that the radiomics model had higher net benefits than the traditional MRI model.

##### CONCLUSION

The bp-MRI radiomics model may be helpful for distinguishing high-grade and low-grade BCa and outperformed the traditional MRI model. Multicenter validation is needed to acquire high-level evidence for its clinical application.

##### CLINICAL RELEVANCE/APPLICATION

Our study shows that the bp-MRI radiomics model presented superior diagnostic performance to the traditional MRI model. This may assist doctors in obtaining the preoperative histological grading of the tumor, which is convenient for determining the treatment strategy for BCa.

#### S3A-SPGU-2 Comparison of Single-shot EPI, Multi-shot EPI, and Reduced Field-of-view in Bladder DWI at 3.0 T

##### Participants

Kentaro Ono, Kurashiki, Japan (*Presenter*) Nothing to Disclose

Tsutomu Tamada, MD, PhD, Kurashiki, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

To compare the image quality of single-shot echo-planar diffusion-weighted imaging (SS-EPI DWI), multi-shot EPI DWI (MS-EPI DWI), and reduced field-of-view DWI (rFOV DWI) in bladder cancer and their diagnostic ability for muscle invasion.

##### METHODS AND MATERIALS

Seventy-three patients who had a multiparametric MRI including SS-EPI DWI, MS-EPI DWI, and rFOV DWI as a preoperative examination for bladder cancer between August 2020 and February 2023 were included in the study. Qualitative image quality was evaluated by three radiologists. Regarding the SS-EPI DWI, MS-EPI DWI, and rFOV DWI, the three items of distortion, wall clarity, and lesion conspicuity were graded in four stages: 1: poor, 2: fair, 3: good, and 4: excellent. Quantitative image quality assessment was performed by a radiologist. The signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and signal intensity ratio (SIR) were used as measures of quantitative evaluation. The control was set to the iliopsoas muscle. Three radiologists assessed the presence of muscle invasion of bladder cancer using Vesical Imaging-Reporting and Data System. Clinical information and pathology results were not known to the readers. The Wilcoxon matched pairs signed ranks test was used to compare qualitative and quantitative scores. The McNemar test and ROC analysis were used to compare diagnostic performance. A  $p$ -value  $< 0.05$  was considered significant.

##### RESULTS

The qualitative scores for distortion were MS-EPI DWI (2.95 to 3.42), rFOV DWI (2.74 to 3.18), and SS-EPI DWI (2.33 to 3.00) in descending order, with significant differences for all combinations. The wall clarity scores were MS-EPI DWI (3.00 to 3.34), SS-EPI

DWI (2.86 to 3.16), and rFOV DWI (2.44 to 2.86) in descending order, and the three readers were in agreement, with significant differences between rFOV DWI and the other two types of DWI. Quantitative evaluation showed no significant difference in SNR and CNR between each test. SIR was higher for MS-EPI DWI (average, 10.5; SD, 4.4), rFOV DWI (average, 6.5; SD, 2.1), and SS-EPI DWI (average, 5.6; SD, 1.5), in that order, with significant differences between each DWI. The diagnostic performance of muscle invasion was good for all DWIs. AUC values were 0.83 to 0.88 for SS-EPI DWI, 0.85 to 0.90 for MS-EPI DWI, and 0.83 to 0.93 for rFOV DWI. There was no significant difference between sequences.

#### **CONCLUSION**

s MS-EPI DWI and rFOV DWI reduced image distortion and MS-EPI DWI improved bladder wall visibility compared to SS-EPI DWI, but did not contribute to improve diagnostic performance of muscle layer invasion.

#### **CLINICAL RELEVANCE/APPLICATION**

If distortion or bladder wall obscuration is seen on SS-EPI DWI during examination, additional MS-EPI DWI can improve image quality.

## Abstract Archives of the RSNA, 2023

S3A-SPHN

### Head & Neck Imaging Sunday Poster Discussions I

#### Sub-Events

#### **S3A-SPHN-1 Osteogenesis Imperfecta: Implications of Using Micro-CT for Visualizing Developmental Variation in the Middle and Inner Ear of OIM Mice**

##### **PURPOSE**

The purpose of our research is to visualize and document anatomic variation in the ears of mice bred to have the Type III OI genetic variant in order to better understand the cause of OI-related hearing loss.

##### **METHODS AND MATERIALS**

3D models of the middle and inner ears were created from micro-CT scans that also employed two new contrast-enhanced methods to visualize the cochlea and middle ear (malleus, incus, and stapes). All CT scanning were done using the new Small Animal Imaging Facility (SAIF). The scan resolution was approximately 20 $\mu$ m. The studied WT and OIM mouse samples include three time points intended to capture a developmental sequence: 0-day-old (WT=20, OIM=29), 7-day-old (WT=23, OIM=23), and 14-day-old mice (WT=22, OIM=18). The visualization software Avizo was then used to digitally segment the bone of the inner ear and middle ear.

##### **RESULTS**

In OIM inner ears, the surrounding otic capsule tended to be more demineralized, exhibiting lower threshold values than WT. This contrasts with WT specimens, where the ossified bone was more distinct from the hollow space of the inner ear. Intrusions in the vestibule were observed in both the 2D slices and the reconstructed 3D models of the OIM inner ears. Comparison of volumes for the right OI and WT inner ears and left OI and WT inner ears indicated statistically significant differences between the genotypes.?

##### **CONCLUSION**

Bony intrusions observed in the vestibules of OIM mice may negatively affect fluid movement within the semicircular canals and vestibule (utricle and saccule), possibly altering the balancing and body positioning abilities of OI mice. This is ongoing research employing additional contrast enhanced CT (CE-CT) methods to visualize not only the bony labyrinths, but also soft tissue, including muscle and cartilage. In addition, more age-points are currently being collected with the aim of elucidating the pathogenesis of osteogenesis imperfecta during different stages of ear development.

##### **CLINICAL RELEVANCE/APPLICATION**

This research uses micro-CT imaging designed to capture a developmental sequence, giving us the potential to elucidate how and when the bony intrusions are impacting surrounding structures. Insight into this anatomical damage may help disambiguate the OI-related pathology, including the distinction between sensorineural vs. mixed hearing loss, unilateral vs. bilateral pathology, and the asymmetric nature of the disease in the ear. Upon completion, this research will demonstrate the efficacy of using these new imaging approaches for studying minute structures of the ear and may markedly advance our understanding of the pathogenesis of OI-related hearing loss.

#### **S3A-SPHN-2 Magnetic Resonance Neurography of Peripheral Trigeminal Nerves: Correlation of Sunderland Class of Nerve Injury on Imaging versus Clinical Neurosensory Testing and its Diagnostic Efficacy**

##### Participants

Shuda Xia, Plano, TX (*Presenter*) Nothing to Disclose

##### **PURPOSE**

Iatrogenic or traumatic injuries to the peripheral trigeminal nerve (PTN) can cause loss of sensation and neuropathic pain in the face and oral cavity. Clinical neurosensory testing (NST) is currently the reference standard for diagnosis but is less reliable within the first 3 months following injury and cannot precisely identify the location of the nerve injury. MR neurography (MRN) has been studied for PTN injury diagnosis but with small sample sizes. The aim of this cross-sectional study was to evaluate the correlation between Sunderland class of nerve injury on MRN and NST and obtain diagnostic efficacy with surgical findings as reference standard.

##### **METHODS AND MATERIALS**

An Institutional Review Board approved this retrospective cross-sectional study of adult patients of all genders with suspected injury of PTN who had both clinical NST by an experienced oral maxillofacial surgeon and MRN interpreted by an expert radiologist. A total of 297 patient records with a chief complaint of PTN neuralgia were identified from the university database. All patient charts were reviewed to identify Sunderland injury class on NST and MRN, previous surgeries, whether surgery was performed after the MRN, and surgical outcomes. Of the cohort, 87 patients had both NST injury grade and Sunderland class injury in their records, and 45 of these patients had surgery. Pearson correlation was obtained and the accuracy of NST and MRI was obtained with surgical and histopathology findings as reference standards. Cohen's weighted Kappa was also calculated.

##### **RESULTS**

There were 20 men and 67 women with an age range of 15 to 81 years. Most (69/87, 79%) injuries resulted from tooth extractions

and implants. On MRN, there were no class I injuries, 26 class II injuries, 26 class III injuries, 26 class IV injuries, and 9 class V injuries. There was a very strong positive correlation between injury grade on MRN and the NST injury class ( $p < .001$ ). There were substantial agreements between NST, MRN, and surgical findings.

## CONCLUSION

The results of this study confirm that MRN adequately provides the injury grade better than NST with improved diagnostic accuracy.

## CLINICAL RELEVANCE/APPLICATION

Prompt non-invasive and accurate diagnostic evaluation of suspected PTN injury is critical for successful management. MRN provides the needed pre-operative information on injury grade and its anatomic localization.

## S3A-SPHN-3 Relationship Between MRI and Clinical Findings of Anatomic Risk Factors in Adult Patients Affected by Obstructive Sleep Apnea/hypopnea Syndrome (OSAHS)

Participants

Maria Paola Belfiore, Naples, Italy (*Presenter*) Nothing to Disclose

## PURPOSE

Identify specific anatomical abnormalities associated with Obstructive Sleep Apnea/hypopnea syndrome (OSAHS), and establish a correlation between the pathological condition and the anatomical changes and enhance treatment planning for future management

## METHODS AND MATERIALS

This case-control study conducted in 2022 investigated the potential of MRI in identifying the causes of upper airway obstruction in OSAHS patients. The study included 30 participants diagnosed with OSAHS and 16 healthy subjects enrolled as a control group, matched for gender, age, height, and weight. All participants underwent MRI examination of the cervical maxillofacial district in the bore of the same 1.5 T magnet. MRI exams revealed significant differences in the upper airway volume, midsagittal nasopharyngeal antero-posterior distance, axial CSA of the nasopharyngeal airway, midsagittal tongue area, soft palatal length, midsagittal soft palatal area, and axial volume of the right and left parapharyngeal adipose tissue in patients with OSAHS compared to controls. Furthermore, the study analyzed the correlation between cephalometric and anatomical measurements and OSAHS severity.

## RESULTS

The results showed a significant association between the severity of OSAHS and soft palate length, soft palate area, Hyoid-Sella distance, and Hyoid-Nasion distance. Soft palate length was closely associated with Hyoid-Sella distance, Hyoid-Nasion distance, and tongue area. The study also evaluated the facial skeletal structure, showing significant differences in intermandibular distance, mandibular depth, and the position of both the maxilla and mandible between the two groups.

## CONCLUSION

Multiple soft tissue and skeletal structures surrounding the upper airways may contribute to the symptoms and clinical severity of OSAHS; in some cases, they may even play a dominant role. MRI has enormous potential in evaluating the three compartments of obstruction: air lumen, soft tissues, and facial skeleton.

## CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of MRI in identifying the causes of upper airway obstruction in adult OSAHS patients. While polysomnography remains the gold standard for OSAHS diagnosis, MRI can offer a valuable alternative method for evaluating the craniomaxillofacial morpho-volumetric characteristics contributing to airway size reduction. This information can assist in determining the most appropriate therapeutic approach and surgical intervention, ultimately improving OSAHS patient outcomes.

## S3A-SPHN-4 Cochlea-carotid Dehiscence: An Underappreciated Condition

## PURPOSE

Cochlea-carotid artery dehiscence (CCD) is the erosion of the bony plate between the cochlea and the petrous segment of the internal carotid artery. In one study of 1,000 temporal bones, there is a histologic prevalence of cochlea-carotid artery dehiscence of 7.7%. It has been reported to be associated with pulsatile tinnitus, conductive hearing loss, sensorineural hearing loss, vertigo, and other otologic disorders. However, the clinical significance of cochlea-carotid artery dehiscence is unknown. Other than a small number of case reports, no large-scale study investigates the radiographic prevalence of CCD and its clinical significance. This study hopes to highlight its clinical significance by retrospectively reviewing a large volume of temporal bone computed tomography (CT) exams and patients' symptoms.

## METHODS AND MATERIALS

This retrospective single-center cross-sectional study was conducted after the institution's IRB approved the study. Consecutive 1,000 patients (2,000 ears) who underwent CT temporal bones were reviewed. CT images were obtained with 0.625 mm thick and 0.3 mm reconstruction interval. First, a radiology resident reviewed all exams for possible CCD. Then, selected cases were reviewed by two board-certified neuroradiologists independently. The discrepancy was resolved by consensus. Possible CCD ears were divided into three categories: 1) dehiscence, 2) thinning/possible dehiscence, and 3) no dehiscence. The location of the dehiscence or thinning/possible dehiscence was recorded. The results were correlated with clinical findings. Duplicated exams and age less than 18 years old were excluded.

## RESULTS

Thirteen temporal bones with CCD were identified in twelve patients, including one patient with bilateral CCD (8 men, 4 women, age: 36-78). The basal turn was affected in eleven ears, and the apical turn was affected in two ears. One patient had progressive sensorineural hearing loss of high frequency of the affected ear. Another patient had bilateral hearing loss, more profound in the affected ear, with episodic dizziness. One patient had no documented otological finding in the chart. Other patients did not have symptoms that might be associated with CCD.

## CONCLUSION

s CCD is a rare condition, as reported in the literature. Its clinical significance is still unknown, although pulsatile tinnitus, conductive hearing loss, sensorineural hearing loss, vertigo, and other otologic disorders have been reported in the literature.

#### **CLINICAL RELEVANCE/APPLICATION**

CCD is a rare condition as reported in the literature. Its clinical significance is still unknown, although pulsatile tinnitus, conductive hearing loss, sensorineural hearing loss, vertigo, and other otologic disorders have been reported.

### **S3A-SPHN-5 Combining Virtual Monoenergetic Imaging and Iterative Metal Artifact Reduction in Photon-counting CT of Patients with Dental Implants**

Participants

Theresa Sophie Patzer, MD, 97080 Würzburg, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Virtual monoenergetic imaging (VMI) and iterative metal artifact reduction (MAR) are established techniques in energy-integrating detector (EID) CT. The artifact suppressing effect of both approaches is not thoroughly investigated in photon-counting detector (PCD) CT. This study aims to evaluate the potential of VMI, MAR, and combinations thereof in PCD-CT for metal artifact reduction in patients with dental implants.

#### **METHODS AND MATERIALS**

In 50 patients with dental implants (25 women; mean age  $62 \pm 9.92$  years), conventional 120 kVp imaging (T3D), VMI, T3DMAR and VMIMAR were compared. VMI datasets were reconstructed at 40, 70, 110, 150 and 190 keV. Objective image quality was assessed by ROI-based measurements of attenuation and respective standard deviations in the most hyper- and hypodense artifacts, as well as in artifact-impaired soft tissue of the mouth floor. Three readers evaluated artifact extent and soft tissue interpretability separately on a five-point scale. The introduction of new artifacts and/or overcorrection of pre-existing artifacts was assessed subjectively.

#### **RESULTS**

MAR substantially reduced hyperdense and hypodense artifacts (T3D 1305.0/-1418.4 HU; T3DMAR 103.2/-46.9 HU), soft tissue impairment (T3D 106.7 HU; T3DMAR 39.7 HU) and image noise (T3D 16.9 HU; T3DMAR 5.2 HU) compared to non-MAR datasets (all  $p=0.001$ ). While VMIMAR =150 keV did not enhance artifact reduction over T3DMAR objectively (all  $p=0.081$ ), VMIMAR =110 keV received superior subjective ratings (all  $p=0.023$ ). Without MAR, VMI displayed no measurable artifact extent reduction (all  $p=0.186$ ). However, VMI =110 keV reduced soft tissue impairment over T3D (all  $p=0.009$ ). VMI facilitated no significant denoising over T3D with or without MAR (all  $p=0.366$ ). VMIMAR =110 keV resulted in less overcorrection than T3DMAR (all  $p=0.001$ ).

#### **CONCLUSION**

While VMI alone presented only minimal metal artifact reduction potential, post-processing using MAR enabled a substantial reduction of hyperdense and hypodense artifacts. The combination of both provided a considerable benefit in subjective artifact reduction compared to MAR alone.

#### **CLINICAL RELEVANCE/APPLICATION**

Combining iterative MAR with VMI represents a potent tool for maxillofacial PCD-CT with dental implants achieving substantial artifact reduction. Thus, these approaches allow for improved image quality, improving delicate detection and evaluation of oral pathologies.

### **S3A-SPHN-6 Comparison of a 3D-real IR with a Ultralong TR and a 3D-FLAIR in the Evaluation of Endolymphatic Hydrops**

#### **PURPOSE**

To evaluate an optimized 3D-real IR sequence with a longer TR (16000 ms) based on the modulated flip angle technique in refocused imaging with extended echo train (MATRIX) for the endolymphatic hydrops (EH) after intravenous (IV) single-dose gadolinium (Gd) administration, and compare it with a heavily T2-weighted 3D-FLAIR sequence with a constant flip angle.

#### **METHODS AND MATERIALS**

The 3D-FLAIR and 3D-real IR sequences were performed in forty patients with definite Meniere's disease (MD) four hours after IV Gd administration. Image qualities of the two sequences were rated and compared. Contrast-to-noise ratios (CNRs) and signal-to-noise ratios (SNRs) of the two sequences were measured for quantitative comparison. EH was graded on the images of the two sequences by two radiologists.

#### **RESULTS**

Scores and CNRs of the 3D-real IR were significantly higher than those of the 3D-FLAIR ( $P < 0.05$ ). SNRs of the two sequences were comparable between the two groups. 3D-real IR had a higher inter- and intra-observer reliability for the grading of cochlear and vestibular EH than 3D-FLAIR. Using 3D-real IR sequence, the detection rate of EH of the whole labyrinth was higher than using 3D-FLAIR (86.6% vs. 73.3%,  $p = 0.031$ ). In the patients with unilateral MD, SNRs in the affected sides were significantly higher than the unaffected sides ( $P < 0.05$ ).

#### **CONCLUSION**

Compared with the 3D-FLAIR sequence, the optimized 3D-real IR with a longer TR may be better with an improved depiction of EH after IV administration of single-dose Gd.

#### **CLINICAL RELEVANCE/APPLICATION**

The optimized 3D-real IR after IV single-dose Gd administration allows better depiction of EH in the labyrinth with improved image quality, excellent inter- and intra-observer agreement, and higher detection rate.

### **S3A-SPHN-7 Application of parotid gland ASL and T2 mapping MRI in Sjögren's syndrome**

## **PURPOSE**

This study aims to explore the application value of ASL and T2 mapping techniques in the assessment and early diagnosis of parotid gland injury in Sjögren's syndrome(SS) patients.

## **METHODS AND MATERIALS**

This study prospectively included 54 first-time confirmed SS patients and 30 healthy volunteers from a tertiary hospital from August 2021 to October 2022. Non parametric Mann Whitney U test was used to compare various parameters between SS patients and healthy volunteers. LSD test was used to compare the differences in parameters between adjacent MRI morphological grading. Spearman rank correlation test was used to analyze the correlation between parotid gland MRI morphological grading and various parameters of SS patients. The combination of logistic regression and receiver operating characteristics is used to evaluate the diagnostic efficacy of various parameters and their combination in distinguishing healthy volunteers from early SS patients and all SS patients.

## **RESULTS**

The parotid gland BF of all SS patients and 0-3 grade SS patients was higher than that of healthy volunteers. There was no statistically significant difference in BF between grade 4 SS patients and healthy volunteers. The T2 value and standard deviation of T2 value in the parotid gland of all SS patients and 0-4 grade SS patients were higher than those of healthy volunteers. The morphological grading of parotid gland MRI (0-3 grades) showed a strong positive correlation with BF ( $r=0.785$ ,  $P<0.001$ ), a moderate positive correlation with T2 value ( $r=0.547$ ,  $P<0.001$ ), and a moderate positive correlation with T2 standard deviation ( $r=0.622$ ,  $P<0.001$ ). The area under the curve of BF is 0.813; The AUC of T2 value is 0.810; The AUC of T2 standard deviation is 0.649. The AUC of the combined diagnosis of BF, T2 value, and T2 value standard deviation is 0.842. The diagnostic efficacy of BF, T2 value, and combined diagnosis is higher than the T2 value standard deviation, while the diagnostic efficacy of combined diagnosis is higher than BF or T2 value.

## **CONCLUSION**

s The BF, T2 values, and standard deviation of T2 values of the parotid gland can distinguish between healthy volunteers and SS patients, reflecting the corresponding changes in the parotid gland of SS patients at different stages. The combination of the three can improve diagnostic efficiency. ASL technology and T2 mapping technology have certain significance in the evaluation and early diagnosis of parotid gland injury in SS patients, and are important supplementary tools for routine MRI diagnosis.

## **CLINICAL RELEVANCE/APPLICATION**

ASL technology and T2 mapping technology have certain significance in the evaluation and early diagnosis of parotid gland injury in SS patients, and are important supplementary tools for routine MRI diagnosis.

#### **S3A-SPIN-1 Deep Learning for Synthesizing Virtual Gadolinium Contrast Enhancement in Rectal Cancer from Noncontrast Conventional MRI Scans: A Multicenter Feasibility Study**

##### **PURPOSE**

Gadolinium-based contrast agents (GBCAs) MRI aids the diagnosis and surveillance of rectal cancer, whereas safety concerns have been raised recently. We aim to explore whether deep learning (DL) can synthesize Virtual T1WI enhancement (VTE) of rectal cancer.

##### **METHODS AND MATERIALS**

DL networks were trained and validated on routine nonenhanced MRI (T1WI, T2WI, DWI-ADC). Diffuse MRI scans included 697 patients with rectal cancer in A Cancer Hospital (533 retrospective, 63 prospective) and B Hospital (101 retrospective). The real T1WI enhancement (RTE) images served as the ground truth. The image quality of input was quantitatively evaluated by Natural Image Quality Evaluator (NIQE). The similarity between VTE and RTE were quantified using Mean Absolute Error (MAE), Peak Signal Noise Ratio (PSNR), Structural Similarity (SSIM) and qualitatively evaluated by two radiologists. Ablation experiment was conducted to explore the best model. T staging was evaluated on VTE and RTE and compared with pathology.

##### **RESULTS**

Quantitative and qualitative evaluation of three-channel RTE was significantly better than that of two-channel or one-channel ( $P < 0.001$ ). In internal validation (IV), external validation (EV) and prospective validation (PV): MAE was  $0.03 \pm 0.01$ ,  $0.04 \pm 0.01$  and  $0.03 \pm 0.01$ ; PSNR was  $25.86 \pm 1.63$ ,  $22.34 \pm 1.21$  and  $25.68 \pm 1.28$ ; SSIM was  $0.87 \pm 0.55$ ,  $0.66 \pm 0.06$  and  $0.88 \pm 0.03$ , accordingly. The qualitative evaluation and T staging accuracy (IV: RTE 70.71%, VTE 71.72%; EV: RTE 69.31%, VTE 69.31%; PV: RTE 71.43%, VTE 73.02%) of VTE was comparable with that of RTE. NIQE was significantly higher with EV ( $P < 0.001$ ). The correlation analysis between NIQE and MAE or SSIM or PSNR was statistically significant ( $P < 0.001$ ).

##### **CONCLUSION**

The deep learning could synthesize enhancement of rectal cancer from nonenhanced conventional MRI scans with good image quality quantitatively and qualitatively and allows accurate assessment of rectal cancer patients' T staging. Our findings could guide the application of VTE to potentially reduce GBCA administration.

##### **CLINICAL RELEVANCE/APPLICATION**

VTE synthesized by deep learning based on clinical routine MRIs can overcome the limitations of RTE and aid in the clinical diagnosis and management of rectal cancer as a noninvasive, safe, cost-efficient and time-saving tool.

#### **S3A-SPIN-2 Development of a Three-Dimensional Expression Method for Ultrasound Images Using Mixed Reality Head-Mounted Displays**

##### **PURPOSE**

This research aimed to develop a real-time three-dimensional (3D) expression of ultrasound images in mixed reality (MR) space to enhance the intuitiveness and understanding of ultrasound images, and to compare its performance with conventional two-dimensional (2D) ultrasound.

##### **METHODS AND MATERIALS**

An MR ultrasound system was developed using the Microsoft HoloLens 2™ MR head-mounted display (HMD), incorporating a 3D camera for SLAM (Simultaneous Localization and Mapping) of the ultrasound transducer. Technical performance was evaluated for MR 2D and MR 3D ultrasound modalities. User evaluation involved 20 healthcare workers (10 medical doctors (MD) group, and 10 non-MD group; 4 nurses, and 6 radiology technicians) who assessed elapsed time, target object position identification score (both of horizontal and vertical position), and shape identification score for every three modalities: 1) conventional 2D ultrasound, 2) MR 2D ultrasound, and 3) MR 3D ultrasound. For each correct identification of the position and shape for a single target object, a score of 1 point was given. The user satisfaction assessment was also conducted regarding the intuitiveness of shape recognition, location recognition, and ease of use in the 3D accumulation process on a scale of 5.

##### **RESULTS**

User evaluation revealed no significant difference in elapsed time, and position identification among the three modalities. Shape identification score was significantly improved with MR 3D ultrasound compared to conventional 2D and MR 2D ultrasound (conventional 2D:  $1.05 \pm 0.76$  [average  $\pm$  standard deviation], MR 2D:  $1.30 \pm 1.13$ , MR 3D:  $3.00 \pm 0.00$ ,  $p < 0.001$ ). All evaluators identified the correct shapes of all target objects, eliminating differences between groups in using MR 3D ultrasound. User satisfaction score in the intuitiveness of shape identification with MR 3D ultrasound was as high as  $4.85 \pm 0.37$ .

##### **CONCLUSION**

s Incorporating 2D ultrasound into the MR space and expressing it in three dimensions through a user-driven 3D accumulation process were both technically feasible to implement. Moreover, the MR 3D ultrasound display was superior to both conventional 2D and MR 2D ultrasound in discerning the shape of the target object, providing a more intuitive visualization.

#### **CLINICAL RELEVANCE/APPLICATION**

HoloLens offers the function for multiple users to simultaneously share the same MR space, which can be implemented when several users are each wearing their own HoloLens device. By employing the technology developed in this study to reconstruct and display the images as 3D MR, it is expected to facilitate sharing of examination contents and promote intuitive understanding among patients with limited anatomical knowledge and clinical support staff.

### **S3A-SPIN-3 A Novel 18F-FDG-PET Based Signature for Non-Small Cell Lung Cancer Prognostication**

Participants

Mitchell Chen, MD, PhD, (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To develop a novel 18F-fluorodeoxyglucose-positron emission tomography (FDG-PET) radiomics predictive model combined with metabolic hotspot to centroid (HOC) metric for patient prognostication in non-small cell lung cancer (NSCLC).

#### **METHODS AND MATERIALS**

Pre-therapy FDG-PET scans from 301 NSCLC patients (age:  $69.1 \pm 9.8$ , male: female (M: F) = 183:118) were acquired between July 2009 and November 2018 and included as the training data. Independent external FDG-PET data were acquired from five centers (n = 257) and used for model validation. Two board-certified clinical radiologists with 8 and 13 years of professional experience segmented the primary tumor using metabolic tumor volume 40% (MTV40) threshold. Additional regions of interests (ROI) were acquired from the peri-tumoral penumbra as annular shells of 1cm in thickness, and from the background lung parenchyma as spheres of 3cm in diameter. Following pre-processing, radiomics features compliant with the Image Biomarker Standardization Initiative (IBSI) were extracted using PyRadiomics from each ROI, normalized and aggregated to form a feature space. Non-reproducible features with an inter-class correlation (ICC) of less than 0.8 were excluded. Cox regression with elastic net regularization was performed to develop a radiomics model with patients' 3-year overall survival as the response vector. Using multivariable regression, this was combined with a novel PET metric developed based on the clonal driver mutation theory of cancer growth, namely the FDG HOC distance, to develop a composite radiomics predictive vector (RPV). Model performance for disease prognostication was tested by stratifying the patients into a high and low risk group using k-means clustering based on RPV.

#### **RESULTS**

In all external testing cohorts, statistically significant stratification of the patients into high and low risk groups was achieved using RPV (p-value < 0.05).

#### **CONCLUSION**

s A model developed based on PET radiomics and HOC can achieve patient prognostication in NSCLC. Comparing to models based on CT or PET radiomics alone, this novel signature captures explainable information on tumour growth, and demonstrates a role of the latter for predicting patient survival in NSCLC.

#### **CLINICAL RELEVANCE/APPLICATION**

Imaging-based metrics such as FDG-PET radiomics and HOC offer a non-invasive way of assessing neoplasms at the time of diagnosis. This can aid in clinical decision making, particularly in cases where tissue sampling is challenging or shows inconclusive results. The information presented by these measurements can additionally give insight into tumor composition and metabolism, thereby advancing an understanding of cancer biology that is not otherwise achievable in vivo.

### **S3A-SPIN-4 AI-assisted Volumetric Segmentation for Metastases in Follow-up CT Scans: A Multi-institutional Reader Study**

Participants

Alessa Hering, PhD, (*Presenter*) Nothing to Disclose

#### **PURPOSE**

AI-assisted techniques for lesion registration and segmentation have the potential to make CT-based tumor follow-up assessment faster and less reader-dependent. However, empirical evidence on the advantages of AI assistance for lymph node and soft tissue metastases in follow-up CT scans is lacking. Therefore, the aim of this study was to assess the efficiency, quality and inter-reader variability of an AI-assisted workflow for volumetric segmentation of lymph node and soft tissue metastases in follow-up CT scans. Three hypotheses were tested: (H1) Assessment time for follow-up lesion segmentation is reduced using an AI-assisted workflow. (H2) The quality of the AI-assisted segmentation is non-inferior to the quality of fully manual segmentation. (H3) The inter-reader variability of the resulting segmentations is reduced with AI assistance.

#### **METHODS AND MATERIALS**

This multi-institutional reader study retrospectively analyzed 126 lymph nodes and 135 soft tissue metastases from 55 patients diagnosed with stage IV melanoma. Given segmentations of these lesions on the baseline scan, three experienced readers from two institutions performed both AI-assisted and manual segmentations on the follow-up scans. The results were then statistically analyzed and compared to a manual segmentation reference standard to assess the quality and accuracy of the AI-assisted workflow.

#### **RESULTS**

AI-assisted segmentation reduced user interaction time significantly by a third (222s vs 336s per patient), achieved similar Dice scores (0.80-0.84 vs 0.81-0.82) and decreased inter-reader variability (median Dice 0.85-1.0 vs 0.80-0.82), compared to manual segmentation. In over 50% of the segmentation propositions within the AI-assisted workflow, two radiologists accepted the results without any further corrections.

#### **CONCLUSION**

s AI-assisted segmentation reduced user interaction time significantly by a third, achieved similar Dice scores and decreased inter-reader variability, compared to manual segmentation. In over 50% of the segmentation propositions within the AI-assisted workflow, two radiologists accepted the results without any further corrections.

#### **CLINICAL RELEVANCE/APPLICATION**

AI-assisted lesion segmentation makes accurate quantification of volumetric tumor growth and other characteristics feasible in clinical routine, enabling earlier and better response assessment.

### **S3A-SPIN-5 Graph-Theoretic Automatic Lesion Tracking and Detection of Patterns of Lesion Changes in Longitudinal CT Studies**

Participants

Leo Joskowicz, PhD, Jerusalem, Israel (*Presenter*) Officer, HighRAD Ltd

#### **PURPOSE**

To evaluate the performance of a novel generic method for tracking individual lesion changes and detecting patterns in liver and lung metastatic lesions in longitudinal CT.

#### **METHODS AND MATERIALS**

We define seven individual lesion change classes: new, disappeared, unique, lone, merged, split, and complex lesion and five lesion change patterns: single, linear, merged, split, and complex pattern to summarize the evolution of lesions over time. The method automatically computes the lesion matchings, the labels of the changes in individual lesions, and the patterns of the lesion changes. It uses a graph-based technique where lesions are vertices and edges are pairings of matched lesions. The inputs are the scans and the organ and lesion segmentations in each scan. It performs pairwise deformable registration of consecutive scans, organs and lesion segmentations, matches overlapping lesions, and computes the changes from the resulting graph. The method was evaluated on lung and liver metastases datasets with 83 scans from 19 patients (mean  $126 \pm 81$  days apart) and 77 scans from 19 patients (mean  $109 \pm 93$  days apart). Ground truth manual lesion segmentations, matchings and changes classification were obtained by an expert radiologist.

#### **RESULTS**

The lung and liver metastases overall individual lesion change class accuracy is 97% and 87%. The patterns of lesion changes were identified with an accuracy of 94% and 80%. The highlighting of unusual lesion labels and lesion change patterns helped the radiologist find missed lesions (57 lungs, 52 liver) and wrongly annotated lesions (1 lungs, 18 liver), accounting for 4.9% and 8.7% of the original ground-truth lesions.

#### **CONCLUSION**

s Our method accurately classifies changes in individual lesion and reliably identifies patterns of lesion changes in liver and lung longitudinal CT studies.

#### **CLINICAL RELEVANCE/APPLICATION**

Automatic lesion change classification and pattern detection in longitudinal CT studies may improve the accuracy and efficiency of radiological interpretation and disease status evaluation.

### **S3A-SPIN-6 Accurate Coverage Assessment in MRI using Deep Learning-Based Landmark Detection**

Participants

Ryan Chamberlain, PhD, Stillwater, MN (*Presenter*) Employee, ImBio, LLC

#### **PURPOSE**

This study aims to develop a deep learning-based MRI coverage detection model. By introducing key points to define coverage, using self-supervised learning to overcome annotation challenges, the model addresses crucial coverage detection obstacles and promotes patient-centered care.

#### **METHODS AND MATERIALS**

Datasets: We used three datasets for train and evaluate the model: Lumbar Spine Open dataset1 (464 T1 and T2-weighted lumbar spine MRI images); IXI MRA dataset2 (nearly 600 MR images from healthy subjects); and TubeTK MRA dataset (100 T1-weighted MRA images from healthy patients). No manual annotations of key points needed. Model: Adapted from Frueh et al.'s paper<sup>3</sup>, we employed the Template Matching Network (TMN) with separate feature encoders for the source image and augmented extracted patch. The stacked feature vectors feed into three fully connected layers, the localizer. We added a detector branch for coverage detection, sharing the localizer's architecture, but yielding binary results (Figure). Augmentation: Techniques include affine transformation, gamma adjustment, and Gaussian blurring. Images and patches are cropped before resizing to the model's input size of  $224 \times 224$ , ensuring flexible image scope and dynamic image/patch size ratios, enhancing model robustness and adaptability. Training: Loss functions comprise log negative likelihood loss for the localizer and cross-entropy loss for the detector, using multi-purpose optimization. StepLR manages learning rate scheduling, and early stopping ensures an efficient training strategy.

#### **RESULTS**

We evaluated our deep learning-based coverage detection model in spine and MRA scenarios. The spine model demonstrated a 4.84mm mean distance in localizing key points, and correctly identified vertebral levels in 55% of cross subject test cases. The model achieved an F1 score of 0.799 in detecting coverage in partial lumbar spine images. The MRA model achieved a 6.65mm mean distance in localization, and qualitatively identified correct locations in two randomly selected cross subject images (see figure).

#### **CONCLUSION**

s Our coverage detection model exhibits strong performance in spine imaging and MRA studies, with promising results in localizing random or manually labeled key points as well as detecting coverage in partial images.

#### **CLINICAL RELEVANCE/APPLICATION**

By ensuring accurate coverage of relevant anatomical structures, our deep learning-based model has the potential to reduce repeat imaging and patient revisits, conserving resources and minimizing risks for patients. By automating the coverage assessment process, the model alleviates the burden on clinicians to manually review images. This innovation ultimately boosts efficiency, and promotes better patient care.

### **S3A-SPIN-7 Discrimination of the Pulmonary Nodules Using the Chest CT Image Features by Homology Method**

#### **PURPOSE**

The degree of lung adenocarcinoma (LAc) invasion is important in determining treatment strategy, but it is not revealed until the pathological diagnosis at surgical treatment. So, we developed a method to determine it from preoperative CT images, but it is also necessary to discriminate the lesion of LAc from normal tissues. Homology is one of the topological concepts and quantifies contact. Homology-based image analysis (HA) can explain the reason for inference based on mathematics. So, we have aimed to discriminate LAc and normal tissues in CT image based on HA.

#### **METHODS AND MATERIALS**

This study uses chest CT images of patients with LAc. Fifty ROIs (regions of interest) were created for each LAc lesion, lung field (no lesion), blood vessels in the lung field, bronchi, and ribs. Next, binarized images were created while varying the CT value. The Betti numbers ( $b_0$ ,  $b_1$ : the number of isolated areas and holes) in the ROI were measured and normalized with the area of ROI. These indices were used as imaging features and compared using Mann-Whitney U test. The relationship between HU and imaging features was plotted as a homology profile. Moreover, we developed a binary classification model based on the support vector machine (SVM) that classifies the ROI for LAc or normal tissue, and five-fold cross-validation was used.

#### **RESULTS**

U test showed that each normal tissue significantly differed for nodules ( $p < 0.05$ ). The performances of SVM-based model are as follows (mean  $\pm$  SD). The discrimination between lung fields and LAc had an accuracy of  $1.00 \pm 0.00$  and area under the ROC curve (AUROC) of  $1.00 \pm 0.00$ , while the discrimination between ribs and LAc had an accuracy of  $0.99 \pm 0.01$  and AUROC  $1.00 \pm 0.00$  were the best results. For the best discrimination between blood vessels and LAc, an accuracy of  $0.91 \pm 0.03$  and AUROC of  $0.97 \pm 0.01$  were obtained, while for the discrimination between bronchi and LAc, an accuracy of  $0.97 \pm 0.01$  and AUROC  $1.00 \pm 0.00$ .

#### **CONCLUSION**

The results suggest that it is possible to extract image features for each tissue by using HA, and that the classification model using those features can classify with excellent performance. Therefore, we will discriminate the ROIs obtained from the automatic contouring technique using the multi-classification model in the future. In conclusion, we succeeded in discriminating the ROI obtained from chest CT images for LAc and normal tissues using the SVM-based model that discriminates the image features by HA.

#### **CLINICAL RELEVANCE/APPLICATION**

We will develop the hybrid model, including this proposed model and our developed model that classifies the invasiveness degree of LAc on preoperative CT images. The hybrid model may not only help in early diagnosis and predicting prognosis but also lead to the discovery of novel valuable indices.

## Abstract Archives of the RSNA, 2023

S3A-SPIR

### Interventional Radiology Sunday Poster Discussions I

#### Sub-Events

#### **S3A-SPIR-1 Comparison of Micro Flow Imaging and Contrast Enhanced Ultrasound in Microwave Ablation of Benign Thyroid Nodules**

##### **PURPOSE**

To explore the application value of micro-flow imaging (MFI) in microwave ablation (MWA) of thyroid nodules by comparing it with contrast-enhanced ultrasound (CEUS).

##### **METHODS AND MATERIALS**

From January 2020 to March 2022, 50 patients with 55 thyroid nodules who underwent MWA in the ultrasound department of our hospital were included. According to the different ablation evaluation methods, they were divided into the CEUS group and the MFI group. Before the operation, CEUS and MFI were used to evaluate the consistency of blood flow inside the nodule. Immediately after ablation, CEUS or MFI was used to evaluate whether the ablation was complete. Follow-up was conducted at 1, 3, and 6 months after the operation and every 6 months thereafter to record the diameter and volume of the nodule, CEUS and MFI were used to evaluate the suspected recurrent nodules.

##### **RESULTS**

There was no significant difference between MFI and CEUS in assessing the internal blood flow of nodules ( $P > 0.05$ ), and the consistency between them was very strong ( $\kappa$  value = 0.81). All nodules showed complete ablation. At 1, 3, 6, and 12 months after the operation, the VRR in the CEUS group was 41%, 61%, 78%, and 89% respectively, and in the MFI group was 41%, 55%, 71%, and 83% respectively, there was no significant statistical difference between the two groups ( $p > 0.05$ ). No serious complications occurred after the operation.

##### **CONCLUSION**

The application effect of MFI in MWA of benign thyroid nodules is consistent with CEUS, and when CEUS cannot be used or unconditionally to use, MFI can be an alternative.

##### **CLINICAL RELEVANCE/APPLICATION**

CEUS can sensitively display the micro blood perfusion in tissues and can be used to differentiate benign and malignant tumors, it plays an essential role in the whole ablation process, which can determine the ablation area before ablation and evaluate the therapeutic effect after ablation. However, CEUS is an invasive and expensive examination, and not suitable for patients with severe cardiopulmonary dysfunction or hypersensitivity to ultrasound contrast agents. Explore a new, non-invasive way to evaluate the efficacy of thyroid nodule ablation will not only help to reduce the cost of patients. Micro-flow imaging (MFI) is a new ultrasound technology that can eliminate tissue motion artifacts while maintaining sensitivity to low-speed blood flow signals by using effective algorithms to visualize microvascular, it has the advantages of being non-invasive, fast, and convenient. In recent years, MFI has gradually been widely used in clinical practice. There are only a few studies on the application of MFI in the thermal ablation process of thyroid nodules. This paper aims to further study the application value of MFI in the MWA process of thyroid nodules by comparing it with CEUS.

#### **S3A-SPIR-2 Reperfusion of Pulmonary Arteriovenous Malformations Treated by Catheter Embolization**

##### **PURPOSE**

339 patients with HHT (Osler disease) underwent screening for manifestation of the disease in the brain, the lung and the liver by one CE MRI study. In 144 patients at least one pulmonary AVM was found and catheter embolization using platinum coils or vascular plugs was performed with initial complete occlusion of the PAVM. However, especially in the lung reperfusion may occur due to reopening of the treated vessel itself or newly developed collateral vessels. The aim of our study was to evaluate patients post treatment of pulmonary AVM's for possible reperfusion.

##### **METHODS AND MATERIALS**

Of 144 patients with previous treatment of PAVMs 117 patients underwent follow-up studies to detect reperfused PAVM by CE MRA. The mean follow-up period was 4 yrs and 8 month. For follow-up a time-resolved MRA was used with injection of a small CM bolus (0.025 mmol/kg BW MultiHance, Bracco). The temporal resolution of the sequence was  $< 3$  sec/dataset with a total number of 72 slices. Thereafter a high resolution CE MRA (0.075 mmol/kg BW MultiHance) was performed. Images were evaluated regarding enhancement of the AVM and if detected, time of enhancement of the draining vein.

##### **RESULTS**

In 77 of 117 patients no reperfusion in follow-up studies was found. In 35 patients reperfusion of the treated vessel and in 5 patients reperfusion of the PAVM was detected due to collateral vessels supplying the PAVM. In one patient reperfusion occurred due to systemic arterial supply from collaterals arising from the intercostal arteries. The mean time between embolization and detection of reperfusion in patients treated at our department was 6 years. 36 of 40 patients with reperfused PAVM were confirmed

by DSA and underwent reembolization. In 4 cases supplying vessels were < 2mm and only further follow-up studies were performed. Reperfusion was detected both after coil embolization and implantation of Amplatzer vascular plug 4. The mean diameter of reperfused vessels was 4.6 mm (SD 1.4).

## CONCLUSION

Reperfusion of initially completely occluded PAVMs might even occur after longer time intervals thus regular follow-up studies are mandatory. CE MR-Angiography can reliably depict reperfusion of PAVM and evaluation of the enhancement kinetics of the draining vein was helpful to distinguish between retrograde filling, filling of the still dilated draining vein via normal lung tissue and reperfusion by reopening of shunt vessels or new collateral supply.

## CLINICAL RELEVANCE/APPLICATION

Reperfusion of embolized PAVM can occur in up to 35 percent of patients and early detection is mandatory to avoid complications e.g. stroke. Dynamic CE MRA directly depicts early enhancement of the draining vein as a sign of reperfusion and thus can give important additional information not gained in conventional acquisitions or CT.

## 33A-SP1R-3 Comparative Prospective Analysis of Digital Variance Angiography and Digital Subtraction Angiography in Prostatic Artery Embolization: A Potential Solution for Radiation Dose Reduction

### Participants

Leona Alizadeh, MD, Frankfurt, Germany (*Presenter*) Nothing to Disclose

### PURPOSE

Prostatic Artery Embolization (PAE) is a complex vascular intervention that requires the use of X-ray angiography imaging with high doses of radiation and iodinated contrast agent. The purpose of this study was to compare the performance of Digital Variance Angiography (DVA) with standard Digital Subtraction Angiography (DSA) in PAE and to evaluate the potential of DVA to reduce radiation exposure and contrast agent use.

### METHODS AND MATERIALS

A prospective observational study was conducted on 26 patients (mean age 72, SD 14.6, range 49-89) in two groups (n=13): Group 1: standard CARE imaging protocol and Group 2: reduced detector dose and image quality pre-settings. All patients underwent PAE at our institution between January and December 2022. The study included a total of 107 acquisitions, from which DSA and DVA images were generated from the same raw series. The Contrast-to-Noise Ratio (CNR) values were calculated, and the image quality was assessed by four experienced readers using a 5-grade-Likert-scale in a randomized blinded survey. Radiation dose data was evaluated by assessment of dose-area-product (DAP) reference point air-kerma (RP), fluoroscopy times and image frames.

### RESULTS

The DVA images provided significantly higher CNR values compared to DSA images, with a median CNR of  $32.2 \pm 9.5$  in Group 1 and  $24.8 \pm 9.9$  for Group 2 vs.  $8.1 \pm 11.1$  for Group 1 DSA and  $7.3 \pm 9.3$  for Group 2 DSA,  $p < 0.001$ . Furthermore, the DVA images received significantly higher Likert scores compared to DSA images, with a median (IQR) value of 4.52 (4-5) for Group 1 DVA 4.12 (3-5) for Group 2 and 3.24 (3-4) for Group 1 DSA and 2.9 (2-4) for Group 2,  $p < 0.001$ . Mean radiation burden in Group 1 was significantly higher by -49%/-45% with a DAP  $17.85 \mu\text{Gy} \cdot \text{m}^2 / \text{frame}$  and RP 0.89 / frame compared to Group 2 with a DAP  $9.62 \mu\text{Gy} \cdot \text{m}^2 / \text{frame}$  and RP 0.49 / frame ( $p < 0.001$ ).

### CONCLUSION

The results of this study demonstrate that DVA has significantly higher CNR compared to DSA for both Groups in PAE procedures. The use of DVA could potentially provide a quality reserve that can be utilized for significant reduction of radiation exposure and iodinated contrast agent in PAE, up to 50-70% without compromising image quality. This may have a significant impact on patient safety during complex procedures such as PAE.

### CLINICAL RELEVANCE/APPLICATION

The implementation of DVA in PAE can significantly reduce radiation exposure, which is a critical factor for improving patient safety during complex vascular interventions. These findings suggest that DVA should be considered as an alternative to DSA in PAE and other similar procedures that require high-quality imaging while minimizing the risk of radiation exposure and potentially also contrast agent use.

## 33A-SP1R-4 Quantitative MRI-based Volumetric Analysis of Percutaneous Sclerotherapy Outcomes in Peripheral Extremity Venous Malformations

### Participants

Amanda Laguna, BS, Laguna Niguel, CA (*Presenter*) Nothing to Disclose

### PURPOSE

To study the changes in MRI radiomic features occurring in peripheral venous malformations (VMs) after treatment using percutaneous sclerotherapy (PS).

### METHODS AND MATERIALS

Our vascular anomalies database was searched for patients with peripheral extremity VMs who were treated by image-guided PS and had completed their treatment plan, and clinical and imaging follow-up between 2005-2022. VMs were manually segmented on pre- and post-treatment T2-weighted (T2-WI) MRI using 3D Slicer software to assess changes in lesion volume and signal intensity (SI). To account for signal parameter differences between pre- and post-treatment T2-WI, the post-treatment T2-WI MRI signal was re-scaled to the pre-treatment T2-WI volume using a simple histogram matching algorithm, which allowed for precise and true calculation of SI change after PS. Therapeutic response was categorized as 0=worse or unchanged, and 1=improvement based on clinical evolution after treatment. Clinical outcome assessment was also scored on a 7-point scale, ranging from -3 (worst) to +3 (maximum improvement), based on patient's perception of symptom improvement. Spearman's rank correlation coefficient ( $\rho$ ) and Paired t-test were used for statistical analysis.

### RESULTS

Eighty-one patients (mean age:  $20 \pm 14$  years; 47 females) with upper (23 lesions) and lower (58) extremity VMs underwent 125 PS treatments (range: 1-6). Different sclerosants were used: alcohol (52 sessions), bleomycin (38), and sotradecol (35). Most patients (77) reported clinical improvement following PS, including mild (8 patients), moderate (22), and significant (47) improvement. The mean change in lesion volume was  $-7.9 \pm 24.6 \text{ cm}^3$  ( $P = .005$ ) and in mean SI was  $-123.1 \pm 162.9$  ( $P < .001$ ). Overall, there was a significant correlation between change in lesion volume and treatment response ( $r = .3$ ,  $P = .004$ ). On subgroup analysis, SI change correlated with clinical outcomes of VMs treated in one session ( $n = 51$ ;  $r = .3$ ,  $P = .01$ ), and VMs treated with bleomycin ( $n = 22$ ;  $r = .4$ ,  $P = .04$ ). While lesion volume change correlated with clinical outcomes of pediatric patients ( $n = 50$ ;  $r = .3$ ,  $P = .03$ ), VMs treated with sotradecol ( $n = 17$ ;  $r = .5$ ,  $P = .02$ ), and VMs located in the foot ( $n = 10$ ;  $r = .6$ ,  $P = .04$ ).

## CONCLUSION

s MRI radiomic features including lesion volume and signal intensity correlate with the clinical outcomes for peripheral VMs treated using PS.

## CLINICAL RELEVANCE/APPLICATION

This study is first to investigate the relationship between signal intensity change of VMs and clinical outcome after PS. The study represents first step for application of complex, comprehensive radiomics in vascular malformations.

### S3A-SP1R-5 Efficacy of 50% Acetic Acid Sclerotherapy for Treatment of Simple Renal Cysts - Comparison of 5-Minutes Dwell time Technique and 3-Minutes Dwell Time Technique

#### PURPOSE

To compare long term follow-up treatment results of single-session sclerotherapy for renal cyst using 50% acetic acid 3-minute dwell technique with those using 50% acetic acid 5-minute dwell technique.

#### METHODS AND MATERIALS

Total 101 simple renal cysts of 97 patients (M:F = 43:54, mean age -  $63 \pm 12.8$  years) underwent single-session 50% acetic acid sclerotherapy using less than 5 minutes (35 cysts, Group I) or 3 minutes (66 cysts, Group II) dwell technique in our institution. An acetic acid volume corresponding to a 5 ~ 40% (mean percentage- 13%) of the aspirated cyst volume was injected into the cysts and removed in less than 5 minutes or 3 minutes with position changes. Follow-up examination was performed using ultrasound or CT images at 3 to 6-months intervals for a minimum of 1 year. All patients were retrospectively reviewed on the therapeutic response and complications. The response was classified as either complete remission (volume reduction, = 95%), partial remission (volume reduction, 50-95%), or failure (volume reduction, = 50%).

#### RESULTS

In 97 simple renal cysts, complete remission on follow-up was observed in 22 of 35 cysts (62.9%) in group I and 46 of 66 cysts (69.7%) in group II. The partial remission on follow-up was observed in 11 of 35 cysts (37.1%) in group I and 20 of 66 cysts (30.3%) in group II. There was no failure in both groups. There were no statistically significant differences in the complete remission and partial remission between the two groups. There was mild post procedure complication in 25 patients, but no major procedure related complication.

## CONCLUSION

s Single-session 50% acetic acid sclerotherapy for the treatment of simple renal cysts using less than 3 minutes dwell technique is an effective and safe therapeutic option for simple renal cyst. 50% acetic acid sclerotherapy with a 3 minutes dwell time, using a volume of about 10% of the aspirated volume, is sufficient for satisfactory results of simple renal cyst sclerotherapy when compared with 50% acetic acid sclerotherapy using 5 minutes dwell time.

## CLINICAL RELEVANCE/APPLICATION

50% acetic acid sclerotherapy show higher complete remission rate than any other ethanol one session sclerotherapy and, also show acetic acid sclerotherapy with 3 minute dwell time is sufficient for complete remission of renal cysts.

### S3A-SP1R-6 Quantification and Analysis of Radiation Dose from Fluoroscopically Guided Prostate Artery Embolization Procedures

#### Participants

Rasha Makkia, PhD, MS, New Haven, CT (*Presenter*) Nothing to Disclose

#### PURPOSE

To quantify patient radiation exposure during PAE and provide radiometric data to inform clinical decision-making regarding the radiation-related deterministic and stochastic risks versus the relative benefits of PAE.

#### METHODS AND MATERIALS

121 PAE procedures were performed between 2018 and 2021 at Yale New Haven Hospital, CT. The collected patient data followed an IRB-approved protocol, including age, height, body weight, and metal implants or contrast in the bladder during the procedure. Dosimetric data included total procedure time, total fluoroscopy time, Cumulative-Air-Kerma (CAK), Kerma-Area-Product (KAP) from fluoroscopy, and total KAP. These dosimetric data were analyzed using Radimetrics software (Bayer HealthCare, NJ). As a surrogate for stochastic risk, the effective dose from each PAE was computed by multiplying the total KAP using a conversion factor of  $0.11 \text{ mSv.Gy}^{-1} \cdot \text{cm}^{-2}$  derived from values in published literature. PAE effective doses were then compared to abdominal-pelvic CT exams for patients who had individual abdominal-pelvic CTs. The CT effective dose was calculated by multiplying the DLP using the standard conversion factor of  $0.015 \text{ mSv.Gy}^{-1} \cdot \text{cm}^{-1}$ . To account for patient size, for each patient, a ratio was derived between the effective dose from PAE and that from abdominal-pelvic CT. To examine the likelihood of deterministic effects, peak skin dose (PSD) calculations were performed for PAE patients with a CAK greater than 3Gy using an in-house Matlab algorithm (MathWorks, MA).

#### RESULTS

The average PAE procedure and fluoroscopy took 150 minutes and 37.1 minutes, accordingly. KAP and CAK had a mean value of  $280 \text{ Gy.cm}^2$ , and  $2.145 \text{ Gy}$ . The average effective dose from PAE fluoroscopy was  $30.8 \text{ mSv}$  and the effective dose from CT was  $9.1 \text{ mSv}$ . The average ratio was 4.1; however, patients with CTs had a higher average PAE dose than patients without CTs due to

greater use of CBCT, DSA, and larger field sizes in earlier patients. PSD was calculated for any PAE exam with a CAK greater than 3Gy. 12 exams had a CAK between 3 and 4Gy, 6 had a CAK between 4 and 5Gy and only 2 had a CAK greater than 5Gy. The maximum PSD calculations were 4Gy and 4.1Gy. There were no deterministic complications reported within 90 days after PAE.

#### **CONCLUSION**

s This quantification data helps provide a standard for which clinicians can draw accurate judgments regarding the risks of PAE and can provide a standard for interventionalists to compare their own procedural radiation dosages during PAE.

#### **CLINICAL RELEVANCE/APPLICATION**

Benign prostatic hyperplasia is a worldwide health problem that significantly impacts men's quality of life. When radiation safety guidelines are followed, it offers effective treatment with a low risk of deterministic or stochastic radiation-related injuries.

Printed on: 04/12/24

## Abstract Archives of the RSNA, 2023

S3A-SPMK

### Musculoskeletal Imaging Sunday Poster Discussions I

#### Sub-Events

#### S3A-SPMK-1 Shear Wave Elastasonography Applied to Synovitis: A Preliminary Study

##### PURPOSE

This study aims to evaluate the utility of shear wave elastasonography (SWE) to identify synovitis in patients who had a history of arthritis within the diagnosis of a defined rheumatological disease.

##### METHODS AND MATERIALS

We performed a B-mode and SWE (US) to a total number of 58 participants divided in 2 groups: group 1 included 29 patients with confirmed active wrist and/or hand synovitis; group 2 included 29 healthy volunteers without suspicion of synovitis. In a subset of patients (n=8), the joint count and the rest of the disease evaluation were performed to the elastasonography to study the correlation between the clinical and radiological findings.

##### RESULTS

The difference in both the mean maximum kPa value and the average joint kPa value was statistically significant between cases and controls: maximum kPa value cases  $38.14 \pm 35.08$  kPa, controls  $4.72 \pm 5.93$  kPa; average joint value cases  $29.77 \pm 26.07$ , controls  $4.17 \pm 5.22$ . The most frequent place to find joint effusion in both cases and controls was the dorsal radiocarpal joint: 41.4% of controls, mean kPa value of  $7.66 \pm 5.39$  kPa, 58.6% of cases, mean kPa value  $40.61 \pm 40.76$  kPa (p-value 0.004). kPa values correlated with disease activity measurements in the 8 patients clinically evaluated at the moment of the SWE.

##### CONCLUSION

s SWE is a promising technique that may have a role in the diagnosis and assessment of synovial inflammatory activity.

##### CLINICAL RELEVANCE/APPLICATION

New semiquantitative ultrasound technique in the diagnosis and in monitoring of therapy of synovitis.

#### S3A-SPMK-2 Zero Time-to-Echo Imaging of the Hand and Wrist in Patients with Rheumatoid Arthritis: Comparison with Radiography and Conventional MRI using CT as Gold Standard

#### Participants

Jun Tsukamoto, MD, Kitakyushu, Japan (*Presenter*) Nothing to Disclose

##### PURPOSE

Zero echo time (ZTE) imaging has been developed to detect signals from the objects with extremely short T2\* value, and this sequence can generate CT-like images from MRI after gray-scale inversion. The aim of this study is to compare ZTE imaging with radiography for the detection of hand and wrist bone erosions in patients with rheumatoid arthritis (RA), using CT as the reference method.

##### METHODS AND MATERIALS

The study was approved by the local ethics committee, and written consent was obtained from all patients. From December 2022 to April 2023, nine consecutive patients with RA were included in this prospective study. They underwent radiography, MRI at 3T (conventional T1-weighted and fat-suppressed T2-weighted imaging, and ZTE imaging), and CT of the bilateral hand and wrist on within 2weeks. MRI evaluation was performed according to the Outcome Measures in Rheumatology Clinical Trials (OMERACT) recommendations. Two certificated radiologists evaluated the images from the three imaging modalities. Bone erosion on images was independently reviewed by the 2 certificated radiologists with a four-point scale (0; normal, 1; discrete erosion, 2; less than 50% of the joint surface, 3; more than 50% of the joint surface). The images were evaluated for bone erosion in 25 sites in each finger and wrist, including the distal radius, the distal ulna, the 8 carpal bones, the first through fifth bases of metacarpal bones, and the proximal and distal aspects of first through fifth metacarpophalangeal joints. One experienced musculoskeletal radiologist performed the CT evaluation and set the findings as gold standard.

##### RESULTS

With CT as the reference method for bone erosions, the sensitivity and specificity of plain radiography, conventional MRI, and ZTE were 51.6/95.3%, 71.1/90.4%, and 93.8/96.3%, respectively. Overall diagnostic performance was significantly better at ZTE than at radiography and conventional MRI images (P<.01). Interobserver agreement on bone erosion assessment was excellent for ZTE imaging (? value of 0.815) but was not excellent for radiography (? value of 0.496) and conventional MRI (? value of 0.648).

##### CONCLUSION

s Zero time-to-echo imaging can provide reliable bone erosion assessment in RA patients.

##### CLINICAL RELEVANCE/APPLICATION

Zero time-to-echo imaging is superior to plain radiography and almost comparable to CT for the detection of bone erosion in RA patients. It can be readily incorporated into the clinical workflow in addition to conventional MRI.

### **53A-SPMK-3 Ultra-high-resolution Photon-counting Detector CT Arthrography of the Ankle: A Feasibility Study**

Participants

Karsten Luetkens, MD, Wuerzburg, Germany (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Assessing the stability of chondral lesions represents a crucial diagnostic imaging task in musculoskeletal imaging, as chondral delamination and subchondral pathologies may not be visible in direct arthroscopy but impact therapeutic concepts. This study was designed to investigate the image quality of ultra-high-resolution ankle arthrography employing photon-counting detector CT.

#### **METHODS AND MATERIALS**

A board-certified radiologist with nine years of experience in musculoskeletal imaging performed bilateral ankle arthrographies in all four cadaveric specimens using ultrasound for guidance. Bilateral arthrograms were acquired in four cadaveric specimens with full-dose (10 mGy) and low-dose (3 mGy) scan protocols. Three convolution kernels with different spatial frequencies were utilized for image reconstruction (750; Br98: 39.0, Br84: 22.6, Br76: 16.5 lp/cm). Seven radiologists subjectively assessed image quality regarding the depiction of bone, hyaline cartilage, and ligaments. Additional quantitative assessment comprised the measurement of noise and computation of contrast-to-noise ratios (CNR).

#### **RESULTS**

While optimal depiction of bone tissue was achieved with the ultra-sharp Br98 kernel ( $p=0.043$ ), visualization of cartilage improved with lower modulation transfer functions at each dose level ( $p=0.014$ ). Interrater reliability was good to excellent for all assessed tissues (intraclass correlation coefficient = 0.805). Noise levels in subcutaneous fat decreased with reduced spatial frequency ( $p<0.001$ ). Notably, low-dose Br76 matched CNR of full-dose Br84 ( $p>0.999$ ) and superseded Br98 ( $p<0.001$ ) in all tissues. No dose-dependent difference was ascertained for any of the tissues with Br98 ( $p > 0.999$ ).

#### **CONCLUSION**

Based on the reported results, photon-counting detector CT arthrography of the ankle with ultra-high-resolution collimation offers stellar image quality and tissue assessability. While bone depiction was found to be superior in combination with an ultra-sharp convolution kernel, soft tissue evaluation benefited from employing lower spatial frequency.

#### **CLINICAL RELEVANCE/APPLICATION**

Photon-counting detector CT arthrography is feasible and allows for depicting even minute anatomy at low radiation dose. The inherent advantages regarding imaging of thin layers of hyaline cartilage ought to be pursued further.

### **53A-SPMK-4 Injury of Anterior Talofibular Ligament in Ankle Based on Ultrafast Synchronized KV/mA Switching Dual Energy CT**

Participants

Jialiang Guo, Guangzhou, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

In this study, the feasibility of diagnosing anterior talofibular ligament (ATFL) injury was explored in both ankle joints using ultrafast synchronized KV/mA switching dual energy CT (DECT), in combination with images of both the non-traumatic sides and the affected sides.

#### **METHODS AND MATERIALS**

Consecutive 41 patients with acute ankle sprain (inversion type) who underwent bilateral ankles scan using DECT (Revolution APEX CT, GE). Axial virtual monochromatic imaging (VMI) at 60 keV with slice thickness of 0.625 mm and water (HAP) image based on material decomposition were reconstructed. The width of ATFL on 60 keV image and the water density of the ligament area on the water (HAP) image in both the healthy and affected ankles were measured respectively. Two radiologists independently evaluated the presence of soft tissue edema around the ATFL and diagnosed the ligament injury finally. Differences between two groups were tested using the Kruskal-Wallis test, and inter-reader agreement was assessed using the Kappa test.

#### **RESULTS**

The width of the ATFL ( $2.2\pm 0.2$ mm) and the water density ( $1025.5\pm 8.3$  mg/cm<sup>3</sup>) were significantly lower on the healthy side compared to the affected side ( $3.5\pm 1.1$ mm,  $1038.6\pm 9.6$  mg/cm<sup>3</sup>, all  $P<0.05$ ). Edema around the ATFL was observed for all patients on the affected side but not on the healthy side. The inter-reader agreement between the two radiologists was very strong ( $K = 0.9$ ).

#### **CONCLUSION**

In ankle DECT imaging, the diagnosis of ATFL injury is reliable by comparing the width of ligament between the healthy side and the affected side, combining the water (HAP) image to evaluate the water density in the ligament area, and subjectively evaluating the edema around ATFL.

#### **CLINICAL RELEVANCE/APPLICATION**

Under virtual monochromatic imaging (VMI) at 60 keV, in combination with a water (HAP) image based on material decomposition in dual energy CT, can accurately diagnose ATFL injuries by comparing the healthy side and the affected side. This provides a feasible imaging technique for patients with ankle ligament injuries who are not suitable for MRI examinations.

### **53A-SPMK-5 A Comparative Study Based on Ultrafast Synchronized KV/mA Switching Dual Energy CT and MRI: Grading of Injuries to the Anterior Talofibular Ligament in Ankle**

Participants

Jialiang Guo, Guangzhou, China (*Presenter*) Nothing to Disclose

## **PURPOSE**

To investigate the diagnosis of anterior talofibular ligament (ATFL) injury using ultrafast synchronized KV/mA switching dual energy CT (DECT) and to evaluate its consistency with MRI grading.

## **METHODS AND MATERIALS**

Consecutive 41 patients with acute ankle sprain (inversion type) who underwent bilateral ankles scan using DECT (Revolution APEX CT, GE). axial virtual monochromatic image (VMI) at 60 keV with slice thickness of 0.625 mm and material decomposition image (water/HAP) were reconstructed. The MRI (Proton Density Weighted Spectral Attenuated Inversion Recovery, PDW SPAIR) scans were performed on the traumatic ankle joint within two weeks. The width of the injured ATFL was measured on both MRI and VMI images, and the continuity of the ligament and the edema around the ligament were evaluated subjectively. Two radiologists independently evaluated the images and provided grading diagnosis of ATFL injury, and the consistency of DECT and MRI diagnostic grading was assessed using the Kappa test. Paired-sample t-test was used to compare the width of ATFL between DECT and MRI.

## **RESULTS**

There was no significant difference in the measured widths of ATFL grade I, II, and III injuries measured on DECT and MRI axial PDW SPAIR images (grade I, II, and III, CT:  $2.2\pm 0.2\text{mm}$ ,  $3.9\pm 0.6\text{mm}$ ,  $5.1\pm 0.6\text{mm}$ ; MRI:  $2.3\pm 0.2\text{mm}$ ,  $3.9\pm 0.6\text{mm}$ ,  $5.1\pm 0.6\text{mm}$ , all  $P > 0.05$ ). The edema within and around the ATFL on the traumatic side can be found in water (HAP) images. In the subjective evaluation of ligament continuity, the agreement between two radiologists is strong ( $K = 0.63$ ). Two radiologists had strong/very strong agreement between the CT diagnostic grading and MRI grading of ATFL injuries ( $K=0.92$ ,  $K=0.78$ ).

## **CONCLUSION**

In ankle DECT imaging, grading of ATFL injuries could be performed through the application of VMI image at 60 keV, combined with measurement of the width of ATFL, edema within and around the ligament, and ATFL continuity, which has a good consistency with MRI, providing the possibility of grading ATFL lesions on CT scans.

## **CLINICAL RELEVANCE/APPLICATION**

Under the condition of VMI imaging at 60 keV, ankle DECT can be used to properly grade ATFL injury by measuring ligament width and subjectively evaluating periligamentous edema and ATFL continuity. This approach showed a good consistency with MRI grading and provided an innovative imaging technique for ankle sprain patients who may not be suitable for MRI scans.

## **S3A-SPMK-6 Frequency of Peroneal Compartment Pathology in a Large Series of Ankle MRIs from a Tertiary Care County US Hospital: Imaging-based Epidemiological Study**

### **PURPOSE**

Peroneal compartment pathology is a frequently misdiagnosed finding or underdiagnosed as simple ankle ligament sprains in patients presenting to the healthcare system with ankle injuries. High-resolution magnetic resonance imaging allows timely identification of these injuries for outlining appropriate treatment. However, these lesions have been studied in only a few small case series, convenient samples, or review articles. The aim of this study was to elucidate the frequency of peroneal compartment pathology in a large series of patients presenting for ankle MRIs with ankle pain and/or injury in our tertiary care county system with the hypothesis that peroneal lesions are a frequent finding.

### **METHODS AND MATERIALS**

A consecutive series of 373 patients with suspected ankle internal derangement at a tertiary care county hospital (ages 13-87 years, all genders) were included. All had undergone 3 Tesla ankle MR imaging with standardized institutional MR imaging protocols. The structured reports were data-mined, and all scans were re-reviewed by a fellowship-trained musculoskeletal radiologist. Any scans performed for tumors or infections were excluded. The scans were re-analyzed for peroneal longus (PL) and peroneal brevis (PB) tenosynovitis and tendinopathy using previously described criteria for pathology in the literature. Descriptive statistics were performed.

### **RESULTS**

There were 404 MRIs from 373 patients, with 292 MRIs (72.3%) from 267 females and 112 MRIs (27.7%) from 106 males. Only 98 (24.3%) MRIs had normal peroneal compartments, and 306 MRIs (75.7%) had ankles with peroneal findings. There were 51 (12.6%) cases of PB tenosynovitis, 57 (14.1%) cases of PL tenosynovitis, 148 (36.6%) cases of PB tendinopathy, 239 (59.2%) cases of PL tendinopathy, 95 (23.5%) partial PB tendon tears, 8 (2.0%) partial PL tendon tears, 2 (0.5%) complete PB tendon tears, and 1 (0.2%) complete PL tendon tear. Peroneal longus tendinopathy was the most common finding.

### **CONCLUSION**

Peroneal compartment pathology is frequent on high-resolution 3T ankle MRIs performed for internal derangements.

### **CLINICAL RELEVANCE/APPLICATION**

The ankle MRI reader should pay close attention to peroneal compartment lesions while evaluating for ankle derangement, as these lesions are frequent.

## **S3A-SPMK-7 Clinical Application of a Deep Learning Model for Osteoporosis Screening using Chest X-rays Taken During Lung Cancer Screening**

### **PURPOSE**

The number of patients suffering from age-related osteoporosis is increasing worldwide. In Japan, osteoporosis screening is conducted in municipalities throughout the country for early detection and treatment, but the screening uptake rate remains at around 5%. To address this issue, we developed a deep learning model to test for osteoporosis from chest X-rays as a new screening method. In Japan, approximately 40 million people undergo lung cancer screening annually, which includes chest X-rays. We focused on this point and conducted a demonstration experiment, believing that it would be possible to screen a large number of citizens for osteoporosis by simultaneously assessing osteoporosis using chest X-rays taken during lung cancer screening.

## **METHODS AND MATERIALS**

The demonstration was conducted in a medium-sized city in Japan with a population of 80,000 from Apr 2022 to Apr 2023. In this city, a medical association was contracted by the local government to conduct lung cancer screening. The examinees had chest X-rays taken at 25 clinics in the city. The chest X-rays are then sent to the medical association's health checkup center for secondary reading. We installed an AI algorithm at the center and performed AI analysis on the chest X-rays of the examinees who had given their consent in advance. The examinees who were found to be in need of further examination (YAM<80%) visited an orthopedic hospital in the city and underwent a bone density test using the DEXA method. Based on the examination and test results, medication was started for those examinees who needed therapeutic intervention. The study obtained the number of people who underwent lung cancer screening, the number of people who consented to AI analysis, the number of people who required inspection, the number of people who visited orthopaedic clinics, and the number of people diagnosed and treated for osteoporosis.

## **RESULTS**

5,290 patients underwent lung cancer screening. Of these, 3,324 patients consented to AI analysis, excluding those already undergoing osteoporosis treatment. Of these, 1,848 patients required further examination. After examination and DEXA, 497 patients were diagnosed with osteoporosis, and treatment was initiated.

## **CONCLUSION**

s The study suggested the usefulness of screening for osteoporosis using chest X-rays taken during lung cancer screening.

## **CLINICAL RELEVANCE/APPLICATION**

The conventional osteoporosis screening examined 185 individuals yearly. By utilizing chest radiographs for screening, 3,324 people could be screened, roughly 18 times more. This method detected about 497 osteoporosis patients, enabling treatment initiation. It's estimated that this approach could prevent 16 hip fractures and reduce medical and nursing care costs by about 29 million yen.

## **S3A-SPMK-8 Application of a Deep Learning Algorithm in Detection of Hardware Complications for the Post-Operative Hip**

Participants

Jin Rong Tan, MD, FRCR, Singapore, Singapore (*Presenter*) Nothing to Disclose

## **PURPOSE**

The most common mechanical failure in the internal fixation of trochanteric hip fractures is the cutout of the sliding screw through the femoral head, with the incidence ranging from 0 to 16.5%. Radiography remains the mainstay for evaluation, both in the immediate postoperative period and at long-term follow-up. The clinical and radiological progression of hardware complications including cutout is often insidious, and can be missed especially in limited resource settings. There is relatively limited literature on the application of deep learning to assess hardware complications on radiographs. Hence, we aim to evaluate the performance of a deep convolutional neural network (DCNN) in detecting and localising implant cutout on plain frontal pelvic radiographs.

## **METHODS AND MATERIALS**

A DCNN was developed using 32,152 pelvic radiographs containing fixation hardware acquired from the emergency department and orthopaedic clinics between January 2016 and December 2020, of which 24,114 and 8,038 were allocated for training (75%) and validation (25%) sets respectively. Presence of cutout was defined as protrusion of the fixation hardware beyond the cortical margins. To determine ground truth labels (cutout present or absent), all radiographs were individually read by 2 board-certified consultant musculoskeletal subspecialty radiologists blinded to the accompanying radiology reports. In doubtful cases, the accompanying report and all imaging performed in the following 6 months were reviewed. Final decision was made by consensus between the 2 musculoskeletal radiologists. Algorithm performance was evaluated with a hold-out test dataset of 8,039 radiographs of which 53 (0.66%) were positive for cutout. The authors also used the visualization algorithm gradient-weighted class activation mapping (Grad-CAM) to assess localization accuracy.

## **RESULTS**

The algorithm achieved an accuracy of 99.5%, a sensitivity of 83%, a specificity of 99.6%, and an AUC of 0.992 for identifying implant cutout. The visualization algorithm showed an accuracy of 25%. Of the 44 true positive cases accurately predicted, there were 11 (25%) instances where the model correctly identified an activation site.

## **CONCLUSION**

s A DCNN can detect implant cutout on PXR with a high accuracy and might assist clinicians to assess the presence of post-operative hardware complications including implant cutout. However, the visualization algorithm is unable to accurately localize the site of cutout; this is work in progress at time of abstract submission

## **CLINICAL RELEVANCE/APPLICATION**

A DCNN can detect implant cutout on PXR with a high accuracy and might assist clinicians to assess the presence of post-operative hardware complications including implant cutout.

S3A-SPMS

### Multisystem Sunday Poster Discussions I

#### Sub-Events

#### S3A-SPMS-1 Metabolic Outcomes of Aging and Obesity: A Longitudinal Study of the Dallas Heart Study Cohort

#### PURPOSE

This study aims to examine the metabolic risk factors in the longitudinal Dallas Heart Study (DHS) cohort. The baseline exam (DHS1) was conducted in 1999-2000, and the current 3rd phase exam (DHS3) has been enrolling since 2020.

#### METHODS AND MATERIALS

Subjects underwent a multi-2D axial T2-weighted spin-echo abdominal MRI (10mm axial section) in DHS1 on Philips 1.5T Intera at the baseline exam and a 3D volumetric T1-weighted gradient-echo whole-body MRI (5mm axial section) in DHS3 on Siemens 3T Prisma. Based on the DHS1 data, manual fat segmentation was previously completed on a single slice at L2-L3 measuring subcutaneous (SAT) and visceral (VAT) cross-sectional areas. On the DHS3 images, fat segmentations were performed on the same slice location corresponding with the subject's DHS1 segmentation. Changes in the segmented SAT and VAT areas between DHS1 and DHS3 were calculated. Subjects' height, weight, and serum laboratory values (lipids, cholesterol, glucose, and insulin) were collected for DHS1 and -3 exams, from which metabolic syndrome (MetS) risk factors were recorded (waist circumference  $\geq 88$ in for women,  $\geq 102$ in for men; blood pressure  $\geq 130/85$ ; LDL  $\geq 130$ ; HDL  $\leq 50$  for women,  $\leq 40$  for men; total cholesterol  $\geq 200$ ; triglycerides  $\geq 150$ ; fasting glucose  $\geq 100$ ; HOMA-IR  $\geq 2.73$ ) for both time points, and metabolic health was categorized as unhealthy ( $\geq 3$  risk factors) or healthy ( $\leq 3$  risk factors). The association between metabolic health and abdominal adiposity (SAT and VAT) was assessed using logistic regression, adjusting for age and sex as covariates.

#### RESULTS

192 subjects from the original DHS1 cohort have thus far returned for DHS3 examination. The median age of this interim cohort is 64 years (43 years at baseline). Over the 21 years, the median weight gain was  $+3.2$  [interquartile range,  $-3.3, +9.3$ ]kg, BMI gain  $+1.3$  [ $-0.6, +3.6$ ]kg/m<sup>2</sup>, SAT change  $+82$  [18, 154]cm<sup>2</sup>, VAT change  $+33$  [ $-9, +69$ ]cm<sup>2</sup>. The prevalence of MetS increased from 53.6% to 63.3%, with 53.9% of previously metabolically healthy subjects becoming metabolically unhealthy in the interim, whereas 29.1% of previously metabolically unhealthy subjects became metabolically healthy. After adjustment for age and sex, VAT, but not SAT, was consistently associated with MetS over 20 years of aging. Gain in VAT was also associated with interval development of MetS in previously metabolically healthy subjects.

#### CONCLUSION

Visceral fat, rather than subcutaneous fat, is consistently associated with MetS through aging, and the gain in visceral fat is associated with the development of MetS.

#### CLINICAL RELEVANCE/APPLICATION

Our preliminary finding in this 20-year longitudinal cohort further strengthens the evidence that visceral fat is implicated in metabolic health.

S3A-SPNMMI

### Nuclear Medicine & Molecular Imaging Sunday Poster Discussions I

#### Sub-Events

#### S3A-SPNMMI-1 **18F-fallypride: a Valuable Agent for Islet Cell-targeted Imaging**

##### PURPOSE

To evaluate the usefulness of the dopamine D2 receptor imaging agent (S)-(-)-N-(1-allylpyrrolidine-2-N-methyl)-5-(3-18F)-2,3-dimethoxy Benzamide (18F-Fallypride) for islet cell targeted imaging.

##### METHODS AND MATERIALS

First, we investigated the effect of different concentrations of the dopamine inhibitor droperidol on the binding of islet cells to 18F-Fallypride. We calculated the cellular uptake by incubating islet cells ( $1.5 \times 10^4$  cells/well) with 18F-Fallypride (3.70 KBq). The rate of 18F-Fallypride uptake rate in six groups of islet cells treated with different concentrations of droperidol was measured, and the 18F-Fallypride uptake by the cells in relation to the inhibitor concentration was plotted. To further investigate the binding of 18F-Fallypride to islet cells in vivo, six groups (A-F) of mice were set up. Group A served as the control while groups B-F were injected with different concentrations of 18F-Fallypride 30 minutes before intravenous injection. After observation for 10 minutes, the pancreas was dissected and sectioned for autoradiography. Lastly, the gray scale of the pancreatic tissue was evaluated and quantified. The overall comparisons among all groups were done using single factor analysis of variance and comparisons among groups were done using the least significant difference test.

##### RESULTS

(1) The 18F-fallypride was  $18.4 \pm 1.21\%$ . The uptake rates of inhibiting groups were  $16.11 \pm 1.37\%$ ,  $15.76 \pm 0.99\%$ ,  $13.9 \pm 1.02\%$ ,  $8.86 \pm 0.73\%$ ,  $7.26 \pm 0.62\%$  and  $6.92 \pm 0.58\%$ , respectively. When the concentration of droperidol was  $1.0 \times 10^{-4}$  mol/L, the 18F-fallypride uptake rate of islet cells was the lowest, and the inhibiting rate was 51.85%. No significant difference was detected in uptake rates for the  $5 \times 10^{-4}$  mol/L compared to  $1.0 \times 10^{-3}$  mol/L droperidol groups ( $P=0.11$  and  $0.06$ ). (2) The autoradiography showed that the pancreas gray value of group A was  $1.21 \times 10^6$  (DLU/mm<sup>2</sup>). The pancreas gray levels of groups B to F were  $0.93 \times 10^6$  (DLU/mm<sup>2</sup>),  $0.77 \times 10^6$  (DLU/mm<sup>2</sup>),  $0.59 \times 10^6$  (DLU/mm<sup>2</sup>),  $0.32 \times 10^6$  (DLU/mm<sup>2</sup>) and  $0.25 \times 10^6$  (DLU/mm<sup>2</sup>), respectively, which decreased with increasing concentration of the inhibitor.

##### CONCLUSION

18F-fallypride specifically and efficiently binds to dopamine receptors on islet cells, and therefore presents as a promising novel radiotracer for islet cells imaging.

##### CLINICAL RELEVANCE/APPLICATION

Islet cell dysfunction and depletion often predispose patients to diabetes mellitus. The development of highly specific with satisfactory visibility in vivo imaging agent can be used for pancreatic islet cells is still a huge challenge due to the small number and scattered patterns of islets (only 1%-2% by volume of the pancreas)

#### S3A-SPNMMI-2 **Clinical Impact of Digital PET/CT Compared to Conventional PET/CT in Patients with Malignant Tumor for Initial Staging**

Participants

Naoto Kawaguchi, MD, Toon, Japan (Presenter) Nothing to Disclose

##### PURPOSE

Digital PET/CT (dPET) systems have improved the detection of small lesions by increasing spatial and temporal resolution and have the potential to allow for accurate staging in patients with malignant tumor. The purpose of this study is to compare 18F-fluorodeoxyglucose (FDG) uptake of lesions and the diagnostic performance for initial disease staging of the dPET with conventional PET/CT (cPET).

##### METHODS AND MATERIALS

Between April and August 2020, 60 patients (mean age,  $66 \pm 13$  years; 31 males) with malignant tumors underwent a single FDG injection and both dPET and conventional cPET with a randomized scan order. We measured the maximum standardized uptake values (SUV<sub>max</sub>) in up to 5 FDG-positive lesions per patients and compared them between the two scanners. Furthermore, two experienced readers independently diagnosed the initial disease staging using the TNM score (The eighth edition of the Union for International Cancer Control) or Lugano classification on both PET imaging. Cases of inconsistency between the two readers were finally determined by the third experienced reader. The final staging results for the two PET modalities were compared with the pathological diagnosis. The institutional ethics committee approved this study protocol in accordance with the ethical guidelines of the Declaration of Helsinki, and all patients provided informed consent.

##### RESULTS

One hundred and twenty-three lesions were analyzed. 14 lesions could only be measured only with dPET. In the remaining 109

lesions, SUVmax was significantly higher on the dPET compared to the cPET ( $12.0 \pm 7.8$  vs.  $8.5 \pm 7.0$ ,  $p < 0.01$ ). Especially in 36 lesions less than 10 mm in diameter, the SUVmax with the dPET was higher in all lesions. 8 of the 60 cases showed differences in staging between the two PET modalities. dPET detected new lymph node metastases in five cases and bone metastasis in one case compared to cPET, four were true positives and two were false positives. Otherwise, the N-factor was changed in two cases on dPET compared to cPET, but one was true negative, and one could not be judged pathologically.

#### **CONCLUSION**

Our study showed that the dPET can better detect small lesions compared to cPET. dPET can have an impact on the diagnosis of metastasis in the initial staging of malignant tumor compared to cPET.

#### **CLINICAL RELEVANCE/APPLICATION**

New digital PET/CT can have a big impact on the diagnosis of metastasis in the initial staging of malignant tumor.

S3A-SPNPM

### Noninterpretive Skills (Beyond Imaging) Sunday Poster Discussions I

#### Sub-Events

#### S3A-SPNPM-Increasing Cost-effectiveness of CT-based Mobile Stroke Units in Germany: A Model-based Economic Analysis<sup>1</sup>

##### PURPOSE

To analyze the design of Computed Tomography (CT) based Mobile Stroke Unit (MSU) programs and operating modes in order to identify major determinants and cut-offs that help improve cost-effectiveness and enable large-scale implementation of MSUs.

##### METHODS AND MATERIALS

Costs of different possible operating modes, varying operating hours including weekend and non-weekend coverage, and personnel were simulated for the German healthcare system. Ischemic stroke incidence, circadian distribution, rates of alternative diagnoses and stroke mimics were included as well as missed cases to model case coverage and patient-level costs in acute stroke care. Based on internationally reported stroke outcomes, a 5-year Markov-Model was used to analyze cost-effectiveness outcomes for varying catchment zone populations.

##### RESULTS

For a catchment zone of 400,000 inhabitants, the 7-day/16-hour MSU coverage resulted in the lowest cost of MSU deployment per ischemic stroke (USD 5,667) whereas the 7-day/24-hour model caused the highest costs (USD 8,285). Comparing stroke care delivered by MSU to regular emergency medical services, MSU achieved an incremental 0.06 quality-adjusted life years (QALY) on average, with an incremental cost-effectiveness ratio of USD 37,348 per QALY. Sensitivity analyses revealed that a catchment zone population below 400,000 inhabitants together with the effect of missing stroke cases at dispatch significantly increased patient-level costs of MSU care.

##### CONCLUSION

When setting up prospective MSU programs, cost-effectiveness can be addressed by taking into account major determinants of MSU operation: For the German healthcare system, the catchment zone should cover at least 400,000 inhabitants and operating modes should include weekend coverage and 12 to 16 hour daytime coverage. Measures to reduce the rate of missed strokes are advised.

##### CLINICAL RELEVANCE/APPLICATION

The economic evaluation of MSU programs aiming at identifying major determinants and thresholds could optimize efficient resource allocation and maximize MSU cost-effectiveness.

#### S3A-SPNPM-Economic Impact in the MRI Department using Artificial Intelligence in MRI Acquisitions<sup>2</sup>

##### Participants

Patricia M. Carrascosa, PhD, Buenos Aires City, Argentina (*Presenter*) Speakers Bureau, General Electric Company

##### PURPOSE

The objective of this work is to project the economic impact of the use of Artificial Intelligence (AI) in an MRI scanner of our institution that has a high demand of scheduled studies between 8 AM to 8 PM. We previously performed an optimization of protocols and validated the new algorithm with AI in terms of image quality and diagnostic accuracy versus conventional studies determining the new time duration of the studies.

##### METHODS AND MATERIALS

During one month we worked with AI system (AIR Recon DL, GE) in two 3T MRI scanners (Signa Architect; GE) in order to obtain the best sequences in terms of image quality, signal to noise and time duration of the studies. After finishing that phase we performed a research comparing the new length time for the sequences and agenda times for each study type, image quality and diagnostic accuracy between two experienced observers to analyzed AI and conventional studies of the same patient respectively. Results have shown no differences regarding diagnosis and image quality but with a significant reduction in scanning times. With that information we will project the economic impact of using AI system in the two scanners per month. The time reduction of the studies varied according to the region. We calculated according to the normal distribution of studies the total minutes regarding each type, we projected the new duration time applying AI, the gained difference in minutes and the additional studies that could be carried out. We calculated the increment in the percentage regarding the number of studies performed in the same time range and also in relation to the total number of patients.

##### RESULTS

The most required studies at our centers were selected for the projection (knee, spine and brain MRI scans). Both scanning times and the assigned agenda time were reduced significantly using AI. The mean scan time without AI technology was 10.3 minutes, while using AI technology was 5.7 minutes. The mean assigned agenda time without AI technology was 16.6 minutes, while using AI

technology was 10 minutes. The time reduction in the projected studies allowed to be able to perform a 638,5 more studies in both scanners in the same time that only 1111 were done. This corresponds to an increment of 57,64%. The global impact regarding the total scanners production would be a 36,6%.

## **CONCLUSION**

s AI in MR is an excellent opportunity to increment the number of studies in centers with high demand and delayed accessibility. In this projection selecting only the more frequent studies required we could project an increment of 35 % in our monthly billing.

## **CLINICAL RELEVANCE/APPLICATION**

Artificial intelligence in MRI scan opens new horizons in terms of image quality, patients experience and cost effectiveness of the MRI department

## **S3A-SPNPM-Testing the Ability of ChatGPT to Generate Differential Diagnoses from Transcribed Radiological Findings in Chest and Cardiac Imaging**

Participants

Shawn Sun, MD, MS, Anaheim, CA (*Presenter*) Nothing to Disclose

## **PURPOSE**

To assess the accuracy and reliability of ChatGPT3.5 and ChatGPT4 in producing a differential diagnosis from transcribed radiological findings of specific chest and cardiac radiology cases.

## **METHODS AND MATERIALS**

A sample of 52 cases from adult and pediatric chest and cardiac imaging were evaluated. Cases were selected from a radiology textbook, from which the answers were used as the gold standard. The case images and history were converted into standardized prompts that contained purely descriptive language of the cases and a query for the most likely diagnosis, top three differential diagnoses, and the corresponding explanations and references from the medical literature. These prompts were fed into the ChatGPT3.5 and ChatGPT4 algorithms. Generated responses were analyzed for accuracy by comparison with the original literature and reliability through manual verification of the generated explanations and citations. The top 1 accuracy and the top 3 accuracy were defined as the percentage of generated responses that matched the original diagnosis and the complete differential provided by the original literature. An additional differential diagnosis score was defined as the proportion of differentials that matched the original literature's answers for each case. Comparisons were made between the results of the two algorithms using a one-tailed two proportion z-test method.

## **RESULTS**

The top 1 accuracy and top 3 accuracy, for ChatGPT3.5 versus ChatGPT4 were 57.7% compared to 69.2% ( $p=0.11$ ) and 11.5% compared to 15.4% ( $p=0.28$ ), respectively. The average differential diagnosis score of ChatGPT3.5 versus ChatGPT4 was 48.1% compared to 55.8% ( $p=0.21$ ). ChatGPT3.5 and ChatGPT4 hallucinated 34.2% versus 9.6% ( $p=0.001$ ) of the references provided and generated 10 total false statements versus 4 total false statements, respectively.

## **CONCLUSION**

s The two generations of ChatGPT were able to generate a differential diagnosis for prompts containing descriptive radiological findings. The contents of these responses matched the expert literature from which the cases originated a minority of the time, though a non-statistically significant improvement was made in the accuracy categories from 3.5 to the 4th generation algorithm. The well-known hallucination effect was encountered more commonly in citations produced than in statements made by the algorithm, both of which improved with the newest generation.

## **CLINICAL RELEVANCE/APPLICATION**

ChatGPT and Large Language Models (LLM) have a large potential to impact clinical and educational medicine. Knowledge of the accuracy and erroneous possibilities of these algorithms will provide a better understanding of the limitations of these new tools.

Printed on: 04/12/24

S3A-SPNR

### Neuroradiology Sunday Poster Discussions I

#### Sub-Events

#### **S3A-SPNR-1 Causal Associations of Genetically Determined Tinnitus with Neuroimaging Traits: Evidence from a Mendelian Randomization Study**

##### Participants

Jing Sun, MD, Beijing, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Potential reverse causality and unmeasured confounding factors are common biases in previous studies of the relationship between tinnitus and neuroanatomical features. Additionally, the causal association between neuroimaging features and the presence of tinnitus is unclear. The aim of this study was to investigate the causal role of tinnitus in the alteration of brain volumetric measures using Mendelian randomization (MR).

##### METHODS AND MATERIALS

Summary-level data from a genome-wide association study (GWAS) of tinnitus were derived from the UK Biobank ( $n = 117,882$ ). GWAS summary statistics for total brain volume, white and gray matter volume and cerebrospinal fluid volume were also obtained ( $n = 33,224$ ). A bidirectional MR analysis was performed to investigate the causal relationship between tinnitus and neuroanatomical features.

##### RESULTS

Genetic susceptibility to tinnitus was causally associated with increased white matter volume (odds ratio [OR] = 2.36, 95% confidence interval [CI] 1.03-5.39,  $p = 0.04$ ) and total brain volume (OR = 2.39, 95% CI 1.05-5.46,  $p = 0.04$ ) but inversely associated with cerebrospinal fluid volume (OR = 0.36, 95% CI 0.16-0.83,  $p = 0.02$ ). However, no causal effect of total brain volume, white matter volume, gray matter volume, or cerebrospinal fluid volume on the presence of tinnitus was detected in the reverse MR study.

##### CONCLUSION

The genetically predicted risk of tinnitus was causally associated with higher white matter volume and total brain volume, independent of any confounding factors, while neuroanatomical features were not causally associated with the presence of tinnitus. Our findings provide evidence supporting the hypothesis that tinnitus has a neurodevelopmental origin at the genetic level.

##### CLINICAL RELEVANCE/APPLICATION

Our findings provide evidence supporting the hypothesis that tinnitus has a neurodevelopmental origin at the genetic level, further elucidating the underlying pathophysiological mechanisms of tinnitus-related brain anatomical impairment.

#### **S3A-SPNR-10 Improving Image Quality of Skull Base with Volume High Definition Reconstruction in a Wide-detector CT System**

##### Participants

Yanan Zhu, Ankang, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the image quality improvement for the skull base with a volume high definition (VHD) reconstruction algorithm on a 16cm wide-detector 256-row CT.

##### METHODS AND MATERIALS

Prospectively enrolled 40 adults (Group 1) for non-enhanced head CT on a 16cm wide-detector 256-row Revolution CT scanner. The CT numbers and their standard deviation (SD) of Medulla Oblongata, cerebellum, brain stem, basal frontal lobe and centrum ovale (used as background) were measured to calculate signal to noise ratio (SNR) and artifact index (AI):  $AI = \sqrt{SD2(ROI) - SD2(\text{centrum ovale})}$ . These values were compared with those of 40 adults in Group 2 who underwent a non-enhanced head CT on a 64-row VCT. All subjects were scanned with a protocol of 120 kVp, and 1.0s rotation time. The tube currents were adjusted to have similar CT dose index (CTDI) for the two systems.

##### RESULTS

There was no statistical difference in the age, thickness of occipital tuberosity, anteroposterior or trans diameters between the two groups. Compared with 64-row CT, the image noise (in HU) with the 256-row CT was reduced by 27% ( $4.39 \pm 0.68$  vs.  $6.00 \pm 1.10$ ) at the Medulla Oblongata, 24% ( $4.48 \pm 0.51$  vs.  $5.86 \pm 0.57$ ) at cerebellum, 33% ( $4.14 \pm 0.51$  vs.  $6.17 \pm 0.74$ ) at brain stem, 39% ( $3.84 \pm 0.58$  vs.  $6.30 \pm 1.19$ ) at the basal frontal lobe and 28% ( $3.16 \pm 0.37$  vs.  $4.36 \pm 0.42$ ) at centrum ovale. This resulted in an increase of 43%, 42%, 76% and 65% in SNR in the four regions, respectively. In addition, the artifacts index was significantly reduced with 256-row CT by 25% ( $2.95 \pm 0.95$  vs.  $3.93 \pm 1.61$ ) at Medulla Oblongata, 20% ( $3.05 \pm 0.93$  vs.  $3.83 \pm 0.88$ ) at cerebellum,

40% (2.54±0.92 vs. 4.26±1.14) at brain stem, and 54% (2.00±1.14 vs. 4.33±1.83) at the basal frontal lobe.

## CONCLUSION

s The CT image quality of the skull base in terms of noise and artifacts was significantly improved on a 256-row wide-detector CT with VHD reconstruction algorithm, compared with a 64-row system at similar radiation dose.

## CLINICAL RELEVANCE/APPLICATION

Improved images of the skull base can be obtained on a wide-detector CT with VHD to overcome physical challenges such as cone beam and scattering, when keeping similar dose to 64-row CT.

## S3A-SPNR-11 Geniculate Ganglion Diverticulum: A Novel MRI Finding in Patient with Idiopathic Intracranial Hypertension

Participants

Ahmed Abdelmonem, MD, MBBS, Woodbridge, VA (*Presenter*) Nothing to Disclose

## PURPOSE

While patients with idiopathic intracranial hypertension (IIH) typically present with headache and/or visual disturbance, pulse-synchronous tinnitus (PST) and hearing loss can be the primary manifestations of this condition in a group of patients. The correct diagnosis for this group can be delayed. Although several MRI signs have been previously described to be associated with IIH, none have been proven to have a high positive predictive value (PPV). In this study, we tested the hypothesis that the presence of the geniculate ganglion diverticulum (GD) is a novel marker for the detection of IIH.

## METHODS AND MATERIALS

This is an IRB-approved single institution retrospective observational study. Brain MRI exams of patients referred by Otolaryngology division over the period of 10 years were reviewed. 400 MRI exams fulfilling inclusion and exclusion criteria were screened for presence of GD by two Neuroradiology fellows independently. In cases of discrepancy in image interpretation, an agreement was reached by reviewing images jointly. A matched control group of cases without GD was compiled. Brain MRI studies of all patients in this study were reviewed for presence of an "empty" sella appearance (ES), a known MRI sign of IIH. Electronic medical records of patients in this study were reviewed for presence of clinical manifestations of IIH. Receiver operator characteristic (ROC) curves were generated to estimate accuracy of each covariate in diagnosing IIH. Area under each ROC curve (AUC) was calculated to identify an accurate prognostic covariate. Statistical analysis was done using R programming language V 4.2.2.

## RESULTS

GD was visualized in MRI exams of 41 patients. GD was not present in the MRI exams of 359 patients. 61 patients were randomly selected from group of 359 patients that did not have GD. A total of 102 patients were included in this study. Studied groups had no significant differences in terms of age, gender, and BMI. GD and ES have a statistically significant correlation with IIH (P-value: < 0.001). There was no correlation between PST and GD (P-value: 0.83). Presence of unilateral or bilateral GD has a similar correlation with IIH (P-value: <0.001). AUC based on GD for predicting IIH was 0.84 (0.79- 0.89) and based on ES was 0.93 (0.89- 0.96). Negative predictive value of both GD and ES for IIH was 100%. PPV of GD for IIH was 31% and this value for ES was 52%.

## CONCLUSION

s There was a statistically significant correlation between the presence of GD and the presence of IIH. There was no statistically significant correlation between the presence of GD and the presence of PST.

## CLINICAL RELEVANCE/APPLICATION

The presence of GD should raise the possibility of IIH, particularly in patients presenting with otologic manifestations such as PST and low-frequency hearing loss.

## S3A-SPNR-12 Development of the Executive Function Networks, Salience and Default Mode Network in Neonates and Assessment of their Interaction with a Machine Learning Framework. A Hypothesis on Von Economo Neurons

## PURPOSE

The Salience network (SN) plays a causal role in switching between the Fronto Parietal Network (FPN) and the Default Mode Network (DMN). The SN plays also a dominant role in the detection of salient stimuli across multiple modalities thus showing overlapping functions and interactions in bottom-up and top-down mechanisms of attention with the Ventral Attention Network (VAN), Dorsal Attention Network (DAN) and Default Mode Network (DMN). Von Economo Neurons (VENs) constitute a preferred route of connection into and from the SN and should, therefore, have a role in the evolution of the connectivity of the SN.

## METHODS AND MATERIALS

In the present study we tested if the SN, FPN, VAN, DAN and DMN connectivity (FC) can infer the gestational age (GA) at birth in a study group of 88 healthy neonates, scanned at 40 weeks of post menstrual age, and with GA at birth ranging from 28 to 40 weeks. We also ascertained whether the FC within each of the SN, FPN, VAN, DAN and DMN was able to infer the average FC of the others. The ability to infer GA at birth or another network's FC was evaluated using a multi-variate data-driven framework.

## RESULTS

The VAN, DAN and the DMN inferred the GA at birth (p<0.05). The SN, FPN, DMN and VAN were able to infer the average FC of the other networks (p<0.05).

## CONCLUSION

s Our findings suggest that it might be too early for the FPN and too late for the SN to predict the GA and the role of the SN as a switch between the FPN and the DMN is not evident in neonates. The functional and structural maturation of the VENs is a critical factor the maturation of the SN, therefore, developmental anomalies of the SN FC may be able to reflect a dysfunction of the VENs.

## CLINICAL RELEVANCE/APPLICATION

Prematurity is a risk factor for both autism and schizophrenia. A lower density of VENs has been demonstrated in both of these pathological conditions. As developmental anomalies of the SN may be able to reflect early dysfunction of the VENs, understanding the pattern of SN's evolution in the newborn lays the foundation for the assessment of its pathological changes.

### S3A-SPNR-13 Treatment Response Prediction in Major Depressive Disorder using Brain Magnetic Resonance Imaging: A Systematic Review and Meta-analysis

#### PURPOSE

To quantify the value of brain magnetic resonance imaging (MRI) in predicting major depressive disorder (MDD) treatment efficacy and to assess performance variations among interventions and biomarkers.

#### METHODS AND MATERIALS

We searched eligible studies in PubMed, Embase, Web of Science, and Science Direct databases before March 22, 2023, using keywords "depress\*", "major depress\*", "MDD", "treatment outcome", "remission", "response", and "MRI". Information including individuals as responders/remitters or non-responders/non-remitters, sensitivity, and specificity were extracted. Logarithm of diagnostic odds ratios [log(DOR)] was summarized, and forest plot was drawn. Sensitivity and specificity were conducted using Reitsma's random effect model. Area under curve (AUC) of summary receiver operating characteristic (SROC) curve was calculated. We conducted Deek's funnel plot asymmetry test to evaluate impact of publication bias. Subgroup analyses were conducted based on MRI modalities (structural MRI [sMRI], resting-state functional MRI [rs-fMRI], task-based fMRI [tb-fMRI]) and interventions (antidepressant and electroconvulsive therapy [ECT]). Antidepressants were subdivided into selective serotonin reuptake inhibitors (SSRI) and mixed medication groups. Meta-regression was conducted among subgroups.

#### RESULTS

We included 44 studies with 2623 MDD participants. Overall, the SROC AUC was 0.875, sensitivity was 77.1%, specificity was 74.1%, and log(DOR) was 2.381. Deek's test indicated a negative correlation between effective sample size and log(DOR) ( $P = 0.008$ ). Rs-fMRI subgroup had higher predictive performance (79.3% sensitivity, 78.2% specificity, AUC 0.891) than tb-fMRI subgroup (74.9% sensitivity, 68.9% specificity, AUC 0.854) in terms of specificity in predicting treatment efficacy ( $P = 0.01$ ). No significant difference was found between sMRI and other modalities. No significant predicting differences were found in antidepressants and ECT, or among ECT, SSRI, and mixed group. Brain biomarkers located in limbic system and frontal were more frequently revealed contributing to prediction in antidepressant subgroup, such as functional connectivity between amygdala and anterior cingulate cortex, while those for ECT were often located in limbic system.

#### CONCLUSION

s Brain MRI has potential to predict MDD treatment efficacy, with rs-fMRI showing higher predictive performance. No significant difference were found between different interventions, but brain biomarkers located in limbic system and frontal lobe may provide clinical relevance.

## CLINICAL RELEVANCE/APPLICATION

Brain MRI biomarkers can predict treatment efficacy of MDD, reducing the financial burden, time of trial, and poor prognosis for patients.

### S3A-SPNR-14 Comparative Analysis of Normative Brain Structural Volumes Between Singapore (SG) and Caucasian Population

#### Participants

Ling Yun Yeow, Singapore, Singapore (*Presenter*) Nothing to Disclose

Chi Long Ho, MD, FRCR, Singapore, Singapore (*Presenter*) Nothing to Disclose

#### PURPOSE

Structural brain volumes vary due to differences in age, gender [males(M), females(F)], geographical location and ethnicity. Currently, MNI is most widely used brain template but it is limited to young/healthy Western population and not representative of other populations. We aim to compare differences between SG Chinese and Caucasian (Cau) brain volumes to address the need for age, gender-and-ethnicity-specific brain templates for accurate stereotactic standardization across structural brains from different individuals. Our aim is also to build a brain volumetry database for SG Chinese population (for now), which is currently lacking in Singapore.

#### METHODS AND MATERIALS

Retrospective T1W MPRAGE brain (N:248) gathered from Parkinson's Progression Markers Initiative (PPMI-Caucasian) database and SG data (N:360) obtained from Sengkang General Hospital. FastSurfer (v2.0.4) used for brain segmentation into 21 regions (some left and right regions combined); brain volumes were normalized using total intracranial volume. Subjects divided into 5 age-groups: 31-40, 41-50, 51-60, 61-70, 71-80 years. If > 2 outliers were present, subjects were removed while the rest of outliers imputed with median (age-and-gender-matched). Wilcoxon tests (Bonferroni corrected) used for comparisons between SG and Cau.

#### RESULTS

In 41-50 age-group, SG(M) have significantly greater cerebral white-matter than Cau(M), but the reversed is true for lateral ventricular volumes, while SG(F) have greater thalamus than Cau(F). SG(M+F) 51-60 age-group have significantly greater 3rd ventricle while SG(M) 71-80 age-group have greater inferior lateral ventricle and CSF compared to Cau(M). In SG 41-50 age-group, M have significantly smaller caudate, pallidum, sub-cortical gray matter, cortex, cerebellum white matter, corpus callosum, cerebellum cortex, total gray matter, hippocampus, putamen, and thalamus than F. In SG 51-60 age-group, M have significantly greater 3rd ventricles than F while reversed is true for cerebellum white matter. In SG 71-80 age-group, M have significantly smaller caudate than F.

#### CONCLUSION

s There are differences in brain structure/volumes between SG and Cau across ages and gender. Building an age, gender-and-population-specific brain volumetry database is paramount to ensure accurate comparison and greater accuracy during brain

registration, especially if comparison to neurological diseased states has to be made.

#### **CLINICAL RELEVANCE/APPLICATION**

Normative brain volumetry database for specific age-group, gender and ethnicity ensures reliable differentiation of healthy from neurological diseased brains for early diagnosis and interventions.

### **S3A-SPNR-2 Brain Functional Connectivity Alterations in the Depressed Adolescents with Suicide Behaviors**

#### **PURPOSE**

To investigate abnormalities of brain functional connectivity (FC) in both gray matter (GM) and white matter (WM) of depressed adolescents with suicide behaviors.

#### **METHODS AND MATERIALS**

Participants included 38 depressed adolescents with suicide behaviors (SA) and 28 healthy control (HC) subjects. FC differences in both gray and white matters between the two groups were identified at whole brain level with FDR corrected, based on resting-state blood oxygenation level-dependent signals. Correlation analyses were further conducted to explore the relationships between FCs and cognitive ability reflected by Wsiconsin card sorting test.

#### **RESULTS**

Age and gender were well matched between two groups (SA mean age =14.8, HC mean age =15.0; 6males and 32 females in SA, 8 males and 20 females in HC). Compared to HC, SA group presented lower FCs in left orbitofrontal area-middle cerebellar peduncle (GM10WM22,  $t=5.43$ ), left orbitofrontal area-right superior cerebellar peduncle (GM10WM45,  $t=5.28$ ), left orbitofrontal area-right corticospinal tract (GM10WM48,  $t=5.18$ ), left ventral posterior cingulate cortex-left sagittal stratum(GM18GM13, $t=4.47$ ), right ventral posterior cingulate cortex-left sagittal stratum (GM65WM13,  $t=4.55$ ), right associative visual cortex-left sagittal stratum (GM69WM13,  $t=3.57$ ), right primary visual cortex-left sagittal stratum (GM71WM13,  $t=4.79$ ), right superior temporal gyrus-left internal capsule(GM66WM8,  $t=4.00$ ), left middle temporal gyrus-left superior corona radiata (GM16WM10,  $t=6.91$ ), right anterior prefrontal cortex-right tapetum(GM73WM28,  $t=3.56$ ), left cingulate gyrus-right tapetum(WM15WM28,  $t=3.47$ ), and left orbitofrontal area-right tapetum(GM10WM28,  $t=4.95$ ). Correlation analyses further revealed that, FCs in GM18WM13 and GM65WM13 were positively associated with the percentage of correct response and negatively correlated with the perseverative response; FC in GM18WM13 was negatively associated with the percentage of perseverative errors; FC in GM71WM13 was positively associated with the percentage of correct response, and negatively associated with the perseverative response and the percentage of perseverative errors; FC in GM69WM13 was negatively correlated with the perseverative response and the percentage of perseverative errors.

#### **CONCLUSION**

s This study identified reduced FCs in essential brain areas of depressed adolescents with suicide behaviors, mainly located in the default mode network and visual network, which was related with impaired cognition.

#### **CLINICAL RELEVANCE/APPLICATION**

The findings suggested the pathophysiology of suicide behaviors in depressed adolescents and might imply targeted brain areas for future treatment of suicide.

### **S3A-SPNR-3 Concurrent Structural and Perfusion Changes in the Brain in Migraineurs with Patent Foramen Ovale: A Perfusion Functional Magnetic Resonance Imaging Study**

#### **PURPOSE**

To investigate the structural and perfusion alterations in the brain and their neural mechanisms in migraineurs with patent foramen ovale(PFO) by jointly applying magnetic resonance imaging in both structural and perfusion modalities.

#### **METHODS AND MATERIALS**

Participants included migraineurs with PFO (n=20) and healthy controls (n=28), matched for age and gender. MRI data acquisition for all subjects was performed on a GE Discovery MR750W 3.0T. Scans were performed during the interictal period of headache attacks in patients. The scanned sequences included T1 Flair,T2 Flair,T2 Propeller,3D T1 Bravo, 3D pcASL sequences. Magnetic resonance image preprocessing and statistical analysis were performed on SPM8,SPM12,CAT12 in MATLAB 2018b. CAT12 and BrainNetViewer software were used to present the results.

#### **RESULTS**

1. There was no statistical difference between the two groups of subjects in terms of gender and age composition ( $P > 0.05$ ).2. VBM analysis was performed using total intracranial volume (TIV), gender, and age as covariates. The gray matter density was found to be reduced in the midbrain and the precuneus in the left inferior temporal gyrus, left middle temporal gyrus, left middle occipital gyrus, left lingual gyrus, left inferior occipital gyrus, and left hippocampus in the patient group ( $P > 0.05$ ).3. SBM analysis was performed using age and gender as covariates. The depth of the sulcus in the insula, superior temporal gyrus, inferior frontal gyrus triangle, temporal pole, lateral prefrontal cortex, internal olfactory cortex, lingual gyrus, hippocampal gyrus, and talar parietal gyrus was found to be reduced in the patient group. The gyrification was reduced in the lateral occipital lobe, superior parietal lobule, cuneus, and precuneus ( $P > 0.05$ ).Comparisons between CBF groups were made using age and sex as covariates. CBF values were found to be elevated in the cerebellum as well as in the left perirhinal cortex, left lingual gyrus, and right lingual gyrus in the patient group. CBF values were decreased in the right middle frontal gyrus, right superior temporal gyrus, and right insula ( $P > 0.05$ ).

#### **CONCLUSION**

s Migraineurs with PFO were found to have multiple eigenvalue changes in brain structure and perfusion, and the brain regions with two or more eigenvalue changes were mainly located in the temporal lobe, frontal lobe, occipital lobe, insula, cuneus, precuneus, and cerebellum.It is suggested that subsequent studies could focus on observing the relevant brain regions.

#### **CLINICAL RELEVANCE/APPLICATION**

This study lays the foundation for the pathological mechanism of the disease and the discovery of relevant imaging markers. It

provides a basis for further research on the relatively specific brain mechanisms as well as the treatment of migraineurs with PFO.

### **S3A-SPNR-5 The Values of DRD4 Genotypes to the Characteristic Clinical Symptoms of ADHD**

#### **PURPOSE**

This study aimed to explore the contribution of the DRD4 gene to the categorical diagnosis of ADHD by using the dynamic fMRI method combined with sliding-window approach.

#### **METHODS AND MATERIALS**

We recruited 109 Chinese Han children with ADHD from the department of psychiatry from the local hospital in China. The recruited children were between 6 years and 14 years old and were diagnosed by three experienced psychiatrists in accordance with the criteria of DSM-V. Also, 34 normal controls (NC) were recruited from a local primary school and were matched for handedness. A 2×3 factor between-subjects general linear model (GLM) implemented using SPM12, including the factors of subtypes (ADHD-C vs. ADHD-I vs. NC) and genotypes (2R-allele vs. non2R-allele), was used to evaluate their effects on intrinsic brain functions. The interaction was modeled as a 2×3 group comparison. Multiple comparison correction was performed using a FWE approach, with a threshold of  $p < 0.05$  and cluster size  $>37$ .

#### **RESULTS**

ADHD-C, ADHD-I groups and NC were divided into six groups according to genotype (DRD4-2R/ADHD-C:  $n = 19$ ; DRD4-non2R/ADHD-C:  $n = 30$ ; DRD4-2R/ADHD-I:  $n = 17$ ; DRD4-non2R/ADHD-I:  $n = 43$ ; DRD4-2R/NC:  $n = 15$ ; DRD4-non2R/NC:  $n = 19$ ). The GLM revealed that there was no significant main effect of DRD4-gene and that of categorical diagnosis. The genotype × categorical diagnosis interaction effects were found to be significant, where increased dALFF variability was found in the right cuneus and lingual gyrus that extended into the calcarine (Figure 1, coordinates: 61, 73, 61) (FWE with a threshold of  $p < .05$  and cluster size  $>37$ ). After post-hoc analysis, for the NC group, 2R-carrier showed increased dALFF variability compared to that of non2R-carriers. For the 2R group, ADHD-I showed decreased dALFF variability compared to that of NC; and for the non2R group, ADHD-C showed increased dALFF variability compared to that of NC (Figure1).

#### **CONCLUSION**

s ADHD-C, ADHD-I and NC with different DRD4 genotypes exhibit opposite temporal variability in the right cuneus. ADHD patients with different DRD4 genotypes have characteristic clinical symptoms. This study provided insight into the brain dysfunction of ADHD from the perspective of dynamic local brain activity, highlighting the important role of DRD4 gene in understanding neurophysiological mechanisms of ADHD.

#### **CLINICAL RELEVANCE/APPLICATION**

This study aimed to explore the contribution of DRD4 gene to the categorical diagnosis of ADHD and whether patients with DRD4 risk gene carriers have characteristic clinical symptoms. To provide the evidence for imaging endophenotypes in differentiating subgroups of potential neurophysiological mechanisms of ADHD.

### **S3A-SPNR-6 Schizophrenia and Gray Matter Heterotopia in the Frontal Lobe: A Finding with Hitherto Little Attention Despite Nowadays High Resolution 3D MR Imaging**

#### **PURPOSE**

Only a handful of cases with gray matter heterotopia (GMH) in schizophrenia are described in the literature from the late '90s through MRI. Yet, postmortem studies detected heterotopic neurons in the white matter (WM) more frequently. The aim was to demonstrate their prevalence using images with higher spatial resolution than before.

#### **METHODS AND MATERIALS**

Inpatients with schizophrenia and an institutional MRI were included in this retrospective study, and consecutive data sets of non-schizophrenic persons served as controls. Two independent radiologists, trained for neuroimaging and blinded to any clinical information, evaluated 3D T1-weighted gradient echo sequences (1 mm<sup>3</sup> voxel size; 1.5 and 3.0 T) to look for GMH. Number and location (periventricular/deeper WM; frontal, parietal, temporal or occipital) of GMH were assessed. Presence of periventricular cysts (PVC), enlarged caves of the septum pellucidum (ECSP), dysgenesis of the corpus callosum (DCC), focal cortical dysplasia (FCD) and polymicrogyria (PMG) were noted, if present. A consensus for cases with disagreements was made in a second read. Fisher's exact and Pearson's  $\chi^2$  test were used to test for differences and relationships, respectively.

#### **RESULTS**

From 01/2013 till 07/2021, MR scans of 214 cases (mean age, 42 yrs; 69% males) and 141 controls (mean age, 46 yrs; 50% males) were analyzed. There was a prevalence of 2.8% ( $n=6/214$ ) of GMH in the patient cohort versus 0% in non-schizophrenic persons ( $p=0.046$ ). All seven lesions were located in the frontal lobe; two of them on both sides in one patient and two patients with GMH in the deeper and not in the periventricular WM. Another finding that was found solely in the patient cohort was the presence of PVC ( $n=3/214$ , 1.4%;  $p=0.218$ ). ECSP were detected in both groups ( $n=6/214$ , 2.8% vs.  $n=4/141$ , 2.8%;  $p=0.613$ ). Raters did not detect DCC, FCD or PMG in both cohorts. There were no relationships between GMH and PVC ( $\chi^2=0.052$ ;  $p=0.950$ ), GMH and ECSP ( $\chi^2=0.177$ ;  $p=0.841$ ), and PVC and ECSP ( $\chi^2=0.088$ ;  $p=0.918$ ). No associations between GMH and baseline characteristics or pre-existing conditions could be made.

#### **CONCLUSION**

s GMH in schizophrenia were found more frequently than expected, as indicated by a prevalence of 2.8%, which might be due to the nowadays higher resolution of structural MRI. All lesions were found in the frontal lobe and even in the deeper WM. Other findings were PVC and ECSP, the latter being also present in controls with almost the same frequency. Interestingly, there were no associations between GMH and epilepsy.

#### **CLINICAL RELEVANCE/APPLICATION**

High resolution 3D T1-weighting detected GMH in 2.8% of schizophrenic patients. These findings may inform personalized approaches to intervention such as in treatment-resistance despite good compliance.

### **S3A-SPNR-7 Multiclass Radiomics-based Models for Pediatric Low-Grade Neuroepithelial Tumors Molecular**

## Subtype Identification Based on Open-Radiomics Protocol

Participants

Khashayar Namdar, MSc, MEng, Toronto, ON (*Presenter*) Nothing to Disclose

### PURPOSE

Pediatric Low-Grade Neuroepithelial Tumor (PLGNT) is the most common type of brain tumor in children, and radiomics-based machine learning (ML) models have been shown to be effective for classifying BRAF fusion and BRAF V600E mutation PLGNT molecular subtypes. We investigate the effect of MRI sequence, image normalization, and radiomics extraction hyperparameters using the Open-Radiomics protocol to provide reproducible results.

### METHODS AND MATERIALS

Our REB-approved retrospective study cohort consisted of 339 children with PLGNT including 143 with BRAF fusion, 71 with BRAF V600E mutation, and 125 tumors with other molecular subtypes. MRI sequences included Fluid-Attenuated Inversion Recovery (FLAIR), T1-weighted (T1), gadolinium-based contrast agent (GBCA) enhanced T1-weighted (T1CE), and T2-weighted (T2) sequences images. Tumor segmentations were provided by a pediatric neuroradiology fellow and verified by a senior pediatric neuroradiologist. PyRadiomics was used for extracting the radiomics features from the regions of interest. We created 72 radiomics datasets using a combination of 4 sequences, 3 sets of radiomics extraction hyperparameters (binWidth of 15, 25, 35), and 6 image normalization methods (NoNormalization, MinMax, ZScore, Histogram Equalization, Gamma normalization with 0.5 and 1.5 as gamma coefficient). We used Random Forest classifiers. For each radiomics dataset, we repeated the train-validation-test (60/20/20) experiment with different data splits and model random states 100 times (7200 tests) and calculated the Area Under ROC Curve (AUC).

### RESULTS

We achieved a test AUC of 0.880 with 95% Confidence Interval (CI) [0.879, 0.882] for BRAF fusion vs BRAF V600E mutation binary classification. The highest average test performance for a specific dataset was achieved using MinMax normalization and binWidth of 25 on T1CE (AUC: 0.890). For 3-class classification, the average one-vs-the-rest (OvR) AUC was 0.789 with 95% CI [0.786, 0.792]. The top-performing dataset was ZScore, binWidth 15, FLAIR, with an average test AUC of 0.816. Unlike binWidth and image normalization, different imaging sequences resulted in statistically significant differences in AUC in both binary and multiclass scenarios.

### CONCLUSION

Among the four imaging sequences in the dataset, T1CE was the best for separating BRAF fusion from V600E mutation. However, radiomic features extracted from FLAIR images outperformed other sequences at differentiating BRAF fusion and mutation from the other subtypes.

### CLINICAL RELEVANCE/APPLICATION

Identification of the molecular subtype of PLGNT is important for treatment planning. Our comprehensive approach ensures that we capture best-performing and reproducible models.

## S3A-SPNR-8 Multiclass Radiomics-based Machine Learning Models for Medulloblastoma Molecular Subtype Identification

Participants

Khashayar Namdar, MSc, MEng, Toronto, ON (*Presenter*) Nothing to Disclose

### PURPOSE

Medulloblastoma (MB) is an aggressive brain tumor in children and qualitative MR imaging features including tumor location within the cerebellum have been shown to differentiate MB subtypes. We develop radiomics-based machine learning (ML) models using MRI Fluid-Attenuated Inversion Recovery (FLAIR) images to classify four MB molecular subtypes (WNT, SHH, group 3, group 4). We follow the Open-Radiomics protocol to achieve reproducible results.

### METHODS AND MATERIALS

Our REB-approved and retrospective study includes 104 pediatric patients with an age range of 1 to 17.2 years (mean age  $7.8 \pm 3.95$  years, 71 males, 68%). Tumor segmentations were provided by two pediatric neuroradiologists. PyRadiomics was used for extracting the radiomics features from the regions of interest (ROIs). The four MB molecular subgroups were identified based on next-generation sequencing panels, fluorescence in situ hybridization, and specialized testing (including RNA methylation array and DNA methylation array). The dataset included 44, 28, 20, and 12 cases of the WNT, SHH, group 3, and group 4 subgroups, respectively. We created 18 radiomics datasets using 3 sets of radiomics extraction hyperparameters (binWidth of 15, 25, 35), and 6 image normalization methods (NoNormalization, MinMax, ZScore, Histogram Equalization, Gamma normalization with 0.5 and 1.5 as gamma coefficient). We used Random Forests as classifiers. For each radiomics dataset, we repeated the experiment with different data splits and model random state 100 times (1800 tests) and calculated the Area Under Receiver Operating Characteristic Curve (AUC).

### RESULTS

When classifying group 3 versus all other subgroups, we achieved an overall test AUC of 0.619 with 95% confidence interval (CI) [0.607, 0.631]. On 4-class classification, the average one-vs-the-rest AUC was 0.703 with 95% CI [0.690, 0.716]. The top-performing dataset was ZScore with binWidth 25, where we achieved average test AUC of 0.750. Analyzing per-class AUCs on the top-performing setting, the highest performance was noted for SHH vs others, where we achieved an average test AUC of 0.845. We also observed significantly higher AUC for group 3 vs others when switched to multiclass classification (0.668).

### CONCLUSION

Performance of radiomics-based ML models for identifying MB subtypes using MR images depends on the subtype, how the model is trained, and how the image is normalized. Our results show ZScore is the best image normalization technique and multiclass classification can improve per-class performance of the models.

### CLINICAL RELEVANCE/APPLICATION

Pretherapeutic identification of MB subtype is important for treatment planning for which we train and evaluate reproducible machine learning models.

### **S3A-SPNR-9 Nodal Properties of Resting-State Brain Functional Network in Childhood and Adolescence**

#### **PURPOSE**

This study aimed to describe and compare the characteristics of changes in the nodal properties of brain functional networks during childhood and adolescence, revealing the developmental trajectories of different brain structures during development.

#### **METHODS AND MATERIALS**

In this study, 42 healthy volunteers aged 6-18 years were right-handed primary and middle school students were recruited, and the subgroup analysis included children (6-12 years, n =19) and adolescents (13-18 years, n =23). Resting-state functional magnetic resonance imaging (fMRI) data were collected using a 3.0T MRI scanner. The topological properties of the functional brain network were analyzed using graph theory.

#### **RESULTS**

Compared with the children group, the nodal efficiency of the superior frontal gyrus, middle frontal gyrus, left dorsolateral fusiform gyrus, and other brain regions in the adolescent group was significantly increased ( $P < 0.05$ , FDR correction) and positively correlated with age. The degree of centrality of the superior frontal gyrus, bilateral inferior frontal gyrus operculum, left medioventral fusiform gyrus, and other brain regions increased significantly ( $P < 0.05$ , FDR correction) and were positively correlated with age. The degree of centrality of the left dorsolateral fusiform gyrus, left rostral cuneus gyrus, and right medial superior occipital gyrus was significantly reduced ( $P < 0.05$ , FDR correction) and negatively correlated with age. The nodal shortest paths in the superior frontal gyrus, left ventrolateral fusiform gyrus, right superior parietal lobule, and other brain regions were significantly reduced ( $P < 0.05$ , FDR correction) and negatively correlated with age.

#### **CONCLUSION**

s The transmission efficiency of the brain core network gradually increased, and the subnetwork function gradually improved in children and adolescents with age. the functional development of each brain area in the occipital visual cortex was uneven and internally functionally differentiated.

#### **CLINICAL RELEVANCE/APPLICATION**

Changes in the topological properties of brain functional network nodes during childhood and adolescence can provide more detailed and intuitive information on the rules of brain development. We believe that our study makes a significant contribution to the literature because it provides evidence-based findings that clinicians and healthcare providers can adopt in actual clinical settings.

S3A-SPOB

### OB/Gynecology Sunday Poster Discussions I

#### Sub-Events

#### **S3A-SPOB-1 Value Addition of Subspecialty Trained Experienced Readers for O-RADS MRI Scoring and Guiding Management for Patients with Adnexal Mass Referred to Gynecology Oncology Multidisciplinary Rounds in a Tertiary Center**

##### Participants

Ankush Jajodia, MBBS, MD, New Delhi, (*Presenter*) Nothing to Disclose

##### PURPOSE

Assess the diagnostic accuracy, interobserver variability, and common lexical errors of the ACR O-RADS scoring system in staff radiologists with less experience and non-fellowship trained.

##### METHODS AND MATERIALS

Patients with an adnexal mass on standard post-contrast pelvic MRI and referred after initial interpretation by a staff radiologist (R3-lacking experience and fellowship experience) to gynec-oncology rounds in a tertiary center. Two fellowship-trained radiologists with different experience levels, R2 (2 years) and R1 (10 years), assigned O-RADS MRI scores independently. Diagnostic accuracies (ROC curve analysis) and agreement between readers were analyzed for each reader. Scores 4 and 5 were assigned malignant. R1 independently assigned misclassification if a malignant lesion scored = 3, a benign lesion scored = 4, or a non-adnexal mass was incorrectly categorized as benign or malignant.

##### RESULTS

Twelve malignant and 36 benign lesions included in the study were assigned O-RADS MRI score malignant (4,5) and benign (1,2,3) in 10 (20.8%) and 38 (79.2%), 15 (31.2%) and 33 (68.8%) and 45 (93.7%) and 3 (6.3%) by R1, R2, and R3 respectively. MR O-RADS score (4,5) associated with malignancy with diagnostic efficacy and areas under the curve values of 0.942 (95 % CI, 0.834-0.989), 0.579 (95 % CI, 0.428-0.720), and 0.553 (95 % CI, 0.403-0.697) obtained for readers R1, R2, and R3 respectively, with statistically significantly different between R1-R2 and R2-R3. Two and eleven lesions were incorrectly classified as benign by R1 and R3 readers. Inter-observer agreement interpretation obtained k values was fair between all readers; 0.435 (95 % CI, 0.224-0.646) for R1-R2, 0.441 (95 % CI, 0.238-0.645) for R2-R3, and 0.440 (95 % CI, 0.192-0.687) for R2-R3 respectively. There were nine correct upgrades and seven correct downgrades to malignant and benign categories by experienced R1 readers. Misclassification in nonexperienced readers was due to misinterpretation of solid tissue (n=14), incorrect interpretation of diffusion images (n=10), and incorrect interpretation of non-dynamic contrast enhancement (n=7).

##### CONCLUSION

Additional interpretation by experienced readers provides incremental diagnostic accuracies in the MR O-RADS score.

##### CLINICAL RELEVANCE/APPLICATION

Experienced readers correctly upgraded 18% malignant lesions with fair inter-observer agreement among readers with various experiences, although the diagnostic accuracies were significantly different between readers. Unnecessary biopsy was avoided in 14.5% by correct downgrading by experienced readers. Incorrect classification of 16% of lesions by experienced readers potentially highlights need to simplify the existing scoring system.

#### **S3A-SPOB-2 Accuracy of the Characterization of Adnexal Masses, Indeterminate at Ultrasonography, Using a Magnetic Resonance Imaging (MRI) Protocol without Contrast: External Validation of the Non-contrast MRI Adnex Score in a Multicentre setting**

##### Participants

Camilla Panico, MD, Rome, Italy (*Presenter*) Nothing to Disclose

##### PURPOSE

The characterization of adnexal masses is critical to guide appropriate patient management. Up to 20% of adnexal masses remain uncharacterized after ultrasound and MRI is needed. The O-RADS MRI score relies on gadolinium-based contrast; however, avoiding contrast is sometimes preferable due to logistical and patient factors. A recent study proposed an alternative (Non-contrast MRI Adnex Score -NCMAS). The purpose of our study is to show the preliminary data of a multicentric prospective evaluation of the NCMAS in characterizing the adnexal masses.

##### METHODS AND MATERIALS

A multicenter observational prospective study has been set up including 16 standing Italian Centers. NCMAS is the Index Test; its aim is to predict the malignancy of the ovarian lesions on the basis of a NCMAS. The score is based on 5 categories. Two radiologists for each center (one senior and one junior) read the images, blinded to the clinical information of the patients except for age. The diagnostic end-point (absence/presence of the malignant tumor) is verified through histopathology after surgery or

through radiological follow-up at 12 months. The diagnostic accuracy of NCMAS is evaluated by measuring sensitivity, specificity, positive and negative predictive values, and ROC curve with area under the curve (AUC). To measure agreement between senior and junior radiologist Kappa statistics is performed. This preliminary analysis includes 45 patients representing about 15% of the total patients to be recruited.

## **RESULTS**

Fifteen out of the 45 patients were classified as malignant using the NCMAS. Comparing these diagnoses with the gold standard we found: sensitivity of 85.71% (95% Conf. Int. 66.13%-98.22%), specificity of 90.32% (Conf. Int. 78,58%-97.96%), positive predictive value of 80% (Conf. Int. 59.54%-95.67%), negative predictive value 93.33% (Conf. Int: 52.78%-99.18%). The malignant lesions correctly classified were 88.89% (Conf. Int. 77.78%-96.29%). The AUC was 88.02% (Conf. Int. 77.14%-98.90%). As to the comparison between senior and junior radiologists, for a diagnosis of a malignant lesion, the agreement was 90.24%, with a Kappa statistic of 0.79 (Conf. Int. 0.59-0.985).

## **CONCLUSION**

s The performance of NCMAS score was externally and prospectively confirmed. Even if found in about 15% of the total calculated sample size, the results are promising. If confirmed, the use of NCMAS may add an important tool in clinical practice when contrast imaging cannot be used for logistic or patient factors.

## **CLINICAL RELEVANCE/APPLICATION**

The results of this study may represent a confident support to the clinical use of non-contrast MRI in diagnosing adnexal masses, undetermined at ultrasonography

S3A-SPPD

### Pediatric Imaging Sunday Poster Discussions I

#### Sub-Events

#### **S3A-SPPD-1 Cardiac Computed Tomography Angiography with and without Bolus Tracking Methods in Infants with Congenital Heart Disease**

#### Participants

Takayuki Yoshiura, BA, RT, Hiroshima, Japan (*Presenter*) Nothing to Disclose

#### PURPOSE

Cardiac computed tomography angiography (CCTA) is useful in congenital heart disease (CHD) diagnosis and plays a major role in treatment. The bolus tracking (BT) methods can accurately predict the optimal scan delay that reflects the hemodynamics of the individual, but the drawback is the increased radiation dose due to pre-monitoring scans. This study aimed to compare the radiation dose, vascular CT number, and image quality of CCTA with and without BT methods for infants with CHD.

#### METHODS AND MATERIALS

This study retrospectively studied 72 consecutive patients with suspected CHD who underwent infant CCTA from December 2017 to April 2022, divided into groups with and without BT methods, in our information system. All scans were performed using a 64-detector row CT scanner (Lightspeed VCT; GE Healthcare, Milwaukee, Wisconsin) with the following parameters: rotation: 0.4 s, helical pitch: 1.375, slice thickness: 0.625 mm, tube voltage: 80 kVp, and automatic tube current modulation with a noise index of 40, iterative reconstruction (IR, blending of 30% of ASIR with FBP) algorithms under the standard kernel/filter reconstruction. Volume CT dose index (CTDI<sub>vol</sub>) and dose length product (DLP) were recorded for all CT scanning, and an effective dose was obtained using conversion factors. The CT number of the ascending aorta (AO) and pulmonary artery (PA), image noise of muscle tissue, and contrast-to-noise ratio (CNR) were measured and calculated.

#### RESULTS

The median values in the groups with and without BT were 2.20 mGy vs. 0.44 mGy for CTDI<sub>vol</sub>, 8.10 mGy·cm vs. 6.20 mGy·cm for DLP, and 0.66 mSv vs. 0.51 mSv for effective dose. The mean values in the groups with and without BT were 471.2 Hounsfield units (HU) and 515.6 HU for AO and 463.2 HU and 512.5 HU for PA, respectively. The mean image noise was 17.3 HU and 17.0 HU in the groups with and without BT ( $p = 0.76$ ), and the mean CNR was 23.9 and 26.5 in both groups ( $p = 0.21$ ).

#### CONCLUSION

s CCTA for infants with CHD without BT methods can reduce the radiation dose while maintaining the CT enhancement of the vessels and image quality compared to CCTA with BT methods.

#### CLINICAL RELEVANCE/APPLICATION

CCTA for infants with CHD can ensure good image quality and reduce radiation dose without using the BT method.

Printed on: 04/12/24

S3A-SPPH

### Physics Sunday Poster Discussions I

#### Sub-Events

#### S3A-SPPH-1 Improved Single-Shot GRASE with Flyback Variable Density Sampling and Deep Neural-Network

##### PURPOSE

To enable highly accelerated (12X) single shot gradient and spin echo (ss-GRASE) sequence without appreciable image artifacts by incorporating flyback variable density sampling coupled to a deep neural network.

##### METHODS AND MATERIALS

**SS-GRASE with flyback variable density sampling:**The sequence diagram was shown in Figure A, where a 3-fold acceleration was achieved using three gradient echoes after each refocusing pulse. This was coupled with variable density sampling for a total of 12-fold acceleration. To minimize phase inconsistency among the gradient echoes, flyback acquisition was employed with three echoes each grouped into different regions of the k-space. **Data Acquisition:**With IRB approval, images were acquired using ss-GRASE on phantom and human brains on a GE 3T Premier scanner. Key sequence parameters were: TR/TE=300/100ms, slice thickness=3mm, FOV=28cm<sup>2</sup>, matrix=256×224, slices=30 to 40, parallel imaging factor=3. A total of 90 slices of phantom and 320 slices of the human brain were acquired. The experiment was repeated using variable density sampling SSFSE with the same parameters except for TR=700ms. **Image Reconstruction:**The acquired data from both ss-GRASE and SSFSE was reconstructed using the parallel imaging compressive sensing (PICS) algorithm provided by BART and fed into the neural network as input and output, respectively. A U-Net architecture was tailored to further remove artifacts from PICS reconstruction. The U-Net consists of a downsampling encoder and an upsampling decoder network with a mirrored and reversed encoder structure (Figure B). The network was trained on an NVIDIA Titan Xp 16GB graphics card. To avoid overfitting, weight-decay (0.01) and random rotation for data augmentation were applied. Adam optimizer was used with a learning rate of 0.0005 for 1000 epochs guided by MSE loss until convergence.

##### RESULTS

The second column of Figure C illustrates the artifacts of PICS reconstruction arising from the phase inconsistency of the three gradient echoes in ss-GRASE. The artifacts can be largely removed using the deep neural network, as evidenced by the improved image quality from both phantom and human brain images (third column).

##### CONCLUSION

The performance of the ss-GRASE sequence was substantially improved with a combination of flyback variable density sampling and a deep neural network. The deep neural network enables reduction of the artifacts which PICS reconstruction fails to address in ss-GRASE.

##### CLINICAL RELEVANCE/APPLICATION

The proposed approach of ss-GRASE enables improved acquisition speed (300ms/slice) and less SAR issue as compared to conventional SSFSE, implying further applications of the technique in freezing motion such as bowel imaging, and SAR-sensitive situations such as pediatric imaging.

#### S3A-SPPH-10 Unpaired MR-CT Translation using Diffusion Model and Cross-modality Structure Extractor

##### PURPOSE

For the breast cancer patients after surgery, MRI scans are required to identify the surgical site and determine the treatment plan, but radiotherapy planning requires extra CT scans. By developing the deep learning model to synthesize CT from MRI images, physicians can reduce the time consumption and do treatment efficiently. Since a dataset containing paired MR and CT images with registration is difficult to be retrieved because of anatomical changes, unpaired MR-CT translation is the key to solve this problem. However, due to the information difference within MRI and CT, unpaired translation across the modalities is still a hard task to be done. In this paper, we propose a novel structure using a cycle-structured diffusion model and an extra algorithm for structure preservation.

##### METHODS AND MATERIALS

The dataset we used is composed of 2D MRI (T2) and CT scans of the patients who underwent partial resection for breast cancer or did radiation therapy. Train set is composed of 3,606 MR scans and 2,770 CT scans from 62 patients, and 543 pairs of MRI and CT from 15 patients were used for test. The proposed model is composed of two generators: Diffusive and Non-Diffusive. Non-diffusive generator  $G'$  is used to make a reference for the diffusive generator  $G$ . Using the image  $G'(x)$  and noisy input  $x_t$ , the diffusive generator focuses on learning the target domain's structure and reconstructing the input image  $x$ . The Modality independent neighborhood descriptor (MIND) algorithm extracts the structural information using the similarity among adjacent patches. This descriptor makes a similar output for the same object regardless of its modality, so it can guide the unsupervised model to keep the structure. We compared our model's result with other unsupervised translation models by quantitative metrics: MSE, PSNR, and SSIM.

##### RESULTS

By the metrics, we can know that our proposed model generates the most similar result with ground truth for both sides: MR to CT

By the metrics, we can know that our proposed model generates the most similar result with ground truth for both sides: MR to CT and CT to MR. The resulting image shows that the diffusive generator contributed well to build realistic images. Also, the MIND loss helped to solve the structure deformation problem, especially in CT to MR conversion.

## CONCLUSION

In this study, we showed bidirectional MR-CT unpaired translation functionality can be raised by adapting a diffusive generator as translation model. In addition, the proposed loss function in this paper can help maintain the structural information and compensate for the essential problem of unpaired translation.

## CLINICAL RELEVANCE/APPLICATION

The synthetic CT image generated by the proposed model and MRI can be used for dose calculation in radiation treatment planning for breast cancer. This method can help physicians to reduce the time consumption and establish precise treatment regions.

## S3A-SPPH- 11 The Superiority of Low-kV Renal Triphasic-enhanced CT with Deep Learning Image Reconstruction in Patient Care over the Conventional Enhanced CT Exam

Participants

Xiaobo Ding, MD, MD, Changchun, China (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate whether the deep learning image reconstruction (DLIR) can provide more patient care through the reduction of radiation dose and contrast agent volume for renal enhanced CT exam.

## METHODS AND MATERIALS

148 patients suspicious of renal lesion were included, 118 patients in the DLIR group and 30 in the conventional enhanced CT (CECT) group. The parameters for DLIR group: rotation speed of 0.5 s, collimation of 128×0.625 mm, pitch of 0.992:1, 50% ASIR-V, noise index (NI) of 9, automatic current modulation, standard kernel, 100 kV and mA range of 100-550 in the arterial phase (AP) and excretion phase (EP) and 120 kV and mA range of 150-500 in the parenchymal phase (PP); retrospective algorithm of DLIR. The volume and injection rate of contrast agent (320 mgI/ml) were 0.9 ml/kg and 3 ml/s. In CECT group: 120 kV, 281 mAs, collimation of 128×0.625 mm, pitch of 0.914:1, level 3 of iDose4, standard(B) filter for all phases. The volume and injection rate of contrast agent (320 mgI/ml) were 1.2 ml/kg and 2.7 ml/s. CT values and standard deviation (SD) of cortex, medulla, subcutaneous adipose tissue (SAT) on AP, parenchyma, pelvis and psoas muscle (PM) and SAT on PP, middle calyx (MC), upper ureter and middle ureter on EP were measured to calculate signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). SD of SAT was defined as background noise. Images were assessed by two readers using a 4-point scale (1. poor; 2. moderate; 3. good; 4. excellent). The CT DIvol and dose-length-product (DLP) was recorded. Student's t-test and Mann Whitney U test were used to analyze the differences between 2 groups.

## RESULTS

There was no difference in BMI between two groups (24.4 vs. 23.4,  $p>0.05$ ). CTDI, DLP and contrast agent volume of DLIR group were significantly lower than those of CECT group (23.7 vs. 70.8 mGy,  $p<0.001$ ; 744.1 vs. 2197.4 mGy $[[$ Unsupported Character - Symbol Font #158;]]cm,  $p<0.001$ ; 62.4 vs. 77.8 ml,  $p<0.001$ ). SNR of parenchyma and upper ureter and CNR of cortex to medulla in DLIR group were significantly higher than those in CECT group (10.83 vs. 7.52; 19.45 vs. 7.12; 11.83 vs. 6.59;  $p<0.001$  each). The SD of SAT was lower in DLIR group, compared to CECT (9.08 vs. 11.11,  $p<0.001$ ). No differences in subjective scores were observed between two groups.

## CONCLUSION

Low-kV enhanced CT exam combined with DLIR algorithm is a feasible method for better patient care, compared to conventional enhanced CT exam.

## CLINICAL RELEVANCE/APPLICATION

The scan speed is faster and image quality is better for the deep learning algorithm of low-dose renal three-phase scan of GE revolution 256 row CT than that of conventional renal three-phase scan of Philips 128 row CT, which could significantly reduce the radiation dose and contrast agent dosage of patients, and reduce the burden of liver and kidney of patients.

## S3A-SPPH- 12 Performance of an Artificial Intelligence-Based Real-time System for Breast Positioning Evaluation and Image Quality Control in Mammography

## PURPOSE

To investigate the effectiveness of an artificial intelligence (AI) system for automated assessment of breast positioning and image quality in mammography.

## METHODS AND MATERIALS

Assessment of breast positioning and image quality was performed by AI system and by two radiographers on 360 images of 90 women. Nine image quality criteria evaluating the appearance of the nipple, breast rotation, pectoral muscle, inframammary fold, pectoral nipple line, shoulder overlap shadow, abdominal skin, contralateral breast and foreign body were used for craniocaudal and mediolateral-oblique views. Image quality of cases were also evaluated with the standards of Mammography Quality Standards Act (MQSA) as grade "adequate" or "inadequate". Intraclass correlation and Cohen's kappa coefficient (?) were used to investigate the correlation and agreement between the radiographer's assessments and AI. The performance of the AI system was evaluated using accuracy, sensitivity, and specificity.

## RESULTS

The AI algorithm demonstrated high accuracy in distinguishing between adequate and inadequate images, with an overall accuracy of 93%, sensitivity of 94% and specificity of 92%. In terms of breast positioning, the AUC of poor imaging quality prediction by AI system according to incomplete gland, incomplete pectoralis muscle, over or insufficient exposure was (0.903 vs 0.937 vs 0.982). Overall accuracy of AI system was 0.958. Inter-observer agreement for breast positioning assessment indicating substantial agreement between the radiographers and AI system ( $\kappa=0.75$ ). A substantial to almost perfect agreement was observed between the radiographers and AI on the nipple in profile ( $\kappa = 0.93$ ) and contralateral breast criterion ( $\kappa = 0.82$ ). We observed a slight to

moderate agreement for the other criteria ( $\kappa = 0.55-0.79$ ).

## CONCLUSION

The AI algorithm demonstrated high accuracy in distinguishing between high and low-quality images and detecting suboptimal breast positioning in mammography. The results showed a high level of agreement between the AI system and the radiographers.

## CLINICAL RELEVANCE/APPLICATION

The high accuracy, sensitivity, and specificity of an AI system for quality control in mammography suggest its potential as a valuable tool for radiologists and technologists in the clinical setting, particularly in low-resource areas where access to experienced radiologists may be limited.

### S3A-SPPH-13 Artificial Intelligence-based Triage of Breast Cancer Screening Mammograms in a Swiss Region: Possible Impact of AI Region's Score Cutoff on Radiologist Workload

Participants

Federica Zanca, PhD, Leuven, Belgium (*Presenter*) Nothing to Disclose

## PURPOSE

To identify the optimal region's score cutoff when using an artificial intelligence (AI) cancer-detection software to triage negative screening examinations into a one-click reporting radiologist work stream, e.g. reader validation of the AI negative result.

## METHODS AND MATERIALS

This prospective multi-center simulation study aims at collecting about 10000 exams from a Swiss screening program. Preliminary data includes 3 months of screening mammograms. AI cancer-detection software (Transpara, Screenpoint Medical, v1.7.1) was used as a concurrent reading to detect potential abnormalities, for all exams collected. The software computes a region score for every marked area (soft tissue lesions and microcalcifications), indicating the likelihood of cancer on a scale from 0-98. Higher scores represent a higher likelihood of cancer. Based on these AI prediction scores, various cutoff points for the highest region score at the exam level (42, 49, 60, 74) were evaluated as thresholds to potentially channel women to the one-click reporting work stream. The different cutoff points were assessed in terms of missed abnormalities. Mean, median and variance of the AI scores were calculated. Data were also stratified per lesion type and breast density.

## RESULTS

500 exams were examined, of which 12 were recalled for further examination (recall rate: 2.4%). Of these, 4 did not return, 5 were benign and 3 were diagnosed as cancer (biopsy proven), resulting in a 0.6% cancer incidence over one screening interval of 2 years. The mean, median and variance of AI scores were, respectively, 13, 0 and 564. There were respectively 0,1,2 and 2 missed cancers in case an AI score cutoff of 42, 49, 60 and 74 was used, corresponding to 0%, 0.2%, 0.4% and 0.4% of all screen-detected cancers in the population. The cutoffs of 42/49/60/74 correspond to 79%/87%/93%/99% of the workload. More data collection and stratification per lesion type and breast density is ongoing.

## CONCLUSION

Preliminary data suggests that a cutoff score of 42 would allow triaging breast cancer screening mammograms with a 99.9% negative predicted value (NPV) into a one-click reporting.

## CLINICAL RELEVANCE/APPLICATION

Using commercial AI software to triage mammogram workflow based on a 99.9% NPV could reduce radiologist workload by 78%.

### S3A-SPPH-2 Development of a Machine Learning Algorithm for Fat-free Mass Estimation: Application to Personalized Contrast Injection in Computed Tomography

Participants

Natalie Heracleous, PhD, BSc, Sion, Switzerland (*Presenter*) Nothing to Disclose

## PURPOSE

Using fat-free mass (FFM) to personalize i.v. contrast volume injection enables reproducible target liver enhancement. However, measuring FFM requires expensive equipment and is time-consuming, limiting its applicability in clinical practice. This study aims at developing a Machine Learning (ML) model to accurately estimate the patient FFM.

## METHODS AND MATERIALS

Previously collected abdominal CT data from 689 adult patients referred for liver lesion characterization or cancer follow-up was used (11 centers, different CT vendors, 2018-2022). This dataset includes various patient characteristics and measurements such as age, gender, weight, height, Body Mass Index (BMI), Size Specific Dose Estimate (SSDE), and FFM measured with Bioelectrical Impedance meter (ground truth (GT)). A multivariate linear regression model was developed for FFM estimation. The correlations of the investigated variables with measured FFM were studied, and the most correlating variables were retained in the final model. The data was divided into training and test sets following the 80/20 rule and were validated using the K-fold technique. The model's performance was evaluated against the GT using Mean Absolute Percentage Error (MAPE), Root Mean Squared Error (RMSE) and R-squared. Our algorithm was also benchmarked against models already existing in the literature by comparing the distributions of the relative differences between theoretical and measured FFM values when applied to our data.

## RESULTS

Preliminary results show a very good performance in predicting the FFM for our patient data sample. The cross-validation results showed the model to be robust for the typical patient profiles in our clinical settings. Specifically, the model showed low MAPE (0.033 +/- 0.003), high R2 (0.91 +/- 0.02) and relatively low standard deviation of residuals RMSE (2.13 +/- 0.23).

## CONCLUSION

Our model can reliably and efficiently estimate the patient FFM to personalize i.v. contrast volume in adult abdominal CT examinations, reducing the time required for its measurement and avoiding the need for expensive equipment.

## CLINICAL RELEVANCE/APPLICATION

The ability to accurately estimate FFM enables effortless personalization of contrast volume injection for a reproducible liver enhancement in clinical practice.

### S3A-SPPH-3 Evaluation of Unsupervised Low-dose Digital Breast Tomosynthesis Denoising using Cycle-consistent Generative Adversarial Network

#### PURPOSE

This study aimed to evaluate the image quality improvement in digital breast tomosynthesis (DBT) with unsupervised cycle-consistent generative adversarial networks (cycle-GANs) during pre-reconstruction processing under low radiation exposure.

#### METHODS AND MATERIALS

The cycle-GAN pre-reconstruction manipulation with filtered back projection (FBP) was compared with and without relative GAN techniques (unsupervised image-to-image translation: UNIT and supervised image-to-image translation: pix2pix). The peak signal-to-noise ratio (PSNR), mean square error (MSE), structural similarity (SSIM), and detectability index ( $d'$ ) in the in-focus plane and artifact spread function (ASF) in the longitudinal direction using a phantom (training; BR3D [model 020, CIRS Inc.], testing; DBT quality control [model 021, CIRS Inc.] and TOR-MAM [Leeds Test Objects Inc.]) at various radiation doses (automatic exposure control reference dose: 1.36 mGy; approximately 50% reduction of reference dose: 0.66 mGy; approximately 75% reduction of reference dose: 0.31 mGy) were used to compare noise reduction and preserved contrast rates.

#### RESULTS

PSNR and MSE were similar to the references with cycle-GAN at 75% and pix2pix at 50% radiation dose reductions of reference, respectively (PSNR: cycle-GAN: 25.19 and 25.81, UNIT: 23.81 and 18.68, pix2pix: 26.46 and 25.92, without GAN (w/o-GAN): 26.03 and 24.07; MSE: cycle-GAN: 0.003 and 0.002, UNIT: 0.004 and 0.013, pix2pix: 0.002 and 0.002, w/o-GAN: 0.002 and 0.003, at 50% and 75% reduced radiation dose, respectively). The SSIM of the images generated by the cycle-GAN model at a 50% reduced radiation dose was similar to that of the reference images acquired at full radiation dose (cycle-GAN: 0.66 and 0.64, UNIT: 0.62 and 0.59, pix2pix: 0.64 and 0.62, w/o-GAN: 0.61 and 0.50 at 50% and 75% reduced radiation dose, respectively).  $d'$  was similar to the reference in cycle-GAN and pix2pix at 50% radiation dose reduction of reference (reference: 2.79, cycle-GAN: 2.80 and 2.71, UNIT: 2.64 and 2.46, pix2pix: 2.82, and 2.58, w/o-GAN: 2.73 and 1.89 at 50% and 75% reduced radiation dose, respectively). ASF revealed a similar distribution (symmetry) to the reference, except for pix2pix. Pix2pix spread the distribution and became asymmetric.

#### CONCLUSION

This phantom experiment revealed the highest usefulness of cycle-GAN in low-dose conditions considering the image quality in the in-focus plane and longitudinal direction, as well as a 50% reduction in the reference.

## CLINICAL RELEVANCE/APPLICATION

The cycle-GAN pre-reconstruction manipulation with FBP can significantly reduce noise with preserved contrast and radiation dose reduction in clinical practice.

### S3A-SPPH-4 MRI Image Generation from CT Images for Cerebral Ischemic Stroke Patients Using Deep Learning

#### PURPOSE

Cerebral ischemic stroke is a leading cause of death and disability worldwide, and timely diagnosis and treatment are crucial for improving patient outcomes. Computed tomography (CT) and magnetic resonance imaging (MRI) are both widely used imaging modalities for diagnosing stroke. However, CT is often the first choice due to its accessibility and speed, while MR provides higher sensitivity and specificity. This study aims to investigate the feasibility of converting CT images of cerebral ischemic stroke patients to MRI using deep learning techniques.

#### METHODS AND MATERIALS

The proposed method utilizes a Cycle Generative Adversarial Network (Cycle-GAN) raised by Jun et al. to learn the mapping between the two modalities and generate synthetic MRI from CT scans. We have added a new attribute to the network, based on the observation that stroke lesions are highly discernible on MR images. The dataset used in this study consists of CT and MR images from 120 patients at Longgang Central Hospital of Shenzhen. Only the MRI input contains attribute information, where the presence or absence of lesions is encoded as one-hot codes. To address the challenge of detecting lesions in CT images and improve the network's feature extraction capabilities, we adjusted the window width and center of the original CT image to 60 and 35, respectively.

#### RESULTS

Experimental results demonstrate that the proposed approach can effectively generate high-quality MRI from CT scans, achieving a peak signal-to-noise ratio (PSNR) of 24.4 dB and a structural similarity index (SSIM) of 0.78. Furthermore, our method outperforms existing image-to-image translation methods in terms of visual quality and quantitative evaluation metrics.

#### CONCLUSION

Deep learning has shown promising results in extracting subtle lesion features from CT images, although the outcomes may differ from those of the original MRI. Nonetheless, the algorithm can still provide valuable insights to medical professionals. While some progress has been made in this area, there is still significant room for improvement. Future research will focus on refining the algorithm and conducting comparative studies with related algorithms.

## CLINICAL RELEVANCE/APPLICATION

Timely diagnosis of Cerebral ischemic stroke is critical. However, traditional MRI scans are time-consuming, while CT imaging is widely available. By using deep learning to convert CT images to MRI, medical professionals can diagnose the condition more quickly and develop appropriate treatment plans.

### S3A-SPPH-5 Semi-Automatic Segmentation of Thymic Epithelial Tumors using U-Net

Participants  
Nathan Lay, PhD, Bethesda, MD (*Presenter*) Inventor, ScanMed

## **PURPOSE**

Volumetric analysis of thymic epithelial lesions can be more informative than RECIST for oncologic follow up but requires laborious segmentation with low reproducibility when done manually. To propose and quantify performance of a U-Net artificial intelligence (AI) model for segmenting thymic epithelial tumors in CT scans with user-provided 3D regions-of-interest.

## **METHODS AND MATERIALS**

A consecutive cohort comprised of 85 CT scans from 60 thymoma patients (mean age: 55 range: 32-75) was queried from a single institution database. Thymic tumors in the thorax were then manually segmented slice-by-slice on axial CT images by trainees or volunteers under the supervision of an expert cardiothoracic radiologist. The cohort was then partitioned into training and validation sets containing 63 CT scans from 45 patients and 22 CT scans from 15 patients respectively. A 2D U-Net was then trained on cropped image slices from 141 tumors over 1000 epochs. Performance was measured using the arithmetic mean and standard deviation of Dice similarity coefficient (DSC) over 3D manual segmentation masks of the whole image. DSC produces a similarity score ranging from 0 to 1 with 1 being a perfect match.

## **RESULTS**

U-Net model snapshots were validated every 10 epochs on cropped image slices coming from 49 validation tumors. The method achieved a peak overall validation Dice similarity coefficient of 0.59 +/- 0.17. This corresponds to validation tumor DSCs of 0.60 +/- 0.09 for thymoma lesions located in the lung parenchyma, 0.68 +/- 0.14 for pleural and 0.57 +/- 0.19 for mediastinal thymoma lesions.

## **CONCLUSION**

The current DSC results of our U-net AI model show promise for volumetric analysis of thymic tumors. Thymic tumors present a complicated and often unnoticed appearance in CT and a larger dataset is likely to produce a more generalizable and performant U-Net model over our current results.

## **CLINICAL RELEVANCE/APPLICATION**

Thymic tumor progression is currently tracked using RECIST v1.1. RECIST is used because it is simple and reproducible, but it is not suitable for some types of pleural thymic tumors. Automatic volumetric analysis can be simple, reproducible and accurate for all thymic tumors.

## **S3A-SPPH-6 Reproducibility of a Deep Learning COVID-19 Classification Model Based on Image Acquisition Dates and Data Resampling**

### **PURPOSE**

To investigate the impact of (1) image acquisition date and (2) data resampling, which was performed to create new training and test sets, on the ability of a deep learning (DL) model to predict COVID-19 diagnosis from chest radiographs (CXRs).

### **METHODS AND MATERIALS**

A DL model using the DenseNet-121 architecture was trained on an original dataset of 9860 COVID+/- patients (disease prevalence: 15.5%) from a single institution. The model was validated on a more current cohort of 5893 patients (disease prevalence: 12.4%) from the same institution but achieved significantly lower performance as evaluated using area under the receiver operating characteristic curve (AUC). To investigate this performance discrepancy, this work (1) compared the International Classification of Diseases 10 (ICD-10) codes between the original dataset and current test set, (2) limited the image acquisition date range of the current test set to that of the original and compared COVID severity scores and age, and (3) retrained the model using a resampling of the original dataset to evaluate whether the original results were due to a statistical anomaly. No training was performed using the current test set.

### **RESULTS**

The original dataset and current test set shared the same top-three ICD-10 codes: (1) screening for other viral disease, (2) age-related osteoporosis, and (3) unspecified osteoarthritis. COVID severity scores of patients with images obtained during the overlap of dates between the test sets failed to achieve a significant difference ( $p=0.06$ ); however, the DL prediction scores indicated more "obvious" cases within the original test set, thus correctly labeling a greater portion of true-positive and true-negative CXRs. There was a significant difference ( $p<0.001$ ) between cohort age, with the current test set having a larger mean (57.9 years  $\pm$  18.3) than the original dataset (54.7 years  $\pm$  18.9). Lastly, retraining the model by resampling the original dataset resulted in an AUC value [95% CI] of 0.71 [0.67, 0.74], significantly lower than the original AUC value of 0.76 [0.73, 0.79]. Importantly, the AUC value of the current test set was no longer statistically less than the AUC value obtained with this resampled original dataset ( $p=0.11$ ).

### **CONCLUSION**

This work examined potential factors that may impact model performance. Resampling the dataset resulted in significantly lower performance, which may explain how different partitions of a dataset (or an entirely new dataset) may yield variable performance.

### **CLINICAL RELEVANCE/APPLICATION**

With the rise of DL use in medical applications, interpretability of models is essential for proper deployment, ensuring an understanding of how various factors may impact model performance and that results are comprehensible.

## **S3A-SPPH-7 Model Calibration by Temperature Scaling of a U-Net Deep Learning Model Trained for the Segmentation of Mesothelioma Tumor: A Pilot Study**

### **PURPOSE**

To produce calibrated pixel-wise label probabilities in the task of mesothelioma segmentation, which will ensure proper generation of probability maps.

## METHODS AND MATERIALS

Temperature scaling (TS) is a post-processing probability calibration method to be used for multi-class classification. For medical image semantic segmentation tasks, the two classes would be "disease" or "no disease." TS estimates a single scalar parameter temperature  $T > 0$ , using the logit  $z_i$  vector as input, where  $i$  is the  $i$ -th image. The temperature is typically optimized only on the validation images and using the negative log-likelihood cost function, as was performed in this work. The calculated temperature "softens" the output of the last activation layer with  $T > 1$  reducing model confidence (i.e., probability predictions),  $T = 1$  indicating no change to the original probability, and  $T < 1$  increasing model confidence. The temperature was calculated for four separate validation sets: left or right hemithorax displaying either tumor only or tumor plus effusion. For the left hemithorax, 275 sections displayed tumor only, and 97 sections displayed tumor plus effusion. For the right hemithorax, 216 sections displayed tumor only, and 101 sections displayed tumor plus effusion.

## RESULTS

The calculated temperatures for tumor only on the left hemithorax, tumor plus effusion on the left hemithorax, tumor only on the right hemithorax, and tumor plus effusion on the right hemithorax were  $T = 3.7, 3.4, 2.3, 2.1$ , respectively. All temperature values were greater than unity, which demonstrated the model's overconfidence prior to calibration.

## CONCLUSION

This work demonstrated the overconfidence of the initial model, as all temperatures were greater than one. This finding is consistent with the literature, since modern neural networks have been reported to be overconfident in their predictions. With a correctly calibrated model, accurate probability maps can be generated, thus streamlining automation of the mesothelioma segmentation task.

## CLINICAL RELEVANCE/APPLICATION

Due to the widespread use of neural networks for medical image classification and segmentation tasks, there is a need to ensure that model outputs are properly calibrated so that the resulting probabilities are indicative of the model's true confidence.

### S3A-SPPH-8 Adaptive Multimodality Medical Image Translation with Total-Body PET

Participants

Yuxi Jin, Shen Zhen, Guangdong, China (*Presenter*) Nothing to Disclose

## PURPOSE

To dynamically generate specified modality images from nonattenuation-corrected PET images according to user requirements.

## METHODS AND MATERIALS

To dynamically translate nonattenuation corrected (NAC) PET images to user-specified modality images, we embed a switch layer after each skip connection in the decoder of UNet. The switch layer learns the scale and offset parameters by two fully connected layers from the switch code. The switch codes are 001/010/100 for attenuation corrected (AC) PET/CT/MRI, respectively, and are coded by one-hot coding. The proposed model can adaptively output the specified modality image by normalizing the input features into the specified modality with the scale and offset parameters. A total of 119 patients scanned with the uEXPLORER scanner and 225 patients scanned with the uPMR scanner were retrospectively enrolled. We selected 13 patient cases as an external validation set for quantitative analysis, and the remaining 108 PET/CT cases and 215 PET/MR cases were used as experimental data to train the proposed network. To better train the proposed model, we mix and slice these data along the axial orientation to obtain two-dimensional images. After excluding 6547 slices for negative samples, we obtained 104286 slice samples in total. We randomly select 83429 samples for training, 10428 samples for validation, and 10429 samples for testing. The quantitative performance is evaluated by PSNR, MAE, and SSIM. The qualitative performance is measured by the error map between the model output and the ground truth.

## RESULTS

Our results achieved small quantification errors (low bias), good image quality (high PSNR), and high similarity (high SSIM) in the different body regions. All modal translation results have a similar appearance as the ground truth. Qualitative and quantitative analyses demonstrated the outstanding performance of the proposed model.

## CONCLUSION

We design a novel deep learning model to realize adaptively multimodality translation. This work can complete one-to-many modality translation, including direct PET attenuation correction (NAC-AC), CT synthesis (PET-CT), and MRI synthesis (PET-MRI). The simulated multimodality images have small qualification errors, good image quality, and high image similarity, which demonstrates that the proposed method is a promising tool in preclinical research, such as tumor contouring, anatomical localization, and dose calculation of radiotherapy.

## CLINICAL RELEVANCE/APPLICATION

The proposed adaptive multimodality medical image translation model can provide more comprehensive and integrated image information, aiding doctors in better understanding a patient's physical condition and making more accurate diagnoses and treatment plans.

### S3A-SPPH-9 Large Language Model (LLM) Passes the Radiology Physics Quiz

Participants

Shakthi Ramasamy, MD, (*Presenter*) Nothing to Disclose

## PURPOSE

With the recent advances in natural language processing, large language models (LLMs) such as GPT-4 have become increasingly powerful in their ability to understand and generate natural language. This study aims to assess the knowledge quiz-taking capacity of GPT-4 and GPT-3.5 for the Radiology Physics quiz.

## METHODS AND MATERIALS

An IRB-approved study was conducted. The study was conducted on a set of 60 multiple-choice questions generated from the Radiology

An IRB approval is not required. The study was conducted on a set of 62 multiple-choice questions compiled from the Radiology Core Physics App, which is used by radiology residents for their board preparations, and the sample questions for the Diagnostic, Nuclear, and Therapeutic content of the Initial Certification for Medical Physics from the American Board of Radiology (ABR) ([theabr.org](http://theabr.org)) website. Image-based questions were excluded from the study due to the limitations of the current GPT models. The questions were typed into the prompt of chat.openai.com models GPT-4 (subscription required) and GPT-3.5 (freely available to the public). The answers were correlated with the respective answer keys. The performance of the models was evaluated for a passing score of 75%. The performance of GPT-4 vs GPT-3.5 was compared using a two-proportion z-test.

## **RESULTS**

GPT-4 and GPT-3.5 took the Radiology Physics quiz, with GPT-4 achieving a success rate of 79% (49 correct) and GPT-3.5 achieving a success rate of 55% (34 correct). A two-proportion z-test was conducted to compare the performances of the two models. The calculated z-score is approximately 2.863, and the p-value is approximately 0.0042. Since the p-value (0.0042) is less than the significance level of 0.05, there is a statistically significant difference between the performances of GPT-4 and GPT-3.5 on the Radiology Physics quiz.

## **CONCLUSION**

The results indicate a significant difference between the performances of GPT-4 and GPT-3.5 on the Radiology Physics quiz. GPT-4 demonstrated a higher success rate, scoring above the passing score. GPT-3.5 had a notably lower success rate, indicating that the newer GPT-4 model has improved knowledge and understanding of radiology core physics compared to its predecessor.

## **CLINICAL RELEVANCE/APPLICATION**

The performance of GPT-4 in the Radiology Physics quiz highlights the potential application of large language models in medical education and training. GPT-4 could be a valuable resource for radiology residents, medical physicists, and other healthcare professionals seeking to enhance their understanding of radiology core physics principles. Additionally, the significant improvement in performance between GPT-3.5 and GPT-4 demonstrates the rapid advancements in natural language processing, indicating a promising future for LLMs in the medical field.

S3A-SPRO

### Radiation Oncology Sunday Poster Discussions I

#### Sub-Events

#### **S3A-SPRO-1 Ten-Year Experience of 5-Fraction Lung Stereotactic Body Radiotherapy (SBRT) for Biopsy-Proven Non-Small Cell Lung Carcinoma (NSCLC)**

#### Participants

John M. Watkins, MD, (*Presenter*) Nothing to Disclose

#### PURPOSE

Describe the local control (LC) and correlative clinicopathologic prognostic factors in patients treated with 5-fraction lung SBRT for biopsy-proven NSCLC.

#### METHODS AND MATERIALS

Intradepartmental quality assurance database of SBRT patients was utilized to identify patients with biopsy-proven NSCLC treated with 5-fraction SBRT at a single institution. Overall survival (OS), disease-free survival (DFS), and LC were measured from SBRT completion to last clinical follow-up or death (with DFS/LC backdated to last clinical follow-up if death occurred more than 3 months after last imaging). Regression analyses were performed on clinical (age, gender, race, tobacco use), radiographic (maximal tumor dimension, T-stage), pathologic (histology), and treatment (target coverage by dose, frequency of SBRT, SBRT start to completion) factors for association with LC. Kaplan-Meier method was employed for survival estimation.

#### RESULTS

Between 2011-2021, 107 patients were identified for inclusion in the present analysis. There were 112 total NSCLC targets, 60 (54%) being adenocarcinoma. Median age at the time of treatment was 75 years old (range, 38-93). Median SBRT dose was 5000 cGy (4500-6000 cGy) delivered over a median treatment time of 9 days (4-45). Median maximal internal target volume (ITV) dose (D 0.1 cc) was 6554 cGy (4497-7660), with median ITV receiving 5000 cGy (V50) and 5500 cGy (V55) of 100% (0-100%) and 98.8% (0-100%), respectively. Median planning target volume (PTV) V50 and V55 were 96.6% (0-100%) and 67.4% (0-99.7%), respectively. At median follow-up of 21 months (1-139), 75 (70%) patients had died. Median survivor follow-up was 39 months (7-139) with an estimated 3-year overall survival of 42.6% (32.6-52.6%). Forty-three patients experienced disease recurrence, of whom 8 had local failures (4 biopsy-proven). Estimated 3-year local control was 86.2% (76.2-96.2%). Univariate analysis of factors associated with LC identified only ITV V50 and PTV V50 as being significantly associated with LC. Estimated 3-year LC for ITV V50 > 98% versus < 98% was 88% and 79%, respectively. Estimated 3-year LC for PTV V50 > 95% versus < 95% was 91% and 75%, respectively.

#### CONCLUSION

s ITV V50 and PTV V50 were the most strongly associated factors with LC after 5-fraction lung SBRT in the present population.

#### CLINICAL RELEVANCE/APPLICATION

SBRT for early-stage NSCLC is an excellent option for inoperable patients or those who decline lobectomy. The present study demonstrates the importance of minimum target coverage on local control in a large population with mature follow-up.

S3A-SPVA

### Vascular Imaging Sunday Poster Discussions I

#### Sub-Events

#### **S3A-SPVA-1 Perivascular Fat Attenuation on CT Angiography is a Biomarker to Identify the Inflammation of Culprit Plaques in Internal Carotid Atherosclerosis**

##### Participants

Ziyu Tian, Jinan, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Our study aimed to evaluate the value of FAI as a tool for measuring plaque inflammation and identifying culprit plaques in internal carotid atherosclerosis.

##### METHODS AND MATERIALS

We analysed patients with internal carotid atherosclerosis who underwent neck CTA examination. The culprit plaque group and nonculprit plaque group were divided based on the clinical diagnosis. We compared the CTA characteristics, and baseline data between the two groups, as well as the FAI at the maximum stenosis, nonstenosis site and the whole ICA. A receiver operating characteristic (ROC) curve was used to determine the diagnostic accuracy of FAI for classifying culprit plaques in patients with bilateral ICA atherosclerotic stenosis.

##### RESULTS

In total, 101 and 94 patients were included in the culprit plaque (mean age, 64.78 years  $\pm$ 8.17; 84 men) and nonculprit plaque groups, respectively (mean age, 66.72 years  $\pm$ 7.51; 80 men). In the nonculprit plaque group, the perivascular FAI around the maximum stenosis site and around the whole ICA were lower than those in the culprit plaque group ( $P < 0.05$ ). In patients with bilateral extracranial ICA stenosis, ROC analysis of atherosclerotic stenosis in combination with FAI performed well in predicting the culprit plaque (AUC=0.863,  $P < 0.001$ ).

##### CONCLUSION

The perivascular FAI may be useful in identifying inflammation and the culprit plaque from ICA atherosclerosis and provides a new monitoring method for risk stratification.

##### CLINICAL RELEVANCE/APPLICATION

To our best knowledge, we first use the novel biomarker perivascular FAI to measure plaque inflammation and identify culprit plaques in internal carotid atherosclerosis. Our study first demonstrated that patients in the culprit plaque group had a higher level of perivascular inflammation measured by FAI than those in the nonculprit group. The noninvasive measurement of FAI can be used to evaluate and identify the local inflammation of culprit plaques in the ICA, which may help to monitor the inflammation progression of atherosclerotic plaques. Furthermore, FAI at the maximum stenosis site combined with stenosis can noninvasively predict the ICA culprit plaques, which enables the recognition of stroke risk patients and guides targeted treatments.

#### **S3A-SPVA-2 Dark Blood Computed Tomography Angiography Combined with Deep Learning Reconstruction for Thickened Carotid Artery Wall Imaging in Takayasu Arteritis Patients**

##### Participants

Tong Su, MD, Beijing, China (*Presenter*) Nothing to Disclose

##### PURPOSE

To assess the capability of a newly developed dark-blood CTA imaging, combined with deep learning reconstruction (DLR), to visualize the thickened carotid artery wall of Takayasu arteritis (TAK) patients, compared with conventional CTA images.

##### METHODS AND MATERIALS

This prospective study continuously recruited fifty-three patients with TAK who underwent neck CTA scans. All acquisitions were performed with a 320 row-detector CT scanner (Aquilion ONE Genesis Edition). Arterial and Delayed phase images were reconstructed using HIR (Adaptive Iterative Dose Reduction [AIDR] 3D) and DLR (Advanced Intelligent Clear-IQ Engine [AiCE]). Afterward, these two groups of images processed with a dedicated software (SURESubtraction) to generate dark-blood images. Therefore, four groups of images were produced for analysis: Delayed-HIR, Delayed-DLR, Dark-blood-HIR, Dark-blood-DLR. Qualitative parameters, including overall image quality, vessel wall visualization ability, and diagnostic confidence index, were rated by two radiologists independently according to a five-point scale. Quantitative parameters, including SNR of vessel wall, CNR between the vessel wall and lumen, were computed and compared. The vessel wall thickness of thickened common carotid artery was measured and the inter-rater variability was evaluated.

##### RESULTS

The qualitative scores of overall image quality presented Delayed-DLR was superior to Delayed-HIR and Dark-blood-DLR was

superior to Dark-blood-HIR (all  $p < 0.001$ ). CTA images processed with dark-blood technique presented higher qualitative scores in terms of vascular wall display ability and diagnostic confidence index, superior to conventional CTA images (all  $p < 0.001$ ). For brachiocephalic trunk, bilateral subclavian arteries and common carotid arteries, the SNRs and the CNR of Dark-blood-DLR images were significantly higher than those of Dark-blood-HIR images. And for bilateral common carotid arteries, the CNR of DLR presented higher quantitative scores than HIR for both delayed and dark-blood phases (all  $p < 0.001$ ). CTA images processed with dark-blood technique presented higher quantitative scores superior to conventional CTA images (all  $p < 0.001$ ). The average vessel wall thickness of carotid arteries measured on dark-blood phases were thicker than delayed phases (all  $p < 0.001$ ). And the highest ICC value between two raters was obtained on Dark-blood-DLR image (ICC 0.958).

#### **CONCLUSION**

s Compared to HIR, dark blood method combined with DLR reconstruction improved CTA image quality, and enhanced the visualization of thickened vessel wall of TAK patients.

#### **CLINICAL RELEVANCE/APPLICATION**

Dark blood method combined with DLR reconstruction is conducive to rapid and accurate measurement of vessel wall thickness.

## Abstract Archives of the RSNA, 2023

S3B-SPBR

### Breast Imaging Sunday Poster Discussions II

#### Sub-Events

#### **S3B-SPBR-1 Evaluation of a Deep-Learning Based Software Tool to Automatically Detect and Quantify Breast Arterial Calcifications on Digital Mammography**

##### Participants

Bilel Ben Jedidia, Champs Sur Marne, France (*Presenter*) Nothing to Disclose

##### PURPOSE

Breast arterial calcification (BAC) has been identified as an independent cardiovascular risk factor but is not routinely documented in mammography reports, partially because manually scoring by radiologists can be time-consuming. The aim of this study was to evaluate an artificial intelligence (AI) software that automatically detects and quantifies BAC.

##### METHODS AND MATERIALS

Women who underwent both 2D mammography and thoracic CT from 2009 to 2018 were retrospectively included in this single-center study. A deep learning based software (iCAD, Nashua, NH, USA) was used to automatically detect and quantify BAC with a 0 to 10 point BAC AI score. Results were compared with a previously described BAC manual score based on radiologists' visual quantification of BAC on the mammogram. Coronary Artery Calcium (CAC) score was manually evaluated using a 12-point scale on CT. Diagnostic performance of marked BAC AI score (defined as a BAC AI score = 5) for the detection of marked CAC (CAC score = 4) was analyzed. R software version 4.0.2 was used to perform the analysis.

##### RESULTS

502 women (mean age: 62 years  $\pm$  16) were included. BAC AI score was highly correlated with BAC manual score (Spearman's correlation 0.83,  $p < 0.01$ ). Marked BAC AI score for the detection of marked CAC had a sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of 32.7%, 96.1%, 71.2%, 83.1% and 81.9%, respectively. Marked BAC AI score was associated with marked CAC with an adjusted odds ratio of 12.139, (95% CI 11.92-12.35,  $p < 0.001$ ).

##### CONCLUSION

Automatic BAC AI score shows a very strong correlation to manual BAC scoring. Marked BAC AI score is associated with marked CAC (CAC score = 4).

##### CLINICAL RELEVANCE/APPLICATION

Automatic BAC AI score could be a useful tool to promote the integration of BAC in the mammography report and improve awareness of a woman's cardiovascular risk status.

#### **S3B-SPBR-2 Comparison of Supplemental Screening with Artificial Intelligence and Breast Ultrasound in Women with Dense Breast**

##### Participants

Su Min Ha, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

Whether using artificial intelligence (AI) system for screening mammography in women with dense breasts can replace supplemental breast ultrasound (US) is not well known. This study aimed to assess the value of supplemental US and AI with screening mammography in women with dense breasts.

##### METHODS AND MATERIALS

A retrospective database search identified consecutive asymptomatic women who underwent digital mammography (DM) and supplemental screening US between January 2017 and December 2018. AI software was applied for mammography, and four-view heat maps with a representative abnormality score per breast were evaluated. A BI-RADS category =3 on US and maximum abnormality score =10 on AI were considered positive results. The cancer detection rate (CDR) per 1000 examinations, sensitivity, specificity, and abnormal interpretation rate (AIR) were estimated and compared.

##### RESULTS

Among 5708 women (mean age  $\pm$  standard deviation: 52.4  $\pm$  7.9), 33 cancers (13 ductal carcinoma in situ and 20 invasive carcinoma) were found. DM alone showed CDR of 2.8 (16/5708; 95% CI: 1.7, 4.5), sensitivity of 48.5% (16/33; 95% CI: 32.5, 64.8), specificity of 94.3% (5350/5675; 95% CI: 93.6, 94.9) and AIR of 6.0% (341/5708; 95% CI: 5.4, 6.6). DM combined with AI showed a CDR of 3.2 per 1000 examinations (18/5708; 95% CI: 1.9, 4.9), sensitivity of 54.5% (18/33; 95% CI: 38.0, 70.2), specificity of 95.3% (5409/5675; 95% CI: 94.7, 95.8) and AIR of 5.0% (284/5708; 95% CI: 4.4, 5.6). DM combined with US yielded a CDR of 5.3 per 1000 examinations (30/5708; 95% CI: 3.6, 7.5), sensitivity of 90.9% (95% CI: 30/33; 95% CI: 76.4, 96.9), specificity of 77.6% (4401/5675; 95% CI: 76.5, 78.6), and AIR of 22% (1304/5708; 95% CI: 21, 24). CDR and sensitivity of DM with supplemental US

were significantly higher than that of DM alone ( $P < .001$ ), but with higher AIR and lower specificity ( $P < .001$ ). DM with AI showed higher specificity ( $P = .001$ ) with lower AIR ( $P = .002$ ) than DM alone, however with comparable CDR and sensitivity ( $P = .157$ ). AI correctly identified one invasive lobular cancer missed by DM and US. US alone detected additional 10 cancers, of which 90% were stage 0 ( $n=4$ ) and stage I ( $n=5$ ) invasive cancers, all node negative.

## CONCLUSION

s DM with supplemental US showed higher cancer detection ability than with supplemental AI in women with dense breasts. Supplemental US detected additional early-stage cancers in women with dense breasts without AI recall.

## CLINICAL RELEVANCE/APPLICATION

The combined use of digital mammography with artificial intelligence cannot replace supplemental breast US in women with dense breasts yet.

### S3B-SPBR-3 Bias-Free Artificial Intelligence: Developing a Deep Learning Algorithm for Diverse Racial Populations in Breast Cancer Diagnosis

Participants

Dogan Polat, MD, Dallas, TX (*Presenter*) Nothing to Disclose

## PURPOSE

This study aimed to develop a deep learning (DL) algorithm to facilitate automated diagnosis of breast cancer using mammography.

## METHODS AND MATERIALS

The algorithm was trained on a total of 136,172 mammograms that includes an isolated partition of Optimam ( $n=103472$ ), DDSM ( $n=2812$ ), and multiple single and multi-institution datasets across southeast Asia, Africa, South America, and Europe ( $n=29888$ ). The algorithm was then tested on 9304 cases [Optimam ( $n=8980$ ) and independent blinded single institution ( $n=324$ )]. Cancers comprised 34.7% ( $n=3226$ ) of 9304 mammograms (23.6% invasive, 8.7% DCIS and 2.5%, unknown types), while 65.3% ( $n=6078$ ) were benign/negative. Race was stratified into five categories: white ( $n=6943$ , 74.6%), Asian ( $n=555$ , 6%), black ( $n=411$ , 4.4%), other ( $n=235$ , 2.5%), and unavailable/withheld ( $n=1160$ , 12.5%). Chi-square tests compared categorical variables, while t-tests and ANOVA compared area under the curve (AUC) of the model for different groups and means. ROC curves are compared in pairwise manner using pROC library in R.

## RESULTS

Mean patient age was 61.1 (SD±7.7). While lesion type information either was not available or negative for 5604 (60.2%) patients, 2544 (27.3%) presented as soft tissue abnormality and 1156 (12.4%) as calcifications. The algorithm achieved AUC of 0.91, 0.95 sensitivity, 0.55 specificity, 0.92 negative predictive value (NPV) and 0.66 positive predictive value (PPV). When stratified by lesion type, the algorithm performed better in characterizing soft tissue lesions [compared to calcification and other lesion types with following parameters AUC, sensitivity, specificity, NPV and PPV: 0.87, 0.9, 0.59, 0.48, 0.93 vs 0.71, 0.8, 0.49, 0.55, 0.76, 0.71 ( $p < 0.001$ )]. Similarly, better diagnostic performance was achieved in detecting invasive cancer than DCIS (AUC 0.87 vs. 0.72,  $p < 0.001$ ), and cancer size  $>20\text{mm}$  vs  $<5\text{mm}$  (AUC 0.87 vs 0.77, respectively  $p < 0.001$ ). Performance was comparable across racial groups with the following AUC, sensitivity, specificity, NPV, and PPV: White (0.90, 0.86, 0.76, 0.92, 0.63), Black (0.92, 0.89, 0.75, 0.96, 0.54), Asian (0.89, 0.86, 0.75, 0.94, 0.54), Other (0.91, 0.85, 0.82, 0.95, 0.59), and Unknown (0.90, 0.90, 0.75, 0.82, 0.86). All racial groups were compared to global AUC and found no significant difference ( $p=1$  for each).

## CONCLUSION

s The algorithm's performance on datasets comprising diverse racial populations is comparable to that of breast radiologists, tested on datasets that include cases representative of real-world clinical settings.

## CLINICAL RELEVANCE/APPLICATION

The mammography DL algorithm showed high diagnostic performance across diverse datasets, comparable to US screening benchmarks, promising for large-scale screening triaging.

### S3B-SPBR-4 Simulating Synthetic Post-contrast Breast MRI from Single Pre-contrast MRI Sequence Using Deep Learning Model

Participants

Su Min Ha, MD, PhD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the feasibility of deep learning model for simulated post-contrast T1-weighted breast MR images generated using single pre-contrast MR image in patients with breast cancer. In addition, to validate the deep model network implemented with five pre-contrast sequences including T2-weighted and diffusion-weighted imaging.

## METHODS AND MATERIALS

In this retrospective study, 363 women with breast cancer and contrast-enhanced breast MRI were identified between June 2019 and December 2019 at a single academic institution. An Extra-Dimensional U-net with visual geometry group was developed to simulate T1-weighted post-contrast images from single pre-contrast T1-weighted images. A total of 330 cases were used for the training set and 24 cases were used for validation set. In addition, we externally validated the deep learning model using five pre-contrast sequences (T1-weighted non-fat suppressed [FS], T1-weighted FS, T2-weighted FS, apparent diffusion coefficient, and diffusion-weighted imaging) [[https://github.com/ecalabr/breast\\_simulated\\_gad](https://github.com/ecalabr/breast_simulated_gad)]. Performance was evaluated qualitatively regarding lesion visibility and five point scale (5: excellent, 4: good, 3: acceptable, 2: poor and 1: unacceptable), and also quantitatively with metrics including peak signal to noise ratio (PSNR) and SSIM (structural similarity index).

## RESULTS

The validation set of 24 MRI examinations in 24 women (mean age, 56 years; range, 43-73 years) were evaluated. There were 23 invasive ductal carcinoma, 1 ductal carcinoma in situ; 19 masses and 1 non-mass, 4 mass with nonmass lesions (mean size, 2.2cm; range, 1.1-7.0cm). With our model, 63% (15/24) were visible and were rated 50% (12/24) good or excellent or acceptable and 50%

(12/24) unacceptable or poor. In comparison, with the open-source deep model, 70% (17/24) lesions were visible and rated 46% (11/24) good or excellent or acceptable, and 54% (13/24) unacceptable or poor. With our developed model, simulated post-contrast T1-weighted breast MR images showed PSNR of 27.10 and SSIM of 0.87.

## CONCLUSION

Our developed model using single pre-contrast T1-weighted imaging is capable of producing the simulated post-contrast MR image, and is comparable to outcomes using suggested deep learning model.

## CLINICAL RELEVANCE/APPLICATION

There is increasing need for non-contrast breast MRI for cancer detection due to gadolinium retention and more accessibility of breast MRI.

### S3B-SPBR-5 Machine Learning-based Texture Analysis of Axillary LNs Using 3-T MRI for Predicting LN Metastasis in Breast Cancer

#### PURPOSE

This study aimed to determine whether texture analysis for 3-T magnetic resonance imaging (MRI) in axillary lymph nodes (LNs) can predict LN metastasis in breast cancer.

#### METHODS AND MATERIALS

This retrospective study included 204 patients who underwent breast and axillary surgery for breast cancer between March 2022 and December 2022. We assessed common features of axillary LNs, including clinicopathologic features and MRI assessment by radiologists, as well as texture features of axillary LNs on contrast-enhanced T1-weighted images using commercial software based on PyRadiomics. The index LN was determined as the LN with the largest cortical thickness. Logistic regression with feature selection was used to reduce the dimensionality of the data (14 clinicopathologic and 869 texture features). Using the selected features, we trained an XGBoost classifier to build common, radiomics, and combined common and radiomics models for predicting LN metastasis. The diagnostic performance of predictive models for LN metastasis was compared by using generalized estimating equation analysis.

#### RESULTS

Of the 204 women, 47 (23%) were diagnosed with LN metastases. The XGBoost classifier with common features, including clinicopathologic and MRI assessment, showed the lowest diagnostic performance (accuracy and area under the receiver operating characteristic curve [AUC], 73.81% and 0.846). The radiomics and combined common and radiomics model with the XGBoost classifier showed better diagnostic performance than that the analysis of common features alone (accuracy and AUC, 90.48% and 0.939, 90.48% and 0.939 vs. 73.81% and 0.846,  $p < 0.05$ ). In addition, the combined common and radiomics model showed a positive predictive value of 100% for predicting LN metastasis.

## CONCLUSION

Texture analysis using an XGBoost classifier for axillary LNs on 3-T MRI may be a useful tool in predicting LN metastasis in patients with breast cancer.

## CLINICAL RELEVANCE/APPLICATION

Machine learning-based texture analysis of axillary LNs using 3T-MRI can help predict axillary LN metastasis and potentially de-escalate axillary surgery in patients with breast cancer.

### S3B-SPBR-6 Artificial Intelligence Helps General Radiologists and Breast Imaging Specialists Find Challenging-to-Detect Cancers

#### Participants

Jiye Kim, PhD, Cambridge, MA (*Presenter*) Employee, RadNet, Inc  
Bryan Haslam, PhD, Cambridge, MA (*Presenter*) Employee, RadNet, Inc

#### PURPOSE

There is growing evidence that AI helps radiologists detect more breast cancers in screening mammography. However, there has been little explanation of how AI helps radiologists with varying levels of specialty. Here, we investigated how AI for DBT helps general radiologists and breast imaging specialists detect breast cancer lesions with varying degrees of how challenging the cancers are to detect.

#### METHODS AND MATERIALS

Following an IRB approved protocol, a reader study was conducted to evaluate the interpretative performance of 18 radiologists including 9 general radiologists and 9 breast imaging specialists. Each reader read 240 retrospectively collected DBT screening exams (100 cancers and 140 non-cancers) once with and once without the aid of AI. General radiologists' and breast imaging specialists' performance, as measured by AUC, were examined with vs without AI. Additionally, cancer exams were sorted by degree of difficulty in two different ways. First, the cancer exams were grouped by the BIRADS assessment given at the time of original clinical interpretation: a) recalled cancers ( $n = 67$ ) were those given a BIRADS 0 and b) non-recalled cancers ( $n = 33$ ) were those given a BIRADS 1 or 2. The non-recalled exams are considered more difficult given that these are the clinically "missed" exams where the interpreting radiologist at the time of exam acquisition deemed there were no suspicious findings for a recall. Second, the cancer exams were subdivided into a) harder ( $n = 16$ ), b) medium ( $n = 11$ ) and c) easier ( $n = 73$ ) cancer cases based on the proportion of the readers in the study that recalled the exam when reading without the aid of AI ( $< 50\%$  recalled,  $50\%$  to  $75\%$  recalled, and  $> 75\%$  recalled, respectively).

#### RESULTS

Overall, both general radiologists (AUC increase of 0.075) and breast imaging specialists (AUC increase of 0.050) demonstrated improved performance when reading with AI than without AI. Across both methods of sorting the cancer exams by difficulty, there were greater improvements with AI when radiologists interpreted more challenging (AUC increase for non-recalled: 0.100, harder: 0.176 and medium: 0.110) than less challenging cancers (recalled: 0.040 and easier: 0.027). The largest boost in performance was

observed for general radiologists on the harder cancers with an AUC improvement of 0.186.

## CONCLUSION

s AI helped both general radiologists and breast imaging specialists improve cancer detection performance overall and to a greater extent for the more challenging cancer cases.

## CLINICAL RELEVANCE/APPLICATION

AI for screening DBT helps radiologists with varying levels of specialty, especially on difficult to detect cancers that would likely go undetected until a future exam, suggesting that AI may help detect these cancers earlier.

### S3B-SPBR-7 Examining the Potential of ChatGPT to Derive Differential Diagnoses from Transcribed Radiological Findings in Breast and Ultrasound Imaging

Participants  
Shawn Sun, MD, MS, Anaheim, CA (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the accuracy and reliability of ChatGPT3.5 and ChatGPT4 in producing a differential diagnosis from transcribed radiological findings of breast and ultrasound radiology cases.

## METHODS AND MATERIALS

A sample of 25 breast and ultrasound imaging cases were selected from a radiology textbook, from which the answers were used as the gold standard. The case images and history were converted into standardized prompts that contained purely descriptive language of the cases and a query for the most likely diagnosis, top three differential diagnoses, and the corresponding explanations and references from the medical literature. These prompts were fed into the ChatGPT3.5 and ChatGPT4 algorithms. Generated responses were analyzed for accuracy by comparison with the original literature and reliability through manual verification of the generated explanations and citations. The top 1 accuracy and the top 3 accuracy were defined as the percentage of generated responses that matched the original diagnosis and the complete differential provided by the original literature. An additional differential diagnosis score was defined as the proportion of differentials that matched the original literature's answers for each case. Comparisons were made between the results of the two algorithms using a one-tailed two proportion z-test method.

## RESULTS

The top 1 accuracy and top 3 accuracy, for ChatGPT3.5 versus ChatGPT4 were 32% compared to 40% ( $p=0.28$ ) and 8.0% compared to 12.0% ( $p = 0.32$ ), respectively. The average differential diagnosis score of ChatGPT3.5 versus ChatGPT4 was 38.9% compared to 45.2% ( $p=0.33$ ). ChatGPT3.5 and ChatGPT4 hallucinated 32.0% versus 8.0% ( $p=0.017$ ) of the references provided and generated 6 total false statements versus 2 total false statements, respectively.

## CONCLUSION

s The ChatGPT algorithms were able to produce a differential diagnosis for prompts containing descriptive radiological findings. The responses matched the expert literature from which the cases originated a minority of the time, though a non-statistically significant improvement was made in the accuracy categories from 3.5 to the 4th generation algorithm. The renowned hallucination effect appeared more frequently in generated citations compared to algorithm-produced statements, with both showing improvement in the latest generation.

## CLINICAL RELEVANCE/APPLICATION

ChatGPT and Large Language Models (LLM) possess considerable potential to transform clinical and educational medicine. Awareness of their accuracy and potential for mistakes will contribute to a more comprehensive understanding of the limitations of such new tools.

### S3B-SPBR-8 Improving Artificial Intelligence (AI) Risk Assessment with Multiple Imaging Modalities and Prior Imaging Data

Participants  
Eliana Goldberg, MD, Bronx, NY (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study is to evaluate the efficacy of multimodal AI algorithms (full field digital mammography (FFDM)/digital breast tomosynthesis (DBT), breast ultrasound (US) and prior imaging) into breast cancer risk assessment models

## METHODS AND MATERIALS

Our IRB-approved research utilized a multimodal AI system trained on a dataset of FFDM, DBT, and US exams. These exams were conducted between 2010 and 2020, involving 1,964,416 exams on 324,978 patients. We used a patient-based 60-10-30 split for training/validation/testing. The testing dataset comprised FFDM/DBT/US from patients not included in the training/validation sets, with histopathology/imaging stability as reference standard. The AI risk model was designed to predict cancer risk at multiple time points: 1 year, 3 years, 5 years, and 10 years based on imaging alone. We compared the model's AUROC, sensitivity, and specificity for each risk assessment interval. We also compared 10-year risk assessments to Tyrer-Cuzick (TC) scores.

## RESULTS

On a test set of 29,845 patients (average age 59.1, standard deviation 11.09, 74,024 exams), 3.05% (910/29845) were diagnosed with breast cancer within 10 years. The AI model achieved AUROC for breast cancer risk assessment as follows: 0.888 (1 year), 0.804 (3 years), 0.770 (5 years), and 0.760 (10 years). Sensitivity was 71.5% (1 year), 52.3% (3 years), 44.0% (5 years), and 40.7% (10 years). For women with dense breasts, AI model AUROC was 0.876 (1 year), 0.779 (3 years), 0.750 (5 years), and 0.739 (10 years). Sensitivity was 69.8% (1 year), 50% (3 years), 42.7% (5 years), and 39.8% (10 years). For women with non-dense breasts, model AUROC was 0.896 (1 year), 0.822 (3 years), 0.781 (5 years), and 0.774 (10 years). Sensitivity was 72.2% (1 year), 52.8% (3 years), 43.1% (5 years), and 39.5% (10 years). Specificity was held constant at 90% for model binarization thresholds. On a random subset of 134 patients with cancer and non-cancer patients, model AUROC was 0.826 (10 years), while TC scores

was 0.644 (10 years). When patients were binarized into high or low risk, AI was more informative than was TC. For example, patients who were assessed as TC high risk but AI low risk had a low incidence of cancer (18.9%; 7/37), whereas patients who were assessed as TC low risk and AI high risk had a high incidence of cancer (89.1%; 33/37).

## **CONCLUSION**

s Multimodal breast cancer risk assessment based on FFDM/DBT, US imaging and prior examinations outperforms standardized risk cancer assessment.

## **CLINICAL RELEVANCE/APPLICATION**

Integrating multiple imaging modalities and prior imaging into AI breast cancer risk assessment models enhances performance, enabling the development of a personalized, data-driven, and evolving screening schedule based on an individual's risk profile over time.

## **S3B-SPBR-9 Self-Supervised Pretrained Vision Transformers for Breast Ultrasound Classification**

### **PURPOSE**

Develop a deep learning model for automated breast ultrasound classification. For computer vision tasks such as this one, convolutional neural networks (CNN) have been the gold standard. Here we study the application of Vision Transformers (ViT) for breast ultrasound classification. Specifically, we examine how the performance of ViT can be improved with self-supervised pretraining.

### **METHODS AND MATERIALS**

A total of 647 breast ultrasound images were collected. A label of either benign or malignant was given to each image by radiologists. Malignant cases were validated with histopathologic results from subsequent fine needle aspiration biopsies. The final dataset included 437 benign and 210 malignant US images (PMID: 31867417). The ViT explored in this study consists of 12 transformer encoder layers with 12 multi-attention heads. First the images are tokenized into patches. The patches are linearly projected and combined with positional encodings before input into the sequence of transformer encoders. We study three pretraining paradigms: random weight initialization, supervised pretraining on ImageNet, and self-supervised pretraining on ImageNet. In supervised learning, annotated labels are used during pretraining. In self-supervised learning, representations are learned without any explicit labels; instead, supervisory signals are derived from the data itself. After the models are pretrained, one fully connected layer is added on top of each model and trained to perform binary classification.

### **RESULTS**

We evaluate our models using five-fold cross validation. The ViT with random weight initialization achieves an AuROC of  $0.67 \pm 0.08$ . The supervised pretrained ViT achieves an AuROC of  $0.88 \pm 0.04$ . The self-supervised pretrained ViT achieves an AuROC of  $0.92 \pm 0.02$ . Visualization of the self-attention heat maps show that the self-supervised ViT can learn semantic segmentation information without any explicit segmentation masks.

## **CONCLUSION**

s We show that self-supervised pretraining offers a performance boost compared to supervised pretraining ViT for breast ultrasound classification. Overall, our results show that with the advances being made in deep learning, it may be worthwhile to renew the discussion on the role of ultrasound in screening for breast cancer.

## **CLINICAL RELEVANCE/APPLICATION**

In the context of breast cancer screening, mammography is the gold standard. Breast ultrasound, despite being widely available and posing no radiation risk, is limited by a high rate of false positives, operator dependency, and a growing shortage of (breast) radiologists. However, advances in deep learning can potentially mitigate these limitations.

## Abstract Archives of the RSNA, 2023

S3B-SPCA

### Cardiac Imaging Sunday Poster Discussions II

#### Sub-Events

#### **S3B-SPCA-1 Inferior Left Atrial Diverticulum Communicating with the Right Atrium or Inferior Vena Cava: CT and Clinical Features**

##### **PURPOSE**

Interatrial communications in atypical locations are found at CT. However, information on imaging findings of atypical or nonseptal communications between two cardiac atria has not been known to dates. The purpose of this study was to evaluate the prevalence, location, size and morphological characteristics of left trial (LA) diverticula communicated with right atrium on cardiac CT.

##### **METHODS AND MATERIALS**

This retrospective study included 222 consecutive patients who underwent cardiac computed tomography and showed incidental inferior LA diverticula (ILAD). The prevalence, number, size, morphological characteristics and location of ILAD communicating with the right atrium or inferior vena cava were analyzed. Shunts were defined as anatomical defects between the two structures with or without visible contrast flow or attenuation step up.

##### **RESULTS**

The prevalence of ILAD with shunt was 9.9% (22/222) among ILADs. Shapes of ILAD with shunt were tubular (n = 12, 54.5%), saccular (n = 8, 36.3%), and network-like appearance (n = 2, 9.1%). Mean ostial diameter of ILAD and mean size of shunt were 6.4 mm, 4.9 mm, respectively. Of the 22 patients, 7 (31.8%) had two or more shunts.

##### **CONCLUSION**

s Cardiac CT helps to detect a new type of interatrial communications which can mimic classical atrial septal defects. Although their clinical significance remains unclear, radiologists should be aware of them and report their findings.

##### **CLINICAL RELEVANCE/APPLICATION**

Our study is the first study to visually assess the category using ECG gated cardiac CT for LA diverticulum with shunt to RA.

#### **S3B-SPCA-2 Cardiac CT-derived Global and Regional Epicardial Adipose Tissue Contributes to Atrial Fibrillation in Patients without Left Atrial Myopathy as Defined by Endocardial Voltage Mapping**

##### **PURPOSE**

Atrial myopathy contributes to the pathogenesis of atrial fibrillation (AF), but many AF patients have no obvious atrial myopathy. Epicardial adipose tissue (EAT) has recently been shown to be greater in AF patients than those without AF. Our aim was to assess the relationship of EAT in AF patients with/without atrial myopathy defined by endocardial voltage mapping.

##### **METHODS AND MATERIALS**

75 AF patients with cardiac CT prior to pulmonary vein ablation were prospectively enrolled. Left atrial (LA) endocardial voltage mapping was performed in all patients. Left atrial myopathy was defined as the sum of all low voltage (<0.5mV) areas (LVA) exceeding 5% of total LA surface area. AF patients were assigned to either LVA- (<5% LVA) or LVA+ (=5% LVA) groups. 48 age-, sex- and BMI-matched patients without AF and structural heart disease/coronary artery disease, who had undergone cardiac CT, were identified as a control group. Total, LA and right atrial (RA) EAT were quantified on CT using fat density thresholding (-195 to -30 HU) after segmenting areas of interest using standard 3D post-processing software. Differences between groups were assessed using one-way ANOVA and relationships were assessed using correlation analysis. Inter-observer variability of EAT analysis was assessed with correlation analysis and Coefficient of Variance (CV) using random subset of 35 AF patients.

##### **RESULTS**

LVA- patients (n=50; 6% f) were younger than LVA+ patients (n=25; 44% f). BMI correlated with total EAT (Spearman r 0.50; p<.01), LA EAT (r 0.47; p<.01) and RA EAT (r 0.41; p<.01) in AF patients and similarly in controls. Between LVA+ and LVA- AF patients, there was no significant difference for total EAT (89.1±41.1cm<sup>3</sup> vs 83.5±31.1cm<sup>3</sup>; P=.5), LA EAT (9.9±5.8cm<sup>3</sup> vs 8.9±3.5cm<sup>3</sup>; P=.6) and RA EAT (7.4±3.8cm<sup>3</sup> vs 7.5±3.1cm<sup>3</sup>; P=.9). Compared to controls, LVA- patients had greater total EAT (80.1±29.3cm<sup>3</sup> vs 56.5±22.1cm<sup>3</sup>; p<.001), greater LA EAT (8.9±3.5cm<sup>3</sup> vs 4.5±1.9cm<sup>3</sup>; p<.001) and greater RA EAT (7.5±3.1cm<sup>3</sup> vs 4.9±2.0cm<sup>3</sup>; p<.001). There was good agreement for total EAT (r=0.99), LA EAT (r=0.98) and RA EAT (r=0.98) between observers (all p<.001) with CV of 3.5%, 6.4% and 6.2% respectively.

##### **CONCLUSION**

s EAT does not differ between AF patient with or without LA myopathy, but EAT is significantly greater among AF patients without LA myopathy compared to controls without AF. These findings suggest that EAT may contribute to the pathogenesis of AF even in the absence of LA myopathy. Strategies to monitor and reduce EAT may help to improve rhythm control in these patients.

## CLINICAL RELEVANCE/APPLICATION

Increased EAT volume may play an important role in AF pathogenesis in patients without LA myopathy; further studies should analyse the effect of EAT reducing treatment and downstream effects on AF incidence.

### S3B-SPCA-3 Metabolic Syndrome is Associated with Impaired Left Atrial and Left Ventricular Deformation and Abnormal Atrioventricular Interaction in Patients with Myocardial Infarction

Participants  
jing liu, MD, Chengdu, China (*Presenter*) Nothing to Disclose

#### PURPOSE

Metabolic syndrome (MetS) is a cluster of cardiovascular risk factors that predicts poor short - or long-term outcomes in patients with myocardial infarction (MI). However, the potential mechanisms influencing prognosis are still unclear. Thus, this study aimed to determine the effect of MetS on left atrial (LA) and left ventricular (LV) deformation and abnormal atrioventricular interactions in MI patients.

#### METHODS AND MATERIALS

A total of 181 MI patients, including 119 without MetS (MI [MetS-]) and 62 with MetS (MI [MetS+]), and 58 controls who underwent 3.0 T cardiac magnetic resonance (CMR) were included. LA ejection fraction [LAEF] and deformation indices (reservoir, conduit, and booster pump function) and LV deformation parameter (global peak radial, circumferential, and longitudinal strain [PS]) based on CMR three-dimensions feature tracking were measured and compared among groups. Correlations of MetS and LV deformation and geometry with LA functional indices were assessed by multivariable linear regression analysis.

#### RESULTS

LA reservoir function (total EF and total strain) and conduit function (passive strain) and LV deformation parameters (radial, circumferential, and longitudinal PS) significantly decreased from the control group, through the MI (MetS-), to MI (MetS+) group (all  $P < 0.05$ ). Compared with controls, the booster pump function (active EF and active strain) was decreased in the MI (MetS+) group (all  $P < 0.05$ ) but preserved in the MI (MetS-) group. Furthermore, multivariate linear regression demonstrated that MetS was independently associated with total and active LAEF, total and passive strain ( $\beta = -0.172$  to  $-0.200$ , all  $P < 0.05$ ) in MI patients; LA reservoir and conduit function were independently associated with LV circumferential PS ( $\beta = 0.230$  to  $0.394$ , all  $P < 0.05$ ) and longitudinal PS ( $\beta = 0.189$  to  $0.354$ , all  $P < 0.05$ ), LA passive strain and strain rate were independently associated with LV mass ( $\beta = -0.178$  and  $-0.298$ , all  $P < 0.05$ ).

#### CONCLUSION

s Coexisting MetS may exacerbate the adverse effects of MI on LA and LV dysfunction. LV circumferential and longitudinal PS are stable predictors of LA three-phasic function; LV hypertrophy is independently associated with LA conduit function.

## CLINICAL RELEVANCE/APPLICATION

These results suggest that metabolic disorders may be important in managing patients with myocardial infarction.

### S3B-SPCA-4 MRI Evaluation by T1 Mapping of the Post Myocardial Infarction Left Ventricular Thrombus

#### PURPOSE

The objective of this study is to evaluate the post myocardial infarction left ventricular thrombus on cardiac MRI by measuring its T1 mapping value, thus to determine the age of thrombus.

#### METHODS AND MATERIALS

This observational retrospective study was performed on all patients scheduled for 3.0 Tesla cardiac MRI post myocardial infarction on our institution from January 2015 to December 2022. 35 patients with a left ventricular thrombus that may be measurable on T1 mapping sequence were included. They were separated in two groups depending on the period of time between the infarct and the MRI - less than three months: group A; more than three months: group B. T1 mapping value was measured for all thrombi.

#### RESULTS

T1 of thrombi was  $1098 \pm 61$  ms in group A and  $1316 \pm 75$  ms in group B,  $p < 0.001$ . T1 of the myocardium was  $1224 \pm 73$  ms in group A and  $1254 \pm 48$  ms in group B,  $p = 0.139$ . T1 of the blood pool was  $1934 \pm 137$  ms in group A and  $2008 \pm 124$  ms in group B,  $p = 0.135$ .

#### CONCLUSION

s Recent thrombi had shorter mapping T1 than old thrombi.

## CLINICAL RELEVANCE/APPLICATION

This method represents a new approach for the age and the maturity of left ventricular thrombus. It provides complementary information for the recommendations of imaging control and anticoagulation therapy.

### S3B-SPCA-5 STEMI Patients: Who Gets What Imaging

#### PURPOSE

Our study aims to determine if hospital and patient characteristics affect what type of imaging modality ST elevated myocardial infarction (STEMI) patients receive.

#### METHODS AND MATERIALS

The National Emergency Department Sample (NEDS) database was retrospectively queried for patients with a primary diagnosis of STEMI. Logistic regression was used to determine the likelihood of receiving ultrasound and fluoroscopy based cardiac imaging with respect to hospital characteristics such as region, teaching status, and trauma level designations. We also looked at patient characteristics including hypertension, hyperlipidemia, and tobacco usage.

## RESULTS

Of the 175,700 patients with a primary diagnosis of STEMI, most were white (74.1%), seen at a non-trauma hospital (49.7%), and insured through medicare (44.8%). Female patients were less likely to get fluoroscopy imaging (OR: .927, 95%CI .871 - .987) than male patients. Black patients were also less likely to get fluoroscopy imaging relative to white patients (OR: .711, 95%CI .583 - .869). Patients with private insurance and patients at teaching hospitals were more likely to get fluoroscopy relative to medicare patients (OR: 1.211, 95%CI 1.069 - 1.371) and patients at non teaching hospitals (OR: 1.563, 95%CI 1.133 - 2.155). Patients at trauma hospitals level 1-3 were more likely to get fluoroscopic cardiac imaging compared to non trauma hospitals: Level 1 (OR: 1.593, 95%CI 1.022 - 2.486), Level 2 (OR: 2.489, 95%CI 1.813 - 3.417), Level 3 (OR: 2.216 95%CI 1.544 - 3.180) Patients with private insurance were more likely to get ultrasound cardiac imaging compared to medicare patients (OR: 1.165, 95%CI 1.025 - 1.325). Trauma level had no effect on patients receiving ultrasound cardiac imaging compared to non trauma: Level 1 (OR: 1.548, 95%CI 0.856 - 2.801), Level 2 (OR: 1.548, 95%CI 0.796 - 2.266), Level 3 (OR: 0.941 95%CI .559 - 1.583)

## CONCLUSION

We found that females and black patients are less likely to receive fluoroscopy imaging relative to male and white patients, respectively. While ongoing gender and race disparities may play a role in these findings, further studies are needed to fully elucidate this relationship. Additionally, private insurance beneficiaries are more likely to get imaged with fluoroscopy. Proximity to hospitals with imaging capabilities and better access to resources may play a role in our findings

## CLINICAL RELEVANCE/APPLICATION

Hospitals and clinicians need to re-evaluate their imaging algorithm for black and female patients. We also found that type of insurance and teaching hospital drastically affects likelihood of receiving fluoroscopy. These findings indicate a deeper health inequality that hospitals and physicians should address together in order to make healthcare more equitable

### S3B-SPCA-6 STEMI Patients: Can Imaging Predict Cost of Stay and Mortality?

#### PURPOSE

Our study aims to determine if imaging modality can predict cost of stay and mortality in patients who have a primary diagnosis of ST elevated myocardial infarction (STEMI).

#### METHODS AND MATERIALS

The national emergency department sample (NEDS) database was retrospectively queried for patients who had a primary diagnosis of STEMI. A multivariate linear regression model was used to account for key clinical covariates including age, sex, race, insurance status, income quartile, teaching status, trauma level, and cardiac risk factors such as tobacco use, coronary artery disease, and hyperlipidemia to determine cost associated with cardiac imaging. Primary outcomes focused on cost associated with use of CT, MRI, fluoroscopy, and ultrasound. A secondary analysis, with the same multivariate model, was performed to determine if certain imaging corresponded to increased odds of death.

## RESULTS

Of the 175,700 patients, in our analysis, that presented to the emergency department with a primary diagnosis of a STEMI, most were female (69.3%), white (74.1%), and had a median income in the 1st quartile (29.4%). There was increased cost associated with all cardiac imaging modalities (relative to patients who did not receive an imaging modality); fluoroscopy (B: 27,630, 95%CI 15,748-39,311), CT (B: 32,757, 95%CI 4,036-61,478), MRI (B: 397,766 380980-414,751), x-ray (24,740, 95%CI 6,426-43,055) and ultrasound (B: 25,492, 95%CI 14,150-36,834). Patients who got imaging with ultrasound (OR: 0.76, 95%CI 0.64-0.90) or fluoroscopy (OR: 0.45 95%CI 0.39-0.53) were less likely to die relative to patients who did not get imaged by those modalities. There was no difference in death rate in patients who were imaged with X-ray (OR:0.79, 95%CI 0.47-1.35) or CT scan (OR: 0.62, 95%CI 0.37-0.1.04).

## CONCLUSION

STEMI patients who get imaging pay significantly more than patients who do not get imaging. However, the use of x-ray or CT scan imaging does not necessarily lead to better outcomes, as shown in the death rates we have found. Each imaging modality is found to increase cost of stay in the tens of thousands of dollars, with MRI, being the exception, increasing cost of stay by hundreds of thousands of dollars.

## CLINICAL RELEVANCE/APPLICATION

Hospitals and clinicians should be encouraged to rethink what type of imaging they order for STEMI patients. Our study shows that CT and X-ray do not decrease mortality rate, while increasing cost of stay for patients by tens of thousands of dollars.

### S3B-SPCA-7 Diagnostic Accuracy of Dynamic Stress CT Myocardial Perfusion with Regadenoson for the Detection of Hemodynamically Significant Coronary Artery Disease

#### Participants

Cesar Urtasun Iriarte I, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the diagnostic performance of dynamic stress CT myocardial perfusion imaging (CT-MPI) in combination with coronary CT angiography (CCTA) to accurately identify hemodynamically significant coronary artery disease (CAD) compared to the gold standard (invasive coronary angiography, ICA; and invasive fractional flow reserve, iFFR).

#### METHODS AND MATERIALS

Between December 2019 and February 2023, 141 patients with suspected or known CAD underwent CCTA and dynamic stress CT-MPI employing regadenoson as stressor. The presence of hemodynamically significant coronary lesions was determined by CCTA (CAD-RADS=3) and CT-MPI (myocardial blood flow relative to remote myocardium<0.85) compared to CCTA alone, using angiographic severity and a iFFR of =0.80 as reference.

## RESULTS

A total of 141 patients (113 males, mean 64.8±10.1 years old, 24 with prior stent implantation) were evaluated. CCTA and CT-MPI

were positive in 67 (47.5%) and 50 (35.5%) patients, respectively. 43 patients (32 males, 65.6±11.1 years old; 93.3% with CAD-RADS =3) who underwent ICA were retained for the statistical analysis. Compared to ICA, the patient-based analysis of CCTA showed a sensitivity of 100%; specificity of 50%, negative predictive value (NPV) of 100% and a positive predictive value (PPV) of 92.5%. The approach comprising CCTA and dynamic stress CT-MPI increased the specificity (97.4%) and PPV (97.4%). The accuracy of the combination of the anatomical and functional techniques was also higher (97.7% vs 93%). Receiver operating curve (ROC) analysis showed improved discrimination accuracy for the combination of CCTA and CT-MPI (0.92; CI 0.74-1; p=0.001) compared with CCTA alone (0.75; CI 0.49-1; p=0.052).

#### **CONCLUSION**

s Dynamic stress CT-MPI with regadenoson offers incremental diagnostic value over CCTA alone for the detection of hemodynamically significant CAD.

#### **CLINICAL RELEVANCE/APPLICATION**

Dynamic stress CT-MPI is an easy-to-perform diagnostic examination technique which increases the specificity and diagnostic accuracy of CCTA alone for the detection of hemodynamically significant CAD.

## Abstract Archives of the RSNA, 2023

S3B-SPCH

### Chest Imaging Sunday Poster Discussions II

#### Sub-Events

#### **S3B-SPCH-1 Quantitative Analysis for Bronchiectasis using Artificial Intelligence-based Bronchial Tapering Ratio in Patients with Chronic Obstructive Pulmonary Disease**

Participants  
Hyejin Park, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Bronchiectasis (BE) is associated with loss of lung function and increased morbidity and mortality. CT is the standard method used to assess bronchiectasis but current imaging methods are limited in assessing the extent of bronchiectasis on CT scans. This study aimed to automatically quantify the extent of bronchiectasis based on an artificial intelligence (AI)-based analysis of bronchial tapering ratio on chest CT and assess the association of quantified bronchiectasis score and exacerbations in patients with chronic obstructive pulmonary disease (COPD).

#### **METHODS AND MATERIALS**

We analyzed the longitudinal cohort data of COPD patients from the Korean Obstructive Lung Disease (KOLD) cohort. The bronchiectasis score accounting the extent of abnormal tapering of inner lumen compared with the proximal airway (bronchial tapering ratio = 1.1, a measure of airway dilatation) in each patients on chest CT scans was analyzed. Quantified bronchiectasis score was correlated with visual analysis by two thoracic radiologists. Multivariable logistic analysis was performed to assess the association between the bronchiectasis score and pulmonary exacerbations on follow-up adjusted by demographics, pulmonary functional measure, and airway CT parameters.

#### **RESULTS**

Total 337 patients (median age, 66 years; 328 men [97%]) were included. Among the 337 patients, 210 (62%) had a history of a least one exacerbation. Bronchiectasis was present based on visual analysis in 148 (43.9%) patients and bronchiectasis score significantly increased as extent of bronchiectasis on visual analysis increased ( $P = .02$ ). During a median 5-year follow-up, the bronchiectasis score was a significant independent predictor of acute exacerbation (adjusted odds ratio [OR], 1.12 [95%CI: 1.03-1.22];  $P = .007$ ) along with wall area percentage on CT (OR, 1.03 [1.01-1.06];  $P = 0.02$ ) and forced expiratory volume in 1 s (OR, 0.98 [0.97-0.99];  $P = 0.002$ ) in multivariable analysis.

#### **CONCLUSION**

s In COPD, artificial intelligence-based CT measures of bronchiectasis based on bronchial tapering ratio were significant predictors for acute exacerbation.

#### **CLINICAL RELEVANCE/APPLICATION**

Evaluation of extent of bronchiectasis on chest CT using artificial intelligence-based bronchial tapering ratio were reliable and automatically quantified extent of bronchiectasis on CT had prognostic implications for COPD exacerbations.

#### **S3B-SPCH-2 Lymphatic Bubble Sign in Lung and Mediastinum: Special CT Feature for the Diagnosis of Pulmonary Lymphatic Malformation with Lymphatic-airway Leakage**

Participants  
MENGKE LIU, BEIJING, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the special CT feature of lymphatic bubble sign (LBS) on HRCT for the diagnosis of pulmonary lymphatic malformation (PLM) with lymphatic-airway or alveolar leakage.

#### **METHODS AND MATERIALS**

Eight hundred and ten patients diagnosed as PPL were collected in this retrospective study from January of 2006 to December of 2022, of which 62 cases with chylous phlegm and plastic bronchitis showed LBS in lung and/or mediastinum on HRCT or CT lymphography. The imaging features of LBS were blinded reviewed by two chest radiologists respectively, including the position, size, quantity, morphology, and dynamic changes of bubbles. All patients were followed up for HRCT within 1-6 months.

#### **RESULTS**

LBS was seen in 62 (7.7%) of 810 patients with PPL, which was located in pulmonary interstitium in 30 cases, paraloobar-fissure with thickening in 5 and mediastinal fat area in 12, both in 20 patients. ALL the LBS manifested multiple lesions, no wall or thin wall and round-like with smooth edges with a size of 3-10mm. A dynamic changes of this sign was showed in all patients with obvious improvement in 56 cases, aggravation 6 and recurrent occurrence in 25 patients on the 1-6 months follow-up CT. In addition, similar lesions were showed in chest wall, ribs and pleural cavity, respectively. The associated-accompanying lesions include ground

glass opacity, interlobular septal thickening, tree-in-bud, chylothorax, chylo-pericardium and mediastinal opacity. All the lesions is not related to thoracic puncture drainage or direct lymphangiography, but patients often have long-term medical history of dyspnea and chronic cough.

## CONCLUSION

s This sign indicates the formation of lymphatic and airway leaks in the lungs, with chylous leakage leading to chylous pneumonia and plastic bronchitis. However, the air in the airway pours back into the lymphatic vessels due to pressure changes and other reasons, forming the LBS. Chest CT has important value in displaying this sign and helps to determine PLMs and chylous leakage and providing strong evidence for clinical treatment.

## CLINICAL RELEVANCE/APPLICATION

LBS strongly favors a diagnosis of pulmonary lymphedema and lymphatic dilatation with lymphatic-airway or alveolar leakage and plastic bronchitis.

### S3B-SPCH-3 Template Matching Method for Accurate Quantification of Cystic Tissue Volume in CT Scans of Diffuse Cystic Lung Disease

Participants

Katie Noonan, BEng, MEng, Dublin, Ireland (*Presenter*) Nothing to Disclose

## PURPOSE

Diffuse Cystic Lung Disease (DCLD) is a broad term used to describe rare lung diseases characterised by the presence of air-filled cysts within the parenchyma of the lungs. Due to their relative scarcity and visual similarity to more prevalent diseases such as emphysema, DCLDs are frequently mis-diagnosed, leading to significantly worse clinical outcomes and a higher burden on the healthcare system. Our research presents a method which accurately identifies cystic regions within DCLD CT scans, achieving a similar standard to expert defined manually annotated cases. Furthermore, the method quantifies cystic tissue volume in the sample, providing a reliable and efficient means of assessment.

## METHODS AND MATERIALS

Template matching methods involve the extraction of image features, such as shape, texture and colour, and correlates them with a pre-defined image template to identify regions of interest. In the context of a Lymphangioleiomyomatosis CT scan, circular regions of low attenuation that exhibit high correlation to a black circle template were isolated and defined as potential cystic regions. The detected regions were then compared with related manually annotated cases which had previously outlined the presence of cystic regions as identified by an expert radiologist.

## RESULTS

The method's performance was evaluated by comparing its results with that of the manual annotations of an expert radiologist. The assessment yielded a Dice Similarity Coefficient of 86%, Precision of 79%, Specificity of 99% and an F1 Score of 88%.

## CONCLUSION

s The high correlation observed between the template matching method and the manually annotated cases outlines the potential of semi-automated feature extraction methods as a faster and less labour-intensive method to quantifying cystic tissue volume across numerous cases. By computing the ratio between cystic and lung tissue volume, this method provides a reliable means of assessing the overall health of lung tissue. The use of such methods has broad implications in clinical settings, where accurate and efficient evaluation of numerous cases is essential.

## CLINICAL RELEVANCE/APPLICATION

The semi-automated method outlined identifies cystic regions comparably to expert radiologists, allowing development of a lung health score based on cystic/lung tissue volume ratio.

### S3B-SPCH-4 Clinical Course and Risk Factors for Development and Progression of Interstitial Lung Disease in Primary Sjögren's Syndrome

Participants

Eunseo Lee, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the long-term course and prognostic factors of patients with primary Sjögren syndrome-associated interstitial lung disease (pSS-ILD).

## METHODS AND MATERIALS

This single-center, retrospective study included 120 pSS patients who underwent at least two high-resolution computed tomography (HRCT) scans between March 2013 and February 2021. Clinical symptoms, laboratory data, HRCT findings, and pulmonary function test results were collected. HRCT were scored blindly by two expert thoracic radiologists: extent of ground glass opacities (GGO), fine/coarse reticulations, and honeycombing, and coarseness score of fibrosis.

## RESULTS

In patients with pSS without ILD at baseline (n=81), no development of ILD was found on follow-up (median, 2.8 years). In patients with pSS-ILD (n=39), total disease extent, extent of coarse reticulation, and traction bronchiectasis increased on HRCT, whereas the extent of GGO decreased at follow-up (median, 3.2 years) (each p<0.001). In progressive group of pSS-ILD (n=19/39, 48.7%), the extent of coarse reticulation and coarseness score of fibrosis were increased at follow-up (p<0.05). Multivariate logistic regression analysis showed that LDH (OR, 1.012) and diffusing capacity for carbon monoxide (OR, 0.922) were independent risk factors for pSS-ILD at baseline. Usual interstitial pneumonia (UIP) pattern on CT (OR, 15.237) and follow-up duration (OR, 1.403) were independent risk factors for disease progression in patients with pSS-ILD. In response to glucocorticoid and/or immunosuppressants, GGO decreased, whereas the extent of fibrosis increased even after treatment.

## CONCLUSION

s In pSS patients with no ILD during baseline evaluation, no newly developed ILD was identified during follow-up over two years. Progression occurred in approximately half of the pSS-ILD patients with slow gradual deterioration. UIP pattern on CT and follow-up duration were independent risk factors for progression of pSS-ILD.

#### **CLINICAL RELEVANCE/APPLICATION**

HRCT is a crucial modality for determining the progression of lung fibrosis in patients with pSS, in addition to the initial screening evaluation for ILD.

### **S3B-SPCH-5 Chest Radiography, Computed Tomography and Magnetic Resonance in Evaluation of Pulmonary Sarcoidosis in Assessment of Disease Progression and Comparison with Pulmonary Function Tests**

Participants

Stephan Altmayer, PhD, Stanford, CA (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To compare radiography, high resolution computed tomography (HRCT), and magnetic resonance imaging (MRI) in the assessment of disease progression in pulmonary sarcoidosis in comparison to pulmonary function tests.

#### **METHODS AND MATERIALS**

In this prospective study of 77 adults diagnosed with sarcoidosis, all subjects underwent baseline pulmonary function testing, chest radiography, HRCT and MRI. Chest radiographs were categorized using the Siltzbach classification system. HRCT and MRI were scored using the Scleroderma Lung Study I system. Pulmonary function was reassessed after 12 months, with progressive disease defined by  $\geq 5\%$  reduction of forced vital capacity (FVC). Differences in median imaging scores were assessed with Student's t-test and Wilcoxon rank-sum test. Correlation between imaging and pulmonary function was investigated using Pearson's and Spearman's rank correlation coefficients. FVC decline was the gold standard on multivariate analysis used to calculate the odds ratios (OR) for progression of disease predicted by imaging, with score thresholds determined by maximum Youden's index. The area under the curve (AUC) of the receiver operating characteristic plot was calculated for each imaging modality.

#### **RESULTS**

There is a strong correlation between chest radiography and MRI ( $r=0.649$ ,  $P < 0.001$ ), and CT and MRI scores ( $r=0.851$ ,  $P < 0.05$ ). CT and MRI scores correlated with FVC (MRI:  $r = -0.584$ ,  $P < 0.001$ ; CT:  $r = -0.308$ ,  $P = 0.049$ ) and diffusing capacity of the lung for carbon monoxide (MRI:  $r = -0.564$ ,  $P = 0.004$ ; CT  $r = -0.216$ ,  $P = 0.017$ ). The AUCs for Radiography, MRI and CT scores were 0.70 (0.49-0.85), 0.51 (0.32-0.75), and 0.76 (0.56-0.90), respectively. Multivariate analysis demonstrated significant prediction of progressive disease by CT (OR = 1.236,  $p = 0.044$ ) and MRI (OR = 1.594,  $p = 0.021$ ).

#### **CONCLUSION**

s MRI may be a viable alternative to HRCT in lung assessment and prediction of disease progression in patients with pulmonary sarcoidosis.

#### **CLINICAL RELEVANCE/APPLICATION**

MRI may be a viable tool for the assessment of disease progression in patients with pulmonary sarcoidosis, although further studies are necessary to validate this tool.

### **S3B-SPCH-6 To Evaluate the Role of the F FDG PET CT in the Idiopathic Pulmonary Fibrosis and Diffuse Parenchymal Lung Disease**

#### **PURPOSE**

The purpose of this study was to evaluate the role of the (18)F-FDG PET/CT in patients with idiopathic pulmonary fibrosis (IPF) and diffuse parenchymal lung disease (DPLD).

#### **METHODS AND MATERIALS**

Seventy-two patients (62 men and 10 women; mean age  $\pm$  SD, 68.7  $\pm$  9.4 y) with IPF ( $n = 36$ ) or other forms of DPLD ( $n = 36$ ) were advised whole body PET/CT and also high-resolution CT (HRCT), which were acquired simultaneously. 18 F FDG was done after injecting the radiotracer and whole-body PET-CT was done after 60 minutes of FDG administration. The amount of the uptake in the pulmonary (18)F-FDG metabolism was quantified as a standardized uptake value (SUV(max)). Along with this scan the HRCT lung was done for each patient and further analysis of the various HRCT patterns of parenchymal involvement as ground-glass opacities or reticulation/honeycombing. Along with this the patients underwent a global health assessment and pulmonary function tests.

#### **RESULTS**

The pulmonary uptake metabolism in 72 of 72 patients was evaluated. The parenchymal pattern of the HRCT is seen as the maximal (18)F-FDG metabolism which was seen predominantly in ground-glass (14/72), reticulation/honeycombing (52/72), and mixed (6/72). The mean SUV(max) in patients with ground-glass and mixed patterns was 2.0  $\pm$  0.4, and in reticulation/honeycombing it was 3.0  $\pm$  1.0 (Mann-Whitney U test,  $P = 0.007$ ). The mean SUV(max) in patients with IPF was 2.9  $\pm$  1.1, and in other DPLD it was 2.7  $\pm$  0.9 (Mann-Whitney U test,  $P = 0.862$ ). The mean mediastinal lymph node SUV(max) (2.7  $\pm$  1.3) correlated with pulmonary SUV(max) ( $r = 0.63$ ,  $P < 0.001$ ). Pulmonary (18)F-FDG uptake correlated with the global health score ( $r = 0.50$ ,  $P = 0.004$ ), forced vital capacity ( $r = 0.41$ ,  $P = 0.014$ ), and transfer factor ( $r = 0.37$ ,  $P = 0.042$ ).

#### **CONCLUSION**

s The increased pulmonary (18)F-FDG metabolism is seen in all the patients with IPF and also other forms of DPLD was observed. Pulmonary (18)F-FDG uptake shows significant changes in the measurements of health and lung physiology in these patients. The analysis showed that the (18)F-FDG metabolism is higher at the site of maximal uptake which corresponds to the areas of reticulation/honeycombing on the HRCT scans other than with ground-glass patterns.

#### **CLINICAL RELEVANCE/APPLICATION**

The role of the Whole body PET-CT is important in various forms of ILD and other pathologies in the chest

## **S3B-SPCH-7 Predictors of Progressive Pulmonary Fibrosis: A Radiologic-Pathologic Correlation Study**

### **PURPOSE**

Progressive pulmonary fibrosis (PPF), which is treatable with anti-fibrotic therapy, is defined as interstitial lung disease (ILD) other than idiopathic pulmonary fibrosis (IPF) that manifests progressive features regardless of standard management. This study evaluates the radiologic-pathologic correlations of PPF and identifies predictors associated with disease progression and survival.

### **METHODS AND MATERIALS**

Between January 2004 and December 2020, 75 patients diagnosed with ILD other than IPF who underwent surgical lung biopsy were retrospectively included. Three chest radiologists reviewed chest computed tomography (CT) features and fibrosis extent on baseline and follow-up CT, and patients were subdivided into PPF and non-PPF based on progression. Two pathologists reviewed cases for pathologic features and the presence of usual interstitial pneumonia (UIP). Overall and progression-free survival were calculated using the Kaplan-Meier method, and the Cox proportional hazard method was used to examine predictors for progressive pulmonary fibrosis and survival.

### **RESULTS**

Regarding radiologic-pathologic correlations, when the pathologic UIP pattern was present in the specimen, it was associated with radiologic honeycombing, traction bronchiectasis, and reticulation ( $p < 0.001$ ). Progression was seen in 42.7% (32/75) of non-IPF ILD patients, with a median progression time of 44 months. Radiologic traction bronchiectasis was identified as the only predictive factor of PPF on the multivariate Cox-proportional hazard method (hazard ratio [HR], 6.54;  $p = 0.003$ ). PPF (HR, 3.96;  $p = 0.013$ ) and advanced age (HR, 1.13,  $p < 0.001$ ) were associated with an increased risk of death in non-IPF ILD patients. The median survival time of PPF was 120 months.

### **CONCLUSION**

A radiologic pattern of traction bronchiectasis was a predictor of PPF, while PPF and advanced age were risk factors for low survival in non-IPF ILD patients.

### **CLINICAL RELEVANCE/APPLICATION**

Recognition of traction bronchiectasis is crucial for predicting PPF in patients with non-IPF ILD, emphasizing the importance of timely initiation of anti-fibrotic therapy in improving patient outcomes.

## **S3B-SPCH-8 Granulomatous and Lymphocytic Interstitial Lung Disease in Common Variable Immunodeficiency: CT Findings and Association with Pulmonary Function Tests**

### **Participants**

Nicholas Landini, MD, PhD, Rome, Italy (*Presenter*) Nothing to Disclose

### **PURPOSE**

Common Variable Immunodeficiency (CVID) may be complicated by Granulomatous and Lymphocytic Interstitial Lung Disease (GL-ILD). GL-ILD includes a wide spectrum of ILD abnormalities, worsening CVID prognosis. We aimed to characterize chest Computed Tomography (CT) findings of GL-ILD, in comparison with CVID patients without GL-ILD, and their association with PFT worsening.

### **METHODS AND MATERIALS**

Patients with CVID followed from 2018 to 2021 were retrospectively evaluated. Inclusion criteria were: GL-ILD diagnosis, CT and PFT performed within one week. Patients on GL-ILD therapy or with the clinical suspicion of infection were excluded. Age and sex matched non-GL-ILD subjects were searched. CT findings, evaluated in consensus by two chest radiologists, were: bronchiectasis, bronchial wall thickening, mucous plugs, tree in bud, mosaic perfusion, small nodules ( $< 10$  mm) and big nodules (multiple  $> 3$ ), consolidation, ground glass opacities (GGO), reticulation, fibrotic ILD, cavitation/necrosis and bands. Small nodules main distribution (centrilobular, perilymphatic or random) was noted. CT abnormalities were assessed in upper, lower fields and whole lungs, describing disease predominance. Presence of enlarged nodes (axis  $> 10$  mm), pleural or pericardial effusion was also assessed. Fisher exact test was computed, assessing Odds Ratios (OR) for GL-ILD against non-GL-ILD. A significant  $p$ -value was set as  $< 0.05$ , with Bonferroni correction for the following PFT: TLC, FEV<sub>1</sub>, FVC and DLCO, % predicted.

### **RESULTS**

38 GL-ILD subjects and 38 controls were identified. Most common GL-ILD CT findings in GL-ILD ( $> 50\%$  patients) were: bronchiectasis, multiple non-perilymphatic small nodules, GGO, consolidations, bands and enlarged nodes. The disease was usually predominant in lower fields (92%). Bronchiectasis, GGO, reticulations, fibrosis and bands were more frequent in lower fields. GGO was associated with TLC worsening, reticulation with all PFT worsening, fibrotic ILD with DLCO ( $p$ -value  $< 0.0125$ ). Considering whole lungs analysis, small nodules, consolidations, reticulations and fibrosis had an OR  $> 10$  in identifying GL-ILD versus non-GL-ILD patients.

### **CONCLUSION**

GL-ILD usually manifests with bronchiectasis, non-perilymphatic nodules, GGO, consolidations, bands and enlarged mediastinal lymph nodes, with a lower field predominance. Reticulation is the main CT finding associated with functional worsening. Small nodules, consolidations, reticulations and fibrotic ILD are highly suggestive of GL-ILD in CVID subjects.

### **CLINICAL RELEVANCE/APPLICATION**

These results provide CT characteristics of GL-ILD that may be helpful in the diagnosis of a such polymorphic disease, verifying their relationships with PFT worsening

## Abstract Archives of the RSNA, 2023

S3B-SPER

### Emergency Radiology Sunday Poster Discussions II

#### Sub-Events

#### S3B-SPER-1 Self-Supervised Machine Learning to Triage Acute Chest Syndrome in Pediatric Patients with SCD

#### Participants

Syed Anwar, PhD, Orlando, FL (*Presenter*) Nothing to Disclose

#### PURPOSE

Children with sickle cell disease (SCD) are at a high risk of poor outcome if they develop pneumonia or acute chest syndrome (ACS). We have developed a machine learning model for ACS prediction using chest radiographs (CXRs), hence triaging children for treatment presented to the emergency department.

#### METHODS AND MATERIALS

We performed a retrospective analysis of children with SCD who had a CXR performed at an urban pediatric emergency department between July 2015 and March 2023. A query of our clinical registry identified 1,115 pediatric SCD patients with "likely ACS" (n=601) or "likely not ACS" (n=514), based on diagnosis code and disposition. We manually reviewed the radiologist impression for each CXR and excluded 28.4% (n=171) of patients in the "likely ACS" group and 5.1% (n=26) of patients initially labeled "likely not ACS". A pre-trained, self-supervised machine learning model was fine-tuned using manually reviewed CXR impressions to predict ACS in future radiographic images. Our deep learning model used a vision transformer and was pre-trained on 400,000 CXRs from publicly available data. The model was earlier tested on other clinical conditions such as covid-19, age, and sex prediction. We report machine learning inference time and the time required to complete the radiologic assessment, reporting timing for both daytime and overnight studies because an attending radiologist is available to review new studies during daytime and evening hours but only reviews images overnight if they are paged directly with a question.

#### RESULTS

The average accuracy of our ACS prediction model was 0.85 with sensitivity of 0.77, specificity of 0.91, and AUC of 0.89. Machine learning inference time was 0.0068 (median) seconds (IQR:0.0065-0.0072) running on machine with NVIDIA RTX A5000 GPU with half-precision (FP16). Daytime studies, completed between 06:00 and 22:00 h, were read by a radiologist within 55.0 (median) minutes (IQR:23.0-115.0). Overnight studies, completed between 22:00 and 06:00 h, were read within 401.5 (median) minutes (IQR:245.25-535.75).

#### CONCLUSION

The model for ACS prediction from CXR has the potential to identify high risk SCD patients in the emergency department in a timely manner with clinically acceptable performance. Our inference time is real-time, allowing for prediction of ACS as soon as a CXR is recorded in the PACS.

#### CLINICAL RELEVANCE/APPLICATION

ACS is associated with mortality and severe morbidity in children with SCD and requires rapid recognition and intervention. At our single site, real-time machine learning prediction has the greatest potential to expedite diagnosis during overnight hours.

## Abstract Archives of the RSNA, 2023

S3B-SPGI

### Gastrointestinal Imaging Sunday Poster Discussions II

#### Sub-Events

#### S3B-SPGI-1 Clinical and Imaging Features of Focal Intrahepatic Biliary Stricture Visualized Only as Duct Dilatation

##### PURPOSE

The percentage of patients with precursor lesions or malignancy due to focal intrahepatic stricture (FIHS) without radiographically demonstrable bile duct abnormality, visualized only as duct dilatation, is currently unknown. Moreover, it is unknown whether there is a variable to differentiate malignant or precursor lesions from non-precursor benign lesions. Therefore, we studied the proportion of patients with FIHSs that were precursor lesions or malignancies. Additionally, we evaluated the clinical variables and MRI features that may discriminate between non-premalignant benign and premalignant/malignant FIHSs.

##### METHODS AND MATERIALS

This retrospective study assessed patients who underwent surgery for FIHS between January 2010 and March 2022. The number and proportion of non-precursor benign lesions, precursors, and malignancies were calculated. Clinical variables and MRI features were compared between non-premalignant benign and premalignant/malignant FIHSs using independent t-tests and chi-square tests for continuous and categorical variables, respectively.

##### RESULTS

Twenty-five patients with confirmed histopathological diagnoses were identified. The study included 13 men (52.0%) and 12 women (48.0%). The median age of all the patients at the first imaging diagnosis was 65 years (range, 43-78 years). Of the 25 FIHS patients, 9 (36%) were diagnosed with cholangiocarcinoma and 6 (24%) were diagnosed with precursor lesions. Among the precursor lesions, five were intraductal papillary neoplasms of the bile duct, and one was biliary intraepithelial neoplasia. Therefore, 15 (60%) had malignant or precursor lesions, and 10 (40%) were diagnosed with non-precursor benign lesions. None of the clinical variables and imaging features used for analysis showed a statistically significant difference between the non-premalignant benign and premalignant/malignant FIHS groups ( $p < .05$ ).

##### CONCLUSION

More than half of FIHSs were malignant or precursor lesions. There were no predictive values for the clinical and imaging parameters. Therefore, a more active strategy for the diagnosis and follow-up imaging should be considered.

##### CLINICAL RELEVANCE/APPLICATION

Patients with FIHS require active treatment including surgical treatment and careful imaging follow-up.

#### S3B-SPGI-2 MRI Screening with Machine Learning-supported Post-processing and Genetics of Multiple Biliary Hamartomas

##### Participants

Philipp Schindler, MD, Muenster, Germany (*Presenter*) Nothing to Disclose

##### PURPOSE

Multiple biliary hamartomas (MBH), also known as "von Meyenburg complexes", are benign and asymptomatic malformations of dilated bile ducts embedded in fibrous stroma, usually smaller than 10 mm. A detailed knowledge of these malformative cystic-like lesions is crucial because they may be misdiagnosed as malignant. The aim of this study was to investigate the feasibility of magnetic resonance imaging (MRI) screening for the detection of MBH with machine learning-supported post-processing and to explore the genetic characteristics of this rare condition.

##### METHODS AND MATERIALS

Five consecutive patients with MBH were prospectively enrolled in this study. All patients underwent high-resolution (3.0 Tesla) contrast-enhanced hepatobiliary MRI and magnetic resonance cholangiopancreatography (MRCP) at baseline to provide a structured report of imaging features of MBH and at 12-month follow-up to exclude progression. A pipeline of 3D k-means clustering based image segmentation was used for detection of cystic-like lesions. Eccentricity was calculated to identify round and oval objects in the cluster and to exclude the biliary tree. Customized next-generation sequencing (NGS) was used to identify the underlying genetic cause of MBH.

##### RESULTS

Baseline MRI showed innumerable small hepatic cystic lesions without contrast enhancement, even in the hepato-biliary phase, and without communication with the biliary tree, allowing the diagnosis of MBH. K-means clustering based image segmentation was feasible for annotation of MBH. Total liver lesion volume remained stable over time (mean volume: 104.8 ml; mean proportion of total liver volume: 8.1%). All patients had a heterozygous missense, truncating, or frameshift mutation in the polycystic kidney and hepatic disease 1 (PKHD1) gene encoding the multidomain integral membrane protein fibrocystin.

##### CONCLUSION

s This preliminary data suggests that machine learning-augmented MRI screening can be used for quantification of MBH. The genetic analysis revealed a potential association between multiple biliary hamartomas and mutations in the PKHD1 gene. These findings provide important insights into the diagnosis of this rare condition.

#### **CLINICAL RELEVANCE/APPLICATION**

Knowledge of MRI findings and genetics of MBH is helpful for a prompt and correct diagnosis, avoiding unnecessary invasive procedures and/or an excessive number of radiological investigations.

#### **S3B-SPGI-3 A Comparison of the Diagnostic Accuracies of Ultrasound and CT in 82 Proven Cases of Acute Cholecystitis**

Participants

Joshua Thurgood, Albuquerque, NM (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To compare the efficacies of US imaging vs CT imaging in the diagnosis of acute cholecystitis in aiming to improve the diagnosis and treatment of patients with acute cholecystitis.

#### **METHODS AND MATERIALS**

We retrospectively collected data on 100 patients with suspected acute cholecystitis and 100 control patients with studies occurring between 3/1/2015 and 3/31/2020. Of the 100 suspected acute cholecystitis patients, 50 had US imaging and 50 had CT imaging done. To be included as a proven case of acute cholecystitis, cases were then screened for cholecystectomy. Due to this, 7 US subjects and 11 CT subjects were removed as they did not undergo cholecystectomy or were treated via a different method. In the control group, 50 patients had US imaging and 50 had CT imaging. All studies were then reviewed by three radiologists of differing experience levels. The data from each reviewer was then combined and tabulated. One reviewer also tabulated data for patients that had both US and CT studies done, which amounted to 47 of the patients with confirmed acute cholecystitis.

#### **RESULTS**

The sensitivity of CT for diagnosing acute cholecystitis was greater than the sensitivity of US, with these being 66.67% and 53.49% respectively. The negative predictive value of CT was also greater than that of US, which were 75.93% and 64.91% respectively. There were no false positives by any of the reviewers, so the specificities and positive predictive values were 100% for both CT and US modalities. Among the 47 patients who had both US and CT studies done, 24 had both positive US and CT for acute cholecystitis, 9 patients had a positive CT and negative US, 4 patients had a positive US and negative CT, and 10 patients had both negative US and CT studies.

#### **CONCLUSION**

s CT was significantly more sensitive and had a higher negative predictive value than US. However, both modalities had lower sensitivities and negative predictive values than what is found in the literature. All three reviewers performed better on CT than US with two performing significantly better with sensitivities improving by 20.63% and 15.98% respectively. The results of our study showed significantly higher performance using CT imaging over US imaging when evaluating for acute cholecystitis. However, we still suggest US as our first imaging test in patients with suspected AC. If the US is negative, CT should be performed. If the CT is negative and there is still strong clinical suspicion for AC, a HIDA scan should be done.

#### **CLINICAL RELEVANCE/APPLICATION**

The research being conducted is significant because time to treatment of acute cholecystitis is most often imaging dependent and understanding the relative efficacies of the two most common initial imaging modalities will lead to increased efficiency and time to treatment of these patients.

#### **S3B-SPGI-4 Ultra-high-resolution Drip-infusion CT Cholangiography with Deep Learning-based Reconstruction: Comparison with Normal-resolution Simulation**

Participants

Atsushi Nakamoto, MD, PhD, Suita, Japan (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the image quality and bile duct delineation of drip-infusion CT cholangiography (DIC-CT) using an ultra-high-resolution CT (UHR CT) with a 1024 x 1024 matrix combined with a deep learning-based reconstruction algorithm in comparison with simulated normal-resolution (NR) images.

#### **METHODS AND MATERIALS**

Twenty-five potential liver transplant donors (13 men and 12 women, age range, 21 to 61 years; mean age, 36.3 years) who underwent DIC-CT using the super-high-resolution (SHR) mode of a UHR CT scanner for preoperative evaluation were included in this retrospective study. SHR images were reconstructed with a 1024 x 1024 matrix and 0.25-mm slice thickness using a deep learning-based reconstruction algorithm. Simulated NR images were reconstructed from the same raw data with a 512 x 512 matrix and 0.5-mm slice thickness using a hybrid iterative reconstruction algorithm. Maximum CT value and contrast-to-noise ratio (CNR) of the common bile duct were compared between SHR and NR images using the paired t-test. Two radiologists independently reviewed the maximum intensity projection images and graded the image quality for delineation of the peripheral bile ducts, image sharpness, image noise, and the overall image quality using a 5-point scale, and the results were compared using the Wilcoxon signed-rank test.

#### **RESULTS**

The maximum CT number of the common bile duct was significantly higher on SHR images than on NR images ( $451.6 \pm 65.0$  vs.  $382.5 \pm 67.4$ ,  $P < .001$ ). CNR was significantly lower on SHR images than on NR images ( $19.8 \pm 4.0$  vs.  $38.9 \pm 12.4$ ,  $P < .001$ ). In qualitative analysis, NR scored significantly higher (i.e. less noise) than SHR for noise ( $4.0 \pm 0.2$  and  $4.1 \pm 0.3$  vs.  $2.0 \pm 0.2$  and  $1.9 \pm 0.3$ ,  $P < .001$ ), whereas SHR scored significantly higher for peripheral bile duct delineation ( $3.6 \pm 0.8$  and  $3.8 \pm 0.5$  vs.  $2.4 \pm 0.8$  and  $2.2 \pm 0.5$ ,  $P < .01$ ), sharpness ( $3.8 \pm 0.6$  and  $3.9 \pm 0.7$  vs.  $2.2 \pm 0.6$  and  $2.1 \pm 0.7$ ,  $P < .001$ ), and overall image quality ( $4.0 \pm 0.6$  and  $3.6 \pm 0.8$  vs.  $2.0 \pm 0.6$  and  $2.4 \pm 0.8$ ,  $P < .01$ ) for both readers.

## CONCLUSION

s UHR CT combined with a deep learning-based reconstruction provided drip-infusion CT cholangiography images with higher spatial resolution and improved the delineation of the peripheral bile duct, despite increased image noise and decreased CNR.

## CLINICAL RELEVANCE/APPLICATION

Ultra-high-resolution CT combined with a deep learning-based reconstruction provides high-quality drip-infusion CT cholangiography and improves peripheral bile duct delineation.

### S3B-SPGI-5 Breath-hold 3D Gradient- and Spin-echo (GRASE) MRCP Compared to Compressed-sensing Highly Accelerated Respiratory-triggered Technique

Participants

Nobuyuki Kawai, MD, Gifu, Japan (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate breath-hold 3D gradient- and spin-echo (GRASE) MRCP compared to respiratory-triggered 3D turbo spin-echo (TSE) MRCP highly accelerated with the compressed sensing-sensitivity encoding (C SENSE).

## METHODS AND MATERIALS

Fifty-eight consecutive patients (30 men, 28 women, mean age 67.2 years) with suspicious having pancreaticobiliary diseases underwent MRCP on a 3-T clinical scanner. All patients underwent breath-hold 3D GRASE MRCP with sensitivity encoding (SENSE) (BH-MRCP; SENSE factor, 2) and respiratory-triggered 3D TSE MRCP highly accelerated with the C SENSE (RT-MRCP; C SENSE factor, 11.6) in a random order. For quantitative image analyses, signal intensity (SI) of biliary ducts and main pancreatic duct (MPD), peribiliary ductal tissue, and peripancreatic ductal tissue were measured. The relative duct-to-periductal contrast ratios (RCs) of each pancreaticobiliary segments were calculated as  $(SI_{duct} - SI_{periduct}) / (SI_{duct} + SI_{periduct})$ , respectively. For qualitative image analyses, two radiologists coincidentally graded conspicuity of biliary ducts, MPD, and pancreatic cystic lesion, and overall image quality between the two sequences using a five-point rating scale. Artifacts were also graded using a four-point rating scale.

## RESULTS

Mean acquisition times in BH-MRCP and RT-MRCP sequence were 23 and 29 seconds, respectively. RCs of all three segments of MPD in BH-MRCP were slightly lower than those in RT-MRCP ( $P = 0.002$ ). Conspicuity of central and peripheral segments of right and left hepatic duct, cystic duct, and common bile duct in BH-MRCP were significantly higher than those in RT-MRCP ( $P = 0.015$ ). Conspicuity of MPD and pancreatic cystic lesion was comparable between the two sequences. Overall image quality in BH-MRCP was significantly higher than that in RT-MRCP ( $P = 0.038$ ). In BH-MRCP, the number of scans with the poor or non-diagnostic image quality (score = 2) in overall image quality was decreased compared with that in RT-MRCP [3.4% (2/58) vs. 8.6% (5/58),  $P = 0.242$ ].

## CONCLUSION

s BH-MRCP provided better image quality and a reduced number of poor or non-diagnostic images compared to RT-MRCP.

## CLINICAL RELEVANCE/APPLICATION

Breath-hold 3D gradient- and spin-echo MRCP provided better image quality compared to respiratory-triggered 3D turbo spin echo MRCP highly accelerated with the compressed sensing-sensitivity encoding.

### S3B-SPGI-7 Ultra-High Resolution T2-weighted PROPELLER MRI of the Rectum with Deep Learning Reconstruction: Assessment of the Image Quality and Diagnostic Performance

Participants

Takahiro Tsuboyama, MD, (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study was to evaluate the impact of ultra-high resolution acquisition with a slice thickness of 1.2 mm and deep learning reconstruction (DLR) on the image quality and diagnostic performance of T2-weighted periodically rotated overlapping parallel lines with enhanced reconstruction (PROPELLER) images for rectal cancer.

## METHODS AND MATERIALS

This prospective study included 34 patients who underwent MRI for the assessment of pretreatment or post-chemoradiotherapy rectal cancer. Written informed consent was obtained. The following four types of axial T2-weighted PROPELLER imaging perpendicular to the tumor were obtained: a slice thickness of 3 mm with conventional reconstruction (3-CR) and DLR (3-DLR), and a slice thickness of 1.2 mm with CR (1.2-CR) and DLR (1.2-DLR). Three radiologists independently evaluated the image quality and assessed the extramural tumor spread, extramural venous invasion (EMVI), lymph node metastasis, and response to chemoradiotherapy if applicable by using a 5-point scoring system. The image quality was compared with Friedman's test. Agreement of the scores obtained with the four types of PROPELLER imaging was assessed by the intraclass correlation coefficient. The diagnostic performance by the three readers were compared with Friedman's test in 22 patients who underwent surgery after MRI.

## RESULTS

In the image quality assessment, 1.2-DLR yielded significantly the best sharpness, rectal and tumor conspicuity, and overall image quality ( $P < 0.05$ ) for all readers. In the diagnostic performance, perfect agreement (ICC value  $> 0.80$ ) was not seen among the four PROPELLER images in all readers regarding extramural tumor spread, EMVI, and complete response. For the diagnosis of extramural tumor spread, specificity and accuracy were significantly lower with 3-DLR (mean, 0.64 and 0.74) and 1.2-DLR (mean, 0.58 and 0.74) than with 3-CR (mean, 0.75 and 0.79) and 1.2-CR (mean, 0.78 and 0.83) ( $P < 0.05$ ). For the diagnosis of venous invasion, sensitivity and accuracy were significantly higher with 1.2-CR (mean, 0.42 and 0.67) and 1.2-DLR (mean, 0.55 and 0.71) than with 3-CR (mean, 0.30 and 0.59) and 3-DLR (mean, 0.36 and 0.56) ( $P < 0.05$ ). There were no significant differences in the diagnostic accuracies of lymph node metastases and complete response.

## CONCLUSION

s Ultra-high resolution PROPELLER T2-weighted MRI using DLR could provide high image quality and accurate detection of venous invasion although it increased false-positive diagnoses of extramural tumor extension.

## CLINICAL RELEVANCE/APPLICATION

Although DLR can provide thin-slice T2-weighted PROPELLER MRI with high image quality, extramural tumor spread should be carefully interpreted because DLR may increase false-positive results.

## S3B-SPGI-8 Deep Learning Segmentation and Radiomics for Automatic Identification and Activity Assessment of CTE Lesions in Crohn's Disease

### PURPOSE

The purpose of this paper is to develop a deep learning automatic segmentation model for the segmentation of Crohn's Disease (CD) lesions in CTE images. Additionally, the radiomics features extracted from the segmented CD lesions will be analyzed, and multiple machine learning classifiers will be built to distinguish CD activity.

### METHODS AND MATERIALS

This retrospective study includes two sets of CTE image data (segmentation dataset and classification dataset). The CD lesions in the segmentation dataset were manually segmented by radiologists, and a deep learning automatic segmentation model based on nnU-Net neural network was developed. The CTE images in the classification dataset were processed using the automatic segmentation model to obtain segmentation results and extract radiomics features. The most optimal features were then selected to build five machine learning classifiers to distinguish CD activity. The performance of the automatic segmentation model was evaluated using the Dice similarity coefficient (DSC), while the performance of the machine learning classifier was evaluated using the area under the curve (AUC), sensitivity, specificity and accuracy.

### RESULTS

The segmentation dataset consisted of 84 CTE examinations of CD patients (60 males) and the classification dataset included a total of 193 CTE examinations of CD patients (136 males). The deep learning segmentation model achieved a DCS value of 0.824 on the testing set. Among the five machine learning classifiers, the Logistic Regression (LR) model showed the highest classification performance in the testing set, with an AUC, sensitivity, specificity and accuracy of 0.862, 0.697, 0.840 and 0.759, respectively.

## CONCLUSION

s Our study demonstrates that a deep learning segmentation model based on the nnU-Net neural network can accurately segment CD lesions in CTE images and build a machine learning classifier to distinguish CD activity based on the extracted radiomics features. This approach can help clinicians assess the severity of patient's disease with greater accuracy.

## CLINICAL RELEVANCE/APPLICATION

Helps radiologists aid in diagnosis and improve diagnostic efficiency, which in turn helps clinicians assess a patient's condition and provide an idea for the next step in treatment.

### Genitourinary Imaging Sunday Poster Discussions II

#### Sub-Events

#### S3B-SPGU-1 Radio-Metabolomics in Predicting Muscle Invasive Status of Bladder Cancer: A Pilot Study

##### Participants

Kangwen He, Wuhan, China (*Presenter*) Nothing to Disclose

##### PURPOSE

Determining muscle invasive status (MIS) of bladder cancer (BCa) is critical for treatment decision making. We attempted to identify the differential metabolites of muscle invasive BCa (MIBC) and non-muscle invasive BCa (NMIBC), and correlate them with MR radiomics features (RFs) to initially explore the biological validation of radiomics in predicting MIS of BCa.

##### METHODS AND MATERIALS

Tumor tissue of 26 patients with BCa (15 MIBC and 11 NMIBC) were collected for integrated non-targeted liquid and gas chromatography-mass spectrometry (LC/MS and GC/MS) metabolomics analysis. Preoperative MRI data were obtained for 19 of these patients (12 MIBC and 7 NMIBC). Differential metabolites were screened using univariate analysis (fold change analysis and Student's t-test) and multivariate analysis (Orthogonal partial least squares discriminant analysis, OPLS-DA). The KEGG database was used for pathway analysis to find significantly dysregulated metabolic pathways ( $p < 0.05$ , impact (IM)  $> 0.1$ ). RFs were extracted from T2-weighted image and DWI of preoperative MRI. After preliminary screening using intraclass correlation coefficient and Student's t-test, RFs were correlated with dysregulated pathway metabolites using Pearson correlation. Receiver operating characteristic curve was used to evaluate the diagnostic performance of RFs in predicting MIS of BCa.

##### RESULTS

A total of 350 significant differential metabolites were identified by metabolomics analysis, and the dysregulated metabolic pathways are predominantly amino acid synthesis pathways (compared with NMIBC group, metabolites in MIBC group were significantly up-regulated in aminoacyl biosynthesis, arginine synthesis, alanine biosynthesis, galactose metabolism and pyrimidine metabolism,  $p < 0.001$ , IM=0.167;  $p = 0.002$ , IM=0.421;  $p = 0.009$ , IM=0.455;  $p = 0.004$ , IM=0.124;  $p = 0.019$ , IM=0.163, respectively). Twenty-four differential metabolites were detected in these 5 metabolic pathways. We initially screened 432 differential RFs in radiomics analysis. Eleven radiomic-metabolomics feature pairs were screened out based on the Pearson correlation coefficient greater than 0.75. The screened RFs were capable in the assessment of MIS (AUC=0.679-0.893).

##### CONCLUSION

Metabolite pathways that can predict MIS of BCa were identified, and were highly correlated with MRI RFs, which may partly explain why radiomics could predict the MIS of BCa.

##### CLINICAL RELEVANCE/APPLICATION

Our study contributes to the identification of non-invasive methods for diagnosing the MIS of BCa, which could reduce the use of current harmful diagnostic techniques, thereby improving BCa management.

#### S3B-SPGU-2 Predicting Renal Allograft Dysfunction using Shear-wave Dispersion Slope

##### Participants

Taekmin Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the role of shear-wave dispersion slope for predicting renal allograft dysfunction.

##### METHODS AND MATERIALS

We retrospectively reviewed 126 kidney transplant recipients (median age 57 years [interquartile range 47-62 years], 60 women) who underwent kidney biopsy for allograft evaluation from November 2022 to February 2023. All patients underwent shear-wave elastography (SWE) examination just before biopsy, and parenchymal stiffness and dispersion slope were obtained in cortex. To reduce subject-to-subject variations, we performed SWE in renal sinus fat for reference tissue. Clinical and pathologic factors related to renal stiffness and dispersion slope were evaluated by multivariable linear regression analysis. We conducted univariate and multivariate analysis to predict acute rejection using imaging parameters including SWE. Diagnostic performance of significant parameters in detecting acute rejection was evaluated by area under the receiver operating curve (AUC) values.

##### RESULTS

Acute rejection was found in 31 out of 126 (24.6%) of the patients. The median cortex-to-sinus stiffness ratio (SR) did not differ between the patients with acute rejection and without rejection (1.21 vs. 1.20,  $P = 0.47$ ), while median cortex-to-sinus dispersion slope ratio (DSR) was higher in patients with acute rejection than in those without rejection (1.4 vs. 1.21,  $P < 0.01$ ). Grade of interstitial fibrosis and tubular atrophy (IFTA) was the only determinant factor for both SR (coefficient, 0.13 per grade;  $P < 0.01$ ) and

DSR (coefficient, 0.10 per grade,  $P=0.01$ ). In multivariate analysis, mean resistive index (OR 1.06, 95% CI 1.02-1.15,  $P<0.01$ ) and DSR (OR 18.3, 95% CI 3.3-101.6,  $P<0.001$ ) were independent factors for predicting acute rejection. The AUC of resistive index, DSR, and combined two parameters were 0.64, 0.68, and 0.74, respectively.

#### **CONCLUSION**

s Shear-wave dispersion slope obtained at SWE may be helpful for identifying renal allograft dysfunction.

#### **CLINICAL RELEVANCE/APPLICATION**

Shear-wave dispersion slope, which reflects the viscosity of tissue, might be used as a reliable noninvasive imaging modality that can help differentiate acute dysfunction from stable graft.

Printed on: 04/12/24

#### S3B-SPHN-1 Fluoroscopic Function in Cone-beam CT Provides Video Fluorographic Swallowing Study

##### PURPOSE

Videofluoroscopic swallowing study (VFSS) is a gold-standard radiological examination for dysphagic patients. Usually, VFSS is performed using whole-body x-ray fluoroscopic unit. This prevents oral radiologists without a whole-body x-ray fluoroscopic unit from performing VFSS. Recently, a cone-beam CT unit equipped with x-ray fluoroscopy has been put into practical use. In this study, we evaluated the cone-beam CT unit's fluoroscopic function whether it is suitable for VFSS.

##### METHODS AND MATERIALS

A cone-beam CT unit for maxillofacial region (VGi evo Evolved 3D Imaging, NewTom, Inc.) was used to take fluoroscopic images. The temporal resolution was 20 and 15 frames per second. The tube current was fixed at 3 mA and tube voltage at 110 kV. The contrast and gamma values of the images were adjusted to clearly observe. First, a phantom modeled living body was subjected. A 4 mm diameter tube was attached to the inside of the phantom and a 40w/v% barium solution (Barytgen HD, FUSHIMI Pharmaceutical Co., Ltd.) was through. Two 2 mm diameter iron balls were also attached to the pharynx of the phantom. One was on the epiglottic valley, and one on the piriform sinus. Then, two healthy adults with no history of dysphagia were subjected. Saliva (with no contrast media), a 40w/v% barium solution, a paste with barium solution (Fruche, House Foods Corp.), and a gelatin jelly with barium solution (Jelly Ace, House Foods Corp.) were used as test foods. Two subjects swallowed a spoonful or 3 ml of each test food. The subject's VFSS images were evaluated using the checking items in the VFSS guideline of the Japanese Society of Dysphagia Rehabilitation.

##### RESULTS

The image of barium solution passed through the tube and 2 mm iron balls were clear observed in the phantom's VFSS images. Swallowing movements without contrast medium allowed clear observation of the anatomical structures these were tongue, pharynx, soft palate, and others. All target evaluation items including the movement of the test food into the epiglottic valley, the piriform sinus, and the esophagus could be observed. The VFSS image of the phantom and two subjects were clear observed in both 20 and 15 frames per second.

##### CONCLUSION

Although there are restrictions on the body position of the subject, a cone-beam CT unit equipped with x-ray fluoroscopy could be applied for practical VFSS examination. It allows the oral radiologists to perform VFSS in minimal clinics. Then, the accurate diagnosis of swallowing function, treatment effects, and the progress of recovery of swallowing function will be possible.

##### CLINICAL RELEVANCE/APPLICATION

This method allows performing VFSS in minimal clinics. The accurate diagnosis of swallowing function, treatment effects, and the progress of recovery of swallowing function will be possible.

#### S3B-SPHN-2 2x Thin-Slice Single-Excitation Wideband MRI (SE-WMRI) for Cranial Nerves Assessment - A Preliminary Study

##### PURPOSE

MRI examination of cranial nerves has always been difficult due to their small sizes and torturous courses of cranial nerves. Thus, multiple techniques have been devised to illustrate each cranial nerve segment. In contrast to the standard heavy T2 sequence, the T2\* gradient echo (GRE) sequence is known to be able to better reveal nuclear and fasciculus segments, as well as intra-tumor microhemorrhages of cranial nerves. Due to the prolonged scan time of high-resolution T2\* imaging, the Single-Excitation Wideband MRI (SE-WMRI) technique is utilized to enhance such MRI acquisition with double the slices in the same field of view (FOV).

##### METHODS AND MATERIALS

This study implements SE-WMRI on a Siemens PRISMA 3T MRI system. Two sets of T2\* full-brain images were acquired from healthy subjects using the standard GRE and SE-WMRI sequences with the following parameters: For standard GRE, TR/TE=500/11.4ms, resolution=0.5 x 0.5 mm, slice number=25 and thickness=4 mm, so the scan time=9:36. For thin-slice SE-WMRI, slice thickness reduced to 2 while slice number increase to 50 to maintain the overall FOV coverage; TR is extended to 1000 ms to enable the scan with extra slices, resulting in a scan time of 9:36.

##### RESULTS

This study utilizes SE-WMRI to achieve 2x slice-direction resolution (2x thinner slices) within the same scan duration and provide finer visualization of cranial nerves 5, 7, and 8. The enhanced resolution and reduced partial-volume effect of SE-WMRI images enable better estimation and tracing of the intra-brainstem fascicular segments, as well as the cisternal segments of the cranial nerves.

## CONCLUSION

s This preliminary study demonstrates SE-WMRI as a potential clinical examination tool, achieving 2x slice-direction resolution (2x thinner slices) within the same duration as standard sequences to provide a more detailed view of the cranial nerves. Since GRE T2\* sequences, used to observe hemorrhage or calcification, are often time-consuming, SE-WMRI can benefit such scans to achieve finer resolution in a reasonable scan time. In the future, this technique will be implemented in existing sequences that only focus on cranial nerves to achieve further acceleration and higher resolution.

## CLINICAL RELEVANCE/APPLICATION

Clinically, GRE T2\* imaging of the cranial nerves is used to observe the fascicular segment and detect microhemorrhage as a hallmark to differentiate meningioma from vestibular Schwannoma, while standard heavy T2 imaging could not. However, the prolonged acquisition time of GRE T2\* imaging limits its practicality. Therefore, SE-WMRI can benefit such scans to achieve high resolution while maintaining scan duration, increasing its usability in clinical scenarios.

## S3B-SPHN-3 Evaluation of Nasopharyngeal Carcinoma Involving the External Membrane of Internal Carotid Artery Based on MRI

### PURPOSE

This study aimed to explore the evaluation method of nasopharyngeal carcinoma involving the external membrane of the internal carotid artery (ICA) based on MRI and propose a new assessment criteria for ICA invasion.

### METHODS AND MATERIALS

A retrospective analysis was conducted on 50 patients of our hospital with pathologically confirmed nasopharyngeal carcinoma who had undergone MRI scans. Based on MRI images, the extent of nasopharyngeal carcinoma infiltrating the ICA wall was classified and evaluated. A new grading system for ICA invasion was proposed which consisted of four levels. In addition, other commonly used assessment criteria were compared and analyzed.

### RESULTS

Through MRI image analysis, 12 cases of nasopharyngeal carcinoma invading the external membrane of the ICA were found in the 50 patients. Among these patients, the newly proposed grading system for ICA invasion could more accurately and comprehensively evaluate the extent of nasopharyngeal carcinoma's invasion of the ICA wall compared to other assessment criteria. It also demonstrated higher sensitivity and specificity.

## CONCLUSION

s The MRI-based grading system for ICA invasion can better evaluate the degree of nasopharyngeal carcinoma's invasion of the ICA wall with high sensitivity and specificity, providing a more accurate diagnosis and treatment plan for patients.

## CLINICAL RELEVANCE/APPLICATION

These research findings are of great significance for the clinical diagnosis and treatment of nasopharyngeal carcinoma and lay the foundation for further exploration of the relationship between ICA invasion and prognosis.

## S3B-SPHN-4 Application of Multidimensional Diffusion MRI in Nasopharyngeal Carcinoma: An Exploratory Cross-sectional Study

Participants

Yingying Chen, Shenzhen, China (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the potential of multidimensional diffusion MRI (Mdd-MRI) in assessing the microscopic diffusion characteristics of nasopharyngeal carcinoma (NPC) and explore its potential application in diagnosing and differentiating tumor pathological subtypes and TNM stage, as well as determining Epstein-Barr virus (EBV) infection status.

### METHODS AND MATERIALS

Sixty-six patients with histologically-confirmed NPC were included in the study. Mdd-MRI was performed with multiple b values to obtain five microscopic diffusion metrics: anisotropic mean kurtosis (MKa), isotropic mean kurtosis (MKi), total mean kurtosis (MKt), and microscopic fractional anisotropy ( $\mu$ FA). For comparison with macroscopic diffusion characteristics, apparent diffusion coefficient (ADC) was obtained through conventional diffusion weighted imaging sequence. Diffusion-related measurements were compared using student t test between NPC tissue and normal nasopharyngeal tissue, among different histopathology, TNM stage, and EBV infection status. Spearman correlation analysis was performed between diffusion-related measurements and T stage.  $P < 0.05$  (two-tailed) indicates significant difference.

### RESULTS

Significant difference was found in ADC between tumor tissue and normal nasopharyngeal tissue ( $P = 6.023e-11$ ). Microscopic metrics and ADC showed significant differences among different primary tumor stages (T1-T4) and a significant correlation with T stage ( $\mu$ FA:  $\rho = 0.52$ ,  $P = 0.00001$ ; MKa:  $\rho = 0.38$ ,  $P = 0.002$ ; MKi:  $\rho = 0.27$ ,  $P = 0.03$ ; MKt:  $\rho = 0.32$ ,  $P = 0.009$  and ADC:  $\rho = -0.36$ ,  $P = 0.003$ ). However, no significant differences were observed in other subgroups, including histopathology, N stage, and M stage, and EBV infection status (all  $P > 0.05$ ).

## CONCLUSION

s Mdd-MRI is a valuable tool for assessing the microscopic diffusion characteristics of NPC. However, it has limited value in diagnosing NPC, differentiating tumor pathological subtypes, N stage, and M stage, and predicting EBV infection status.

## CLINICAL RELEVANCE/APPLICATION

Mdd-MRI can be a useful technique in assessing the microscopic diffusion characteristics of NPC, providing insights into tumor heterogeneity from a novel diffusion perspective.

### **S3B-SPHN-5 Demonstrating the Facial Nerve in the Parotid Gland using 3 Dimension Fast Field Echo Imaging**

#### **PURPOSE**

To assess the performance of three-dimension fast field echo imaging (T2WI-3D-FFE) in displaying the intraparotid facial nerve (IFN) and localizing the tumor.

#### **METHODS AND MATERIALS**

Seventy-nine patients with parotid tumors who underwent T2WI-3D-FFE were retrospectively enrolled (Table 1). The T2WI-3D-FFE images were reconstructed with curvilinear planar reconstruction (CPR) by two radiologists independently. The identification certainty of IFN was scored with an arbitrary scale of 0-3. The tumor locations were categorized as deep or superficial on the basis of direct and 2 indirect methods (the facial nerve line (FNL) and retromandibular vein (RMVL)). Surgical localization was considered as the criterion standard. The diagnostic accuracy, sensitivity and specificity for localizing parotid lesions using each method were calculated and compared using the McNemar tests.

#### **RESULTS**

The main trunk, temporofacial division, and cervicofacial division of IFN were visualized in 100%, 52% and 46% of patients, respectively on the reconstructed T2WI-3D-FFE images. The diagnostic accuracy, sensitivity, specificity, positive predictive value, and negative predictive value for localizing deep lobe lesions using direct method were 96.2%, 88.9%, 91.7%, 80%, 98.6%, respectively. These findings were significantly higher than FNL and RMVL in sensitivity ( $P < 0.05$ ). The relationship between the tumor and the main trunk of the facial nerve was correctly predicted in 93.67% (74/79) of images (Table 3).

#### **CONCLUSION**

s T2WI-3D-FFE can provides detailed morphological information on the nerve relative to adjacent structures preoperatively.

#### **CLINICAL RELEVANCE/APPLICATION**

Intraparotid facial nerve (IFN) imaging is a clinical challenge in MRI that it is difficult to differentiate parotid gland tumors from facial nerve on conventional MRI. It is great demand to develop new diagnostic technology to accurately display peripheral nerve and tumor for avoiding intraoperative injury.

### **S3B-SPHN-6 A Phantom Study on the Impact of Combined Deep Learning Reconstruction and Metal Artifacts Reduction Algorithm on CT Image Quality in Different Scanning Conditions for Maxillofacial Region with Metal Implants**

#### **PURPOSE**

This study aimed to investigate the impact of combining deep learning image reconstruction (DLIR) and metal artifacts reduction (MAR) algorithms on the quality of CT images with metal implants under different scanning conditions.

#### **METHODS AND MATERIALS**

A phantom of pig's maxillofacial region designed for image quality assessment was used to acquire data at three dose levels (CTDIvol: 20/10/5/ mGy). The raw data were reconstructed using filtered back projection (FBP), adaptive statistical iterative reconstruction with Veo at a level of 50% (AV50), and DLIR (TrueFidelity™) at three levels (low, medium, and high). Regions of interest (ROIs) were selected in different tissues (near/far fat, near/far muscle, near/far bone) both with and without metal implants and artifact. The signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and metal artifact index (MAI) were calculated, and subjective image quality was assessed on a 5-point Likert scale by two experienced radiologists.

#### **RESULTS**

(1) In the same scanning condition, no significant difference was found in Hounsfield unit (HU) values among the five algorithms in different tissues. However, DLIR-L, DLIR-M, and DLIR-H produced a smaller standard deviation (SD) than that of FBP and AV50 ( $P < 0.05$ ). (2) DLIR showed a better noise reduction compared to FBP and AV50 ( $P < 0.05$ ). The SNRs showed a decreasing trend in the order of DLIR, FBP, and AV50 in three tissues. The CNR decreased in the order of DLIR, AV50, and FBP in fat and muscle, except bone. FBP led to the highest MAI in both near and far fat. (3) Both observers rated the reconstruction algorithms with MAR as having lower artifact scores than those without MAR in all three types of tissues ( $P < 0.01$ , except the far shadow and bloom of bone,  $P = 1.0$ ). The level of artifact reduction was superior while increasing the level of DLIR ( $P < 0.05$ ) and both observers agreed that DLIR produced better results in artifact reduction compared with FBP and AV50. The subjective image quality decreased in the order of DLIR, AV50, and FBP ( $P < 0.01$ ).

#### **CONCLUSION**

s The combination of DLIR and MAR algorithms can improve image quality and significantly reduce metal artifacts, providing a higher clinical application value.

#### **CLINICAL RELEVANCE/APPLICATION**

Reducing metal implant artifacts is a major concern in medical imaging. The combination of deep learning reconstruction algorithm (DLIR) and metal artifacts reduction (MAR) algorithm provides a viable alternative choice compared to conventional methods such as FBP and AV50. Using DLIR with MAR, both image quality and metal artifact reduction are improved. This approach can have a significant impact on tumor diagnosis, particularly in cases of oral neoplasms where metal artifacts can obscure critical details.

### **S3B-SPHN-7 The Feasibility Study of Virtual-unenhanced-scan Instead of Conventional True-non-contrast Scan in Neck CT Examination**

#### **PURPOSE**

To explore the feasibility of virtual-unenhanced (VUE) scan instead of true non-contrast (TNC) scan in the energy spectrum CT neck imaging of the Revolution 256-row wide volume detector.

#### **METHODS AND MATERIALS**

Twenty patients who underwent neck plain scan were collected, and GE Revolution 256 CT was used to perform true non-contrast

neck scan and energy spectrum enhanced scan. True non-contrast scan tube voltage is 120kV, and the iterative reconstruction level ASIR-V weight is 30%. The energy spectrum enhancement scan mode (GSI) tube voltage is 80kV-140kV instantaneous switching, and the other scan parameters are consistent with the true non-contrast scan. Post-processing to obtain VUE images in arterial phase and venous phase. The AW4.7 workstation was used to measure the CT value and SD value of subcutaneous fat, the CT value of the common carotid artery and the CT value of the sternocleidomastoid muscle. The subjective evaluation was performed by two deputy chief imaging physicians on the basis of conventional unenhanced scans. The iodine removal ability of virtual unenhanced scans was scored by a double-blind method. Using SPSS 23.0 software, the CT value, SD and SNR of the 3 groups of images were compared by one-way ANOVA analysis, the subjective scores were compared by Kruskal-Wallis H test.

## **RESULTS**

The CT values of common carotid artery in true non-contrast, arterial and venous phases of VUE were  $48.10 \pm 5.67$ ,  $67.35 \pm 12.36$ ,  $56.12 \pm 11.69$ , respectively, with little change but statistical difference ( $p < 0.05$ ). The CT values of sternocleidomastoid muscle were  $57.52 \pm 12.65$ ,  $54.37 \pm 9.38$ ,  $58.52 \pm 10.1$ , no statistical difference ( $p > 0.05$ ); The SD were  $6.41 \pm 2.36$ ,  $5.97 \pm 1.20$ ,  $6.18 \pm 1.93$ , respectively, and there was no statistical difference ( $p > 0.05$ ). The subjective iodine removal effect scores were  $3.25 \pm 0.44$  and  $4.00 \pm 0.52$  for arterial and intravenous VUE respectively, with statistical differences ( $p < 0.05$ ), the intravenous VUE score was higher. Conventional plain scan CTD<sub>Ivol</sub> ( $10.86 \pm 1.44$ ) mSv, energy spectrum arterial and venous enhancement CTD<sub>Ivol</sub> are each ( $9.99 \pm 1.30$ ) mSv, virtual plain scan and energy spectrum enhancement are 35.21% lower than conventional plain scan and energy spectrum enhancement CTD<sub>Ivol</sub>.

## **CONCLUSION**

s VUE image quality has the potential to replace true non-contrast scan images. The effect of VUE during intravenous phase is better, which can effectively reduce the patient's radiation dose.

## **CLINICAL RELEVANCE/APPLICATION**

VUE image has the potential to replace true non-contrast scan images. The effect of intravenous VUE is better, which can effectively reduce the radiation dose of patients. It can be promoted and used in patients with neck tumors that require multiple reexaminations.

S3B-SPIN

### Imaging Informatics Sunday Poster Discussions II

#### Sub-Events

#### S3B-SPIN-1 Multi-parametric MRI Brain Tumor Diagnosis with Memorizing Transformer

##### PURPOSE

Deep learning has been widely utilized in MRI diagnosis. Among them, transformers have gained increasing popularity due to their ability to handle multiple modalities. However, its application has been hindered because acquiring large-scale multimodal MR data is expensive and time-consuming. To narrow the gap, we designed a transformer architecture with external memory, which memorizes the attention from the historical training process to reduce the reliance on large-scale dataset.

##### METHODS AND MATERIALS

During training, the external memory stores a paired query and value from each attention head. Importantly, this design is efficient and does not incur any additional computation cost. During inference, the cached memory is used to enhance local attention through K nearest neighbor lookup. This improves the overall performance of the model. We implemented this external memory design on an 8-layer vision transformer with 8 attention heads in each layer and the dimension of the tokens were set to 256, but it can be incorporated into any transformer-based model (Fig. a). Evaluations were performed on a dataset of 147 brain post-treatment malignant glioma cases, each of which included five MRI sequences, T1-weighted (T1w), T2-weighted (T2w), fluid-attenuated inversion recovery (FLAIR), gadolinium-enhanced T1w (GdT1w), and amide proton transfer-weighted (APTw) MR images, for classifying treatment effect and tumor recurrence. For each scan, the 3D APTw MRI protocol provided 15 slices, so all volumetric MR images had 15 instances. Each instance included T1w, T2w, FLAIR, GdT1w, and APTw images with the matrix shape of 5 (sequences) × 256 (pixels) × 256 (pixels). A proportion of 80% on the case-level was split as the training set (n=118) and the remaining 20% as the test set.

##### RESULTS

The baseline was the ViT without external memory. Our method achieved an AUC of 0.848 ( $p < 0.001$ ), which improves 5.15% of the plain ViT's AUC of 0.806 ( $p < 0.001$ ). The accuracy is 0.779, the precision is 0.625, the sensitivity is 0.818, the specificity is 0.818 and the F1-score is 0.709 (Fig. b).

##### CONCLUSION

In this work, we propose a memorizing transformer for the small-scale multi-parametric MR image analysis. The method stores the attention in the training process and applies them to the inference stage with KNN lookup, which thus costs no extra GPU run-in memory. The method can increase the plain transformer AUC by 5.15%, which confirms the effectiveness of our method.

##### CLINICAL RELEVANCE/APPLICATION

We propose a memorizing transformer for the small-scale multi-parametric MR image analysis that can increase the plain transformer AUC.

#### S3B-SPIN-2 Consistent and Efficient Image Segmentation in the German Nationwide RACOON Consortium

##### Participants

Bianca Lassen-Schmidt, PhD, Bremen, Germany (*Presenter*) Nothing to Disclose

##### PURPOSE

Multi-center studies, including large cohorts, require software tools that ensure consistent and efficient segmentation of image data. In the RACOON project, all German university hospitals jointly work with identical software systems. Here we analyze the segmentation tool of the first RACOON trial retrospectively and discuss the requirements for such a tool.

##### METHODS AND MATERIALS

In this study, a cohort of 14,023 patients (47% female, mean age 54.6 years, mean BMI 23.4) from 36 German university hospitals was collected and evaluated by radiologists. The datasets included chest CT with 22 different disease groups. Of the total cohort, 20% (2394 datasets) were randomly selected and processed using the segmentation and annotation toolkit SATORI. This client-server application is highly configurable and was utilized to provide a guided lung segmentation workflow, including automated segmentation of the lungs, lung lobes, and ground glass opacities. Additionally, other anatomical structures and pathologies could be manually or semi-automatically segmented.

##### RESULTS

The overall performance of SATORI was evaluated by 35 radiologists with varying levels of experience using the tool, ranging from 1 (less use) to 5 (frequent use) on a Likert scale of 1 (poor) to 5 (excellent). The mean overall performance rating for SATORI was 2.7. Analysis of the ratings from the different user groups, based on their intensity of use (IoU), revealed that 5/5/6/8/10 radiologists with an IoU 1/2/3/4/5 rated the performance as 1.8/2.2/2.3/2.9/3.4, respectively. A Wilcoxon rank sum test was performed to compare the ratings between inexperienced (IoU 1-3) and experienced (IoU 4-5) readers, and a difference was found

(P = 0.01). Seven radiologists reported occasional freezing or slowness as the reason for a negative rating.

## CONCLUSION

s SATORI showed promise in achieving consistent image segmentation in the RACOON project. Users with more experience rated it higher, likely due to a learning effect. SATORI is being prepared for three more RACOON studies, with improvements to usability and network connection logging to address occasional freezing. Future enhancements include individual worklists for readers and a review tool for communication between reader and reviewer. Three key requirements for segmentation software in large multi-center studies to ensure consistent and efficient image segmentation are guided workflows, simultaneous use by multiple users, and highly automatic segmentation tools. "Funded by „NUM 2.0" (FKZ: 01KX2121)".

## CLINICAL RELEVANCE/APPLICATION

Multi-center studies provide heterogeneous data, more readers, and enough data for studies with rare pathologies. Nonetheless, segmentation software needs to meet specific requirements.

### S3B-SPIN-3 Clinical Study of Low Radiation Dose Combined with Deep Learning Image Reconstruction Algorithm for Detection of Liver Metastases

Participants

Nana Liu, Zhengzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

The aim was to investigate whether low radiation doses combined with DLIR algorithms improve liver image quality and liver metastasis detection compared with ASiR-V algorithms.

## METHODS AND MATERIALS

195 patients with suspected liver lesions who needed abdominal enhanced CT scans were collected. Conventional radiation dose examination (tube current of 400 mA) was performed during the first venous phase and low radiation dose examination (200 mA or 120 mA) was performed during the second venous phase. Patients were divided into a 50% radiation dose reduction group and a 70% radiation dose reduction group according to the different tube currents at the second venous phase. All images were reconstructed with ASiR-V50%, DLIR-L, DLIR-M and DLIR-H. Quantitative parameters including subcutaneous fat noise, CT values and SNR of liver, pancreas, portal vein and muscle, and contrast-noise ratio of liver metastases were compared with one way ANOVA test. Qualitative parameters including image quality, noise, contrast, lesion conspicuity, and diagnostic confidence score were compared with Kruskal-Wallis H test. The number and size of liver metastases detected by the ASiR-V50% algorithm at standard radiation doses were used as a reference standard, and the detection rates of liver metastases of different sizes were calculated for each algorithm under low radiation dose conditions.

## RESULTS

Objective evaluation: The noise and SNR of ASiR-V50% at standard dose were comparable to DLIR-M at 50% lower dose and 70% lower dose, while DLIR-H at 50% lower dose and 70% lower dose had lower noise and higher SNR and CNR. Subjective evaluation: Compared with the ASiR-V50% of standard dose, both DLIR-M and DLIR-H with 50% reduced dose could maintain the image quality, and DLIR-M and DLIR-H with 70% reduced dose had reduced image quality but still met the diagnostic requirements with a subjective score >3. Lesion detection rate: The lesion detection rates for ASiR-V50%, DLIR-L, DLIR-M, and DLIR-H at 50% lower doses were 90.2%, 89.2%, 91.4%, and 89.9%, respectively. All algorithms were able to detect all lesions larger than 1 cm. The lesion detection rates were 69.4%, 70.5%, 73.3%, and 71.3% for ASiR-V50%, DLIR-L, DLIR-M, and DLIR-H at 70% lower doses, respectively.

## CONCLUSION

s Compared to ASiR-V50%, DLIR can improve the objective and subjective image quality, as well as lesion conspicuity and diagnostic confidence of liver metastases. DLIR can maintain or improve image quality at 50% radiation dose reduction while preserving the detection of liver metastases larger than 1 cm.

## CLINICAL RELEVANCE/APPLICATION

DLIR can maintain or improve image quality at 50% radiation dose reduction while preserving the detection of liver metastases larger than 1 cm.

### S3B-SPIN-4 Standard and Low-dose Virtual Noncontrast Imaging using Deep Learning Image Reconstruction at Abdominal Dual-energy CT

Participants

Nana Liu, Zhengzhou, China (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the image quality and lesion detectability of virtual noncontrast (VUE) images from standard-dose and low-dose abdominal dual-energy CT (DECT)

## METHODS AND MATERIALS

This prospective study included 30 patients who underwent standard-dose and low-dose portal venous abdominal DECT in the same breath hold. VUE images were reconstructed from with iterative reconstruction (IR), DLIR at medium (DM) and high levels (DLIR-H) respectively. The absolute error of VUE CT attenuation (VUEerror) compared with true noncontrast (TUE) images reconstructed by IR was measured in multiple organs. The signal-to-noise (SNR) ratio for the measured organs were calculated. Two board-certified radiologists rated the qualitative assessment of image noise, image contrast, overall image quality, and lesion conspicuity on a 5-point scale. Interreader agreement was evaluated using the kappa analysis .

## RESULTS

The VUE image attenuation values for all measured organs were lower than TUE images, with standard- and low-dose VUEerror less than 5 HU in 40% and 23%, and less than 10 HU in 90% and 67%, respectively. The SNR for all organs and subjective ratings for all categories in VUE images were greater than TUE images. Among all VUE images, DLIR-M showed highest in all subjective ratings. The

lesion detection rate in the low-dose VUE images was lower compared to standard-dose VUE images.

## CONCLUSION

Dual-energy CT with DLIR allows for the reconstruction of standard-dose abdominal VNC images with accurate attenuation values, good image quality and lesion detectability compared with true noncontrast images.

## CLINICAL RELEVANCE/APPLICATION

DLIR had a significantly lower image noise, higher SNR and higher overall image quality of VUE images than the ASiR-V60%.

## S3B-SPIN-5 Prediction of T2DM using MRI Fat Fraction Maps of Ectopic Fat Deposition, Abdominal Wall Muscle Fat and Bone Marrow Adipose Tissue

Participants

Qi An, Dalian, China (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of our study was to quantitatively assess the abdominal wall muscle adipose tissue (AMAT) and bone marrow adipose tissue (BMAT) content and ectopic adipose deposition in patients with Type 2 diabetes mellitus (T2DM) by MRI fat fraction maps to explore independent risk factors that can predict T2DM.

## METHODS AND MATERIALS

A total of 345 participants who underwent 1.5 T or 3.0 T MRI examination of upper abdomen were included in our study. The MRI images of all patients included IDEAL-IQ or mDixon Quant sequence. The fat fraction (FF) and area of visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), AMAT were obtained at the level of the L1 and L2 vertebral bodies by Image J (National Institutes of Health, USA), and the FF and area of BMAT were automatically calculated at the level of the T12 and L1 vertebral bodies by the software where the mean of BMAT were computed. The hepatic fat fraction (HFF) and pancreatic fat fraction (PFF) were semi-automatically measured by Smart ROI on the post-processing platform (Intellispace Portal, ISP, Philips, Holland). The binary Logistic regression analysis and receiver operating characteristic (ROC) curve were used to evaluate the predictive ability of independent risk factors for T2DM.

## RESULTS

VAT area, VAT FF, HFF, PFF, BMAT FF, AMAT area and AMAT FF of the T2DM group were higher than the non-T2DM group and SAT FF was lower ( $P < 0.05$ ). However there was no statistically significant difference in SAT area of two groups ( $P > 0.05$ ). The binary logistic regression model analysis showed that SAT FF, VAT area and PFF were independent risk factors for T2DM, and OR values were 0.920, 1.007 and 1.073, respectively. The ROC curve shown that area under the curve (AUC) values of SAT FF, VAT area and PFF were 0.609, 0.681 and 0.786 respectively, and the sensitivity were 0.441, 0.676 and 0.750 respectively, and the specificity were 0.798, 0.625 and 0.773. The AUC values predicted by SAT FF combined with VAT area and PFF for T2DM were 0.787, with the sensitivity of 0.853 and the specificity of 0.661. The differences of AUC values were compared by Delong test, and the results showed that the AUC values of PFF and their combination were higher than those of SAT FF and VAT area ( $P < 0.05$ ).

## CONCLUSION

In this study, we found that SAT FF, VAT area and PFF are independent risk factors for T2DM, and PFF is a better predictor of T2DM than SAT FF and VAT area.

## CLINICAL RELEVANCE/APPLICATION

Our findings further deepened our understanding of the relationship among ectopic fat deposition, AMAT and BMAT. In addition, we found that PFF is a better independent risk factor for T2DM, so quantitative evaluation of PFF fat content in patients with T2DM by non-invasive MRI fat maps can better predict and evaluate the occurrence, progress and prognosis of T2DM.

## S3B-SPIN-6 Cardiac CT to MR Image Conversion Using Generative Diffusion Models

Participants

Albert Song, La Jolla, CA (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate whether 1) a generative diffusion model, trained exclusively with cardiac MRI data, could be used to perform intermodality image conversion from cardiac CTA to cine SSFP MRI and 2) if these synthesized SSFP images can be used as inputs for other MRI-specific CNNs.

## METHODS AND MATERIALS

With HIPAA compliance and IRB approval, we retrospectively collected 222 cardiac MRIs to train a diffusion model to synthesize SSFP images from image edges. MRI exams were split 70/15/15 for training, validation, and testing. To evaluate cross-modality image conversion, we retrospectively identified an additional 30 patients who underwent both cardiac CTA and MRI within  $7 \pm 8$  months, between 4/2020 and 3/2023 (age  $47 \pm 20$  years, 13 male). The diffusion CNN was used to synthesize SSFP images from CTA. To show that synthesized SSFP images are superior inputs for MRI-specific CNNs, we used an existing MRI-trained 2D UNet to segment the synthetic SSFP and source CTA images and compared them against manual segmentations. Cardiac volumes were then compared between synthetic and real cine SSFP images. Statistical analyses included comparison of segmentation overlap using Dice and comparison of cardiac volumetry using Pearson correlation and paired t-test with a type I error threshold of 0.05.

## RESULTS

For the following results, segmentation Dice scores are presented in order of epicardium, myocardium, and endocardium. For short axis CTA images, median Dice was 0.900 (IQR:0.844-0.932), 0.689 (0.597-0.752), and 0.906 (0.853-0.938), respectively. For synthesized-SSFP images, median Dice was 0.926 (IQR: 0.893 - 0.945), 0.757 (0.682 - 0.812), and 0.920 (0.866 - 0.948), respectively. Mean Dice scores were significantly higher for synthetic SSFP images relative to CTA images ( $p < 0.001$  for each task, paired t-test). Volumetric measurements from synthesized and real SSFP images correlated well for EDV ( $r=0.77$ ), ESV ( $r=0.83$ ), and EF ( $r=0.88$ ).

## CONCLUSION

s Diffusion models can be used to perform intermodality image conversion, including synthesizing SSFP images from CTA. Volumetric measurements of cardiac function using synthetic SSFP images generated from cardiac CTA correlated well with direct measurements from cardiac MRI.

## CLINICAL RELEVANCE/APPLICATION

Diffusion models may enable intermodality image conversion to facilitate cross-modality image quantification, segmentation, and comparison for cardiac CTA and MRI.

## S3B-SPIN-7 AI Enhancement: Emulating Radiologists' Approach for Automated Contrast Phase Detection in Abdominal CT Scans

Participants

Eduardo Reis, MD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

## PURPOSE

The accurate determination of contrast phases in abdominal CT scans is essential for the deployment of downstream artificial intelligence (AI) applications and reliable quantification of imaging biomarkers. DICOM tags are often used to identify contrast phases, but they can be unreliable. To address this challenge, we present an image-based AI algorithm that emulates how radiologists visually assess the enhancement patterns of key anatomical structures to determine the contrast phase. Our goal is to enhance the reliability and generalizability of contrast phase detection, independent of DICOM tags, and to facilitate its integration into clinical workflows by open sourcing the tool through an easy-to-use AI pipeline.

## METHODS AND MATERIALS

We obtained 739 abdominal CT exams, and included 1545 axial series, split into a 1183 and 362 for training and testing. Each patient's data was exclusively allocated to one set. The series were labeled as non-contrast, arterial, venous, or delayed using the "Series Description" DICOM tag. A radiologist reviewed each series to confirm or correct labels. Key anatomical structures, such as aorta, portal vein, inferior vena cava, renal parenchyma, and renal pelvis, were segmented using our open-source AI toolbox and radiomic features were extracted. An Extreme Gradient Boosting (XGBoost) classifier was trained to classify CT images into four contrast phases. The performance was evaluated using accuracy, sensitivity, specificity and F1 scores on internal and external validation datasets. External validation was performed on 209 scans (582 series) from "VinDr-Multiphase CT", a publicly available dataset that included non-contrast, arterial and venous scans.

## RESULTS

In internal validation, we achieved an overall accuracy of 92% and F1 scores of 97% for non-contrast, 79% for arterial, 92% for venous, and 95% for delayed phases. In external validation, we achieved an accuracy of 89%, and F1 scores of 97% for non-contrast, 87% for arterial, and 81% for venous phases. The performance improvement of the arterial class on external validation shows generalization capability despite limited training examples for this class. The algorithm was made publicly available through an open-source platform.

## CONCLUSION

s The proposed AI-based algorithm accurately detects contrast phases in abdominal CT scans independent of DICOM tags. The successful external validation demonstrates the algorithm's generalizability and robustness.

## CLINICAL RELEVANCE/APPLICATION

Contrast detection is crucial for deploying AI methods and ensuring the reliability of quantitative imaging biomarkers. The proposed algorithm serves as a valuable tool for enhancing AI applicability in medical imaging, allowing integration with other AI algorithms.

## Abstract Archives of the RSNA, 2023

S3B-SPIR

### Interventional Radiology Sunday Poster Discussions II

#### Sub-Events

#### S3B-SPIR-1 Shear Wave Elastography Evaluates the Efficacy of Microwave Ablation on Thyroid Nodules

##### PURPOSE

As a minimally invasive technique, percutaneous microwave ablation (MWA) has been applied as an alternative to thyroid surgery for benign thyroid nodules. Coagulation necrosis occurs and stiffness changes in thyroid tissue after ablation. Shear wave elastography (SWE) has been used to differentiate the malignant thyroid from benign nodules. But it has seldom been applied to monitor the change of thyroid nodules after ablation. The study aimed to investigate the efficacy of MWA on thyroid nodules and the effect of stiffness on the efficacy of MWA.

##### METHODS AND MATERIALS

Sixty-seven thyroid nodules treated with MWA were included between June 2021 and April 2023. All nodules were pathologically confirmed benign, and the maximum diameter was within 3 cm. SWE was performed to quantify the stiffness of nodules. The size, volume, volume reduction rate (VRR), and stiffness value of thyroid nodules were recorded before and at one, three, and six months after ablation. Thyroid nodules are classified as hard nodules or soft nodules according to the value of SWE. Compare the VRR between hard and soft nodules during post-ablation follow-up.

##### RESULTS

All nodules were completely ablated, and no complications occurred. The VRR of thyroid nodules gradually increased after ablation, and the VRR at one, three, and six months after ablation were 52.3% [interquartile range (IQR): 35.6-74.1%], 57.6% (IQR: 37.2-78.4%), and 74.9% (IQR: 50.4-90.2%), respectively ( $P<0.05$ ). The study showed that the stiffness of the nodules increased post-ablation compared with pre-ablation ( $P<0.05$ ). The stiffness value peaked one month after ablation and then gradually decreased ( $P<0.05$ ). The mean of SWE before ablation, and at one, three, and six months after ablation were  $36.7\pm 9.5$ KPa,  $76.5\pm 10.2$ KPa,  $62.8\pm 11.4$ KPa, and  $46.9\pm 9.5$ KPa, respectively ( $P<0.05$ ). Compared with soft nodules, hard nodules have a lower VRR after ablation ( $P<0.05$ ).

##### CONCLUSION

SWE is a noninvasive, sensitive and repeatable technique which can be applied to evaluate the efficacy of MWA of thyroid nodules and postoperative follow-up.

##### CLINICAL RELEVANCE/APPLICATION

SWE has been used for noninvasive and quantitative evaluation of the efficacy of MWA on thyroid nodules and postoperative follow-up.

#### S3B-SPIR-2 The Role of Contrast-enhanced Ultrasound in the Biopsies of Peripheral Pulmonary Lesions: A Retrospective Multicenter Study by using Propensity Score Analysis

##### PURPOSE

To compare the performance of conventional US and contrast-enhanced US (CEUS) as guiding tools in percutaneous transthoracic needle biopsy (PTNB) and evaluate the role of CEUS in PTNB for peripheral pulmonary lesions (PPLs).

##### METHODS AND MATERIALS

Patients with PPLs who received PTNB between 2017 and 2022 were retrospectively enrolled at four medical centers. According to whether pre-biopsy CEUS was performed, patients were divided into CEUS and US groups. The sampling success rate and the diagnostic accuracy of PTNB stratified by lesion size were analyzed. One-to-one propensity score-matching (PSM) analysis was performed using the nearest-neighbor matching method.

##### RESULTS

A total of 1027 lesions were analyzed: there were 634 in US group (mean age, 59 years  $\pm$  13 [standard deviation], 413 men) and 393 in CEUS group (mean age, 61 years  $\pm$  13 [standard deviation], 270 men). The CEUS group produced more acceptable samples than the US group (98.2% vs. 95.7%,  $p = .03$ ) and improved diagnostic accuracy (96.9% vs. 94.2%,  $p = .042$ ), and sensitivity (96.9% vs. 94.0%,  $p = .03$ ). PSM and stratified analyses ( $n = 358$  per group) indicated that the sample success rate (99.0% vs. 95.7%,  $p = .04$ ) and diagnostic accuracy (98.5% vs. 92.9%,  $p = .006$ ) of the CEUS group was higher than that of the US group for 2-7cm PPLs but not for lesions larger than 7cm (sample success rate: 96.9% vs. 97.1%,  $p = .93$ ; diagnostic accuracy: 95.0% vs. 99.0%,  $p = .08$ ).

##### CONCLUSION

CEUS-guided PTNB has a higher sampling success rate and diagnostic accuracy than US in 2-7cm PPLs. For PPLs larger than 7cm, consistent diagnostic accuracy can be achieved by well-trained biopsy operators whether using US or CEUS as the guide tool.

## CLINICAL RELEVANCE/APPLICATION

This study aims to investigate the role of CEUS in guiding PTNB of PPLs. The findings of this study can provide a detailed reference for selecting biopsy imaging guidance with a stratification criterion.

### S3B-SP1R-3 Comparison Between Percutaneous Transthoracic Co-axial Needle CT-guided Biopsy and Transbronchial Lung Biopsy for the Diagnosis of Persistent Pulmonary Consolidation

Participants

Juan Wang, Beijing, China (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study is to compare the diagnostic yield and the complication rate between percutaneous transthoracic CT-guided co-axial needle biopsy (PTCNB) and transbronchial lung biopsy (TBLB) in persistent pulmonary consolidation.

## METHODS AND MATERIALS

From January 1, 2016 to December 31, 2020, we have retrospectively enrolled a total of 155 consecutive patients with persistent pulmonary consolidation who underwent both TBLB and PTCNB. The diagnostic accuracy, specificity, sensitivity and complication rate of the two biopsy methods for persistent lung consolidation has been compared. According to histopathological and microbiological analysis, the results of biopsy specimens were categorized as follows: malignant, specific benign, non-specific benign and non-diagnostic. The final diagnosis was established by surgical resection or clinicoradiological follow-up for at least 12 months following biopsy. Diagnostic yield of PTCNB/TBLB was defined as the percentage of the true diagnosis from biopsy as malignant and specific benign lesions.

## RESULTS

According to the standard reference, the final biopsy diagnoses of 11 cases were confirmed true malignant based on the surgical resections, the remaining were confirmed by clinical and imaging follow-up for at least 12 months. The overall diagnostic accuracy, sensitivity and specificity of PTCNB for malignant diagnosis were 91.61%, 72.34% and 100%, whereas of TBLB were 87.74%, 59.57% and 100%. At the same time, the overall diagnostic accuracy, sensitivity and specificity of PTCNB for specific benign diagnosis were 84.25%, 64.71% and 100%, whereas of TBLB were 63.23%, 16.18% and 100%. The diagnostic yield of PTCNB and TBLB were 50.32% and 25.16% respectively. For the TBLB-based negative cases, PTCNB provided a definite diagnostic yield of 37.93%. There were 45(45/155, 29.03%), 22(22/155, 14.19%) and 13(13/155, 8.39%) patients who experienced pneumothorax, intrapulmonary hemorrhage and hemoptysis respectively in PTCNB, while there were only 5(5/155, 3.22%) cases of mild intraprocedural bleeding occurring in TBLB.

## CONCLUSION

s PTCNB is an effective and safe modality, associated with higher diagnostic yield and better diagnostic accuracy compared to TBLB for persistent consolidation, especially as the complementary method for TBLB-based negative lung lesions.

## CLINICAL RELEVANCE/APPLICATION

In this study, we compared the diagnostic yield and the complication rate between percutaneous transthoracic CT-guided coaxial needle biopsy (PTCNB) and transbronchial lung biopsy (TBLB) of persistent pulmonary consolidation. Clinical physicians may choose appropriate biopsy method according to our study.

### S3B-SP1R-4 PI3K $\delta$ Inhibitor PI-3065 Induces Apoptosis in Hepatocellular Carcinoma Cells by Targeting Surviving

## PURPOSE

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors worldwide, and its clinical treatment remains challenging. The development of new treatment regimens is important for effective HCC treatment. This research design to explore the anti-tumor function of PI3K  $\delta$  inhibitor PI-3065 on HCC and its potential mechanism.

## METHODS AND MATERIALS

CCK8 and flow cytometry were used to determine the activity of HCC cells treated with PI-3065. Apoptosis of HCC cells treated with PI-3065 were evaluated by hoechst staining and western blot. Mitochondrial staining and extraction were used to detect the mitochondrial state of HCC cells. SK-HEP-1 cells effectively transfected with survivin siRNA and plasmid overexpressed with survivin were treated with PI-3065, and then the apoptosis level of cells was evaluated by hoechst staining and western blot. The effects of PI-3065 on migration and colony formation of HCC cells were evaluated by wound-healing assay and colony formation assay. SK-HEP-1-derived xenograft tumor model in nude mice were constructed and administered by intragastric administration for 14 days. The control group were given the same dose of placebo. At the end point, the anti-hepatoma activity of PI-3065 in vivo was evaluated according to the volume, weight and protein changes of transplanted tumor.

## RESULTS

We found that PI-3065 dose- and time-dependently reduced HCC cell viability and induced apoptosis while posing no obvious apoptotic toxicity in normal liver cells. Further mechanistic analysis showed that PI-3065 induced apoptosis mainly by inhibiting survivin protein expression, decreasing mitochondrial membrane potential, and promoting cytochrome C release. Simultaneously, PI-3065 markedly suppressed the colony formation, migration, and epithelial-mesenchymal transition abilities of HCC cells. Furthermore, transplantation of nude mice with HCC tumors showed that PI-3065 inhibits HCC tumor growth in vivo by targeting survivin.

## CONCLUSION

s PI-3065 specifically inhibited survivin expression and exerted anti-HCC activity in vivo and in vitro, suggesting that it may serve as an effective antitumor drug for HCC treatment, which warrants further study.

## CLINICAL RELEVANCE/APPLICATION

In this study, we confirmed for the first time that PI-3065 can exert anti-HCC activity by inducing cell apoptosis in vivo and in vitro, which indicated that PI-3065 has great potential in clinical practice. Further studies have confirmed that PI-3065 has no toxicity to normal hepatocytes, and its safety and efficacy may provide a new choice for the treatment of HCC patients.

### **S3B-SPIR-5 Sono-activated Oxygen/Sulfate Dual-Radical Nanotherapy for Combined Cancer Suppression Infected Wound Repair**

Participants

Xiaohui Qiao, Shanghai, China (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To explore an all-in-one therapy for cooperatively fighting cancer, infection and boosting wound repair for patients with advanced superficial cancers or after surgical intervention to avoid multiple drug abuse and resultant adverse effects.

#### **METHODS AND MATERIALS**

The ultrasound-activated nanosensitizer PHMP was dexterously designed for combined therapy of cancer and infected wound based on oxygen/sulfate dual-radical nanotherapy. Firstly, the in vitro cancer cell killing action was proved using CCK-8 assay and fluorescence staining after the cells being treated with PHMP + US. Then, the in vitro migration promoting and bacteriostatic action was assessed through scratch test and detecting the bacteria viability respectively. Finally, the in vivo tumor-suppressive effect and repair function to the infected skin defect of PHMP + US was evaluated by constructing the subcutaneous melanoma and full thickness *S. aureus* infected skin wound model, and then monitoring tumor size, wound area as well as analyzing histological characteristics.

#### **RESULTS**

In the PHMP + US group, the descended cell viability and apparent cell death were observed, and the narrower scratch gap and fewer bacterial colonies were displayed. Simultaneously, the tumors undergoing PHMP + US disposal exhibited poor growth, distinct cell apoptosis and lower proliferation ability. In addition, the infected wounds in the PHMP + US group healed the fastest and demonstrated well-organized collagen fiber and skin structure.

#### **CONCLUSION**

s The in vitro and in vivo results suggests that US-activated PHMP can effectively inhibit tumor and promote infected wound repair.

#### **CLINICAL RELEVANCE/APPLICATION**

This study highlights the overall treatment of later stage or postoperative cancers accompanied by infectious wounds with a single US-activated multifunctional intervention which bypasses the side effects of polypharmacy and systemic administration of anticancer drugs/antibiotics. Such a conception delves the maximum capacity of each member and meanwhile reduces the harm to the minimum, which is of vast prospect in clinical transformation.

### **S3B-SPIR-6 Elucidation of the Microvascular Embolization Effects of Imipenem/Cilastatin Evaluation at the Level of Microvessels using Monochromatic X-ray in Vivo Study**

#### **PURPOSE**

To elucidate the characteristics of Imipenem/Cilastatin (IPM/CS) as an embolic material in vivo.

#### **METHODS AND MATERIALS**

Three healthy Japanese white rabbits (approximately 3 kg each) were used. A portion of one ear of each rabbit was injected subcutaneously with picibanil (0.5 KE) to create an inflammation-induced model. High spatial resolution microangiography was performed using monochromatic X-rays extracted from synchrotron radiation facility (Super Photon ring-8; SPring-8). Under anesthesia, an elastomer needle (26 G) was placed in the intermediate branch of the auricular artery, and pre-embolization angiography was performed. Then, embolization was performed from the intermediate branch of the auricular artery using a mixture of IPM/CS (0.2 g) and non-ionic contrast agent (2 ml). Angiography was performed during embolization, and at 3, 10, 20, 30, 40, 50, 60, 70, 80, and 90 minutes after embolization. The embolized vascular diameter was evaluated from the images during embolization, and the recanalization time was defined as after embolization time of "total artery area of post embolization / total artery area of pre embolization × 100" was ≥100 %. ROIs were set in both normal (n=3) and inflammation-induced (n=3) sites, and comparisons were made between the two groups.

#### **RESULTS**

The mean diameter of the embolized vessels immediately after embolization was 267±58.35 μm, with a range of 174-363 μm. In the follow-up observations after embolization, the normal vessels recanalized at an average of 70 minutes (case1: 101% on 70 min later, case2: 100% on 90 min later and case3: 101% on 50min later). In contrast, the vessels in the inflammation-induced areas did not show recanalization during the 90 minutes observation period.

#### **CONCLUSION**

s The characteristics of IPM/CS as an embolic material in vivo were elucidated. In vivo, much larger vessels are embolized than the actual particle size. It was also suggested that the embolization effect duration might differ between normal and inflammation-induced areas.

#### **CLINICAL RELEVANCE/APPLICATION**

The analgesic effect of IPM/CS embolization for pain associated with chronic arthritis has been clinically confirmed, and it may potentially become a basic data for the development of new embolic materials as alternatives to IPM/CS.

#### S3B-SPMK-1 Feasibility Study on Classification of Meniscus Damage Based on MRI Radiomics

##### PURPOSE

To explore the value of machine learning(ML)models based on MRI radiomics features in predicting the degree of meniscus injury.

##### METHODS AND MATERIALS

MRI images of 732 knee menisci were retrospective analyzed. The menisci were randomly divided into a training group (n=512) and a validation group (n=220) at a ratio of 7:3. Radiomic features were extracted from the sagittal and coronal proton density-weighted fat suppression images. The Minimum redundancy maximum relevance (mRMR) and least absolute shrinkage and selection operator (LASSO) were used for data dimension reduction and feature selection. Then, based on the optimal features, we constructed a four-category classification model with different ML methods, and its diagnostic performance was quantified by the area under the receiver operating characteristic curve (AUC).

##### RESULTS

Eighteen significant radiomic features (10 from sagittal and 8 from coronal images) were selected for model construction. The Macro AUC of support vector machine, logistic regression, Gaussian process, random forest, quadratic discriminant analysis and Bagging decision tree model were 0.876, 0.871, 0.870, 0.869, 0.868 and 0.868, respectively. The best-performing models for each lesion grade were: random forest for normal meniscus (AUC=0.948), logistic regression for grade 1 meniscus injury (AUC=0.833), Bagging decision tree for grade 2 (AUC=0.805) and random forest (AUC=0.902) for grade 3 meniscus injury.

##### CONCLUSION

s The ML models based on MRI radiomics features can accurately assess the type of meniscal injury.

##### CLINICAL RELEVANCE/APPLICATION

By accurately assessing the type of meniscal injury, ML can enhance the reliability and reproducibility of the diagnosis and help radiologists make clinical decisions.

#### S3B-SPMK-2 Enhancing Patient-Centered Radiology Reports with Generative Artificial Intelligence: Adding Value to Radiology Reporting

##### Participants

Jiwoo Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

##### PURPOSE

To evaluate the efficacy of AI-generated radiology reports in terms of report processing and providing high-quality, easily understandable reports that can address patient questions and to estimate the accuracy and artificial hallucination of AI-generated radiology reports.

##### METHODS AND MATERIALS
