Sixty-eight consecutive patients suspected with 28 brain tumors, 14 musculoskeletal diseases, 14 uterine or ovarian tumors and 12 prostatic cancers were prospectively scanned with conventional MR protocols and new MR protocols, which were obtained same sequences with reducing matrix sizes ranged from 50% to 70%. Then, each conventional MR data was reconstructed with DLR with and without fine recon, and all new protocol data were reconstructed with PIQE as well as DLR with and without fine recon (total five data sets). To compare scan time reduction and quantitative spatial resolution improvement among all protocols, mean examination time including reconstruction time and edge slope width (ESW) between two different structures were compared among five protocols by Tukey's HSD test. To evaluate qualitative spatial resolution improvement, overall image quality and diagnostic confidence level were assessed by 5-point scales and compared among all protocols by Wilcoxon's signed rank test.

#### RESULTS

Mean examination times of new MR protocols were significantly shorter than that of conventional protocols ( $p < 0.05$ ), although mean examination time had no significant differences among all new protocols. Mean ESW of new protocol with PIQE ( $1.1 \pm 0.3 \text{ mm}$ ) was significantly smaller than that of all protocols except conventional protocol with DLR and fine recon ( $1.4 \pm 0.4 \text{ mm} = \text{other ESWs} = 1.8 \pm 0.4 \text{ mm}$ ,  $p < 0.05$ ). Overall image quality and diagnostic confidence level of new protocol with PIQE were significantly higher than those of others except conventional protocol with DLR and fine recon (overall image quality:  $p < 0.0001$ , diagnostic confidence level:  $p < 0.0001$ ). Artifact of new protocol with PIQE was significantly smaller than those of others without conventional protocol with DLR and fine recon ( $p < 0.0001$ ).

#### CONCLUSION

PIQE has superior potential to DLR with and without fine reconstruction for reducing temporal resolution and improving spatial resolution, although fine reconstruction can only improve image quality of DLR at conventional protocol.

#### CLINICAL RELEVANCE/APPLICATION

PIQE has superior potential to DLR with and without fine reconstruction with reducing temporal resolution and improving spatial resolution.

### Early Detection of Myocardial Involvement by Noncontrast T1 $\rho$ Mapping of Cardiac Magnetic Resonance in Type 2 Diabetes Mellitus

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center

Xiaohu Li, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the feasibility of T1 $\rho$  in detecting myocardial fibrosis in type 2 diabetes mellitus (T2DM) patients by comparing with native T1 and Extracellular volume (ECV) fraction.

#### METHODS AND MATERIALS

35 T2DM patients free of cardiovascular symptoms and preserved ventricular systolic function and 30 healthy controls were prospectively enrolled for T1 mapping, T2 mapping T1 $\rho$  mapping, and late gadolinium enhancement (LGE) examination. ECV mps were calculated using pre- and post-contrast T1 maps. Global native T1, T1 $\rho$ , ECV and 2D global longitudinal strain (GLS) values were generated in respective maps. Receiver operating curves were used to show the diagnostic performance of ECV, T1 $\rho$ , GLS and native T1 in distinguishing T2DM patients and controls. The Student's t-test, Pearson's chi-squared test, Pearson correlation coefficient (r) and Delong test were used in this study.  $P < 0.05$  indicates statistical significance.

#### RESULTS

The global ECV and T1 $\rho$  of T2DM group (ECV =  $32.1 \pm 3.2\%$ , T1 $\rho$  =  $53.1 \pm 2.0$  msec) were significantly higher than those of controls (ECV =  $26.2 \pm 1.6\%$ , T1 $\rho$  =  $51.6 \pm 3.8$  msec) (all  $P < 0.001$ ), whether there was no significant difference in native T1 between T2DM and controls ( $P = 0.264$ ). The GLS decreased significantly in T2DM patients ( $-16.5 \pm 2.4\%$  vs.  $-18.3 \pm 2.6\%$ ,  $P = 0.015$ ). The T1 $\rho$  and native T1 were associated with ECV (Pearson's  $r = 0.50$  and  $0.25$ , respectively, both  $P < 0.001$ ), the native T1, T1 $\rho$ , and ECV were associated with hemoglobin A1c (Pearson's  $r = 0.41$ ,  $0.52$ , and  $0.61$ , respectively, all  $P < 0.05$ ), the ECV were associated with diabetes duration (Pearson's  $r = 0.41$ ,  $P = 0.016$ ). The AUC of ECV, T1 $\rho$ , GLS, and native T1 were  $0.869$ ,  $0.810$ ,  $0.659$ , and  $0.524$ , respectively.

#### CONCLUSION

In T2DM patients, T1 $\rho$  may be a new noncontrast cardiac magnetic resonance technique for identifying myocardial diffuse fibrosis, and T1 $\rho$  may be more sensitive than native T1 in the detection of myocardial diffuse fibrosis.

#### CLINICAL RELEVANCE/APPLICATION

It has shown that T1 $\rho$  mapping allow early detection of myocardial diffuse fibrosis in diabetic monkeys. However, T1 $\rho$  has not been reported in patients with type 2 diabetes mellitus (T2DM). In this project, the purpose of this study is to evaluate the feasibility of T1 $\rho$  in detecting myocardial diffuse fibrosis in T2DM in a comparison with myocardial native T1 and ECV.

### Changes in Brain Susceptibility in Wilson's Disease Patients: A Quantitative Susceptibility Mapping Study

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center

Xiaohu Li, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To reveal changes in the susceptibility of the caudate nucleus (CN), putamen (Put), and globus pallidus (GP) in patients with neurological and hepatic Wilson's disease (WD) by quantitative susceptibility mapping (QSM).

#### **METHODS AND MATERIALS**

We retrospectively analyzed brain MRI images of 33 patients diagnosed with Wilson's disease (WD) and 20 age-matched controls. All subjects underwent brain T1-weighted, T2-weighted, and QSM images using a 1.5T MRI scanner. The QSM maps were calculated using STISuite toolbox. The quantitative susceptibility of the CN, Put, and GP was analyzed using region-of-interest analysis on QSM maps. The differences among the neurological WD patients, hepatic patients, and controls were compared.

#### **RESULTS**

Susceptibility values were significantly higher in all examined structures (CN, Put, GP) in patients with neurological WD compared to controls (all  $P < 0.05$ ) and hepatic WD patients (all  $P < 0.05$ ). No statistically significant differences were found in susceptibility values between patients with hepatic WD and controls (all  $P > 0.05$ ).

#### **CONCLUSION**

The QSM technique is a valuable tool for detecting changes in susceptibility in the brain of WD patients, indicating abnormal metal deposition. Notably, our findings suggest that neurological WD patients exhibit more severe susceptibility changes than hepatic WD patients. Therefore, QSM can be utilized as a complementary method to detect brain injury in WD patients.

#### **CLINICAL RELEVANCE/APPLICATION**

Quantitative magnetic susceptibility imaging (QSM) is an advanced MRI technique for magnetic susceptibility evaluation, providing accurate quantitative measurements of the spatial distribution of magnetic susceptibility

### Vendor-independent MRI Pulse Sequence Development to Increase Comparability in Cross-vendor Imaging Studies

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center

Simon Konstandin, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Magnetic Resonance Imaging is a complex and versatile imaging method, given by the ability to visualize various contrasts and physiological processes. MRI research is commonly achieved by implementing new pulse sequences in vendor-specific development environments. During the last years, vendor-independent MRI frameworks gained attention. Previously, we introduced a vendor-independent MRI pulse sequence development framework that provides a product-like experience on-site, called gammaSTAR [Cordes C et al. Magn Reson Med 2020;83(4):1277-90.]. Until today, none of these frameworks was able to run the same MRI sequence on the MRI hardware of the three largest MRI vendors: Siemens, GE and Philips. In this abstract, for the first time, we show cross-vendor use of gammaSTAR MRI sequences on all three platforms.

#### METHODS AND MATERIALS

A modular web frontend (free version here: [gamma-star.mevis.fraunhofer.de](http://gamma-star.mevis.fraunhofer.de)) is used to implement MRI sequences and export them into a generalized sequence format. This does not consist of fixed hardware instructions, but holds the fundamental calculation logic of the implemented MRI sequence, allowing for product-like interaction with the MRI sequence and protocol. gammaSTAR driver software is implemented using the vendors development environments to interpret the gammaSTAR sequences and translate events into the vendor-specific hardware commands.

#### RESULTS

MRI experiments show the feasibility of running MRI sequences developed in the vendor-independent gammaSTAR framework on Siemens, GE and Philips MRI scanners. Image quality is similar to corresponding product MRI sequences and the framework allows for the same protocol interaction and positioning. Low cross-vendor comparability of conventional MRI arises from underlying implementation differences. The use of the same MRI sequence for execution on different MRI hardware allows, for the first time, a comparison of the exact same MRI sequence in a multi-vendor scenario.

#### CONCLUSION

MRI sequences developed in gammaSTAR were for the first time executed on hardware platforms of all three major MRI vendors. This will eventually open up science and improve the significance of multi-vendor clinical trials by harmonizing imaging technology.

#### CLINICAL RELEVANCE/APPLICATION

The current state of vendor-centric MRI pulse sequence development limits reuse of MRI applications for different MRI models, software versions. The execution of generalized MRI sequences on MRI hardware of the three largest MRI vendors presents a chance for higher comparability in multi-vendor clinical trials, between follow-ups acquired in different clinics and re-use of MRI sequences for opening up science and accelerating the way of innovation into clinical practice.

### Egress Pathways of Intrinsic CSF Outflow Altered by Physical Exercise in Healthy Humans

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center

Mitsue Miyazaki, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate egress pathways of intrinsic CSF outflow and their quantitative metrics using a spin-labeling MRI technique on healthy adults with active and sedentary lifestyles. We also examined changes in the CSF outflow metrics in sedentary adults after they increased their physical activity levels for three weeks.

#### METHODS AND MATERIALS

Eighteen healthy adults with informed consent were enrolled in this study using a clinical 3-Tesla MRI scanner. We classified participants into two groups based on reported time spent sitting per day (active group < 7 hours or an average of  $5.3 \pm 0.7$  and sedentary group = 7 hours or an average of  $10.4 \pm 1.7$ ). To reveal the effect of exercise, the sedentary individuals were asked to increase their activity to at least about 3.5 hours per week for 3 weeks. To elucidate intrinsic CSF outflow pathways and quantitative metrics, we studied a signal increase ratio (SIR) of time-resolved images at various inversion times (TI). Our hypothesis is that intrinsic CSF egress pathways of 1) dura mater to superior sagittal sinus (SSS), via parasagittal dura (PSD), and 2) the lower PSD pathway from the perivascular space of subcortical or bridging veins. We also measured quantitative outflow metrics at 5 segmented region-of-interests (ROIs); upper PSD, middle PSD, lower PSD, SSS, and entire SSS.

#### RESULTS

The active lifestyle group shows greater intrinsic CSF outflow metrics in peak height (PH), relative CSF volume (rCFV), and relative CSF flow (rCFF) ( $p < 0.05$ ) in all above ROIs than the sedentary lifestyle group. However, the sedentary group shows increased outflow metrics after 3 weeks of increased physical activity. This improvement was notable at the PSD, where outflow metrics were highest among the active group and after exercise in sedentary group. These quantitative CSF results indicate a new pathway of CSF outflow from the lower PSD to the SSS that is most evident in physically active individuals.

#### CONCLUSION

The results show that physical exercise alters CSF outflow metrics to a greater degree in the lower PSD pathway, which may be responsible for the perivascular space of cortical veins or subpial space.

#### CLINICAL RELEVANCE/APPLICATION

Our findings in healthy adults with active and sedentary lifestyles reveal differences in quantitative CSF outflow metrics related to activity levels. These quantitative outflow findings at the lower PSD add credence to the hypothesis of a distinct, recruitable second pathway of CSF egress from the subpial space to the SSS, with potential implications for future use as a biomarker for cognitive decline and/or therapeutic targeting in aging and neurodegeneration.

### A Robust Spectroscopic Imaging Sequence for 7T Brain Glioma Evaluation

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center

Jullie W. Pan, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To implement a robust fast targeted spectroscopic imaging sequence at 7T for brain tumors. While 3T single voxel spectroscopy is an excellent acquisition, with limited scan time, small voxel targets, and the need to place single voxels by the technologist can be difficult. These problems can be better managed with higher SNR at 7T; however, 7T can be difficult for spectroscopy with limited RF and susceptibility. We implement the decoupled transceiver coil and a high degree shim insert with an efficient spatial encoding strategy to assess its performance in glioma patients.

#### METHODS AND MATERIALS

With IRB oversight, tumor patients were recruited from Tumor Board review (10 patients recruited; 9 completed). An 8 channel pTx Siemens 7T Terra, decoupled transceiver and very high order shim (VHOS) insert was used. After whole brain MP2RAGE imaging and RF shimming, the target regions were identified. For optimal shimming, single slices were studied, shimmed using a high accuracy field map with the VHOS insert. A moderate echo TE=40ms spectroscopic imaging sequence encoded with a noncartesian rosette trajectory was used (32x32 resolution, 4.5min single slice). First level SAR monitoring was used. Automated LCModel curve fit was used to determine metabolite ratios. Values of maximum Ch/NAA value in the region of the lesion were used to identify 3 groups of abnormality:  $\geq 1.7$ ,  $\geq 0.9$  to  $< 1.7$  or  $< 0.9$ . All studies were blinded to clinical and imaging data to independently compare clinical to spectroscopic imaging group.

#### RESULTS

Fig. 1 shows data from a patient with two regions of interest. Based on literature and the patient data, the ratios for Ch/NAA and Ch/Cr were used for initial classification (control value for parenchymal Ch/NAA  $0.56 \pm 0.17$ , Ch/Cr  $1.03 \pm 0.15$ ). The spectroscopic group based on the maximum Ch/NAA in the region of tumor was compared with their clinical group, either active tumor, treatment effect or no change, Table 1. N=5 patients with Ch/NAA  $\geq 1.7$  were classified with active tumor; 1 patient classified as normal had low Ch/NAA  $< 0.9$ . The remaining 3 patients ( $0.9 \leq \text{Ch/NAA} < 1.7$ ) were clinically described as treatment effect (1), progression (1) or no change (1); the last "no change" patient was identified 6mos later to have progression.

#### CONCLUSION

At 7T with the decoupled transceiver and high degree shim insert, the spectroscopic imaging was able to identify patients with active tumor. An intermediate threshold for Ch/NAA of 0.9 to 1.7 identified those with treatment effect or very early recurrence. With additional data, better classification may be possible.

#### CLINICAL RELEVANCE/APPLICATION

We have implemented 7T methods that can acquire robust spectroscopic images in glioma patients which can contribute to a better or earlier understanding of the tumor state.

### Deep Learning Prediction of Post-Radiation Magnetic Resonance Images to Inform Stereotactic Radiotherapy of Breast Cancer Metastases to the Brain

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center

Natarajan Raghunand, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Changes on standard multiparametric MRI (mpMRI), including T1-weighted unenhanced (T1w) and contrast-enhanced (T1wCE), T2-weighted (T2w), Fluid-Attenuated Inversion Recovery (FLAIR), and Apparent Diffusion Coefficient of water (ADC) images are mechanistically relatable to voxel-level tumor response to Radiation Therapy (RT). While Stereotactic Radiosurgery (SRS) provides high local control rates for the management of Breast Cancer Metastases to the Brain (BCMB), tools to enable voxel-level optimization of RT dose plans for local tumor control with minimal toxicity to normal tissues do not exist. We have trained deep learning “forward models” to predict post-SRS T1w, T1wCE, T2w, FLAIR and ADC maps from the corresponding 5 pre-SRS mpMRIs and the delivered RT dose map. We also trained an “inverse model” to predict the delivered RT dose map from 5 pre-SRS and 5 post-SRS mpMRI images. The overarching goal is to enable the radiation oncologist to compute the RT dose map to achieve prescribed post-SRS values of ADC, T1wCE, T1w, T2w and FLAIR within the GTV, simulate mpMRI outcomes and iteratively optimize RT plans for local control of BCMB.

#### METHODS AND MATERIALS

Planning CT images and associated RT dose maps, and T1w, T1wCE, T2w, FLAIR images and ADC maps acquired pre-SRS, post-SRS, and at tumor recurrence were curated from 27 BCMB patients (18 Training, 9 Test) with confirmed controlled and locally recurrent metastases. Patients were treated with SRS dose of 1-40 Gy between 2013-2019. After co-registration to the planning CT, all mpMRIs were intensity-calibrated, variance-normalized and scaled. A pix2pix framework used to predict post-SRS MRIs from pre-SRS MRIs and the RT dose map (5 forward models). Another pix2pix model was trained to predict the RT dose map from pre-SRS and post-SRS MRIs (inverse model).

#### RESULTS

On testing, forward model accuracy for predicting the direction of post-SRS intensity change within the Gross Tumor Volume (GTV) was highest for T1wCE (83%), followed by T1w (77%), FLAIR (75%), T2w (68%), and ADC (46%). In agreement with expectations, higher RT doses within the GTV are predicted by the inverse model to achieve greater suppression of intensity on T1wCE and/or higher ADC within the GTV post-SRS.

#### CONCLUSION

We have demonstrated the feasibility of predicting post-RT mpMRI images from pre-RT mpMRIs and the delivered RT dose map. For a given set of pre-RT mpMRIs, we have also demonstrated the feasibility of predicting the RT dose map that would be required to achieve prescribed post-RT intensities within the GTV.

#### CLINICAL RELEVANCE/APPLICATION

We present a new paradigm in RT planning, viz., voxel-level optimization of SRS dose to achieve prescribed post-SRS mpMRI characteristics of treated tumors using the presented forward and inverse models.

W2-SPVA-1

### Tele-robotic Ultrasound Usability Testing on a Phantom

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center

Leah Groves, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Annually, 16 million North American patients struggle to access diagnostic ultrasound (US) services due to sonographer shortages. Rural and remote patients are required to travel excessive distances to access diagnostic US services, which can be time-consuming and expensive resulting in patients failing to attend their appointments. The aim of this study is to validate a proof-of-concept tele-robotic US system which serves to make diagnostic healthcare more accessible.

#### METHODS AND MATERIALS

The equipment used in the study included the Kinova Gen 3 robot, Clarius L7 US probe, the Inverse3 (input device), and an advanced deep-vein thrombosis (DVT) phantom. First, seven sonographers performed freehand DVT scans on the phantom. After successful training, each sonographer performed a teleoperated DVT scan, where they controlled the robot using the input device. The required US images, clot diameter, and scan duration were recorded for the freehand and teleoperated scans. The users then completed a survey, where various parameters were ranked on a scale of 1-5, with 5 being optimal. Next, each user performed three teleoperated scans with three random and counter-balanced latencies (0, 300, 600 ms). They started at a standardized position, located the clot, and measured its diameter. The duration of each test was recorded.

#### RESULTS

The clot diameters collected using freehand and teleoperated US were  $1.1 \pm 0.2$  cm and  $1.0 \pm 0.3$  cm, respectively. The time associated with performing the freehand and teleoperated DVT scans were  $8.7 \pm 3.8$  min and  $8.0 \pm 2.0$  min, respectively. The usability survey yielded the following average rankings for input device features: naturalism and usable workspace, 3.4; ergonomics, 3.9; ease of use, 4.3. The rankings for the robotic system features were: smoothness, 3.1; naturalism, 3.4; range of motion, 3.6; and control accuracy, control ease, and synchronicity, 3.7. The clot diameter collected with teleoperated US were  $1.2 \pm 0.24$  cm,  $1.1 \pm 0.32$  cm, and  $1.1 \pm 0.24$  cm for 0, 300, and 600 ms latencies, respectively. The duration of the tests subject to 0, 300, 600 ms latencies were  $1.3 \pm 0.69$  min,  $1.4 \pm 0.69$  min, and  $1.9 \pm 0.68$  min, respectively.

#### CONCLUSION

This study provides a proof-of-concept for the use of teleoperated diagnostic US as sonographers were able to measure the clot diameter within 0.1 cm of their freehand equivalent without increasing the time required for the scan. Latencies up to 600 ms did not affect the accuracy of the resultant clot diameter or scan time.

#### CLINICAL RELEVANCE/APPLICATION

The results of this proof of concept study encourages the continued pursuit of teleoperated US research as there is a strong potential it could result in more patients obtaining diagnostic US, improved outcomes from earlier diagnosis, and safer pregnancies.

W2-SPVA-2

### **Diagnostic Accuracy of Photon-Counting CT Angiography in Lower Extremity Peripheral Artery Disease: A Head-to-Head Comparison with Invasive Angiography**

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center

Niklas Verloh, MD (*Presenter*) Speaker, Bayer AG; Research Funded, Bayer AG

#### **PURPOSE**

CT Angiography (CTA) has gained increasing importance in assessing the presence and severity of peripheral artery disease (PAD). However, the diagnostic performance of the lower leg vasculature remains challenging due to small vessel diameters and impaired image quality caused by the blooming of calcified plaques. Recently introduced photon-counting detector CT (PCD-CT) technology may overcome these limitations. Therefore, we aimed to investigate and compare the diagnostic accuracy of PCD-CT for PAD of the lower leg with invasive digital subtraction angiography (DSA) as the reference standard.

#### **METHODS AND MATERIALS**

Consecutive patients with suspected PAD of the lower leg, who underwent CT and DSA within 48 hours, were prospectively included. Five series were reconstructed using dedicated vascular kernels (Bv40, Bv44, Bv48, Bv56, and Bv60). DSA of the lower extremities was acquired in two orthogonal orientations as the gold standard. To assess and compare the diagnostic performance of the different PCD-CT reconstructions, two interventional radiologists assessed all PCD-CT and DSA data independently in random order. They were blinded to the type of reconstruction. First, overall image quality was rated on a 5-Point Likert scale (5=excellent). Secondly, the presence and diagnostic confidence (5-Point Likert scale; 5=excellent) of potentially hemodynamic-relevant stenosis (=50%) was assessed.

#### **RESULTS**

Among twenty-three patients included in the final analysis (70±11 years, 39% female), six hemodynamic-relevant stenoses were detected on DSA. The highest overall image quality was found for the Bv56 and the Bv60 kernel (4 [4-4]; 4 [3-5];  $p=0.001$ ), followed by softer kernels. Also, the Bv56 kernel yielded the highest sensitivity (83.33%) and specificity (94.12%) for the detection of potentially relevant stenosis with the highest diagnostic confidence (4 [3-5];  $p=0.001$ ) and inter-reader agreement ( $k=0.7$ ), similarly followed by Bv60 and softer kernels.

#### **CONCLUSION**

PCD-CT CTA with a sharp vascular kernel (Bv56) allows for detecting relevant stenosis in the lower leg vasculature with high diagnostic accuracy and confidence. These results can potentially strengthen the role of CTA in the workup of patients with known or suspected PAD and reduce the number of invasive diagnostic DSA.

#### **CLINICAL RELEVANCE/APPLICATION**

CTA is important in the workup of PAD but remains challenging due to small vessel caliber and potential blooming artifacts. PCD-CT CTA with a sharp vascular kernel may improve image quality and, thus, patient management. Using PCD-CT may ultimately reduce the need for invasive diagnostic procedures.

### Science Session (Generative AI)

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center Theater 1

#### Sub-Events

#### **W2-STCE1- Advanced Oncologist Assistance: Generating Alarms for new Oncologic Issues based on Radiologic Reports of Serial CT Scans with GPT-4** 1

Na Yeon Han (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Abdominal CT play crucial roles for assessment of treatment response for cancer patients. However, radiologic reports often lack standardization, encompassing a plethora of information beyond cancer-related findings. Moreover, the multitude of test results conducted in cancer patients can be overwhelming, leading oncologists occasionally missing critical findings. This study aims to investigation on the feasibility of generative AI to generating the alarm for clinically significant oncologic Issues in serial CT reports.

#### **METHODS AND MATERIALS**

We studied 101 patients with various primary tumors, obtaining two consecutive radiologic reports per patient. We designed 4 multiple-choice questions to assess oncologic issues in the reports. Questions were designed to contain progressively added specific conditions, such as radiologic report's chronological sequence, precise criteria for oncologic issues, and the patient's treatment status. GPT-4 (July 20 Version) was asked to choose the correct answer based on radiologic reports among the four alternatives for each question. Consensus ground truth was established by two blinded radiologists. Since GPT-4 does not always output the same answer, each question was repeated three times, and the most frequently occurring value was recorded. GPT-4 responses were compared to ground truth, and the model's performance was compared using McNemar-Test. P-values < 0.05 were considered statistically significant.

#### **RESULTS**

Among 101 patients, 31 had no new oncologic issues, 18 improved, 18 remained stable, and 34 worsened. GPT-4 showed accuracy rate of 0.92 (93/101) for Question (Q)1; 0.97 (98/101) for Q2; 0.99 (100/101) for Q3 and 0.99 (100/101) for Q4. Accuracy rate was significantly higher for Q2 (p-value of 0.041) and for Q3 and Q4 (p-value of 0.023) than for Q1. Upon reviewing the radiologic report of one patient who had incorrect output for Q3 and Q4, we identified an error in the consensus review. This error arose from the fact that the lesion, which had already been mentioned in report 1, was reported as a "newly developed lesion" in report 2, resulting in an erroneous entry of the ground truth.

#### **CONCLUSION**

In this study, utilizing GPT-4 to generate alarms for new oncologic issues in radiologic reports of Serial CT Scans demonstrated high performance, particularly when specific questions were asked. These results indicate the potential for various future studies using generative AI to enhance interpretation accuracy and prevent important information omission in patient care.

#### **CLINICAL RELEVANCE/APPLICATION**

Using GPT-4 to provide accurate alarms for new oncologic issues based on radiologic reports can help reduce oncologists' data review time and prevent patient information omissions.

#### **W2-STCE1- Generative Language Model for Risk-Specific Metabolic Health Report Generation from Deep Learning-Based Opportunistic Assessment of Lung Cancer Screening CT** 2

Florian A. Huber, MD (*Presenter*) Nothing to Disclose

## PURPOSE

The majority of CT examinations cover large body volumes that allow for the assessment of imaging biomarkers to predict bone health and cardiometabolic risk. Novel deep learning-based automated post-processing and analysis techniques allow opportunistic screening using routine clinical CTs. We aimed to prove the feasibility of generating personalized metabolic reports using a novel proprietary generative AI tool (GPT-4, OpenAI) in combination with a custom deep learning-based post-processing algorithm for opportunistic assessment of CT examinations in a diverse US metropolitan population.

## METHODS AND MATERIALS

Demographic and CT data of 5442 patients who underwent low-dose CT of the lungs for lung cancer screening were included. All imaging was acquired in accordance with institutional protocol standards (peak tube voltage: 120 kVp, tube current modulation: = 80 mAs, pitch: 1.25 to 1.5, rotation time: = 500 milliseconds). A validated deep learning-based assessment tool was used for automated evaluation of bone mineral density (BMD), liver steatosis, aortic calcification, and muscle mass and quality. We performed interrogative strings with a generative tool based on GPT-4 that was aware of clinical and academic knowledge published until 2021. Subsequently, the language model was asked to provide personalized patient-readable health reports for a combination of 5 different clinical findings (aortic calcification, sarcopenia, myosteatosis, BMD, liver steatosis). Results were tested for all present scenarios of possible disease combinations and assessed for readability, appropriateness, and impact on patient management using a 4-point Likert scale (absent, poor, satisfactory, excellent for each parameter separately in each of the 5 clinical findings, see Figure 1). Descriptive statistics were applied to evaluate results from the generated personalized health reports.

## RESULTS

We identified 70 clinical scenarios among our cohort. The generative AI model was able to provide individual reports for each scenario (n=70, 100%). Average ratings were considered excellent, with total scores as follows (median, range; maximum score in each category: 15): 14[13-15] for readability, 13[12-15] for appropriateness, 13[11-14] for clinical impact.

## CONCLUSION

Generative models are capable of translating medical information into patient-centered health reports at excellent overall quality.

## CLINICAL RELEVANCE/APPLICATION

The application of opportunistic CT assessment algorithms can be linked with novel generative language tools to improve patient interaction and understandability of clinical findings unrelated to primary clinical requests.

## W2-STCE1- Utilizing Large Language Models for Neuro-Oncologic Prediction: A Multi-Center Study on 3 Magnetic Resonance Imaging Reports

Maliha R. Imami, MEng (*Presenter*) Nothing to Disclose

## PURPOSE

Central nervous system tumors are a leading cause of cancer-related mortality worldwide. Longitudinal neuroimaging data with magnetic resonance (MR) imaging is essential for evaluating radiographic response and prognosis. We aimed to develop large language models (LLMs) using MR imaging reports for the automated curation of neuro-oncologic outcomes across a diverse array of brain tumor types to enhance prognostication accuracy.

## METHODS AND MATERIALS

We retrieved MR reports and clinical data from patients with intracranial brain tumors from two large academic centers in the United States. 9,055 free-text radiology reports from a cohort of 1,580 brain tumor patients were manually annotated for: (1) cancer presence or absence and (2) tumor stability (stable versus progressive disease). Three LLMs (ClinicalBERT, BlueBERT, and ELECTRA) and four baseline NLP models (CNN, RNN, GRU, LSTM) were developed. Models were trained and validated with data from Institution-1 and externally tested on Institution-2 reports. Performance was compared via weighted-F1 and accuracy; model decision interpretability tools were generated. Multivariate cox proportional hazards regressions were used to correlate model output with survival.

## RESULTS

For cancer presence task, the training dataset from Institution-1 had 4,621 reports (70.4% "cancer present") and 3,954 external test reports (55.4% "cancer present") from Institution-2. The tumor stability task had 5,017 training reports (74.2% "stable/improving") and 4,038 testing reports (81.1% "stable/improving"). The three LLMs demonstrated superiority over baseline models and ELECTRA exhibited the best performance among the LLMs for both tasks. For cancer presence, ELECTRA achieved a weighted F1-score of 0.822, accuracy of 0.822, sensitivity of 0.804, and specificity of 0.836. Weighted F1-score, accuracy, sensitivity, and specificity were 0.933, 0.934, 0.807, and 0.963 for tumor stability, respectively. Hazard ratios revealed higher mortality risk for patients with reports classified as cancer present (3x) and progressive disease (2x). Sample interpretability outputs are provided.

## **CONCLUSION**

Our ELECTRA transformer was able to extract salient neuro-oncologic outcomes from unstructured radiology reports and risk stratify patients in a sample-efficient and explainable manner. These results illustrate utility of LLMs for effective prediction of clinically salient neuro-oncologic outcomes.

## **CLINICAL RELEVANCE/APPLICATION**

Automated, explainable LLM frameworks can provide clinicians involved in neuro-oncologic care with rapid and reliable interpretation of imaging findings to streamline workflows, risk stratify patients and facilitate longitudinal monitoring.

### Advanced Oncologist Assistance: Generating Alarms for new Oncologic Issues based on Radiologic Reports of Serial CT Scans with GPT-4

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center Theater 1

Na Yeon Han (*Presenter*) Nothing to Disclose

#### PURPOSE

Abdominal CT play crucial roles for assessment of treatment response for cancer patients. However, radiologic reports often lack standardization, encompassing a plethora of information beyond cancer-related findings. Moreover, the multitude of test results conducted in cancer patients can be overwhelming, leading oncologists occasionally missing critical findings. This study aims to investigation on the feasibility of generative AI to generating the alarm for clinically significant oncologic Issues in serial CT reports.

#### METHODS AND MATERIALS

We studied 101 patients with various primary tumors, obtaining two consecutive radiologic reports per patient. We designed 4 multiple-choice questions to assess oncologic issues in the reports. Questions were designed to contain progressively added specific conditions, such as radiologic report's chronological sequence, precise criteria for oncologic issues, and the patient's treatment status. GPT-4 (July 20 Version) was asked to choose the correct answer based on radiologic reports among the four alternatives for each question. Consensus ground truth was established by two blinded radiologists. Since GPT-4 does not always output the same answer, each question was repeated three times, and the most frequently occurring value was recorded. GPT-4 responses were compared to ground truth, and the model's performance was compared using McNemar-Test. P-values < 0.05 were considered statistically significant.

#### RESULTS

Among 101 patients, 31 had no new oncologic issues, 18 improved, 18 remained stable, and 34 worsened. GPT-4 showed accuracy rate of 0.92 (93/101) for Question (Q)1; 0.97 (98/101) for Q2; 0.99 (100/101) for Q3 and 0.99 (100/101) for Q4. Accuracy rate was significantly higher for Q2 (p-value of 0.041) and for Q3 and Q4 (p-value of 0.023) than for Q1. Upon reviewing the radiologic report of one patient who had incorrect output for Q3 and Q4, we identified an error in the consensus review. This error arose from the fact that the lesion, which had already been mentioned in report 1, was reported as a "newly developed lesion" in report 2, resulting in an erroneous entry of the ground truth.

#### CONCLUSION

In this study, utilizing GPT-4 to generate alarms for new oncologic issues in radiologic reports of Serial CT Scans demonstrated high performance, particularly when specific questions were asked. These results indicate the potential for various future studies using generative AI to enhance interpretation accuracy and prevent important information omission in patient care.

#### CLINICAL RELEVANCE/APPLICATION

Using GPT-4 to provide accurate alarms for new oncologic issues based on radiologic reports can help reduce oncologists' data review time and prevent patient information omissions.

### Generative Language Model for Risk-Specific Metabolic Health Report Generation from Deep Learning-Based Opportunistic Assessment of Lung Cancer Screening CT

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center Theater 1

Florian A. Huber, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The majority of CT examinations cover large body volumes that allow for the assessment of imaging biomarkers to predict bone health and cardiometabolic risk. Novel deep learning-based automated post-processing and analysis techniques allow opportunistic screening using routine clinical CTs. We aimed to prove the feasibility of generating personalized metabolic reports using a novel proprietary generative AI tool (GPT-4, OpenAI) in combination with a custom deep learning-based post-processing algorithm for opportunistic assessment of CT examinations in a diverse US metropolitan population.

#### METHODS AND MATERIALS

Demographic and CT data of 5442 patients who underwent low-dose CT of the lungs for lung cancer screening were included. All imaging was acquired in accordance with institutional protocol standards (peak tube voltage: 120 kVp, tube current modulation: = 80 mAs, pitch: 1.25 to 1.5, rotation time: = 500 milliseconds). A validated deep learning-based assessment tool was used for automated evaluation of bone mineral density (BMD), liver steatosis, aortic calcification, and muscle mass and quality. We performed interrogative strings with a generative tool based on GPT-4 that was aware of clinical and academic knowledge published until 2021. Subsequently, the language model was asked to provide personalized patient-readable health reports for a combination of 5 different clinical findings (aortic calcification, sarcopenia, myosteotosis, BMD, liver steatosis). Results were tested for all present scenarios of possible disease combinations and assessed for readability, appropriateness, and impact on patient management using a 4-point Likert scale (absent, poor, satisfactory, excellent for each parameter separately in each of the 5 clinical findings, see Figure 1). Descriptive statistics were applied to evaluate results from the generated personalized health reports.

#### RESULTS

We identified 70 clinical scenarios among our cohort. The generative AI model was able to provide individual reports for each scenario (n=70, 100%). Average ratings were considered excellent, with total scores as follows (median, range; maximum score in each category: 15): 14[13-15] for readability, 13[12-15] for appropriateness, 13[11-14] for clinical impact.

#### CONCLUSION

Generative models are capable of translating medical information into patient-centered health reports at excellent overall quality.

#### CLINICAL RELEVANCE/APPLICATION

The application of opportunistic CT assessment algorithms can be linked with novel generative language tools to improve patient interaction and understandability of clinical findings unrelated to primary clinical requests.

### Utilizing Large Language Models for Neuro-Oncologic Prediction: A Multi-Center Study on Magnetic Resonance Imaging Reports

Wednesday, Nov. 29 9:00AM - 9:30AM Room: Learning Center Theater 1

Maliha R. Imami, MEng (*Presenter*) Nothing to Disclose

#### PURPOSE

Central nervous system tumors are a leading cause of cancer-related mortality worldwide. Longitudinal neuroimaging data with magnetic resonance (MR) imaging is essential for evaluating radiographic response and prognosis. We aimed to develop large language models (LLMs) using MR imaging reports for the automated curation of neuro-oncologic outcomes across a diverse array of brain tumor types to enhance prognostication accuracy.

#### METHODS AND MATERIALS

We retrieved MR reports and clinical data from patients with intracranial brain tumors from two large academic centers in the United States. 9,055 free-text radiology reports from a cohort of 1,580 brain tumor patients were manually annotated for: (1) cancer presence or absence and (2) tumor stability (stable versus progressive disease). Three LLMs (ClinicalBERT, BlueBERT, and ELECTRA) and four baseline NLP models (CNN, RNN, GRU, LSTM) were developed. Models were trained and validated with data from Institution-1 and externally tested on Institution-2 reports. Performance was compared via weighted-F1 and accuracy; model decision interpretability tools were generated. Multivariate cox proportional hazards regressions were used to correlate model output with survival.

#### RESULTS

For cancer presence task, the training dataset from Institution-1 had 4,621 reports (70.4% "cancer present") and 3,954 external test reports (55.4% "cancer present") from Institution-2. The tumor stability task had 5,017 training reports (74.2% "stable/improving") and 4,038 testing reports (81.1% "stable/improving"). The three LLMs demonstrated superiority over baseline models and ELECTRA exhibited the best performance among the LLMs for both tasks. For cancer presence, ELECTRA achieved a weighted F1-score of 0.822, accuracy of 0.822, sensitivity of 0.804, and specificity of 0.836. Weighted F1-score, accuracy, sensitivity, and specificity were 0.933, 0.934, 0.807, and 0.963 for tumor stability, respectively. Hazard ratios revealed higher mortality risk for patients with reports classified as cancer present (3x) and progressive disease (2x). Sample interpretability outputs are provided.

#### CONCLUSION

Our ELECTRA transformer was able to extract salient neuro-oncologic outcomes from unstructured radiology reports and risk stratify patients in a sample-efficient and explainable manner. These results illustrate utility of LLMs for effective prediction of clinically salient neuro-oncologic outcomes.

#### CLINICAL RELEVANCE/APPLICATION

Automated, explainable LLM frameworks can provide clinicians involved in neuro-oncologic care with rapid and reliable interpretation of imaging findings to streamline workflows, risk stratify patients and facilitate longitudinal monitoring.

#### **W3-SSBR08-1 Contrast-Enhanced Mammography-Guided Biopsy for MRI-Detected Lesions: Feasibility and Factors Predicting Success**

Yuying Cao, BSC (*Presenter*) Nothing to Disclose

#### PURPOSE

This study assessed the utility of stereotactic contrast-enhanced mammography (CEM)-guided biopsy for MRI-detected lesions. Biopsy success rate was evaluated as well as factors that may predict success. Patient satisfaction and radiologist confidence level were also assessed.

#### METHODS AND MATERIALS

94 women (mean age 54.9 + 11.3 years) were enrolled in this prospective IRB-approved study, with 114 MRI-suspicious lesions BI-RADS 4A or greater for which CEM biopsy was attempted. Biopsy success was defined by enhancing lesion retrieval, biopsy clip position on post-procedure mammogram, and radiology-pathology correlation. Surveys were given to patients and clinicians. Success rate was evaluated with the Wilson score interval. Lesion characteristics {size, type [mass, focus, or non-mass enhancement (NME); distribution; internal enhancement pattern], patient breast density, MRI kinetics, MRI background parenchymal enhancement (BPE)} from successful and failed biopsies were compared using Wilcoxon rank-sum test (breast density, MRI BPE), two-sample t-test (lesion size), and Fisher's exact test (all others).

#### RESULTS

Of 114 MRI-detected breast lesions, 15 proved malignant. 69/114 (61%, 95% CI 51-69) successfully underwent CEM-guided biopsy, including 12 malignant lesions. Of the 45 failures, 41 (91.1%) were due to lack of enhancement on CEM, with no CEM biopsy attempted; 35/45 (77.8%) were then biopsied using MR guidance and 3 proved malignant. Successful CEM biopsy was more likely for larger lesions (mean = 21.5 + 25.3 mm vs 10.0 + 9.3 mm,  $P=0.004$ ). NME lesion type was associated with success ( $P=0.01$ ), comprising 46/69 (66.7%) successful biopsies and 19/45 (42.2%) failures. NMEs were further compared between successful and failed groups, and no association was found for distribution ( $P=0.2$ ); internal enhancement pattern (homogeneous vs heterogeneous vs clumped vs clustered ring) was of borderline significance ( $P=0.05$ ). No association was found between success and MRI kinetics ( $P=0.5$ ). No differences were found between successful and failed biopsies for breast density ( $P=0.3$ ) or BPE ( $P=0.6$ ). Patient satisfaction was rated 4.8/5 + 0.7. For enhancing lesions, radiologist confidence in biopsy success was rated 4.4/5 + 0.8.

#### CONCLUSION

CEM-guided biopsy for MRI-detected lesions had a 61% success rate. Larger lesion size and NME lesion type were associated with success. Patients were overall satisfied with the procedure, and radiologists were overall confident in success.

#### CLINICAL RELEVANCE/APPLICATION

Evaluation of success rate of CEM-guided biopsy for MRI-detected lesions along with factors associated with success may inform guidelines regarding CEM biopsy use, and elucidate which MRI lesions should undergo attempted CEM biopsy.

#### **W3-SSBR08-2 Deep Learning Based Contrast Dose Reduction in Breast MRI Using Synthetic Low-dose Images**

Venkata, MSc (*Presenter*) Employee, Subtle Medical, Inc; Stockholder, Subtle Medical, Inc

## PURPOSE

Gadolinium-based contrast agent (GBCA)-enhanced breast MRI is widely used for breast cancer screening and evaluating treatment response. Due to various safety concerns of GBCAs, including long-term tissue deposition, there is a need for dose reduction. In this work, we investigate the feasibility of a deep learning (DL) method for contrast dose reduction in dynamic contrast-enhanced (DCE) breast MRI, using synthesized low-dose images.

## METHODS AND MATERIALS

Previously, a DL model was trained to synthesize full-dose CE brain MRI images from real pre-contrast and 10% low-dose images. This DL dose reduction model was repurposed to synthesize post-contrast breast MRI images (Synth-Gad) from real pre-contrast images and synthetic low-dose (Synth-Low) images (Fig 1A). The synthetic low-dose breast images were generated from pre- (Pre-Gad) post-contrast (Real-Gad) images, using a vision transformer that was trained with brain MRI data (Fig 1B) to perform arbitrary low-dose simulation. DCE breast MRI data from 60 patients (30 internal, 30 Duke Breast MRI public dataset) were used for evaluation. The CE images were normalized and co-registered to Pre-Gad, and the first time point post injection was used as Real-Gad. In order to simplify the intensity normalization process, axial images were manually cropped to remove signals posterior to the pectoral muscles. Left right sides were separated and processed individually by the DL model. Similarity metrics (PSNR SSIM) were calculated between Real-Gad and Synth-Gad images. Enhancement kinetic curves (time post injection vs signal intensity - SI) were drawn with Pre-Gad, Real-Gad and the other CE time points along with the average SI of Synth-Low and Synth-Gad images.

## RESULTS

The mean PSNR SSIM between Real- Synth-Gad was ( $31.55 \pm 3.26$  dB  $0.85 \pm 0.07$ ). Qualitative examples shown in (Fig 1C) demonstrate that enhancement patterns in Synth-Gad images are similar to those present in Real-Gad images. The corresponding enhancement kinetic curves show that the SI of Real Synth-Gad images are similar and the SI of Synth-Low is lower indicating the reduced contrast dose.

## CONCLUSION

Quantitative and qualitative assessment has shown that DL based contrast dose reduction is feasible in breast MRI. Though shown using synthetic low-dose images, the DL model can be extended to real low-dose images thus significantly reducing the amount of contrast dose used in breast MRI procedures.

## CLINICAL RELEVANCE/APPLICATION

Enhancement patterns of DL-synthesized DCE images are similar to standard dose images and can be used for contrast dose reduction in breast MRI exams, reducing both patient and environmental exposure to GBCAs.

### W3-SSBR08-3 **Keynote Speaker: Why are We Still Giving Gadolinium on a Breast MR? Do We Have To?**

Rebecca Rakow-Penner, MD, PhD (*Presenter*) Research Grant, General Electric Company; Consultant, Human Longevity Inc; Stockholder, CureMetrix, Inc; Stock options, CorTechs Labs, Inc

### W3-SSBR08-4 **Contrast-Enhanced Breast Imaging: A Head-To-Head Comparison of CEM and MRI Regarding Lesion Conspicuity**

Ambra Santonocito, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Contrast-enhanced Magnetic Resonance Imaging (MRI) is considered the most sensitive method for detection of breast cancer. Contrast-enhanced mammography (CEM) relies on a similar principle, highlighting tissue vasculature which is pathologically altered by malignant transformation. Our study aims to compare lesion conspicuity in CEM against MRI in patients with suspicious breast lesions.

## METHODS AND MATERIALS

Two blinded readers retrospectively evaluated a sample of 463 suspicious findings in a population of 441 consecutive patients (mean age 68 +- 5.5) who underwent CEM and CE-MRI from October 2018 to September 2022, with an average time interval between CEM and MRI of 10 days. Each reader rated the qualitative lesion conspicuity on each image using a visual grading scale from 1 to 5, with 5 representing perfect conspicuity. Interoperator agreement was evaluated. Data were compared using Visual Grading Characteristics (VGC) analysis providing the area under the curve (AUC). A sub-analysis was also performed for malignant and benign lesions.

## RESULTS

Visual grading characteristics of lesion conspicuity scores found a statistically significant AUC of 0.692 (95%-CI 0.658-0.726,  $p < 0.001$ ) in favor of MRI. On MRI, 15.6% (R1) and 16.8% (R2) of the lesions showed no enhancement, while 26.6% (R1)

and 27.4% (R2) showed perfect conspicuity. On CEM, 41.9% (R1) and 47.5% (R2) of the lesions showed no enhancement, while 13.2% (R1) and 12.7% (R2) showed perfect conspicuity. Sub-analysis results also showed a statistically significant AUC of 0.688 (0.630-0.746 95%CI,  $p < 0.001$ ) for malignant lesions, as well as for benign lesions with an AUC of 0.763 (0.713-0.813 95%CI,  $p < 0.001$ ). Regarding the visibility of malignant lesions on MRI only 0.6% (R1) and 1.9% (R2) showed no enhancement; while 54.4% (R1) and 55% (R2) presented with perfect conspicuity. On CEM, 13.1% (R1) and 16.2% (R2) of the malignant lesions showed no enhancement, while 30% (R1) and 30.6% (R2) were assigned the maximum conspicuity category. For benign lesions, the highest category of lesion conspicuity was observed in 19.2% (R1) and 19.8% (R2) on MRI and in 7.3% (R1) and 5.6% (R2) on CEM. Benign lesions that demonstrated no enhancement on MRI were observed in 10.2% (R1) and 13% (R2) compared to 46.6% (R1) and 52.5% (R2) on CEM.

## CONCLUSION

Our results showed better visibility of lesions on MRI both for benign and malignant lesions compared to CEM. A significantly higher rate of low or not enhancing lesions has to be expected using CEM.

## CLINICAL RELEVANCE/APPLICATION

Although CEM offers similar diagnostic results on lesion enhancement compared to MRI, its sensitivity to detect enhancements is lower. The application of CEM in clinical practice needs specific training and a multimodal approach.

## W3-SSBR08-5 The Radiogenomic Model Based on Subregions of DCE-MRI Can Simultaneously Predict the Pathological Complete Response and Prognosis of Patients with Triple-Negative Breast Cancer

Xinyi Gao, MD (*Presenter*) Nothing to Disclose

### PURPOSE

TNBC is highly heterogeneous, different patients respond differently to neoadjuvant chemotherapy. We aim to use subregions to characterize spatial heterogeneity of tumors, develop radiogenomic models to accurately predict pathological complete response (pCR), and explore their potential value in predicting prognosis.

### METHODS AND MATERIALS

We collected baseline dynamic contrast material-enhanced magnetic resonance imaging (DCE-MRI), clinicopathological, and genomic data of patients with triple-negative breast cancer (TNBC) who received neoadjuvant chemotherapy from August 2011 to March 2022. The tumor was divided into multiple phenotypically consistent subregions based on four kinetic parameters at DCE-MRI. Radiomics features were extracted from subregions and peritumoral regions, and time domain features were extracted from tumor body. Logistic regression was used to construct three radiomics-only models and two models integrating clinicopathological and genomic features. Prognostic implications of the models were assessed by measuring disease-free survival (DFS) using KM survival curve and multivariable Cox regression.

### RESULTS

Finally, 315 patients had both radiomics and clinicopathological features were included in the study, of which 98 patients also had genomic features. The radiomics Model (Model 3) fused subregional, peritumoral and time domain features could well predict pCR with an AUC of 0.79. The predictive ability of the pathology-radiomics model (PRM) incorporating clinicopathological features was improved (AUC=0.88). The genomics-pathology-radiomics model (GPRM) constructed by further incorporating genomic features achieved the highest predictive ability (AUC=0.93). Model 3, PRM and GPRM had the ability to layer DFS ( $P = 0.034, 0.001$  and  $0.019$ , respectively).

## CONCLUSION

The subregional MRI-based radiomics-only and radiogenomic models provide markers of treatment and prognosis in TNBC. The radiogenomic model that integrate radiomics, clinicopathology, and genomic features is superior to other models.

## CLINICAL RELEVANCE/APPLICATION

The models can simultaneously predict efficacy and prognosis of TNBC, help to identify patients who may not achieve pCR, help clinicians make appropriate treatment and surgical decisions, and ultimately improve patients' prognosis.

## W3-SSBR08-6 Quantitative Parameters from Dual-Layer Spectral Detector CT for Differentiating Benign and Malignant Breast Lesions and Predicting Breast Cancer Biomarker Expression

Han Xia (*Presenter*) Nothing to Disclose

### PURPOSE

To evaluate the performance of quantitative parameters derived from dual-layer spectral detector CT (DLCT) for differentiating between benign and malignant breast lesions and predicting the level of immunohistochemical biomarker expression in breast cancer.

## **METHODS AND MATERIALS**

This study prospectively enrolled consecutive patients suspected of breast cancer who underwent preoperative dual-phase contrast-enhanced DLCT. Lesions were classified as benign or malignant, and the malignant lesions were further classified based on expression levels of immunohistochemical biomarkers. Mean and maximum value of CT attenuation of conventional CT-images and virtual non-contrast enhanced imaging (VNC), effective atomic number (Zeff) in arterial and venous phases were measured, the ratios of the values in breast lesions to the values in normal breast tissue and muscle were all calculated. The areas under the operating characteristic curve (AUC) were used to evaluate the performance. The correlations between DLCT parameters and immunohistochemical biomarkers of cancer were analyzed.

## **RESULTS**

127 patients with 144 breast lesions were finally included, of which 110 were malignant lesions. The univariable analysis showed significant differences in the ratios of mean IC and mean Zeff between breast cancer to normal breast tissues in venous phase (VR\_B\_NICMean and VR\_B\_NZefMean) and maximum CT attenuation at VNC (VNCmax) between malignant and benign lesions ( $p < 0.05$ ). ER-positive group and PR-positive group both showed lower VNCmax than ER-negative group and PR-negative group ( $p < 0.05$ , AUC of 0.63 and 0.649), VNCmax was negatively correlated with the value of ER and PR expression ( $r = -0.157 \sim -0.307$ ). There is no significant difference between HER2-positive and HER2-negative groups. For ki-67, the ratios of maximum Zeff and CT attenuation in venous phase between breast cancer to normal breast tissues demonstrated significant difference ( $P < 0.05$ ). Both of them were negatively correlated with the value of ki67 ( $r = -0.078 \sim -0.144$ ). In the multivariable analysis, the combination of VR\_B\_NICMean, VR\_B\_NZefMean and VNCmax can distinguish benign and malignant breast lesions, which had an AUC of 0.753, a sensitivity of 74.5%, a specificity of 67.6% and an accuracy of 72.9%.

## **CONCLUSION**

Quantitative parameters from DLCT is a feasible way of differentiating benign and malignant breast lesions and identifying the expression of immunohistochemical biomarkers of breast cancer.

## **CLINICAL RELEVANCE/APPLICATION**

It is essential to differentiate benign and malignant breast lesions and the expression of immunochemical biomarkers of breast cancer for breast management. DLCT can help in the assessment of appropriate therapy and prognosis prior to primary tumor biopsy.

### Contrast-Enhanced Mammography-Guided Biopsy for MRI-Detected Lesions: Feasibility and Factors Predicting Success

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S406A

Yuying Cao, BSC (*Presenter*) Nothing to Disclose

#### PURPOSE

This study assessed the utility of stereotactic contrast-enhanced mammography (CEM)-guided biopsy for MRI-detected lesions. Biopsy success rate was evaluated as well as factors that may predict success. Patient satisfaction and radiologist confidence level were also assessed.

#### METHODS AND MATERIALS

94 women (mean age 54.9 + 11.3 years) were enrolled in this prospective IRB-approved study, with 114 MRI-suspicious lesions BI-RADS 4A or greater for which CEM biopsy was attempted. Biopsy success was defined by enhancing lesion retrieval, biopsy clip position on post-procedure mammogram, and radiology-pathology correlation. Surveys were given to patients and clinicians. Success rate was evaluated with the Wilson score interval. Lesion characteristics {size, type [mass, focus, or non-mass enhancement (NME); distribution; internal enhancement pattern], patient breast density, MRI kinetics, MRI background parenchymal enhancement (BPE)} from successful and failed biopsies were compared using Wilcoxon rank-sum test (breast density, MRI BPE), two-sample t-test (lesion size), and Fisher's exact test (all others).

#### RESULTS

Of 114 MRI-detected breast lesions, 15 proved malignant. 69/114 (61%, 95% CI 51-69) successfully underwent CEM-guided biopsy, including 12 malignant lesions. Of the 45 failures, 41 (91.1%) were due to lack of enhancement on CEM, with no CEM biopsy attempted; 35/45 (77.8%) were then biopsied using MR guidance and 3 proved malignant. Successful CEM biopsy was more likely for larger lesions (mean = 21.5 + 25.3 mm vs 10.0 + 9.3 mm,  $P=0.004$ ). NME lesion type was associated with success ( $P=0.01$ ), comprising 46/69 (66.7%) successful biopsies and 19/45 (42.2%) failures. NMEs were further compared between successful and failed groups, and no association was found for distribution ( $P=0.2$ ); internal enhancement pattern (homogeneous vs heterogeneous vs clumped vs clustered ring) was of borderline significance ( $P=0.05$ ). No association was found between success and MRI kinetics ( $P=0.5$ ). No differences were found between successful and failed biopsies for breast density ( $P=0.3$ ) or BPE ( $P=0.6$ ). Patient satisfaction was rated 4.8/5 + 0.7. For enhancing lesions, radiologist confidence in biopsy success was rated 4.4/5 + 0.8.

#### CONCLUSION

CEM-guided biopsy for MRI-detected lesions had a 61% success rate. Larger lesion size and NME lesion type were associated with success. Patients were overall satisfied with the procedure, and radiologists were overall confident in success.

#### CLINICAL RELEVANCE/APPLICATION

Evaluation of success rate of CEM-guided biopsy for MRI-detected lesions along with factors associated with success may inform guidelines regarding CEM biopsy use, and elucidate which MRI lesions should undergo attempted CEM biopsy.

### Deep Learning Based Contrast Dose Reduction in Breast MRI Using Synthetic Low-dose Images

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S406A

Srivathsa P. Venkata, MSc (*Presenter*) Employee, Subtle Medical, Inc; Stockholder, Subtle Medical, Inc

#### PURPOSE

Gadolinium-based contrast agent (GBCA)-enhanced breast MRI is widely used for breast cancer screening and evaluating treatment response. Due to various safety concerns of GBCAs, including long-term tissue deposition, there is a need for dose reduction. In this work, we investigate the feasibility of a deep learning (DL) method for contrast dose reduction in dynamic contrast-enhanced (DCE) breast MRI, using synthesized low-dose images.

#### METHODS AND MATERIALS

Previously, a DL model was trained to synthesize full-dose CE brain MRI images from real pre-contrast and 10% low-dose images. This DL dose reduction model was repurposed to synthesize post-contrast breast MRI images (Synth-Gad) from real pre-contrast images and synthetic low-dose (Synth-Low) images (Fig 1A). The synthetic low-dose breast images were generated from pre- (Pre-Gad) post-contrast (Real-Gad) images, using a vision transformer that was trained with brain MRI data (Fig 1B) to perform arbitrary low-dose simulation. DCE breast MRI data from 60 patients (30 internal, 30 Duke Breast MRI public dataset) were used for evaluation. The CE images were normalized and co-registered to Pre-Gad, and the first time point post injection was used as Real-Gad. In order to simplify the intensity normalization process, axial images were manually cropped to remove signals posterior to the pectoral muscles. Left right sides were separated and processed individually by the DL model. Similarity metrics (PSNR SSIM) were calculated between Real-Gad and Synth-Gad images. Enhancement kinetic curves (time post injection vs signal intensity - SI) were drawn with Pre-Gad, Real-Gad and the other CE time points along with the average SI of Synth-Low and Synth-Gad images.

#### RESULTS

The mean PSNR SSIM between Real- Synth-Gad was ( $31.55 \pm 3.26$  dB  $0.85 \pm 0.07$ ). Qualitative examples shown in (Fig 1C) demonstrate that enhancement patterns in Synth-Gad images are similar to those present in Real-Gad images. The corresponding enhancement kinetic curves show that the SI of Real Synth-Gad images are similar and the SI of Synth-Low is lower indicating the reduced contrast dose.

#### CONCLUSION

Quantitative and qualitative assessment has shown that DL based contrast dose reduction is feasible in breast MRI. Though shown using synthetic low-dose images, the DL model can be extended to real low-dose images thus significantly reducing the amount of contrast dose used in breast MRI procedures.

#### CLINICAL RELEVANCE/APPLICATION

Enhancement patterns of DL-synthesized DCE images are similar to standard dose images and can be used for contrast dose reduction in breast MRI exams, reducing both patient and environmental exposure to GBCAs.

### Contrast-Enhanced Breast Imaging: A Head-To-Head Comparison of CEM and MRI Regarding Lesion Conspicuity

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S406A

Ambra Santonocito, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Contrast-enhanced Magnetic Resonance Imaging (MRI) is considered the most sensitive method for detection of breast cancer. Contrast-enhanced mammography (CEM) relies on a similar principle, highlighting tissue vasculature which is pathologically altered by malignant transformation. Our study aims to compare lesion conspicuity in CEM against MRI in patients with suspicious breast lesions.

#### METHODS AND MATERIALS

Two blinded readers retrospectively evaluated a sample of 463 suspicious findings in a population of 441 consecutive patients (mean age 68 +- 5.5) who underwent CEM and CE-MRI from October 2018 to September 2022, with an average time interval between CEM and MRI of 10 days. Each reader rated the qualitative lesion conspicuity on each image using a visual grading scale from 1 to 5, with 5 representing perfect conspicuity. Interoperator agreement was evaluated. Data were compared using Visual Grading Characteristics (VGC) analysis providing the area under the curve (AUC). A sub-analysis was also performed for malignant and benign lesions.

#### RESULTS

Visual grading characteristics of lesion conspicuity scores found a statistically significant AUC of 0.692 (95%-CI 0.658-0.726,  $p < 0.001$ ) in favor of MRI. On MRI, 15.6% (R1) and 16.8% (R2) of the lesions showed no enhancement, while 26.6% (R1) and 27.4% (R2) showed perfect conspicuity. On CEM, 41.9% (R1) and 47.5% (R2) of the lesions showed no enhancement, while 13.2% (R1) and 12.7% (R2) showed perfect conspicuity. Sub-analysis results also showed a statistically significant AUC of 0.688 (0.630-0.746 95%CI,  $p < 0.001$ ) for malignant lesions, as well as for benign lesions with an AUC of 0.763 (0.713-0.813 95%CI,  $p < 0.001$ ). Regarding the visibility of malignant lesions on MRI only 0.6% (R1) and 1.9% (R2) showed no enhancement; while 54.4% (R1) and 55% (R2) presented with perfect conspicuity. On CEM, 13.1% (R1) and 16.2% (R2) of the malignant lesions showed no enhancement, while 30% (R1) and 30.6% (R2) were assigned the maximum conspicuity category. For benign lesions, the highest category of lesion conspicuity was observed in 19.2% (R1) and 19.8% (R2) on MRI and in 7.3% (R1) and 5.6% (R2) on CEM. Benign lesions that demonstrated no enhancement on MRI were observed in 10.2% (R1) and 13% (R2) compared to 46.6% (R1) and 52.5% (R2) on CEM.

#### CONCLUSION

Our results showed better visibility of lesions on MRI both for benign and malignant lesions compared to CEM. A significantly higher rate of low or not enhancing lesions has to be expected using CEM.

#### CLINICAL RELEVANCE/APPLICATION

Although CEM offers similar diagnostic results on lesion enhancement compared to MRI, its sensitivity to detect enhancements is lower. The application of CEM in clinical practice needs specific training and a multimodal approach.

### The Radiogenomic Model Based on Subregions of DCE-MRI Can Simultaneously Predict the Pathological Complete Response and Prognosis of Patients with Triple-Negative Breast Cancer

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S406A

Xinyi Gao, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

TNBC is highly heterogeneous, different patients respond differently to neoadjuvant chemotherapy. We aim to use subregions to characterize spatial heterogeneity of tumors, develop radiogenomic models to accurately predict pathological complete response (pCR), and explore their potential value in predicting prognosis.

#### METHODS AND MATERIALS

We collected baseline dynamic contrast material-enhanced magnetic resonance imaging (DCE-MRI), clinicopathological, and genomic data of patients with triple-negative breast cancer (TNBC) who received neoadjuvant chemotherapy from August 2011 to March 2022. The tumor was divided into multiple phenotypically consistent subregions based on four kinetic parameters at DCE-MRI. Radiomics features were extracted from subregions and peritumoral regions, and time domain features were extracted from tumor body. Logistic regression was used to construct three radiomics-only models and two models integrating clinicopathological and genomic features. Prognostic implications of the models were assessed by measuring disease-free survival (DFS) using KM survival curve and multivariable Cox regression.

#### RESULTS

Finally, 315 patients had both radiomics and clinicopathological features were included in the study, of which 98 patients also had genomic features. The radiomics Model (Model 3) fused subregional, peritumoral and time domain features could well predict pCR with an AUC of 0.79. The predictive ability of the pathology-radiomics model (PRM) incorporating clinicopathological features was improved (AUC=0.88). The genomics-pathology-radiomics model (GPRM) constructed by further incorporating genomic features achieved the highest predictive ability (AUC=0.93). Model 3, PRM and GPRM had the ability to layer DFS ( $P = 0.034, 0.001$  and  $0.019$ , respectively).

#### CONCLUSION

The subregional MRI-based radiomics-only and radiogenomic models provide markers of treatment and prognosis in TNBC. The radiogenomic model that integrate radiomics, clinicopathology, and genomic features is superior to other models.

#### CLINICAL RELEVANCE/APPLICATION

The models can simultaneously predict efficacy and prognosis of TNBC, help to identify patients who may not achieve pCR, help clinicians make appropriate treatment and surgical decisions, and ultimately improve patients' prognosis.

### Quantitative Parameters from Dual-Layer Spectral Detector CT for Differentiating Benign and Malignant Breast Lesions and Predicting Breast Cancer Biomarker Expression

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S406A

Han Xia (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the performance of quantitative parameters derived from dual-layer spectral detector CT (DLCT) for differentiating between benign and malignant breast lesions and predicting the level of immunohistochemical biomarker expression in breast cancer.

#### METHODS AND MATERIALS

This study prospectively enrolled consecutive patients suspected of breast cancer who underwent preoperative dual-phase contrast-enhanced DLCT. Lesions were classified as benign or malignant, and the malignant lesions were further classified based on expression levels of immunohistochemical biomarkers. Mean and maximum value of CT attenuation of conventional CT-images and virtual non-contrast enhanced imaging (VNC), effective atomic number (Zeff) in arterial and venous phases were measured, the ratios of the values in breast lesions to the values in normal breast tissue and muscle were all calculated. The areas under the operating characteristic curve (AUC) were used to evaluate the performance. The correlations between DLCT parameters and immunohistochemical biomarkers of cancer were analyzed.

#### RESULTS

127 patients with 144 breast lesions were finally included, of which 110 were malignant lesions. The univariable analysis showed significant differences in the ratios of mean IC and mean Zeff between breast cancer to normal breast tissues in venous phase (VR\_B\_NICMean and VR\_B\_NZefMean) and maximum CT attenuation at VNC (VNCmax) between malignant and benign lesions ( $p < 0.05$ ). ER-positive group and PR-positive group both showed lower VNCmax than ER-negative group and PR-negative group ( $p < 0.05$ , AUC of 0.63 and 0.649), VNCmax was negatively correlated with the value of ER and PR expression ( $r = -0.157 \sim -0.307$ ). There is no significant difference between HER2-positive and HER2-negative groups. For ki-67, the ratios of maximum Zeff and CT attenuation in venous phase between breast cancer to normal breast tissues demonstrated significant difference ( $P < 0.05$ ). Both of them were negatively correlated with the value of ki67 ( $r = -0.078 \sim -0.144$ ). In the multivariable analysis, the combination of VR\_B\_NICMean, VR\_B\_NZefMean and VNCmax can distinguish benign and malignant breast lesions, which had an AUC of 0.753, a sensitivity of 74.5%, a specificity of 67.6% and an accuracy of 72.9%.

#### CONCLUSION

Quantitative parameters from DLCT is a feasible way of differentiating benign and malignant breast lesions and identifying the expression of immunohistochemical biomarkers of breast cancer.

#### CLINICAL RELEVANCE/APPLICATION

It is essential to differentiate benign and malignant breast lesions and the expression of immunochemical biomarkers of breast cancer for breast management. DLCT can help in the assessment of appropriate therapy and prognosis prior to primary tumor biopsy.

Prabhakar Rajiah, MD, FRCR (*Presenter*) Nothing to Disclose

##### W3-SSCA07-2 **Head-to-Head Comparison of On-Site Computed Tomography-Derived Fractional Flow Reserve using Different Algorithms: Preliminary Results**

Jing Luo (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare the diagnostic results of on-site computed tomography-derived fractional flow reserve (CT-FFR) using different algorithms.

#### METHODS AND MATERIALS

This retrospective study included 124 consecutive patients with CAG-confirmed severe stenosis (stenosis =70%) in at least one vessel. The same set of coronary CT angiography raw images of the patients were simultaneously sent to a 3D computational flow dynamics (CFD)-based CT-FFR(M-software) and a reduced-order CFD-based CT-FFR(K-software) on-site servers for analysis and comparison. CT-FFR measurements included lesion-specific CT-FFR (measurement location was at 2 cm distal to the stenosis), vessel-specific CT-FFR (measurement location was at the distal-most vessel with diameter of 2 mm) and ?CT-FFR (difference between proximal and distal CT-FFR of the lesion).

#### RESULTS

More coronary arteries processing failed in 3D-CFD model than in reduced-order CFD model (18 vs. 6,  $P=0.012$ ). The most of lesion-specific CT-FFR, vessel-specific CT-FFR and ?CT-FFR values of LAD, LCX and RCA based on reduced-order CFD model were higher than those based on 3D-CFD model (all  $p < 0.05$ ). On Spearman correlation analysis, the degree of stenosis and plaque characteristics identified by two software were significantly correlated (all  $p < 0.001$ ). CT-FFR values based on 3D-CFD model showed a tendency to correlate more closely with the plaque characteristics than reduced-order CFD model. The lesion-specific CT-FFR values based on 3D-CFD model were significantly correlated with calcification score (all  $p < 0.001$ ), but vessel-specific CT-FFR values did not correlate with calcification score. On Bland-Altman analysis, the mean difference (95% limits of agreement) of lesion-specific CT-FFR between two software in LAD, LCX and RCA is 0.02(-0.03-0.08), 0.09(0.01-0.18), 0.14(0.07-0.21), respectively. The mean difference (95% limits of agreement) of vessel-specific CT-FFR between two software in LAD, LCX and RCA is 0.07(0.01-0.12), 0.00(-0.04-0.05), 0.11(0.05-0.17), respectively.

#### CONCLUSION

The results of CT-FFR measured by different algorithms were significantly different, and CT-FFR based on reduced-order CFD model showed a tendency to higher values than 3D-CFD model.

#### CLINICAL RELEVANCE/APPLICATION

This study found that the use of different algorithms can affect the results of CT-FFR, suggesting that the influence of algorithms should be considered when using CT-FFR software. Further prospective studies with catheter-based FFR comparisons are needed in future.

##### W3-SSCA07-3 **Feasibility of Coronary CT Angiography-based Fractional Flow Reserve Using a Clinical Photon-Counting Detector CT System**

Zsarnoczay, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Coronary CT angiography (CCTA)-based fractional flow reserve (CT-FFR) allows the noninvasive determination of the functional severity of anatomic lesions in patients with coronary artery disease. The aim of this study was to intra-individually compare CT-FFR between photon-counting detector (PCD) and conventional energy-integrating detector (EID) CT systems.

## METHODS AND MATERIALS

In this single-center prospective study, adults who underwent CCTA on an EID-CT system were recruited for research PCD-CT scans between July 2021 to March 2022. EID-CT images were reconstructed with Bv36 kernel, iterative reconstruction strength level 3, and at 0.5 mm slice thickness. PCD-CT images were post-processed with settings matched to EID-CT as close as possible using a Bv36 kernel, quantum iterative reconstruction level 3, at a virtual monoenergetic level 55 keV and 0.6 mm slice thickness. CT-FFR was obtained semi-automatically using a prototype on-site machine learning algorithm by two readers. The lowest CT-FFR value was used for the per-patient analysis and a CT-FFR =0.75 was considered hemodynamically significant. Correlation and reliability between CT-FFREID-CT and CT-FFRPCD-CT were assessed with Spearman ( $r$ ) and intraclass correlation coefficients (ICC).

## RESULTS

A total of 23 patients (63 years  $\pm$  10; 7 women) were included. The median time between EID-CT and PCD-CT was 6 days (IQR, 3 - 11 days). Comparison of CT-FFREID-CT vs. CT-FFRPCD-CT showed no significant difference and strong agreement in the per-vessel analysis (CT-FFREID-CT: 0.87 [0.71-0.94] vs. CT-FFRPCD-CT: 0.87 [0.76-0.93],  $p$  = 0.119, mean bias 0.02, limits of agreement (LoA) -0.15/0.19,  $r$  = 0.85, ICC = 0.93) and in the per-patient analysis (CT-FFREID-CT: 0.80 [0.61-0.85] vs. CT-FFRPCD-CT: 0.76 [0.65-0.85],  $p$  = 0.520, mean bias 0.02, LoA -0.15/0.20,  $r$  = 0.89, ICC = 0.93). CT-FFR =0.75 was observed in 10 patients with EID-CT and 9 patients with PCD-CT.

## CONCLUSION

PCD-CT-based CT-FFR evaluation is feasible and correlates well with EID-CT-based CT-FFR.

## CLINICAL RELEVANCE/APPLICATION

CCTA-based CT-FFR using PCD-CT is a feasible option, yielding results comparable to those of EID-CT when applying similar reconstruction techniques.

## W3-SSCA07-4 Coronary Artery Calcium Scoring on Photon-Counting Detector CT: Towards a New Standard 2.0

Nicola Fink, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Coronary artery calcium (CAC) scoring using the Agatston score is a well-established method for calcium quantification and cardiovascular risk assessment. However, this method is known to have suboptimal rescan reproducibility. For energy-integrating detector (EID)-CT, a new, multivendor validated protocol has already been proposed. The present study aimed to investigate the score variability of photon-counting detector (PCD)-CT-based CAC scoring and to propose a new protocol with less radiation dose and improved score reproducibility. The performance of this new proposed PCD-CT protocol was compared to the previously proposed multivendor EID-CT protocol.

## METHODS AND MATERIALS

An anthropomorphic phantom simulating three chest diameters and containing nine calcifications was scanned on a clinical PCD-CT. Scans were performed using routine protocols as well as different tube voltages (90 and 120 kVp), tube currents (four radiation dose levels from 100 to 25%), slice thicknesses (3 and 1 mm) and quantum iterative reconstructions (QIR, strength 1-4). To evaluate interscan variability, each phantom was scanned five times per protocol with slight movements between the scans. The standard PCD-CT protocol was defined as using 120kVp, 100% dose and 3mm slice thickness. Agatston scores, the number of detected calcifications and image noise were assessed. All results using the proposed PCD-CT protocol were compared to corresponding values from the standard PCD-CT and the previously proposed EID-CT protocols.

## RESULTS

Compared to the standard PCD-CT protocol, score variability decreased by 20.2% when using a thin-sliced protocol at 120kVp with 25% dose reduction, and even by 37.2% when additionally using QIR2. Comparing this new PCD-CT protocol with the proposed EID-CT protocol, showed 66.1% lower score variability. The proposed PCD-CT protocol also met the recommended noise target and did not exceed the upper threshold for increased possibility of false-positives. While  $6.0 \pm 0.0$  and  $7.0 \pm 0.4$  calcifications were detected using the PCD-CT standard and the proposed EID-CT protocol, respectively,  $7.1 \pm 0.7$  calcifications were detected when using the proposed PCD-CT protocol at QIR2. Agatston scores from the proposed PCD-CT protocol were comparable to those using the standard PCD-CT and the proposed EID-CT protocol for every phantom size ( $p > 0.05$ ).

## CONCLUSION

Score variability and calcification detectability in PCD-CT-based CAC scoring can be improved using a thin-slice, 25%-reduced dose protocol at 120kVp.

## CLINICAL RELEVANCE/APPLICATION

This proposed PCD-CT protocol has the potential to allow reproducible CAC quantification in clinical practice at lower radiation dose and seems to perform better than the proposed, multivendor EID-CT protocol.

## W3-SSCA07-5 Parametric Image Generation from the Static Computed Tomography Perfusion with Convolutional Neural Network

Jun Dong (*Presenter*) Nothing to Disclose

## PURPOSE

To explore the accessibility of a dynamic parametric image, the myocardial blood flow (MBF), with the static myocardial computed tomography perfusion (CTP) image so as to circumvent the conventional dynamic input function in order to substantially decrease the requisite radiation exposure.

## METHODS AND MATERIALS

This retrospective study was approved by the hospital's Ethics Committee. 183 subjects with intermediate-to-high pretest probabilities of obstructive coronary artery disease (CAD) were enrolled. All subjects were screened with the dynamic myocardial CTP examination and the MBF was derived correspondingly. A convolutional neural network (CNN) was applied to convert the input simulated static CTP into MBF. Pretraining was applied to boost the model performance. For the evaluation of output MBF, different criteria like the structural similarity index measure (SSIM), peak signal-to-noise ratio (PSNR) and root mean square error (RMSE) were utilized to estimate the image quality, clinical functional assessments were also applied to the output MBF to distinguish the ischemia myocardium segments. The consistency and correlation between the output and the real MBF were also analyzed.

## RESULTS

The output MBF was highly close to the referenced MBF. The overall average SSIM, between the synthetic MBF and the target reached 0.91. According to a receiver operating curve (ROC) analysis of ischemic segments, the synthetic MBF had an area under the curve (AUC) of 0.938, showing excellent functionality. Overall, the testing results illustrated adequate consistency and correlation.

## CONCLUSION

The quality of the output parametric image is acceptable and the clinical functionality of the output MBF is satisfactory. However, since the static CTP used in this study is obtained via simulation, validation of the dose reduction reliability and the actual clinical applications still need further investigation.

## CLINICAL RELEVANCE/APPLICATION

The output parametric image is satisfactory in clinical functionality therefore it has the potential of reducing the radiation dose.

### Coronary Artery Calcium Scoring on Photon-Counting Detector CT: Towards a New Standard 2.0

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E352

Nicola Fink, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Coronary artery calcium (CAC) scoring using the Agatston score is a well-established method for calcium quantification and cardiovascular risk assessment. However, this method is known to have suboptimal rescan reproducibility. For energy-integrating detector (EID)-CT, a new, multivendor validated protocol has already been proposed. The present study aimed to investigate the score variability of photon-counting detector (PCD)-CT-based CAC scoring and to propose a new protocol with less radiation dose and improved score reproducibility. The performance of this new proposed PCD-CT protocol was compared to the previously proposed multivendor EID-CT protocol.

#### METHODS AND MATERIALS

An anthropomorphic phantom simulating three chest diameters and containing nine calcifications was scanned on a clinical PCD-CT. Scans were performed using routine protocols as well as different tube voltages (90 and 120 kVp), tube currents (four radiation dose levels from 100 to 25%), slice thicknesses (3 and 1 mm) and quantum iterative reconstructions (QIR, strength 1-4). To evaluate interscan variability, each phantom was scanned five times per protocol with slight movements between the scans. The standard PCD-CT protocol was defined as using 120kVp, 100% dose and 3mm slice thickness. Agatston scores, the number of detected calcifications and image noise were assessed. All results using the proposed PCD-CT protocol were compared to corresponding values from the standard PCD-CT and the previously proposed EID-CT protocols.

#### RESULTS

Compared to the standard PCD-CT protocol, score variability decreased by 20.2% when using a thin-sliced protocol at 120kVp with 25% dose reduction, and even by 37.2% when additionally using QIR2. Comparing this new PCD-CT protocol with the proposed EID-CT protocol, showed 66.1% lower score variability. The proposed PCD-CT protocol also met the recommended noise target and did not exceed the upper threshold for increased possibility of false-positives. While  $6.0 \pm 0.0$  and  $7.0 \pm 0.4$  calcifications were detected using the PCD-CT standard and the proposed EID-CT protocol, respectively,  $7.1 \pm 0.7$  calcifications were detected when using the proposed PCD-CT protocol at QIR2. Agatston scores from the proposed PCD-CT protocol were comparable to those using the standard PCD-CT and the proposed EID-CT protocol for every phantom size ( $p > 0.05$ ).

#### CONCLUSION

Score variability and calcification detectability in PCD-CT-based CAC scoring can be improved using a thin-slice, 25%-reduced dose protocol at 120kVp.

#### CLINICAL RELEVANCE/APPLICATION

This proposed PCD-CT protocol has the potential to allow reproducible CAC quantification in clinical practice at lower radiation dose and seems to perform better than the proposed, multivendor EID-CT protocol.

### Parametric Image Generation from the Static Computed Tomography Perfusion with Convolutional Neural Network

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E352

Jun Dong (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the accessibility of a dynamic parametric image, the myocardial blood flow (MBF), with the static myocardial computed tomography perfusion (CTP) image so as to circumvent the conventional dynamic input function in order to substantially decrease the requisite radiation exposure.

#### METHODS AND MATERIALS

This retrospective study was approved by the hospital's Ethics Committee. 183 subjects with intermediate-to-high pretest probabilities of obstructive coronary artery disease (CAD) were enrolled. All subjects were screened with the dynamic myocardial CTP examination and the MBF was derived correspondingly. A convolutional neural network (CNN) was applied to convert the input simulated static CTP into MBF. Pretraining was applied to boost the model performance. For the evaluation of output MBF, different criteria like the structural similarity index measure (SSIM), peak signal-to-noise ratio (PSNR) and root mean square error (RMSE) were utilised to estimate the image quality, clinical functional assessments were also applied to the output MBF to distinguish the ischemia myocardium segments. The consistency and correlation between the output and the real MBF were also analyzed.

#### RESULTS

The output MBF was highly close to the referenced MBF. The overall average SSIM, between the synthetic MBF and the target reached 0.91. According to a receiver operating curve (ROC) analysis of ischemic segments, the synthetic MBF had an area under the curve (AUC) of 0.938, showing excellent functionality. Overall, the testing results illustrated adequate consistency and correlation.

#### CONCLUSION

The quality of the output parametric image is acceptable and the clinical functionality of the output MBF is satisfactory. However, since the static CTP used in this study is obtained via simulation, validation of the dose reduction reliability and the actual clinical applications still need further investigation.

#### CLINICAL RELEVANCE/APPLICATION

The output parametric image is satisfactory in clinical functionality therefore it has the potential of reducing the radiation dose.

#### **W3-SSCH07-1 Artificial Intelligence-based Automated Matching of Pulmonary Nodules on Follow-up Chest CT**

Matthias P. Fabritius, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The follow-up of pulmonary nodules, including matching and measuring identical pulmonary nodules on serial computed tomography (CT) scans can be tedious and time-consuming. This study aimed to assess the performance of an artificial intelligence (AI)-based system for automated matching of nodules in serial CT scans of the chest.

#### METHODS AND MATERIALS

In this study, 100 patients (62 [57-69] years; 46% female) with pulmonary nodules and at least two successive chest CT scans (total CT scans included: n=253) were included. Regardless of whether the included patients received two or three CT scans, each follow-up was evaluated separately, resulting in 153 follow-up examinations. All data sets were analyzed using a cloud-based AI-based algorithm prototype for automated nodule matching. The matching rate and the root causes for incorrect matching (false-positive detection; missed matching; incorrect assignment) were evaluated in the ten largest lesions (5-30mm) registered on baseline CT. In addition, the dependence of the matching rate on nodule number and localization (parenchymal; peripheral; juxtavascular; juxtaphrenic) was analyzed.

#### RESULTS

By focusing on the ten largest lesions registered in baseline CT, 1,141 lesions were identified, of which 964 (84.5%) were correctly detected and matched. When considering only nodules registered in both scans, correct matching rate was 97.8%. The median per case matching rate was 90.0% (80.0-100.0%). While the correct matching rate was similar in follow-ups with less than 20 and 20-50 nodules (100.0% [80.0-100.0%] vs. 90.0% [80.0-100.0%]; p=0.37), it was significantly lower in follow-ups with more than 50 nodules (80.0% [65.0-90.0%]; p<0.05) with an overrepresentation of missed nodule matching. Furthermore, the matching rate was significantly higher in parenchymal, peripheral, and juxtavascular than in juxtaphrenic nodules (91.8% vs. 84.4% vs. 82.4% vs. 71.1%; p<0.001). Missed matching was overrepresented in juxtavascular and incorrect assignment of two non-identical nodules in juxtaphrenic nodules.

#### CONCLUSION

The correct automated matching rate of metastatic pulmonary nodules in follow-up examinations was high but depends on localization and number of nodules.

#### CLINICAL RELEVANCE/APPLICATION

The algorithm enables precise nodule matching, thus provides a good basis for standardized assessment. Knowing strengths and weaknesses depending on nodule number and localization allows an accurate interpretation of AI results.

#### **W3-SSCH07-4 Clinical and Radiologic Predictors of Unresectability in Malignant Pleural Mesothelioma**

Maria Mayoral Penalva, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

The current clinical staging of malignant pleural mesothelioma (MPM) is often discordant with the pathologic staging, particularly the T-component. The International Association for the Study of Lung Cancer (IASLC) Mesothelioma Staging Project developed a simple methodology to take reproducible measurements of pleural thickness (PT) and provide precise prognosis. Surgical procedures are complex and potentially morbid. Accurate evaluation of preoperative imaging with the inclusion of PT measurements may provide valuable information when assessing the surgical risk. We aimed to determine the utility of clinical and radiologic features to predict unresectability in MPM.

## METHODS AND MATERIALS

Twenty-two descriptive radiologic features were retrospectively evaluated on preoperative CT and/or PET/CT scans for patients who were thought to be resectable and taken to the operation room for attempted resection. The maximum and sum PT measurements at three levels of the thorax (upper-, middle- and lower-levels) were obtained according to the IASLC methodology. Clinical and radiologic features, including clinical stage, were compared between resectable and unresectable tumors by univariate analysis and logistic regression models.

## RESULTS

Of 133 patients, 69 (52%) had resectable and 64 (48%) unresectable MPM. Differences among groups regarding asbestos exposure ( $p=0.005$ ), neoadjuvant treatment ( $p=0.001$ ), clinical T-stage ( $p<0.0001$ ), all PT measurements ( $p<0.05$ ), PT pattern ( $p<0.0001$ ) and degree ( $p=0.033$ ), extrapleural space obliteration ( $p<0.0001$ ), extension to subphrenic space ( $p<0.0004$ ), and a combination of variables that represented extensive diaphragmatic contact or chest wall involvement ( $p=0.002$ ) and/or mediastinal invasion ( $p<0.0001$ ) were found to be statistically significant. In the multivariate analysis, the model that included neoadjuvant chemotherapy, degree of pleural thickening (encasement vs discontinuous), upper-level maximum PT, extrapleural fat obliteration and a combination of variables that represented mediastinal infiltration obtained the highest diagnostic performance (AUC 0.876). The feature that added the most value to this model was extrapleural space obliteration (OR 5.33; 95% CI, 1.97 - 14.45;  $p=0.001$ ). Another model that integrated clinical and radiologic variables through clinical T-stage assessment also obtained a very strong diagnostic performance (AUC 0.879).

## CONCLUSION

Selected clinical and radiologic features appear to be strong predictors of unresectability in MPM.

## CLINICAL RELEVANCE/APPLICATION

A more accurate prediction of unresectability in the preoperative assessment of patients with MPM may avoid unnecessary surgery and prompt initiation of nonsurgical treatments.

## W3-SSCH07-6 Time to Lung Cancer Surgery and Factors Associated with Delayed Surgery in a Lung Cancer Screening Program

Raquelle H. El Alam, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Patient pathways from suspicious imaging until surgical treatment for lung cancer vary and in some instances cause considerable delay. The aim of this study was to identify factors associated with this delay.

## METHODS AND MATERIALS

: In this study, we evaluated patients in the Lung Cancer Screening (LCS) program across a large tertiary healthcare network from 5/2015 through 10/2021 who underwent surgical resection for a malignant lung nodule. The analysis was performed on patients with Lung-RADS 4B/4X which should be considered for biopsy or surgery rather than follow-up imaging. We evaluated the relationship between lung cancer surgical delay and several factors including Lung-RADS category (4B versus 4X), site of surgery (2 academic sites and 1 community site), smoking status (current versus former smoker), median income by zip code, initial biopsy finding (benign/nondiagnostic versus malignant), patient's language (English versus non-English speaking), patient's race (White versus non-White), and patient's age. A cut-off of more than 60 days between screening CT and surgery was considered as delay.

## RESULTS

During the study period, a total of 21366 LCS CTs were performed in 9050 patients, and 267 pathologically-proven lung cancers were identified. Of these, 227 went to surgical treatment, and 150 of these patients were Lung-RADS 4B/4X, with 59 Lung-RADS 4B and 91 Lung-RADS 4X. Time from LCS CT to surgery ranged from 8 to 585 days with a median of 52 days, and interquartile range of 36-75 days. 60 of 150 experienced delay to surgery of > 60 days. A statistically significant difference between surgical delay and 2 academic sites was observed ( $p=.045$ ) with 14 (29 %) out of 48 experiencing delays in academic site 1 versus 42 (48 %) out of 88 in academic site 2; delays occurred in 4 (29 %) out of 14 in community site. In addition, patients from zip codes with higher median income were less likely to experience delays, with odds ratio for delay 0.88 per \$10,000 ( $p=.02$ ). There was no statistically significant difference in delays by smoking status (current smoker versus former smoker,  $p=.09$ ), Lung-RADS category ( Lung-RADS-4B versus Lung-RADS 4X,  $p=.38$ ), biopsy result (initially

benign or nondiagnostic biopsy versus cancer,  $p=.5$ ), language (English versus non-English speaking,  $p=.15$ ), race (white versus non-white,  $p=.31$ ), and age ( $p=.27$ ).

#### **CONCLUSION**

Patients in a lung cancer screening frequently experience long intervals between a suspicious finding and surgery. Delays were associated with site of care and median income by zip code.

#### **CLINICAL RELEVANCE/APPLICATION**

Surgical delays for lung cancer may exacerbate disparities in care, particularly among patients from low-income areas.

### Artificial Intelligence-based Automated Matching of Pulmonary Nodules on Follow-up Chest CT

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S404

Matthias P. Fabritius, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The follow-up of pulmonary nodules, including matching and measuring identical pulmonary nodules on serial computed tomography (CT) scans can be tedious and time-consuming. This study aimed to assess the performance of an artificial intelligence (AI)-based system for automated matching of nodules in serial CT scans of the chest.

#### METHODS AND MATERIALS

In this study, 100 patients (62 [57-69] years; 46% female) with pulmonary nodules and at least two successive chest CT scans (total CT scans included: n=253) were included. Regardless of whether the included patients received two or three CT scans, each follow-up was evaluated separately, resulting in 153 follow-up examinations. All data sets were analyzed using a cloud-based AI-based algorithm prototype for automated nodule matching. The matching rate and the root causes for incorrect matching (false-positive detection; missed matching; incorrect assignment) were evaluated in the ten largest lesions (5-30mm) registered on baseline CT. In addition, the dependence of the matching rate on nodule number and localization (parenchymal; peripheral; juxtavascular; juxtaphrenic) was analyzed.

#### RESULTS

By focusing on the ten largest lesions registered in baseline CT, 1,141 lesions were identified, of which 964 (84.5%) were correctly detected and matched. When considering only nodules registered in both scans, correct matching rate was 97.8%. The median per case matching rate was 90.0% (80.0-100.0%). While the correct matching rate was similar in follow-ups with less than 20 and 20-50 nodules (100.0% [80.0-100.0%] vs. 90.0% [80.0-100.0%]; p=0.37), it was significantly lower in follow-ups with more than 50 nodules (80.0% [65.0-90.0%]; p<0.05) with an overrepresentation of missed nodule matching. Furthermore, the matching rate was significantly higher in parenchymal, peripheral, and juxtavascular than in juxtaphrenic nodules (91.8% vs. 84.4% vs. 82.4% vs. 71.1%; p<0.001). Missed matching was overrepresented in juxtavascular and incorrect assignment of two non-identical nodules in juxtaphrenic nodules.

#### CONCLUSION

The correct automated matching rate of metastatic pulmonary nodules in follow-up examinations was high but depends on localization and number of nodules.

#### CLINICAL RELEVANCE/APPLICATION

The algorithm enables precise nodule matching, thus provides a good basis for standardized assessment. Knowing strengths and weaknesses depending on nodule number and localization allows an accurate interpretation of AI results.

### Time to Lung Cancer Surgery and Factors Associated with Delayed Surgery in a Lung Cancer Screening Program

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S404

Raquelle H. El Alam, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Patient pathways from suspicious imaging until surgical treatment for lung cancer vary and in some instances cause considerable delay. The aim of this study was to identify factors associated with this delay.

#### METHODS AND MATERIALS

: In this study, we evaluated patients in the Lung Cancer Screening (LCS) program across a large tertiary healthcare network from 5/2015 through 10/2021 who underwent surgical resection for a malignant lung nodule. The analysis was performed on patients with Lung-RADS 4B/4X which should be considered for biopsy or surgery rather than follow-up imaging. We evaluated the relationship between lung cancer surgical delay and several factors including Lung-Rads category (4B versus 4X), site of surgery (2 academic sites and 1 community site), smoking status (current versus former smoker), median income by zip code, initial biopsy finding (benign/nondiagnostic versus malignant), patient's language (English versus non-English speaking), patient's race (White versus non-White), and patient's age. A cut-off of more than 60 days between screening CT and surgery was considered as delay.

#### RESULTS

During the study period, a total of 21366 LCS CTs were performed in 9050 patients, and 267 pathologically-proven lung cancers were identified. Of these, 227 went to surgical treatment, and 150 of these patients were Lung-RADS 4B/4X, with 59 Lung-RADS 4B and 91 Lung-RADS 4X. Time from LCS CT to surgery ranged from 8 to 585 days with a median of 52 days, and interquartile range of 36-75 days. 60 of 150 experienced delay to surgery of > 60 days. A statistically significant difference between surgical delay and 2 academic sites was observed ( $p=.045$ ) with 14 (29 %) out of 48 experiencing delays in academic site 1 versus 42 (48 %) out of 88 in academic site 2; delays occurred in 4 (29 %) out of 14 in community site. In addition, patients from zip codes with higher median income were less likely to experience delays, with odds ratio for delay 0.88 per \$10,000 ( $p=.02$ ). There was no statistically significant difference in delays by smoking status (current smoker versus former smoker,  $p=.09$ ), Lung-RADS category ( Lung-RADS-4B versus Lung-RADS 4X,  $p=.38$ ), biopsy result (initially benign or nondiagnostic biopsy versus cancer,  $p=.5$ ), language (English versus non-English speaking,  $p=.15$ ), race (white versus non-white,  $p=.31$  ), and age ( $p= .27$ ).

#### CONCLUSION

Patients in a lung cancer screening frequently experience long intervals between a suspicious finding and surgery. Delays were associated with site of care and median income by zip code.

#### CLINICAL RELEVANCE/APPLICATION

Surgical delays for lung cancer may exacerbate disparities in care, particularly among patients from low-income areas.

### W3-SSER02-1 Multi-Parameter Spectral CT Enhanced Imaging for Differential Diagnosis of Portal Vein Thrombosis and Malignant Thrombosis

Zhihao Wang (*Presenter*) Nothing to Disclose

#### PURPOSE

This study is to investigate the differential diagnostic performance of spectral-based image-enhanced imaging for portal vein thrombosis (PVT) and malignant thrombus (MT), with the aim of enhancing the clinical efficiency of differential diagnosis between the PVT and MT.

#### METHODS AND MATERIALS

This retrospective study included 100 patients with portal vein thrombosis who underwent spectral CT imaging from February 2023 to April 2023. According to clinical data and pathological diagnosis, 52cases of portal vein thrombosis and 48 cases of malignant thrombosis were enrolled. Using post-processing software, conventional CT images (CI), iodine density maps (ID), effective atomic number maps (Z-eff), and spectral curves were reconstructed from the spectral data. Regions of interest (ROIs) were drawn at the site of occlusion, and CT values (CIHU), iodine density values (ID), effective atomic numbers (Z-eff), and spectral curve slopes were measured (?HU). Independent sample t-tests were used to analyze the differences between parameters. A single-factor logistic regression was used to evaluate the predictive probability of spectral multi-parameters for portal vein thrombosis and tumor thrombus, and a spectral multi-parameter combined model was established. Receiver operating characteristic (ROC) curves were plotted, and the area under the curve (AUC) and cutoff value were calculated to compare the diagnostic efficacy of various spectral parameters in differentiating portal vein thrombosis and tumor thrombus.

#### RESULTS

Compared to CT values (AUC 0.92, cutoff value 142.5, sensitivity 86%, specificity 93%), ID values (AUC 0.965, cutoff value 3.24, sensitivity 92%, specificity 96.5%), Z-eff values (AUC 0.952, cutoff 12.05 , sensitivity 90%, specificity 96.2%), and ? HU values (AUC 0.962, sensitivity 96%, specificity 95%), the multi-parameter spectral combined model (AUC 0.97, sensitivity 94%, specificity 97%) exhibits the highest discriminatory power in distinguishing between portal vein thrombosis and malignant thrombosis.

#### CONCLUSION

The multi-parameter spectral combined model exhibits superior differential diagnostic capabilities compared to traditional CT values and various spectral parameters for distinguishing between portal vein thrombosis and cancer thrombus.

#### CLINICAL RELEVANCE/APPLICATION

Spectral multi-parameter CT can help clinicians accurately determine the nature, lesion homogeneity, location, size, and adjacent relationship of portal vein thrombi. This provides more accurate imaging evidence for the early diagnosis, treatment strategy, and prognosis prediction of tumor patients.

### W3-SSER02-2 High-Pitch Head CT in Uncooperative Emergency Department Patients With Acute Head and Neck Trauma: Evaluation of Image Quality and Detection of Acute Intracranial Pathologies

Daniel Heinrich Leitner, BSc (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate image quality and diagnostic accuracy of acute intracranial pathologies of an unenhanced high-pitch head CT protocol used in uncooperative Emergency Department (ED) patients after acute trauma in comparison to standard CT protocols.

## METHODS AND MATERIALS

This retrospective study was IRB approved with a waiver for informed consent. We compared a novel high-pitch (1.55) head CT protocol (CTDIVOL 34.4 mGy) on a dual-source CT platform used in uncooperative ED patients and 1:1 age-matched ED patients who underwent standard-pitch (0.55) head CT protocol (CTDIVOL 39.5 mGy) after acute trauma and scanned between 01/2023 and 03/2023. Gray matter (GM) signal-to-noise ratio (SNR), white matter (WM) SNR, GM-WM contrast-to-noise ratio (CNR), and posterior fossa artifact index (PFAI) were compared. Two radiologists performed qualitative image evaluation of intracranial and bone structures, artifacts, and diagnostic evaluation for acute intracranial pathologies and fractures.

## RESULTS

Results: In total, 41 patients [male, n=27 (65.9%), 68±20 years] were scanned using high-pitch CT protocol. Only one scan had poor image quality due to motion (2.4%). Quantitative image evaluation did not show significant differences between high-pitch and standard protocols: GM SNR, mean±SD, 18.5±3.5 vs. 17.2±2.9, WM SNR, 15.5±2.5 vs. 14.7±2.2, GM-WM CNR 2.3±0.6 vs 2.2±0.5, PFAI, 3.5±0.3, all p=0.41. Grey-white differentiation [median (IQR); 5(4, 5) vs. 5 (4, 5)], delineation of cerebrospinal fluid spaces (5 vs. 5), mastoid cells (5 vs. 5) and bone structures (5 vs. 5) were rated very good for both protocols w/o significant differences (all p=0.05). Artifacts in the supratentorial region were low in both protocols (p=0.09), while beam-hardening artifacts in the infratentorial region were slightly worse in high-pitch scans [2 (1,3) vs. 1 (1,2), p=0.001]. Diagnostic confidence to evaluate for intracranial hemorrhage, brain herniation and fracture was very good for both protocols w/o significant differences. Interrater agreement for the detection of intracranial hemorrhages (n=18), herniation (n=9) and fractures (n=6) was excellent for both protocols (? ,1.0).

## CONCLUSION

High-pitch head CT protocol provides similar image quality to standard head CT protocol and is a safe and robust alternative in uncooperative ED patients to evaluate for acute intracranial pathologies after trauma.

## CLINICAL RELEVANCE/APPLICATION

ED patients after acute head trauma are frequently uncooperative and difficult to evaluate. High-pitch head CT is a robust protocol that allows scans in less than 1 second and provides excellent image quality to evaluate for acute intracranial pathologies and fractures.

## W3-SSER02-3 Serum Creatinine Testing in the Emergency Department Prior to Contrast-Enhanced CT Exam Does Not Typically Change Patient Management

Jennifer S. McDonald, PhD (*Presenter*) Research Grant, General Electric Company;Scientific Advisor, General Electric Company;Consultant, General Electric Company

## PURPOSE

Standard practices and guidelines recommend or require that a recent serum creatinine (SCr) result (typically within 7-30 days) must be available in the medical record or a SCr test must be ordered before a patient receives intravenous ICM. However this practice adds cost and time, potentially delaying imaging, diagnosis and patient management, particularly in patients who present to emergency departments (ED). The purpose of this retrospective study was to examine SCr testing performed in the emergency department of a large quaternary center prior to performing a contrast-enhanced CT exam and determine how frequently this testing changed patient management.

## METHODS AND MATERIALS

This retrospective study consisted of all adult and pediatric patients that presented to our ED from 1/1/2017 to 1/1/2020 and had a contrast-enhanced CT exam ordered during the ED visit. At our institution, patients with a pre-CT eGFR<30 ml/min may not receive contrast at the discretion of the ordering provider and radiologist. All patient, laboratory, and radiology data was retrieved by automated search and chart review. Pre-CT eGFR was calculated for each patient from the serum creatinine (SCr) result using the MDRD equation.

## RESULTS

A total of 19,127 ED visits with CECT were included in the study. Most visits had a SCr result available before the CECT was ordered (n=17,370, 91%). Median turnaround time between SCr order and result was 34 minutes (IQR 26-46 minutes). In almost all ED visits where SCr testing was performed and results were available pre-CECT, the patient's eGFR result was > 30 ml/min (n=17,139, 99%), with only a small number of patients with eGFR <30 ml/min (n=231, 1.3%). A CECT exam was still performed in 179 of the eGFR <30 ml/min patients (62%). In 46 patients (20% of eGFR<30 ml/min patients, 0.24% of

cohort) the CECT was canceled out of concern for CIN. In those 46 canceled cases, four of the patients underwent a CECT in the 60 days following the ED visit.

#### **CONCLUSION**

Serum creatinine testing in the ED did not affect the decision to perform a CECT exam in the vast majority of cases.

#### **CLINICAL RELEVANCE/APPLICATION**

Most patients with eGFR<30 ml/min who presented to the ED received a CECT. Creatinine testing prior to iodinated contrast material exposure may not be necessary in patients presenting to the emergency department, as the benefit of administering contrast in acute situations likely outweighs the risk of contrast-induced acute kidney injury.

### **W3-SSER02-4 Relationship Between Injury Severity and Trauma Whole-Body CT Report Turnaround Times**

Nathan Sarkar, BS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Background/Purpose: Trauma is a leading cause of death in the United States. Whole-Body CT is frequently used to screen trauma patients for major injuries and hemorrhage, as well as for surgical planning. However, delayed Report Turn-Around-Time (RTAT) remains a bottleneck in the flow of patient management in trauma, especially severely injured patients.

#### **METHODS AND MATERIALS**

Methods: This dataset consisted of 11,251 patients who underwent admission trauma whole body CT from two trauma centers within a single hospital system; a level I tertiary care trauma center (n=9043) and a regional urban level II trauma center (n=2208). Patients were selected between July 2016 and September 2022. Patients were discretized by age index ( $\geq 55$  or  $< 55$  years), polytrauma (ISS =16), whether they required any transfusion, or massive transfusion (MT) defined as  $\geq 10$  units of Packed Red Blood Cells (PRBCs) within 24 hours, and by shock index (HR/SBP)  $>$  or  $= 1$ , where a value  $> 1$  indicates hemodynamic shock. Bivariate comparisons of medians were performed with the Mann-Whitney U test. Tests of proportions were performed using the Chi square test. In all cases, p-value  $< 0.05$  was considered statistically significant.

#### **RESULTS**

Results: Overall median RTAT was 24 minutes (IQR: 4-48). RTAT was significantly longer in those in hemodynamic shock (37 minutes vs 22 minutes,  $p < 0.0001$ ), those with polytrauma (ISS=16 vs ISS<16) (34 minutes vs 21 minutes,  $p < 0.0001$ ), those who received massive transfusion versus those who did not (47.5 minutes vs 24 minutes,  $p < 0.0001$ ), those who ultimately expired (41 minutes vs 23 minutes,  $p < 0.0001$ ), the older cohort (age $> 55$ ) (28 minutes vs 22 minutes,  $p < 0.0001$ ), and those with penetrating vs blunt injuries (27 minutes vs 23 minutes,  $p = 0.001$ ).

#### **CONCLUSION**

Conclusion: Multiple markers of traumatic injury severity were associated with longer RTATs, despite evidence showing that more severely injured patients require faster diagnosis and treatment. The field of trauma radiology must search for ways to improve the RTAT in patients who are severely injured with time-sensitive injuries.

#### **CLINICAL RELEVANCE/APPLICATION**

Existing evidence shows that more severely injured trauma patients require faster diagnosis and treatment. However, we found that multiple markers of traumatic injury severity were associated with longer report turn-around times.

### **W3-SSER02-5 Occult Fractures in the Tibial Plateau: 3D Augmented X-Ray Pilot Study**

Luis Fandino, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The tibial plateau (TP) is a common site of missed fractures on conventional radiographs (CR). 3D augmented X-ray is a new cone beam-based tomography imaging concept that provides CRs along with digital tomography images that can be reformatted in axial, coronal, and sagittal planes with 0.5mm slice thickness. The purpose of this study is to evaluate the value of 3D Augmented X-ray in the detection of fractures of the tibial plateau.

#### **METHODS AND MATERIALS**

Over the course of 4 months, 23 patients referred from the Emergency Department with a high clinical suspicion for knee fracture were evaluated with a 3D Augmented X-ray exam (Multitom RAX, Siemens Healthineers, Germany). Three radiologists with 12-, 4- and 1-year experience sequentially reviewed CR and 3D images in a blinded fashion and recorded their confidence level for the absence/presence of a TP fracture on a 5-point ordinal scale (definitely absent, likely absent, neutral, likely present, definitely present). The ground-truth for presence of fracture was established by either subsequent magnetic resonance imaging (MRI) or consensus of three musculoskeletal radiology specialists. The confidence levels were entered into software for receiver-operating characteristic (ROC) analysis. Reader-average area-under-curve (AUC) values were obtained from this analysis and compared for CR versus 3D.

## RESULTS

5 TP fractures were identified by reference standard (21.7% of exams, 95% CI: 7.5-43.7%). The reviewer with 12 years of experience identified two of these fractures on CR, while all 5 were identified using the 3D images, with no false positives in either case. The fractures identified only on 3D were all located in the lateral tibial plateau, winter sports injuries, relatively small, and were managed without surgery. Image quality was generally adequate. Reader averaged AUC values for TP fractures were  $0.800 \pm .087$  for CR and  $0.957 \pm 0.433$  for 3D. Accounting for correlations from a paired study design, the 90% confidence interval for the difference ("3D minus CR") in reader-averaged AUC is [0.0220,0.2918]. The difference is statistically significant with 90% confidence (p-value: 0.056).

## CONCLUSION

This pilot study suggests 3D Augmented X-rays detect more fractures than conventional radiography (>90% confidence, p-value: 0.056).

## CLINICAL RELEVANCE/APPLICATION

3D Augmented X-ray technology using cone-beam digital tomography generated images can detect subtle tibial plateau fractures that may be missed on conventional radiography.

## W3-SSER02-6 **Change in Emergency Department Length of Stay Following Routine Adoption of Dual-Energy Computed Tomography (DECT) to Differentiate Intracranial Hemorrhage from Calcification**

Ngoc-Anh Tran, MD (*Presenter*) Nothing to Disclose

## PURPOSE

DECT is an advanced technique shown to improve accuracy in distinguishing intracranial hemorrhage (ICH) from calcification which can be challenging on conventional CT. The purpose of this study is to quantify emergency department (ED) length of stay (LOS) before after implementing automated DECT processing in the evaluation of indeterminate intracranial hyperdensities, with the hypothesis that DECT decreases repeat imaging ED LOS.

## METHODS AND MATERIALS

Retrospective chart review at a level 1 trauma center ED 1-year before (7/2016-6/2017) after (7/2018-6/2019) implementing DECT head protocol with automated post-processing of calcium map virtual non-calcium images. Included were patients scanned for headache, trauma or fall, who were discharged home from the ED; excluded were those admitted, taken to the operating room, or left against medical advice (pre-DECT n=908, post-DECT n=1170). Intracranial hyperdensities were identified by report or imaging review, excluding those determined to represent calcification by classic location, morphology, or Hounsfield units>100, leaving only indeterminate hyperdensities (pre-DECT n=17, post-DECT n=18). Primary outcome measure was ED LOS. Secondary measures were number of CT scans with follow-up imaging. Student t-test Mann-Whitney test were used for continuous data; Chi2 for dichotomous/categorical variables.

## RESULTS

There were no difference in patient demographics (age, sex, and CT head indication) between the pre post-DECT cohorts. There was a significant difference in ED LOS in the final cohorts: mean pre-DECT LOS=421 minutes (mins), post-DECT LOS=272 mins, mean LOS reduction=149 mins. Change in baseline LOS increased from 20 mins (p=0.002) to 149 mins after the exclusion criteria (p=0.003). Increased ED LOS correlated with increased frequency of neurosurgical consultation repeat CT head for indeterminate hyperdensities. There were no other major changes in the ED workflow or care algorithm to explain these differences.

## CONCLUSION

Automatic DECT postprocessing improves characterization of ICH & calcium, decreasing ED LOS for a select group of patients by reducing unnecessary neurosurgical consultation & repeat imaging. These changes may improve ED workflow, efficiency, cost, as well as patient care & outcomes.

## CLINICAL RELEVANCE/APPLICATION

Increased advanced diagnostic imaging is a major contributor to increased ED LOS, which is linked to increased healthcare costs, poorer quality of care/patient outcomes, increased mortality, and is an important quality metric which many hospitals aim to safely minimize. The potential downstream outcomes of improved differentiation of ICH calcium using DECT include decreased repeat imaging, hospital-to-hospital transfers, ED LOS.

### Multi-Parameter Spectral CT Enhanced Imaging for Differential Diagnosis of Portal Vein Thrombosis and Malignant Thrombosis

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E451B

Zhihao Wang (*Presenter*) Nothing to Disclose

#### PURPOSE

This study is to investigate the differential diagnostic performance of spectral-based image-enhanced imaging for portal vein thrombosis (PVT) and malignant thrombus (MT), with the aim of enhancing the clinical efficiency of differential diagnosis between the PVT and MT.

#### METHODS AND MATERIALS

This retrospective study included 100 patients with portal vein thrombosis who underwent spectral CT imaging from February 2023 to April 2023. According to clinical data and pathological diagnosis, 52 cases of portal vein thrombosis and 48 cases of malignant thrombosis were enrolled. Using post-processing software, conventional CT images (CI), iodine density maps (ID), effective atomic number maps (Z-eff), and spectral curves were reconstructed from the spectral data. Regions of interest (ROIs) were drawn at the site of occlusion, and CT values (CIHU), iodine density values (ID), effective atomic numbers (Z-eff), and spectral curve slopes were measured (?HU). Independent sample t-tests were used to analyze the differences between parameters. A single-factor logistic regression was used to evaluate the predictive probability of spectral multi-parameters for portal vein thrombosis and tumor thrombus, and a spectral multi-parameter combined model was established. Receiver operating characteristic (ROC) curves were plotted, and the area under the curve (AUC) and cutoff value were calculated to compare the diagnostic efficacy of various spectral parameters in differentiating portal vein thrombosis and tumor thrombus.

#### RESULTS

Compared to CT values (AUC 0.92, cutoff value 142.5, sensitivity 86%, specificity 93%), ID values (AUC 0.965, cutoff value 3.24, sensitivity 92%, specificity 96.5%), Z-eff values (AUC 0.952, cutoff 12.05, sensitivity 90%, specificity 96.2%), and ? HU values (AUC 0.962, sensitivity 96%, specificity 95%), the multi-parameter spectral combined model (AUC 0.97, sensitivity 94%, specificity 97%) exhibits the highest discriminatory power in distinguishing between portal vein thrombosis and malignant thrombosis.

#### CONCLUSION

The multi-parameter spectral combined model exhibits superior differential diagnostic capabilities compared to traditional CT values and various spectral parameters for distinguishing between portal vein thrombosis and cancer thrombus.

#### CLINICAL RELEVANCE/APPLICATION

Spectral multi-parameter CT can help clinicians accurately determine the nature, lesion homogeneity, location, size, and adjacent relationship of portal vein thrombi. This provides more accurate imaging evidence for the early diagnosis, treatment strategy, and prognosis prediction of tumor patients.

### High-Pitch Head CT in Uncooperative Emergency Department Patients With Acute Head and Neck Trauma: Evaluation of Image Quality and Detection of Acute Intracranial Pathologies

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E451B

Daniel Heinrich Leitner, BSc (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate image quality and diagnostic accuracy of acute intracranial pathologies of an unenhanced high-pitch head CT protocol used in uncooperative Emergency Department (ED) patients after acute trauma in comparison to standard CT protocols.

#### METHODS AND MATERIALS

This retrospective study was IRB approved with a waiver for informed consent. We compared a novel high-pitch (1.55) head CT protocol (CTDIVOL 34.4 mGy) on a dual-source CT platform used in uncooperative ED patients and 1:1 age-matched ED patients who underwent standard-pitch (0.55) head CT protocol (CTDIVOL 39.5 mGy) after acute trauma and scanned between 01/2023 and 03/2023. Gray matter (GM) signal-to-noise ratio (SNR), white matter (WM) SNR, GM-WM contrast-to-noise ratio (CNR), and posterior fossa artifact index (PFAI) were compared. Two radiologists performed qualitative image evaluation of intracranial and bone structures, artifacts, and diagnostic evaluation for acute intracranial pathologies and fractures.

#### RESULTS

Results: In total, 41 patients [male, n=27 (65.9%), 68±20 years] were scanned using high-pitch CT protocol. Only one scan had poor image quality due to motion (2.4%). Quantitative image evaluation did not show significant differences between high-pitch and standard protocols: GM SNR, mean±SD, 18.5±3.5 vs. 17.2±2.9, WM SNR, 15.5±2.5 vs. 14.7±2.2, GM-WM CNR 2.3±0.6 vs 2.2±0.5, PFAI, 3.5±0.3, all p=0.41. Grey-white differentiation [median (IQR); 5(4, 5) vs. 5 (4, 5)], delineation of cerebrospinal fluid spaces (5 vs. 5), mastoid cells (5 vs. 5) and bone structures (5 vs. 5) were rated very good for both protocols w/o significant differences (all p=0.05). Artifacts in the supratentorial region were low in both protocols (p=0.09), while beam-hardening artifacts in the infratentorial region were slightly worse in high-pitch scans [2 (1,3) vs. 1 (1,2), p=0.001]. Diagnostic confidence to evaluate for intracranial hemorrhage, brain herniation and fracture was very good for both protocols w/o significant differences. Interrater agreement for the detection of intracranial hemorrhages (n=18), herniation (n=9) and fractures (n=6) was excellent for both protocols (? ,1.0).

#### CONCLUSION

High-pitch head CT protocol provides similar image quality to standard head CT protocol and is a safe and robust alternative in uncooperative ED patients to evaluate for acute intracranial pathologies after trauma.

#### CLINICAL RELEVANCE/APPLICATION

ED patients after acute head trauma are frequently uncooperative and difficult to evaluate. High-pitch head CT is a robust protocol that allows scans in less than 1 second and provides excellent image quality to evaluate for acute intracranial pathologies and fractures.

W3-SSER02-3

### **Serum Creatinine Testing in the Emergency Department Prior to Contrast-Enhanced CT Exam Does Not Typically Change Patient Management**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E451B

Jennifer S. McDonald, PhD (*Presenter*) Research Grant, General Electric Company; Scientific Advisor, General Electric Company; Consultant, General Electric Company

#### **PURPOSE**

Standard practices and guidelines recommend or require that a recent serum creatinine (SCr) result (typically within 7-30 days) must be available in the medical record or a SCr test must be ordered before a patient receives intravenous ICM. However this practice adds cost and time, potentially delaying imaging, diagnosis and patient management, particularly in patients who present to emergency departments (ED). The purpose of this retrospective study was to examine SCr testing performed in the emergency department of a large quaternary center prior to performing a contrast-enhanced CT exam and determine how frequently this testing changed patient management.

#### **METHODS AND MATERIALS**

This retrospective study consisted of all adult and pediatric patients that presented to our ED from 1/1/2017 to 1/1/2020 and had a contrast-enhanced CT exam ordered during the ED visit. At our institution, patients with a pre-CT eGFR <30 ml/min may not receive contrast at the discretion of the ordering provider and radiologist. All patient, laboratory, and radiology data was retrieved by automated search and chart review. Pre-CT eGFR was calculated for each patient from the serum creatinine (SCr) result using the MDRD equation.

#### **RESULTS**

A total of 19,127 ED visits with CECT were included in the study. Most visits had a SCr result available before the CECT was ordered (n=17,370, 91%). Median turnaround time between SCr order and result was 34 minutes (IQR 26-46 minutes). In almost all ED visits where SCr testing was performed and results were available pre-CECT, the patient's eGFR result was > 30 ml/min (n=17,139, 99%), with only a small number of patients with eGFR <30 ml/min (n=231, 1.3%). A CECT exam was still performed in 179 of the eGFR <30 ml/min patients (62%). In 46 patients (20% of eGFR <30 ml/min patients, 0.24% of cohort) the CECT was cancelled out of concern for CIN. In those 46 canceled cases, four of the patients underwent a CECT in the 60 days following the ED visit.

#### **CONCLUSION**

Serum creatinine testing in the ED did not affect the decision to perform a CECT exam in the vast majority of cases.

#### **CLINICAL RELEVANCE/APPLICATION**

Most patients with eGFR <30 ml/min who presented to the ED received a CECT. Creatinine testing prior to iodinated contrast material exposure may not be necessary in patients presenting to the emergency department, as the benefit of administering contrast in acute situations likely outweighs the risk of contrast-induced acute kidney injury.

### Relationship Between Injury Severity and Trauma Whole-Body CT Report Turnaround Times

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E451B

Nathan Sarkar, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Background/Purpose: Trauma is a leading cause of death in the United States. Whole-Body CT is frequently used to screen trauma patients for major injuries and hemorrhage, as well as for surgical planning. However, delayed Report Turn-Around-Time (RTAT) remains a bottleneck in the flow of patient management in trauma, especially severely injured patients.

#### METHODS AND MATERIALS

Methods: This dataset consisted of 11,251 patients who underwent admission trauma whole body CT from two trauma centers within a single hospital system; a level I tertiary care trauma center (n=9043) and a regional urban level II trauma center (n=2208). Patients were selected between July 2016 and September 2022. Patients were discretized by age index ( $\geq 55$  or  $< 55$  years), polytrauma (ISS =16), whether they required any transfusion, or massive transfusion (MT) defined as  $\geq 10$  units of Packed Red Blood Cells (PRBCs) within 24 hours, and by shock index (HR/SBP)  $>$  or  $= 1$ , where a value  $> 1$  indicates hemodynamic shock. Bivariate comparisons of medians were performed with the Mann-Whitney U test. Tests of proportions were performed using the Chi square test. In all cases, p-value  $< 0.05$  was considered statistically significant.

#### RESULTS

Results: Overall median RTAT was 24 minutes (IQR: 4-48). RTAT was significantly longer in those in hemodynamic shock (37 minutes vs 22 minutes,  $p < 0.0001$ ), those with polytrauma (ISS=16 vs ISS<16) (34 minutes vs 21 minutes,  $p < 0.0001$ ), those who received massive transfusion versus those who did not (47.5 minutes vs 24 minutes,  $p < 0.0001$ ), those who ultimately expired (41 minutes vs 23 minutes,  $p < 0.0001$ ), the older cohort (age $> 55$ ) (28 minutes vs 22 minutes,  $p < 0.0001$ ), and those with penetrating vs blunt injuries (27 minutes vs 23 minutes,  $p = 0.001$ ).

#### CONCLUSION

Conclusion: Multiple markers of traumatic injury severity were associated with longer RTATs, despite evidence showing that more severely injured patients require faster diagnosis and treatment. The field of trauma radiology must search for ways to improve the RTAT in patients who are severely injured with time-sensitive injuries.

#### CLINICAL RELEVANCE/APPLICATION

Existing evidence shows that more severely injured trauma patients require faster diagnosis and treatment. However, we found that multiple markers of traumatic injury severity were associated with longer report turn-around times.

### Occult Fractures in the Tibial Plateau: 3D Augmented X-Ray Pilot Study

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E451B

Luis Fandino, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The tibial plateau (TP) is a common site of missed fractures on conventional radiographs (CR). 3D augmented X-ray is a new cone beam-based tomography imaging concept that provides CRs along with digital tomography images that can be reformatted in axial, coronal, and sagittal planes with 0.5mm slice thickness. The purpose of this study is to evaluate the value of 3D Augmented X-ray in the detection of fractures of the tibial plateau.

#### METHODS AND MATERIALS

Over the course of 4 months, 23 patients referred from the Emergency Department with a high clinical suspicion for knee fracture were evaluated with a 3D Augmented X-ray exam (Multitom RAX, Siemens Healthineers, Germany). Three radiologists with 12-, 4- and 1-year experience sequentially reviewed CR and 3D images in a blinded fashion and recorded their confidence level for the absence/presence of a TP fracture on a 5-point ordinal scale (definitely absent, likely absent, neutral, likely present, definitely present). The ground-truth for presence of fracture was established by either subsequent magnetic resonance imaging (MRI) or consensus of three musculoskeletal radiology specialists. The confidence levels were entered into software for receiver-operating characteristic (ROC) analysis. Reader-average area-under-curve (AUC) values were obtained from this analysis and compared for CR versus 3D.

#### RESULTS

5 TP fractures were identified by reference standard (21.7% of exams, 95% CI: 7.5-43.7%). The reviewer with 12 years of experience identified two of these fractures on CR, while all 5 were identified using the 3D images, with no false positives in either case. The fractures identified only on 3D were all located in the lateral tibial plateau, winter sports injuries, relatively small, and were managed without surgery. Image quality was generally adequate. Reader averaged AUC values for TP fractures were  $0.800 \pm .087$  for CR and  $0.957 \pm 0.433$  for 3D. Accounting for correlations from a paired study design, the 90% confidence interval for the difference ("3D minus CR") in reader-averaged AUC is [0.0220,0.2918]. The difference is statistically significant with 90% confidence (p-value: 0.056).

#### CONCLUSION

This pilot study suggests 3D Augmented X-rays detect more fractures than conventional radiography (>90% confidence, p-value: 0.056).

#### CLINICAL RELEVANCE/APPLICATION

3D Augmented X-ray technology using cone-beam digital tomography generated images can detect subtle tibial plateau fractures that may be missed on conventional radiography.

### Change in Emergency Department Length of Stay Following Routine Adoption of Dual-Energy Computed Tomography (DECT) to Differentiate Intracranial Hemorrhage from Calcification

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E451B

Ngoc-Anh Tran, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

DECT is an advanced technique shown to improve accuracy in distinguishing intracranial hemorrhage (ICH) from calcification which can be challenging on conventional CT. The purpose of this study is to quantify emergency department (ED) length of stay (LOS) before after implementing automated DECT processing in the evaluation of indeterminate intracranial hyperdensities, with the hypothesis that DECT decreases repeat imaging ED LOS.

#### METHODS AND MATERIALS

Retrospective chart review at a level 1 trauma center ED 1-year before (7/2016-6/2017) after (7/2018-6/2019) implementing DECT head protocol with automated post-processing of calcium map virtual non-calcium images. Included were patients scanned for headache, trauma or fall, who were discharged home from the ED; excluded were those admitted, taken to the operating room, or left against medical advice (pre-DECT n=908, post-DECT n=1170). Intracranial hyperdensities were identified by report or imaging review, excluding those determined to represent calcification by classic location, morphology, or Hounsfield units>100, leaving only indeterminate hyperdensities (pre-DECT n=17, post-DECT n=18). Primary outcome measure was ED LOS. Secondary measures were number of CT scans with follow-up imaging. Student t-test Mann-Whitney test were used for continuous data; Chi2 for dichotomous/categorical variables.

#### RESULTS

There were no difference in patient demographics (age, sex, and CT head indication) between the pre post-DECT cohorts. There was a significant difference in ED LOS in the final cohorts: mean pre-DECT LOS=421 minutes (mins), post-DECT LOS=272 mins, mean LOS reduction=149 mins. Change in baseline LOS increased from 20 mins (p=0.002) to 149 mins after the exclusion criteria (p=0.003). Increased ED LOS correlated with increased frequency of neurosurgical consultation repeat CT head for indeterminate hyperdensities. There were no other major changes in the ED workflow or care algorithm to explain these differences.

#### CONCLUSION

Automatic DECT postprocessing improves characterization of ICH & calcium, decreasing ED LOS for a select group of patients by reducing unnecessary neurosurgical consultation & repeat imaging. These changes may improve ED workflow, efficiency, cost, as well as patient care & outcomes.

#### CLINICAL RELEVANCE/APPLICATION

Increased advanced diagnostic imaging is a major contributor to increased ED LOS, which is linked to increased healthcare costs, poorer quality of care/patient outcomes, increased mortality, and is an important quality metric which many hospitals aim to safely minimize. The potential downstream outcomes of improved differentiation of ICH calcium using DECT include decreased repeat imaging, hospital-to-hospital transfers, ED LOS.

#### **W3-SSGI12-1 The Nine Important Imaging Signs of Intraductal Papillary Neoplasm of the Bile Duct (IPNB): A Reappraisal of 342 Cases been Resected**

Xinyi Gao, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

intraductal papillary neoplasm of the bile duct (IPNB)--- are rare that have special clinical, imaging features, and pathological results. IPNB has recently been further classified into "so-called IPNBs" (Type-1) and "narrow-sense papillary cholangiocarcinomas" (Type-2), but their differential diagnosis is challenging. Our study aimed to reevaluate these two types CT and MR Images to find some valuable signs. The purpose of understanding these signs is to improve the accuracy of preoperative diagnosis.

#### METHODS AND MATERIALS

342 patients (from our hospital, 2013-2023) who underwent papillary bile-duct tumor resection were included. We used nine CT/MRI features (I, thread sign; II, papilla sign; III, biliary dilatation; IV, hepatic lobe atrophy; V, cyst; VI, combined calculus; VII, common bile duct stenosis; VIII, combined IPMN, and IX, clonorchiosis history) to score these tumors. Meanwhile, we used five pathological features (location, mucin secretion, histological type, low/intermediate-dysplasia component, and proportion of the invasive component), CA-199, CEA and immunohistochemical results also included in the score. Tumor scoring 10-16 were classified as Type-1, 0-5 as Type-2, and 6-9 as Type- Unclassifiable. In addition, we compared the nine scores of the images with the pathology scores of 342 tumors.

#### RESULTS

The 342 papillary bile-duct tumor patients were divided into three groups, consisting of 30 Type-1, 61 Type-2, and 251 type- Unclassifiable, which means uncertain gray-zone tumors occupying the largest proportion of IPNB. The invasive component has a correlation with imaging features.

#### CONCLUSION

The imaging scoring system worked well for IPNB to reflect a continuous spectrum of pathological features.

#### CLINICAL RELEVANCE/APPLICATION

Through retrospective analysis of 342 large IPNB samples, we can establish an imaging scoring system for accurate preoperative evaluation of tumors in the bile ducts.

#### **W3-SSGI12-2 Disease Severity Prognostication in Primary Sclerosing Cholangitis Patients using Gadoteric Acid-Enhanced MRI: A Validation of the Anali Score and Comparison with the Potential Functional Stricture**

Sami Ba-Ssalamah (*Presenter*) Nothing to Disclose

#### PURPOSE

To validate the Anali scores with and without gadolinium (ANALIGd and ANALInoGd) and to compare their prognostic ability with the recently-proposed potential functional stricture (PFS), based on the hepatobiliary phase (HBP) of gadoteric acid-enhanced MRI (GA-MRI) in PSC patients.

## METHODS AND MATERIALS

Three readers scored the Anali scores components, including intrahepatic bile duct change severity, hepatic dysmorphism, liver parenchymal heterogeneity, and portal hypertension on GA-MRI, including T2-MRCP, to generate ANALIGd and ANALInoGd. They also evaluated 20-minute HBP images for PFS, i.e., absent contrast excretion in first order bile ducts (i.e., LHD/RHD/CHD/CBD) or none at all vs normal biliary excretion, i.e., no functional stricture (NFS). Inter- and intrareader agreement were assessed and Kaplan-Meier curves generated for survival analysis. Uni- and multivariate Cox regression analyses were performed to evaluate association between ANALInoGd, ANALIGd, and PFS with clinical scores, labs and outcomes.

## RESULTS

For 129 patients, mean age 41.4 years, ICC agreement was almost perfect (0.95) for PFS, and substantial (0.74), for ANALInoGd. ANALIGd, agreement was better on HBP than arterial-phase, (0.66 vs 0.81). Univariate Cox regression showed that the hazard ratio (HR) of decompensated cirrhosis, orthotopic liver transplantation (OLT) or death was 7.3 for PFS ( $p < 0.001$ ) vs (6.1,  $p < 0.001$ ) for ANALInoGd vs (7.9,  $p < 0.004$ ) for the HBP and (4.5,  $p < 0.125$ ) for the arterial-phase of the ANALIGd. Multivariate analyses for PFS, Anali scores and clinical scores identified the PFS and ANALIGd HBP as independent risk factors with HRs (3.7,  $p < 0.028$  and 3.2,  $p = 0.021$ , respectively).

## CONCLUSION

GA-MRI-derived parameters, including the Anali scores and PFS can noninvasively predict clinical outcomes in PSC patients. The HBP scores, including PFS and ANALIGd appear more robust.

## CLINICAL RELEVANCE/APPLICATION

Prognostic model using three-dimensional MRCP and gadoxetic acid enhanced MRI can be used to determine PSC severity non-invasively.

### W3-SSGI12-3 **Bile Duct DWI Abnormalities: Potential Biomarker Predicting Ischemic Cholangiopathy in ABO-incompatible Liver Transplant Recipients**

Kyowon Gu, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Ischemic cholangiopathy (IC) remains a significant complication in ABO incompatible liver transplantation (ABOi-LT) patients despite the introduction of Rituximab and plasmapheresis, impacting graft survival and patient outcomes. This study aimed to evaluate the potential of postoperative diffusion-weighted imaging (DWI) in predicting IC development in ABOi-LT patients.

## METHODS AND MATERIALS

A total of 56 ABOi-LT patients underwent postoperative magnetic resonance cholangiography (MRCP) including DWI, during the postoperative hospitalization period. Two independent readers assessed periportal diffusion restriction, periportal edema, wall thickening, associated signal alteration of liver parenchyma, bile duct dilatation, and stricture site on MRCP. Inter-reader agreement was determined using Cohen's kappa method for DWI abnormality which was categorized as normal, equivocal or abnormal. Endoscopic retrograde cholangiopancreatography (ERCP) was conducted for patients with abnormal liver function tests during follow-up. IC was considered present if multifocal or diffuse stricture, excluding anastomosis sites, was observed. Progression of IC was also assessed and categorized as biliary dilatation, abscess formation, or hepatic necrosis causing graft failure.

## RESULTS

The median follow-up period was 346.5 days, with a median interval of 17.5 days (range, 7-37) between ABOi-LT and MRCP. Substantial inter-reader agreement was observed in assessing DWI abnormality (Kappa = 0.710). In one case, DWI was not suitable for evaluation due to artifact caused by portal vein stent. The median interval between LT and ERCP demonstrating IC was 109 days (range, 21-510). Patients with periportal DWI abnormality on postoperative MRCP ( $n=18$ ) exhibited a significant difference in the ratio of developing IC during follow-up ( $p=0.029$ ). Among 15 patients with biliary stricture on ERCP, 5 showed progressive stricture or complications. Periportal DWI abnormality was significantly associated with a higher likelihood of progressive biliary stricture ( $p=0.007$ ).

## CONCLUSION

Postoperative DWI abnormalities demonstrate potential as a non-invasive imaging modality for predicting IC development and progression following ABOi-LT. Early identification of at-risk patients may facilitate timely interventions, potentially improving graft survival and patient outcomes.

## CLINICAL RELEVANCE/APPLICATION

Postoperative diffusion-weighted imaging abnormalities of the bile duct can be used as a biomarker predicting ischemic cholangiopathy after ABO-incompatible liver transplantation.

### **W3-SSGI12-5 Differentiating between Benign and Malignant Ampullary Strictures: A Prediction Model using Contrast Enhanced MR Imaging and Clinical Findings**

Jonghun Woo, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To construct a predictive nomogram for differentiating malignant from benign ampullary strictures using contrast-enhanced magnetic resonance imaging (MRI) findings combined with clinical findings.

#### **METHODS AND MATERIALS**

In this retrospective study, 76 patients with ampullary stricture (51 benign and 25 malignant) who underwent contrast-enhanced MRI were included. Various imaging findings of the ampulla, bile duct, main pancreatic duct, and periampullary area were evaluated and clinical findings including the presence of jaundice, carbohydrate antigen 19-9 level, and history of cholecystectomy were collected. Among them, statistically significant findings were identified using univariable and multivariable logistic regression analyses. A nomogram was constructed to differentiate benign and malignant ampullary strictures and was internally validated.

#### **RESULTS**

Multivariable analysis revealed that jaundice (odds ratio [OR]: 12.41,  $p = 0.019$ ), presence of ampullary mass (OR: 8.42,  $p = 0.047$ ), bulging ampulla (OR: 8.32,  $p = 0.033$ ), and diffusion restriction of the ampulla (OR: 42.76,  $p = 0.004$ ) were significant factors for predicting the presence of malignant ampullary stricture and were used to construct a nomogram. Among them, diffusion restriction of the ampulla showed the highest OR and predictor point on the nomogram. The calibration plots showed excellent agreement between the predicted probabilities and the actual rates of malignant ampullary strictures, on internal validation.

#### **CONCLUSION**

Combination of clinical and imaging findings could aid in predicting malignant ampullary strictures using significant findings of jaundice, presence of ampullary mass, bulging ampulla, and diffusion restriction of the ampulla. A predictive nomogram based on contrast-enhanced MR imaging findings combined with clinical findings can be useful for differentiating between benign and malignant ampullary strictures.

#### **CLINICAL RELEVANCE/APPLICATION**

The nomogram constructed using contrast-enhanced MRI and clinical findings could aid in predicting malignant ampullary strictures.

### **W3-SSGI12-6 Improvement of Diagnosis of Adjacent Organ Invasion of Extrahepatic Bile Duct Cancer by Adding Arterial and Delayed Phases**

Eisuke Mukaida, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The purpose of our study was to clarify the role of dynamic computed tomography (CT) in the diagnosis of extrahepatic bile duct (EHD) cancer involving adjacent organs.

#### **METHODS AND MATERIALS**

This retrospective study included patients who were pathologically diagnosed with EHD cancer between January 2011 and December 2021 and had undergone dynamic contrast-enhanced CT before previous biliary intervention, surgery, or chemotherapy. For each patient, the mean CT values of the abdominal aorta, portal vein (PV), hepatic parenchyma, pancreatic parenchyma, and EHD cancer were measured during each phase. In patients who had undergone surgery, two radiologists independently reviewed the CT images in the portal, dual (adding arterial phase), and triple phases (adding delayed phase). Two radiologists assessed the biliary segment-wise longitudinal tumor extent, arterial and PV invasion, organ invasion, and regional lymph node metastasis on a five-point scale for each phase. The performances of the portal, dual, and triple phase images were compared using the sensitivity, specificity, and AUC of each reader's results for pathological diagnosis.

#### **RESULTS**

In total, 120 patients (mean age,  $71.7 \pm 8.8$ ; 84 males) were evaluated for CT values. Contrast peaks of EHD cancer, hepatic parenchyma, and PV were observed in the portal phase. Among them, 80 patients were evaluated on a five-point scale. The AUC of pancreatic, duodenal, and arterial invasion increased with the addition of the phase at each observer (observer 1, 0.79 to 0.93,  $p < 0.01$ , 0.71 to 0.86,  $p = 0.04$ , 0.74 to 0.99,  $p = 0.02$ , respectively; observer 2, 0.88 to 0.96,  $p = 0.01$ , 0.73 to 0.94,  $p < 0.01$ , 0.80 to 0.99,  $p = 0.04$ , respectively). Statistically, the AUC for biliary segment-wise longitudinal tumor extent, hepatic, and PV invasion did not change with the addition phase.

## **CONCLUSION**

Addition of the arterial and delayed phases increased the AUC of pancreatic, duodenal, and arterial invasion.

## **CLINICAL RELEVANCE/APPLICATION**

Histological evaluation of patients with EHD cancer often reveals invasion of adjacent organs, which may lead to curative resection failure or early postoperative recurrence. Because the adjacent organs of EHD cancer vary according to the site of origin, the diagnostic performance of adjacent organ invasion may be influenced by contrast effects specific to that organ; however, no reports have been retrieved on this effect. Our results provide an important preoperative imaging strategy to achieve R0 resection of EHD cancer.

### **The Nine Important Imaging Signs of Intraductal Papillary Neoplasm of the Bile Duct (IPNB): A Reappraisal of 342 Cases been Resected**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N228

Xinyi Gao, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

intraductal papillary neoplasm of the bile duct (IPNB)--- are rare that have special clinical, imaging features, and pathological results. IPNB has recently been further classified into "so-called IPNBs" (Type-1) and "narrow-sense papillary cholangiocarcinomas" (Type-2), but their differential diagnosis is challenging. Our study aimed to reevaluate these two types CT and MR Images to find some valuable signs. The purpose of understanding these signs is to improve the accuracy of preoperative diagnosis.

#### **METHODS AND MATERIALS**

342 patients (from our hospital, 2013-2023) who underwent papillary bile-duct tumor resection were included. We used nine CT/MRI features (I, thread sign; II, papilla sign; III, biliary dilatation; IV, hepatic lobe atrophy; V, cyst; VI, combined calculus; VII, common bile duct stenosis; VIII, combined IPMN, and IX, clonorchiosis history) to score these tumors. Meanwhile, we used five pathological features (location, mucin secretion, histological type, low/intermediate-dysplasia component, and proportion of the invasive component), CA-199, CEA and immunohistochemical results also included in the score. Tumor scoring 10-16 were classified as Type-1, 0-5 as Type-2, and 6-9 as Type- Unclassifiable. In addition, we compared the nine score features of the images with the pathology scores of 342 tumors.

#### **RESULTS**

The 342 papillary bile-duct tumor patients were divided into three groups, consisting of 30 Type-1, 61 Type-2, and 251 type- Unclassifiable, which means uncertain gray-zone tumors occupying the largest proportion of IPNB. The invasive component has a correlation with imaging features.

#### **CONCLUSION**

The imaging scoring system worked well for IPNB to reflect a continuous spectrum of pathological features.

#### **CLINICAL RELEVANCE/APPLICATION**

Through retrospective analysis of 342 large IPNB samples, we can establish an imaging scoring system for accurate preoperative evaluation of tumors in the bile ducts.

### **Disease Severity Prognostication in Primary Sclerosing Cholangitis Patients using Gadoteric Acid-Enhanced MRI: A Validation of the Anali Score and Comparison with the Potential Functional Stricture**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N228

Sami Ba-Ssalamah (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To validate the Anali scores with and without gadolinium (ANALIGd and ANALInoGd) and to compare their prognostic ability with the recently-proposed potential functional stricture (PFS), based on the hepatobiliary phase (HBP) of gadoteric acid-enhanced MRI (GA-MRI) in PSC patients.

#### **METHODS AND MATERIALS**

Three readers scored the Anali scores components, including intrahepatic bile duct change severity, hepatic dysmorphism, liver parenchymal heterogeneity, and portal hypertension on GA-MRI, including T2-MRCP, to generate ANALIGd and ANALInoGd. They also evaluated 20-minute HBP images for PFS, i.e., absent contrast excretion in first order bile ducts (i.e., LHD/RHD/CHD/CBD) or none at all vs normal biliary excretion, i.e., no functional stricture (NFS). Inter- and intrareader agreement were assessed and Kaplan-Meier curves generated for survival analysis. Uni- and multivariate Cox regression analyses were performed to evaluate association between ANALInoGd, ANALIGd, and PFS with clinical scores, labs and outcomes.

#### **RESULTS**

For 129 patients, mean age 41.4 years, ICC agreement was almost perfect (0.95) for PFS, and substantial (0.74), for ANALInoGd. ANALIGd, agreement was better on HBP than arterial-phase, (0.66 vs 0.81). Univariate Cox regression showed that the hazard ratio (HR) of decompensated cirrhosis, orthotopic liver transplantation (OLT) or death was 7.3 for PFS ( $p < 0.001$ ) vs (6.1,  $p < 0.001$ ) for ANALInoGd vs (7.9,  $p < 0.004$ ) for the HBP and (4.5,  $p < 0.125$ ) for the arterial-phase of the ANALIGd. Multivariate analyses for PFS, Anali scores and clinical scores identified the PFS and ANALIGd HBP as independent risk factors with HRs (3.7,  $p < 0.028$  and 3.2,  $p = 0.021$ , respectively).

#### **CONCLUSION**

GA-MRI-derived parameters, including the Anali scores and PFS can noninvasively predict clinical outcomes in PSC patients. The HBP scores, including PFS and ANALIGd appear more robust.

#### **CLINICAL RELEVANCE/APPLICATION**

Prognostic model using three-dimensional MRCP and gadoteric acid enhanced MRI can be used to determine PSC severity non-invasively.

### **Bile Duct DWI Abnormalities: Potential Biomarker Predicting Ischemic Cholangiopathy in ABO-incompatible Liver Transplant Recipients**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N228

Kyowon Gu, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Ischemic cholangiopathy (IC) remains a significant complication in ABO incompatible liver transplantation (ABOi-LT) patients despite the introduction of Rituximab and plasmapheresis, impacting graft survival and patient outcomes. This study aimed to evaluate the potential of postoperative diffusion-weighted imaging (DWI) in predicting IC development in ABOi-LT patients.

#### **METHODS AND MATERIALS**

A total of 56 ABOi-LT patients underwent postoperative magnetic resonance cholangiography (MRCP) including DWI, during the postoperative hospitalization period. Two independent readers assessed periportal diffusion restriction, periportal edema, wall thickening, associated signal alteration of liver parenchyma, bile duct dilatation, and stricture site on MRCP. Inter-reader agreement was determined using Cohen's kappa method for DWI abnormality which was categorized as normal, equivocal or abnormal. Endoscopic retrograde cholangiopancreatography (ERCP) was conducted for patients with abnormal liver function tests during follow-up. IC was considered present if multifocal or diffuse stricture, excluding anastomosis sites, was observed. Progression of IC was also assessed and categorized as biliary dilatation, abscess formation, or hepatic necrosis causing graft failure.

#### **RESULTS**

The median follow-up period was 346.5 days, with a median interval of 17.5 days (range, 7-37) between ABOi-LT and MRCP. Substantial inter-reader agreement was observed in assessing DWI abnormality (Kappa = 0.710). In one case, DWI was not suitable for evaluation due to artifact caused by portal vein stent. The median interval between LT and ERCP demonstrating IC was 109 days (range, 21-510). Patients with periportal DWI abnormality on postoperative MRCP (n=18) exhibited a significant difference in the ratio of developing IC during follow-up (p=0.029). Among 15 patients with biliary stricture on ERCP, 5 showed progressive stricture or complications. Periportal DWI abnormality was significantly associated with a higher likelihood of progressive biliary stricture (p=0.007).

#### **CONCLUSION**

Postoperative DWI abnormalities demonstrate potential as a non-invasive imaging modality for predicting IC development and progression following ABOi-LT. Early identification of at-risk patients may facilitate timely interventions, potentially improving graft survival and patient outcomes.

#### **CLINICAL RELEVANCE/APPLICATION**

Postoperative diffusion-weighted imaging abnormalities of the bile duct can be used as a biomarker predicting ischemic cholangiopathy after ABO-incompatible liver transplantation.

### Differentiating between Benign and Malignant Ampullary Strictures: A Prediction Model using Contrast Enhanced MR Imaging and Clinical Findings

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N228

Jonghun Woo, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To construct a predictive nomogram for differentiating malignant from benign ampullary strictures using contrast-enhanced magnetic resonance imaging (MRI) findings combined with clinical findings.

#### METHODS AND MATERIALS

In this retrospective study, 76 patients with ampullary stricture (51 benign and 25 malignant) who underwent contrast-enhanced MRI were included. Various imaging findings of the ampulla, bile duct, main pancreatic duct, and periampullary area were evaluated and clinical findings including the presence of jaundice, carbohydrate antigen 19-9 level, and history of cholecystectomy were collected. Among them, statistically significant findings were identified using univariable and multivariable logistic regression analyses. A nomogram was constructed to differentiate benign and malignant ampullary strictures and was internally validated.

#### RESULTS

Multivariable analysis revealed that jaundice (odds ratio [OR]: 12.41,  $p = 0.019$ ), presence of ampullary mass (OR: 8.42,  $p = 0.047$ ), bulging ampulla (OR: 8.32,  $p = 0.033$ ), and diffusion restriction of the ampulla (OR: 42.76,  $p = 0.004$ ) were significant factors for predicting the presence of malignant ampullary stricture and were used to construct a nomogram. Among them, diffusion restriction of the ampulla showed the highest OR and predictor point on the nomogram. The calibration plots showed excellent agreement between the predicted probabilities and the actual rates of malignant ampullary strictures, on internal validation.

#### CONCLUSION

Combination of clinical and imaging findings could aid in predicting malignant ampullary strictures using significant findings of jaundice, presence of ampullary mass, bulging ampulla, and diffusion restriction of the ampulla. A predictive nomogram based on contrast-enhanced MR imaging findings combined with clinical findings can be useful for differentiating between benign and malignant ampullary strictures.

#### CLINICAL RELEVANCE/APPLICATION

The nomogram constructed using contrast-enhanced MRI and clinical findings could aid in predicting malignant ampullary strictures.

### Improvement of Diagnosis of Adjacent Organ Invasion of Extrahepatic Bile Duct Cancer by Adding Arterial and Delayed Phases

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N228

Eisuke Mukaida, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of our study was to clarify the role of dynamic computed tomography (CT) in the diagnosis of extrahepatic bile duct (EHD) cancer involving adjacent organs.

#### METHODS AND MATERIALS

This retrospective study included patients who were pathologically diagnosed with EHD cancer between January 2011 and December 2021 and had undergone dynamic contrast-enhanced CT before previous biliary intervention, surgery, or chemotherapy. For each patient, the mean CT values of the abdominal aorta, portal vein (PV), hepatic parenchyma, pancreatic parenchyma, and EHD cancer were measured during each phase. In patients who had undergone surgery, two radiologists independently reviewed the CT images in the portal, dual (adding arterial phase), and triple phases (adding delayed phase). Two radiologists assessed the biliary segment-wise longitudinal tumor extent, arterial and PV invasion, organ invasion, and regional lymph node metastasis on a five-point scale for each phase. The performances of the portal, dual, and triple phase images were compared using the sensitivity, specificity, and AUC of each reader's results for pathological diagnosis.

#### RESULTS

In total, 120 patients (mean age, 71.7±8.8; 84 males) were evaluated for CT values. Contrast peaks of EHD cancer, hepatic parenchyma, and PV were observed in the portal phase. Among them, 80 patients were evaluated on a five-point scale. The AUC of pancreatic, duodenal, and arterial invasion increased with the addition of the phase at each observer (observer 1, 0.79 to 0.93,  $p<0.01$ , 0.71 to 0.86,  $p=0.04$ , 0.74 to 0.99,  $p=0.02$ , respectively; observer 2, 0.88 to 0.96,  $p=0.01$ , 0.73 to 0.94,  $p<0.01$ , 0.80 to 0.99  $p=0.04$ , respectively). Statistically, the AUC for biliary segment-wise longitudinal tumor extent, hepatic, and PV invasion did not change with the addition phase.

#### CONCLUSION

Addition of the arterial and delayed phases increased the AUC of pancreatic, duodenal, and arterial invasion.

#### CLINICAL RELEVANCE/APPLICATION

Histological evaluation of patients with EHD cancer often reveals invasion of adjacent organs, which may lead to curative resection failure or early postoperative recurrence. Because the adjacent organs of EHD cancer vary according to the site of origin, the diagnostic performance of adjacent organ invasion may be influenced by contrast effects specific to that organ; however, no reports have been retrieved on this effect. Our results provide an important preoperative imaging strategy to achieve R0 resection of EHD cancer.

#### W3-SSGI13-1 **Quantitative DCE-MRI Parameters Combined with Apparent Diffusion Coefficient for Evaluation of T Stage in Resectable Gastric Adenocarcinoma**

Yan Liangliang (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the feasibility of dynamic contrast-enhanced magnetic resonance imaging quantitative DCE parameters combined with apparent diffusion coefficient (ADC) values for predicting T stage of gastric adenocarcinoma.

#### METHODS AND MATERIALS

95 patients with gastric adenocarcinoma who underwent DCE-MRI and DWI from April 2018 to January 2020 were retrospectively enrolled. The Kruskal Wallis test was used to compare differences in quantitative DCE parameters or ADC values between different T stages of gastric cancer (GC). Multivariate logistic regression was used to identify independent predictors of GC of T1 + 2, T3 + 4a stages or T1 + 2 + 3, T4a stages. ROC curves were used to determine the optimal parameters and diagnostic efficacy for predicting GC of T1 + 2, T3 + 4a stages or T1 + 2 + 3, T4a stages.

#### RESULTS

Quantitative DCE parameters Ktrans, Kep, and ADC values were useful in identifying different T stages of GC ( $p < 0.001$ ,  $0.002$ ,  $0.008$ , respectively). Ktrans, Kep, and ADC were independent risk factors for predicting GC of T1 + 2, T3 + 4a stages. The area under the curve, sensitivities, specificities of Ktrans, Kep, ADC, Ktrans + Kep + ADC were 0.769, 0.751, 0.731, 0.893; 80.0%, 70.0%, 80.0%, 74.7%; 70.7%, 74.7%, 65.3%, 90.0%, respectively. Meanwhile, Ktrans and ADC were independent risk factors for predicting GC of T1 + 2 + 3, T4a stages. The area under the curve, sensitivities, specificities of Ktrans, ADC, Ktrans + ADC were 0.709, 0.643, 0.782; 57.7%, 65.4%, 57.7%; 81.2%, 58.0%, 89.9%, respectively.

#### CONCLUSION

Quantitative DCE parameters combined with ADC values can be used to identify T stage of gastric adenocarcinoma.

#### CLINICAL RELEVANCE/APPLICATION

Quantitative DCE parameters combined with ADC values can be used to identify T stage of gastric adenocarcinoma, which provides a theoretical basis for evaluating the malignancy of gastric adenocarcinoma and the selection of treatment options.

#### W3-SSGI13-3 **Prediction of Epithelial-to-mesenchymal Transition Molecular Subtype using CT Radiomics in Gastric Cancer**

Chaeyoung Lim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Epithelial-to-mesenchymal transition (EMT) subtype gastric cancer (GC) is known to demonstrate extremely poor prognosis. The purpose of the research is to develop and evaluate a prediction model for identifying Epithelial-to-mesenchymal transition (EMT) subtype gastric cancer (GC) using computed tomography (CT) radiomics and clinicopathologic factors.

## METHODS AND MATERIALS

This retrospective study included 418 patients with GC who underwent primary resection and molecular subgroup analysis between October 1995 and May 2008. Using preoperative CT images, we extracted 1,223 CT radiomics features from the volume of interest on portal venous phase images. Radiomics features for the prediction model were selected based on a filter method with correlation matrix and variance inflation factor (VIF), and an embedded method with least absolute shrinkage and selection operator (LASSO). To develop the radiomics-based prediction model, patient data were randomly divided into development (70%) and validation (30%) datasets. We used logistic regression (LR) and random forest (RF) algorithms with 5 repeated 5-fold cross-validation for model development. The area under the curve (AUC) was calculated to evaluate their performances. Clinicopathologic factors were added to evaluate the increase in predictive performance.

## RESULTS

70 patients had EMT subtype GC and 348 patients with non-EMT subtype based on transcriptome analysis. There were 276 men (66.0%) with median age 59 (range: 24-86). The AUCs of the CT radiomics-based prediction models were 0.824 and 0.736 for development and testing, respectively, using LR, and 1.000 and 0.692 for development and testing, respectively, using RF. After adding clinicopathologic factors of age, tumor size, signet ring cell type, and Lauren classification, the AUCs of the models using LR were 0.849 and 0.840 for development and testing, respectively, and the AUCs of the models using RF were 1.000 and 0.827 for development and testing, respectively.

## CONCLUSION

Our study demonstrated that a prediction model using CT radiomics for the EMT subtype of GC showed good performance, and the addition of clinicopathologic factors improved its predictive performance.

## CLINICAL RELEVANCE/APPLICATION

CT radiomics and clinicopathologic factors can predict EMT subtype GC with good performance.

### **W3-SSGI13-4 Contrast-enhanced Computed Tomography-based Radiomics to Predict Resectability in Patients with Gastric Cancer Invading the Pancreas Treated with Neoadjuvant Chemotherapy**

Xiaoyi Chen, BS (*Presenter*) Nothing to Disclose

## PURPOSE

The pancreas is the most vulnerable to invasion by gastric cancer, and combined resection is extremely difficult and traumatic. However, the assessment of resectability during the available examinations is limited. The purpose of this study is to construct a radiomics model for predicting the resectability for the patients receiving neoadjuvant chemotherapy with gastric cancer invading the pancreas.

## METHODS AND MATERIALS

843 gastric cancer patients suspected of having the pancreas invaded from two centers between January 2018 and January 2023 were collected. All patients received neoadjuvant chemotherapy with capecitabine and oxaliplatin (XELOX), and were evaluated by the MDT team to recommend surgery based on the latest preoperative contrast-enhanced computed tomography (CE-CT). Patients were divided into radical resection (R0) and non-radical resection (NO-R0) group based on their medical and pathological records, with 602 (Center 1) and 241 (Center 2) patients in the training and validation groups, respectively. The radiomic features were extracted after segment the whole tumor and pancreatic regions in all the slices with the latest preoperative tri-phase CE-CT. Clinical model, tri-phase radiomics signatures and combined nomogram were constructed. Two methods were employed to achieve dimensionality reduction: (I) the Least Absolute Shrinkage and Selection Operator (LASSO); and (II) the Minimum Redundancy Maximum Relevance (mRMR) algorithms. We utilized Logistic regression, Support Vector Machine (SVM), Decision Tree and Adaptive Boosting tree (AdaBoost) algorithms as the machine learning classifiers. The performance of the models was evaluated by ROC, Decision Curve Analysis (DCA) and calibration curve.

## RESULTS

615 and 228 patients with R0 and NO-R0 were included. In the validation group, the AUC of the clinical model was 0.712 (95% CI: 0.654-0.770). The tri-phase radiomics features combined with the SVM algorithm was the best radiomics signature with an AUC of 0.806 (95% CI: 0.748-0.864). The nomogram was the best predictive model with an AUC of 0.862 (95% CI: 0.804-0.919). In the training and validation groups, the calibration and DCA curves of the nomogram showed satisfactory result.

## CONCLUSION

The nomogram has good accuracy and stability in distinguishing whether patients with gastric cancer invading the pancreas can undergo R0 after neoadjuvant chemotherapy.

## CLINICAL RELEVANCE/APPLICATION

Current guidance on resectability mainly relies on the surgeon's techniques and preoperative examinations. The radiomics model can provide a reference for the success rate and best timing of surgery.

### W3-SSGI13-6 **Diagnostic Value of MR on Metastatic Lymph Node after Neoadjuvant Therapy in Esophageal Squamous Cell Carcinoma: A Prospectively Comparative Study on Node-to-Node Basis**

Shuo Yan (*Presenter*) Nothing to Disclose

#### PURPOSE

To analyze the multiple features of lymph node on pre-treatment and preoperative esophageal MR and to establish a diagnostic model on node-to-node basis that could accurately diagnose the metastatic lymph nodes after NAC or NAC+ICI therapy.

#### METHODS AND MATERIALS

The medical records and pretreatment and preoperative esophageal MR images of 112 patients who underwent NAC or NAC+ICI combined radical esophagectomy between December 2020 and October 2022 were prospectively collected. Based on the node-to-node basis, comparison of MR, surgical findings and pathological findings of lymph nodes were conducted. The diagnostic efficacy of esophageal MR on metastatic lymph nodes was evaluated with pathology as the gold standard. The ROC curve was used to analyze the diagnostic accuracy of MR features, and the markers independently correlated to the risk of lymph node metastasis were analyzed by Logistic regression, and a multiparameter diagnostic model was established based on the results of Logistic regression. The pathological findings that could affect the diagnostic performance of MR multiparameter model were explored.

#### RESULTS

In the study of diagnostic performance of MR for metastatic lymph nodes after NAC or NAC+ICI treatment according to MR-surgery-pathology comparison on node-to-node basis, multivariate Logistic regression analysis showed that lymph node location based on the station of the Japanese Society for Esophageal Diseases (JSED), preoperative ring-like enhancement, degree of preoperative delayed enhancement, and increased DWI signal intensity after treatment were independent predictors for metastatic lymph nodes ( $p < 0.05$ ). The multiparameter combined model constructed with the above MR features showed good diagnostic performance, with an AUC of 0.82 (95% CI: 0.78-0.86), a sensitivity of 85.9% and a specificity of 64.9%. The diagnostic sensitivity of the MR model for metastatic lymph nodes elevated with the increase of size of lymph nodes, and the sensitivity were all over 75.0%. For patients with tumors of high or low risk of metastasis, the diagnostic accuracies of MR were all over 70.0%.

#### CONCLUSION

The combined diagnostic model based on multiparameter of pre-treatment and preoperative MR features could accurately identify metastatic lymph nodes of esophageal squamous cell carcinoma after NAC or NAC+ICI therapy.

## CLINICAL RELEVANCE/APPLICATION

A combination of MR features of lymph nodes could provide valuable information for the preoperative diagnosis of metastasis and N stage on node-to-node basis.

Printed on: 08/22/24

### Quantitative DCE-MRI Parameters Combined with Apparent Diffusion Coefficient for Evaluation of T Stage in Resectable Gastric Adenocarcinoma

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N227B

Yan Liangliang (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the feasibility of dynamic contrast-enhanced magnetic resonance imaging quantitative DCE parameters combined with apparent diffusion coefficient (ADC) values for predicting T stage of gastric adenocarcinoma.

#### METHODS AND MATERIALS

95 patients with gastric adenocarcinoma who underwent DCE-MRI and DWI from April 2018 to January 2020 were retrospectively enrolled. The Kruskal Wallis test was used to compare differences in quantitative DCE parameters or ADC values between different T stages of gastric cancer (GC). Multivariate logistic regression was used to identify independent predictors of GC of T1 + 2, T3 + 4a stages or T1 + 2 + 3, T4a stages. ROC curves were used to determine the optimal parameters and diagnostic efficacy for predicting GC of T1 + 2, T3 + 4a stages or T1 + 2 + 3, T4a stages.

#### RESULTS

Quantitative DCE parameters  $K_{trans}$ ,  $K_{ep}$ , and ADC values were useful in identifying different T stages of GC ( $p < 0.001$ ,  $0.002$ ,  $0.008$ , respectively).  $K_{trans}$ ,  $K_{ep}$ , and ADC were independent risk factors for predicting GC of T1 + 2, T3 + 4a stages. The area under the curve, sensitivities, specificities of  $K_{trans}$ ,  $K_{ep}$ , ADC,  $K_{trans} + K_{ep} + ADC$  were 0.769, 0.751, 0.731, 0.893; 80.0%, 70.0%, 80.0%, 74.7%; 70.7%, 74.7%, 65.3%, 90.0%, respectively. Meanwhile,  $K_{trans}$  and ADC were independent risk factors for predicting GC of T1 + 2 + 3, T4a stages. The area under the curve, sensitivities, specificities of  $K_{trans}$ , ADC,  $K_{trans} + ADC$  were 0.709, 0.643, 0.782; 57.7%, 65.4%, 57.7%; 81.2%, 58.0%, 89.9%, respectively.

#### CONCLUSION

Quantitative DCE parameters combined with ADC values can be used to identify T stage of gastric adenocarcinoma.

#### CLINICAL RELEVANCE/APPLICATION

Quantitative DCE parameters combined with ADC values can be used to identify T stage of gastric adenocarcinoma, which provides a theoretical basis for evaluating the malignancy of gastric adenocarcinoma and the selection of treatment options.

### Prediction of Epithelial-to-mesenchymal Transition Molecular Subtype using CT Radiomics in Gastric Cancer

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N227B

Chaeyoung Lim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Epithelial-to-mesenchymal transition (EMT) subtype gastric cancer (GC) is known to demonstrate extremely poor prognosis. The purpose of the research is to develop and evaluate a prediction model for identifying Epithelial-to-mesenchymal transition (EMT) subtype gastric cancer (GC) using computed tomography (CT) radiomics and clinicopathologic factors.

#### METHODS AND MATERIALS

This retrospective study included 418 patients with GC who underwent primary resection and molecular subgroup analysis between October 1995 and May 2008. Using preoperative CT images, we extracted 1,223 CT radiomics features from the volume of interest on portal venous phase images. Radiomics features for the prediction model were selected based on a filter method with correlation matrix and variance inflation factor (VIF), and an embedded method with least absolute shrinkage and selection operator (LASSO). To develop the radiomics-based prediction model, patient data were randomly divided into development (70%) and validation (30%) datasets. We used logistic regression (LR) and random forest (RF) algorithms with 5 repeated 5-fold cross-validation for model development. The area under the curve (AUC) was calculated to evaluate their performances. Clinicopathologic factors were added to evaluate the increase in predictive performance.

#### RESULTS

70 patients had EMT subtype GC and 348 patients with non-EMT subtype based on transcriptome analysis. There were 276 men (66.0%) with median age 59 (range: 24-86). The AUCs of the CT radiomics-based prediction models were 0.824 and 0.736 for development and testing, respectively, using LR, and 1.000 and 0.692 for development and testing, respectively, using RF. After adding clinicopathologic factors of age, tumor size, signet ring cell type, and Lauren classification, the AUCs of the models using LR were 0.849 and 0.840 for development and testing, respectively, and the AUCs of the models using RF were 1.000 and 0.827 for development and testing, respectively.

#### CONCLUSION

Our study demonstrated that a prediction model using CT radiomics for the EMT subtype of GC showed good performance, and the addition of clinicopathologic factors improved its predictive performance.

#### CLINICAL RELEVANCE/APPLICATION

CT radiomics and clinicopathologic factors can predict EMT subtype GC with good performance.

### Contrast-enhanced Computed Tomography-based Radiomics to Predict Resectability in Patients with Gastric Cancer Invading the Pancreas Treated with Neoadjuvant Chemotherapy

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N227B

Xiaoyi Chen, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

The pancreas is the most vulnerable to invasion by gastric cancer, and combined resection is extremely difficult and traumatic. However, the assessment of resectability during the available examinations is limited. The purpose of this study is to construct a radiomics model for predicting the resectability for the patients receiving neoadjuvant chemotherapy with gastric cancer invading the pancreas.

#### METHODS AND MATERIALS

843 gastric cancer patients suspected of having the pancreas invaded from two centers between January 2018 and January 2023 were collected. All patients received neoadjuvant chemotherapy with capecitabine and oxaliplatin (XELOX), and were evaluated by the MDT team to recommend surgery based on the latest preoperative contrast-enhanced computed tomography(CE-CT). Patients were divided into radical resection(R0) and non-radical resection (NO-R0) group based on their medical and pathological records, with 602 (Center 1) and 241 (Center 2) patients in the training and validation groups, respectively. The radiomic features were extracted after segment the whole tumor and pancreatic regions in all the slices with the latest preoperative tri-phase CE-CT. Clinical model, tri-phase radiomics signatures and combined nomogram were constructed. Two methods were employed to achieve dimensionality reduction: (I) the Least Absolute Shrinkage and Selection Operator (LASSO); and (II) the Minimum Redundancy Maximum Relevance (mRMR) algorithms. We utilized Logistic regression, Support Vector Machine (SVM), Decision Tree and Adaptive Boosting tree (AdaBoost) algorithms as the machine learning classifiers. The performance of the models was evaluated by ROC, Decision Curve Analysis (DCA) and calibration curve.

#### RESULTS

615 and 228 patients with R0 and NO-R0 were included. In the validation group, the AUC of the clinical model was 0.712 (95% CI: 0.654-0.770). The tri-phase radiomics features combined with the SVM algorithm was the best radiomics signature with an AUC of 0.806 (95% CI: 0.748-0.864). The nomogram was the best predictive model with an AUC of 0.862 (95% CI: 0.804-0.919). In the training and validation groups, the calibration and DCA curves of the nomogram showed satisfactory result.

#### CONCLUSION

The nomogram has good accuracy and stability in distinguishing whether patients with gastric cancer invading the pancreas can undergo R0 after neoadjuvant chemotherapy.

#### CLINICAL RELEVANCE/APPLICATION

Current guidance on resectability mainly relies on the surgeon's techniques and preoperative examinations. The radiomics model can provide a reference for the success rate and best timing of surgery.

### **Diagnostic Value of MR on Metastatic Lymph Node after Neoadjuvant Therapy in Esophageal Squamous Cell Carcinoma: A Prospectively Comparative Study on Node-to-Node Basis**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N227B

Shuo Yan (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To analyze the multiple features of lymph node on pre-treatment and preoperative esophageal MR and to establish a diagnostic model on node-to-node basis that could accurately diagnose the metastatic lymph nodes after NAC or NAC+ICI therapy.

#### **METHODS AND MATERIALS**

The medical records and pretreatment and preoperative esophageal MR images of 112 patients who underwent NAC or NAC+ICI combined radical esophagectomy between December 2020 and October 2022 were prospectively collected. Based on the node-to-node basis, comparison of MR, surgical findings and pathological findings of lymph nodes were conducted. The diagnostic efficacy of esophageal MR on metastatic lymph nodes was evaluated with pathology as the gold standard. The ROC curve was used to analyze the diagnostic accuracy of MR features, and the markers independently correlated to the risk of lymph node metastasis were analyzed by Logistic regression, and a multiparameter diagnostic model was established based on the results of Logistic regression. The pathological findings that could affect the diagnostic performance of MR multiparameter model were explored.

#### **RESULTS**

In the study of diagnostic performance of MR for metastatic lymph nodes after NAC or NAC+ICI treatment according to MR-surgery-pathology comparison on node-to-node basis, multivariate Logistic regression analysis showed that lymph node location based on the station of the Japanese Society for Esophageal Diseases (JSED), preoperative ring-like enhancement, degree of preoperative delayed enhancement, and increased DWI signal intensity after treatment were independent predictors for metastatic lymph nodes ( $p < 0.05$ ). The multiparameter combined model constructed with the above MR features showed good diagnostic performance, with an AUC of 0.82 (95% CI: 0.78-0.86), a sensitivity of 85.9% and a specificity of 64.9%. The diagnostic sensitivity of the MR model for metastatic lymph nodes elevated with the increase of size of lymph nodes, and the sensitivity were all over 75.0%. For patients with tumors of high or low risk of metastasis, the diagnostic accuracies of MR were all over 70.0%.

#### **CONCLUSION**

The combined diagnostic model based on multiparameter of pre-treatment and preoperative MR features could accurately identify metastatic lymph nodes of esophageal squamous cell carcinoma after NAC or NAC+ICI therapy.

#### **CLINICAL RELEVANCE/APPLICATION**

A combination of MR features of lymph nodes could provide valuable information for the preoperative diagnosis of metastasis and N stage on node-to-node basis.

#### **W3-SSGI14-1 Intravoxel Incoherent Motion Diffusion-Weighted Imaging (IVIM-DWI) of Pancreas for Non-invasive Assessment of $\beta$ -cell Dysfunction in Patients with Hyperglycemia**

Ping Liu, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

Approximately 50% of the  $\beta$ -cell function is impaired for most patients with type 2 diabetes mellitus (T2DM) at the time of diagnosis, and probably commences years before diagnosis. Early detection of damaged  $\beta$ -cell function may help provide timely protection and stop the final progression of patients with hyperglycemia to T2DM. Animal tests considered that the impaired  $\beta$ -cell function may be associated with the damaged pancreatic microstructure. The pancreatic microstructural changes may serve as the biomarker for  $\beta$ -cell dysfunction. Thus, we evaluate the microstructural changes of the pancreas in patients with hyperglycemia employing intravoxel incoherent motion diffusion-weighted imaging (IVIM-DWI) and explore the correlation between the imaging marker and the damage of  $\beta$ -cell function.

#### METHODS AND MATERIALS

60 hyperglycemic patients and 22 healthy controls were included. IVIM-DWI and the blood examination were performed, and calculated the  $\beta$ -cell function indexes. We divided patients into three grades according to diagnostic criteria, prediabetes (n= 10), T2DM diagnosed by isolated 2-h glucose increasing (n= 10), T2DM diagnosed by fasting and 2-h glucose increasing simultaneously (n= 40), and compared them with healthy controls. We observed the relationship between the imaging parameters with the  $\beta$ -cell function indexes and the diagnostic performance of the parameters for the grades of hyperglycemia.

#### RESULTS

The imaging parameters of ADC, Dt, and Dp gradually decreased among the groups, and the significant difference existed of them: ADC (p< 0.0001), Dt (p< 0.0001), Dp (p= 0.013). The optimal diagnostic performance of the parameters for differentiating the grades of hyperglycemia was Dt. There were some correlations between imaging metrics with  $\beta$ -cell function indexes (p< 0.05).

#### CONCLUSION

IVIM-DWI of pancreases is a reliable and non-invasive tool with great potential in detecting the early damaged  $\beta$ -cell function when the DM is still in the insidious stage, and help to avoid the development of hyperglycemia to DM.

#### CLINICAL RELEVANCE/APPLICATION

IVIM-DWI measurements can effectively detect the microstructure and microcirculation changes of the pancreas, which also can effectively distinguish T2DM from hyperglycemia. It may be a promising, noninvasive method for identifying the damaged  $\beta$ -cell function especially for patients with early-stage hyperglycemia but without obvious clinical manifestation or history of DM. And this could facilitate to timely prevent and effectively manage the T2DM.

#### **W3-SSGI14-2 Prediction of Microvascular Invasion and Vessels Encapsulated Tumor Clusters in Hepatocellular Carcinoma by Multi-frequency Magnetic Resonance Elastography: A Preliminary Study**

Lin Hui Zhong, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To explore the feasibility of multi-frequency magnetic resonance elastography (mf-MRE) for predicting microvascular invasion (MVI+) and further forecasting MVI+ combined vessels encapsulated tumor clusters (VETC+) (MVI+ VETC+) in hepatocellular carcinoma (HCC) patients.

## METHODS AND MATERIALS

The study protocol was approved by the local Research Ethics Committee. Informed consent was obtained from all subjects. A total of 328 patients with clinical proposed HCC were prospectively recruited and undergone conventional MRI and mf-MRE (the parameter presented in table 1) on 3.0T MRI, which were divided into two-class (Task 1: MVI+ vs MVI-; Task 2: MVI+ VETC+ vs no MVI+ VETC+) with the pathological findings (Fig 1). Patients' clinical data were collected, conventional MRI imaging features were evaluated, and  $c$  (m/s) and  $f$  (rad) were measured with mf-MRE in the tumor and background liver parenchyma. For above data, clinical model, radiomics model, mf-MRE model and all were developed to predict the task 1 and task 2 (Table 2,3). Predictive efficacy was evaluated using the area under the ROC curve (AUC). The clinical utility of the models was evaluated by decision curve analysis (DCA), and its calibration was evaluated (Fig 2,3).

## RESULTS

A total of 124 patients (MVI+ (n=49) vs MVI- (n=75); MVI+ VETC+ (n=29) vs no-MVI+ VETC+ (n=95) with postoperative pathologically confirmed HCC were included. For task1: Multifactorial logistic regression results showed that intratumoral artery, smoothness of tumor margin and tumor stiffness  $c$  were independent risk factors for MVI+ ( $P < 0.05$ ). The AUC values for Models A-B were 0.850 (0.788-0.911), 0.742 (0.655-0.829). Model C had the highest specificity (0.89), AUC value 0.911 (0.864-0.959), sensitivity and accuracy (0.86 and 0.82, respectively). For task2: Multifactorial logistic regression results showed that AFP, DCP and intratumoral artery were independent risk factors for MVI+ VETC+ ( $P < 0.05$ ). The AUC values for Models A-C were 0.773 (0.689-0.858), 0.709 (0.623-0.794) and 0.718 (0.612-0.824). Model D had the highest AUC value 0.854 (0.788-0.921) and sensitivity (0.97).

## CONCLUSION

The multi-frequency MRE mechanical parameters can predict MVI, MVI+ & VETC+ status preoperatively. Clinical, radiomics and mf-MRE combined model can enhance the prediction of MVI, MVI+ & VETC+ efficacy and had the most AUC.

## CLINICAL RELEVANCE/APPLICATION

The incorporation of multi-frequency MRE into routine sequences of liver MRI examinations is expected to be used to accurately predict MVI, VETC+/MVI+ status preoperatively, which can assist clinicians in determining treatment plans and provide more accurate protocols for risk stratification of patients with hepatocellular carcinoma after resection.

## W3-SSGI14-3 Amide Proton Transfer MRI for Treatment Response of Locally Advanced Rectal Cancer Following Neoadjuvant Chemotherapy and Radiation Therapy

Lan Zhang, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Precise evaluation of treatment response is the premise of the selection of the following treatment strategies for patients with locally advanced rectal cancer (LARC) after neoadjuvant chemotherapy and radiation therapy (NCRT). Unfortunately a recent meta-analysis concluded that the overall accuracy of MRI including T2-weighted images (T2WI) and diffusion-weighted images (DWI) was only 52%. For better evaluating treatment response of LARC after NCRT, a more accurate imaging biomarker is desirable. Amide proton transfer-weighted (APT<sub>w</sub>) imaging is a molecular MRI technique that generates image contrast based predominantly on the amide protons in mobile cellular proteins and peptides that are endogenous in tissue. We thus conducted the present study to determine whether APT<sub>w</sub> imaging is precise in evaluating treatment response of LARC after NCRT by comparing to T2WI and DWI.

## METHODS AND MATERIALS

Patients with histological diagnostic rectal cancer and clinical T3-4 or N+ were prospectively recruited into this institutional review board-approved study. All participants were scanned at 3.0T (Ingenia CX, Philips Healthcare, Best, the Netherlands) using standard rectal protocols (T1WI, T2WI, DWI, contrast-enhanced) and APT<sub>w</sub>-imaging at baseline and after NCRT, imaging parameters listed in Table 1. Total mesorectal excision was performed and pathological tumor regression stage (TRG) was evaluated. Two readers manually drew regions of interest (ROIs) on the APT maps by using a free and open software (3D slicer 5.0.3, NA-MIC, NAC, BIRN, NCIGT and the Slicer Community) and histogram analysis performed. Independent sample t test or Mann-Whitney U test, receiver operating characteristic (ROC) analysis with the area under the curve (AUC) were performed.

## RESULTS

Eight patients with tumors TRG0 and 26 patients with tumors TRG123, were included. The mean APT were significantly lower in TRG0 group than TRG123 ( $P = 0.043$ ). The AUC of the APT mean and T2WIDWI in predicting TRG0 tumors were 0.73 and 0.66. When specificity was maximized (both the APT and the T2WIDWI were required to have positive findings), the AUC of

the combined MRI diagnosis for TRG0 was 0.70. When sensitivity was maximized (either the APT or the T2WIDWI showed positive findings), the AUC for combined MRI was 0.77.

#### **CONCLUSION**

APTw imaging is precise in evaluating treatment response of LARC after NCRT, meanwhile combining APTw imaging and T2WIDWI is more potential.

#### **CLINICAL RELEVANCE/APPLICATION**

As a useful biomarker for evaluating treatment response of LARC after NCRT, APTw imaging may have great potential applications for the selection of treatment strategies.

### **W3-SSGI14-5 Deep Learning-based Super-resolution Algorithm Tailored to Partial Fourier Acquisitions for the Multi-arterial Phase Images: Improvement of the Image Quality to Assess the Small Hypervascular Hepatic Tumor on Gadoteric Acid-enhanced Liver MRI**

Sumin Yun, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To assess the impact of a deep learning-based super-resolution algorithm tailored to partial Fourier acquisitions for the multi arterial phase (AP) images in patients with small hypervascular hepatic tumor on gadoteric acid enhanced liver MRI.

#### **METHODS AND MATERIALS**

We retrospectively enrolled 55 patients (33 men, 22 women; mean age: 64.90 years) with clinically or pathologically confirmed hepatic hypervascular tumors between December 2022 and February 2023 with the following inclusion criteria: patients with hypervascular hepatic tumor (lesser than 3 cm) who performed multi AP gadoteric acid enhanced MRI. For the multi AP images, two radiologists analyzed and compared the image qualities between two image sets: standard T1 weighted VIBE image (VIBESD) and T1 weighted VIBE image reconstructed with deep learning-based super-resolution algorithm tailored to partial Fourier acquisitions (VIBEDL). Quantitative image analysis including signal to noise ratio (SNR), contrast to noise ratio (CNR) and noise was performed. We also performed qualitative assessment with Likert scale including motion artifact (MA), liver edge (LE), hepatic vessel clarity (HVC) and image quality (IQ). The average of the two reader's results was used for further analysis. The paired t-test was used for quantitative analysis, and the Wilcoxon rank sum test was used for qualitative analysis.

#### **RESULTS**

Finally, 55 patients were enrolled (33 patients, HCC; 4 patients, cholangiocarcinoma; 6 patients, metastases; 1 patient, hepatic adenoma; 3 patients, focal nodular hyperplasia; 8 patients, hemangioma). The SNR, CNR and noise were significantly improved in VIBEDL compared to VIBESD (SNR on AP1, 741.62 vs. 494.06; SNR on AP2, 839.51 vs. 506.92; CNR on AP1, 277.35 vs. 177.43; CNR on AP2, 320.39 vs. 180.51; noise on AP1, 0.53 vs. 0.82; noise on AP2, 0.51 vs. 0.87, all p-values < 0.05). The LE, HVC, and IQ were significantly improved in VIBEDL compared to VIBESD (LE on 1 st AP, 1.22 vs. 1.61; LE on 2 nd AP, 1.21 vs. 1.65; HVC on 1 st AP, 1.24 vs. 1.39; HVC on 2 nd AP, 1.20 vs. 1.53; IQ on 1 st AP, 1.17 vs. 1.45; IQ on 2 nd AP, 1.17 vs. 1.47, all p-values < 0.05). The MA was not statistically improved in VIBEDL compared to VIBESD (MA on 1 st AP, 1.12 vs. 1.15; MA on 2 nd AP, 1.16 vs. 1.18, p=0.18 and 0.16, respectively).

#### **CONCLUSION**

For gadoteric acid-enhanced liver MRI, VIBEDL can improve the quality of multi AP images in patients with small hypervascular hepatic tumor.

#### **CLINICAL RELEVANCE/APPLICATION**

The gadoteric acid enhanced MRI is an excellent tool but weak arterial enhancement is one of the weakness. VIBEDL was able to improve image quality. Especially, VIBEDL can overcome the weak arterial enhancement resulting in the increased CNR.

### **W3-SSGI14-6 Dilution and Slow Injection with Care Bolus Technique can Reduce Artifacts and Optimise Timing of Arterial-phase Gadoteric Acid-enhanced MRI: A Large-cohort Study**

Antonia Kristic, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the effect of dilution and slow injection of gadoteric acid (GA) using automated fluoroscopic triggering on liver MRI arterial-phase (AP) acquisition timing, artifact frequency, and lesion visibility.

#### **METHODS AND MATERIALS**

Saline-diluted 1:1 of 10 ml fixed-dose gadoteric acid was injected at 1 mL/s (total volume 20 ml) into 1985 consecutive patients for 3T liver MRI. Initially, one abdominal radiologist with 5 years of experience who did not participate in the analysis

assessed all MR exams, comparing them to previous and follow up images, as well as the radiology report on record. . This served as the standard of reference for lesion detection and characterization. Then, 3 readers independently evaluated the AP images for artifact type [truncation (TA), transient severe motion (TSM) or mixed], for artifact severity, acquisition timing and, if present, focal liver lesion visibility. AP artifact-severity impact on diagnostic performance was rated on a 5-point scale, AP acquisition timing on a 4-point scale, and AP visibility of = 5 mm hypervascular lesions on a 4-point scale. One reader assessed the presence of ascites, pleural effusions and cirrhosis

## **RESULTS**

A total of 1793 exams, (male =891 (49.7%), female =902 (50.3%)), with a mean age of 56.3 y, were included. Diagnostic-quality arterial-phase images included 1163 (67.8%) without artifacts, 415 (24.2%) with minimal, and 171 (9.8%) with moderate artifacts. Only 44 patients (2.5%) had non-diagnostic exams, 39 (2.2%) with severe AP artifacts and 5 (0.3%) with uninterpretable images. The inter-rater agreement between the three readers was substantial (Kappa =0.670,  $p<0.001$ ). AP acquisition timing was optimal in 1567 (91.3%) exams. In 366 (21.3%) exams there was ascites, in 319 (18.6%) pleural effusions and in 352 (20.5%) liver cirrhosis. Artifact occurrence was significantly higher with ascites ( $p=0.002$ ), pleural effusions ( $p<0.001$ ), and advanced age ( $p=0.006$ ).

## **CONCLUSION**

Combined dilution and slow injection of gadoxetic acid with MR-fluoroscopic triggering results in well-timed arterial-phase images and few severe- or non-diagnostic arterial-phase artifacts, 2.5%.

## **CLINICAL RELEVANCE/APPLICATION**

A fixed dose of 10 ml gadoxetic acid with 1:1 saline dilution injected at 1ml/s produces high-quality images with negligible AP artifacts.

### Prediction of Microvascular Invasion and Vessels Encapsulated Tumor Clusters in Hepatocellular Carcinoma by Multi-frequency Magnetic Resonance Elastography: A Preliminary Study

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N226

Lin Hui Zhong, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the feasibility of multi-frequency magnetic resonance elastography (mf-MRE) for predicting microvascular invasion (MVI+) and further forecasting MVI+ combined vessels encapsulated tumor clusters (VETC+) (MVI+ VETC+) in hepatocellular carcinoma (HCC) patients.

#### METHODS AND MATERIALS

The study protocol was approved by the local Research Ethics Committee. Informed consent was obtained from all subjects. A total of 328 patients with clinical proposed HCC were prospectively recruited and undergone conventional MRI and mf-MRE (the parameter presented in table 1) on 3.0T MRI, which were divided into two-class (Task 1: MVI+ vs MVI-; Task 2: MVI+ VETC+ vs no MVI+ VETC+) with the pathological findings (Fig 1). Patients' clinical data were collected, conventional MRI imaging features were evaluated, and  $c$  (m/s) and  $f$  (rad) were measured with mf-MRE in the tumor and background liver parenchyma. For above data, clinical model, radiomics model, mf-MRE model and all were developed to predict the task 1 and task 2 (Table 2,3). Predictive efficacy was evaluated using the area under the ROC curve (AUC). The clinical utility of the models was evaluated by decision curve analysis (DCA), and its calibration was evaluated (Fig 2,3).

#### RESULTS

A total of 124 patients (MVI+ (n=49) vs MVI- (n=75); MVI+ VETC+ (n=29) vs no-MVI+ VETC+ (n=95) with postoperative pathologically confirmed HCC were included. For task1: Multifactorial logistic regression results showed that intratumoral artery, smoothness of tumor margin and tumor stiffness  $c$  were independent risk factors for MVI+ ( $P < 0.05$ ). The AUC values for Models A-B were 0.850 (0.788-0.911), 0.742 (0.655-0.829). Model C had the highest specificity (0.89), AUC value 0.911 (0.864-0.959), sensitivity and accuracy (0.86 and 0.82, respectively). For task2: Multifactorial logistic regression results showed that AFP, DCP and intratumoral artery were independent risk factors for MVI+ VETC+ ( $P < 0.05$ ). The AUC values for Models A-C were 0.773 (0.689-0.858), 0.709 (0.623-0.794) and 0.718 (0.612-0.824). Model D had the highest AUC value 0.854 (0.788-0.921) and sensitivity (0.97).

#### CONCLUSION

The multi-frequency MRE mechanical parameters can predict MVI, MVI+ & VETC+ status preoperatively. Clinical, radiomics and mf-MRE combined model can enhance the prediction of MVI, MVI+ & VETC+ efficacy and had the most AUC.

#### CLINICAL RELEVANCE/APPLICATION

The incorporation of multi-frequency MRE into routine sequences of liver MRI examinations is expected to be used to accurately predict MVI, VETC+/MVI+ status preoperatively, which can assist clinicians in determining treatment plans and provide more accurate protocols for risk stratification of patients with hepatocellular carcinoma after resection.

### Amide Proton Transfer MRI for Treatment Response of Locally Advanced Rectal Cancer Following Neoadjuvant Chemotherapy and Radiation Therapy

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N226

Lan Zhang, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Precise evaluation of treatment response is the premise of the selection of the following treatment strategies for patients with locally advanced rectal cancer (LARC) after neoadjuvant chemotherapy and radiation therapy (NCRT). Unfortunately a recent meta-analysis concluded that the overall accuracy of MRI including T2-weighted images(T2WI) and diffusion-weighted images(DWI) was only 52%. For better evaluating treatment response of LARC after NCRT, a more accurate imaging biomarker is desirable. Amide proton transfer-weighted (APT<sub>w</sub>) imaging is a molecular MRI technique that generates image contrast based predominantly on the amide protons in mobile cellular proteins and peptides that are endogenous in tissue. We thus conducted the present study to determine whether APT<sub>w</sub> imaging is precise in evaluating treatment response of LARC after NCRT by comparing to T2WI and DWI.

#### METHODS AND MATERIALS

Patients with histological diagnostic rectal cancer and clinical T3-4 or N+ were prospectively recruited into this institutional review board-approved study. All participants were scanned at 3.0T (Ingenia CX, Philips Healthcare, Best, the Netherlands) using standard rectal protocols (T1WI, T2WI, DWI, contrast-enhanced) and APT<sub>w</sub>-imaging at baseline and after NCRT, imaging parameters listed in Table 1. Total mesorectal excision was performed and pathological tumor regression stage(TRG) was evaluated. Two readers manually drew regions of interest (ROIs) on the APT maps by using a free and open software (3D slicer 5.0.3, NA-MIC, NAC, BIRN, NCIGT and the Slicer Community) and histogram analysis performed. Independent sample t test or Mann-Whitney U test, receiver operating characteristic (ROC) analysis with the area under the curve (AUC) were performed.

#### RESULTS

Eight patients with tumors TRG0 and 26 patients with tumors TRG123, were included. The mean APT were significantly lower in TRG0 group than TRG123(P ,0.043). The AUC of the APT mean and T2WIDWI in predicting TRG0 tumors were 0.73 and 0.66. When specificity was maximized (both the APT and the T2WIDWI were required to have positive findings), the AUC of the combined MRI diagnosis for TRG0 was 0.70. When sensitivity was maximized (either the APT or the T2WIDWI showed positive findings), the AUC for combined MRI was 0.77.

#### CONCLUSION

APT<sub>w</sub> imaging is precise in evaluating treatment response of LARC after NCRT, meanwhile combining APT<sub>w</sub> imaging and T2WIDWI is more potential.

#### CLINICAL RELEVANCE/APPLICATION

As a useful biomarker for evaluating treatment response of LARC after NCRT, APT<sub>w</sub> imaging may have great potential applications for the selection of treatment strategies.

### Deep Learning-based Super-resolution Algorithm Tailored to Partial Fourier Acquisitions for the Multi-arterial Phase Images: Improvement of the Image Quality to Assess the Small Hypervascular Hepatic Tumor on Gadoteric Acid-enhanced Liver MRI

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N226

Sumin Yun, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the impact of a deep learning-based super-resolution algorithm tailored to partial Fourier acquisitions for the multi arterial phase (AP) images in patients with small hypervascular hepatic tumor on gadoteric acid enhanced liver MRI.

#### METHODS AND MATERIALS

We retrospectively enrolled 55 patients (33 men, 22 women; mean age: 64.90 years) with clinically or pathologically confirmed hepatic hypervascular tumors between December 2022 and February 2023 with the following inclusion criteria: patients with hypervascular hepatic tumor (lesser than 3 cm) who performed multi AP gadoteric acid enhanced MRI. For the multi AP images, two radiologists analyzed and compared the image qualities between two image sets: standard T1 weighted VIBE image (VIBESD) and T1 weighted VIBE image reconstructed with deep learning-based super-resolution algorithm tailored to partial Fourier acquisitions (VIBEDL). Quantitative image analysis including signal to noise ratio (SNR), contrast to noise ratio (CNR) and noise was performed. We also performed qualitative assessment with Likert scale including motion artifact (MA), liver edge (LE), hepatic vessel clarity (HVC) and image quality (IQ). The average of the two reader's results was used for further analysis. The paired t-test was used for quantitative analysis, and the Wilcoxon rank sum test was used for qualitative analysis.

#### RESULTS

Finally, 55 patients were enrolled (33 patients, HCC; 4 patients, cholangiocarcinoma; 6 patients, metastases; 1 patient, hepatic adenoma; 3 patients, focal nodular hyperplasia; 8 patients, hemangioma). The SNR, CNR and noise were significantly improved in VIBEDL compared to VIBESD (SNR on AP1, 741.62 vs. 494.06; SNR on AP2, 839.51 vs. 506.92; CNR on AP1, 277.35 vs. 177.43; CNR on AP2, 320.39 vs. 180.51; noise on AP1, 0.53 vs. 0.82; noise on AP2, 0.51 vs. 0.87, all p-values < 0.05). The LE, HVC, and IQ were significantly improved in VIBEDL compared to VIBESD (LE on 1 st AP, 1.22 vs. 1.61; LE on 2 nd AP, 1.21 vs. 1.65; HVC on 1 st AP, 1.24 vs. 1.39; HVC on 2 nd AP, 1.20 vs. 1.53; IQ on 1 st AP, 1.17 vs. 1.45; IQ on 2 nd AP, 1.17 vs. 1.47, all p-values < 0.05). The MA was not statistically improved in VIBEDL compared to VIBESD (MA on 1 st AP, 1.12 vs. 1.15; MA on 2 nd AP, 1.16 vs. 1.18, p=0.18 and 0.16, respectively).

#### CONCLUSION

For gadoteric acid-enhanced liver MRI, VIBEDL can improve the quality of multi AP images in patients with small hypervascular hepatic tumor.

#### CLINICAL RELEVANCE/APPLICATION

The gadoteric acid enhanced MRI is an excellent tool but weak arterial enhancement is one of the weakness. VIBEDL was able to improve image quality. Especially, VIBEDL can overcome the weak arterial enhancement resulting in the increased CNR.

### **Dilution and Slow Injection with Care Bolus Technique can Reduce Artifacts and Optimise Timing of Arterial-phase Gadoteric Acid-enhanced MRI: A Large-cohort Study**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: N226

Antonia Kristic, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the effect of dilution and slow injection of gadoteric acid (GA) using automated fluoroscopic triggering on liver MRI arterial-phase (AP) acquisition timing, artifact frequency, and lesion visibility.

#### **METHODS AND MATERIALS**

Saline-diluted 1:1 of 10 ml fixed-dose gadoteric acid was injected at 1 mL/s (total volume 20 ml) into 1985 consecutive patients for 3T liver MRI. Initially, one abdominal radiologist with 5 years of experience who did not participate in the analysis assessed all MR exams, comparing them to previous and follow up images, as well as the radiology report on record. This served as the standard of reference for lesion detection and characterization. Then, 3 readers independently evaluated the AP images for artifact type [truncation (TA), transient severe motion (TSM) or mixed], for artifact severity, acquisition timing and, if present, focal liver lesion visibility. AP artifact-severity impact on diagnostic performance was rated on a 5-point scale, AP acquisition timing on a 4-point scale, and AP visibility of = 5 mm hypervascular lesions on a 4-point scale. One reader assessed the presence of ascites, pleural effusions and cirrhosis

#### **RESULTS**

A total of 1793 exams, (male =891 (49.7%), female =902 (50.3%), with a mean age of 56.3 y, were included. Diagnostic-quality arterial-phase images included 1163 (67.8%) without artifacts, 415 (24.2%) with minimal, and 171 (9.8%) with moderate artifacts. Only 44 patients (2.5%) had non-diagnostic exams, 39 (2.2%) with severe AP artifacts and 5 (0.3%) with uninterpretable images. The inter-rater agreement between the three readers was substantial (Kappa =0.670,  $p < 0.001$ ). AP acquisition timing was optimal in 1567 (91.3%) exams. In 366 (21.3%) exams there was ascites, in 319 (18.6%) pleural effusions and in 352 (20.5%) liver cirrhosis. Artifact occurrence was significantly higher with ascites ( $p = 0.002$ ), pleural effusions ( $p < 0.001$ ), and advanced age ( $p = 0.006$ ).

#### **CONCLUSION**

Combined dilution and slow injection of gadoteric acid with MR-fluoroscopic triggering results in well-timed arterial-phase images and few severe- or non-diagnostic arterial-phase artifacts, 2.5%.

#### **CLINICAL RELEVANCE/APPLICATION**

A fixed dose of 10 ml gadoteric acid with 1:1 saline dilution injected at 1ml/s produces high-quality images with negligible AP artifacts.

### Genitourinary Imaging (Evolving Clinical Applications of Prostate MRI)

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E350

Sadhna Verma, MD (*Moderator*) Nothing to Disclose  
Sandeep S. Arora, MBBS (*Moderator*) Research support, Profound Medical Inc

#### Sub-Events

#### **W3-SSGU05-1 MRI for the Detection of Aggressive Prostate Cancer in Patients on Active Surveillance using the Precise Criteria: A Multicentre Study**

Francesco Giganti, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

The PRECISE recommendations provide a 1-to-5 scale to evaluate the radiological change on serial MRI in patients on active surveillance for prostate cancer: PRECISE 1-2 denotes radiological regression, PRECISE 3 indicates stability and PRECISE 4-5 implies progression. We present the data for the validation of the PRECISE scoring system as a tool to predict disease progression in a multi-centre international setting.

#### METHODS AND MATERIALS

We collected data from 22 centres across the world and applied two entry criteria: i) at least two scans (baseline and follow-up); ii) at least two biopsies (baseline and follow-up, the latter after the second MR). Local radiologists reported according to the PRECISE recommendations. Histological progression was defined as any increase in Gleason score from baseline biopsy (that could include only Gleason 3+3 or also low-risk Gleason 3+4 disease as per local institutional protocols). Progression-free survival (PFS) was estimated using Kaplan-Meier curves. Multivariable Cox hazards model tested the predictive role of PRECISE.

#### RESULTS

A total of 1,556 patients were included in this analysis, 1389 (89%) of which had Gleason 3+3 and 167 (11%) had Gleason 3+4 disease at baseline. Median follow-up was 48 months (IQR 26-75 months), and 513 (33%) patients experienced histological progression. For PRECISE 1-2 (n=158), PFS was 88% at two years and 77% at five years from first follow-up MRI, while for PRECISE 4-5 (n=413), PFS was 52% and 35%, respectively. In those patients with PRECISE 3 [stability] and visible lesions (n=597), 2- and 5-year PFS was 76% and 50%, while for PRECISE 3 [stability] and non-visible (NV) lesions (n=388), PFS was similar to PRECISE 1-2 (two- and five-year PFS: 91% and 80%; Log Rank  $p < 0.001$ ). At multivariable analysis, PRECISE 4-5 remained an independent predictor of histological progression (hazard ratio 2.63, 95% CI 1.82-3.79;  $p < 0.0001$ ).

#### CONCLUSION

Our work has validated a new MRI-based scoring system to assess disease progression during AS internationally and will contribute to the creation of a risk model that incorporates both clinical and radiological data to fully benefit from prostate MRI and targeted biopsies. This will help identify the number of patients on AS with more aggressive disease and a higher likelihood of developing advanced prostate cancer in a timely manner.

#### CLINICAL RELEVANCE/APPLICATION

PRECISE can contribute to the creation of a risk model that incorporates both clinical and radiological data.

#### **W3-SSGU05-2 MRI-guided Active Surveillance without Re-biopsies in Patients with ISUP Grade Group 1 and 2 Prostate Cancer -The PROMM-AS Study**

Birte Valentin, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the ability of mpMRI to reduce guideline-mandated biopsy and to predict ISUP grade group upgrading in patients with ISUP1 and ISUP2 PC. Using this MR-guided pathway, AS disqualification rate thought to be reduced to 15%.

## METHODS AND MATERIALS

In this prospective single-center cohort study patients with ISUP GG 1 and 2 PC after MRI/TRUS fusion-guided biopsy were included and the 2-year outcome of an mpMRI-guided AS protocol (PROMM-AS) were analyzed. All men underwent mpMRI 12 months after inclusion. In case of stable mpMRI according to PRECISE criteria, re-biopsy was deferred and follow-up mpMRI after 24 months performed. In case of mpMRI progression or at the end of study, follow-up MRI/TRUS fusion-guided biopsy was indicated. Sensitivity, specificity, positive (PPV) and negative predictive values (NPV) for ISUP GG upgrading on MRI were calculated and regression analyses were performed.

## RESULTS

In total, 101 patients (60 with ISUP1 and 41 with ISUP2) were analyzed. Histopathological progression occurred in total in 29 patients. Thus, the aim of reducing AS disqualification to 15% could not be reached. In the ISUP1 subgroup, 18 patients had progression, whereas 11 patients progressed in ISUP2 subgroup. Sensitivity, specificity, PPV and NPV for PRECISE was 94%, 64%, 81% and 88% in the ISUP1 and 92%, 50%, 92% and 50% in ISUP2 subgroup, respectively. On regression analysis, initial PSA ( $p < 0.001$ ), and higher PRECISE scores (4-5) ( $p = 0.005$ ) were significant predictors of histological progression in ISUP1 and higher PRECISE score ( $p = 0.009$ ), initial PI-RADS ( $p = 0.009$ ), previous negative biopsy ( $p = 0.02$ ) and percentage of Gleason pattern 4 ( $p = 0.04$ ) in ISUP2 PC.

## CONCLUSION

MRI-guided monitoring of patients on AS including PRECISE criteria avoids unnecessary follow-up biopsies in 88% of patients with ISUP1 and predicts grade group upgrading over a follow-up period of 2 years in both ISUP1 and ISUP2.

## CLINICAL RELEVANCE/APPLICATION

Avoidance of unnecessary follow-up biopsies as well as prediction of grade group upgrade in patients undergoing AS by MRI-guided monitoring.

## W3-SSGU05-3 Magnetic Resonance Imaging-Led Active Surveillance for Prostate Cancer: Outcomes From a Large Cohort Study

Cameron Englman, BSc, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Active surveillance (AS) is a management option for low- and favourable intermediate-risk prostate cancer (PCa) that includes prostate-specific antigen (PSA) monitoring, MRI, and follow-up biopsies. We report on the clinical, histological, and radiological outcomes from our MRI-led AS cohort.

## METHODS AND MATERIALS

A total of 1,019 patients were enrolled in our AS programme between June 1997 and September 2022. Inclusion criteria include low-risk Gleason score (GS) 3+3 or favourable intermediate-risk GS 3+4 PCa at entry, PSA  $< 20$ ng/ml, and at least two MR scans (baseline and follow-up). Primary outcomes were: i) event-free survival (EFS) defined as a transition to treatment or watchful waiting, histological upgrade to GS 4+3 or higher, or death; ii) treatment-free survival (TFS). Secondary outcomes included the rates of all-cause mortality, PCa-related mortality, transition to treatment, radiological progression, and histological upgrade. We used Kaplan-Meier curves, log-rank tests, t-tests, and one-way analysis of variance.

## RESULTS

The cohort consisted of 6,179 total person-years of follow-up (median = 68 months). Overall EFS and TFS were significantly lower for patients with GS 3+4 and MR-visible (V) disease at baseline (log-rank test:  $p < 0.001$ ). The five-year rates were similar for patients with GS 3+3, V and GS 3+4, non-visible (NV) disease at baseline. The rate of all-cause mortality was low (4.7 deaths/1,000 person-years) with no deaths related to PCa, and the overall survival rate was high (97.2%). In total, 287 patients (28%) were treated (46.4 patients/1000 person-years) with radical treatment ( $n = 143$ ), focal therapy ( $n = 130$ ), hormone deprivation ( $n = 17$ ), or watchful waiting ( $n = 18$ ). There was a significant difference in the percentage of patients experiencing radiological progression in those with a visible lesion and higher GS at baseline (GS 3+3, NV = 98/358 [27.4%]; GS 3+3, V = 123/344 [35.7%]; GS 3+4, NV = 37/137 [27.2%]; GS 3+4, V = 72/180 [40%];  $p = 0.003$ ) and histological upgrade (GS 3+3, NV = 8/358 [2.2%]; GS 3+3, V = 13/344 [3.8%]; GS 3+4, NV = 7/137 [5.1%]; GS 3+4, V = 13/180 [7.2%];  $p = 0.042$ ).

## CONCLUSION

The rates of survival and initiation-of-treatment in our MR-led AS cohort were comparable to published data from mandated protocol based-biopsy during AS, suggesting that such an approach (stable MRI and PSA kinetics) can safely defer or omit follow-up biopsy.

## CLINICAL RELEVANCE/APPLICATION

This is the largest single-centre cohort study of patients undergoing MRI-led AS to date. The rates for survival and treatment were comparable to AS regimes that utilise protocol-mandated follow-up biopsies. Patients on AS can be safely monitored with MRI and the decision to biopsy can be based according to MRI findings and PSA (including PSA density) kinetics.

### **W3-SSGU05-4 Magnetic Resonance Imaging PI-RADS Score as an Independent Predictor of Active Surveillance Prostate Cancer Outcome: Data from the Large Cohort Michigan Urological Surgery Improvement Collaborative (MUSIC)**

Kiran R. Nandalur, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The active surveillance decision-making process for prostate cancer typically involves PSA and Gleason score, with MRI utilization becoming increasingly common. The purpose of our study was to evaluate the association of baseline MRI findings with surveillance outcomes of 1) treatment-free survival and 2) high-grade prostate cancer-free survival.

#### **METHODS AND MATERIALS**

We identified men in the Michigan Urological Surgery Improvement Collaborative database (46 hospital based/academic/private practice urology groups) with National Comprehensive Cancer Network (NCCN) very low/low (low) risk and favorable intermediate risk prostate cancer who underwent MRI within 3 months of initial biopsy and enrolled in active surveillance (AS) from June 2016 to June 2020. The primary objective was to determine the association of MRI PI-RADS score (positive result defined as =4 lesion) with treatment-free survival, defined as definitive treatment. Secondary outcome was reclassification to high-grade prostate cancer (=grade group 3) on surveillance biopsy. Multivariable Cox proportional hazards regression models were constructed and adjusted for pathologic, clinical, and demographic factors. Subset analysis was performed for biopsy-based genomic score, if available.

#### **RESULTS**

Total of 2374 men were included with median age 64.4 years (interquartile range (IQ) 59.0-70.0) with median follow-up 31.6 months (IQ: 19.0-43.0). Approximately 81.5% and 68.0% of patients remained on AS at 3 and 5 yr, respectively. For the entire cohort, PI-RADS=4 lesion was associated with an increased risk of definitive therapy (hazard ratio (HR) 2.21 (95% confidence interval (CI): 1.80-2.71,  $p < 0.0001$ ) and biopsy reclassification (HR 1.98 (95% CI: 1.37-2.85,  $p = 0.0003$ ) on multivariable analysis. For low-risk prostate cancer patients ( $n = 1840$ ), PI-RADS=4 lesion was associated with an increased risk of definitive therapy (HR 2.25 (95% CI: 1.76-2.89,  $p < 0.0001$ ) and biopsy reclassification (HR 2.29 (95% CI: 1.44-3.64,  $p = 0.0005$ ). For favorable intermediate risk prostate cancer patients ( $n = 534$ ), PI-RADS=4 lesion was associated with an increased risk of definitive therapy (HR 2.04 (95% CI: 1.43-2.91,  $p < 0.0001$ ) but not biopsy reclassification ( $p = 0.09$ ). Genomic score showed no significant association with definitive therapy or biopsy reclassification.

#### **CONCLUSION**

In this large, multicenter cohort study, upfront MRI PI-RADS score was a significant independent predictor of definitive treatment and biopsy reclassification in men undergoing active surveillance for prostate cancer.

## CLINICAL RELEVANCE/APPLICATION

Baseline MRI PI-RADS score may help tailor the intensity of surveillance testing for men on active surveillance for prostate cancer.

### **W3-SSGU05-5 A Novel Integration of Multiparametric MRI-based Deep Learning Classifier and Clinical Parameters to Improve Long-term Prediction of Postoperative Biochemical Recurrence-Free Survival of Prostate Cancer**

Min Je Kim, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Biochemical recurrence (BCR) following radical prostatectomy (RP) remains the first sign of aggressive disease, hence, a better assessment of the likelihood of long-term post-RP BCR-free survival is crucial. We aimed to evaluate the potential of a combined clinical-deep learning (DL) model for predicting postoperative BCR-free survival in men with prostate cancer (PCa).

#### **METHODS AND MATERIALS**

Between 2008 and 2009, 437 patients with PCa from a single institution who underwent 3 Tesla multiparametric MRI (mpMRI) followed by RP were included in this retrospective study. Radiomics features were extracted from T2 weighted imaging, apparent diffusion coef& 7;cient maps, and dynamic contrast-enhanced imaging that manually delineated the index tumors on mpMRI. Radiomic signatures (RM-Multi) were built using radiomics features on the training set, and the integrated models (CRM-Multi) were built by adding the clinical characteristics with a stratified five-fold cross-validation. The Cox proportional-hazards model used deep features of mpMRI derived from a newly curated deep neural network (an

EfficientNetB0 network pretrained with large-scale natural images) for long-term BCR-free survival prediction following RP. A DL model (DLM-deep feature) and a clinical-DL combined model (CDLM-deep feature) were constructed. We compared the prognostic performance and clinical benefit of various models for BCR-free survival following RP.

## RESULTS

With a median follow-up of 61 months, 110 of 437 (25.2%) patients experienced BCR. The DLM-deep features yielded a higher hazard ratio (HR) (4.37, 95% confidence interval (CI) 0.00-8.83,  $P=0.0219$ ), concordance index (C-index) (0.74, 95% CI 0.59-0.88), and integrated time-dependent area under the curve (iAUC) 0.77 than RM-Multi (HR 2.73, 95% CI 0.39-5.06,  $P=0.68$ ; C-index 0.66, 95% CI 0.57-0.76, and iAUC 0.68). Most importantly, the combined model incorporating DL-based deep features and clinical risk factors (CDLM-Deep feature) achieved the best performance with an HR (7.72, 95% CI 1.24-14.19,  $P=0.0008$ ), C-index (0.89, 95% CI 0.65-0.88), and iAUC 0.93, while the radiomics model incorporating clinical variables (CRM-Multi) demonstrated only moderate predictive power (HR 5.59, 95% CI 3.38-7.79,  $P=0.0007$ ; C-index 0.83, 95% CI 0.72-0.93, iAUC 0.87).

## CONCLUSION

We demonstrated the high performance of integrating deep features from original mpMRI using a radiomic DL approach with the clinicopathological risk factors to predict the long-term BCR-free survival following RP in patients with PCa.

## CLINICAL RELEVANCE/APPLICATION

Our novel DL risk model could facilitate prognostication based on routine prostate mpMRI, facilitating patient stratification following RP and individualized postoperative management.

### W3-SSGU05-6 Can a Biparametric MRI-based AI Model Assist in Detecting Locally Recurrent Prostate Cancer in Post-radiotherapy Patients?

Enis C. Yilmaz, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the performance of a biparametric MRI (bpMRI)-based artificial intelligence (AI) model in detecting local recurrence in patients who received radiotherapy for prostate cancer (PCa).

## METHODS AND MATERIALS

This retrospective study included patients under investigation for PCa recurrence after definitive radiotherapy who were scanned at mpMRI and underwent MRI/US fusion-guided and/or systematic biopsy. An expert genitourinary radiologist prospectively read each case prior to the biopsy sessions utilizing all multiparametric MRI sequences including dynamic contrast enhanced MRI. All scans were evaluated by an automated prostate lesion detection model which was developed on a multi-institutional dataset of 1240 treatment-naïve patients on bpMRI. The AI model's recurrent cancer detection rate was compared to the radiologist read using the Wald test with biopsy outcomes serving as ground truth. Subgroup analyses were conducted based on radiotherapy technique (external beam radiation treatment [EBRT] or brachytherapy) and prostate volume quartiles to investigate the impact of these factors on AI model performance.

## RESULTS

Sixty-two patients (median age, 70; interquartile range [IQR], 65-75 years) with a median prostate volume of 27.55 mL (IQR, 21-34 mL) were included. A total of 56 cancer foci were identified in 46 patients in histopathological assessment. The AI model identified 40 cancer foci in 35 patients and achieved a sensitivity of 76.1% (35/46) and 71.4% (40/56) on patient- and lesion-level, respectively. The radiologist PCa detection performance was higher than the AI model on both patient-level (91.3% versus 76.1%,  $P=0.02$ ) and lesion-level (87.5% versus 71.4%,  $P=0.01$ ). The mean number of false positive calls of the AI model and the radiologist were 0.35 (range: 0-2) and 0.34 (range: 0-2), respectively. The AI performed better in the post-EBRT subgroup as compared to the post-brachytherapy subgroup on both patient-level (EBRT: 81.5% [22/27] vs. brachytherapy: 68.4% [13/19]) and lesion-level (EBRT: 79.4% [27/34] vs. brachytherapy: 59.1% [13/22]). The sensitivity of the AI was numerically best in the quartile of largest prostate volumes (>34 mL) with a patient- and lesion-level sensitivity of 100% ( $n=11/11$ ) and 94.1% ( $n=16/17$ ), respectively.

## CONCLUSION

A bpMRI-based AI model can be used to detect the majority of histopathologically verified recurrent PCa lesions after radiotherapy. AI performance was better among patients with larger glands and those who received EBRT.

## CLINICAL RELEVANCE/APPLICATION

An automated prostate lesion detection tool was able to identify most of the locally recurrent PCa in post-radiotherapy patients without utilizing dynamic contrast enhanced MRI.

## Abstract Archives of the RSNA, 2023

W3-SSGU05-1

### **MRI for the Detection of Aggressive Prostate Cancer in Patients on Active Surveillance using the Precise Criteria: A Multicentre Study**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E350

Francesco Giganti, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The PRECISE recommendations provide a 1-to-5 scale to evaluate the radiological change on serial MRI in patients on active surveillance for prostate cancer: PRECISE 1-2 denotes radiological regression, PRECISE 3 indicates stability and PRECISE 4-5 implies progression. We present the data for the validation of the PRECISE scoring system as a tool to predict disease progression in a multi-centre international setting.

#### **METHODS AND MATERIALS**

We collected data from 22 centres across the world and applied two entry criteria: i) at least two scans (baseline and follow-up); ii) at least two biopsies (baseline and follow-up, the latter after the second MR). Local radiologists reported according to the PRECISE recommendations. Histological progression was defined as any increase in Gleason score from baseline biopsy (that could include only Gleason 3+3 or also low-risk Gleason 3+4 disease as per local institutional protocols). Progression-free survival (PFS) was estimated using Kaplan-Meier curves. Multivariable Cox hazards model tested the predictive role of PRECISE.

#### **RESULTS**

A total of 1,556 patients were included in this analysis, 1389 (89%) of which had Gleason 3+3 and 167 (11%) had Gleason 3+4 disease at baseline. Median follow-up was 48 months (IQR 26-75 months), and 513 (33%) patients experienced histological progression. For PRECISE 1-2 (n=158), PFS was 88% at two years and 77% at five years from first follow-up MRI, while for PRECISE 4-5 (n=413), PFS was 52% and 35%, respectively. In those patients with PRECISE 3 [stability] and visible lesions (n=597), 2- and 5-year PFS was 76% and 50%, while for PRECISE 3 [stability] and non-visible (NV) lesions (n=388), PFS was similar to PRECISE 1-2 (two- and five-year PFS: 91% and 80%; Log Rank  $p < 0.001$ ). At multivariable analysis, PRECISE 4-5 remained an independent predictor of histological progression (hazard ratio 2.63, 95% CI 1.82-3.79;  $p < 0.0001$ ).

#### **CONCLUSION**

Our work has validated a new MRI-based scoring system to assess disease progression during AS internationally and will contribute to the creation of a risk model that incorporates both clinical and radiological data to fully benefit from prostate MRI and targeted biopsies. This will help identify the number of patients on AS with more aggressive disease and a higher likelihood of developing advanced prostate cancer in a timely manner.

#### **CLINICAL RELEVANCE/APPLICATION**

PRECISE can contribute to the creation of a risk model that incorporates both clinical and radiological data.

### **MRI-guided Active Surveillance without Re-biopsies in Patients with ISUP Grade Group 1 and 2 Prostate Cancer -The PROMM-AS Study**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E350

Birte Valentin, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To assess the ability of mpMRI to reduce guideline-mandated biopsy and to predict ISUP grade group upgrading in patients with ISUP1 and ISUP2 PC. Using this MR-guided pathway, AS disqualification rate thought to be reduced to 15%.

#### **METHODS AND MATERIALS**

In this prospective single-center cohort study patients with ISUP GG 1 and 2 PC after MRI/TRUS fusion-guided biopsy were included and the 2-year outcome of an mpMRI-guided AS protocol (PROMM-AS) were analyzed. All men underwent mpMRI 12 months after inclusion. In case of stable mpMRI according to PRECISE criteria, re-biopsy was deferred and follow-up mpMRI after 24 months performed. In case of mpMRI progression or at the end of study, follow-up MRI/TRUS fusion-guided biopsy was indicated. Sensitivity, specificity, positive (PPV) and negative predictive values (NPV) for ISUP GG upgrading on MRI were calculated and regression analyses were performed.

#### **RESULTS**

In total, 101 patients (60 with ISUP1 and 41 with ISUP2) were analyzed. Histopathological progression occurred in total in 29 patients. Thus, the aim of reducing AS disqualification to 15% could not be reached. In the ISUP1 subgroup, 18 patients had progression, whereas 11 patients progressed in ISUP2 subgroup. Sensitivity, specificity, PPV and NPV for PRECISE was 94%, 64%, 81% and 88% in the ISUP1 and 92%, 50%, 92% and 50% in ISUP2 subgroup, respectively. On regression analysis, initial PSA ( $p < 0.001$ ), and higher PRECISE scores (4-5) ( $p = 0.005$ ) were significant predictors of histological progression in ISUP1 and higher PRECISE score ( $p = 0.009$ ), initial PI-RADS ( $p = 0.009$ ), previous negative biopsy ( $p = 0.02$ ) and percentage of Gleason pattern 4 ( $p = 0.04$ ) in ISUP2 PC.

#### **CONCLUSION**

MRI-guided monitoring of patients on AS including PRECISE criteria avoids unnecessary follow-up biopsies in 88% of patients with ISUP1 and predicts grade group upgrading over a follow-up period of 2 years in both ISUP1 and ISUP2.

#### **CLINICAL RELEVANCE/APPLICATION**

Avoidance of unnecessary follow-up biopsies as well as prediction of grade group upgrade in patients undergoing AS by MRI-guided monitoring.

### Magnetic Resonance Imaging-Led Active Surveillance for Prostate Cancer: Outcomes From a Large Cohort Study

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E350

Cameron Englman, BSc, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Active surveillance (AS) is a management option for low- and favourable intermediate-risk prostate cancer (PCa) that includes prostate-specific antigen (PSA) monitoring, MRI, and follow-up biopsies. We report on the clinical, histological, and radiological outcomes from our MRI-led AS cohort.

#### METHODS AND MATERIALS

A total of 1,019 patients were enrolled in our AS programme between June 1997 and September 2022. Inclusion criteria include low-risk Gleason score (GS) 3+3 or favourable intermediate-risk GS 3+4 PCa at entry, PSA <20ng/ml, and at least two MR scans (baseline and follow-up). Primary outcomes were: i) event-free survival (EFS) defined as a transition to treatment or watchful waiting, histological upgrade to GS 4+3 or higher, or death; ii) treatment-free survival (TFS). Secondary outcomes included the rates of all-cause mortality, PCa-related mortality, transition to treatment, radiological progression, and histological upgrade. We used Kaplan-Meier curves, log-rank tests, t-tests, and one-way analysis of variance.

#### RESULTS

The cohort consisted of 6,179 total person-years of follow-up (median = 68 months). Overall EFS and TFS were significantly lower for patients with GS 3+4 and MR-visible (V) disease at baseline (log-rank test:  $p < 0.001$ ). The five-year rates were similar for patients with GS 3+3, V and GS 3+4, non-visible (NV) disease at baseline. The rate of all-cause mortality was low (4.7 deaths/1,000 person-years) with no deaths related to PCa, and the overall survival rate was high (97.2%). In total, 287 patients (28%) were treated (46.4 patients/1000 person-years) with radical treatment ( $n=143$ ), focal therapy ( $n=130$ ), hormone deprivation ( $n=17$ ), or watchful waiting ( $n=18$ ). There was a significant difference in the percentage of patients experiencing radiological progression in those with a visible lesion and higher GS at baseline (GS 3+3, NV = 98/358 [27.4%]; GS 3+3, V = 123/344 [35.7%]; GS 3+4, NV = 37/137 [27.2%]; GS 3+4, V = 72/180 [40%];  $p=0.003$ ) and histological upgrade (GS 3+3, NV = 8/358 [2.2%]; GS 3+3, V = 13/344 [3.8%]; GS 3+4, NV = 7/137 [5.1%]; GS 3+4, V = 13/180 [7.2%];  $p=0.042$ ).

#### CONCLUSION

The rates of survival and initiation-of-treatment in our MR-led AS cohort were comparable to published data from mandated protocol based-biopsy during AS, suggesting that such an approach (stable MRI and PSA kinetics) can safely defer or omit follow-up biopsy.

#### CLINICAL RELEVANCE/APPLICATION

This is the largest single-centre cohort study of patients undergoing MRI-led AS to date. The rates for survival and treatment were comparable to AS regimes that utilise protocol-mandated follow-up biopsies. Patients on AS can be safely monitored with MRI and the decision to biopsy can be based according to MRI findings and PSA (including PSA density) kinetics.

### **Magnetic Resonance Imaging PI-RADS Score as an Independent Predictor of Active Surveillance Prostate Cancer Outcome: Data from the Large Cohort Michigan Urological Surgery Improvement Collaborative (MUSIC)**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E350

Kiran R. Nandalur, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The active surveillance decision-making process for prostate cancer typically involves PSA and Gleason score, with MRI utilization becoming increasingly common. The purpose of our study was to evaluate the association of baseline MRI findings with surveillance outcomes of 1) treatment-free survival and 2) high-grade prostate cancer-free survival.

#### **METHODS AND MATERIALS**

We identified men in the Michigan Urological Surgery Improvement Collaborative database (46 hospital based/academic/private practice urology groups) with National Comprehensive Cancer Network (NCCN) very low/low (low risk and favorable intermediate risk prostate cancer who underwent MRI within 3 months of initial biopsy and enrolled in active surveillance (AS) from June 2016 to June 2020. The primary objective was to determine the association of MRI PI-RADS score (positive result defined as =4 lesion) with treatment-free survival, defined as definitive treatment. Secondary outcome was reclassification to high-grade prostate cancer (=grade group 3) on surveillance biopsy. Multivariable Cox proportional hazards regression models were constructed and adjusted for pathologic, clinical, and demographic factors. Subset analysis was performed for biopsy-based genomic score, if available.

#### **RESULTS**

Total of 2374 men were included with median age 64.4 years (interquartile range (IQ) 59.0-70.0) with median follow-up 31.6 months (IQ: 19.0-43.0). Approximately 81.5% and 68.0% of patients remained on AS at 3 and 5 yr, respectively. For the entire cohort, PI-RADS=4 lesion was associated with an increased risk of definitive therapy (hazard ratio (HR) 2.21 (95% confidence interval (CI): 1.80-2.71,  $p<0.0001$ ) and biopsy reclassification (HR 1.98 (95% CI: 1.37-2.85,  $p=0.0003$ ) on multivariable analysis. For low-risk prostate cancer patients ( $n=1840$ ), PI-RADS=4 lesion was associated with an increased risk of definitive therapy (HR 2.25 (95% CI: 1.76-2.89,  $p<0.0001$ ) and biopsy reclassification (HR 2.29 (95%CI: 1.44-3.64,  $p=0.0005$ ). For favorable intermediate risk prostate cancer patients ( $n=534$ ), PI-RADS=4 lesion was associated with an increased risk of definitive therapy (HR 2.04 (95% CI: 1.43-2.91,  $p<0.0001$ ) but not biopsy reclassification ( $p=0.09$ ). Genomic score showed no significant association with definitive therapy or biopsy reclassification.

#### **CONCLUSION**

In this large, multicenter cohort study, upfront MRI PI-RADS score was a significant independent predictor of definitive treatment and biopsy reclassification in men undergoing active surveillance for prostate cancer.

#### **CLINICAL RELEVANCE/APPLICATION**

Baseline MRI PI-RADS score may help tailor the intensity of surveillance testing for men on active surveillance for prostate cancer.

### **A Novel Integration of Multiparametric MRI-based Deep Learning Classifier and Clinical Parameters to Improve Long-term Prediction of Postoperative Biochemical Recurrence-Free Survival of Prostate Cancer**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E350

Min Je Kim, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Biochemical recurrence (BCR) following radical prostatectomy (RP) remains the first sign of aggressive disease, hence, a better assessment of the likelihood of long-term post-RP BCR-free survival is crucial. We aimed to evaluate the potential of a combined clinical-deep learning (DL) model for predicting postoperative BCR-free survival in men with prostate cancer (PCa).

#### **METHODS AND MATERIALS**

Between 2008 and 2009, 437 patients with PCa from a single institution who underwent 3 Tesla multiparametric MRI (mpMRI) followed by RP were included in this retrospective study. Radiomics features were extracted from T2 weighted imaging, apparent diffusion coefficient maps, and dynamic contrast-enhanced imaging that manually delineated the index tumors on mpMRI. Radiomic signatures (RM-Multi) were built using radiomics features on the training set, and the integrated models (CRM-Multi) were built by adding the clinical characteristics with a stratified five-fold cross-validation. The Cox proportional-hazards model used deep features of mpMRI derived from a newly curated deep neural network (an EfficientNetB0 network pretrained with large-scale natural images) for long-term BCR-free survival prediction following RP. A DL model (DLM-deep feature) and a clinical-DL combined model (CDLM-deep feature) were constructed. We compared the prognostic performance and clinical benefit of various models for BCR-free survival following RP.

#### **RESULTS**

With a median follow-up of 61 months, 110 of 437 (25.2%) patients experienced BCR. The DLM-deep features yielded a higher hazard ratio (HR) (4.37, 95% confidence interval (CI) 0.00-8.83,  $P=0.0219$ ), concordance index (C-index) (0.74, 95% CI 0.59-0.88), and integrated time-dependent area under the curve (iAUC) 0.77 than RM-Multi (HR 2.73, 95% CI 0.39-5.06,  $P=0.68$ ; C-index 0.66, 95% CI 0.57-0.76, and iAUC 0.68). Most importantly, the combined model incorporating DL-based deep features and clinical risk factors (CDLM-Deep feature) achieved the best performance with an HR (7.72, 95% CI 1.24-14.19,  $P=0.0008$ ), C-index (0.89, 95% CI 0.65-0.88), and iAUC 0.93, while the radiomics model incorporating clinical variables (CRM-Multi) demonstrated only moderate predictive power (HR 5.59, 95% CI 3.38-7.79,  $P=0.0007$ ; C-index 0.83, 95% CI 0.72-0.93, iAUC 0.87).

#### **CONCLUSION**

We demonstrated the high performance of integrating deep features from original mpMRI using a radiomic DL approach with the clinicopathological risk factors to predict the long-term BCR-free survival following RP in patients with PCa.

#### **CLINICAL RELEVANCE/APPLICATION**

Our novel DL risk model could facilitate prognostication based on routine prostate mpMRI, facilitating patient stratification following RP and individualized postoperative management.

### Can a Biparametric MRI-based AI Model Assist in Detecting Locally Recurrent Prostate Cancer in Post-radiotherapy Patients?

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E350

Enis C. Yilmaz, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the performance of a biparametric MRI (bpMRI)-based artificial intelligence (AI) model in detecting local recurrence in patients who received radiotherapy for prostate cancer (PCa).

#### METHODS AND MATERIALS

This retrospective study included patients under investigation for PCa recurrence after definitive radiotherapy who were scanned at mpMRI and underwent MRI/US fusion-guided and/or systematic biopsy. An expert genitourinary radiologist prospectively read each case prior to the biopsy sessions utilizing all multiparametric MRI sequences including dynamic contrast enhanced MRI. All scans were evaluated by an automated prostate lesion detection model which was developed on a multi-institutional dataset of 1240 treatment-naïve patients on bpMRI. The AI model's recurrent cancer detection rate was compared to the radiologist read using the Wald test with biopsy outcomes serving as ground truth. Subgroup analyses were conducted based on radiotherapy technique (external beam radiation treatment [EBRT] or brachytherapy) and prostate volume quartiles to investigate the impact of these factors on AI model performance.

#### RESULTS

Sixty-two patients (median age, 70; interquartile range [IQR], 65-75 years) with a median prostate volume of 27.55 mL (IQR, 21-34 mL) were included. A total of 56 cancer foci were identified in 46 patients in histopathological assessment. The AI model identified 40 cancer foci in 35 patients and achieved a sensitivity of 76.1% (35/46) and 71.4% (40/56) on patient- and lesion-level, respectively. The radiologist PCa detection performance was higher than the AI model on both patient-level (91.3% versus 76.1%,  $P=0.02$ ) and lesion-level (87.5% versus 71.4%,  $P=0.01$ ). The mean number of false positive calls of the AI model and the radiologist were 0.35 (range: 0-2) and 0.34 (range: 0-2), respectively. The AI performed better in the post-EBRT subgroup as compared to the post-brachytherapy subgroup on both patient-level (EBRT: 81.5% [22/27] vs. brachytherapy: 68.4% [13/19]) and lesion-level (EBRT: 79.4% [27/34] vs. brachytherapy: 59.1% [13/22]). The sensitivity of the AI was numerically best in the quartile of largest prostate volumes (>34 mL) with a patient- and lesion-level sensitivity of 100% ( $n=11/11$ ) and 94.1% ( $n=16/17$ ), respectively.

#### CONCLUSION

A bpMRI-based AI model can be used to detect the majority of histopathologically verified recurrent PCa lesions after radiotherapy. AI performance was better among patients with larger glands and those who received EBRT.

#### CLINICAL RELEVANCE/APPLICATION

An automated prostate lesion detection tool was able to identify most of the locally recurrent PCa in post-radiotherapy patients without utilizing dynamic contrast enhanced MRI.

#### W3-SSIN05-1 Prompting for Generalizable Clinical Concept Extraction from Radiology Reports

Kawshik Kannan, MS, BEng (*Presenter*) Employee, Covera Health

#### PURPOSE

Radiology reports describe various anatomical structures, creating a need to extract only the sentences pertaining to a particular structure to identify the corresponding pathology. This paper introduces STITCH (Structured Information Tagger for Clinical Health-records), a prompt based model that can detect sentence relevance for new, unseen anatomical structures and concepts in a zero-shot manner.

#### METHODS AND MATERIALS

STITCH is a BERT based model that uses adapters for parameter-efficient learning. Given a sentence and an anatomical structure, it determines if the sentence describes the anatomical structure. For this study, we used 8503 studies manually annotated for the presence of pathologies in 25 structures (17 in knee, 8 in shoulder), with a total of 55k sentence-structure pairs for training, 12k for validation and 15k for testing. Moreover, when a concept cannot be succinctly stated with a prompt, the model can learn soft prompts from the continuous vocabulary space to appropriately describe the concept.

#### RESULTS

The model that was trained on knee structures generalizes to unseen shoulder structures, achieving a sensitivity, specificity of 0.83, 0.80 whereas a n-way classifier model trained on shoulder data achieves a sensitivity, specificity of 0.82, 0.89 . However, the model trained on both knee and shoulder structures reaches a sensitivity, specificity of 0.95, 0.85, showcasing the benefits of training with more anatomical structures and sentences. Furthermore, as an unseen task, STITCH was used to detect post-operative changes in reports using soft prompts. This model was trained on knee post-op sentences and achieves 0.81, 0.998 for unseen shoulder post-op sentences whereas a standard binary classifier achieves scores of 0.62, 0.993, sensitivity, specificity respectively. With the advent of large language models changing the direction of the field, STITCH is attractive in part due to its lightweight architecture and task-specific representations which are easier to evaluate.

#### CONCLUSION

The prompt based task formulation used for STITCH alongside a large number of anatomical structures allows the model to generalize to predicting sentence relevance for unseen concepts.

#### CLINICAL RELEVANCE/APPLICATION

Automatic detection of structures in reports can help comprehend large datasets and ease downstream tasks such as pathology extraction, cohort building, outcome tracking and quality assessment.

#### W3-SSIN05-2 Automated Categorization of Pathology in Radiology Report Impressions by GPT-4; A Tool to Enable Precision Education

Michael P. Recht, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The ACGME has adopted a learner centered competency based education model that requires residents to master specific knowledge skills and achieve key milestones. A significant component of resident education is based on daily readouts with

attendings. It is easy to track the volume and type of examinations interpreted but difficult to measure the breadth of pathology seen and the accuracy of resident interpretations. An automated method that categorizes the pathology listed in the impression of the resident's preliminary report as well as in the final report would provide objective metrics of both. The goal of this study is to assess the accuracy of GPT-4 in categorizing the pathology that is described in the impression of radiology reports.

## **METHODS AND MATERIALS**

A list of 204 pathologies based on our residency's musculoskeletal curriculum and the ABR Core Exam Blueprints was created. Impressions were extracted from 190 de-identified musculoskeletal (MSK) reports (105 Xray, 44 CT, and 41 MR). To identify and extract the pathologies from the impressions in a machine-readable form, we constructed an input prompt for GPT-4 that asked it to list any of the listed pathologies that were mentioned as definite or possible findings as a CSV file. To reduce uncertainty in the output, we used python and GPT-4 webservices, to process each report 5 times and generated a list of pathologies that were mentioned as definite or possible in at least 3 of the 5 answers. An experienced MSK radiologist reviewed the output and identified missing or incorrectly listed pathologies.

## **RESULTS**

All outputs only included pathologies from the input list. GPT identified 306 of the 311 definite findings and 84 of the 90 possible findings correctly. It identified 25 false positive definite findings and 22 false positive possible findings. Given 38760 binary tests (190 reports x 204 pathologies) the recall, specificity, and precision for the definite findings are 98.4%, 99.9% and 92.4%. and for the possible findings 93.3%, 99.9%, and 79.2%.

## **CONCLUSION**

With a well-engineered prompt, GPT4 is able to automatically and accurately identify pathologies in radiology impressions and output them in a machine-readable form with excellent accuracy. It is likely that that its performance can be further improved by fine-tuning the prompt and the description of the pathologies in the pick list. The method is easy to implement and may be generalizable to other areas.

## **CLINICAL RELEVANCE/APPLICATION**

Automated categorization of pathology contained in radiology reports can be an important tool to enable precision radiology resident education.

### **W3-SSIN05-3 Keynote Speaker**

George L. Shih, MD, MS (*Presenter*) Consultant, MD.ai, Inc; Shareholder, MD.ai, Inc

### **W3-SSIN05-4 Large Language Models for Zero-shot Application of a Clinical Reporting System (CAD-RADS) to Unstructured Reports**

Veit Sandfort, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

Large language models (LLMs) are rapidly increasing in performance and are now capable of performing tasks guided only by natural language instructions, without domain-specific training data (zero-shot). This enables the automatic processing of unstructured radiology reports with minimal development effort. We sought to determine the performance of LLMs in deriving the appropriate CAD-RADS category from unstructured coronary CTA reports.

## **METHODS AND MATERIALS**

Fully anonymized CCTA reports (n=500) from four hospitals across three US regions (East, Midwest, and Southwest) were obtained from Segmed Inc. CAD-RADS categories were determined by three cardiovascular experts, and any mention of CAD-RADS in the reports was manually removed to avoid bias. We used three LLMs for the analysis: gpt-3.5-turbo (ChatGPT, OpenAI) and two LLMs derived from publicly available MetaAI models (LLaMA): Stanford ALPACA 7B and 13B. The prompt used for all LLMs included: the CCTA report, CAD-RADS definitions, and instructions to provide a CAD-RADS category as output. Of note, no prompt optimization was performed. LLMs' performance to achieve accurate CAD-RADS scores was evaluated with Cohen's kappa using expert-derived scores as the reference standard.

## **RESULTS**

CAD-RADS categories were removed from 152 (30.4%) CCTA reports. ChatGPT showed good agreement with expert-derived scores with a Cohen's kappa of 0.67 (CI 0.62 - 0.72), and a significantly higher performance compared to Alpaca 7B and 13B (see figure). Alpaca 13B showed significantly higher performance compared to Alpaca 7B, with Cohen's kappa 0.44 (CI 0.40 - 0.49) vs. 0.23 (CI 0.19 - 0.28), respectively.

## **CONCLUSION**

OpenAI's ChatGPT showed good performance in assigning CAD-RADS categories to unstructured coronary CTA reports while both locally run ALPACA models showed lower performance compared to ChatGPT, with the 13B model performing better than

the 7B model.

### **CLINICAL RELEVANCE/APPLICATION**

LLM-assisted CAD-RADS categorization without the need for extensive development or generation of training data enables rapid deployment in the setting of quality improvement, administrative analyses, billing, research, and report quality control and can accelerate the development of clinical NLP models. We also suspect this method could be useful for other reporting and data systems (RADS).

### **W3-SSIN05-5 A Comparative Analysis of Modern Clinical NLP Tools From Amazon, Google, Azure, and John Snow Labs on Pediatric Radiology Reports**

Shruti Hegde, MSc (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To quantify the differences in the performance of commercial clinical natural language processing (NLP) tools on pediatric radiology reports.

#### **METHODS AND MATERIALS**

Four commercial NLP systems for clinical electronic health record data, Amazon Comprehend Medical (AWS), Google Healthcare Natural Language API (GC), Azure Text analytics for Health (AZ), and John Snow Lab's spark NLP models for radiology reports (SP), were evaluated on 88,766 pediatric (Mean age:  $8 \pm 7.5$  years, Male/Female ratio: 1.2) radiology reports for chest radiography examinations. Clinical NLP systems performed four major tasks: named entity recognition, entity linking, relationship detection, and assertion detection. Uncertainty associated with entities extracted by each NLP task is reported as a probabilistic score (0 - 1). Anonymized reports were submitted as REST API queries for AWS, GC, and AZ; for SP, an academic license was used, and inference was performed locally on the radiology specific model. Outputs in JSON format were harmonized, and initial analysis focused on medical conditions, findings, diagnosis, symptoms, and diseases. Lemmatization and stemming were performed on extracted medical entities to standardize them between the four services and compared. The range of uncertainty scores reported by each system for pneumonia and atelectasis were quantified. Cosine similarity measures between each NLP service on all extracted medical entities are also calculated and reported.

#### **RESULTS**

Total (unique) medical entities detected by AWS, AZ, GC, and SP were 867,477 (25,670), 455,297 (11,574), 1,175,674 (29,566), and 972,151 (38,115), respectively. After stemming, 4,577 common entities remained. Mean (min-max) uncertainty scores for pneumonia extraction: AWS 0.986 (0.501-0.999), AZ 0.999 (0.599-0.999), GC 0.982 (0.550-1.0), SP 0.87 (0.325-0.987). For atelectasis, the scores were: AWS 0.874 (0.302-0.997), AZ 0.998 (0.513-0.999), GC 0.831(0.550-1.0), SP 0.917 (0.427-0.990). For cosine similarity, GC and SP was highest (0.83), AZ and SP were lowest (0.46).

#### **CONCLUSION**

Major differences in the extracted medical entities and the associated uncertainty scores for named entity recognition on pediatric CXR radiology reports were observed between 4 commercial clinical NLP services even after standardization of the outputs. Further analysis with manual oversight is required to understand the discrepancies between each system.

### **CLINICAL RELEVANCE/APPLICATION**

As clinical NLP services are becoming mainstream and are playing an increasing role in both Radiology research and quality assurance/ improvement, it is important to understand the uncertainties associated with each service before they can be used for downstream tasks.

### **W3-SSIN05-6 Comparative Performance of Artificial Intelligence Large Language Models on Diagnostic Radiology In-Training Exam**

Christopher Kaufmann, MD, MS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

There is limited and often unclear information on the accuracy and sources of publicly available AI tools such as ChatGPT, Bard, BingChat specifically related to radiology domains. While these tools are powerful search and assistive reference aids, in order for a radiologist to decide how, if at all, to utilize these assistive AI technologies, the output accuracy, relevance, and reliability needs to be better understood. This study attempts to compare the latest publicly accessible AI large language models (LLMs) across multiple subspecialty areas of radiology.

#### **METHODS AND MATERIALS**

The American College of Radiology Diagnostic In-Training Exam (ACR DXIT) practice test question set from July 2022 were filtered to exclude image-based questions (n=64 image dependent, n=42 image independent questions). The image independent questions were distributed across various radiology disciplines including breast, cardiothoracic, GI/GU, musculoskeletal, neuroradiology, nuclear, pediatrics, ultrasound, interventional and radiology physics. Three publicly available

AI LLMs platforms (OpenAI ChatGPT 3.5 4.0, Google BARD, and Windows BingChat) were used to evaluate for correct answer responses to the input test questions. The questions were entered into the AI interface in their original text format without prompting or modification guidance, except for one instance which flagged a question answer word for "inappropriate content".

## **RESULTS**

ChatGPT 4.0 answered 90.5% correctly (n=38 of 42) and ChatGPT 3.5 answered 79% of questions correctly (33 of 42). While overall improvement was noted using GPT4, 2 previously correct responses using GPT3.5 were outputted incorrectly using GPT4. Google Bard answered 71% correctly in which all 3 draft responses were correct (n=30 of 42). There were partially correct responses (lack of concordance across 3 output drafts) in 14% of Bard outputs (n=6 of 42). BingChat performed the lowest with 60% correct (n=25 of 42).

## **CONCLUSION**

Performance of the latest ChatGPT4-0 on the image-independent ACR DXIT practice set questions was above 90% correct. The results demonstrate the powerful efficiency and improving accuracy of evolving publicly available AI tools when applied to the radiology specific domain. As LLMs evolve into more discipline specific AI support tools, determining the trustworthiness and up-to-date accuracy of these AI technologies will remain key criteria for their ultimate clinical adoption and use in practice.

## **CLINICAL RELEVANCE/APPLICATION**

With the rapid, almost daily evolution of readily available AI technologies such as ChatGPT, Bard, or BingChat, determining their radiology-domain specific performance and output reliability is important for potential use in radiology practice.

### Prompting for Generalizable Clinical Concept Extraction from Radiology Reports

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S402

Kawshik Kannan, MS, BEng (*Presenter*) Employee, Covera Health

#### PURPOSE

Radiology reports describe various anatomical structures, creating a need to extract only the sentences pertaining to a particular structure to identify the corresponding pathology. This paper introduces STITCH (STRUCTURED Information Tagger for Clinical Health-records), a prompt based model that can detect sentence relevance for new, unseen anatomical structures and concepts in a zero-shot manner.

#### METHODS AND MATERIALS

STITCH is a BERT based model that uses adapters for parameter-efficient learning. Given a sentence and an anatomical structure, it determines if the sentence describes the anatomical structure. For this study, we used 8503 studies manually annotated for the presence of pathologies in 25 structures (17 in knee, 8 in shoulder), with a total of 55k sentence-structure pairs for training, 12k for validation and 15k for testing. Moreover, when a concept cannot be succinctly stated with a prompt, the model can learn soft prompts from the continuous vocabulary space to appropriately describe the concept.

#### RESULTS

The model that was trained on knee structures generalizes to unseen shoulder structures, achieving a sensitivity, specificity of 0.83, 0.80 whereas a n-way classifier model trained on shoulder data achieves a sensitivity, specificity of 0.82, 0.89 . However, the model trained on both knee and shoulder structures reaches a sensitivity, specificity of 0.95, 0.85, showcasing the benefits of training with more anatomical structures and sentences. Furthermore, as an unseen task, STITCH was used to detect post-operative changes in reports using soft prompts. This model was trained on knee post-op sentences and achieves 0.81, 0.998 for unseen shoulder post-op sentences whereas a standard binary classifier achieves scores of 0.62, 0.993, sensitivity, specificity respectively. With the advent of large language models changing the direction of the field, STITCH is attractive in part to its lightweight architecture and task-specific representations which are easier to evaluate.

#### CONCLUSION

The prompt based task formulation used for STITCH alongside a large number of anatomical structures allows the model to generalize to predicting sentence relevance for unseen concepts.

#### CLINICAL RELEVANCE/APPLICATION

Automatic detection of structures in reports can help comprehend large datasets and ease downstream tasks such as pathology extraction, cohort building, outcome tracking and quality assessment.

### Automated Categorization of Pathology in Radiology Report Impressions by GPT-4; A Tool to Enable Precision Education

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S402

Michael P. Recht, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The ACGME has adopted a learner centered competency based education model that requires residents to master specific knowledge skills and achieve key milestones. A significant component of resident education is based on daily readouts with attendings. It is easy to track the volume and type of examinations interpreted but difficult to measure the breadth of pathology seen and the accuracy of resident interpretations. An automated method that categorizes the pathology listed in the impression of the resident's preliminary report as well as in the final report would provide objective metrics of both. The goal of this study is to assess the accuracy of GPT-4 in categorizing the pathology that is described in the impression of radiology reports.

#### METHODS AND MATERIALS

A list of 204 pathologies based on our residency's musculoskeletal curriculum and the ABR Core Exam Blueprints was created. Impressions were extracted from 190 de-identified musculoskeletal (MSK) reports (105 Xray, 44 CT, and 41 MR). To identify and extract the pathologies from the impressions in a machine-readable form, we constructed an input prompt for GPT-4 that asked it to list any of the listed pathologies that were mentioned as definite or possible findings as a CSV file. To reduce uncertainty in the output, we used python and GPT-4 webservices, to process each report 5 times and generated a list of pathologies that were mentioned as definite or possible in at least 3 of the 5 answers. An experienced MSK radiologist reviewed the output and identified missing or incorrectly listed pathologies.

#### RESULTS

All outputs only included pathologies from the input list. GPT identified 306 of the 311 definite findings and 84 of the 90 possible findings correctly. It identified 25 false positive definite findings and 22 false positive possible findings. Given 38760 binary tests (190 reports x 204 pathologies) the recall, specificity, and precision for the definite findings are 98.4%, 99.9% and 92.4%. and for the possible findings 93.3%, 99.9%, and 79.2%.

#### CONCLUSION

With a well-engineered prompt, GPT4 is able to automatically and accurately identify pathologies in radiology impressions and output them in a machine-readable form with excellent accuracy. It is likely that that its performance can be further improved by fine-tuning the prompt and the description of the pathologies in the pick list. The method is easy to implement and may be generalizable to other areas.

#### CLINICAL RELEVANCE/APPLICATION

Automated categorization of pathology contained in radiology reports can be an important tool to enable precision radiology resident education.

### Large Language Models for Zero-shot Application of a Clinical Reporting System (CAD-RADS) to Unstructured Reports

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S402

Veit Sandfort, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Large language models (LLMs) are rapidly increasing in performance and are now capable of performing tasks guided only by natural language instructions, without domain-specific training data (zero-shot). This enables the automatic processing of unstructured radiology reports with minimal development effort. We sought to determine the performance of LLMs in deriving the appropriate CAD-RADS category from unstructured coronary CTA reports.

#### METHODS AND MATERIALS

Fully anonymized CCTA reports (n=500) from four hospitals across three US regions (East, Midwest, and Southwest) were obtained from Segmed Inc. CAD-RADS categories were determined by three cardiovascular experts, and any mention of CAD-RADS in the reports was manually removed to avoid bias. We used three LLMs for the analysis: gpt-3.5-turbo (ChatGPT, OpenAI) and two LLMs derived from publicly available MetaAI models (LLaMA): Stanford ALPACA 7B and 13B. The prompt used for all LLMs included: the CCTA report, CAD-RADS definitions, and instructions to provide a CAD-RADS category as output. Of note, no prompt optimization was performed. LLMs' performance to achieve accurate CAD-RADS scores was evaluated with Cohen's kappa using expert-derived scores as the reference standard.

#### RESULTS

CAD-RADS categories were removed from 152 (30.4%) CCTA reports. ChatGPT showed good agreement with expert-derived scores with a Cohen's kappa of 0.67 (CI 0.62 - 0.72), and a significantly higher performance compared to Alpaca 7B and 13B (see figure). Alpaca 13B showed significantly higher performance compared to Alpaca 7B, with Cohen's kappa 0.44 (CI 0.40 - 0.49) vs. 0.23 (CI 0.19 - 0.28), respectively.

#### CONCLUSION

OpenAI's ChatGPT showed good performance in assigning CAD-RADS categories to unstructured coronary CTA reports while both locally run ALPACA models showed lower performance compared to ChatGPT, with the 13B model performing better than the 7B model.

#### CLINICAL RELEVANCE/APPLICATION

LLM-assisted CAD-RADS categorization without the need for extensive development or generation of training data enables rapid deployment in the setting of quality improvement, administrative analyses, billing, research, and report quality control and can accelerate the development of clinical NLP models. We also suspect this method could be useful for other reporting and data systems (RADS).

### A Comparative Analysis of Modern Clinical NLP Tools From Amazon, Google, Azure, and John Snow Labs on Pediatric Radiology Reports

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S402

Shruti Hegde, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

To quantify the differences in the performance of commercial clinical natural language processing (NLP) tools on pediatric radiology reports.

#### METHODS AND MATERIALS

Four commercial NLP systems for clinical electronic health record data, Amazon Comprehend Medical (AWS), Google Healthcare Natural Language API (GC), Azure Text analytics for Health (AZ), and John Snow Lab's spark NLP models for radiology reports (SP), were evaluated on 88,766 pediatric (Mean age:  $8 \pm 7.5$  years, Male/Female ratio: 1.2) radiology reports for chest radiography examinations. Clinical NLP systems performed four major tasks: named entity recognition, entity linking, relationship detection, and assertion detection. Uncertainty associated with entities extracted by each NLP task is reported as a probabilistic score (0 - 1). Anonymized reports were submitted as REST API queries for AWS, GC, and AZ; for SP, an academic license was used, and inference was performed locally on the radiology specific model. Outputs in JSON format were harmonized, and initial analysis focused on medical conditions, findings, diagnosis, symptoms, and diseases. Lemmatization and stemming were performed on extracted medical entities to standardize them between the four services and compared. The range of uncertainty scores reported by each system for pneumonia and atelectasis were quantified. Cosine similarity measures between each NLP service on all extracted medical entities are also calculated and reported.

#### RESULTS

Total (unique) medical entities detected by AWS, AZ, GC, and SP were 867,477 (25,670), 455,297 (11,574), 1,175,674 (29,566), and 972,151 (38,115), respectively. After stemming, 4,577 common entities remained. Mean (min-max) uncertainty scores for pneumonia extraction: AWS 0.986 (0.501-0.999), AZ 0.999 (0.599-0.999), GC 0.982 (0.550-1.0), SP 0.87 (0.325-0.987). For atelectasis, the scores were: AWS 0.874 (0.302-0.997), AZ 0.998 (0.513-0.999), GC 0.831(0.550-1.0), SP 0.917 (0.427-0.990). For cosine similarity, GC and SP was highest (0.83), AZ and SP were lowest (0.46).

#### CONCLUSION

Major differences in the extracted medical entities and the associated uncertainty scores for named entity recognition on pediatric CXR radiology reports were observed between 4 commercial clinical NLP services even after standardization of the outputs. Further analysis with manual oversight is required to understand the discrepancies between each system.

#### CLINICAL RELEVANCE/APPLICATION

As clinical NLP services are becoming mainstream and are playing an increasing role in both Radiology research and quality assurance/ improvement, it is important to understand the uncertainties associated with each service before they can be used for downstream tasks.

### Comparative Performance of Artificial Intelligence Large Language Models on Diagnostic Radiology In-Training Exam

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S402

Christopher Kaufmann, MD, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

There is limited and often unclear information on the accuracy and sources of publicly available AI tools such as ChatGPT, Bard, BingChat specifically related to radiology domains. While these tools are powerful search and assistive reference aids, in order for a radiologist to decide how, if at all, to utilize these assistive AI technologies, the output accuracy, relevance, and reliability needs to be better understood. This study attempts to compare the latest publicly accessible AI large language models (LLMs) across multiple subspecialty areas of radiology.

#### METHODS AND MATERIALS

The American College of Radiology Diagnostic In-Training Exam (ACR DXIT) practice test question set from July 2022 were filtered to exclude image-based questions (n=64 image dependent, n=42 image independent questions). The image independent questions were distributed across various radiology disciplines including breast, cardiothoracic, GI/GU, musculoskeletal, neuroradiology, nuclear, pediatrics, ultrasound, interventional and radiology physics. Three publicly available AI LLMs platforms (OpenAI ChatGPT 3.5 4.0, Google BARD, and Windows BingChat) were used to evaluate for correct answer responses to the input test questions. The questions were entered into the AI interface in their original text format without prompting or modification guidance, except for one instance which flagged a question answer word for "inappropriate content".

#### RESULTS

ChatGPT 4.0 answered 90.5% correctly (n=38 of 42) and ChatGPT 3.5 answered 79% of questions correctly (33 of 42). While overall improvement was noted using GPT4, 2 previously correct responses using GPT3.5 were outputted incorrectly using GPT4. Google Bard answered 71% correctly in which all 3 draft responses were correct (n=30 of 42). There were partially correct responses (lack of concordance across 3 output drafts) in 14% of Bard outputs (n=6 of 42). BingChat performed the lowest with 60% correct (n=25 of 42).

#### CONCLUSION

Performance of the latest ChatGPT4-0 on the image-independent ACR DXIT practice set questions was above 90% correct. The results demonstrate the powerful efficiency and improving accuracy of evolving publicly available AI tools when applied to the radiology specific domain. As LLMs evolve into more discipline specific AI support tools, determining the trustworthiness and up-to-date accuracy of these AI technologies will remain key criteria for their ultimate clinical adoption and use in practice.

#### CLINICAL RELEVANCE/APPLICATION

With the rapid, almost daily evolution of readily available AI technologies such as ChatGPT, Bard, or BingChat, determining their radiology-domain specific performance and output reliability is important for potential use in radiology practice.

#### **W3-SSIN06-1 Identification and Mitigation of Bias in Multi-Modal Pulmonary Embolism Data to Improve Survival Analysis Prediction**

Shreyas Kulkarni, BS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Bias in healthcare unfairly impacts lower socioeconomic populations and can be baked into predictive modeling datasets. This is a problem in multimodal datasets where different biases can pool together. Our purpose is to develop a model that debiases multimodal Pulmonary Embolism (PE) datasets and to improve survival prediction (SP) over the current clinical standard of Pulmonary Embolism Severity Index (PESI).

#### **METHODS AND MATERIALS**

918 PE patients with 3978 CTPA images and 918 clinical reports were collected from 3 institutions including race, ethnicity, gender, survival time-to-event labels, and the 11 PESI variables. We built feature extraction networks using GatorTron to extract text features from clinical notes and PEnet to extract imaging features. We then developed 3 SP modules, each based on a single mode of data: PESI variables, clinical text features, and imaging features. For a multimodal prediction, the different outputs from the 3 SPs were integrated into a CoxPH. Each SP module contained a baseline and a debiased version. Debiasing used disentanglement learning to measure and mitigate bias. We then ran experiments to compare PESI predictions against our debiased multimodal SP model, evaluating within and debiasing 1 population bias factor: race (White or not White), Ethnicity (Latino or not Latino), or Gender (Male or Female). C-index was used to measure accuracy of survival predictions, with higher c-indexes meaning more accurate predictions.

#### **RESULTS**

Compared to PESI, our debiased multimodal SP had higher c-indexes and lower biases across all three potential population biases of race, ethnicity, and gender. Additionally, while PESI c-indexes showed great variations within population bias groups, our debiased SP achieved more consistent predictions within the groups. The Latino PESI c-index was 0.481 which was significantly lower than the non-Latino PESI c-index of 0.687, indicating PESI's poor prognostic value for Latino populations. After ethnicity debiasing, the debiased SP Latino c-index was 0.731 and 0.723 for non-Latino populations. A similar result occurred with gender disentanglement with a female PESI c-index of 0.529 and male PESI c-index of 0.739. Our gender debiased SP had a female c-index of 0.763 and a male c-index of 0.785.

#### **CONCLUSION**

Our results demonstrate that disentangling population bias in multimodal datasets is possible and improves SP. The debiased multimodal SP was also more accurate and equitable for populations relative to the standard of PESI.

#### **CLINICAL RELEVANCE/APPLICATION**

Our work demonstrates a method to minimize population biases in multimodal datasets while producing a debiasing SP model that is more equitable and accurate than the current clinical standard of PESI. We offer an improvement in equity.

#### **W3-SSIN06-2 Total Data in Radiology Exams Increase More than Appreciated by the Increase in Number of Exams**

Tomas Bjerner, MD, PhD (*Presenter*) Medical Advisory Board, Carestream Health, Inc

## PURPOSE

Scanners for radiological examinations can examine an increasing number of patients per time unit and generate increasing amounts of data per scanned patient. Most radiology departments follow their production in number of examinations and reports of increasing workload for radiologists are available in the literature. The increase in workload for radiologists can be assumed to, at least in part, depend on the number of studies read and the complexity of the studies. The complexity of studies might be related to the amount of data within them and in some countries, there are systems addressing the complexity of exams using relative value units (RVU). The aim of the present study is to estimate the development of the workload for radiologists over time including both number of examinations and complexity (approximated by the amount of stored data).

## METHODS AND MATERIALS

The total number of stored data, images, series and studies in the PACS database (Philips VuePACS 12.2.8, Best, the Netherlands) in a regional health care organization including a tertiary imaging center in Sweden for the years 2009-2022 were calculated. Data for CT and MR were used and only production from within the healthcare organization was included (imported studies from other hospitals were omitted). From these numbers the average size of a study could be calculated as well as the change of these parameters over time.

## RESULTS

Over the period 2009-2022 the number of CT studies increased by 87.2% equal to 4.9% per year. Over the same period, stored data for these studies increased more than 6 times (525%) or 15.1% per year. The number of images increased by 459% or 14.2% per year. This resulted in the average CT study increasing from 229 to 765MB (234%) during this time span. Over the same period the number of MR studies increased 101% equal to 5.5% per year. Over the same period, stored data for these studies increased more than 5 times (412%) or 13.4% per year. The number of images increased by 364% or 12.5% per year. This resulted in the average MR study increasing from 84.7 to 216MB (155%) during this time span.

## CONCLUSION

Over the period 2009-2022, the data in studies for radiologists to analyze increased 5-6 times while the number of studies only doubled. This was mainly due to the increased number of images in studies. This resulted in an increase in the workload for reading radiologists that is higher than when only the number of studies is considered.

## CLINICAL RELEVANCE/APPLICATION

Over the period 2009-2022, total data in exams for radiologists to analyze increased 5-6 times while the corresponding number of studies only doubled. This ratio is important when planning the workload in a radiology department.

## W3-SSIN06-3 The Comprehensive Open Federated Ecosystem (COFE): Enabling Impactful Healthcare Studies

Sarthak Pati, MSc (*Presenter*) Nothing to Disclose

## PURPOSE

Robustness generalizability of artificial intelligent (AI) models is dependent on using ample diverse data. Data ownership legal hurdles hinder access to such data in the current paradigm of multi-site collaborations. To address these, we introduce the community-driven Comprehensive Open Federated Ecosystem (COFE), which intends to make distributed healthcare AI more accessible by leveraging zero/low code principles. COFE models get to learn across data silos using federated learning (FL) we assess their performance on diverse out-of-distribution datasets using federated evaluation (FE). As initial use-cases, COFE enabled the Federated Tumor Segmentation (FeTS) Initiative, which focused on the boundary detection of histologically-distinct brain tumor sub-compartments in MRI scans, the FeTS Challenge, the first FL-focused community benchmark.

## METHODS AND MATERIALS

We designed COFE to be agnostic to data type (imaging, EHR, genomics) the model to train. COFE offered an end-to-end solution to the FeTS initiative through 4 distinct modes of operation: data preprocessing, automatic tumor sub-compartment delineation by label fusion of pre-trained AI models, manual refinement of these delineations FL using the Linux Foundation's OpenFL. Additionally, building upon the collaborative network of the FeTS initiative we used MedPerf to conduct the FeTS Challenge, which followed a clinical trial design to evaluate AI methods on real-world conditions.

## RESULTS

In the FeTS Initiative, we observe an average improvement of 25% in the accuracy of the model on each collaborator's validation data when compared to a model trained on publicly available data. Notably, the difficult regions of the tumor showed the most improvement, with the most prominent being the region for surgical intervention, the tumor core, which improved by 33%. In the FeTS Challenge, inference-time data augmentation combined with post-processing yielded optimal results.

## CONCLUSION

Our findings on FeTS support that COFE enables training of a consensus AI model that has gained knowledge from data of geographically distinct collaborators, while the data of each collaborator are always retained within their institution, overcoming legal & ownership hurdles. At the same time, it can perform evaluations of pretrained models across completely out-of-distribution datasets to quantify the robustness & generalizability of the model.

## CLINICAL RELEVANCE/APPLICATION

Federated Learning allows training of AI models using diverse datasets without sharing the data, while Federated Evaluation allows AI models to be trained on true out-of-sample data. Combined, this would result in more robust models without raising ethical dilemmas.

### W3-SSIN06-4 **Anonymizing Radiographs and Making Them "AI Ready" Using a Deep Learning Algorithm**

Bardia Khosravi, MD, MPH (*Presenter*) Nothing to Disclose

#### PURPOSE

Radiographs play a crucial role in medical care by providing valuable information about a patient's anatomy and potential pathologies. Most radiographs contain radio-opaque markers that display information such as the side, positioning, radiographer initials, and often patient identifier. In this study, we develop a deep learning (DL) model that detects and selectively removes these markers from images to enable de-identified data sharing and improve the suitability of images for training robust deep learning models.

#### METHODS AND MATERIALS

To create our ground-truth dataset, we annotated 2000 pelvic radiographs collected between 2000 and 2021. Each marker area was annotated with a bounding box. The data was then split at the patient level into 60%/20%/20% for training, validation, and testing, respectively. Images were resampled to 512x512 pixels, and a YOLOv5-x model was trained to localize markers. Mean average precision at a 50% threshold (mAP-50) was reported as a measure of model performance on the test set. While removing identification markers is important, laterality markers contain valuable information that helps guide the pre-processing pipeline of deep learning models. We developed an image processing algorithm that examines each marker area and sends it to an OCR algorithm for characterization. In our case, laterality markers were retained if "R" and "L" characters were detected in the image (Figure 1). To externally validate the model, we applied it to chest radiographs from the validation set of the CheXpert dataset to assess its performance on data from different body parts and organizations.

#### RESULTS

The model reached a mAP-50 of 0.99 and 0.98 on the validation and internal test sets, respectively. It had a de-identification accuracy of 100% (400/400) on the test set, with a false-positive rate of 1% (8/632). The retention accuracy was 93% (359/386). On the external set of chest radiographs, the model successfully removed markers from 96% of radiographs (221/231). After fine-tuning on 20 CheXpert radiographs, the model was able to remove markers from 99.6% (230/231) of chest radiographs.

## CONCLUSION

We present a pipeline for de-identifying radiographs by selectively removing patient identifiers. This model can be easily refined to effectively detect radiographic markers on a wide variety of x-rays, demonstrating its generalizability.

## CLINICAL RELEVANCE/APPLICATION

Radiographic markers hinder data sharing and the development of public, multi-centric datasets and can introduce spectrum bias, which can lead to overfitting when training DL models. A robust de-identification algorithm capable of removing these markers could facilitate inter-institutional data sharing and more robust DL model training.

### W3-SSIN06-5 **Evaluating Radiologist Recall from Memory: A Data Protection Study on X-ray Image Re-identification**

Vanessa Wyrwoll, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To date there are no reliable measures for radiologist's re-identification rate in the literature. This study quantifies the rate at which experienced radiologists can re-identify chest radiographs from memory, and thus, the risk of an "accidental" reidentification when working with de-identified radiographic data sets.

#### METHODS AND MATERIALS

We conducted an online survey with 22 radiologists from the RACOON network, consisting of 38 university clinics. Readers had 3.9+-1.82 years of clinical experience on average. All participants created structured reports for chest radiographs of five different patients sequentially (phase 1). Each radiograph was assigned a pseudonym displayed alongside the image. 24

hours after completion of this task, participants were presented with ten different, randomly selected chest radiographs (phase 2). For half of the participants, these included a follow up study of one patient of phase 1. For each image, participants were asked to match a specific patient from phase 1 to the radiographs of phase 2.

## RESULTS

From 210 answers, 163 were correct with 0 true positives and 10 false positives. Readers took 8.9+-12.5 seconds to respond in phase 2, which had no correlation to accuracy (mean accuracy 77.6%). False positive rate (FPR) is greater than 0.141 ( $p=0.049$ ). The true positive rate (TPR) is less than to be expected by random input with weak evidence ( $p=0.144$ ). This illustrates that the probability of correctly identifying a patient in a set of pictures was less and the number of mistakenly recognized images has been greater than expected at random. Also, according to this study, the probability of a patient being incorrectly identified as the target patient ranges from 13% to 24.5% (95% CI).

## CONCLUSION

Readers falsely assumed patient reidentification in 17.6% of cases. Even for a moderately-sized pool of patients from which images might have been sampled, the reader cannot rule out misidentifications at a high level of confidence. For example, if candidate images have been sampled from a population the size of 80 million, the likelihood of a claimed match being correct would be 0.0000067%.

## CLINICAL RELEVANCE/APPLICATION

Provided that images with rare and distinctive anatomical features have been excluded, recollection from memory is not a relevant data privacy risk when dealing with large public data sets of radiographs that have been de-identified by DICOM header anonymization, even under the pessimistic assumption that the correct patient is part of the data set. If the population from which patients may have been sampled is sufficiently large, the large number of incorrectly identified patients renders the likelihood of a presumed identification being correct minute.

## W3-SSIN06-6 Safe Medical AI in Diagnostic Informatics: Defending Adversarial Attacks

Degan Hao, MS (*Presenter*) Intern, F. Hoffmann-La Roche Ltd

## PURPOSE

Deep learning-based computer aided diagnosis are being actively developed and evaluated for clinical translation and deployment, especially in the frontier of mammographic breast cancer diagnosis. Deep learning diagnosis models however are shown vulnerable to adversarial attacks - where adversarial data, i.e., data corrupted intentionally by small perturbations, can fool a deep learning model to produce misdiagnosis. This creates a threat to safely deploy deep learning models in clinical imaging informatics workflow. The purpose of this study is to develop and evaluate a novel technical framework to defend adversarial attacks in the context of a deep learning-based breast cancer diagnosis model.

## METHODS AND MATERIALS

In this IRB-approved study, we identified a dataset of 4,346 mammograms from a cohort of 1,284 women who underwent full-field digital mammography for breast cancer screening. We first built a diagnosis model using a VGG-16 network to classify breast cancer (366 biopsy-proven malignancy) vs. normal (918 negative cases). We evaluated two types of adversarial attacks: (1) white-box attack (attackers know about AI model parameters) where adversarial data were generated by the projected gradient descent method to insert adversarial noises to mammogram images, and (2) black-box attacks (attackers have no access to AI model parameters) where adversarial data were generated by intentionally inserting or removing tumorous tissue in mammograms. To defend the attacks, we designed a novel defense framework using the adversarial training strategy (i.e., enhanced model training using adversarial data), where we developed a regularization algorithm to facilitate learning adversarially robust features for classification and a label independent data augmentation to resolve the common issue of data leakage introduced by black-box data synthesis. We used five-fold cross validation to compare the AUC values of the proposed adversarial training vs. regular training without our method.

## RESULTS

The breast cancer diagnosis model has an AUC of 0.668 with regular training. Under white-box attack, the model's performance degrades to an AUC of 0.415, but our proposed framework brings the AUC to 0.673. Likewise, black-box attack downgrades the model to an AUC of 0.461 but our framework brings the AUC to 0.637.

## CONCLUSION

The proposed defending framework can make the breast cancer diagnosis model resilient to both white-box and black-box adversarial attacks.

## CLINICAL RELEVANCE/APPLICATION

In active efforts of deploying medical AI into clinical informatics workflow, our proposed method can effectively defend potential adversarial attacks, ensuring safe and secure use of AI for patient care.

W3-SSIN06-1

### Identification and Mitigation of Bias in Multi-Modal Pulmonary Embolism Data to Improve Survival Analysis Prediction

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S401

Shreyas Kulkarni, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Bias in healthcare unfairly impacts lower socioeconomic populations and can be baked into predictive modeling datasets. This is a problem in multimodal datasets where different biases can pool together. Our purpose is to develop a model that debiases multimodal Pulmonary Embolism (PE) datasets and to improve survival prediction (SP) over the current clinical standard of Pulmonary Embolism Severity Index (PESI).

#### METHODS AND MATERIALS

918 PE patients with 3978 CTPA images and 918 clinical reports were collected from 3 institutions including race, ethnicity, gender, survival time-to-event labels, and the 11 PESI variables. We built feature extraction networks using GatorTron to extract text features from clinical notes and PENet to extract imaging features. We then developed 3 SP modules, each based on a single mode of data: PESI variables, clinical text features, and imaging features. For a multimodal prediction, the different outputs from the 3 SPs were integrated into a CoxPH. Each SP module contained a baseline and a debiased version. Debiasing used disentanglement learning to measure and mitigate bias. We then ran experiments to compare PESI predictions against our debiased multimodal SP model, evaluating within and debiasing 1 population bias factor: race (White or not White), Ethnicity (Latino or not Latino), or Gender (Male or Female). C-index was used to measure accuracy of survival predictions, with higher c-indexes meaning more accurate predictions.

#### RESULTS

Compared to PESI, our debiased multimodal SP had higher c-indexes and lower biases across all three potential population biases of race, ethnicity, and gender. Additionally, while PESI c-indexes showed great variations within population bias groups, our debiased SP achieved more consistent predictions within the groups. The Latino PESI c-index was 0.481 which was significantly lower than the non-Latino PESI c-index of 0.687, indicating PESI's poor prognostic value for Latino populations. After ethnicity debiasing, the debiased SP Latino c-index was 0.731 and 0.723 for non-Latino populations. A similar result occurred with gender disentanglement with a female PESI c-index of 0.529 and male PESI c-index of 0.739. Our gender debiased SP had a female c-index of 0.763 and a male c-index of 0.785.

#### CONCLUSION

Our results demonstrate that disentangling population bias in multimodal datasets is possible and improves SP. The debiased multimodal SP was also more accurate and equitable for populations relative to the standard of PESI.

#### CLINICAL RELEVANCE/APPLICATION

Our work demonstrates a method to minimize population biases in multimodal datasets while producing a debiasing SP model that is more equitable and accurate than the current clinical standard of PESI. We offer an improvement in equity.

### Total Data in Radiology Exams Increase More than Appreciated by the Increase in Number of Exams

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S401

Tomas Bjerner, MD, PhD (*Presenter*) Medical Advisory Board, Carestream Health, Inc

#### PURPOSE

Scanners for radiological examinations can examine an increasing number of patients per time unit and generate increasing amounts of data per scanned patient. Most radiology departments follow their production in number of examinations and reports of increasing workload for radiologists are available in the literature. The increase in workload for radiologists can be assumed to, at least in part, depend on the number of studies read and the complexity of the studies. The complexity of studies might be related to the amount of data within them and in some countries, there are systems addressing the complexity of exams using relative value units (RVU). The aim of the present study is to estimate the development of the workload for radiologists over time including both number of examinations and complexity (approximated by the amount of stored data).

#### METHODS AND MATERIALS

The total number of stored data, images, series and studies in the PACS database (Philips VuePACS 12.2.8, Best, the Netherlands) in a regional health care organization including a tertiary imaging center in Sweden for the years 2009-2022 were calculated. Data for CT and MR were used and only production from within the healthcare organization was included (imported studies from other hospitals were omitted). From these numbers the average size of a study could be calculated as well as the change of these parameters over time.

#### RESULTS

Over the period 2009-2022 the number of CT studies increased by 87.2% equal to 4.9% per year. Over the same period, stored data for these studies increased more than 6 times (525%) or 15.1% per year. The number of images increased by 459% or 14.2% per year. This resulted in the average CT study increasing from 229 to 765MB (234%) during this time span. Over the same period the number of MR studies increased 101% equal to 5.5% per year. Over the same period, stored data for these studies increased more than 5 times (412%) or 13.4% per year. The number of images increased by 364% or 12.5% per year. This resulted in the average MR study increasing from 84.7 to 216MB (155%) during this time span.

#### CONCLUSION

Over the period 2009-2022, the data in studies for radiologists to analyze increased 5-6 times while the number of studies only doubled. This was mainly due to the increased number of images in studies. This resulted in an increase in the workload for reading radiologists that is higher than when only the number of studies is considered.

#### CLINICAL RELEVANCE/APPLICATION

Over the period 2009-2022, total data in exams for radiologists to analyze increased 5-6 times while the corresponding number of studies only doubled. This ratio is important when planning the workload in a radiology department.

### The Comprehensive Open Federated Ecosystem (COFE): Enabling Impactful Healthcare Studies

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S401

Sarthak Pati, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Robustness generalizability of artificial intelligent (AI) models is dependent on using ample diverse data. Data ownership legal hurdles hinder access to such data in the current paradigm of multi-site collaborations. To address these, we introduce the community-driven Comprehensive Open Federated Ecosystem (COFE), which intends to make distributed healthcare AI more accessible by leveraging zero/low code principles. COFE models get to learn across data silos using federated learning (FL) we assess their performance on diverse out-of-distribution datasets using federated evaluation (FE). As initial use-cases, COFE enabled the Federated Tumor Segmentation (FeTS) Initiative, which focused on the boundary detection of histologically-distinct brain tumor sub-compartments in MRI scans, the FeTS Challenge, the first FL-focused community benchmark.

#### METHODS AND MATERIALS

We designed COFE to be agnostic to data type (imaging, EHR, genomics) the model to train. COFE offered an end-to-end solution to the FeTS initiative through 4 distinct modes of operation: data preprocessing, automatic tumor sub-compartment delineation by label fusion of pre-trained AI models, manual refinement of these delineations FL using the Linux Foundation's OpenFL. Additionally, building upon the collaborative network of the FeTS initiative we used MedPerf to conduct the FeTS Challenge, which followed a clinical trial design to evaluate AI methods on real-world conditions.

#### RESULTS

In the FeTS Initiative, we observe an average improvement of 25% in the accuracy of the model on each collaborator's validation data when compared to a model trained on publicly available data. Notably, the difficult regions of the tumor showed the most improvement, with the most prominent being the region for surgical intervention, the tumor core, which improved by 33%. In the FeTS Challenge, inference-time data augmentation combined with post-processing yielded optimal results.

#### CONCLUSION

Our findings on FeTS support that COFE enables training of a consensus AI model that has gained knowledge from data of geographically distinct collaborators, while the data of each collaborator are always retained within their institution, overcoming legal & ownership hurdles. At the same time, it can perform evaluations of pretrained models across completely out-of-distribution datasets to quantify the robustness & generalizability of the model.

#### CLINICAL RELEVANCE/APPLICATION

Federated Learning allows training of AI models using diverse datasets without sharing the data, while Federated Evaluation allows AI models to be trained on true out-of-sample data. Combined, this would result in more robust models without raising ethical dilemmas.

### Anonymizing Radiographs and Making Them "AI Ready" Using a Deep Learning Algorithm

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S401

Bardia Khosravi, MD, MPH (*Presenter*) Nothing to Disclose

#### PURPOSE

Radiographs play a crucial role in medical care by providing valuable information about a patient's anatomy and potential pathologies. Most radiographs contain radio-opaque markers that display information such as the side, positioning, radiographer initials, and often patient identifier. In this study, we develop a deep learning (DL) model that detects and selectively removes these markers from images to enable de-identified data sharing and improve the suitability of images for training robust deep learning models.

#### METHODS AND MATERIALS

To create our ground-truth dataset, we annotated 2000 pelvic radiographs collected between 2000 and 2021. Each marker area was annotated with a bounding box. The data was then split at the patient level into 60%/20%/20% for training, validation, and testing, respectively. Images were resampled to 512x512 pixels, and a YOLOv5-x model was trained to localize markers. Mean average precision at a 50% threshold (mAP-50) was reported as a measure of model performance on the test set. While removing identification markers is important, laterality markers contain valuable information that helps guide the pre-processing pipeline of deep learning models. We developed an image processing algorithm that examines each marker area and sends it to an OCR algorithm for characterization. In our case, laterality markers were retained if "R" and "L" characters were detected in the image (Figure 1). To externally validate the model, we applied it to chest radiographs from the validation set of the CheXpert dataset to assess its performance on data from different body parts and organizations.

#### RESULTS

The model reached a mAP-50 of 0.99 and 0.98 on the validation and internal test sets, respectively. It had a de-identification accuracy of 100% (400/400) on the test set, with a false-positive rate of 1% (8/632). The retention accuracy was 93% (359/386). On the external set of chest radiographs, the model successfully removed markers from 96% of radiographs (221/231). After fine-tuning on 20 CheXpert radiographs, the model was able to remove markers from 99.6% (230/231) of chest radiographs.

#### CONCLUSION

We present a pipeline for de-identifying radiographs by selectively removing patient identifiers. This model can be easily refined to effectively detect radiographic markers on a wide variety of x-rays, demonstrating its generalizability.

#### CLINICAL RELEVANCE/APPLICATION

Radiographic markers hinder data sharing and the development of public, multi-centric datasets and can introduce spectrum bias, which can lead to overfitting when training DL models. A robust de-identification algorithm capable of removing these markers could facilitate inter-institutional data sharing and more robust DL model training.

### Evaluating Radiologist Recall from Memory: A Data Protection Study on X-ray Image Re-identification

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S401

Vanessa Wyrwoll, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To date there are no reliable measures for radiologist's re-identification rate in the literature. This study quantifies the rate at which experienced radiologists can re-identify chest radiographs from memory, and thus, the risk of an "accidental" reidentification when working with de-identified radiographic data sets.

#### METHODS AND MATERIALS

We conducted an online survey with 22 radiologists from the RACOON network, consisting of 38 university clinics. Readers had 3.9+-1.82 years of clinical experience on average. All participants created structured reports for chest radiographs of five different patients sequentially (phase 1). Each radiograph was assigned a pseudonym displayed alongside the image. 24 hours after completion of this task, participants were presented with ten different, randomly selected chest radiographs (phase 2). For half of the participants, these included a follow up study of one patient of phase 1. For each image, participants were asked to match a specific patient from phase 1 to the radiographs of phase 2.

#### RESULTS

From 210 answers, 163 were correct with 0 true positives and 10 false positives. Readers took 8.9+-12.5 seconds to respond in phase 2, which had no correlation to accuracy (mean accuracy 77.6%). False positive rate (FPR) is greater than 0.141 ( $p=0.049$ ). The true positive rate (TPR) is less than to be expected by random input with weak evidence ( $p=0.144$ ). This illustrates that the probability of correctly identifying a patient in a set of pictures was less and the number of mistakenly recognized images has been greater than expected at random. Also, according to this study, the probability of a patient being incorrectly identified as the target patient ranges from 13% to 24.5% (95% CI).

#### CONCLUSION

Readers falsely assumed patient reidentification in 17.6% of cases. Even for a moderately-sized pool of patients from which images might have been sampled, the reader cannot rule out misidentifications at a high level of confidence. For example, if candidate images have been sampled from a population the size of 80 million, the likelihood of a claimed match being correct would be 0.0000067%.

#### CLINICAL RELEVANCE/APPLICATION

Provided that images with rare and distinctive anatomical features have been excluded, recollection from memory is not a relevant data privacy risk when dealing with large public data sets of radiographs that have been de-identified by DICOM header anonymization, even under the pessimistic assumption that the correct patient is part of the data set. If the population from which patients may have been sampled is sufficiently large, the large number of incorrectly identified patients renders the likelihood of a presumed identification being correct minute.

### Safe Medical AI in Diagnostic Informatics: Defending Adversarial Attacks

Wednesday, Nov. 29 9:30AM - 10:30AM Room: S401

Degan Hao, MS (*Presenter*) Intern, F. Hoffmann-La Roche Ltd

#### PURPOSE

Deep learning-based computer aided diagnosis are being actively developed and evaluated for clinical translation and deployment, especially in the frontier of mammographic breast cancer diagnosis. Deep learning diagnosis models however are shown vulnerable to adversarial attacks - where adversarial data, i.e., data corrupted intentionally by small perturbations, can fool a deep learning model to produce misdiagnosis. This creates a threat to safely deploy deep learning models in clinical imaging informatics workflow. The purpose of this study is to develop and evaluate a novel technical framework to defend adversarial attacks in the context of a deep learning-based breast cancer diagnosis model.

#### METHODS AND MATERIALS

In this IRB-approved study, we identified a dataset of 4,346 mammograms from a cohort of 1,284 women who underwent full-field digital mammography for breast cancer screening. We first built a diagnosis model using a VGG-16 network to classify breast cancer (366 biopsy-proven malignancy) vs. normal (918 negative cases). We evaluated two types of adversarial attacks: (1) white-box attack (attackers know about AI model parameters) where adversarial data were generated by the projected gradient descent method to insert adversarial noises to mammogram images, and (2) black-box attacks (attackers have no access to AI model parameters) where adversarial data were generated by intentionally inserting or removing tumorous tissue in mammograms. To defend the attacks, we designed a novel defense framework using the adversarial training strategy (i.e., enhanced model training using adversarial data), where we developed a regularization algorithm to facilitate learning adversarially robust features for classification and a label independent data augmentation to resolve the common issue of data leakage introduced by black-box data synthesis. We used five-fold cross validation to compare the AUC values of the proposed adversarial training vs. regular training without our method.

#### RESULTS

The breast cancer diagnosis model has an AUC of 0.668 with regular training. Under white-box attack, the model's performance degrades to an AUC of 0.415, but our proposed framework brings the AUC to 0.673. Likewise, black-box attack downgrades the model to an AUC of 0.461 but our framework brings the AUC to 0.637.

#### CONCLUSION

The proposed defending framework can make the breast cancer diagnosis model resilient to both white-box and black-box adversarial attacks.

#### CLINICAL RELEVANCE/APPLICATION

In active efforts of deploying medical AI into clinical informatics workflow, our proposed method can effectively defend potential adversarial attacks, ensuring safe and secure use of AI for patient care.

#### W3-SSMK08-1 Association Between Abdominal CT Measurements of Body Composition and Waitlist Mortality in Kidney Transplant Candidates

Omid Shafaat, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Body mass index (BMI) is often used to determine kidney transplant (KT) candidacy. However, this measure of body composition has several limitations including the inability to accurately capture dry weight in KT candidates undergoing dialysis. Objective CT-based measures of body composition may improve pre- KT risk stratification and capture physiologic aging more accurately. We quantified the association between three CT-based body composition measurements (sarcopenia, myosteatosis, and sarcopenic obesity) and waitlist mortality in KT candidates.

#### METHODS AND MATERIALS

We leveraged a prospective cohort of 828 KT candidates from 2010-2022 with clinically obtained CT scans that included the third lumbar vertebral level using adjusted competing risk regression. Body composition measurements, including skeletal muscle index (SMI) and skeletal muscle radiation attenuation (SM-RA) were obtained using OsiriX software by drawing a closed polygon and using the region of interest tool. Sarcopenia was defined as an SMI < 50 cm<sup>2</sup> /m<sup>2</sup> for males and an SMI < 39 cm<sup>2</sup> /m<sup>2</sup> for females. Myosteatosis was defined as an SM-RA < 41 mean HU for recipients with a BMI < 25 kg/m<sup>2</sup> and an SM-RA < 33 mean HU for recipients with a BMI = 25 kg/m<sup>2</sup>. Sarcopenic obesity was defined as a BMI = 30 kg/m<sup>2</sup> for sarcopenic recipients. Differences in characteristics were tested using Fisher's exact tests for categorical, ANOVA tests for normally distributed continuous, and Kruskal-Wallis tests for non-normally distributed continuous variables.

#### RESULTS

Among 828 KT candidates, 570 (68.8%) had myosteatosis, 352 (42.5%) had sarcopenia, and 94 (11.4%) had sarcopenic obesity. Sarcopenia (aSHR=1.04, 95%CI:0.74-1.47) and sarcopenic obesity (aSHR=1.28, 95%CI:0.83-2.04) were not associated with mortality. Patients with myosteatosis were at a 1.62-fold elevated risks of mortality (95%CI:1.07-2.45). When stratified by age, sarcopenic obesity (aSHR=2.21, 95%CI:1.28-3.83), and myosteatosis (aSHR=1.95, 95%CI:1.18-3.21) were associated with an elevated risk among candidates <65 years but not among those =65 years. Sarcopenic obesity was also associated with waitlist mortality among frail candidates (aHR=2.54, 95%CI:1.28-5.05).

#### CONCLUSION

Myosteatosis was associated with elevated risks of waitlist mortality in KT candidates. Furthermore, sarcopenic obesity was associated with elevated risks of waitlist mortality among younger KT candidates and among those who are frail.

#### CLINICAL RELEVANCE/APPLICATION

Clinicians should implement CT- based body composition measurements as a tool to improve risk prediction. Identifying high risk patients allows for ample time to implement early interventions such as prehabilitation.

#### W3-SSMK08-2 Bone Marrow Biopsies: Is CT, Fluoroscopy, or No Imaging Guidance the Most Cost-Effective Strategy

Madalena Da Silva Cardoso, MS, BA (*Presenter*) Nothing to Disclose

## PURPOSE

To determine the most cost-effective strategy for bone marrow biopsies.

## METHODS AND MATERIALS

A decision analytic model from the health care system perspective was used to evaluate the cost-effectiveness of three bone marrow biopsy techniques, no-imaging, CT guided, and fluoroscopy guided, for patients with high clinical concern for multiple myeloma. The time horizon used was 1 month to focus on the costs and impact on quality of life that this biopsy workflow has on this patient population. Model input data on utilities, costs, and probabilities were obtained from comprehensive literature review and expert opinion. Costs were estimated in 2023 U.S. dollars. Primary effectiveness outcome was quality adjusted life days (QALD).

## RESULTS

CT guided biopsy was the most cost-effective strategy as it was the most effective, 15.75 QALDs, had the highest net monetary benefit (NMB), \$4,095, and an incremental cost-effectiveness ratio (ICER) of \$169, below the willingness to pay threshold. Fluoroscopy guided biopsy was excluded by extended dominance as it had a higher ICER, \$294, than a strategy (CT) that produced more effectiveness (15.62 vs 15.75 QALDs). No imaging had the lowest effectiveness, 15.26 QALDs, and 2nd highest NMB, \$4,089. The model was sensitive to the probability of getting a diagnostic biopsy result for each of the three strategies. Probabilistic sensitivity analysis found CT guided biopsy to be the most cost-effective in 100% of simulations over a wide range of willingness to pay thresholds.

## CONCLUSION

CT guided biopsy appears to be the most cost-effective strategy for bone marrow biopsy in patients suspected of multiple myeloma.

## CLINICAL RELEVANCE/APPLICATION

While CT guidance appears to be the most cost-effectiveness biopsy strategy, consideration of resource availability and the impact that these biopsies have on overall CT scanner workflow and capacity should be considered when deciding on the best way to perform these biopsies.

## W3-SSMK08-3 Radiomics Analysis Based on CT for the Diagnosis of Ewing Sarcoma and Osteosarcoma

Ying Liu, MD (*Presenter*) Nothing to Disclose

## PURPOSE

This study aimed to develop and validate radiomics models on the basis of computed tomography (CT) and clinical features for the diagnosis of Ewing sarcoma (ES) and Osteosarcoma(OS).

## METHODS AND MATERIALS

A total of 294 ES and OS patients from June 2009 to August 2022 were retrospectively involved in this study, and the patients enrolled before September 2019 were randomly divided into a train cohort (n=195) and a test cohort (n=49) according to a ratio of 8:2. Fifty patients (25 cases of OS, 25 cases of ES) in our hospital from September 2019 to August 2022 were defined as independent internal validation cohort. We manually segmented the tumor lesions along the tumor margins on CT-enhanced (CTE) images. The intralesional region and the intra-and perilesional regions of 3mm were defined as region of interest (ROIs) for the radiomics features analysis. The most valuable radiomics features for differential diagnosis of ES were selected using analysis of variance (ANOVA) and the least absolute shrinkage and selection operator (LASSO), and then the radiomics models (CTE and CTE+3mm models) and clinical-radiomics models (CTE\_clinical and CTE+3mm\_clinical models) were established. The performance of different models were evaluated by the area under the operating characteristic curve (AUC), accuracy (ACC), sensitivity, and specificity. The comparisons between AUCs of the radiomics models were conducted by using DeLong test.

## RESULTS

The AUC values of CTE and CTE+3mm models obtained by applying the Gaussian process (GP) classifier were higher than other models, and the AUC values were 0.907/0.903/0.912 and 0.896/0.898/0.891 in the train cohort, test cohort and internal validation cohort, respectively (The AUC values of CTE model using logistic regression [LR] classifier: 0.905, 0.877 and 0.899; the AUC values of CTE+3mm model using LR classifier: 0.876, 0.873 and 0.883). There was no statistically significant difference between the diagnostic effectiveness of the two models in the train cohort, test cohort and internal validation cohort ( $P>0.05$ ). There was no statistically significant difference between the AUC values of the clinical-radiomics models and radiomics models in the test cohort and internal validation cohort ( $P>0.05$ ).

## CONCLUSION

The radiomics models based on CT-enhanced images can be used for the differential diagnosis of ES and OS, and the diagnostic efficiency of the CTE+3mm model covering intra-tumoral and peritumoral features has not improved compared with the CTE model.

## CLINICAL RELEVANCE/APPLICATION

In summary, the CT based radiomics model could be an accurate auxiliary diagnostic tool for the differentiation of ES and OS, which may relatively improve the diagnostic efficiency of clinicians.

### W3-SSMK08-5 **Analysis of Shoulder Kinematics and Determination of Scapulohumeral Rhythm Using a Machine Learning Algorithm and Dynamic Digital Radiography Images**

John M. Sabol, PhD (*Presenter*) Employee, Konica Minolta, Inc

#### PURPOSE

Dynamic digital radiography (DDR) is a novel imaging technique that utilizes a pulsed x-ray source and rapid read-out detector to acquire radiographs at 6 or 15 Hz. DDR has been applied to several thoracic and musculoskeletal imaging applications. Although dynamic visualization of anatomy is useful to detect numerous pathologies, quantitative assessment of joint motion may improve sensitivity and specificity of DDR in diagnosis and evaluation of therapy response. Manual measurement suffers from inter- and intra-reader variability and is impractical given the large number of images. This studies purpose is to evaluate the performance of an Artificial Intelligence/Machine Learning (ML) algorithm to quantify scapulohumeral rhythm (SHR) and demonstrate proof of concept use the tool to differentiate multiple shoulder pathologies.

#### METHODS AND MATERIALS

A prototype ML algorithm using an HRNet classification architecture, an efficient approach for pose estimation, was trained on 447 images from 267 cases to recognize the humerus and scapula positions, calculate the scapulo-thoracic and gleno-humeral angles, and thus determine the SHR across the complete range of abduction. The performance of this algorithm was evaluated by comparison with manual human reader measurements on a unique dataset (not used for training or testing) of 73 shoulder exams (23 normal controls, 41 rotator cuff tears, 9 adhesive capsulitis, as determined by clinical exam and MRI). Two trained physician readers measured the SHR at 30-60, 60-90 and 30-90 degrees of glenohumeral motion. The AI and human measurements were compared using intra class correlations (ICC).

#### RESULTS

A total of 219 paired measurements were made by both the ML algorithm and manual physician methods. For SHR the inter-reader reliability was excellent between the two manual measurements (ICC 0.87 (95% CI 0.75-0.93)). Moderate reliability was observed between the manual and ML measurements of SHR. The SHR evaluated across the range of motion was shown to be an effective means of differentiating the pathologic shoulders from each other and the normal controls.

#### CONCLUSION

The prototype ML algorithm shows promise as a practical and efficient means to determine SHR and has potential to diagnose shoulder conditions by automated analysis of scapular and humeral kinematics. Further training using more specific anatomic landmarks and a larger dataset is required to improve the agreement with manual measurements of SHR.

## CLINICAL RELEVANCE/APPLICATION

Dynamic digital radiography enables dynamic assessment of shoulder kinematics and visualization of pathologic motion. ML quantitative assessment can automatically determine the SHR and has potential for efficient characterization of normal and pathologic motion.

### W3-SSMK08-6 **Identifying Patients at Risk for Bone Non-Union: Evaluation of Dual-Energy CT-derived Metrics in Distal Radius Fractures**

Leon D. Gruenewald, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Distal radius fractures (DRF) are among the most diagnosed fractures in emergency departments, and bone non-union is a significant complication that can lead to persistent pain and functional limitations. Despite the clinical implications, there is currently no established approach to identify patients at risk for bone non-union. The purpose of this study was to evaluate various metrics derived from routine CT scans of the distal radius to identify patients at risk of bone non-union.

#### METHODS AND MATERIALS

The distal radius of patients who underwent dual-energy CT (DECT) between 01/2016 and 08/2021 was retrospectively analysed. Cortical HU, trabecular HU, cortical thickness, and DECT-based bone mineral density (BMD) were obtained from all examinations. Patient files and follow-up images of patients were examined for the occurrence of bone non-union. Receiver-operating characteristic (ROC) analysis identified AUC values for BMD, HU values and cortical thickness, and logistic regression models were used to evaluate their associations with the occurrence of bone non-union.

## **RESULTS**

263 patients (median age, 52 years; interquartile range 36 - 64; 132 women; 192 fractures) were included in this study. ROC curve analysis demonstrated a significantly higher AUC value for DECT-derived BMD compared to cortical HU, trabecular HU and cortical thickness (0.83 vs. 0.63, 0.60 and 0.56, respectively;  $P < .01$ ). Logistic regression models confirmed a significant association of lower DECT-derived BMD with the occurrence of bone non-union (Odds Ratio, 0.93;  $P < .001$ ), but not of cortical HU, trabecular HU or cortical thickness ( $P > .05$  for all values, respectively).

## **CONCLUSION**

CT examinations of the distal radius obtained in clinical routine may serve as a useful tool in identifying patients at risk of developing bone non-union. In this context, dual-energy CT-derived bone mineral density is a better predictor of bone non-union compared to cortical HU, trabecular HU, and cortical thickness.

## **CLINICAL RELEVANCE/APPLICATION**

By using one or multiple of the suggested CT-metrics, ideally DECT-based BMD, radiologists could predict the likelihood of bone non-union in patients with distal radius fractures. This can help in determining the optimal treatment strategy and follow-up plan for patients.

### Association Between Abdominal CT Measurements of Body Composition and Waitlist Mortality in Kidney Transplant Candidates

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E450A

Omid Shafaat, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Body mass index (BMI) is often used to determine kidney transplant (KT) candidacy. However, this measure of body composition has several limitations including the inability to accurately capture dry weight in KT candidates undergoing dialysis. Objective CT-based measures of body composition may improve pre- KT risk stratification and capture physiologic aging more accurately. We quantified the association between three CT-based body composition measurements (sarcopenia, myosteotosis, and sarcopenic obesity) and waitlist mortality in KT candidates.

#### METHODS AND MATERIALS

We leveraged a prospective cohort of 828 KT candidates from 2010-2022 with clinically obtained CT scans that included the third lumbar vertebral level using adjusted competing risk regression. Body composition measurements, including skeletal muscle index (SMI) and skeletal muscle radiation attenuation (SM-RA) were obtained using OsiriX software by drawing a closed polygon and using the region of interest tool. Sarcopenia was defined as an SMI < 50 cm<sup>2</sup> /m<sup>2</sup> for males and an SMI < 39 cm<sup>2</sup> /m<sup>2</sup> for females. Myosteotosis was defined as an SM-RA < 41 mean HU for recipients with a BMI < 25 kg/m<sup>2</sup> and an SM-RA < 33 mean HU for recipients with a BMI = 25 kg/m<sup>2</sup>. Sarcopenic obesity was defined as a BMI = 30 kg/m<sup>2</sup> for sarcopenic recipients. Differences in characteristics were tested using Fisher's exact tests for categorical, ANOVA tests for normally distributed continuous, and Kruskal-Wallis tests for non-normally distributed continuous variables.

#### RESULTS

Among 828 KT candidates, 570 (68.8%) had myosteotosis, 352 (42.5%) had sarcopenia, and 94 (11.4%) had sarcopenic obesity. Sarcopenia (aSHR=1.04, 95%CI:0.74-1.47) and sarcopenic obesity (aSHR=1.28, 95%CI:0.83-2.04) were not associated with mortality. Patients with myosteotosis were at a 1.62-fold elevated risks of mortality (95%CI:1.07-2.45). When stratified by age, sarcopenic obesity (aSHR=2.21, 95%CI:1.28-3.83), and myosteotosis (aSHR=1.95, 95%CI:1.18-3.21) were associated with an elevated risk among candidates <65 years but not among those =65 years. Sarcopenic obesity was also associated with waitlist mortality among frail candidates (aHR=2.54, 95%CI:1.28-5.05).

#### CONCLUSION

Myosteotosis was associated with elevated risks of waitlist mortality in KT candidates. Furthermore, sarcopenic obesity was associated with elevated risks of waitlist mortality among younger KT candidates and among those who are frail.

#### CLINICAL RELEVANCE/APPLICATION

Clinicians should implement CT- based body composition measurements as a tool to improve risk prediction. Identifying high risk patients allows for ample time to implement early interventions such as prehabilitation.

### **Bone Marrow Biopsies: Is CT, Fluoroscopy, or No Imaging Guidance the Most Cost-Effective Strategy**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E450A

Madalena Da Silva Cardoso, MS, BA (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To determine the most cost-effective strategy for bone marrow biopsies.

#### **METHODS AND MATERIALS**

A decision analytic model from the health care system perspective was used to evaluate the cost-effectiveness of three bone marrow biopsy techniques, no-imaging, CT guided, and fluoroscopy guided, for patients with high clinical concern for multiple myeloma. The time horizon used was 1 month to focus on the costs and impact on quality of life that this biopsy workflow has on this patient population. Model input data on utilities, costs, and probabilities were obtained from comprehensive literature review and expert opinion. Costs were estimated in 2023 U.S. dollars. Primary effectiveness outcome was quality adjusted life days (QALD).

#### **RESULTS**

CT guided biopsy was the most cost-effective strategy as it was the most effective, 15.75 QALDs, had the highest net monetary benefit (NMB), \$4,095, and an incremental cost-effectiveness ratio (ICER) of \$169, below the willingness to pay threshold. Fluoroscopy guided biopsy was excluded by extended dominance as it had a higher ICER, \$294, than a strategy (CT) that produced more effectiveness (15.62 vs 15.75 QALDs). No imaging had the lowest effectiveness, 15.26 QALDs, and 2nd highest NMB, \$4,089. The model was sensitive to the probability of getting a diagnostic biopsy result for each of the three strategies. Probabilistic sensitivity analysis found CT guided biopsy to be the most cost-effective in 100% of simulations over a wide range of willingness to pay thresholds.

#### **CONCLUSION**

CT guided biopsy appears to be the most cost-effective strategy for bone marrow biopsy in patients suspected of multiple myeloma.

#### **CLINICAL RELEVANCE/APPLICATION**

While CT guidance appears to be the most cost-effectiveness biopsy strategy, consideration of resource availability and the impact that these biopsies have on overall CT scanner workflow and capacity should be considered when deciding on the best way to perform these biopsies.

### Radiomics Analysis Based on CT for the Diagnosis of Ewing Sarcoma and Osteosarcoma

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E450A

Ying Liu, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aimed to develop and validate radiomics models on the basis of computed tomography (CT) and clinical features for the diagnosis of Ewing sarcoma (ES) and Osteosarcoma(OS).

#### METHODS AND MATERIALS

A total of 294 ES and OS patients from June 2009 to August 2022 were retrospectively involved in this study, and the patients enrolled before September 2019 were randomly divided into a train cohort (n=195) and a test cohort (n=49) according to a ratio of 8:2. Fifty patients (25 cases of OS, 25 cases of ES) in our hospital from September 2019 to August 2022 were defined as independent internal validation cohort. We manually segmented the tumor lesions along the tumor margins on CT-enhanced (CTE) images. The intralesional region and the intra-and perilesional regions of 3mm were defined as region of interest (ROIs) for the radiomics features analysis. The most valuable radiomics features for differential diagnosis of ES were selected using analysis of variance (ANOVA) and the least absolute shrinkage and selection operator (LASSO), and then the radiomics models (CTE and CTE+3mm models) and clinical-radiomics models (CTE\_clinical and CTE+3mm\_clinical models) were established. The performance of different models were evaluated by the area under the operating characteristic curve (AUC), accuracy (ACC), sensitivity, and specificity. The comparisons between AUCs of the radiomics models were conducted by using DeLong test.

#### RESULTS

The AUC values of CTE and CTE+3mm models obtained by applying the Gaussian process (GP) classifier were higher than other models, and the AUC values were 0.907/0.903/0.912 and 0.896/0.898/0.891 in the train cohort, test cohort and internal validation cohort, respectively (The AUC values of CTE model using logistic regression [LR] classifier: 0.905, 0.877 and 0.899; the AUC values of CTE+3mm model using LR classifier: 0.876, 0.873 and 0.883). There was no statistically significant difference between the diagnostic effectiveness of the two models in the train cohort, test cohort and internal validation cohort ( $P>0.05$ ). There was no statistically significant difference between the AUC values of the clinical-radiomics models and radiomics models in the test cohort and internal validation cohort ( $P>0.05$ ).

#### CONCLUSION

The radiomics models based on CT-enhanced images can be used for the differential diagnosis of ES and OS, and the diagnostic efficiency of the CTE+<sub>3mm</sub> model covering intra-tumoral and peritumoral features has not improved compared with the CTE model.

#### CLINICAL RELEVANCE/APPLICATION

In summary, the CT based radiomics model could be an accurate auxiliary diagnostic tool for the differentiation of ES and OS, which may relatively improve the diagnostic efficiency of clinicians.

### Analysis of Shoulder Kinematics and Determination of Scapulothoracic Rhythm Using a Machine Learning Algorithm and Dynamic Digital Radiography Images

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E450A

John M. Sabol, PhD (*Presenter*) Employee, Konica Minolta, Inc

#### PURPOSE

Dynamic digital radiography (DDR) is a novel imaging technique that utilizes a pulsed x-ray source and rapid read-out detector to acquire radiographs at 6 or 15 Hz. DDR has been applied to several thoracic and musculoskeletal imaging applications. Although dynamic visualization of anatomy is useful to detect numerous pathologies, quantitative assessment of joint motion may improve sensitivity and specificity of DDR in diagnosis and evaluation of therapy response. Manual measurement suffers from inter- and intra-reader variability and is impractical given the large number of images. This study's purpose is to evaluate the performance of an Artificial Intelligence/Machine Learning (ML) algorithm to quantify scapulothoracic rhythm (SHR) and demonstrate proof of concept use of the tool to differentiate multiple shoulder pathologies.

#### METHODS AND MATERIALS

A prototype ML algorithm using an HRNet classification architecture, an efficient approach for pose estimation, was trained on 447 images from 267 cases to recognize the humerus and scapula positions, calculate the scapulothoracic and glenohumeral angles, and thus determine the SHR across the complete range of abduction. The performance of this algorithm was evaluated by comparison with manual human reader measurements on a unique dataset (not used for training or testing) of 73 shoulder exams (23 normal controls, 41 rotator cuff tears, 9 adhesive capsulitis, as determined by clinical exam and MRI). Two trained physician readers measured the SHR at 30-60, 60-90 and 30-90 degrees of glenohumeral motion. The AI and human measurements were compared using intra class correlations (ICC).

#### RESULTS

A total of 219 paired measurements were made by both the ML algorithm and manual physician methods. For SHR the inter-reader reliability was excellent between the two manual measurements (ICC 0.87 (95% CI 0.75-0.93)). Moderate reliability was observed between the manual and ML measurements of SHR. The SHR evaluated across the range of motion was shown to be an effective means of differentiating the pathologic shoulders from each other and the normal controls.

#### CONCLUSION

The prototype ML algorithm shows promise as a practical and efficient means to determine SHR and has potential to diagnose shoulder conditions by automated analysis of scapular and humeral kinematics. Further training using more specific anatomic landmarks and a larger dataset is required to improve the agreement with manual measurements of SHR.

#### CLINICAL RELEVANCE/APPLICATION

Dynamic digital radiography enables dynamic assessment of shoulder kinematics and visualization of pathologic motion. ML quantitative assessment can automatically determine the SHR and has potential for efficient characterization of normal and pathologic motion.

### Identifying Patients at Risk for Bone Non-Union: Evaluation of Dual-Energy CT-derived Metrics in Distal Radius Fractures

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E450A

Leon D. Gruenewald, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Distal radius fractures (DRF) are among the most diagnosed fractures in emergency departments, and bone non-union is a significant complication that can lead to persistent pain and functional limitations. Despite the clinical implications, there is currently no established approach to identify patients at risk for bone non-union. The purpose of this study was to evaluate various metrics derived from routine CT scans of the distal radius to identify patients at risk of bone non-union.

#### METHODS AND MATERIALS

The distal radius of patients who underwent dual-energy CT (DECT) between 01/2016 and 08/2021 was retrospectively analysed. Cortical HU, trabecular HU, cortical thickness, and DECT-based bone mineral density (BMD) were obtained from all examinations. Patient files and follow-up images of patients were examined for the occurrence of bone non-union. Receiver-operating characteristic (ROC) analysis identified AUC values for BMD, HU values and cortical thickness, and logistic regression models were used to evaluate their associations with the occurrence of bone non-union.

#### RESULTS

263 patients (median age, 52 years; interquartile range 36 - 64; 132 women; 192 fractures) were included in this study. ROC curve analysis demonstrated a significantly higher AUC value for DECT-derived BMD compared to cortical HU, trabecular HU and cortical thickness (0.83 vs. 0.63, 0.60 and 0.56, respectively;  $P < .01$ ). Logistic regression models confirmed a significant association of lower DECT-derived BMD with the occurrence of bone non-union (Odds Ratio, 0.93;  $P < .001$ ), but not of cortical HU, trabecular HU or cortical thickness ( $P > .05$  for all values, respectively).

#### CONCLUSION

CT examinations of the distal radius obtained in clinical routine may serve as a useful tool in identifying patients at risk of developing bone non-union. In this context, dual-energy CT-derived bone mineral density is a better predictor of bone non-union compared to cortical HU, trabecular HU, and cortical thickness.

#### CLINICAL RELEVANCE/APPLICATION

By using one or multiple of the suggested CT-metrics, ideally DECT-based BMD, radiologists could predict the likelihood of bone non-union in patients with distal radius fractures. This can help in determining the optimal treatment strategy and follow-up plan for patients.

#### Sub-Events

#### **W3-SSNR10-1 Prospective Validation of Accelerated Brain MRI Using Deep Learning-Based Reconstruction: Simultaneous Application to Spin-Echo and Gradient-Echo Sequence**

Kyu Sung Choi, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the effectiveness of brain MRI with deep learning-based fast reconstructed MRI (DL-FR) by comparing qualitative and quantitative image quality of conventional MRI for both spin-echo and gradient-echo sequences.

#### METHODS AND MATERIALS

In this multi-reader, multi-sequence, and multi-vendor prospective study, both synthetic and conventional MRI pairs with T1-weighted, T2-weighted, T2-FLAIR, and 3D T1-weighted images from 100 subjects (29 males; 57.3±16.0 years; 34 subjects with GE, 35 with Philips, and 31 with Siemens), were examined by 4 blinded neuroradiologists. The images were randomized, and evaluated for overall image quality, delineation of structures, and artifacts using 5-point Likert scale, in the two separate sessions. Intraclass correlation coefficient was calculated for Inter-reader agreement. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) was obtained for both 3D T1w and T2 FLAIR. For quantitative analysis, volumetric analysis of brain parcellation and white matter T2 hyperintensity (WMH) was performed using LesionQuant (LQ) and NeuroQuant (NQ), respectively.

#### RESULTS

DL-FR showed median 41% (24-51%) reduced acquisition time with improvements in overall image quality (mean±SD, 3.79±0.72 vs. 3.40±0.63,  $p<0.001$ ); and enhanced structure delineation (3.59±0.81 vs. 3.45±0.77,  $p<0.001$ ), while lesion conspicuity (3.34±1.05 vs. 3.26±1.08,  $p=0.32$ ), Fazekas scale (2.24±1.40 vs 2.18±1.40,  $p=0.37$ ), enlarged perivascular space grading (1.93±1.21 vs 1.90±1.20,  $p=0.65$ ), and image artifacts (3.78±0.73 vs. 3.79±0.69,  $p=0.47$ ) was comparable. Inter-reader agreement was moderate to substantial ( $\kappa=0.74$  for structure and lesion delineation;  $\kappa=0.52$  for artifact; and  $\kappa=0.55$  for overall quality), indicating reliable qualitative assessments. SNR and CNR was increased compared to conventional MRI (82.0±23.1 vs 31.4±10.8,  $p=0.02$ ; and 12.4±4.1 vs 4.4±11.2,  $p=0.02$ ). In the volumetric analysis, no significant differences were observed in 1253 out of 1276 (98.2%) regional volumes ( $r=0.92\pm0.10$ , range 0.38-1.00), with the exception of the deep gray matter including thalamus. Additionally, 5 out of 6 (83.3%) lesion categories showed no significant differences, except for juxtacortical lesion counts ( $r=0.64\pm0.29$ , range 0.12-0.92).

#### CONCLUSION

Deep learning-based fast reconstruction significantly improves the efficiency and quality of brain MRI in both spin-echo and gradient-echo sequences without compromising lesion detection and quantitative volumetric analysis.

#### CLINICAL RELEVANCE/APPLICATION

Enhanced image quality and reduced acquisition time provided by deep learning-based fast reconstruction may facilitate better diagnostics at lower healthcare costs.

#### **W3-SSNR10-2 DICOM-based Deep Learning Generated Synthetic STIR Spine Images are Interchangeable with and Offer Better Quality than Conventional STIR MR Scans**

Lawrence Neil N. Tanenbaum, MD, FACR (*Presenter*) Speaker, General Electric Company; Speaker, Siemens AG; Speaker, Guerbet SA; Speaker, Koninklijke Philips NV; Consultant, icoMetrix NV; Consultant, Subtle Medical, Inc; Consultant,

## PURPOSE

Purpose Deep learning (DL) image reconstruction allows faster MR acquisitions while matching or exceeding standard of care (SOC) and can create synthetic images from existing data sets. This multicenter, multi-reader spine study evaluated the performance of synthetically created STIR (Syn-STIR) compared to acquired STIR (Acq-STIR).

## METHODS AND MATERIALS

Material Methods From a multicenter, multi-scanner database of 328 clinical cases, a non-reader neuroradiologist randomly selected 110 spine MRI studies in 93 patients (sagittal T1, T2, STIR) and classified into five categories of disease and normal. A DICOM-based DL application generated a Syn-STIR series from the Sag T1 and T2. Five radiologists (3 neuro, 1 MSK, 1 generalist) rated STIR quality and classified disease pathology (study 1, n=80). They then assessed the presence or absence of findings typically evaluated with STIR in patients with trauma (study 2, n=30). The readers evaluated studies with either Acq-STIR or Syn-STIR in a blinded and randomized fashion with a 1-month washout period. Interchangeability of Acq-STIR and Syn-STIR was assessed using a non-inferiority threshold of 10%.

## RESULTS

Results For classification, there was a decrease in inter-reader agreement expected by randomly introducing Syn-STIR of 3.23%. For trauma, there was an overall increase in inter-reader agreement by +1.9%. The lower bound of confidence for both exceeded the non-inferiority threshold, indicating interchangeability of Syn-STIR with Acq-STIR. Both Wilcoxon signed-rank and t-test showed higher IQ scores for Syn-STIR over Acq-STIR ( $P < 0.0001$ ).

## CONCLUSION

Conclusion Syn-STIR spine MR images were diagnostically interchangeable with Acq-STIR, while providing significantly higher image quality, suggesting routine clinical practice potential.

## CLINICAL RELEVANCE/APPLICATION

Clinical relevance DL generated synthetic STIR spine MR images were interchangeable with a conventionally acquired STIR, while providing significantly higher image quality, suggesting the potential to replace them in clinical practice, the reducing overall scan times and enhancing the patient experience.

## W3-SSNR10-3 Deep-Learning Based Contrast Boosting Improves Lesion Visualization and Image Quality: A Multi-Reader Study on Diagnostically Interchangeability with Standard Contrast Enhanced MRI of Brain Tumors

Srivathsa P. Venkata, MSc (*Presenter*) Employee, Subtle Medical, Inc; Stockholder, Subtle Medical, Inc

## PURPOSE

Higher Gadolinium contrast doses in brain tumor imaging can increase lesion sensitivity, but larger doses elevate safety concerns. Here, we evaluate the clinical performance of a deep learning (DL) based method for boosting contrast, without increasing dose, relative to standard-dose images in a multireader study.

## METHODS AND MATERIALS

We analyzed data from 40 patients ( $63 \pm 14$  years, 20 female) undergoing brain MRI with contrast. Contrast boosted (CB) images were generated using pre-contrast standard post-contrast (SC) 3D T1w images as input (Fig 1A). Three readers (board-certified radiologists with 9, 15, 18 years of experience) were presented 100 cases in a blinded randomized fashion. Each case contained a pre-contrast T1w image and either a SC (N=40) or CB image (N=40). 20 cases were repeated. Readers made a diagnostic classification (Dx) (6 classes: glioma, meningioma, lymphoma, metastasis, other tumor, or none) and rated post-contrast images for lesion enhancement, border delineation, internal morphology, vessel conspicuity, and overall image quality (IQ) using a 5-point Likert scale. Inter- intra-reader variability (RV) was assessed using Cohen's Kappa intraclass correlation coefficients. Wilcoxon signed rank tests were conducted on qualitative measures to compare SC and CB images. We assessed whether images were diagnostically interchangeable (DI) by the decrease in inter-RV when comparing SC vs CB to SC alone (10% limit for non-inferiority testing). Quantitative metrics (lesion-to-brain ratio - LBR and contrast enhancement % - CEP) were computed on SC CB with respect to the pre-contrast.

## RESULTS

CB images were rated higher than SC for lesion enhancement, delineation, morphology and IQ (Fig 1B, all  $p < 0.005$ ). Vessel conspicuity was rated as being unlikely to affect Dx in a lower % of CB images (82% vs 93%). Fig 1C visualizes some examples. Inter-RV for Dx was similar for paired SC CB (0.523 vs 0.475), or when comparing SC to CB images (0.496). Intra-RV increased for CB over SC (0.969 vs 0.844). The decrease in inter-RV when interchanging SC with CB was 5.2% (CI: [-5.7%, 9.6%]; 1000 bootstrapped samples) and SC CB were considered DI (non-inferiority test,  $p = 0.02$ , Fig 1D). LBR CEP for CB ( $5.22 \pm 1.43$  89.95%) were significantly better ( $p < 0.0001$ ) than those of SC ( $3.78 \pm 0.90$  185.10%).

## CONCLUSION

This study establishes that CB images have superior qualitative perception for lesion features and IQ, and are DI with SC images for tumor categorization. Future studies will evaluate CB performance on more contrast sensitive tasks.

## CLINICAL RELEVANCE/APPLICATION

DL-synthesized contrast boosted images offer better visualization of pathology and have interchangeable diagnostic performance with standard contrast images for tumor categorization.

### W3-SSNR10-4 **A Generative Adversarial Network Approach for Low-Field to High-Field Image Translation**

Alfredo Lucas, BS, MS (*Presenter*) Nothing to Disclose

## PURPOSE

Portable low-field strength (64mT) MRI scanners promise to increase access to neuroimaging for clinical and research purposes but produce images of lower quality and resolution compared to high field strength scanners. In this study, we developed and evaluated a deep learning method to generate high-field quality brain images from low-field inputs using a paired dataset of multiple sclerosis (MS) patients scanned at 64mT and 3T.

## METHODS AND MATERIALS

A total of 65 MS patients were scanned on portable 64mT (Hyperfine) and standard 3T scanners (Siemens) at Penn or NIH with T1, T2 and FLAIR acquisitions at both field strengths. Using 32/65 patients, we trained a generative adversarial network (GAN) architecture for low to high field image super resolution and translation that consisted of two main parts. The first half consists of 3 pix2pix layers in parallel, each trained on a different orthogonal imaging plane with T1, T2, and FLAIR images as input channels. The second half consists of a 3D patch-based U-Net that combines the parallel outputs from the first half into a cohesive volume. We used the 33 remaining subjects as out-of-sample test subjects.

## RESULTS

All presented results reflect out-of-sample test subjects. Reconstructed high-field output images demonstrated visually superior quality than low-field input images. Quantitatively, reconstructed outputs had significantly higher structural similarity (SSIM) to paired high-field images than input low-field images across T1 (pFDR=0.006), FLAIR (pFDR=0.03), and T2 (pFDR=0.024) contrasts. Measuring thalamic volumes, a clinically relevant MS biomarker, using a state-of-the-art segmentation pipeline (SynthSeg), our reconstructed outputs outperformed another published super resolution algorithm (SynthSR) in producing results approximating 3T and correcting undersegmentation seen at 64mT. Total MS lesion volume based on automated segmentation (MiMOSA) in our reconstructed outputs was better correlated (Spearman's Rho = 0.65) with high-field volumes, than original low-field volumes (Spearman's Rho = 0.55). MS lesions also appeared more conspicuous in our reconstructed outputs than original input images.

## CONCLUSION

Our generative adversarial network approach for low-field to high-field super resolution generates synthetic high-field images that have comparable visual and quantitative quality, regional volumetry, and lesion burden, as their paired high-field counterparts.

## CLINICAL RELEVANCE/APPLICATION

Enhancing portable low-field MRI image quality can boost clinician confidence, leading to wider adoption of these affordable, accessible technologies, benefiting patients who may not have had access to MR imaging before.

### W3-SSNR10-5 **Development of Paired-CycleGAN-based Deep Learning Algorithm for MRI Harmonization: Validation in Follow-up MRI Evaluation in Post-treatment Glioma Patients**

Roh-Eul Yoo, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

To develop a paired CycleGAN-based deep learning algorithm for MRI harmonization and to validate its utility on follow-up MRI evaluation in post-treatment glioma patients

## METHODS AND MATERIALS

This retrospective study included 184 datasets from 64 post-treatment glioma patients from January 2006 to September 2020, who showed no significant change in MRI readings during 3 follow-up (FU) examinations with the second MRI taken at a different MRI vendor. The data were randomly split into the training and validation sets in a 8:2 ratio. Paired-CycleGAN was trained to generate harmonized second FU MRI images with the similar image impression as the baseline MRI images. Unlike traditional CycleGAN, we modulated the model to learn head-to-head images containing slices at the same position in a different domain. We trained the proposed model with two training metrics, structural similarity index measure (SSIM) and learned perceptual image patch similarity (LPIPS). The mean and standard deviation of intensity values, contrast-to-noise

ratios (CNR) of gray matter (GM) and white matter (WM), and 3D SSIM score were used to assess the harmonized images in the validation set. A five-point diagnostic confidence scale and the presence of change in lesion characteristics (border, size, contrast, internal morphology) were evaluated by a blinded reader.

## RESULTS

As the training progressed, LPIPS score typically decreased, while SSIM score increased. The changes in 3D SSIM score between the baseline and harmonized FU images were higher than those between the baseline and original FU images (0.87 vs. 0.82,  $P < .001$  [Siemens to Philips]; 0.89 vs. 0.83 [Philips to Siemens],  $P < .001$ ). Differences compared to baseline in the mean and standard deviation of intensity values and CNR of GM and WM were lower in the harmonized FU images than in original FU images (All  $P < .001$ ). In the reader evaluation study, more cases were read to be not changed on harmonized FU images and the diagnostic confidence was significantly higher with harmonized FU images than with original FU images ( $4.8 \pm 0.4$  vs.  $4.4 \pm 0.6$ ,  $P < .001$ ).

## CONCLUSION

A paired CycleGAN-based deep learning algorithm showed good performance in MRI harmonization and resulted in increased diagnostic confidence in follow-up MRI evaluation in post-treatment glioma patients.

## CLINICAL RELEVANCE/APPLICATION

Glioma patients often undergo follow-up MRI examinations after standard treatment in different scanners due to limited MR resources; our paired-CycleGAN-based MRI harmonization technique may increase the diagnostic confidence in follow-up MRI evaluation in post-treatment glioma patients in such clinical setting.

## W3-SSNR10-6 The Relaxation Normalized Proton Transfer Rate MRAPTR in the Evaluation of pH Changes of the Acute Cerebral Infarction

Jianzhong Yin, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Amide proton transfer (APT) imaging is sensitive to intracellular pH and has shown great potential for the evaluation of cerebral strokes. The relaxation normalized proton transfer rate MRAPTR has shown improved quantification of pH contrast. This study aimed to explore the different abilities between the relaxation normalized proton transfer rate MRAPTR and the routine MTR<sub>asym</sub> metrics for evaluating acute strokes.

## METHODS AND MATERIALS

6 normal subjects and 106 patients with ischemic stroke were enrolled. All patients underwent an MRI examination including T1WI, T2WI, DWI, and APTw imaging. The magnetization transfer ratio asymmetry (MTR<sub>asym</sub>) and magnetization transfer and relaxation normalized proton transfer rate (MRAPTR) were analyzed. The interobserver and repeatability of the APT(w) signal were assessed by ICCs. The Mann-Whitney U tests were used to compare the difference between infarction lesions and contralateral normal regions of different APTw metrics. The receiver operating characteristic curve (ROC) analysis was used to evaluate the diagnostic efficiency of MTR<sub>asym</sub> and MRAPTR for infarction. The reverse rate of MTR<sub>asym</sub> and MRAPTR was also compared by the ANOVA test.

## RESULTS

The ICCs of MRAPTR were similar to those of MTR<sub>asym</sub> for the interobserver agreement and intersite reliability analysis. But MRAPTR value was closer to the baseline than MTR<sub>asym</sub>, and the data distribution was more centralized. The APTw metric maps showed a decreased MTR<sub>asym</sub> and MRAPTR, which implied an acidosis and decreased proton exchange in the infarction lesions. The MTR<sub>asym</sub> and MRAPTR at the infarction lesions showed obviously differences toward contralateral normal regions ( $P = 0.001$  and  $< 0.001$ , respectively). But APTw metrics at the infarction lesions were elevated in some cases, which implied a reversal of the APT results. MRAPTR showed a significantly decreased reverse rate of the infarction lesions compared to the MTR<sub>asym</sub> (24.5% and 2.8%, respectively). MRAPTR had better efficiency than MTR<sub>asym</sub> in reflecting acute ischemic lesions.

## CONCLUSION

APTw metrics exhibited similar repeatability in this study, but MRAPTR was more stable than MTR<sub>asym</sub>. Both APTw metrics could reflect ischemic lesions and MRAPTR had better efficiency than MTR<sub>asym</sub>.

## CLINICAL RELEVANCE/APPLICATION

These results demonstrated that pH-weighted imaging could reveal acidosis in patients with acute ischemic stroke.

## Abstract Archives of the RSNA, 2023

### Prospective Validation of Accelerated Brain MRI Using Deep Learning-Based Reconstruction: Simultaneous Application to Spin-Echo and Gradient-Echo Sequence

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353C

Kyu Sung Choi, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the effectiveness of brain MRI with deep learning-based fast reconstructed MRI (DL-FR) by comparing qualitative and quantitative image quality of conventional MRI for both spin-echo and gradient-echo sequences.

#### METHODS AND MATERIALS

In this multi-reader, multi-sequence, and multi-vendor prospective study, both synthetic and conventional MRI pairs with T1-weighted, T2-weighted, T2-FLAIR, and 3D T1-weighted images from 100 subjects (29 males; 57.3±16.0 years; 34 subjects with GE, 35 with Philips, and 31 with Siemens), were examined by 4 blinded neuroradiologists. The images were randomized, and evaluated for overall image quality, delineation of structures, and artifacts using 5-point Likert scale, in the two separate sessions. Intraclass correlation coefficient was calculated for Inter-reader agreement. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) was obtained for both 3D T1w and T2 FLAIR. For quantitative analysis, volumetric analysis of brain parcellation and white matter T2 hyperintensity (WMH) was performed using LesionQuant (LQ) and NeuroQuant (NQ), respectively.

#### RESULTS

DL-FR showed median 41% (24-51%) reduced acquisition time with improvements in overall image quality (mean±SD, 3.79±0.72 vs. 3.40±0.63,  $p<0.001$ ); and enhanced structure delineation (3.59±0.81 vs. 3.45±0.77,  $p<0.001$ ), while lesion conspicuity (3.34±1.05 vs. 3.26±1.08,  $p=0.32$ ), Fazekas scale (2.24±1.40 vs 2.18±1.40,  $p=0.37$ ), enlarged perivascular space grading (1.93±1.21 vs 1.90±1.20,  $p=0.65$ ), and image artifacts (3.78±0.73 vs. 3.79±0.69,  $p=0.47$ ) was comparable. Inter-reader agreement was moderate to substantial ( $\kappa=0.74$  for structure and lesion delineation;  $\kappa=0.52$  for artifact; and  $\kappa=0.55$  for overall quality), indicating reliable qualitative assessments. SNR and CNR was increased compared to conventional MRI (82.0±23.1 vs 31.4±10.8,  $p=0.02$ ; and 12.4±4.1 vs 4.4±11.2,  $p=0.02$ ). In the volumetric analysis, no significant differences were observed in 1253 out of 1276 (98.2%) regional volumes ( $r=0.92\pm0.10$ , range 0.38-1.00), with the exception of the deep gray matter including thalamus. Additionally, 5 out of 6 (83.3%) lesion categories showed no significant differences, except for juxtacortical lesion counts ( $r=0.64\pm0.29$ , range 0.12-0.92).

#### CONCLUSION

Deep learning-based fast reconstruction significantly improves the efficiency and quality of brain MRI in both spin-echo and gradient-echo sequences without compromising lesion detection and quantitative volumetric analysis.

#### CLINICAL RELEVANCE/APPLICATION

Enhanced image quality and reduced acquisition time provided by deep learning-based fast reconstruction may facilitate better diagnostics at lower healthcare costs.

### **DICOM-based Deep Learning Generated Synthetic STIR Spine Images are Interchangeable with and Offer Better Quality than Conventional STIR MR Scans**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353C

Lawrence Neil N. Tanenbaum, MD, FACR (*Presenter*) Speaker, General Electric Company; Speaker, Siemens AG; Speaker, Guerbet SA; Speaker, Koninklijke Philips NV; Consultant, icoMetrix NV; Consultant, Subtle Medical, Inc; Consultant, Columbo; Consultant, iMedis; Consultant, Agamon; Consultant, FUJIFILM Holdings Corporation

#### **PURPOSE**

Purpose Deep learning (DL) image reconstruction allows faster MR acquisitions while matching or exceeding standard of care (SOC) and can create synthetic images from existing data sets. This multicenter, multi-reader spine study evaluated the performance of synthetically created STIR (Syn-STIR) compared to acquired STIR (Acq-STIR).

#### **METHODS AND MATERIALS**

Material Methods From a multicenter, multi-scanner database of 328 clinical cases, a non-reader neuroradiologist randomly selected 110 spine MRI studies in 93 patients (sagittal T1, T2, STIR) and classified into five categories of disease and normal. A DICOM-based DL application generated a Syn-STIR series from the Sag T1 and T2. Five radiologists (3 neuro, 1 MSK, 1 generalist) rated STIR quality and classified disease pathology (study 1, n=80). They then assessed the presence or absence of findings typically evaluated with STIR in patients with trauma (study 2, n=30). The readers evaluated studies with either Acq-STIR or Syn-STIR in a blinded and randomized fashion with a 1-month washout period. Interchangeability of Acq-STIR and Syn-STIR was assessed using a non-inferiority threshold of 10%.

#### **RESULTS**

Results For classification, there was a decrease in inter-reader agreement expected by randomly introducing Syn-STIR of 3.23%. For trauma, there was an overall increase in inter-reader agreement by +1.9%. The lower bound of confidence for both exceeded the non-inferiority threshold, indicating interchangeability of Syn-STIR with Acq-STIR. Both Wilcoxon signed-rank and t-test showed higher IQ scores for Syn-STIR over Acq-STIR ( $P < 0.0001$ ).

#### **CONCLUSION**

Conclusion Syn-STIR spine MR images were diagnostically interchangeable with Acq-STIR, while providing significantly higher image quality, suggesting routine clinical practice potential.

#### **CLINICAL RELEVANCE/APPLICATION**

Clinical relevance DL generated synthetic STIR spine MR images were interchangeable with a conventionally acquired STIR, while providing significantly higher image quality, suggesting the potential to replace them in clinical practice, the reducing overall scan times and enhancing the patient experience.

### Deep-Learning Based Contrast Boosting Improves Lesion Visualization and Image Quality: A Multi-Reader Study on Diagnostically Interchangeability with Standard Contrast Enhanced MRI of Brain Tumors

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353C

Srivathsa P. Venkata, MSc (*Presenter*) Employee, Subtle Medical, Inc; Stockholder, Subtle Medical, Inc

#### PURPOSE

Higher Gadolinium contrast doses in brain tumor imaging can increase lesion sensitivity, but larger doses elevate safety concerns. Here, we evaluate the clinical performance of a deep learning (DL) based method for boosting contrast, without increasing dose, relative to standard-dose images in a multireader study.

#### METHODS AND MATERIALS

We analyzed data from 40 patients ( $63 \pm 14$  years, 20 female) undergoing brain MRI with contrast. Contrast boosted (CB) images were generated using pre-contrast standard post-contrast (SC) 3D T1w images as input (Fig 1A). Three readers (board-certified radiologists with 9, 15, 18 years of experience) were presented 100 cases in a blinded randomized fashion. Each case contained a pre-contrast T1w image and either a SC (N=40) or CB image (N=40). 20 cases were repeated. Readers made a diagnostic classification (Dx) (6 classes: glioma, meningioma, lymphoma, metastasis, other tumor, or none) and rated post-contrast images for lesion enhancement, border delineation, internal morphology, vessel conspicuity, and overall image quality (IQ) using a 5-point Likert scale. Inter- intra-reader variability (RV) was assessed using Cohen's Kappa intraclass correlation coefficients. Wilcoxon signed rank tests were conducted on qualitative measures to compare SC and CB images. We assessed whether images were diagnostically interchangeable (DI) by the decrease in inter-RV when comparing SC vs CB to SC alone (10% limit for non-inferiority testing). Quantitative metrics (lesion-to-brain ratio - LBR and contrast enhancement % - CEP) were computed on SC CB with respect to the pre-contrast.

#### RESULTS

CB images were rated higher than SC for lesion enhancement, delineation, morphology and IQ (Fig 1B, all  $p < 0.005$ ). Vessel conspicuity was rated as being unlikely to affect Dx in a lower % of CB images (82% vs 93%). Fig 1C visualizes some examples. Inter-RV for Dx was similar for paired SC CB (0.523 vs 0.475), or when comparing SC to CB images (0.496). Intra-RV increased for CB over SC (0.969 vs 0.844). The decrease in inter-RV when interchanging SC with CB was 5.2% (CI: [-5.7%, 9.6%]; 1000 bootstrapped samples) and SC CB were considered DI (non-inferiority test,  $p = 0.02$ , Fig 1D). LBR CEP for CB ( $5.22 \pm 1.43$  89.95%) were significantly better ( $p < 0.0001$ ) than those of SC ( $3.78 \pm 0.90$  185.10%).

#### CONCLUSION

This study establishes that CB images have superior qualitative perception for lesion features and IQ, and are DI with SC images for tumor categorization. Future studies will evaluate CB performance on more contrast sensitive tasks.

#### CLINICAL RELEVANCE/APPLICATION

DL-synthesized contrast boosted images offer better visualization of pathology and have interchangeable diagnostic performance with standard contrast images for tumor categorization.

### A Generative Adversarial Network Approach for Low-Field to High-Field Image Translation

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353C

Alfredo Lucas, BS, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

Portable low-field strength (64mT) MRI scanners promise to increase access to neuroimaging for clinical and research purposes but produce images of lower quality and resolution compared to high field strength scanners. In this study, we developed and evaluated a deep learning method to generate high-field quality brain images from low-field inputs using a paired dataset of multiple sclerosis (MS) patients scanned at 64mT and 3T.

#### METHODS AND MATERIALS

A total of 65 MS patients were scanned on portable 64mT (Hyperfine) and standard 3T scanners (Siemens) at Penn or NIH with T1, T2 and FLAIR acquisitions at both field strengths. Using 32/65 patients, we trained a generative adversarial network (GAN) architecture for low to high field image super resolution and translation that consisted of two main parts. The first half consists of 3 pix2pix layers in parallel, each trained on a different orthogonal imaging plane with T1, T2, and FLAIR images as input channels. The second half consists of a 3D patch-based U-Net that combines the parallel outputs from the first half into a cohesive volume. We used the 33 remaining subjects as out-of-sample test subjects.

#### RESULTS

All presented results reflect out-of-sample test subjects. Reconstructed high-field output images demonstrated visually superior quality than low-field input images. Quantitatively, reconstructed outputs had significantly higher structural similarity (SSIM) to paired high-field images than input low-field images across T1 (pFDR=0.006), FLAIR (pFDR=0.03), and T2 (pFDR=0.024) contrasts. Measuring thalamic volumes, a clinically relevant MS biomarker, using a state-of-the-art segmentation pipeline (SynthSeg), our reconstructed outputs outperformed another published super resolution algorithm (SynthSR) in producing results approximating 3T and correcting undersegmentation seen at 64mT. Total MS lesion volume based on automated segmentation (MiMOSA) in our reconstructed outputs was better correlated (Spearman's Rho = 0.65) with high-field volumes, than original low-field volumes (Spearman's Rho = 0.55). MS lesions also appeared more conspicuous in our reconstructed outputs than original input images.

#### CONCLUSION

Our generative adversarial network approach for low-field to high-field super resolution generates synthetic high-field images that have comparable visual and quantitative quality, regional volumetry, and lesion burden, as their paired high-field counterparts.

#### CLINICAL RELEVANCE/APPLICATION

Enhancing portable low-field MRI image quality can boost clinician confidence, leading to wider adoption of these affordable, accessible technologies, benefiting patients who may not have had access to MR imaging before.

### Development of Paired-CycleGAN-based Deep Learning Algorithm for MRI Harmonization: Validation in Follow-up MRI Evaluation in Post-treatment Glioma Patients

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353C

Roh-Eul Yoo, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop a paired CycleGAN-based deep learning algorithm for MRI harmonization and to validate its utility on follow-up MRI evaluation in post-treatment glioma patients

#### METHODS AND MATERIALS

This retrospective study included 184 datasets from 64 post-treatment glioma patients from January 2006 to September 2020, who showed no significant change in MRI readings during 3 follow-up (FU) examinations with the second MRI taken at a different MRI vendor. The data were randomly split into the training and validation sets in a 8:2 ratio. Paired-CycleGAN was trained to generate harmonized second FU MRI images with the similar image impression as the baseline MRI images. Unlike traditional CycleGAN, we modulated the model to learn head-to-head images containing slices at the same position in a different domain. We trained the proposed model with two training metrics, structural similarity index measure (SSIM) and learned perceptual image patch similarity (LPIPS). The mean and standard deviation of intensity values, contrast-to-noise ratios (CNR) of gray matter (GM) and white matter (WM), and 3D SSIM score were used to assess the harmonized images in the validation set. A five-point diagnostic confidence scale and the presence of change in lesion characteristics (border, size, contrast, internal morphology) were evaluated by a blinded reader.

#### RESULTS

As the training progressed, LPIPS score typically decreased, while SSIM score increased. The changes in 3D SSIM score between the baseline and harmonized FU images were higher than those between the baseline and original FU images (0.87 vs. 0.82,  $P < .001$  [Siemens to Philips]; 0.89 vs. 0.83 [Philips to Siemens],  $P < .001$ ). Differences compared to baseline in the mean and standard deviation of intensity values and CNR of GM and WM were lower in the harmonized FU images than in original FU images (All  $P < .001$ ). In the reader evaluation study, more cases were read to be not changed on harmonized FU images and the diagnostic confidence was significantly higher with harmonized FU images than with original FU images ( $4.8 \pm 0.4$  vs.  $4.4 \pm 0.6$ ,  $P < .001$ ).

#### CONCLUSION

A paired CycleGAN-based deep learning algorithm showed good performance in MRI harmonization and resulted in increased diagnostic confidence in follow-up MRI evaluation in post-treatment glioma patients.

#### CLINICAL RELEVANCE/APPLICATION

Glioma patients often undergo follow-up MRI examinations after standard treatment in different scanners due to limited MR resources; our paired-CycleGAN-based MRI harmonization technique may increase the diagnostic confidence in follow-up MRI evaluation in post-treatment glioma patients in such clinical setting.

W3-SSNR10-6

### The Relaxation Normalized Proton Transfer Rate MRAPTR in the Evaluation of pH Changes of the Acute Cerebral Infarction

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353C

Jianzhong Yin, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Amide proton transfer (APT) imaging is sensitive to intracellular pH and has shown great potential for the evaluation of cerebral strokes. The relaxation normalized proton transfer rate MRAPTR has shown improved quantification of pH contrast. This study aimed to explore the different abilities between the relaxation normalized proton transfer rate MRAPTR and the routine MRT<sub>asym</sub> metrics for evaluating acute strokes.

#### METHODS AND MATERIALS

6 normal subjects and 106 patients with ischemic stroke were enrolled. All patients underwent an MRI examination including T1WI, T2WI, DWI, and APTw imaging. The magnetization transfer ratio asymmetry (MTR<sub>asym</sub>) and magnetization transfer and relaxation normalized proton transfer rate (MRAPTR) were analyzed. The interobserver and repeatability of the APT(w) signal were assessed by ICCs. The Mann-Whitney U tests were used to compare the difference between infarction lesions and contralateral normal regions of different APTw metrics. The receiver operating characteristic curve (ROC) analysis was used to evaluate the diagnostic efficiency of MTR<sub>asym</sub> and MRAPTR for infarction. The reverse rate of MTR<sub>asym</sub> and MRAPTR was also compared by the ANOVA test.

#### RESULTS

The ICCs of MRAPTR were similar to those of MTR<sub>asym</sub> for the interobserver agreement and intersite reliability analysis. But MRAPTR value was closer to the baseline than MTR<sub>asym</sub>, and the data distribution was more centralized. The APTw metric maps showed a decreased MTR<sub>asym</sub> and MRAPTR, which implied an acidosis and decreased proton exchange in the infarction lesions. The MTR<sub>asym</sub> and MRAPTR at the infarction lesions showed obviously differences toward contralateral normal regions ( $P = 0.001$  and  $< 0.001$ , respectively). But APTw metrics at the infarction lesions were elevated in some cases, which implied a reversal of the APT results. MRAPTR showed a significantly decreased reverse rate of the infarction lesions compared to the MTR<sub>asym</sub> (24.5% and 2.8%, respectively). MRAPTR had better efficiency than MTR<sub>asym</sub> in reflecting acute ischemic lesions.

#### CONCLUSION

APTw metrics exhibited similar repeatability in this study, but MRAPTR was more stable than MTR<sub>asym</sub>. Both APTw metrics could reflect ischemic lesions and MRAPTR had better efficiency than MTR<sub>asym</sub>.

#### CLINICAL RELEVANCE/APPLICATION

These results demonstrated that pH-weighted imaging could reveal acidosis in patients with acute ischemic stroke.

#### W3-SSNR11-1 A Weakly Supervised Method for Brain Tumor Segmentation in MR Images

Jay Yoo, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Segmentation of regions of interest (ROIs) for identifying abnormalities is a leading problem in medical imaging. Machine Learning (ML) generally requires manually annotated ground-truth segmentations, demanding extensive time and resources from radiologists. We present a novel weakly supervised (WS) approach that utilizes image-level labels such as the presence of tumor, which are much simpler to acquire, to automatically segment ROIs in Magnetic Resonance Imaging (MRI) scans without requiring ground truth annotations for training.

#### METHODS AND MATERIALS

This REB-approved retrospective study included two MRI datasets: 1) in-house dataset of pediatric low-grade neuroepithelial tumors (PLGNT) (N=340), 2) public Multimodal Brain Tumor Segmentation Challenge 2020 (BraTS) dataset (N=369). Seeds indicating regions likely and unlikely to contain tumors were inferred from a model trained to detect the presence of tumors. A generative adversarial network was trained to convert cancerous 2D scans to healthy variants. The seeds and L1 maps, which are the absolute difference between images and their non-cancerous variants, were used to train a segmentation model without utilizing ground truth manual segmentations. To evaluate the efficacy of our method for downstream clinical tasks, for each patient MRI volume, we extracted Radiomic features from the 5 largest WS slice segmentations among the volume's top 25% WS slice segmentations. The top WS slice segmentations were estimated using the L1 maps. Random forest models were trained on the Radiomic features to predict the genetic markers (BRAF fusion vs BRAF V600E mutation) and pathology (low-grade glioma vs high-grade glioma) of tumors for the PLGNT and BraTS datasets, respectively.

#### RESULTS

Tumor classification using Radiomic features extracted from our WS segmentations achieved a mean test Area Under the Receiver Operating Characteristic Curve (AUC) of  $0.822 \pm 3.20e-2$  on the PLGNT dataset and a mean test AUC of  $0.933 \pm 9.17e-3$  on the BraTS dataset. For comparison, using the 5 largest manual segmentations from each patient volume achieved mean test AUCs of  $0.830 \pm 2.04e-2$  on the PLGNT dataset and  $0.958 \pm 1.27e-2$  on the BraTS dataset.

#### CONCLUSION

The proposed WS method generates segmentations that are nearly as effective as manually annotated segmentations on downstream tumor classification tasks without the need for manually acquired ground truth annotations for training. Removing the need for radiologists to manually segment brain tumors can expedite diagnosis and treatment.

#### CLINICAL RELEVANCE/APPLICATION

The proposed approach allows for MR images to be reliably segmented without the need for manual annotations, relieving radiologists of the need to manually segment any images for training ML models.

#### W3-SSNR11-2 AI System for Precise ASD Assessment Using sMRI

Mostafa Abdelrahim, BSc (*Presenter*) Nothing to Disclose

## PURPOSE

Autism Spectrum Disorder (ASD) affects communication, social interaction, and behavior as a neurological disorder. Due to the diverse symptoms and severity levels experienced by individuals, it is considered a spectrum disorder. This study aims to use morphological markers extracted from Structure Magnetic Resonance (sMRI) scans and their correlation with Social Responsiveness Scale (SRS) behavioral scores to classify patients as ASD or TD

## METHODS AND MATERIALS

The proposed framework for Machine Learning (ML) consists of two major steps. Firstly, morphological markers are extracted from various brain areas that correlate with the severity level of the Social Responsiveness Scale (SRS) behavioral analysis reports. Secondly, the extracted markers from different brain areas generate different ML models that are stacked to train Support Vector Machine (SVM) based classifiers to diagnose subjects as autistic or control and determine the severity level in case of an autistic diagnosis. The ML-Based diagnostic system is tested on the Autism Brain Imaging Data Exchange-II (ABIDE-II) dataset (521 autistic and 593 control subjects) provided by the Autism Brain Imaging Data Exchange. It's worth noting that this system is the first ML-Based system that can determine the severity of autism

## RESULTS

The proposed ML-Based system using SVM achieved an overall accuracy of 94% with a sensitivity of 98.18% and specificity of 95.56% on the ABIDE-II database on average using 5-fold cross-validation with statistical significance  $p < 0.001$

## CONCLUSION

In conclusion, this study demonstrates that autism can be diagnosed and its severity determined using morphological markers extracted from sMRI scans, based on the correlation with SRS behavioral analysis reports. It's worth noting that our approach is not limited to SRS reports and can also be used with other behavioral reports, such as the Autism Diagnostic Observation Schedule (ADOS) reports. Furthermore, the proposed system is not limited to ASD, and it can be utilized for the diagnosis of any brain disorder

## CLINICAL RELEVANCE/APPLICATION

Early and accurate diagnosis of ASD is crucial for improving the quality of life for individuals with the disorder. Additionally, precise determination of autism severity and its position on the autism spectrum can aid in better management of the disorder and reduce treatment costs

## W3-SSNR11-3 Bidirectional Connectivity Alterations in Schizophrenia: A Multivariate, Machine-Learning Approach

Minchul Kim, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

It is well known that altered functional connectivity is the core pathophysiology of schizophrenia. However, there is debate on the direction of connectivity alterations, i.e., increasing or decreasing. In this study, we aimed to determine the direction of the connectivity alteration associated with schizophrenia using a multivariate, data-driven approach.

## METHODS AND MATERIALS

Resting-state functional magnetic resonance imaging data were acquired from 109 individuals with schizophrenia and 120 controls across two openly available datasets. A whole-brain resting-state functional connectivity (rsFC) matrix was computed for each individual. A modified connectome-based predictive model (CPM) with a support vector machine (SVM) was used to classify patients and controls. We conducted a series of multivariate classification analyses using three different feature sets, increased, decreased, and both increased and decreased rsFC.

## RESULTS

For both datasets, combining information from both increased and decreased rsFC matrices substantially improved prediction accuracy (Dataset 1: accuracy = 70.2%, permutation  $p = 0.001$ ; Dataset 2: accuracy = 64.4%, permutation  $p = 0.003$ ). When tested across datasets, prediction models using decreased and both increased and decreased rsFC performed above chance. The identified predictive features of decreased rsFC were similarly distributed between the two datasets.

## CONCLUSION

These findings suggest that bidirectional alterations in rsFC are distributed in the brains of individuals with schizophrenia, with the pattern of decreased connectivity being more similar across different populations.

## CLINICAL RELEVANCE/APPLICATION

Our data-driven and machine learning approach suggests a somewhat universal pattern of decreases in rsFC in schizophrenia, while increased rsFCs exist but are more heterogeneous, findings which may deepen the understanding of the

pathophysiology of schizophrenia. Additionally, our results suggest a promising direction for future research on the detection of individual patients with schizophrenia.

### **W3-SSNR11-4 Urgent vs Non-urgent Triage of CTB Based on a Comprehensive AI Model: Validation on a Ground-Truthed, Real-World Dataset**

Richard G. Abramson, MD, MS (*Presenter*) Consultant, ICON plc;

#### **PURPOSE**

Artificial intelligence (AI) shows promise in reducing radiological reporting costs by identifying studies with potential time-critical pathology for urgent reporting overnight. This retrospective study assessed the performance of a comprehensive AI model which detects 130 findings on brain CT (CTB) in differentiating cases that were urgent.

#### **METHODS AND MATERIALS**

Predictions of the Annalise Enterprise CTB AI model were post-processed into a single output score aiming to maximise identification of urgent cases. 51 of the 130 CTB findings, including infarcts, venous thrombosis, fractures, intracranial haemorrhage and mass effect, were considered as urgent based on the need for immediate triage to prevent significant patient morbidity/mortality. Consultant radiologists blinded to the model outputs ground-truthed a test dataset of 2807 CTB cases, comprising 1193 urgent and 1614 non-urgent studies which were mutually exclusive from model training data at the patient level. Performance on bootstrapped samples of the test data for 2000 cases with 12.5% prevalence of urgent findings (approximating real world emergency departments) was reported at thresholds determined from model training data aiming to predict 25%, 40%, and 50% of cases as non-urgent.

#### **RESULTS**

The post-processed output achieved an AUC of 0.92 on the overall dataset (42% urgent cases). On sampled datasets of 2000 cases with 12.5% prevalence of urgent findings, at the target 25% non-urgent threshold, the model achieved a sensitivity of 0.99 (0.98-1.00), specificity of 0.18 (0.16-0.19), a negative predictive value (NPV) of 1.00 (0.99-1.00), with 15% (14%-17%) of cases predicted negative, with 1 (0-4) false negatives. At the target 40% non-urgent threshold, sensitivity was 0.98 (0.96-1.00), specificity was 0.31 (0.29-0.33), NPV was 0.99 (0.98-1.00) with 27% (25%-29%) cases predicted negative and 5 (1-10) false negatives. At the 50% target non-urgent threshold, sensitivity was 0.97 (0.95-0.99), specificity was 0.40 (0.37-0.42), NPV was 0.99 (0.98-1.00) with 35% (37%-42%) cases predicted negative and 7 (2-13) false negatives. False negatives tended to be subtle cerebral infarcts.

#### **CONCLUSION**

Processing the CTB AI model outputs into a single score to distinguish urgent from non-urgent cases was shown to have effective performance. This internal validation produced metrics suggesting viability in settings such as the emergency department, the clinical efficacy and financial benefit of which could be evaluated in future prospective studies.

#### **CLINICAL RELEVANCE/APPLICATION**

Many health jurisdictions routinely send non-contrast CT brain scans for overnight reporting. Confidently identifying non-urgent scans allows for cost savings by delaying reporting until the next day.

### **W3-SSNR11-5 Hierarchical Feature Learning and Identification of Alzheimer's Disease with Resting-state fMRI: A Multiscale Research**

Zhiyuan Ding (*Presenter*) Nothing to Disclose

#### **PURPOSE**

A hierarchical framework was applied, including contrastive learning and graph neural network, for analyzing Alzheimer's Disease (AD) from the healthy on multi-scale levels (voxel, brain area and sample level) with resting-state fMRI automatically.

#### **METHODS AND MATERIALS**

149 AD cases and 102 healthy controls (HCs) were investigated (table 1). For all cases, The resting-state fMRI (rs-fMRI) and high-resolution 3D T1WI images were acquired on a SIEMENS Trio 3T scanner. The rs-fMRI data contains 240 time points (TR=2000ms), and each time point is composed of 64×64×41 voxels. The single voxel size is 3.4×3.4×3mm<sup>3</sup>. The rs-fMRI data is processed using DPARSF. Brain ROIs of AD dataset are processed based on automated anatomical labeling (AAL) template (90 ROIs) respectively. BOLD signals with variance less than 0.1 are removed by filtering and standardized normalized. The framework we applied involves two stages to extract voxel, brain area (ROI) and sample level features step by step (Figure 1). Firstly, on the voxel level, a network is employed to perform voxel-level clustering and feature extraction in a contrastive learning manner using BOLD signals as input (Figure 2). Secondly, on the ROI level, graph neural network is constructed by taking weighted averaged ROI features as node features to extract disease-specific sample-level features in a contrastive manner. Finally, we use the sample-level features as the input for the population-based graph neural network (GNN) classifier in reference (Figure 3).

## RESULTS

The sample features extracted from rs-fMRI features in AD vs HC have the following effects on the identification: 0.768 in accuracy, 0.770 in AUC, 0.764 in TPR, 0.776 in 1-FPR. It can be inferred that the extracted sample-level features starting from voxel level have effective identification performance.

## CONCLUSION

1. The voxel-ROI-sample hierarchical framework for analyzing the functional brain network generates disease-sensitive sample-level features that reflect the differences between groups. 2. Our results demonstrate that the applied framework achieves high accuracy in AD diagnosis.

## CLINICAL RELEVANCE/APPLICATION

Using a multi-scale framework starting from the voxel level is an effective computer-aided method to assist clinicians in identifying AD from healthy individuals. Our findings demonstrate the effectiveness of starting at the voxel level and then extracting sample level features for identifying AD diseases. This approach offers a new perspective for the study of AD.

## W3-SSNR11-6 Comparative Effectiveness of Two Comprehensive Artificial Intelligence (AI) Solutions for Large Vessel Occlusion (LVO) Detection and Perfusion Deficits in Acute Ischemic Stroke (AIS)

Ashlesha S. Udare, MBBS, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To compare the diagnostic performance of two FDA-approved comprehensive AI solutions in LVO detection using identical CTA datasets in a series of consecutive code-stroke patients. To determine whether the automated CTP estimation of ischemic core and penumbra volumes are significantly different and their comparison to the final infarct volume (FIV) on the 48-hour DWI MRI.

## METHODS AND MATERIALS

IRB approval with waiver of consent was obtained for retrospective collection of consecutive head and neck CTA and CTP performed for acute code strokes between April 2020-Sept 2021. Inclusion criteria: Adequate quality CTA/CTP imaging DICOM dataset complete processing by both AI software solutions. Exclusion criteria: Technically inadequate images or errors in processing by either AI solutions. Isolated posterior circulation, ACA, M3/M4 LVOs. Ground truth for LVO detection was the final report by the neuroradiologist. Reader 2, blinded to prior reads, re-evaluated CTAs to detect and classify LVOs: ICA, M1 and M2 to evaluate segment-wise performance. AI1 was used in the real-world setting, and the same dataset was run through the AI2 platform. The sensitivity, specificity, PPV, NPV, and accuracy for LVO detection of the 2 AI solutions were compared to the ground truth. McNemar test to evaluate if they were significantly different. Paired t-test was used to identify differences in automated CTP volumes. Bland-Altman analysis was used to determine if there was significant difference between the automated CTP volumes and FIV.

## RESULTS

Of 633 code stroke studies, 529 CTA 192 CTP studies were deemed adequate quality. 69 (13%) patients had LVO 460 (87%) had no LVO per ground truth. For all types of LVO detection, there was no significant difference between the sensitivity of AI1 (0.77) AI2 (0.75). However, there was significant difference in the specificity PPV of the two AI solutions. Sensitivities for isolated M2 segment LVO detection were much lower. Mismatch volumes between the two AI solutions were significantly different, particularly at larger mismatch range. In the non-reperfusion group there was significant difference between  $T_{max} > 6$  and FIV with AI1 overestimating the volumes in most instances.

## CONCLUSION

Performance of both AI solutions for M2 occlusions was low with significant difference in their specificities. Divergent performance for  $T_{max} > 6$  volumes could impact treatment decisions.

## CLINICAL RELEVANCE/APPLICATION

Both AI solutions should be used as a support tool for triage and not for final diagnosis. High specificity of AI2 reduces the number of unnecessary notifications and mobile alerts to the on-call stroke team. Automated CTP cut-offs used in AIS endovascular trials are not uniformly applicable across the spectrum of FDA approved AI solutions.

### A Weakly Supervised Method for Brain Tumor Segmentation in MR Images

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353B

Jay Yoo, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Segmentation of regions of interest (ROIs) for identifying abnormalities is a leading problem in medical imaging. Machine Learning (ML) generally requires manually annotated ground-truth segmentations, demanding extensive time and resources from radiologists. We present a novel weakly supervised (WS) approach that utilizes image-level labels such as the presence of tumor, which are much simpler to acquire, to automatically segment ROIs in Magnetic Resonance Imaging (MRI) scans without requiring ground truth annotations for training.

#### METHODS AND MATERIALS

This REB-approved retrospective study included two MRI datasets: 1) in-house dataset of pediatric low-grade neuroepithelial tumors (PLGNT) (N=340), 2) public Multimodal Brain Tumor Segmentation Challenge 2020 (BraTS) dataset (N=369). Seeds indicating regions likely and unlikely to contain tumors were inferred from a model trained to detect the presence of tumors. A generative adversarial network was trained to convert cancerous 2D scans to healthy variants. The seeds and L1 maps, which are the absolute difference between images and their non-cancerous variants, were used to train a segmentation model without utilizing ground truth manual segmentations. To evaluate the efficacy of our method for downstream clinical tasks, for each patient MRI volume, we extracted Radiomic features from the 5 largest WS slice segmentations among the volume's top 25% WS slice segmentations. The top WS slice segmentations were estimated using the L1 maps. Random forest models were trained on the Radiomic features to predict the genetic markers (BRAF fusion vs BRAF V600E mutation) and pathology (low-grade glioma vs high-grade glioma) of tumors for the PLGNT and BraTS datasets, respectively.

#### RESULTS

Tumor classification using Radiomic features extracted from our WS segmentations achieved a mean test Area Under the Receiver Operating Characteristic Curve (AUC) of  $0.822 \pm 3.20e-2$  on the PLGNT dataset and a mean test AUC of  $0.933 \pm 9.17e-3$  on the BraTS dataset. For comparison, using the 5 largest manual segmentations from each patient volume achieved mean test AUCs of  $0.830 \pm 2.04e-2$  on the PLGNT dataset and  $0.958 \pm 1.27e-2$  on the BraTS dataset.

#### CONCLUSION

The proposed WS method generates segmentations that are nearly as effective as manually annotated segmentations on downstream tumor classification tasks without the need for manually acquired ground truth annotations for training. Removing the need for radiologists to manually segment brain tumors can expedite diagnosis and treatment.

#### CLINICAL RELEVANCE/APPLICATION

The proposed approach allows for MR images to be reliably segmented without the need for manual annotations, relieving radiologists of the need to manually segment any images for training ML models.

### AI System for Precise ASD Assessment Using sMRI

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353B

Mostafa Abdelrahim, BSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Autism Spectrum Disorder (ASD) affects communication, social interaction, and behavior as a neurological disorder. Due to the diverse symptoms and severity levels experienced by individuals, it is considered a spectrum disorder. This study aims to use morphological markers extracted from Structure Magnetic Resonance (sMRI) scans and their correlation with Social Responsiveness Scale (SRS) behavioral scores to classify patients as ASD or TD

#### METHODS AND MATERIALS

The proposed framework for Machine Learning (ML) consists of two major steps. Firstly, morphological markers are extracted from various brain areas that correlate with the severity level of the Social Responsiveness Scale (SRS) behavioral analysis reports. Secondly, the extracted markers from different brain areas generate different ML models that are stacked to train Support Vector Machine (SVM) based classifiers to diagnose subjects as autistic or control and determine the severity level in case of an autistic diagnosis. The ML-Based diagnostic system is tested on the Autism Brain Imaging Data Exchange-II (ABIDE-II) dataset (521 autistic and 593 control subjects) provided by the Autism Brain Imaging Data Exchange. It's worth noting that this system is the first ML-Based system that can determine the severity of autism

#### RESULTS

The proposed ML-Based system using SVM achieved an overall accuracy of 94% with a sensitivity of 98.18% and specificity of 95.56% on the ABIDE-II database on average using 5-fold cross-validation with statistical significance  $p < 0.001$

#### CONCLUSION

In conclusion, this study demonstrates that autism can be diagnosed and its severity determined using morphological markers extracted from sMRI scans, based on the correlation with SRS behavioral analysis reports. It's worth noting that our approach is not limited to SRS reports and can also be used with other behavioral reports, such as the Autism Diagnostic Observation Schedule (ADOS) reports. Furthermore, the proposed system is not limited to ASD, and it can be utilized for the diagnosis of any brain disorder

#### CLINICAL RELEVANCE/APPLICATION

Early and accurate diagnosis of ASD is crucial for improving the quality of life for individuals with the disorder. Additionally, precise determination of autism severity and its position on the autism spectrum can aid in better management of the disorder and reduce treatment costs

### **Bidirectional Connectivity Alterations in Schizophrenia: A Multivariate, Machine-Learning Approach**

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353B

Minchul Kim, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

It is well known that altered functional connectivity is the core pathophysiology of schizophrenia. However, there is debate on the direction of connectivity alterations, i.e., increasing or decreasing. In this study, we aimed to determine the direction of the connectivity alteration associated with schizophrenia using a multivariate, data-driven approach.

#### **METHODS AND MATERIALS**

Resting-state functional magnetic resonance imaging data were acquired from 109 individuals with schizophrenia and 120 controls across two openly available datasets. A whole-brain resting-state functional connectivity (rsFC) matrix was computed for each individual. A modified connectome-based predictive model (CPM) with a support vector machine (SVM) was used to classify patients and controls. We conducted a series of multivariate classification analyses using three different feature sets, increased, decreased, and both increased and decreased rsFC.

#### **RESULTS**

For both datasets, combining information from both increased and decreased rsFC matrices substantially improved prediction accuracy (Dataset 1: accuracy = 70.2%, permutation  $p = 0.001$ ; Dataset 2: accuracy = 64.4%, permutation  $p = 0.003$ ). When tested across datasets, prediction models using decreased and both increased and decreased rsFC performed above chance. The identified predictive features of decreased rsFC were similarly distributed between the two datasets.

#### **CONCLUSION**

These findings suggest that bidirectional alterations in rsFC are distributed in the brains of individuals with schizophrenia, with the pattern of decreased connectivity being more similar across different populations.

#### **CLINICAL RELEVANCE/APPLICATION**

Our data-driven and machine learning approach suggests a somewhat universal pattern of decreases in rsFC in schizophrenia, while increased rsFCs exist but are more heterogeneous, findings which may deepen the understanding of the pathophysiology of schizophrenia. Additionally, our results suggest a promising direction for future research on the detection of individual patients with schizophrenia.

### Urgent vs Non-urgent Triage of CTB Based on a Comprehensive AI Model: Validation on a Ground-Truthed, Real-World Dataset

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353B

Richard G. Abramson, MD, MS (*Presenter*) Consultant, ICON plc;

#### PURPOSE

Artificial intelligence (AI) shows promise in reducing radiological reporting costs by identifying studies with potential time-critical pathology for urgent reporting overnight. This retrospective study assessed the performance of a comprehensive AI model which detects 130 findings on brain CT (CTB) in differentiating cases that were urgent.

#### METHODS AND MATERIALS

Predictions of the Annalise Enterprise CTB AI model were post-processed into a single output score aiming to maximise identification of urgent cases. 51 of the 130 CTB findings, including infarcts, venous thrombosis, fractures, intracranial haemorrhage and mass effect, were considered as urgent based on the need for immediate triage to prevent significant patient morbidity/mortality. Consultant radiologists blinded to the model outputs ground-truthed a test dataset of 2807 CTB cases, comprising 1193 urgent and 1614 non-urgent studies which were mutually exclusive from model training data at the patient level. Performance on bootstrapped samples of the test data for 2000 cases with 12.5% prevalence of urgent findings (approximating real world emergency departments) was reported at thresholds determined from model training data aiming to predict 25%, 40%, and 50% of cases as non-urgent.

#### RESULTS

The post-processed output achieved an AUC of 0.92 on the overall dataset (42% urgent cases). On sampled datasets of 2000 cases with 12.5% prevalence of urgent findings, at the target 25% non-urgent threshold, the model achieved a sensitivity of 0.99 (0.98-1.00), specificity of 0.18 (0.16-0.19), a negative predictive value (NPV) of 1.00 (0.99-1.00), with 15% (14%-17%) of cases predicted negative, with 1 (0-4) false negatives. At the target 40% non-urgent threshold, sensitivity was 0.98 (0.96-1.00), specificity was 0.31 (0.29-0.33), NPV was 0.99 (0.98-1.00) with 27% (25%-29%) cases predicted negative and 5 (1-10) false negatives. At the 50% target non-urgent threshold, sensitivity was 0.97 (0.95-0.99), specificity was 0.40 (0.37-0.42), NPV was 0.99 (0.98-1.00) with 35% (37%-42%) cases predicted negative and 7 (2-13) false negatives. False negatives tended to be subtle cerebral infarcts.

#### CONCLUSION

Processing the CTB AI model outputs into a single score to distinguish urgent from non-urgent cases was shown to have effective performance. This internal validation produced metrics suggesting viability in settings such as the emergency department, the clinical efficacy and financial benefit of which could be evaluated in future prospective studies.

#### CLINICAL RELEVANCE/APPLICATION

Many health jurisdictions routinely send non-contrast CT brain scans for overnight reporting. Confidently identifying non-urgent scans allows for cost savings by delaying reporting until the next day.

### Hierarchical Feature Learning and Identification of Alzheimer's Disease with Resting-state fMRI: A Multiscale Research

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353B

Zhiyuan Ding (*Presenter*) Nothing to Disclose

#### PURPOSE

A hierarchical framework was applied, including contrastive learning and graph neural network, for analyzing Alzheimer's Disease (AD) from the healthy on multi-scale levels (voxel, brain area and sample level) with resting-state fMRI automatically.

#### METHODS AND MATERIALS

149 AD cases and 102 healthy controls (HCs) were investigated (table 1). For all cases, The resting-state fMRI (rs-fMRI) and high-resolution 3D T1WI images were acquired on a SIEMENS Trio 3T scanner. The rs-fMRI data contains 240 time points (TR=2000ms), and each time point is composed of  $64 \times 64 \times 41$  voxels. The single voxel size is  $3.4 \times 3.4 \times 3$ mm<sup>3</sup>. The rs-fMRI data is processed using DPARSF. Brain ROIs of AD dataset are processed based on automated anatomical labeling (AAL) template (90 ROIs) respectively. BOLD signals with variance less than 0.1 are removed by filtering and standardized normalized. The framework we applied involves two stages to extract voxel, brain area (ROI) and sample level features step by step (Figure 1). Firstly, on the voxel level, a network is employed to perform voxel-level clustering and feature extraction in a contrastive learning manner using BOLD signals as input (Figure 2). Secondly, on the ROI level, graph neural network is constructed by taking weighted averaged ROI features as node features to extract disease-specific sample-level features in a contrastive manner. Finally, we use the sample-level features as the input for the population-based graph neural network (GNN) classifier in reference (Figure 3) .

#### RESULTS

The sample features extracted from rs-fMRI features in AD vs HC have the following effects on the identification: 0.768 in accuracy, 0.770 in AUC, 0.764 in TPR, 0.776 in 1-FPR. It can be inferred that the extracted sample-level features starting from voxel level have effective identification performance.

#### CONCLUSION

1. The voxel-ROI-sample hierarchical framework for analyzing the functional brain network generates disease-sensitive sample-level features that reflect the differences between groups. 2. Our results demonstrate that the applied framework achieves high accuracy in AD diagnosis.

#### CLINICAL RELEVANCE/APPLICATION

Using a multi-scale framework starting from the voxel level is an effective computer-aided method to assist clinicians in identifying AD from healthy individuals. Our findings demonstrate the effectiveness of starting at the voxel level and then extracting sample level features for identifying AD diseases. This approach offers a new perspective for the study of AD.

W3-SSNR11-6

### Comparative Effectiveness of Two Comprehensive Artificial Intelligence (AI) Solutions for Large Vessel Occlusion (LVO) Detection and Perfusion Deficits in Acute Ischemic Stroke (AIS)

Wednesday, Nov. 29 9:30AM - 10:30AM Room: E353B

Ashlesha S. Udare, MBBS, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare the diagnostic performance of two FDA-approved comprehensive AI solutions in LVO detection using identical CTA datasets in a series of consecutive code-stroke patients. To determine whether the automated CTP estimation of ischemic core and penumbra volumes are significantly different and their comparison to the final infarct volume (FIV) on the 48hour DWI MRI.

#### METHODS AND MATERIALS

IRB approval with waiver of consent was obtained for retrospective collection of consecutive head and neck CTA and CTP performed for acute code strokes between April 2020-Sept 2021. Inclusion criteria: Adequate quality CTA/CTP imaging DICOM dataset complete processing by both AI software solutions. Exclusion criteria: Technically inadequate images or errors in processing by either AI solutions. Isolated posterior circulation, ACA, M3/M4 LVOs. Ground truth for LVO detection was the final report by the neuroradiologist. Reader 2, blinded to prior reads, re-evaluated CTAs to detect and classify LVOs: ICA, M1 and M2 to evaluate segment-wise performance. AI1 was used in the real-world setting, and the same dataset was run through the AI2 platform. The sensitivity, specificity, PPV, NPV, and accuracy for LVO detection of the 2AI solutions were compared to the ground truth. McNemar test to evaluate if they were significantly different. Paired t-test was used to identify differences in automated CTP volumes. Bland-Altman analysis was used to determine if there was significant difference between the automated CTP volumes and FIV.

#### RESULTS

Of 633 code stroke studies, 529 CTA 192 CTP studies were deemed adequate quality. 69(13%) patients had LVO 460(87%) had no LVO per ground truth. For all types of LVO detection, there was no significant difference between the sensitivity of AI1(0.77) AI2(0.75). However, there was significant difference in the specificity PPV of the two AI solutions. Sensitivities for isolated M2 segment LVO detection were much lower. Mismatch volumes between the two AI solutions were significantly different, particularly at larger mismatch range. In the non-reperfusion group there was significant difference between  $T_{max}>6$  and FIV with AI1 overestimating the volumes in most instances.

#### CONCLUSION

Performance of both AI solutions for M2 occlusions was low with significant difference in their specificities. Divergent performance for  $T_{max}>6$  volumes could impact treatment decisions.

#### CLINICAL RELEVANCE/APPLICATION

Both AI solutions should be used as a support tool for triage and not for final diagnosis. High specificity of AI2 reduces the number of unnecessary notifications and mobile alerts to the on-call stroke team. Automated CTP cut-offs used in AIS endovascular trials are not uniformly applicable across the spectrum of FDA approved AI solutions.

W3-STCE1

### Science Session (Sustainability in Imaging)

Wednesday, Nov. 29 10:00AM - 10:30AM Room: Learning Center Theater 1

#### Sub-Events

#### **W3-STCE1- Safety of gadopixelenol for magnetic resonance imaging (MRI): a pooled analysis of eight studies**

Eric Lancelot, PharmD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Gadopixelenol (Elucirem™, Guerbet) is a new high relaxivity macrocyclic gadolinium-based contrast agent (GBCA) registered in US and currently under review by EU regulatory authorities. The aim of this analysis was to evaluate the global safety of gadopixelenol based on pooled data from all completed clinical studies.

#### **METHODS AND MATERIALS**

Data were obtained from eight phase I to III clinical studies. Overall, 1047 patients or healthy volunteers received gadopixelenol (0.025 to 0.3 mmol/kg), including 80 patients aged 2-17 years (0.05 mmol/kg). In cross-over studies, 791 patients also received another GBCA (gadobenate dimeglumine or gadobutrol), administered at 0.1 mmol/kg. Safety data included post-injection adverse events (AEs), laboratory measures, vital signs, and electrocardiograms (ECG).

#### **RESULTS**

Most subjects (67.6%) received gadopixelenol at 0.05 mmol/kg. AEs considered related to gadopixelenol by the investigators were reported for 8.5% of the subjects. Similar rates of AEs were reported with the other GBCAs in comparative studies. The most common AEs related to gadopixelenol were injection site pain (1.9%), headache (1.3%), nausea (0.7%) and injection site coldness (0.6%). Most AEs were of mild (83.3%) or moderate (12.8%) intensity. Three severe AEs were related to gadopixelenol: injection site pain (2 patients) and upper abdominal pain (1 patient). One serious AE was assessed as related to gadopixelenol (blood creatinine increase of mild intensity). All resolved. Among the pediatric patients, 2 (2.5%) experienced AEs related to gadopixelenol: a mild QT interval prolongation and a moderate maculopapular rash. A good safety profile was also observed in other sensitive populations, such as elderly patients, and patients with renal impairment. No safety concerns were raised from vital signs, laboratory parameters, and ECG data. The thorough QT study confirmed the cardiac safety of gadopixelenol.

#### **CONCLUSION**

Gadopixelenol showed a good safety profile consistent with other GBCAs when used for MRI of the central nervous system and other body regions in adults and pediatric patients aged 2-17 years.

#### **CLINICAL RELEVANCE/APPLICATION**

Gadopixelenol, used at half the standard dose of other GBCAs thereby reducing the total cumulative dose of gadolinium by 50%, could be of particular importance in patients requiring repeated MRIs. Further, a reduced dose reduces the carbon footprint.

#### **W3-STCE1- Energy Consumption, Cost and Carbon Footprint of Point-of-Care Medical 3D Printing**

Alina Carolin Seifert, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To investigate the energy consumption, cost and carbon footprint of point-of-care medical 3D printing in a university hospital setting.

## METHODS AND MATERIALS

Our radiology and craniomaxillofacial departments jointly operate an interdisciplinary 3D print lab with multiple facilities, performing 3D printing in both research and clinical settings and including any of the existing standard types of 3D printing technologies. Out of the 1700 annually produced anatomic models, a substantial portion is created in our point-of-care facility adjacent to the radiology department, where 13 3D printers, 3 post-processing stations, 2 PC workstations and 1 air cleaner are operated. Devices were equipped with kilowatt-hour energy measurement sensors (1-second sampling rate [1 Hz]). Measurements and log files from 03/23/2023 - 04/21/2023 were analyzed and segmented into system modes (off, idle, active). Energy consumption and carbon emissions overall, per 3D printer and for individual 3D print jobs were calculated. Annual energy consumption, electricity cost, carbon emissions and cost saving opportunities were estimated based on the available data.

## RESULTS

Total energy consumption of all point-of-care devices over 30 days was 363 kWh. The projected annual electricity demand of the 3D print lab thus adds up to 4'356 kWh, with resulting costs of \$3'746 (local electricity price: \$0.86/kWh) and carbon emissions of 558 kgCO<sub>2</sub>eq (national specific carbon intensity: 0.128 kgCO<sub>2</sub>eq/kWh). 9 out of the 13 tracked 3D printers were never switched off during the study period, with 56-67% of their energy consumption being attributed to nonproductive idle time (range: 13.3±0.1 - 80.7±2.0 Watt/hour). Switching the printers off could result in annual energy savings of 40 - 571 kWh per printer (cost savings: \$34 - 491, carbon savings: 5 - 73 kgCO<sub>2</sub>eq). Depending on the printer, energy consumption during print jobs ranged between 45±5 - 203±40 Watt/hour, thus 2.5-3 times higher compared with idle mode. Linear regression analysis of individual prints confirmed near perfect positive linear correlation between print duration and energy consumption for all printers ( $r= 0.994 - 0.999$ ), thus allowing to accurately predict energy consumption, electricity cost and carbon emissions per future print job / anatomic model.

## CONCLUSION

Energy consumption and carbon footprint of point-of-care medical 3D printing are low compared to imaging equipment used for raw data acquisition (e.g. CT). Nevertheless, substantial saving potential is present during nonproductive idle mode, which can increase energy efficiency.

## CLINICAL RELEVANCE/APPLICATION

Knowledge on cost and carbon-saving potentials can help 3D print labs to decrease their carbon footprint and operational cost simultaneously.

## W3-STCE1- As Low as Reasonably Achievable: Reducing plastic waste and optimizing cost efficiency in musculoskeletal interventional procedures.

Angela Atinga, MBBChir, FRCPC (*Presenter*) Nothing to Disclose

## PURPOSE

Assess potential cost savings and waste diversion by employing the ALARA principle (As Low as Reasonably Achievable) in relation to materials utilized in performing common musculoskeletal interventional procedures by comparing a) our institution's preset procedure tray and b) the hypothetical usage of essential, individualized items (ALARA materials) over a calendar year.

## METHODS AND MATERIALS

Retrospective study. Local PACS search was performed, between January 1, 2022 and December 31, 2022, with the following search terms: injection and/or aspiration. Results were confined to fluoroscopic and ultrasound guided procedures performed by musculoskeletal radiologists at our institution. The contents, mass, and cost of a) a preset procedure tray and b) ALARA materials were obtained. The following metrics were calculated: cost savings, number of items per category diverted from landfill, and mass of waste diverted from landfill (per procedure and per year).

## RESULTS

893 musculoskeletal imaging procedures were performed at our institution in 2022 (358 fluoro guided injections, 47 fluoro guided aspirations, 280 US guided aspirations, and 208 US guided aspirations). ALARA items consist of: 3 cc syringe, 5 cc syringe, 1 drape, 1 bandage, 1 piece of gauze, 22 g needle, 25 gauge needle. Total mass of these items is 49.1 g. Total cost of the ALARA items is \$9.28. Pre-set tray includes the aforementioned items, in addition to: 20 cc syringe, 1 scalpel, 20 g needle, 2 plastic vials, 1 plastic 6 inch ruler, 1 plastic tray, 2 towels, 2 stick sponges, 1 plastic wrap, 6 glass slides, 3 pieces of gauze, and 1 plastic bag. These latter items are not used and are considered waste. Total mass of the unused items is 200.5 g. Total cost of the tray is \$15.17. Cost savings is \$5.89, or 38.2%, per procedure. Total cost savings is \$5259.77 per year. A total of 893 syringes, scalpels, needles, plastic rulers, trays, wraps, bags; 1786 plastic vials, towels, stick sponges; 2679 pieces of gauze; and 5358 glass slides would be diverted from landfill. Mass of waste diverted from landfill is 201 g per procedure, or 179.4 kg per year. The mass equivalent is that of two average American males. The % reduction in waste (by mass) is 83.2%.

## **CONCLUSION**

Sole usage of ALARA materials in common MSK interventional procedures would yield a cost savings of 38.2% and waste reduction of 83.2% (per procedure and year) at our institution.

## **CLINICAL RELEVANCE/APPLICATION**

ALARA materials for image guided procedures yields significant cost savings and waste reduction -- much of which is plastic. Implementation of such a paradigm would represent an important step towards sustainability in radiology and the health care sector as a whole.

#### **METHODS AND MATERIALS**

Retrospective study. Local PACS search was performed, between January 1, 2022 and December 31, 2022, with the following search terms: injection and/or aspiration. Results were confined to fluoroscopic and ultrasound guided procedures performed by musculoskeletal radiologists at our institution. The contents, mass, and cost of a) a preset procedure tray and b) ALARA materials were obtained. The following metrics were calculated: cost savings, number of items per category diverted from landfill, and mass of waste diverted from landfill (per procedure and per year).

#### **RESULTS**

893 musculoskeletal imaging procedures were performed at our institution in 2022 (358 fluoro guided injections, 47 fluoro guided aspirations, 280 US guided aspirations, and 208 US guided aspirations). ALARA items consist of: 3 cc syringe, 5 cc syringe, 1 drape, 1 bandage, 1 piece of gauze, 22 g needle, 25 gauge needle. Total mass of these items is 49.1 g. Total cost of the ALARA items is \$9.28. Pre-set tray includes the aforementioned items, in addition to: 20 cc syringe, 1 scalpel, 20 g needle, 2 plastic vials, 1 plastic 6 inch ruler, 1 plastic tray, 2 towels, 2 stick sponges, 1 plastic wrap, 6 glass slides, 3 pieces of gauze, and 1 plastic bag. These latter items are not used and are considered waste. Total mass of the unused items is 200.5 g. Total cost of the tray is \$15.17. Cost savings is \$5.89, or 38.2%, per procedure. Total cost savings is \$5259.77 per year. A total of 893 syringes, scalpels, needles, plastic rulers, trays, wraps, bags; 1786 plastic vials, towels, stick sponges; 2679 pieces of gauze; and 5358 glass slides would be diverted from landfill. Mass of waste diverted from landfill is 201 g per procedure, or 179.4 kg per year. The mass equivalent is that of two average American males. The % reduction in waste (by mass) is 83.2%.

#### **CONCLUSION**

Sole usage of ALARA materials in common MSK interventional procedures would yield a cost savings of 38.2% and waste reduction of 83.2% (per procedure and year) at our institution.

#### **CLINICAL RELEVANCE/APPLICATION**

ALARA materials for image guided procedures yields significant cost savings and waste reduction -- much of which is plastic. Implementation of such a paradigm would represent an important step towards sustainability in radiology and the health care sector as a whole.

W3-STCE2

### Science Session (Imaging of Immunotherapy)

Wednesday, Nov. 29 10:00AM - 10:30AM Room: Learning Center Theater 2

#### Sub-Events

#### **W3-STCE2- Morphologic Variations Quantified Over Time for Unresectable Primary Liver Tumors after Checkpoint Inhibition as an Alternate to Standard Response Criteria** 1

Laetitia Saccenti, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

In the setting of immunotherapies, conventional response criteria (ie RECIST 1.1, or mRECIST, iRECIST) may not be perfectly reflective of molecular responses in liver cancer. The aim of this study was to assess the feasibility of quantification of morphologic changes in tumors during immunotherapy, as a reflection of response or survival, as an alternative to conventional imaging criteria

#### **METHODS AND MATERIALS**

Retrospective single-center analysis was performed in patients with unresectable hepatocellular carcinoma (HCC) or cholangiocarcinoma, previously enrolled in clinical trials combined immunotherapy (tremelimumab +/- durvalumab) and locoregional treatment (ablation or transarterial chemoembolization). Conventional response (RECIST 1.1) was assessed at 6-month follow-up. The biggest target lesion was manually segmented on the axial slice with maximum diameter on contrast enhanced CT (ImageJ). Solidity (area/convex hull area) and circularity ( $4\pi \times \text{area} / \text{perimeter}^2$ ) of tumors were calculated at baseline and at 6-months follow up. Patients (target tumors) were stratified by survival at 9 months. Non-paired t-tests were done using R (v.4.3.1)

#### **RESULTS**

From the 68 patients enrolled in clinical trials, 26 did not have target lesions separate from volumes treated by locoregional therapies, 16 had less than 6 months overall survival (OS) and 2 had no follow-up CT available. 25 evaluable patients (4 with cholangiocarcinoma and 21 with HCC) were included. 14/25 had extra hepatic disease. Median OS was 360 days (IQR 286-586). 50 tumors were manually segmented (25 at baseline, and 25 at 6-months). Target tumors included liver tumors (64%), lymphadenopathy (24%), adrenal metastasis (4%) and bone metastasis (4%). At 6-month follow up, according to RECIST 1.1, 13/25 (52%) patients had progressive disease, 11/25 (44%) has a stable disease and 1/25 (4%) patient had a partial response. Poor outcome tumors at 9 months (5/25) had higher solidity and higher circularity at 6-month follow-up than good outcome tumors (20/25), (respectively  $0.936 \pm 0.042$  versus  $0.973 \pm 0.007$ ,  $p=0.002$ , and  $0.765 \pm 0.095$  versus  $0.845 \pm 0.044$ ,  $p=0.005$ ). At baseline, their solidity and circularity were similar (respectively  $0.951 \pm 0.030$  versus  $0.951 \pm 0.032$ ,  $p=0.358$ , and  $0.778 \pm 0.103$  versus  $0.805 \pm 0.105$ ,  $p=0.494$ )

#### **CONCLUSION**

Tumor morphology can evolve during treatment and disease progression and may correlate with outcomes.

#### **CLINICAL RELEVANCE/APPLICATION**

Quantitative morphologic variations such as circularity and solidity merit further consideration as factors in response criteria, and may be associated with survival in this limited feasibility assessment. Larger datasets, automatic segmentation, 3D analysis, radiomic or deep learning tools may facilitate further study.

#### **W3-STCE2- Improving Clear Cell Renal Cell Carcinoma PD-L1 Expression Prediction from CT Radiomics with Green Learning** 2

Alexander Shieh, MD (*Presenter*) Nothing to Disclose

## PURPOSE

PD-L1 is one of the most widely used immunotherapy targets for treating clear cell renal cell carcinoma (ccRCC). Previous studies showed feasibility of predicting PD-L1 from ccRCC radiomics but the performance was not great. This study aimed to improve the prediction of PD-L1 using features extracted from ccRCC tumors coupled with the Green Learning (GL) approach. GL is a suite of lightweight methods that may add advantage to prediction performance compared with conventional machine learning (ML).

## METHODS AND MATERIALS

The PD-L1 levels of 52 ccRCC patients were determined using quantitative multiplex immunofluorescence (mIF) from tissue samples. The mIF method is automated and considers the entire tumor opposed to the conventional immunohistochemistry (IHC) method that required manual counting on small areas. Two methods in the GL suite were used: the Discriminant Feature Test (DFT) for feature dimension reduction and Least-square Normal Transform (LNT) for new feature generation. DFT was used to select a subset of 1708 radiomic features extracted from multiphase CT volumes of ccRCC. LNT then adds an adaptive feature. Both DFT and LNT are entirely data-driven. Together the selected and newly generated features became the input to an XGBoost classifier to predict PD-L1 level. Five-fold cross-validation was used to develop the models.

## RESULTS

The GL pipeline achieved AUROC of 0.76 (95% CI: [0.62, 0.89]) for PD-L1 > 1%, 0.85 (95% CI: [0.70, 1.00]) for PD-L1 > 5% and 0.88 (95% CI: [0.80, 0.96]) for PD-L1 > 10%. Conventional ML without GL only had AUROC 0.61 for PD-L1 > 1%, 0.75 for PD-L1 > 5% and 0.85 for PD-L1 > 10%. The GL approach provides performance benefits across all experiments. Feature importance analysis showed the new feature generated by LNT ranked 7th, 14th, 4th in the three experiments.

## CONCLUSION

Radiomics analysis enhanced by the GL pipeline can predict PD-L1 levels in ccRCC with better performance. The DFT method is effective in feature selection and the LNT method generates feature with high importance.

## CLINICAL RELEVANCE/APPLICATION

Predicting PD-L1 levels in ccRCC patients may help patient selection and prognosis prediction for immunotherapy. Identifying patients who benefit the most from immunotherapy is crucial, yet conventional tissue-based analysis is resource-intensive. Radiomics analysis provides a non-invasive modality that is readily available in clinical scans. GL is a set of novel methods that are lightweight and achieved good empirical performance with imaging data. Unlike deep learning methods, GL methods do not need large scale optimization and are data-efficient. We demonstrated the effectiveness of GL used in improving radiomics analysis for immunotherapy patient selection.

## W3-STCE2- Development and clinical validation of an AI-based assistive software tool for automated detection and quantification of amyloid-related imaging abnormalities

Dirk Smeets, PhD (*Presenter*) Employee, icoMetrix NV

## PURPOSE

Amyloid-related imaging abnormalities (ARIA) are brain magnetic resonance imaging (MRI) findings associated with the use of amyloid beta-directed monoclonal antibody therapies in Alzheimer's disease (AD). ARIA monitoring is important to inform treatment dosing decisions and might be improved through assistive software. As such, we developed an artificial intelligence (AI)-based software for assisting radiological interpretation of brain MRI scans in patients monitored for ARIA, and assessed its clinical performance.

## METHODS AND MATERIALS

We conducted a multireader multicase study to compare the diagnostic performance of radiologists assessing ARIA on MRI scans from patients treated with aducanumab, both unassisted and assisted by the AI-based software. The study encompassed 199 cases from the EMERGE, ENGAGE and PRIME clinical trials and 16 U.S. board certified radiologists with a range of experience. Radiologists reported the presence and severity of ARIA-E and ARIA-H, either assisted or unassisted by the software. Of all cases, 44 did not contain ARIA findings, 84 had both ARIA-E and ARIA-H and the remaining cases had either ARIA-E (n = 39) or ARIA-H (n = 36) only, according to consensus of 3 experts. The co-primary study endpoints were the difference between assisted and unassisted detection accuracy of ARIA-E and ARIA-H separately, assessed with the area under the receiver operating characteristics curve (AUC), where the reader assessments for ARIA severity were compared against a consensus of 3 experts.

## RESULTS

Radiologists assisted by the AI-based software were significantly better in detecting ARIA. Assisted reading performance was superior (vs unassisted) for both ARIA detection co-primary endpoints, with an AUC difference of 0.051 (95% CI: 0.020, 0.083) for ARIA-E (p=0.001) and 0.044 (95% CI: 0.017, 0.070) for ARIA-H (p=0.001). The average assisted AUC was 0.873 (95% CI: 0.835, 0.911) for ARIA-E detection, and 0.825 (95% CI: 0.781, 0.869) for ARIA-H detection. Sensitivity increased

significantly from 70.9% (unassisted) to 86.5% (assisted) for ARIA-E detection, and from 68.7% to 79.0% for ARIA-H detection, while specificity remained above 80% for the detection of both ARIA types.

#### **CONCLUSION**

Radiological reading performance is significantly improved when using the developed AI-based software. Hence, the software can be a clinically impactful tool to improve safety monitoring and management of AD patients treated with amyloid beta-directed monoclonal antibody therapies.

#### **CLINICAL RELEVANCE/APPLICATION**

Radiological assessment of ARIA can be significantly improved using AI-based software and may contribute to improved safety monitoring of patients treated with amyloid beta-directed monoclonal antibody therapies.

W5A-SPBR-1

### Correlation between Sarcopenia Evaluated with CT and Toxicity in Patients Affected by Breast Cancer during Adjuvant Chemotherapy

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Marco Di Girolamo, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Recent evidences suggest that in severe depletion of skeletal muscle, known as sarcopenia, the anti-cancer therapy is associated with poor prognosis and toxicity. Sarcopenia, often unrecognized, affects patients with low, normal or high body mass index (BMI). Aim of this study was to evaluate the association between lumbar skeleton muscle status (LSMI) evaluated with CT scans and toxicity in breast cancer patients receiving standard adjuvant chemotherapy

#### METHODS AND MATERIALS

22 breast cancer women (mean age:55) receiving epirubicin-based chemotherapy were enrolled in a prospective study. Skeletal muscle cross-sectional area at the third lumbar vertebra was measured by CT scans and sarcopenia was defined using the cut off point for LSMI of  $<38.5 \text{ cm}^2/\text{m}^2$ . BMI and BSA were measured at every cycle of chemotherapy. CT scan was performed before the first and fourth cycle of chemotherapy. Toxicity was assessed after every cycle of treatment and it was graded according to the National Cancer Institute Common Toxicity Criteria. Serum samples were evaluated at every cycle to determine drug concentrations.

#### RESULTS

Before the first cycle of chemotherapy, 86.36% of patients were classified as sarcopenic. The sarcopenia mean value was  $32.22 \text{ cm}^2/\text{m}^2$  (SD: 5.78), and no differences by age and BMI were found. The BMI mean value was 23.97 (SD: 4.32). After the fourth cycle of chemotherapy the BMI mean value was 24.19 (SD: 4.74; range) and the sarcopenia mean value was  $32.18$  (SD: 5.68). 18% of patients reported severe toxicities (grade 3 or 4). Sarcopenia mean values were found significantly different ( $p$ -value 0.048) in patients with severe toxicity compared with patients with absent/mild toxicities (mean value: 27.17, SD, 3.27 versus 33.30, SD, 5.55, respectively). Changes in LSMI were associated with significant changes in toxicities ( $p$ -value 0.004). In 18% of patients with a severe toxicity, a decrease in LSMI values after the 4th cycle of chemotherapy was always detected.

#### CONCLUSION

Preliminary analysis of available data showed an association between sarcopenia and toxicities, suggesting also that sarcopenia could be considered an early condition in breast cancer.

#### CLINICAL RELEVANCE/APPLICATION

If the association between changes in sarcopenia and toxicities will be confirmed in larger population, the measure of LSMI with CT scan could be used to personalized the dose of chemotherapy

### Complex Interplay of MRI and Clinicopathology Variables in pCR Prediction across Breast Cancer Subtypes

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Sarah Eskreis-Winkler, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Breast cancers exhibit different rates of pathologic complete response (pCR) according to tumor receptor status: HR+/HER2-, HER2+, and triple negative (TNBC). Deep learning (DL) models using MR have been developed for pCR prediction, but the comparative performance of pCR prediction for different subtypes has not yet been investigated. Herein, we build pCR prediction models for each subtype, compare performance across subtypes, and explore relationships to clinicopathology (CP) models.

#### METHODS AND MATERIALS

This IRB-approved HIPAA-compliant study included 719 breast MRs performed between 2014-2018 on breast cancer patients prior to neoadjuvant chemotherapy. Tumor subtype, pCR status, and CP variables were collected, including age, race, cancer history, clinical stage, nuclear grade, histological grade, and histology. A ResNet50-based architecture was built to predict pCR for each subtype using MR. Data was randomly split 80/10/10 into training, tuning and testing. Pre-contrast, post-contrast, subtraction, and T2 images were co-registered; tumor ROIs were automatically segmented and passed through the model. Final hyperparameters: 25 epochs; learning rate  $2e-4$ , batch size 64. A penalized logistic regression model was built to predict pCR using CP variables alone. Patients were randomly assigned to training and testing with an 80/20 split. ROC curves were generated and AUCs were calculated for each subtype, for the MR and CP models. DeLong's test assessed statistical significance of differences in model performance.

#### RESULTS

Breast MRs included 210 HR+/HER2- (5050 axial slices), 349 HER2+ (8325 axial slices) and 160 TNBC (4521 axial slices) cases. Test set AUCs for the MR models were 0.62 for HR+/HER2-, 0.48 for HER2+, and 0.78 for TNBC. The best AUC (i.e. TNBC) was statistically significantly higher than to the worst AUC (i.e. HER2+) ( $p < 0.001$ ). For the CP model, test set AUCs were 0.80 for HR+/HER2-, 0.68 for HER2+, and 0.55 for TNBC.

#### CONCLUSION

DL-based MR model performance for pCR prediction varies by subtype with the TNBC (AUC = 0.78) significantly outperforming HER2+. In contrast, the CP model exhibited poor performance for TNBC (AUC = 0.55). This suggests synergistic potential for pCR prediction using medical images and CP. We are actively working to develop a composite model that integrates multimodality inputs to optimize pCR prediction across all patients and all tumor subtypes.

#### CLINICAL RELEVANCE/APPLICATION

DL-based MR models for pCR prediction perform better on some tumor subtypes than others, providing complimentary information to clinicopathology variables. This suggests synergistic potential for pCR prediction using a multimodality approach, enabling optimization of treatment planning for all breast cancer patients.

W5A-SPBR-3

### What is the Optimal Post Contrast Timing of Breast MRI to Evaluate Residual Tumor during the Course of Neoadjuvant Chemotherapy

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Phuong T. Duong, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Patients undergoing neoadjuvant chemotherapy (NAC) are often monitored using dynamic contrast enhanced (DCE)-MRI, a sensitive tool for residual tumor assessment. NAC can have antiangiogenic effects that can impact accurate assessment of residual tumors. Purpose of this study is to evaluate the optimal post contrast timing to evaluate residual tumor during the course of NAC.

#### METHODS AND MATERIALS

An IRB approved study was performed. Publicly available 351 MRI exams from 117 breast cancer patients undergoing NAC in the ACRIN 6698 multi-institution trial were used for this study. The average age of patients was 49 y.o. (+/-11). Of 117 patients, 36 patients (30.8%) achieved pathologic complete response (pCR) and 81 patients (69.2%) did not (non-pCR). Of 117 patients, 36 patients (30.7%) had triple negative tumors (ER-,PR-,HER2-), 30 patients (25.6%) had HER2+ tumors and 51 patients (43.6%) had ER+/HER2- tumors. The MRI exams included those from pretreatment [T0], early NAC treatment [T1], and mid-NAC treatment [T2]. For each tumor, we calculated the time to peak (TTP) to achieve maximal tumor enhancement and evaluated changes in TTP over the course of NAC treatment. TTP was calculated by segmenting the tumor and calculating the phase with maximum signal intensity measured within the tumor. TTP subanalysis was performed comparing patients with tumors that achieved pCR vs non-pCR and between subtypes of breast cancer. Statistical significance was determined with  $p < 0.05$  from a 2-tailed paired t-test.

#### RESULTS

The TTP increased significantly over the course of NAC treatment. The TTP at T1 was 265 sec (+/-151), at T2 was 314 s (+/- 314) and at T3 was 385 s (+/- 183). The average TTP increase of 159 s (+/- 146) from T0 to T2 was statistically significant ( $p < 0.05$ ). Tumors of patients that achieved pCR had significantly greater change in TTP from T0 to T1 compared to non-pCR [183 s (+/-147) vs. 15 s (+/- 103),  $p < 0.05$ ]. Patients with triple negative and HER2+ tumors had greater change in TTP from T0 to T1 compared to ER+/HER2- tumors [90 s (+/-212) and 63 s (+/- 209) vs. 5 s (+/- 229)] but was not statistically significant.

#### CONCLUSION

The optimal post contrast timing of breast MRI increases with NAC likely due to antiangiogenic treatment effects. DCE-MRI protocol should include delayed post dynamic sequences inclusive of 314 s to 385 s to enable maximal tumor enhancement to best evaluate residual tumor during NAC, particularly in triple negative and HER2+ tumors. A significant increase in TTP from T0 to T1 could be a possible novel biomarker of pCR but needs further studies.

#### CLINICAL RELEVANCE/APPLICATION

In the setting of NAC, the most optimal timing of breast MRI is likely on the delayed post contrast images and should be part of the evaluation to most accurately assess residual breast tumor.

### Correlation of MRI and Pathological Responses after Neoadjuvant Chemotherapy with Disease-Free Survival in Breast Cancer Patients: Subtype Analysis

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Ricardo Fernandes Da Cunha, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To correlate response evaluation after neoadjuvant chemotherapy (NAC), assessed by magnetic resonance imaging (MRI) and pathology, with disease-free survival (DFS) in breast cancer patients, according to the subtype.

#### METHODS AND MATERIALS

This single-center, IRB-approved, retrospective cohort study included consecutive breast cancer patients who underwent NAC and preoperative breast MRI. Pathologic response was assessed through the residual cancer burden (RCB) system, and absence of invasive carcinoma in the breast and axilla was defined as complete pathological response (pCR or RCB-0). Radiological complete response (rCR) was defined as the absence of abnormal enhancement in the tumor site on MRI. Kaplan-Meier estimator was used to estimate the disease-free survival. Cox regression analysis was used to estimate hazard ratio (HR) values.

#### RESULTS

750 patients were included with mean age of 47 years (range: 26-90 years). The most common immunophenotype was Luminal (n=362; 48.3%), followed by triple-negative (n=198; 26.4%) and Her-2 overexpressed (n=190; 25.3%). Most patients (n=474; 63.2%) had clinical stage III at diagnosis. Overall, 34.5% of the patients had rCR, while 30.3% had pCR. During a mean follow-up of 72 months, patients who had both rCR and pCR had a better DFS curve, while patients with non-rCR and non-pCR had worse DFS curve, and those who had rCR or pCR presented an intermediate curve (LogRank p=0.001). The statistically significant difference on DFS curves persisted for triple-negative (LogRank p<0.001) and Her-2 overexpressed subtypes (LogRank p = 0.014), but not for luminal tumors (LogRank p=0.495). Cox regression showed a higher risk of recurrence in patients with non-rCR and non-pCR (HR: 8.686; p=0.003), those who had non-pCR and rCR (HR: 7.658; p=0.008), and those who had pCR and non-rCR (HR: 3.644; p=0.109), when compared to patients with rCR and pCR.

#### CONCLUSION

The association of MRI and pathological responses after NAC might better stratify the risk of recurrence and prognosis in breast cancer patients, particularly for the triple-negative subtype.

#### CLINICAL RELEVANCE/APPLICATION

Association of response evaluation after neoadjuvant chemotherapy by pathology and MRI allows better stratification of prognosis than both criteria used alone.

### Features of MRI Screen-Detected Breast Cancers

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Naveen Ghuman, BS, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Breast cancer is a leading cause of death in women in the United States. Supplemental screening with breast MRI in addition to mammography is recommended annually for patients who have greater than 20% lifetime risk for breast cancer. While there is robust data regarding features of screen-detected breast cancer using mammography, there is limited data regarding MRI screen-detected cancers. This study aims to identify features of breast cancers initially detected by MRI.

#### METHODS AND MATERIALS

In this institutional review board-approved retrospective study, breast MRIs performed between August 1, 2016 and July 30, 2022 identified 51 screen-detected breast cancers in 48 patients. Clinical and imaging features of all eligible cancers were recorded, as well as frequency of cancer type and clinical stage.

#### RESULTS

During the study period, 51 MRI-screen detected cancers were identified in 48 patients. Most cancers (33/51, 64.8%) were invasive and most (45/51, 88.2%) were stage 0 or I at diagnosis. At the end of the study period, 1/48 (2.1%) had metastasis (in a patient with recurrent angiosarcoma), 1/48 (2.1%) had died from other causes, and 46/47 (97.9%) had no evidence of disease following treatment. Final pathology showed that 26/51 (51.0%) of MRI screen-detected cancers were invasive ductal carcinoma, 6/51 (11.8%) invasive lobular carcinoma, 1/51 (2.0%) angiosarcoma and 18/51 (35.3%) DCIS. MRI-screen detected cancers most commonly presented as a mass (26/51, 51%) or non-mass enhancement (NME) (25/51, 47.1%), with only 1/51 (2%) presenting as a focus. Internal T2 signal was hypointense to fibroglandular tissue in 4/51 (7.8%), isointense in 29/51 (56.9%) and hyperintense in 18/51 (35.3%). Of those cancers that presented as a mass, the majority 15/27 (55.6%) had an irregular shape, 13/27 (48.1%) had irregular margins, and 15/27 (55.6%) had homogeneous internal enhancement. Of those that presented as NME, the majority 13/24 (54.2%) were linear NME and had homogeneous internal enhancement 15/24 (62.5%). Many of the cancers were in patients who had prior MRI exams (37/51, 72.5%).

#### CONCLUSION

MRI screen-detected cancers were most often invasive, rather than in situ, cancers. Cancers detected by MRI screening had an excellent prognosis in our study population, supporting the clinical utility of breast MRI in the early diagnosis of breast cancer. Common MRI presentations included an irregular mass and linear non-mass enhancement.

#### CLINICAL RELEVANCE/APPLICATION

Screening MRI often detected small, invasive breast cancers, underscoring its clinical importance in women at high risk for breast cancer. Understanding the most common imaging presentations of MRI-screen-detected cancers may guide interpretation and diagnostic performance of the exam.

### Does the Addition of MRI Help in Cancer Detection in Women with Low Breast Tissue Density in a Population-based High-risk Breast Screening Program

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

David G. Martin, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The High-Risk Ontario Breast Screening Program (HROBSP) screens women ages 30-69 who are confirmed to be at high risk of developing breast cancer (gene mutation carriers or lifetime risk =25%) with annual mammography and breast MRI. Mammographic breast tissue density (BTD) is an independent risk factor for breast cancer, and the sensitivity of mammography is diminished in women with dense versus fatty breasts. We aimed to compare cancer detection rate (CDR) according to BTD and determine if breast MRI in HROBSP patients with fatty BTD is necessary given the improved sensitivity of mammography.

#### **METHODS AND MATERIALS**

IRB approved retrospective review of all HROBSP breast MRIs performed at our institution from 04/04/2016 to 06/05/2022 was conducted. For each study, BI-RADS® BTD was recorded, and charts were reviewed to identify patients with breast cancers diagnosed during the screening period. Imaging was reviewed to determine if the cancer was seen on mammography, MRI or both.

#### **RESULTS**

6468 MRIs were reviewed (2082 patients) over 6-year study period. 66 cancers were detected in all (cancer detection rate (CDR)=10.2/1000); 5(7.6%) detected in category A, 20(30.3%) in B, 34(51.5%) in C and 7(10.6%) in D. 468(7.2%) MRIs were performed in 12.5%(260/2082) women with category A, who had 4 cancers (80%) detected on MRI alone and 1 cancer on both mammography and MRI. There was no difference in CDR by BTD (CDR for category A=10.7/1000, B=8.6/1000, C=11.8/1000, and D=9.1/1000, p=0.7).

#### **CONCLUSION**

Adjunctive screening with breast MRI in HROBSP patients is necessary for women with category A density breasts, despite the increased sensitivity of mammography in this patient population.

#### **CLINICAL RELEVANCE/APPLICATION**

The HROBSP program with yearly mammography and breast MRI aids in early detection of breast cancer in all women, regardless of breast density.

W5A-SPBR-7

### Outcomes of Supplemental Breast MRI in a High Risk Screening Program

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Stamatia V. Destounis, MD (*Presenter*) Medical Advisory Board, iCad, Inc

#### PURPOSE

The Tyrer-Cuzick (TC) model has increasingly been used to identify high-risk women in breast imaging centers. The accuracy of the model has been studied in several patient cohorts, but, outcomes of using the TC model to make supplemental breast MRI recommendations are less reported. We studied the incidence of breast cancer and tumor characteristics at a community-based breast imaging center to better understand the outcomes of the risk assessment program.

#### METHODS AND MATERIALS

A retrospective analysis of patients participating in the risk assessment program starting in December 2016 was performed. Patients with a TC lifetime risk score >20% were offered supplemental MRI screening and are defined as high-risk (HR) in this study. Data were collected from the electronic health record, including Breast MRI data and cancer outcomes, and was matched to the risk assessment and imaging studies data. We limited our cohort to those with at least 5 years of follow-up. Patients with history of breast cancer prior to the first risk assessment, patients who were under 40 or over 79 years old, and patients without a valid TC score were excluded.

#### RESULTS

There were 54,706 patients who met study inclusion criteria with median age of 57, at median follow-up time of 5.2 years during which 2,259 cancers arose. The HR group was comprised of 8,737 (15.5%) patients (median age 52); LR group had a median age of 58 ( $P < 0.001$ ). Of HR patients, there were 2,108 (24.1%) who had breast MRI with a high-risk exam indication (median age 51). Odds ratio (OR) for breast cancer for the total HR group compared to the LR group was 1.50 (95% CI: 1.36 to 1.67,  $P < 0.0001$ ). OR for the HR group who were getting MRI compared to the LR group was 1.47 (95% CI: 1.21 to 1.78,  $P < 0.0001$ ). OR for the HR group who were not getting MRI compared to the LR group was 1.51 (95% CI: 1.35 to 1.70,  $P < 0.0001$ ). When considering tumor size of T2 or greater as large, the OR for a larger tumor when comparing the HR group to the LR was 0.57 (95% CI: 0.39 to 0.84,  $P = 0.0038$ ). For the HR group with MRI the OR was 0.39 (95% CI: 0.17 to 0.91,  $P = 0.029$ ) and the OR for HR group without MRI was 0.63 (95% CI: 0.42 to 0.96,  $P = 0.030$ ). Though not statistically significant, 12.9% of cancers in the LR group were node positive, compared to 6.4% in the HR group with MRI ( $P = 0.0698$ ).

#### CONCLUSION

Supplemental MRI screening in high-risk women can lead to earlier detection of breast cancer, finding tumors at lower stage that may lower the burden of disease. Further investigation in how to improve the uptake of high-risk interventions such as breast MRI screening will be beneficial.

#### CLINICAL RELEVANCE/APPLICATION

This study reports the impact of offering supplemental breast MRI as part of a large breast screening program. This high-risk cohort had an increased cancer rate and smaller tumors.

### Application Value of Imaging Manifestations Combined with Tumor-Related Diffusion-Weighted Imaging Models in Predicting Molecular Subtype of Breast Invasive Ductal Carcinoma

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Cece Dong (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate and compare the value of MR imaging manifestations and 6 tumor-related DWI models in predicting the molecular subtypes of breast invasive ductal carcinoma (IDC).

#### METHODS AND MATERIALS

This study included 100 patients with breast IDC confirmed by pathological examination in our hospital. All the patients underwent routine MRI and multiple-b-value DWI examinations on a 3T scanner (MAGNETOM Vida, Siemens, Erlangen, Germany). The scanning parameters are shown in Table 1. The patients were divided into three groups, including luminal (n=72), HER-2 overexpressing (n=13), and triple-negative (n=15) subtypes. The value in predicting the molecular subtype of IDC was evaluated in terms of imaging manifestations and quantitative parameters of DWI models. All the 14 quantitative parameters (CTRW\_a, CTRW\_β, CTRW\_D, FROC\_β, FROC\_D, FROC\_μ, DKI\_D, DKI\_K, IVIM\_D, IVIM\_D\*, IVIM\_f, Mono\_ADC, SEM\_a, and SEM\_DDC) of the 6 DWI models were calculated by an in-house developed software called BoDiLab based on Python 3.7. All ROI measurements were done on the ITK-SNAP. Univariate and multivariate regression analysis were performed to screen independent predictive factors for different molecular subtypes, and a combined model was established, which was then visualized with a nomogram. ROC curves were used to assess the diagnostic performance of each parameters or model in discriminating molecular subtypes. All the analysis was performed using the software SPSS 26.0 and R language.

#### RESULTS

Margin burr and rim enhancement were independent imaging manifestation-related predictors of triple-negative breast cancer (TNBC) ( $P < 0.05$ ), which showed high diagnostic performance when combined with CTRW\_a and DKI\_K (AUC/sensitivity/specificity value of 0.870/80.0%/88.2%) (Figure 1). Luminal IDC was more likely to appear with margin burrs ( $P < 0.05$ ), and the diagnostic performance was higher when combined with CTRW\_a, DKI\_K, and IVIM\_f. HER-2-overexpressing IDC was commonly accompanied by peritumoral edema ( $P < 0.05$ ), and IVIM\_f showed high diagnostic value for this subtype (Table 2, 3). Nomogram for predicting the TNBC and luminal subtype were shown in figure 2.

#### CONCLUSION

The combined diagnostic model based on imaging manifestations and multiple DWI quantitative parameters has high diagnostic value in predicting the molecular subtype of breast IDC, and the parameters may be used as non-invasive biomarkers in future clinical practice.

#### CLINICAL RELEVANCE/APPLICATION

This study explored the value of MRI manifestations combined with different DWI quantitative parameters in predicting the molecular subtypes for breast IDC, which may have guiding significance for the formulation of individualized treatment strategies in clinical practice.

### Diagnostic Accuracy of Spectral CT Aortograms for the Detection of Acute Myocardial Infarction

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Dene Ellis, BMBS (*Presenter*) Nothing to Disclose

#### PURPOSE

Acute myocardial infarction (MI) presentation is often atypical and unclear, justifying further investigations for other causes of chest pain. Thus, in modern practice CT aortograms (CTAs) are essential to exclude acute aortic syndrome (AAS). Despite being a non-dedicated study for the assessment of coronary heart disease (CHD), new spectral CT technologies may enable interrogation of coronary abnormalities or discernible myocardial perfusion defects. The aim of this study is to assess the diagnostic performance of gated-spectral CTAs in diagnosing acute MI. This will help to determine the prevalence of acutely presenting CT-imaging features by measuring myocardial Hounsfield Unit (HU) values indicative of evolving regional ischaemia.

#### METHODS AND MATERIALS

Retrospective consecutive cohort analysis was conducted to include acute chest pain patients that underwent urgent gated-spectral CTAs as a triple rule-out test for AAS at a large tertiary centre, over 12 months (Jan-Dec 2022). CTAs performed for reasons other than acute pain (e.g. trauma) were excluded. Data sources included patients' electronic records and the institution's PACS, to collate patients' demographics, clinical information, imaging findings, outcomes of further investigations and definitive management. This enabled correlation with troponin levels, ECG, and echocardiographic observations. On CTAs, LV myocardial hypo-enhancement HU was measured after visual assessment by two cardiac-trained radiologists to localise culprit diseased coronary arteries.

#### RESULTS

In a total of 309 CTAs, n=30 (9.7%) studies showed regional myocardial hypo-enhancement, confirmed later as acute MI. Of those, n=18/30 (60%); underwent urgent invasive angiography, where n=13 received percutaneous interventions and n=7 required urgent coronary artery bypass graft (CABG) surgery. Two patients died shortly after CTA acquisition, one of which had a post-mortem examination confirming a large territory MI. CTA yields an 90.9% sensitivity, 99.3% specificity and 98.4% accuracy in identifying acute MI (prevalence-adjusted). Ischaemic myocardial regional hypo-enhancement was (HU=50, SD=17.7) significantly lower ( $p<0.001$ ) than healthy myocardium (HU=126, SD=19.4).

#### CONCLUSION

At our institution, gated-spectral CTA has been utilised to investigate equivocal acute chest pain presentations in the emergency setting. The benefits of its excellent diagnostic accuracy can be achieved by educating reporting radiologists and cardiologists.

#### CLINICAL RELEVANCE/APPLICATION

Gated-spectral CTA can preclude the need for post-mortem examination, but it is most beneficial in reducing time-to-intervention by avoiding unnecessary further tests, especially in equivocal NSTEMI cases.

### Measurement Accuracy of Aortic Valve Annulus with and without Whole-heart Motion Correction Algorithm in Multi-slice CT for Pre-operative TAVI: Compared to 3D Transesophageal Echocardiography

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Takayuki Yoshiura, BA, RT (*Presenter*) Nothing to Disclose

#### PURPOSE

Accurate measurements of the aortic valve annulus with multi-slice CT (MSCT) are required for the success of pre-operative transcatheter aortic valve implantation (TAVI) procedure. The whole-heart motion correction (MC) algorithm is useful for reducing aortic annulus motion artifacts and is expected to measurement accuracy. The purpose of this study is to investigate the measurement accuracy of the aortic valve annulus with and without MC algorithm in MSCT compared to three-dimensional transesophageal echocardiography (3D TEE).

#### METHODS AND MATERIALS

We retrospectively analyzed 15 patients who underwent TAVI. The three mutually perpendicular planes so that the cross-sectional plane just passed through the plane of the lowest point of the aortic valve leaflet attachment, and the resulting section was the aortic annulus plane. The axial plane was reconstructed for the minimum aortic annulus diameter, and the valsalva and aortic annulus diameter were measured using 256-slice CT (Revolution Apex; GE Healthcare, Milwaukee, Wisconsin). We created an annulus plane on 3D TEE (EPIQ CVx; Koninklijke Philips Ultrasound, USA) using the same method as CT, and measured the minimum diameter of the valsalva and aortic annulus in the sagittal plane. All CT images were using the with and without MC algorithms and compared to 3D TEE measurements.

#### RESULTS

The measured mean diameter of valsalva for axial plane was 30.00 mm and 28.61 mm for with and without MC algorithms. The measured mean diameter of valsalva for the sagittal plane was 30.22 mm for 3D TEE, showing a significant difference between without MC algorithm and 3D TEE ( $p < 0.01$ ), but not between with MC algorithm and 3D TEE ( $p > 0.05$ ). The measured mean diameter of aortic annulus for the axial plane was 20.20 mm and 19.53 mm for with and without MC algorithms. The measured diameter of aortic annulus for the sagittal plane 20.50 mm for 3D TEE, showing a significant difference between without MC algorithm and 3D TEE ( $p < 0.01$ ), but not between with MC algorithm and 3D TEE ( $p > 0.05$ ).

#### CONCLUSION

MC algorithm in MSCT enabled the accurate measurements of aortic valve annulus for pre-operative TAVI.

#### CLINICAL RELEVANCE/APPLICATION

The application of MC algorithm in MSCT is useful for the accurate measurements of aortic valve annulus for pre-operative TAVI.

### Association between Coronary Sinus Flow Estimated by Dynamic Coronary CT Angiography and $^{13}\text{N}$ -ammonia PET-derived Myocardial Flow Reserve

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Michinobu Nagao, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Coronary sinus (CS) flow is regulated by global myocardial blood flow (MBF) and directly affects myocardial flow reserve (MFR) reduction. We devised a new method for CS flow quantification using 320-row dynamic coronary CT angiography (CCTA) and investigated the relationship between CS flow determined via CCTA and MBF or MFR values obtained via  $^{13}\text{N}$ -ammonia positron emission tomography ( $^{13}\text{N}$ -PET).

#### METHODS AND MATERIALS

Forty patients with moderate to severe coronary artery stenosis on dynamic CCTA who subsequently underwent adenosine-stress  $^{13}\text{N}$ -PET were enrolled in this study. Time-attenuation curves of the CS and the ascending aorta were extracted from dynamic CCTA data. The upslope of the CS was defined as the initial slope of the CS attenuation increase divided by that of the ascending aorta. CS start time (s) was defined as the timepoint between the peak aortic attenuation and the initial increase in CS attenuation. Global MBF was calculated from dynamic  $^{13}\text{N}$ -PET data. Global MFR was defined as the ratio of adenosine-stress MBF to the rest MBF.

#### RESULTS

The CS upslope was moderately positively correlated with rest MBF (Pearson correlation coefficient  $r$ , 0.443;  $p$  = 0.004), and CS start time was moderately negatively correlated with MFR ( $r$ , -0.540;  $p$  < 0.001). The diagnostic performance predicting MFR < 2.0 according to the following criteria: CS starting time > -0.36 seconds was 86% sensitivity, 76% specificity, and an area under the curve of 0.83.

#### CONCLUSION

Dynamic CCTA-estimated CS flow measurements were significantly correlated with  $^{13}\text{N}$ -PET-derived MBF and MFR values. A delayed CS start time can be used to predict a significant decrease in MFR in coronary artery disease.

#### CLINICAL RELEVANCE/APPLICATION

This method may help estimate MFR even in facilities that do not have a PET scanner.

Printed on: 08/22/24

W5A-SPCA-4

### Impact of Super-Resolution Deep Learning Reconstruction Technique on Dynamic Myocardial Computed Tomography Perfusion Imaging

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Tomoro Morikawa, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Super-resolution deep-learning reconstruction (SR-DLR) is a novel computed tomography (CT) image reconstruction technique using a deep convolutional neural network that allows for improvement of spatial resolution on CT images as with ultra-high-resolution CT. This study aims to evaluate the impact of SR-DLR on the image quality and hemodynamic parameter of dynamic myocardial computed tomography perfusion (CTP) by comparing with hybrid iterative reconstruction (HIR) and DLR.

#### METHODS AND MATERIALS

This retrospective study included 26 patients who underwent dynamic myocardial CTP with pharmacological stress using 320-detector-row CT scanner for assessing coronary artery disease. The CTP images were reconstructed with HIR, DLR, and SR-DLR. For qualitative image quality assessment, overall visual score was evaluated on 4-point scale (1=poor, 4=excellent). For quantitative image quality assessment, CT attenuation and standard deviation in the myocardium (septum and lateral wall) and blood pool were recorded to calculate the image noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR). Additionally, the CT attenuation profile across the myocardium and blood pool was generated to measure the edge rise slope (ERS) and edge rise distance (ERD). For hemodynamic parameter assessment, overall CT-derived myocardial blood flow (CT-MBF) was quantified. These results were compared among three different CTP images reconstructed by HIR, DLR, and SR-DLR.

#### RESULTS

The mean visual image quality score on SR-DLR was better than on HIR and DLR (3.6 vs 2.2 and 2.8;  $p < 0.01$ ). The median image noise on SR-DLR was significantly lower than on HIR and DLR (15.6 vs 23.1 and 17.8;  $p < 0.01$ ). The mean SNR and CNR on SR-DLR were significantly higher than on HIR and DLR (SNR: 9.7 vs 7.3 and 7.9,  $p < 0.01$ ; CNR: 28.5 vs 20.1 and 23.4,  $p < 0.01$ ). The median ERD on SR-DLR was significantly shorter than on HIR and DLR (2.3 vs 3.0 and 2.6;  $p < 0.01$ ), and the mean ERS on SR-DLR was significantly steeper than on HIR and DLR (168.4 vs 126.1 and 151.2;  $p < 0.01$ ). There was no significant difference in mean CT-MBF among the three different CTP images reconstructed by HIR, DLR, and SR-DLR (2.37, 2.38 vs 2.39 mL/g/min).

#### CONCLUSION

SR-DLR was superior to HIR and DLR with respect to the image noise and the sharpness of myocardial margins without altering CT-MBF quantification in dynamic myocardial CTP imaging.

#### CLINICAL RELEVANCE/APPLICATION

SR-DLR allows for improving the image noise and sharpness more effectively than conventional reconstruction techniques in dynamic myocardial CTP imaging without requiring hardware changes. SR-DLR has a potential to improve the detectability of myocardial perfusion abnormality by taking advantage of the high spatial resolution and noise reduction capability.

### Deep-Learning Image Reconstruction Algorithm: Impact on Plaque Analysis in Coronary Computed Tomography Angiography

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Domenico De Santis, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Plaque composition in Coronary Computed Tomography Angiography (CCTA) relies on plaque density measurements and subsequent partition in different components: lipid, fibro-fatty, and calcified. Newly developed deep-learning image reconstruction algorithms (DLIR) hold promises to replace iterative reconstructions in CCTA, granting high image quality, low dose, and no detrimental effect on image texture; however, different strength levels may have an impact in plaque features extraction. The aim of this study was to assess the influence of DLIR at different strength levels on coronary plaque analysis.

#### METHODS AND MATERIALS

Forty consecutive patients (mean age  $61.9 \pm 15.4$  y) who underwent clinically indicated retrospectively ECG-gated CCTA were included in the study. CT scans were performed on a 128-row CT scanner (Revolution EVO, GE Healthcare) with the following parameters: tube voltage, 100 kV; tube current: 200 mA; detector collimation: .625 mm, rotation time: .6 s, automatically adjusted spiral pitch from .16 to .30, and matrix:  $512 \times 512$  pixels. A fixed amount (60 mL) of iodinated contrast medium (Iomeprol 400) was intravenously administered at a flow-rate of 5 mL/s. Raw data were reconstructed using ASiR-V 50% and DLIR at three strength levels (DLIR\_L, DLIR\_M, and DLIR\_H). Plaque analysis was performed using a dedicated software (SurePlaque, Canon Medical Systems, Japan): plaque burden, plaque volume, mean density, and plaque composition were assessed on a per-vessel analysis. Statistical analysis was performed by means of Kruskal-Wallis H Test, followed by Dunn's test for pairwise comparisons.

#### RESULTS

Fifty-seven plaques were analyzed for each reconstruction, for a total of 228 plaques. Total plaque burden was 61.1%, plaque volume was 132 mm<sup>3</sup>, and mean density was 179 HU. DLIR at different strength levels did not show statistically significant differences in the three parameters (all  $P = .906$ ). In terms of plaque composition, no differences have been found for fibro-fatty and calcified components ( $P = .503$  and  $= .821$ , respectively). The mean density of lipid plaques was statistically different among the four algorithms ( $P = .013$ ), in particular pairwise comparison showed difference between DLIR\_L and DLIR\_H ( $P = .009$ ).

#### CONCLUSION

DLIR has no impact on overall plaque analysis compared to routinely applied ASiR-V; DLIR\_L might return lower density values for lipid plaque component.

#### CLINICAL RELEVANCE/APPLICATION

DLIR grants reliable coronary plaque analysis; therefore, it can be safely implemented in CCTA examinations. DLIR\_L impact on lipid component should not hinder plaque analysis, since lower lipid density values broaden the density differences with fibro-fatty plaque component.

### Evaluation of Dual-Source Photon-Counting CT Virtual Monoenergetic Imaging of Coronary Arteries in TAVI Patients

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Daniel Overhoff, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Transcatheter aortic valve implantation (TAVI) is a widely utilized valve replacement procedure. The coronary arteries must be assessed before each procedure, which is usually done using invasive catheter angiography. The photon counting detector-CT (PCD-CT) yields the possibility to evaluate the specifications of the valve and the coronary arteries with a one-stop-shop approach. The aim of this study was to evaluate the impact of low energy virtual monoenergetic images (VMI+) objective image parameters (vessel enhancement, noise (standard deviation of vessel attenuation), signal to noise ratio (SNR), contrast to noise ratio (CNR)) of the coronary arteries in pre-TAVI CT examinations.

#### METHODS AND MATERIALS

We retrospectively analyzed 125 pre-TAVI CT datasets from a first generation Dual-Source PCD-CT (Naeotom alpha, Siemens Healthineers, Forchheim Germany). The coronary arteries were analyzed in virtual monoenergetic images ranging from 40 to 100 keV in 15 keV steps. Maximum vessel density Hounsfield Units (HU) were measured for Left main (LM), Right coronary artery (RCA), Left circumflex (LCX) and Left anterior descending (LAD) at the proximal vessel segment. Signal-to-noise ratio and contrast-to-noise ratio were calculated.

#### RESULTS

A total of 125 patients (73 male/52 female) were included in the final assessment. Maximum intraluminal enhancement of coronary arteries was measured for 40keV ( $1123\pm 312$ HU) with decreasing density values with increasing keV values (100keV  $220\pm 55$ HU). SNR showed a significant reciprocal values with highest SNR at 100keV compared to 40keV ( $14.55\pm 9.47$  vs  $10.68\pm 6.68$   $p<0.001$ ). The CNR, in turn, demonstrated significantly improved values at lower keV levels. (40keV vs 100keV/  $26.37\pm 10.15$  vs  $8.50\pm 3.50$   $p<0.001$ ). There were no significant gender differences in the above changes.

#### CONCLUSION

PCD-CT virtual monoenergetic images offer the possibility to improve the image quality for the assessment of the coronary arteries in pre-TAVI-CT. The highest vascular contrast and CNR are achieved at 40keV. SNR is highest at 100keV and decreases at lower keV levels.

#### CLINICAL RELEVANCE/APPLICATION

PCD-CT virtual monoenergetic images yield the possibility of potential reduction of contrast media and an optimization of image quality with reduction of radiation dose for the analysis of coronary arteries in TAVI patients.

### Impact of Different AI User Interfaces on Lung Nodule and Mass Detection on Chest Radiographs

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Jennifer S. Tang, MBBS, FRANZCR (*Presenter*) Founder, STAT Innovations Pty Ltd

#### PURPOSE

To explore the impact of different user interfaces (UIs) for artificial intelligence (AI) outputs on radiologist performance and user preference in detecting lung nodules and masses on chest radiographs.

#### METHODS AND MATERIALS

A retrospective paired-reader study with a 4 week washout period was used to evaluate three different AI UIs compared with no AI output. Ten radiologists (8 radiology attendings and 2 trainees) evaluated 140 chest radiographs (81 with histologically confirmed nodules and 59 confirmed as normal by CT), with either no AI or one of three UI outputs: 1) text only, 2) combined AI confidence score and text, or 3) combined text, AI confidence score and image overlay. Areas under the receiver operating characteristic curve (AUCs) were calculated to compare radiologist diagnostic performance with each UI with performance without AI. Radiologists reported their user interface preference.

#### RESULTS

AUC improved when radiologists used the text-only output compared with no AI (0.87 vs 0.82,  $p$ -value<0.001). There was no difference in performance for the combined text and AI confidence score output compared with no AI (0.77 vs 0.82,  $p$ -value=0.46) and for the combined text, AI confidence score and image overlay output compared with no AI (0.80 vs 0.82,  $p$ -value=0.66). Eight of the 10 radiologists (80%) preferred the combined text, AI confidence score and image overlay output over the other two interfaces.

#### CONCLUSION

Text only UI output significantly improved radiologist performance compared with no AI in the detection of lung nodules and masses on chest radiographs, but user preference did not correspond with user performance.

#### CLINICAL RELEVANCE/APPLICATION

Understanding the impacts of how different user interfaces may alter reader performance is a crucial aspect of AI implementation in radiology.

### Physics-based Data Augmentation to Improve Chest X-ray Abnormality Classification

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Heejun Shin, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Many AI methods to detect chest X-ray (CXR) abnormalities have demonstrated promising results by adopting image pre-processing techniques (e.g., histogram equalization (HE), contrast limited adaptive histogram equalization (CLAHE), and unsharp masking (UM)). However, those methods showed limited diagnostic performance when applied to CXRs with different image characteristics from various X-ray scanners. Here, we propose an X-ray physics-based data augmentation (i.e., XPA) that perturbs CXRs during AI training to overcome this problem.

#### METHODS AND MATERIALS

Unlike conventional image pre-processing methods (e.g., HE, CLAHE, and UM) that normalize CXRs before AI training and testing, XPA randomly perturbs image characteristics on training CXRs by applying a series of image processing methods (e.g., gamma correction for contrast perturbation) to mimic hardware-related changes (e.g., voltage, current, etc.) during AI training. Seven datasets from different X-ray machines (digital radiography (DR) or computed radiography (CR)) and institutions were collected. One dataset was from a Vietnam hospital and annotated by a radiologist as normal or abnormal (e.g., opacity, etc.) for AI (7,202 CXRs for training; 1,278 CXRs for testing (VHDR1)). Four datasets were from Indonesian hospitals, including a dataset acquired from a portable X-ray machine (IHCR1,Portable:204; IHCR2 :227; IHCR3:356; IHDR2:1,909 CXRs) and annotated for AI testing. Two datasets (i.e., Shenzhen (SZDR3) and Montgomery (MGCR4)) were from public domains as testing data. We trained four AI models (EfficientNet-B6) using HE, CLAHE, UM, and proposed XPA to classify CXRs as normal or abnormal and compared their diagnostic performance. To check the capability of each method to cover CXRs from different machines, only the CXRs acquired using the DR system in the Vietnam hospital were utilized for training.

#### RESULTS

For VHDR1 (internal test dataset), the diagnostic performance of all AI models was not statistically significant (i.e.,  $p$ -value $>0.05$ ). However, in most of the test datasets, the AI model with XPA outperformed the others, including the datasets acquired from the different CR detectors (IHCR2, IHCR3, and MGCR4), portable X-ray machine (IHCR1,Portable; AUC: 0.950 for XPA; 0.924 for HE; 0.920 for CLAHE; 0.891 for UM;  $p$ -value $<0.05$ ), and DR detectors (IHDR2 and SZDR3).

#### CONCLUSION

The diagnostic performance of the AI model was improved with XPA for the CXR datasets from different X-ray machines (i.e., DR, CR, and portable machines) compared to those of the other AI models with conventional image pre-processing methods.

#### CLINICAL RELEVANCE/APPLICATION

The proposed AI showed potential clinical usage when the CXRs were acquired using various X-ray scanners.

### Investigating the Feasibility of Using AI to Detect Unreported Chronic Disease Findings on Chest X-Ray in a Retrospective Aged Patient Dataset

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Jonathan S. Luchs, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study evaluates the feasibility of using an artificial intelligence (AI) model to retrospectively identify 27 chronic disease findings in an aged patient chest X-ray (CXR) dataset. The aim of this study was to investigate the ability of the AI model to identify findings not previously reported in the radiologists' report. This aims to validate the usefulness of AI as a quality improvement device to improve the characterization of patient cardiovascular disease risk.

#### METHODS AND MATERIALS

The study dataset consisted of 1,261 CXRs from patients  $\geq 65$  years, collected from outpatient clinics. CXR images were retrospectively processed by the AI for the presence of predefined chronic disease findings. As a comparison, the radiologist report was manually reviewed for the presence/absence of these findings, with findings considered absent if they were not mentioned in the report. In cases where there was a discrepancy between the model and report, a radiologist adjudicator evaluated the CXR scan to determine ground truth (GT), i.e. if the finding was overcalled or under called by the AI model/radiologist.

#### RESULTS

Reported prevalence of findings varied between the AI model and report. The AI model reported 505, 731, 650 and 783 instances of cardiomegaly, unfolded aorta (UA), aortic arch calcification (AAC) and spine arthritis (SA), compared to 194, 12, 622 and 562 in the report, respectively. There were 133, 48 and 29 instances of lower, upper, and diffuse interstitial thickening reported by the AI model, compared to 554, 553 and 557 in the report, respectively. Across all findings, Cohen's Kappa agreement was 0.17, indicating slight agreement. Comparison with the GT showed that cardiomegaly, UA, AAC and SA were underreported in the report compared to the AI model (report sensitivity (sens): 0.32, 0.02, 0.54, 0.44, vs. AI model sens: 0.83, 0.86, 0.75, 0.75, respectively). This resulted in 68%, 98%, 46%, and 56% of these findings being missed by the report, while 17%, 14%, 25%, and 25% were missed by the AI model. Conversely, diffuse, lower and upper interstitial thickening were over reported compared to the AI model, as shown by reduced specificity of the report (report; 0.58, 0.58, 0.58 vs. AI; 0.99, 0.92, 0.96, respectively).

#### CONCLUSION

AI models in medical imaging have typically focused on radiological finding detection to provide diagnostic assistance to radiologists. Here we present evidence that a quality improvement AI device can enhance patient care and management through the detection of under and over reporting of chronic disease findings.

#### CLINICAL RELEVANCE/APPLICATION

Chronic diseases are often incidentally detected on CXR but not reported due to their low-risk nature. However, these findings can be significant predictors of patient health risk.

### **Multiclass Labelling of Foreign Hardware on Chest Radiographs using a Convolutional Neural Network**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Leon Chalil, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To assess the accuracy of transfer learning with a pre-trained convolutional neural network (CNN) in detecting multiple classes of medical devices and other foreign bodies on chest radiographs.

#### **METHODS AND MATERIALS**

A total of 2000 de-identified, publicly available chest radiographs were binary labelled for the presence of 18 different types of foreign bodies by two radiology fellows. The images were split into training and validation data sets (80:20 ratio). A pre-trained ResNet50 convolutional neural network model based on weights obtained from ImageNet was loaded from the TensorFlow environment. The top layer was removed and replaced with a single densely connected layer. The ResNet50 pretrained model expects a 224 x 224 x 3 channel input. The x-ray images were down sampled to 224 x 224 using simple averaging.

#### **RESULTS**

After several epochs the neural network could correctly classify the presence or absence of different medical devices or foreign objects with an accuracy of 78-99% on the validation data set, and 10/17 classes were detected with >90% accuracy. This model did show high average specificity (98% [93-100%]) but variable sensitivity (57% [11-100%]) across classes, likely attributable to the small size of the dataset and high similarity in form and position of several devices.

#### **CONCLUSION**

Transfer learning using a pre-trained neural network permits high accuracy classification of foreign bodies and medical devices on chest radiographs without the need for hyperparameter tuning. Larger datasets and improved annotation will be required to further improve the performance of future models.

#### **CLINICAL RELEVANCE/APPLICATION**

These findings represents an important step towards more accurate and rapid confirmation of device presence in comparatively undifferentiated CXRs.

### Radiomics Analysis for Predicting Progression of Part-Solid Nodules on CT

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Shiny Weng, BA, BA (*Presenter*) Nothing to Disclose

#### PURPOSE

Radiomics, with its diverse set of features, has the potential to reveal novel avenues for identifying malignant nodules and detecting subtle patterns not visible to the naked eye. In clinical practice, identifying progressive nodules is crucial for detecting malignancies. Hence, this study aims to explore the statistical significance of radiomic and clinical features in predicting overall growth in part-solid nodules (PSNs).

#### METHODS AND MATERIALS

In this retrospective study, institutional chest CT scans between 2015 and 2019 were collected. Corresponding radiology reports were used to extract ground truth labels for nodules' growth status (i.e., increase vs. unchanged), as well as other related information such as nodule size, location, slice, component sizes, and compared studies. An automated NLP pipeline was used for the extraction, and manual review was used to ensure the dataset's accuracy. Additionally, associated CT scans were run through a commercial nodule characterization algorithm. The parameters generated from this algorithm, such as nodule size and location, were then compared and matched with the extracted features from the original radiology reports.

#### RESULTS

The final dataset consists of 1276 PSNs, and ground truth labels are available for 1009 PSNs (830 unchanged, 166 growing, 13 decreasing). From this dataset and using radiomic (from pyRadiomics) and clinical features (e.g., patient age, gender), we developed various ML models for predicting growth in PSNs, of which Random Forests achieved the highest AUC of 0.78 on the validation set. Moreover, in the statistical analyses of the association of radiomic and clinical features with nodule progression, 88 radiomic features were statistically significant ( $p < 0.05$ ) based on a Mann-Whitney U Test. Such radiomic features include Surface Volume Ratio, Zone Variance, and Small Dependence High Gray Level Emphasis, all of which had high feature importance for identifying progressive nodules in the Random Forests model. Among clinical features, Patient Age exhibited high feature importance. 75 features were used for the Random Forests model, which were selected using random forest importance, recursive feature elimination, and univariate selection.

#### CONCLUSION

We developed a model to identify nodule progression from a predictive set of radiomic and clinical features, achieving an AUC of 0.78 on the validation set. Additionally, we have assembled a labeled dataset of 1009 PSNs, which includes various attributes such as nodule size, type, and location.

#### CLINICAL RELEVANCE/APPLICATION

By employing radiomics, statistical analysis, and machine learning, we may produce accurate early characterization of growing adenocarcinoma spectrum nodules and optimize management and outcomes.

### Artificial Intelligence System for Identification of Overlooked Lung Metastasis in Abdominal CTs of Patients with Malignancy

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Hye Soo Cho (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate whether an artificial intelligence (AI) system can identify metastatic nodules in basal lungs covered by abdominal CTs initially overlooked by radiologists.

#### METHODS AND MATERIALS

We retrospectively abdominal CT images with the following inclusion criteria: a) CTs obtained from patients with any solid organ malignancy between March 1st and 31st, 2019 in a single institution; b) abdominal CT interpreted as negative for metastasis in covered basal lungs. Patients who underwent chest CT on the same day with abdominal CT, and patients lost to follow-up within 3 years without clinical diagnosis of lung metastasis. The reference standards for the diagnosis of lung metastasis were confirmed by the review of medical records and subsequent CT images. An AI system that can automatically detect lung nodules in CT images was retrospectively applied. The AI results were reviewed by a radiologist to confirm the lesion is a true lung nodule with the possibility of metastasis. The detection yield (the proportion of true-positive results among entire patients), sensitivity, and positive predictive value (PPV) of the AI system and the radiologist who reviewed AI results were evaluated, for the identification of patients with basal lung metastasis overlooked during the initial interpretation.

#### RESULTS

A total of 878 patients (66% men; mean age 65 years) were included. The most common primary malignancy was hepatocellular carcinoma (411, 47%), followed by stomach (169, 19%) and colorectal cancer (11%). Lung metastases were diagnosed in 69 patients (7.8%) within 3 years from the abdominal CT. Among them, 12 patients (1.4%) had overlooked metastasis in the basal lungs covered by the abdominal CT. The AI system identified 319 lesions in 176 patients (positive rate, 20%). Among the 319 AI results, 261 (81.8%) were true lung nodules by the radiologists' review, and 25 (7.8%) were metastatic nodules overlooked during the initial interpretation. The detection yield, sensitivity, and PPV of the AI system to identify patients with overlooked basal lung metastasis were 1.4% (12/878), 100% (12/12), and 6.8% (12/176), respectively. Meanwhile, the radiologist's review of AI results resulted in the detection yield, sensitivity, and PPV of 1.4% (12/878), 100% (12/12), and 14% (12/86), respectively.

#### CONCLUSION

In patients with solid organ malignancies, an AI system exhibited excellent sensitivity for the identification of metastases in basal lungs covered by abdominal CTs that radiologists initially overlooked.

#### CLINICAL RELEVANCE/APPLICATION

An AI system may help radiologists not overlook small lung basal lung metastasis in abdominal CTs by providing feedback to the radiologists in case of suspicions, which could be an efficient method to reduce interpretation errors.

### **Surveillance Breeds Conformity! Multicenter, Post-market Surveillance of a Multi-finding AI Algorithm for the Interpretation of Chest Radiographs**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Giridhar Dasegowda, MBBS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Post-market surveillance of AI algorithms can help assess real world performance and impact of AI algorithms. We performed a multicenter, post-market surveillance (PMS) of a multi-finding AI algorithm for the interpretation of chest radiographs (CXR).

#### **METHODS AND MATERIALS**

Our retrospective, multicenter study included 2066 consecutive CXRs obtained from 7 practices across 7 geographically diverse states in India. CXRs belonged to 1167 men and 899 women with a mean age of  $46 \pm 17$  years. All centers had Qure.AI CXR algorithm implemented in routine clinical interpretation of CXRs. For a fraction of CXRs, AI outputs were either unavailable due to technical difficulties or not used due to low confidence interval for the findings. All consecutive CXRs from the centers were de-identified and uploaded on the annotation platform. An experienced thoracic radiologist blinded to the AI output evaluated the CXRs to establish the ground truth. We compared the performance of AI-aided and unaided clinical interpretation of CXRs. Sensitivity, specificity, ROC AUC with 95% confidence interval were used to evaluate the performance.

#### **RESULTS**

The AI output had a better standalone performance compared to radiology reports (AUC of 0.72 - 0.90, sensitivity 44%-83% and specificity 81%-100%). The overall reporting performance for cardiomegaly, nodule, opacities, blunted costophrenic angle, cavity and to differentiate normal from abnormal CXRs compared to the ground truth had an AUC of 0.62 - 0.75, 28%-88% sensitivities and 56%-100% specificities. The performance of radiologists improved significantly with AI-aided reporting over those CXRs reported without AI outputs at the time of reporting with an effective increase in 6%-19% in AUC ( $p < 0.01$ ).

#### **CONCLUSION**

Our PMS study demonstrates an overall improvement in the radiologists' performance with AI-aided interpretation of CXRs.

#### **CLINICAL RELEVANCE/APPLICATION**

In the real-world application, the assessed AI algorithm improves the interpretation of for CXRs.

### The Path to Successful AI Adoption in Radiology: Investigating Hurdles in The Computer-Assisted Diagnosis Implementation within Hospital Settings

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

James H. Scrivner JR, MBA, ARRT (*Presenter*) Nothing to Disclose

#### PURPOSE

To demonstrate that AI implementation in hospital radiological practice requires careful business assessment and planning: from the end-user experiences to training and workflow adjustments.

#### METHODS AND MATERIALS

Radiologists who agreed to participate in quantitative and qualitative surveys were prospectively recruited from December 2022 to April 2023. To identify the challenges in AI adoption, this study measured the CAD technology acceptance and diffusion using an extended diffusion framework, namely the Extended Technology Acceptance Model (ETAM) based on 1) Unified Theory of Acceptance and Use of Technology (UTAUT) and 2) Diffusion of Technology (DOI). This integrated model evaluated the interaction of CAD and radiologists by incorporating the latent structures of trust, accuracy, efficiency, adoption, and diffusion from a behavioral, psychological, and social perspective. Following the ACR Data Science Institute Artificial Intelligence survey (2020), this study also collected information on AI usage, demographics, and AI performance evaluation.

#### RESULTS

A total of 10 radiologists participated in qualitative interviews and 68 radiologists participated in quantitative surveys (~5% response rate). The overall perception of clinical AI usage is higher than national usage (39% versus 26%). The findings highlighted several challenges facing the adoption of AI in radiology. While most participants expressed trust in AI innovation, they demonstrated major hurdles in AI adoption, including interpretation time and time management issues. The major concerns are in the poor integration and usability caused by the lack of radiologists' involvement in user testing. As a result, many participants used AI only as a second reader or triage tool.

#### CONCLUSION

While the potential benefits of AI in healthcare are widely acknowledged, it is important to recognize that the adoption of AI technology is not guaranteed simply by implementing AI tools. Successful AI adoption requires careful consideration of factors such as user training, workflow integration, and the development of appropriate governance and validation frameworks.

#### CLINICAL RELEVANCE/APPLICATION

As the use of AI solutions for improving diagnostic accuracy gains significant attention, the need for an operational framework that would involve radiologists as end-users becomes increasingly apparent. Such a framework would guide the deployment, interoperability, and validation of AI in clinical practice, ultimately contributing to the development of safe and effective AI-based diagnostic tools. This study documents operational issues and proposes initial guidelines for clinical implementations.

### Identifying and Communicating Urgent Findings in Emergency Radiology: A Scoping Review

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Lucas Corallo, BSc (*Presenter*) Nothing to Disclose

#### PURPOSE

To determine existing published standards for the identification and communication of critical actionable imaging findings in emergency radiology. To identify the associated facilitators and barriers to the communication and management of critical imaging findings.

#### METHODS AND MATERIALS

A scoping review of published literature was performed through 2 databases (PubMed, Embase) with search terms pertaining to critical findings in emergency radiology. Articles and guidelines published in all languages from January 2010 to September 2022 were considered. Screening of database hits using pre-established inclusion criteria was performed by 3 analysts with reconciliation of discordance by consensus. A gray literature search for societal guidelines and high-impact policies was added to the database search. Data extraction included the following: year, country, resource type, scope/purpose, participants, context, standards to identifying/communicating critical findings, facilitators/barriers, method type, recommendations, applicability, and disclosures.

#### RESULTS

60 records were included in the final analysis, including 12 societal/commission guidelines. Among the included guidelines, no standardized lists of critical findings were identified, however, recommendations to create a local policy for critical findings were made in 5/12 guidelines. Reference to critical findings policies from the Joint Commission (16/60 articles), and ACR (30/60 articles) were most frequent. Standards used by centres for critical findings often applied a formal list of findings or classifications based on acuity. Among standards based on acuity (n=12), a 3-tier classification system was most common. Standards for communication included direct closed-loop communication for high acuity findings, with more flexible communication channels for less acute findings. Interventions for critical findings management most frequently fell into 4 categories: electronic (n=7), hybrid electronic/admin (n=5), feedback/education (n=5), and administrative (n=2).

#### CONCLUSION

There are variable standards, policies, and interventions for the management of critical findings in emergency radiology. ACR and Joint Commission standards were most frequently applied. Interventions applied EMR-based strategies, call-centres, and traditional phone/fax. Further research should seek to evaluate consistency and efficiency of closed-loop communication protocols, provider satisfaction, and patient outcomes.

#### CLINICAL RELEVANCE/APPLICATION

Summarizes the policies around critical results reporting in emergency radiology. Provides a guide for consensus building, innovation and rapid adoption towards greater patient safety, and provider satisfaction.

Printed on: 08/22/24

### **Sensitivity of MRI to Detect Microscopic Fat in Adrenal Adenomas: Comparison of 2D Dual Gradient-echo and 3D DIXON Techniques**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Abdullah Khan, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To compare the sensitivity of 2D dual gradient-echo and 3D DIXON chemical shift MRI (CSI) for detecting microscopic fat in adrenal adenomas.

#### **METHODS AND MATERIALS**

We performed a retrospective study of 35 patients (15 male, 20 female, mean age 61.8 years) with adrenal nodules who underwent both 2D dual gradient-echo and 3D DIXON T1-weighted CSI on a 1.5T scanner. The signal intensity (SI) of the nodules was obtained using a single ROI in the center of the nodule (comprising at least 2/3rds the nodule diameter) and the signal intensity index (SII) was calculated [ $100 \times (\text{SI in phase} - \text{SI out of phase}) / \text{SI in phase}$ ]. Reference standard for the diagnosis of 29 adenomas was made by no change in nodule size or growth  $< 3\text{mm/year}$  in long axis for at least 1 year on follow up imaging ( $n=19$ ), unenhanced CT attenuation of  $< 10$  HU ( $n=8$ ), or pathology ( $n=2$ ). The mean time to imaging follow up was 4.5 years (range 1.1-10.5 years). The diagnosis of metastasis was made by pathology ( $n=1$ ) and nodule growth  $> 3\text{mm/year}$  in a patient with known cancer ( $n=1$ ). There was one pheochromocytoma diagnosed by pathology. Three nodules had no adequate reference standard. Sensitivity for the diagnosis of adrenal adenoma was determined using a SII of  $> 16.5\%$ .

#### **RESULTS**

There were 35 nodules (mean size 22 mm, range 11-55 mm). The SII was higher on 2D CSI compared to 3D DIXON in 80% (28/35) of nodules by a mean of 14.4%. Of the 29 adenomas, the SII was higher on 2D CSI compared to 3D DIXON in 90% (26/29) of nodules. Among adenomas, the mean SII was 48% on 2D CSI and 33% on 3D DIXON ( $p=.02$ ). Sensitivity for the diagnosis of adenoma was 89.7% (26/29; 95% CI 72.7-97.8%) for 2D and 75.9% (22/29; 95% CI 56.5-89.7%) for 3D DIXON. None of the 3 non-adenomas had SII  $> 16.5\%$  on either technique.

#### **CONCLUSION**

2D dual gradient-echo CSI has a higher sensitivity for detection of microscopic fat in adrenal nodules and the diagnosis of adrenal adenoma than the 3D DIXON technique. The sensitivity of 2D dual gradient-echo CSI for adrenal adenoma is approximately 90%.

#### **CLINICAL RELEVANCE/APPLICATION**

Adrenal MRI protocols should include 2D dual gradient-echo CSI and not rely solely on 3D DIXON techniques for the diagnosis of adrenal adenomas.

### Deep Learning Reconstruction Improves Image Quality of Acquired and Computed Diffusion-weighted MR Imaging of the Liver

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Hiromitsu Onishi, MD, PhD (*Presenter*) Research Grant, General Electric Company; Speakers Bureau, General Electric Company

#### PURPOSE

Image noise is the main problem in diffusion-weighted (DW) MR imaging. Deep learning reconstruction (DLR) can improve the image quality of MR imaging. The aim of this study was to determine whether DLR can improve the image quality of acquired and computed DW images of the liver.

#### METHODS AND MATERIALS

This retrospective study included 44 consecutive patients with suspected focal liver lesions who underwent liver MR examinations with a 3.0-T system. DW images of the whole liver were acquired at b-values of 0 and 1000 s/mm<sup>2</sup> during breath-hold (TR/TE = 4500/76 msec, 5 mm thickness, and 96×96 matrix). Computed high b-value DW images (b = 1500 s/mm<sup>2</sup>) were synthesized from the acquired DW images. One radiologist measured the signal-to-noise ratio (SNR) of the liver parenchyma and the contrast-to-noise ratio (CNR) between malignant tumors and parenchyma on acquired and computed DW images with and without DLR. Another radiologist assessed image quality using a five-point visual scoring system (1 [unacceptable] to 5 [excellent]). Results were compared using paired t-test for quantitative assessment and Wilcoxon signed rank test for visual assessment of image quality.

#### RESULTS

Both acquired and computed DW images with DLR had significantly higher SNRs and CNRs than DW images without DLR; mean SNR was 13.6 versus 9.4 for acquired images ( $P < .001$ ) and 8.1 versus 5.9 for computed images ( $P < .001$ ), and mean CNR was 56.6 versus 37.2 ( $P < .001$ ) and 33.7 versus 23.6 ( $P < .001$ ), respectively. Qualitative analyses showed that DLR significantly improved image noise and image sharpness ( $P < .001$  for each), but did not change motion artifacts and signal loss just below the heart. DW imaging with DLR also demonstrated superior overall image quality compared to DW imaging without DLR; median score was 4 versus 2 for acquired images ( $P < .001$ ), 3 versus 2 for computed images ( $P < .001$ ).

#### CONCLUSION

DLR efficiently reduced image noise and significantly improved the image quality of both acquired and computed DW MR images of the liver.

#### CLINICAL RELEVANCE/APPLICATION

Deep learning reconstruction improves the image quality of liver diffusion-weighted images with a short acquisition time and can greatly contribute to the efficiency of liver MR examinations.

### **Radiologic Response and Association with Prognosis in Patients Treated with Transarterial Radioembolization or Stereotactic Body Radiation Therapy for HCC**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Sangyun Lee, MS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Transarterial radioembolization (TARE) and stereotactic body radiation therapy (SBRT) are locoregional therapies for potentially resectable and unresectable HCC. A limited number of studies have evaluated radiologic treatment response and association with prognosis in radiation-based therapy-treated HCC. We evaluated the radiologic appearance of post-TARE and SBRT-treated images of HCCs to assess treatment response and identify its association with prognosis.

#### **METHODS AND MATERIALS**

We retrospectively identified 104 patients (77 males; mean age  $\pm$  SD, 65.9  $\pm$  12.6 years) treated with SBRT (68 patients, 83.4%) and TARE (36 patients, 34.6%) from 2015 to 2022. Pre- and post-treatment contrast-enhanced CT or MRI scans performed 3 months after treatment were evaluated for treatment response according to the following rules: no intralesional APHE as nonviable; stability or decrease in size and/or degree of intralesional APHE as non-progressing; new or increased size of intralesional APHE as viable disease. Pre- and post-treatment AFP levels, tumor and APHE component size, portal vein tumor thrombus, etiology of liver disease, overall survival (OS) and progression-free survival (PFS) were recorded. Cox proportional hazards model and Kaplan-Meier curves with log-rank test were used for statistical analysis.

#### **RESULTS**

The mean size of HCC was 4.9 cm, and 25 patients (24%) had portal vein tumor thrombus. The mean AFP level was 2314.3 ng/mL. Median follow-up was 20.6 months (range, 3-142), with 29 (27.9%) deaths and 69 (66.3%) disease progressions. Sixty-three (60.6%) patients achieved non-viable disease at least once during follow-up. At the first 3-month follow-up, 40 (38.5%), 43 (41.3%), and 21 (20.2%) patients had nonviable, non-progressing, and viable disease, respectively. In univariate analysis, radiologic response at 3 months and nonviable disease ever during follow-up were significantly associated with OS, but only radiologic response at 3 months was the independent factor in multivariate analysis ( $p = 0.009$ ). For PFS, viable disease at the first 3-month follow-up, nonviable disease ever during follow-up, tumor size, male sex, and initial AFP level were the independent predictors in multivariate analysis ( $p = 0.034$ ). The type of radiotherapy did not affect OS or PFS. The 2-year cumulative OS for non-viable, non-progressing, and viable disease was 96.6%, 72.6%, and 67.9%, respectively.

#### **CONCLUSION**

Response to radiotherapy at 3 months and during follow-up assessed by changes in radiologic APHE significantly correlated with OS and PFS.

#### **CLINICAL RELEVANCE/APPLICATION**

Persistent APHE 3 months after radiotherapy for HCC may indicate a poor prognosis.

### Comparing Early Treatment Response as Assessed by RECIST 1.1, mRECIST, and Choi Criteria in HCC Treated with Atezolizumab plus Bevacizumab

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Seung Hoon Choi, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Atezolizumab plus bevacizumab (Ate/Beva) is endorsed as first-line systemic therapy for unresectable HCC ineligible for transplantation or locoregional therapy. Given the anti-angiogenic effect of the regimen, RECIST version 1.1 may underestimate the treatment response, potentially leading to unnecessary early discontinuation of the therapy. We aimed to compare RECIST 1.1, modified RECIST (mRECIST), and Choi criteria in assessing early treatment response in Ate/Beva-treated HCCs and their correlations with overall survival (OS) and progression-free survival (PFS).

#### METHODS AND MATERIALS

From May 2022 to December 2022, 42 patients (36 men; mean  $\pm$  SD age, 61.9  $\pm$  12.9 years) who received Ate/Beva for unresectable HCC without prior systemic therapy were retrospectively included. Pre-treatment and the first post-treatment contrast-enhanced CT or MRI scans, performed after completion of at least three cycles of Ate/Beva, were reviewed by two abdominal radiologists to assess treatment response according to RECIST 1.1, mRECIST, and Choi criteria. OS and PFS were recorded. Kaplan-Meier curves with log-rank test and Cohen's kappa were used for the statistical analysis.

#### RESULTS

The median time from the start of Ate/Beva to the first response assessment was 99 days (range, 51-182 days). Responders (patients with a complete or partial response) were 10 (23.8%), 13 (31.0%), and 18 (42.9%) when evaluated by RECIST 1.1, mRECIST, and Choi criteria, respectively. One (2.4%) and two (4.8%) patients classified as having progressive disease (PD) by RECIST 1.1 were re-assessed as stable disease and partial response by mRECIST and Choi criteria, respectively. The inter-reader agreement  $\kappa$  for RECIST 1.1, mRECIST, and Choi criteria was 0.85, 0.75, and 0.85, respectively. Responders identified by RECIST 1.1 did not show a significant correlation with OS ( $p = 0.082$ ), while those identified by mRECIST and Choi were correlated with prolonged OS ( $p$ s = 0.049). Responders identified by all three criteria showed a significant correlation with PFS ( $p$ s = 0.029). Cumulative 1-year PFS rates for responders were 72%, 76.4%, and 78.4% for RECIST 1.1, mRECIST, and Choi, respectively, and 74.4%, 72.4%, and 66.7% for non-responders.

#### CONCLUSION

In Ate/Beva-treated HCC, only a small number of PDs identified by RECIST 1.1 were re-classified as non-PD by mRECIST and Choi, indicating similar performance in the assessment of treatment failure. mRECIST and Choi criteria identified more early responders to treatment than RECIST 1.1 and significantly correlated with prolonged OS and PFS.

#### CLINICAL RELEVANCE/APPLICATION

mRECIST and Choi criteria may be more accurate than RECIST 1.1 in identifying early responders to Ate/Beva and may better assess prognosis.

### Value of Liver Volumetry for the Evaluation of Treatment Response to Hepatic Artery Infusion Chemotherapy Compared with RECIST 1.1 Criteria in Uveal Melanoma Patients with Liver Metastases

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Sebastian Zensen, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

In uveal melanoma patients with liver metastases, short-term evaluation of treatment response to hepatic artery infusion chemotherapy (HAIC) using the Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 criteria is often challenging due to the diffuse metastatic spread to the liver. Because of the diffuse organ involvement, liver enlargement can frequently be observed and easily assessed by liver volumetry. Therefore, this study aims to compare RECIST 1.1 and LV for the evaluation of HAIC treatment response.

#### METHODS AND MATERIALS

Treatment response was evaluated in 143 patients by RECIST 1.1 and liver volumetry on CT imaging performed before and after first HAIC. The mean age was  $65.1 \pm 10.9$  years, 54% were female. To establish an appropriate threshold to differentiate between stable disease (SD) and progressive disease (PD) in liver volumetry, various increases in liver volume were assessed. Overall survival (OS) was calculated from first HAIC to patient death using Kaplan-Meier test. Multivariate analysis was performed for RECIST 1.1 and liver volumetry.

#### RESULTS

The median OS (mOS) was 13.5 months (95% CI 11.2-15.8 months). In liver volumetry, a threshold of 10% increase in liver volume was suited to identify patients with significantly reduced OS (SD: 103/143 patients, mOS 15.9 months; PD: 40/143 patients, 6.6 months;  $p < 0.001$ ). Compared to RECIST 1.1, liver volumetry is the only significant prognostic factor that can identify a decreased OS.

#### CONCLUSION

In uveal melanoma patients with liver metastases, a threshold of 10% increase in liver volume is suitable to identify patients with a significantly shortened life expectancy by liver volumetry.

#### CLINICAL RELEVANCE/APPLICATION

Liver volumetry is an appropriate method for evaluating treatment response in uveal melanoma patients with liver metastases and offers advantages over RECIST 1.1 criteria.

### **DW-MRI of the Abdomen for the Preoperative Detection of Liver Metastasis from Pancreatic Cancer to Prevent Futile Surgeries: A Meta-analysis**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Stephan Altmayer, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Recent studies have shown the superior diagnostic performance of diffusion-weighted magnetic resonance imaging (DW-MRI) for detecting liver metastasis. Despite the advantage of DW-MRI, the most recent 2022 National Comprehensive Cancer Network guidelines do not routinely recommend performing MRI on all patients who may have resectable disease. Our purpose was to perform a systematic review and meta-analysis to evaluate if diffusion-weighted magnetic resonance imaging (DW-MRI) adds value compared to contrast-enhanced computed tomography (CECT) alone in the preoperative evaluation of pancreatic cancer.

#### **METHODS AND MATERIALS**

MEDLINE, EMBASE, and Cochrane databases were searched for relevant published studies through October 2022. Studies met eligibility criteria if they evaluated the per-patient diagnostic performance of DW-MRI in preoperative patients with pancreatic cancer compared to CECT. Our primary outcome was to determine the proportion of futile surgeries potentially prevented using DW-MRI, defined as those in which CECT was negative and DW-MRI was positive for liver metastasis. The secondary outcome was to determine the proportion of cases in which DW-MRI changes management, a composite outcome that includes false positive liver metastasis on CECT, indeterminate lesions on CECT, and the primary outcome. Per-patient sensitivity and specificity of DW-MRI were also calculated using a random-effects model.

#### **RESULTS**

9 studies met the inclusion criteria with a total of 1121 patients, 172 of which had liver metastasis (15.3%). The average size of the hepatic lesions was smaller than 10 mm in all 6 studies that reported this data. The mean time between CT and MRI was reported for 7 out of 9 studies and was often fewer than 28 days. The proportion of futile surgeries potentially reduced by DW-MRI was 6.0% (95% CI, 3.0-11.6%), yielding a number necessary to treat of 16.6. The proportion of cases that DW-MRI changed management was 18.1% (95% CI, 9.9- 30.7), corresponding to an NNT of 5.5. The heterogeneity was high for both primary (of I<sup>2</sup> = 86%) and secondary (I<sup>2</sup> = 94%) outcomes. The per-patient sensitivity and specificity of DW-MRI was 92.4% (95% CI, 87.4-95.6%) and 97.3% (95% CI, 96.0- 98.1) with no heterogeneity.

#### **CONCLUSION**

The potential NNT of DW-MRI to prevent potential futile surgeries in patients with pancreatic cancer and occult liver metastasis on CECT was 16.6.

#### **CLINICAL RELEVANCE/APPLICATION**

A significant number of subcentimeter liver metastases are not identified in the preoperative staging of pancreatic cancer with CECT. DW-MRI may add value in the evaluation of this patients with a potential NNT to prevent one futile pancreatic resection of CECT of 16.

### Quantitative PSMA PET and Multiparametric MRI features may help Predict Aggressive Prostate Cancer on Whole-Mount Histopathology

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Ida Sonni, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Two aggressive histopathological subtypes of prostate cancer (PC) include intraductal carcinoma (IDC) and the large cribriform growth pattern. The goal of this analysis was to assess which quantitative features of preoperative 68Ga-PSMA-11 PET/CT (PSMA PET) and multiparametric magnetic resonance imaging (mpMRI) correlate and predict cribriform/IDC patterns on post robotic prostatectomy (RALP) whole mount histopathology (WMHP).

#### METHODS AND MATERIALS

With IRB approval and HIPAA compliance, we derived a study cohort of PC patients who underwent PSMA PET <3 months prior to RALP and WMHP with description of the presence/absence of cribriform/IDC pattern between 05/2019 and 08/2022. A nuclear medicine physician contoured all PC lesions on PSMA PET, after matching them with a GU pathologist on WMHP. PSMA PET metrics (SUVmax, SUVmean, tumor volume, total lesion activity - TLA) were extracted. A sub-analysis was conducted on patients with available quantitative measures on pre-surgical mpMRI. All PIRADS=3 lesions on mpMRI were contoured and quantitative parameters were extracted: mean apparent diffusion coefficient (ADC,  $\times 10^{-6} \text{mm}^2/\text{s}$ ),  $K_{\text{trans}}$  (min-1),  $K_{\text{ep}}$ (min-1), iAUC (mMsec). All matching lesions were categorized as sub-cohort 1 (SC 1) cribriform+/IDC-, (SC 2) cribriform+/IDC+, and (SC 3) cribriform-/IDC-. One way-ANOVA assessed significant differences among the imaging parameters in the three sub-cohorts. The area under the curve (AUC) from ROC analysis was used to assess the ability of imaging metrics to predict the presence of aggressive PC features on WMHP.

#### RESULTS

The PSMA PET analysis comprised 77 patients (82 lesions) with mean PSA at time of RALP of 9.07 ng/ml  $\pm$  5.8. On WMHP, SC 1, 2 and 3 comprised 21/83, 41/83, and 20/83 lesions with significant differences in SUVmean and TLA among these sub-cohorts ( $p=0.003$  and  $0.039$ ). On AUC analysis, SUVmean predicted the aggressive PC features on WMHP with 67% accuracy. The PSMA PET/mpMRI cohort comprised 52 patients (53 lesions) with mean PSA at time of RALP of 9.67 ng/ml  $\pm$  6.76. On WMHP, SC 1, 2 and 3 comprised 17/53, 25/53, and 10/53 lesions with significant differences in SUVmean on PSMA PET and ADC on mpMRI among the three sub-cohorts ( $p=0.031$  and  $0.018$ ). On AUC analysis, SUVmean and ADC predicted aggressive PC on WMHP with 65% and 63% accuracy, respectively

#### CONCLUSION

Significantly elevated SUVmean on PSMA PET and lower ADC on mpMRI predicted the presence of aggressive PC features (cribriform pattern and IDC) on WMHP with moderate AUC on ROC analysis.

#### CLINICAL RELEVANCE/APPLICATION

The ability to predict the presence of pathology features of aggressive PC is critical in case WMHP is not available. Presurgical PSMA PET and mpMRI quantitative parameters can help identify these features with moderate accuracy.

### Diagnostic Value of Very Early Diffusion Weighted Changes at MRI after Single-Dose Ablative Radiation Therapy (SDART) for Organ-confined Prostate Cancer

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Cammillo R. Talei Franzesi (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate diagnostic value of diffusion-weighted (DWI) MRI early changes, 1 hour after treatment, in patients with organ confined unfavorable prostate cancer (PCa) treated with Single-Dose Ablative Radiation Therapy (SDART), in comparison with biochemical markers (PSA and testosterone).

#### METHODS AND MATERIALS

Twenty four patients treated with a single fraction of 24 Gy to the whole prostate with urethra sparing in association with androgen deprivation therapy (ADT) were prospectively enrolled. MRI was performed before SDART (time 0), one-hour post-SDART (time 1), and 3-month after treatment (time 2). All patients were examined on a 3.0-T MRI scanner (Ingenia; Philips Healthcare) with a phased-array external coil, with bowel preparations and 20mg of butyl-scopolamine (Buscopan) intravenously administered; the bladder was filled with 120cc of saline solution, to simulate the same conditions during irradiation. MRI was performed with axial T1-weighted TSE sequences and high resolution multi-planar T2-weighted TSE sequences. Diffusion weighted imaging (DWI) was acquired with six b-values (0,50,100,150,800,1600mm<sup>2</sup>/s) and Apparent Diffusion Coefficient (ADC) (0,800) maps were calculated. Finally, axial contrast-enhanced dynamic imaging was obtained during intravenous injection of gadobutrol (0.1 mmol/kg, flow rate of 2.5 ml/s). ADC values were calculated at time 0,1, and 2 by placing region-of-interests (ROI) on ADC maps and the results were compared with PSA and testosterone blood levels at time 0 and 2.

#### RESULTS

Median patient's age was 78 years (range 61-84). Median prostate volume was 36.2 cc (range 10-60). An increase of ADC value of tumor lesion of 27% (range 7%-69%) and 54% (range 20%-83%) was registered at time 1 and time 2 respectively, compared to the baseline. Median prostate volume was found unchanged at time 1, while decreased by about 25% (range 9%-59%) at time 2. At 3-months follow-up, all patients were found bNED with PSA and testosterone levels of <0.01 ng/ml and <0.20 ng/ml, respectively, and 9 of them obtained a complete response.

#### CONCLUSION

Our findings demonstrated high diagnostic value of DWI imaging with good correlation between very early changes (one-hour after treatment) in ADC values after SDART and later tumor response (biochemical and imaging) in patients with unfavorable PCa.

#### CLINICAL RELEVANCE/APPLICATION

DWI with ADC values could be used as an early biomarker of treatment outcome in patients treated with SDART of the whole prostate with urethra sparing.

### Operating Characteristics of ATA 2015 Thyroid Nodule Risk Malignancy in Colombian Population

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Nicole Erazo Morera, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Determine the operating characteristics of the ATA 2015 ultrasound risk classification of thyroid nodules in Colombian population, to see if it can be standardized and applied as it is in American population.

#### METHODS AND MATERIALS

We conducted a retrospective quantitative diagnosing test study, where the operating characteristics for the ATA 2015 risk stratification scale was determined. The study was carried out between Sept 2020- Sept 2021. Population: Patients with thyroid nodules with thyroid US in the imaging department of the HUSI (a fourth level institution in Bogotá, Colombia) with an indication for biopsy or surgical removal of the nodule according to ATA 2015. Data collection was carried out by two radiologists from the Radiology Department of the HUSI, one of them with 6 yrs of experience and one of them in training with 3 yrs of experience. Patients with very low and low suspicion nodules according to the 2015 ATA classification were defined as negative whereas intermediate and high suspicion of malignancy were defined as positive. These results were compared with a mixed gold standard, where true negatives are Bethesda II or surgical specimen with benign pathological report, and true positives are Bethesda V/VI or surgical piece positive for malignancy.

#### RESULTS

For a "high" risk in the ATA classification, the Likelihood Ratio values for both cases yield results close to 4, being slightly higher when risk III of the BETHESDA classification is excluded. For the "intermediate" classification, the two combinations have a Likelihood Ratio close to 1, indicating an indeterminate result for those that cannot be classified as malignant and benign. For the "low" and "very low" classification, the LR is below 1, when risk III of the BETHESDA classification is excluded and taken into account.

#### CONCLUSION

The present study demonstrates that the ATA 2015 sonographic risk stratification scale can be used and implemented in the Colombian population in a similar way to the American population. It is especially applicable if the thyroid nodule evaluated by ultrasonography presents characteristics of "low" or "high" risk of malignancy with a confidence of 95% for an established risk of 5-10% or 70-90% respectively. The category with the lowest sensitivity and specificity is the "intermediate" which is not statistically significant in any of the analyses.

#### CLINICAL RELEVANCE/APPLICATION

Validation, of an already used risk stratification scale, in the Colombian population, understanding in which cases there must be a careful appliance (specifically intermediate risk nodule) in this population base.

### Utility of Radiomics Features in Predicting Human Papillomavirus Status in Head and Neck Squamous Cell Carcinoma: A Systemic Review and Meta-analysis

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Golnoosh Ansari, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Human papilloma virus (HPV) is one of the main risk factors and a potential prognostic indicator for head and neck squamous cell carcinoma (HNSCC). We sought to analyze the value of radiomics features in the determination of HPV status in HNSCC as an alternative to immunohistochemical typing.

#### METHODS AND MATERIALS

A systemic search was conducted on PubMed, Scopus and other major web-based repositories using the search terms HPV, Radiomics, HNSCC, head and neck, papilloma and oropharyngeal SCC. Diagnostic accuracy measures, and the confusion matrix of each study were extracted and the data were utilized to perform meta-analysis based on the random effects model. Fagan's nomogram was used to determine clinical utility. Deek's funnel plot was used to determine publication bias.

#### RESULTS

Twenty six articles were included in the systemic review and 14 were used for the meta-analysis. The median radiomics quality score was 9 out of 36, showing an overall poor quality in the currently available literature. There was no significant publication bias among the publications included in the meta-analysis. The overall sensitivity of the included studies equaled 0.772 (0.73, 0.809) and the overall specificity equaled 0.763 (0.714, 0.806). The I<sup>2</sup> statistic showed that heterogeneities for sensitivity and specificity were medium (I<sup>2</sup> = 56.91%, and 55.44%, respectively). Only one percent of the heterogeneity witnessed was due to threshold effect.. Diagnostic odds ratio equaled (DOR) 10.932 (7.847, 15.23). Using a radiomics model generated on cross-sectional imaging would increase the post-test probability to 82% from 58% with a positive likelihood ratio of 3 when the pretest was positive. When the pretest was negative the post-test probability decreased to 29% with a negative likelihood ratio of 0.3.

#### CONCLUSION

Radiomics features showed moderate success in the determination of HPV status in HNSCCC and could be employed when conventional para-clinical laboratory methods are not available. More studies, especially those trained and tested on multiple independent datasets, are needed to determine the clinical utility of radiomics trained machine learning models in this regard.

#### CLINICAL RELEVANCE/APPLICATION

As currently there are no FDA-approved diagnostic modalities for the determination of HPV status in HNSCC, radiomics features may be able to act as a means of "virtual biopsy" and alleviate the need for IHC staining.

### The Value of Texture Features based on Dynamic Contrast-enhanced Magnetic Resonance Imaging in Predicting the Efficacy of Radiotherapy and Chemotherapy in Nasopharyngeal Carcinoma

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Nan Wang (*Presenter*) Nothing to Disclose

#### PURPOSE

the purpose of this study was to explore the value of texture features based on DCE-MRI in predicting the efficacy of radiotherapy and chemotherapy in primary NPC.

#### METHODS AND MATERIALS

1. SubjectsForty-nine patients with NPC who underwent nasopharyngeal/cervical DCE-MRI examination and confirmed by pathology were analyzed retrospectively. According to the follow-up of MR and/or pathology after 6 months of treatment, the efficacy of radiotherapy and chemotherapy of NPC was divided into two groups: poor prognosis group (residue or recurrence) (n=22) and good prognosis group (no residue and recurrence) (n=27).2.Image analysis A 3.0T MR (Signa HDxt, GE Medical Systems, Milwaukee, WI, USA) scanner was used with an 8-channel phased array coil in the head and neck.The permeability parameters of the DCE-MRI images: Ktrans, Kep, and Ve functional maps were imported into 3D Slicer software. Two imaging diagnostic physicians manually sketched the ROI. (Fig. 1, 2). Record the texture feature parameters of each functional map respectively.

#### RESULTS

1.DCE- measured by two observers. The texture feature parameters of the MRI function map are consistent (ICC values are all>0.75) (Table 1)2. the MinimumKtrans signal intensity and JointAverageKep of the good prognosis group were higher than those of the poor prognosis group, while the values of AutocorrelationKtrans, JointAverageKtrans, SumAverageKtrans, AutocorrelationKep, and SumAverageKep were lower than those of the poor prognosis group, and the difference was statistically significant (Table 2). However, there is no difference in the texture parameters of the Ve signal intensity map.3. ROC analysis of Ktrans and Kep signal intensity map texture parameters to identify NPC efficacy (Table 3). The area under the curve predicted by the threshold of Autocorrelation, JointAverage, and SumAverage of Kep signal strength was the largest, which was 0.684, the sensitivity was 81.48%, and the specificity was 59.09% (figure 3).

#### CONCLUSION

The texture feature based on DCE-MRI has potential value in predicting the efficacy of radiotherapy and chemotherapy in nasopharyngeal carcinoma before treatment.

#### CLINICAL RELEVANCE/APPLICATION

nasopharyngeal carcinoma is a tumor with significant geographical distribution and is a common malignant tumor of the head and neck in southern China. Radiotherapy and chemotherapy are considered the first choice of treatment, but there are still patients with poor prognoses (residue or recurrence) due to treatment failure. Early prediction of the efficacy of radiotherapy and chemotherapy can optimize the treatment plan of NPC patients and improve the survival cycle, which has significant clinical significance.

### Multi-parameter Quantitative Magnetic Resonance in Early Assessment of Radiation Induced Parotid Damage in Nasopharyngeal Carcinoma Patients after Intensity Modulated Radiotherapy

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Zhifeng Xu (*Presenter*) Nothing to Disclose

#### PURPOSE

The aim of this study was to investigate the value of Intravoxel Incoherent Motion Imaging (IVIM) and 3D Pulsed Continuous Arterial Spin Labeling (ASL) in assessing dynamic changes of parotid gland (PG) in nasopharyngeal carcinoma (NPC) patients after radiotherapy (RT).

#### METHODS AND MATERIALS

A total of 18 patients with NPC underwent Intensity-Modulated Radiotherapy (IMRT) were enrolled. All patients underwent conventional MRI, and IVIM and ASL imaging for bilateral PGs within 2 weeks before RT (pre-RT), 1 week and 3 months after RT (post-RT). Pure diffusion coefficient (D), pseudo-diffusion coefficient (D\*), perfusion fraction (F) and blood flow (BF) were analyzed.

#### RESULTS

From pre-RT to 1W post-RT, D and CBF values both increased significantly [change rate, 39.28% (38.23%) and 60.84% (54.88%)], and continued to increase significantly from 1W post-RT to 3M post-RT [change rate, 55.44% (40.56%) and 120.39% (128.74%)]. From pre-RT to 1W post-RT, F value increased significantly [change rate, 28.13% (44.66%)], and then decreased significantly from 1W post-RT to 3M post-RT, whereas no significant differences was found between pre-RT to 3M post-RT. From pre-RT to 1w post-RT and 1M post-RT, D\* value decreased significantly [change rate, -41.86% (51.71%) and -29.11% (42.67%)]. No significant difference was found between different post-RT time intervals. There was a significant positive correlation between percentage change in  $\Delta$ CBF1W and radiation dose ( $R=0.548$ ,  $p=0.001$ ).

#### CONCLUSION

Both IVIM-DWI and ASL can help to detect/predict radiation-induced parotid damage in early stage after RT. They may contribute to clarify the correlations between damage of PGs and patient-/treatment-related variables by assessing individual microcapillary perfusion and tissue diffusivity.

#### CLINICAL RELEVANCE/APPLICATION

To reveal the mechanism of parotid radiation injury, realize early non-invasive diagnosis, and allow patients to obtain timely treatment to improve the quality of life of patients

Printed on: 08/22/24

### Prognostic Significance of MRI-Defined Sarcopenia in Patients with Nasopharyngeal Carcinoma: A Propensity Score Matched Analysis of Real-World Data

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Shuyi Liu (*Presenter*) Nothing to Disclose

#### PURPOSE

Image-defined sarcopenia is linked to increased mortality among patients with cancer. Nevertheless, its effect on patients with nasopharyngeal carcinoma (NPC) is incompletely established. This study's aim was to investigate the prognostic significance of MRI-defined sarcopenia at the level of the third cervical vertebra (C3) on the survival of patients undergoing concurrent chemoradiotherapy (CCRT) ± inducing chemotherapy (IC) for NPC treatment

#### METHODS AND MATERIALS

1,307 patients from two tertiary centers who had stage II-IVa NPC diagnosis between July 1, 2010, and September 30, 2019, were included in this retrospective study. Sarcopenia was defined using skeletal muscle index (SMI) determined through baseline MRI at the C3 level. The association of sarcopenia with overall survival (OS) and progression-free survival (PFS) was assessed by computing the Hazard ratios (HRs). Using 1:1 propensity score matching (PSM) analysis, Cox regression models were adjusted for age, body mass index (BMI), sex, and treatment. The PSM analysis revealed 331 pairs. We also conducted a stratification analysis using BMI and treatment strategies.

#### RESULTS

The patients' median (range) age was 48 (18-80) years, with 821 patients (62.8%) presenting with sarcopenia. Before and after PSM, sarcopenia was an independent risk factor for both OS and PFS (all  $P < 0.05$ ). However, BMI was not substantially linked to tumor progression and overall mortality (all  $P > 0.05$ ). Sarcopenic patients showed lower rates of OS (HR = 2.00, 95% CI: 1.54-2.60,  $P < 0.001$ ) and PFS (HR = 1.67, 95% CI: 1.35-2.07,  $P < 0.001$ ) in contrast with nonsarcopenic patients. Similar findings were obtained after PSM. According to stratification analysis, being overweight was linked to a protective effect in nonsarcopenic patients only. In addition, sarcopenic patients showed similar OS and PFS regardless of the treatment modality.

#### CONCLUSION

Sarcopenia is underrecognized in NPC patients. Measurement of sarcopenia using routine MRI scans in NPC patients provided significant prognostic information, outperforming BMI. Patients with sarcopenia failed to benefit from an additional IC regimen.

#### CLINICAL RELEVANCE/APPLICATION

Sarcopenia could be used as a marker for predicting NPC patients' prognoses before treatment utilizing MRI images.

### Automated Quantification of Uncertainty for Emphysema Evaluation from CT Images using Hybrid Bayesian Deep Learning

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Antonio Porras Perez, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Emphysema quantification from computed tomography (CT) images is important to evaluate chronic obstructive pulmonary disease (COPD). Although volume-adjusted lung density (ALD) can be used for prognosis, it has shown sensitivity to variations between scanners and there are no metrics of its reliability. We present a hybrid Bayesian deep learning model to predict lung density from CT images that can quantify both the aleatoric and the epistemic uncertainty, which are associated with the imaging protocol and the prediction, respectively. These measures of reliability can be used during clinical evaluation.

#### METHODS AND MATERIALS

Inspiratory lung CTs from 1,936 COPDGene participants (age  $59.36 \pm 9.00$  years; 1,038 female) were used. The data were randomly split into training (80%), validation (10%) and test images (10%). We trained a model to predict lung density at the 15th percentile of the CT histogram (Perc15) and quantify ALD. Our model consisted of convolutional blocks that quantify CT image features followed by fully connected layers. The final layer was Bayesian and weights were trained as probabilistic distributions instead of point estimates. ALD was calculated as the product of predicted Perc15 and the ratio of observed versus expected lung volume. Aleatoric and epistemic uncertainty were estimated over 50 stochastic forward passes in the test set. Deep learning ALD (DL-ALD) was compared to conventional ALD, and Cox proportional hazards models were used to determine the association between uncertainty and mortality.

#### RESULTS

The average root mean squared error for DL-ALD was 4.70 (95% CI: 4.68, 4.73). The mean aleatoric uncertainty was 23.77 (95% CI: 13.04, 34.51). The mean epistemic uncertainty was 1.22 (95% CI: 0.73, 1.71). DL-ALD was significantly associated with mortality ( $p < 0.001$ ) when adjusting for age, body mass index, smoking status, gender, and race. Adjusting for DL-ALD and demographics, epistemic uncertainty had a significant positive association with mortality ( $p = 0.013$ ) but aleatoric uncertainty did not ( $p = 0.134$ ).

#### CONCLUSION

DL-ALD performs as well as conventional ALD in predicting survival but it provides measures of uncertainty. This represents a substantial improvement over conventional methods that cannot estimate uncertainty. Aleatoric uncertainty associated with imaging protocol was higher than uncertainty from the model. Additionally, higher model uncertainty was associated with increased mortality risk, suggesting a need for reliability metrics to improve survival prediction through ALD.

#### CLINICAL RELEVANCE/APPLICATION

Uncertainty estimation when evaluating emphysema through hybrid Bayesian deep learning improves reliability of lung density measures over conventional image intensity-based analysis.

### Deep Learning Model for Acute Respiratory Distress Syndrome (ARDS) Detection in the Pediatric Intensive Care Unit (PICU) Setting

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Vahid Khalkhali, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Acute respiratory distress syndrome (ARDS) is a significant cause of morbidity and mortality in the pediatric intensive care unit (PICU). ARDS diagnosis involves chest x-ray criteria combined with clinical and laboratory parameters. Machine learning models have demonstrated utility in the detection of ARDS on chest radiographs.

#### METHODS AND MATERIALS

In this retrospective, IRB-approved study, we identified 368 children admitted to the PICU with a diagnosis of ARDS, at a large pediatric academic center from 2014 to 2019. A single randomly selected radiograph from all patients admitted to the PICU without a diagnosis of ARDS during 2018 was used to establish the control cohort, (n=1127). The train:validation:test ratio was 60/20/20. Using transfer learning, we utilized a pretrained convolutional neural network (CNN) structure to determine the diagnosis of ARDS (PyTorch, version 1.2). The criterion was to minimize weighted cross-entropy loss. Area under the receiver operating characteristics (AUROC) was the main performance metric. Two pediatric radiologists independently assigned labels of ARDS to the training-set, and interrater reliability was calculated. Correlations between radiologists and the models were calculated using Pearson correlation and Cohen's Kappa. All statistical analysis used Type-I error of 5% and power of 80%.

#### RESULTS

The interrater reliability between the radiologists was 94.5% (Cohen's Kappa of 85.8%) for the training cohort. The ARDS diagnostic performance of two radiologists yielded an AUROC (balanced accuracy) of 72.5%, while the DenseNet161 model achieved 86.0% (AUROC of 92.5%) and ensemble of models reach to 83.7% (AUROC of 93.5%). Radiologist diagnoses were only 81% correlated (Cohen's Kappa 51.6%) with the DenseNet161 model and 83% (Cohen's Kappa 60.5%) with ensemble of models. While Pearson correlation between two radiologists were high (> 90%) on the test set, the difference between the detection of different models were statistically significant ( $p < 0.01$ ).

#### CONCLUSION

Using transfer learning, we trained a CNN to reliably detect ARDS in the PICU and compared its performance with the diagnostic rates of two experienced radiologists. Machine learning can automatically detect ARDS on chest radiographs, with a performance which parallels those of radiologists.

#### CLINICAL RELEVANCE/APPLICATION

Deep learning detection of ARDS could improve the triage of patients in the intensive care unit before the availability of dedicated pediatric radiologist reads.

### Predicting the Occurrence of Immune Checkpoint Inhibitor-related Pneumonitis on Non-small Cell Lung Cancer Patients via Deep Learning

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Janardhana Ponnatapura, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Immune-checkpoint inhibition (ICI) has conveyed a paradigm shift in advanced lung cancer treatment in recent years. However, ICI therapy related pneumonitis, which is an immune related adverse event (irAE), can limit delivery of treatment to some patients. With overall incidence of nearly 6%, it is considered one of the more common irAEs resulting in a significant burden of morbidity and mortality in the lung cancer population. Predicting ICI-pneumonitis is crucial for identifying at-risk patients and adjusting their treatment to prevent the occurrence of ICI-pneumonitis. We in this study try to predict ICI-pneumonitis based on patients' imaging and clinical data.

#### METHODS AND MATERIALS

We collected data from 1,254 lung cancer patients who received immunotherapy between 2015 and 2021. In the dataset, 53 patients developed ICI-pneumonitis and were included in this study. Another 41 patients who received immunotherapy without developing ICI-pneumonitis were randomly selected and used as a control group. We proposed a deep learning framework to predict ICI-pneumonitis based on deep learning features and radiomics features. A vision transformer was first pre-trained on over 25,000 CT scans from the NLST dataset and then used to extract deep learning features. Radiomics features were extracted using the Python pyradiomics package after lung segmentation. After feature selection, 17 deep features and 20 radiomic features were used for prediction. A network with three fully connected layers was trained for ICI-pneumonitis prediction using five-fold cross-validation.

#### RESULTS

Using only deep learning features, we achieved an AUC of 0.934 (95%CI: [0.883, 0.986]). Similarly, with only radiomics features, the prediction AUC was 0.928 (95%CI: [0.873, 0.982]). When combining deep features with radiomics features, the prediction accuracy further improved to an AUC of 0.958 (95%CI: [0.917, 0.999]).

#### CONCLUSION

Our proposed method can predict the occurrence of ICI-pneumonitis with high accuracy, indicating the potential for using deep learning to predict ICI-pneumonitis in advanced lung cancer patients receiving immunotherapy. This approach could be valuable for treatment planning in the future.

#### CLINICAL RELEVANCE/APPLICATION

Prediction of ICI pneumonitis will have an important positive impact as early detection and timely recognition are critical to initiate prompt treatment and prevent further morbidity and mortality for these oncology patients.

### **SAMConvex: Fast Discrete Optimization for Deformable CT Registration using Multi-scale Self-supervised Anatomical Embedding and Correlation Volume**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Zi Li (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Deformable image registration is a fundamental medical image analysis task. Estimating displacement vector field via a cost volume computed in the feature space suffers excessive computation burdens. Moreover, existing feature descriptors only extract local features incapable of representing the global semantic information that is important for handling large transformations. To address these issues, we propose SAMConvex, a fast coarse-to-fine discrete optimization method for CT image registration. It includes a decoupled convex optimization procedure to obtain deformation fields based on a self-supervised anatomical embedding (SAM) feature extractor that captures both local and global information.

#### **METHODS AND MATERIALS**

Our proposed model, named SAMConvex, consists of two major components: (1) A discriminative feature extractor based on a SAM that encodes global and local embeddings for each voxel. The global embeddings memorize the 3D contextual information of body parts on a coarse resolution level, while the local embeddings differentiate adjacent structures with similar appearances. (2) A lightweight correlation pyramid that constructs multi-scale 6D cost volume by taking the inner product of SAM embeddings. With coarse-to-fine strategy, we estimate a sequence of deformation fields. The final field is computed via the composition of all the deformation fields. We conduct the registration in 3 levels of resolutions. The registration performance is extensively evaluated in two inter-patient registration datasets, i.e., Abdomen CT (20 patients for train and 10 for test), and HeadNeck CT (62/10 patients for train/test) and intra-patient Lung CT (35 patients, each with inspiratory and expiratory breath-hold CT pairs). The average Dice score computed for the labeled organs is used to evaluate the accuracy.

#### **RESULTS**

SAMConvex outperforms state-of-the-art registration methods, such as LapIRN, and Deeds, over all three datasets with an average 2.4% Dice score improvement as compared to the second-best performing method (Deeds). E.g., SAMConvex is consistently better than the second-best (Deeds) and third-best (LapIRN) registration methods on most examined abdominal organs, in 11 out of 13 organs. Moreover, as an optimization-based method, SAMConvex only takes  $\sim 2s$  for one paired scans, as compared to  $\sim 100s$  required by Deeds.

#### **CONCLUSION**

The proposed deep registration model (SAMConvex) demonstrates state-of-the-art accuracy, good generalization, and high computation efficiency over previous leading models.

#### **CLINICAL RELEVANCE/APPLICATION**

The proposed algorithm can accurately register the CT scans. The method can be applied in various downstream tasks such as longitudinal lesion quantification and image-guided radiotherapy.

W5A-SPIN-5

### Effective Opportunistic Screening for Colorectal Cancer using Abdominal or Chest Noncontrast CTs

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Mingyan Qiu, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

We designed an AI model for detecting colorectal cancer (CRC) using noncontrast chest or abdominal CT scans, which offers the advantage of opportunistic screening a broad asymptomatic population.

#### METHODS AND MATERIALS

The training data consisted of 1,561 3D noncontrast abdominal CTs from a single hospital, including 566 cases with pathology-confirmed CRC and 995 cases without CRC. The initial CRC masks in the training set were manually annotated on the venous phase CT by an experienced radiologist (10-yr), referring to reports as needed. We then employed a robust image registration method to register the annotated mask from venous to noncontrast CT for model training. Our AI model is a UNet for segmentation of CRC and colorectum, which is further enhanced by a classification branch and is trained end-to-end to classify the patient as CRC or normal. To improve the differentiation of CRC tumor from colorectal content and normal tissues, we designed a content augmentation method and a contrastive loss. The model performance was evaluated on an internal hold-out test cohort comprising 147 patients with CRC and 153 normal cases, and external test cohorts comprising 181 abdominal CTs with CRC, one chest CT with CRC, and 2,477 normal chest CTs from three centers. One radiologist specialized in CRC imaging (20-yr) is invited for the reader study on the hold-out test cohort.

#### RESULTS

On the internal test cohort, the model had an area under the curve of 0.978, sensitivity of 91.2%, and specificity of 97.4%; while the radiologist's sensitivity was 79.6% and specificity was 97.4%. Moreover, the model outperformed the radiologist in detecting early-stage CRC (T1 33.3% vs. 16.7%, T2 75.0% vs. 50.0%). On the external test cohorts, the model's sensitivity was 80.7% and 100% for abdominal CTs and chest CT, respectively; and the specificity was 99.6% for normal chest CT. Additionally, a preliminary comparison shows that our approach has comparable performance and may even outperform the established CRC screening tests in both sensitivity and specificity, such as CT colonography (Sens 90%, Spec 86%) and FIT (Sens 74%, Spec 95%).

#### CONCLUSION

The proposed model could detect colorectal cancer tumors on chest and abdominal noncontrast CT scans with a high sensitivity and specificity, exceeding the sensitivity of an experienced radiologist specialized in CRC imaging.

#### CLINICAL RELEVANCE/APPLICATION

Our study aims to investigate a novel, non-invasive, opportunistic screening solution for colorectal cancer using noncontrast CT and AI. The multi-center experimental results show that our solution achieves both high sensitivity and specificity, indicating that opportunistic population-based CRC screening in asymptomatic adults could potentially be performed in abdominal and chest CT.

### Deep Learning Analysis of Chest Radiographs to Predict Coronary Artery Calcium and Triage Patients Deferrable from CT

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Yisak Kim (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop a deep learning (DL) model to predict the coronary artery calcium (CAC) using chest radiographs (CRs), validate its performance in patients from different institution and investigate the clinical utility of the model as a triage tool for deferring additional computational tomography (CT) scan.

#### METHODS AND MATERIALS

We retrospectively searched adult patients who had undergone both a calcium score CT and posteroanterior chest radiography within a 3-month period from three different institutions; a total of 4,858 radiographs (age  $60.6 \pm 12.2$ ; women 2,458) from institution A, 4,109 radiographs (age  $61.0 \pm 12.3$ ; women 1,823) from institution B, and 979 radiographs (age  $57.0 \pm 11.3$ ; women 334) from institution C. Patients from institution A and B were used as a developmental cohort, and institution C as an external test cohort. The total Agaston scores calculated from CT were divided into 5 grades: 0, 1-100, 11-100, 100-400, and over 400, and considered ground truth labels. Images were cropped to fit the lung and heart area and normalized using energy bands and a region of interest obtained by heart segmentation. total of six different image sets were generated; original, lung area and heart area for non-normalized and energy bands normalized. Separate DL models based on DenseNet-161 were individually trained for each of six image sets and the final performance was calculated using ensemble theses six models. Conditional Ordinal Regression for Neural Networks (CORN) method was used for 5 ordinal CAC grade classification.

#### RESULTS

Binary classification between under and over 100 CAC scores attained AUCs of 0.81, 0.79, 0.83, 0.77 on validation dataset, internal test A, internal test B and external test respectively. All test datasets showed more than 99% sensitivity at a threshold of sensitivity rate 99% attained from validation, and showed specificity of 27%, 28%, 18% and 26% for validation dataset, internal test A, internal test B and external test respectively. Using a threshold of sensitivity rate 99% attained from validation dataset, the DL model correctly identified 23.7% (66 of 278) and 14% (101 of 722) of patients in the internal test set A and B as CAC score under 100 so that additional CT scan may be deferred. Among them, true individuals showing CAC score under 100 (NPV) were 100% (66 of 66) and 98% (99 of 101) in the internal test set A and B respectively. On the external test set, DL model was able to defer 21.5% of all patients (212 of 977), and the NPV was 99.1% (210 of 212).

#### CONCLUSION

DL model could predict the CAC from CRs and could be used for helping clinical decision-makings such as taking additional CT.

#### CLINICAL RELEVANCE/APPLICATION

The proposed model may assist in deferring additional CT scans using CRs by triaging patients with a under 100 CAC score.

### Uncovering Hidden Lesions - Incidental Ring Hyperenhancing Liver Micronodules in Computed Tomography during Hepatic Arteriography Guidance in Percutaneous Thermal Ablation of Colorectal Liver Metastasis

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Jessica A. Marques Silva, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To describe and evaluate the nature of incidental ring hyperenhancing liver micronodules (RHLMs) detected on computed tomography during hepatic arteriography (CTHA) in patients with colorectal liver metastases (CLM) undergoing percutaneous ablation.

#### METHODS AND MATERIALS

Twenty-two CLM patients who underwent 24 CTHA-guided percutaneous thermal ablation sessions (AS) for 41 CLMs were included. CTHA images were obtained before and after ablation for tumor targeting and ablation margins assessment. Two radiologists independently reviewed pre-ablation images, and the interobserver agreement was assessed using Cohen's kappa. Incidental RHLMs were defined as small nodules with continuous ring enhancement visible in late arterial phase on three planes, with an average Hounsfield Unit at least twice that of adjacent liver parenchyma, not detected on baseline imaging. The nature of incidental RHLMs was determined by histological confirmation and/or follow-up image assessment. A biomechanical deformable image registration (DIR) method was used to map incidental RHLMs and newly detected CLMs on follow-up CT imaging. RHLMs were considered as CLMs if their segmentations overlapped.

#### RESULTS

The median time from baseline contrast-enhanced cross-sectional and/or functional imaging to AS was 29.4 days ( $\pm$  19.1 days). 25 incidental RHLMs with a mean largest diameter of 0.8 cm (range 0.3-1.7) were identified in 41.7% (10 of 24) of the AS. The agreement between two observers on identifying incidental RHLMs was almost perfect ( $\kappa = 0.907$ ). 4 incidental RHLMs were ablated during the AS given their similarity to targeted CLMs. Of the remaining 21 incidental RHLMs, 71.4% (15 of 21) disclosed to be CLMs, with 20% (3 of 15) confirmed by histology and 80% (12 of 15) by follow-up imaging using a DIR method at a mean time of 52 days ( $\pm$  27.8 days) post-ablation. The nature of the last 28.6% (6 of 21) incidental RHLMs was unknown, but no intrahepatic progression was observed on follow-up after chemotherapy.

#### CONCLUSION

Incidental RHLMs can be an early indicator of small CLMs, as confirmed by histology and DIR-based imaging analysis. Further investigation is needed to evaluate their relevance, as CLM resection is the only potentially curative treatment for liver-limited disease.

#### CLINICAL RELEVANCE/APPLICATION

The presence of incidental ring hyperenhancing liver micronodules on computed tomography during hepatic arteriography can indicate early-stage colorectal liver metastasis, which could impact the treatment approach.

### Added Value of Kupffer-phase Imaging of Sonazoid-enhanced Ultrasound in Liver Ablation

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Dae Woong Kim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the usefulness of Kupffer-phase imaging (KPI) in Sonazoid-enhanced ultrasound (SZUS) for local ablation of liver tumors and to identify factors related to tumor conspicuity on the KPI of SZUS.

#### METHODS AND MATERIALS

A total of 73 patients with 112 liver tumors (95 HCCs and 17 non-HCCs), who underwent gadoxetic acid-enhanced MRI (Gd-EOB-MRI), B-mode planning US (BPUS), and SZUS-assisted radiofrequency ablation (RFA) from January 2020 to February 2023, were included. RFA was performed by an experienced radiologist using SZUS/MR image fusion, 30 to 50 minutes after intravenous injection of Sonazoid. The characteristics of both patients and liver tumors were evaluated. Tumor conspicuity was assessed sequentially using a 4-point scoring scale on hepatobiliary phase (HBP) of Gd-EOB-MRI, BPUS, and KPI of SZUS at 1-week intervals by the consensus of two experienced abdominal radiologists. The tumor echogenicity on BPUS were classified into hypoechoic and non-hypoechoic groups. Conspicuity scores of 1 and 2 were classified as the poor conspicuity group, while scores of 3 and 4 were classified as the good conspicuity group. We also investigated factors related to tumor conspicuity on the KPI of SZUS, as well as the technical success rate of RFA.

#### RESULTS

The mean size of tumors was  $13.1 \pm 5.9$  mm. There was no significant difference in size or location between HCCs and non-HCCs. The tumor conspicuity score on KPI of SZUS ( $2.88 \pm 0.85$ ) was higher than that of BPUS ( $1.85 \pm 0.74$ ). The correlation between tumor conspicuity on KPI of SZUS and HBP of Gd-EOB-MRI was higher than that of BPUS and KPI of SZUS (HCCs [ $rs=0.38$ ,  $p<0.001$ ], non-HCCs [ $rs=0.76$ ,  $p<0.001$ ], and total [ $rs=0.44$ ,  $p<0.001$ ] versus HCCs [ $rs=0.33$ ,  $p<0.001$ ], non-HCCs [ $rs=0.31$ ,  $p=0.224$ ], and total [ $rs=0.34$ ,  $p<0.001$ ]). The factors related to tumor conspicuity on KPI of SZUS were hypoechoic on BPUS and good conspicuity on HBP of Gd-EOB-MRI ( $p=0.034$  and  $p=0.01$ , respectively). The technical success rate of RFA using KPI was 97.3%.

#### CONCLUSION

KPI of SZUS could be a valuable tool for successful liver ablation in cases where the tumor is not clearly visible on BPUS but is well-defined on the HBP of Gd-EOB-MRI.

#### CLINICAL RELEVANCE/APPLICATION

When liver tumors are not clearly visible on ultrasound, performing liver ablation can be challenging. Although SZUS has the potential to improve tumor conspicuity, it is not widely used in liver ablation due to various limitations including its high cost, unpredictable effect on improving tumor visibility, short duration of the vascular phase, and long waiting time for KPI. However, using KPI of SZUS for liver ablation can significantly reduce procedure time and improve the technical success rate, especially when liver tumors are clearly visible on HBP of Gd-EOB-MRI.

### Post Embolization Syndrome Following Histotripsy: An Indicator of Immune Activation

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Nathan E. Loudon, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Post-embolization syndrome (PES) is a reported phenomenon that can occur following transarterial chemoembolization (TACE) or radioembolization (TARE). It is thought to occur as a result of immune and inflammatory response to cell death during tumor necrosis. The most commonly described symptoms are pain, fever, and leukocytosis. The purpose of this study was to determine whether these symptoms would be seen following histotripsy at higher or lower frequency compared to TACE or TARE.

#### METHODS AND MATERIALS

This was a single center IRB approved retrospective cohort study which compared post-embolization syndrome symptoms of fever, right upper quadrant abdominal pain, and leukocytosis among patients who underwent ablation of liver tumors using histotripsy (n=10), TARE (n=32), or TACE (n=34). Our analysis considered size of largest lesion, tumor type, LR category, and BCLC staging.

#### RESULTS

When adjusted for the size of the lesion and tumor type (HCC vs non-HCC), the odds of experiencing fever were 7.17 times higher in patients who underwent histotripsy compared to TACE (95% CI = 1.16 - 52.33, p=.039), and 50 times higher compared to TARE (95% CI = 5.74 - 1589.36, p=.003). The odds of experiencing abdominal pain were 14.70 times higher in the histotripsy group compared to TACE (95% CI = 2.09 - 302.12, p=.02) and 50 times higher compared to TARE (95% CI = 7.02 - 1307.34, p=.001). The histotripsy group had a smaller change in WBC from pre to post treatment compared to TACE (2.49, 95% CI = 0.34 - 4.64, p=0.024), and no statistically significant difference in WBC change compared to TARE.

#### CONCLUSION

As histotripsy becomes a more widely available treatment offered to patients it is important to understand the range of expected clinical symptoms which can occur following ablation. This study suggests that patients who undergo histotripsy are more likely to experience fever and abdominal pain following ablation compared to TACE and TARE.

#### CLINICAL RELEVANCE/APPLICATION

Histotripsy is a novel ablation modality and as such its expected post-treatment symptoms are still being elucidated. Pre-clinical data have shown that histotripsy is highly immunogenic on both a local and systemic level. PES is thought to be a result of inflammatory and immune response to tumor ablation. Studying the incidence of PES in this population could provide valuable insights into the clinical manifestations of immune activity following ablation.

### Prediction of Initial Lung Microwave Ablation Zone Through Tumor and Ablation Characteristics

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Daniel H. Kim, BA, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the effect of tumor and ablation characteristics on dimensions and size of lung microwave ablation zone and establish a prediction model.

#### METHODS AND MATERIALS

This IRB-approved, HIPAA compliant study cohort involved patients who underwent CT-guided lung microwave ablation for their malignancy between 2012 to 2023. All patient demographics, treatment history, tumor characteristics, ablation duration, and maximum temperature (Tmax) reached were recorded. The peripheral location was defined as the area within 2cm from the edge of the visceral pleura. Ablation images without specific intraprocedural labels indicating post-initial ablation or cases without complete ablation details were excluded. The initial ablation zone was represented by the elliptical ground-glass opacity surrounding the target site and its dimensions were measured. Dataset was divided into 70% training and 30% test set and univariate and multivariate linear regression models were used to build a prediction model for the major axis, minor axis, and area of the ablation zone.

#### RESULTS

This study cohort was composed of 89 lesions that underwent microwave ablations. Of these ablations, 25 were with history of prior lung radiation therapy (Hrad) (28%) and 7 with history of prior lung surgery (Hsurg) (8%), and 45 lesions were located at the peripheral region. The median duration of the initial ablation was 1.5 minutes ranging from 0.5 to 10 minutes, the power used was 65W for all ablations, and mean of Tmax was  $100 \pm 17^\circ\text{C}$ . The measured mean major, minor axes, and area were  $3.1 \pm 0.8\text{cm}$ ,  $1.8 \pm 0.5\text{cm}$ , and  $4.7 \pm 2.5\text{cm}^2$ . A parsimonious prediction model was built keeping only the predictors with  $p < 0.15$ . For the major axis, duration ( $p < 0.001$ ), Tmax ( $p = 0.002$ ), Hsurg ( $p < 0.001$ ), and Hrad ( $p = 0.102$ ) were predictors. For minor axis, duration ( $p < 0.001$ ), Tmax ( $p < 0.001$ ), Hsurg ( $p = 0.001$ ), and peripheral location ( $p = 0.099$ ) were predictors. For the area, duration ( $p < 0.001$ ), Tmax ( $p < 0.001$ ), and Hsurg ( $p < 0.001$ ) were predictors. The fitted model equation for major axis was:  $3.176 + 0.597 * \log(\text{duration}) - 0.003 * (\text{Tmax}) - 0.302 * (\text{Hrad}) + 1.146 * (\text{Hsurg})$  with test root mean square error (RMSE)=0.55,  $R^2=0.29$ . The equation for minor axis was:  $1.575 + 0.332 * \log(\text{duration}) + 0.001 * (\text{Tmax}) + 0.022 * (\text{Hsurg}) + 0.106 * (\text{peripheral})$  with test RMSE=0.53,  $R^2=0.33$ . The equation for area was:  $5.772 + 2.431 * \log(\text{duration}) - 0.021 * (\text{Tmax}) + 1.658 * (\text{Hsurg})$  with test RMSE=2.11,  $R^2=0.40$ .

#### CONCLUSION

Lung tumor and ablation characteristics are shown to be significant predictors of microwave ablation dimensions and size which can be used to establish a prediction model.

#### CLINICAL RELEVANCE/APPLICATION

Estimate of lung microwave ablation dimensions and size can aid in effective treatment of lung tumors.

### **Efficacy and Safety of Tract Cautery for Lung Microwave Ablation**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Daniel H. Kim, BA, MS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the efficacy and safety of tract cautery for lung microwave ablation through comparison of post-procedure complication rate.

#### **METHODS AND MATERIALS**

This IRB-approved, HIPAA compliant study involved patients who underwent lung microwave ablation for their malignancy between 2012 to 2021. All patient demographics, treatment history, tumor characteristics, ablation details were collected. The study cohort was divided into whether tract cautery was conducted during probe removal. Immediate, persistent, and enlarging pneumothorax (PTX) were each defined as the observation of PTX on CT or chest radiograph during the termination of procedure, detection of non-expanding PTX, and expanding PTX for 3-5 hours post-procedure. Other complications including pleural effusion, delayed complication (more than one week), and post-procedural interventions needed for management of complications were recorded. A subgroup analyses of patients with no history of radiation therapy were also included. Univariate and multivariate logistic regression models were used to compare differences in complication rates.

#### **RESULTS**

This study cohort was composed of 171 lung microwave ablation sessions of 62 patients (mean age  $59 \pm 12$ ). 58/171 were with history of radiation therapy of the lung (33.9%) and 33/171 were with history of lung surgery (19.3%). 80 ablations exhibited immediate PTX, 45 persistent PTX, 19 enlarging PTX, 26 pleural effusion, 8 delayed complications, and 14 required interventions. Tract cautery was conducted in 126/171 ablations. Patients who did not receive tract cautery had 10 times the odds of exhibiting delayed complications than patients who did receive tract cautery ( $p=0.003$ ). Ablations with tumor size less than 1cm and history of emphysema had 5.9 times ( $p=0.035$ ) and 5.7 times ( $p=0.032$ ) the odds of requiring interventions. Increasing the total ablation time by 1 minute was associated with a 24% reduction in odds of delayed complications. Furthermore, a subgroup of ablations composed of patients without history of lung radiation therapy included 81 ablations with and 32 without tract cautery. This subgroup showed ablations conducted without tract cautery had 3.0 times the odds of exhibiting enlarging PTX ( $p=0.026$ ) and 5.3 times the odds of requiring interventions ( $p=0.026$ ) compared to ablations conducted with tract cautery.

#### **CONCLUSION**

Utilizing tract cauterization in lung microwave ablation shows significant reduced incidence of post-ablation delayed complications and enlarging PTX and interventions in patient without history of lung radiation therapy.

#### **CLINICAL RELEVANCE/APPLICATION**

Tract cautery proves to be a useful method in reducing complications and interventions required for management of complications.

### Pre-ablation Biopsy and the Effect of Histopathologic Grade on Thermal Ablation Outcomes for Hepatocellular Carcinoma

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Abinaya Ramakrishnan (*Presenter*) Nothing to Disclose

#### PURPOSE

Thermal ablation has been increasingly used as a minimally invasive treatment for hepatocellular carcinoma (HCC), with clinical outcomes comparable to surgical resection. While prior studies have analyzed the influence of size, location, and morphology on ablation outcomes, few have examined the role of histopathologic grade. This is partly because standard of care in LI-RADS 5 HCCs does not require biopsy. In this study, we determined the relationship between histopathological grade of the tumor on the clinical outcome after thermal ablation using time to local tumor progression-free survival (LTPFS) and overall survival (OS).

#### METHODS AND MATERIALS

Between February 2015 to November 2022, 186 patients with nodular LI-RADS 5 HCCs that underwent ablation (MWA=165, RFA=21 with biopsies within prior 3 months) were included in this single-center, retrospective cohort study. All tumors were histologically classified using WHO criteria as Poor (n=25), Moderately (n=119), or Well (n=42) differentiated. Patients underwent continuous follow-up imaging to determine local tumor progression free survival (LTPFS). After retrospective review of medical records and follow-up MRI examinations, the rates of LTPFS and OS hazard ratios from Kaplan-Meier method were calculated and compared among the groups.

#### RESULTS

Pre-ablation histopathologic grade was identified as a significant predictor for post-thermal ablation outcomes. Poorly-differentiated HCCs had significantly shorter LTPFS compared to well-differentiated HCCs (hazard ratio [0.21, 0.07-0.6],  $p=0.008$ ). Poorly-differentiated HCCs also had shorter LTPFS compared to moderately-differentiated HCCs (hazard ratio [0.68, 0.33-1.39],  $p=0.28$ ), although this difference was not significant. In terms of OS, poorly-differentiated HCCs had significantly shorter OS compared to well-differentiated HCCs [0.20, 0.07-0.59,  $p=0.0035$ ],  $p=0.0082$ ) and moderately-differentiated HCCs [hazard ratio [0.61, 0.3-1.25],  $p=0.0035$ ).

#### CONCLUSION

Poorly-differentiated HCCs was an important prognostic biomarker correlating with shorter LTPFS as well as OS after thermal ablation of HCC. While not currently considered standard of care, HCC biopsy prior to ablation can help tailor more aggressive patient-specific treatment planning and surveillance protocol.

#### CLINICAL RELEVANCE/APPLICATION

Pre-ablation biopsies in HCC patients can play a critical role in the management of patients post-ablation. Poorly differentiated tumors may benefit from more aggressive treatment and surveillance given shorter LTPFS and OS.

### Radiomics Analysis based on Dual-energy CT Hydroxyapatite (HAP)-fat Decomposition Technique for Osteoporosis Prediction

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Jinling Wang (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop and validate a radiomics model based on the hydroxyapatite (HAP)-fat material decomposition (MD) images of dual-energy CT for osteoporosis prediction.

#### METHODS AND MATERIALS

83 patients who underwent dual-energy CT included L1-L5 and quantitative computed tomography (QCT) were collected. With QCT as the reference standard, the patients were divided into two groups according to the guidelines introduced by the International Society for Clinical Densitometry (ISCD) and American College of Radiology (ACR), osteoporosis of the spine was defined as a BMD value  $<80$  mg/cm<sup>3</sup>, and non-osteoporosis (osteopenia and normal) was defined as a BMD value  $\geq 80$  mg/cm<sup>3</sup>. Radiomic features were selected from HAP-fat MD images of dual-energy CT. A radiomics model was constructed from linear combinations of the selected features weighted by their coefficients. The ROC curve was performed to evaluate the performance of the radiomics model.

#### RESULTS

The radiomics model, which comprised 8 selected radiomics features (shape\_Maximum2DDiameterColumn, shape\_Maximum2DDiameterSlice, shape\_Sphericity, firstorder\_10Percentile, firstorder\_90Percentile, firstorder\_Skewness, gldm\_LargeDependenceHighGrayLevelEmphasis, gldm\_LargeDependenceLowGrayLevelEmphasis) based on HAP-fat MD images of dual-energy CT, showed excellent differential ability with AUC of 0.999 (95%CI, 0.987-1.000), sensitivity of 0.983, specificity of 1.000, negative prediction value of 0.960, positive prediction value of 1.000 in the cohort. The discrimination performance of the radiomics model to identify osteoporosis from non-osteoporosis (osteopenia and normal) showed high accuracy of 98.8% in the cohort.

#### CONCLUSION

The radiomics model comprised 8 selected radiomics features had excellent ability to predict osteoporosis based on dual-energy CT HAP-fat MD images.

#### CLINICAL RELEVANCE/APPLICATION

The prevalence of osteoporosis in the population is increasing year by year. One of the reference standards for the diagnosis of osteoporosis today is the volumetric BMD measured by QCT, but the QCT post-processing process is very complex and requires additional phantom calibration, etc. Our proposed radiomics model based on HAP-fat material decomposition images can serve as a useful tool for osteoporosis prediction and has the potential to be applied in clinical treatment planning in the future.

### Clinical Impact of the Results of Spine Biopsy in Patients with Suspected Discitis-Osteomyelitis

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Joey Mustafa (*Presenter*) Nothing to Disclose

#### PURPOSE

Vertebral osteomyelitis is a serious and potentially life-threatening condition that is challenging to diagnose and treat. Image-guided biopsy is often performed to identify the causative microorganism. Previous studies have primarily focused on the yield of the cultures from these biopsies, but the impact of these results on clinical management has not been thoroughly studied. The objective of this study is to evaluate the impact of image-guided biopsy on the clinical management of vertebral osteomyelitis.

#### METHODS AND MATERIALS

This retrospective study was conducted using patient data from a single academic institution in the USA, and included patients who underwent CT-guided biopsy for suspected vertebral osteomyelitis between January 2013 and April 2022. The study aimed to calculate the positivity rate of the biopsy sampling and assess how the biopsy results impacted the clinical management of patients with vertebral osteomyelitis. Specifically, the study examined whether clinicians changed the management of vertebral osteomyelitis through narrowing or broadening of antibiotic regimens based on the biopsy results.

#### RESULTS

The study included 92 patients who underwent CT-guided bone biopsy for suspected vertebral osteomyelitis. Cultures from biopsy sampling were positive in 35% of patients. In 18% of all cases, the antibiotic regimen was changed based on the biopsy results and the specific organism identified. In contrast, the biopsy results had no significant impact on the subsequent antibiotic protocol in 82% of cases ( $\chi^2=40.96$ ;  $P<0.0001$ ), either because the cultures were negative, the organism could have been predicted without biopsy, or other clinical factors.

#### CONCLUSION

The study highlights the challenges in diagnosing and treating vertebral osteomyelitis, as well as the limitations of image-guided biopsy in impacting the clinical management of this condition. The biopsy results did not lead to a change in the antibiotic regimen for the vast majority of cases. The risks and benefits of biopsy should be carefully considered in light of this knowledge.

#### CLINICAL RELEVANCE/APPLICATION

Spine biopsies can be challenging procedures and the yield of such procedures may be low. This is the only study we are aware of that examines the clinical impact of biopsies performed for suspected discitis-osteomyelitis and the results show that biopsy/culture results do not change clinical management in the majority of patients.

### Prediction of High-Risk Cytogenetic Status in Multiple Myeloma using Dual-energy Spectral Computed Tomography

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Siya Shi (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the predictive value of quantitative parameters derived from dual-energy spectral computed tomography (DESCT) for a high-risk cytogenetic (HRC) status in multiple myeloma (MM) patients.

#### METHODS AND MATERIALS

This study involved 24 MM patients with 102 lesions who had undergone spinal DESCT. Among them, 5 patients with 18 lesions were diagnosed with HRC status, including the presence of at least one of the following cytogenetic abnormalities (CAs): del(17p), t (4;14), t (14;16), t (14;20), gain (1p), or p53 mutation. The quantitative parameters of DESCT parameters were generated by the regions of interest defined on lesions. Univariate logistic regression was performed to determine the relevant variables with HRC status. The least absolute shrinkage and selection operator (LASSO) was used to build a model for predicting the HRC status. Waterfall plot was used to visualize the performance of the model. Receiver operating characteristic (ROC) analysis was performed to determine potential utility of the model and the sensitivity and specificity determined by the Youden Index were also calculated.

#### RESULTS

Statistical differences were observed according to univariate logistic regression including Mono 40- Kev, Ca (Fat), Ca (Water), Fat (Ca), Fat (HAP), HAP (Fat), HAP (Water), Water (Ca), Water (HAP) and Effective atomic number (Eff-Z) (all  $P < 0.05$ ). Fat (HAP) and Water (Ca) were selected according to LASSO to build a prediction model for HRC status. Waterfall plot demonstrated the favorable predictive performance of the model. ROC analysis indicated the area under the curve was 0.799 (95% confidence interval: 0.656-0.942) with sensitivity of 0.722, specificity of 0.857 and Youden index of 0.579.

#### CONCLUSION

Analysis of DESCT offers potential as a quantitative method to predict the HRC status in MM.

#### CLINICAL RELEVANCE/APPLICATION

The DESCT quantitative parameters could be used to predict HRC in MM patients and to facilitate treatment selection and prognosis prediction.

### Opportunistic Screening for Acute Vertebral Fractures on Routine Abdominal or Chest CT using an Automated Deep Learning Model

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Jonghun Woo, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop an opportunistic screening model based on deep learning algorithm to detect recent vertebral compression fractures in abdominal or chest CT

#### METHODS AND MATERIALS

This retrospective single center design study collected 1309 coronal reformatted images from abdomen, pelvis or chest CT, performed within the preceding two months in patients recently diagnosed with a vertebral compression fracture or normal spine on spinal MRI. They consists of 504 recent fracture labeled images (119 patients, mean age  $61.6 \pm 19.2$ [SD], M: F=64:55) and 805 normal unlabeled images (115 patients, mean age  $56.2 \pm 15.0$ [SD], M: F=68:47) from September 2018 to April 2022. One radiologic resident and one board certified musculoskeletal radiologist participated in image selection and manual labeling the fractured segment on each CT images. Image selection in recent fracture group was made on the condition that two out of three radiologic findings suggestive of a recent fracture such as cortical step-off, impaction of trabeculae, or visual fracture line were included and three images per each fractured vertebral segment were obtained. For the CT image of the normal patient group, 7 images were obtained at the same interval between the most anterior vertebral body and the posterior vertebral body in the coronal scan. The labeled 480 images and unlabeled 700 images was split randomly into training set, validation set, and internal test set in a ratio of 75%:10%:15%, respectively. Remained labeled 24 images and unlabeled 105 images was included for secondary internal validation set. The primary outcome was test accuracy, precession, and F1 score. Neuro-T (version 2.3.3; Neurocle Inc), a commercially available software was used in establishing algorithm

#### RESULTS

For training, validation and internal test set, the algorithm achieved 99.86 % test accuracy, 91.22 % precision, and 89.18 % F1 score, respectively for detection of recent vertebral compression fracture. Then in secondary internal validation set, our system achieved 99.90% test accuracy, 74.93 % precision and 78.30 % F1 score, respectively.

#### CONCLUSION

Automated deep learning model showed high accuracy in test set and also in internal validation set. If this algorithm is applied opportunistically to daily abdomen or chest CT evaluation, it will be helpful for early detection of vertebral compression fracture.

#### CLINICAL RELEVANCE/APPLICATION

Automated deep learning model showed high accuracy in test set and also in internal validation set. If this algorithm is applied opportunistically to daily abdomen or chest CT evaluation, it will be helpful for early detection of vertebral compression fracture.

### Detection of Bone Marrow Edema in Vertebral Compression Fractures using Deep Learning Segmentation Quantitative Material Density Imaging in Fast kVp-switched Dual Energy CT

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Reisuke Nishihara (*Presenter*) Nothing to Disclose

#### PURPOSE

Water (hydroxyapatite, [HAP]) material density images derived from dual energy CT (DECT) are used to detect bone marrow edema (BME) in vertebral compression fractures (VCF). However, task-irrelevant anatomy is also enhanced in water (HAP) images, and this can affect BME detection accuracy. This study investigates the diagnostic performance of BME in VCF using water (HAP) density images with deep learning (DL) bone segmentation.

#### METHODS AND MATERIALS

172 vertebral bodies, from the images of 20 patients who underwent both DECT and MRI between Dec 2021 and Feb 2023 for suspected VCF, were included in this study. Vertebral bodies with heights of less than 4 mm, and those imaged after percutaneous vertebroplasty, were excluded. DECT was performed using a 256-row fast kVp switching dual energy CT (Revolution CT, GE HealthCare). Virtual monochromatic images (VMI, 70 keV with 0.625 mm-slices) were reconstructed and processed using dedicated software (Spectral Bone Marrow [SBM], GE HealthCare). SBM generates a bone mask using a DL-based DECT bone segmentation algorithm. This mask defines bone regions upon which water (HAP) material density images are overlaid on the base VMI. The window width and level of the color overlay images are set to optimize visualization of bone marrow. This fully automatic procedure yields 2.5 mm-slice axial, sagittal and coronal water (HAP) density-VMI fused images. Presence of BME was assessed by MRI. Two radiologists, blinded to the MRI results, evaluated each vertebral body for the presence of BME on the water (HAP) density-VMI fused image using a binary classification. Sensitivity, specificity, positive predicted value (PPV) and negative predicted value (NPV) were assessed using MRI as reference standard. Regions of interest (ROI) were placed on each vertebral body. Cut-off values of water (HAP) density were calculated using ROC analysis.

#### RESULTS

The DECT-based algorithm detected BME with 100% sensitivity, 98% specificity, 96% PPV and 100% NPV. A cutoff value of 996.6 mg/cm<sup>3</sup> provided 96 % sensitivity and 99% specificity.

#### CONCLUSION

The DECT BME detection algorithm demonstrates excellent performance in VCF, as evidenced by quantitative analysis as well as concordance with radiologist impressions.

#### CLINICAL RELEVANCE/APPLICATION

Currently, BME diagnosis in VCF is mainly performed using MRI. This work demonstrates that, thanks to advances in deep learning-based segmentation, quantitative projection-based material decomposition direct from projection views, and VMI-water (HAP) image fusion, DECT may provide a viable alternative. DECT may improve patient throughput vs MRI owing to shorter scan time and increase availability because of lower cost per scan.

### The Value of Trabecular Bone Score in the Reclassification of Bone Quality in Chinese Postmenopausal Women

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Fang Wang (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the clinical value of trabecular bone score (TBS) in the reclassification of bone quality in Chinese postmenopausal women.

#### METHODS AND MATERIALS

The retrospective study included Chinese postmenopausal women who had dual X-ray absorptiometry (DXA) examination between September 2022 and April 2023. DXA images were analyzed to measure bone mineral density (BMD) at lumbar spine (LS), left hip (LH), and femoral neck (FN). was calculated by the TBS iNsite software (version 3.0.0.15). The degradation of bone microstructure was determined following the cutoff values: TBS = 1.310 (normal); 1.230 = TBS = 1.310 (partially degraded); and TBS < 1.230 (degraded). The DXA parameters and clinical characteristics were compared among different BMD categories (normal, osteopenia, osteoporosis) by using rank sum test. Factors related to TBS were determined by Spearman correlation analysis.  $P < 0.05$  was considered statistically significant.

#### RESULTS

A total of 300 subjects were included in this study, with 100 subjects per bone mass category. There was no significant difference in the age between any two of the groups ( $P > 0.05$ ). The TBS was significantly lower in osteoporosis ( $1.212 \pm 0.075$ ,  $P < 0.001$ ) and osteopenia groups ( $1.291 \pm 0.085$ ,  $P < 0.001$ ) than in normal BMD group ( $1.345 \pm 0.097$ ). Significant differences for BMI, weight and DXA parameters were also observed between any two of the groups. For normal BMD group, 3% of subjects still showed degraded microstructure. The number was obviously increased in both osteopenia (7.67%) and osteoporosis (19.66%) groups. For partially degraded microstructure, 8%, 11.33% and 11.34% of subjects were observed in normal BMD, osteopenia and osteoporosis groups, respectively. Spearman correlation analysis showed that the factors related to low TBS were age, weight, BMI, BMD and T-score.

#### CONCLUSION

TBS and BMD were significantly lower in the osteoporosis group than in osteopenia and normal BMD groups. Low TBS was associated with age, weight, BMI, and BMD at lumbar spine, left hip and femur neck. It was notable that a proportion of Chinese postmenopausal women with osteopenia and normal BMD still suffered from degraded microstructure according to their TBS.

#### CLINICAL RELEVANCE/APPLICATION

BMD and TBS are essentially two different and independent indices to describe bone quantity and quality, respectively. Patients with osteopenia may also have degraded bone, which is at higher risk of fracture but not easily detected in clinical. However, in combination of BMD, TBS is able to uncover the presence of these patients. Therefore, TBS is also of great value for the clinical management of Chinese patients with osteoporosis and those at risk of fracture, as well as for treatment decisions and recommendations.

### TBS Helps Identify Degraded Bone Microstructure in Chinese PHPT Patients

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Wang Ling, MBBS (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the value of trabecular bone score (TBS) in evaluating the bone microstructure in Chinese primary hyperparathyroidism (PHPT).

#### METHODS AND MATERIALS

We performed a retrospective study of Chinese PHPT patients who were diagnosed between August 2022 to April 2023. The patients all underwent dual-energy X-ray absorptiometry (DXA) examination. Patients without DXA or TBS examination, and suffering from disease that might affect bone metabolism were excluded. Normal control and case groups were matched for age and sex. TBS for each subject was evaluated based on their lumbar spine DXA image by the TBS iNsight software (version 3.0.0.15). The integrity of bone microarchitecture was evaluated based on different TBS cutoff values: TBS = 1.310 (normal microstructure), 1.230 = TBS = 1.310 (partially degraded microarchitecture), and TBS < 1.230 (degraded microarchitecture). The difference of DXA parameters, including TBS and BMD, and clinical information between the groups were analyzed by T-test and Rank sum test.  $P < 0.05$  was considered as significant.

#### RESULTS

A total of 18 Chinese PHPT patients (female: male = 7: 2) and 35 age- and sex-matched controls were included in the study. The bone mass index (BMI) of the included patients was at 15-35kg/m<sup>2</sup>. There were 21 and 14 subjects with normal BMD and bone mass loss in the control group, respectively. Clinical characteristics, including height, weight and BMI, were not significantly different between the groups. A significant difference was observed for lumbar spine BMD ( $P = 0.000$ ) and TBS ( $P = 0.026$ ), as well as left hip (LH) and femoral neck (FN) BMD ( $P = 0.000$  for both) between the control and case groups. In particular, in terms of the mean value, TBS of PHPT groups indicated degraded microstructure, while no degradation was observed in the control group. BMD and TBS were significantly correlated in both groups (PHPT:  $r = 0.891$ ,  $p = 0.000$ ; control group:  $r = 0.569$ ,  $p = 0.000$ ).

#### CONCLUSION

Lumbar spine BMD and TBS was significantly lower in Chinese PHPT patients than control group. In addition, there was a significant correlation between TBS and BMD in PHPT and the control group. In the basis of BMD, TBS could be used to better evaluate the microstructure of Chinese PHPT patients and therefore their fracture risk.

#### CLINICAL RELEVANCE/APPLICATION

BMD does not reflect bone microstructure and hence bone strength. Trabecular bone score (TBS) is a textural index that evaluates pixel gray-level variations in the lumbar spine DXA image, providing an indirect index of trabecular microarchitecture. TBS could be a useful tool to evaluate the bone microstructure of Chinese PHPT patients, providing a better evaluation of their fracture risk.

### Correlation between Volumetric CT Tumor Burden and Circulating Tumor DNA as Response Parameters in Patients with Advanced Metastatic Melanoma Undergoing Immunotherapy

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Anna Streckenbach, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Circulating tumor DNA (ctDNA) is a promising tool for treatment monitoring of patients with advanced melanoma, as it may serve as a measure of tumour burden. There is a need to understand the correlation between visual tumour burden assessed by imaging and ctDNA levels. Thus, the purpose of our study was to compare ctDNA values with volumetric tumor burden assessed by computed tomography as indicators for therapy response in melanoma patients undergoing immunotherapy.

#### METHODS AND MATERIALS

In this retrospective, institutional review board approved study, a total of 35 patients (19 male, 16 female, age 63 +/- 17) with histologically confirmed metastatic melanoma (AJCC v8 stages III/IV) underwent systemic immunotherapy. All patients received a baseline and at least 2 subsequent staging CT examination after initiation of therapy. This resulted in a total of 107 CT examinations, including a body CT scan (neck, chest and abdomen) as well as cranial CT or MRI. The volumetric tumor burden was measured separately in different anatomical regions (bones, lung, liver, lymph node, cutaneous and brain metastases) using a dedicated commercially available software tool. The total tumor burden as well as subgroup analysis of different metastatic sites were correlated with the plasma ctDNA levels at each follow-up time point. The detection of somatic mutations in plasma DNA included hotspot analyses in 5 different genes: BRAF, EGFR, KRAS, NRAS, PIC3CA.

#### RESULTS

Lymph node metastases were the most common metastatic site (53.6%), followed by lung metastases (30.7%) and subcutaneous metastases (26.9%) and brain metastases (26.9%). The mean ctDNA level was 0.99 %/mL and the mean volumetric total tumor burden was 118 mL. There was a statistically significant difference for relative changes in total tumor burden and ctDNA levels between non-responders (progressive disease [PD]) and responders (partial response [PR] and complete response [CR]). A strong and statistically significant correlation was observed between relative changes of ctDNA levels and total tumor burden ( $r= 0.87$ ;  $p<0.05$ ). Of note, subgroup correlation of the two most frequent sites of metastasis (lymph node, lung) between tumor burden and ctDNA levels was moderate ( $r= 0.6$ ;  $p<0.05$ ).

#### CONCLUSION

Changes in both total tumor burden and ctDNA can be used for precise response assessment in advanced melanoma patients undergoing immunotherapy. Given the strong correlation between the two markers, inherent challenges of immunotherapy response assessment such as pseudo-progression could be identified and differentiated earlier.

#### CLINICAL RELEVANCE/APPLICATION

Combining imaging with other biomarkers is vital to address inherent challenges of immunotherapy response assessment such as pseudo-progression.

### Immuno-PET Imaging of B7-H4 Immune Checkpoint in Prostate Cancer

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Manoj Kumar, MS, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

B7-H4 is an immune checkpoint sibling of PD-L1 that suppresses T-cells' tumor-killing functions. In addition to cancer cells, B7-H4 is also expressed by tumor-associated macrophages (M $\phi$ ), comprising 30-50% of tumor stromal cell populations. This study aimed to design and develop a novel B7-H4 immunoPET probe and perform the first proof-of-concept B7-H4 immunoPET imaging.

#### METHODS AND MATERIALS

Anti-B7-H4 mAb was functionally characterized and tested using ELISA assay. The antibody was conjugated with chelator NODAGA-NHS and labeled with radioisotope copper-64 ( $^{64}\text{Cu}$ ). Tumor xenografts were generated in C57BL/6J mice by subcutaneously injecting TRAMP-C2 prostate cancer cells on the right flank. 5 mice/group were intraperitoneally injected with either PBS, B7-H4 mAb (10mg/kg) to block B7-H4, or chlodronate liposome (15mg/kg) to cause M $\phi$  depletion. MicroPET imaging was performed post-tail vein injection of 100 $\mu\text{Ci}$   $^{64}\text{Cu}$ -B7-H4-mAb. Radiotracer uptake was measured as the maximum percentage injected dose per gram body weight (max %ID/g). Statistical significance was determined using two-way ANOVA with Tukey correction for multiple testing.

#### RESULTS

Immunoconjugation yielded a chelator-to-antibody ratio of 1.8-2.2 and 94-98% radiochemical purity of radiotracer  $^{64}\text{Cu}$ -B7-H4-mAb with an average specific activity of 2645.45 mCi/ $\mu\text{mol}$ . The immunoreactivity of  $^{64}\text{Cu}$ -B7-H4-mAb was similar to that of naked B7-H4 mAb, with unaffected potency in targeting B7-H4 protein moiety. PET imaging demonstrated tumor uptake of radiotracer as  $13.12 \pm 4.867$ ,  $36.38 \pm 5.71$ , and  $42.16 \pm 11.95$  %ID/g at 4-, 24-, and 48 hours, respectively. By comparison, the radiotracer uptake in B7-H4 blocked tumors was  $10.56 \pm 2.26$ ,  $25.92 \pm 6.28$ , and  $27.20 \pm 11.01$  %ID/g at 4-, 24, and 48 hours, respectively. Blocking B7-H4 in vivo significantly reduced radiotracer uptake at the 48-hour time point ( $p=0.0088$ ). Depletion of M $\phi$  also demonstrated a non-significant tendency of reduced tumor uptake radiotracer ( $8.34 \pm 4.37$ ,  $26.04 \pm 4.08$ ,  $35.42 \pm 10.22$  at 4-, 24-, and 48 hours, respectively). Immunohistochemical staining of B7-H4 demonstrated significantly stronger protein levels in untreated tumors compared to B7-H4 blocked or M $\phi$  depleted group.

#### CONCLUSION

The new  $^{64}\text{Cu}$ -B7-H4-mAb radiotracer showed preferential tumor accumulation. In vivo B7-H4 blocking and M $\phi$  depletion reduced the tumor accumulation of the new radiotracer; however, a statistically significant difference was only observed between the control and the blocked group at 48 hours.

#### CLINICAL RELEVANCE/APPLICATION

The new B7-H4 immunoPET probe is a clinically translatable imaging biomarker that could inform clinical trial design immediately. B7-H4 PET imaging could guide clinical decision-making to improve therapeutic benefits.

### Prostate-specific Membrane Antigen (PSMA) as a Novel Theranostic Target in Glioblastoma Multiforme (GBM): Feasibility Study in a Preclinical Xenograft Model

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Steven Pan, BSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Glioblastoma (GBM) is the most common and aggressive primary malignant brain tumor. Accurate differentiation of viable tumor versus treatment-related change and delivery of targeted therapies is critical to improving clinical outcomes. Prostate specific membrane antigen (PSMA) has recently entered clinical practice as a theranostic (ie diagnostic PET and radionuclide) target in malignancies such as prostate cancer, and PSMA expression in GBM has recently been shown. The purpose of our study was to confirm PSMA expression in GBM with immunohistochemistry (IHC), and to evaluate PSMA as a radionuclide target in a mouse model of GBM.

#### METHODS AND MATERIALS

IRB and IACUC approval was obtained for the human tissue and in vivo mouse model components of the study. IHC was performed in tissue specimen from six GBM patients to validate PSMA expression. Subcutaneous xenografting of a mosaic tumor model consisting of a PSMA+ endothelial cell line and a GBM stem cell line was performed in 5 mice. Three mice were treated with 1 mCi of [Lu177]-PSMA, and tumor localization of radionuclide was validated using post-treatment single-photon computerized tomography (SPECT) imaging. Treatment response was assessed with longitudinal monitoring of tumor size using calipers to measure length (L) and width (W), and estimating ellipsoid volume (V) through the modeling formula,  $V = 0.5 \times L \times W^2$

#### RESULTS

In 5/5 (100%) patient tumor specimen, IHC demonstrated PSMA expression in both tumor stroma as well as tumor vasculature, noting inter-patient heterogeneity. Post-therapy [Lu177]-PSMA SPECT demonstrated specific localization of radionuclide in the subcutaneous tumor xenograft in 3/3 (100%) mice, validating in vivo expression of PSMA in our mosaic model as well as delivery of radionuclide to the tumor site. Treated tumors demonstrated reduction in tumor volume and slowed growth compared to the untreated control group, although no animal demonstrated complete tumor killing.

#### CONCLUSION

We validated previous pilot studies showing PSMA expression in human GBM specimen. We further demonstrate feasibility of PSMA-targeted radionuclide therapy in our in vivo mouse xenograft model, with evidence of partial response. Our findings support further evaluation of PSMA as an emerging theranostic target in GBM, both as a standalone approach and in combination with other therapeutic strategies. Future directions include correlative studies between PSMA expression and clinical outcomes to further elucidate its potential for personalized therapies and a predictor for clinical outcomes.

#### CLINICAL RELEVANCE/APPLICATION

This study combines human GBM tissue and mouse model investigations to validate PSMA as an emerging theranostic target in GBM and has the potential to improve clinical outcomes.

### **Burnout Among Radiology Physicians: A Systematic Review and Call to Action**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Nader Ashraf, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Burnout is on the rise among physicians, including radiologists, with prevalence rates exceeding 50%. Burnout in healthcare can result in medical errors, malpractice suits, low patient satisfaction, and poor care delivery. Hence, we aimed to systematically review studies reporting the prevalence of burnout in physicians in the radiology department and to provide an overview of the factors associated with burnout among radiologists.

#### **METHODS AND MATERIALS**

Searches were run from inception until November 13th, 2022, in multiple databases. This systematic review included studies that addressed the prevalence of burnout in radiologists of any sample size, using a valid method of assessment, reporting estimates of overall burnout syndrome or its subdimensions, and were cross-sectional, observational, or prospective survey peer-reviewed studies, without restrictions on publication time or language, following the PICOS framework. Data were extracted into a standardized Excel® sheet and descriptive statistics were generated by the same program.

#### **RESULTS**

Twenty-two cross-sectional studies involving 4230 radiology physicians in 7 countries published between 1996 and 2022 reporting on burnout were included. Fifteen studies (68.2%, n = 3181) were conducted in the United States. The studies had a range of participants from 26 to 460, with a median of 156 and an interquartile range of 89-265. Only 81.8% of the studies identified the gender of their sample, with 57.7% males and 42.3% females. The overall burnout prevalence estimates were reported by 13 studies (59.1%) and varied from 33% to 88%. High burnout prevalence estimates were reported by only 5 studies (22.7%) and ranged from 5% to 62%. Still, the prevalence estimates from these studies cannot be combined nor compared due to the variability in burnout assessment techniques, definitions, and outcomes, as well as statistical heterogeneity.

#### **CONCLUSION**

We identified 22 studies with a high degree of heterogeneity reporting prevalence estimates on burnout among radiologists. Burnout in radiology is increasing globally, with prevalence estimates reaching 88% and 62% for overall and high burnout, respectively, and a myriad of factors identified to be contributing to the increased prevalence. This data should be used as a starting point for discussion to evaluate and resolve these difficulties in the global radiology work environment.

#### **CLINICAL RELEVANCE/APPLICATION**

With the modest number of studies included and the significant methodological discrepancies, there is a need for further high-quality and methodologically robust studies conducted with standardization of burnout definition and assessment techniques.

### Exploring the Potential of Microsoft Bing Chatbot for Answering Patient Questions Regarding Radiologic Examinations and Procedures

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Ian J. Kuckelman, BS, MPH (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the accuracy and completeness of AI chatbot responses to questions commonly asked by patients regarding radiologic examinations and procedures.

#### METHODS AND MATERIALS

We developed ten conversational-style questions for three common radiologic examinations and procedures (CT abdomen, MRI spine, and bone biopsy) and asked them to the Microsoft Bing Chatbot in two trials across three different settings, "More Creative", "More Balanced", and "More Precise". Two reviewers, one an attending radiologist with eight years of experience and the other a fourth-year medical student, independently compared the responses provided by the Chatbot to a gold-standard resource—radiologyinfo.org—and rated them for accuracy and completeness on a scale of 1-3, (1-incorrect/incomplete, potentially harmful; 2-mostly correct/complete, unlikely to cause confusion or harm; and 3-entirely correct/complete). Descriptive statistics were calculated. Differences in accuracy and completeness ratings were compared by chatbot setting and exam type with a Kruskal-Wallis test. Inter-rater reliability was assessed using Cohen's kappa statistic.

#### RESULTS

Of the 180 total responses collected, 166 (92%) were rated as "entirely correct" and 14 (8%) as "mostly correct". For completeness, 119 responses (66%) were rated "complete" and 61 (34%) "mostly complete." Both reviewers rated all responses as either "entirely correct/complete" or "mostly correct/complete", with no responses rated as "inaccurate" or "incomplete" by either reviewer. Neither completeness nor accuracy differed significantly by chatbot setting or exam type. Inter-rater agreement was moderate with a Kappa of 0.66.

#### CONCLUSION

Our study shows that the Microsoft Bing Chatbot has potential as a tool for patient education regarding radiologic examinations and procedures. Directing patients to this online resource represents a potentially cost-effective way for health systems and providers to provide patients with important information regarding how to prepare for a procedure, as well as reduce patient anxiety and improve overall experience. Limitations include potential variability of responses based on question phrasing and the omission of important information not explicitly requested.

#### CLINICAL RELEVANCE/APPLICATION

AI-powered chatbots show potential as a tool for patient education associated with radiologic examinations and procedures.

### Can ChatGPT Answer Questions about Lung Cancer and Screening

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Hana L. Haver, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The recent surge of worldwide interest in dialogue-based artificial intelligence (AI) large language models (LLM) such as ChatGPT is prompting evaluation of information available on such platforms. Early studies have found that ChatGPT provides generally appropriate clinical recommendations in areas ranging from cardiovascular disease, antibiotic selection for infectious diseases and breast cancer. Lung cancer remains a leading cause of death in the United States, so we sought to evaluate how ChatGPT would respond to fundamental questions about lung cancer prevention, screening and the Lung CT screening Reporting and Data System (Lung-RADS).

#### METHODS AND MATERIALS

In February 2023, we submitted 25 questions to ChatGPT and asked it to generate three answers, as inconsistencies among answers are reported. Three fellowship-trained cardiothoracic radiologists graded each set of responses based on clinical judgment as 1) "appropriate," 2) "inappropriate", or 3) "inconsistent" if the responses contained inappropriate or varied information, respectively. Final appropriateness for each set was determined by the majority of reviewer responses, which were summarized using descriptive statistics.

#### RESULTS

ChatGPT-generated responses were determined to be appropriate for 76% (19/25) questions in both contexts by three fellowship-trained cardiothoracic radiologists. Four of 25 (16%) generated responses were characterized as inappropriate and 2/25 (8%) as inconsistent in both hypothetical contexts (Table 1). Inappropriate and inconsistent responses were related to lung cancer screening indication and frequency as well as those related to the Lung-RADS lexicon.

#### CONCLUSION

ChatGPT demonstrates the potential to automate provision of healthcare information related to lung cancer prevention and screening. ChatGPT performed more poorly on topics about lung cancer compared to previous reports on clinically appropriate information to questions about cardiovascular disease and breast cancer. This difference could be due to lack of information about lung cancer versus cardiovascular disease in the model's training dataset. Radiologist oversight remains critical, given the inappropriate and inconsistent radiology-specific information. Future study of applications for LLMs to improve healthcare education and counseling is encouraged.

#### CLINICAL RELEVANCE/APPLICATION

ChatGPT generates largely appropriate answers to questions about lung cancer prevention and screening, though gaps remain in specific radiology topics and physician oversight remains imperative.

### Assessment for Carotid Atherosclerotic Plaque using Vessel Wall Magnetic Resonance Imaging: A Multi-reader ROC Study to Determine Optimal Sequence for Detecting Vessel Wall Calcification

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Hideki Ishimaru, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

We aimed to compare conventional vessel wall MR imaging techniques and quantitative susceptibility mapping to determine the optimal sequence for detecting carotid artery calcification.

#### METHODS AND MATERIALS

Twenty-two patients who underwent carotid vessel wall MR imaging and neck CT were enrolled. Four slices of 6-mm sections from the bilateral internal carotid bifurcation were subdivided into 4 segments according to clock position (0-3, 3-6, 6-9, and 9-12) and assessed for calcification. Two blinded radiologists independently reviewed a total of 704 segments and scored the likelihood of calcification using a 5-point scale on T1-, T2-, PD-weighted imaging, the first echo-time images of FLASH, and quantitative susceptibility mapping. Quantitative susceptibility mapping was calculated using phase images of FLASH. The observer performance for detecting calcification was evaluated by a multireader, multiple-case receiver operating characteristic study. Weighted  $\kappa$  statistics were calculated to assess interobserver agreement with respect to calcification scoring.

#### RESULTS

Quantitative susceptibility mapping had a mean area under the receiver operating characteristic curve of 0.85, which was significantly higher than that of any other sequence ( $p < 0.01$ ) and showed substantial interreader agreement ( $\kappa = 0.68$ ). When a segment with a score of 3-5 was defined as positive and a segment with a score of 1-2 was defined as negative, the sensitivity and specificity of QSM were 0.75 and 0.87, respectively.

#### CONCLUSION

Quantitative susceptibility mapping was the most reliable MR sequence for the detection of plaque calcification.

#### CLINICAL RELEVANCE/APPLICATION

A low signal on quantitative susceptibility mapping is a reliable marker of carotid plaque calcification.

### Contribution of Cerebral Microbleeds and Sleep Quality to Persistent Post-concussive Working-Memory Decline Through Glymphatic Clearance Dysfunction

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Yung-Chieh Chen, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Cerebral microbleeds (CMBs) and sleep disorders are linked to persistent cognitive decline after a concussion (mild traumatic brain injury, mTBI). However, the pathomechanism is not fully understood. We hypothesized that the inefficient glymphatic clearance function may contribute to prolonged working-memory dysfunction, which may be partially attributed to both poor sleep and concussion-related CMBs.

#### METHODS AND MATERIALS

We conducted a 1-year prospective magnetic resonance imaging (MRI) and neuropsychological study on patients with concussion (N=61) and demographically matched controls (N=61). Susceptibility-weighted MRI was used to detect CMBs. The diffusion tensor imaging analysis along the perivascular space (DTI-ALPS) index was used to evaluate glymphatic function. The Pittsburgh sleep quality index (PSQI) and digit span (DS) scores were employed to assess participants' sleep quality and working memory, respectively. The baseline DTI-ALPS index, PSQI scores, and the demographic data were used to train the machine learning-based model to predict the 1-year DS score.

#### RESULTS

Patients with CMBs demonstrated a lower DTI-ALPS index compared with patients without CMBs and controls. Additionally, patients demonstrated poorer sleep quality than controls. The 1-year DS score was significantly correlated with both glymphatic diffusivity (DTI-ALPS;  $r=0.592$ ,  $p<0.001$ ) and sleep quality (PSQI;  $r=-0.551$ ,  $p<0.001$ ) assessed at baseline. Potential baseline biomarkers, such as the number of CMBs, DTI-ALPS index, and PSQI score, the confounding factors, including age, sex, education level, and duration from injury to MRI, were employed as the potential feature factors to predict long-term working memory function (1-year DS score). We then developed several machine learning-based models using the key features selected by the Lasso method to predict the DS score at the 1-year follow-up. Among the models, the Gaussian Process Regression method yielded the best predictions of the 1-year DS score, with an  $R^2$  value of 0.78 and a root-mean-squared error of 2.8827.

#### CONCLUSION

CMB and poor sleep quality are contributing factors for glymphatic dysfunction, as measured using the DTI-ALPS index, and related to persistent postconcussive working-memory impairment. Our systematic analyses not only further our understanding of glymphatic dysfunction after concussion but also provide a framework for precise and personalized predictions of protracted cognitive decline.

#### CLINICAL RELEVANCE/APPLICATION

The study highlights the importance of monitoring sleep quality and glymphatic function in patients with concussion, and suggests a potential therapeutic target for preventing persistent cognitive dysfunction after concussion.

W5A-SPNR-12

### Magnetic Resonance Imaging in Traumatic Brain Injury Patients and Associations with In-hospital Outcomes: Analysis of a National Representative Sample

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Nnamdi J. Omenuko, MD, MPH (*Presenter*) Nothing to Disclose

#### PURPOSE

Magnetic Resonance Imaging (MRI) has gained increasing attention due to its superior ability to visualize brain tissue injury. Several studies have demonstrated the superior diagnostic accuracy of MRI compared to computed tomography (CT) which is the most used imaging modality in the acute setting. The presence of intracranial hemorrhage has been associated with poor outcomes in traumatic brain injury patients. Therefore, the appropriate use of imaging modalities is crucial in predicting outcomes and providing optimal care. We aim to study the use of MRI in Traumatic Brain Injury (TBI) patients and their associations with in-hospital outcomes.

#### METHODS AND MATERIALS

The National Inpatient Sample (NIS) was queried for MRI use, discharge disposition, length of hospital stays, intracranial hemorrhage, and in-hospital mortality among those with TBI in 2015. The effect of MRI use on these endpoints was evaluated using bivariate and multivariate regression analysis independently, controlling for significant baseline differences in demographics, comorbidities, and hospital status.

#### RESULTS

A total of 45293 patients admitted with a diagnosis of TBI were included in this study. 25.7 %, 35.6%, 24.0%, and 14.6% of the patients were in age groups 20-40, 40-65, 65-80, and >80, respectively. 55% of the patients were female. 58% were Whites, while Hispanic, Black, and other races accounted for 17%, 14%, and 9%, respectively. In the unadjusted analysis, inpatient CT brain was associated with lower rates of mortality (unadjusted OR 0.657, 95% CI 0.163-2.651) compared to those who did not have a CT scan. Inpatient CT use was also associated with lower odds of short hospital stays (unadjusted OR 0.810, 95% CI 0.729-0.900) compared to those who did not. After adjusting for confounders, MRI and CT use was not significantly associated with in-hospital mortality, discharge disposition, length of stay, or inpatient complications.

#### CONCLUSION

We present that there seems to be no difference in inpatient outcomes and complications when MRI is used in the evaluation of traumatic brain injuries. Clinical decision-making regarding the use of MRI versus CT scan in TBI patients should be based on the severity of the injury and clinical presentation. Further research is needed to explore the long-term outcomes.

#### CLINICAL RELEVANCE/APPLICATION

The clinical relevance of comparing MRI use versus CT scan in TBI patients lies in the potential to improve in-hospital outcomes. The appropriate imaging modality can provide accurate and timely diagnosis, which can lead to better treatment decisions and improved patient outcomes. Understanding the associations between these imaging modalities and in-hospital outcomes can aid in clinical decision-making and lead to better patient care.

### Quantitative Analysis of Calcification in Cerebral Microvasculature by Micro-computed Tomography (microCT)

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Janet Back, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Vascular calcification (VC) is a predictor of both cardiovascular and cerebrovascular events. While it is known that coronary VC results in impaired vasomotor response and reduced myocardial perfusion, less is known about the prevalence and impact of VC in brain microcirculation. We examined the distribution of intracranial calcification in a cohort of human cadavers using micro-computed tomography (microCT). We aimed to exhibit the feasibility of quantifying calcification volume (CV) in cadaveric brain vasculature using microCT and apply this method to compare CV across brain regions in which VC has been incidentally noted in case studies.

#### METHODS AND MATERIALS

In a cohort of elderly human donor cadavers with and without dementia documented at time of death, brain tissue was sampled bilaterally from basal ganglia (BG), substantia nigra (SN), subventricular zone (SVZ), hippocampus (Hc), and posterior cingulate cortex (PCC). Samples were scanned by microCT at 10  $\mu$ m resolution. 3D-reconstructed images were segmented into standardized regions of interest (ROI) and thresholded at the level of calcium detection (130 Hounsfield units). CV was defined as voxel quantity  $\geq$ 130 HU within each ROI; CVs exceeding .01% per ROI were considered "positive". Findings were confirmed by histologic evaluation using Alizarin red calcium-binding stain.

#### RESULTS

All subjects exhibited parenchymal and/or vascular calcification in at least one region. Calcification volume exceeding .01% per ROI for the no dementia cohort (n=6) was 83% globus pallidus (GP), 66% SN, 17% SVZ, 17% Hc, and 33% PCC compared to the dementia cohort (n=6) which was 100% GP, 33% SN, 50% SVZ, 100% Hc, and 100% PCC. Prevalence of Hc and PCC was significantly greater in subjects with documented dementia compared to age-matched subjects (n=12,  $p < 0.01$ ).

#### CONCLUSION

Our findings demonstrate the utility of microCT for quantifying CV in human brain tissue. All subjects exhibited calcification in at least one brain region, indicating that intracranial calcification is more prevalent than published estimates (~30% in general population). Consistent with the literature, VC was most prevalent in the GP. Subjects with dementia exhibited significantly higher Hc and PCC CVs than age-matched subjects without dementia. This finding supports recently published evidence of increased Hc and BG calcification in human cadaveric brains with Alzheimer's disease relative to age-matched controls. Expansion of our study cohort remains ongoing in order to further investigate this relationship.

#### CLINICAL RELEVANCE/APPLICATION

Analyzing the patterns of VC in cerebral vasculature using microCT can aid in the development of therapeutics against cerebrovascular and neurodegenerative diseases.

### Predictors of Positive Remodeling in Patients with Acute Ischemia Stroke

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Li-Ping Ma, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The aim of this study was to compare the differences in the culprit plaques characteristics between positive remodeling (PR) and non-positive remodeling (NPR) patterns in patients with acute ischemia stroke (AIS), and to evaluate potential relative risk factors for PR of intracranial atherosclerosis (ICAS).

#### METHODS AND MATERIALS

Patients with AIS recruited and underwent the HR-VWI scan within 2 weeks after onset. Plaque morphological parameters, as well as clinical variables of both PR and NPR groups were compared using non-parametric tests. A binary logistic regression model was used to analyze the parameters promoting the development of PR, and further determine the independent predictors of PR. The sensitivity and specificity of the model were tested by receiver operating characteristic curve.

#### RESULTS

In all, 84 eligible patients (mean age  $58.07 \pm 1.35$  years, 66 (78.6%) were male) were assigned to the PR (n=28, 33.3%) or NPR (n=56, 66.4%) group according to remodeling ratio (RR). Compared with the NPR group, the PR group had a greater plaque area ( $P < 0.001$ ), greater wall area (WA) ( $P < 0.001$ ), longer plaque length ( $P = 0.018$ ), larger RR ( $P < 0.001$ ), higher blood glucose ( $P = 0.01$ ) and a greater number of HBP ( $P = 0.16$ ). Binary Logistic regression analysis showed that plaque area was independently associated with PR (OR 3.71, 95% CI, 1.49-9.24).

#### CONCLUSION

HR-VWI can identify positive remodeling in ICAS with large plaque area, suggesting a high burden of intracranial vascular lesions and promoting PR.

#### CLINICAL RELEVANCE/APPLICATION

To evaluate the effect of plaque morphological properties and clinical parameters on cerebrovascular remodeling patterns to improve the classification of cardiovascular risk.

W5A-SPNR-5

### Early Brain Amyloid Accumulation on PET in Military Instructors Exposed to Sub-concussive Blast Injuries

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Carlos Leiva-Salinas, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Traumatic brain injury (TBI) is the leading cause of disability in young adults. Recurrent TBI is associated with a wide range of neurologic sequelae, but the contributing factors behind the development of such chronic encephalopathy are poorly understood. Purpose: To quantify early amyloid beta (A $\beta$ ) deposition in the brain of otherwise healthy adult men exposed to repeated subconcussive blast injury using amyloid PET.

#### METHODS AND MATERIALS

In this prospective study from January 2020 to December 2021, military instructors routinely exposed to repeat blast events were evaluated at two different time points: baseline, prior to blast exposure from breacher or grenade, and approximately 5 months after baseline, after blast exposure. Age-matched healthy controls not exposed to blasts and without a history of prior brain injury were evaluated at similar two time points. Neurocognitive evaluation was performed with standard neuropsychological testing for both groups. Analysis of PET data consisted of SUV measurements in six relevant brain regions, and whole brain voxel-based statistical approach.

#### RESULTS

All participants were men (9 controls, 9 blast-exposed). The median age of the controls was 33 years.; IQR: [32, 36]. That of the blast-exposed group was 33; IQR: [30, 34] ( $p=0.824$ ). In the latter, four brain regions showed significantly increased amyloid deposition after blast exposure: infero-medial frontal lobe, precuneus, anterior cingulum and superior parietal lobule ( $P$  values=0.004, 0.02, 0.002, and 0.003 respectively). No amyloid deposition was observed in the controls. Discriminant analysis based on regional changes of amyloid accumulation correctly classified all 9 healthy controls as a healthy controls (100%) and 7 of the 9 blast-exposed (78%) as a blast-exposed. Based on the above voxel-based analysis, whole brain parametric maps of early abnormal early amyloid uptake were obtained. Conclusion: Early brain amyloid accumulation was identified and quantified on PET in otherwise healthy adult men exposed to repetitive subconcussive traumatic events.

#### CONCLUSION

Early brain amyloid accumulation was identified and quantified on PET in otherwise healthy adult men exposed to repetitive subconcussive traumatic events.

#### CLINICAL RELEVANCE/APPLICATION

Our results might have direct clinical implications; if the individuals that are at risk of developing amyloid-related neurotoxicity can be identified, therapies to clear A $\beta$  in the brain might reduce or slow the development of long-term secondary traumatic encephalopathy.

Printed on: 08/22/24

### Optimizing Traumatic Brain Injury Prognosis Prediction: Leveraging Machine Learning with CT Imaging and GFAP/UCH-L1 Blood Biomarkers

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Burak B. Ozkara, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to develop an interpretable machine learning (ML)-based predictive model that combines clinical variables, blood biomarkers, and imaging biomarkers to improve the prognostic prediction, triage management, and treatment strategy in traumatic brain injury (TBI) patients.

#### METHODS AND MATERIALS

In this retrospective cohort study, 662 patients transported to the emergency department with a trauma alert and suspected TBI were screened. Data extraction from electronic medical records included demographic and clinical information. Blood samples were collected and analyzed for GFAP and UCH-L1 using a sandwich enzyme-linked immunosorbent assay. Non-contrast head CT scans were assessed by neuroradiologists for TBI common data elements (CDEs). The collected data was used as input for the ML models. Three outcomes were designed to predict: discharged or admitted for further management (prediction 1), in hospital mortality (prediction 2), and course of hospital stay (prediction 3). Machine learning models, including XGBoost, Random Forest, decision tree, support vector machines, and logistic regression, were trained using the training sets to compare their performances. Cross-validation and hyperparameter tuning were employed. SHapley Additive exPlanations (SHAP) values were used to evaluate the relative significance of predictor factors.

#### RESULTS

A total of 440 patients were finally included. Random Forest models achieved the best performance. For prediction 1 (discharged or admitted for further management), the test set accuracy was 0.95, and the Kappa value was 0.88. For prediction 2 (deceased or not deceased), the accuracy was 0.98, with a Kappa value of 0.49. In prediction 3 (admission only, prolonged stay, or neurosurgery performed), the Random Forest model achieved an accuracy of 0.82 and a Kappa value of 0.72 during the testing phase. SHAP analyses showed that the three most important features for prediction 1 were other major extracranial injury, hemorrhage, UCH - L1. The top three features for prediction 2 were Glasgow Coma Scale, age, GFAP. GFAP, subdural hemorrhage volume, and pneumocephalus were the five most significant features for prediction 3.

#### CONCLUSION

Our study demonstrates the potential of ML models in predicting the hospital course and mortality of TBI patients using non-contrast CT CDEs and blood biomarkers GFAP and UCH - L1. Blood biomarkers like GFAP and UCH - L1 were among the significant variables for prediction, demonstrating the originality of our study.

#### CLINICAL RELEVANCE/APPLICATION

These models may help physicians tailor individualized care plans and provide more accurate prognostic information for patients.

### Asymmetric Cerebral Perfusion Abnormalities are Hallmark in Chronic Traumatic Brain Injury Imaging

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Farzaneh Rahmani, MD, MPH (*Presenter*) Nothing to Disclose

#### PURPOSE

Advanced MRI methods identify biomarkers of grey or white matter damage including perfusion defects, diffusion abnormalities or atrophy. These biomarkers might improve sensitivity for detection of chronic traumatic brain injury (TBI), even when acute evidence of the insult are subtle or absent on conventional imaging sequences.

#### METHODS AND MATERIALS

Sixty-seven participants (29 men and 38 women, age:  $47.1 \pm 13.5$ ) with a history of traumatic brain injury were enrolled from individuals referred to the Neuroevolution LLC. under IRB exemption #Pro00071328. Participants were required to be at least 18 years old and have a T1-weighted brain MRI acquired within 3 months of the date of injury. Additionally, 60 participants (26 men and 34 women, age:  $47.8 \pm 13.1$ ) had arterial spin labeling (ASL) perfusion and 55 had diffusion MRI (dMRI) scans available. Volumetric assessments were done using the Neuroreader program which is FDA-cleared, yielding absolute, normalized and standardized volumes for 83 cortical and subcortical brain structures. The Neuro Reader index (NR-index) was defined as the regional z-score divided by the size of the normative database, while the left-right asymmetry scores were calculated as described in prior work. ASL-MRICloud was used to extract relative regional cerebral blood flow (rCBF) and their respective z-score maps. Abnormal white matter (WM) fractional anisotropy (FA) was identified through comparison of automated ROI defined regions to age and sex-matched references.

#### RESULTS

Regions with highest prevalence of abnormal NR-index included the bilateral cerebellar grey matters, lateral ventricles, pallidi and the right temporal lobe. Significant left-right asymmetry was seen in the frontal lobes in 31%, in parietal lobes in 25%, in occipital lobes, and in temporal lobes in 31% of the participants, while the pallidi were most likely to demonstrate left-right asymmetry among subcortical regions. Similarly, Figure 1 demonstrate a significant left-right asymmetry in the average perfusion z-score map of all participants, with a distinct right frontal: left parietal, coup-contrecoup pattern. WM FA was found to be abnormally low ( $< -2$  z-score) in 7.3% and 9.1% of participants in the right and left internal capsules. Rate of FA abnormality was even lower in the splenium (3.6%) and genu (1.8%) of IC, right and left parietal WM (0% AND 3.6), and right and left frontal WM (1.8% and 0%).

#### CONCLUSION

Asymmetric abnormalities in brain perfusion are common in chronic post TBI setting and their prevalence exceeds those of volumetric or diffusion abnormalities.

#### CLINICAL RELEVANCE/APPLICATION

This work establishes the added importance of advanced neuroimaging techniques, namely perfusion imaging, in identifying evidence of chronic TBI.

### Differences in Corpus Callosum White Matter Integrity in mTBI Patients with and without PTSD Comorbidity

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Priya Santhanam, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aims to compare corpus callosum diffusion tensor imaging (DTI) findings in mild traumatic brain injury (mTBI) patients who presented either with or without post-traumatic stress disorder (PTSD) symptomology.

#### METHODS AND MATERIALS

DTI and clinical data were obtained from retrospective chart review of 451 civilian patients (mean age 43 years, range 13-82) with clinically diagnosed mTBI. Patients were identified as having PTSD if presenting with signs and symptoms consistent with the Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-V) diagnostic criteria. The corpus callosum and its subregions (anterior/inferior, anterior, mid-body, posterior, posterior-inferior) were defined by hand tracing in Olea Sphere (v3.0 SP12). Fractional anisotropy (FA) values were compared between patients with mTBI only and those with mTBI+PTSD by Mann-Whitney U test.

#### RESULTS

FA was lower in patients with mTBI+PTSD as compared to those with mTBI only in the corpus callosum overall and within all subregions. Statistical comparisons between groups found FA was significantly lower in the whole corpus callosum ( $p < 0.001$ ) as well as in the anterior/inferior ( $p = 0.003$ ), anterior ( $p < 0.001$ ), mid-body ( $p = 0.006$ ), posterior ( $p = 0.007$ ), and posterior/inferior ( $p = 0.017$ ) subregions individually.

#### CONCLUSION

Patients with mTBI and comorbid PTSD had reduced white matter integrity across the corpus callosum. While the contribution of PTSD to brain injured patients is not well-understood, some prior research indicates a possible influence of PTSD in military TBI populations. Further examination is needed to determine any mechanism for concomitant trauma and PTSD in civilian patients.

#### CLINICAL RELEVANCE/APPLICATION

White matter integrity in the corpus callosum of trauma patients may be further compromised for those with mTBI and PTSD comorbidity.

### **Black Hole Pattern on Diffusion Weighted Images (DWI) May Help Predict Placental Invasiveness in Women at High Risk for Placenta Accreta Spectrum (PAS) Disorders**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Charis Bourgioti, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To quantify placental inhomogeneity using 'black hole' pattern on diffusion weighted imaging (DWI) in women at high risk for placenta accreta spectrum (PAS) disorders; to investigate its predictive ability for presence and degree of placental invasiveness.

#### **METHODS AND MATERIALS**

Between 3/2018 and 9/2022, 59 pregnant women underwent dedicated prenatal MRI for placental evaluation with a 3.0T unit. All women underwent C-section within 6 weeks from MRI. DWI data were prospectively compiled for review by two experienced genitourinary radiologists and manual placental segmentation for each participant was performed. Black hole, a pattern previously observed by the readers only on high b value DWI, was defined by consensus as a discrete intraplacental areas of signal loss on high b value (1500) images. A semi-automated algorithm using 28.70 as a threshold pixel value was applied to locate placental holes and calculate the total number of placental voxels (3D), total number of hole voxels, volume of hole voxels (mm<sup>3</sup>) and % of hole voxels/total placental voxels. Statistical analysis was performed for possible association of the above parameters with presence and grade of PAS. Intraoperative/histological findings were the standard of reference. Statistical significance (p) was set to 0.05.

#### **RESULTS**

Fifty women (mean age:37 years, mean gestational age:33 weeks) were evaluable and formed the study group. Significant differences were detected between normal placenta and presence of PAS regarding the total number of placental voxels (p=0.02), number of hole voxels (p=0.02) and volume of holes (p=0.03). Total number of hole voxels and hole volume were significantly lower in normal placentas than in accreta/increta (grade I/II, p=0.04, p=0.04) or percreta (grade III, p=0.005, p=0.01) cases. No differences were detected in the above parameters for PAS grading.

#### **CONCLUSION**

Total number of voxels and volume of intraplacental black holes on DWI, may serve as yet another prognosticator for PAS disorders.

#### **CLINICAL RELEVANCE/APPLICATION**

Quantification of placental inhomogeneity on functional MRI may enable the development of deep learning algorithms for predicting PAS disorders.

### Evaluating Fetal Bowel Wall Function by Ultrasound Microvascular Flow Imaging

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Xueleli Li, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study summarized the characteristics of fetal mesenteric blood flow perfusion at various gestational weeks, and aimed to establish the feasibility of microvascular flow (MV-Flow) technology in evaluating intestinal wall blood flow and function.

#### METHODS AND MATERIALS

This retrospective study analyzed 35 meconium peritonitis (MP) fetuses and 160 healthy fetuses in our medical center from March 2020 to December 2022. The vascular index (VI) of superior mesenteric artery region obtained by automatic ellipse method and manual method were compared. The correlation between the region of interest VI and gestational weeks was analyzed. A subgroup analysis of MP operative group vs. MP non-operative group was performed, and a prediction model for surgical treatment was established.

#### RESULTS

There was no difference in VI value of the mesenteric blood perfusion region between automatic ellipse method and manual method ( $51.40 \pm 8.58\%$  vs  $50.82 \pm 8.05\%$ ,  $p=0.534$ ). There was no significant change in VI as the gestational age increased (correlation coefficient=0.005,  $p=0.946$ ). Compared with MP non-operative group, the operative group has significantly more cesarean deliveries (100% vs 52.9%,  $p=0.003$ ), shorter pregnancy duration ( $34.76 \pm 2.16w$  vs.  $37.48 \pm 1.55w$ ,  $p<0.001$ ), lower infant weight ( $2762.141 \pm 452.76kg$  vs.  $3225.88 \pm 339.98kg$ ,  $p=0.003$ ), more persistent ascites cases (92.9% vs. 52.9%,  $p=0.021$ ), more intestinal wall echo reduction cases (57.1% vs. 5.9%,  $p=0.004$ ), and lower VI ( $18.57 \pm 5.51\%$  vs.  $39.41 \pm 7.02\%$ ,  $p<0.001$ ). In risk factor analysis, VI value was significantly associated with surgical treatment after birth (OR=0.689; 95% CI: 0.511-0.929). A prediction model for surgical treatment of newborns was established: Logit (P)=8.86 - (0.37\* VI) +(1.49\* ascites). The AUC of the ROC curve of the prediction model is 0.857 (95% CI: 0.75-0.95), with 78.6% sensitivity, and 88.2% specificity.

#### CONCLUSION

MV-Flow imaging can quantify the fetus bowel wall blood flow perfusion. There is no correlation between the VI value of mesenteric regional blood flow perfusion and gestational week. In fetuses with meconium peritonitis, the VI value of mesenteric blood flow is significantly reduced, suggesting the increased possibility of intestinal wall necrosis and post-natal surgical treatment.

#### CLINICAL RELEVANCE/APPLICATION

The findings of the current study provide information about evaluating fetus bowel wall function using ultrasound MV-Flow imaging, which could improve the prenatal diagnosis of meconium peritonitis in the fetus, and predict surgical treatment after birth.

### Usefulness of the Air Gap Methods during Pediatric Computed Tomography

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Takanori Masuda, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Purpose: The air gap methods can be used as the primary scatter reduction method in order to reduce patient dose. The purpose of this study was to compare the radiation dose and image noise between conventional setting and air gap setting methods during the pediatric chest computed tomography (CT).

#### METHODS AND MATERIALS

We used newborn pediatric anthropomorphic phantom with a 64 detector-row CT scanner with helical scan modes from the apex of the lung to the diaphragm. Compare with the conventional setting (group A), the pediatric anthropomorphic phantom was positioned 10 cm away from the table using a plastic with low X-ray absorption in air gap methods (group B). A real-time skin dosimeter (RD - 1000; TORECK CO, Kanagawa, Japan) was placed and inserted into the phantom center of the body, the surface of the body back, and the right and left mammary glands. The phantom was then scanned 10 times using each protocol. The measured dose values of the RD - 1000 were compared for each methods.

#### RESULTS

The measured dose values of the group A were 1.44 at the center, 1.46 at the back, and 1.64 at the mammary gland, respectively. The measured dose values of the group B were 1.30 at the center, 1.35 at the back, and 1.53 at the mammary gland, respectively. Compared with the Group A, it was possible to reduce the exposure dose by approximately 10% at the group B ( $p < 0.05$ ). The image noises were 9.3 HU at the group A and 8.0 HU at the group B. Compared with the Group A, it was possible to reduce the image noise by approximately 15% at the group B ( $p < 0.05$ ).

#### CONCLUSION

By using the air gap methods, it is possible to reduce the exposure dose and image noise approximately 10 % during pediatric chest CT.

#### CLINICAL RELEVANCE/APPLICATION

The reduction of the radiation dose and image noise according to the as low as reasonably achievable (ALARA) principle requires optimizing the scan protocol by using air gap methods.

### Comparison of Conventional and Compressed SENSE Sequences on MRI of Brain in Paediatric Population

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Isha S. Shah, MBBS (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare the quality and image acquisition time between conventional and Compressed SENSE sequences on magnetic resonance imaging (MRI) of brain in paediatric population.

#### METHODS AND MATERIALS

Thirty children (below the age of 18 years) undergoing MRI of brain were included in this study after obtaining Ethical clearance from the institute. In addition to the routine clinical protocol for brain, one Compressed SENSE sequence was added. 2D - T1, T2, and FLAIR axial sequences were acquired for brain using conventional and Compressed SENSE techniques. One of each sequence was acquired in 10 patients undergoing an MRI brain study on a 3T MRI using coil 32 channel coil for adults and paediatric 8ch head coil for neonates. Two consultant radiologists (with 35 years and 5 years of experience in radiology) independently scored the image quality using the 5-point Likert scale based on resolution, visualisation of anatomical regions, grey-white matter differentiation, sharpness of the image and artefacts. The subjective criteria details for image quality as per the 5-point Likert scale were: non-diagnostic (1), poor (2), moderate (3), good (4) and excellent (5). 2D T1 sequence was acquired with parameters as FOV 230\*183\*130mm, voxel size 0.575\*0.75, TE-20ms, TR-2000ms, CS factor-2, 2D T2 sequence was acquired with parameters FOV 230\*230\*149mm, voxel size 0.55\*0.65, TE-3000ms, TR-80ms, CS factor-2.2 and 2D FLAIR was acquired with parameters FOV 210\*168\*149mm, voxel size 0.7\*1.42mm, TE-140ms, TR-11000ms, CS factor-2.

#### RESULTS

The time reduction achieved with 2D T1 at 2 reduction factor were 60 seconds(24%), with 2D T2 at reduction factor of 2.2 66 seconds(47.83%) and with 2D FLAIR at reduction factor 2 66 seconds(40%). Inter-rater agreement for overall diagnostic confidence was rated higher for Compressed SENSE (k - 0.632) than conventional (k - 0.464). Nonsignificant statistical difference was found regarding image quality and image contrast ratio between both techniques.

#### CONCLUSION

Compressed SENSE has potential in reducing the image acquisition time without compromising the image quality and diagnostic confidence. Motion artefacts are also reduced with reduction in time with the use of Compressed SENSE sequence.

#### CLINICAL RELEVANCE/APPLICATION

Acceleration achieved with compressed SENSE sequences can cause an overall reduction in the acquisition time without compromising image quality. This consequently results in reduction of anaesthetic dose administered which is of clinical concern in paediatric population.

### **Preliminary Study on the Clinical Staging of Primary Lower Extremity Lymphedema by STIR Soft Tissue Radial Measurements**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

MENGKE LIU (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Exploring the value of magnetic resonance-based measurement of two-dimensional radial data of the limb in assessing the clinical staging of primary lower extremity lymphedema (PLEL)

#### **METHODS AND MATERIALS**

A retrospective collection of 132 patients diagnosed with primary LEL by our hospital was made, and all patients underwent MR examination of the lower extremities. Short Time Inversion Recovery (STIR) sequences were used to measure the total longitudinal and transverse soft tissue diameter (TD), musculoskeletal diameter (MD) and subcutaneous soft tissue diameter (S) of the lower leg, and the difference between TD and SD on the affected and the healthy side (DTD, DSD) were calculated respectively. The patients were staged according to the International Society of Lymphology (ISL) clinical staging criteria in 2020. Statistical analysis of all measurements was performed to determine the feasibility of MRI measurements for clinical staging of PLEL

#### **RESULTS**

The correlation between the transverse diameter TD ( $R=0.492$ ), SD ( $R=0.596$ ), DTD ( $R=0.608$ ), and DSD ( $R=0.620$ ) and clinical stage was significantly greater than that between the longitudinal diameter TD ( $R=0.430$ ), SD ( $R=0.532$ ), DTD ( $R=0.547$ ), and DSD ( $R=0.519$ ), and the highest correlation between the transverse diameter DSD and clinical stage. The values of TD, SD, DTD and DSD in stage I were significantly lower than those in stage II and III ( $P<0.05$ ), but there was no significant difference between stage II and III ( $P>0.05$ ). The area under the curve (AUC) of the transverse diameter to identify clinical stage was greater than that of the longitudinal diameter, with the transverse DSD (AUC=0.930) having the highest AUC value to identify stage I with stage II.

#### **CONCLUSION**

Based on the fact that MRI measurement of soft tissue trajectories can be used as a quantitative method for clinical staging of unilateral PLEL. We recommend the subcutaneous soft tissue difference of transverse diameter as the best measure to distinguish stage I from stage II lymphedema

#### **CLINICAL RELEVANCE/APPLICATION**

MRI can quantitatively assess the severity of primary lower extremity lymphedema, facilitating clinical decision making and improving prognosis.

W5A-SPPH-11

### **Radiomics Based on MRI to Distinguish between Stage I and II Primary Lower Extremity Lymphedema**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

MENGKE LIU (*Presenter*) Nothing to Disclose

#### **PURPOSE**

A feasible and valid method for detecting and staging LEL would facilitate clinical development of appropriate treatment and management strategies. The present study aims to establish an MRI-based imaging radiomics model and a radiomics-clinical model for primary lower extremity lymphedema (LEL) and to evaluate its role in identifying the clinical stages (stages I-II) of primary LEL.

#### **METHODS AND MATERIALS**

96 patients with primary LEL were retrospectively collected (67 in the training cohort and 29 in the validation cohort) and classified into stage I and II according to the International Society of Lymphology (ISL) clinical staging criteria. Radiomics features were extracted automatically from the region of interest (ROI) manually outlined on the Short Time Inversion Recovery (STIR) sequence images by radiologists applying the Dr. Wise Multimodal Research Platform. Selected radiomics features were retained to construct the radiomics model. Clinical factors that are statistically significant in identifying stages I and II were selected, and a radiomics-clinical model combining imaging radiomics features and significant clinical factors was established. The performance of the two models was evaluated using ROC curves. The clinical usefulness of the models was assessed using decision curve analysis (DCA).

#### **RESULTS**

A total of 1743 radiomics features were extracted, then the features were filtered by F Test, and finally, 20 features were selected to construct the radiomics model. The radiomics-clinical model, which was based on the radiomics signature and 4 clinical factors, showed superior discriminatory efficacy compared with the radiomics model alone (area under the curve (AUC) in the training cohort: 0.997 vs. 0.961, the validation cohort: 0.914 vs. 0.900). The clinical usefulness of radiomics-clinical model was confirmed by DCA.

#### **CONCLUSION**

The MRI-based radiomics model was able to effectively identify the clinical stages I and II of primary LEL. The discrimination performance of the radiomics-clinical model was superior to that of the radiomics model alone.

#### **CLINICAL RELEVANCE/APPLICATION**

A MRI-based radiomics model has the ability to identify the clinical stages of LEL of primary LEL.

### White Matter Clustering using Conformal Mapping

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Elena Greco, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Diffusion Tensor Imaging (DTI) facilitates the delineation of white matter fiber tracts in the brain. Clustering white matter fiber bundles by various methods has been a research focus over the past decade. We propose a deep neural network which requires a novel approach to data normalization, augmentation, and problem formulation.

#### METHODS AND MATERIALS

Conformal mapping is a technique used to establish a bijective mapping of one shape into its topologically equivalent target shape; the bijectivity ensures that the mapping is invertible and unique. We used volumetric transformations in which not only the surface of the shape is reshaped into the target shape but every point inside the shape is also transformed. Eleven epilepsy patients without structural brain abnormalities were retrospectively reviewed. Diffusion-weighted imaging was obtained with a multiband spin-echo echo planar imaging sequence on a 3 Tesla MR system (Siemens Vida or Prisma) using a 64-channel head and neck coil. A total of 64 diffusion directions were obtained. Diffusion data were preprocessed, and orientation distribution function was estimated. Whole brain tractography was then created using deterministic tracking. Fiber tracts from the 11 patients are mixed forming the dataset comprising 2469292 fiber tracts. The dataset was divided into training, test, and validation sets in a 3:1:1 ratio. The neural network classifier is based on the VGG 16 architecture and contains two convolution layers with 32 and 64 feature maps followed by two fully connected dense layers. The network uses rectified linear units as the activation function. Fiber tracts with length less than 30 mm or greater than 300 mm are filtered out, and all the fiber tracts are resampled to contain 50 points, flipped in order, and convolved with a 1D Gaussian filter for data augmentation. The fiber tracts are then mapped into a spherical space using the conformal mapping. The neural network is trained with a batch size of 500 fibers, a learning rate of 0.0001, and categorical cross-entropy is minimized using Adam optimizer in 10 epochs.

#### RESULTS

The confusion matrix for the classification is shown in figure 1. All accuracies for 26 tracts exceeded 0.890379.

#### CONCLUSION

We presented a deep learning framework for clustering white matter fibers using a volumetric conformal mapping approach and the initial experiments showed promising results.

#### CLINICAL RELEVANCE/APPLICATION

We aim to automate this process and further this algorithm such that the deep learning tools can eliminate all the noisy fibers and identify the appropriate anatomical clusters based on whole brain tractography. We also aim to expand this algorithm to identify white matter tracts in the presence of pathologies that can change the anatomy of the tracts.

### Investigation of the Inherent Challenges Associated with Quantitative $^{90}\text{Y}$ PET-CT Imaging towards Improved Dosimetric Accuracy in $^{90}\text{Y}$ SIRT Therapies

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Niamh McArdle, BSc, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Yttrium-90 ( $^{90}\text{Y}$ ) PET-CT imaging for dose verification following  $^{90}\text{Y}$  selective internal radiation therapy (SIRT) has a number of associated dosimetric quantification challenges. SIRT tumours can be irregularly shaped, multi-nodular and have heterogeneous activity distributions. Partial volume effects (PVE) and high background activity due to low number of true coincidences further contribute to degradation of quantification accuracy. Accordingly, the objective of this research is to further investigate the effects of PVE, heterogeneity and background activity in  $^{90}\text{Y}$  PET-CT imaging, towards more accurate patient dosimetry for  $^{90}\text{Y}$  SIRT therapies.

#### METHODS AND MATERIALS

$^{90}\text{Y}$  PET-CT imaging datasets were acquired using a Siemens Biograph Horizon PET-CT scanner. 3D-printed non-spherical objects, representative of clinical data and designed using a novel radiomics analysis approach, were employed to assess the effects of PVEs for non-spherical lesions. Recovery Coefficient (RC) curves were generated by filling spherical and non-spherical objects with known  $^{90}\text{Y}$  activities, submerged in a water phantom for a range of object-to-background ratios (10:1, 20:1, 25:1, 30:1). The effects of tumour heterogeneity was investigated using novel 3D-printed phantoms, with phantom infills of 0%, 20%, 40% and 60%.  $^{90}\text{Y}$  sensitivity measurements and the effects of inherent background activity from the lutetium oxyorthosilicate crystals were investigated using an anthropomorphic thorax phantom, assessing noise levels in the lung and liver fields.

#### RESULTS

The effects of heterogeneous distributions and PVE for spherical and non-spherical objects on the quantitative accuracy of  $^{90}\text{Y}$  PET-CT imaging will be presented. In addition, results on the implications of background activity on quantitative  $^{90}\text{Y}$  imaging will be quantified by means of noise equivalent count rate, background variability and contrast recovery. Correction factors accounting for heterogeneity, PVE,  $^{90}\text{Y}$  activity recovery (0.84) and LSO background activity (4 - 8 kBq/ml) will be investigated and presented.

#### CONCLUSION

Inherent background activity, low PET count rate, high random fractions and PVEs at small volumes are some of the inherent challenges associated with quantitative  $^{90}\text{Y}$  PET-CT imaging following SIRT therapies. Evaluating and correcting for these limitations is necessary to improve quantification accuracy, and for identifying any mismatch between pre- and post-treatment dosimetry, thus allowing for improvements towards improved personalised dosimetry.

#### CLINICAL RELEVANCE/APPLICATION

This research aims to improve the quantitative accuracy of  $^{90}\text{Y}$  PET-CT imaging post SIRT therapy to facilitate improved accuracy in the dosimetry estimation for SIRT therapy patients.

### Deep Learning Image Reconstruction Impacts on Robustness of CT Radiomics Features: Opportunity for Minimizing Radiomics Variability

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Jingyu Zhong, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the influence of deep learning image reconstruction (DLIR) on robustness of CT radiomics features.

#### METHODS AND MATERIALS

A standardized phantom with sixteen clinical-relevant densities was scanned under single-energy CT (SECT) and dual-energy CT (DECT) modes at standard and half (20 and 10 mGy) dose level. Images of SECT 120 kVp and corresponding DECT 120 kVp-like virtual monochromatic images were generated with six reconstruction algorithms: filtered back-projection (FBP), adaptive statistical iterative reconstruction-Veo at 40% (AV-40) and 100% (AV-100) blending levels, and DLIR algorithm at low (DLIR-L), medium (DLIR-M) and high (DLIR-L) strength levels, resulting twenty-four image sets. 94 radiomic features were extracted via Pyradiomics. Reproducibility of radiomic features was evaluated between SECT and DECT scan modes, between standard and half dose levels, across reconstruction algorithms in reference to FBP images, and across all image sets, using intraclass correlation coefficient (ICC) and concordance correlation coefficient (CCC).

#### RESULTS

The average percentage of features with ICC > 0.90 and CCC > 0.90 were 11.35% and 11.17% between SECT and DECT scans. The reproducibility between scan modes did not obviously changed with the increasing strength level of DLIR algorithm. The average percentage of features with ICC > 0.90 and CCC > 0.90 between images acquired at 10 and 20 mGy dose levels were 28.55% and 27.40%. The reproducibility between dose levels increased with the increasing strength level of DLIR algorithm within SECT scans, but DLIR-M images showed highest reproducibility within DECT scans. The average percentage of features with ICC > 0.90 and CCC > 0.90 in reference to FBP images decreased from 27.93% to 17.82%, and from 27.66% to 17.29%, respectively, with the increasing strength level of DLIR. The AV-40 images resulted average percentage of features with ICC > 0.90 and CCC > 0.90 of 26.06% and 25.80% in reference to FBP images, and 18.88% and 18.62% for AV-100 images, respectively. Within SECT scans, DLIR-H images at 10 mGy presented percentage of features with ICC > 0.90 and CCC > 0.90 of 79.78% and 76.60%, respectively, comparing to DLIR-M images at 20 mGy.

#### CONCLUSION

DLIR and IR algorithms potentially alters minable information in images, while DLIR algorithm provides opportunity for minimizing radiomics variability.

#### CLINICAL RELEVANCE/APPLICATION

DLIR and IR algorithms potentially alters deeper information hidden in the images, indicating that radiomics models based on images with different reconstruction algorithms must be interpreted with caution. However, DLIR algorithm has potential for minimizing radiomics variability, which opens possibility for generalizable radiomics model.

### Using Fully Synthetic Training Data to Automate Clinical CT-ACR Phantom Analysis

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Morgan A. Daly, BSc (*Presenter*) Nothing to Disclose

#### PURPOSE

We aim to illustrate the feasibility of using a convolutional neural network (CNN) trained solely on simulated input data to perform meaningful clinical medical physics tasks. We demonstrate this by automating detection and alignment of the HU module of the CT-ACR phantom (Gammex 464).

#### METHODS AND MATERIALS

All training and validation data was generated on-the-fly using a computational phantom generator that uses four parameters to control phantom placement: x and y position, simulated reconstruction field of view (FOV), and rotation. These were randomly sampled in the ranges: x, y position: [-50 mm, 50 mm], FOV: [200 mm, 510 mm], and rotation: [-50°, 50°]. A ResNet50-based network was trained to predict a feature vector consisting of the x, y position, FOV, and rotation for a given input 256x256 phantom image. The model was evaluated on 5 clinical images of the HU module acquired on a Siemens Force scanner with labels manually calculated by aligning simulated phantoms with the clinical image. Mean absolute error (MAE) between the network-predicted features and manually aligned features were quantified and reported, and a visual assessment was performed.

#### RESULTS

The MAE of the features produced by the model on a computational phantom test set (n=100) were:  $x=0.90 \pm 0.6\text{mm}$ ,  $y=0.53 \pm 0.4\text{mm}$ ,  $\text{FOV}=2.81 \pm 1.9\text{mm}$ ,  $\text{rotation}=0.84 \pm 0.7$ . The MAE of the transformations produced by the CNN on the set of 5 real ACR phantom scan images:  $x = 2.77 \pm 5.0$ ,  $y = 9.72 \pm 20.3$ ,  $\text{FOV} = 17.78 \pm 24.4$ ,  $\text{rotation} = 3.52 \pm 4.2$ . In a visual assessment, the model achieves excellent agreement with clinical scans that are moderately misaligned (the likeliest to occur in routine practice). In one test case with more substantial misalignment (a large FOV) the disagreement between the input and the model prediction was apparent.

#### CONCLUSION

The trained network does an acceptable job of predicting the correct parameters to align the HU module of the CT-ACR phantom, which can be used to automate phantom analysis. Methodologically, we have illustrated that CNNs trained on fully-synthetic data can be directly applied to clinical tasks, and additional augmentation of the synthetic data (e.g., noise, table-like objects in frame) could further improve performance. Finally, we hope that interpretable feature outputs will help build confidence in the broader use of clinical AI in medical physics and quantitative imaging.

#### CLINICAL RELEVANCE/APPLICATION

These methods could generalize automated analysis to any phantom without the need for image acquisition or manual annotation. Synthetic data as ground truth could aid in training networks for more complex clinical/medical tasks.

### A Comparison Among LowRes, HighRes and Cascaded CNNs for Segmentation of Cardiac CT Images in TAVR Patients

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

James W. Goldfarb, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Cardiac CT is routinely used for pre-planning aortic valve repair. Segmentation of cardiac structures would enable the calculation of several quantitative values (e.g., EF, LVM). The optimal convolutional neural network (CNN) for this task can be limited by hardware memory, compute power, and segmentation speed. We compared the segmentation of cardiac CT images using three CNN architectures to determine which anatomical structures require a larger CNN.

#### METHODS AND MATERIALS

We used 56 training and 200 testing contrast CT angiograms in patients with aortic valve disease for TAVR planning. Eleven regions were annotated for training: AscAorta, DescAorta, InfVenaCava, LeftAtrium, RightAtrium, LeftVentricle, RightVentricle, LVMycardium, and aortic valve leaflets (calcified and non-calcified). We trained three CNN 3DUnet architectures with increasing memory and compute requirements: LowRes, HighRes, and Cascaded. We statistically analyzed the Dice Coefficient (DC), Intersection-over-Union (IoU), and volumes of regions at systole and diastole. Visual assessment of 3D renderings was performed to detect failed segmentations.

#### RESULTS

DC and IoU were slightly higher ( $p < 0.001$ ) for the cascaded network compared to the low and high resolution CNNs (DC: 0.93 vs 0.92, 0.92) and (IoU: 0.87 vs 0.86, 0.86). Although the segmentation volume intraclass correlation (ICC) was excellent (0.94-0.99), 10% of the HighRes segmentations had at least one region with a failed segmentation vs 2% of LowRes vs 0% of the cascaded CNN ( $p < 0.001$ ). The cascaded CNN had a small (0.6% +/- 0.58%) difference in large structures but a larger difference in smaller calcified structures (18.73% +/- 13.8%).

#### CONCLUSION

A cascaded CNN performs the best both qualitatively and quantitatively. For segmentation of large structures such as the left ventricle, small segmentation errors do not affect quantitative values. However, for finer segmentation such as aortic valve calcium or calcified leaflets, a cascaded or high-resolution network is necessary.

#### CLINICAL RELEVANCE/APPLICATION

For segmentation of large structures such as the left ventricle or left atrium, a LowRes CNN is sufficient. However, if higher resolution structures are also segmented (as is done in an aortic valve calcium score), a cascaded CNN is necessary. This has implications for the required GPU/CPU memory and compute power for timely segmentation, especially when the typical 20 cardiac phases are segmented.

### High Spatial Resolution Diffusion Tensor Imaging Aided by Synthetic-MRI: An Application of Sixfold Multiparameter Quantitative MRI (MP6-qMRI)

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Hernan Jara, PhD (*Presenter*) Author with royalties, World Scientific Publishing;

#### PURPOSE

In diffusion tensor MR imaging (DTI), the spatial resolution of the mean diffusivity (MD) and fractional anisotropy (FA) maps depend on the spatial resolution of the diffusion encoded images ( $b > 0$ ) as well as the  $b_0$  images. We investigate spatial resolution improvements in DTI maps resulting from using high spatial resolution synthetic  $b_0$  images as substitute to the standard  $b_0$  images, which are acquired at lower resolution to shorten scan time.

#### METHODS AND MATERIALS

Two healthy volunteers (37yo male, and 59yo male) were scanned with local IRB approval. The modular MP6-qMRI turbo spin echo (TSE) pulse sequence was implemented on a 3T Ingenia Elition X whole body scanner (Philips Healthcare) by concatenating with same pre-scan settings high resolution Triple-TSE and half in plane spatial resolution DTI-TSE modules (Fig. 1A). All modules were implemented without fat suppression and generated 80 contiguous slices. Key scanning parameters were a) Triple-TSE modules (9.5min):  $TR_{long} = 16s$ ,  $TR_{short} = 0.5s$ ,  $TE_1 = 10ms$ ,  $TE_2 = 110ms$ , voxel =  $0.47 \times 0.47 \times 2mm^3$  and b) DTI module (11min):  $TR = 25.4s$ ,  $TE_{eff} = 72ms$ , voxel =  $0.94 \times 0.94 \times 2mm^3$ . The unified MP6-qMRI relaxometry and DTI processing pipeline was programmed in Python (version 3.9.13) with the Anaconda Navigator (version 2.3.2). The primary (nPD-T1-T2) qMRI maps were calculated according to the Bloch equation solution as applicable for the Triple-TSE pulse sequence. DTI maps were calculated according to the Bloch-Torrey equation as in DIPY tensor reconstruction (<https://dipy.org/>).

#### RESULTS

For both volunteers, the MP6-qMRI framework yielded high quality MD (Fig. 1B) and FA (Fig. 1C) maps with full head coverage and with imperceptible geometric distortion artifacts. Furthermore, MD and FA maps obtained with calibrated synthetic  $b_0$  had superior spatial resolution providing improved anatomic delineation that is most noticeable for white-to-gray matter differentiation and for improved delineation of the extra cranium.

#### CONCLUSION

Added benefits of using turbo spin echo multiparameter qMRI frameworks are the opportunities of reducing magnetic inhomogeneity distortions, and of increasing the spatial resolution of DTI maps (MD and FA) by means of Synthetic MRI. Hence, MP6-qMRI can extend the usefulness of DTI to magnetically inhomogeneous regions such as the extra-cranium and the neck and with higher spatial resolution.

#### CLINICAL RELEVANCE/APPLICATION

Use of turbo spin echo based MP6-qMRI and Synthetic MRI can extend clinical applications of diffusion tensor MRI for assessing the extra-cranium and nasal cavity structures with negligible geometric distortions.

### To Biopsy or Not to Biopsy? Feasibility of Predicting Gleason Score as a Pre-biopsy Gatekeeper in Prostate Cancer Patients using Multimodal Patient Features

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Nathalie Mertens (*Presenter*) Nothing to Disclose

#### PURPOSE

The diagnosis of prostate cancer (PCa) is based on a prostate biopsy. Even though this diagnosis is important for further treatment decision, a biopsy is painful and can result in adverse effects for the patient. In this study, we aim at developing a biopsy gatekeeper by predicting the Gleason score (GS) using a machine learning (ML) classification model. Therefore, results from various diagnostic screening examinations are combined with patient-specific variables to explore the feasibility of a binary ML model to predict GS >6 and thus the need for biopsy in PCa patients.

#### METHODS AND MATERIALS

Patients screened in our hospital (n=295) underwent a digital rectal examination (DRE), transrectal ultrasound (TRUS) and a screening magnetic resonance (MR) examination. Preceding the MR examination, prostate-specific antigen (PSA) and prostate health index (PHI) blood tests were acquired on the same day. Patients obtained a TRUS-guided biopsy to detect PCa, as determined by the GS. Various classification models were explored to predict GS <7 and =7 using 7 features: TRUS- and DRE findings, PSA and PHI density results, prostate imaging-reporting and data system (PI-RADS) score, as well as patient-specific variables being age and genetic risk. 28 model architectures are constructed by combining 3 components: (1) a scaler (Robust or Standard); (2) a sampler to balance the dataset (Synthetic Minority Oversampling TEchnique or Adaptive Synthetic) and (3) a classifier (Logistic Regression - LR, Random Forest, K-Nearest Neighbours, Decision Tree, Support Vector Machine - SVM, Gaussian Naive Bayes - GNB, or Gradient Boosting). To minimize bias, a stratified 10-fold cross validation is implemented. Hyperparameter tuning for the 28 model architectures resulted in training 2188 models. All models are trained to maximize the area under the curve (AUC). The classification is done with threshold set to 0.35.

#### RESULTS

The AUC for predictions of GS is 0.77 (95% CI 0.67-0.87). 3 features, being PI-RADS, PHI density and age, were revealed as significant predictors for GS ( $p=0.006$ ,  $p=0.001$  and  $p=0.001$  respectively). This finding was confirmed by the selectKBest algorithm selecting the 3 most important features for GS prediction. Repeating the model with these 3 features resulted in LR, SVM and GNB as best classifiers, with AUC respectively 0.81 (95% CI 0.66-0.97), 0.82 (95% CI 0.66-0.98) and 0.84 (95% CI 0.68-1.0).

#### CONCLUSION

This study demonstrates the potential of using a ML algorithm to predict the need of prostate biopsy. This way, physicians could opt to eliminate a biopsy which is painful for the patients and could cause adverse effects.

#### CLINICAL RELEVANCE/APPLICATION

This study aims at developing a ML model as a pre-biopsy gatekeeper to eliminate unneeded biopsies in PCa.

### Quantitative Evaluation of Primary Lower Extremity Lymphedema Staging using STIR: A Preliminary Study

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

MENGKE LIU (*Presenter*) Nothing to Disclose

#### PURPOSE

The staging of primary lower extremity lymphedema (LEL) is difficult and vital in clinical work, and Short time inversion recovery (STIR) sequence of MRI can be used for quantitative assessment of primary lower extremity lymphedema due to its high soft tissue resolution. So we evaluated the value of STIR-based soft tissue area measurements for staging primary lower extremity lymphedema.

#### METHODS AND MATERIALS

90 consecutive patients with clinically diagnosed primary lower limb lymphoedema from January 2017 to December 2019 in Beijing Shijitan Hospital were enrolled retrospectively. STIR sequence was applied to measure the total, muscle, bone, and subcutaneous areas in the upper 1/3 level of the bilateral lower calf. The difference between the affected and unaffected calf regarding the subcutaneous area was obtained.  $(\text{Subcutaneous area})/(\text{bone area})$  and  $(\text{subcutaneous area})/(\text{muscle area})$  were calculated. According to the International Society of Lymphology (ISL) clinical staging standard in 2020, all patients were divided into stages I, II and III. Statistical analysis was performed to determine the validity of MRI measurements in staging LEL.

#### RESULTS

Clinical stages were I in 33 patients, II in 44 patients, and III in 13 patients. There are significant differences in the difference in subcutaneous area of limbs, subcutaneous/bone and subcutaneous/muscle between stage I and II as well as between stage I and III ( $P < 0.001$ ), but not between stage II and III ( $P = 0.706, 0.329, 0.229$ , respectively). There was a positive correlation between the clinical stage and difference in subcutaneous area of limbs ( $\rho = 0.752, P < 0.001$ ), subcutaneous/bone ( $\rho = 0.747, P < 0.001$ ) and subcutaneous/muscle ( $\rho = 0.709, P < 0.001$ ). For staging primary lower extremity lymphedema, receiver operator characteristic (ROC) curves indicated that difference in subcutaneous area of limbs had the best discrimination ability among parameters [area under the ROC curve (AUC) = 0.950; 95% Confidence Interval (CI): 0.875 - 0.987; sensitivity: 95.45%, specificity: 84.85%], followed by subcutaneous/bone [AUC = 0.930; 95%(CI): 0.848 - 0.975; sensitivity: 77.27%, specificity: 93.94%] and subcutaneous/muscle [AUC = 0.895; 95%(CI): 0.804 - 0.953; sensitivity: 77.27%, specificity: 90.91%].

#### CONCLUSION

The measurement of the soft tissue area by STIR may be used as an auxiliary method for staging primary lower extremity lymphedema. For patients with unilateral primary lower extremity lymphedema, the difference in subcutaneous area of limbs could be a specific indicator to distinguish clinical stage I from II.

#### CLINICAL RELEVANCE/APPLICATION

STIR enables quantitative assessment of primary lower extremity lymphedema.

W5A-SPRO-1

### Can Serial Brain Metastases MRI Radiomics Kinetics Predict Stereotactic Radiation and Immunotherapy Outcomes?

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Hesham Elhalawani, MD, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Radiation necrosis (RN) remains to be the primary dose-limiting toxicity of stereotactic radiosurgery (SRS), especially in combination with immunotherapy (IO). This debilitating adverse event is often confused with tumor regrowth, posing significant diagnostic and therapeutic challenges. This study employed magnetic resonance imaging (MRI) radiomics to quantify sub-acute radiation-induced changes in irradiated BM and their value in predicting treatment response.

#### METHODS AND MATERIALS

Following IRB approval, we queried our single-institution dataset to identify adult patients with brain metastases managed with SRS and IO between 2006 and 2021. We collected patient, disease, and treatment variables. Specifically, per-BM outcomes were categorized as RN (radiographic and/or symptomatic), progressive disease (PD), or neither (NA). All patients had diagnostic pre- and post-SRS contrast-enhanced T1-weighted MRIs. Individual BMs were manually segmented in MIM Software (Beachwood, OH). 1061 hand-crafted radiomic features were computed per lesion using IBEX Software. Feature reduction followed using Spearman's correlation coefficient (0.3 cut-offs). Simple then multiple nominal logistic regressions (SLR and MLR) with Bonferroni correction ensued to model the risk of RN, PD, or NA using JMP software.

#### RESULTS

92 patients with 301 BM of NSCLC, melanoma, and renal cell carcinoma primaries were included. All patients received brain SRS and IO. RN, PD, or NA occurred in 74 (24.6%), 75 (24.9%), and 152 (50.5%) BM, respectively. 39 radiomic features significantly changed post-SRS ( $p < 0.01$ ). Using MLR modeling, we created a 3-feature radiomic RN predictor (ROC AUC 0.71). The model included post-SRS BM surface area, texture (GLCM 3D Homogeneity), and pre-RT BM roundness. A 5-feature radiomic signature could predict RN and PD risk (ROC AUC 0.71) based on pre-SRS GLCM 3D texture feature, 3 post-SRS shape features (surface area, mean breadth, and roundness), in addition to delta-volume.

#### CONCLUSION

SRS and IO induce changes in BM shape, MRI texture, and signal intensity that radiomics can capture. Pre-SRS, post-SRS, and percent changes of these radiomic feature values could correlate to post-therapy tumor control or radiation necrosis. Pursuing model external validation, combination with clinical variables, and integrating other MRI sequences is imperative before larger-scale adoption of this novel diagnostic approach.

#### CLINICAL RELEVANCE/APPLICATION

The premise of our study is to employ to develop an artificial intelligence-powered MRI radiomic predictor of BM treatment outcomes. These serial 'virtual digital biopsies' could guide cost-effective follow-ups and earlier personalized interventions to improve patients' quality of life.

### Fast Imaging of Lenticulostriate Arteries by Combining High-Resolution Black-blood T1-weighted with Variable Flip Angles & Compressed Sensitivity Encoding

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Yukun Zhang (*Presenter*) Nothing to Disclose

#### PURPOSE

To visualize and characterize lenticulostriate arteries (LSAs) in a short time on a 3.0T MR scanner, we investigated the feasibility of high-resolution black-blood T1-weighted with variable flip angles (T1w TSE-VFA) accelerated by compressed sensitivity encoding (CS-SENSE) and further identify the optimal acceleration factors (AF) for routine clinical use.

#### METHODS AND MATERIALS

Twenty-five healthy volunteers (13 males, and 12 females, the age ranged from 27 to 68 years, with a median age of 58 years) and 20 patients with cerebrovascular disease (12 males, 8 females, mean age:  $64.3 \pm 8.9$  years) were prospectively enrolled. Volunteers underwent T1w TSE-VFA sequences with different AFs, including conventional sensitivity encoding (SENSE) AF=3 and CS-SENSE AF=3, 4, 5, and 6 (The scanning time was 510s, 480s, 361s, 298s, and 245, respectively) at 3 Tesla. The image quality and the display of LSAs of T1w TSE-VFA protocols were evaluated through objective evaluation (contrast ratio [CR Callosum /WM, CR Brainstem /WM, CR Ependecephalon /WM], number of LSAs, total length of LSAs, and average length of LSAs) and subjective evaluation (overall image quality, scores on LSAs). Comparisons were performed among the 5 sequences to select the best AF. All patients underwent both T1w TSE-VFA with optimal AF and digital subtraction angiography (DSA) examination, and the number of LSAs of both was compared.

#### RESULTS

The pair-wise comparisons among CS3, CS4, and SENSE3 showed no statistically significant differences in the objective measurement and subjective evaluation in (all  $P > 0.05$ , Fig.1 and Fig.2). There was no statistically significant difference in the LSA counts on 1 side measured by DSA and CS4 in patients (3, 3 - 3 and 3, 3 - 3,  $P = 0.384$ , Fig.3).

#### CONCLUSION

CS3 can provide a better LSA display but takes a long time (480s, 6% reduction); CS4 can balance the visualization of LSAs and acquisition time (361s, a 30% reduction) and is recommended for routine clinical application.

#### CLINICAL RELEVANCE/APPLICATION

T1w TSE-VFA accelerated by CS-SENSE can be used as a non-invasive head microvasculature examination in asymptomatic subjects and patients with cerebrovascular disease, which will be an important asset in preventive medicine.

### Acceleration of Time-of-flight Magnetic Resonance Angiography by Intelligence-assisted Compressed Sensing

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center

Yukun Zhang (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare the image quality of time-of-flight magnetic resonance angiography (3D TOF-MRA) accelerated by sensitivity encoding (SENSE), compressed sensing (CS), and intelligence-assisted compressed sensing (ACS) with different acceleration factors (AF) to optimize the sequence

#### METHODS AND MATERIALS

Fourteen healthy volunteers were prospectively recruited and underwent 3D TOF-MRA scans with different AFs, including SENSE AF = 3; CS AF=3; ACS AF = 3, 5, 7, and 9 (The scanning time was 189s, 170s, 165, 150s, 136, and 115, respectively) at 3.0 T. Two radiologists delineated the regions of interest (ROI) for the callosum, right and left middle cerebral artery (MCA), and adjacent white matter on raw images. The signal intensity and standard deviation were recorded for further calculation of the signal to noise ratio (SNR) and contrast to noise ratio (CNR). Meanwhile, the overall image quality of 3D TOF-MRA with different AFs and 9 pre-defined arteries structures (intracranial segment of the bilateral ICAs, the anterior cerebral artery, the MCA, the distal bilateral vertebral arteries, and the basilar artery) were scored using 4-point scale subjective criteria. The difference in measurement data and subjective score between different AFs was analyzed by pairs comparison (LSD-t test).

#### RESULTS

In the objective evaluation (Table 2), ACS7 and ACS9 had significantly lower CNR callosum than SENSE3, CS3, ACS3, and ACS5 ( $P>0.05$ ); ACS3 was significantly higher than SENSE3 in SNRR-MCA, SNRL-MCA, CNR L-MCA ( $P>0.05$ ). In the subjective evaluation (Fig.1 and Table 2), CS3, CS5, and CS9 are different from SENSE3 in overall image quality evaluation ( $P>0.05$ ); and there was no significant difference in the evaluation of arteries structures ( $P<0.05$ ).

#### CONCLUSION

Compared with SENSE and CS, the better imaging quality of craniocerebral arteries could be obtained using 3D TOF MRA based on ACS with a shorter time, especially with AF of 5

#### CLINICAL RELEVANCE/APPLICATION

Compared with SENSE and CS, 3D TOF-MRA accelerated by ACS can further shorten the scanning time while maintaining the image quality, which greatly increases the comfort and success rate of MR Scanning

### Breast Cancer Risk Models: Observations From a Multi-Site Database of Women Screened for Breast Cancer

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Emily F. Conant, MD (*Presenter*) Research Grant, Hologic, Inc; Advisory Panel, Hologic, Inc; Research Grant, OM1, Inc; Research Grant, iCad, Inc; Advisory Panel, iCad, Inc; Speaker, WebMD LLC

#### PURPOSE

With emerging interest in risk-based screening strategies and known disparities in breast cancer outcomes by race, risk models need to address gaps in risk assessment. To inform questions about the inclusion of characteristics like race in these models, we explored associations between race, breast cancer risk factors (including Gail risk score) and breast cancer detection in a large, real-world cohort.

#### METHODS AND MATERIALS

This retrospective cohort study used electronic medical record, radiology, and tumor registry data from five healthcare organizations. Women 40-79 years old with no history of breast cancer, non-missing race data, and =1 screening exam between 2016-2020, were included. Cancer detection rates (CDR) were calculated per 1,000 screens. Logistic regression models were used to estimate odds ratios (OR) and 95% confidence intervals (CI) for the associations between age, race, breast density and risk status (Gail model) and CDR.

#### RESULTS

The cohort included 1,563,019 screenings (123,371 Asian, 203,412 Black, 56,961 Other, 1,179,274 White). Both Black and White women were on average  $58 \pm 10$  years of age and slightly older than Asian or women of Other race (mean age  $54 \pm 9$  years). Asian women had significantly higher breast density versus other groups (52% mostly heterogeneously dense; 15% extremely dense tissue). Elevated breast cancer risk status varied by race; 16% Asian, 23% Black, 17% Other, 31% White. Overall CDRs (per 1,000 screens) by race were; Asian 4.9 [95% CI 4.5, 5.3]; Black 5.3 [95% CI 5.0, 5.6]; Other 4.2 [95% CI 3.7, 4.7]; White 5.2 [95% CI 5.1, 5.3]. Among women identified as elevated risk, CDRs differed slightly as compared to White women: Asian 6.6 [95% CI 5.5, 7.8]  $p=0.26$ ; Black 6.7 [95% CI 6.0, 7.5]  $p=0.05$ ; Other 4.9 [95% CI 3.7, 6.5]  $p=0.20$ ; White 5.9 [95% CI 5.7, 6.2]. After adjusting for age ( $p<0.001$ ), density ( $p<0.001$ ) and risk ( $p=0.001$ ), no statistically significant association between race and CDR remained ( $p=0.25$ ) (Figure).

#### CONCLUSION

In a large real-world cohort, we observed meaningful differences in breast cancer risk factors and risk scores by race. Racial differences in cancer detection rates do not persist after adjusting for age, breast density and Gail score. Careful consideration should be given to the use of risk models in the clinical setting. The observed misalignment in risk scores and breast cancer detection rates suggest the potential for insufficient capture of risk factors and the need to better understand the drivers of racial differences in mammography outcomes.

#### CLINICAL RELEVANCE/APPLICATION

It is critical to understand which risk factors may underlie recognized racial disparities in breast cancer burden in order to optimize risk models used to support clinical decision making for screening prioritization.

### Diagnostic Performance of Diffuse Optical Spectroscopic Imaging for Breast Cancer According to Clinical Factors

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Yeji Kwon (*Presenter*) Nothing to Disclose

#### PURPOSE

Although breast cancer screening programs have reduced the mortality rate of breast cancer patients by about 20%, the sensitivity of mammography decreases to 30-48% in dense breast. On the contrary, there are concerns regarding the potential elevation of false positive rates when ultrasound is employed. It has been suggested that optical imaging could enhance the specificity of breast imaging, but this has not been conclusively established. This study aims to evaluate the impact of clinical factors on the diagnostic performance of diffuse optical spectroscopic imaging/discrete multi-wavelength near-infrared spectrum (DOSI/DMW-NIRS) for breast malignancy.

#### METHODS AND MATERIALS

Our institutional review board granted approval for this investigation, and signed informed consent was obtained. From September 2021 to June 2022. In this study, 85 participants were enrolled, of which 23 participants were excluded. Among the exclusions, 4 participants refused to participate or had unavailable biopsy results, 4 participants had absent raw or chromophore data, and 15 participants were unavailable for analysis due to the subareolar location of the lesion. Total of 62 women with 62 breast lesions (37 malignant, 25 benign) biopsied under US guidance were analyzed. DOSI/DMW-NIRS was used to quantify the chromophores (HbO<sub>2</sub>, HHb, THC, StO<sub>2</sub>, water, lipid, and TOI) of lesions and then the computed chromophore ratios were compared to those of contralateral normal breasts. Lesions were categorized by demographic (age, BMI, bra cup size, and menstrual cycle phase) and sonographic variables (tumor diameter, depth, distance from nipple, vascularity, breast thickness, and BI-RADS category), and areas under the curve (AUCs) were compared between subgroups.

#### RESULTS

TOI ratio showed the highest AUC value (0.904, 95% confidence interval: 0.831-0.977), followed by water (0.836, 95% confidence interval: 0.736-0.936) for diagnosing breast malignancy among the seven chromophore values. TOI ratio demonstrated no significant difference in diagnostic performance among all subgroups ( $p$ -value $>0.05$ ). The diagnostic performance of water ratio differed according to breast thickness ( $p$ -value: 0.033) and distance from nipple ( $p$ -value: 0.011). The diagnostic performance of THC and HbO<sub>2</sub> differed according to BMI ( $p$ -value 0.0119 and 0.0056, respectively) and menstrual cycle ( $p$ -values: 0.011 and 0.006, respectively).

#### CONCLUSION

TOI ratio evaluated with DOSI/DMW-NIRS shows strong diagnostic performance regardless of demographic and sonographic parameters.

#### CLINICAL RELEVANCE/APPLICATION

TOI ratio evaluated with DOSI/DMW-NIRS has the potential to be generally applied to various clinicoradiologic condition to diagnose breast cancer.

### **A Systematic Review and Meta-Analysis of Online Patient Education Materials in Breast Cancer: Is Readability the Only Story**

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Joey Gu, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Online patient education materials (OPEMs) are an increasingly popular resource for women seeking information about breast cancer. The AMA recommends written patient material to be at or below a 6th grade level to meet the general public's health literacy, but breast cancer readability studies have found reading levels to be much higher than the AMA's recommended level. Metrics such as quality, understandability, and actionability also heavily influence the usability of health information, and thus should be evaluated alongside readability. A systematic review and meta-analysis was conducted to determine: 1) Average readability scores and reporting methodologies of breast cancer readability studies; and 2) Inclusion frequency of additional metrics associated with health literacy.

#### **METHODS AND MATERIALS**

A registered systematic review and meta-analysis was conducted in Ovid MEDLINE, Web of Science, Embase.com, CENTRAL via Ovid, and ClinicalTrials.gov in June 2022 in adherence with the PRISMA 2020 statement. Eligible studies performed readability analyses on English-language breast cancer-related OPEMs. Study characteristics, readability data, and reporting of non-readability health literacy metrics were extracted. Meta-analysis estimates were derived from generalized linear mixed modeling.

#### **RESULTS**

The meta-analysis included 30 studies yielding 4,462 OPEMs. Overall, average readability was 11.81 (95% CI [11.14, 12.49]), with a significant difference ( $p < 0.001$ ) when grouped by OPEM categories. Commercial and government organizations had the highest average readability at 12.2 [11.3, 13.0] and 12.0 [11.3, 12.7], respectively; non-profit organizations had one of the lowest at 11.3 [10.6, 12.0]. Readability also varied by index, with New Fog, Lexile, and FORCAST having the lowest average scores (9.4, 10.4, and 10.7, respectively). Only 57% of studies calculated average readability with more than two indices. Only 60% of studies assessed other OPEM metrics associated with health literacy.

#### **CONCLUSION**

Average readability of breast cancer OPEMs is almost double the AMA's recommended 6<sup>th</sup> grade reading level. Readability reporting is currently not standardized - multiple indices should be used and averaged together with an interval estimate to capture a more comprehensive picture of reading grade level. Additional non-readability OPEM metrics are also inconsistently reported and may help convey the usefulness of information presented.

#### **CLINICAL RELEVANCE/APPLICATION**

Beyond readability, the quality, understandability, and actionability of OPEMs are important components to aid shared decision-making and may be critical to increased screening rates and breast cancer awareness.

### Examining the Barriers to Breast Cancer Early Diagnosis in Uganda: A Prospective Study

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Adrian M. Jaramillo-Cardoso, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Women diagnosed with breast cancer (BRC) in Uganda have a 5-year mortality rate of 50%. Early diagnosis is an appropriate strategy for downstaging disease in low-resource settings, but women face significant barriers to accessing care (e.g., clinical examination, ultrasound, tissue diagnosis); assessing these barriers is a key step in designing successful programs. For the first time, we report findings from a prospective study examining the trajectory of care among Ugandan women with breast symptoms presenting for care.

#### METHODS AND MATERIALS

450 symptomatic women attending 5 community health clinics in Uganda were recruited and followed for six months. Participants completed questionnaires at baseline and six months, which collected data on demographics, barriers to care, and provider's recommendations for care (baseline), and actions taken at 6-months (follow-up). Logistic regression and multiple regression models were used to assess the relationship between delay (< or > 90 days) and sociodemographic factors. Differences in adherence to provider recommendations at 6 months were assessed via Pearson X2 test/Wilcoxon Rank Sum test.

#### RESULTS

442 (98.2%) completed follow-up. Breast lumps and pain were the main symptoms. 57.3% waited >90 d before seeking care, of whom 27.9% delayed >1 year. After multivariate analysis, rural setting (OR=13.34) and symptoms at time of presentation (OR=0.30) were significantly associated with delay. At 6 months, 184/442 (41.6%) were referred to either diagnostic imaging or tissue biopsy (+/-) imaging. 137/184 (74.5%) did not adhere to recommendations. Positive initial breast symptoms ( $\chi^2=9.3$ ,  $P=0.01$ ) and older women ( $P=0.002$ ) were more likely to follow provider's recommendations. 22/47 (46.8%) were diagnosed with breast cancer, a diagnostic yield of 46.8%. Main reasons for no action at 6 mo. for the 137 were: resolution of breast symptoms (40.0%), decision to wait for symptoms to resolve (19.2%), provider said that it was nothing to worry about (18.3%), and financial barriers (17.5%), despite 85.6% endorsing full understanding of need for follow-up. We estimated an additional 32 undiagnosed cancers in this group, a BRC rate of 12%.

#### CONCLUSION

Low adherence to follow-up recommendations for diagnostic care should be an area of focus for programs to improve BRC outcomes in Uganda.

#### CLINICAL RELEVANCE/APPLICATION

To increase effectiveness of diagnosis programs in Uganda, interventions should prioritize breast health education in the community, and removing barriers to accessing diagnostic services.

### Point of Care Breast Cancer Risk Assessment Increases Rates of Supplemental MRI Screening Among Women Undergoing Screening Mammography

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Jocelyn Cheng (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of our study was to examine the impact of providing point of care breast cancer risk assessment (CRA) with results provided to patients at the time of annual screening mammography on rates of supplemental screening completion with MRI.

#### METHODS AND MATERIALS

We performed a retrospective review of patients who underwent breast imaging from November 2019 through May 2021. We examined the total number of screening mammograms performed one year prior to the cancer risk assessment (CRA) intervention start date ( $n=5,431$ , (epoch 1) 11/1/2019-5/1/2020), the total number of screening mammograms performed in patients who completed CRA for six months after the CRA intervention start date ( $n=1,976$ , (epoch 2) 11/1/2020-5/1/2021), and the total number of patients who underwent screening mammography but did not complete CRA intervention for six months after CRA intervention start date ( $n=4,578$ , (epoch 2) 11/1/2020-5/1/2021). We used an interrupted time series design and analysis with a natural control to evaluate rate of MRI completion before and following integration of the Tyrer-Cuzick CRA screening tool. We identified which patients underwent supplemental screening with MRI during the 12 months following each time period to calculate the change in rate of supplemental screening completion based on intervention. Supplemental imaging rates with MRI was modeled over time between pre- and post-intervention windows using a generalized linear mixed model (GLMM) with sandwich estimation and assuming binary distribution where observations are nested within patients.

#### RESULTS

The cohort included 11,985 women who underwent screening mammography during the study period. During epoch 1, no patients received CRA, 0% (0/5,431). During epoch 2, 30% (1,976/6,554) received CRA and 70% (4,578/6,554) did not. Before the implementation of CRA (epoch 1), the rate of MRI was 2.8% (152/5,431). After the implementation of CRA (epoch 2), the rate of MRI among patients who did NOT undergo CRA intervention was 3.2% (144/4,578); for those who did receive CRA, the MRI rate was 6.0% (118/1,976),  $p<.05$ .

#### CONCLUSION

Receiving point of breast care risk assessment at time of screening mammography doubled the rate of follow-up screening with MRI as compared to the rate among patients who did not receive the intervention (3.1% to 6.0%,  $p<.05$ ). Our facility reached maximum capacity for MRI screening after implementation of CRA intervention; the increased volume of follow-up screening MRI following introduction of CRA was likely limited by this constraint.

#### CLINICAL RELEVANCE/APPLICATION

Study findings will inform practices about supplemental screening yield after implementation of point of care risk assessment.

### **Pushing the Envelope in Breast Conserving Surgery: Is Multiple-wire Localization (3 or more wires) Associated with Increased Risk of Compromised Margins**

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Yoav Amitai, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

In the last two decades there has been a paradigm shift with breast conserving surgery (BCS) being applied to larger and more extensive breast malignancies. The aim of this study is to examine the success of BCS being performed in patients with extensive breast malignancies requiring at least 3 wires for localization, and to assess possible risk factors for failure.

#### **METHODS AND MATERIALS**

We performed a retrospective single center review of 232 patients who underwent BCS between 2010 and 2020 requiring at least 3 wires for localization. The cohort included a control group of 232 single-wire BCS patients chronologically matched with the multiple-wire group. Patients with either invasive malignancy or ductal carcinoma in situ (DCIS) were included in the study. Clinical, radiological and pathological data was collected. Proportions of positive surgical margins, re-lumpectomies and conversion to mastectomy were calculated.

#### **RESULTS**

In the multiple-wire group the patients were younger (mean age 57 vs 63.1,  $P < 0.001$ ), had larger tumors (mean size 5.1cm vs 1.2 cm,  $p < 0.001$ ), had higher rate calcifications on mammogram (71.9% vs 17.2%,  $P < 0.001$ ) and higher rate of DCIS component (72.3% vs 38.4%,  $P < 0.001$ ); a higher proportion underwent neoadjuvant treatment (29.9% vs 9.9%,  $P = 0.001$ ). Positive surgical margins were higher in the multiple-wire group (13.4% vs 7.3%,  $P = 0.03$ ), which lead to higher proportions of re-lumpectomies or conversion to mastectomies (7.3% vs 4.3%,  $P = 0.17$ ). On multivariate analysis, patients with positive margins were more likely to have a DCIS component (77.1% vs 52.8% ,  $p = 0.006$ ) and positive ER hormonal status (93.5% vs 85.1%,  $p = 0.048$ ). The number of wires was not an independent predictor of positive margins. breast density, presence of calcifications on mammogram, type of tumor (unifocal vs multifocal/multicentric), tumor size, surgical specimen volume, undergoing Neoadjuvant treatment, undergoing magnetic resonance imaging and use of oncoplastic techniques did not predict margin status.

#### **CONCLUSION**

BCS requiring 3 or more wires is associated with a higher proportion of positive margins. The increased risk of positive margins appears to be related to type of tumor (DCIS component and ER status) rather than to the number of wires.

#### **CLINICAL RELEVANCE/APPLICATION**

This information may be useful for pretreatment planning of extensive breast malignancies, especially those suitable for BCS.

### Upgrade Rates of Atypical Ductal Hyperplasia, Atypical Lobular Hyperplasia, and Flat Epithelial Atypia at a Community-based Breast Imaging Center

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Posy J. Seifert, DO (*Presenter*) Nothing to Disclose

#### PURPOSE

To review the prevalence of breast malignancy (invasive or noninvasive) at surgical excision in patients who had atypical ductal hyperplasia (ADH), atypical lobular hyperplasia (ALH) and flat epithelial atypia (FEA) on needle core biopsy.

#### METHODS AND MATERIALS

A retrospective chart review was performed on patients who had atypical ductal hyperplasia (ADH), atypical lobular hyperplasia (ALH) or flat epithelial atypia (FEA) on breast needle core biopsy at a community-based breast center between 1/1/2011 to 12/31/2022. There was a total of approximately 909 atypical diagnoses on core needle biopsy in 876 patients during this time (ADH, ALH or FEA). Exclusion criteria included co-existing malignancy in the ipsilateral breast, or needle core biopsy pathology demonstrating atypia bordering on DCIS. Data collected included patient demographics, lesion characteristics, and correlation with surgical biopsy or follow-up imaging.

#### RESULTS

There was a total of 909 diagnoses of ADH, ALH or FEA in 876 patients on needle core biopsy. The average patient age was 57.8 years. Diagnoses on needle core biopsy were as follows: 651 ADH, 180 ALH, 78 FEA. Collectively, the majority of ADH, ALH and FEA lesions were presented as microcalcifications (69%). Of the ADH lesions, the majority presented as microcalcifications (71%), followed by 16% masses. ALH most frequently presented as microcalcifications (56%), followed by 20% masses. Eighty-three percent of FEA presented as microcalcifications, followed by 6% architectural distortion. All were recommended for open surgical biopsy (OSB)- 46 lesions did not undergo excision. Twenty percent of the atypical lesions that underwent OSB (n=173/863) upgraded to malignancy at excision; 31% (n=53) invasive carcinoma and 69% (n=120) non-invasive. Specifically, 153/651 ADH upgraded (24%), 16/180 ALH upgraded (9%), and 4/78 FEA (5%).

#### CONCLUSION

We found that 20% of the atypical lesions evaluated in this review upgraded to carcinoma at excision; most of the upgrades were ADH lesions. While surgical excision of ALH and FEA is controversial, our data suggests that it may be warranted. More research is needed to determine the optimal follow-up protocol for ALH and FEA.

#### CLINICAL RELEVANCE/APPLICATION

ADH, ALH and FEA are some of the high-risk lesions that are frequently recommended for surgical excision when diagnosed on core needle biopsy, though controversy exists.

### Deep Learning for Contrast Medium and Radiation Reduction in Coronary CT

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Giuseppe Tremamunno, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The aim of the study was to evaluate the performance of high-strength deep learning image reconstructions (DLIR-H) in maintaining or improving image quality of coronary CT angiography (CCTA) under the “double low” condition (reduced radiation dose and contrast medium dose), compared with conventional 100kVp - ASiR-V protocol.

#### METHODS AND MATERIALS

In this single-center study, from June to December 2022, clinically indicated CCTA of consecutive patients with BMI < 30 kg/m<sup>2</sup> were prospectively included and randomly assigned (1:1 ratio) into three groups: group A (100 kVp, ASiR-V 50% and iodine delivery rate [IDR] =1.8); group B (80 kVp, DLIR-H, and IDR =1.4), and group C (80 kVp, DLIR-H and IDR =1.2). Radiation and contrast dose, objective image quality (vascular attenuation, image noise, contrast-to noise ratio [CNR], signal-to-noise ratio [SNR]) and subjective image quality were compared among the three groups. To assess the objective image quality, regions of interest were drawn in the left pectoral muscle as a reference, in the ascending aorta and in the main coronary arteries. Subjective image quality was rated using a 4-point Likert scale.

#### RESULTS

144 CCTA were evaluated. Group B and C significantly reduced radiation dose compared to Group A ( $2.16 \pm 0.8$  mSv and  $1.99 \pm 0.6$  mSv, respectively, VS  $3.6 \pm 1$  mSv;  $P < 0.001$ ). Group B and group C outperformed group A in terms of lower contrast media dose, with a decreasing trend from group A to group C ( $57.7 \pm 6.7$  mL,  $51.5 \pm 6.3$  mL, and  $42.9 \pm 3.8$  mL, respectively); all the differences among the groups were statistically significant ( $P < 0.001$ ). Group B and C also achieved significantly higher SNR, CNR, and lower background noise compared to group A (all  $P < 0.001$ ). In terms of subjective image quality, group B obtained the highest score, significantly higher than group A ( $P < 0.001$ ) and group C ( $P < 0.05$ ).

#### CONCLUSION

In non-obese patients, “double low” CCTA protocol coupled with DLIR-H significantly reduces radiation and contrast medium dose while improving image quality, compared to conventional CCTA protocol.

#### CLINICAL RELEVANCE/APPLICATION

The “double low” CCTA protocol coupled with DLIR-H allows us to have excellent image quality while reducing radiation and contrast media burden; therefore, it can be safely implemented in non-obese patients. Further investigations focused on diagnostic accuracy are needed.

### Basic Verification of Myocardial Extracellular Volume Quantification by Prototype Photon Counting Detector CT

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Seitaro Oda, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aimed to investigate the accuracy of myocardial extracellular volume (ECV) quantification by prototype photon counting detector CT (PCD-CT) and the influence of the radiation dose and spectral image settings.

#### METHODS AND MATERIALS

We used a multi-energy CT phantom simulating the blood pool and myocardium. The solid rods representing blood and soft tissue were used as pre-contrast CT. Besides, the solid rods including different iodine concentrations (2 mgI/mL and 4 mgI/mL) were used as post-contrast CT. The tube voltage was set at 120 kVp and three types of tube current (105mAs, 150mAs, 300mAs) applied. Virtual monoenergetic images (VMI) at 50-100 keV were reconstructed. The ECV value was calculated from the CT numbers between pre-contrast and post-contrast. Hematocrit of blood for ECV calculation was fixed at 0.5. We compared the accuracy of ECV values at each monoenergetic level.

#### RESULTS

There was a small but significant difference in ECV values at each keV level in each radiation dose setting. ECV tended to be overestimated at higher keV in all radiation dose settings. There was a significant difference in the variability of ECV values among keV levels in all three radiation dose settings, with higher keV having greater variability. The variation was particularly large in the low dose setting. In all radiation dose settings, the residual values were significantly larger at higher keV levels: the average residual values at 105mAs, 150mAs and 300mAs settings were 0.5%-6.1%, 0.4%-4.5% and 0.3%-4.9%, respectively. In 150mAs and 300mAs settings, the residual values were smaller at 50keV and 60keV with no significant difference.

#### CONCLUSION

When quantifying myocardial ECV with PCD-CT, it was necessary to set appropriate VMI keV and radiation dose settings because the keV levels can cause differences in the quantification value and measurement variation. This PCD-CT system enabled accurate myocardial ECV quantification at 50 and 60 keV in 150mAs and 300mAs settings.

#### CLINICAL RELEVANCE/APPLICATION

Accurate myocardial ECV quantification is feasible using PCD-CT with appropriate keV settings.

### Evaluation of Coronary Artery Stents with Ultra-High-resolution Photon-Counting CT: Analysis Of the Optimal Reconstruction Kernel

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Yue Sun (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the impact of reconstruction kernel on the image quality of coronary artery stents with ultra-high-resolution photon-counting CT (UHR-PCCT) in a phantom model

#### METHODS AND MATERIALS

Six different coronary stents in a coronary phantom were examined at a tube voltage of 120kV. Images were reconstructed using vascular kernels of 11 sharpness levels based on three matrix sizes (matrix size of 512×512 pixels: Bv44, Bv48, Bv56; matrix size of 768×768 pixels: Bv60, Bv64, Bv68; matrix size of 1024×1024 pixels: Bv72, Bv76, Bv80, Bv84 and Bv89), using quantum iterative reconstruction (QIR) at a strength level of 3, and a slice thickness of 0.2 mm. Images with the Bv44 kernel, QIR at a strength level of 3, and a slice thickness of 0.4 mm served as the reference. Image noise and signal-to-noise ratio (SNR) were measured automatically using Python (Version 3.5). The sharpness and the attenuation effects of the stents were objectively evaluated with 10%-90% edge rise distance (ERD), 10%- 90% edge rise slope (ERS) and stent lumen attenuation increase ratio (SAIR). The visible diameter of the coronary stent was measured by the peak-to-peak CT attenuation of stent strut. The overall image quality of the coronary stents was subjectively scored on a 5-point scale (1= poor [poor vessel definition, severe artifacts, diagnostic information impaired], 5= excellent [clear stent strut definition, minimal blooming artifacts from the stent, and diagnostic information sufficient]). Friedman test or Kruskal Wallis test was used to check for differences between the reconstructions as appropriate. The Benjamini-Hochberg procedure was used to adjust P values for multiple comparisons.

#### RESULTS

Reconstructions with the Bv44 kernel and a slice thickness of 0.4 mm showed lowest image quality (3[2-3]) and lowest vessel sharpness (ERD:  $0.42 \pm 0.03$  mm; ERS:  $2498.25 \pm 403.83$  HU/mm) (all  $P < 0.05$ ). Considering reconstructions with a slice thickness of 0.2 mm, reconstructions with the Bv72 to the Bv89 kernel had highest image noise and lowest SNR (all  $P < 0.05$ ). Reconstructions with the Bv44 to the Bv56 kernel demonstrated a lower stent sharpness (all  $P < 0.05$ ). No difference was demonstrated among reconstruction kernels in terms of SAIR and the ratio of the visible stent lumen diameter to the true diameter. The overall image quality of coronary stents for reconstructions with the Bv60 to the Bv68 kernel (median score of 5) were favored by the readers.

#### CONCLUSION

UHR-PCCT enables the visualization of coronary stents with an excellent image quality and high sharpness. Reconstructions with the Bv60 to the Bv68 kernel may be optimal for evaluation of coronary artery stents.

#### CLINICAL RELEVANCE/APPLICATION

UHR-PCCT with the Bv60 to the Bv68 kernel allows improvement of coronary stent evaluation.

### Photon-Counting Detector CT Angiography of the Coronary Arteries: Intra-Individual Comparison of Image Quality to Conventional Energy-integrating Detector CT Angiography

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Daniel Pinos, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The aims of this study were to determine the objective and subjective image quality of coronary computed tomography angiography (CCTA) on a clinical dual-source photon-counting detector CT (PCD-CT) and to compare the image quality to conventional dual-source energy-integrating detector CT (EID-CT) in the same patients.

#### METHODS AND MATERIALS

Twenty prospectively enrolled patients ( $67.5 \pm 9.0$  years, 28.5 median BMI, 75% male) underwent PCD-CT and EID-CCTA at an average interval of 11 days. Contrast agent protocol and radiation dose were matched between the PCD- and EID-CCTA. Polychromatic images were reconstructed for both EID- and PCD-CT, while virtual monoenergetic images (VMI) were created at 40, 45, 50, 55, 60 and 70 keV for PCD-CT. Contrast-to-noise ratio (CNR) was calculated for each coronary artery by two blinded readers. Stratification analysis of patients was performed according to BMI [high ( $>30$  kg/m<sup>2</sup>) vs low ( $<30$  kg/m<sup>2</sup>)]. For subjective analysis, readers scored image noise, vessel attenuation, vessel sharpness and overall quality using a 1-5 Likert scale.

#### RESULTS

Compared with EID-CT, attenuation and image noise of the coronary arteries were higher for all PCD-CT VMI reconstructions (all  $p < 0.008$ ). Coronary artery CNR values from PCD-CT monoenergetic and polychromatic reconstructions were all significantly higher than CNR values from EID-CT (all  $p < 0.008$ ). A proportionally greater increase in CNR of 33.1% was found in high BMI patients averaged over all reconstructions. Subjective scores of image noise, vessel attenuation, vessel sharpness and overall quality were significantly higher for 55, 60, and 70 keV compared to EID-CT (all  $p < 0.05$ ).

#### CONCLUSION

The improved objective and subjective image quality of PCD-CCTA compared to EID-CCTA may offer better visualization of the coronary arteries for a wide array of patients, especially those with high BMI.

#### CLINICAL RELEVANCE/APPLICATION

The improved image quality of CCTA with PCD has the potential advantages of lower radiation dose, better detection of coronary artery disease, and better visualization in obese patient.

### Deep Learning-Based Myocardial Strain Analysis from Cine MR Image: A Comparative Study of Unet and ResUnet

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Dayeong An, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study is to develop a deep learning (DL)-based network for measuring myocardial regional function from conventional cine magnetic resonance (MRI) images, combining the advantages of cardiac magnetic resonance feature tracking (CMR-FT) and MRI tagging while minimizing their respective limitations in assessing regional cardiac function.

#### METHODS AND MATERIALS

Modified Unet and ResUnet architectures were implemented and trained to handle spatiotemporal data. Deeper layers and dilated convolutional blocks were incorporated to increase the receptive field and improve multi-scale feature learning. A custom loss function was employed for better optimization. Paired cine MR images and myocardial displacement fields generated from corresponding tagged images were acquired at matching locations and timepoints. The dataset comprised 1280 images (64 MRI slices with 20 cine and tagged images per slice). Data were split into training, validation, and test datasets as 80%, 10%, and 10%, respectively. Random flip data augmentation was performed. Radial and circumferential strains at end-systolic were measured using the American Heart Association (AHA) 6-segment model.

#### RESULTS

After 100 epochs, accuracies were 87% for Unet and 86% for ResUnet with losses of 0.6% and 0.7%, respectively. Mean±SD global strains for tagging, Unet, and ResUnet were Err = 15.4±8.4, Ecc = -15.3±8.3; Err = 17.1±10.3, Ecc = -14.7±9.1; and Err = 17.8±10.2, Ecc = -15.6±9.2, respectively. Unet and ResUnet achieved mean squared errors (MSE) of 0.5 and 0.46, peak signal-to-noise ratios (PSNR) of 71.62 and 72.08, structural similarity indices (SSIM) of 91.7 and 92.4, and Pearson correlation coefficients (PCC) of 92.9 and 95.9, respectively, compared to MRI tagging. Paired t-test revealed no statistically significant differences in strains between conventional and Unet methods ( $p>0.05$ ). However, significant differences were observed in radial AHA sectors 2 and 4, and circumferential AHA sector 1 between conventional and ResUnet methods ( $p<0.05$ ).

#### CONCLUSION

The study results demonstrate the feasibility of using deep learning-based networks, particularly the modified Unet architecture adapted for spatiotemporal data analysis, for assessing regional cardiac function in a clinical setting without the need for acquiring MRI tagged images. Potentially, this network can be used to reduce MRI scan time and allow for more adoption of strain imaging for evaluating different cardiovascular diseases.

#### CLINICAL RELEVANCE/APPLICATION

The deep learning-based networks adapted for spatiotemporal data analysis provides an efficient and accurate alternative to MRI tagging for assessment of regional cardiac function for early detection of cardiovascular diseases.

### Coronary Artery Calcium Quantification with Super Resolution Deep-learning Reconstruction Algorithm: An Anthropomorphic Phantom Study

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Shinsuke Shigematsu (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the impact of a novel super-resolution deep-learning reconstruction (SR-DLR) algorithm on coronary artery calcium (CAC) quantification in comparison with filtered back projection (FBP), hybrid iterative reconstruction (HIR), model-based iterative reconstruction (MBIR), and normal resolution deep-learning reconstruction (NR-DLR) algorithms.

#### METHODS AND MATERIALS

A QRM Thorax phantom with cardiac calcification inserts containing three different amounts of hydroxyapatite with three different diameters was used for this study. The phantom was placed inside a body ring (400×300 mm diameter) and scanned on a 320-row scanner with a tube voltage of 120 kVp. Scanning was performed with six tube currents ranging from 100 to 350 mA in 50 mA increments (CTDIvol: 1.4 to 5.1 mGy). Images were reconstructed using FBP, HIR (AIDR3D), MBIR (FIRST), NR-DLR (AiCE), and SR-DLR (PIQE) at a 3 mm slice thickness. Image noise, contrast-to-noise ratio (CNR), and task-based detectability index of calcifications were quantified. CAC volume and Agatston score were measured semi-automatically; the relative volume measurement error from the nominal CAC volume (360.6 mm<sup>3</sup>) was calculated for each reconstruction at each radiation dose level. Using the Agatston scores obtained at 350 mA as a reference for each reconstruction, the relative measurement errors at lower radiation doses (100-300 mA) were calculated. Using the Agatston scores obtained on 350-mA FBP images as a clinical reference, the relative measurement errors of each reconstruction at each radiation dose were also calculated.

#### RESULTS

SR-DLR yielded the lowest image noise, the highest CNR, and the highest CAC detectability index among all reconstructions at each radiation dose level. The lowest measurement errors in CAC volume relative to nominal volume and the Agatston score relative to reference dose (350 mA) were obtained with SR-DLR at all dose levels. When the Agatston score at 350-mA FBP was used as a reference, SR-DLR showed a systematic underestimation at all radiation doses (relative measurement error < -7.6%).

#### CONCLUSION

SR-DLR may improve image quality and facilitate accurate CAC quantification even at lower radiation doses, but its clinical application requires caution due to the deviation of the Agatston score from the conventional high-dose FBP setting.

#### CLINICAL RELEVANCE/APPLICATION

The novel SR-DLR algorithm may yield accurate detection and quantification of CAC due to its excellent noise and spatial resolution characteristics, but the clinical evaluation for potential impact on risk classification and patient management is warranted before routine clinical use.

### Deep Learning-Based Prediction of Left Ventricular Ejection Fraction Using Chest Radiographs: Potential Role in Pre-Screening Individuals in Health Checkup Populations

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Hye Soo Cho (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop and validate deep learning automatic prediction algorithms (DLLV) for left ventricular ejection fraction (LVEF) from chest radiographs (CRs), and explore its potential role as pre-screening target individuals for echocardiography in health checkup populations.

#### METHODS AND MATERIALS

To develop DLLV, patients who received CR and echocardiography at the same day at Seoul National University Hospital (SNUH) between 2016 and 2021 were retrospectively collected. 32,137 CRs from 23,616 patients (12,854 men [54%]; mean age, 69 [IQR, 62-80] years old) were included and randomly split into training (n= 25,709), validation (n= 3,214), internal test (n= 3,214) datasets. LVEF measured on echocardiogram was used as reference standard. ResNet50 was used as backbone convolutional neural network while final layers were adapted to predict LVEF in ranges of [0, 35, 50, 65, 100] (classification branch) and exact LVEF values (regression branch). For external testing, two independent cohorts were collected: 1) 5440 patients (2867 men [53%]; 66 [55-66] years old) who received same day CR and echocardiography at SNUH in 2015 (SNUH cohort) and 2) 28,034 individuals (17252 men [62%]; 56 [50-63] years old) at Healthcare System Gangnam Center between 2015-2021 (HCS health checkup cohort) were retrospectively collected. Prediction performance of DLLV was evaluated using area under the receiver operating characteristic curve (AUROC).

#### RESULTS

In internal test dataset, DLLV showed AUROCs of 0.79 (95% CI, 0.78-0.81) and 0.80 (0.79-0.81) in predicting patients with LVEF =35% and =50%, respectively. In SNUH cohort, 8% (459/5440) and 2% (123/5440) of the patients showed LVEF =35% and 50% on same day echocardiogram, and DLLV exhibited AUROC of 0.85 (0.84-0.86) in predicting LVEF =35% and 0.78 (0.77-0.80) in predicting LVEF =50%. In HCS cohort, only 0.2% (62/28,034) of the individuals showed LVEF =50%, and none showed LVEF =35%. DLLV showed AUROC of 0.74 (0.74, 0.75) in detecting those with LVEF =50%. When selective recommendation of echocardiography was assumed depending on DLLV results from CRs (i.e., those with DLLV >5%), DLLV could screen 68% (42/62) of individuals with LVEF =50% by recommending echocardiography for 8655 among 28,034 individuals (70% reduction of examinations). Only 0.1% (20/19,329) showed abnormal LVEF among individuals echocardiography was not recommended by DLLV.

#### CONCLUSION

DLLV exhibited promising performance in predicting patients' LVEF from CRs. In a health checkup cohort, DLLV showed potential in pre-screening individuals who may need echocardiography.

#### CLINICAL RELEVANCE/APPLICATION

Selective recommendation of echocardiography using DLLV may enhance chance of opportunistic screening and reduce expanse from unnecessary examinations.

### Missed Diagnosis on Chest X-Ray: Auditing Large Volumes of Data with the Help of Comprehensive Artificial Intelligence

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Arpit Talwar, MBBS, MMed (*Presenter*) Nothing to Disclose

#### PURPOSE

Chest x-rays (CXR) are the most common imaging modality in radiology and also one of the earliest imaging modalities to be developed. Despite many decades of experience in this modality, the diagnostic error rate has remained relatively unchanged. This could partly due to the lack of consistent feedback to radiologists when reporting CXRs. The purpose of the current study was to detect the rate of missed diagnoses on CXRs reported in a busy teaching hospital environment and demonstrate an efficient method of auditing the CXRs.

#### METHODS AND MATERIALS

A consecutive cohort of adult (= 18 years) CXRs reported normal within the St. Vincent's Hospital Melbourne Imaging Department were retrospectively collected and de-identified. A commercially available system (Annalise Enterprise CXR) was applied over included studies to identify cases predicted by the AI to contain one or more of 60 findings deemed significant/critical. The discrepancy between original radiology report and AI predictions were reviewed by a radiologist with over 10 years-experience to evaluate the level of agreement between radiologists and the AI-predictions, and the number of missed findings determined through subsequent review.

#### RESULTS

A total of 1559 CXRs reported in 2016 were retrospectively collected and de-identified. All of these studies were successfully processed by the AI system. The AI detected significant abnormalities in 169 of the studies. Of these, 97 were confirmed to have significant missed findings by the reporting radiologist. The most common missed findings were pulmonary nodules (16%), pleural effusions (16%), spinal compression fractures (12%) airspace opacities (11%), acute rib fractures (9%) along with a number of other significant missed findings of hilar lymphadenopathy, pulmonary artery enlargement, bone lesions, interstitial thickening, pulmonary congestion, two shoulder dislocations and an acute clavicle fracture.

#### CONCLUSION

The study demonstrates a time-effective means for auditing CXRs in a busy radiology department within a teaching hospital in order to provide constructive feedback to radiologists and trainees. A total of 1559 CXRs were automatically processed by AI allowing the radiologist to review the findings with 97 findings deemed significant out of the 169 studies detected by AI.

#### CLINICAL RELEVANCE/APPLICATION

Integration of a comprehensive AI model in a real-world reporting environment has the potential to improve radiologist performance, ultimately improving patient care.

### Assessment of Intensive Care Unit Physician Performance and Perception towards AI Utilizing a Concurrent-Read Endotracheal Tube Detection Algorithm on Portable Chest Radiographs: A Multi-Reader, Multi-Case Study

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Kaustav Bera, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

AI tools to detect and measure endotracheal tubes (ETT) on frontal chest radiograph (CXR) are primarily used by radiologists. The purpose of this study was to compare the interpretation time and performance improvement of ICU physicians for detection and measurement of ETT without and with concurrent AI assist. We also assessed the perception of the readers towards AI before and after the exercise in the form of multiple choice questionnaire.

#### METHODS AND MATERIALS

A fully crossed multi-reader and multi-case reader study was conducted. 34 participating physicians engaged in critical care (16 fellowship-trained attendings; 18 physicians-in-training [15 fellows; 3 residents]) were enrolled and retrospectively interpreted 100 CXRs (50 with ET tube; 50 without) in two reading scenarios (once without and once with AI assist). Readers were also asked to self-record the interpretation times. Interpretations of any given case set with and without AI would be separated by 4 weeks of washout. The physician and AI interpretations were compared to the reference standard measurements by board-certified cardiothoracic radiologist (10 years experience). Sensitivity, specificity, PPV, NPV was used to evaluate performance. Performance and time to interpretation was compared between AI assisted and unassisted scenarios using Fisher's exact test and Wilcoxon rank sum test. A pre- and post-completion survey was also administered and analyzed using the Likert scale.

#### RESULTS

We here present preliminary results for the first set before washout. Only completed surveys were taken for analysis (30%). AI had sensitivity, specificity, PPV, NPV and likelihood ratio of .98, .98, .98, .98, 49 ( $p < .001$ ) when compared to reference standard. Mean reader performance in terms of sensitivity, specificity and likelihood ratio were improved from 0.98, 0.91, 15 to 1, 0.97, 20 ( $p < .001$ ). The average interpretation time per case was significantly reduced by approximately 52% (median time 25 secs vs 16.5 secs;  $p < .01$ ). Following the completion of set 1 of the study, 75% of respondents expressed the desire to use AI in their clinical practice. Interestingly 63% of respondents had answered that they had no prior experience with AI at the beginning of the study.

#### CONCLUSION

An FDA approved AI tool for detecting and measuring ETT distance on frontal CXRs showed excellent agreement with the ground truth, and significantly improved interpretation times as well as overall performance for ICU physicians across a broad spectrum of experience levels.

#### CLINICAL RELEVANCE/APPLICATION

ETT AI tool showed excellent accuracy as well as helped ICU physicians improve their performance and time to interpretation. This paves the way for future prospective studies and ultimately bedside clinical deployment.

### Consecutive Cohort Analysis with Natural Language Processing (NLP) and Multi-finding AI Algorithm for Chest Radiographs: Multidimensional Opportunity for QA/QC

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Emiliano Garza Frias, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess if comprehensive discrepancy analysis of findings between NLP-based radiology reports search and a multi-finding, image-based AI algorithm can help audit quality of chest radiograph (CXR) reporting in community and quaternary healthcare settings.

#### METHODS AND MATERIALS

Our IRB-approved, HIPAA-compliant, retrospective study included 3760 consecutive CXRs (PA/AP /or lateral views) from 3760 adult patients (age>18years) in two community and quaternary care hospitals. We queried an NLP-based radiology report search engine (Microsoft Nuance) for the presence of following findings: optimal/misplaced/absent lines/tubes (endotracheal tube, esophageal tube, pulmonary arterial and central venous catheters), solitary pulmonary nodule (SPN), pneumonia, simple pneumothorax, tension pneumothorax, pneumomediastinum, pneumoperitoneum, osteopenia, and compression vertebral fractures. Each radiology report (Rad1) was manually reviewed for presence of these findings by at least 1/5 participating physicians. Each CXR was processed with a multi-finding AI algorithm (Annalise.AI) for presence of the same findings. CXRs with discrepant finding between the NLP-Rad1 and the AI was blindly assessed by either one or two thoracic radiologists (Rad2/3) based on the discrepancies to establish the standard of reference. The data were analyzed with descriptive statistics.

#### RESULTS

NLP/Rad1 and AI had high true positive and true negative concordance for CXR findings (lowest: 86.7%, 3260/3760; highest 98.8%, 3708/3760). Among the 3760 CXRs, the AI correctly identified false-negative (FNr) and false positive findings (FPr) in radiology reports for simple pneumothorax (FNr 0.4% [13/3760], FPr 0.2% [7/3760]); pneumonia (7.1% [270/3760], 1.2% [44/3760]), SPN (1.6% [60/3760], 1.7%[65/3760]), osteopenia (5.3% [200/3760], 0.2% [8/3760]), and compression fractures (3.1%, [114/3760], 0.2% [8/3760])

#### CONCLUSION

Consecutive discrepancy analysis of NLP-based radiology reports search and AI outputs can help identify a substantial proportion of missed and overcalled CXR findings with low false positive or false negative frequencies.

#### CLINICAL RELEVANCE/APPLICATION

Our proposed framework of NLP/AI for consecutive discrepancy analysis has broad applications such as a second reader to avoid missed or miscalled findings, and in peer-review and QA/QC efforts.

### Glucose Metabolic Rate from Dynamic $^{18}\text{F}$ -FDG PET/CT Scan to Differentiate Sarcoid Lymph Nodes from Malignant Lesions

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Akihiro Inoue, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Long-term fasting  $^{18}\text{F}$ -Fludeoxyglucose positron emission tomography (FDG-PET) has contributed to the diagnosis of active inflammation in cardiac sarcoidosis (CS). In the diagnosis of FDG-PET, an accumulation of active sarcoid lymph nodes is often difficult to differentiate from lymphatic metastasis or lymphoma. In differentiating active sarcoid lymph nodes from malignant lesions, we investigate the potential of the glucose metabolic rate ( $\text{MR}_{\text{glc}}$ ,  $\text{mg}/\text{min}/100\text{ml}$ ) that is a new quantification of glucose metabolic kinetics derived from dynamic FDG-PET scan with a silicon photomultiplier.

#### METHODS AND MATERIALS

100 CS patients and 67 cancer-bearing patients who underwent dynamic FDG PET/CT scan with a silicon photomultiplier between March 2021 and December 2022 were enrolled. Mediastinal or hilar lymph nodes with  $\text{SUV}_{\text{max}} = 3$  in sarcoidosis patients and metastatic or primary lesions with  $\text{SUV}_{\text{max}} = 3$  in cancer-bearing patients were included in the analysis.  $\text{MR}_{\text{glc}}$  was derived from tissue and plasma blood time-activity concentration curves using the Patlak linearization approach, with data acquired between 30 and 50 min after injection in dynamic FDG-PET/CT. Then, 60 minutes later, a standard scan performed. Active lesion was defined as  $\text{SUV}_{\text{max}} > 3.0$  on standard whole body image. Use of parametric horizontal-axial image, mean value in VOI (size  $1.5\text{cm}^3$ ) was measured.

#### RESULTS

Forty-seven lymph node lesions from 25 of 100 CS patients and 39 malignant lesions from 27 of 67 cancer-bearing patients were included in the analysis. SUV and  $\text{MR}_{\text{glc}}$  for sarcoid lymph nodes were significantly lower than those for malignant lesions (SUV,  $4.93 \pm 2.09$  vs.  $5.95 \pm 2.32$ ;  $\text{MR}_{\text{glc}}$ ,  $2.42 \pm 1.26$  vs.  $3.57 \pm 1.57$ ;  $p < 0.001$ ). Receiver-operating-characteristic analysis revealed that the ability to discriminate sarcoid lymph nodes and malignant lesions was the area under the curve (AUC) of 0.71, 77% sensitivity, and 60% specificity for SUV, AUC of 0.74, 80% sensitivity, and 66% specificity for  $\text{MR}_{\text{glc}}$ , and AUC of 0.76, 90% sensitivity, and 62% specificity for the ratio of  $\text{MR}_{\text{glc}}$  to SUV, respectively.

#### CONCLUSION

$\text{MR}_{\text{glc}}$  and the ratio of  $\text{MR}_{\text{glc}}$  to SUV are significantly lower for sarcoid lymph nodules than malignant. The use of  $\text{MR}_{\text{glc}}$  improves sarcoid lymph nodes identification over SUV alone.

#### CLINICAL RELEVANCE/APPLICATION

The ability to distinguish between sarcoid and metastatic lymph nodes with FDG-PET will lead to accurate staging of malignant tumors.

### Incremental Prognostic Value of Deep learning-based Quantification of Macroangiopathic Aortic Changes for Cardiovascular Mortality in Heavy Smokers

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Alexander Rau, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Macroangiopathic changes of the aorta are a common manifestation of cardiovascular (CV) disease. Currently, maximum diameter is the only prognostic measure used in clinical practice, despite quantification of other macroangiopathic changes (e.g. calcification) is available on computed tomography (CT) imaging. Thus, we applied a deep learning model to automatically quantify macroangiopathic changes of the aorta and investigated their prognostic value for CV mortality in a high-risk population of heavy smokers.

#### METHODS AND MATERIALS

We used a deep learning model to automatically segment the aorta on lung screening chest CTs of participants enrolled in the National Lung Screening Trial at baseline and one-year follow-up. The following features were quantified: maximum diameter (cm), volume (deciliter) and calcifications (ml, categorized into tertiles). We assessed the association between (I) baseline features and CV and (II) the change of features within one year and CV mortality via multivariable Cox proportional hazard regression adjusted for traditional CV risk factors including smoking and hypertension. Harrel's c-index was used to compare the predictive value of the features.

#### RESULTS

Among 24,770 participants at baseline (mean age  $61.4 \pm 5.0$  years; 59.2% male) 440 (1.8%) CV deaths occurred over a mean follow-up of  $6.3 \pm 1.0$  years. In univariate models, C-index of aortic volume and calcifications were significantly higher compared to diameter (c-index 0.63 and 0.66 vs. 0.61;  $p=0.02$ ) for the prediction of CV mortality. After adjustment for traditional CV risk factors, volume (aHR: 1.04 [1.01-1.08];  $p=0.008$ ) and calcification (aHR: 2.53 [1.87-3.41];  $p<0.001$ ) remained significantly associated with CV mortality whereas the association for diameter was attenuated. In subjects with one year follow-up available ( $n=22,140$  individuals, mean age  $61.4 \pm 4.9$  years; 58.3% male with a 1.5% CV), the strongest association was found between an increase in calcifications and CV mortality (aHR highest tertile: of 1.74 [1.32-2.29],  $p<.001$ ) after multivariable adjustment for traditional CV risk factors.

#### CONCLUSION

Deep learning can automatically quantify macroangiopathic changes of the aorta on lung screening chest CTs and identify individuals at high risk of CV mortality beyond traditional risk factors.

#### CLINICAL RELEVANCE/APPLICATION

Deep learning-based quantification of macroangiopathic aortic changes can identify individuals at risk of CV mortality beyond traditional risk factors in a high-risk population of heavy smokers. This enables opportunistic risk assessment to improve personalized prevention and treatment strategies.

### “Dependent Contrast Layering Sign” on CT: Preliminary Cross Sectional Descriptive Study

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Youssef Mohsen, MD, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

CT findings of contrast layering in the dependent part of the central venous system have been reported to be associated with compromised cardiac function and imminent cardiac arrest. To the best of our knowledge, there is no systemic research on this finding and its association with cardiac arrest and mortality. Therefore we studied the radiologic findings of dependent contrast layering in vascular structures on CT and its clinical implications.

#### METHODS AND MATERIALS

This single center retrospective study involved a list of 226 patients obtained by searching PACS reports for the keywords “layering of contrast”, “pooling of contrast” or “dependent layering of contrast” in contrast enhanced CT chest and CT abdomen performed between Jan 2008 and Jan 2022. Two body radiologists reviewed for the dependent layering of contrast in vascular structures and parenchyma of abdominal organs. Clinical data were investigated from electronic medical records. The frequencies of the radiologic findings in association with clinical data were analyzed.

#### RESULTS

Dependent contrast layering in the vascular structures is demonstrated in 21 patients (9.3%, mean age:  $67.4 \pm 12.4$ ). Layering of contrast is shown in the IVC ( $n=19$ , 90.4%), hepatic vein ( $n=17$ , 80.9%), liver parenchyma ( $n=7$ , 30.3%), right atrium ( $n=5$ , 23.8%), and other organs ( $n=10$ , 47.6%). Among the 21 patients, 6 patients (28.5%) had cardiac arrest within 24 hours, all of which occurred within 2 hours. 11 patients (52.3%) died during their hospital stay. Layering in the right atrium shows the highest rate of cardiac arrest within 2 hours (4 of 5, 80%) followed by liver parenchyma (5 of 7, 71.4%). Reflux into liver parenchyma shows the highest rate of death during the same hospital stay (4 of 7, 57.1%). The mean number of involved structures per patient is  $3.29 \pm 2.0$  (range 1-9). It is higher in patients who died during the same hospital stay ( $4.25 \pm 1.15$ ) compared to those who survived ( $3.3 \pm 2.02$ ). The mean number of involved structures is similar between the cardiac arrest ( $3.29 \pm 1.98$ ) and non-cardiac arrest ( $3.28 \pm 2.08$ ) groups. The mean left ventricular ejection fraction (LVEF) was  $38 \pm 12\%$  (range 15-67). LVEF was less than 40% in 52% (10 of 19) of patients. The the shock index was 0.9 or higher in 66.6% (12 of 18) of patients and its mean was  $1.08 \pm 0.50$  (range 0.5-2.6).

#### CONCLUSION

The CT findings of dependent contrast layering in the central venous system are related to high rates of imminent cardiac arrest and mortality.

#### CLINICAL RELEVANCE/APPLICATION

Radiologists and technicians need to recognize these findings to alert clinicians the risk of cardiac arrest. Our study provides important preliminary data for radiologists and clinicians to recognize the significance of “Dependent contrast layering sign” for clinical decision-making.

### Performance of a Novel Intravascular Tantalum Oxide-based CT Contrast for Enhancement and Conspicuity of Thoracic Vasculature in an Animal Model: Total and Relative Contrast Material Advantage

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Maurice M. Heimer, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare a novel intravenous tantalum oxide (TaCZ) nanoparticle CT contrast agent to conventional iodinated (Iopromide) CT contrast agent for thoracic artery and vein visualization in a rabbit model.

#### METHODS AND MATERIALS

Five New Zealand White rabbits were serially placed in a human-torso-sized adipose-equivalent encasement and scanned on a clinical CT system (Philips IQon, Best, Netherlands) before and 6, 40, 75, 136, and 240 sec after IV injection of 540 mg element (Ta or I) per kilogram of body weight of TaCZ or Iopromide. Animals were scanned twice, once with each contrast agent. Absolute contrast enhancement of the aortic arch, pulmonary trunk, superior vena cava, and subclavian vein was measured in Hounsfield Units (HU) by averaging three regions of interest drawn in the center of the lumen minus corresponding non-contrast measurements. Randomized imaging series were viewed on a clinical PACS system to rate vascular conspicuity on a 5-point Likert scale (0 = no vascular enhancement; 1 = faintly seen or visible but discontinuous; 2 = adequate contrast of main vessel, not all branches seen; 3 = good contrast of main vessel and depiction of branches; 4 = excellent contrast of main vessel and deep branches).

#### RESULTS

Mean vascular enhancement was significantly higher for TaCZ in all examined blood vessels at all time points compared to Iopromide; aortic arch at 6s (263 vs. 217;  $p < 0.01$ ), at 40s (265 vs. 145;  $p < 0.01$ ), at 75s (240 vs. 119;  $p < 0.01$ ), at 136s (217 vs. 93;  $p < 0.01$ ) and at 240s (183 vs. 73;  $p < 0.01$ ), pulmonary artery at 6s (296 vs. 266;  $p < 0.01$ ), at 40s (263 vs. 138;  $p < 0.01$ ), at 75s (246 vs. 102;  $p < 0.01$ ), at 136s (213 vs. 83;  $p < 0.01$ ) and at 240s (174 vs. 64;  $p < 0.01$ ), superior vena cava at 6s (307 vs. 211;  $p < 0.01$ ), at 40s (255 vs. 127;  $p < 0.01$ ), at 75s (239 vs. 96;  $p < 0.01$ ), at 136s (196 vs. 79;  $p < 0.01$ ) and at 240s (169 vs. 49;  $p < 0.01$ ) and the subclavian vein at 6s (280 vs. 225;  $p < 0.01$ ), at 40s (254 vs. 111;  $p < 0.01$ ), at 75s (236 vs. 86;  $p < 0.01$ ), at 136s (205 vs. 67;  $p < 0.01$ ), and at 240s (170 vs. 54;  $p < 0.01$ ). The mean vascular enhancement of TaCZ at a 136s delay provided comparable results to the 6s arterial phase of Iopromide (213 vs. 223;  $p > 0.05$ ). Overall, vascular enhancement correlated well with perceived vascular conspicuity scores for both agents.

#### CONCLUSION

TaCZ provides both an absolute and relative contrast advantage compared to Iopromide for improved visualization of the thoracic arteries and veins across a broad range of timepoints after contrast injection.

#### CLINICAL RELEVANCE/APPLICATION

TaCZ gives superior prolonged thoracic vascular enhancement over iodine agents at CT and warrants clinical testing as a means to improve the quality and consistency of CT angiograms and venograms.

W5B-SPER-1

### Channeling the Neuroradiology Crystal Ball: Predicting Presenting Symptoms Associated with Imaging-Proven Acute Cord Compression in the Emergency Department

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Mercy H. Mazurek (*Presenter*) Nothing to Disclose

#### PURPOSE

Spinal cord compression (CC) can result from both atraumatic and traumatic causes. CC commonly presents with back pain, urinary incontinence, lower extremity weakness, and malignancy, among others. While the occurrence of these symptoms is high, the prevalence of CC due to both atraumatic and traumatic causes is low. Understanding the clinical symptoms that are associated with CC may better inform the utilization of imaging in the emergency department (ED) to reduce costs and provide efficient care.

#### METHODS AND MATERIALS

This retrospective study analyzed patients who underwent our ED's abbreviated survey spine MRI protocol for suspected CC from 2018 to 2022. The survey protocol includes sagittal T2 and short-TI inversion-recovery (STIR), with optional axial T2. Imaging reports were reviewed by a blinded, board-certified neuroradiologist and characterized as positive or negative for CC. Demographic factors and presenting symptoms were extracted from the electronic medical record and compared among patients with imaging-positive acute CC vs negative. Univariate analysis was performed using the student's t-test and chi-squared test. A multivariate logistic regression was performed with stepwise backwards elimination where the variable with the largest P value was removed in a stepwise fashion in each iteration until all variables on the final model had a  $P < .20$ .

#### RESULTS

A total of 845 patients (mean age  $57 \pm 19$  years, 45% female) received a survey spine MRI for suspected CC during the study period. Of these, 23% presented with trauma, 55% back pain, 29% lower extremity weakness, 5.7% history of malignancy, 14% urinary incontinence, 6.0% bowel incontinence, 14% neck pain, 20% numbness, 7.3% ataxia, and 6.4% hyperreflexia. There were 725 (85%) and 120 (14%) patients negative and positive for CC, respectively. In the univariate model, trauma, back pain, numbness, ataxia, and hyperreflexia were significantly associated with having a positive study (Table 1). In the multivariate model, trauma, back pain, lower extremity weakness, urinary or bowel incontinence, numbness, ataxia, and hyperreflexia were significantly associated with being positive for acute CC (Table 2).

#### CONCLUSION

Presenting symptoms of trauma, back pain, lower extremity weakness, urinary or bowel incontinence, numbness, ataxia, and hyperreflexia were significantly associated with positive CC findings on ED survey spine evaluation in the ED. These results may inform which patients should receive triage priority in the ED.

#### CLINICAL RELEVANCE/APPLICATION

Understanding the symptoms associated with acute CC informs efficient utilization of abbreviated, CC-specific survey spine MRI protocols to limit unnecessary imaging studies thereby expediting diagnosis and emergent treatment.

W5B-SPGI-1

### Preoperative Prediction of Ki-67 Expression in Hepatocellular Carcinoma by Spectral Imaging on Dual-Energy CT

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Caiyun Li, BMedSc, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the value of quantitative spectral parameters measured on a dual-energy CT in preoperative predicting the expression level of Ki-67 in HCC.

#### METHODS AND MATERIALS

91 HCC patients underwent both pathological examination and two-phase contrast-enhanced CT scanning with spectral imaging mode were included in this study. According to Ki-67 expression determined by the Ki-67 positivity rate (Ki-67%), patients were divided into two groups: high expression group (Ki-67% > 20%, n = 51) and low expression group (Ki-67% = 20%, n = 40). CT values on 100 and 140 keV monochromatic energy images (HU<sub>100-140keV</sub>), normalized effective atomic number (Neff-Z), water density (D<sub>water</sub>), fat density (D<sub>fat</sub>) were measured and calculated. The parameters comparison between groups, receiver operation curve for prediction efficacy evaluation were conducted.

#### RESULTS

The Neff-Z, D<sub>fat</sub>, HU<sub>100-140keV</sub> and D<sub>water</sub> in high expression group were significantly higher than those in low expression group (all P < 0.05). In prediction of Ki-67 expression, the AUCs of Neff-Z, D<sub>fat</sub>, HU<sub>100-140keV</sub> and D<sub>water</sub> were 0.650, 0.677, 0.692-0.750, 0.777. The corresponding sensitivities were 0.647, 0.804, 0.529-0.824 and 0.961, respectively. The specificities were 0.600, 0.525, 0.825-0.625 and 0.475, respectively. D<sub>water</sub> showed highest Ki-67 expression prediction performance, with AUC of 0.777. The multi-variable analysis combining spectral CT parameters and morphological characteristics improved the prediction efficiency (AUC=0.814).

#### CONCLUSION

The spectral parameters (Neff-Z, D<sub>fat</sub>, HU<sub>100-140keV</sub> and D<sub>water</sub>) obtained by contrast-enhanced spectral imaging on dual-energy CT can be used to predict Ki-67 expression in HCC, the efficiency would be improved by multi-parameter analysis combining spectral CT parameters and morphologic features.

#### CLINICAL RELEVANCE/APPLICATION

Ki-67 was a significant marker for HCC prognosis and clinical decision, however current method to evaluate Ki-67 always needs surgery, which is detrimental for assessing patients who lost surgery chance. Contrast-enhanced spectral imaging on dual-energy CT provides various parameters to predict cell proliferation in HCC with good performance, shedding lights in clinical diagnosis and therapeutic strategy decision.

### The Added Value of Reduced field-of-view IRIS-DWI Sequence for T2WI Sequence in T Staging of Rectal Cancer

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Ziyou Wang (*Presenter*) Nothing to Disclose

#### PURPOSE

Oblique axial high-resolution T2WI(HR-T2WI)was the recommended sequence for rectal cancer T staging.We attempted to evaluate the added value of reduced field-of-view (rFOV) IRIS-DWI sequence for T2WI sequence in evaluating T staging of rectal cancer.

#### METHODS AND MATERIALS

All patients underwent rectal MRI examinations in our institution between June 2022 and November 2022 . rFOV IRIS-DWI and oblique axial HR-T2WI images were acquired using a 3.0T MR scanner (Ingenia Elition, Philips, Best, the Netherlands) (Table 1). All patients were evaluated in two rounds by two methods. First, one senior radiologist (Y.K.M.) with more than 7 years of experience in rectal cancer MRI evaluated the T staging based on oblique axial HR-T2WI images and recorded the diagnosis confidence. Second, the same radiologist (Y.K.M.) reevaluated the T staging based on rFOV IRIS-DWI and HR-T2WI images after one-week interval.The diagnosis confidence was also recorded. The radiologist was blind to the detailed pathologic T staging. MedCalc statistical software (version 20.116) was used for data analysis. The accuracy of two diagnosis methods between oblique axial HR-T2WI and T2WI + rFov IRIS were compared by paired  $\chi^2$ -test. Paired sample t-test was used to compare the diagnosis confidence between the two diagnosis methods. ROC curve was used to evaluate the diagnostic performance for pT3 staging.  $P < 0.05$  indicated the difference was statistically significant.

#### RESULTS

Twenty-seven patients with rectal cancer were enrolled in this retrospective study. The average age was  $66.7 \pm 6.9$  years, and there were 15 (56%) males(Table 2). The diagnosis accuracy for pT1-pT2 and pT3 was 58.3% and 73.3% according to oblique axial HR-T2WI. According to the oblique axial HR-T2WI and rFOV IRIS-DWI, 11 patients (91.7%) in 12 pT1-T2 staging patients and 14 patients (93.3%) in 15 pT3 staging patients were accurately diagnosed ( $P < 0.0001$ ) (Table 3). Based on T2WI + rFOV IRIS-DWI imaging showed higher diagnosis confidence, and the diagnosis confidence were 2.9 and 2.37 in all patients ( $P < 0.001$ ) .For pT2 and pT3 staging subgroups, the diagnosis confidence based on T2WI + rFOV IRIS-DWI imaging also showed higher confidence (2.8 vs. 2.1,  $P = 0.01$ ; 2.93 vs. 2.53,  $P = 0.009$ , respectively) (Table 4). ROC analysis showed the diagnosis performance based on T2WI + rFOV IRIS-DWI imaging was superior to T2WI sequence. The AUC, sensitivity and specificity were 0.928, 93.3%, 91.7% and 0.658, 73.3%, 58.3% ,respectively(  $P = 0.002$ )(Table 5, Figure 3).

#### CONCLUSION

rFOV IRIS-DWI combined T2WI imaging provide higher diagnosis confidence and higher diagnosis accuracy for rectal cancer T staging.

#### CLINICAL RELEVANCE/APPLICATION

rFOV IRIS-DWI improved the diagnosis performance in rectal cancer T staging.

### Impact of MRI after CT on the Therapeutic Decision of Pancreatic Adenocarcinoma

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Walid Tibermacine, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this work is to determine the impact of MRI after CT on the therapeutic decision of pancreatic adenocarcinoma.

#### METHODS AND MATERIALS

It's a prospective, cross-sectional and evaluative study over 24 months from January 2020 to December 2021 of patients suspected of having pancreatic cancer.

#### RESULTS

A total of 117 cases of patients were included, aged 34-91 years with an average age of  $62 \pm 11$  years and a sex ratio of 1.25. The average diameter is  $43.61 \pm 15.268$  mm. The TDM and MRI assessment of resectability was performed according to NCCN version 1.2020 criteria. 46 patients (i.e. 39.3%) were at the metastasis stage, 36 patients (i.e. 30.8%) resectable, 19 patients (i.e. 16.2%) locally advanced and 16 patients (i.e. 13.7%) borderline resectability. To determine the impact of MRI after CT on the treatment decision, we compared the staging of the resectability of each of the two techniques by referring to surgery for resectability and metastases and to MRI data for characterization of liver damage. The analysis showed that in 15 patients (i.e. 12.8%) the therapeutic approach was changed on MRI after CT.

#### CONCLUSION

Complementary MRI to CT led to changes in resectability and therapeutic management in a significant proportion of patients with ADCP

#### CLINICAL RELEVANCE/APPLICATION

Complementary MRI to CT => changed resectability and therapeutic management

Printed on: 08/22/24

### Imaging Features Prognostic of Overall Survival in Patients with Advanced Hepatocellular Carcinoma Undergoing Systemic Therapy

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Kathleen Ruchalski, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Modified RECIST measures arterial enhancement of liver lesions in hepatocellular carcinoma (HCC), evaluating treatment related alterations in tumor viability not captured by size alone. However mRECIST clinical translation to advanced HCC and ability to predict response to systemic therapy is less well reported. Our objective is to evaluate for imaging features beyond RECIST 1.1 which correlate with overall survival (OS) in advanced HCC.

#### METHODS AND MATERIALS

This is a retrospective study of patients with advanced HCC at our institution enrolled in clinical trials for systemic treatment between 2015-2022. Patient characteristics and OS were obtained. Liver tumor imaging features on baseline CT or MRI chest, abdomen pelvis were analyzed. Relationship to overall survival (OS) was assessed by cox regression model and log rank test.

#### RESULTS

Of 74 patients, we identified 53 who met our criteria, enrolled in a clinical trial with baseline imaging. There were 40 (75.5%) men and 13 (24.5%) women with a mean age of 66.2 years (SD=9.5). Median OS was 31.5 months. Percent total liver tumor involvement n= (%) included: < 25% n=25 (47.2), 25-50% n=20 (37.7), 51-75% n=8 (15.1) patients. Multifocal liver disease and macrovascular invasion were present in 41 (77.4%) and 25 (47.2%) of patients respectively. Individual liver lesions measured on average 41.7mm (SD=28.2) on arterial phase. Lesion margins were characterized as infiltrative (n=14 (13.2%)), irregular (n=19 (17.9%)), well circumscribed (n=60 (56.6%)) and N/0 (n=13 (12.3%)). Arterial enhancement patterns were described as central heterogeneous in 41 (38.6%), homogeneous: 24 (22.6%), partial enhancement: 15 (14.2%), rim only: 11 (10.4%) and no enhancement in 15 (14.2%) patients respectively. Multifocal liver disease was associated with significantly increased risk of death (p=0.043). Patients with partially enhancing liver lesion had improved survival compared to those with central heterogeneously enhancing tumor (HR=0.28; p=0.044). Individual liver lesion size (p=0.399), margin (p=0.289) and % liver involvement (p=0.125) did not correlate with OS.

#### CONCLUSION

While lesion size was not prognostic, presence of multifocal liver disease and central heterogeneous tumor enhancement were poor prognostic features of OS for advanced HCC.

#### CLINICAL RELEVANCE/APPLICATION

Although further investigation is required, reporting imaging findings on multifocal liver disease and arterial enhancement pattern may provide prognostic information for patients with advanced HCC undergoing systemic therapy.

### Deep Learning Prostate MRI Progression Risk Interval Prediction

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Christian Roest, MSc (*Presenter*) Grant, Siemens AG

#### PURPOSE

MRI follow up is increasingly used to manage patients with low-risk prostate cancer, (PCa) but lacks personalization of follow-up timing. Therefore, We propose a novel AI approach to predict the time to prostate cancer progression.

#### METHODS AND MATERIALS

This retrospective study was performed on a dataset of 875 patients that underwent an MRI of the prostate between 2014 and 2021. Patients received follow-up MRIs and targeted biopsy for all PI-RADS=3 lesions. This study defined progression as the detection of ISUP>1 PCa at follow-up. A novel deep learning model was developed and trained to predict progression-free survival (PFS) based on the MRI and available clinical parameters (PSA, PSA density, prostate volume, and age). Five-fold cross-validation was used to obtain likelihood scores for the three-year risk of progression in each patient. Patients were stratified into high- and low-risk groups based on their predicted likelihood of progression, with an equal number of patients in each group. Kaplan-Meier analyses validated whether the predicted likelihood accurately predicted PFS. Finally, the C-index was calculated to assess the prognostic accuracy of our model.

#### RESULTS

Our AI model's predictions were significantly associated with PFS in the test data ( $p < 0.0001$ ). The C-index was  $0.72 \pm 0.05$ , indicating that our model was a good predictor of PFS. PFS was significantly better in patients predicted to be at low-risk of disease progression, when measured after two years ( $95.3 \pm 0.04\%$  vs  $84.9 \pm 0.02\%$ ,  $p = 0.008$ ), three years ( $92.7 \pm 0.05\%$  vs  $73.3 \pm 0.04\%$ ,  $p = 0.008$ ) and four years ( $87.7 \pm 0.12\%$  vs  $62.8 \pm 0.04\%$ ,  $p = 0.008$ ).

#### CONCLUSION

Our novel AI approach accurately predicted PFS from prostate MRI and clinical information.

#### CLINICAL RELEVANCE/APPLICATION

An improved predictor for the time to progression based on MRI and clinical parameters may improve MRI follow-up protocols by enabling more personalized interval timing and decision making.

### Detection of Clinically Significant Prostate Cancer in Men with a Negative Initial Round of Targeted Biopsies and Highly Suspicious Multiparametric Magnetic Resonance Findings

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Debora Z. Recchimuzzi, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to evaluate the frequency of imaging-pathology discordance and the rate of csPCa detection on repeat TBx.

#### METHODS AND MATERIALS

This single-center, retrospective study of prospectively generated data, included all men who underwent mpMRI and had a PIRADS score 4 or 5 at our institution between Jan/2017 and Nov/2022. The frequency of imaging pathology discordance (PI-RADS score 4 or 5 lesion and no csPCa on TBx) and the rate of csPCa (grade group 2 or higher) detection on a repeat TBx (MRI-TRUS fusion or in-bore biopsy) were determined. Univariate analysis and multiple analysis with logistical regression were used to identify potential parameters associated with true-negative targeted biopsies, including PSA, PSA density, prostate volume as measured by MRI and ADC measurement.

#### RESULTS

Of the 4047 men reviewed, 63% (2581/4047) had PI-RADS 4 or 5 lesions on mpMRI followed by TBx. In 40% (1050/2581) of these men, TBx did not reveal csPCa. Among these 1050 men with discordant imaging-pathology findings, 18% (191/1050) men had a repeat targeted biopsy (MRI-TRUS fusion or MRI guided inbore), and 40 men underwent radical prostatectomy for grade group 1 disease. Repeat TBx identified csPCa in 35% (67/191) of the men who underwent a second TBx. The frequency of csPCa at repeat biopsy was significantly higher for PIRADS 5 (45%; 32/70) compared to PIRADS 4 lesions (28%; 35 of 121) ( $p=$ ).

#### CONCLUSION

A negative targeted biopsy of a highly suspicious lesion on mpMRI must be interpreted with caution and early repeat biopsy should be considered, particularly in men with PI-RADS 5 lesions.

#### CLINICAL RELEVANCE/APPLICATION

Multiple studies have demonstrated that men with highly suspicious (PI-RADS score 4 and 5) prostate lesions at multiparametric MRI (mpMRI) are highly likely to harbor clinically significant prostate cancer (csPCa). The degree of suspicion on multiparametric MRI is the strongest predictor of a positive targeted biopsy with positive rates of 70% to 90% when the MRI findings are highly suspicious for PCa. It is known that prostate biopsies - including targeted biopsies (TBx) - are vulnerable to sampling error. Discordance between histologic and imaging findings may indicate, therefore, that the lesion may not have been sampled adequately, highlighting the importance of a systematic post-biopsy imaging-pathology concordance review.

### Quantitative Gland Function Analysis in Dry Mouth Patient using T1, T2 and PD Mapping based on the Multi-dynamic Multi-echo Method

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Chena Lee, DDS, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Dry mouth is a subjective complaint of dryness of intraoral cavity and the primary etiology is the hypofunction of salivary gland. Clinical diagnosis is conducted by collecting patient's whole saliva and evaluate the volume and this is a time consuming cumbersome examination. Thus, the current study aimed to utilize T1, T2 and PD mapping as diagnostic tool for parotid gland dysfunction in dry mouth patients.

#### METHODS AND MATERIALS

Dry mouth (n = 32) and control subjects (n = 30) that underwent magnetic resonance imaging (MRI) from July 2020 to December 2022 were reviewed. The T1, T2, and PD mapping of the parotid gland were evaluated simultaneously based on the multi-dynamic multi-echo (MDME) MR imaging. The values from control and dry mouth group were compared using Mann-Whitney test and receiver operating characteristic (ROC) curve analyses.

#### RESULTS

The mean of T1, T2-relaxation time and PD value of the gland in dry mouth group were 606.90 ms, 91.63 ms, and 82.37 pu, respectively. The mean of T1, T2-relaxation time and PD value of control group were 628.08 ms, 80.69 ms and 91.12 pu. The T2- relaxation time and PD value showed significant difference between the dry mouth and control group while there no significant difference between two groups in T1-relaxation value. The area under the ROC curve (AUC) was 0.8164 and 0.7564 respectively for T2-relaxation time and PD value. The diagnostic performance between T2-relaxation time and PD value were not significantly different (p-value = 0.4851).

#### CONCLUSION

The T2-relaxation time and PD value can be used as quantitative indicators of dry mouth due to hypofunction of parotid gland and the performance of T2-relaxation time presented higher diagnostic ability. Further study with large population could be led to more accurate result.

#### CLINICAL RELEVANCE/APPLICATION

T2 and PD mapping, based on the MDME technique, presented diagnostic ability for detecting parotid gland hypo function and could be utilized as quantitative tool for dry mouth diagnosis in clinic.

### **From Suspected to Confirmed : Intrathecal Gadolinium-Enhanced MR Cisternography as a Key Diagnostic Modality in CSF Rhinorrhoea**

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Priyanka Prajapati, MBBS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To establish the role and diagnostic accuracy of Intrathecal gadolinium enhanced MR Cisternography in clinically suspected cases of CSF rhinorrhoea

#### **METHODS AND MATERIALS**

As of now, a total of 19 consecutive patients with active or suspected CSF rhinorrhea have been included in this study. History of trauma was present in 8 patients (42%), endoscopic surgery in 5 patients (26%), spontaneous in 6 patients (32%). Most of the patients had CT PNS which showed evidence of skull base fractures, defects or erosions. We used mixture of non-ionic iodinated contrast (5 ml of iohexol; Omnipaque 300) with Gadolinium (0.4 ml of gadobutrol; Gadovist) along with normal saline (5 ml of 0.9 % normal saline) for injecting into the intrathecal space. MR sequences were taken approximately 30-40 minutes after the contrast injection. For all patients, hemodynamic studies (heart rate, blood pressure) and evaluation of neurologic status were performed.

#### **RESULTS**

We observed objective CSF leakage in 11 of 19 patients (58%). The CSF leak was located in the cribriform plate in 7 patients (37%), in the superior wall of the sphenoid sinus/planum sphenoidale in 4 patients (21%), fovea ethmoidalis/roof of ethmoid sinus in 2 patients (11%), through the post-operative sella turcica defect in 1 patient (5%), including multiple defects identified in 4 patients (21%). No objective CSF leakage in spite of bony defect was seen in 4 patients (21%). No bony defect and no objective CSF leakage were seen in 4 patients (21%). Surgical closure of CSF leak was performed in all patients with positive findings on cisternography and the site of leak was confirmed intraoperatively. Post-procedure 6 patients (32%) had mild headache. No other adverse event were noted.

#### **CONCLUSION**

MR cisternography after the intrathecal administration of gadolinium represents an effective and minimally invasive method for evaluating suspected CSF fistulas along the skull base. It provides multiplanar capabilities and high resolution without risk of radiation exposure and is an excellent approach to depict the anatomy of CSF spaces and CSF fistulas. Furthermore, use of combination of non-ionic iodinated contrast with gadolinium increase the distribution of contrast in subarachnoid space and improve the resolution when compared with just using gadolinium No significant gross neurologic abnormalities were observed during the initial examination or during follow-up.

#### **CLINICAL RELEVANCE/APPLICATION**

CSF rhinorrhoea is potentially very serious because of the risk of an ascending infection which could produce fulminant meningitis. Exact identification of the location of the CSF fistula is important for proper surgical planning, increases the chances of dural repair and can prevent complications.

### Tracheal Cartilage Calcification and Glucose Metabolism in Aging Adults Assessed by <sup>18</sup>F-NaF and <sup>18</sup>F-FDG PET/CT

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

NilooFaralsadat Motamedi, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to examine if <sup>18</sup>F-sodium fluoride (<sup>18</sup>F-NaF) and <sup>18</sup>F-fluorodeoxyglucose (FDG) PET/CT can be used to measure physiological calcification and glucose metabolism of the tracheal cartilage, respectively, and whether there was any association with aging.

#### METHODS AND MATERIALS

Out of 139 healthy control subjects from the CAMONA study (NCT01724749), a total of 128 subjects in whom tracheal cartilage could be segmented on <sup>18</sup>F-NaF-PET/CT (mean age  $48.58 \pm 14.44$  years, 51.56% males) were included in the analysis. Similarly, a total of 119 subjects (mean age  $48.46 \pm 14.34$  years, 54% males) in whom tracheal cartilage could be segmented on FDG-PET/CT were included in the analysis. The PET/CT acquisitions were performed 90 minutes after <sup>18</sup>F-NaF administration and 60 minutes after FDG administration. The mean standardized uptake value (SUV<sub>mean</sub>) of both tracers was measured by assigning regions of interest (ROIs) around the cartilage using OsiriX software (Pixmeo SARL, Bernex, Switzerland). To assess the relationship of tracheal calcification and glucose metabolism with aging, Pearson correlation analysis was performed between age and the <sup>18</sup>F-NaF and FDG, respectively.

#### RESULTS

A statistically insignificant positive correlation was present between age and <sup>18</sup>F-NaF SUV<sub>mean</sub> ( $r=0.094$ ,  $p=0.28$ ) (Figure 1). Similarly, there was a statistically insignificant negative correlation observed between age and FDG SUV<sub>mean</sub> ( $r=-0.125$ ,  $p=0.17$ ) (Figure 2).

#### CONCLUSION

<sup>18</sup>F-NaF- and FDG-PET/CT can be used to measure physiological calcification and glucose metabolism of the tracheal cartilage. Although the results were statistically insignificant, there was a trend of an increase in physiological calcification and a decrease in glucose metabolism of the tracheal cartilage with aging, as assessed by <sup>18</sup>F-NaF- and FDG-PET/CT, respectively. Prospective studies with larger sample sizes and longitudinal in subjects of varying ages are needed to continue investigation into changes in tracheal cartilage calcification and metabolism with aging.

#### CLINICAL RELEVANCE/APPLICATION

To assess calcification and glucose metabolism of tracheal cartilage with aging by <sup>18</sup>F-NaF and FDG PET/CT, age-related trends were observed, and further studies are needed to confirm clinical significance.

Printed on: 08/22/24

### Relationship between Cochlear Implant Patients' Auditory Outcomes and Insertion Length and Angulation

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Paloma Puyalto, PhD, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Cochlear implants are transducers that transform the acoustic waves into electrical signals to stimulate the cochlear nerve in patients that suffer unilateral or bilateral, deep or severe, neurosensorial deafness that do not benefit from an auditory prostheses. The main objective of this study was to determine whether a deeper cochlear implant insertion within the cochlea, in terms of length and grade, results in improved auditory performance.

#### METHODS AND MATERIALS

After IRB approval a cohort of 46 patients with 50 cochlear implants were prospectively reviewed. A temporal bone HRCT was performed before and after cochlear implantation. Prior and post-implantation audiometric studies and functional clinical variables such as speaking on the phone, listening to music, or time in months needed till auditory rehabilitation was optimal were recorded and correlated to the electrode insertion depth in terms of length and insertion angle grades.

#### RESULTS

21 men and 25 women (29-78 y.o) with a 2 to 63 years story of neurosensorial deafness were analyzed. 4-12 electrodes were encountered within the cochlea in HRCT. A median of 88.7% of the cochlea was covered. The insertion angle ranged between 90° and 720° with  $\mu=536^\circ$  and  $s=146.40^\circ$ . Two years after implantation, there was a median of 11 (3-12) final functioning electrodes. 76% of patients achieved >70% bisyllabic discrimination at 60 dB, 60% used phones after implantation, 26% listened to music, Less than a year was the median time to finish hearing rehabilitation for 38%, followed by 12 to 24 months for 34% and 24 months for 28%. There was a correlation between the angle of insertion and the length of the inserted implant with a correlation coefficient of 0.846 ( $p<0.01$ ). A statistical correlation between the number of electrodes, length and insertion angle within the cochlea, and audiometric values, speaking at the phone, or the number of months of rehabilitation after the procedure was found ( $p<0,01$ ) although the ability to listen to music after cochlear implantation showed no statistic correlation with radiographic variables.

#### CONCLUSION

Better auditory outcomes are obtained in terms of audiometric values and functional recovery the deeper the cochlear implants are inserted into the cochlea.

#### CLINICAL RELEVANCE/APPLICATION

The cochlear coverage of the implant should be checked using a post-operative HRCT in patients with insufficient auditory results. Since these patients' functional outcomes are suboptimal it will be necessary to intensify and optimize the implant programming strategies in those with fewer than 8 functional electrodes inside the cochlea in post-surgical HRCT, or even to consider early replacement.

### A New XAI Framework with Feature Explainability for Tumors Decision-making in Ultrasound Data

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Fajin Dong JR, MD,MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The value of implementing artificial intelligence (AI) on ultrasound screening for thyroid cancer has been acknowledged, with numerous early studies confirming AI might help physicians acquire more accurate diagnoses. However, the black box nature of AI decision-making process makes it difficult for users to grasp the foundation of AI's prediction. Furthermore, explainability is not only related to AI performance but also responsibility and risk in medical diagnosis. In this paper, we offer Explainer, an intrinsically explainable framework that can categorize images and create heatmaps highlighting the regions where its prediction is based on.

#### METHODS AND MATERIALS

This study included 19341 2D ultrasound images (9171 horizontal views and 10170 vertical views) of 7714 thyroid nodules obtained from 7236 individuals from October 2019 to May 2021, with pathological results and physician annotated TI-RADS features are used to train and test the robustness of the proposed framework. Then we conducted a benign-malignant classification study to whether physicians perform better under the assistance of Explainer than diagnose alone or with Gradient-weighted Class Activation Mapping (Grad-CAM).

#### RESULTS

Reader studies show that the Explainer can achieve more accurate diagnosis while providing explaining heatmaps and that physicians' performances are improved when assisted by the Explainer. Case study confirms that the Explainer can locate more reasonable and feature-related regions than the Grad-CAM.

#### CONCLUSION

The Explainer offers physicians a tool to understand the basis of AI predictions and to evaluate its reliability, which has the potential to unbox the black box of medical imaging AI.

#### CLINICAL RELEVANCE/APPLICATION

In the case study comparing heatmaps generated by Explainer and Grad-CAM, Explainer is capable of locating more reasonable and feature-related regions. Evidence proves that in ultrasound images explaining tasks, our method is more detailly.

### Diagnosis of Malignancy in Surgery after Radiofrequency Ablation of Benign Thyroid Nodule

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Jung Hee Shin, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Nodule regrowth after radiofrequency ablation (RFA) of symptomatic large benign thyroid nodules is sometimes diagnosed as malignancies during surgery. This study aimed to assess the ultrasound (US) characteristics of thyroid nodules later diagnosed as cancer, predictive factors for cancer after RFA, and preventive methods for these cancers to avoid RFA procedure.

#### METHODS AND MATERIALS

We reviewed the medical records of 134 consecutive patients with 148 nodules who underwent RFA between 2008 and 2016 for the debulking of symptomatic benign thyroid nodules. We investigated the pre-RFA characteristics of the thyroid nodules, changes at follow-up after RFA, and final surgical pathology.

#### RESULTS

Nodule regrowth after RFA for benign nodules was observed in 36 (24.3%) of the 148 nodules. Malignancies were confirmed in seven (19.4%) of the 36 regrown nodules. Of the 22 nodules removed surgically, pre-RFA mean maximal diameter was significantly higher for malignant nodules than for benign nodules ( $3.89 \pm 0.98$  vs  $5.23 \pm 1.52$  cm,  $P = .01$ ). There was no difference in the regrowth interval between benign and malignant nodules ( $P = .19$ ). Volume reduction rate at 12 months was lower for malignant nodules than for benign nodules ( $51.16 \pm 13.81\%$  vs  $73.68 \pm 20.15\%$ ,  $P = .02$ ). Pre-RFA benignity of all seven malignant nodules was confirmed using two ultrasound (US)-guided fine-needle aspirations (FNAs), except for one nodule confirmed using US-guided core needle biopsy (CNB). The regrown malignant nodules were diagnosed as suspicious for follicular neoplasms using CNB. Histological examination of the malignant nodules during surgery after RFA revealed follicular thyroid carcinomas, except for one follicular variant of papillary thyroid carcinoma.

#### CONCLUSION

Symptomatic large thyroid nodules confirmed to be benign prior to RFA should be considered false-negative FNA results. In RFA patients, CNB prevents delay in cancer diagnosis.

#### CLINICAL RELEVANCE/APPLICATION

Considering false-negative fine-needle aspiration results in symptomatic large benign thyroid nodules before radiofrequency ablation, core needle biopsies should be included in the revised RFA guidelines to prevent delayed cancer diagnosis.

### Deep Learning Based Synthetic Contrast Enhanced T1 Map for Contrast Agent-free Myocardial Extracellular Volume (ECV) Mapping in Cardiac MRI

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Sebastian Nowak, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the utility of generative adversarial networks (GAN) to generate artificial contrast enhanced (CE) T1 maps for creation of synthetic extracellular volume (ECV) maps of the myocardium.

#### METHODS AND MATERIALS

This study includes 1086 cardiac MRI exams with native and CE T1 maps in 3 short axis slices of 986 patients undergoing MRI for various clinical indications between January 2019 and August 2021. Manual myocardium segmentations of 522 slices were used to develop a U-Net for image cropping prior to rigid registration. All registered native and CE T1 map pairs were inspected and excluded if rigid registration failed due to dissimilar contraction phase, resulting in 2074 curated T1 map pairs from 827 patients (age:  $48 \pm 19$  years, 344 female). Of those, 191 native and CE T1 map pairs from 78 patients were defined as hold-out test set with hematocrit available within 48h prior to imaging, allowing for creation of reference 'real' ECV maps. With the remaining cases a U-Net generator was trained with L1 loss and 5-fold cross validation in combination with a PatchGAN discriminator to generate synthetic CE T1 maps from native T1 maps. Note that for ECV calculation, the correct enhancement ratio of blood to myocardium is crucial rather than prediction of exact CE T1 values. Two ECV maps were created for the test set: one using the real and one using the synthetic CE T1 map. The difference between the synthetic and real mean ECV (?ECV) within the myocardium was calculated, and their correlation was quantified with the Pearson correlation coefficient (R). To investigate whether the GAN simply linearly transforms the input native T1 maps, the correlation of the real mean ECV with the mean of the native T1 maps was also compared with the correlation between synthetic and real ECV. Bootstrapping with 1000 resamples were used for calculating 95% confidence intervals.

#### RESULTS

The synthetic mean ECV values in the myocardium showed a high correlation to the real ECV (R: 0.81 [0.74-0.86]), which was significantly higher compared to the correlation of the native T1 and real ECV values (R: 0.61 [0.51-0.69]). A mean ?ECV of  $2.30 \pm 2.04$  % was observed in the hold-out test set.

#### CONCLUSION

Generation of synthetic CE T1 maps from native T1 maps by GANs shows promising results for contrast agent-free estimation of myocardial ECV. The results motivate multicenter studies including more patients with appropriate MRI examination and hematocrit to also investigate direct generation of synthetic ECV without hematocrit and contrast agent use.

#### CLINICAL RELEVANCE/APPLICATION

Deep learning based generation of synthetic CE T1 maps from native T1 maps for synthetic ECV calculation might facilitate faster cardiac MRI examinations without the use of gadolinium-based contrast agents.

### Development and Validation of a CAD System with Reduced False Positives for Bone Metastasis on Chest CT

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Yena C. Kang, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop and validate a computer-aided diagnosis (CAD) system using a deep learning (DL) with improved specificity for detecting bone metastasis on chest CT for accurate and efficient workflow in lung cancer screening.

#### METHODS AND MATERIALS

In this retrospective study, a CAD system was developed using DL algorithm trained on 3,809 chest CT scans (age  $57.7 \pm 71$ ; women 3,533) obtained from the patients who had various cancer origins (breast: 131, colorectal: 24, lung: 11 and others 34), including 825 with confirmed bone metastasis. The diagnostic performance was evaluated using both internal and external test set of 200 (age  $55.7 \pm 58$ ; women 157; 40 confirmed bone metastasis) and 50 (age  $66.1 \pm 46$ ; women 15; all confirmed bone metastasis) chest CT scans, respectively. The bone metastasis was annotated slice-by-slice indicating whether the lesion exists or not, and the confirmed bone metastasis cases included up to 63 lesions in a single scan. A DL algorithm based on DenseNet-161 was trained with axial slices from CT scans. Each slice was individually assessed whether it contains bone metastasis or not. The axial slices were converted into window level of 800 and window width of 1,500, for better visualization of the bone area. Diagnostic performance was evaluated in a patient-based manner using the maximum prediction value of all slices as the representative prediction value for the patient. For internal test, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated and for external test, only sensitivity was evaluated as positive cases were considered only. Additionally, the performance of subgroups by primary cancer was evaluated.

#### RESULTS

The DL based CAD system achieved specificity, sensitivity, PPV, and NPV of 92%, 70%, 92%, and 68% for the internal test, and sensitivity of 86% for the external test in patient-based manner. For the internal test, the specificity of subgroups by primary cancer was 90%, 100%, 88% and 93%, and the sensitivity was 63%, 100%, 100%, and 71% for breast, colorectal, lung and other origins.

#### CONCLUSION

We successfully developed and validated a CAD system with high specificity thus reducing false positive cases for bone metastasis evaluation on chest CT.

#### CLINICAL RELEVANCE/APPLICATION

The proposed system can be applied to lung cancer screening, providing a valuable tool for efficient workflow. Further studies are warranted to assess the performance in different clinical settings and malignancies.

### Integrating Clinical Data with AI to Optimize Decision-making in Prostate MRI

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Nadia S. Moreira Da Silva (*Presenter*) Employee, Lucida Medical

#### PURPOSE

To determine whether combining prostate MRI AI-based decision support outputs, clinical data and PI-RADS scores in a multi-modal predictive model enhances detection of clinically significant prostate cancer.

#### METHODS AND MATERIALS

MRI, clinical history, histopathology, and PI-RADS scores were obtained retrospectively from five sites in a multi-vendor, multiple field strength study. After exclusions for AI contraindications including prior treatment and quality issues, model training used data from 352 patients and a held-out test set comprised data from 235 patients (Gleason grade group (GGG)=2, prevalence 34%). Our automated multi-stage AI-based software segments and calculates the volume of prostate whole gland and transition zone (TZ) on MRI, and segments and scores lesions/patients for GGG=2 disease likelihood. Biopsy-verified GGG=2 was used as ground truth, with MRI-negative patients not undergoing biopsy assumed negative. Sensitivity, specificity, and AUC were evaluated at patient level on the held-out test set, with 95% confidence intervals obtained through bootstrapping. Combinations of AI, clinical and PI-RADS data were tested for significant improvement to the AI score and PI-RADS assessment, at pre-determined thresholds equivalent to PI-RADS 3.

#### RESULTS

mpMRI PI-RADS scores alone detected GGG=2 with sensitivity 1.00 (95% CI 1.00-1.00), specificity 0.67 (0.61-0.75) and AUC 0.94 (0.91-0.97). GGG=2 was detected by bpMRI AI with sensitivity 0.97 (0.93-1.00), specificity 0.55 (0.47-0.62) and AUC 0.88 (0.84-0.92). Combining AI score and TZ-PSA density (PSAD) improved specificity (sensitivity 0.95 (0.90-0.99), specificity 0.70 (0.63-0.77) and AUC 0.90 (0.85-0.93)). The addition of AI and TZ-PSAD to PI-RADS scores maintained high sensitivity of 0.99 (0.96-1.00), while significantly improving specificity to 0.83 (0.77-0.89, KS p-value<0.001) and AUC to 0.96 (0.93-0.98, DeLong p-value 0.003). TZ volume based PSAD had modest additional benefit compared to whole-prostate PSAD. Other variables offered <5% specificity improvements or non-significant benefits. Findings with bpMRI and mpMRI AI models were similar. Limitations: Most MRI-negative cases did not receive biopsy in this retrospective study.

#### CONCLUSION

The use of PSAD improves the predictive accuracy of prostate MRI AI decision support, with significant improvement in specificity at similar sensitivity. Combining PI-RADS, PSAD and AI offers substantial improvement compared to AI or PI-RADS assessments alone.

#### CLINICAL RELEVANCE/APPLICATION

The improved specificity achieved through integrating patient PSAD and radiologists' PI-RADS scores with AI software can potentially reduce false positive cases, further aiding patient selection for biopsy using MRI.

### Deep Learning to Predict Fat and Appendicular Skeletal Masses from Chest Radiograph

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Ki Duk Kim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To predict fat and appendicular skeletal muscle (ASM) masses from chest radiograph (CXR), which can be highly beneficial for analyzing the health impacts of body composition.

#### METHODS AND MATERIALS

A total of 40,369 CXRs with body composition, including fat and ASM, from a tertiary hospital's health screening center was used. Fat and ASM were acquired using bioelectrical impedance analysis (BIA). The Inception v3 architecture was used to predict body composition, and assessment to determine the impact of demographics, such as age, sex, height, and weight, on the model's performance was conducted. Deep label distribution learning with additional Mean-Variance (MV) loss was used to train the network. Two independent unseen test datasets comprising 1,000 individuals each, which follows normal distribution and uniform distribution of age, from same center were used. The mean average error (MAE) and Pearson's correlation coefficient (r) between BIA and model prediction were evaluated. Correlation analyses and Bland-Altman plots were also presented.

#### RESULTS

The age of test dataset was  $56.732 \pm 10.519$  and  $54.421 \pm 19.160$  (range from 20 to 90), respectively for test set of normal distribution and test set of uniform distribution. And the ASM was  $25.839 \pm 5.814$  and  $25.709 \pm 6.152$ , respectively. Sex was sampled evenly for both datasets. In the test set of normal distribution, MAEs of the models without information and without MV loss, without information and with MV loss, with information and without MV loss, and both with information and MV loss for predicting fat were 1.773, 1.673, 1.564, and 1.564, respectively. All model significantly correlated with BIA with decent r scores of 0.805, 0.839, 0.855, and 0.861, respectively ( $P < 0.001$  in all model). In the uniform distribution set, MAEs were 1.945, 1.844, 1.773, and 1.726 respectively, while r scores were 0.805, 0.849, 0.853, and 0.860, respectively ( $P < 0.001$  in all model). In the normal distribution set, MAEs of each model for ASM were 1.309, 1.181, 1.307, and 1.172 respectively. All model showed decent r scores of 0.927, 0.932, 0.981, and 0.940 ( $P < 0.001$  in all model) with the same order. In the uniform test dataset, MAEs were 1.424, 1.250, 1.376, and 1.278, respectively, while r scores were 0.920, 0.932, 0.930, and 0.932, respectively ( $P < 0.001$  in all model).

#### CONCLUSION

deep learning model of CXR can precisely predict fat and muscle masses. Demographics and MV loss can significantly enhance the predicting power of the model

#### CLINICAL RELEVANCE/APPLICATION

Prediction of fat and ASM from CXR can be applied to a variety of clinical fields, such as sarcopenia assessment, prognosis prediction of cancer patients, precision medicine for optimum drug dose estimation in inpatient settings.

### Long-Term Survival after Percutaneous CT and US guided Microwave Ablation of Pathologically Proven Renal Cell Carcinoma

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Daniel H. Kim, BA, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the long-term overall (OS), cancer-specific (CSS), and local tumor progression (LTP)-free survival of patients who underwent percutaneous microwave ablation (MWA) of pathologically proven renal cell carcinoma (RCC).

#### METHODS AND MATERIALS

This IRB-approved, HIPAA compliant study included patients who underwent percutaneous MWA between 2013 and 2017 of biopsy-proven RCCs. All patient demographics, tumor characteristics, procedural technical outcomes, and pre- and post-procedural estimated glomerular filtration rate (eGFR) were evaluated. OS, CSS, and LTP-free survival were calculated and Kaplan-Meier analysis was performed. Complications were classified per the Clavien-Dindo system.  $\chi^2$  test was used for proportions for categorical outcomes excluding repeated measures for patients and a paired t-test for differences in eGFR.

#### RESULTS

The study cohort comprised 86 biopsy-proven RCCs from 81 patients (mean age:  $67.6 \pm 16.9$ ) and were 62% male. The median follow-up period was 76.8 months (1 to 123 months). The mean tumor size was 2.8cm (0.7cm to 7.0cm) and RCC lesions were more commonly located on the right side (60.5%), anterior (41.9%), lower pole (44.2%), and endophytic (69.8%). Primary and secondary technical success was achieved in 88.4% (76/86) in a single session and 90% (9/10) in two sessions with overall technical success of 100%. The 5-year and 10-year OS, CSS, and LTP-free survival rates were 82.7%, 90.8%, and 84.3% and 75.7%, 84.7%, and 82.9%, respectively. RCC = 4cm ( $p=0.016$ ) was predictive of LTP. There were no significant changes in pre-ablation and 2-3 years post-ablation eGFR (58.5 vs 58.4 mL/min/1.73m<sup>2</sup>,  $p=0.932$ ). There was a 2% overall incidence of complications, all grade I.

#### CONCLUSION

Percutaneous CT and US guided MWA of biopsy-proven RCC was safe and effective with excellent long-term OS, CSS, and LTP-free outcomes within 10 years from initial treatment.

#### CLINICAL RELEVANCE/APPLICATION

Image-guided ablative therapies are a safe and effective treatment option for renal cell carcinoma with durable long-term survival rates.

### Long-Term Survival after CT and US Guided Radiofrequency Ablations of T1a and T4 Pathologically Proven Renal Cell Carcinomas

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Daniel H. Kim, BA, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

To determine the long-term overall, renal cell carcinoma (RCC)-specific, and progression-free survival of patients who underwent percutaneous radiofrequency ablation (RFA) of pathologically proven RCC.

#### METHODS AND MATERIALS

This IRB-approved, HIPAA compliant study included patients who underwent percutaneous RFA between 2004 and 2015 of their biopsy-proven RCCs. All patient demographics, tumor characteristics, procedural technical outcomes, and pre- and post-procedural estimated glomerular filtration rate (eGFR) were collected. Overall survival (OS), and local tumor progression (LTP)-free survival were calculated by Kaplan-Meier survival curves. In addition, a subcohort analysis of the RCC T1a and T4 was conducted to examine the RCC-specific survival (RSS) rate with Kaplan Meier survival analysis. Complications were classified per the Clavien-Dindo system.  $\chi^2$  test was used for proportions for categorical outcomes and paired t test was used for changes in eGFR.

#### RESULTS

The study cohort comprised 129 biopsy-proven RCCs from 101 patients (mean age:  $68.5 \pm 12.4$ ). Primary technical success was achieved in 91.5% (118/129) of ablations and secondary technical success was achieved in 90.9% (10/11) of ablations with remaining one lesion requiring three ablations. The median of the follow-up period was 136 months (1 to 230 months) with mean tumor size of 2.3cm (0.5cm to 8.0cm). RCC lesions were more commonly located on the right (52.7%), in the midpole (37.2%), and were endophytic (54.3%). The study cohort comprised the following RCC subtypes: clear cell (69%), epithelial neoplasm (16%), papillary (11%), and chromophobe (5%). There was a slight decrease in preprocedure eGFR relative to 2-3 years postprocedure eGFR (59.2 vs 55.4 mL/min/1.73m<sup>2</sup>;  $p=0.003$ ). There were 6 complications mostly grade I-III. The 15-year OS and LTP-free survival rates were 63.6% and 92.2% in 101 patients and 129 lesions. The T1a and T4 subcohorts comprised 65 patients and 32 patients with a 15-year RSS rate of 96.5% and 82.7%.

#### CONCLUSION

Image-guided percutaneous RFA of RCCs was safe with durable 15-year OS rate of 63.6%, LTP-free survival rate of 92.2%, and RSS rate of 96.5% and 82.7% in the T1a and T4 subcohorts.

#### CLINICAL RELEVANCE/APPLICATION

Percutaneous CT and US guided radiofrequency ablation was safe with excellent 15-year durable responses in both T1a and T4 subcohorts.

### **No-touch Radiofrequency Ablation versus Tumor Puncture Microwave Ablation for Small Hepatocellular Carcinoma: Comparison of Treatment Outcomes**

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Jae Hyun Kim, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The aim of this study was to compare the therapeutic outcomes between no-touch (NT) radiofrequency ablation (RFA) and tumor puncture microwave ablation (MWA) for single hepatocellular carcinomas  $\leq 4$  cm.

#### **METHODS AND MATERIALS**

A total of 335 patients who underwent NT RFA (n=155) or tumor puncture MWA (n=180) for single HCCs  $\leq 4$  cm were included in this retrospective study. A matched cohort comprising 121 patients from each group was selected after propensity score matching analysis to adjust for potential biases. This study assessed the therapeutic outcomes after ablation including technical success, local tumor progression (LTP), and major complications. Cumulative LTP rates were estimated using the Kaplan-Meier method.

#### **RESULTS**

A total of 242 patients (mean age, 66.2 years  $\pm$  9.5 [standard deviation]; 183 men) were evaluated. The technical success rates were 99.2% [120/121] vs. 100% [121/121] in the NT RFA and MWA groups, respectively ( $P>0.05$ ). The estimated 1- and 2-year cumulative LTP rates in the NT RFA were 2.2% and 3.1%, respectively, and were not significantly different from the 3.0% and 6.0% observed in the MWA group ( $P=0.279$ ). There was no significant difference in the major complication rate between the NT RFA and MWA groups (1.7% [2/121] vs. 0.8% [1/121],  $P=1.000$ ).

#### **CONCLUSION**

Tumor puncture MWA showed comparable therapeutic outcomes including LTP and major complication rates to those of NT RFA in single HCCs ( $\leq 4$  cm).

#### **CLINICAL RELEVANCE/APPLICATION**

NT RFA and tumor puncture MWA are potentially effective and safe treatment options for small HCCs ( $\leq 4$  cm).

### Perfusion CT for Early Prediction of Treatment Response of Cryoablation in Renal Cell Carcinoma

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Oyunbold Lamid-Ochir (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate quantitative analysis of perfusion CT (pCT) for assessment of early treatment response after cryoablation in renal tumors.

#### METHODS AND MATERIALS

A total 54 patients with renal tumors who had treated by CT-guided percutaneous cryoablation in our institution from June 2014 to August 2016. Twenty-seven patients were selected, who underwent pCT before and after within 1 week, 1, 3, 6 months and 1-year treatment. Perfusion parameters including arterial flow perfusion (AFP) as tumor maximum, minimum, average and average changes and tumor diameter, freezing time, treatment cycles and progression-free-survival were analyzed and compared. The effects of treatment response were evaluated by RECIST standards version 1.1 as a non-responder and responder.

#### RESULTS

Twenty-seven patients (22 men, 5 women: age,  $68 \pm 12$  y.o.) evaluated as quantitative analysis with pCT. Five of 27 patients were non-responders, and 22 patients were responder. The mean AFP values were significantly different between non-responder ( $46.6 \pm 25.8$ ) and responder ( $25.1 \pm 6.1$ ) at 1 month after cryoablation ( $p < 0.05$ ). ROC analysis demonstrated that tumor average (AFP) at 1 month had the cut-off of perfusion value (29.95) and area under curve (0.94), with sensitivity and specificity of 100% and 84.2%, respectively ( $p < 0.05$ ). Percent of progression free-survival was 100% (cut-off  $< 29.95$ ) and 66.7% (cut-off  $> 29.95$ ) for 32 months observation.

#### CONCLUSION

pCT was able to evaluate and predict therapeutic effects of cryoablation at 1 month after treatment. It can offer both morphologic and functional evaluation, providing a quantitative assessment of residual tumor vascularization after treatment.

#### CLINICAL RELEVANCE/APPLICATION

pCT can be predicted to responder and non-responder at 1 month after cryoablation and might be earlier than dynamic CE-CT. Also, it can detect minimal focal perfusion changes whether the tumor is shrinking or without tumor volume changes.

### **SAR-COOL: Sarcoma Cryoablation Outcomes and Optimization of Life**

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Koustav Pal, MBBS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the local tumor progression-free survival following cryoablation of recurrent or metastatic soft tissue sarcoma (STS) lesions.

#### **METHODS AND MATERIALS**

A single-institution retrospective analysis of patients with a histopathological diagnosis of metastatic STS who underwent percutaneous cryoablation (PC) from January 2022 to April 2023 was performed. . Patients with less than 60 days of follow-up and those treated for more than four lesions during one procedure were excluded. Complications were categorized based on the Common Terminology Criteria for Adverse Events (CTCAE) classification system. R software version 4.2.3 was used for analysis. (We aim to further analyze the outcomes of 239 patients with 391 procedures from Jan. 2016 to April 2023)

#### **RESULTS**

61 patients who underwent PC for 84 STS lesions met the eligibility criteria. There were 21 different histological subtypes of sarcoma in the study, with the two most common being leiomyosarcoma (20/61) and liposarcoma (16/61). The median size of sarcoma lesions was 2.1 cm (range 0.4 to 13.4). Complete response at six months was achieved in 81% of the treated lesions. Local tumor progression-free survival was 86.1% at 6 months and 77.3% at 1 year. The overall survival was 97.2% at 1 year. Chemotherapy free time for patients was 54.57% at 6 months. The complication rate was 14%, with 56.55% classified as CTCAE grade 3 or higher. Subgroup analysis for leiomyosarcoma vs. liposarcoma demonstrated an overall survival of 100% vs. 90.9% at 12 months, respectively. Local tumor-free progression was 86.7% at 6 months and 86.7% at 12 months for liposarcoma. Leiomyosarcoma demonstrated 91.97% local tumor-free progression at 6 months and 46.4% at 12 months. There was no statistically significant difference between the two groups ( $p=0.37$ ).

#### **CONCLUSION**

PC of STS and its metastases is a safe and effective treatment modality.

#### **CLINICAL RELEVANCE/APPLICATION**

Surgical resection is a cornerstone in the management of recurrent or oligometastatic soft tissue sarcoma. Percutaneous cryoablation is a minimally invasive technique that may complement surgical approaches. This study demonstrates that cryoablation can achieve high local control rates with durable responses in this patient population.

### The Next Frontier in Lumbar Spine MR Bone Imaging: Harnessing the Power of Super-Resolution Deep Learning Reconstruction

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Masamichi Hokamura (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aims to assess the effectiveness of super-resolution deep-learning-based reconstruction (SR-DLR), which leverages k-space properties, on the image quality of lumbar spine magnetic resonance (MR) bone imaging using a 3D multi-echo in-phase sequence.

#### METHODS AND MATERIALS

In this retrospective study, 29 patients who underwent lumbar spine MRI, including an MR bone imaging sequence, between January and April 2023, were analyzed. Images were reconstructed with and without SR-DLR (Matrix sizes: 960 x 960 and 320 x 320, respectively). The signal-to-noise ratio (SNR) of the vertebral body and spinal canal, along with the contrast and contrast-to-noise ratio (CNR) between the vertebral body and spinal canal, were quantitatively evaluated. Furthermore, the slope at half-peak points of the profile curve drawn across the posterior border of the vertebral body was calculated. Two radiologists independently assessed image noise, contrast, artifacts, sharpness, and overall image quality of both image types using a 4-point scale. Interobserver agreement was evaluated using weighted kappa coefficients, and quantitative and qualitative scores were compared via the Wilcoxon signed-rank test.

#### RESULTS

In this retrospective study, 29 patients who underwent lumbar spine MRI, including an MR bone imaging sequence, between January and April 2023, were analyzed. Images were reconstructed with and without SR-DLR (Matrix sizes: 960 x 960 and 320 x 320, respectively). The signal-to-noise ratio (SNR) of the vertebral body and spinal canal, along with the contrast and contrast-to-noise ratio (CNR) between the vertebral body and spinal canal, were quantitatively evaluated. Furthermore, the slope at half-peak points of the profile curve drawn across the posterior border of the vertebral body was calculated. Two radiologists independently assessed image noise, contrast, artifacts, sharpness, and overall image quality of both image types using a 4-point scale. Interobserver agreement was evaluated using weighted kappa coefficients, and quantitative and qualitative scores were compared via the Wilcoxon signed-rank test.

#### CONCLUSION

SR-DLR, which is based on k-space properties, has the potential to enhance the image quality of lumbar spine MR bone imaging utilizing a 3D gradient echo in-phase sequence.

#### CLINICAL RELEVANCE/APPLICATION

The application of SR-DLR can lead to improvements in lumbar spine MR bone imaging quality.

### Application of Material Decomposition Technique based on Dual-energy CT in the Differential Diagnosis of Acute and Old Thoracolumbar Fracture

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Mingyue Wang, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

To identify acute and old thoracolumbar vertebral compression fractures by using material decomposition technique based on dual-energy CT (DECT).

#### METHODS AND MATERIALS

A total of 12 patients with acute trauma or diagnosed compression fracture who underwent thoracolumbar DECT and MR scanning in Shenzhen Qianhai Shekou Free Trade Zone Hospital from June 2022 to February 2023 were retrospectively collected. 24 cases about vertebral compression fracture was found in DECT and MRI (fat suppressed T2WI). The time about patients took DECT and MRI examination from the first day they get injured to 2 weeks after they got fractured. A total of 16 vertebral bodies' data were collected, including 8 patients with old fractures. All patients had a fracture injury time of more than six months. Water (Iodine), Water (Calcium) and Water (HAP)-based on material decomposition images were reconstructed. The signals of edema area is calculated from water density values and water difference values in three material decomposition images in both area of acute fractured vertebrae and old fractured vertebrae. With reference to bone marrow edema area of fracture based on MRI. A paired T test was used to compare the difference in water density between acute vertebral fracture edema and old compression fractures. A two-factor ANOVA was used to compare the difference in water density values between edematous fractured vertebrae and old compression fractured vertebrae among three material images sets.

#### RESULTS

The water density values for Water (Iodine), Water (Calcium) and Water (HAP) images were significant higher in the acute fracture edema vertebral bodies compared to old compression fracture vertebral bodies (1147.6mg/cm<sup>3</sup> Vs 1040.9mg/cm<sup>3</sup>, 1089.4mg/cm<sup>3</sup> Vs 1014.4mg/cm<sup>3</sup> and 996.7mg/cm<sup>3</sup> Vs 972.2mg/cm<sup>3</sup>, respectively, all  $P < 0.001$ ). There was a significant statistical difference in the water difference values between the acute fractured vertebrae and the old compression fractured vertebrae ( $P < 0.001$ ), and with the largest water difference values in the Water (Iodine) image.

#### CONCLUSION

The water density values for Water (Iodine), Water (Calcium) and Water (HAP)-based material decomposition images can distinguish acute thoracolumbar fractures from old compression fractures on dual-energy CT examination. Water (Iodine) images showed the best discrimination.

#### CLINICAL RELEVANCE/APPLICATION

The measurement of water density values for material decomposition images based on dual-energy CT, can improve the clarity of diagnosis of acute thoracolumbar fractures and old compression fractures, and also avoid confusion caused by contraindications to MRI examination. This is a valuable aid for both patients and clinical practice.

### Application of Dual-energy CT Single Energy Reconstruction Technique in Acute Fractures of Thoracolumbar Spine with Bone Marrow Edema

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Mingyue Wang, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

To identify bone marrow edema in acute thoracolumbar fractures by using single-energy reconstruction technique based on dual-energy CT (DECT).

#### METHODS AND MATERIALS

A total of 18 patients with acute trauma or diagnosed compression fracture who had thoracolumbar DECT and MR scanning in Shenzhen Qianhai Shekou Free Trade Zone Hospital from June 2022 to February 2023 were retrospectively collected. 20 cases about vertebral compression fracture was found in DECT and MRI (fat suppressed T2WI). The time about patients took DECT and MRI examination from the first day they get injured to 2 weeks after they got fractured. 40KeV images, 70KeV images, 100KeV images, 140KeV images-based on single energy reconstruction technique were reconstructed. On the median sagittal plane of the Water (Ca) pseudo-color image, the fracture bone marrow edema area was identified. According to the edema areas shown by MRI, manually delineated the region of interest. CT values of the edema area of the fractured vertebra and the normal vertebra were recorded at different Single energy. All edema areas of compression fractures were use MRI fat suppressed T2WI sequences as reference. A paired T test was used to compare the difference in CT values between the fractured edema vertebra and the normal vertebra under different single energies. A two-factor ANOVA was used to compare the difference in CT values between oedematous fractured vertebrae and normal vertebrae at four keV sets.

#### RESULTS

The CT values of vertebrae with acute fracture edema vertebral bodies compared with normal vertebral bodies measured at 40KeV, 70 KeV, 100 KeV and 140KeV were (691.5Hu Vs 252.9Hu, 319.1Hu Vs 106.1Hu, 222.4Hu Vs 67.9Hu and 183.1Hu Vs 52.5Hu, respectively, all  $P < 0.001$ ). There was a significant statistical difference in the difference in CT values between the acutely fractured vertebrae and the normal vertebrae ( $P < 0.001$ ), and with the greatest difference in CT values in the 40KeV image.

#### CONCLUSION

The single energy values of 40KeV, 70 KeV, 100 KeV and 140KeV images can differentiate bone marrow edema from normal vertebral body on acute thoracolumbar fracture dual-energy CT scan. The greatest difference in CT value is at 40KeV. Combined with Water (Ca) material density film, it can provide a more accurate diagnosis of acute thoracolumbar fracture edema.

#### CLINICAL RELEVANCE/APPLICATION

The measurement of single-energy reconstruction on dual-energy CT, combined with Water (Ca) material density picture, can improve the clarity of diagnosis of thoracolumbar fractures and bone marrow edema, and also avoid confusion caused by contraindications to MRI examination. This is a valuable aid for both patients and clinical practice.

### Assessing the Combined Efficacy of Radiofrequency Ablation and Kyphoplasty with Radiation Treatment for Painful Spine Metastases

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Chloe Issa, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare kyphoplasty ablation with and without radiotherapy for the treatment of patients with painful metastatic neoplastic disease to the spine.

#### METHODS AND MATERIALS

Between 3/2019 and 08/2022, 59 kyphoplasty procedure were performed for palliation of metastatic spine disease. 21 patients (36.2%) with metastatic tumor received radiation in addition to kyphoplasty/RF ablation to palliate pain: 9 patients (47.4%) had prior radiation, 2 patients (10.5%) had concurrent, and 10 patients (1.4%) had radiation therapy after. 37 painful metastatic spinal tumors were treated with kyphoplasty ablation without radiation. The primary neoplastic disease was as follows: multiple myeloma (n=17, 28.8%), breast (n=15, 25.4%), lung (n=7, 11.9%), prostate (n= 6, 10.2%), lymphoma and colorectal (each n= 3, 5.1%), urothelial (n= 2, 3.4%), thyroid, pancreas adenocarcinoma, renal cell, and metastatic adenoid cystic (each n=1, 3.3%). Pain relief was evaluated by the visual analogue scale (VAS) score, disability by the Oswestry Disability Index (ODI), performance status by the Karnofsky Performance Status Scale (KPS) score and ECOG score before and within 3-months after the procedure. The highest documented VAS, ODI, KPSS, and ECOG scores pre- and post-procedure was recorded. A P value < 0.05 was considered statistically significant.

#### RESULTS

Technical success was achieved in all patients. Table 1 compares demographics, pre procedural and post procedural pain, disability, and functional scores between the two groups. The median change in VAS, ODI, KPSS, and ECOG scores from baseline to three months was not significantly different between the two groups. There were no major complications.

#### CONCLUSION

The study suggests adding radiation therapy to kyphoplasty/RFA for palliation of metastatic neoplastic disease to the spine may not significantly change pain, disability, or performance status scores. Further studies with a larger number of subjects and longer follow-up and prospective design are needed to validate these findings.

### Symmetry Plane Analysis for Determination of Vertebral Rotation

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Dillon Haughton, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Accurate vertebral rotation measurements are crucial in the understanding and treating of spinal pathologies. Many methods exist to aid in determining this metric, with the most common and widely accepted method utilizing axial CT scans being the Aaro-Dahlborn method. This method is simple and accurate but is limited due to errors when used by inexperienced users. It only considers one axial cut through the vertebra limiting its accuracy when the vertebra is rotated in sagittal and coronal planes. We propose a new method using symmetry planes calculated by iterative closest point registration and pairwise assignment of curves, as an alternative to the Aaro-Dahlborn method in determining vertebral rotation. Our method considers the entire vertebra and is an automated method applied post segmentation, which would limit operator error.

#### METHODS AND MATERIALS

Our method was coded in python utilizing a Jupyter notebook compatible with 3DSlicer. It was tested on segmented vertebrae from the VERSE2020 opensource dataset. 812 vertebrae with no gross pathology were selected from the VERSE2020 database and processed utilizing our method for feasibility analysis. Out of those 812, 96 vertebrae from 8 randomly selected CT scans were divided up among two medical students who performed measurements utilizing the Aaro-Dahlborn method. Correlation-coefficients and Bland-Altman plots were calculated to determine the alignment between the two methods.

#### RESULTS

Out of 812 vertebrae analyzed, 799 had their vertebral rotation successfully calculated using our algorithm (98% success rate). Correlation coefficient was calculated at 87% amongst the 96 vertebrae whose vertebral rotation was determined manually against our method. Bland-Altman plotting showed mean difference of -0.51 degrees, a +2 standard deviation of 2.2 degrees and -2 standard deviation of -3.2 degrees.

#### CONCLUSION

Our method had similar accuracy to the Aaro-Dahlborn manual method. Our method was also demonstrated to work with a wide variety of normal vertebrae. This provides a quick and efficient means of determining vertebral rotation and can act as an objective reference due to no post-segmentation user input. As segmentation algorithms for individual vertebrae become more accessible and the process is simple manually, we don't see this as a limiting factor to the utility of our method. An extension of our method can also be applied to determining the rotation of vertebrae in both sagittal and coronal planes, which could greatly contribute to our understanding of vertebral movements.

#### CLINICAL RELEVANCE/APPLICATION

Improvement in speed and accuracy of methods of determining vertebral rotation will further our understanding of vertebral movements in pathologies such as back pain and scoliosis.

### How Effective is Radiofrequency Ablation with Kyphoplasty at Decreasing Narcotic and Analgesic Requirements in Painful Spine Metastases

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Chloe Issa, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

To determine the effect of radiofrequency ablation (RF) in conjunction with kyphoplasty on pain relief and analgesic requirements in patients with painful metastatic disease to the spine.

#### METHODS AND MATERIALS

Between 3/2019 and 8/2022, 59 kyphoplasty/RF ablations were performed. The median age was 63 years old (IQR, 55-69) with a male-to-female ratio of 0.97. The primary neoplastic diseases were as follows: multiple myeloma (n=17, 28.8%), breast (n=15, 25.4%), lung (n=7, 11.9%), prostate (n= 6, 10.2%), lymphoma and colorectal (each n= 3, 5.1%), urothelial (n= 2, 3.4%), thyroid, pancreas adenocarcinoma, renal cell, and metastatic adenoid cystic carcinoma (each n=1, 3.3%). Pain relief was evaluated by the highest visual analogue scale (VAS) score before and within 3-months after the procedure. The number of non-opioid and opioid pain medications that were taken before, at 1-mo, and 3-mo after the procedure was recorded. A two tailed p value < 0.05 was considered statistically significant.

#### RESULTS

Technical success was achieved in all patients. The median VAS score decreased from 10 (IQR, 8-10) to 2(IQR, 0-4) after the procedure (p< 0.001) and 2 (IQR, 2-3) at 3 months after procedure (p < 0.001). Table 1 demonstrates the number (and percentages) of patients who were taking non-opioid and opioid analgesics before the Kyphoplasty/ablation, and at 1-mo and 3-mo after the procedure. Overall, use of opioid medications decreased at 1-mo and 3-mo after the procedure.

#### CONCLUSION

RFA in conjunction with kyphoplasty appears to provide meaningful clinical improvement in VAS pain scores and decrease requirements for narcotic medications in patients with metastatic disease to the spine.

#### CLINICAL RELEVANCE/APPLICATION

### How Effective is Radiofrequency Ablation with Kyphoplasty at Improving Pain Scores in Burdensome Spinal Metastases

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Chloe Issa, BS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To determine the improvement in pain, performance status and disability index, and the safety of radiofrequency ablation (RFA) in conjunction with kyphoplasty for the treatment of painful metastatic neoplastic disease to the spine.

#### **METHODS AND MATERIALS**

Between 3/2019 and 8/2022, 59 kyphoplasty RFAs were performed. The median age was 63 (IQR, 55-69) with a M:F ratio of 0.97. There were 11 different primary cancers; multiple myeloma was the most prevalent (n=17, 28.8%). Pain relief was evaluated by the Visual Analog Scale (VAS); performance status by the ECOG and Karnofsky Performance Status Scale (KPS), Disability by the Oswestry Disability Index (ODI). The highest VAS, ECOG, KPS and ODI score pre- and within 3 months post-procedure were recorded. A two-tailed p value < 0.05 was considered statistically significant.

#### **RESULTS**

Technical success was achieved in all patients. Within 3 months from the procedure, the median VAS score decreased from 10 (IQR, 8-10) to 2 (IQR, 2-3,  $p < 0.001$ ). The median ECOG performance status score improved from 3 (IQR, 2-3) to 1 (IQR, 1-2) ( $p < 0.001$ ). The median KPS increased from 50 (IQR, 40-60) to 75 (IQR, 62.5-90) ( $p < 0.001$ ). The median ODI decreased from 66.5 (IQR, 49.8-80) to 20.5 (IQR, 13-26) ( $p < 0.001$ ). There were no major complications.

#### **CONCLUSION**

RFA in conjunction with kyphoplasty is safe and provides meaningful clinical improvement in VAS, ECOG, KPS, and ODI scores in patients with pain due to metastatic disease to the spine, when measured at post procedure follow-up within 3 months of the procedure.

#### **CLINICAL RELEVANCE/APPLICATION**

### Value of MRI in the Staging of Klippel-Trenaunay Syndrome Complicated with Lower Extremity Lymphedema

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Xingpeng Li (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the value of MRI in the staging of Klippel-Trenaunay syndrome (KTS) complicated with lower extremity lymphedema.

#### METHODS AND MATERIALS

Thirty-four patients who were diagnosed as KTS complicated with lower extremity lymphedema were recruited in this retrospective study from July of 2011 to November of 2021. Referring to the clinical staging standard of lower extremity lymphedema of the international society of lymphology in 2020, all patients were divided into two groups including stable stage and advanced stage. The MRI indexes of the two groups were recorded and were statistically compared: longitudinal involvement range of lymphedema, thickened parts of skin and subcutaneous soft tissue, signs of subcutaneous soft tissue edema (parallel line sign, grid sign, band sign, honeycomb sign, lymph lake sign, crescent sign and star cloud sign).

#### RESULTS

Compared with stable stage, patients in advanced stage demonstrated older onset age ( $P < 0.05$ ). For imaging features, the proportion of honeycomb sign are higher in advanced stage than stable stage ( $P < 0.05$ ). While no statistical difference was found in the incidence of parallel line sign, grid sign, band sign, lymph lake sign, crescent sign, star cloud sign, skin and subcutaneous soft tissue thickening, range of lymphedema in lower limbs (all  $P > 0.05$ ). The sensitivity, specificity, positive predictive value, negative predictive value and accuracy of honeycomb sign in the diagnosis of advanced lower extremity lymphedema were 55.00%, 92.86%, 91.67%, 59.09% and 70.59%, respectively.

#### CONCLUSION

MRI is of great value in KTS complicated with lower extremity lymphedema. Honeycomb sign is an important imaging index for the diagnosis of advanced KTS complicated with lower extremity lymphedema.

#### CLINICAL RELEVANCE/APPLICATION

It is necessary to evaluate the severity of edema with MR for KTS complicated with lower extremity lymphedema, which is very important for therapeutic options.

### Correlation of FLT PET Findings with Histopathology in the Assessment of Response to Neoadjuvant Chemoradiotherapy in Pancreatic Cancer: Comparison with FDG PET

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Yuka Yamamoto, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Although the role of FDG PET has been proposed in pancreatic cancer, a high percentage of patients have diabetes due to pancreatic cancer. Therefore, the rate of false negative results is high due to elevated plasma glucose levels. On the other hand, 3'-deoxy-3'-18F-fluorothymidine (FLT) is being studied to assess tumor proliferating activity. We evaluated the ability of FLT PET to predict the response to neoadjuvant chemoradiotherapy in pancreatic cancer, in comparison with FDG.

#### METHODS AND MATERIALS

FDG and FLT PET/CT studies were performed before and after neoadjuvant chemoradiotherapy in 19 patients with pancreatic cancer. The values of maximum standardized uptake value (SUV<sub>max</sub>) at the primary tumor obtained before and after neoadjuvant chemoradiotherapy are SUV<sub>before</sub> and SUV<sub>after</sub>, respectively. Percent change was calculated according to the following equation:  $(SUV_{before} - SUV_{after}) \times 100 / SUV_{before}$ . In the FDG PET analysis, patients with a blood glucose level of 200 mg/dL or higher at the time of the FDG PET/CT scan were excluded from the analysis. Based on histopathological analysis of the specimens obtained at surgery, the patients were classified as pathologic responders or pathologic non-responders.

#### RESULTS

Nine patients were found to be pathologic responders and 10 pathologic non-responders. Three patients were excluded from before therapy FDG PET analysis due to their high blood glucose levels. The FDG SUV<sub>after</sub> in pathologic responders was significantly lower than that in pathologic non-responders ( $p=0.03$ ). The FLT percent change in pathologic responders was significantly higher than that in pathologic non-responders ( $p=0.028$ ).

#### CONCLUSION

Based on the results of this preliminary study in a small patient sample, FLT PET seems to be as useful as FDG PET for predicting response to neoadjuvant chemoradiotherapy in pancreatic cancer. FLT PET does not require fasting prior to imaging and is not dependent on blood glucose levels, making it a potentially more convenient technique of evaluation in pancreatic cancer.

#### CLINICAL RELEVANCE/APPLICATION

FLT PET does not require fasting prior to imaging and is not dependent on blood glucose levels, making it a potentially more convenient technique of evaluation in pancreatic cancer.

### Textural Indices Extracted from FMISO and FLT PET/CT for Predicting IDH1 Mutation in Newly Diagnosed High-grade Gliomas

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Yuka Yamamoto, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Tumor hypoxia and proliferation have been recognized as determinant factors characterizing tumor aggressiveness in high-grade gliomas. To clarify in vivo hypoxia and proliferation in relation to isocitrate dehydrogenase (IDH) mutation, we retrospectively analyzed texture indices extracted from 18F-fluoromisonidazole (FMISO) PET/CT and 3'-deoxy-3'-18F-fluorothymidine (FLT) PET/CT in newly diagnosed high-grade gliomas.

#### METHODS AND MATERIALS

Thirty-three patients with newly diagnosed high-grade (WHO grade III and IV) gliomas were included in this study. They underwent both PET/CT studies with FMISO and FLT before surgery. The maximal standardized uptake value (SUVmax) and 31 texture indices were measured. Texture indices were extracted from four different matrices computed for each volume of interest: gray-level co-occurrence matrix, gray-level run length matrix, neighborhood gray-level difference matrix, and gray-level zone length matrix. The PET parameters in relation to IDH1 mutation status were statistically analyzed.

#### RESULTS

The value of FMISO SUVmax and FLT SUVmax of IDH1-mutant tumors was significantly lower than the corresponding value of IDH1-wildtype tumors. Fifteen of 31 texture indices (Homogeneity, Energy, Contrast, Dissimilarity, Short-run emphasis, Long-run emphasis, Low grey-level run emphasis, High grey-level run emphasis, Short-run low grey-level emphasis, Short-run high grey-level emphasis, Long-run low grey-level emphasis, Run percentage, Low grey-level zone emphasis, High grey-level zone emphasis, and Short-zone high grey-level emphasis) extracted from both FMISO and FLT PET/CT significantly differed between IDH1-mutant tumors and IDH1-wildtype tumors. In addition, 5 texture indices (Entropy, Short-zone low grey-level emphasis, Long-zone low grey-level emphasis, Zone length non-uniformity, and Zone percentage) extracted from FLT PET/CT significantly differed between IDH1-mutant tumors and IDH1-wildtype tumors. In receiver operating characteristic analysis, Entropy extracted from FLT PET/CT was the best discriminative index for predicting IDH1 mutation status.

#### CONCLUSION

These preliminary results indicate that texture indices extracted from FMISO and FLT PET/CT, especially Entropy extracted from FLT PET/CT, seem to be useful for predicting IDH1 mutation status in patients with newly diagnosed high-grade gliomas.

#### CLINICAL RELEVANCE/APPLICATION

Texture indices extracted from FMISO and FLT PET/CT, especially Entropy extracted from FLT PET/CT, seem to be useful for predicting IDH1 mutation status in patients with newly diagnosed high-grade gliomas.

### Enhancing Patient Communication with Chat-GPT in Radiology: Evaluating the Efficacy and Readability of Answers to Common Imaging-related Questions

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Emile B. Gordon, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess ChatGPT's accuracy, relevance, and readability in answering common imaging-related questions and examine the effect of a simple prompt on these parameters.

#### METHODS AND MATERIALS

22 imaging-related questions were developed based on previously described categories important to patients: safety, report, procedure, preparation, meaning, and medical staff. Each question was asked three times on the ChatGPT-3.5 platform, both with and without a short prompt which instructed the model to "provide an accurate, and easy-to-understand response that is suited for an average person". Responses were evaluated by four board-certified radiologists for accuracy, consistency and relevance. Readability was assessed by Flesch Kincaid Grade Level (FKGL). Statistical comparisons were performed using chi-square tests, paired student's t-tests.

#### RESULTS

264 answers were assessed for both unprompted and prompted queries, resulting in a total of 528 evaluations. The model demonstrated a high degree of accuracy at 83% (218/264), with no significant difference for prompted responses at 87% (229/264,  $P=.2$ ). 72% (63/88) of answers were consistent across all three repeats, increasing to 86% (76/88) when prompted ( $P=0.02$ ). Essentially no responses were irrelevant, scoring at least partially relevant for 99% (261/264) of both sets of responses. Fewer responses were considered fully relevant at 67% (176/264), though this increased significantly to 80% when prompted (210/264) ( $P=.001$ ). The average FKGL was high at 13.6 [12.9-14.2] and did not significantly change with the prompt (13.0 [12.41-13.60],  $P=.2$ ). None of the responses reached the eighth grade readability level generally recommended for patient-facing materials.

#### CONCLUSION

ChatGPT demonstrates potential for accurate, consistent, and relevant imaging-related question responses. Readability levels exceed recommendations, reflecting currently available patient education materials. Prompts reduced response variability and yielded more targeted information but did not improve readability, possibly due to limitations in deviating from pre-trained knowledge without more detailed prompting.

#### CLINICAL RELEVANCE/APPLICATION

The study demonstrates ChatGPT's potential to increase accessibility to health information and to streamline production of patient-facing educational materials. Addressing readability limitations and employing prompt engineering strategies could optimize ChatGPT for imaging-related patient concerns, but cautious implementation and further research is needed.

### Evaluation of Accuracy, Completeness, and Length of Rads-Lit Outputs: A Novel Patient-Facing Artificial Intelligence Literacy Tool

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Rushabh H. Doshi, MPH, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Radiology reports frequently incorporate intricate medical jargon and lengthy text, which can lead to misunderstandings, anxiety, and erroneous interpretation for patients. By leveraging novel natural language processing (NLP) open-source technology, we developed a patient-centric tool aimed at simplifying radiology reports. Here, we test the accuracy, completeness, and length of the outputs from our tool.

#### METHODS AND MATERIALS

We engineered a proof-of-concept patient-facing radiology literacy website by harnessing OpenAI's application programming interface. Our model was specifically configured to optimize the readability of outputs (Flesch-Kincaid Grade Level: 6.68, Gunning Fog: 9.22, Coleman-Liau: 6.16, Automated Readability Index: 8.56). Three radiologists examined 62 radiology reports across modalities such as CT, MRI, X-Ray, PET, and U/S. For each of the 62 reports, the radiologists reviewed the clinical impressions and the corresponding simplified output, and evaluated the output for accuracy, completeness, and extraneous information using single-item Likert-type scales.

#### RESULTS

Two attending radiologists and one radiology resident assessed 62 Rads-Lit outputs using a five-level Likert scale, ranging from 1 (Strongly Disagree, 0-20% agreement) to 5 (Strongly Agree, 80-100% agreement). The evaluations demonstrated that the Rads-Lit outputs were factually accurate, with a median rating of 5 (80-100% agreement), and the first and third quartiles at 4 (60-80% agreement) and 5 (80-100% agreement), respectively. The outputs were also found to be complete in relation to the original radiologist reports, with a median rating of 5 (80-100% agreement), and the first and third quartiles at 4 (60-80% agreement) and 5 (80-100% agreement), respectively. Furthermore, the radiologists strongly disagreed that the outputs were excessively long or filled with extraneous information, as indicated by median rating, first quartile, and third quartile at 1 (0-20% agreement).

#### CONCLUSION

Our tool demonstrates promising results, showing that the Rads-Lit outputs frequently maintained factual accuracy and completeness in relation to the original radiologist reports while avoiding being lengthy or containing extraneous information. These findings suggest that the Rads-Lit tool has the potential to improve patient literacy and activation by enhancing the readability of their radiology reports. Further research is necessary to corroborate these findings and assess the broader impact of Rads-Lit on patient populations.

#### CLINICAL RELEVANCE/APPLICATION

This study evaluates the potential of novel NLP technology to improve patient literacy and health outcomes by reducing anxiety and erroneous interpretations in radiology reports.

### Which Procedures Bring in the Most Medicare Reimbursement and RVUs for the Individual Diagnostic Radiologist

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Aditya Khurana, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate which specific imaging examinations result in the most wRVUs and reimbursement for individual radiologists serving the US Medicare population.

#### METHODS AND MATERIALS

Imaging claims 2013-2020 submitted by diagnostic radiologists were extracted from the CMS POSPUF database outpatient imaging claims made for beneficiaries of US Medicare Part B. These data were merged with year specific CMS professional relative value unit (wRVU) files. The total number of wRVUs as well as standardized Medicare reimbursement produced by each imaging procedure, was calculated for each radiologist. For each radiologist, the imaging examination that resulted in the largest number of wRVUs and reimbursement from 2013 to 2020 was determined. The frequency in which each CPT code produced the most wRVUs or reimbursement for an individual radiologist per year was tallied.

#### RESULTS

In 2013, 5992 individual radiologists (20.3% of all radiologists) produced the largest number of imaging exam specific wRVUs interpreting screening mammography (CPT G0202), followed by CT head without contrast (CPT 70450) for 5866 radiologists (19.8%), CT abdomen and pelvis with contrast (CPT 74177) for 4475 radiologists (15.1%), single view chest radiograph (CPT 71010) for 2542 radiologists (8.6%), and CT abdomen and pelvis with and without contrast (CPT 74176) for 1387 radiologists (4.7%). In 2020, 8095 individual radiologists (25.2% of all radiologists) produced the largest number of imaging exam specific wRVUs from CT abdomen and pelvis with contrast (CPT 74177), followed by screening mammography (CPT 77067) for 5932 radiologists (18.5%), CT head without contrast (CPT 70450) for 4691 radiologists (14.6%), single view chest radiograph (CPT 71045) for 2223 radiologists (6.9%), and MRI brain without and with contrast (CPT 70553) for 1318 radiologists (4.1%). For each year evaluated the order of the five CPT codes that most frequently produced the most Medicare reimbursement for individual radiologists was constant. Screening mammography (G0202/77067) was the most frequent highest reimbursed CPT code across diagnostic radiologists, followed by CT abdomen and pelvis with contrast (CPT 74177), CT head without contrast (CPT 70450), single view chest radiograph (CPT 71010), and MRI brain without and with contrast (CPT 70553).

#### CONCLUSION

Over time, the same imaging exams have consistently brought in the most reimbursement for the individual radiologist. This study documents the procedures that are likely to be a larger proportion of any radiology practice participating in Medicare.

#### CLINICAL RELEVANCE/APPLICATION

This data shows which exams are the most important for a practice to generate revenue to maintain quality services for patients.

### A Preliminary 4D Flow MRI Analysis of Blood Flow Characteristics in Cerebral Veins of Adults

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Chihang Dai, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate blood flow characteristics in the cerebral veins of adults using 4-dimensional flow magnetic resonance (4D Flow MRI).

#### METHODS AND MATERIALS

A total of 65 volunteers prospectively underwent 4D Flow MRI and 12 volunteers underwent repeated scans during one month in a single center. Velocity, average blood flow rate (Flowavg), and blood flow patterns of cerebral sinuses were evaluated for each volunteer. The mastoid emissary veins, posterior condylar emissary veins, and oblique occipital sinuses were also evaluated.

#### RESULTS

The mean age of volunteers was  $36.31 \pm 11.05$  years old, including 3 (50.8%) females and 32 (49.2%) males. 4D Flow MRI data showed good reproducibility. The velocity and Flowavg of the superior sagittal sinus increased along the direction of flow. Flowavg near torcular herophili were 3.14 times that through the straight sinus. Slight fluctuations were found within a cardiac cycle. A vortex flow pattern was shown in 12.3% of torcular herophili, 7.5% of the transverse-sigmoid junction and 51.3% of jugular bulbs and was associated with increased blood flow velocity/rate in the upstream sinuses. Mastoid emissary veins, posterior condylar emissary veins and oblique occipital sinuses were all drained in the extracranial direction.

#### CONCLUSION

Cerebral veins, including venous sinuses and emissary veins, could be measured visually and quantitatively in vivo by 4D Flow MRI. Cerebral veins' velocity varied with segments and showed slight fluctuations within a cardiac cycle. The analysis of cerebral blood flow in healthy volunteers lays the foundation for the study of cerebral venous system diseases.

#### CLINICAL RELEVANCE/APPLICATION

4D Flow MRI is a reliable method for the evaluation of hemodynamic characteristics of intracranial venous sinuses. Intracranial venous blood flow, including venous sinuses and emissary veins, could be measured visually and quantitatively in vivo. Individual segments of venous sinuses show characteristic changes in velocity and slight fluctuations within a cardiac cycle were observed. The vortex flow pattern is not uncommon in normal individuals and may be related to increased blood flow in upstream sinuses. The mastoid emissary veins, posterior condylar emissary veins, and oblique occipital sinuses were all drained in the extracranial direction. The approaches used during the current study may enable further hemodynamic research into pulsatile tinnitus, idiopathic intracranial hypertension, vascular malformation and sinus thrombosis.

### **A New Era in Time-of-Flight MR Angiography: Assessing the Impact of High-Resolution Deep Learning Reconstruction on Intracranial MRA Image Quality**

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Masamichi Hokamura (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study aims to assess the effect of super-resolution deep learning-based reconstruction (SR-DLR), which uses k-space properties, on image quality of intracranial time-of-flight (TOF) magnetic resonance angiography (MRA) at 3T.

#### **METHODS AND MATERIALS**

This retrospective study involved 35 patients who underwent MRA using a 3T MRI system with SR-DLR based on k-space properties in October and November 2022. We reconstructed MRA with SR-DLR (Matrix = 1008 x 1008) and without SR-DLR (Matrix = 336 x 336). We measured the SNR, contrast, and CNR in the basilar artery (BA) and the anterior cerebral artery (ACA) and the sharpness of the posterior cerebral artery (PCA) using the slope of the signal intensity profile curve at the half-peak points. Two radiologists evaluated image noise, artifacts, contrast, sharpness, and overall image quality of the two image types using a 4-point scale. We compared quantitative and qualitative scores between images with and without SR-DLR using the Wilcoxon signed-rank test.

#### **RESULTS**

The SNRs, contrasts, and CNRs were significantly higher in images with SR-DLR than those without SR-DLR ( $p < 0.001$ ). The slope was significantly greater in images with SR-DLR than those without SR-DLR ( $p < 0.001$ ). The qualitative scores in MRAs with SR-DLR were significantly higher than MRAs without SR-DLR ( $p < 0.001$ ).

#### **CONCLUSION**

SR-DLR with k-space properties can offer the benefits of increased spatial resolution without the associated drawbacks of longer scan times and reduced SNR and CNR in intracranial MRA.

#### **CLINICAL RELEVANCE/APPLICATION**

SR-DLR can enhance the image quality of intracranial MRA.

### **Super-Resolution Deep Learning-Based Reconstruction in Hippocampal MRI: A Volunteer Study Emphasizing Comparison with Actual High-Resolution Images**

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Takeshi Nakaura, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The objective of this study is to compare the impact of super-resolution deep learning-based reconstruction (SR-DLR) employing k-space properties and standard-resolution DLR on image quality for thin-slice T2-weighted hippocampal magnetic resonance imaging (MRI).

#### **METHODS AND MATERIALS**

Thirteen healthy volunteers participated in this study, undergoing standard-resolution (Matrix = 320 x 320) and high-resolution thin-slice T2-weighted hippocampal MRI (Matrix = 960 x 960) on a 3-T MRI system. Standard-resolution MRI was reconstructed with and without DLR (Matrix = 320 x 320) and with SR-DLR (Matrix = 960 x 960), while high-resolution MRI was reconstructed with and without DLR (Matrix = 960 x 960). Signal-to-noise ratio (SNR), and contrast and contrast-to-noise ratio (CNR) between white and grey matter in the hippocampus, as well as the slope of the transparent septum, were measured. Two radiologists were asked to rank the image noise, contrast, artifacts, sharpness, and overall image quality of all five protocols. Results of quantitative and qualitative analyses are presented as the median and interquartile range (IQR), and those between standard-resolution MRI without DLR and other protocols were compared using the Wilcoxon signed-rank test with Holm correction.

#### **RESULTS**

The SNRs and CNRs were significantly higher in standard-resolution images with SR-DLR (SNR: 21.01 (IQR:18.17, 29.5); CNR: 7.5 (IQR:6.4, 8.37)) than those without SR-DLR (SNR: 17.22 (IQR:14.46, 19.31); CNR: 7.5 (IQR:6.4, 8.37)) ( $p < 0.001$ ). The SNRs and CNRs were significantly lower in real high-resolution MRIs with DLR (SNR: 10.4 (IQR:9.91, 11.06); CNR: 4.84 (IQR:2.99, 5.43)) or without DLR (SNR: 10.4 (IQR:9.91, 11.06); CNR: 2.24 (IQR:1.43, 2.38)) than those in standard-resolution MRIs without DLR ( $p < 0.001$ ). There were no statistically significant differences in contrast in all protocols ( $p > 0.05$ ). The best ranks were assigned for the standard-resolution images with SR-DLR in all qualitative analyses, and these were significantly better than those of the standard-resolution images without DLR in the sharpness and overall image quality ( $p < 0.01$ ).

#### **CONCLUSION**

In this volunteer study, the technique of enhancing the resolution of standard-resolution hippocampal MRI using SR-DLR demonstrated the potential to provide higher image quality in a shorter acquisition time compared to real high-resolution hippocampal MRI.

#### **CLINICAL RELEVANCE/APPLICATION**

SR-DLR in standard-resolution hippocampal MRI improves image quality, including sharpness and overall quality, compared to actual high-resolution images. This technique offers the potential for higher image quality in a shorter acquisition time, enhancing the clinical utility of hippocampal MRI.

### AI-based Virtual Synthesis of Methionine PET from Contrast-Enhanced MRI: Development and External Validation Study

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Hiroataka Takita, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To generate synthetic methionine PET images from contrast-enhanced MRI (CE-MRI) through an artificial intelligence (AI)-based image-to-image translation model and to compare its performance for grading and prognosis of gliomas with that of real PET.

#### METHODS AND MATERIALS

An AI-based model to generate synthetic methionine PET images from CE-MRI was developed and validated from patients who underwent both methionine PET and CE-MRI at a university hospital from January 2007 through December 2018 (Institutional set). Pearson correlation coefficients of maximum and mean tumor-to-normal background uptake (T/N<sub>max</sub>, T/N<sub>mean</sub>, respectively) ratios and lesion volume between synthetic and real PET were calculated. Two additional open-source glioma databases of preoperative CE-MRI without methionine PET were the external test set. Using the T/N ratio, the area under the curve of the receiver operating characteristic curve (AUC-ROC) for classifying high- and low-grade gliomas and an overall survival (OS) analysis was evaluated.

#### RESULTS

The institutional set included 362 patients (mean age, 49±19 years; training=294, validation=34, test=34). In the institutional test set, Pearson correlation coefficients were 0.68 (95% CI: 0.47, 0.81), 0.76 (0.59, 0.86), and 0.92 (0.85, 0.95) for T/N<sub>max</sub> ratio, T/N<sub>mean</sub> ratio, and lesion volume, respectively. The external test set included 344 patients with glioma (mean age, 53±15 years; high-grade=269). The AUC-ROC by T/N<sub>max</sub> ratio was 0.81 (95% CI: 0.75, 0.86) and the OS analysis showed a statistically significant difference between high- (two-year survival rate=27%) and low-T/N<sub>max</sub> ratio groups (two-year survival rate=71%; P<.001).

#### CONCLUSION

The AI-based model-generated synthetic methionine PET images strongly correlated with real PET, and showed good performance for glioma grading and prognostication.

#### CLINICAL RELEVANCE/APPLICATION

Methionine PET is useful for the management of glioma. But radiation exposure and a lack of molecular imaging facilities limit its use. Since CE-MRIs are generally obtained for patients with suspected brain tumors in routine clinical situations, synthetic methionine PET images can be obtained from CE-MRIs without the aforementioned inconveniences or additional examination.

### Twinkling T2 STAR: Robust Radiomics Features for Reliable Cerebral Microbleeds Classifier

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Hiroki Nakajima, RT (*Presenter*) Nothing to Disclose

#### PURPOSE

Cerebral microbleeds (MBs) have gained attention due to the increased availability of high-field-strength MR systems, as a higher microbleed burden is associated with an increased risk of ischemic stroke and cerebral hemorrhage. We aimed to identify robust Radiomics features between scans in the T2 GRE sequence and evaluate their diagnostic performance using machine learning-based classifiers.

#### METHODS AND MATERIALS

We used two cohorts of subjects who underwent T2 GRE imaging in 3T MRI systems. We retrospectively reviewed 20 cases with twice T2 GRE sequences acquired in one examination from 2021 to 2022, and prospectively collected 75 subjects as hold-out test data in 2022. We defined 16x16px regions of interest (ROIs) based on a manual radiologist's annotation of MBs and randomly set up equal numbers of ROIs in other locations. We obtained 91 Radiomics features for these ROIs and measured intra-class coefficients (ICCs) to determine robust features between imaging sessions. Then, we selected seven features with ICCs greater than 0.95 to train and validate a support vector machine (SVM) classifier with the leave-one-out method. Furthermore, a radiologist randomly displayed 16x16px images for the hold-out test group and rated MBs-likeness on a 0-100 continuous variable. We evaluated the diagnostic performance using the area under the ROC curves (AUC) for univariate logistic analysis of each Radiomics feature, SVM classifier, and radiologist.

#### RESULTS

For ICC evaluation and modeling, we used 212 MBs (432 total ROIs) and 192 MBs (387 total ROIs) for the test group. Regarding the inter-imaging reproducibility, 9 (10%) features had ICCs less than 0.8, and 26 (29%) had ICCs less than 0.9. Seven of the 32 (35%) features with ICCs greater than 0.95 were used to train SVM. In the test group, SVM's diagnostic performance was 0.96 recall, 0.67 precision, and 0.73 accuracy, with an AUC of 0.88 (0.85-0.92). The AUC for SVM was significantly higher ( $P < .01$ ) than the AUC for each feature alone (0.48-0.85) and not significantly lower than the radiologist's AUC of 0.91 (0.89-0.95) ( $P = .15$ ).

#### CONCLUSION

We identified robust Radiomic features inter-imaging of the T2 GRE sequence and demonstrated that an SVM classifier with these features had a comparable AUC to the radiologist.

#### CLINICAL RELEVANCE/APPLICATION

Assessing reproducibility of Radiomics features between two T2 GRE imaging sessions, we identified robust features and developed an SVM classifier to improve cerebral MB detection, potentially reducing stroke and hemorrhage risk.

### Quantitative Multiparametric MRI and Machine Learning based Model to differentiate Progression from Pseudo-progression in Glioblastoma: Towards Precision Neuro-Oncology

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Archith Rajan, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

We hypothesize that radiomic features derived from conventional MRI sequences, diffusion tensor imaging (DTI) and dynamic susceptibility contrast (DSC)-perfusion-weighted imaging (PWI) along with molecular signatures will facilitate accurate distinction of true progression (TP) from pseudoprogression<sup>1,2</sup> (PsP) in glioblastoma (GBM) patients with high accuracy.

#### METHODS AND MATERIALS

A cohort of 75 GBM patients exhibiting new/increasing enhancing lesions within 6 months after completion of standard-of-care therapy, were included in this study. These patients were classified as TP (n=55) or PsP (n=20) based on histological features or mRANO criteria<sup>3</sup>. Motion and eddy current corrected DTI derived maps [mean diffusivity (MD), fractional isotropy (FA), coefficient of linear (CL), planar (CP) and spherical anisotropy (CS)] and DSC-PWI derived cerebral blood volume (CBV) map, FLAIR images were co-registered to post-contrast (PC) T1-weighted images. A semiautomatic approach was used to segment contrast-enhancing regions. The median values of DTI metrics and CBV were computed. The CBV values were normalized with contralateral normal brain regions to obtain relative CBV (rCBV). The top 90th percentile rCBV values were also measured (rCBV<sub>90</sub>)<sup>4,5</sup>. O6-methylguanine-DNA-methyltransferase (MGMT) promoter status was noted from all of these patients. To address the issue of imbalanced sample size between TP and PsP, synthetic-minority-oversampling-technique (SMOTE) was applied to augment PsP cases from 20 to 35 resulting in a total sample size of 110. A random forest (RF) algorithm was applied to select the optimized features using a sequential forward feature selection (SFFS) approach. The data were randomly split into training (n=90) and testing (n=20) sets. A 6-fold cross-validation approach was also applied to training dataset. To develop a robust prediction model in distinguishing TP from PsP, several machine learning classifiers were employed. Receiver operating characteristic curve analyses were performed to determine the diagnostic accuracies.

#### RESULTS

The best nine diagnostic performances of multiple machine learning algorithms, and feature selection modules are presented in Table 1. RBF support vector machine (SVM) classifier was selected to build the predictive model in distinguishing TP from PsP with a training accuracy of 90.9%, cross-validation accuracy of 85.5% and testing accuracy of 85%.

#### CONCLUSION

Machine learning model using multi-parametric MRI and molecular signatures is a promising approach to differentiate TP from PsP in GBM patients.

#### CLINICAL RELEVANCE/APPLICATION

Multiparametric MRI combined with machine learning could successfully differentiate True Progression from Pseudoprogression in Glioblastomas.

### Impact of Radiographic Signs of Advanced and Severe Cerebral Venous Thrombosis on the Efficacy of Endovascular Treatments

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Mihir Khunte (*Presenter*) Nothing to Disclose

#### PURPOSE

To study the benefit of endovascular treatment (EVT) with thrombolytics and/or thrombectomy as a treatment option for cerebral venous thrombosis (CVT) in comparison with conservative medical management.

#### METHODS AND MATERIALS

The National Inpatient Sample database 2016-2020 was queried to identify adult patients (18 years or older) with CVT. Patient demographics, medical comorbidities, CVT risk factors, and CVT manifestations were identified. The presence of radiographic signs of advanced and severe CVT (venous stroke, cerebral edema, and intracranial hemorrhage) were recorded. Primary and secondary outcomes were good discharge outcomes and in-hospital mortality, respectively.

#### RESULTS

17,130 CVT patients were identified; 945 (5.5%) received EVT. EVT patients were more likely to have strokes (35.4% vs. 21.8%,  $p < 0.001$ ), edema (35.4% vs. 20.1%,  $p < 0.001$ ), and hemorrhage (37.6% vs. 19.7%,  $p < 0.001$ ). After multivariable adjustments, EVT for patients without stroke, edema, or hemorrhage was moderately associated with higher odds of good outcomes (OR 1.86 [95%CI 0.98 - 3.53],  $p = 0.059$ ) and resulted in zero deaths. However, with increasing burden of radiographic signs of advanced CVT measured by the cumulative presence of stroke, edema, and hemorrhage, EVT was associated with decreasing odds of good outcomes and increasing odds of in-hospital mortality compared to medical management (interaction  $p = 0.046$  and  $0.029$ , respectively).

#### CONCLUSION

EVT may be beneficial for patients who have not yet developed overt parenchymal manifestations of backpressure changes, and the presence of stroke, edema, and hemorrhage may diminish the comparative effectiveness of EVT over medical management.

#### CLINICAL RELEVANCE/APPLICATION

EVT may be beneficial in subset of patients with CVT who lack radiographic signs of advanced and severe CVT such as venous stroke, cerebral edema, and intracranial hemorrhage.

### Associations of Quantitative and Qualitative Intracranial Aneurysm Wall Enhancement Indices to Wall Instability and Risk Stratification Scores

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Abhinav Patel, MBBS (*Presenter*) Nothing to Disclose

#### PURPOSE

The mortality and morbidity among patients with ruptured Intracranial Aneurysms (IAs) remain as high as 50% despite the low incidence of IAs (3-50/100000). The PHASES score was established to quantify IA rupture risk, whereas the ELAPSS score was established to quantify risk of growth in IA size. MR-Vessel Wall Imaging (VWI) has gained popularity in assessing a number neurovascular diseases including IAs. Aneurysm wall enhancement (AWE) is utilized as a marker of wall instability. We evaluate two distinct quantified measures of post-contrast T1-SPACE AWE in conjunction with the PHASES and ELAPSS scores as a sign of wall instability.

#### METHODS AND MATERIALS

We conducted an IRB approved study of patients with unruptured IAs scanned using VWI protocol between January 2018 to December 2022. AWE was evaluated qualitatively and quantitatively on T1-SPACE sequences. IA Wall Morphology (IAWM) was evaluated on catheter angiography. Quantified AWE values were obtained using 3-point ROIs on the IA wall and normalized with white matter signal intensity obtained using 10 mm circular ROIs. Percentage change in normalized AWE from pre to post contrast imaging was calculated. Furthermore, a ratio of post-contrast quantified AWE to post-contrast pituitary infundibulum (PI) signal intensity (AWPI ratio) was also calculated. Pearson correlation test, and unpaired t-tests were used to assess statistical correlations in SPSS v28. P-value was set at 0.05.

#### RESULTS

We evaluated 271 IAs in 219 patients (Age: 63.31 +/- 13.17, 24-89, 165 female). The mean size of IAs was 5.12mm +/- 3.91 mm, 2-30 and the mean PHASES score was 4.31 +- 2.73, 0-16. Qualitatively, AWE was seen in 141 (52%) IAs and irregular IAWM in 132 (48.7%). PHASES score showed a moderately strong correlation to AWPI ratio,  $r = 0.439$ , and to percentage increase in AWE,  $r = 0.334$ . ELAPSS score also showed a moderately strong correlation to AWPI ratio,  $r = 0.487$  and percentage increase in AWE,  $r = 0.367$ . AWPI ratio showed as stronger correlation than percentage increase to both PHASES and ELAPSS scores. The mean PHASES and ELAPSS scores for IAs with AWE were 5.36 and 18.48 whereas in IAs without AWE, these scores calculated to be 3.31 and 10.93, respectively, ( $p < 0.001$ )

#### CONCLUSION

Our findings demonstrates a correlation between increased AWPI, Percentage Increase and higher PHASES score, ELAPSS score .

#### CLINICAL RELEVANCE/APPLICATION

The results of this finding suggests a possible use of both qualitative and quantitative evaluation of AWE, particularly an increased AWPI ratio as a marker of wall instability. This could be utilized to evaluate the progression of wall instability and to guide therapeutic intervention.

W5B-SPNR-4

### Impact of White Matter Hyperintensities on Structural Connectivity and Cognition in Cognitively Intact Older Adults

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Mohammad Taghvaei, MD, MPH (*Presenter*) Nothing to Disclose

#### PURPOSE

White matter hyperintensities (WMH) on T2-weighted fluid-attenuated inversion recovery (FLAIR) magnetic resonance imaging (MRI) are nearly ubiquitous in aging. Prior studies suggest that both the volume and the spatial distribution of WMH lesions are predictive of cognitive performance decrements. WMH lesion burden has also been associated with both the severity and progression rate of Alzheimer's pathology. We used indirect brain mapping with virtual lesion tractography in older control subjects from the Alzheimer's Disease Neuroimaging Initiative (ADNI) study to test the hypothesis that the extent of specific white matter (WM) tract disconnection due to WMH is associated with corresponding cognitive performance decrements.

#### METHODS AND MATERIALS

Demographic information, structural MRI data, PET imaging, neuropsychological test scores, and CSF analysis from 481 cognitively intact ADNI subjects were obtained. WMH lesions mask were extracted from the FLAIR MRI of these subjects and applied as a region of avoidance for fiber tracking in 50 Human Connectome Project (HCP) subjects' diffusion MRI data to estimate tract disconnection caused by each WMH lesion mask for 8 WM pathways. The direct relationship of global WMH lesions burden or tract disconnections with performance in specific cognitive domains, as well as the mediation effect of specific tract disconnection on WMH lesion related cognitive performance decrement in the corresponding domain were assessed.

#### RESULTS

Global WMH lesion burden was significantly associated with global cognitive measures ( $p=0.011$ ), episodic memory ( $p=0.015$ ), executive function, and processing speed ( $p=0.018$ ). Further, estimated tract disconnection in the right inferior fronto-occipital fasciculus, right frontal aslant tract, right inferior longitudinal fasciculus, and right superior longitudinal fasciculus disconnection mediated the effect of WMH lesion volume on executive function, the left uncinate fasciculus disconnection mediated the effect of WMH lesion volume on memory, and the right frontal aslant tract disconnection mediated the effect of WMH lesion volume on language.

#### CONCLUSION

Tract-specific disconnections caused by WMH lesions mediate cognitive domain-specific decrements in cognitive performance in cognitively intact older adults.

#### CLINICAL RELEVANCE/APPLICATION

The spatial distribution of WMH lesions and the extent of particular WM tracts involvement by them could predict decrement in corresponding cognitive domains.

### Hyperintensities in the Anterior Portion of the Callosal Splenium on FLAIR: A Large Cohort Study

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Sera Kasai (*Presenter*) Nothing to Disclose

#### PURPOSE

Although hyperintensity in the anterior portion of the callosal splenium on FLAIR (aCS-hyperintensity) is a common finding in elderly adults (Figure), no previous studies with large sample sizes have examined the clinical significance of the aCS-hyperintensity. In this large elderly population study, we aimed to investigate the associations of aCS-hyperintensity with cerebro- and cardiovascular risk factors and cognitive decline. In addition, to illustrate the probable mechanism thereof, we compared the clinical significances of the aCS-hyperintensity with those of the other MRI measurements.

#### METHODS AND MATERIALS

This cross-sectional study included 2,110 participants (median age, 69 years; 61.1% females) who underwent 3T MRI. The participants were grouped as 215 with mild cognitive impairment (MCI) and 1,895 cognitively normal older adults (NOAs). Two neuroradiologists evaluated aCS-hyperintensity by using a four-point scale (none, mild, moderate, and severe) (Figure). Periventricular hyperintensities (PVHs) were also rated on a four-point scale according to the Fazekas scale. The total intracranial volume (ICV), total brain volume, choroid plexus volume (CPV), and lateral ventricle volume (LVV) were calculated.

#### RESULTS

For the cerebro- and cardiovascular risk factors, the logistic regression analysis showed that diabetes was the main predictor of aCS-hyperintensity after adjusting for potential confounders (age, sex, hypertension, hyperlipidemia, BMI, smoking status, alcohol frequency, and medical history) ( $p < 0.01$ ). On the other hand, PVH was associated with a presence of hypertension ( $p < 0.01$ ). The aCS-hyperintensity rated as "severe" was associated with a presence of MCI. The logistic regression analysis for the imaging factors showed that PVH was significant independent predictor of aCS-hyperintensity ( $p < 0.01$ ). The LVV was also an independent predictor of aCS-hyperintensity when brain volume and PVH grade was added to the analyses ( $p < 0.01$ ).

#### CONCLUSION

Cerebral small vessel disease due to diabetes is a major contributor to the development of aCS-hyperintensity. Cerebrospinal fluid clearance failure may also relate to aCS-hyperintensity, which may offer new insights into the pathologic processes underlying MCI.

#### CLINICAL RELEVANCE/APPLICATION

Although aCS-hyperintensity is a common finding in elderly adults, its severity may associate with cerebral small vessel disease due to diabetes and MCI presence.

### Radiological and Clinical Characteristics of N<sub>2</sub>O Related Myeloneuropathy: A Multicenter Study

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Paula Heredia Cacha, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The aim of this work is to report the clinical and imaging features of nitrous oxide (N<sub>2</sub>O) recreational abuse related myeloneuropathy.

#### METHODS AND MATERIALS

We conducted a retrospective multicenter study. The inclusion criteria were: (i) neurological symptoms, (ii) history of recreational N<sub>2</sub>O abuse, (iii) myeloneuropathy on MRI. The exclusion criteria were: (i) other causes of myelopathy (ii) absence of strong temporal association with N<sub>2</sub>O consumption. Demographic, clinical and laboratory data were collected. Imaging patterns, treatments and patients' outcomes were analyzed.

#### RESULTS

We included 40 patients (age: 24 ± 4 years; 18 ?) from 8 tertiary care centers. The study period was from December 2020 to April 2023. A chronic consumption (at least weekly for = 3 months) of N<sub>2</sub>O was present in 77% of the patients (26/34). All patients (40/40) presented with paresthesia, 36/36 with distal onset. Other main complaints were unsteady gait (38/40; 95%) and limb weakness (23/40; 58%). When measured, homocysteine level was elevated (32/33; 97%), while vitamin B12 level was mostly normal (20/34; 58%). Nerve conduction studies were often altered (23/32; 72%). Typical MRI features of subacute combined degeneration (SCD) of the spinal cord in cervical and upper thoracic cord were often seen (35/40; 86%, fig. 1A). Contrast enhancement of SCD was present in 5/35 of the patients (14%, fig. 1B). In 3 patients, a brain MRI was performed in first place for ataxia and 3D-FLAIR sequence suggested upper cervical abnormalities in its lowest slices (Fig. 1C). Atypical MRI findings (5/40) consisted of (i) cone involvement associated with exclusively lateral columns involvement (1/5, fig. 1D) and (ii) abnormally extensive lesion to lower thoracic cord (4/5; fig. 1F). 20% (7/35) of patients showed cauda equina roots enhancement (Fig. 1E). Patients were treated mainly with vitamin B12 supplementation (36/38; 95%). When follow-up information was present (12/40), recovery was slowly progressive, with persistent paresthesia (10/12; 80%).

#### CONCLUSION

N<sub>2</sub>O-induced myeloneuropathy, mostly due to functional vitamin B12 deficiency, typically appears on MRI as SCD involving the cervical and upper thoracic cord. However, atypical radiological findings exist, and cauda equina roots enhancement is possible, even though not described yet in literature. In addition, cerebral MRI can pinpoint the correct diagnosis when not suspected.

#### CLINICAL RELEVANCE/APPLICATION

N<sub>2</sub>O is a popular recreational drug among young adults. Social awareness on N<sub>2</sub>O side effects is poor and clinicians lack on information on vitamin B12 deficiency-related myeloneuropathy, a common N<sub>2</sub>O toxic effect.

### 3D SPACE MRI of the Transverse Ligament in Whiplash Associated Disorder

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Bo Mi Chung, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To describe the 3D SPACE MRI findings of transverse ligament (TL) in whiplash associated disorder (WAD), and to compare them with nontraumatic group.

#### **METHODS AND MATERIALS**

Cervical spine MRIs were retrospectively analyzed including 46 patients with WAD and 62 patients in the nontraumatic group. Axial 2D T2-SPACE images were used for image analysis. The symmetry of lateral atlantodental interval (LADI) and the morphology grade of TL was evaluated by two radiologists, using a four-point scale (0 = homogeneous low SI with normal thickness, 1 = high SI with normal thickness, 2 = reduced thickness, 3 = full-thickness rupture or indistinguishable from surrounding structures). The presence of atlantoaxial instability and the number of cervical levels with degeneration was evaluated.

#### **RESULTS**

Among the WAD patients, 17% showed asymmetric LADI and 39% showed high-grade TL morphology grade (grade 2 or 3). The high-grade TL change group had a significantly higher mean age than the low-grade group. There was no significant difference in WAD stage or grade between the high-grade and low-grade TL change groups. High-grade TL changes were significantly more frequent in the WAD group compared to the nontraumatic group, and the number of degenerative levels was lesser in the WAD group. Logistic regression analysis revealed that a lesser number of degenerative levels and high-grade TL changes were independent predictors for WAD.

#### **CONCLUSION**

High-grade TL changes were significantly more frequent in the WAD group compared to the nontraumatic group.

#### **CLINICAL RELEVANCE/APPLICATION**

The evaluation of TL using 3D SPACE MRI sequence can be useful in the evaluation and management of the WAD patients.

### **Predicting Outcome of the Epidural Blood Patch in Spontaneous Intracranial Hypotension by using an Artificial Intelligent Aided Quantitative MRI Approach**

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Jyhwen Chai, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Spontaneous intracranial hypotension (SIH) is a disorder of spinal CSF leakage with uncertain pathogenesis that presents challenges in reliable diagnosis and treatment. Though epidural blood patching (EBP) is commonly used, response rates are variable and predictors are lacking. In this study, we aimed to predict the outcome of EBP treatment in SIH patients using a quantitative MRI approach aided by artificial intelligence (AI).

#### **METHODS AND MATERIALS**

We recruited 30 SIH patients with typical orthostatic headache and characteristic MRI findings of spinal CSF leakages, and 26 healthy volunteers. In addition to brain MRI, we used retrospective ECG-gated cine phase-contrast (PC) sequences to measure fluctuating CSF flow, and a heavy 3D-T2WI of the whole spine to identify CSF leakage and quantify spinal CSF volume. We used YOLO algorithms of AI models for object detection and semantic segmentation of CSF space on spine images, and a pulsatility-based segmentation (PUBS) method combined to measure CSF flow dynamics in the cine PC-MRI.

#### **RESULTS**

Our results showed that SIH patients had significantly lower mean and peak CSF flux at the level of the 2nd cervical spine and a smaller volume of whole spinal CSF compared to healthy volunteers. The optimal cut-off values to distinguish the two groups were 1.00 ml/s and 3.53 ml/s for mean and peak flux, respectively, with the best AUC of 0.821 and 0.833 ( $p < 0.001$ ). The cut-off value of whole spinal CSF volume was 64.9 ml/s with the AUC of 0.694 ( $p < 0.05$ ). Using these two cut-off values of CSF flux, we divided 25 of 30 SIH patients accepting EBP into two groups based on high and low CSF flow dynamics one week after treatment. 25 of 30 SIH patients who underwent EBP were divided into high and low CSF flow dynamics groups. Of the 13 patients with high CSF flow dynamics and much improvement in orthostatic headache, 10 received one EBP and 3 received two. Nine of the 12 patients with low flow dynamics and persistent symptoms required more than two EBPs.

#### **CONCLUSION**

Our study suggests that CSF flow parameters in the upper cervical spine are more sensitive than spinal CSF volume measurement in detecting early pathophysiological alterations in SIH patients after EBP treatment. AI-aided quantitative MRI has the potential to effectively predict the treatment response of EBP in SIH patients.

#### **CLINICAL RELEVANCE/APPLICATION**

AI-aided quantitative MRI could be an effective tool for predicting the treatment response of epidural blood patching in patients with spontaneous intracranial hypotension (SIH).

### The Application of Radiomics in Predicting Intraoperative Massive Bleeding in Cesarean Scar Pregnancy Patients

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Feng Gao (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop a comprehensive model based on MRI radiomics signatures and independent risk factors for predicting the risk of intraoperative massive bleeding in cesarean scar pregnancy (CSP) patients.

#### METHODS AND MATERIALS

In total, 119 patients with CSP who underwent surgery were retrospectively reviewed. According to surgical records, intraoperative bleeding greater than 100ml was defined as intraoperative massive bleeding. All subjects were randomly separated into the training and testing sets at a ratio of 7:3. The radiomics signatures from the gestational sac (GS) and decidua (DEC) regions were respectively extracted in T2WI. Variance analysis, univariate correlation analysis (cutoff = 0.7), general univariate analysis and Gradient Boosting Decision Tree (GBDT) selection were performed orderly to select features. Seven image geometric features and eight clinical features were recorded and analyzed. Information with statistically significant differences was utilized in conjunction with the selected radiomics features to construct predictive models via the logistic regression model. Models were evaluated through ROC and AUC analysis. Decision curve analysis (DCA) evaluated the clinical usefulness of the constructed models, while Delong's test compared performance differences.

#### RESULTS

Thirty-seven patients suffered intraoperative massive bleeding and 82 patients did not. Five, eight, and nine radiomics features were selected from DEC, GS, and DEC+GS cohort, respectively. Seven features were statistically differently between GS and DEC (all  $p < 0.05$ ), and were included into the model as predictive features. AUCs of test datasets were 0.856, 0.843, and 0.846 for DEC, GS, and DEC+GS, respectively. Calibration curves with H-L test  $p$  values  $> 0.05$  showed good fitness for all three models. Delong's tests revealed no statistical differences among AUCs, indicating similar predictive abilities of the models. DCA showed that blood loss prediction models are beneficial when threshold probability ranges from 0.02 to 0.78.

#### CONCLUSION

A prediction model composed of T2WI-based radiomics features, image geometric features and clinical parameters could be applied to guide the gynecologists assess the risk of intraoperative bleeding in CSP patients before surgery.

#### CLINICAL RELEVANCE/APPLICATION

CSP refers to an ectopic pregnancy in which the GS is implanted into the scar of a previous cesarean section uterine incision. It may cause uncontrollable bleeding, uterine rupture, and even require hysterectomy during surgery. Our combined prediction model can preoperatively, accurately, and noninvasively identify high-risk individuals. For these high-risk individuals, preoperative intervention can be taken to avoid the massive bleeding.

### Accelerated Three-dimensional Susceptibility Weighted Imaging of the Whole Spine of Fetus at 3T

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Ziyan Sun, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

The aims of this study were to evaluate the image quality, vertebral visibility and diagnostic performance in suspected fetal vertebral pathologies of three-dimensional (3D) susceptibility weighted imaging (SWI) of the whole spine column at 3T magnetic resonance imaging (MRI) and compared these with those of conventional protocol and ultrasonography (US).

#### METHODS AND MATERIALS

A total of 37 pregnant women (gestation age 22 to 39 weeks, average  $29 \pm 3$  weeks) with suspected fetal vertebral anomalies by ultrasound (US) screening underwent 3.0T MR imaging with 3D SWI, conventional two-dimensional (2D) half-fourier acquisition single-shot turbo spin-echo (HASTE) and 3D true fast imaging with steady-state precession (True FISP). The acquisition time of each protocol was recorded. Signal-to-noise ratios (SNRs) and contrast-to-noise ratios (CNRs) were determined in representative interest regions of fetal thoracic vertebrae and compared among three pulse sequences. Two radiologists rated image quality independently in random order on a 5-point scale. Kappa coefficients were computed to assess inter-observer reliability. Receiver operating characteristic curves were generated, and the area under the curve (AUC) was used to compare the diagnostic performance of each protocol in vertebral deformities.

#### RESULTS

The acquisition time was 15 s for 3D-SWI and 17 s for 3D True FISP, significantly shorter than conventional HASTE (37 s; both  $P < 0.01$ ). Of the three protocols, The SNR was highest on 3D True FISP, while the CNR was highest on 3D SWI. Visualization of all segments of the whole spine by 3D SWI was comparable with 3D True FISP. In contrast, 3D SWI and 3D True FISP depicted cervical and sacrococcygeal vertebrae better than HASTE. The weighted kappa statistic was 0.70-0.89 to evaluate the image quality of all segments of the whole spine, indicating good to excellent interobserver agreement. 3D SWI had the highest diagnostic performance for detecting fetal vertebral anomalies (AUC = 0.92).

#### CONCLUSION

3D-SWI is feasible for improved visualization of the whole fetal vertebral column and their congenital malformations with adequate image quality, thereby providing a supplementary method to conventional MR imaging.

#### CLINICAL RELEVANCE/APPLICATION

Our preliminary results suggest that 3D-SWI enables superior 3D visualization of 3D sequences take an advantage in display of the overall structure of the spine compared with conventional 2D sequences. A potential use of the 3D sequence is to define the degree of scoliosis or precise localization of deformed vertebrae. 3D sequences could be a useful addition to the routine examination of the fetal vertebrae, facilitating the incorporation of this technique into routine patient studies.

### Doppler Ultrasound Gated Fetal Cardiac MRI in an Unselected Population: A Clinical Feasibility Study

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Roland Cronenberg, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Doppler ultrasound-based gating of fetal cardiac MRI has shown promising results in late pregnancy but has not been tested in younger fetuses <26 weeks of gestation in a clinical setting yet. The aim was to investigate the feasibility of ultrasound-gated fetal cardiac imaging in clinical routine during whole-body-MRI and the association of image quality with gestational age.

#### METHODS AND MATERIALS

We included 23 singleton pregnancies with clinical indication for fetal whole-body-MRI with and without suspected cardiac anomalies. Standard protocols for body and CNS MRI were performed, followed by gated cine-balanced steady state free precession sequences of the fetal heart in three planes (four-chamber-view (4C), short (2S) and long (2L) axis two-chamber-views). Image quality was rated "good" if there was depiction of both atria and ventricles in the four-chamber-view, and of the left atrium and ventricle in the long and short axis two-chamber view without artifacts. In case of displaced planes or artifacts but possible identification of cardiac anatomic structures, image quality was rated as "moderate". If no recognizability was given, images were rated "non diagnostic". Image quality was correlated with gestational week (GW) groups (GW <26, GW 26-31, GW >31).

#### RESULTS

We evaluated a total of 69 cardiac MRI sequences in 23 fetuses (70% with and 30% without suspected cardiac anomalies; GW <26: 30.4%, GW 26-31: 30.4%, GW >31: 39.1%; mean: 28+6 GW +/-30.4 days). Overall, image quality was "good" in 31 (45%) of the cardiac sequences and "moderate" in 21 (30%). Seventeen (25%) were "non diagnostic". Differences in image quality were significant between the cardiac planes ( $p=.013$ ) with best quality of the 2S and poorest quality of the 2L. Highest image quality was found in the youngest fetuses <26 GW ("good" in 57%, "moderate" in 19%, "non diagnostic" in 24%); followed by fetuses >31 GW ("good" in 48%, "moderate" in 41%, "non diagnostic" in 11%) and fetuses between 26 and 31 GW ("good" in 29%, "moderate" in 29%, "non diagnostic" in 43%). There was no significant difference between age groups ( $p=.158$  for 4C,  $p=.595$  for 2S,  $p=.178$  for 2L).

#### CONCLUSION

Doppler ultrasound gated fetal cardiac MRI with diagnostic quality in 75% of cardiac planes is feasible during clinical routine whole-body-MRI already in the second trimester of pregnancy. Image quality is not associated with gestational age.

#### CLINICAL RELEVANCE/APPLICATION

Fetal cardiac MRI in the second and third trimester of pregnancy could be included in a whole-body MRI protocol as a complementary imaging method to echocardiography in congenital heart disease when ultrasound conditions are limited.

### Automatic Quantification of Fetal Brain Gyrfication Based on MRI in Control and in Fetuses with Polymicrogyria and Lissencephaly

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Dafna Ben Bashat, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Current imaging assessment of fetal brain gyrfication is performed qualitatively and subjectively using both ultrasound and MRI. A few previous studies suggested methods for quantification of fetal gyrfication based on 3D reconstruction of MRI, which requires unique data and is time-consuming. In this study, we aimed to develop an automatic pipeline for gyrfication assessment based on routinely acquired fetal MRI 2D data, quantify normal changes with gestation, and measure differences in fetuses with lissencephaly and polymicrogyria compared with controls (fetuses with normal gyrfication).

#### METHODS AND MATERIALS

Coronal T2 weighted MRI data of 162 fetuses retrospectively collected from two clinical sites were included: 134 control fetuses, 12 with lissencephaly, 13 with polymicrogyria, and three suspected with lissencephaly based on ultrasound, yet with normal MRI diagnosis. The developed automatic pipeline included brain detection, brain component segmentation and identification of the right and left hemisphere, and calculating five gyrfication parameters separately for each hemisphere based on the area and ratio between the contours of the cerebrum and its convex hull.

#### RESULTS

In control fetuses, all parameters were changed significantly along gestational age ( $p < 0.05$ ), providing developmental curves on a wide range of gestation (27-37 weeks). Compared with controls, fetuses with lissencephaly showed significant reductions in all gyrfication parameters ( $p = 0.02$ ). Similarly, but less pronounced, significant reductions were detected for fetuses with polymicrogyria in several parameters ( $p = 0.001$ ). The three suspected fetuses showed normal gyrfication, supporting MRI diagnosis.

#### CONCLUSION

This study presents a pipeline for automatically quantifying fetal brain gyrfication and provides normal developmental curves from a large cohort. These curves differentiated fetuses with lissencephaly and polymicrogyria significantly, demonstrating lower values. The method may aid radiological assessment and improve the early identification of fetuses with cortical malformation.

#### CLINICAL RELEVANCE/APPLICATION

The method suggested in this study provides a quantitative assessment of fetal brain gyrfication, and can aid radiological diagnosis and improve early identification of fetuses with cortical malformation.

### Deep-learning Reconstruction for Reducing Slice Thickness and Radiation Dose in Pediatric CT: Matched Pair Comparisons with Standard Dose Thick Slice Iterative Reconstruction

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Ryota Harai (*Presenter*) Nothing to Disclose

#### PURPOSE

Low-dose and thin-slice image acquisition is desirable for pediatric CT, but increased image noise can compromise image quality and diagnostic confidence. Deep learning reconstruction (DLR) may be a promising technique to simultaneously reduce radiation dose and slice thickness due to its excellent noise reduction performance. This study aimed to compare the image quality between standard-dose, thick-slice (3 mm) hybrid iterative reconstruction (HIR) and low-dose, thin-slice (0.5 mm) deep-learning reconstruction DLR in pediatric CT.

#### METHODS AND MATERIALS

This retrospective study included 76 children (=6 years) who underwent 80-kVp contrast-enhanced CT using standard dose (n=38) and low dose (n=38) protocols on a 320-row scanner. Patient age and body weight were matched between the standard and low dose groups. The standard dose images were reconstructed at a 3 mm slice thickness using the HIR algorithm; the lower dose images were reconstructed at a 0.5 mm slice thickness using the HIR and DLR algorithms. The size-specific dose estimate (SSDE) was compared between groups. For quantitative image analysis, image noise and contrast-to-noise ratio (CNR) at the hepatic parenchyma, abdominal aorta, and portal vein were quantified. For qualitative assessment, noise magnitude, noise texture, edge sharpness, partial volume effect, artifacts, and diagnostic confidence were subjectively rated on a four-point scale.

#### RESULTS

There were no significant differences in age ( $24.1 \pm 23.0$  vs.  $24.2 \pm 23.0$  months,  $p=0.98$ ) and body weight ( $9.9 \pm 4.6$  vs.  $10.2 \pm 5.8$  kg,  $p=0.80$ ) between the standard and low dose groups. The SSDE of the low dose group was 60% lower than that of the standard dose group ( $3.3 \pm 0.9$  vs.  $8.3 \pm 1.6$  mGy,  $p<0.01$ ). DLR considerably reduced the quantitative image noise and improved CNR and subjective image quality of the low dose 0.5 mm images compared to HIR (all,  $p<0.001$ ). Compared to the standard dose 3 mm HIR images, the low dose 0.5 mm DLR images showed significantly lower quantitative image noise ( $p=0.02$ ) and equivalent CNR in all structures analyzed (all,  $p>0.11$ ). The low dose 0.5 mm DLR images achieved superior subjective scores for diagnostic confidence compared to standard-dose 3 mm HIR images ( $p<0.01$ ).

#### CONCLUSION

In pediatric CT, the application of DLR to low-dose thin-slice (0.5 mm) images can yield equivalent or even better subjective and objective quality compared to standard-dose thick-slice (3 mm) HIR images.

#### CLINICAL RELEVANCE/APPLICATION

DLR allows reduction of both radiation dose and slice thickness in pediatric CT without increasing image noise and degrading the subjective image quality compared to the HIR algorithm.

### Extending Coronary Calcium Scoring to New Protocols using a Specificity Criterion

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Scott Hsieh, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Coronary calcium is scored today using the Agatston algorithm, which was devised for 3-mm thick slices at 120 kVp. Scanners today offer protocols with thinner slices, better in-plane resolution, lower kVp, different mAs, advanced reconstruction, or new technologies such as multi-energy or photon counting detector CT. A framework is desired to adapt the Agatston algorithm threshold to these variations while maintaining an acceptable false positive rate. We propose to do this directly by imposing a specificity criterion. Because our interest is in detecting smaller calcifications, we do not impose a minimum size criterion.

#### METHODS AND MATERIALS

For each scan, we select a series of control regions (2 ml each, matching the volume of the coronary arteries) in a nearby, uniform anatomic area or in an anthropomorphic phantom of matched patient size and protocol. The 95th percentile of the maxima of these control regions is selected as the scoring threshold to ensure a Type I error rate of 5%. An adjustment is made for the mean difference in CT number between the control regions and coronary arteries, if any. We tested this framework on numerical simulations and an anthropomorphic phantom with 10 small calcifications (from 0.4 to 0.8 mm in size) that was scanned with different energy integrating detector CT (EID-CT) or photon counting detector CT (PCD-CT) protocols, all at matched dose.

#### RESULTS

In numerical simulations, our framework selected CT thresholds between 74 to 212 HU depending on the dose level and reconstruction kernel used. Higher doses improved sensitivity, but all scans had equivalent specificity. The sharper kernel increased sensitivity for small, bright calcifications but decreased sensitivity for large, less bright calcifications because the threshold increased with sharpness. In the anthropomorphic phantom, with a medium-sharp Qr54 EID-CT with 0.6 mm thick slices, a threshold of 410 HU was selected, and sensitivity was 40%. With a sharper Qr66 kernel, the threshold increased to 1015 HU and the sensitivity fell to 30%. With PCD-CT and a Qr68 kernel, the threshold decreased to 357 HU threshold because of the higher resolution capability of PCD-CT and sensitivity increased to 90%. No false positives were seen in these cases.

#### CONCLUSION

A specificity criterion provides a disciplined approach for selecting an Agatston scoring threshold. This allows objective detection of coronary calcium in new protocols and was demonstrated on high resolution protocols from PCD-CT.

#### CLINICAL RELEVANCE/APPLICATION

Coronary calcium scoring algorithms must be modified to take advantage of new scanner capabilities. We provide a general framework for making modifications that is especially useful for new, higher resolution CT protocols.

### Impact of Deep Learning Reconstruction on Radiation Dose Reduction and Cancer Risk in CT Examinations: A Real-World Clinical Analysis

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Naoki Kobayashi, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study is to estimate the degree to which the introduction of Deep Learning Reconstruction (DLR) into clinical settings may reduce the radiation dose and the risk of radiation-induced cancer from CT examinations, utilizing real-world clinical data.

#### METHODS AND MATERIALS

In our institution, we retrospectively collected scanning information for two distinct periods based on the date of DLR implementation: the 12 months immediately prior to the introduction of DLR, when iterative reconstruction (IR) was used for routine CT, and the 12 months following the implementation of DLR, when the routine CT reconstruction was switched to DLR. Inclusion criteria consisted of adult patients (aged 20 to 100 years) who underwent body CT during this period on specific CT units where DLR was introduced. The dose management system, Radimetrics™ (Bayer), was used to collect dose data and to estimate the equivalent dose for each organ and the effective dose for the whole body. From the dose data, we calculated the reduction rate of the average dose upon the implementation of the DLR. Utilizing the R package, "LARisk 1.0.0", we also estimated the lifetime attributable risk (LAR) for each CT examination based on exposure dosage estimates. We summarized the LARs by age, gender, and organ, and evaluated the degree to which the LAR was altered before and after the implementation of DLR. The number of radiation-induced cancers before and after the introduction of DLR was also estimated.

#### RESULTS

A total of 6,172 cases prior to and 6,423 cases following the implementation of DLR were incorporated into the analysis. The total effective dose in body CT was significantly lower post-DLR introduction ( $15.8 \pm 10.6$  mSv) compared to pre-DLR introduction ( $27.9 \pm 14.1$  mSv) ( $p < 0.001$ ), amounting to a 43% dose reduction. The decrease in radiation dose resulted in a substantial reduction in the risk of radiation-induced cancer, with particularly notable benefits in a group of relatively young women. The estimated annual incidence of radiation-induced cancers was 0.261% (16.1 out of 6,172) prior to the introduction of DLR and 0.139% (8.9 out of 6,423) following its implementation.

#### CONCLUSION

Our single-center study suggests that the implementation of DLR has the possibility to reduce radiation dose and radiation-induced cancers by nearly half in the clinical routine CT compared with the iterative reconstruction.

#### CLINICAL RELEVANCE/APPLICATION

This study shows the degree to which the introduction of DLR contributes to a reduction in radiation dose and thus in the incidence of radiation-induced cancer.

### **A Fundamental Investigation into the Behavior of Active Collimators in Multi-detector CT Systems under Varying Imaging Conditions**

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Ryo Moriwake, BS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study aims to investigate that the effects with and without active collimator usage on dose profiles in the body axis direction and over-range length when scan conditions are altered.

#### **METHODS AND MATERIALS**

We used a 80-detector row CT scanner. A polymethyl methacrylate (PMMA) phantom with a diameter of 16 cm was placed at the center of the gantry rotation. The high-accuracy Thimble ionization chambers (10X6-0.6CT, Radcal) was inserted in the center of the phantom with a scan length of 10 cm to include scattered radiation. The scan parameters were set as follows: tube voltage of 120 kV, tube current and rotation speed set to 50 mAs, and various combinations of detector rows of  $0.5 \times 80$  mm,  $0.5 \times 64$  mm, and  $1.0 \times 40$  mm were used at three pitch factor levels: High Definition, Standard, and High Speed. Each measurement was performed three times, and the axial dose profiles and over-range lengths were determined for each scan condition.

#### **RESULTS**

The dose profiles in the Z axial direction with and without AC were wider in each scan condition with AC than without AC. The dose profiles in the body axial direction during the change of imaging conditions tended to differ depending on the rotation speed and the number of detector rows. The widest dose profile was observed at high speeds. The over-range length was approximately 18 to 45 mm. The over-range length was particularly large at the combination of 0.5 sec,  $1.0 \times 40$  mm, and high speed.

#### **CONCLUSION**

By comparing the dose profiles with and without AC, the operation of AC was confirmed. It was also confirmed that the operation of the AC depends on the imaging conditions. Overrange lengths ranged from about 18 to 45 mm, The overrange length was particularly large for the combination of 0.5 sec,  $1.0 \times 40$  mm, and high speed.

#### **CLINICAL RELEVANCE/APPLICATION**

The use of active collimator may reduce over-range. Since the over-range varies depending on the scan conditions, it is important to understand the effect of overrange in advance for children with a short scan range. In addition, the use of a semiconductor detector may make it possible to easily determine the effect of over-range.

### Effect of Radiation Dose on CT Attenuation of Photon Counting CT Scanner: A Phantom Study

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Jingjuan Liu, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

NAEOTOM Alpha is the new generation CT scanner (Siemens Healthineers, Forchheim, Germany) which epoch-makingly used the semiconductor material for detector. The new detector system could convert photons directly into electronic signals to improve the utilization of photons and result in a lower noise, a higher resolution and image quality. Compared with the mixed image in dual source system, NAEOTOM Alpha would generate a monoenergetic image of 70keV as the 'standard' image for doctors' diagnosis. In this project, we want to first evaluate the accuracy and change of CT attenuation with different mono-energetic images using a liver nodule phantom.

#### METHODS AND MATERIALS

We applied a liver nodule phantom (QRM, Möhrendorf, Germany) consisting of the anthropomorphic abdomen phantom body, the liver and spleen insert in this project. The liver insert contains multiple oval and spherical lesions of different sizes and in two kinds of densities. The phantom was scanned with the standard QuantumPlus protocol on NAEOTOM Alpha in 3 different scanning modes (Spiral, Flash and Sequence). In each mode, the tube voltage was set at 120kV and 140kV. Each scan was performed for 3 times to reduce the errors. All images were reconstructed as SPP image with a kernel of Qr40, slice thickness of 2mm and increment of 2mm and imported into the post-processing workstation (Syngo.Via VB70, Siemens Healthineers, Forchheim, Germany) for measurement. All statistical analysis was performed with Python 3.10.11. The difference between measured results and standard CT attenuation was tested with student T test. A p value smaller than 0.05 was considered as significant.

#### RESULTS

As shown in Fig.1, the CT attenuation is close to the standard value when the mono-energy is around 70keV for abdomen region, low-density and high-density lesions, with no significant difference when compared with the standard values. For liver region, for Spiral and Sequence mode, the CT values were close to the standard value when the mono-energy is around or lower than 55keV, while 60keV for Flash mode. For the spleen region, the CT attenuations are close to the standard value when the mono-energy is around 65keV.

#### CONCLUSION

From the result, we could conclude that the CT attenuations of 70keV image are close to the standard value for the abdomen region, low-density and high-density lesions in the liver. However, 65keV image for spleen and 60keV image for liver seem to be closer to standard value. This could help the doctors in clinical routines to decide the parameters.

#### CLINICAL RELEVANCE/APPLICATION

To lay the foundation for the further promotion of photon CT to clinical applications.

Printed on: 08/22/24

### Comparison of Non-gated, High-pitch Cardiac CTA in Pediatric Patients under 1 Year of Age: Energy Integrating Detector vs Photon Counting Detector CT

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Scott M. Bugenhagen, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To determine image quality and radiation doses on photon counting detector (PCD) CT compared to conventional energy-integrated detector (EID) CT in under 1 year old congenital heart disease (CHD) patients.

#### METHODS AND MATERIALS

This study involved an Institutional-Review-Board (IRB) approved retrospective analysis of CHD patients that underwent clinically indicated CT angiography examinations using dual-source EID-CT (Siemens Healthineers, SOMATOM Force) and dual-source PCD-CT (Siemens Healthineers, NAEOTOM Alpha). All examinations, regardless of detector technologies, were acquired with non-gated, high-pitch technique (3.2) and automated exposure control. All PCD scans used 120kV and 55keV reconstructions, while EID scans used automated kV technology with tube potential of 70 and 80kV. Patient characteristics (age, body mass index, patient weight) as well as dose descriptors including volume CT dose index (CTDIvol), dose length product (DLP), and size-specific dose estimate (SSDE), were recorded and compared. Image quality assessment was based on review of the 4 major coronary arteries and was scored on an 8 point scale: 3 points for right coronary artery (RCA) (1 for origin, 2 for origin + proximal, 3 for origin + proximal + distal), 1 point for left main coronary artery (LMCA) (seen or not seen), and 2 points for the left anterior descending artery (LAD) and left circumflex artery (LCA) arteries (1 for proximal and 2 for proximal + distal). Parametric (t-test) testing was used for statistical evaluation.

#### RESULTS

29 and 24 CT examinations were included for EID and PCD, respectively. There were no overall differences in demographic characteristics including mean (standard deviation) patient age [0.137 vs 0.157 years,  $P = 0.844$ ], body mass index [14.2 (+/- 2.5) vs 13.9 (+/-2/5) kg/m<sup>2</sup>,  $P = 0.5$ ], or patient weight [3.63 vs 3.62 kg,  $P = 0.9$ ]. In comparison with EID CT, PCD CT had significantly lower mean CTDIvol [0.48 vs 0.39 mGy,  $P=0.001$ ]. SSDE [1.005 vs 0.951 mGy,  $P = 0.11$ ] and DLP [7.07 vs 5.66 mGy cm,  $P =0.06$ ] differences were non-significant. There was negligible difference in image quality (visualization of coronary arteries) ( $P = 0.19$ ).

#### CONCLUSION

Our experience indicates that radiation doses in non-gated high-pitch cardiac PCD-CT in children are similar to or lower than those of current EID-CT, while subjective image quality is maintained.

#### CLINICAL RELEVANCE/APPLICATION

Similar to lower doses in non-gated high-pitch cardiac PCD-CT compared to EID-CT supports use of PCD-CT in cardiac imaging in children.

### Correlation of Human Observer Impression of X-ray Fluoroscopy and Angiography Image Quality with Technical Changes to Image Quality

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Jelena Mihailovic, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Perceived angiographic image quality is a combination of image formation technical factors and image processing. No standard methods to measure angiography quality exists due to the combination of spatio-temporal anatomical variability and non-linear image processing. However, methods to assess image quality are needed to optimize radiation dose and image quality in the clinical practice. The purpose of this work was to develop and validate methods to measure observer impression of angiographic image quality.

#### METHODS AND MATERIALS

Multi-frame images of the thorax of a euthanized pig were acquired to provide an anatomical background. Detector dose (DD) was varied from 6 to 200 nGy (increments 2x) to provide background with a wide range of quantum SNR. For each DD images with 0.6 and 1.0 mm focal spots (FS) were acquired to assess FS blur. Two stents with/without 0.5 mm separation and a synthetic right coronary artery (RCA) with spherical defects were embedded as test objects into the pig images. Embedded test objects included motion to mimic cardiac function. Quantitative observer (n=14) performance was measured through 2AFC test of whether stents were touching and by observer count of RCA defects. Subjective impressions of quality were measured through visual analog scale (VAS) response to statements assessing small object details, noise impression, and overall image quality. The paired t-test was used to describe significance of observer response changes associated with DD or FS size.

#### RESULTS

Proportion of correct responses of stent separation and number of RCA defects reported changed significantly with DD increment in the range 6-100 nGy ( $p < 0.05$ ). While there was a trend which favored the 0.6 vs. 1.0 mm FS for these quantitative assessments, this was not significant. VAS measurements changed significantly with both DD increment in the range 24-100 nGy and with FS size for a given DD ( $p < 0.05$ ). Quantitative and subjective measurements were highly correlated. The most sensitive measurement was VAS assessment of small object details.

#### CONCLUSION

Compared to quantitative human observer assessment, measurement of subjective impression of image quality demonstrated higher sensitivity for image quality changes associated with quantum SNR and focal spot size. These findings embolden future work to assess quality of fluoroscopy and angiography images using subjective measurements. Our strategy to ensure rigor is systematic, self-conscious study design, data collection, and interpretation.

#### CLINICAL RELEVANCE/APPLICATION

For cardiovascular imaging procedures, defining image quality is complex task because it relates to numerous dynamic variables. Feedback from the end user can lead to more accurate and reproducible measurements.

### Is it Possible to Achieve Consistent Outcomes in CT NSCLC Radiomics? An In-depth Exploration of the Sources of Uncertainties

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Gary Ge, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Radiomics features have been used in machine learning models to quantify tissue characteristics that are not observable by clinicians to aid in the prediction of clinical decisions and outcomes. However, there are still many uncertainties involved in this process which reduce the robustness of results and limit its clinical implementation. We investigate the impact of each component in the radiomics pipeline on predicting clinical outcomes.

#### METHODS AND MATERIALS

A thorough review of over 120 CT lung radiomics studies was conducted to examine current. Patient images were retrospectively retrieved from a GE VCT scanner. The lung nodules were manually delineated using Eclipse to define a region of interest. First-order features were extracted with IBEX and high-order features were extracted using Python. Clinical features were retrieved from the Kentucky Cancer Registry (KCR). The features were organized into five feature sets, Radiomic (low), Radiomic (high), Radiomic (high+low), Clinical, and Radiomic+Clinical. Prediction of 2-year survival was investigated. Cohort size was examined by extracting balanced sub-cohorts of the original cohort to be run in parallel to the original cohort. The included feature selection methods are: ANOVA, LASSO, MI, mRMR, and Relief. The number of selected features used for model training was also established as a variable for examination, ranging from 5 to 25 features. The included predictive models are: SVC, Naïve-Bayes, DT, RF, LR, GBoost, and kNN. Model validation methods were also examined, using 2-, 5-, and 10-fold cross-validation (CV).

#### RESULTS

496 patient image sets are retrieved for use in this analysis. CT datasets are fairly balanced, with 237 patients  $\leq$  2 years survival and 259 patients  $>$  2 years survival. A total of 1419 first-order features, 360 high-order wavelet features, and 9 clinical features are included in the feature sets. Statistical analysis is done using Kruskal-Wallis for within-group analysis and further pairwise testing establishes relative rankings. A total of 17220 AUCs involving all combinations shows certain trends. Overall CT lung cancer radiomic stability favors larger cohort size, Clinical and Radiomic+Clinical feature sets, mRMR feature selection, RF predictive model, and 10-fold CV.

#### CONCLUSION

Radiomic feature selection and machine learning methods are inter-dependent. Appropriate inclusion of different feature types and choice of feature selection can improve predictive power for clinical outcome.

#### CLINICAL RELEVANCE/APPLICATION

Conducting systematic analysis of each phase of the radiomic workflow may heighten general understanding of uncertainties that contribute to unstable outcomes, thus potentially improving the robustness of future radiomic studies.

### **A Data Dashboard Approach to Improving Image Analysis: Survival Prediction of Patients with Bladder Cancer after Cystectomy based on Clinical, Radiomics, and Deep Learning Descriptors**

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Di Sun, MEng, BEng (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To predict the 5-year survival of bladder cancer patients after radical cystectomy by combining clinical, radiomics, and deep learning (DL) descriptors (CRD).

#### **METHODS AND MATERIALS**

With IRB approval, we collected clinical information and CTU scans from 163 patients with bladder cancer who underwent neoadjuvant chemotherapy followed by radical cystectomy. Five-year survival data were collected. We split the data into three sets: training (55 alive (A); 37 deceased (D)); validation (4 A; 3 D); and test (20 A; 44 D). The clinical information collected included post-surgery pathologic stage, lymphovascular invasion, pathologic node stage, if patients underwent chemotherapy, or adjuvant radiotherapy. The nomogram by Shariat was used to predict the survival of patients. Radiomics and DL descriptors were extracted from CTU images. Each patient had two CTU scans (before and during/after chemotherapy), forming a pre- and post-treatment pair. We used our AI-CALS algorithm to segment the lesions. To train and validate the DL convolution neural network (DL-CNN), hybrid ROIs extracted from the lesion area were used. A total of 182 radiomics features were extracted from the lesions, including grey level, morphological, and texture features from the post-treatment scans (post features) and the percentage difference between pre- and post-treatment features (difference features). Backpropagation neural network was used to classify the radiomics features. The area under receiver operating characteristic curve (AUC) and Kaplan-Meier analysis were used to evaluate the classification performance on the test set.

#### **RESULTS**

The nomogram model achieved an AUC of  $0.82 \pm 0.06$  on the test set; DL-CNN achieved an AUC of  $0.71 \pm 0.07$ ; and the classification based on radiomics features had an AUC of  $0.73 \pm 0.07$ . By combining all CRD descriptors, we obtained an AUC of  $0.87 \pm 0.05$ . The differences between any pairs of AUCs did not reach significance ( $p > 0.05$ ), which likely relates to sample size. The median survival times by Kaplan-Meier analysis for the two classes (deceased or alive) were 1.2 and 5 years ( $p < 0.001$ ) as estimated by the nomogram model, and 1.6 and 5 years ( $p = 0.007$ ) estimated based on CRD descriptors.

#### **CONCLUSION**

While larger data sets are needed, this study demonstrates that combining the radiomics and DL descriptors with clinical information holds promise for improving the prediction of the 5-year survival of bladder cancer patients after radical cystectomy.

#### **CLINICAL RELEVANCE/APPLICATION**

The CRD descriptors has the potential to improve the prediction of the 5-year survival of bladder cancer patients after radical cystectomy. Accurate assessment of 5-year survival offers potential benefits with patient counseling and postoperative surveillance strategies.

### **Fissure Integrity Scores in Pre-treatment Chest CT Images as a Biomarker for Predicting a Target Lobar Collapse with Endobronchial Valve Implantation in Subjects with Emphysema**

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Dallas Tada, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

We propose to build an initial endobronchial valve (EBV) prediction model using quantitative CT measurements to evaluate the response of emphysema patients to EBV implantation for a targeted lobe.

#### **METHODS AND MATERIALS**

The study retrospectively collected 127 anonymized pre-treatment EBV CT scans. Selection criteria for the targeted lobe for EBV implantation is based on the highest emphysema density and largest degree of heterogenous emphysema between the targeted and the ipsilateral adjacent lobe. A fissure integrity score (FIS) is used as a primary quantitative biomarker for the development of the EBV prediction model. Previous work on fissure segmentation and integrity assessment used a deep learning approach that segments pulmonary fissure and quantifies FIS for the right horizontal fissure (RHF), right oblique fissure (ROF), and left oblique fissure (LOF). An FIS is defined as the percentage of complete fissure voxels along the surface of the interlobar region. Fissures are categorized as complete with a FIS of  $\geq 90\%$ ; otherwise, a fissure is considered incomplete. Separate FIS for the right fissures are calculated based on the targeted lobe for lobar exclusion (i.e., upper lobar boundary for a targeted right upper lobe). Successful EBV placement in a targeted lobe is described as a reduction of  $\geq 50\%$  of its total lung capacity (TLC). A reduction of less than 50% of targeted lobe volume reduction (TLVR) does not achieve the desired lobar collapse. Statistical analysis of FIS and EBV volume reduction is applied to assess the significance of fissure completeness and EBV placement.

#### **RESULTS**

FIS and TLVR comparisons are separated by total sample size and targeted lobes. For all targeted lobes, a mean ( $\pm$ SD) FIS of 0.93 ( $\pm$ 0.05) and 0.72 ( $\pm$ 0.26) was attained for successful and unsuccessful TLVR, respectively. Subjects with complete target lobe fissure are likely to experience TLVR by six-fold compared to subjects with incomplete target lobe FIS (Odds Ratio = 6.05,  $p$ -value=0.001). All targeted lobes and the right upper lobe achieved a TLVR ( $p$ -value < 0.01); the left lobes and right lower lobe did not achieve statistical significance.

#### **CONCLUSION**

Quantified fissure integrity scores are essential for the foundation of the EBV prediction model, but additional quantitative biomarkers may improve the efficacy for the model.

#### **CLINICAL RELEVANCE/APPLICATION**

The development of a prediction model that will more successfully identify emphysema patients that respond to EBV treatment helps guide treatment decisions for clinicians and manages medical resources.

### Practicing Precision Medicine: Using Machine Learning to Predict Time-to-Surgery in Renal Cell Carcinoma under Active Surveillance

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Shiva Singh, MBBS (*Presenter*) Nothing to Disclose

#### PURPOSE

Clear cell renal carcinomas (ccRCCs) in VHL patients are typically managed with active surveillance (AS) until the tumor reaches 3 cm, when surgical resection is recommended. While current guidelines suggest annual screening with abdominal imaging, tailoring imaging frequency to each patient's tumor growth rate can reduce unnecessary radiation exposure and metastasis risk. This study aims to use MRI-based machine learning algorithms to predict the time to 3 cm threshold and design personalized imaging protocols for VHL patients.

#### METHODS AND MATERIALS

The retrospective study included 40 vHL patients with 68 histopathologically-confirmed ccRCCs (size 1-2 cm) undergoing AS according to institutional protocol. Tumor segmentation was performed on all available pre-operative scans using ITK-SNAP and radiomics features were extracted from co-registered pre-contrast and post-contrast sequences using PyRadiomics. A growth curve was plotted for each tumor, and the time taken for each tumor to grow to 3 cm (T3) from the initial time point was calculated using the respective growth curve's fitted line equation. Based on T3, the tumors were classified into three categories: aggressive (<365 days), moderate (1-3 years), and slow (>3 years). Stacked ensemble technique with random forest and XGBoost were used for training models to predict T3 based on radiomics features. Five-fold cross-validation was used and the model was benchmarked on 100 different combinations (85% train and 15% test) to find the best model which was reported with F1 score, and the area under the curve of the receiver operating characteristic curve (AUC-ROC).

#### RESULTS

A total of 40 patients (28 males) with mean age of  $44 \pm 3$  years and mean follow-up of  $2.9 \pm 1$  year were studied. Median volumetric growth rate of 1.8 cm<sup>3</sup> and diametric growth rate of 0.91 cm/year was observed. The best model showed an accuracy of 0.67 and F1-score of 0.67, 0.70 and 0.62 was observed with aggressive, moderate and slow tumor class respectively. AUC of ROC drawn for aggressive, moderate, and slow class were 0.65, 0.71 and 0.76. A Matthews Correlation Coefficient of 0.58 reveals a moderately well predicted analysis.

#### CONCLUSION

The use of MRI-based machine learning algorithms can predict the time to 3 cm threshold and classify tumors into aggressive, moderate, and slow-growing categories for VHL patients with ccRCCs, providing a personalized imaging protocol. However, moderate accuracy of the model suggests the need for large dataset and external validation to improve the performance.

#### CLINICAL RELEVANCE/APPLICATION

Tailoring imaging frequency based on the predicted time to 3 cm can reduce unnecessary radiation exposure and financial burden for slow-growing tumors as well as enables timely resection of aggressive lesion.

### Deep Learning-enabled Automatic Sarcopenia Analysis in Abdominal CT: Finding an Association with Cardiovascular Disease in Korean Population

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Sihwan Kim, BSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Little studies have shown that sarcopenia can increase the risk of cardiovascular disease, we aimed to investigate the association between a sarcopenia and cardiovascular mortality for the Korean population.

#### METHODS AND MATERIALS

Data were retrospectively collected from non-contrast enhanced abdominal CT scans between 2005 and 2017. The number of abdominal CT scans was 641, the CT data is scanned from 352 males (54.9%) and 289 females (45.1%). Among the abdominal CT data, 141 patients (21.9%) had cardiovascular disease (CVD). Mean age of studied data was about 64 yrs (64 for male and 63 for female). The sarcopenia is defined by the sex-specific L3 skeletal muscle area (SMA) threshold referenced as 117.04 cm<sup>2</sup> for male and 71.39 cm<sup>2</sup> for female. The SMA value of L3 vertebra level was calculated using automatic body composition analysis software (ClariMetabo, ClariPi, Seoul, Republic of Korea).

#### RESULTS

In the study data (n = 641), 75 patients (11.7%) had the sarcopenia. The result showed that 46.7% of Sarcopenia group had the CVD, compared to 18.7% in the non-sarcopenia group. The odds ratio for CVD event was 3.79 [95%CI: 2.30-6.26]. However, the correlation was 0.22 (p<0.0001) in the Phi correlation coefficient analysis, indicating a weak positive correlation. Among the sarcopenia patients, the CVD risk was 2.83 [95%CI: 0.79-10.6] times higher in male than in female.

#### CONCLUSION

Automated analysis of abdominal CT imaging markers based on deep learning showed that patients with sarcopenia are more likely to have the cardiovascular disease compared to normal people in the Korean population.

#### CLINICAL RELEVANCE/APPLICATION

Deep learning-based automatic muscle mass analysis in abdominal CT is expected to contribute to improving human survival by predicting the risk of cardiovascular disease due to the sarcopenia at an early stage.

### Feasibility of Artificial Intelligence-supported Assessment of Dual-energy Computed Tomography for Measuring Bone Mineral Density: Correlation with Quantitative CT

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Ya L. Li I (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the precision and agreement between BMD measurements performed in DECT-derived hydroxyapatite (HAP) concentration of the L1 vertebra to L3 vertebra and automated, AI-supported assessment of DECT-derived HAP concentrations with European Spine Phantom (ESP) compared with quantitative CT (QCT).

#### METHODS AND MATERIALS

Data acquisitions were performed on Revolution CT (GE Healthcare, Waukesha, WI) at 120kV with 0.8r/s and 100 and 500mA, fast tube voltage switching between high and low energy (140/80kVp) with 0.5r/s and 240 and 365mA using ESP (No. 145, Germany ORM company). Mindways QCT PRO workstation can automatically generate ROIs and analyze BMD. For DECT-derived HAP values, ROI (468.78mm<sup>2</sup>) was set as the median plane of the vertebral body avoiding cortical bone and its pedicle, and the HAP values of the L1, L2, and L3 were measured from the axial-view HAP (Water)-based material decomposition images on a dedicated GE AW 4.7 Workstation. For automated assessment of DECT-derived HAP concentration was performed by a new fully automatic BMD analysis with AI technology: Firstly, using spectral CT images as the original input, process detects, names, segments and recognizes the orientation of the vertebral body within the image; Secondly, system automatically selects the most suitable three vertebrae for evaluation, recognizes their direction and central plane, segments and extracts the three-dimensional structure of the vertebrae based on vertebral body segmentation; Thirdly, system automatically calculates ROIs in trabecular bone; Lastly, system generates personalized bone density reports. Paired t test and Pearson correlation were to determine the differences and association between two measurements.

#### RESULTS

The CTDIvol with QCT were 5.53mGy in 100mA and 27.66mGy in 500mA, whilst DECT were 5.80mGy in 240mA and 9.25mGy in 365mA. QCT-derived BMD values of the L1, L2, and L3 were 53.60±0.27, 106.25±0.11, 202.76±0.23mg/cm<sup>3</sup>, respectively. The DECT-derived HAP-Water values of the L1, L2, and L3 were 45.25±0.42, 89.2±0.86, 180.00±0.15mg/cm<sup>3</sup> with tube current of 240mA, whilst 39.46±0.51, 88.64±0.74, 170.1±0.38mg/cm<sup>3</sup> with tube current of 365mA. The DECT-derived HAP-Water values of the L1, L2, and L3 with AI were 44.2±0.87, 94.73±0.32, 173.22±0.71mg/cm<sup>3</sup> with tube current of 240mA, and 41.23±0.23, 92.03±0.74, 173.79±0.78mg/cm<sup>3</sup> with tube current of 365mA. There was a strong positive correlation between two methods ( $r=0.91$ ,  $P<0.0001$ ).

#### CONCLUSION

The automated, AI-supported assessment of DECT-derived HAP concentration of the three vertebrae is feasible to measure BMD values and potentially aid a help in opportunistic osteoporosis screening in high-risk populations.

#### CLINICAL RELEVANCE/APPLICATION

none

### External Review of High CT Doses: Reasons and Improvements

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

William F. Sensakovic, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To review reasons for high CT dose cases during external review and implement improvements to improve review workflow.

#### METHODS AND MATERIALS

An in-house built external CT dose review was clinically implemented in August of 2021. Cases exceeding machine Dose Notification Values are automatically retained for review. For each case a technologist records possible reasons for the high dose and final review, updating of reasons, and sign-off is performed in-system by a qualified medical physicist or a supervisor/team lead with physicist final review. Summary statistics related to number of review cases and the reason for high doses as well as the rate of cases referred for review were calculated.

#### RESULTS

A total of 4,212 cases for 3098 unique patients were reviewed across our 21 CTAP sites. Mean CTDIvol was 62.3 Gy  $\pm$  22.9 Gy. Cases exceeded notification values by 15.5%  $\pm$  18.5% on average. 31.2% of cases exceed the notification value by less than 5%. A reason for the high dose was included in 3,994 cases (94.8%). In those that listed a reason for the high dose, 3,678 (92.1%) included large patient size at part or all of the reason for the high doses. Mean BMI of patients in reviewed cases was 42.5  $\pm$  10.9. BMI data was missing from 791 cases (18.8%). The next most frequent reasons were presence of shoulders (typically in neck scans) at 250 cases (6.3%) and misplacement of arms at 174 cases (4.4%). The presence of implants and casts was mentioned in 68 cases (1.7%) and combo scan across anatomy 46 (1.2%). No other reason exceeded 1% of the cases.

#### CONCLUSION

Most cases only exceed notification values by a small amount and represent only a small risk to the patient. The vast majority of external review cases are due to patient size and are generally considered appropriate. Other major issues include arm placement, combinations studies, and studies across the neck and into the shoulders. Our external review software lists BMI when available to improve physics workflow.

#### CLINICAL RELEVANCE/APPLICATION

Physics workflow can be improved in external review by listing indicators of patient size along with other basic demographics to reduce the need for searching for such information. It is important that size indicators are available for systems to pull and autopopulate for external review.

### Low-dose 4D Head and Neck Computed Tomography Angiography Conducted via Helical Scans Jointing with ECG-gated Axial Scans: Study in Image Quality

Wednesday, Nov. 29 12:45PM - 1:15PM Room: Learning Center

Jinhui Zhang (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the image quality of low-dose 4D head and neck computed tomography angiography (CTA) conducted via helical scans jointing with ECG-gated axial scans, compared with conventional standard-dose spiral scanning.

#### METHODS AND MATERIALS

This study enrolled 100 patients suspected with Cerebral aneurysm and received head and neck CTA. The patients were divided into two groups according to the scanning methods. Group A (n=50) performed helical neck CTA jointing (pitch=0.992: 1) with ECG-gated axial head CTA at 20%-110% R-R interval in sequence, noise index (NI) was set as 8 HU and rotation time was 0.35 s. Group B (n=50) received normal conventional helical scanning with pitch of 0.984: 1, NI of 5 HU, rotation time of 5 s. Regions of interest were placed at the bifurcation of internal carotid artery and M1 segment of middle cerebral artery. CT values and SD values of ROIs and muscle or white matter were measured, and SNR and CNR were calculated. The overall image quality was subjectively scored using a 5-scale method. The radiation dose, subjective and objective image evaluation results were compared.

#### RESULTS

Compared with Group B, Group A had a decreased DLP by 34.6% (A vs. B:  $558.92 \pm 57.01$  vs.  $944.88 \pm 86.05$  mGy·cm,  $P < 0.001$ ). For bifurcation of internal carotid artery, the two group images showed no statistical difference in CT values (A vs. B:  $545.58 \pm 93.92$  vs.  $535.66 \pm 71.30$ ), SD ( $11.35 \pm 2.51$  vs.  $10.70 \pm 2.48$ ), SNR [ $48.16$  (20.99) vs.  $49.43$  (21.46)] and CNR ( $62.87 \pm 16.02$  vs.  $66.74 \pm 16.04$ ), with all  $P > 0.05$ . For M1 segment of middle cerebral artery, the two group images also showed no statistical difference in CT values ( $528.68 \pm 124.60$  vs.  $513.32 \pm 71.22$ ), SD [ $14.09$  (4.18) vs.  $11.94$  (3.65)], SNR [ $39.99$  (17.05) vs.  $45.57$  (17.60)] and CNR ( $54.99 \pm 14.56$  vs.  $50.83 \pm 12.76$ ), with all  $P > 0.05$ . Regarding subjective scoring, both the two-group images met diagnostic requirements and the difference was not statistically significant ( $P > 0.05$ ).

#### CONCLUSION

For head and neck CTA, low-dose helical scans jointing with ECG-gated axial scans showed comparable head and neck artery displays with standard-dose conventional helical scanning.

#### CLINICAL RELEVANCE/APPLICATION

Aneurysm is at risk of rupture, and monitoring of its pulsatility with the cardiac cycle shows predictive value, where ECG-gated 4D CTA potentially be helpful. However, 4D scans may increase the risk of radiation doses, in this study, we found that helical combined ECG-gated axial scan with exposure during 20% -110% R-R interval could obtain comparable artery visualization with conventional helical

W5-STCE1

### Science Session (Theranostics)

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center Theater 1

#### Sub-Events

#### **W5-STCE1- A <sup>18</sup>F-FDG PET Based Nomogram to Diagnose Cancer-associated Cachexia and Predict Prognosis: A Multicenter Study**

Zhicheng Jin, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This multi-center study attempts to develop and externally validate a nomogram that combines fluorine-18-fluorodeoxyglucose (18F-FDG) PET features and results from the routine clinical biochemistry tests to diagnose cancer-associated cachexia. Furthermore, the potential utility of this nomogram for prognostic assessment is examined.

#### **METHODS AND MATERIALS**

A retrospective analysis was conducted on 18F-FDG PET/CT data collected from 658 cancer patients in two centers. 390 patients (mean age: 61 ± 12 years; 221 men) were included in the development cohort, while 268 patients (54 ± 14; 135 men) were included in the validation cohort. The results from routine clinical tests of blood samples that are indicative of metabolic functions, as well as organ- and tissue-specific FDG uptake were obtained followed by logistic regression analyses to identify independent variables associated with cancer-associated cachexia. The area under the receiver operating characteristic curve (AUC), calibration curve, and decision curve analysis were then used to determine the diagnostic accuracy, discriminative ability, and clinical effectiveness of the nomograms. Cox regression and Kaplan-Meier curves were applied to evaluate the predictability of the nomogram on overall survival.

#### **RESULTS**

Age (odds ratio [OR], 2.219; P = 0.002), hemoglobin (OR, 1.956; P = 0.009), maximum standardized uptake value (SUV) of the liver (OR, 2.848; P < 0.001), and minimum SUV of the subcutaneous fat (OR, 3.895; P ? 0.001) were found as independent predictors of cachexia. The combined nomogram incorporating these variables achieved an AUC of 0.772 in identifying cancer-associated cachexia in the development cohort and an 0.706 in the external validation cohort, respectively. The calibration curve and decision curve analysis indicated that the combined nomogram is effective clinically in diagnosing cancer-associated cachexia. Kaplan-Meier curves analysis showed that overall survival can be categorized using the combined nomogram (P ? 0.001).

#### **CONCLUSION**

Reported nomogram combining radiological information with <sup>18</sup>F-FDG PET data of cancer patients and biochemical results in routine clinical blood tests enables diagnosing cachexia and predicting its effect on the prognosis.

#### **CLINICAL RELEVANCE/APPLICATION**

In conclusion, the combined nomogram with measurements from routine clinical blood tests and FDG PET can diagnose cancer-associated cachexia and predict clinical outcomes of patients with cachexia. This new method may provide a non-invasive and quantitative tool in oncology clinical practice.

#### **W5-STCE1- Fast Magnetic Resonance Angiography of the Cervical Arteries Without Gadolinium Contrast: Clinical Evaluation of Highly Compressed SENSE accelerated Relaxation-Enhanced Angiography without Contrast and Triggering (REACT) in Patients with Acute Ischemic Stroke**

Kenan Kaya, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Because of methodical disadvantages of Contrast-enhanced magnetic resonance angiography (CE-MRA) and potential allergic reactions to contrast agent, native MRA techniques have gained increased interest. The purpose of this study was to evaluate a highly accelerated novel 3D flow-independent MRA sequence (Relaxation-Enhanced Angiography without Contrast and Triggering (REACT)) for fast imaging of the extracranial arteries in acute ischemic stroke (AIS).

## METHODS AND MATERIALS

In this retrospective single-center study, 76 consecutive patients ( $68.2 \pm 16.4$  years, 54 males) with AIS were included. Patients received a standard protocol including Compressed SENSE (CS) accelerated (factor 7) 3D isotropic REACT (fixed scan time: 01:20 min) and CS accelerated (factor 6) 3D isotropic CE-MRA. Two radiologists independently assessed scans for the presence of extracranial internal carotid artery (ICA) stenosis with concomitant diagnostic confidence using a 5-point scale (5=excellent). Vessel quality of the cervical arteries as well as the overall presence of artifacts and image noise were subjectively scored on 5-point scales (5=excellent/none). For objective comparison, apparent signal- and contrast-to-noise ratios (aSNR/aCNR) were measured at the common carotid artery (CCA) and ICA (C1 segment).

## RESULTS

Considering CE-MRA as the standard of reference, REACT yielded a sensitivity of 84.1% and specificity of 93.5 % for any and of 88.5 % and 100 % for clinically relevant (=50%) extracranial ICA stenosis. Diagnostic confidence was comparable between both techniques ( $3.7 \pm 0.5$  in REACT vs.  $3.8 \pm 0.5$  in CE-MRA;  $P=.03$ ), REACT obtained an almost perfect accordance with CE-MRA regarding the grading of disease (Cohen's Kappa 0.84). Overall presence of artifacts and vessel quality was comparable between both techniques for the majority of analyzed segments with REACT yielding higher scores at the common carotid arteries ( $4.3 \pm 0.6$  vs.  $3.8 \pm 0.9$ ;  $P < .001$ ) whereas CE-MRA obtained higher scores at V2- and V3-segments of the vertebral arteries ( $3.9 \pm 0.8$  vs.  $3.3 \pm 0.5$ ;  $P < .001$  and  $3.9 \pm 0.8$  vs.  $3.3 \pm 0.5$ ;  $P < .001$ ). REACT showed a lower image noise ( $3.8 \pm 0.6$  vs.  $3.6 \pm 0.7$ ;  $P=0.024$ ) with higher aSNR ( $52.5 \pm 15.1$  vs.  $37.9 \pm 12.5$ ;  $P < .001$ ) and aCNR ( $49.4 \pm 15.0$  vs.  $34.7 \pm 12.3$ ;  $P < .001$ ) than CE-MRA for all vessels combined.

## CONCLUSION

In a very short scan time, highly compressed SENSE accelerated REACT provides a high sensitivity and specificity for extracranial ICA stenosis time while yielding to CE-MRA comparable vessel quality in AIS.

## CLINICAL RELEVANCE/APPLICATION

Given its short acquisition time, high diagnostic performance, and sufficient image quality, REACT proves to be a clinically applicable method to depict the extracranial arteries in acute ischemic stroke.

## W5-STCE1-3 Development of Theranostic $^{177}\text{Lu}$ -labeled Semiconducting Polymer Dots (pDots) for the Treatment of Head and Neck Cancer

Min-Tzu Ku, PhD, RT (*Presenter*) Nothing to Disclose

## PURPOSE

The superior capabilities of pDots in near-infrared II (NIR-II) imaging have been demonstrated in previous studies. This study aims to develop  $^{177}\text{Lu}$ -labeled pDots and evaluate their potential as a theranostic agent for the treatment of head and neck cancer.

## METHODS AND MATERIALS

The pDots utilized in this study were generously provided by Prof. Yang-Hsiang Chan from National Yang Ming Chiao Tung University, Taiwan. These pDots were modified with ethylenediamine through amide bond formation with carboxyl groups on their surface. Subsequently, chelates (p-SCN-Bn-DTPA) were introduced to produce DTPA-modified pDots. The radiolabeling process involved incubating  $^{177}\text{Lu}$ - $\text{LuCl}_3$  and DTPA-modified pDots in a citrate buffer solution at  $40^\circ\text{C}$  for 1 hour. To evaluate the therapeutic efficacy of  $^{177}\text{Lu}$ -pDots, SAS cells were inoculated in the right flank of nude mice. NIR-II imaging was conducted using a system equipped with a 793-nm laser generator and an InGaAs camera.

## RESULTS

The radiochemical yield of  $^{177}\text{Lu}$ -pDots was  $8 \pm 3\%$  with high radiochemical purity. Remarkably, the radiolabeling process had no adverse impact on the size distribution and light absorption/emission properties of pDots. NIR-II imaging confirmed the successful delivery of  $^{177}\text{Lu}$ -pDots to the tumor, reaching its highest uptake at 24 hours after intravenous injection. Biodistribution studies supported these findings, showing tumor uptake values of  $7.1 \pm 1.9\% \text{ID/g}$  and  $5.2 \pm 2.1\% \text{ID/g}$  at 24 and 48 hours post-injection, respectively. Upon administering  $^{177}\text{Lu}$ -pDots and performing 793-nm laser irradiation, the tumor temperature increased to approximately  $42^\circ\text{C}$ , achieving mild photothermal therapy (PTT) conditions. However, the PTT primarily induced elevated blood vessel permeability, which facilitated subsequent drug accumulation, rather than exhibiting significant therapeutic efficacy. In the treatment studies, tumor-bearing mice treated with fractionated  $^{177}\text{Lu}$ -pDots exhibited tumor growth retardation, while both the control group and mice receiving a single round of  $^{177}\text{Lu}$ -pDots

showed continuous tumor volume increase. Notably, the fractionated  $^{177}\text{Lu}$ -pDots-treated group did not experience severe body weight reduction, indicating superior biosafety.

#### **CONCLUSION**

In this study, we successfully developed theranostic  $^{177}\text{Lu}$ -pDots, functioning as a versatile agent for angiography, photothermal conversion, and radiotherapy.

#### **CLINICAL RELEVANCE/APPLICATION**

$^{177}\text{Lu}$ -pDots offer promising potential as an innovative radiopharmaceutical therapy agent for cancer treatment while also enabling noninvasive imaging for pharmacokinetic analysis. Moreover, their compatibility makes them an excellent candidate for combining radiopharmaceutical therapy with photothermal therapy.

W5-STCE1-1

### A <sup>18</sup>F-FDG PET Based Nomogram to Diagnose Cancer-associated Cachexia and Predict Prognosis: A Multicenter Study

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center Theater 1

Zhicheng Jin, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This multi-center study attempts to develop and externally validate a nomogram that combines fluorine-18-fluorodeoxyglucose (<sup>18</sup>F-FDG) PET features and results from the routine clinical biochemistry tests to diagnose cancer-associated cachexia. Furthermore, the potential utility of this nomogram for prognostic assessment is examined.

#### METHODS AND MATERIALS

A retrospective analysis was conducted on <sup>18</sup>F-FDG PET/CT data collected from 658 cancer patients in two centers. 390 patients (mean age: 61 ± 12 years; 221 men) were included in the development cohort, while 268 patients (54 ± 14; 135 men) were included in the validation cohort. The results from routine clinical tests of blood samples that are indicative of metabolic functions, as well as organ- and tissue-specific FDG uptake were obtained followed by logistic regression analyses to identify independent variables associated with cancer-associated cachexia. The area under the receiver operating characteristic curve (AUC), calibration curve, and decision curve analysis were then used to determine the diagnostic accuracy, discriminative ability, and clinical effectiveness of the nomograms. Cox regression and Kaplan-Meier curves were applied to evaluate the predictability of the nomogram on overall survival.

#### RESULTS

Age (odds ratio [OR], 2.219; P = 0.002), hemoglobin (OR, 1.956; P = 0.009), maximum standardized uptake value (SUV) of the liver (OR, 2.848; P < 0.001), and minimum SUV of the subcutaneous fat (OR, 3.895; P ? 0.001) were found as independent predictors of cachexia. The combined nomogram incorporating these variables achieved an AUC of 0.772 in identifying cancer-associated cachexia in the development cohort and an 0.706 in the external validation cohort, respectively. The calibration curve and decision curve analysis indicated that the combined nomogram is effective clinically in diagnosing cancer-associated cachexia. Kaplan-Meier curves analysis showed that overall survival can be categorized using the combined nomogram (P ? 0.001).

#### CONCLUSION

Reported nomogram combining radiological information with <sup>18</sup>F-FDG PET data of cancer patients and biochemical results in routine clinical blood tests enables diagnosing cachexia and predicting its effect on the prognosis.

#### CLINICAL RELEVANCE/APPLICATION

In conclusion, the combined nomogram with measurements from routine clinical blood tests and FDG PET can diagnose cancer-associated cachexia and predict clinical outcomes of patients with cachexia. This new method may provide a non-invasive and quantitative tool in oncology clinical practice.

### **Fast Magnetic Resonance Angiography of the Cervical Arteries Without Gadolinium Contrast: Clinical Evaluation of Highly Compressed SENSE accelerated Relaxation-Enhanced Angiography without Contrast and Triggering (REACT) in Patients with Acute Ischemic Stroke**

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center Theater 1

Kenan Kaya, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Because of methodical disadvantages of Contrast-enhanced magnetic resonance angiography (CE-MRA) and potential allergic reactions to contrast agent, native MRA techniques have gained increased interest. The purpose of this study was to evaluate a highly accelerated novel 3D flow-independent MRA sequence (Relaxation-Enhanced Angiography without Contrast and Triggering (REACT)) for fast imaging of the extracranial arteries in acute ischemic stroke (AIS).

#### **METHODS AND MATERIALS**

In this retrospective single-center study, 76 consecutive patients ( $68.2 \pm 16.4$  years, 54 males) with AIS were included. Patients received a standard protocol including Compressed SENSE (CS) accelerated (factor 7) 3D isotropic REACT (fixed scan time: 01:20 min) and CS accelerated (factor 6) 3D isotropic CE-MRA. Two radiologists independently assessed scans for the presence of extracranial internal carotid artery (ICA) stenosis with concomitant diagnostic confidence using a 5-point scale (5=excellent). Vessel quality of the cervical arteries as well as the overall presence of artifacts and image noise were subjectively scored on 5-point scales (5=excellent/none). For objective comparison, apparent signal- and contrast-to-noise ratios (aSNR/aCNR) were measured at the common carotid artery (CCA) and ICA (C1 segment).

#### **RESULTS**

Considering CE-MRA as the standard of reference, REACT yielded a sensitivity of 84.1% and specificity of 93.5 % for any and of 88.5 % and 100 % for clinically relevant (=50%) extracranial ICA stenosis. Diagnostic confidence was comparable between both techniques ( $3.7 \pm 0.5$  in REACT vs.  $3.8 \pm 0.5$  in CE-MRA;  $P=.03$ ), REACT obtained an almost perfect accordance with CE-MRA regarding the grading of disease (Cohen's Kappa 0.84). Overall presence of artifacts and vessel quality was comparable between both techniques for the majority of analyzed segments with REACT yielding higher scores at the common carotid arteries ( $4.3 \pm 0.6$  vs.  $3.8 \pm 0.9$ ;  $P <.001$ ) whereas CE-MRA obtained higher scores at V2- and V3-segments of the vertebral arteries ( $3.9 \pm 0.8$  vs.  $3.3 \pm 0.5$ ;  $P <.001$  and  $3.9 \pm 0.8$  vs.  $3.3 \pm 0.5$ ;  $P <.001$ ). REACT showed a lower image noise ( $3.8 \pm 0.6$  vs.  $3.6 \pm 0.7$ ;  $P=0.024$ ) with higher aSNR ( $52.5 \pm 15.1$  vs.  $37.9 \pm 12.5$ ;  $P <.001$ ) and aCNR ( $49.4 \pm 15.0$  vs.  $34.7 \pm 12.3$ ;  $P <.001$ ) than CE-MRA for all vessels combined.

#### **CONCLUSION**

In a very short scan time, highly compressed SENSE accelerated REACT provides a high sensitivity and specificity for extracranial ICA stenosis time while yielding to CE-MRA comparable vessel quality in AIS.

#### **CLINICAL RELEVANCE/APPLICATION**

Given its short acquisition time, high diagnostic performance, and sufficient image quality, REACT proves to be a clinically applicable method to depict the extracranial arteries in acute ischemic stroke.

### Science Session (Generative AI)

Wednesday, Nov. 29 12:15PM - 12:45PM Room: Learning Center Theater 2

#### Sub-Events

#### **W5-STCE2- AI chatbots' ability to provide accurate information relevant to the informed consent process 1 for musculoskeletal radiology procedures**

Nikhil Patil (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The purpose of this study was to evaluate the accuracy of ChatGPT by OpenAI and Bard by Google's responses to prompts relevant to the informed consent process prior to musculoskeletal (MSK) radiology procedures.

#### **METHODS AND MATERIALS**

In this study we chose six common MSK procedures performed by radiologists. For each procedure, five prompts relating to procedure description, risks, benefits, alternatives, and implications of not proceeding were inputted into ChatGPT-4 and Bard. Each response was graded independently on a 5-point Likert scale by two reviewers using a grading rubric designed by two musculoskeletal radiology subspecialists. Each chatbot's response length and response time were collated and compared. Kappa Cohen coefficients and paired t-tests were used to conduct statistical analysis.

#### **RESULTS**

30 prompts across six MSK procedures were assessed. ChatGPT performed superiorly to Bard based on Likert grading of responses ( $4.4 \pm 0.8$  vs  $3.8 \pm 1.0$ ,  $p < 0.01$ ). Weighted kappa Cohen coefficients were 0.799 and 0.763 for ChatGPT and Bard responses, respectively, showing substantial inter-rater reliability. There was no significant difference in response length between ChatGPT and Bard ( $2034 \pm 361$  characters vs  $2052 \pm 462$  characters,  $p = 0.84$ ). ChatGPT's response time was significantly greater than Bard's ( $34 \pm 2$  seconds vs  $6 \pm 1$  seconds,  $p < 0.0001$ ).

#### **CONCLUSION**

ChatGPT and Bard provide generally accurate information with regards to common MSK procedure descriptions, their risks and benefits, and description of alternative options. However, neither chatbot can currently consistently provide concise, error-free, and clinically comprehensive answers. Both AI chatbots frequently provide extraneous information and rarely communicated the relative probability of risks. AI chatbots may potentially have a future role in the informed consent process alongside physician involvement.

#### **CLINICAL RELEVANCE/APPLICATION**

Informed consent prior to musculoskeletal radiology procedures is essential. The effectiveness of artificial intelligence chatbots as a potential patient resource has yet to be evaluated.

#### **W5-STCE2- Artificial intelligence chatbots' understanding of the risks and benefits of computed 2 tomography and magnetic resonance imaging scenarios**

Jia Cheng Yao, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Often, patients may seek online information about imaging procedures they may potentially undergo. The purpose of this study was to assess the accuracy of information that artificial intelligence (AI) chatbots provide pertaining to common imaging scenarios' risks, benefits, and alternatives.

## METHODS AND MATERIALS

14 imaging-related scenarios pertaining to computed tomography (CT) or magnetic resonance imaging (MRI) were used. Factors such as the use of contrast, the presence of renal disease, and whether the patient was pregnant were included in this analysis. For each scenario, three prompts for outlining the 1) risks, 2) benefits, and 3) alternative imaging choices were inputted into ChatGPT and Bard. Grading criteria were generated by two staff radiologists. A 5-point Likert scale was used by two independent reviewers (senior radiology residents) to grade responses.

## RESULTS

ChatGPT performed superiorly to Bard in accurately responding to prompts per Likert grading ( $4.35 \pm 0.67$  vs  $3.25 \pm 1.03$ ,  $p < 0.0001$ ). There was substantial agreement between independent reviewer grading for ChatGPT ( $\kappa = 0.621$ ) and Bard ( $\kappa = 0.684$ ). Response length was not significantly different between ChatGPT and Bard ( $2087 \pm 256$  characters vs  $2162 \pm 369$  characters,  $p = 0.24$ ). Response time was significantly longer for ChatGPT ( $34 \pm 2$  seconds vs  $8 \pm 1$  seconds,  $p < 0.0001$ ).

## CONCLUSION

ChatGPT performed superiorly to Bard in accurately outlining risks, benefits, and alternatives to common imaging scenarios that was consistent with what radiologists at a large tertiary care center would communicate. Although both chatbots generally provided accurate information, they also typically provided vast amounts of additional information that was not directly relevant to responding to the prompt. This may exacerbate patient anxiety. Due to the lack of detailed, scientific reasoning, these AI chatbots in their current form likely would not be useful for patients seeking in depth information.

## CLINICAL RELEVANCE/APPLICATION

The effectiveness of artificial intelligence chatbots such as ChatGPT and Bard in providing accurate information relevant to medical imaging informed consent has yet to be investigated.

## W5-STCE2- Top of the Class: GPT-4 Achieves Near Perfect Score and Outperforms Popular Large Language Models in Radiology Board Exam

Mahad S. Rehman, BS, BA (*Presenter*) Nothing to Disclose

## PURPOSE

Artificial intelligence (AI) and machine learning technologies continue to advance and integrate into the medical field. Among them, large language models (LLM) hold significant potential for assisting with interpreting complex information. However, limited research has been published comparing the performance of these models. This study aims to compare the results of four well known LLMs: GPT-4, GPT-3.5, Claude, and Google Bard in answering radiology board exam-style questions. The findings of this research will provide essential insights into the efficacy of these AI models in radiology and their potential application in medical education.

## METHODS AND MATERIALS

In this exploratory prospective study performed from July 12th, 2023 to July 21st, 2023, 150 multiple-choice questions designed to match the style, content, and difficulty of the American Board of Radiology examinations were compiled. Questions containing an image component were omitted. The compiled question bank was used to query LLM accuracy. Performance by each LLM was evaluated and compared. Data were analyzed using ANOVA and chi-squared analysis followed by post-hoc analysis with Bonferroni correction ( $\alpha < 0.0125$ ).

## RESULTS

On a 150-question bank of mainly higher-order diagnostic and management multiple choice questions designed for radiology qualifying board exams, GPT-4 achieved a score of 99% (148/150) and outperformed all other LLMs in this study. GPT-3.5 generated correct responses for 64% (96/150) of questions, while Claude scored 63% (94/150), and Bard scored 41% (62/150). GPT-4 performed significantly better on the question bank when compared to GPT-3.5, Claude, and Bard ( $p < 0.001$ ). Additionally, Bard performed significantly worse than GPT-3.5 and Claude ( $p < 0.001$ ). No significant difference was found between GPT-3.5 and Claude.

## CONCLUSION

Our research revealed that GPT-4 significantly outperforms GPT-3.5, Claude, and Bard in interpreting radiology board-style questions. Notably, GPT-3.5 and Claude performed comparably, while Bard was the least effective. This indicates the rapid progression of AI and LLMs in the comprehension of complex medical information. As AI and LLMs continue to improve, they have the potential to greatly contribute to the education and proficiency of radiologists. Our results suggest that newer models, such as GPT-4, could be invaluable in supplementing medical education and radiology board exam preparation, thereby advancing the field of radiology.

## CLINICAL RELEVANCE/APPLICATION

This study underscores the improving proficiency of LLMs in interpreting radiology board-style questions, suggesting its potential as a powerful educational tool, capable of enhancing clinical decision-making and patient care.

GPT-3.5 generated correct responses for 64% (96/150) of questions, while Claude scored 63% (94/150), and Bard scored 41% (62/150). GPT-4 performed significantly better on the question bank when compared to GPT-3.5, Claude, and Bard ( $p < 0.001$ ). Additionally, Bard performed significantly worse than GPT-3.5 and Claude ( $p < 0.001$ ). No significant difference was found between GPT-3.5 and Claude.

#### CONCLUSION

Our research revealed that GPT-4 significantly outperforms GPT-3.5, Claude, and Bard in interpreting radiology board-style questions. Notably, GPT-3.5 and Claude performed comparably, while Bard was the least effective. This indicates the rapid progression of AI and LLMs in the comprehension of complex medical information. As AI and LLMs continue to improve, they have the potential to greatly contribute to the education and proficiency of radiologists. Our results suggest that newer models, such as GPT-4, could be invaluable in supplementing medical education and radiology board exam preparation, thereby advancing the field of radiology.

#### CLINICAL RELEVANCE/APPLICATION

This study underscores the improving proficiency of LLMs in interpreting radiology board-style questions, suggesting its potential as a powerful educational tool, capable of enhancing clinical decision-making and patient care.

Lynn J. Savic, MD (*Moderator*) Research Grant, Guerbet SA

#### Sub-Events

#### **W6-SSIR03-1 Ultra-High-Resolution K-Edge Imaging for Assessment Of Residual Blood Flow after Embolization with Radiopaque Beads: A Feasibility Study on a Prototype Deep-Silicon Photon-Counting Scanner**

Nariman Nezami, MD (*Presenter*) Consultant, CAPS Medical Ltd

#### PURPOSE

Photon-counting detector (PCD) CT K-edge imaging enables differentiation of multiple contrast agents and can produce co-registered density maps of these agents. PCD-CT also allows for the creation of material maps with a resolution in the range of 100-200  $\mu\text{m}$ . Iodine-filled radiopaque embolization beads are commonly used for treatment of hypervascular tumors. Differentiating between iodine-filled beads and iodine-based contrast agents (IBCA) can be challenging. The goal of this study was to assess the feasibility of using K-edge imaging of gadolinium-based contrast agents (GBCA) to create density maps of iodine and Gd for the evaluation of vascular embolization and residual blood flow in ultra-high-resolution (UHR) on a clinical deep-silicon PCD-CT prototype.

#### METHODS AND MATERIALS

We 3D-printed 7 identical models of tumor vasculature. Among these, four models were filled with either IBCA or GBCA. The remaining three models were injected with iodine-filled microspheres ( $d=100\text{-}300\ \mu\text{m}$ ), to simulate tumor embolization, and then filled with GBCA. Three tumor models were placed inside a large phantom (diameter 200 mm) filled with ballistic gel, and four tumor models were placed inside an anthropomorphic chest phantom. The phantoms were scanned on a whole-body prototype deep-Si PCD-CT scanner with 8 energy bins, at 120 kVp and 255-300 mAs, with 1 s-rotation time. Virtual monoenergetic images (VMIs), I density, and water density maps were reconstructed with filtered-backprojection (FBP) using a prototype UHR kernel with 10% modulation transfer function cutoff of 21.2 lp/cm. We estimated the concentration of IBCA and GBCA in the phantom using I density and water maps generated from the 8 bin spectral projections.

#### RESULTS

We achieved clear visualization of the embolization vessel with I-filled microspheres and the residual perfusion with GBCA. We did not detect any significant cross contamination between the two contrast agents in material density maps. The error in estimating IBCA concentration was -0.7-1.1 mg I/mL for various mixtures of IBCA (0-35 mg I/mL) with GBCA and water. The error in GBCA concentration estimates was -0.3-0.7 mg Gd/mL for mixtures of GBCA (0-10 mg Gd/mL) with IBCA and water.

#### CONCLUSION

Ultra-high-resolution spectral deep-Si PCD-CT can detect and quantify concentrations of iodine- and gadolinium-based contrast agents to assess residual blood flow in models of embolized tumors. The availability of 8 energy bins allows several materials with different K-edges to be differentiated.

#### CLINICAL RELEVANCE/APPLICATION

UHR K-edge imaging of embolized vessels makes it possible to visualize iodine in the microspheres while simultaneously measuring the residual blood flow via a second K-edge contrast agent containing materials such as Gd.

#### **W6-SSIR03-2 MRI-guided Microwave Ablation using Dual Applicators with EPI-based Real-time MR Thermometry**

Aiming Lu, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

To demonstrate the feasibility of using two microwave (MW) needles simultaneously to improve the treatment efficiency of MRI-guided MW ablation (MRgMWA).

## METHODS AND MATERIALS

Ex vivo tissue experiments have demonstrated MRgMWA with two MW needles can be achieved with acceptable MR thermometry (MRT). Smaller spacing between the needles resulted in consolidated tumor coverage sooner while large spacing could potentially create a larger overall treatment zone. Based on these results, a MRgMWA procedure of a hepatic tumor on a patient was performed on a 1.5T MRI scanner using two MRI-configured MWA systems (Medwaves). IRB approval was obtained. Patient was under general anesthesia and placed on the MR table in a supine position. Under ultrasound guidance, two MW needles were inserted into the hepatic lesion ~2.7cm apart and ~10cm from the skin. Using both needles simultaneously, a 4-min MWA was first performed for 4 minutes. Next, the needles were repositioned, and a 2nd ablation was performed for 7.5 minutes. Real-time MRT was obtained during the ablations using a Visualase workstation. To minimize respiratory motion artifacts, scanning was manually synchronized with the patient's respiratory cycle. With a 3s acquisition window, one frame (5 slices) was acquired in each cycle during expiration using a multiple-shot EPI sequence. The relative position of the anterior phased array coil to the needles was adjusted to reduce noise due to electromagnetic interference (EMI). In addition, a few ablations using a single needle were also performed at different locations to cover the entire tumor.

## RESULTS

Real-time temperature maps with good image quality were obtained during the majority of the first ablation using two needles, clearly demonstrating evolution of the ablation zone surrounding each needle. However, significant noise due to intermittent EMI occurred in a few frames, which compromised the usefulness of the tissue damage map. After adjusting the coil placement (slightly increasing the distance between the coil and the needles), no such noise contamination were observed and reasonable MR thermometry were obtained throughout the 2nd ablation using two needles. Contrast-enhanced images demonstrated appropriate lack of enhancement within the lesion. Patient tolerated procedure well with no immediate complications.

## CONCLUSION

This work demonstrated that acceptable real-time MRT can be obtained during MRgMWA using two MW needles simultaneously, which could significantly increase the treatment efficiency.

## CLINICAL RELEVANCE/APPLICATION

MRgMWA using a single needle can be time-consuming for large tumors. This work demonstrated that MRgMWA using two needles can be achieved with real-time MRT to improve the treatment efficiency.

## W6- SSIR03-4 In Vivo Investigation of US-Triggered Vancomycin Release from a Novel Prophylactic Spinal Device in a Sheep Model

Flemming Forsberg, PhD (*Presenter*) Research Grant, Canon Medical Systems Corporation; Research support, Canon Medical Systems Corporation; Research support, General Electric Company; Speaker, General Electric Company; Research support, Siemens AG; Research Grant, Butterfly Network, Inc; Research support, Lantheus Medical Imaging, Inc; Research support, Bracco Group

## PURPOSE

Bacterial infection following spinal fusion is a major clinical concern, with up to 20% incidence, despite aggressive peri-operative antibiotic treatments. Thus, we have designed and evaluated an US-activated bulk release system to combat post-surgical bacterial survival.

## METHODS AND MATERIALS

Vancomycin (VAN, 400 µg/mL) and Sonazoid were reconstituted using sterile water. PLA clips (1 cm<sup>3</sup>) were 3D-printed with an interior reservoir (0.3 cm<sup>3</sup>) for carrying drug payload. Clips were loaded with ~180 µL VAN solution and 50 µL Sonazoid (~72 mg total VAN loading). Loaded clips were sealed with a hand-crafted PLA film (0.05 ± 0.01 mm thick). Under IACUC approval, clips were surgically implanted by removing the spinous process at L2 and L5 in 8 sheep (2 sites/sheep, n = 16 sites). Sheep were recovered and allowed unrestricted exercise. Two control sheep (4 sites) were sacrificed at 96 hr post-implantation for analysis. Six sheep (12 sites) were re-anesthetized at 72 hr post-implantation and each site was insonated for 20 min using a Logiq E9 scanner with a C1-6 probe in power Doppler mode (1.7 MHz frequency, 5.4 kHz PRF, 100% power, ~146 mW/cm<sup>2</sup> intensity). After 72 hr, the animals were sacrificed for analysis. Results are reported as mean ± standard deviation. Statistical analysis was performed with GraphPad Prism 8 (a < 0.05).

## RESULTS

All sheep tolerated the procedures with no adverse effects. The PLA films on all the control clips were intact (4/4, 100%). These films were then manually punctured and the fluid remaining inside the clips was collected for analysis with Nanodrop UV-Vis. The fluid inside the clips was mostly clear in nature, similar to the initial loading solution. The cranial clips contained a

VAN solution of  $295.1 \pm 36.3$   $\mu\text{g/mL}$ , while the caudal clips contained a VAN solution of  $270.4 \pm 20.3$   $\mu\text{g/mL}$  ( $p = 0.36$  between sites). Most of the VAN solution was retained within the clips ( $p = 0.12$  compared to stock solution). The PLA films on the insonated clips were all ruptured (12/12, 100%). Any remaining fluid inside the clips was collected, and was bloody and/or cloudy in nature, further supporting film compromise and fluid exchange. Due to the cloudy and bloody nature of the retrieved remnants of fluid inside the clips, these samples could not be evaluated with UV-Vis, but wound fluid analysis via LC-MS is in progress.

#### **CONCLUSION**

These results demonstrate the ability to produce US-triggered release of an encapsulated prophylactic solution, and an important proof of concept for continuing large animal model evaluations.

#### **CLINICAL RELEVANCE/APPLICATION**

Existing methods are only partially successful in preventing infection after spinal fusion surgery. We designed an US-activated system for release of prophylactics to combat post-surgical infection.

### Ultra-High-Resolution K-Edge Imaging for Assessment Of Residual Blood Flow after Embolization with Radiopaque Beads: A Feasibility Study on a Prototype Deep-Silicon Photon-Counting Scanner

Wednesday, Nov. 29 1:30PM - 2:30PM Room: E353B

Nariman Nezami, MD (*Presenter*) Consultant, CAPS Medical Ltd

#### PURPOSE

Photon-counting detector (PCD) CT K-edge imaging enables differentiation of multiple contrast agents and can produce co-registered density maps of these agents. PCD-CT also allows for the creation of material maps with a resolution in the range of 100-200  $\mu\text{m}$ . Iodine-filled radiopaque embolization beads are commonly used for treatment of hypervascular tumors. Differentiating between iodine-filled beads and iodine-based contrast agents (IBCA) can be challenging. The goal of this study was to assess the feasibility of using K-edge imaging of gadolinium-based contrast agents (GBCA) to create density maps of iodine and Gd for the evaluation of vascular embolization and residual blood flow in ultra-high-resolution (UHR) on a clinical deep-silicon PCD-CT prototype.

#### METHODS AND MATERIALS

We 3D-printed 7 identical models of tumor vasculature. Among these, four models were filled with either IBCA or GBCA. The remaining three models were injected with iodine-filled microspheres ( $d=100\text{-}300\ \mu\text{m}$ ), to simulate tumor embolization, and then filled with GBCA. Three tumor models were placed inside a large phantom (diameter 200 mm) filled with ballistic gel, and four tumor models were placed inside an anthropomorphic chest phantom. The phantoms were scanned on a whole-body prototype deep-Si PCD-CT scanner with 8 energy bins, at 120 kVp and 255-300 mAs, with 1 s-rotation time. Virtual monoenergetic images (VMIs), I density, and water density maps were reconstructed with filtered-backprojection (FBP) using a prototype UHR kernel with 10% modulation transfer function cutoff of 21.2 lp/cm. We estimated the concentration of IBCA and GBCA in the phantom using I density and water maps generated from the 8 bin spectral projections.

#### RESULTS

We achieved clear visualization of the embolization vessel with I-filled microspheres and the residual perfusion with GBCA. We did not detect any significant cross contamination between the two contrast agents in material density maps. The error in estimating IBCA concentration was -0.7-1.1 mg I/mL for various mixtures of IBCA (0-35 mg I/mL) with GBCA and water. The error in GBCA concentration estimates was -0.3-0.7 mg Gd/mL for mixtures of GBCA (0-10 mg Gd/mL) with IBCA and water.

#### CONCLUSION

Ultra-high-resolution spectral deep-Si PCD-CT can detect and quantify concentrations of iodine- and gadolinium-based contrast agents to assess residual blood flow in models of embolized tumors. The availability of 8 energy bins allows several materials with different K-edges to be differentiated.

#### CLINICAL RELEVANCE/APPLICATION

UHR K-edge imaging of embolized vessels makes it possible to visualize iodine in the microspheres while simultaneously measuring the residual blood flow via a second K-edge contrast agent containing materials such as Gd.

##### W6-SSNMMI06-2 Dual-Tracer Dynamic PET Imaging on the Long-Axial Field-Of-View PennPET Explorer: A Proof-Of-Principle Study With [<sup>18</sup>F]Fluoroglutamine and [<sup>18</sup>F]Fluorodeoxyglucose

Daniel Kwon, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Multi-tracer imaging would facilitate patient logistics, while providing the most accurate complementary molecular information of the patient's disease. Taking advantage of increased sensitivity of the long axial field-of-view (AFOV) PennPET Explorer, we assessed the feasibility of a dynamic dual-PET tracer study using [<sup>18</sup>F]FDG and [<sup>18</sup>F]Fluoroglutamine (FGln) for both diagnosis and kinetic modeling in a patient with primary ER+/PR-/HER2- breast cancer.

#### METHODS AND MATERIALS

Dynamic PET imaging using a 7-10 mCi dose of [<sup>18</sup>F]FGln with a 60 min scan duration was used to determine the volume of distribution (VD) of breast tumors, an indirect measure of glutamine metabolism. By subsampling to emulate lower doses, we showed the PennPET Explorer (AFOV = 1.4 m) enables accurate calculation of the VD with a 1 mCi dose and an scan duration of 30 minutes. A patient was injected with 1.1 mCi of [<sup>18</sup>F]FGln and scanned for 29 minutes, and then was injected with 11.3 mCi of [<sup>18</sup>F]FDG and scanned for 60 minutes. Two volumes of interest were drawn over the tumor and left ventricle, representing tumor and plasma radioactivity. A one tissue-two compartment, and a two tissue-three compartment model was used to model [<sup>18</sup>F]FGln and [<sup>18</sup>F]FDG kinetics, respectively. We projected the [<sup>18</sup>F]FGln signal using Laplace transformation and Adam-Bashforth approximation. We deconvoluted the [<sup>18</sup>F]FDG signal by subtracting the absolute measured uptake by the projected [<sup>18</sup>F]FGln signal. Kinetics analyses were performed using Pmod (ver 3.7) and compared to that of mfEvolve's Multi-Tracer analysis.

#### RESULTS

We obtained diagnostic-quality PET images and kinetic parameters of both [<sup>18</sup>F]FGln and [<sup>18</sup>F]FDG in a single scanning session. The SUVMean and VD of [<sup>18</sup>F]FGln was 2.2 and 0.857 mL/cm<sup>3</sup>, respectively. [<sup>18</sup>F]FDG at 60 minutes post-injection showed a negligible difference between uncorrected SUVMean and corrected SUVMean (2.96 and 2.91). In contrast, the Ki of the uncorrected and corrected [<sup>18</sup>F]FDG kinetics were 0.0174 mL/min/cm<sup>3</sup> and 0.0154 mL/min/cm<sup>3</sup>, respectively (11.5% difference). MFEvolve multi-tracer kinetics also showed a Ki of 0.0154 mL/min/cm<sup>3</sup>.

#### CONCLUSION

We show the feasibility of dual-tracer imaging with the same radioisotope (<sup>18</sup>F) using acceptable doses of PET tracers through the PennPET Explorer. While minimal differences were found between the convoluted and deconvoluted [<sup>18</sup>F]FDG uptakes, accurate kinetics measurements require deconvolution. Future large-scale studies are required to validate this approach for clinical use using conventional PET-CT scanners.

## CLINICAL RELEVANCE/APPLICATION

We validate one of the first clinical dual-tracer PET imaging studies to facilitate patient logistics and convey the most accurate picture of the patient's disease.

### W6- SSNMMI06- LAMP-1 Targeted PET Imaging for Detection of Adenocarcinomas

3

Bahar Ataenia, MD, MPH (*Presenter*) Nothing to Disclose

#### PURPOSE

Lysosomal-associated membrane protein 1 (LAMP-1) is mainly expressed on the lysosomal membrane, and its cell surface localization is suggested to be involved in cancer progression, invasion, and metastasis. An increase in the proportion of cell surface displayed LAMP-1 compared to total cellular expression is suggested to increase the risk of metastasis. This study is the first to investigate LAMP-1 as an imaging target in cancer.

#### METHODS AND MATERIALS

Anti-LAMP-1 monoclonal antibody was conjugated to deferoxamine and labeled with <sup>89</sup>Zirconium. Pooled IgG was used as the negative control probe. MDA-MB-231 breast cancer and Caco2 colon cancer cell lines were implanted subcutaneously in nude mice. Mice underwent imaging by either the anti-LAMP-1 or the control probe. PET/CT imaging was performed 24, 72, and 168 hours post-injection. Tissue microarrays (TMAs) of breast, colon, and prostate cancer and their corresponding normal tissue were stained for LAMP-1. Pan-cancer bioinformatics analysis was performed on publicly available datasets to assess the expandability of the results to other cancers. Spatial transcriptomic analysis was performed on a breast ductal carcinoma public dataset.

#### RESULTS

Tumors were visible on PET as early as 24 hours post-injection. The LAMP-1 probe had significantly higher uptake compared to the control IgG probe in both models at all three imaging time points (MDA-MB-231 SUV<sub>max</sub> at 168h:  $12.96 \pm 5.68$  vs.  $4.39 \pm 2.41$ , p-value = 0.003 and Caco2 SUV<sub>max</sub> at 168h:  $8.53 \pm 3.03$  vs.  $3.38 \pm 1.25$ , p-value < 0.001). The mean fluorescent signal intensity of LAMP-1 in malignant TMA cores of the prostate ( $2872 \pm 1105$  vs.  $948 \pm 497.9$ , p-value < 0.05), pancreas ( $1785.8 \pm 1238.61$  vs.  $403.33 \pm 453.5$ , p-value < 0.05), colon ( $2597 \pm 1829$  vs.  $304 \pm 128$ , p-value < 0.01) and breast ( $3077 \pm 621$  vs.  $380 \pm 25$ , p-value < 0.05) were significantly higher compared to normal tissue. LAMP-1 gene expression was higher in malignant breast, colon, esophagus, stomach, pancreas, and prostate samples compared to the related normal samples (p-value < 0.0001 for all). The expression of LAMP-1 was higher in ductal regions compared to other regions of breast ductal carcinoma samples in the spatial transcriptomic analysis.

#### CONCLUSION

Imaging of the cell surface expressed LAMP-1 in breast and colon cancer is feasible by immunoPET. LAMP-1 targeting can be expanded to carcinomas of other origins based on the supporting genomic and proteomic evidence. Therefore, LAMP-1 has a strong potential as a theranostic target in cancer.

## CLINICAL RELEVANCE/APPLICATION

LAMP-1 targeted theranostics can improve patient outcomes by enabling timely diagnosis and personalized, targeted therapy for breast and colon adenocarcinomas. This approach can be expanded to other epithelial carcinomas.

### W6- SSNMMI06- Torso Synthetic CT Generation by Integrating Deep Learning and Segmentation for PET/MR

4

Jin Uk Heo, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

Positron Emission Tomography (PET)/Magnetic Resonance (MR) is an imaging modality with several advantages over PET/CT, such as superior soft tissue contrast and simultaneous PET and MR acquisition. While PET/CT using fluorodeoxyglucose (FDG) is crucial in oncology for diagnosis and staging, accurate MR-based attenuation correction (MRAC) remains challenging. Consequently, Standard Uptake Values (SUVs), normalized radiotracer concentration values, are not accurate. To resolve this, using a synthetic CT (sCT) for MRAC has become the preferred approach. Nevertheless, sCT generation using deep convolutional neural networks (DCNN) for torso imaging, the most common FDG-PET field of view, has not yet been solved.

#### METHODS AND MATERIALS

Using Dixon MR data, our proposed method, URcGANmod, combines a DCNN architecture that integrates U-net Residual Network conditional Generative Adversarial Network model (URcGAN) to generate a preliminary sCT, and a segmentation technique identifying air voxels to reduce SUV error, particularly in the lung. The DCNN employs overlapping patches to allow the generalizability of applying the trained network for body-specific PET/MR applications. We recruited 29 patients undergoing clinical FDG-PET/CT scans to receive PET/MR scans. We compared our method against four methods: 1)

threshold-based segmentation, 2) machine learning-based voxel-wise segmentation (TFCALC) which was previously successful in the abdominopelvic region, 3) TFCALC with the segmentation (TFCALCmod), and 4) URcGAN.

## **RESULTS**

Using 15 training dataset, the proposed method generates superior sCT image quality than other methods with mean absolute difference of  $32 \pm 4$  HU per voxel. The DCNN-based methods (URcGAN and URcGANmod) achieve better SUV accuracy with less than 0.007 g/mL SUV mean error and less than 10% SUV error with a standard deviation of less than 6%. Our proposed method can generate sCT in approximately 30 seconds, which is clinically practical.

## **CONCLUSION**

We demonstrated the feasibility of combining DCNN and segmentation to improve MRAC accuracy in torso FDG-PET/MR. By utilizing all four Dixon sequence images, our method improves SUV accuracy in the lungs and archives less than 10% SUV error for all evaluated organs. Considering the accuracy of sCT and SUV, our proposed method warrants further studies in longitudinal multicenter trials.

## **CLINICAL RELEVANCE/APPLICATION**

Our proposed method has the potential to improve the quantitative accuracy and reliability of FDG-SUV in torso PET/MR imaging, thereby supporting quantitative monitoring of disease progression and treatment response and harmonization needed for multicenter clinical trials. Additionally, the sCT could be used to support MR-only Radiation Treatment.

### Dual-Tracer Dynamic PET Imaging on the Long-Axial Field-Of-View PennPET Explorer: A Proof-Of-Principle Study With [ $^{18}\text{F}$ ]Fluoroglutamine and [ $^{18}\text{F}$ ]Fluorodeoxyglucose

Wednesday, Nov. 29 1:30PM - 2:30PM Room: E352

Daniel Kwon, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Multi-tracer imaging would facilitate patient logistics, while providing the most accurate complementary molecular information of the patient's disease. Taking advantage of increased sensitivity of the long axial field-of-view (AFOV) PennPET Explorer, we assessed the feasibility of a dynamic dual-PET tracer study using [ $^{18}\text{F}$ ]FDG and [ $^{18}\text{F}$ ]Fluoroglutamine (FGln) for both diagnosis and kinetic modeling in a patient with primary ER+/PR-/HER2- breast cancer.

#### METHODS AND MATERIALS

Dynamic PET imaging using a 7-10 mCi dose of [ $^{18}\text{F}$ ]FGln with a 60 min scan duration was used to determine the volume of distribution (VD) of breast tumors, an indirect measure of glutamine metabolism. By subsampling to emulate lower doses, we showed the PennPET Explorer (AFOV = 1.4 m) enables accurate calculation of the VD with a 1 mCi dose and an scan duration of 30 minutes. A patient was injected with 1.1 mCi of [ $^{18}\text{F}$ ]FGln and scanned for 29 minutes, and then was injected with 11.3 mCi of [ $^{18}\text{F}$ ]FDG and scanned for 60 minutes. Two volumes of interest were drawn over the tumor and left ventricle, representing tumor and plasma radioactivity. A one tissue-two compartment, and a two tissue-three compartment model was used to model [ $^{18}\text{F}$ ]FGln and [ $^{18}\text{F}$ ]FDG kinetics, respectively. We projected the [ $^{18}\text{F}$ ]FGln signal using Laplace transformation and Adam-Bashforth approximation. We deconvoluted the [ $^{18}\text{F}$ ]FDG signal by subtracting the absolute measured uptake by the projected [ $^{18}\text{F}$ ]FGln signal. Kinetics analyses were performed using Pmod (ver 3.7) and compared to that of mFEvolve's Multi-Tracer analysis.

#### RESULTS

We obtained diagnostic-quality PET images and kinetic parameters of both [ $^{18}\text{F}$ ]FGln and [ $^{18}\text{F}$ ]FDG in a single scanning session. The SUVMean and VD of [ $^{18}\text{F}$ ]FGln was 2.2 and 0.857 mL/cm<sup>3</sup>, respectively. [ $^{18}\text{F}$ ]FDG at 60 minutes post-injection showed a negligible difference between uncorrected SUVMean and corrected SUVMean (2.96 and 2.91). In contrast, the Ki of the uncorrected and corrected [ $^{18}\text{F}$ ]FDG kinetics were 0.0174 mL/min/cm<sup>3</sup> and 0.0154 mL/min/cm<sup>3</sup>, respectively (11.5% difference). MFEvolve multi-tracer kinetics also showed a Ki of 0.0154 mL/min/cm<sup>3</sup>.

#### CONCLUSION

We show the feasibility of dual-tracer imaging with the same radioisotope ( $^{18}\text{F}$ ) using acceptable doses of PET tracers through the PennPET Explorer. While minimal differences were found between the convoluted and deconvoluted [ $^{18}\text{F}$ ]FDG uptakes, accurate kinetics measurements require deconvolution. Future large-scale studies are required to validate this approach for clinical use using conventional PET-CT scanners.

#### CLINICAL RELEVANCE/APPLICATION

We validate one of the first clinical dual-tracer PET imaging studies to facilitate patient logistics and convey the most accurate picture of the patient's disease.

### LAMP-1 Targeted PET Imaging for Detection of Adenocarcinomas

Wednesday, Nov. 29 1:30PM - 2:30PM Room: E352

Bahar Ataeinia, MD, MPH (*Presenter*) Nothing to Disclose

#### PURPOSE

Lysosomal-associated membrane protein 1 (LAMP-1) is mainly expressed on the lysosomal membrane, and its cell surface localization is suggested to be involved in cancer progression, invasion, and metastasis. An increase in the proportion of cell surface displayed LAMP-1 compared to total cellular expression is suggested to increase the risk of metastasis. This study is the first to investigate LAMP-1 as an imaging target in cancer.

#### METHODS AND MATERIALS

Anti-LAMP-1 monoclonal antibody was conjugated to deferoxamine and labeled with <sup>89</sup>Zirconium. Pooled IgG was used as the negative control probe. MDA-MB-231 breast cancer and Caco2 colon cancer cell lines were implanted subcutaneously in nude mice. Mice underwent imaging by either the anti-LAMP-1 or the control probe. PET/CT imaging was performed 24, 72, and 168 hours post-injection. Tissue microarrays (TMAs) of breast, colon, and prostate cancer and their corresponding normal tissue were stained for LAMP-1. Pan-cancer bioinformatics analysis was performed on publicly available datasets to assess the expandability of the results to other cancers. Spatial transcriptomic analysis was performed on a breast ductal carcinoma public dataset.

#### RESULTS

Tumors were visible on PET as early as 24 hours post-injection. The LAMP-1 probe had significantly higher uptake compared to the control IgG probe in both models at all three imaging time points (MDA-MB-231 SUV<sub>max</sub> at 168h:  $12.96 \pm 5.68$  vs.  $4.39 \pm 2.41$ , p-value = 0.003 and Caco2 SUV<sub>max</sub> at 168h:  $8.53 \pm 3.03$  vs.  $3.38 \pm 1.25$ , p-value < 0.001). The mean fluorescent signal intensity of LAMP-1 in malignant TMA cores of the prostate ( $2872 \pm 1105$  vs.  $948 \pm 497.9$ , p-value < 0.05), pancreas ( $1785.8 \pm 1238.61$  vs.  $403.33 \pm 453.5$ , p-value < 0.05), colon ( $2597 \pm 1829$  vs.  $304 \pm 128$ , p-value < 0.01) and breast ( $3077 \pm 621$  vs.  $380 \pm 25$ , p-value < 0.05) were significantly higher compared to normal tissue. LAMP-1 gene expression was higher in malignant breast, colon, esophagus, stomach, pancreas, and prostate samples compared to the related normal samples (p-value < 0.0001 for all). The expression of LAMP-1 was higher in ductal regions compared to other regions of breast ductal carcinoma samples in the spatial transcriptomic analysis.

#### CONCLUSION

Imaging of the cell surface expressed LAMP-1 in breast and colon cancer is feasible by immunoPET. LAMP-1 targeting can be expanded to carcinomas of other origins based on the supporting genomic and proteomic evidence. Therefore, LAMP-1 has a strong potential as a theranostic target in cancer.

#### CLINICAL RELEVANCE/APPLICATION

LAMP-1 targeted theranostics can improve patient outcomes by enabling timely diagnosis and personalized, targeted therapy for breast and colon adenocarcinomas. This approach can be expanded to other epithelial carcinomas.

### Torso Synthetic CT Generation by Integrating Deep Learning and Segmentation for PET/MR Attenuation Correction

Wednesday, Nov. 29 1:30PM - 2:30PM Room: E352

Jin Uk Heo, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

Positron Emission Tomography (PET)/Magnetic Resonance (MR) is an imaging modality with several advantages over PET/CT, such as superior soft tissue contrast and simultaneous PET and MR acquisition. While PET/CT using fluorodeoxyglucose (FDG) is crucial in oncology for diagnosis and staging, accurate MR-based attenuation correction (MRAC) remains challenging. Consequently, Standard Uptake Values (SUVs), normalized radiotracer concentration values, are not accurate. To resolve this, using a synthetic CT (sCT) for MRAC has become the preferred approach. Nevertheless, sCT generation using deep convolutional neural networks (DCNN) for torso imaging, the most common FDG-PET field of view, has not yet been solved.

#### METHODS AND MATERIALS

Using Dixon MR data, our proposed method, URcGANmod, combines a DCNN architecture that integrates U-net Residual Network conditional Generative Adversarial Network model (URcGAN) to generate a preliminary sCT, and a segmentation technique identifying air voxels to reduce SUV error, particularly in the lung. The DCNN employs overlapping patches to allow the generalizability of applying the trained network for body-specific PET/MR applications. We recruited 29 patients undergoing clinical FDG-PET/CT scans to receive PET/MR scans. We compared our method against four methods: 1) threshold-based segmentation, 2) machine learning-based voxel-wise segmentation (TFCALC) which was previously successful in the abdominopelvic region, 3) TFCALC with the segmentation (TFCALCmod), and 4) URcGAN.

#### RESULTS

Using 15 training dataset, the proposed method generates superior sCT image quality than other methods with mean absolute difference of  $32 \pm 4$  HU per voxel. The DCNN-based methods (URcGAN and URcGANmod) achieve better SUV accuracy with less than 0.007 g/mL SUV mean error and less than 10% SUV error with a standard deviation of less than 6%. Our proposed method can generate sCT in approximately 30 seconds, which is clinically practical.

#### CONCLUSION

We demonstrated the feasibility of combining DCNN and segmentation to improve MRAC accuracy in torso FDG-PET/MR. By utilizing all four Dixon sequence images, our method improves SUV accuracy in the lungs and archives less than 10% SUV error for all evaluated organs. Considering the accuracy of sCT and SUV, our proposed method warrants further studies in longitudinal multicenter trials.

#### CLINICAL RELEVANCE/APPLICATION

Our proposed method has the potential to improve the quantitative accuracy and reliability of FDG-SUV in torso PET/MR imaging, thereby supporting quantitative monitoring of disease progression and treatment response and harmonization needed for multicenter clinical trials. Additionally, the sCT could be used to support MR-only Radiation Treatment.

#### **W6-SSOB03-1 DWI Radiomics Model for Endometrial Cancer Risk Stratification Correlates with Tumor Choline Metabolism Using MR Spectroscopy**

Yen Po Lin, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Radiomics models offer little explainability due to a lack of biological insights. The study aims to develop a radiomics risk model using routine DW MRI to predict the high-risk group for nodal metastasis or cancer recurrence in endometrial cancer and correlate the model with the choline levels and metabolic pathways.

#### METHODS AND MATERIALS

Between August 2015 and July 2018, 356 patients with pre-treatment DWI MRI were recruited and had 105 volumetric radiomic features extracted from each tumor. A radiomic risk score (Rad-Score) was developed using the LASSO regression model to predict nodal metastasis or cancer recurrence in the training cohort (n=287) and validated in the validation cohort (n=69); furthermore, 230 patients underwent 1H MR spectroscopy to evaluate tumor choline levels, and endometrial tumors (n=70) were analyzed using a high-resolution NMR system to correlate tissue levels of choline-related metabolites. Student's-t test was used to compare high- and low-risk groups and the McNemar test to compare the performance of Rad-Score and ESMO classification.  $P < .05$  was used for statistical significance.

#### RESULTS

Seventeen selected radiomics features were further incorporated into a Rad-Signature along with pre-operative clinical parameters including age, clinical tumor size, histopathology (endometrial vs. non-endometrioid), and histological grade (1 and 2 vs. 3). The Rad-Signature accurately discriminated nodal metastasis or recurrence in the test set, with a sensitivity of 78.6%, specificity of 74.5%, and accuracy of 75.4%, showing comparable performance with the post-operatively based ESMO classification: sensitivity of 85.7%, specificity of 76.4%, and accuracy of 78.3%. Radiometabolic analysis found significant associations between Rad-Score and increased endometrial total choline levels on 1H MR spectroscopy ( $P = .034$ ) and increased in tissue levels ( $P = .019$ ).

#### CONCLUSION

High-risk patients with endometrial cancer may have increased choline metabolism that could be linked to the radiomic risk model generated from routine DWI MRI.

#### CLINICAL RELEVANCE/APPLICATION

By developing a radiomic risk score using routine DW MRI and establishing its association with increased choline metabolism, this study shows promising translational relevance in providing a personalized approach to therapy for high-risk endometrial cancer patients.

#### **W6-SSOB03-4 Performance of Preoperative Radiological Peritoneal Index and its Agreement with Laparoscopic findings to Predict Suboptimal Primary Debulking Surgery in Ovarian Cancer**

Giuseppe Avesani, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Upfront cytoreduction is considered the best therapeutic option for ovarian cancer, but only if complete; the most used tool to predict complete resection is the Peritoneal Index (PI), which is based on laparoscopic findings. Our first aim is to investigate the performance of radiological PI assessed on preoperative CTs to predict incomplete debulking; the secondary objectives are to evaluate the agreement between radiological and laparoscopic PI and the reproducibility of radiological PI among different radiologists.

## METHODS AND MATERIALS

In this IRB-approved observational study, we prospectively collected CTs of patients with ovarian cancer candidates for primary debulking surgery between January 2021 and December 2022. We analyzed the 6 parameters of PI (diaphragm, liver surface, great omentum, parietal peritoneum, stomach wall/lesser omentum and intestinal involvement); we also noted if mesenteric retraction or hepatic hilum involvement were present (absolute contraindications to surgery). The involvement of each parameter was independently assessed by two radiologists with 3 and 10 years of expertise in gynecologic imaging before surgery and compared with laparoscopic findings (standard of reference). As for the laparoscopic PI, a radiological PI=8 was considered predictive of unresectable surgery. Discrepancies were solved by consensus. The performance of radiological PI was tested by calculating sensitivity, specificity, positive and negative predictive values and accuracy. The agreement was assessed by using weighted Cohen's K coefficient.

## RESULTS

We included 145 patients. The radiological PI showed a sensitivity of 0.54 (0.95 CI 0.38-0.70), specificity of 0.93 (CI 0.88-0.97), positive predictive value of 0.68 (CI 0.50-0.83) and negative predictive value of 0.89 (CI 0.82-0.94), with an overall accuracy of 0.85 (CI 0.79-0.90). The Cohen's K coefficient of radiological and laparoscopic PI was 0.76 for diaphragm, 0.80 for liver surface, 0.90 for great omentum, 0.78 for parietal peritoneum, and 0.67 for parietal peritoneum stomach wall/lesser omentum, 0.52 for intestinal involvement and 0.47 for mesenteric involvement. The overall agreement between radiologists was 0.72.

## CONCLUSION

Radiologic PI had good overall accuracy in predicting incomplete surgical debulking and showed good reproducibility among radiologists. The agreement with laparoscopic PI was good, with the weakest agreement for mesenteric and intestinal involvement. However, its sensitivity was too low for patients' surgery selection.

## CLINICAL RELEVANCE/APPLICATION

CT is a useful tool for surgical planning; the radiological PI may help in programming the right surgical procedures but cannot be used as a screening tool for surgery selection.

## W6-SSOB03-5 Feasibility of Synthetic Magnetic Resonance Imaging for Deciding Whether Neoadjuvant Chemoradiotherapy and Predicting its Short-term Efficacy in Cervical Cancer: Comparison with High Resolution T2WI and DWI

Xiaorong Ou (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the feasibility of a synthetic MRI sequence (MAGnetic resonance imaging Compilation; MAGiC) for deciding whether neoadjuvant chemoradiotherapy (NCRT) and predicting its short-term efficacy (STE) in the cervical cancer (CC) patients, in comparison to high resolution T2-weighted imaging (hrT2WI) and diffusion weighted imaging (DWI).

## METHODS AND MATERIALS

The study protocol was approved by the local Research Ethics Committee. Informed consent was obtained from all subjects. 244 patients suspected of CC were enrolled and undergone the pre-treatment MAGIC, conventional MRI (hrT2WI) and DWI on 3.0T MRI (the parameter presented in Table 1). For those CC patients underwent NCRT, hrT2WI were performed again at 2 months after NCRT for evaluating STE (completed response (CR) and no-CR group). MAGIC can generate synthetic morphologic images (synthetic T2WI, syT2WI) and quantitative synthetic images (synthetic T1, T2 and PD maps) (Fig 1). For the syT2WI, the tumor staging was assessed and decided whether NCRT for CC patients (hrT2WI as the reference). For the quantitative synthetic images, T1, T2, PD value were measured by regions of interests (ROIs) (Fig 2) to analysis the predictive performance of STE after NCRT (apparent diffusion coefficient (ADC) as the reference). In addition, the image quality of syT2WI and hrT2WI were assessed with 4-point scale for each of anatomical details display, distortion, artifacts and lesion conspicuity.

## RESULTS

44 out of 75 confirmed CC patients were performed NCRT and followed up at least 2 months (Fig 3). For the image quality, syT2WI was no significant differences with comparison of hrT2WI in above four aspects (All  $P > 0.05$ ; Table 2, Fig 2). For deciding whether NCRT, the accuracy, sensitivity, and specificity of sy-T2WI were 0.899, 0.947 and 0.999 in CC patients (Table 3). For the quantitative synthetic images, T2, T1 and ADC values had a significant differences to identified CR from no-CR

groups ( $P < 0.05$ ) but PD ( $P > 0.05$ ; Table 4). Furthermore, T2 (AUC: 0.825) and T1 value (AUC: 0.795) had a similar predictive performance for STE after NCRT compared with ADC (AUC: 0.789, all  $P > 0.05$ ) (Table 5, Fig 4). However, T1 combined T2 could not improve the predictive performance for STE with comparison of ADC (AUC: 0.818 vs 0.789)(Table 5, Fig 4).

## CONCLUSION

MAGiC can derive synthetic morphologic images and quantitative synthetic images in one acquisition, which is a promising technique and feasibility for accurately deciding whether NCRT and predicting STE in CC patients.

## CLINICAL RELEVANCE/APPLICATION

MAGiC is a reliable technique for facilitating the synthetic morphologic images and quantitative synthetic images, which should be as an alternative of hrT2WI and DWI for deciding whether NCRT and predicting STE in CC patients.

## W6-SSOB03-6 Preoperative Staging by [<sup>18</sup>F]FDG-PET/CT in a Large Endometrial Cancer Cohort: Diagnostic Performance, Incidental Findings and Therapeutic Delay

Ankush Gulati (*Presenter*) Nothing to Disclose

## PURPOSE

To compare the diagnostic performance of PET/CT when using FDG-positive locoregional lymph nodes and metabolic primary tumor volume (MTV) for predicting lymph node metastases (LNM) and disease-specific survival in a large endometrial cancer (EC) cohort. To assess the extent and nature of incidental PET-CT findings and their impact on therapeutic delay.

## METHODS AND MATERIALS

In 559 EC patients (among whom 58% (327/559) underwent lymphadenectomy), the preoperative FDG-PET/CT parameters FDG-positive (SUVmax  $>2.5$ ) locoregional lymph nodes (FDGposLN) and MTV (primary tumor volume with standard uptake value [SUV]  $>2.5$ ) were retrospectively recorded. The diagnostic performance of FDGposLN and MTV for predicting LNM and disease-specific survival was compared using area under the receiver operating characteristic curves (ROC AUC) and Kaplan-Meier curves with log rank test, respectively. All reported incidental FDG-PET/CT findings and results from subsequent follow-ups were recorded. Time between FDG-PET/CT and primary EC treatment was compared between groups with/without incidental FDG-PET/CT findings.

## RESULTS

FDGposLN/MTV yielded AUCs of 0.73/0.72 for predicting LNM (verified by histology). FDG positive lymph nodes and high MTV ( $>27$  ml) were significantly associated with poor disease-specific survival ( $p < 0.001$  for both). Incidental PET/CT findings were reported in 31% (172/559) of the EC cohort, which was followed by follow-up examinations in 22% (125/559). These examinations led to the diagnosis of synchronous cancers in 15/559 (2.7%) patients [breast- (n=4), thyroid- (n=4), colon- (n=1), lung- (n=2) cancers and lymphoma (n=4)], and premalignant colonic polyps in 9/563 (1.6%) patients. Among all patients undergoing PET/CT (n=559), 10% (57/559) had their follow-up examination due to incidental PET/CT finding before start of primary EC treatment. Median time between FDG-PET/CT and primary EC treatment was 28 days (inter quartile range (IQR): 21-35) in this patient group (n=57), versus 15 days (IQR 8-23) in the remaining EC cohort (n=506).

## CONCLUSION

FDG positive lymph nodes and MTV  $>27$  ml yield similar performance for predicting LNM preoperatively, and both FDG markers indicate poor prognosis. Incidental PET/CT findings requiring clarification before primary EC treatment led to a small treatment delay, while uncovering synchronous primary cancers in 2.7% of the EC patients.

## CLINICAL RELEVANCE/APPLICATION

Preoperative FDG-PET/CT is valuable for predicting metastatic lymph nodes and prognosis in EC. Incidental findings are common (in 31%) and represent synchronous cancer in 2.7%, but does not cause considerable therapeutic delay.

### **Feasibility of Synthetic Magnetic Resonance Imaging for Deciding Whether Neoadjuvant Chemoradiotherapy and Predicting its Short-term Efficacy in Cervical Cancer: Comparison with High Resolution T2WI and DWI**

Wednesday, Nov. 29 1:30PM - 2:30PM Room: S405

Xiaorong Ou (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To investigate the feasibility of a synthetic MRI sequence (MAGnetic resonance imaging Compilation; MAGiC) for deciding whether neoadjuvant chemoradiotherapy (NCRT) and predicting its short-term efficacy (STE) in the cervical cancer (CC) patients, in comparison to high resolution T2-weighted imaging (hrT2WI) and diffusion weighted imaging (DWI).

#### **METHODS AND MATERIALS**

The study protocol was approved by the local Research Ethics Committee. Informed consent was obtained from all subjects. 244 patients suspected of CC were enrolled and undergone the pre-treatment MAGiC, conventional MRI (hrT2WI) and DWI on 3.0T MRI (the parameter presented in Table 1). For those CC patients underwent NCRT, hrT2WI were performed again at 2 months after NCRT for evaluating STE (completed response (CR) and no-CR group). MAGiC can generate synthetic morphologic images (synthetic T2WI, syT2WI) and quantitative synthetic images (synthetic T1, T2 and PD maps) (Fig 1). For the syT2WI, the tumor staging was assessed and decided whether NCRT for CC patients (hrT2WI as the reference). For the quantitative synthetic images, T1, T2, PD value were measured by regions of interests (ROIs) (Fig 2) to analysis the predictive performance of STE after NCRT (apparent diffusion coefficient (ADC) as the reference). In addition, the image quality of syT2WI and hrT2WI were assessed with 4-point scale for each of anatomical details display, distortion, artifacts and lesion conspicuity.

#### **RESULTS**

44 out of 75 confirmed CC patients were performed NCRT and followed up at least 2 months (Fig 3). For the image quality, syT2WI was no significant differences with comparison of hrT2WI in above four aspects (All  $P > 0.05$ ; Table 2, Fig 2). For deciding whether NCRT, the accuracy, sensitivity, and specificity of sy-T2WI were 0.899, 0.947 and 0.999 in CC patients (Table 3). For the quantitative synthetic images, T2, T1 and ADC values had a significant differences to identified CR from no-CR groups ( $P < 0.05$ ) but PD ( $P > 0.05$ ; Table 4). Furthermore, T2 (AUC: 0.825) and T1 value (AUC: 0.795) had a similar predictive performance for STE after NCRT compared with ADC (AUC: 0.789, all  $P > 0.05$ ) (Table 5, Fig 4). However, T1 combined T2 could not improve the predictive performance for STE with comparison of ADC (AUC: 0.818 vs 0.789) (Table 5, Fig 4).

#### **CONCLUSION**

MAGiC can derive synthetic morphologic images and quantitative synthetic images in one acquisition, which is a promising technique and feasibility for accurately deciding whether NCRT and predicting STE in CC patients.

#### **CLINICAL RELEVANCE/APPLICATION**

MAGiC is a reliable technique for facilitating the synthetic morphologic images and quantitative synthetic images, which should be as an alternative of hrT2WI and DWI for deciding whether NCRT and predicting STE in CC patients.

### Preoperative Staging by [<sup>18</sup>F]FDG-PET/CT in a Large Endometrial Cancer Cohort: Diagnostic Performance, Incidental Findings and Therapeutic Delay

Wednesday, Nov. 29 1:30PM - 2:30PM Room: S405

Ankush Gulati (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare the diagnostic performance of PET/CT when using FDG-positive locoregional lymph nodes and metabolic primary tumor volume (MTV) for predicting lymph node metastases (LNM) and disease-specific survival in a large endometrial cancer (EC) cohort. To assess the extent and nature of incidental PET-CT findings and their impact on therapeutic delay.

#### METHODS AND MATERIALS

In 559 EC patients (among whom 58% (327/559) underwent lymphadenectomy), the preoperative FDG-PET/CT parameters FDG-positive (SUV<sub>max</sub> >2.5) locoregional lymph nodes (FDGposLN) and MTV (primary tumor volume with standard uptake value [SUV] >2.5) were retrospectively recorded. The diagnostic performance of FDGposLN and MTV for predicting LNM and disease-specific survival was compared using area under the receiver operating characteristic curves (ROC AUC) and Kaplan-Meier curves with log rank test, respectively. All reported incidental FDG-PET/CT findings and results from subsequent follow-ups were recorded. Time between FDG-PET/CT and primary EC treatment was compared between groups with/without incidental FDG-PET/CT findings.

#### RESULTS

FDGposLN/MTV yielded AUCs of 0.73/0.72 for predicting LNM (verified by histology). FDG positive lymph nodes and high MTV (>27 ml) were significantly associated with poor disease-specific survival ( $p < 0.001$  for both). Incidental PET/CT findings were reported in 31% (172/559) of the EC cohort, which was followed by follow-up examinations in 22% (125/559). These examinations led to the diagnosis of synchronous cancers in 15/559 (2.7%) patients [breast- (n=4), thyroid- (n=4), colon- (n=1), lung- (n=2) cancers and lymphoma (n=4)], and premalignant colonic polyps in 9/563 (1.6%) patients. Among all patients undergoing PET/CT (n=559), 10% (57/559) had their follow-up examination due to incidental PET/CT finding before start of primary EC treatment. Median time between FDG-PET/CT and primary EC treatment was 28 days (inter quartile range (IQR): 21-35) in this patient group (n=57), versus 15 days (IQR 8-23) in the remaining EC cohort (n=506).

#### CONCLUSION

FDG positive lymph nodes and MTV >27 ml yield similar performance for predicting LNM preoperatively, and both FDG markers indicate poor prognosis. Incidental PET/CT findings requiring clarification before primary EC treatment led to a small treatment delay, while uncovering synchronous primary cancers in 2.7% of the EC patients.

#### CLINICAL RELEVANCE/APPLICATION

Preoperative FDG-PET/CT is valuable for predicting metastatic lymph nodes and prognosis in EC. Incidental findings are common (in 31%) and represent synchronous cancer in 2.7%, but does not cause considerable therapeutic delay.

### **W6-SSPH10-1 Can We Improve Quantification of Slow Flow in Metastatic Renal Carcinoma with Novel Long Ensemble Power Doppler Ultrasound Sequences?**

Sergio J. Sanabria (*Presenter*) Nothing to Disclose

#### PURPOSE

To show Proof-Of-Concept of Long-Ensemble Coherence-Based Ultrasound Power Doppler sequences (LEAD) for early-stage quantification of angiogenesis changes in Metastatic Renal Carcinoma (mRCC). The current standard of care is CT/MRI at 12 weeks to determine responder/non-responder (revised RECIST v1.1.1 guideline).

#### METHODS AND MATERIALS

15 patients scheduled for a combination of antiangiogenesis and immunotherapy mRCC treatment were recruited over 24 months. Ultrasound basal exams and F/U after 6 weeks of treatment were performed. Real-time clinical Power Doppler (PD) was acquired with a Siemens S2000 system. A Verasonics research scanner with harmonic B-mode was used to reconstruct LEAD offline (ensemble length 3s, 500 Hz). A 7.5 MHz linear transducer was used for lesion depths < 40 mm and a 3.0 MHz curvilinear probe was used for larger depths. Two radiologists independently analyzed each image for internal lesion flow (1a), peripheral flow (1b) or no flow (0). Tumor size variations were quantified in B-mode images. Doppler flow surface changes were also assessed in LEAD and PD images.

#### RESULTS

The lesion diameter ranged from 0.43 to 11.22 cm, with a mean value of 3.33 cm, while lesion depth was 1 to 11 cm (mean 5 cm). From a total of 67 lesion examinations, in 25% of Doppler images, LEAD show superior diagnostic image quality than conventional Power Doppler, while no diagnostic differences were observed in 74% of the images. Eight RECIST v.1.1.1 responder cases were compared with eight RECIST v.1.1 non-responder cases. The changes in Doppler Flow Surface at 6 weeks with respect to basal exam show higher significance ( $p = 0.09$ ) than the geometric changes in lesion size ( $p = 0.67$ ).

#### CONCLUSION

Our results show potential for ultrasound as an alternative for early stage-therapy response monitoring of mRCC after 6 weeks. Ultrafast-Coherence-Based Doppler imaging sequences allow increasing ensemble length, therefore increasing flow resolution, minimizing imaging artifacts and detecting more vessels than conventional Power Doppler.

#### CLINICAL RELEVANCE/APPLICATION

mRCC is the 8th most common cancer in the U.S., with a 5-year survival rate of 12%. Since 2019, Tyrosine Kinase Inhibitors (TKI) combined with Immune Checkpoint Inhibitors (ICI) have become the standard-of-care. Currently, therapy response is monitored after 12 weeks of therapy with CT/MR according to changes in tumor diameter (RECIST v1.1.1). Ultrasound is non-invasive and well-suited for therapy monitoring. Quantitative ultrasound methods based on novel Doppler Flow sequences show potential for early stage assessment of TKI + ICI therapeutical response, thereby minimizing treatment toxicity.

### **W6-SSPH10-2 Development of Deep Learning Based Segmentation Method Using U-Net for Evaluation of Breast Density on Ultrasound Images**

Min-Ying Su, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Many research studies have been devoted to developing automatic segmentation for quantitative assessment of breast density, which may serve as a biomarker to improve the accuracy of breast cancer risk assessment. There are only few studies reporting the development of automatic segmentation for breast ultrasound (US). The purpose of this study is to develop a U-Net segmentation method for clinical US images.

## METHODS AND MATERIALS

Women with dense breasts on mammography, without pathological finding, were included. The US images from the upper outer quadrant of 110 patients were used for training. An experienced radiologist manually outlined the superficial boundary demarcating the layer of subcutaneous fat, and the deep boundary demarcating the layer of the retromammary fat and muscle, with the middle layer containing the fibroglandular tissue. Within the middle layer, the fat lobules were further outlined, so the remaining area could be assigned as the glandular tissue component (GTC, Figure 1). These 4 regions were used as the ground truth to train the U-net model. For testing, a total of 1,348 images from 337 patients were used, and the quality of segmentation was reviewed. Three radiologists interpreted the images to determine the density category, and the agreements were analyzed.

## RESULTS

In the training dataset, the U-Net model can identify the superficial and deep boundaries for most cases, and the percentage of layer- 1, 2, 3 was calculated. The correlation coefficient between the U-net output and the ground truth was  $R^2 = 0.946$ ,  $0.824$ , and  $0.866$ , respectively (Figure 2). The segmentation quality in the testing dataset was acceptable in 1,188 (88%) images, and unacceptable in 160 (12%). The failure of the deep border ( $n=117$ , 73.1%) was due to difficulties in distinguishing the retromammary fat from uninvolved GTC which has hypoechoic appearance similar to fat; the failure of both superficial and deep borders ( $n=38$ , 23.8%) was due to minimal amount of fibroglandular tissue in fatty breasts; and there were only 5 cases with failure of superficial border ( $n=5$ , 3.1%). The inter-observer agreement among radiologists was poor to moderate ( $k=0.16-0.41$ ).

## CONCLUSION

The radiologists' agreement for breast density was poor to moderate, presumably due to the limited information from a small-selected area. Deep learning based U-Net algorithm provided a promising method, which achieved acceptable segmentation in 88%. However, further segmentation of the GTC requires a large training dataset with well-defined ground truth.

## CLINICAL RELEVANCE/APPLICATION

Assessment of density on breast US by radiologists was not reliable. U-Net may provide a standardized method to determine the subcutaneous and retromammary fat layers, and the GTC within the mammary zone.

## W6- SSPH10-3 Anisotropic Stiffness Biomarkers by Torsional Wave Elastography may Non-invasively Predict the Skin Pathology: Pilot Test

Guillermo Rus (*Presenter*) Nothing to Disclose

## PURPOSE

Skin is one of the organs whose viscoelastic properties is not fully understood. Besides being highly nonlinear and dependent on the orientation of Langer's lines [Kalra, et al. 2016], they are mainly governed by the collagen, elastin and cell structure, which strongly changes under pathological conditions (Keratoacanthoma, Basal cell carcinoma, Squamous cell carcinoma, melanoma). It supports our hypothesis that elastography has the potential to noninvasively predict histopathology of skin tumors [Chang, JM, et al. 2011]. Thus, we have developed both a new concept of torsional shear waves ideally suited to interrogate surface and subsurface stiffness, as well as a new set of mechanical biomarkers.

## METHODS AND MATERIALS

24 patients were recruited for the study while 18 of them met the eligibility criteria and were enrolled for the tests. The tests were carried out after obtaining informed consent from participants and receiving ethical approval. Tests were done using a torsional wave elastography device developed in our lab generating shear elastic waves at 0.4-1 kHz frequencies. The probe provides three biomarkers: elasticity, viscosity and anisotropy [Callejas, A, et al. 2017]. Healthy tissue was tested for comparison with pathological tissue. The type of the lesions was classified through the histopathology test. The stiffness ratio was calculated by comparing shear wave velocity between pathological and healthy tissue and then compared to the histopathology result to evaluate accuracy in distinguishing between lesions.

## RESULTS

A ratio threshold of 1.9 classifies benign from malignant tumors. 13 lesions were diagnosed as malignant (melanoma, BCC, SCC) and 5 were benign. Since this is an ongoing study, a larger sample size will be presented at the conference. Some results are closely clustered together due to the proximity of the stiffness ratio, but all the results were correlated well with histopathology results.

## CONCLUSION

The promising initial results suggest TWE could be a useful tool for diagnosing skin pathologies. Further research will evaluate its robustness and reliability.

## CLINICAL RELEVANCE/APPLICATION

The TWE technology has shown potential for noninvasive screening and precise extraction of skin mechanical properties by considering four biomarkers.

### W6-SSPH10-4 **Influence of Variability in Attenuation Compensation on Quantitative Ultrasound Measurements in Heterogeneous Media**

Victor B. Barrere, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Quantitative ultrasound (QUS) applies a set of techniques to estimate acoustic parameters independent of the imaging platform with pretty good results in vivo. It remains challenging to apply in heterogeneous media, in particular because the attenuation from overlying tissues consists in a critical unpredictable bias. The purpose of this study is to investigate the effect of variability of estimated attenuation of overlying tissues on the estimation of BSC of target tissues in median nerve (MN), as it consists in a complex heterogeneous tissue overlaid by complex composite tissues already described in the literature.

#### METHODS AND MATERIALS

Several methods of attenuation estimation are compared: spectral difference method (SDM), spectral log difference method (SLDM), and methods that combine average values of tissue attenuation reported in the literature with the estimated thickness of each overlying tissue (LIBM). The variabilities of the attenuation parameters estimates are compared among the three methods in a median nerve of a single subject in vivo, and in a multi layered phantoms of well monitored properties. An estimation of the variability on BSC due to the different attenuation compensation techniques is described.

#### RESULTS

Values of attenuation were pretty variable in attenuation parameters for SDM methods in the MN (CV is over 1.3 for attenuation coefficients) and in overlying tissues but SLDM and LIBM provided pretty consistent values (CV below 0.25 for attenuation coefficients). SDM and SLDM presented important variabilities in iBSC (CV is over 104.7), though, whereas LIBM gave pretty focused iBSC values (CV is below 60).

## CONCLUSION

Accounting for the attenuation of overlying tissue layers by using the SLDM and compensating based on values from the literature reduced variability in attenuation-based outcomes, compared with SDM. However, our data also reveal that sources of variability beyond those in attenuation parameters alone also impact backscatter measurements. For the evaluation of MN at the level of the wrist, in the critical case overlying tissues couldn't be identified, we suggest to use the values obtained from SLDM ( $a=1.19 \text{ dB}\cdot\text{cm}^{-1}\cdot\text{MHz}^{-b}$  and  $b=1.13$ ) as an overall attenuation value for the composite tissue overlying the nerve at the level of the wrist.

## CLINICAL RELEVANCE/APPLICATION

This work has implications for the application of QUS to in vivo assessment of peripheral nerves and possibly other complex and heterogeneous tissue types. Directions are provided for QUS clinical studies in vivo as a function of the target tissue and the probe location. The phantom study and the model provide an indicator of the quality of the compensation and directions to improve attenuation compensation to come closer to ideal experimental conditions.

### W6-SSPH10-5 **The Development of a Kinetic Model to Estimate Uptake Rate of Microbubbles in Axillary Sentinel Lymph Nodes Using Lymphosonography**

Priscilla Machado, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

A better understanding of the lymphatic system flow kinetics may help with sentinel lymph node (SLN) evaluations. This study developed an initial kinetic model to estimate the lymphatic flow and uptake rate of the microbubbles in axillary SLNs using lymphosonography.

#### METHODS AND MATERIALS

12 female healthy-volunteers received 4 subcutaneous Sonazoid (GE HealthCare) injections around a 2-cm region in the upper-outer quadrant of the breast (total: 1.0ml). Lymphosonography was performed using a S3000 HELX scanner (Siemens Healthineers) at specific time-points. Microbubble concentration was mathematically represented using a two-compartment model that assumes concentration of microbubble in lymphatics feeding the SLN,  $C_1(t)$ , as a function of time,  $t$ :  $C_1(t) = C_0 e^{-k_1 t}$ ,  $C_0$  concentration of microbubble injected, fraction of  $C_0$  making it into afferent lymph vessels feeding the

SLN and  $k_l$  a rate constant governing rate of loss of microbubble concentration at injection site. Microbubble concentration was assumed to either internalize into macrophages, governed by a rate constant,  $k_i$ , proportional to the number of macrophages and the rate of microbubble uptake per macrophage; or be eliminated from the SLN through washout at the lymphatic flow rate,  $F_l$ . The resulting equation represents the concentration of microbubbles in a SLN,  $C_{node}(t) = C_{node}(0) e^{-(k_i + F_l)t} + \int_0^t C_{node}(\tau) e^{-(k_i + F_l)(t-\tau)} u(\tau) d\tau$ , where  $*$  represents the convolution operator, and  $u(t)$  is a step function. Eq (2) yields three parameters of fit:  $k_i$ ,  $F_l$ , and  $k_l$ , where the main parameter related to the concentration of macrophages in the SLN, which is related to the tumor burden, is  $k_i$ .  $C_{node}(t) = C_{node}(0) e^{-k_l t} + \int_0^t C_{node}(\tau) e^{-(k_i + F_l)(t-\tau)} u(\tau) d\tau$

## RESULTS

Average estimates of  $k_i$ ,  $F_l$ , and  $k_l$  were  $0.90 \pm 0.06 \text{ min}^{-1}$ ,  $2 \pm 1 \text{ min}^{-1}$ , and  $0.09 \pm 0.06 \text{ min}^{-1}$ , respectively. Large variances (>50%) were observed in  $F_l$  and  $k_l$  amongst patients. However, the variance in  $k_i$ —the main parameter of interest—was found to be less than 10% of the mean.

## CONCLUSION

Results show potential of this methodology to assess  $k_i$  as a potential non-invasive biomarker of tumor burden, with  $k_i$  expected to be lower in SLNs with cancer, which will be investigated in future research.

## CLINICAL RELEVANCE/APPLICATION

The use of flow kinetics may help with SLN evaluations in breast cancer patients where  $k_i$  is expected to be lower in SLNs with cancer owing to a lower concentration of macrophages.

## W6-SSPH10-6 Remote Ultrasound Detection using Laser Interferometry

Kaitlyn Kim, BS (*Presenter*) Nothing to Disclose

## PURPOSE

Conventional modalities for ultrasound wave detection currently utilize piezoelectric transducers or medical ultrasound probes. However, these sensors can cause variability in image quality depending on the skill of the user or may cause discomfort to the subject, as direct contact to the skin is required with the use of ultrasonic gel. We present a laser interferometer for ultrasound detection. Through laser interferometry, remote detection of ultrasound and photoacoustics is shown, eliminating direct contact of the transducer with the skin.

## METHODS AND MATERIALS

The photoacoustic effect involves the absorption of radiant energy such as a short-pulsed laser, resulting in a thermoelastic expansion that emits wideband ultrasound waves. Using a Polytec laser vibrometer, which uses a Mach-Zehnder interferometer, we demonstrated the detection of PA generated ultrasound waves. A pulsed Alexandrite laser with a pulsewidth of 900ps was used to excite a water phantom containing an absorbing polymer. The laser vibrometer was focally aligned to capture the signal. Five runs were completed with varying pulse laser energies, each with no averaging and 200 mJ being the highest. Next, a vibrometer with scanning capabilities was used. An area was set around a water phantom, which was used as the medium, and scan points were set to provide information from multiple points on the target. A 5 MHz focused ultrasound transducer was used to send ultrasonic waves using a pulser/receiver system.

## RESULTS

The interferometer system was able to capture signals with no averaging for varied energy levels from a therapeutic laser. Even with the laser pulse energy at the lowest level, a distinct waveform can be observed. We demonstrate the results from the scanned phantom using the vibrometer, which provides a grid map demonstrating regions where the greatest amplitude is observed on the phantom surface.

## CONCLUSION

The remote detection of ultrasound waves produced by a high energy therapeutic laser and a 5 MHz ultrasound transducer is demonstrated. Scanning results show that 2D imaging with an interferometer is possible with high accuracy. Our non-contact ultrasound detection system, based on a laser interferometer, surpasses current PZT-based methods used in medical practice without patient contact. However, lengthy inspection times remain a challenge that can be resolved by adopting parallel detection and faster initial screening methods followed by localized imaging.

## CLINICAL RELEVANCE/APPLICATION

The laser vibrometer can also be applied to clinical proton beams, detecting the waves generated. Remote detection would simplify monitoring of the proton beam, as the device is simply placed towards the beam, and would not obstruct the path.

### Influence of Variability in Attenuation Compensation on Quantitative Ultrasound Measurements in Heterogeneous Media

Wednesday, Nov. 29 1:30PM - 2:30PM Room: E353C

Victor B. Barrere, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Quantitative ultrasound (QUS) applies a set of techniques to estimate acoustic parameters independent of the imaging platform with pretty good results in vivo. It remains challenging to apply in heterogeneous media, in particular because the attenuation from overlying tissues consists in a critical unpredictable bias. The purpose of this study is to investigate the effect of variability of estimated attenuation of overlying tissues on the estimation of BSC of target tissues in median nerve (MN), as it consists in a complex heterogeneous tissue overlaid by complex composite tissues already described in the literature.

#### METHODS AND MATERIALS

Several methods of attenuation estimation are compared: spectral difference method (SDM), spectral log difference method (SLDM), and methods that combine average values of tissue attenuation reported in the literature with the estimated thickness of each overlying tissue (LIBM). The variabilities of the attenuation parameters estimates are compared among the three methods in a median nerve of a single subject in vivo, and in a multi layered phantoms of well monitored properties. An estimation of the variability on BSC due to the different attenuation compensation techniques is described.

#### RESULTS

Values of attenuation were pretty variable in attenuation parameters for SDM methods in the MN (CV is over 1.3 for attenuation coefficients) and in overlying tissues but SLDM and LIBM provided pretty consistent values (CV below 0.25 for attenuation coefficients). SDM and SLDM presented important variabilities in iBSC (CV is over 104.7), though, whereas LIBM gave pretty focused iBSC values (CV is below 60).

#### CONCLUSION

Accounting for the attenuation of overlying tissue layers by using the SLDM and compensating based on values from the literature reduced variability in attenuation-based outcomes, compared with SDM. However, our data also reveal that sources of variability beyond those in attenuation parameters alone also impact backscatter measurements. For the evaluation of MN at the level of the wrist, in the critical case overlying tissues couldn't be identified, we suggest to use the values obtained from SLDM ( $a=1.19 \text{ dB}\cdot\text{cm}^{-1}\cdot\text{MHz}^{-b}$  and  $b=1.13$ ) as an overall attenuation value for the composite tissue overlying the nerve at the level of the wrist.

#### CLINICAL RELEVANCE/APPLICATION

This work has implications for the application of QUS to in vivo assessment of peripheral nerves and possibly other complex and heterogeneous tissue types. Directions are provided for QUS clinical studies in vivo as a function of the target tissue and the probe location. The phantom study and the model provide an indicator of the quality of the compensation and directions to improve attenuation compensation to come closer to ideal experimental conditions.

### The Development of a Kinetic Model to Estimate Uptake Rate of Microbubbles in Axillary Sentinel Lymph Nodes Using Lymphosonography

Wednesday, Nov. 29 1:30PM - 2:30PM Room: E353C

Priscilla Machado, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

A better understanding of the lymphatic system flow kinetics may help with sentinel lymph node (SLN) evaluations. This study developed an initial kinetic model to estimate the lymphatic flow and uptake rate of the microbubbles in axillary SLNs using lymphosonography.

#### METHODS AND MATERIALS

12 female healthy-volunteers received 4 subcutaneous Sonazoid (GE HealthCare) injections around a 2-cm region in the upper-outer quadrant of the breast (total: 1.0ml). Lymphosonography was performed using a S3000 HELX scanner (Siemens Healthineers) at specific time-points. Microbubble concentration was mathematically represented using a two-compartment model that assumes concentration of microbubble in lymphatics feeding the SLN,  $C_l$ , as a function of time,  $t$ :  $C_l(t) = C_0 e^{-k_l t}$ ,  $C_0$  concentration of microbubble injected, fraction of  $C_0$  making it into afferent lymph vessels feeding the SLN and  $k_l$  a rate constant governing rate of loss of microbubble concentration at injection site. Microbubble concentration was assumed to either internalize into macrophages, governed by a rate constant,  $k_i$ , proportional to the number of macrophages and the rate of microbubble uptake per macrophage; or be eliminated from the SLN through washout at the lymphatic flow rate,  $F_l$ . The resulting equation represents the concentration of microbubbles in a SLN,  $C_{node}(t) = \int_0^t C_0 e^{-k_l \tau} * e^{-(k_i + F_l)(t-\tau)} u(t-\tau) dt$ , where  $*$  represents the convolution operator, and  $u(t)$  is a step function. Eq (2) yields three parameters of fit:  $k_i$ ,  $F_l$ , and  $k_l$ , where the main parameter related to the concentration of macrophages in the SLN, which is related to the tumor burden, is  $k_i$ .

#### RESULTS

Average estimates of  $k_i$ ,  $F_l$ , and  $k_l$  were  $0.90 \pm 0.06 \text{ min}^{-1}$ ,  $2 \pm 1 \text{ min}^{-1}$ , and  $0.09 \pm 0.06 \text{ min}^{-1}$ , respectively. Large variances (>50%) were observed in  $F_l$  and  $k_l$  amongst patients. However, the variance in  $k_i$ —the main parameter of interest—was found to be less than 10% of the mean.

#### CONCLUSION

Results show potential of this methodology to assess  $k_i$  as a potential non-invasive biomarker of tumor burden, with  $k_i$  expected to be lower in SLNs with cancer, which will be investigated in future research.

#### CLINICAL RELEVANCE/APPLICATION

The use of flow kinetics may help with SLN evaluations in breast cancer patients where  $k_i$  is expected to be lower in SLNs with cancer owing to a lower concentration of macrophages.

### Remote Ultrasound Detection using Laser Interferometry

Wednesday, Nov. 29 1:30PM - 2:30PM Room: E353C

Kaitlyn Kim, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Conventional modalities for ultrasound wave detection currently utilize piezoelectric transducers or medical ultrasound probes. However, these sensors can cause variability in image quality depending on the skill of the user or may cause discomfort to the subject, as direct contact to the skin is required with the use of ultrasonic gel. We present a laser interferometer for ultrasound detection. Through laser interferometry, remote detection of ultrasound and photoacoustics is shown, eliminating direct contact of the transducer with the skin.

#### METHODS AND MATERIALS

The photoacoustic effect involves the absorption of radiant energy such as a short-pulsed laser, resulting in a thermoelastic expansion that emits wideband ultrasound waves. Using a Polytec laser vibrometer, which uses a Mach-Zehnder interferometer, we demonstrated the detection of PA generated ultrasound waves. A pulsed Alexandrite laser with a pulsewidth of 900ps was used to excite a water phantom containing an absorbing polymer. The laser vibrometer was confocally aligned to capture the signal. Five runs were completed with varying pulse laser energies, each with no averaging and 200 mJ being the highest. Next, a vibrometer with scanning capabilities was used. An area was set around a water phantom, which was used as the medium, and scan points were set to provide information from multiple points on the target. A 5 MHz focused ultrasound transducer was used to send ultrasonic waves using a pulser/receiver system.

#### RESULTS

The interferometer system was able to capture signals with no averaging for varied energy levels from a therapeutic laser. Even with the laser pulse energy at the lowest level, a distinct waveform can be observed. We demonstrate the results from the scanned phantom using the vibrometer, which provides a grid map demonstrating regions where the greatest amplitude is observed on the phantom surface.

#### CONCLUSION

The remote detection of ultrasound waves produced by a high energy therapeutic laser and a 5 MHz ultrasound transducer is demonstrated. Scanning results show that 2D imaging with an interferometer is possible with high accuracy. Our non-contact ultrasound detection system, based on a laser interferometer, surpasses current PZT-based methods used in medical practice without patient contact. However, lengthy inspection times remain a challenge that can be resolved by adopting parallel detection and faster initial screening methods followed by localized imaging.

#### CLINICAL RELEVANCE/APPLICATION

The laser vibrometer can also be applied to clinical proton beams, detecting the waves generated. Remote detection would simplify monitoring of the proton beam, as the device is simply placed towards the beam, and would not obstruct the path.

### Science Session (Generative AI)

Wednesday, Nov. 29 1:30PM - 2:00PM Room: Learning Center Theater 1

#### Sub-Events

#### **W6-STCE1- GPT-4 Analysis of MRI Reports in Suspected Myocarditis: A Multicenter Study** 1

Kenan Kaya, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The diagnosis of myocarditis is based on clinical symptoms, laboratory results, and cardiac MRI. The correct interpretation and integration of MRI findings require radiological expertise and knowledge. The Generative Pre-trained Transformer 4 (GPT-4) is a large language model capable of generating semantically coherent responses and logical decisions on text-based inputs and requests. The aim of this study was to investigate the potential of GPT-4 for decision-making and final interpretation of MRI reports in suspected myocarditis.

#### **METHODS AND MATERIALS**

This is a retrospective study including 400 patients with suspected myocarditis from eight centers. The following text-based input information was provided to the GPT-4 network and to three radiologists with different levels of experience (R1: 1 year, R2: 2 years, and R3: 4 years): MRI reports (structured (n=100) and unstructured (n=100)), applied sequences, laboratory results, patient age, sex, and clinical symptoms. The final interpretation of the report indicating the presence or absence of myocarditis was not provided. GPT-4 and the radiologists were prompted to provide a dichotomous statement (yes/no) regarding the presence of myocarditis. The accuracy, sensitivity, and specificity of GPT-4 and the readers for the diagnosis of myocarditis were calculated by comparing their findings to the final diagnosis of an expert reader with 6 years of experience in cardiac MRI. The results were obtained using contingency tables while a  $\chi^2$ -Test was employed to compare the diagnoses of the radiologists and GPT-4. A p-value of  $<.05$  was considered statistically significant.

#### **RESULTS**

GPT-4 showed an accuracy of 82%, sensitivity of 86%, and specificity of 79%. These results did not differ significantly from the performance of radiologist R1 (accuracy=87%, sensitivity=85%, specificity=88%,  $p=.05$ ), but were inferior to radiologists R2 (accuracy=97%, sensitivity=93%, specificity=99%,  $p=.001$ ) and R3 (accuracy=89%, sensitivity=77%, specificity=98%,  $p<.0001$ ).

#### **CONCLUSION**

Using multicenter data, GPT-4 achieved good performance in interpreting heterogeneous text-based cardiac MRI findings for myocarditis diagnosis, which was in the range of the inexperienced reader. GPT-4-based analysis of text-based findings could serve as a supportive tool in interpreting and decision-making in cardiac imaging.

#### **CLINICAL RELEVANCE/APPLICATION**

GPT-4 achieved a good performance in interpreting multicenter report-based cardiac MRI findings. Its use as a supportive tool for interpreting findings and decision-making in clinical practice, particularly for inexperienced readers, is conceivable.

#### **W6-STCE1- Exploring Racial Disparities in Imaging Datasets via Generative AI: A Path to Enhanced Model Transparency** 2

Bardia Khosravi, MD, MPH (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Addressing potential biases in healthcare data is pivotal. This study leverages generative deep learning (DL) methods to identify radiographic variances related to race in patients undergoing total hip arthroplasty (THA). The study aims to demonstrate the feasibility of using generative AI on large scale imaging data to uncover anatomical differences between White and African American patients.

## METHODS AND MATERIALS

We used pelvic radiographs from an institutional THA patient registry covering the period from Jan 1997 to Oct 2021. The radiographs were characterized using proven DL models determining the projection plane, laterality, and the presence or absence of prosthesis. Patient demographics such as age, sex, self-reported race, and body mass index were also recorded. Using denoising diffusion probabilistic models (DDPM), synthetic radiographs conditioned on these demographics and image characteristics were generated. Post-model training, 60 high-resolution transformation videos were created, transitioning from a radiograph of a White patient to that of an African American patient, with all variables held constant, Figure 1. Two MSK radiologists and two orthopedic surgeons, as expert evaluators, characterized systematic differences in the images. The inter-rater agreement was assessed using Gwet's AC1 (GAC), with a value of >0.60 indicating substantial agreement.

## RESULTS

The study incorporated 480,407 pelvic radiographs from 15,127 unique patients (52% female, 1% African American). The expert panel identified six characteristics that demonstrated systematic differences between the races. African American patients displayed decreased inter-acetabular distance (GAC: 0.83), a higher degree of osteoarthritis (GAC: 0.82), a more elliptical obturator foramen (GAC: 0.80), reduced femoral neck-shaft angle (GAC: 0.76), an elongated pelvis ring (GAC: 0.61), and increased femoral metaphyseal cortical thickness (GAC: 0.60). All differences were statistically significant (p-values <0.001).

## CONCLUSION

The study demonstrates the effective use of generative AI models for detecting anatomical differences between White and African American patients. African American patients had a significantly higher osteoarthritis severity compared to White patients, suggesting healthcare access disparities at early stages of disease.

## CLINICAL RELEVANCE/APPLICATION

Generative DL models can aid in detecting previously unrecognized anatomical differences between races in medical imaging datasets. Knowledge of these variations can assist in creation of datasets that better represent the population and also detection of datasets that may contain high racial bias, leading to the development of more transparent and unbiased AI models.

## W6-STCE1- Leveraging Chat GPT-4 for Automatic Labeling of Lung Cancer Staging from Chest CT and PET-CT Reports: A Multimodal and Multilingual Approach

Jinwoo Kim, MD (*Presenter*) Nothing to Disclose

## PURPOSE

This study investigated the performance of Chat GPT-4 as an automatic labeler of lung cancer staging from contrast enhanced-chest CT and F-18 FDG PET-CT free-text reports.

## METHODS AND MATERIALS

We utilized 8th edition of the TNM classification for lung cancer document as specialized knowledge base and the GPT-4 model was used to label the lung cancer staging from the contrast enhanced-chest CT and F-18 FDG PET-CT free-text reports in English or Korean. The ground truth staging labels were determined by consensus of thoracic radiologist and thoracic nuclear radiologist. Chest CT and PET/CT free-text reports were used to compare the GPT-4 model's performance against radiologist, nuclear radiologist, non-radiology physician, senior and junior radiology residents with brief training.

## RESULTS

Upon analysis of the 100 free-text reports, each representing different staging levels of lung cancer, the GPT-4 model accurately performed lung cancer staging in accordance with the 8th edition of the TNM classification. The average performance of the GPT-4 models, with an F1 score of  $0.792 \pm 0.061$ , did not exhibit significant differences compared to the average performance of human readers, which scored an F1 of  $0.849 \pm 0.106$  ( $P = .10$ ). The model demonstrated labeling performance comparable to that of the human labeling including non-radiology physician and junior radiology resident. Further, the model provided time and cost savings compared to the human labeling.

## CONCLUSION

Chat GPT-based algorithms have the potential to assist the decision-making for clinical lung cancer staging in accordance with 8<sup>th</sup> edition of the TNM classification. Notably, the model also performed well for interpretation in a variety of multimodal and multilingual imaging reports.

## CLINICAL RELEVANCE/APPLICATION

Generative AIs, like Chat GPT, possess the potential to aid in clinical lung cancer staging decision-making.

W6-STCE2

### Science Session (Theranostics)

Wednesday, Nov. 29 1:30PM - 2:00PM Room: Learning Center Theater 2

#### Sub-Events

### **W6-STCE2- PSMA PET-Supported Differential Diagnosis of Dural-Based Intracranial Lesions in Patients with Metastatic Prostate Cancer: A Common Clinical Scenario with Implications for Theranostic Management.**

Divya Yadav, MBBS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

PSMA PET and peptide radionuclide therapy (PRRT) has emerged as a powerful theranostic tool in prostate cancer management. Dural metastases are relatively uncommon, occurring in 1-6% of cases, though probably underdiagnosed given autopsy studies. Meningiomas are the most common primary brain tumor, and thus may be encountered as an incidental finding in patients undergoing whole-body PSMA PET for prostate cancer evaluation. PSMA PET findings in meningioma have not previously been studied. We performed a comparative analysis between PSMA PET SUV in prostate cancer dural metastases and meningioma, with contrast-enhanced MRI and/or CT as reference standard.

#### **METHODS AND MATERIALS**

Retrospective report search of all [Ga68]- and [F18]-PSMA PET/CT performed at our institution for the past 3 years was performed to identify patients with 1.) calvarial/dural prostate cancer metastases and 2.) meningiomas based on MRI and/or CT appearance. Histopathological correlation and follow up imaging were also used wherever available to support the diagnosis. Maximum SUV of target lesions and the parotid were used to calculate SUV ratio (SUVR) for normalization purposes, to control for uptake differences between [Ga68]- and [F18]-PSMA. Mann-Whitney-tests and descriptive statistics were performed to compare SUVR between groups.

#### **RESULTS**

18 male patients (median age 76, range 59-96 years) with rising PSA underwent [Ga68]- and [F18]-PSMA PET/CT for prostate cancer and were found to have a total of 30 PSMA-avid calvarial/ dural-based lesions. 24 lesions were radiographically classified as prostate cancer metastases and 6 as meningioma. Metastases had significantly higher median SUV and SUVR than meningiomas (13.2 [95% CI: 8.2, 18.6] vs 2.6 [95% CI: 1.9, 4.5],  $p = 0.001$ , and 2.4 [95% CI: 0.6, 2.4] vs 0.3 [95% CI: 0.2, 0.4],  $p < 0.0001$ , respectively).

#### **CONCLUSION**

Meningiomas represent an important differential diagnosis when encountering dural-based lesions in patients with prostate cancer undergoing theranostic management. Our findings demonstrate mild PSMA avidity in meningiomas, significantly below that of prostate cancer metastases. Quantitative SUV analysis can accurately differentiate these entities and thereby optimize management.

#### **CLINICAL RELEVANCE/APPLICATION**

Intracranial metastases in prostate cancer carry poor prognosis. SUV quantification can differentiate metastases from meningiomas in prostate cancer patients undergoing theranostic evaluation.

### Breast Imaging (AI and Deep Learning Applications in Screening and Risk Assessment)

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S406B

Wendy B. Demartini, MD (*Moderator*) Advisory Board, Kheiron Medical Technologies Ltd  
Manisha Bahl, MD, MPH (*Moderator*) Consultant, Lunit Inc; Expert Advisory Committee, 2nd.MD  
Sarah Eskreis-Winkler, MD (*Moderator*) Nothing to Disclose

#### Sub-Events

#### **W7-SSBR09-1 Performance of a Deep Learning Image-Based Five-Year Breast Cancer Risk Model in Predicting DCIS and Invasive Breast Cancer**

Wendy B. Demartini, MD (*Presenter*) Advisory Board, Kheiron Medical Technologies Ltd

#### PURPOSE

To estimate the performance of a deep learning image-based five-year breast cancer risk model in patients who develop DCIS vs. invasive breast cancer within five years of screening mammography.

#### METHODS AND MATERIALS

This retrospective, multicenter international study included 31,016 consecutive bilateral 2D full field digital screening mammograms from a U.S. screening center and 10,673 from a European screening center from January 2011 through December 2016. These exams were not part of model training. Cancer outcomes and type (pure DCIS vs any invasive breast cancer) were obtained from local tumor registries. Cancer rates were defined as total cancers diagnosed after the index mammogram/total exams and were calculated for DCIS (excluding invasive cancer cases) and invasive cancers (excluding pure DCIS cases). Model performance was compared using areas under the receiver operating characteristic curve (AUCs) ( $p < .05$ ) with 95% confidence intervals.

#### RESULTS

The U.S. center included 937 total cancers diagnosed post index mammogram, for a 3.0% cancer positive rate. Invasive cancers accounted for 60.5% (567) of total cancers; DCIS accounted for 31.4% (294); remaining 8.1% (75) were of unknown or ambiguous cancer type. The European center included 250 total five-year cancers representing a 2.3% cancer positive rate. Invasive cancers accounted for 74.4% (186) of total cancers; DCIS accounted for 22.8% (57); remaining 2.8% (7) were of unknown or ambiguous cancer type. AUC by breast cancer type: U.S. center invasive cancers 0.79 [95% CI 0.77, 0.81] ( $n = 30,646$ ) vs U.S. center DCIS 0.73 [95% CI 0.70, 0.76] ( $n = 30,373$ ) ( $p < .001$ ); European center invasive cancers 0.80 [95% CI 0.76, 0.83] ( $n = 10,609$ ) vs European center DCIS 0.75 [95% CI 0.68, 0.82] ( $n = 10,480$ ) ( $p = .253$ ).

#### CONCLUSION

The deep learning model performed consistently at or above 0.73 AUC for predicting invasive breast cancers and DCIS across multi-site centers in the U.S. and Europe. At the U.S center, predictive performance was higher for invasive cancer compared to that for DCIS.

#### CLINICAL RELEVANCE/APPLICATION

Deep-learning based five-year breast cancer risk prediction can effectively identify the risk of both invasive breast cancers and DCIS in U.S. and European screening programs.

#### **W7-SSBR09-2 Beyond Mammographic Breast Density: Superior Performance of Image-Based DL Model to Predict Breast Cancer Risk**

Christiane K. Kuhl, MD, PhD (*Presenter*) Advisory Board, Guerbet SA; Speaker, Bracco Group; Speaker, Bayer AG

## PURPOSE

To compare predictive performance of a new deep learning five-year breast cancer risk prediction model to mammographic breast density in identifying patients with a higher burden of cancer in screening programs in the U.S. and Europe.

## METHODS AND MATERIALS

This retrospective, multicenter international study included 30,198 consecutive bilateral 2D full field digital screening mammograms from a U.S. screening center and 10,672 from a European screening center from January 2011 through December 2016. Breast density assessments (dense vs not dense) were extracted from electronic medical records. Cancer outcomes were obtained from local tumor registries. Cancers included DCIS and any invasive breast cancer. NCCN thresholds were used to categorize five-year risk predictions from the calibrated DL model as follows: average risk < 1.7%, intermediate risk > 1.7% and < 3.0%, and high risk > 3.0%. We used logistic regression to model the relationship (via Odds Ratios) between positive five-year cancer outcome and the explanatory variables of predicted risk category and breast density, with an interaction term between risk category and breast density, to determine if the relationship between risk category and cancer outcome differs between those with not dense and dense breasts. We also analyzed average marginal effect (AME) of risk level and breast density. Analyses used average risk as the reference for risk category and not dense as the reference for breast density.

## RESULTS

The DL model consistently categorized exams with similar future cancer rates regardless of breast density. Odds ratios for predictors (n= 40,870): intermediate risk category 2.54 [95% CI 1.88-3.42] (p<.001); high risk category 9.60 [95% CI 7.65-12.17] (p<.001); dense breast tissue 1.16 [95% CI 0.88-1.54] (p=.301); intermediate risk category x dense breast tissue 0.93 [95% CI 0.62-1.38] (p=.703); high risk category x dense breast tissue 0.74 [95% CI 0.54-1.02] (p=.069). Average marginal effects (AME) analysis: intermediate risk category AME 2.43 [95% CI 1.99, 2.97] (p<.0001); high risk category AME 8.19 [95% CI 6.99, 9.61] (p<.0001); dense breast tissue AME 1.05 [95% CI 0.90, 1.24] (p=0.522).

## CONCLUSION

A deep-learning based model using only mammography images to predict five-year breast cancer risk effectively differentiates risk across breast density categories. Breast density is an ineffective measure to identify patients with a higher cancer burden in a mammography screening program.

## CLINICAL RELEVANCE/APPLICATION

An image based deep-learning model exceeds breast density in predicting future breast cancer risk and provides a more effective method to guide clinical decision making regarding supplemental imaging and risk reduction.

## W7-SSBR09-3 Deep Learning Model Translates Imaging Biomarkers to Predict Future DCIS vs Invasive Breast Cancer Risk Across Races

Leslie Lamb, MD, MSc (*Presenter*) Nothing to Disclose

## PURPOSE

A deep learning (DL) algorithm was previously designed to predict a patient's risk of developing breast cancer at multiple time points using mammographic image biomarkers alone. The purpose of this study was to compare the predictive accuracy of DL image-only model to predict future DCIS vs invasive breast cancer across races.

## METHODS AND MATERIALS

This retrospective, multisite study included consecutive patients >30 years undergoing routine bilateral screening mammography from 01/10/2009 to 01/10/2018 at five facilities with at least five years of follow-up. A DL 5-year model was used to assess risk. Women with a personal history of breast cancer were excluded. No mammograms included were used for model development. Patient demographics were retrieved from electronic medical records. Cancer outcomes were obtained through linkage to a regional tumor registry. DL model performance was compared using areas under the receiver operating characteristic curve (AUCs) with DeLong test (p<0.05).

## RESULTS

83871 bilateral screening mammograms in 48984 patients met inclusion criteria. Mean patient age was 59y (IQR: 51-68y). 17013/83871 (20.3%) had a family history of breast cancer. 65660/83871 (78.3%) were in post-menopausal and 18211/83871 (21.7%) in pre-menopausal patients. 49686/83697 (59.4%) had non-dense and 34011/83697 (40.6%) had dense breasts. 68621/83871 (81.8%) of patients were White, 4376/83871 (5.2%) Asian, 4140/83871 (4.9%) Black and 5426/83871 (6.5%) were other races. The AUC of DL model in predicting DCIS was 0.71 (95% confidence interval [CI]: 0.65, 0.77) and invasive malignancy was 0.70 (95% CI: 0.67, 0.74) across all patients. The AUC in predicting DCIS was significantly higher in Black vs White patients (0.92, 95% CI: 0.87, 0.97 vs 0.70, 95% CI: 0.64, 0.77, respectively, p<0.001). There was no evidence of a significant difference in predicting DCIS in Asian vs White patients (0.66, 95% CI: 0.32, 1.00 vs 0.70, 95% CI: 0.64, 0.77, respectively, p=0.798). There was no evidence of a significant difference in

predicting invasive disease in Black vs White (0.73, 95% CI: 0.63, 0.83 vs 0.71, 95% CI: 0.67, 0.74, respectively,  $p=0.592$ ) or Asian vs White (0.68, 95% CI: 0.54, 0.83 vs 0.71, 95% CI: 0.67, 0.74, respectively,  $p=0.988$ ) patients.

## **CONCLUSION**

Mammograms contain highly predictive biomarkers of future cancer risk. A DL model using screening mammography alone can accurately discriminate patients at risk of developing DCIS and invasive disease across races.

## **CLINICAL RELEVANCE/APPLICATION**

A DL image-only risk model can provide increased access to an equitable accurate risk assessment tool for both DCIS and invasive malignancy prediction across races.

## **W7-SSBR09-4 External Evaluation of a Mammography-based Deep Learning Model for Breast Cancer Risk Prediction in a High-risk, Diverse Population**

Olasubomi J. Omoleye, MBBS (*Presenter*) Nothing to Disclose

### **PURPOSE**

To externally evaluate a mammography-based deep learning (MG-DL) model, Mirai, for breast cancer (BC) risk prediction in a high-risk, diverse population; assess its predictive performance across BC subtypes; and compare its accuracy with breast density and final BI-RADS assessment categories.

### **METHODS AND MATERIALS**

After excluding 169 exams with time-to-cancer <6 months, 6266 screening mammograms acquired from 2043 participants enrolled in a cancer risk clinic between 2006 and 2020 were retrospectively evaluated in this case-control study. Pathologically confirmed invasive carcinoma or ductal carcinoma in situ (DCIS) of the breast was the primary outcome. MG-DL risk scores were primary predictors. Breast density and final BI-RADS assessment were comparative predictors.

### **RESULTS**

The mean age at mammography was 56.4 (SD: 11.2) years. 910 participants (44.5%) were African American (AA) and 853 (41.8%) White. 15.3% had a known family history of BC, 30.5% had a history of benign breast disease (BBD), and 4.8% were known carriers of BC-predisposing gene mutations. Mirai had one- and five-year areas under the receiver operating characteristic curve (AUC) of 0.71 [95% CI: 0.68-0.74] and 0.65 [0.64-0.67] respectively. Mirai showed better near-term accuracy in non-dense vs dense breasts: 1-year AUC 0.72 [0.63-0.81] vs 0.58 [0.45-0.72], although this was not statistically significant ( $p = 0.10$ ). Mirai and BI-RADS assessment 1-year AUCs were not significantly different: 0.68 [0.61-0.75] and 0.73 [0.66-0.79] respectively,  $p = 0.34$ . However, for 2-5-year prediction, Mirai outperformed BI-RADS (5-year AUC 0.63 vs 0.54; all  $p = 0.0016$ ). Mirai also outperformed both visually assessed and AI-generated breast density categories at all time points (5-year AUC 0.62 vs 0.48 vs 0.52; all  $p < 0.0001$ ). The MG-DL model showed higher discrimination for low- and intermediate- vs high-grade cancers (5-year AUCs 0.63 [0.57-0.70] and 0.63 [0.61-0.67] vs 0.58 [0.54-0.62],  $p < 0.05$ ). In image-mirroring experiments, utilizing only images of the future-unaffected breast as model input led to significantly lower performance of the MG-DL model, suggesting that its predictions were probably based on the detection of ipsilateral premalignant patterns.

## **CONCLUSION**

We evaluated an MG-DL model in a high-risk population and suggested that an important driver of its performance may be the detection of premalignant mammographic features. Our results support further examination of MG-DL models for BC risk prediction in high-risk, diverse groups.

## **CLINICAL RELEVANCE/APPLICATION**

Externally evaluating MG-DL models in high-risk, diverse groups who stand to benefit the most from more accurate risk prediction is pertinent to inform further testing in prospective BC interception trials.

## **W7-SSBR09-5 Screening Mammography: Can a Deep Learning Model Support Expanded Screening of Patients in Their 40s**

Ray C. Mayo III, MD (*Presenter*) Nothing to Disclose

### **PURPOSE**

There is international consensus on the importance of screening patients in their 50s and 60s, but wide variation in recommendations for screening patients in their 40s. We measured the potential contribution of an image-based deep learning model to identify patients 40-49 at five-year breast cancer risk similar to that of patients aged 50-69.

### **METHODS AND MATERIALS**

This retrospective study included 30,212 consecutive bilateral 2D full field digital screening mammograms from January 2011 through December 2016 from six facilities at a U.S. screening program. Patient demographics were extracted from electronic medical records and cancer outcomes obtained from local tumor registries. Age categories included 40-49, 50-69, and >70.

Cancer positive exams were defined as exams with breast cancer diagnosed following the mammogram. Five-year calibrated risk predictions from the DL model were used to group exams as average (<1.7%), intermediate (> 1.7%) and high (> 3.0%) risk based on NCCN thresholds. We estimated the percents of exams for each threshold by age group and compared observed cancer rates (cancer positive exams/all exams) across risk and age groups. Chi-squared tests were used to measure statistical differences across independent risk and age groups.

## RESULTS

Across all ages, cancer rates were 1.0%, 5.0% and 7.0% for average, intermediate and high-risk groups (n=30,212, Chi-squared 691.50, p<.0001). Cancer rates increased with each age group: 1.6% (40-49), 3.2% (50-69), and 6.0% (>70) (n=30,212, Chi-squared 149.91, p<.0001). Within each age group, DL risk score thresholds distinguished exams in patients with lower and higher cancer rates. For patients in their 40s, cancer rates were 0.7%, 3.3% and 5.1% in average, intermediate and high-risk subgroups (n=8,208, Chi-squared 126.99, p<.0001). 37% of exams for patients in their 40s were identified as intermediate risk, with a five-year cancer rate of 3.3%, compared to a similar cancer rate of 3.2% for exams in patients 50-69. 16% of exams in patients in their 40s were identified as high risk, with a five-year cancer rate of 5.1%, compared to a similar cancer rate of 5.0% for patients aged 50-69 at intermediate risk.

## CONCLUSION

A DL image-based risk model can identify significant numbers of patients in their 40s who have five-year future breast cancer risk similar to that in patients aged 50-69 in screening programs. A DL risk model can support more informed decision making for patients 40-49 and their providers regarding when to start screening.

## CLINICAL RELEVANCE/APPLICATION

For programs that do not offer routine screening to patients aged 40-49 and for those with variable engagement of these patients in screening, a DL image-based model has the potential to support enhanced screening of this key age group.

## W7-SSBR09-6 Preliminary Results of Implementing AI into Breast Cancer Screening in the Capital Region of Denmark

Andreas D. Lauritzen, PhD (*Presenter*) (Former) Researcher, ScreenPoint Medical BV, NL Scientific Assistant at Gentofte Hospital, DK

## PURPOSE

This study assessed the screening quality before and after AI was implemented in a population-based breast cancer screening program. Based on a large prior simulation study, an AI system supporting a stratified reading protocol and decision support was implemented into screening in the Capital Region of Denmark as of November 18th 2021.

## METHODS AND MATERIALS

In the Capital Region of Denmark women aged 50-69 years are screened biennially. For women screened before AI implementation from October 1st 2020 to November 17th 2021, all screens were read independently by two breast radiologists. For women screened with AI from November 18th 2021 to December 31st 2022, all screens were assessed by the AI system Transpara (ScreenPoint Medical) producing an exam score from 1-10 reflecting the probability of breast cancer. Screens with an exam score =7 (=5 before May 3rd 2022) were read by AI and a single senior breast radiologist. The remaining women were read by two radiologists with access to decision support with markings by the AI system. Screen detected breast cancers (invasive or DCIS) were histologically confirmed. Screening quality was measured using recall rate, cancer detection rate (CDR), rate of invasive cancers, rate of small cancers (=1cm), rate of node-negative cancers, and false-positive (FP) rate. For CDR and FP rate, women screened after October 1st 2022, were excluded to allow for 90 days of follow up. For rates of invasive, small, and node-negative cancers, women screened after July 3rd 2022 were excluded to have 180 days of follow up. Outcomes were compared before and after AI (jointly for both exam score thresholds) using the Chi2 test. We further measured the reading workload reduction.

## RESULTS

59,573 women were screened before AI and 74,596 women with AI. The recall rate decreased from 3.10% to 2.42% (P < .001) in screening with AI. CDR increased from 0.69% to 0.83% (P < .01). Rate of invasive cancers decreased from 84.8% to 79.9% but not significantly (P = .10). Rate of small cancers increased from 38.9% to 48.0% (P = .04). Rate of node-negative cancers increased from 76.7% to 80.9%, but not significantly (P = .30). FP rate decreased from 2.41% to 1.66% (P < .001). Reading workload was reduced by 34.2%.

## CONCLUSION

Screening with AI in the Capital Region of Denmark increased CDR while the recall and FP rates decreased. Small invasive cancers were more often diagnosed. Rates of invasive and node-negative cancers did not significantly change. Our findings suggest that AI improved screening quality while considerably reducing radiologists' workload.

## **CLINICAL RELEVANCE/APPLICATION**

Screening with AI safely reduced both reading and clinical workload, and results indicated that invasive cancers were more frequently diagnosed while small, suggesting earlier detection.

### Performance of a Deep Learning Image-Based Five-Year Breast Cancer Risk Model in Predicting DCIS and Invasive Breast Cancer

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S406B

Wendy B. Demartini, MD (*Presenter*) Advisory Board, Kheiron Medical Technologies Ltd

#### PURPOSE

To estimate the performance of a deep learning image-based five-year breast cancer risk model in patients who develop DCIS vs. invasive breast cancer within five years of screening mammography.

#### METHODS AND MATERIALS

This retrospective, multicenter international study included 31,016 consecutive bilateral 2D full field digital screening mammograms from a U.S. screening center and 10,673 from a European screening center from January 2011 through December 2016. These exams were not part of model training. Cancer outcomes and type (pure DCIS vs any invasive breast cancer) were obtained from local tumor registries. Cancer rates were defined as total cancers diagnosed after the index mammogram/total exams and were calculated for DCIS (excluding invasive cancer cases) and invasive cancers (excluding pure DCIS cases). Model performance was compared using areas under the receiver operating characteristic curve (AUCs) ( $p < .05$ ) with 95% confidence intervals.

#### RESULTS

The U.S. center included 937 total cancers diagnosed post index mammogram, for a 3.0% cancer positive rate. Invasive cancers accounted for 60.5% (567) of total cancers; DCIS accounted for 31.4% (294); remaining 8.1% (75) were of unknown or ambiguous cancer type. The European center included 250 total five-year cancers representing a 2.3% cancer positive rate. Invasive cancers accounted for 74.4% (186) of total cancers; DCIS accounted for 22.8% (57); remaining 2.8% (7) were of unknown or ambiguous cancer type. AUC by breast cancer type: U.S. center invasive cancers 0.79 [95% CI 0.77, 0.81] ( $n = 30,646$ ) vs U.S. center DCIS 0.73 [95% CI 0.70, 0.76] ( $n = 30,373$ ) ( $p < .001$ ); European center invasive cancers 0.80 [95% CI 0.76, 0.83] ( $n = 10,609$ ) vs European center DCIS 0.75 [95% CI 0.68, 0.82] ( $n = 10,480$ ) ( $p = .253$ ).

#### CONCLUSION

The deep learning model performed consistently at or above 0.73 AUC for predicting invasive breast cancers and DCIS across multi-site centers in the U.S. and Europe. At the U.S center, predictive performance was higher for invasive cancer compared to that for DCIS.

#### CLINICAL RELEVANCE/APPLICATION

Deep-learning based five-year breast cancer risk prediction can effectively identify the risk of both invasive breast cancers and DCIS in U.S. and European screening programs.

### Beyond Mammographic Breast Density: Superior Performance of Image-Based DL Model to Predict Breast Cancer Risk

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S406B

Christiane K. Kuhl, MD, PhD (*Presenter*) Advisory Board, Guerbet SA; *Speaker*, Bracco Group; *Speaker*, Bayer AG

#### PURPOSE

To compare predictive performance of a new deep learning five-year breast cancer risk prediction model to mammographic breast density in identifying patients with a higher burden of cancer in screening programs in the U.S. and Europe.

#### METHODS AND MATERIALS

This retrospective, multicenter international study included 30,198 consecutive bilateral 2D full field digital screening mammograms from a U.S. screening center and 10,672 from a European screening center from January 2011 through December 2016. Breast density assessments (dense vs not dense) were extracted from electronic medical records. Cancer outcomes were obtained from local tumor registries. Cancers included DCIS and any invasive breast cancer. NCCN thresholds were used to categorize five-year risk predictions from the calibrated DL model as follows: average risk < 1.7%, intermediate risk > 1.7% and < 3.0%, and high risk > 3.0%. We used logistic regression to model the relationship (via Odds Ratios) between positive five-year cancer outcome and the explanatory variables of predicted risk category and breast density, with an interaction term between risk category and breast density, to determine if the relationship between risk category and cancer outcome differs between those with not dense and dense breasts. We also analyzed average marginal effect (AME) of risk level and breast density. Analyses used average risk as the reference for risk category and not dense as the reference for breast density.

#### RESULTS

The DL model consistently categorized exams with similar future cancer rates regardless of breast density. Odds ratios for predictors (n= 40,870): intermediate risk category 2.54 [95% CI 1.88-3.42] (p<.001); high risk category 9.60 [95% CI 7.65-12.17] (p<.001); dense breast tissue 1.16 [95% CI 0.88-1.54] (p=.301); intermediate risk category x dense breast tissue 0.93 [95% CI 0.62-1.38] (p=.703); high risk category x dense breast tissue 0.74 [95% CI 0.54-1.02] (p=.069). Average marginal effects (AME) analysis: intermediate risk category AME 2.43 [95% CI 1.99, 2.97] (p<.0001); high risk category AME 8.19 [95% CI 6.99, 9.61] (p<.0001); dense breast tissue AME 1.05 [95% CI 0.90, 1.24] (p=0.522).

#### CONCLUSION

A deep-learning based model using only mammography images to predict five-year breast cancer risk effectively differentiates risk across breast density categories. Breast density is an ineffective measure to identify patients with a higher cancer burden in a mammography screening program.

#### CLINICAL RELEVANCE/APPLICATION

An image based deep-learning model exceeds breast density in predicting future breast cancer risk and provides a more effective method to guide clinical decision making regarding supplemental imaging and risk reduction.

### External Evaluation of a Mammography-based Deep Learning Model for Breast Cancer Risk Prediction in a High-risk, Diverse Population

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S406B

Olasubomi J. Omoleye, MBBS (*Presenter*) Nothing to Disclose

#### PURPOSE

To externally evaluate a mammography-based deep learning (MG-DL) model, Mirai, for breast cancer (BC) risk prediction in a high-risk, diverse population; assess its predictive performance across BC subtypes; and compare its accuracy with breast density and final BI-RADS assessment categories.

#### METHODS AND MATERIALS

After excluding 169 exams with time-to-cancer <6 months, 6266 screening mammograms acquired from 2043 participants enrolled in a cancer risk clinic between 2006 and 2020 were retrospectively evaluated in this case-control study. Pathologically confirmed invasive carcinoma or ductal carcinoma in situ (DCIS) of the breast was the primary outcome. MG-DL risk scores were primary predictors. Breast density and final BI-RADS assessment were comparative predictors.

#### RESULTS

The mean age at mammography was 56.4 (SD: 11.2) years. 910 participants (44.5%) were African American (AA) and 853 (41.8%) White. 15.3% had a known family history of BC, 30.5% had a history of benign breast disease (BBD), and 4.8% were known carriers of BC-predisposing gene mutations. Mirai had one- and five-year areas under the receiver operating characteristic curve (AUC) of 0.71 [95% CI: 0.68-0.74] and 0.65 [0.64-0.67] respectively. Mirai showed better near-term accuracy in non-dense vs dense breasts: 1-year AUC 0.72 [0.63-0.81] vs 0.58 [0.45-0.72], although this was not statistically significant ( $p = 0.10$ ). Mirai and BI-RADS assessment 1-year AUCs were not significantly different: 0.68 [0.61-0.75] and 0.73 [0.66-0.79] respectively,  $p = 0.34$ . However, for 2-5-year prediction, Mirai outperformed BI-RADS (5-year AUC 0.63 vs 0.54; all  $p = 0.0016$ ). Mirai also outperformed both visually assessed and AI-generated breast density categories at all time points (5-year AUC 0.62 vs 0.48 vs 0.52; all  $p < 0.0001$ ). The MG-DL model showed higher discrimination for low- and intermediate- vs high-grade cancers (5-year AUCs 0.63 [0.57-0.70] and 0.63 [0.61-0.67] vs 0.58 [0.54-0.62],  $p < 0.05$ ). In image-mirroring experiments, utilizing only images of the future-unaffected breast as model input led to significantly lower performance of the MG-DL model, suggesting that its predictions were probably based on the detection of ipsilateral premalignant patterns.

#### CONCLUSION

We evaluated an MG-DL model in a high-risk population and suggested that an important driver of its performance may be the detection of premalignant mammographic features. Our results support further examination of MG-DL models for BC risk prediction in high-risk, diverse groups.

#### CLINICAL RELEVANCE/APPLICATION

Externally evaluating MG-DL models in high-risk, diverse groups who stand to benefit the most from more accurate risk prediction is pertinent to inform further testing in prospective BC interception trials.

### Screening Mammography: Can a Deep Learning Model Support Expanded Screening of Patients in Their 40s

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S406B

Ray C. Mayo III, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

There is international consensus on the importance of screening patients in their 50s and 60s, but wide variation in recommendations for screening patients in their 40s. We measured the potential contribution of an image-based deep learning model to identify patients 40-49 at five-year breast cancer risk similar to that of patients aged 50-69.

#### METHODS AND MATERIALS

This retrospective study included 30,212 consecutive bilateral 2D full field digital screening mammograms from January 2011 through December 2016 from six facilities at a U.S. screening program. Patient demographics were extracted from electronic medical records and cancer outcomes obtained from local tumor registries. Age categories included 40-49, 50-69, and >70. Cancer positive exams were defined as exams with breast cancer diagnosed following the mammogram. Five-year calibrated risk predictions from the DL model were used to group exams as average (<1.7%), intermediate (> 1.7%) and high (> 3.0%) risk based on NCCN thresholds. We estimated the percents of exams for each threshold by age group and compared observed cancer rates (cancer positive exams/all exams) across risk and age groups. Chi-squared tests were used to measure statistical differences across independent risk and age groups.

#### RESULTS

Across all ages, cancer rates were 1.0%, 5.0% and 7.0% for average, intermediate and high-risk groups (n=30,212, Chi-squared 691.50, p<.0001). Cancer rates increased with each age group: 1.6% (40-49), 3.2% (50-69), and 6.0% (>70) (n=30,212, Chi-squared 149.91, p<.0001). Within each age group, DL risk score thresholds distinguished exams in patients with lower and higher cancer rates. For patients in their 40s, cancer rates were 0.7%, 3.3% and 5.1% in average, intermediate and high-risk subgroups (n=8,208, Chi-squared 126.99, p<.0001). 37% of exams for patients in their 40s were identified as intermediate risk, with a five-year cancer rate of 3.3%, compared to a similar cancer rate of 3.2% for exams in patients 50-69. 16% of exams in patients in their 40s were identified as high risk, with a five-year cancer rate of 5.1%, compared to a similar cancer rate of 5.0% for patients aged 50-69 at intermediate risk.

#### CONCLUSION

A DL image-based risk model can identify significant numbers of patients in their 40s who have five-year future breast cancer risk similar to that in patients aged 50-69 in screening programs. A DL risk model can support more informed decision making for patients 40-49 and their providers regarding when to start screening.

#### CLINICAL RELEVANCE/APPLICATION

For programs that do not offer routine screening to patients aged 40-49 and for those with variable engagement of these patients in screening, a DL image-based model has the potential to support enhanced screening of this key age group.

### Preliminary Results of Implementing AI into Breast Cancer Screening in the Capital Region of Denmark

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S406B

Andreas D. Lauritzen, PhD (*Presenter*) (Former) Researcher, ScreenPoint Medical BV, NL Scientific Assistant at Gentofte Hospital, DK

#### PURPOSE

This study assessed the screening quality before and after AI was implemented in a population-based breast cancer screening program. Based on a large prior simulation study, an AI system supporting a stratified reading protocol and decision support was implemented into screening in the Capital Region of Denmark as of November 18th 2021.

#### METHODS AND MATERIALS

In the Capital Region of Denmark women aged 50-69 years are screened biennially. For women screened before AI implementation from October 1st 2020 to November 17th 2021, all screens were read independently by two breast radiologists. For women screened with AI from November 18th 2021 to December 31st 2022, all screens were assessed by the AI system Transpara (ScreenPoint Medical) producing an exam score from 1-10 reflecting the probability of breast cancer. Screens with an exam score =7 (=5 before May 3rd 2022) were read by AI and a single senior breast radiologist. The remaining women were read by two radiologists with access to decision support with markings by the AI system. Screen detected breast cancers (invasive or DCIS) were histologically confirmed. Screening quality was measured using recall rate, cancer detection rate (CDR), rate of invasive cancers, rate of small cancers (=1cm), rate of node-negative cancers, and false-positive (FP) rate. For CDR and FP rate, women screened after October 1st 2022, were excluded to allow for 90 days of follow up. For rates of invasive, small, and node-negative cancers, women screened after July 3rd 2022 were excluded to have 180 days of follow up. Outcomes were compared before and after AI (jointly for both exam score thresholds) using the Chi2 test. We further measured the reading workload reduction.

#### RESULTS

59,573 women were screened before AI and 74,596 women with AI. The recall rate decreased from 3.10% to 2.42% ( $P < .001$ ) in screening with AI. CDR increased from 0.69% to 0.83% ( $P < .01$ ). Rate of invasive cancers decreased from 84.8% to 79.9% but not significantly ( $P = .10$ ). Rate of small cancers increased from 38.9% to 48.0% ( $P = .04$ ). Rate of node-negative cancers increased from 76.7% to 80.9%, but not significantly ( $P = .30$ ). FP rate decreased from 2.41% to 1.66% ( $P < .001$ ). Reading workload was reduced by 34.2%.

#### CONCLUSION

Screening with AI in the Capital Region of Denmark increased CDR while the recall and FP rates decreased. Small invasive cancers were more often diagnosed. Rates of invasive and node-negative cancers did not significantly change. Our findings suggest that AI improved screening quality while considerably reducing radiologists' workload.

#### CLINICAL RELEVANCE/APPLICATION

Screening with AI safely reduced both reading and clinical workload, and results indicated that invasive cancers were more frequently diagnosed while small, suggesting earlier detection.

### Science Session with Keynote: Cardiac Imaging (Workflow and Economics)

Wednesday, Nov. 29 3:00PM - 4:00PM Room: N226

Karen G. Ordovas, MD, MS (*Moderator*) Nothing to Disclose

Bradley D. Allen, MD, MS (*Moderator*) Consultant, Circle Cardiovascular Imaging Inc; Speaker, WebMD LLC

#### Sub-Events

#### W7-SSCA08-1 Trends in Medicare Utilization of Cardiac CT

Mustafa Al-Ogaili, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate provider and geographical distribution of Cardiac CT scans among the Medicare population between Radiologists and Cardiologists.

#### METHODS AND MATERIALS

All cardiac CT CPT codes were extracted from the Part B POSPUF database for the years 2013-2020. Volumes are presented by practice setting and provider type. Practice settings include facility (hospital based) and non-facility (offices). Provider types include "cardiologists" for cardiologists and electrophysiologists, "radiologists" for diagnostic and interventional radiologists, and "other" for the remaining. Market share was calculated as the % of total volumes interpreted by each provider type.

#### RESULTS

38,806 cardiac CT exams were performed in 2013, and 112,909 (+190.6%) in 2020. The cardiac CT exam utilization rate increased from 1.1/1,000 Medicare enrollees in 2013 to 3.2 (+190.9%) in 2020. In 2013, cardiologists interpreted 19,913 (49.2% market share) exams, followed by radiologists 17,306 (42.8%). In 2020, radiologists interpreted 69,552 (58.4%), followed by cardiology 44,165 (37.1%). In the facility (hospital) practice setting, 20,189 cardiac CT exams were performed in 2013, to 71,733 (+ 255.3%) in 2020. In 2013, radiologists interpreted 11,334 (52.0%) facility based exams, and cardiologists 9,332 (48%). In 2020, radiologists interpreted 44,867 (58.3%) facility based exams, and cardiologists 28,905 (41.7%). In the non-facility (office) practice setting, 18,617 cardiac CT exams were performed in 2013, to 41,176 (+121.2%) in 2020. In 2013, cardiologists interpreted 10,591 (56.8%) facility based exams, and radiologists 5,972 (32.0%). In 2020, radiologists interpreted 24,685 (58.6%) non-facility based exams, and cardiologists 15,260 (41.4%).

#### CONCLUSION

Cardiac CT utilization in the Medicare population has increased significantly in the last decade. In 2013, cardiologists interpreted the majority (49.2%) of these studies, and in 2020 radiologists interpreted the most (58.4%). The rate of growth of cardiac CT may have exceeded the capacity of cardiologists to interpret and radiologists likely developed increased capabilities to provide these services, especially in non-facility settings. Given the dramatic increases in utilization, further research is advised to ensure the appropriate use of limited imaging resources.

#### CLINICAL RELEVANCE/APPLICATION

Use of cardiac CT has increased, with radiologists increasing their market share of these studies in all practice settings.

#### W7-SSCA08-2 Trends in Medicare Utilization of Cardiac MRI

Zahra Beizavi, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate provider and geographical distribution of Cardiac MRI interpretation among the Medicare population between Radiologists and Cardiologists

## METHODS AND MATERIALS

All "Cardiac MRI" CPT codes as classified by the NITOS system (a validated imaging CPT classification tool) were extracted from the Part B POSPUF database for the years 2013-2019. Interpreting providers were grouped into three, "Cardiology" for Cardiology of Electrophysiology; "Radiology" for both diagnostic and interventional, and "Other" for the remaining. Place of service was analyzed. A dichotomy between non-facility ("O") and facility ("F") charges which can be interpreted to mean hospital vs private office. Not only were absolute volumes of exams were analyzed but market share (% of total volumes) of Cardiac MRI interpretation was also analyzed between the three provider types and the place of service distinctions.

## RESULTS

13354 cardiac MRI exams were performed in 2013, and 31662 (+57.8%) in 2020. The cardiac MRI exam utilization rate increased from 3.6/10,000 Medicare enrollees in 2013 to 8.4 (+133.3%) in 2020. In 2013, cardiologists interpreted 7817 (58.5% market share) exams, followed by radiologists 4719 (35.3%). In 2020, radiologists interpreted 11422 (36.1%), followed by cardiology 18270 (57.7%). In the facility (hospital) practice setting, 10611 cardiac MRI exams were performed in 2013, to 27072 (+155.1%) in 2020. In 2013, radiologists interpreted 3600 (33.9%) facility based exams, and cardiologists 6272 (59.1%). In 2020, radiologists interpreted 9353 (34.5%) facility based exams, and cardiologists 16318 (60.3%). In the non-facility (office) practice setting, 2743 cardiac MRI exams were performed in 2013, to 4590 (+67.3%) in 2020. In 2013, cardiologists interpreted 1545 (56.3%) non-facility based exams, and radiologists 1119 (40.7%). In 2020, radiologists interpreted 2069 (45.1%) non-facility based exams, and cardiologists 1952 (42.5%).

## CONCLUSION

Nationally, the number of Cardiac MRI examinations increased annually. Cardiology consistently performed the majority of exams from 2013 to 2020.

Within the facility setting, Cardiology consistently had the majority of and increased their market share of Cardiac MRI interpretation. In the non-facility setting, Radiology had the minority of market share but overtook Cardiology from 2013-2014 and had the majority in 2020.

## CLINICAL RELEVANCE/APPLICATION

Use of cardiac MRI has increased, with radiologists increasing their market share of these studies in all practice settings.

## W7-SSCA08-3 Impact of AI Assistance on Reader Accuracy and Agreement of Plaque Assessment in Coronary Computed Tomography Angiography

Roberto Fari (*Presenter*) Nothing to Disclose

## PURPOSE

This study aims to investigate the impact of AI assistance on plaque evaluation using coronary computed tomography angiography (CCTA). For clinical implementation, inter-observer variability and diagnostic accuracy of plaque assessment without and with AI assistance is essential.

## METHODS AND MATERIALS

We included CCTA images from ten patients with suspected CAD, each divided into 17 cardiac segments resulting in 170 segments for analysis. For the reference standard, three experts independently interpreted the images per segment unaided. The majority vote was used to determine the reference standard; when no majority was reached a conflict read was performed. Three independent study readers interpreted and scored the images, providing a CAD-RADS score for each segment in two reading sessions: with and without AI assist, with a minimum of 4 weeks apart. The AI system utilized in this study was based on a deep learning algorithm specifically designed for lesion detection and quantification. Data were analysed on inter-observer agreement between study readers and on categorical CAD-RADS agreement compared to the reference standard, with and without AI assistance.

## RESULTS

Unaided readers agreed with each other about CAD-RADS in 83.7% of segments (142). When using AI assistance, the inter-reader agreement increased to 91.4% (155) ( $p=0.019$ ). When agreement is relaxed to a difference in CAD-RADS  $<1$ , unaided readers agreed with each other in 96.7% of segments, while using AI assistance significantly improved this agreement to 99.6% ( $p=0.016$ ). When considering only segments with CAD, the unaided readers agreed with each other about the CAD-RADS in 79.8% of segments, the use of AI improved this agreement to 89.3% ( $p=0.018$ ). Compared with the reference standard, unaided readers reported the correct CAD-RADS grade in 80.1% of segments, under-reported the grade by 1 in 6.3% of segments, over-reported the grade by 1 in 10.0% of segments, and had a more serious reporting inaccuracy ( $>1$  grade) in 3.6% of segments. When using AI assistance, readers reported the correct CAD-RADS grade in 83.1% of segments, under-reported the grade by 1 in 7.3% of segments, over-reported the grade by 1 in 7.3% of segments, and had a more serious reporting inaccuracy ( $>1$  grade) in 2.2% of segments.

## CONCLUSION

In this study, AI assistance has shown to significantly reduce inter-observer variability and improve the accuracy in plaque assessment when using CCTA, suggesting its potential as a valuable tool in clinical practice.

## CLINICAL RELEVANCE/APPLICATION

Implementation of AI assistance into clinical workflow significantly improved inter-reader agreement and accuracy in CCTA plaque detection and assessment. This single-centre data can serve as pilot data for a larger multi-centre study.

### W7-SSCA08-4 **Cardiac MRI Dataset Balancing using Atlas Deformations and Style Transfer**

Carles Garcia-Cabrera, BEng, MEng (*Presenter*) Nothing to Disclose

#### PURPOSE

The integration of machine learning algorithms into the analysis of Cardiac Magnetic Resonance Imaging (CMR) images holds immense promise in supporting diagnostic and treatment planning activities. However, the effectiveness of these methods is contingent on access to high quality training data, which can be problematic to obtain given the restricted availability of well-balanced datasets. In this work, we explore the problem of dataset balancing in the context of semantic segmentation for CMR. We investigated the effectiveness of synthetic dataset balancing on scans with pathologies that are unseen to the model. In particular, we made efforts on Hypertrophic Cardiomyopathies (HCM) and Dilated Right Ventricle (DRV).

#### METHODS AND MATERIALS

For this study, we trained our model on data from the MMs2 challenge, including 7 pathologies. For the training of our model, we employed just the 40 healthy subjects of MMs2. To complement this data, we added the data from a public atlas, 20 atlas deformations simulating hearts with HCM, and 20 with DRV. The addition involved deforming and slicing the atlas and then performing image-to-image style transfer, which consisted of a machine learning network that preserves the spatial consistency of the image while importing the style of a CMR image to the sliced atlas. The segmentation was performed with a standard U-Net network.

#### RESULTS

The proposed method involving adding deformations from the atlas and performing an image-to-image style transfer resulted in a significant improvement in the segmentation of myocardium, with up to a 4.63% increase in accuracy compared to the baseline method that did not use deformations. The proposed method also showed a mean improvement of 2.29% in all tissues of subjects with DRV. The proposed method outperformed the baseline method by 1.15% in the entire test set, consisting of 160 subjects, achieving a mean DICE score of 0.793.

## CONCLUSION

Incorporating deformations from a healthy atlas, which simulated morphologies from pathology datasets, improved the accuracy of automated tools that assist clinicians in diagnostics. This has the potential to expedite and facilitate the identification of pathologies, particularly in patient cohorts that are not included in the original dataset.

## CLINICAL RELEVANCE/APPLICATION

Accurate segmentation of cardiac tissues is essential for reliable Ejection Fraction calculation, improving automated tools, reducing diagnostic times, and easing the burden on healthcare professionals. Synthetic dataset balancing could lead to the development of tools that maintain performance across the diverse range of subjects in society, improving patient outcomes, increasing clinical workflow efficiency, and alleviating the strain on healthcare systems.

### W7-SSCA08-5 **Development of Artificial Intelligence-Based Approach for Automatic Classification of Cardiovascular Disease using Late Gadolinium Enhancement Imaging**

Youngjoong Yang, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Late gadolinium enhancement (LGE) sequence is helpful for classifying and diagnosing various cardiovascular diseases using cardiac magnetic resonance imaging. Many studies have been incorporating artificial intelligence (AI) technology to enhance the usefulness and convenience of LGE-based diagnosis. We propose an AI-based approach in automatically classifying three kinds of non-ischemic cardiomyopathy and normal controls using LGE images.

#### METHODS AND MATERIALS

A total of 79 MRI studies were retrospectively collected, consisting of normal (n=20), hypertrophic cardiomyopathy [HCM] (n=20), dilated cardiomyopathy [DCM] (n=19), and cardiac amyloidosis [CA] (n=20). Three types of LGE images (2-chamber, 4-chamber, and short-axis series) were used for disease classification. 2-chamber and 4-chamber are single-slice, while short-axis is multi-slice. The collected data is validated by a cardiac specialist and labeled into 4 categories. The training and test data were divided in a ratio of 9:1. 2D convolutional neural network models were developed to classify the LGE

images and a separate model was created for the three types of images. The input was preprocessed with image processing technique such as cropping, normalization, and histogram equalization. We utilized the VGG16 models as the backbone network and added convolution and fully connected layers to generate an output. Additionally, heatmap was extracted from global averaging layer and overlaid to visualize the part of LGE image that contributed the most to the classification. Each model predicted whether the LGE image was to represent normal, HCM, DCM, or CA, and the final decision was determined by a decision algorithm that integrated the predictions of three models.

## **RESULTS**

The test data was randomly selected with 2 cases from each of the 4 categories. In the test, the DL models using the 2-chamber and 4-chamber images predicted disease category with an accuracy of 100% for each and the model using short-axis images showed an accuracy of 95.9%. Among the short-axis images in 49 slices, there were two cases of misclassification, with normal being predicted as DCM and normal being predicted as HCM, respectively. The final diagnosis determined by the integrated algorithm correctly identified all test cases.

## **CONCLUSION**

Our method shows a high accuracy for the classification of cardiovascular disease on LGE images.

## **CLINICAL RELEVANCE/APPLICATION**

Our AI-based approach may contribute to LGE-based automatic classification of cardiovascular diseases, if additional researches with larger subjects and external validation can address the issue of a high dependency on the dataset.

The addition involved deforming and slicing the atlas and then performing image-to-image style transfer, which consisted of a machine learning network that preserves the spatial consistency of the image while importing the style of a CMR image to the sliced atlas. The segmentation was performed with a standard U-Net network.

#### RESULTS

The proposed method involving adding deformations from the atlas and performing an image-to-image style transfer resulted in a significant improvement in the segmentation of myocardium, with up to a 4.63% increase in accuracy compared to the baseline method that did not use deformations. The proposed method also showed a mean improvement of 2.29% in all tissues of subjects with DRV. The proposed method outperformed the baseline method by 1.15% in the entire test set, consisting of 160 subjects, achieving a mean DICE score of 0.793.

#### CONCLUSION

Incorporating deformations from a healthy atlas, which simulated morphologies from pathology datasets, improved the accuracy of automated tools that assist clinicians in diagnostics. This has the potential to expedite and facilitate the identification of pathologies, particularly in patient cohorts that are not included in the original dataset.

#### CLINICAL RELEVANCE/APPLICATION

Accurate segmentation of cardiac tissues is essential for reliable Ejection Fraction calculation, improving automated tools, reducing diagnostic times, and easing the burden on healthcare professionals. Synthetic dataset balancing could lead to the development of tools that maintain performance across the diverse range of subjects in society, improving patient outcomes, increasing clinical workflow efficiency, and alleviating the strain on healthcare systems.

### Development of Artificial Intelligence-Based Approach for Automatic Classification of Cardiovascular Disease using Late Gadolinium Enhancement Imaging

Wednesday, Nov. 29 3:00PM - 4:00PM Room: N226

Youngjoong Yang, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Late gadolinium enhancement (LGE) sequence is helpful for classifying and diagnosing various cardiovascular diseases using cardiac magnetic resonance imaging. Many studies have been incorporating artificial intelligence (AI) technology to enhance the usefulness and convenience of LGE-based diagnosis. We propose an AI-based approach in automatically classifying three kinds of non-ischemic cardiomyopathy and normal controls using LGE images.

#### METHODS AND MATERIALS

A total of 79 MRI studies were retrospectively collected, consisting of normal (n=20), hypertrophic cardiomyopathy [HCM] (n=20), dilated cardiomyopathy [DCM] (n=19), and cardiac amyloidosis [CA] (n=20). Three types of LGE images (2-chamber, 4-chamber, and short-axis series) were used for disease classification. 2-chamber and 4-chamber are single-slice, while short-axis is multi-slice. The collected data is validated by a cardiac specialist and labeled into 4 categories. The training and test data were divided in a ratio of 9:1. 2D convolutional neural network models were developed to classify the LGE images and a separate model was created for the three types of images. The input was preprocessed with image processing technique such as cropping, normalization, and histogram equalization. We utilized the VGG16 models as the backbone network and added convolution and fully connected layers to generate an output. Additionally, heatmap was extracted from global averaging layer and overlaid to visualize the part of LGE image that contributed the most to the classification. Each model predicted whether the LGE image was to represent normal, HCM, DCM, or CA, and the final decision was determined by a decision algorithm that integrated the predictions of three models.

#### RESULTS

The test data was randomly selected with 2 cases from each of the 4 categories. In the test, the DL models using the 2-chamber and 4-chamber images predicted disease category with an accuracy of 100% for each and the model using short-axis images showed an accuracy of 95.9%. Among the short-axis images in 49 slices, there were two cases of misclassification, with normal being predicted as DCM and normal being predicted as HCM, respectively. The final diagnosis determined by the integrated algorithm correctly identified all test cases.

#### CONCLUSION

Our method shows a high accuracy for the classification of cardiovascular disease on LGE images.

#### CLINICAL RELEVANCE/APPLICATION

Our AI-based approach may contribute to LGE-based automatic classification of cardiovascular diseases, if additional researches with larger subjects and external validation can address the issue of a high dependency on the dataset.

#### **W7-SSCH08-1 Improved Pulmonary Arterial Evaluation using Photon-counting High-Pitch Multi-energy Pulmonary CTA Compared to Energy-Integrating Detector Single-energy High Pitch and Dual-energy Pulmonary CTA**

Mariana Yalon, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare image quality, iodine signal, and radiation dose of pulmonary CTA acquired to detect pulmonary embolism (PE) using photon-counting-detector CT (PCD CT) at high pitch multi-energy scanning mode (ME FLASH) compared to conventional dual-source energy-integrating-detector (EID) CT using either single-energy high pitch acquisition (SE FLASH) or dual-energy (DE) with routine pitch.

#### METHODS AND MATERIALS

This retrospective, case-control study consisted of 150 clinical pulmonary CTA exams (50 PCD ME FLASH; 50 EID FLASH; and 50 EID DE). Cases were matched by patient weight. CT number and noise measurements were measured from the main to segmental pulmonary arteries using 120 kV threshold low, 120 kV, and mixed kV images, respectively. Three readers independently reviewed anonymized, randomized exams, rating each case, using a 4-point Likert scale (1 = worst, and 4 = best) for: contrast enhancement in pulmonary arteries; motion artifacts in aorta, coronary, and lobar to subsegmental pulmonary arteries; lung image quality; pulmonary blood volume (PBV) map quality and contribution to reader confidence in diagnosis.

#### RESULTS

150 patients underwent PCD ME FLASH (n=50; mean wt. 93 kg; mean contrast 82.6 ± 3.0 cc), EID SE FLASH (n=50; mean wt. 88.6 kg; mean contrast 91.2 ± 1.7 cc), or EID DE (n=50; mean wt. 86 kg; mean contrast 75 ± 3.0 cc). For all readers, when comparing PCD to EID SE FLASH and EID DE, contrast enhancement in the pulmonary arteries was rated slightly but significantly higher at PCD (4.6 ± 0.6 vs 4.4 ± 0.7 vs 4.3 ± 0.7; p < 0.001), as was lung image quality (3.3 ± 0.5 vs 3.1 ± 0.5 vs 3.2 ± 0.6; p = 0.017). PCD ME FLASH had significantly fewer motion artifacts in the aortic root and coronary arteries (3.4 ± 0.7 vs 3.0 ± 1.0 vs 3.1 ± 0.8; p = 0.002), central to segmental pulmonary arteries (p < 0.004), and peripherally (3.9 ± 0.3 vs 3.7 ± 0.5 vs 3.7 ± 0.4; p = 0.002). PCD PBV maps had similar quality (3.1 ± 0.7 vs 3.1 ± 0.5) and contribution to reader confidence (1.3 ± 0.5 vs 1.3 ± 0.6) as EID DE. CT numbers in pulmonary arteries were significantly greater at PCD (p < 0.001 for all comparisons). PCD ME FLASH had significantly lower radiation dose (CTDIvol: 8.1 ± 2.5 vs 16.2 ± 8.5 vs 9.6 ± 6.8 mGy; p < 0.001).

#### CONCLUSION

PCD-CT ME FLASH demonstrated higher contrast enhancement in pulmonary arteries with fewer motion artifacts and improved lung image quality compared to EID DE and EID SE FLASH modes at lower radiation and contrast doses.

#### CLINICAL RELEVANCE/APPLICATION

High pitch multi-energy PCD CT can lower radiation dose while increasing iodine signal and decreasing motion artifacts for pulmonary CTA exams.

## **W7-SSCH08-2 Photon-Counting Detector CT Pulmonary Angiography for Diagnosis of Acute Pulmonary Embolism: Evaluation of Image Quality and Iodine-Distribution Maps**

Pauline Pannenbecker, MD, BA (*Presenter*) Nothing to Disclose

### **PURPOSE**

To assess objective and subjective image quality of morphologic images and associated color-coded iodine-distribution maps, as well as radiation dose of CT pulmonary angiography (CTPA) with clinical photon-counting detector CT (PCD CT) compared to standard energy-integrating detector (EID) CTPA.

### **METHODS AND MATERIALS**

120 participants receiving CTPA for suspected pulmonary embolism (PE) were prospectively enrolled into this randomized IRB-approved study. After exclusion of three participants the final collective consisted of 117 participants. Of those, 58 received CTPA on a 1st generation PCD CT scanner (Siemens Naeotom Alpha) and 59 on a 3rd generation EID CT scanner (Siemens Somatom Force). CTPA scans were performed with matched scan protocols (50 ml contrast medium, flow rate 4 ml/sec) at 120 kV (PCD) resp. 90/ Sn150 kV (EID). For PCD pitch was set at 2.0, in case of EID pitch is technically limited to 0.55 in Dual-Energy mode. Pulmonary artery CT attenuation, signal-to-noise ratio (SNR), and contrast-to-noise-ratio (CNR) were assessed as objective criteria of CTPA image quality. Perfused blood volume (PBV) values were recorded for objective image quality assessment of color-coded iodine-distribution maps. Subjective ratings of image quality were obtained by three readers (four-point scale) and were compared for morphologic images (at polychromatic standard reconstructions and at 60 keV using virtual monoenergetic imaging and ) and color-coded iodine-distribution maps. Radiation dose parameters (CTDIvol, dose length product, size specific dose estimate, effective dose [ED]) were compared between both cohorts.

### **RESULTS**

CNR and SNR within evaluated pulmonary vessels were higher in the PCD group (for 60 keV and polychromatic images respectively, all  $p < 0.05$ ). CT attenuation values and PBV values of iodine-maps were similar in both groups ( $p > 0.05$ ). Regarding subjective image quality, two of three readers preferred morphologic images obtained with PCD ( $p < 0.05$ ). For iodine maps, no significant differences were ascertained between PCD and EID ( $p > 0.05$ ). All assessed radiation dose parameters favored the PCD group (ED 2.2 [interquartile range 1.0] mSv vs. 2.8 [1.1] mSv; all  $p < 0.05$ ).

### **CONCLUSION**

With comparable input parameters, PCD CTPA provides higher subjective and objective image quality with regards to morphologic images, equal image quality of iodine-maps as well as reduced radiation dose compared to conventional dual-energy pulmonary angiography with EID technology.

### **CLINICAL RELEVANCE/APPLICATION**

PCD CT allows for spectral assessment of pulmonary vessels and parenchyma with excellent image quality at high pitch settings, which is especially beneficial in patients with suspected PE who frequently present with dyspnea.

## **W7-SSCH08-3 Chest CTA Imaging with Photon-counting CT: Comparison of Image Quality with Energy-Integrating-Detector (EID) CT in 142 Patients**

Martine J. Remy-Jardin, MD, PhD (*Presenter*) Research Grant, Siemens AG; Speaker, Siemens AG

### **PURPOSE**

To compare the overall image quality of chest CT angiographic (CTA) examinations obtained with photon-counting-detector CT (PCD-CT) and energy-integrating-detector (EID-CT).

### **METHODS AND MATERIALS**

The study population included 71 consecutive patients (Group 1) with no infiltrative or destructive lung disease who had been referred for chest CTA obtained with PCD-CT (Naeotom Alpha; Siemens Healthineers) using the multienergy mode (collimation: 144 x 0.4mm; 120 kVp; pitch: 1.5; IQ level: 80). A paired population of 71 patients (Group 2) with no infiltrative or destructive lung disease was retrospectively selected on the basis of (a) a similar injection protocol (60 mL of a 40% contrast agent; flow rate: 4 mL/s), comparable age ( $\pm 5$  years) and weight ( $\pm 5$  kg); and (b) a chest CTA obtained with a 3rd-generation dual-source CT equipment (Somatom Force; Siemens Healthineers) using a dual-energy mode (collimation: 64x0.6x2 mm; pitch: 0.55). Morphologic imaging consisted of contiguous 1-mm thick lung and mediastinal images (Group 1 : 70 keV images; Group 2 : averaged images from both tubes) using the same kernel (Br36) and comparable levels of iterative reconstruction (QIR 3; ADMIRE 3). Perfusion imaging was obtained by subtraction of low- and high monoenergetic images using the eXamine prototype.

## RESULTS

Compared to Group 2, Group 1 examinations showed : (a) a significantly lower DLP ( $172.6 \pm 55.1$  vs  $339.4 \pm 75.6$  mGy.cm;  $p < 0.0001$ ) corresponding to a 52% dose reduction, and shorter duration of data acquisition ( $0.93 \pm 0.1s$  vs  $3.98 \pm 0.35s$ ;  $p < 0.0001$ ); (b) no significant difference in the attenuation values within central pulmonary arteries ( $372.60 \pm 55.1$  HU vs  $420.0 \pm 131.3$  HU;  $p = 0.32$ ) and aorta ( $375.2 \pm 90.3$  HU vs  $394.7 \pm 92.3$  HU;  $p = 0.15$ ); (c) a higher level of objective image noise ( $9.55 \pm 1.8$  HU vs  $6.88 \pm 1.5$  HU;  $p < 0.0001$ ), lower SNR ( $43.1 \pm 17.9$  vs  $64.6 \pm 27.6$ ;  $p < 0.0001$ ) and CNR ( $37.3 \pm 17.4$  vs  $55.7 \pm 26.5$ ;  $p < 0.0001$ ). On perfusion images (a) the mean level of attenuation did not differ ( $p = 0.05$ ) nor did the rating of subjective image noise ( $p = 0.16$ ); (b) the distribution of scores of fissure visualization differed between the 2 groups ( $p < 0.0001$ ) with a higher proportion of fissures sharply delineated in Group 1 ( $n = 60$ ; 84.5% versus  $n = 26$ ; 26.6%); (c) the rating of cardiac motion artifacts significantly differed between the 2 groups ( $p < 0.0001$ ) with a higher percentage of mild artifacts in Group 1 ( $n = 69$ ; 97.2%) than in Group 2 ( $n = 19$ ; 26.8%).

## CONCLUSION

PCD-CT provided comparable morphologic image quality at 70 keV and superior perfusion imaging with a 52% dose reduction.

## CLINICAL RELEVANCE/APPLICATION

Spectral imaging with PCD-CT provides comparable image quality between 70 keV images and averaged images of DSCT with improved quality of perfusion imaging at lower radiation dose.

## W7-SSCH08-4 DECT Material Decomposition: The Value in Detection of Lymph Nodes Metastasis in Breast Cancer

Ibrahim Yel, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the diagnostic performance of a dual-energy computed tomography (DECT)-based technique using iodine quantification and fat fraction analysis for the detection of lymph node (LN) metastases in patients with breast cancer.

## METHODS AND MATERIALS

30 female patients (mean age,  $63.12 \pm 14.2$  years) with breast cancer who underwent pre-operative dual-energy chest CT were included. Histological report after LN excision served as the reference standard. Iodine concentration and fat fraction were determined by performing region-of-interest (ROI) measurements on venous DECT iodine maps. Receiver operating characteristic (ROC) curve analysis was performed to estimate the optimal threshold for discriminating between metastatic and non-metastatic LNs.

## RESULTS

A total of 214 lymph nodes were evaluated, divided into axillary (metastatic: 46, normal: 101), mediastinal (metastatic: 20, normal: 26), and intramammary (metastatic: 10, normal: 11). DECT-based fat fraction values showed significant differences between metastatic ( $10.8 \pm 6.2$  %) and non-metastatic LNs ( $38.8 \pm 17.7$  %) ( $p < 0.0001$ ). Absolute iodine concentrations showed no significant differences ( $2.3$  vs  $2.0$  mg/dl;  $p = 0.25$ ). The optimal fat fraction threshold for the diagnosis of metastatic LNs was 17.8 % with a sensitivity of 89% and specificity of 93%.

## CONCLUSION

DECT material decomposition fat fraction can identify metastatic LNs, overtaking the morpho-volumetric limitation of conventional CT in LN assessment.

## CLINICAL RELEVANCE/APPLICATION

Lymph node (LN) involvement is a crucial prognostic factor with a 40% reduction in 5-year survival rates for those with LN metastases. With the DECT fat fraction analysis, metastatic LN can be identified regardless of the morphological appearance and can be used as a diagnostic biomarker.

## W7-SSCH08-6 Optimal Monoenergetic Levels for Osteoporosis Screening in Photon Counting Detector CT: Preliminary In Vivo and Phantom Study

Fernando U. Kay, MD, PhD (*Presenter*) Research Grant, Edwards Lifesciences Corporation

## PURPOSE

Osteoporosis often goes undetected. Trabecular bone attenuation (TBA) measurements from routine chest CT can be utilized for opportunistic detection. While photon counting detector CT (PCD-CT) has benefits over energy integrating detector CT (EID-CT), optimal virtual monoenergetic (VMI) levels for PCD-CT compatibility with EID-CT thresholds are unclear. This study aims to identify the VMI keV levels on PCD-CT that best correspond to EID-CT for osteoporosis screening to maintain backward compatibility.

## **METHODS AND MATERIALS**

IRB-approved study with 30 patients (median age 63.5 years, range 30-82) who underwent both PCD-CT (Naetom Alpha, Siemens) and EID-CT (Aquilion, Toshiba) within a median interval of 102 days (range 55-371). All CTs were obtained at the late arterial phase post contrast. PCD-CT used 120 kVp, automated exposure control (AEC), 0.8 pitch, and 0.25 s rotation time. Diagnostic images had 2-mm thick slices at 60 keV (Br44 kernel, QIR 3). Additional reconstructions ranged from 60 to 75 keV at 1 keV intervals (Qr40f kernel, QIR 3) to identify the optimal keV levels. EID-CT employed 120 kVp, AEC, 0.8 pitch, and 0.50 s rotation time, with 2-mm thick reconstructions (FC18 kernel, standard AIDR). A radiologist measured TBA using a 1.0 cm<sup>2</sup> ROI at the anterior compartment of the trabecular bone at the same level (within T12/L1) on both CTs. Cases were excluded if visible metastatic disease was present. Phantom experiments followed the same scanning protocols, using a QRM chest phantom with Gammex Rods calcium concentrations of 20, 50, and 100 mg/mL.

## **RESULTS**

Mean phantom rods CT numbers on EID-CT were  $55.4 \pm 16.0$  (20 mg/mL),  $140.4 \pm 18.7$  (50 mg/mL), and  $308.5 \pm 17.1$  HU (100 mg/mL). 73 keV had a bias of  $0.8 \pm 2.3$  HU across all rods between PCD-CT and EID-CT, which was the smallest bias, while 71 keV bias was  $8.2 \pm 2.9$  HU. The CTD<sub>divol</sub> for PCD-CT and EID-CT were  $7.8 \pm 2.1$  and  $10.7 \pm 3.5$  mGy, respectively ( $p < 0.001$ ). TBA measurements at 60 keV were significantly higher than those obtained from EID-CT, with mean values of  $212.5 \pm 63.5$  versus  $159.9 \pm 44.5$  HU, respectively ( $p < 0.001$ ). Bone density at 71 keV was  $167.6 \pm 51.3$  HU and were most comparable to EID-CT ( $P = 0.07$ ), with a bias of  $0.7 \pm 11.5$  HU.

## **CONCLUSION**

Optimized energy levels for vascular assessment and soft tissue contrast may not align with EID-CT thresholds for detecting low bone mineral density. Our study recommends a 71-73 keV range for improved backward compatibility between PCD-CT and EID-CT.

## **CLINICAL RELEVANCE/APPLICATION**

This study establishes a benchmark for the ideal energy range in PCD-CT VMI reconstructions to maintain compatibility with EID-CT-based osteoporosis detection thresholds, laying the groundwork for future research on the benefits of this novel CT technology.

### Improved Pulmonary Arterial Evaluation using Photon-counting High-Pitch Multi-energy Pulmonary CTA Compared to Energy-Integrating Detector Single-energy High Pitch and Dual-energy Pulmonary CTA

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E350

Mariana Yalon, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare image quality, iodine signal, and radiation dose of pulmonary CTA acquired to detect pulmonary embolism (PE) using photon-counting-detector CT (PCD CT) at high pitch multi-energy scanning mode (ME FLASH) compared to conventional dual-source energy-integrating-detector (EID) CT using either single-energy high pitch acquisition (SE FLASH) or dual-energy (DE) with routine pitch.

#### METHODS AND MATERIALS

This retrospective, case-control study consisted of 150 clinical pulmonary CTA exams (50 PCD ME FLASH; 50 EID FLASH; and 50 EID DE). Cases were matched by patient weight. CT number and noise measurements were measured from the main to segmental pulmonary arteries using 120 kV threshold low, 120 kV, and mixed kV images, respectively. Three readers independently reviewed anonymized, randomized exams, rating each case, using a 4-point Likert scale (1 = worst, and 4 = best) for: contrast enhancement in pulmonary arteries; motion artifacts in aorta, coronary, and lobar to subsegmental pulmonary arteries; lung image quality; pulmonary blood volume (PBV) map quality and contribution to reader confidence in diagnosis.

#### RESULTS

150 patients underwent PCD ME FLASH (n=50; mean wt. 93 kg; mean contrast 82.6 ± 3.0 cc), EID SE FLASH (n=50; mean wt. 88.6 kg; mean contrast 91.2 ± 1.7 cc), or EID DE (n=50; mean wt. 86 kg; mean contrast 75 ± 3.0 cc). For all readers, when comparing PCD to EID SE FLASH and EID DE, contrast enhancement in the pulmonary arteries was rated slightly but significantly higher at PCD (4.6 ± 0.6 vs 4.4 ± 0.7 vs 4.3 ± 0.7; p < 0.001), as was lung image quality (3.3 ± 0.5 vs 3.1 ± 0.5 vs 3.2 ± 0.6; p = 0.017). PCD ME FLASH had significantly fewer motion artifacts in the aortic root and coronary arteries (3.4 ± 0.7 vs 3.0 ± 1.0 vs 3.1 ± 0.8; p = 0.002), central to segmental pulmonary arteries (p < 0.004), and peripherally (3.9 ± 0.3 vs 3.7 ± 0.5 vs 3.7 ± 0.4; p = 0.002). PCD PBV maps had similar quality (3.1 ± 0.7 vs 3.1 ± 0.5) and contribution to reader confidence (1.3 ± 0.5 vs 1.3 ± 0.6) as EID DE. CT numbers in pulmonary arteries were significantly greater at PCD (p < 0.001 for all comparisons). PCD ME FLASH had significantly lower radiation dose (CTDIvol: 8.1 ± 2.5 vs 16.2 ± 8.5 vs 9.6 ± 6.8 mGy; p < 0.001).

#### CONCLUSION

PCD-CT ME FLASH demonstrated higher contrast enhancement in pulmonary arteries with fewer motion artifacts and improved lung image quality compared to EID DE and EID SE FLASH modes at lower radiation and contrast doses.

#### CLINICAL RELEVANCE/APPLICATION

High pitch multi-energy PCD CT can lower radiation dose while increasing iodine signal and decreasing motion artifacts for pulmonary CTA exams.

### Chest CTA Imaging with Photon-counting CT: Comparison of Image Quality with Energy-Integrating-Detector (EID) CT in 142 Patients

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E350

Martine J. Remy-Jardin, MD, PhD (*Presenter*) Research Grant, Siemens AG; Speaker, Siemens AG

#### PURPOSE

To compare the overall image quality of chest CT angiographic (CTA) examinations obtained with photon-counting-detector CT (PCD-CT) and energy-integrating-detector (EID-CT).

#### METHODS AND MATERIALS

The study population included 71 consecutive patients (Group 1) with no infiltrative or destructive lung disease who had been referred for chest CTA obtained with PCD-CT (Naeotom Alpha; Siemens Healthineers) using the multienergy mode (collimation: 144 x 0.4mm; 120 kVp; pitch: 1.5; IQ level: 80). A paired population of 71 patients (Group 2) with no infiltrative or destructive lung disease was retrospectively selected on the basis of (a) a similar injection protocol (60 mL of a 40% contrast agent; flow rate: 4 mL/s), comparable age ( $\pm 5$  years) and weight ( $\pm 5$  kg); and (b) a chest CTA obtained with a 3rd-generation dual-source CT equipment (Somatom Force; Siemens Healthineers) using a dual-energy mode (collimation: 64x0.6x2 mm; pitch: 0.55). Morphologic imaging consisted of contiguous 1-mm thick lung and mediastinal images (Group 1 : 70 keV images; Group 2 : averaged images from both tubes) using the same kernel (Br36) and comparable levels of iterative reconstruction (QIR 3; ADMIRE 3). Perfusion imaging was obtained by subtraction of low- and-high monoenergetic images using the eXamine prototype.

#### RESULTS

Compared to Group 2, Group 1 examinations showed : (a) a significantly lower DLP ( $172.6 \pm 55.1$  vs  $339.4 \pm 75.6$  mGy.cm;  $p < 0.0001$ ) corresponding to a 52% dose reduction, and shorter duration of data acquisition ( $0.93 \pm 0.1$ s vs  $3.98 \pm 0.35$ s;  $p < 0.0001$ ); (b) no significant difference in the attenuation values within central pulmonary arteries ( $372.60 \pm 55.1$  HU vs  $420.0 \pm 131.3$  HU;  $p = 0.32$ ) and aorta ( $375.2 \pm 90.3$  HU vs  $394.7 \pm 92.3$  HU;  $p = 0.15$ ); (c) a higher level of objective image noise ( $9.55 \pm 1.8$  HU vs  $6.88 \pm 1.5$  HU;  $p < 0.0001$ ), lower SNR ( $43.1 \pm 17.9$  vs  $64.6 \pm 27.6$ ;  $p < 0.0001$ ) and CNR ( $37.3 \pm 17.4$  vs  $55.7 \pm 26.5$ ;  $p < 0.0001$ ). On perfusion images (a) the mean level of attenuation did not differ ( $p = 0.05$ ) nor did the rating of subjective image noise ( $p = 0.16$ ); (b) the distribution of scores of fissure visualization differed between the 2 groups ( $p < 0.0001$ ) with a higher proportion of fissures sharply delineated in Group 1 ( $n = 60$ ; 84.5% versus  $n = 26$ ; 26.6%); (c) the rating of cardiac motion artifacts significantly differed between the 2 groups ( $p < 0.0001$ ) with a higher percentage of mild artifacts in Group 1 ( $n = 69$ ; 97.2%) than in Group 2 ( $n = 19$ ; 26.8%).

#### CONCLUSION

PCD-CT provided comparable morphologic image quality at 70 keV and superior perfusion imaging with a 52% dose reduction.

#### CLINICAL RELEVANCE/APPLICATION

Spectral imaging with PCD-CT provides comparable image quality between 70 keV images and averaged images of DSCT with improved quality of perfusion imaging at lower radiation dose.

### DECT Material Decomposition: The Value in Detection of Lymph Nodes Metastasis in Breast Cancer

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E350

Ibrahim Yel, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the diagnostic performance of a dual-energy computed tomography (DECT)-based technique using iodine quantification and fat fraction analysis for the detection of lymph node (LN) metastases in patients with breast cancer.

#### METHODS AND MATERIALS

30 female patients (mean age,  $63.12 \pm 14.2$  years) with breast cancer who underwent pre-operative dual-energy chest CT were included. Histological report after LN excision served as the reference standard. Iodine concentration and fat fraction were determined by performing region-of-interest (ROI) measurements on venous DECT iodine maps. Receiver operating characteristic (ROC) curve analysis was performed to estimate the optimal threshold for discriminating between metastatic and non-metastatic LNs.

#### RESULTS

A total of 214 lymph nodes were evaluated, divided into axillary (metastatic: 46, normal: 101), mediastinal (metastatic: 20, normal: 26), and intramammary (metastatic: 10, normal: 11). DECT-based fat fraction values showed significant differences between metastatic ( $10.8 \pm 6.2$  %) and non-metastatic LNs ( $38.8 \pm 17.7$  %) ( $p < 0.0001$ ). Absolute iodine concentrations showed no significant differences (2.3 vs 2.0 mg/dl;  $p = 0.25$ ). The optimal fat fraction threshold for the diagnosis of metastatic LNs was 17.8 % with a sensitivity of 89% and specificity of 93%.

#### CONCLUSION

DECT material decomposition fat fraction can identify metastatic LNs, overtaking the morpho-volumetric limitation of conventional CT in LN assessment.

#### CLINICAL RELEVANCE/APPLICATION

Lymph node (LN) involvement is a crucial prognostic factor with a 40% reduction in 5-year survival rates for those with LN metastases. With the DECT fat fraction analysis, metastatic LN can be identified regardless of the morphological appearance and can be used as a diagnostic biomarker.

### Optimal Monoenergetic Levels for Osteoporosis Screening in Photon Counting Detector CT: Preliminary In Vivo and Phantom Study

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E350

Fernando U. Kay, MD, PhD (*Presenter*) Research Grant, Edwards Lifesciences Corporation

#### PURPOSE

Osteoporosis often goes undetected. Trabecular bone attenuation (TBA) measurements from routine chest CT can be utilized for opportunistic detection. While photon counting detector CT (PCD-CT) has benefits over energy integrating detector CT (EID-CT), optimal virtual monoenergetic (VMI) levels for PCD-CT compatibility with EID-CT thresholds are unclear. This study aims to identify the VMI keV levels on PCD-CT that best correspond to EID-CT for osteoporosis screening to maintain backward compatibility.

#### METHODS AND MATERIALS

IRB-approved study with 30 patients (median age 63.5 years, range 30-82) who underwent both PCD-CT (Naetom Alpha, Siemens) and EID-CT (Aquilion, Toshiba) within a median interval of 102 days (range 55-371). All CTs were obtained at the late arterial phase post contrast. PCD-CT used 120 kVp, automated exposure control (AEC), 0.8 pitch, and 0.25 s rotation time. Diagnostic images had 2-mm thick slices at 60 keV (Br44 kernel, QIR 3). Additional reconstructions ranged from 60 to 75 keV at 1 keV intervals (Qr40f kernel, QIR 3) to identify the optimal keV levels. EID-CT employed 120 kVp, AEC, 0.8 pitch, and 0.50 s rotation time, with 2-mm thick reconstructions (FC18 kernel, standard AIDR). A radiologist measured TBA using a 1.0 cm<sup>2</sup> ROI at the anterior compartment of the trabecular bone at the same level (within T12/L1) on both CTs. Cases were excluded if visible metastatic disease was present. Phantom experiments followed the same scanning protocols, using a QRM chest phantom with Gammex Rods calcium concentrations of 20, 50, and 100 mg/mL.

#### RESULTS

Mean phantom rods CT numbers on EID-CT were 55.4 ± 16.0 (20 mg/mL), 140.4 ± 18.7 (50 mg/mL), and 308.5 ± 17.1 HU (100 mg/mL). 73 keV had a bias of 0.8 ± 2.3 HU across all rods between PCD-CT and EID-CT, which was the smallest bias, while 71 keV bias was 8.2 ± 2.9 HU. The CTDIvol for PCD-CT and EID-CT were 7.8 ± 2.1 and 10.7 ± 3.5 mGy, respectively (p < 0.001). TBA measurements at 60 keV were significantly higher than those obtained from EID-CT, with mean values of 212.5 ± 63.5 versus 159.9 ± 44.5 HU, respectively (p < 0.001). Bone density at 71 keV was 167.6 ± 51.3 HU and were most comparable to EID-CT (P = 0.07), with a bias of 0.7 ± 11.5 HU.

#### CONCLUSION

Optimized energy levels for vascular assessment and soft tissue contrast may not align with EID-CT thresholds for detecting low bone mineral density. Our study recommends a 71-73 keV range for improved backward compatibility between PCD-CT and EID-CT.

#### CLINICAL RELEVANCE/APPLICATION

This study establishes a benchmark for the ideal energy range in PCD-CT VMI reconstructions to maintain compatibility with EID-CT-based osteoporosis detection thresholds, laying the groundwork for future research on the benefits of this novel CT technology.

### Gastrointestinal Imaging (Pancreas Diffuse Disease)

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S404

Kristen Olinger, MD (*Moderator*) Nothing to Disclose  
Abraham Fourie Bezuidenhout, MD (*Moderator*) Nothing to Disclose

#### Sub-Events

#### W7-SSGI15-2 **Paraduodenal Pancreatitis in the Covid-19 Pandemic Era**

Peter Liaw, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Paraduodenal or groove pancreatitis is an underrecognized and uncommon form of chronic pancreatitis centered in the pancreaticoduodenal groove, typically seen in middle aged males with a history of alcohol use. Although previous publications have described the impact of COVID-19 on other forms of pancreatitis, little is known about the impact of the COVID-19 pandemic on patients presenting with paraduodenal pancreatitis. Our objective was to describe the prevalence, demographics, imaging findings, and associations of paraduodenal pancreatitis before and during the COVID-19 pandemic.

#### METHODS AND MATERIALS

The radiology information system was searched for patients who underwent abdominal CT or MRI for suspected paraduodenal pancreatitis between 2017 and 2022. Patients that underwent imaging between 2017 and 2019 were designated pre-COVID-19, and those imaged between 2020 and 2022 were designated as during COVID-19 pandemic. All studies were reviewed by two fellowship trained abdominal radiologists for imaging findings of paraduodenal pancreatitis, blinded to clinical information. Concurrent imaging findings of hepatic steatosis were noted.

#### RESULTS

A total of 72 patients with suspected paraduodenal pancreatitis were identified between 2017 and 2022. Electronic medical records were reviewed for final patient diagnosis established at the pancreaticobiliary multidisciplinary conference. Subsequently, 36 patients with alternate diagnoses were excluded. 7 patients [mean age, 45±9 years; 7 men, 0 women] were diagnosed with paraduodenal pancreatitis in the pre-COVID-19 cohort. 2/7 (29%) patients had the pure form, 5/7 (71%) had the segmental form and 0 patients had concurrent hepatic steatosis. 29 patients [mean age, 56±17 years; 14 men, 15 women] were diagnosed with paraduodenal pancreatitis in the during COVID-19 cohort. 15/29 (52%) patients had the pure form, 14/29 (48%) had the segmental form and 8/29 (28%) patients had concurrent hepatic steatosis.

#### CONCLUSION

We report a four-fold increase in patients presenting with paraduodenal pancreatitis during a similar time period prior to and during the COVID-19 pandemic. The demographic of patients presenting with paraduodenal pancreatitis during the COVID-19 pandemic was no longer predominantly male, and almost one third of patients presented with concurrent hepatic steatosis.

#### CLINICAL RELEVANCE/APPLICATION

Radiologists should be aware of the increase in incidence and change in demographics of paraduodenal pancreatitis in the COVID-19 pandemic era as well as concurrent hepatic steatosis reported in almost one third of patients.

#### W7-SSGI15-3 **Normal Pancreatic Microanatomy Visible with Photon-Counting CT**

Erik Brandt, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Photon-Counting CT (PCCT) has the advantage of increased spatial resolution. Hence, radiologists will be able to visualize previously unseen anatomical structures. The pancreas has a complex anatomy both macroscopically and microscopically. We

aim to investigate if normal anatomical structures not visible with current generation energy integrating CT-scanners (EID CT) becomes visible with PCCT scanners.

## **METHODS AND MATERIALS**

We reviewed the literature regarding inconsistently seen macro- and micro-anatomical structures of the pancreas on EID CT systems. Afterwards we reviewed PCCT scans from 20 consecutive patients without pancreatic pathology, scanned in the workup of pancreatic cancer with a contrast enhanced multiphase protocol over the upper abdomen (late arterial phase, portal venous phase and late venous phase). A subspecialized radiologist assessed the visibility of the main and accessory pancreatic ducts, side ducts, hepatopancreatic ampulla, major papilla, minor papilla, smaller pancreatic arteries and veins, lymphatic confluence, regional lymph nodes, coeliac ganglia, and coeliac plexus. In addition, measurements were made of the size of the main, accessory, side-ducts, and ganglia. Attenuation was measured in all three contrast-phases of ganglia and two lymph nodes.

## **RESULTS**

The main duct was visible in 20 / 20 patients in the head, body, and tail of the pancreas. The average size of the accessory duct was 1,2mm and it was visible in 20 / 20 patients. More than ten side-ducts were visible in 18 / 20 patients. The average diameter of the visible side-ducts was 0,5mm. Both the major and minor papillae were visible in 20 / 20 cases. Four arteries to the pancreaticoduodenal arcade were visible in 20 / 20 patients. Lymph nodes in all regional pancreatic lymph node stations were visible in 18 / 20 patients. The lymphatic confluence was visible in 20/20 patients. The coeliac ganglion was visible on both sides in 20 / 20 patients. The ganglia showed an increasing iodine enhancement from the late arterial phase to the late venous phase. In contrast, all evaluated lymph nodes showed the highest iodine enhancement in either the late arterial or portal venous phase with washout in the late venous phase. The coeliac plexus was visible in 20 / 20 patients.

## **CONCLUSION**

In PCCT scans of the pancreas, previously unseen anatomy (side ducts, papillae, pancreaticoduodenal arteries, lymph nodes, nerve ganglia and plexus) is consistently visible in patients without pancreatic pathology.

## **CLINICAL RELEVANCE/APPLICATION**

This has important implications for the evaluation of pancreatic disease and the differentiation of pathology from normal anatomy. Normal anatomy could very likely be confused for pathology if radiologists are unaware of it.

## **W7-SSGI15-5 Association of Pancreatic Steatosis and Atrophy with Type II Diabetes Mellitus**

Ashish Dua, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

Assessment of pancreatic steatosis and volume in patients with type-II diabetes mellitus and to look for association of DM with these parameters.

## **METHODS AND MATERIALS**

We prospectively evaluated 66 patients with diabetes and 47 non-diabetic patients, age group 40-65 years who underwent unenhanced Computed Tomography of abdomen for some abdominal complaints. Cases had adequately controlled blood sugar levels, none of the cases or controls had any systemic co-morbidities. Parameters noted: 1) Pancreatic steatosis indirectly, as: Difference between pancreatic and splenic attenuation (HU p-s), and ratio of pancreatic to splenic attenuation (HU p/s); and 2) Pancreatic volume (using inbuilt volume application in CT). After matching, t-test and Mann-Whitney-test were applied for calculating p-values. Receiver Operating Curves (ROC) were made for finding cut-off values of pancreatic steatosis and pancreatic volume with optimal sensitivity and specificity.

## **RESULTS**

Pancreatic fat content was significantly high ( $p < 0.001$ ) in patients with type-II diabetes (HU p-s of  $-13.2 \pm 7.9$  and HU p/s of  $0.73 \pm 0.15$ ) compared to non-diabetics (HU p-s of  $-6.7 \pm 5.9$  and HU p/s of  $0.86 \pm 0.12$ ). Pancreatic volume was significantly low ( $p < 0.001$ ) in patients with type-II DM ( $48 \pm 13.7$  cm<sup>3</sup>) compared to non-diabetic patients ( $63.6 \pm 17.3$  cm<sup>3</sup>). Thus, pancreatic steatosis and atrophy may act as surrogate marker for type-II DM.

## **CONCLUSION**

Pancreatic steatosis and atrophy are significantly associated with type-II DM. These changes if found in high-risk individual incidentally on imaging, might represent overt or impending DM. These findings should be reported as it would prompt complete biochemical work-up. Early diagnosis of DM can mitigate disabilities and complications related to it. Thus, pancreatic steatosis and atrophy may act as a surrogate biomarker for diagnosis of overt or impending type II DM.

## **CLINICAL RELEVANCE/APPLICATION**

Considering the enormous diabetic burden in the world, lab investigations alone may not suffice and an adjunct diagnostic modality might help us know the diabetic status of a lot of undiagnosed individuals. Pancreatic imaging can play a pivotal adjunct role in assessment of the diabetic status of people since imaging investigations have become rampant and people get

ultrasound, CT scan and MRI frequently for various diseases. Adequate knowledge on imaging of pancreas can help us know the diabetic status of individuals who may not be unaware of their diabetic status and have had this disease for long duration.

## **W7-SSGI15-6 MRI Quantitative Assessment of Age-related Changes in Pancreatic Margins in Subjects Without Pancreatic Disease**

Giulia A. Zamboni, MD (*Presenter*) Nothing to Disclose

### **PURPOSE**

To quantitatively evaluate age-related changes of pancreatic margins on Magnetic Resonance in patients without history or signs of pancreatic pathology, as a possible reference for future studies assessing the relationship between parenchymal margins and pancreatic disease.

### **METHODS AND MATERIALS**

IRB approval was not required for this retrospective study. We included patients without history, suspicion, or imaging findings of pancreatic pathology who underwent abdominal MR scans (1.5T and 3T) between August 2021 and August 2022. A computer-assisted quantitative analysis of the pancreatic margins was performed using in-house software on Fat-Suppressed T1-Weighted images, drawing multiple ROIs on the anterior margins of the body and tail, where the pancreas abuts retroperitoneal fat. The root mean square deviation SD of the actual border from the average boundary line (Pancreatic Margin Score, PMS) was obtained. Higher mean PMS values reflect an increased lobularity of the pancreatic profile at imaging, while lower PMS values reflect a straightened profile. The population was divided into 4 groups by age (group 1: <30 years; group 2: 30-49 years; group 3: 50-69 years; group 4: ≥70 years). The PMS values were compared across groups by applying the one-way ANOVA test; a p value <0.05 was chosen as significant.

### **RESULTS**

A significant difference ( $p < 0.05$ ) across the four groups was observed of the mean PMS, with values increasing with age:  $0.315 \pm 0.0579$  in group 1,  $0.341 \pm 0.0747$  in group 2,  $0.374 \pm 0.117$  in group 3 and  $0.419 \pm 0.158$  in group 4.

### **CONCLUSION**

The analysis of the pancreatic margins revealed different results based on age, which reflects the qualitative changes seen in the morphology of the pancreas with aging, especially an increase in lobularity.

### **CLINICAL RELEVANCE/APPLICATION**

The Pancreatic Margin Score (PMS) reflects qualitative changes of the pancreatic profile at imaging. Knowing the normal values of PMS could allow to use PMS as a diagnostic tool for pancreatic diseases.

#### W7-SSGI16-1 CT in a Prone Position in Preoperative Evaluation of Inguinal Hernia: Comparison with CT in a Supine Position

Akitoshi Inoue, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Inguinal hernia is provoked by gravity and intraabdominal pressure. The purpose of this study was to estimate the impact of a prone position CT scan in diagnosing inguinal hernia.

#### METHODS AND MATERIALS

A total of 125 patients ( $68.0 \pm 14.0$  y.o.; female=12) treated with inguinal hernia repair scanned CT at both supine and prone positions were retrospectively enrolled. Patients were scanned for clinical abdominopelvic supine CT and subsequently underwent pelvic prone CT. The inguinal region was free by placing towels on the abdominal walls and thighs during prone CT scanning. A surgeon reviewed medical records to archive the classification based on anatomy (internal, external, or femoral) and hernial orifice diameter ( $=1.5$ ,  $1.5-3.0$ ,  $3.0=$ ). Two radiologists (R1, R2) blinded to the surgical diagnosis independently read supine or prone CT to record the confidence level of absence or presence of inguinal hernia (0=absent; 50=equivocal; 100=present) for 250 inguinal regions in separated sessions separated by at least 3 weeks. The confidence score was translated to the magnitude score which is an absolute value from 50 (range: 0--50). In another session, the readers compared supine and prone CT and recorded preference in diagnosing inguinal hernia using a 5-point Likert scale (1=prone CT is worse, 3=equal, 5=prone CT is better).

#### RESULTS

A total of 140 inguinal hernias (96 external inguinal, 41 internal inguinal, 2 mixed inguinal, and 1 femoral hernia) were surgically recorded in the enrolled patients. The diameter of the hernial orifice was  $=1.5$  ( $n=29$ ),  $1.5-3.0$  ( $n=75$ ),  $3.0=$  ( $n=25$ ), and not recorded ( $n=11$ ). Prone CT shows similar accuracy (R1—0.704 vs. 0.720; R2—0.804 vs. 0.792) with higher sensitivity (R1—0.823 vs. 0.783; R2—0.830 vs. 0.707) but lower specificity (R1—0.550 vs. 0.627; R2—0.771 vs. 0.900) than supine CT. The magnitude value of prone CT was improved in true positive (R1—40.0 vs. 37.5;  $P=0.067$ , R2—41.1 vs. 37.2;  $P=0.005$ ) and degraded in true negative (R2—41.7 vs. 44.4;  $P=0.001$ ). R1 diagnosed 10 (external [ $n=10$ ]) and R2 diagnosed 19 inguinal hernias (external [ $n=14$ ], internal [ $n=4$ ], combined [ $n=1$ ]) on prone CT but not supine CT. Two radiologists preferred prone CT (R1— $3.56 \pm 0.76$ , R2— $3.50 \pm 0.65$ ).

#### CONCLUSION

CT scan at a prone position is helpful in revealing inguinal hernias and improving radiologists' confidence level despite the increased false positive case.

#### CLINICAL RELEVANCE/APPLICATION

Prone CT facilitates delineating of clinically significant inguinal hernia by provoking inguinal hernia with gravity effect and may contribute to the surgical planning.

#### W7-SSGI16-2 Does Incidentally Detected Mesenteric Panniculitis at CT ever Represent early Lymphoma?

Geneghee Kim (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the likelihood that the characteristic CT pattern of mesenteric panniculitis with soft tissue haziness and scattered normal appearing lymph nodes of the small bowel mesentery represents early lymphoma in patients without a prior history of cancer.

## METHODS AND MATERIALS

Patients with incidentally reported mesenteric panniculitis at CT between 1/1/04-12/31/12 were identified from PACS query, excluding those with a prior diagnosis of cancer. CT images were reviewed to confirm that a characteristic pattern of mesenteric haziness and lymph nodes was present. Additional analyses of the mesenteric fat (degree/ROI measurement/presence of fat halo and/or peripheral encapsulation) and lymph nodes (presence/size) were done. Demographic characteristics (age, gender, height, and weight) were collected. Longitudinal follow up was determined by EMR review. Length of follow up and onset of any cancers/lymphoma were recorded.

## RESULTS

225 individuals (age  $57.9 \pm 12.6$ ; 163 males, 62 females) were included. BMI  $31.8 \pm 6.7$ . Mean follow-up was 9.3 years  $\pm 4.0$  with 68.4% (154/225) with follow-up = 8 years. No individuals (0/225) developed lymphoma in the small bowel mesentery over follow up. 4/225 did develop a future lymphoma but with involvement other than of the small bowel mesentery, including salivary gland, mediastinum, spleen/bone marrow, and retroperitoneum. Mesenteric ROI mean  $-67.6 \text{ HU} \pm 17.5$  with a subjective grading of mild haziness 48.9% (110/225); moderate/marked 51.1% (115/225). 69.8% (157/225) with a fat halo around mesenteric vessels and lymph nodes; 88.4% (199/225) had a thin soft tissue rim encapsulating the mesenteric fat. Mean size of largest mesenteric lymph node was  $5.8 \text{ mm} \pm 2.1$ , typically flat with a fatty hilum.

## CONCLUSION

CT findings in the small bowel mesentery characteristic of mesenteric panniculitis are unlikely to represent early lymphoma suggesting that a recommendation of imaging follow up is unnecessary.

## CLINICAL RELEVANCE/APPLICATION

Follow-up imaging is not necessary when a characteristic CT appearance of mesenteric panniculitis is present, leading to optimized utilization of finite imaging resources.

## W7-SSGI16-3 Splenic Measurement as Potential Imaging Biomarker for Infective Endocarditis in Patients with a History of Intravenous Drug Use

James Nash, MBA (*Presenter*) Nothing to Disclose

## PURPOSE

Endocardial inflammation associated with infective endocarditis (IE) is catastrophic without timely diagnosis, and often-non-specific symptoms may delay recognition. Duke Criteria is used to diagnose those suspected of having IE and relies on a constellation of pathologic, clinical and/or echocardiographic findings that do not include splenomegaly. Patients with intravenous drug use (IVDU) history are disproportionately afflicted with IE and demonstrate a higher splenomegaly prevalence. We sought to compare traditional 2D measurements and semi-automated 3D segmentation volumes from computed tomography (CT) to identify splenomegaly and consider its association with IE in this population.

## METHODS AND MATERIALS

We performed a retrospective analysis of patients treated at our institution between 4/1/11-6/5/21. We included all IVDU patients who received an abdominal CT, regardless of IE status. Of the 2,009 results, we randomly selected 117 IE-positive individuals and matched them by age and sex to those without documented IE. We then performed splenic CT measurements of these 234 patients via craniocaudal (CC) length, ellipsoid volume, and semi-automated 3D segmentation techniques.

## RESULTS

For each measurement technique, splenic size was statistically larger for IE-positive patients than for their IE-negative matches. Mean CC lengths were 13.2 (SD 3.19) and 11.2 (SD 2.39) ( $p < 0.001$ ), ellipsoid volumes were 484 (SD 336) and 297 (SD 165) ( $p < 0.001$ ), and semi-automated 3D segmentation volumes were 603 (SD 470) and 374 (SD 221) ( $p < 0.001$ ) (2D measurements were in cm, 3D volumes were in  $\text{cm}^3$ ). For ellipsoid volume, the maximum single-variable accuracy of 69% corresponded with a 400mL cutoff, with corresponding sensitivity and specificity of 56% and 82%. At 180mL, sensitivity of 90% corresponded with a specificity of 23%, with an odds ratio of 1.47 per additional 100mL increase. We observed a strong association between CC length and the two volumetric techniques, as evidenced by a Pearson correlation of 0.91. The association between ellipsoid and semi-automated 3D segmentation volumes was even stronger, with a Pearson of 0.97. Among two volumetric measurement techniques, semi-automated 3D segmentation values were consistently larger than ellipsoid.

## CONCLUSION

For patients with an IVDU history, there was an associated increase in splenic size for those with documented IE. Additionally, splenic CT measurement techniques were strongly correlated with one another, though with notable absolute differences.

## CLINICAL RELEVANCE/APPLICATION

Splenomegaly measured by CT may be an important screening tool to identify IVDU patients that have undiagnosed or underlying IE, especially as a participatory value within a multi-variable model.

### **W7-SSGI16-4 Postprandial Changes in Spleen Stiffness Assessed with Magnetic Resonance Elastography (MRE)**

Vitaliy Atamaniuk, MSc, BEng (*Presenter*) Nothing to Disclose

#### PURPOSE

Magnetic Resonance Elastography (MRE) is a powerful imaging technique for detecting pathological changes in parenchymal organs such as the liver and spleen. However, the assessed value of tissue stiffness may be biased by various factors. This study aimed to evaluate the postprandial changes in spleen stiffness using MRE in a large sample of healthy volunteers.

#### METHODS AND MATERIALS

One hundred healthy volunteers who met inclusion criteria (mean age  $23 \pm 2$  years, 35 men and 65 women) were enrolled in this prospective, single institutional, ethics board-approved study. MRE examinations were conducted in the fasting state and 30 minutes after consuming a 1000 kcal meal. Additionally, MRE was repeated 1 hour and 30 minutes and 2 hours and 30 minutes after the meal for a randomly selected group of 14 participants. A team comprised of a radiologist and an MRE technician drew three to five regions of interest on three to five consecutive axial spleen slices to assess splenic stiffness. Statistical analyses included Mann-Whitney, Wilcoxon-signed rank, Spearman rank correlation, and Friedman tests.

#### RESULTS

The results showed a statistically significant ( $p < 0.001$ ) postprandial increase in splenic stiffness 30 minutes after the meal ( $5.47 \pm 0.66$  kPa vs.  $5.09 \pm 0.63$  kPa in the fasting state), which gradually decreased but remained higher than in the fasting state even 2 hours 30 minutes after food intake.

#### CONCLUSION

In conclusion, food intake causes a statistically significant elevation of splenic stiffness that persists for at least 2 hours and 30 minutes. The study findings support the recommendation for patients to fast for no less than 3 to 4 hours before undergoing splenic MRE examinations.

#### CLINICAL RELEVANCE/APPLICATION

The results of this study demonstrate the statistically significant impact of meal intake on splenic stiffness, highlighting the need for patients to fast before splenic MRE to ensure accurate assessments of spleen stiffness.

### **W7-SSGI16-5 Impact of Prophylactic Platelet Transfusion in Thrombocytopenic Patients Undergoing Ultrasonography-Guided Percutaneous Liver Biopsy**

Hyeon Ji Jang, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Controversy remains regarding the usefulness of prophylactic platelet concentrate (PC) transfusion in preventing bleeding after liver biopsy in thrombocytopenic patients, especially in cirrhosis. Our study aimed to determine the impact of prophylactic PC transfusion on ultrasonography (US)-guided percutaneous liver biopsies. Risk factors for post-biopsy bleeding were identified.

#### METHODS AND MATERIALS

This retrospective study analyzed US-guided liver biopsies performed at our institution from 2018 to 2022. Thrombocytopenia was classified as mild (platelet [ $\times 10^9/L$ ]  $>75$  and  $<150$ ), moderate (50-75), and severe ( $<50$ ). Bleeding was defined as major (requiring blood transfusion, radiologic/surgical intervention, or resulting in death) or minor (new intra-abdominal hematoma identified after biopsy not requiring intervention). Logistic regression analysis was conducted to evaluate the association between bleeding and demographics/imaging characteristics.

#### RESULTS

We analyzed 5337 procedures on 5240 patients, including 755 procedures in thrombocytopenia (644 mild, 76 moderate, and 35 severe). PC transfusion was given before 53 procedures (in 13 mild, 22 moderate, and 18 severe thrombocytopenia). Multivariable analysis showed that major and minor bleeding were associated with the presence and severity of

thrombocytopenia, prolonged INR, and abnormal liver function test ( $P < 0.05$ ), but not with PC transfusion. Subgroup analyses showed no association between PC transfusion and decreased bleeding incidence in thrombocytopenia, regardless of severity or cirrhosis presence. In 614 procedures performed in cirrhotic patients, the severity of thrombocytopenia was associated with bleeding ( $P = .015$ ), but the association with severe thrombocytopenia was marginally insignificant (odds ratio [OR], 3.17; 95% confidence interval [CI], 0.99-10.10). Among the imaging characteristics of targeted liver mass, mass size was associated with major bleeding (OR, 1.06; 95% CI, 1.02-1.11), and vascular abutment was associated with minor bleeding (OR, 1.46; 95% CI, 1.16-1.83).

#### **CONCLUSION**

Prophylactic PC transfusion was not associated with reduction in the bleeding incidence in thrombocytopenic patients regardless of the cirrhotic status. Severe thrombocytopenia was not associated with the occurrence of bleeding in cirrhotic patients. Prophylactic platelet transfusion may not be mandatory for thrombocytopenic patients planning percutaneous US-guided liver biopsy, even those with severe thrombocytopenia.

#### **CLINICAL RELEVANCE/APPLICATION**

PC transfusion may not be mandatory for thrombocytopenic patients undergoing US-guided percutaneous liver biopsy, regardless of the severity of thrombocytopenia or the presence of cirrhosis.

#### **W7-SSGI16-6 A Comparative Study of SonoVue and Sonazoid for Contrast-Enhanced Ultrasound CT/MRI Fusion-Guidance during Radiofrequency Ablation of Poorly Visualized Hepatic Malignancies: A Prospective Intra-Individual Analysis**

Heesoo Kim, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The study aimed to evaluate the effectiveness of two contrast agents, SonoVue (SV) and Sonazoid (SZ), used in contrast-enhanced ultrasound (CEUS)-CT/MRI fusion imaging (FI), in improving the visibility of inconspicuous liver malignancies ( $\leq 4$  cm) on B-mode ultrasound (US) for guiding percutaneous radiofrequency ablation (RFA). Additionally, the radiologists' preference between SonoVue-CT/MRI fusion imaging (SV-FI) and Sonazoid-CT/MRI fusion imaging (SZ-FI) was determined.

#### **METHODS AND MATERIALS**

A total of 23 patients with inconspicuous hepatic malignancies on B-mode US were enrolled in this prospective study. The patients underwent real-time CEUS FI with CT/MRI on the same day, utilizing both SV and SZ. Tumor visibility and radiologists' preferences were assessed and graded using a 4-point scale during the dynamic phases of both SV-FI and SZ-FI and the Kupffer phase of SZ-FI.

#### **RESULTS**

The tumor visibility scores obtained from both CEUS-CT/MRI FI were significantly better than those obtained from US-FI. Indeed, SV-FI and SZ-FI demonstrated comparable visibility scores when corresponding phases were compared ( $p > 0.05$ ). However, the Kupffer phase images of SZ-FI displayed superior visibility scores ( $3.70 \pm 0.56$  vs  $2.96 \pm 0.88$ ;  $p = 0.002$ ) than the late vascular phase images of SV-FI. The radiologists favored SZ-FI in a higher number of cases, exhibiting moderate inter-observer agreement (Kappa value = 0.587; 95% CI, 0.403-0.772).

#### **CONCLUSION**

Although CEUS-CT/MRI FI with either SV or SZ substantially improved the visibility of tumors that were inconspicuous on US-CT/MRI FI, radiologists preferred SZ to SV to guide the RFA procedure.

#### **CLINICAL RELEVANCE/APPLICATION**

Our study highlights the benefits of incorporating CEUS into FI to improve the detection of hepatic tumors, as it provides enhanced visibility based on increased vascularity and more precise delineation of tumor margins, as previously shown in other studies. Moreover, adding CEUS to FI can correct the misregistration of US-CT/MRI FI using a rigid transformation matrix through manual co-registration of the target tumor on CEUS and CT/MRI with greater accuracy. Therefore, in the context of thermal ablation, CEUS-CT/MRI FI plays a crucial role in enabling physicians to accurately localize tumors, devise a comprehensive ablation plan, and continuously monitor the ablation process in real time.

### CT in a Prone Position in Preoperative Evaluation of Inguinal Hernia: Comparison with CT in a Supine Position

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S405

Akitoshi Inoue, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Inguinal hernia is provoked by gravity and intraabdominal pressure. The purpose of this study was to estimate the impact of a prone position CT scan in diagnosing inguinal hernia.

#### METHODS AND MATERIALS

A total of 125 patients ( $68.0 \pm 14.0$  y.o.; female=12) treated with inguinal hernia repair scanned CT at both supine and prone positions were retrospectively enrolled. Patients were scanned for clinical abdominopelvic supine CT and subsequently underwent pelvic prone CT. The inguinal region was free by placing towels on the abdominal walls and thighs during prone CT scanning. A surgeon reviewed medical records to archive the classification based on anatomy (internal, external, or femoral) and hernial orifice diameter ( $=1.5$ ,  $1.5-3.0$ ,  $3.0=$ ). Two radiologists (R1, R2) blinded to the surgical diagnosis independently read supine or prone CT to record the confidence level of absence or presence of inguinal hernia (0=absent; 50=equivocal; 100=present) for 250 inguinal regions in separated sessions separated by at least 3 weeks. The confidence score was translated to the magnitude score which is an absolute value from 50 (range: 0--50). In another session, the readers compared supine and prone CT and recorded preference in diagnosing inguinal hernia using a 5-point Likert scale (1=prone CT is worse, 3=equal, 5=prone CT is better).

#### RESULTS

A total of 140 inguinal hernias (96 external inguinal, 41 internal inguinal, 2 mixed inguinal, and 1 femoral hernia) were surgically recorded in the enrolled patients. The diameter of the hernial orifice was  $=1.5$  ( $n=29$ ),  $1.5-3.0$  ( $n=75$ ),  $3.0=$  ( $n=25$ ), and not recorded ( $n=11$ ). Prone CT shows similar accuracy (R1—0.704 vs. 0.720; R2—0.804 vs. 0.792) with higher sensitivity (R1—0.823 vs. 0.783; R2—0.830 vs. 0.707) but lower specificity (R1—0.550 vs. 0.627; R2—0.771 vs. 0.900) than supine CT. The magnitude value of prone CT was improved in true positive (R1—40.0 vs. 37.5;  $P=0.067$ , R2—41.1 vs. 37.2;  $P=0.005$ ) and degraded in true negative (R2—41.7 vs. 44.4;  $P=0.001$ ). R1 diagnosed 10 (external [ $n=10$ ]) and R2 diagnosed 19 inguinal hernias (external [ $n=14$ ], internal [ $n=4$ ], combined [ $n=1$ ]) on prone CT but not supine CT. Two radiologists preferred prone CT (R1— $3.56 \pm 0.76$ , R2— $3.50 \pm 0.65$ ).

#### CONCLUSION

CT scan at a prone position is helpful in revealing inguinal hernias and improving radiologists' confidence level despite the increased false positive case.

#### CLINICAL RELEVANCE/APPLICATION

Prone CT facilitates delineating of clinically significant inguinal hernia by provoking inguinal hernia with gravity effect and may contribute to the surgical planning.

### Does Incidentally Detected Mesenteric Panniculitis at CT ever Represent early Lymphoma?

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S405

Geneghee Kim (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the likelihood that the characteristic CT pattern of mesenteric panniculitis with soft tissue haziness and scattered normal appearing lymph nodes of the small bowel mesentery represents early lymphoma in patients without a prior history of cancer.

#### METHODS AND MATERIALS

Patients with incidentally reported mesenteric panniculitis at CT between 1/1/04-12/31/12 were identified from PACS query, excluding those with a prior diagnosis of cancer. CT images were reviewed to confirm that a characteristic pattern of mesenteric haziness and lymph nodes was present. Additional analyses of the mesenteric fat (degree/ROI measurement/presence of fat halo and/or peripheral encapsulation) and lymph nodes (presence/size) were done. Demographic characteristics (age, gender, height, and weight) were collected. Longitudinal follow up was determined by EMR review. Length of follow up and onset of any cancers/lymphoma were recorded.

#### RESULTS

225 individuals (age  $57.9 \pm 12.6$ ; 163 males, 62 females) were included. BMI  $31.8 \pm 6.7$ . Mean follow-up was 9.3 years  $\pm 4.0$  with 68.4% (154/225) with follow-up = 8 years. No individuals (0/225) developed lymphoma in the small bowel mesentery over follow up. 4/225 did develop a future lymphoma but with involvement other than of the small bowel mesentery, including salivary gland, mediastinum, spleen/bone marrow, and retroperitoneum. Mesenteric ROI mean  $-67.6 \text{ HU} \pm 17.5$  with a subjective grading of mild haziness 48.9% (110/225); moderate/marked 51.1% (115/225). 69.8% (157/225) with a fat halo around mesenteric vessels and lymph nodes; 88.4% (199/225) had a thin soft tissue rim encapsulating the mesenteric fat. Mean size of largest mesenteric lymph node was  $5.8 \text{ mm} \pm 2.1$ , typically flat with a fatty hilum.

#### CONCLUSION

CT findings in the small bowel mesentery characteristic of mesenteric panniculitis are unlikely to represent early lymphoma suggesting that a recommendation of imaging follow up is unnecessary.

#### CLINICAL RELEVANCE/APPLICATION

Follow-up imaging is not necessary when a characteristic CT appearance of mesenteric panniculitis is present, leading to optimized utilization of finite imaging resources.

### Splenic Measurement as Potential Imaging Biomarker for Infective Endocarditis in Patients with a History of Intravenous Drug Use

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S405

James Nash, MBA (*Presenter*) Nothing to Disclose

#### PURPOSE

Endocardial inflammation associated with infective endocarditis (IE) is catastrophic without timely diagnosis, and often-non-specific symptoms may delay recognition. Duke Criteria is used to diagnose those suspected of having IE and relies on a constellation of pathologic, clinical and/or echocardiographic findings that do not include splenomegaly. Patients with intravenous drug use (IVDU) history are disproportionately afflicted with IE and demonstrate a higher splenomegaly prevalence. We sought to compare traditional 2D measurements and semi-automated 3D segmentation volumes from computed tomography (CT) to identify splenomegaly and consider its association with IE in this population.

#### METHODS AND MATERIALS

We performed a retrospective analysis of patients treated at our institution between 4/1/11-6/5/21. We included all IVDU patients who received an abdominal CT, regardless of IE status. Of the 2,009 results, we randomly selected 117 IE-positive individuals and matched them by age and sex to those without documented IE. We then performed splenic CT measurements of these 234 patients via craniocaudal (CC) length, ellipsoid volume, and semi-automated 3D segmentation techniques.

#### RESULTS

For each measurement technique, splenic size was statistically larger for IE-positive patients than for their IE-negative matches. Mean CC lengths were 13.2 (SD 3.19) and 11.2 (SD 2.39) ( $p < 0.001$ ), ellipsoid volumes were 484 (SD 336) and 297 (SD 165) ( $p = < 0.001$ ), and semi-automated 3D segmentation volumes were 603 (SD 470) and 374 (SD 221) ( $p < 0.001$ ) (2D measurements were in cm, 3D volumes were in  $\text{cm}^3$ ). For ellipsoid volume, the maximum single-variable accuracy of 69% corresponded with a 400mL cutoff, with corresponding sensitivity and specificity of 56% and 82%. At 180mL, sensitivity of 90% corresponded with a specificity of 23%, with an odds ratio of 1.47 per additional 100mL increase. We observed a strong association between CC length and the two volumetric techniques, as evidenced by a Pearson correlation of 0.91. The association between ellipsoid and semi-automated 3D segmentation volumes was even stronger, with a Pearson of 0.97. Among two volumetric measurement techniques, semi-automated 3D segmentation values were consistently larger than ellipsoid.

#### CONCLUSION

For patients with an IVDU history, there was an associated increase in splenic size for those with documented IE. Additionally, splenic CT measurement techniques were strongly correlated with one another, though with notable absolute differences.

#### CLINICAL RELEVANCE/APPLICATION

Splenomegaly measured by CT may be an important screening tool to identify IVDU patients that have undiagnosed or underlying IE, especially as a participatory value within a multi-variable model.

### Postprandial Changes in Spleen Stiffness Assessed with Magnetic Resonance Elastography (MRE)

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S405

Vitaliy Atamaniuk, MSc, BEng (*Presenter*) Nothing to Disclose

#### PURPOSE

Magnetic Resonance Elastography (MRE) is a powerful imaging technique for detecting pathological changes in parenchymal organs such as the liver and spleen. However, the assessed value of tissue stiffness may be biased by various factors. This study aimed to evaluate the postprandial changes in spleen stiffness using MRE in a large sample of healthy volunteers.

#### METHODS AND MATERIALS

One hundred healthy volunteers who met inclusion criteria (mean age  $23 \pm 2$  years, 35 men and 65 women) were enrolled in this prospective, single institutional, ethics board-approved study. MRE examinations were conducted in the fasting state and 30 minutes after consuming a 1000 kcal meal. Additionally, MRE was repeated 1 hour and 30 minutes and 2 hours and 30 minutes after the meal for a randomly selected group of 14 participants. A team comprised of a radiologist and an MRE technician drew three to five regions of interest on three to five consecutive axial spleen slices to assess splenic stiffness. Statistical analyses included Mann-Whitney, Wilcoxon-signed rank, Spearman rank correlation, and Friedman tests.

#### RESULTS

The results showed a statistically significant ( $p < 0.001$ ) postprandial increase in splenic stiffness 30 minutes after the meal ( $5.47 \pm 0.66$  kPa vs.  $5.09 \pm 0.63$  kPa in the fasting state), which gradually decreased but remained higher than in the fasting state even 2 hours 30 minutes after food intake.

#### CONCLUSION

In conclusion, food intake causes a statistically significant elevation of splenic stiffness that persists for at least 2 hours and 30 minutes. The study findings support the recommendation for patients to fast for no less than 3 to 4 hours before undergoing splenic MRE examinations.

#### CLINICAL RELEVANCE/APPLICATION

The results of this study demonstrate the statistically significant impact of meal intake on splenic stiffness, highlighting the need for patients to fast before splenic MRE to ensure accurate assessments of spleen stiffness.

### Impact of Prophylactic Platelet Transfusion in Thrombocytopenic Patients Undergoing Ultrasonography-Guided Percutaneous Liver Biopsy

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S405

Hyeon Ji Jang, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Controversy remains regarding the usefulness of prophylactic platelet concentrate (PC) transfusion in preventing bleeding after liver biopsy in thrombocytopenic patients, especially in cirrhosis. Our study aimed to determine the impact of prophylactic PC transfusion on ultrasonography (US)-guided percutaneous liver biopsies. Risk factors for post-biopsy bleeding were identified.

#### METHODS AND MATERIALS

This retrospective study analyzed US-guided liver biopsies performed at our institution from 2018 to 2022. Thrombocytopenia was classified as mild (platelet [ $\times 10^9/L$ ]  $>75$  and  $<150$ ), moderate (50-75), and severe ( $<50$ ). Bleeding was defined as major (requiring blood transfusion, radiologic/surgical intervention, or resulting in death) or minor (new intra-abdominal hematoma identified after biopsy not requiring intervention). Logistic regression analysis was conducted to evaluate the association between bleeding and demographics/imaging characteristics.

#### RESULTS

We analyzed 5337 procedures on 5240 patients, including 755 procedures in thrombocytopenia (644 mild, 76 moderate, and 35 severe). PC transfusion was given before 53 procedures (in 13 mild, 22 moderate, and 18 severe thrombocytopenia). Multivariable analysis showed that major and minor bleeding were associated with the presence and severity of thrombocytopenia, prolonged INR, and abnormal liver function test ( $P < 0.05$ ), but not with PC transfusion. Subgroup analyses showed no association between PC transfusion and decreased bleeding incidence in thrombocytopenia, regardless of severity or cirrhosis presence. In 614 procedures performed in cirrhotic patients, the severity of thrombocytopenia was associated with bleeding ( $P = .015$ ), but the association with severe thrombocytopenia was marginally insignificant (odds ratio [OR], 3.17; 95% confidence interval [CI], 0.99-10.10). Among the imaging characteristics of targeted liver mass, mass size was associated with major bleeding (OR, 1.06; 95% CI, 1.02-1.11), and vascular abutment was associated with minor bleeding (OR, 1.46; 95% CI, 1.16-1.83).

#### CONCLUSION

Prophylactic PC transfusion was not associated with reduction in the bleeding incidence in thrombocytopenic patients regardless of the cirrhotic status. Severe thrombocytopenia was not associated with the occurrence of bleeding in cirrhotic patients. Prophylactic platelet transfusion may not be mandatory for thrombocytopenic patients planning percutaneous US-guided liver biopsy, even those with severe thrombocytopenia.

#### CLINICAL RELEVANCE/APPLICATION

PC transfusion may not be mandatory for thrombocytopenic patients undergoing US-guided percutaneous liver biopsy, regardless of the severity of thrombocytopenia or the presence of cirrhosis.

### **A Comparative Study of SonoVue and Sonazoid for Contrast-Enhanced Ultrasound CT/MRI Fusion-Guidance during Radiofrequency Ablation of Poorly Visualized Hepatic Malignancies: A Prospective Intra-Individual Analysis**

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S405

Heesoo Kim, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The study aimed to evaluate the effectiveness of two contrast agents, SonoVue (SV) and Sonazoid (SZ), used in contrast-enhanced ultrasound (CEUS)- CT/MRI fusion imaging (FI), in improving the visibility of inconspicuous liver malignancies (= 4 cm) on B-mode ultrasound (US) for guiding percutaneous radiofrequency ablation (RFA). Additionally, the radiologists' preference between SonoVue- CT/MRI fusion imaging (SV-FI) and Sonazoid-CT/MRI fusion imaging (SZ-FI) was determined.

#### **METHODS AND MATERIALS**

A total of 23 patients with inconspicuous hepatic malignancies on B-mode US were enrolled in this prospective study. The patients underwent real-time CEUS FI with CT/MRI on the same day, utilizing both SV and SZ. Tumor visibility and radiologists' preferences were assessed and graded using a 4-point scale during the dynamic phases of both SV-FI and SZ-FI and the Kupffer phase of SZ-FI.

#### **RESULTS**

The tumor visibility scores obtained from both CEUS-CT/MRI FI were significantly better than those obtained from US-FI. Indeed, SV-FI and SZ-FI demonstrated comparable visibility scores when corresponding phases were compared ( $p > 0.05$ ). However, the Kupffer phase images of SZ-FI displayed superior visibility scores ( $3.70 \pm 0.56$  vs  $2.96 \pm 0.88$ ;  $p=0.002$ ) than the late vascular phase images of SV-FI. The radiologists favored SZ-FI in a higher number of cases, exhibiting moderate inter-observer agreement (Kappa value = 0.587; 95% CI, 0.403-0.772).

#### **CONCLUSION**

Although CEUS-CT/MRI FI with either SV or SZ substantially improved the visibility of tumors that were inconspicuous on US-CT/MRI FI, radiologists preferred SZ to SV to guide the RFA procedure.

#### **CLINICAL RELEVANCE/APPLICATION**

Our study highlights the benefits of incorporating CEUS into FI to improve the detection of hepatic tumors, as it provides enhanced visibility based on increased vascularity and more precise delineation of tumor margins, as previously shown in other studies. Moreover, adding CEUS to FI can correct the misregistration of US-CT/MRI FI using a rigid transformation matrix through manual co-registration of the target tumor on CEUS and CT/MRI with greater accuracy. Therefore, in the context of thermal ablation, CEUS-CT/MRI FI plays a crucial role in enabling physicians to accurately localize tumors, devise a comprehensive ablation plan, and continuously monitor the ablation process in real time.

#### **W7-SSMK09-1 Neck Pain and Headache Frequency are Associated with Trapezius Muscle T2 from MRI in Young Adults with Tension-type Headache**

Nico Sollmann, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Tension-type headache (TTH) is the most prevalent primary headache disorder. Neck pain is commonly associated with primary headaches and the trigeminocervical complex (TCC) refers to the convergence of trigeminal and cervical afferents onto neurons of the brainstem, thus conceptualizes the emergence of headache in relation to neck pain. However, no objective biomarkers exist for the myofascial involvement in primary headaches. This study aimed to investigate the involvement of the trapezius muscles in primary headache disorders by quantitative magnetic resonance imaging (MRI), and to explore associations between muscle T2 values and headache and neck pain frequency.

#### METHODS AND MATERIALS

Fifty participants (41 females, age range 20-31 years; 16 tension-type headache [TTH-], 12 mixed-type TTH plus migraine episodes [TTH+], and 22 healthy controls [HC]) prospectively underwent fat-suppressed T2-prepared three-dimensional (3D) turbo spin-echo MRI. The bilateral trapezius muscles were manually segmented, followed by muscle T2 extraction. Associations between muscle T2 values and the presence of neck pain, number of days with headache (considering the 30 days prior to imaging using a headache calendar), and number of myofascial trigger points (mTrPs) as determined by manual palpation of the trapezius muscles were analyzed using mixed effects and regression models (adjusting for age, sex, and body mass index).

#### RESULTS

The TTH+ group demonstrated the highest muscle T2 values (right side:  $31.4 \pm 1.2$  ms, left side:  $31.4 \pm 0.8$  ms) as compared to the TTH- group ( $p < 0.001$ ) or HC group ( $p < 0.001$ ). Muscle T2 was significantly associated with the number of headache days ( $\beta$  coefficient: 2.04,  $p = 0.04$ ) and the presence of neck pain (odds ratio: 2.26,  $p = 0.04$ ). With muscle T2 as the predictor, the area under the curve (AUC) for differentiating between HC and the TTH+ group was 0.82. There was no statistically significant association between muscle T2 and the number of mTrPs of the trapezius muscles ( $p > 0.05$ ).

#### CONCLUSION

Increased T2 values of the trapezius muscles may represent an objective imaging biomarker for myofascial involvement in primary headache disorders, which could help to improve patient phenotyping and therapy evaluation. Pathophysiologically, the increased muscle T2 values could be interpreted as a surrogate of subtle neurogenic inflammation and peripheral sensitization within myofascial tissues.

#### CLINICAL RELEVANCE/APPLICATION

Muscle T2 mapping could be used to stratify patients with primary headaches and to track potential treatment effects for monitoring (e.g., following peripheral magnetic stimulation or physiotherapy to the neck and shoulder muscles).

#### **W7-SSMK09-2 Significant Age-related Differences between Lower Leg Muscles of Elderly and Young Subjects Detected by Ultrashort Echo Time (UTE) Magnetization Transfer (MT) Modeling**

Saeed Jerban, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

To determine if ultrashort echo time (UTE) magnetization transfer (MT) modeling is a sensitive MRI-based technique to detect age-related changes in muscles.

## METHODS AND MATERIALS

The lower legs of 31 healthy young (28±6 yo) and 20 elderly (75±6 yo) female volunteers were imaged using UTE-MRI sequences on a 3T MRI (MR750, GE) in a standard GE knee coil. Institutional review board approval and written informed consent was obtained for all recruited subjects. Subjects in the elderly group were active, ambulant, and had a recent bone densitometry scan in their medical records confirming no osteoporosis. The imaging slab was centered at the tibial midshaft. A 3D-UTE-Cones-MT sequence (pulse power=500°, 1000°, and 1500°; frequency offset=2, 5, 10, 20, and 50kHz; TR=100 ms; FA=7°; 9 spokes per MT preparation) was performed for the two-pool MT modeling (1, 2). Field of view, matrix dimension, in-plane pixel size, slice thickness, and total scan time were 14cm, 160×160, 0.87×0.87mm<sup>2</sup>, 5mm, and 15 mins, respectively. A T1 of 1s was used as the input for the MT modeling. Cones sequence (TR=100, TE=2.2 ms) was performed additionally to provide a high-contrast image for the selection of regions of interest (ROIs). Average macromolecular proton fraction (MMF) and T2 (T2-MM), in addition to water T2 (T2-W) and magnetization transfer ratio (MTR), were calculated for the four following muscles; anterior tibialis muscle (ATM), posterior tibialis muscle (PTM), soleus muscle (SM), and combined lateral muscles (LM, includes peroneus longus and extensor digitorum longus). The Wilcoxon rank sum test was used to compare young and elderly groups. P-values <0.05 were considered significant.

## RESULTS

Fig.1A-B show representative muscle ROIs (yellow dashed line) selected on axial images of the lower leg using the Cones UTE-MRI sequence and Cones at TE=2.2ms. Average differences in MTR and UTE-MT modeling results between young and elderly groups are presented in Fig.1C (Table1). Fig.1D shows boxplots of the MRI results for the young and elderly groups. MTR, MMF, and T2-MM were significantly lower for the muscles of the elderly group. T2-W was significantly higher in the elderly group. MMF and T2-W presented the highest age-related changes (>18% for MMF and >20% for T2-W).

## CONCLUSION

MMF obtained from UTE-MRI-MT modeling, as a surrogate measure for collagen content, showed a significant reduction in the elderly lower leg muscles while T2-W was increased. This study highlighted UTE-MRI-MT techniques as a proper quantitative method to assess the impact of aging on human muscles.

## CLINICAL RELEVANCE/APPLICATION

A UTE-MRI-based technique that can detect changes in skeletal muscles due to aging by estimating the collagen content in tendons may help diagnose and monitor age-related diseases.

## W7-SSMK09-3 The Not-So-Inferior Infraspinatus Muscle: Predictors of Infraspinatus Muscle Degeneration with an Isolated Supraspinatus Tendon Tear

Rebekah Lawrence, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Determine the demographic and clinical factors that predict infraspinatus muscle degeneration in individuals with an isolated supraspinatus tendon tear.

## METHODS AND MATERIALS

A retrospective analysis was performed using the medical records of patients who had a shoulder MRI interpreted by 1 of 3 fellowship-trained musculoskeletal radiologists since the implementation of a standardized MRI 3T protocol within our healthcare system. Demographic (e.g., age, sex) and clinical data (e.g., tear size, muscle degeneration, co-morbidities) were collected. Patients with an isolated supraspinatus tendon tear (n=121) were assigned to one of two groups based on whether any infraspinatus muscle degeneration was present. Logistic regression was used to assess the univariate relationships between infraspinatus muscle degeneration and patient and clinical data, while least absolute shrinkage and selector operator (LASSO) logistic regression was used to assess the multivariable relationship.

## RESULTS

Of the patients with an isolated supraspinatus tendon tear, 16.5% had evidence of infraspinatus muscle degeneration. The presence of infraspinatus muscle degeneration was independently associated with cardiovascular disease (P=0.01), supraspinatus muscle degeneration (P<0.01), and subscapularis muscle degeneration (P=0.01). When the multivariable relationship is assessed, supraspinatus muscle degeneration emerged as the only variable of significant importance for detecting infraspinatus muscle degeneration (specificity: 87.1%, sensitivity: 80.0%).

## CONCLUSION

Infraspinatus muscle degeneration is not uncommon in individuals with an isolated supraspinatus tear and is most associated with concomitant supraspinatus muscle degeneration. Degeneration of the infraspinatus muscle may be especially

problematic due to the muscle's crucial role supporting dynamic shoulder function. Indeed, infraspinatus muscle degeneration has been associated with higher retear rates and poorer clinical outcomes following arthroscopic rotator cuff repair. These findings highlight the need for clinicians to specifically assess the status of each rotator cuff muscle, even when the tendon itself is intact.

#### **CLINICAL RELEVANCE/APPLICATION**

Infraspinatus muscle degeneration is not uncommon with an isolated supraspinatus tendon tear and is important to identify given that specifically its presence is associated with higher retear rates and poorer clinical outcomes following arthroscopic rotator cuff repair.

#### **W7-SSMK09-6 Serial Changes of MR Neurography in the Experimental Autoimmune Neuritis: Differences between Fat Saturation T2 Weighted Image and Contrast Enhanced Fat Saturation T1 Weighted Image**

Dong-Ho Ha (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Experimental autoimmune neuritis (EAN) is the mostly used animal model of human Guillain-Barré syndrome (GBS), an inflammatory demyelinating disorder of peripheral nervous system. MRI of peripheral nerve, MR neurography (MRN), is increasingly being used for the evaluation of peripheral neuropathies directly and sequentially. Although increased signal of peripheral nerve on fat suppression T2-weighted image (FS-T2 WI) and enhanced FS T1-WI are well known in cases of EAN, time course of MRN findings have not yet been fully examined. In this study, we attempted to clarify the serial changes of MRN findings on FS T2-WI and enhanced FS T1-WI in the EAN animal model.

#### **METHODS AND MATERIALS**

Institutional Animal Care and Use Committee approval was obtained. To obtain the EAN animal model, 8 female Lewis rats (ages: 6-8 weeks, 150-180 g; Japan SLC, Japan) were immunized with subcutaneous fat injection of synthetic P2 peptide. After immunization, clinical score (neurologic status) of EAN and serial MR examinations were performed on week 1, week 2, week 3, week 4, week 5, week 6, week 7, and week 8. The changes of peripheral nerves on MRN were evaluated on lumbosacral plexus and sciatic nerves.

#### **RESULTS**

Rat EAN was induced successfully. All cases showed neurologic changes (paraplegia), and abnormal MRN findings on FS T2-WI and enhanced FS T1-WI. The clinical score, FS T2-WI MRN, and enhanced FS T1-WI MRN showed similar sequential changes (Fig 1.). At 2 weeks and 3 weeks, clinical scores, MRN grades of FS T2 WI and Enhanced FS T1W, were maximum. And then, these changes were declined over time. After 6 weeks, most of cases was returned to normal neurologic status and obtained functional recoveries. This time period was considered to be a recovery state. The enhanced FS T1-WI MRN showed normal signal intensity of peripheral nerve, but FS T2-WI MRN still noted abnormal high signal of peripheral nerves.

#### **CONCLUSION**

Both FS T2-WI and Enhanced FS T1-WI MRN were useful for the diagnosis of EAN. However, after 6 weeks, enhanced FS T1-WI MRN were more correlated with clinical score.

#### **CLINICAL RELEVANCE/APPLICATION**

The FS T2-WI is a preferred sequence to diagnosis the peripheral neuropathy owing to providing high contrast and high resolution image. Enhanced FS T1-WI with Gd-DTPA was usually used in cases suspected of tumor, infection, polyneuritis, etc. We thought that both FS T2-WI and Enhanced FS T1-WI were useful for the diagnosis of peripheral neuritis. In addition, normalized MRN findings on enhanced FS-T1 WI can be used to predict recovered clinical status of peripheral neuritis.

#### Sub-Events

#### W7-SSMK10-1 **Enthesis Assessment Using Ultrashort Echo Time Magnetic Resonance Imaging (UTE-MRI) Adiab-T1p in Psoriatic Arthritis**

Dina Moazamian, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study investigates the utility of the quantitative 3D ultrashort echo time (UTE) Adiab-T1 $\rho$  fat-sat (FS) magnetic resonance imaging (MRI) technique to quantify differences in the Achilles tendons and entheses in patients with psoriatic arthritis disease (PSA) compared with asymptomatic volunteers.

#### METHODS AND MATERIALS

Institutional review board approval and written informed consent were obtained for all recruited subjects. Achilles tendons of forty-two PSA patients (59 $\pm$ 15 years old, 38% female) and thirty-seven asymptomatic volunteers (32  $\pm$ 10 years old, 51% female) were scanned in the sagittal plane on a 3T clinical scanner (MR750, GE) employing a 3-inch surface coil. The 3D UTE-Adiab-T1 $\rho$  FS technique was used with the following parameters: TR=450ms, spin-locking time (TSL)=0, 12, 24, and 48 ms (number of adiabatic full passage (AFP) pulse=0,2,4, and 8), FA=10 $^\circ$ , number of spokes=25; bandwidth=1500, Slice thickness=2mm, Number of slices=36, FOV=12 $\times$ 12cm $^2$ , matrix size =256 $\times$ 256. The total scan time was 10 mins. Two different regions of interest (ROIs) for each participant were selected manually, one on the entheses (close to the calcaneus bone) and the other one on the pure tensile Achilles tendon (Fig.1A). UTE-MRI markers were calculated for the two groups and were compared using the Mann-Whitney-U test. P values <0.05 were considered significant.

#### RESULTS

T1 $\rho$  pixel maps of a representative patient and an asymptomatic volunteer are presented in Fig.1 B and Fig.1 C, respectively. The average and standard deviation of UTE-Adiab-T1 $\rho$  (ms) measures for entheses in patients with PSA compared to asymptomatic was 11.4 $\pm$ 2.6ms vs. 10.4 $\pm$ 2.4ms (p<0.01), respectively, and UTE-Adiab-T1 $\rho$  (ms) measures for the Achilles tendon of patients with PSA compared to the asymptomatic group was 10.2 $\pm$ 2.8ms vs. 7.7 $\pm$ 1.6ms (p<0.001) (Fig.1D-E). Significant differences in T1 $\rho$  values of entheses and tendons were found between the PSA and asymptomatic volunteers. The T1 $\rho$  differences between the asymptomatic volunteer and PSA groups were higher in the tendons (29.8%) than the entheses (9.6%).

#### CONCLUSION

The UTE-Adiab-T1 $\rho$  technique can be used as a quantitative method for assessing entheses. The significantly higher T1 $\rho$  values in the entheses of PSA patients could be due to a lower proteoglycan content or less organized fibers. The mechanisms underlying these relaxation differences should be investigated thoroughly in future studies.

#### CLINICAL RELEVANCE/APPLICATION

The UTE-Adiab-T1 $\rho$  sequence is capable of evaluating entheses and tendons and may be able to detect abnormalities in PSA patients and ultimately be used for treatment monitoring.

#### W7-SSMK10-2 **Non-invasive MRI Assessment of Infrapatellar Fat Pad in Adult Mice with Obesity and Load-induced Post-traumatic Osteoarthritis**

Aurea V. Mohana-Borges, MD, MSc (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate in a preclinical murine model of obesity and load-induced post-traumatic osteoarthritis (PTOA) 1) the volume and composition of the infrapatellar fat pad (IFP) using the quantitative MRI volumetry and T2 mapping and 2) to compare the IFP T2 mapping with subcutaneous adipose tissue (SAT).

## METHODS AND MATERIALS

In this cross-sectional study, male C57BL/6 mice were randomly assigned at 16 weeks to a high-fat diet (HFD) (n=9) or a control-fat diet (CFD) (n=7). At 36 weeks, using an ElectroForce 3100 instrument, the right limbs underwent sham in the CFD group and compression-induced ligamentous injury in the HFD group. The left limbs of the HFD mice were left unloaded and used for comparison. Four weeks post-injury (40 weeks), animals were anesthetized and sacrificed. Subsequently, MRI was performed on a 3T scanner (Bruker Biospec) using a 10 mm receiving-only surface coil. Images were acquired in the sagittal plane with a multi-slice multi-echo (MSME) sequence, with TR= 800 ms, TE1-TE10 = 6.9 - 69.0 ms, slice thickness= 0.06 mm, acquisition matrix = 333x333, bandwidth = 300 Hz/pixel, spatial resolution = 60x60x60 micron, and acquisition time = 55.5h. The first echo was used for the morphological assessment of IFP, bone, ligaments, and joint effusion, and the ten echoes for IFP T2 mappings. Two musculoskeletal radiologists independently evaluated the images. Histological reference standard was acquired. Shapiro-Wilk, ANOVA, and ICC correlation were used.

## RESULTS

After MRI evaluation, two mice were excluded from the analysis, one from each group. IFP volume and T2 values were significantly reduced in HFD-PTOA group in comparison to CFD and HFD-only groups (p=0.001). Mean IFP volume and T2 values in CFD, HFD-only, and HFD-PTOA groups were 1.05 mm<sup>3</sup> (± 0.13), 1.05 mm<sup>3</sup> (±0.10), and 0.49 mm<sup>3</sup> (±0.27), and 74.78 ms (±11.7), 66.24 ms (±11.1), and 44.33 ms (±12.8), respectively. There was a statistically significant difference between the T2 values of IFP and SAT in HFD-PTOA group (p <0.001). Hypertrophic osteophytes and joint effusion were only observed in the HFD-PTOA group. The histologic analysis performed demonstrated IFP fibrosis in HFD/PTOA group. IFP volumetry and T2 mapping were normally distributed (p>0.05). There was an excellent interobserver agreement (ICC > 0.9).

## CONCLUSION

PTOA in obese adult mice is associated with dramatic changes in IFP, characterized by decreased fat pad volume and T2 values. In addition, compositional MRI can identify differences between IFP and SAT in obese mice with PTOA.

## CLINICAL RELEVANCE/APPLICATION

There is a gap in knowledge of the characteristics of the infrapatellar fat pad and subcutaneous adipose tissue evaluated noninvasively by quantitative MRI in pre-clinical models of osteoarthritis.

## W7-SSMK10-3 Hardware Failure Detection in Spine Radiography using AI

Ji Weon Lee, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To train a deep learning (DL) model to detect hardware failure in post-operative spine radiography, using both positive and negative images of the same patients as training data to overcome the lack of data.

## METHODS AND MATERIALS

We downloaded 624K spine radiography reports from one hospital (2003 to 2022) and split them into individual words. 1768 keywords were designated as "post-operative" and "hardware failure" words. By searching for reports with two or more overlapping keywords, 316 patients were confirmed by a radiologist to have at least one image of hardware failure. From these patients, 11,321 spine radiography jpg images (75% lateral, 18% anterior, and 6% oblique views) were downloaded, including images negative for hardware failure (median 40 images/patient, over a median of 4.7 years). 5,054 images were positive for hardware failure and labeled with 7 classes of bounding boxes: ASD (Adjacent segment disease), loosening, protrusion, migration, rod fracture, screw fracture, and subsidence. Since the dataset included serial follow up images, the labels included subtle findings of hardware failure at an early phase. Label imbalance was adjusted by augmentation techniques (flip and Gaussian noise). A total of 14,919 images were used to train a Yolov5 and tested on 600 images that were not seen in the training set. The prediction was classified as correct if the predicted bounding box overlapped the ground truth by more than 50% with the correct label. An optimal confidence score threshold was selected at the maximum sensitivity of the predicted bounding boxes. Using the best-performing weights and optimal confidence score threshold, we tested the model on 10 images downloaded from Radiographics (<https://pubs.rsna.org/journal/radiographics>).

## RESULTS

The model's sensitivity in predicting any hardware failure was 88.2%, with a positive predictive value of 0.76 for the predicted bounding boxes at a confidence threshold of 0.088. The best and worst performing labels were screw fracture and protrusion: Sensitivities 98.6% and 60%. Lateral views performed better than oblique views (89.6% vs. 87.6%). Out of the 10 Radiographics images, the model predicted 4 true positives, 3 true negatives, and 3 false positive predictions.

## CONCLUSION

We trained a DL model to detect 7 types of hardware failure in post-operative spine radiography. The model correctly identified 7 out of 10 images from Radiographics.

## CLINICAL RELEVANCE/APPLICATION

1. AI can help the detection of hardware failure in post-operative spine radiography. 2. Multiple images of the same patients can be used as negative and positive training data to overcome the lack of data.

## W7-SSMK10-4 Unicompartamental Knee Arthroplasties: Radiographic Findings Associated with Conversion to Total Knee Arthroplasty

Anna L. Falkowski, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To identify radiographic findings after unicompartamental knee arthroplasty (UKA) that might lead to conversion to total knee arthroplasty (TKA).

### METHODS AND MATERIALS

IRB-approval and informed consent were obtained for this retrospective study. Radiographs of patients with UKA before conversion to TKA were compared to an asymptomatic control group without conversion. Radiographic findings like a linear osteolytic rim, circumscribed osteolysis, material integrity and positioning, periprosthetic fractures, and osteoarthritis (OA) in the lateral and patellofemoral compartments were evaluated.

### RESULTS

99 patients were included (61% male; 60/99; and 39% female; 39/99). The conversion group consisted of 42 patients, the asymptomatic control group of 57. Mean age of subjects was 67 years (range 44-88 years; standard deviation  $\pm 9.7$  years). The conversion group showed a linear osteolytic rim at the femoral component in 16.7% (versus 10.5% asymptomatic control group), and at the tibial component in 54.8% (30.7%). Circumscribed osteolysis was present in 1.2% (0%) of femoral, and 8.3% (0%) of tibial components. OA was more advanced in the conversion group for all compartments: 1.) Lateral femorotibial compartment (no OA conversion group 23.8% / asymptomatic control group 56.7%; mild OA 48.8%/38.1%; moderate OA 17.9%/5.2%; severe OA 9.5%/0%); 2.) Patellofemoral compartment (no OA 6%/11.8%; mild OA 57.1%/70.6%; moderate OA 33.3%/16.4%; severe OA 3.6%/1.2%). Statistically significant differences between the conversion group versus the asymptomatic control group were found for tibial osteolytic rim ( $p=0.014$ ) and osteolysis (0.008), femoral (0.045) material integrity, femorotibial ratio (0.040), OA of lateral femorotibial ( $<0.001$ ) and patellofemoral compartment (0.008).

### CONCLUSION

Features commonly present in patients needing a conversion from UKA to TKA were tibial osteolytic rim and osteolysis. Additionally, OA was more advanced in the conversion group at the lateral femorotibial compartment and patellofemoral compartment compared to the asymptomatic control group.

### CLINICAL RELEVANCE/APPLICATION

Survival rates of unicompartamental knee arthroplasties are known to be lower than total knee arthroplasties. The radiological features described here can be used to identify an indication for conversion to total knee arthroplasty.

## W7-SSMK10-5 Assessment of Image Quality of the Bone-implant Interface of in-vivo Acetabular Cup Implants using Photon-counting Detector CT: Effect of Tin Pre-filtration

Pauline de Klerk, MSc (*Presenter*) Nothing to Disclose

### PURPOSE

To assess the visualization of the bone-implant interface of acetabular cup implants using photon-counting detector (PCD) CT with and without additional tin filtration in a clinical setting.

### METHODS AND MATERIALS

Fourteen total hip replacements (THR) in 13 orthopedic patients (five men [age range 57 - 84 years] and eight women [age range 46 - 84 years]), underwent a clinically indicated PCD-CT (Siemens NAEOTOM Alpha). Seven patients were scanned using 140 kVp and seven patients using 140 kVp with an additional tin filtration (Sn140). All scans were acquired in ultra-high resolution mode (120x0.2mm). The image data were reconstructed with different slice thickness ([0.2mm - 0.6mm]) and kernel strengths (56, 76, 89) with and without metal artifact reduction (iMAR). Two experienced musculoskeletal radiologists assessed the ability to determine osseointegration of the cup based on four image quality criteria using a 5-point Likert scale. Bone contrast, contrast-to-noise ratio (CNR) of bone/fat and trabecular and cortical sharpness was performed as quantitative measures.

## **RESULTS**

Image quality was rated highest for 0.2 mm slice thickness and Br89 kernel across all four criteria for both the 140 kVp [2.9 - 3.4] and Sn140 kVp [3.5 - 3.9] by both radiologists. Reconstruction with 0.6mm/Qr76 and 0.6mm/Qr56/iMAR were rated with an average range of 1.4 - 2.5 for 140 kVp and 1.5 - 3.1 for Sn140 kVp. In all cases and for all image criteria the 0.2mm/Br89 was preferred above the Qr76 and Qr56/iMAR by both observers. Both radiologists preferred 0.2mm/Br89 reconstructions acquired using Sn140kVp (difference 0.3-0.7 points compared to 140kVp). Quantitative measurements confirmed significantly improved bone contrast as well as trabecular and cortical sharpness using 0.2mm/Br89. Tin pre-filtration did not affect the CNR at 0.2mm/Br89 but tended to decrease cortical sharpness.

## **CONCLUSION**

High resolution PCD-CT allows for adequate in-vivo assessment of the bone-implant interface. Additional tin filtration seems preferred by radiologists, possibly due to reduced metal artifacts.

## **CLINICAL RELEVANCE/APPLICATION**

The use of tin pre-filtration improves subjective image quality in high resolution PCD-CT assessment of osseointegration after joint replacement surgery. PCD-CT may be valuable in discriminating a loosened THR as the source of pain from other differential diagnoses such as benign musculoskeletal conditions.

### Enthesis Assessment Using Ultrashort Echo Time Magnetic Resonance Imaging (UTE-MRI) Adiab-T1p in Psoriatic Arthritis

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E451B

Dina Moazamian, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study investigates the utility of the quantitative 3D ultrashort echo time (UTE) Adiab-T1 $\rho$  fat-sat (FS) magnetic resonance imaging (MRI) technique to quantify differences in the Achilles tendons and entheses in patients with psoriatic arthritis disease (PSA) compared with asymptomatic volunteers.

#### METHODS AND MATERIALS

Institutional review board approval and written informed consent were obtained for all recruited subjects. Achilles tendons of forty-two PSA patients (59 $\pm$ 15 years old, 38% female) and thirty-seven asymptomatic volunteers (32  $\pm$ 10 years old, 51% female) were scanned in the sagittal plane on a 3T clinical scanner (MR750, GE) employing a 3-inch surface coil. The 3D UTE-Adiab-T1 $\rho$  FS technique was used with the following parameters: TR=450ms, spin-locking time (TSL)=0, 12, 24, and 48 ms (number of adiabatic full passage (AFP) pulse=0,2,4, and 8), FA=10 $^\circ$ , number of spokes=25; bandwidth=1500, Slice thickness=2mm, Number of slices=36, FOV=12 $\times$ 12cm<sup>2</sup>, matrix size =256 $\times$ 256. The total scan time was 10 mins. Two different regions of interest (ROIs) for each participant were selected manually, one on the entheses (close to the calcaneus bone) and the other one on the pure tensile Achilles tendon (Fig.1A). UTE-MRI markers were calculated for the two groups and were compared using the Mann-Whitney-U test. P values <0.05 were considered significant.

#### RESULTS

T1 $\rho$  pixel maps of a representative patient and an asymptomatic volunteer are presented in Fig.1 B and Fig.1 C, respectively. The average and standard deviation of UTE-Adiab-T1 $\rho$  (ms) measures for entheses in patients with PsA compared to asymptomatic was 11.4 $\pm$ 2.6ms vs. 10.4 $\pm$ 2.4ms ( $p$ <0.01), respectively, and UTE-Adiab-T1 $\rho$  (ms) measures for the Achilles tendon of patients with PsA compared to the asymptomatic group was 10.2 $\pm$ 2.8ms vs. 7.7 $\pm$ 1.6ms ( $p$ <0.001) (Fig.1D-E). Significant differences in T1 $\rho$  values of entheses and tendons were found between the PSA and asymptomatic volunteers. The T1 $\rho$  differences between the asymptomatic volunteer and PSA groups were higher in the tendons (29.8%) than the entheses (9.6%).

#### CONCLUSION

The UTE-Adiab-T1 $\rho$  technique can be used as a quantitative method for assessing entheses. The significantly higher T1 $\rho$  values in the entheses of PSA patients could be due to a lower proteoglycan content or less organized fibers. The mechanisms underlying these relaxation differences should be investigated thoroughly in future studies.

#### CLINICAL RELEVANCE/APPLICATION

The UTE-Adiab-T1 $\rho$  sequence is capable of evaluating entheses and tendons and may be able to detect abnormalities in PSA patients and ultimately be used for treatment monitoring.

### Non-invasive MRI Assessment of Infrapatellar Fat Pad in Adult Mice with Obesity and Load-induced Post-traumatic Osteoarthritis

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E451B

Aurea V. Mohana-Borges, MD, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate in a preclinical murine model of obesity and load-induced post-traumatic osteoarthritis (PTOA) 1) the volume and composition of the infrapatellar fat pad (IFP) using the quantitative MRI volumetry and T2 mapping and 2) to compare the IFP T2 mapping with subcutaneous adipose tissue (SAT).

#### METHODS AND MATERIALS

In this cross-sectional study, male C57BL/6 mice were randomly assigned at 16 weeks to a high-fat diet (HFD) (n=9) or a control-fat diet (CFD) (n=7). At 36 weeks, using an ElectroForce 3100 instrument, the right limbs underwent sham in the CFD group and compression-induced ligamentous injury in the HFD group. The left limbs of the HFD mice were left unloaded and used for comparison. Four weeks post-injury (40 weeks), animals were anesthetized and sacrificed. Subsequently, MRI was performed on a 3T scanner (Bruker Biospec) using a 10 mm receiving-only surface coil. Images were acquired in the sagittal plane with a multi-slice multi-echo (MSME) sequence, with TR= 800 ms, TE1-TE10 = 6.9 - 69.0 ms, slice thickness= 0.06 mm, acquisition matrix = 333x333, bandwidth = 300 Hz/pixel, spatial resolution = 60x60x60 micron, and acquisition time = 55.5h. The first echo was used for the morphological assessment of IFP, bone, ligaments, and joint effusion, and the ten echoes for IFP T2 mappings. Two musculoskeletal radiologists independently evaluated the images. Histological reference standard was acquired. Shapiro-Wilk, ANOVA, and ICC correlation were used.

#### RESULTS

After MRI evaluation, two mice were excluded from the analysis, one from each group. IFP volume and T2 values were significantly reduced in HFD-PTOA group in comparison to CFD and HFD-only groups ( $p=0.001$ ). Mean IFP volume and T2 values in CFD, HFD-only, and HFD-PTOA groups were 1.05 mm<sup>3</sup> ( $\pm 0.13$ ), 1.05 mm<sup>3</sup> ( $\pm 0.10$ ), and 0.49 mm<sup>3</sup> ( $\pm 0.27$ ), and 74.78 ms ( $\pm 11.7$ ), 66.24 ms ( $\pm 11.1$ ), and 44.33 ms ( $\pm 12.8$ ), respectively. There was a statistically significant difference between the T2 values of IFP and SAT in HFD-PTOA group ( $p < 0.001$ ). Hypertrophic osteophytes and joint effusion were only observed in the HFD-PTOA group. The histologic analysis performed demonstrated IFP fibrosis in HFD/PTOA group. IFP volumetry and T2 mapping were normally distributed ( $p > 0.05$ ). There was an excellent interobserver agreement (ICC > 0.9).

#### CONCLUSION

PTOA in obese adult mice is associated with dramatic changes in IFP, characterized by decreased fat pad volume and T2 values. In addition, compositional MRI can identify differences between IFP and SAT in obese mice with PTOA.

#### CLINICAL RELEVANCE/APPLICATION

There is a gap in knowledge of the characteristics of the infrapatellar fat pad and subcutaneous adipose tissue evaluated noninvasively by quantitative MRI in pre-clinical models of osteoarthritis.

### Assessment of Image Quality of the Bone-implant Interface of in-vivo Acetabular Cup Implants using Photon-counting Detector CT: Effect of Tin Pre-filtration

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E451B

Pauline de Klerk, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the visualization of the bone-implant interface of acetabular cup implants using photon-counting detector (PCD) CT with and without additional tin filtration in a clinical setting.

#### METHODS AND MATERIALS

Fourteen total hip replacements (THR) in 13 orthopedic patients (five men [age range 57 - 84 years] and eight women [age range 46 - 84 years]), underwent a clinically indicated PCD-CT (Siemens NAEOTOM Alpha). Seven patients were scanned using 140 kVp and seven patients using 140 kVp with an additional tin filtration (Sn140). All scans were acquired in ultra-high resolution mode (120x0.2mm). The image data were reconstructed with different slice thickness ([0.2mm - 0.6mm]) and kernel strengths (56, 76, 89) with and without metal artifact reduction (iMAR). Two experienced musculoskeletal radiologists assessed the ability to determine osseointegration of the cup based on four image quality criteria using a 5-point Likert scale. Bone contrast, contrast-to-noise ratio (CNR) of bone/fat and trabecular and cortical sharpness was performed as quantitative measures.

#### RESULTS

Image quality was rated highest for 0.2 mm slice thickness and Br89 kernel across all four criteria for both the 140 kVp [2.9 - 3.4] and Sn140 kVp [3.5 - 3.9] by both radiologists. Reconstruction with 0.6mm/Qr76 and 0.6mm/Qr56/iMAR were rated with an average range of 1.4 - 2.5 for 140 kVp and 1.5 - 3.1 for Sn140 kVp. In all cases and for all image criteria the 0.2mm/Br89 was preferred above the Qr76 and Qr56/iMAR by both observers. Both radiologists preferred 0.2mm/Br89 reconstructions acquired using Sn140kVp (difference 0.3-0.7 points compared to 140kVp). Quantitative measurements confirmed significantly improved bone contrast as well as trabecular and cortical sharpness using 0.2mm/Br89. Tin pre-filtration did not affect the CNR at 0.2mm/Br89 but tended to decrease cortical sharpness.

#### CONCLUSION

High resolution PCD-CT allows for adequate in-vivo assessment of the bone-implant interface. Additional tin filtration seems preferred by radiologists, possibly due to reduced metal artifacts.

#### CLINICAL RELEVANCE/APPLICATION

The use of tin pre-filtration improves subjective image quality in high resolution PCD-CT assessment of osseointegration after joint replacement surgery. PCD-CT may be valuable in discriminating a loosened THR as the source of pain from other differential diagnoses such as benign musculoskeletal conditions.

W7-SSNR12

### Neuroradiology (Techniques and Methods: Diffusion, Perfusion, and Other Techniques)

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E353B

Nicoletta Anzalone, MD (*Moderator*) Nothing to Disclose  
Seyedmehdi Payabvash, MD (*Moderator*) Nothing to Disclose

#### Sub-Events

#### **W7-SSNR12-1 High Resolution Neck CT Angiography for Stenosis Quantification: A Prospective Patient Study Comparing Photon-counting Detector CT and Energy-integrating Detector CT**

Felix E. Diehn, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare photon-counting detector (PCD) and conventional energy-integrating detector (EID) CT for stenosis quantification on neck CTA.

#### METHODS AND MATERIALS

Adult patients with at least mild stenosis of at least one carotid bulb/proximal internal carotid artery (ICA) undergoing head/neck CTA exams at EID underwent a PCD research CTA. Dual-energy scanning protocol was used on EID-CT (100/150Sn, 192x0.6mm detector configuration) with a medium sharp kernel and iterative reconstruction (Qr54-3). High-resolution (HR) scan mode was used on PCD-CT (120 kV, 120x0.2mm). Images were reconstructed at 0.6mm slice thickness using a closely matched standard resolution kernel (Qr56-3). HR images with the sharpest kernel (Qr89) were reconstructed on PCD-CT at thinnest slice thickness, 0.2mm. A dedicated deep convolutional neural network (HR-CNN) denoising algorithm was trained using HR patient images and applied to the HR series. For each stenosis, a neuroradiology reader evaluated the 4 different series in randomized and blinded fashion. The reader scored relative preference for each series (from 1, most preferred, with greatest confidence in evaluating the stenosis, to 4, least preferred). The reader measured the stenoses on each series (minimal luminal diameter at the maximal level of stenosis). A second reader measured the maximal luminal diameter of the normal caliber more distal ICA to enable % stenosis calculations, and categorized plaque type.

#### RESULTS

10 adult patients with 14 carotid bulb/proximal ICA stenoses were included (age  $73\pm 6$  years, 3 females). PCD-HR-CNN images were most preferred and EID images least: mean preference scores were  $1.43\pm 0.65$  PCD-HR-CNN,  $3.86\pm 0.36$  EID. Stenosis measurements on PCD-HR (with or without CNN) were less severe than on EID; mean 46% PCD-HR-CNN, 45% PCD-HR, 51% EID ( $p=0.010$  PCD-HR-CNN vs. EID;  $p=0.014$  PCD-HR vs. EID). 3 stenoses harbored heavily calcified plaque and 2 additional mixed plaques demonstrated calcifications along the lumen at the maximal stenosis. In these 5 stenoses, preference for PCD including PCD-HR-CNN over EID was also strong; mean preference scores were  $1.40\pm 0.55$  PCD-HR-CNN,  $1.80\pm 0.84$  PCD-HR,  $3.60\pm 0.55$  EID. Stenosis measurements on PCD-HR (with or without CNN) were also less severe than on EID; mean 59% PCD-HR-CNN and PCD-HR, 65% EID ( $p=0.018$  PCD-HR-CNN vs. EID,  $p=0.036$  PCD-HR vs. EID).

#### CONCLUSION

PCD-CT provides preferred CTA image quality for carotid stenosis compared to EID-CT, especially when PCD-HR mode is combined with an HR-CNN denoising algorithm. EID tends to overestimate carotid stenosis, particularly in calcified plaques.

#### CLINICAL RELEVANCE/APPLICATION

PCD can facilitate CTA assessment of carotid stenoses, including when HR mode is combined with a HR-CNN denoising algorithm.

#### **W7-SSNR12-2 Unsupervised Discovery of Microstructural Deviations in Diffusion MRI Tractometry of Adolescents with ADHD**

Justin Huynh, BS, MS (*Presenter*) Nothing to Disclose

## PURPOSE

Diagnosis of attention deficit hyperactivity disorder (ADHD) is complex, relying on criteria sensitive to subjective biases. Alternatively, structural and functional variations in imaging may reflect underlying psychopathology and etiology of ADHD and provide rich data sources enabling more objective diagnosis. Though promising, these variations are still not well understood or characterized. The purpose of this study is to discover and visualize hidden structural patterns of diffusion weighted imaging (DWI) derived white matter (WM) tractography and fractional anisotropy (FA) measurements among adolescent patients with ADHD using unsupervised deep learning.

## METHODS AND MATERIALS

Diffusion weighted imaging (DWI) from a subset of 1704 patients from the Adolescent Brain Cognitive Development (ABCD) Study was gathered. DWI was processed with Automated Fiber Quantification (AFQ) to extract individual subject white matter (WM) fiber bundles for 30 major WM tracts. Fractional anisotropy (FA) was computed at 80 equally spaced nodes along the length of each tract, and used as input for the deep learning model. An autoencoder was trained to reproduce the FA values of 1371 subjects. After training, the model was evaluated on an independent testing set of 333 patients, 193 with behavior problem monitor (BPM) greater than 70, the clinical threshold for ADHD, and 140 with BPM less than 60, no ADHD. Anomaly scores using absolute error (AE) along the WM tracts were computed between predicted and inputted FA values. Anomaly score profiles were averaged and compared between all patients with and without ADHD.

## RESULTS

Mean absolute error (MAE) between predicted and actual FA values was 0.041, significantly different between subjects with and without ADHD (0.042 vs 0.038,  $p=0.041$ ). Comparing absolute error anomaly scores between subjects with and without ADHD along 30 WM tracts reveals significant differences in 9 tracts: left arcuate fasciculus (ARC\_L,  $p=0.006$ ), left cingulum cingulate gyrus (CGC\_L,  $p=0.020$ ), left corticospinal tract (CST\_L,  $p=0.007$ ), right corticospinal tract (CST\_R,  $p=0.006$ ), frontoparietal (FP,  $p=0.0168$ ), right inferior fronto-occipital fasciculus (IFO\_R,  $p=0.033$ ), left inferior longitudinal fasciculus (ILF\_L,  $p=0.002$ ), superior parietal lobe ( $p=0.041$ ) and temporal lobe ( $p=0.008$ ).

## CONCLUSION

The unsupervised autoencoder-based approach identified anomalous FA profiles in patients with ADHD, revealing significant differences in 9 out of 30 WM tracts.

## CLINICAL RELEVANCE/APPLICATION

This method identifies microstructural deviations in patients' DWI in an unsupervised manner, providing a promising step towards finding imaging biomarkers that can be used to diagnose ADHD in a quantitative, objective diagnostic framework.

## W7-SSNR12-3 Evaluation of the Effect of Exercise on Glymphatic and Meningeal Lymphatic Vessel Flow Using Quantitative MR Imaging With Intravenous Contrast Injection

Roh-Eul Yoo, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

To quantitatively evaluate the effect of physical exercise on glymphatic and meningeal lymphatic vessel flow using dynamic T1 mapping and arterial spin labeling technique in healthy normal volunteers

## METHODS AND MATERIALS

This randomized clinical trial included 37 healthy normal volunteers from March 2021 to July 2022. Subjects were randomly assigned in a 1:1 ratio to perform a single session (acute group) or a 12-week program (chronic group) of cycle ergometer exercise. Dynamic T1 mapping (baseline and 0.5h and 12 h after IV contrast injection) was performed before and after the exercise to quantify the glymphatic flow. Precontrast inversion-recovery alternate ascending/descending directional navigation (IR-ALADDIN) was obtained before and after the exercise to quantify the meningeal lymphatic vessel flow. The change in T1 values between baseline and 0.5h ( $\Delta T1$ ) at the putamen and percent signal change at meningeal lymphatic vessels adjacent to the superior sagittal sinus were measured and compared between pre-exercise and post-exercise states.

## RESULTS

$\Delta T1$  at the putamen increased from 25.7 ms (IQR, 24.3-34.2 ms) to 34.7 ms (IQR, 31.4-40.7 ms) in the chronic exercise group ( $P = .01$ ). For the chronic exercise group, the averaged percent signal changes in meningeal lymphatic vessels also increased from  $4.63\% \pm 0.38$  to  $5.81\% \pm 0.4$  after the exercise ( $P = .005$ ). However, in the acute exercise group,  $\Delta T1$  at the putamen did not significantly differ between the pre-exercise (30.3 ms [IQR, 25.4-39.6 ms]) and post-exercise states (28.4 ms [IQR, 19.4-41.4 ms]) ( $P = .72$ ). Averaged percent signal changes in meningeal lymphatic vessels also did not significantly differ between the pre-exercise ( $4.69\% \pm 0.38$ ) and the post-exercise ( $4.66\% \pm 0.31$ ) states ( $P = .95$ ).

## CONCLUSION

Chronic cycle ergometer exercise had a positive effect on the glymphatic and meningeal lymphatic vessel flow in healthy normal volunteers.

## CLINICAL RELEVANCE/APPLICATION

Increased physical exercise has been shown to slow the progression of cognitive decline in dementia and mild cognitive impairment. Our results suggest increased glymphatic and meningeal lymphatic vessel flow as the potential mechanism of the slowing effect of physical exercise in dementia and mild cognitive impairment and highlight the importance of exercise intervention in such patients.

### W7-SSNR12-4 **Ultra-High-Resolution Dual-Contrast Brain Imaging with Deep-Silicon Photon-Counting CT: A Phantom Study**

Amir Pourmorteza, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Photon-counting detector (PCD) CT can distinguish two contrast agents with K-edge imaging. This enables the visualization of two different phases of perfusion at one time point via injection of two contrast agents at different times and imaging both simultaneously. Spectral information can create material density maps and allow for beam hardening and cupping artifacts corrections that are typical of conventional head CT. A new technology, edge-on-irradiated deep-Si PCD, promises improved simultaneous high spectral and spatial resolution vs existing CdTe/CdZnTe PCDs. Here we assess the performance of deep-Si PCD-CT for ultra-high-resolution (150  $\mu\text{m}$ ) dual-contrast imaging of the brain.

#### METHODS AND MATERIALS

A human skull filled with ballistic gel is used to hold 24 vials containing calibrated mixtures of iodine- and gadolinium-based contrast agents (IBCA, GBCA) with water with IBCA ranging from 0.1-35 mg I/mL and GBCA, from 0.5-10 mg Gd/mL. A water phantom with two dilutions of IBCA and GBCA, without any mixtures of the two, is used to calibrate the linear material decomposition (MD) algorithm. The phantoms are scanned on a prototype deep-Si PCD-CT scanner with 8 energy bins, at 120 kVp, 300 mAs, and 0.5 s rotation. Basis material maps are computed from the 8 energy bins and reconstructed using a filtered-backprojection (FBP) with a prototype high-resolution kernel having 10% MTF cutoff at 21.2 lp/cm, and  $117 \times 117 \times 416 \mu\text{m}^3$  voxel size. The basis material maps are then transformed to IBCA and GBCA maps using MD. The error in estimated concentrations is calculated in ROIs ( $d > 4 \text{ mm}$ ). Wilcoxon test is used to compare differences, with  $p < 0.05$  considered statistically significant.

#### RESULTS

The range of error in estimating IBCA and GBCA concentrations were -1.02-1.50 mg I/mL and -0.01-2.3 mg Gd/mL, respectively. No significant bias in error was found in vials with single contrast to mixtures of both contrast agents. Also, no significant difference in error was found with location in the skull which indicates that results are not affected by cupping artifact.

#### CONCLUSION

Deep-Si PCD-CT could quantify concentrations of IBCA and GBCA in a collection of mixtures of the two contrast agents, without being affected by cupping artifacts caused by the skull. This is a study on a prototype scanner with FBP reconstruction and linear MD. Further studies are warranted to assess the improvement in material map accuracy offered by model-based and deep-learning-based reconstruction and MD algorithms.

## CLINICAL RELEVANCE/APPLICATION

UHR dual-contrast imaging with 8 energy bin deep-Si PCD-CT makes it possible to visualize registered images of different phases of contrast enhancement e.g., arterial, venous, or delayed, of brain tissue and pathologies with high resolution ( $\sim 150 \mu\text{m}$ ).

### W7-SSNR12-5 **Point-Of-Care Brain MRI: Update on Preliminary Results From a Single-Center Retrospective Study in the Neurocritical Care Setting**

Brian G. Yep, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Point-of-care (POC) MRI is a new imaging technology that allows for bedside low field brain MRI and demonstrates promise for use in the neurocritical care setting when traditional high field MRI may be difficult obtaining. Early detection of ischemia, hemorrhage, or increased intracranial pressure can be valuable in the management of critically ill patients. The purpose of this study is to expand on prior data obtained from a 64mT POC MRI system deployed in the neuroscience ICU (NICU) department to provide further support for the application of POC MRI in the critical care setting.

#### METHODS AND MATERIALS

After IRB approval, data was collected from September 2022 to February 2023 comparing capabilities of brain POC MRI to CT and fixed MRI. An additional 21 POC MRI scans were compared to preceding CT within 72 hours, and a follow-up 1.5T or 3T

MRI within 72 hours. Turnaround time, examination limitations, and relevant findings were assessed. Descriptive statistics were employed to analyze clinical variables.

## RESULTS

A total of 22 patients who underwent POC MRI were included in this study (67% male, median age 60 years [IQR 48-71 years]). Preceding CT was performed in 19 (90%) of these patients, of which, follow-up fixed MRI was performed in 5 (26%). No acute intracranial abnormality was observed for 3 of the 19 CTs (16%), an impression that was confirmed by POC MRI. Diffusion weighted imaging was noted to be of non-diagnostic quality in 4 (19%). Of those with preceding CT, POC MRI detected acute infarct in 6 (32%), intracerebral hemorrhage in 9 (47%), and mass effect in 8 (42%). POC MRI confirmed all findings from preceding CT, without failure of detection of any abnormality. Furthermore, the 5 fixed MRI studies did not reveal any additional findings. Additionally, POC MRI demonstrated anoxic brain injury for one patient too unstable to transport to CT or fixed MRI. The median POC MRI scan time was 43 min [IQR 40-81 min], time to image was 68 min, and turnaround time (order time to scan completion) was 123 min.

## CONCLUSION

This study expands previous work demonstrating POC MRI accessibility in critically ill patients. POC MRI gives the advantage of increased speed and convenience of bedside detection of acute intracranial injury, including in this case, the ability to image a critically ill patient who was too unstable to transport out of the NICU for a CT exam.

## CLINICAL RELEVANCE/APPLICATION

This technology is promising in critically ill patients too unstable to transport where early MRI access is critical for improved survival and better patient outcomes.

## W7-SSNR12-6 Regional Cerebral Blood Flow Correlate With Transcriptional and Cellular Signatures in Tinnitus

Jixin Luan, MD (*Presenter*) Nothing to Disclose

## PURPOSE

We aimed to examine alterations in tinnitus patients brain regional cerebral blood flow (CBF) using arterial spin labeling (ASL), and applied an integrative imaging transcriptomics approach to identify transcriptional and cellular correlates of these changes.

## METHODS AND MATERIALS

Participants included tinnitus patients (n = 56) and non-tinnitus controls (n = 62), matched for age, sex, education. CBF images were collected and analyzed using ASL. Regional microarray expression data were obtained from 6 postmortem brains provided by the Allen Human Brain Atlas (AHBA). We used the abagen toolbox to process and map the transcriptomic data from the Desikan-Killiany Atlas. To examine the association between the healthy brain transcriptome and region CBF in tinnitus, we used partial least square regression (PLS). We then used all genes in PLS1+ and PLS1- to conduct further bioinformatics analyses investigating whether these genes map to common and relevant biological pathways. We also investigated whether our PLS1+ and PLS1- subsets of genes were particularly enriched for genes of specific brain cell types. In our study, we used a spin-based method to correct for potential confounding effects of spatial autocorrelation.

## RESULTS

Compared with non-tinnitus controls, tinnitus patients exhibited increased CBF, primarily in left transverse temporal (FDR < 0.05). The first PLS component (PLS1) explained the highest proportion of CBF changes (30.29%) and did so above chance (Pboot = 0.001). Notably, we found that the PLS1 weighted gene expression map was spatially correlated with the case-control CBF t-map (Pearson's r = 0.59, pspin < 0.05). Using gene ontological (GO) analyses with the PLS1- gene list, we found enrichment for a number of GO terms-biological pathways broadly mapping to the protein phosphorylation. We found that downweighted genes were significantly associated with GABAergic neurons.

## CONCLUSION

Our findings bridge levels to connect genes, biological pathways, and cell classes to in vivo imaging correlates of tinnitus, particularly the processes involving protein phosphorylation.

## CLINICAL RELEVANCE/APPLICATION

This study provides insight into the cellular and molecular changes associated with tinnitus, and the identification of altered regional cerebral blood flow and associated gene expression patterns can guide the development of personalized therapies that target specific biological pathways and cell types implicated in tinnitus.

### High Resolution Neck CT Angiography for Stenosis Quantification: A Prospective Patient Study Comparing Photon-counting Detector CT and Energy-integrating Detector CT

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E353B

Felix E. Diehn, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare photon-counting detector (PCD) and conventional energy-integrating detector (EID) CT for stenosis quantification on neck CTA.

#### METHODS AND MATERIALS

Adult patients with at least mild stenosis of at least one carotid bulb/proximal internal carotid artery (ICA) undergoing head/neck CTA exams at EID underwent a PCD research CTA. Dual-energy scanning protocol was used on EID-CT (100/150Sn, 192x0.6mm detector configuration) with a medium sharp kernel and iterative reconstruction (Qr54-3). High-resolution (HR) scan mode was used on PCD-CT (120 kV, 120x0.2mm). Images were reconstructed at 0.6mm slice thickness using a closely matched standard resolution kernel (Qr56-3). HR images with the sharpest kernel (Qr89) were reconstructed on PCD-CT at thinnest slice thickness, 0.2mm. A dedicated deep convolutional neural network (HR-CNN) denoising algorithm was trained using HR patient images and applied to the HR series. For each stenosis, a neuroradiology reader evaluated the 4 different series in randomized and blinded fashion. The reader scored relative preference for each series (from 1, most preferred, with greatest confidence in evaluating the stenosis, to 4, least preferred). The reader measured the stenoses on each series (minimal luminal diameter at the maximal level of stenosis). A second reader measured the maximal luminal diameter of the normal caliber more distal ICA to enable % stenosis calculations, and categorized plaque type.

#### RESULTS

10 adult patients with 14 carotid bulb/proximal ICA stenoses were included (age  $73\pm 6$  years, 3 females). PCD-HR-CNN images were most preferred and EID images least: mean preference scores were  $1.43\pm 0.65$  PCD-HR-CNN,  $3.86\pm 0.36$  EID. Stenosis measurements on PCD-HR (with or without CNN) were less severe than on EID; mean 46% PCD-HR-CNN, 45% PCD-HR, 51% EID ( $p=0.010$  PCD-HR-CNN vs. EID;  $p=0.014$  PCD-HR vs. EID). 3 stenoses harbored heavily calcified plaque and 2 additional mixed plaques demonstrated calcifications along the lumen at the maximal stenosis. In these 5 stenoses, preference for PCD including PCD-HR-CNN over EID was also strong; mean preference scores were  $1.40\pm 0.55$  PCD-HR-CNN,  $1.80\pm 0.84$  PCD-HR,  $3.60\pm 0.55$  EID. Stenosis measurements on PCD-HR (with or without CNN) were also less severe than on EID; mean 59% PCD-HR-CNN and PCD-HR, 65% EID ( $p=0.018$  PCD-HR-CNN vs. EID,  $p=0.036$  PCD-HR vs. EID).

#### CONCLUSION

PCD-CT provides preferred CTA image quality for carotid stenosis compared to EID-CT, especially when PCD-HR mode is combined with an HR-CNN denoising algorithm. EID tends to overestimate carotid stenosis, particularly in calcified plaques.

#### CLINICAL RELEVANCE/APPLICATION

PCD can facilitate CTA assessment of carotid stenoses, including when HR mode is combined with a HR-CNN denoising algorithm.

### Unsupervised Discovery of Microstructural Deviations in Diffusion MRI Tractometry of Adolescents with ADHD

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E353B

Justin Huynh, BS, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

Diagnosis of attention deficit hyperactivity disorder (ADHD) is complex, relying on criteria sensitive to subjective biases. Alternatively, structural and functional variations in imaging may reflect underlying psychopathology and etiology of ADHD and provide rich data sources enabling more objective diagnosis. Though promising, these variations are still not well understood or characterized. The purpose of this study is to discover and visualize hidden structural patterns of diffusion weighted imaging (DWI) derived white matter (WM) tractography and fractional anisotropy (FA) measurements among adolescent patients with ADHD using unsupervised deep learning.

#### METHODS AND MATERIALS

Diffusion weighted imaging (DWI) from a subset of 1704 patients from the Adolescent Brain Cognitive Development (ABCD) Study was gathered. DWI was processed with Automated Fiber Quantification (AFQ) to extract individual subject white matter (WM) fiber bundles for 30 major WM tracts. Fractional anisotropy (FA) was computed at 80 equally spaced nodes along the length of each tract, and used as input for the deep learning model. An autoencoder was trained to reproduce the FA values of 1371 subjects. After training, the model was evaluated on an independent testing set of 333 patients, 193 with behavior problem monitor (BPM) greater than 70, the clinical threshold for ADHD, and 140 with BPM less than 60, no ADHD. Anomaly scores using absolute error (AE) along the WM tracts were computed between predicted and inputted FA values. Anomaly score profiles were averaged and compared between all patients with and without ADHD.

#### RESULTS

Mean absolute error (MAE) between predicted and actual FA values was 0.041, significantly different between subjects with and without ADHD (0.042 vs 0.038,  $p=0.041$ ). Comparing absolute error anomaly scores between subjects with and without ADHD along 30 WM tracts reveals significant differences in 9 tracts: left arcuate fasciculus (ARC\_L,  $p=0.006$ ), left cingulum cingulate gyrus (CGC\_L,  $p=0.020$ ), left corticospinal tract (CST\_L,  $p=0.007$ ), right corticospinal tract (CST\_R,  $p=0.006$ ), frontoparietal (FP,  $p=0.0168$ ), right inferior fronto-occipital fasciculus (IFO\_R,  $p=0.033$ ), left inferior longitudinal fasciculus (ILF\_L,  $p=0.002$ ), superior parietal lobe ( $p=0.041$ ) and temporal lobe ( $p=0.008$ ).

#### CONCLUSION

The unsupervised autoencoder-based approach identified anomalous FA profiles in patients with ADHD, revealing significant differences in 9 out of 30 WM tracts.

#### CLINICAL RELEVANCE/APPLICATION

This method identifies microstructural deviations in patients' DWI in an unsupervised manner, providing a promising step towards finding imaging biomarkers that can be used to diagnose ADHD in a quantitative, objective diagnostic framework.

### Evaluation of the Effect of Exercise on Glymphatic and Meningeal Lymphatic Vessel Flow Using Quantitative MR Imaging With Intravenous Contrast Injection

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E353B

Roh-Eul Yoo, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To quantitatively evaluate the effect of physical exercise on glymphatic and meningeal lymphatic vessel flow using dynamic T1 mapping and arterial spin labeling technique in healthy normal volunteers

#### METHODS AND MATERIALS

This randomized clinical trial included 37 healthy normal volunteers from March 2021 to July 2022. Subjects were randomly assigned in a 1:1 ratio to perform a single session (acute group) or a 12-week program (chronic group) of cycle ergometer exercise. Dynamic T1 mapping (baseline and 0.5h and 12 h after IV contrast injection) was performed before and after the exercise to quantify the glymphatic flow. Precontrast inversion-recovery alternate ascending/descending directional navigation (IR-ALADDIN) was obtained before and after the exercise to quantify the meningeal lymphatic vessel flow. The change in T1 values between baseline and 0.5h ( $\Delta T1$ ) at the putamen and percent signal change at meningeal lymphatic vessels adjacent to the superior sagittal sinus were measured and compared between pre-exercise and post-exercise states.

#### RESULTS

$\Delta T1$  at the putamen increased from 25.7 ms (IQR, 24.3-34.2 ms) to 34.7 ms (IQR, 31.4-40.7 ms) in the chronic exercise group ( $P = .01$ ). For the chronic exercise group, the averaged percent signal changes in meningeal lymphatic vessels also increased from  $4.63\% \pm 0.38$  to  $5.81\% \pm 0.4$  after the exercise ( $P = .005$ ). However, in the acute exercise group,  $\Delta T1$  at the putamen did not significantly differ between the pre-exercise (30.3 ms [IQR, 25.4-39.6 ms]) and post-exercise states (28.4 ms [IQR, 19.4-41.4 ms]) ( $P = .72$ ). Averaged percent signal changes in meningeal lymphatic vessels also did not significantly differ between the pre-exercise ( $4.69\% \pm 0.38$ ) and the post-exercise ( $4.66\% \pm 0.31$ ) states ( $P = .95$ ).

#### CONCLUSION

Chronic cycle ergometer exercise had a positive effect on the glymphatic and meningeal lymphatic vessel flow in healthy normal volunteers.

#### CLINICAL RELEVANCE/APPLICATION

Increased physical exercise has been shown to slow the progression of cognitive decline in dementia and mild cognitive impairment. Our results suggest increased glymphatic and meningeal lymphatic vessel flow as the potential mechanism of the slowing effect of physical exercise in dementia and mild cognitive impairment and highlight the importance of exercise intervention in such patients.

### Ultra-High-Resolution Dual-Contrast Brain Imaging with Deep-Silicon Photon-Counting CT: A Phantom Study

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E353B

Amir Pourmorteza, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Photon-counting detector (PCD) CT can distinguish two contrast agents with K-edge imaging. This enables the visualization of two different phases of perfusion at one time point via injection of two contrast agents at different times and imaging both simultaneously. Spectral information can create material density maps and allow for beam hardening and cupping artifacts corrections that are typical of conventional head CT. A new technology, edge-on-irradiated deep-Si PCD, promises improved simultaneous high spectral and spatial resolution vs existing CdTe/CdZnTe PCDs. Here we assess the performance of deep-Si PCD-CT for ultra-high-resolution (150  $\mu\text{m}$ ) dual-contrast imaging of the brain.

#### METHODS AND MATERIALS

A human skull filled with ballistic gel is used to hold 24 vials containing calibrated mixtures of iodine- and gadolinium-based contrast agents (IBCA, GBCA) with water with IBCA ranging from 0.1-35 mg I/mL and GBCA, from 0.5-10 mg Gd/mL. A water phantom with two dilutions of IBCA and GBCA, without any mixtures of the two, is used to calibrate the linear material decomposition (MD) algorithm. The phantoms are scanned on a prototype deep-Si PCD-CT scanner with 8 energy bins, at 120 kVp, 300 mAs, and 0.5 s rotation. Basis material maps are computed from the 8 energy bins and reconstructed using a filtered-backprojection (FBP) with a prototype high-resolution kernel having 10% MTF cutoff at 21.2 lp/cm, and  $117 \times 117 \times 416 \mu\text{m}^3$  voxel size. The basis material maps are then transformed to IBCA and GBCA maps using MD. The error in estimated concentrations is calculated in ROIs ( $d > 4 \text{ mm}$ ). Wilcoxon test is used to compare differences, with  $p < 0.05$  considered statistically significant.

#### RESULTS

The range of error in estimating IBCA and GBCA concentrations were -1.02-1.50 mg I/mL and -0.01-2.3 mg Gd/mL, respectively. No significant bias in error was found in vials with single contrast to mixtures of both contrast agents. Also, no significant difference in error was found with location in the skull which indicates that results are not affected by cupping artifact.

#### CONCLUSION

Deep-Si PCD-CT could quantify concentrations of IBCA and GBCA in a collection of mixtures of the two contrast agents, without being affected by cupping artifacts caused by the skull. This is a study on a prototype scanner with FBP reconstruction and linear MD. Further studies are warranted to assess the improvement in material map accuracy offered by model-based and deep-learning-based reconstruction and MD algorithms.

#### CLINICAL RELEVANCE/APPLICATION

UHR dual-contrast imaging with 8 energy bin deep-Si PCD-CT makes it possible to visualize registered images of different phases of contrast enhancement e.g., arterial, venous, or delayed, of brain tissue and pathologies with high resolution ( $\sim 150 \mu\text{m}$ ).

### Point-Of-Care Brain MRI: Update on Preliminary Results From a Single-Center Retrospective Study in the Neurocritical Care Setting

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E353B

Brian G. Yep, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Point-of-care (POC) MRI is a new imaging technology that allows for bedside low field brain MRI and demonstrates promise for use in the neurocritical care setting when traditional high field MRI may be difficult obtaining. Early detection of ischemia, hemorrhage, or increased intracranial pressure can be valuable in the management of critically ill patients. The purpose of this study is to expand on prior data obtained from a 64mT POC MRI system deployed in the neuroscience ICU (NICU) department to provide further support for the application of POC MRI in the critical care setting.

#### METHODS AND MATERIALS

After IRB approval, data was collected from September 2022 to February 2023 comparing capabilities of brain POC MRI to CT and fixed MRI. An additional 21 POC MRI scans were compared to preceding CT within 72 hours, and a follow-up 1.5T or 3T MRI within 72 hours. Turnaround time, examination limitations, and relevant findings were assessed. Descriptive statistics were employed to analyze clinical variables.

#### RESULTS

A total of 22 patients who underwent POC MRI were included in this study (67% male, median age 60 years [IQR 48-71 years]). Preceding CT was performed in 19 (90%) of these patients, of which, follow-up fixed MRI was performed in 5 (26%). No acute intracranial abnormality was observed for 3 of the 19 CTs (16%), an impression that was confirmed by POC MRI. Diffusion weighted imaging was noted to be of non-diagnostic quality in 4 (19%). Of those with preceding CT, POC MRI detected acute infarct in 6 (32%), intracerebral hemorrhage in 9 (47%), and mass effect in 8 (42%). POC MRI confirmed all findings from preceding CT, without failure of detection of any abnormality. Furthermore, the 5 fixed MRI studies did not reveal any additional findings. Additionally, POC MRI demonstrated anoxic brain injury for one patient too unstable to transport to CT or fixed MRI. The median POC MRI scan time was 43 min [IQR 40-81 min], time to image was 68 min, and turnaround time (order time to scan completion) was 123 min.

#### CONCLUSION

This study expands previous work demonstrating POC MRI accessibility in critically ill patients. POC MRI gives the advantage of increased speed and convenience of bedside detection of acute intracranial injury, including in this case, the ability to image a critically ill patient who was too unstable to transport out of the NICU for a CT exam.

#### CLINICAL RELEVANCE/APPLICATION

This technology is promising in critically ill patients too unstable to transport where early MRI access is critical for improved survival and better patient outcomes.

### Regional Cerebral Blood Flow Correlate With Transcriptional and Cellular Signatures in Tinnitus

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E353B

Jixin Luan, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

We aimed to examine alterations in tinnitus patients' brain regional cerebral blood flow (CBF) using arterial spin labeling (ASL), and applied an integrative imaging transcriptomics approach to identify transcriptional and cellular correlates of these changes.

#### METHODS AND MATERIALS

Participants included tinnitus patients ( $n = 56$ ) and non-tinnitus controls ( $n = 62$ ), matched for age, sex, education. CBF images were collected and analyzed using ASL. Regional microarray expression data were obtained from 6 postmortem brains provided by the Allen Human Brain Atlas (AHBA). We used the abagen toolbox to process and map the transcriptomic data from the Desikan-Killiany Atlas. To examine the association between the healthy brain transcriptome and region CBF in tinnitus, we used partial least square regression (PLS). We then used all genes in PLS1+ and PLS1- to conduct further bioinformatics analyses investigating whether these genes map to common and relevant biological pathways. We also investigated whether our PLS1+ and PLS1- subsets of genes were particularly enriched for genes of specific brain cell types. In our study, we used a spin-based method to correct for potential confounding effects of spatial autocorrelation.

#### RESULTS

Compared with non-tinnitus controls, tinnitus patients exhibited increased CBF, primarily in left transverse temporal ( $FDR < 0.05$ ). The first PLS component (PLS1) explained the highest proportion of CBF changes (30.29%) and did so above chance ( $P_{boot} = 0.001$ ). Notably, we found that the PLS1 weighted gene expression map was spatially correlated with the case-control CBF t-map (Pearson's  $r = 0.59$ ,  $p_{spin} < 0.05$ ). Using gene ontological (GO) analyses with the PLS1- gene list, we found enrichment for a number of GO terms-biological pathways broadly mapping to the protein phosphorylation. We found that downweighted genes were significantly associated with GABAergic neurons.

#### CONCLUSION

Our findings bridge levels to connect genes, biological pathways, and cell classes to in vivo imaging correlates of tinnitus, particularly the processes involving protein phosphorylation.

#### CLINICAL RELEVANCE/APPLICATION

This study provides insight into the cellular and molecular changes associated with tinnitus, and the identification of altered regional cerebral blood flow and associated gene expression patterns can guide the development of personalized therapies that target specific biological pathways and cell types implicated in tinnitus.

#### **W7-SSNR13-1** Developing an Anatomically Valid Segmentation Protocol for Early Tau Regions in Alzheimer's Disease: The Anterior Medial Temporal Lobe Cortices

Niyousha Sadeghpour, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The anterior portion of the medial temporal lobe (MTL) is one of the earliest regions showing tau deposition in Alzheimer's disease (AD) and hence a key focus area for AD imaging biomarkers. However, the anatomical variability of the anterior MTL presents a challenge for segmentation protocols. Leveraging a novel postmortem dataset with histology and MRI, we aimed to develop a histologically-informed segmentation protocol for the anterior entorhinal cortex (ERC), Brodmann Area (BA) 35, and BA36 for in vivo 3 tesla (T) MRI.

#### METHODS AND MATERIALS

Digitized 50- $\mu$ m thick MTL Nissl-stained coronal histology sections from 20 cases were annotated by expert neuroanatomists. These cases were 61 to 97 years of age (female to male ratio of 1:1) and were with and without neurodegenerative diseases (11 vs. 9 cases) to ensure broad generalizability of the protocol. The histology sections were registered to same-subject 0.2x0.2x0.2-mm<sup>3</sup> 9.4 T postmortem MRI and were analyzed together to determine the location of the histological borders of the MTL cortices in relation to anatomical landmarks observable on MRI.

#### RESULTS

The anterior histological border distances of ERC, BA35 and BA36 were evaluated with respect to various anatomical landmarks observable on MRI, including temporal pole, the hippocampus, amygdala, collateral sulcus (CS) and limen insulae. The distance relative to the hippocampus was chosen, as there was relatively low between-subject variability in distance (comparing standard deviations) and this region is easily identifiable on MRI. The ERC starts 4.75 mm (median value) anterior to the hippocampus, BA35 9.25 mm and BA36 10.25 mm. Next, we analyzed the location of the ERC on histology sections. We determined that regardless of the depth of the CS, the inferior border of the ERC is on average at the edge of the CS and the superior border at the superior edge of the parahippocampal gyrus, but at the halfway point for the first section with ERC. We then studied histology sections for BA35 borders and determined that for sections where the inferior border of ERC serves as the medial border for BA35, the lateral border is on average located at the fundus of the CS. These segmentation rules can be applied to T1-MRI. There were no differences between the cases with and without neurodegenerative diseases in the location of these borders.

#### CONCLUSION

We are developing a histology grounded segmentation protocol for the anterior MTL cortices to add to an existing automated segmentation which already includes the posterior MTL. Segmentation rules for remaining borders are under development.

#### CLINICAL RELEVANCE/APPLICATION

This histologically-informed segmentation protocol is expected to improve the efficacy of imaging biomarkers for tau deposition in early AD.

## **W7-SSNR13-3 Initial Deployment of a Semi-automated Pipeline Measuring Brain Structural Change for Clinical Brain MRI Reporting**

Ilya M. Nasrallah, MD, PhD (*Presenter*) Speaker, Biogen Idec Inc; Advisory Board, Eisai Co, Ltd

### **PURPOSE**

To implement and validate an image processing pipeline based on open-source resources for quantification of brain atrophy and white matter hyperintensity volume for differential diagnosis of neurodegenerative disease.

### **METHODS AND MATERIALS**

The neuroimaging pipeline uses deep learning-based skull stripping<sup>1</sup>, multi-atlas tissue segmentation<sup>2</sup>, and lesion segmentation<sup>3</sup> modules to generate tabular data comprising intracranial volume-adjusted regional and global volume measurements and machine learning metrics measuring Alzheimer's disease (AD)-typical atrophy (SPARE-AD)<sup>4</sup> and image-based brain age<sup>5</sup>. These individual measures are placed in context of age and sex-matched reference data drawn from a dataset of cognitively normal (N=2935) and AD (N=1833) participants harmonized using ComBat<sup>6</sup>. The containerized pipeline was deployed on a server running the open-source toolkit Kaapana (kaapana.ai, DKFZ, Heidelberg, Germany). Clinical studies with 1 mm isotropic T1 and T2 FLAIR DICOM images were processed. Clinical data was extracted from the electronic medical record regarding clinical diagnoses and the original radiologist report. Radiology reports were analyzed for ascertainment of the presence features indicating neurodegenerative disease. Diagnosis groups were compared using t-tests.

### **RESULTS**

The test sample comprised 11 patients aged 62-93; 6 with possible/probable AD ('AD cohort') and 5 non-AD diagnoses ('nonAD cohort'; psychiatric disease, frontotemporal lobar degeneration, and vascular dementia). The original radiology report noted medial temporal lobe/hippocampal volume (HV) loss in 17% of the AD cohort and 20% of the nonAD cohort. The AD cohort had significantly lower mean (SD) HV (6.3mL±0.8 vs 7.4mL±0.5, p=0.01) and higher mean SPARE-AD (0.3±1.3 vs -1.1±0.8, p=0.03). 67% of AD cases and 0% of nonAD had HV >1 SD below the mean; 67% of AD cases had positive SPARE-AD scores while 100% of nonAD had negative SPARE-AD scores. 90% of reports qualitatively mentioned WMH burden. Quantitation showed significantly higher mean WMH volume in the nonAD group (9.2mL±3.4 vs 3.6mL±3.4, p=0.01); WMH volumes were highest in cases with vascular dementia.

### **CONCLUSION**

A semi-automated imaging quantification pipeline based on open-source resources can produce clinically relevant biomarkers that are frequently missing from radiology reports. These measures provide personalized diagnostic information relevant on the individual level.

### **CLINICAL RELEVANCE/APPLICATION**

Open-source tools may provide broader access to quantitative measures and machine learning measures that can improve or support radiologist and referring physician diagnoses.

## **W7-SSNR13-4 International Multicenter Phase 2 Dose Finding Study of Gadoquatrane: A Dose of 0.04 mmol Gd/kg bw of Gadoquatrane Has Similar Efficacy to 0.1 mmol Gd/kg bw of Gadobutrol**

Benjamin P. Liu, MD (*Presenter*) Speakers Bureau, Guerbet SA; Research Grant, Guerbet SA; Research Grant, Bayer AG

### **PURPOSE**

To establish a dose of gadoquatrane with similar efficacy as gadobutrol for use in contrast-enhanced (CE) MRI of the CNS in adults, via an adaptive dose finding study.

### **METHODS AND MATERIALS**

This phase 2 multicenter, single-blind cross-over study included adult patients with known or highly suspected CNS lesions and aimed to investigate potentially different doses of gadoquatrane in cohorts of 50 evaluable patients per dose level. Patients received two CE MRI exams, one with gadobutrol at 0.1 mmol Gd/kg body weight (bw), the other one with gadoquatrane starting with a dose of 0.04 mmol Gd/kg bw. The primary efficacy endpoint was overall diagnostic preference based on a randomized paired blinded read. The secondary objective was to show non-inferiority of gadoquatrane to gadobutrol based on the sum of lesion visualization parameters (contrast enhancement, border delineation and internal morphology). Efficacy evaluations were performed by 3 independent central blinded readers. Signal intensity (SI), contrast to noise ratio (CNR), signal to noise ratio (SNR) at 5 min, 10 min and 15 min post injection were measured. Adverse events (AE) were monitored up to 1 day after second MRI.

### **RESULTS**

57 patients (23 men, 34 women) were enrolled in 17 sites in 4 countries (USA, Germany, Bulgaria and Japan). 50 patients were evaluable for the primary efficacy endpoint. The efficacy of gadoquatrane at a dose of 0.04 mmol Gd/kg bw was confirmed. The overall diagnostic preference was similar for gadoquatrane and gadobutrol. The sum of lesion visualization

parameter scores (border delineation + contrast enhancement + internal morphology, scale of 3-11) at 5 min post injection was similar for gadoquatrane and gadobutrol (average reader mean score +8.94 for gadoquatrane and +9.00 for gadobutrol [ $p < 0.0001$  for non-inferiority]). For all 3 visualization parameters, all 3 readers and the average reader consistently showed mean differences between gadoquatrane and gadobutrol near zero, indicating no difference in performance between agents. SI, CNR and SNR measurements confirmed that both agents at the investigated doses and time points had similar signal enhancement parameters. Four patients experienced treatment-emergent AEs, and one AE (toothache) was considered related to gadoquatrane. All AEs had a maximum intensity of mild.

#### **CONCLUSION**

A dose of 0.04 mmol Gd/kg bw of gadoquatrane has similar efficacy results to 0.1 mmol Gd/kg bw of gadobutrol and is supported for the further development of gadoquatrane.

#### **CLINICAL RELEVANCE/APPLICATION**

CE-MRI is the standard of care in diagnostic imaging procedures of the CNS. Gadoquatrane will enable lowering of the gadolinium dose by 60% compared to current standard of care macrocyclic GBCAs.

#### **W7-SSNR13-5 Development and Evaluation of High Resolution QSM Template of the Older Adult Brain**

Rasheed Abid, BSc (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Quantitative susceptibility mapping (QSM) is an important tool for studying age-related brain pathologies that can disrupt iron or calcium homeostasis or cause demyelination. However, a high-resolution QSM template of the older adult brain is not currently available. The purpose of this work is twofold: a) to construct a high resolution QSM template of the older adult brain, and b) compare the new template to existing templates in terms of image quality and representativeness of the older adult brain.

#### **METHODS AND MATERIALS**

T1-weighted MPRAGE (1x1x1 mm<sup>3</sup>) and T2\*-weighted multi-echo gradient echo (0.7x0.7x1.3 mm<sup>3</sup>) 3T MRI data collected on the 400 non-demented older adults (50% male; 64.9-98.9 years of age; 54% white, 43% black) participating in the construction of the MIITRA atlas were used for this study. MEDI toolbox was used to generate a QSM image of each of the participants from the multi-echo gradient echo data. N4bias field correction followed by upsampling was performed on the first echo of the GRE data of each of the subjects and finally converted to synthetic T1w images using `mri_synthsr`. These synthetic images were then rigidly registered to the T1w images using ANTs. The resulting transformations were combined with the non-linear transformations generated in the construction of the MIITRA T1-weighted template and the combined transform was used to forward-map susceptibility maps of each of the subjects to the MIITRA T1w template space. Finally sparse representation based data-fusion implementation was used to generate the final 0.5mm isotropic MIITRA QSM template.

#### **RESULTS**

The QSM template exhibits high image sharpness and clearly visible brain structures upon visual inspection. Higher magnetic susceptibility can be observed in the regions of basal ganglia, midbrain and cerebellum, as expected. Furthermore, magnetic susceptibility is higher in cortical gray matter compared to white matter, and also in white matter of the occipital lobe compared to prefrontal white matter, also in accordance with published literature. The MIITRA QSM template also required less deformation for spatial normalization of older adult data compared to other templates.

#### **CONCLUSION**

This work developed a high quality 0.5mm resolution QSM template for the MIITRA atlas using data from a large, diverse, community cohort of non-demented older adults, and demonstrated that the new template exhibited high image quality and is more representative of the older adult brain compared to other templates. The new template will be made available for download at [www.nitrc.org/projects/miitra](http://www.nitrc.org/projects/miitra).

#### **CLINICAL RELEVANCE/APPLICATION**

QSM templates can be used to study disruption in iron or calcium related homeostasis due to age-related brain pathologies.

#### **W7-SSNR13-6 Amide Proton Transfer Weighted Imaging Analysis of Cerebral Metabolism Changes in T2DM Patients**

Wei-wei Wang, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Amide proton transfer weighted (APT<sub>w</sub>) technology was used to analyze the metabolic changes of brain in patients with T2DM and explore the related factors.

## **METHODS AND MATERIALS**

A total of 64 subjects were prospectively collected and divided into T2DM group and control group according to grouping criteria, including 37 patients in T2DM group and 27 healthy controls. Within one week before or after the MRI scan, the clinical data, laboratory indicators and cognitive scores of the subjects were recorded. All the subjects used Philips Ingenia CX 3.0 T MR for MRI data acquisition, and the sequence included axial FFE T1 sequence, axial FFE T2 sequence, axial TSE Flair sequence, sagittal 3D T1 TFE sequence and axial 3D TSE APTw sequence. The APTw values of grey and white matter were analyzed by SPM 8 software. Independent two sample t test was used to compare the difference between two groups. Pearson correlation analysis was used to analyze the correlation between APTw values in brain regions with significant differences and demographic data, laboratory indicators and cognitive scores.  $P < 0.05$  was considered statistically significant.

## **RESULTS**

Compared with the control group, APTw of white matter was increased in T2DM group ( $0.507 \pm 0.128$ ,  $0.600 \pm 0.136$ ,  $P = 0.007$ ). No significant difference was showed in APTw of gray matter between the two groups ( $1.085 \pm 0.154$ ,  $1.099 \pm 0.113$ ,  $P = 0.668$ ). The correlation analysis found negative correlation between APTw of white matter and CVLT accuracy of long time delay selection and recognition ( $r = -0.315$ ,  $P = 0.011$ ) and visual space perception score ( $r = -0.298$ ,  $P = 0.017$ ). No correlation was found between white matter APTw values and demographic and clinical data ( $P > 0.05$ ). No correlation was found between APTw values of grey matter and demographic data, clinical data and cognitive scores ( $P > 0.05$ ).

## **CONCLUSION**

Only the increased APTw value was found, suggesting that it was related to the abnormal changes in the concentration of metabolites in the patients' white matter. However, there was no significant correlation between white matter APTw value and demographic data and clinical data. It was also found that increased white matter APTw was associated with decreased cognitive level in T2DM patients.

## **CLINICAL RELEVANCE/APPLICATION**

APTw can reflect the abnormal changes of brain metabolism in T2DM patients from the molecular level, providing new imaging evidence for understanding the neuropathological mechanism of diabetic brain injury.

### Amide Proton Transfer Weighted Imaging Analysis of Cerebral Metabolism Changes in T2DM Patients

Wednesday, Nov. 29 3:00PM - 4:00PM Room: E353C

Wei-wei Wang, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Amide proton transfer weighted (APT<sub>w</sub>) technology was used to analyze the metabolic changes of brain in patients with T2DM and explore the related factors.

#### METHODS AND MATERIALS

A total of 64 subjects were prospectively collected and divided into T2DM group and control group according to grouping criteria, including 37 patients in T2DM group and 27 healthy controls. Within one week before or after the MRI scan, the clinical data, laboratory indicators and cognitive scores of the subjects were recorded. All the subjects used Philips Ingenia CX 3.0 T MR for MRI data acquisition, and the sequence included axial FFE T1 sequence, axial FFE T2 sequence, axial TSE Flair sequence, sagittal 3D T1 TFE sequence and axial 3D TSE APT<sub>w</sub> sequence. The APT<sub>w</sub> values of grey and white matter were analyzed by SPM 8 software. Independent two sample t test was used to compare the difference between two groups. Pearson correlation analysis was used to analyze the correlation between APT<sub>w</sub> values in brain regions with significant differences and demographic data, laboratory indicators and cognitive scores.  $P < 0.05$  was considered statistically significant.

#### RESULTS

Compared with the control group, APT<sub>w</sub> of white matter was increased in T2DM group ( $0.507 \pm 0.128$ ,  $0.600 \pm 0.136$ ,  $P = 0.007$ ). No significant difference was showed in APT<sub>w</sub> of gray matter between the two groups ( $1.085 \pm 0.154$ ,  $1.099 \pm 0.113$ ,  $P = 0.668$ ). The correlation analysis found negative correlation between APT<sub>w</sub> of white matter and CVLT accuracy of long time delay selection and recognition ( $r = -0.315$ ,  $P = 0.011$ ) and visual space perception score ( $r = -0.298$ ,  $P = 0.017$ ). No correlation was found between white matter APT<sub>w</sub> values and demographic and clinical data ( $P > 0.05$ ). No correlation was found between APT<sub>w</sub> values of grey matter and demographic data, clinical data and cognitive scores ( $P > 0.05$ ).

#### CONCLUSION

Only the increased APT<sub>w</sub> value was found, suggesting that it was related to the abnormal changes in the concentration of metabolites in the patients' white matter. However, there was no significant correlation between white matter APT<sub>w</sub> value and demographic data and clinical data. It was also found that increased white matter APT<sub>w</sub> was associated with decreased cognitive level in T2DM patients.

#### CLINICAL RELEVANCE/APPLICATION

APT<sub>w</sub> can reflect the abnormal changes of brain metabolism in T2DM patients from the molecular level, providing new imaging evidence for understanding the neuropathological mechanism of diabetic brain injury.

#### W7-SSPD04-1 Feasibility of 4D Flow MRI for Quantification of Hepatic Outflow in Children After Liver Transplantation and Comparison with Color Doppler Ultrasound

Jan Moritz Seliger, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Assessment of the feasibility of 4D Flow MRI to quantify hepatic outflow in children after liver transplantation and comparison with current standard bedside color Doppler ultrasound (US).

#### METHODS AND MATERIALS

We retrospectively analyzed 11 children (median age 11 years, 1 - 17 years) who underwent liver transplantation (full organ, right lateral or left lateral). All children underwent quantitative color Doppler US assessment of the hepatic vessels and 4D flow MRI at 3T. Color Doppler US and b-Mode standard transverse and longitudinal planes were recorded with full liver coverage. Intrahepatic quantitative flow measurements were performed in the main hepatic vein 1-2 cm distant to the anastomosis. Flow measurements with Doppler US were performed with angle correction for assessment of maximum and minimum velocities (US-Vmax and US-Vmin). At corresponding anatomic positions, hepatic outflow was quantified on 4D flow MRI with through plane velocities (MR-Vmin and MR-Vmax). Doppler US-derived and 4D flow-derived parameters were compared using linear regression analyses and Wilcoxon rank tests.

#### RESULTS

In all cases, the hepatic venous outflow tract was detectable on both 4D flow MRI and Doppler US. US-Vmax and US-Vmin revealed no significant differences between 4D flow MRI and Doppler US (MR-Vmax  $31.8 \pm 14.1$  cm/s vs. mean US-Vmax  $31.5 \pm 10.0$  cm/s and mean MR-Vmin  $-4.3 \pm 5.0$  cm/s vs. mean US-Vmin  $3.7 \pm 16.4$  cm/s, both  $p > 0.05$ ). Maximum and minimum velocities showed weak correlations between 4D flow MRI and Doppler US (Vmax:  $R = 0.42$ ,  $p = 0.18$  and Vmin:  $R = 0.32$ ,  $p = 0.34$ ).

#### CONCLUSION

4D flow MRI is feasible for non-invasive quantification of hepatic outflow in children after liver transplantation. Our results suggest that 4D flow MRI and color Doppler US have comparable accuracy in measuring hepatic venous flow velocities.

#### CLINICAL RELEVANCE/APPLICATION

Establishing 4D flow MRI as supplement to US assessment may improve non-invasive postoperative monitoring after liver transplantation in children, warranting further evaluation in patients with post-transplant venous stenosis.

#### W7-SSPD04-2 Reader Confidence with Use of Ferumoxytol in Liver Tumor Staging

Mara O'Connor, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Magnetic Resonance Imaging (MRI) with hepatobiliary contrast agent is important in the evaluation of pediatric liver tumors. Staging includes extent of liver involvement and annotation factors for vessel involvement. While Gadoxetate disodium (Eovist, Bayer HealthCare) is advantageous in lesion characterization, it is not a dedicated blood pool contrast agent. Ferumoxytol (Feraheme, AMAG Pharmaceuticals) is an iron oxide nanoparticle with a long intravascular half-life and strong

MRI signal. We hypothesize ferumoxytol (Fe) improves inter-reader reliability and reader confidence in evaluation for tumor involvement of the vasculature.

## **METHODS AND MATERIALS**

We identified MRIs with dual contrast (Eovist (Eo) and Fe) performed for baseline liver tumor staging. Images were uploaded into an anonymous dicom viewer as a random mix of Eo and Fe cases. The Eo cases contained 3-phase axial dynamic, 2-minute axial, and 30-minute axial and coronal sequences. The Fe set contained coronal MR-angiogram (MRA) with axial and sagittal reformats. Four reviewers rated portal and hepatic venous and inferior vena cava (IVC) involvement and their confidence level for all image sets provided in random order. Cases were re-paired after review with tabulation of changes in scores between contrasts. Inter-reader reliability was calculated using paired Cohen's kappa, intraclass correlation coefficients, and Fleiss multirater kappa.

## **RESULTS**

Eight cases (median age 3.4 (intraquartile range 0.8 - 10.3) years; 50% female; 2 hepatocellular carcinoma, 6 hepatoblastoma) were reviewed as 16 sets of images. Reviewers were unsure of 28 vessels with Eo and 2 with Fe. For Eovist cases, all 4 reviewers rated 1 case as nondiagnostic and were not confident in portal veins in 4 cases and hepatic veins in 6 cases. For Fe, 2 reviewers were not confident in portal veins in 1 case. On average, 2 reviewers changed their staging per venous structure. Reviewers changed from patent on Eo to invaded/thrombosed on Fe in 6 portal veins and 3 right hepatic veins. They changed from invaded/thrombosed on Eo to patent on Fe in 3 portal veins. Inter-reader reliability was significantly higher in all vessels with Fe ( $p < 0.003$ ). However, reliability was low in general, especially for the IVC and hepatic veins.

## **CONCLUSION**

Ferumoxytol MRA appears to increase reader confidence and inter-reader reliability in vascular staging of liver tumors. However, overall inter-reader reliability was fair to moderate at best.

## **CLINICAL RELEVANCE/APPLICATION**

Vessel assessment is important in pediatric liver tumor staging. Ferumoxytol MR angiography appears to increase inter-reader reliability and reader confidence and may be a useful addition to pediatric liver tumor staging.

## **W7-SSPD04-3 Implementation of a 4D Free-Breathing Variable Density Stack-Of-Stars Functional Magnetic Resonance Urography in Young Children Without Sedation**

Jakob Spogis, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

Functional magnetic resonance urography (MRU) has been well established in the diagnostic workup of urinary tract anomalies in children. However, standard dynamic contrast-enhanced (DCE) images acquired in Cartesian order of the k-space are prone to respiratory motion artifacts. The purpose of this study was to implement and compare a newly introduced 4D free-breathing high spatiotemporal resolution DCE-MRI with radial sampling order for functional MRU (4D MRU) in pediatric patients and to compare its image quality and analyzability with Standard Cartesian MRU.

## **METHODS AND MATERIALS**

We retrospectively evaluated 4D MRU performed without general anesthesia between 09/2021 and 12/2022 and compared them with matched pairs (age, affected kidney, diagnosis) of Standard Cartesian MRU. Image analysis was performed by two radiologists independently regarding the following criteria using a 4-point Likert scale: overall image quality, diagnostic confidence, respiratory motion artifacts as well as sharpness and contrast of aorta, kidneys, and ureters. We also measured vertical kidney motion due to respiratory motion and compared the variance for each kidney using F-test. Both radiologists calculated the volume, split renal volume (vDRF), split renal Patlak function (pDRF), and split renal function considering the volume and Patlak function (vpDRF) for each kidney. Values were compared using Bland-Altman plots and F-test.

## **RESULTS**

40 children (20 for 4D and Standard Cartesian) were enrolled. 10 children of each group were examined using the feed-and-sleep technique (median age 8.9 months), 10 were awake (median age 8.6 years). Overall image quality, diagnostic confidence, respiratory motion artifacts, and sharpness and contrast of the aorta, kidneys, and ureters were rated significantly better for 4D compared to Standard Cartesian by both readers ( $p$  ranging from  $<0.0001$  to  $0.005$ ). Vertical kidney motion was significantly less pronounced in 4D for both kidneys (both  $p < 0.001$ ). There was a significantly lesser variance in the differences between the two readers for vpDRF in 4D MRU ( $p = 0.0003$ ). In contrast, no significant difference could be demonstrated for volume ( $p = 0.05$ ), vDRF ( $p = 0.93$ ), and pDRF ( $p = 0.14$ ).

## **CONCLUSION**

We demonstrated the feasibility of applying a 4D free-breathing variable density stack-of-stars imaging for functional MRU in young pediatric patients with improved image quality, fewer motion artifacts, and improved functional analyzability.

## CLINICAL RELEVANCE/APPLICATION

Respiratory motion artifacts often interfere with the analyzability of MRU in children. With 4D MRU we could implement a DCE MRI sequence with superb image quality despite free breathing significantly improving the diagnostic confidence in clinical routine.

### W7-SSPD04-4 Feasibility of Renal Artery Flow Quantitation in Pediatric Patients Using 4D Flow MRI

Tammy Kim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To demonstrate feasibility of time-resolved flow-sensitive four-dimensional (4D) MRI for quantification of renal artery hemodynamics in a clinical pediatric population.

#### METHODS AND MATERIALS

Patients who underwent 4D flow MRI during work up of underlying abdominal pathology in the past 6 months were retrospectively identified. Flow was quantified using Arterys web-based flow analysis software in predefined anatomic regions of the abdominal aorta and renal arteries. Flow volumes and maximum velocities were recorded. Inter-observer variability was assessed using Bland-Altman and regression techniques.

#### RESULTS

15 patients (7 male, mean age 9.6 years, range [2, 17]) received 4D flow MRI. Flow averaged 0.28 L/min [0.05, 0.56], 0.29 L/min [0.07, 0.76], and 1.66 L/min [0.47, 3.29] in the left renal artery, right renal artery, and aorta respectively. Flow rate correlated moderately with age for the left renal artery ( $r=0.61$ ,  $p=0.0009$ ), right renal artery ( $r=0.41$ ,  $p=0.01$ ), and aorta ( $r=0.61$ ,  $p=0.006$ ). Bland-Altman analysis showed excellent inter-observer agreement, with mean difference of -0.01 L/min in the left renal artery, which was not significant on 1-tail t-test ( $p=0.3$ ) or regression analysis ( $r^2=0.04$ ,  $p=0.51$ ). Similarly, mean inter-observer difference was -0.03 L/min in the right renal artery, not significant on significant on 1-tail t-test ( $p=0.3$ ) or regression analysis ( $r^2=0.01$ ,  $p=0.68$ ). Finally, mean inter-observer difference was -0.02 L/min in the aorta, not significant on significant on 1-tail t-test ( $p=0.88$ ) or regression analysis ( $r^2=0$ ,  $p=0.85$ ).

#### CONCLUSION

4D flow MRI assessment of renal arteries is feasible in a pediatric population, with excellent inter-observer agreement.

## CLINICAL RELEVANCE/APPLICATION

4D flow MRI provides anatomic and functional assessment of vascular flow, and allows for evaluation of smaller, tortuous vessels, which is less reliable on 2D phase contrast MRI. Feasibility has been shown in various vessels for adults; however, renal artery applications in the pediatric population have not yet been explored. Though more studies are required to determine the clinical utility of this modality, 4D flow MRI represents a promising noninvasive, non-ionizing method of comprehensive renal vascular flow assessment.

### W7-SSPD04-5 The Differences in Diagnostic Models of NEC by Combining Radiomics Features and Non-radiomics Feature

Chaogang Lu (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop a traditional radiomics model of abdominal X-ray images of NEC and a joint model of radiomics and non-radiomics feature to evaluate the differences in diagnostic efficacy of the different models on the entire data set.

#### METHODS AND MATERIALS

In this retrospective study, we collected images of 252 NEC patients ( $n=131$ ) and non-NEC patients ( $n=121$ ) who underwent abdominal X-ray in 2016-2022, and divided them into training set ( $n=146$ ), testing set ( $n=62$ ), and validation set ( $n=44$ ). Non-radiomics feature called Abdominal Chest Ratio (ACR) was calculated by measuring the length diameter of the abdominal cavity and the thoracic cavity in the thoracoabdominal anteroposterior radiograph. Radiomics features were extracted by using traditional radiomics methods and were used to construct radiomics models. The models radiomics features combined with ACR and Radscore combined with ACR were built separately by logistic regression. The area under the receiver operating characteristic curve (AUC) was used to evaluate the models' performance for the diagnosis of NEC.

#### RESULTS

ACR and Radscore independently achieved an AUC of 0.682 versus 0.885 on the whole data set. The models ACR combined with Radscore and ACR combined with feature based on the training set both achieved an AUC of 0.893 on the entire data set; based on the testing set and validation set, the models achieved an AUC of 0.885 versus 0.868 and of 0.888 versus 0.757 respectively.

## **CONCLUSION**

The diagnostic efficacy of the model which Radscore combined with the non-radiomics feature was superior to the model radiomics features combined with the non-radiomics feature.

## **CLINICAL RELEVANCE/APPLICATION**

Necrotizing enterocolitis (NEC) is one of the most common gastrointestinal emergencies in neonates, and X-ray is its preferred imaging modality. Current X-ray image diagnostic or predictive models of the disease are mainly modeled using deep learning methods. Through this study, we explored the effect of traditional radiomics methods in establishing models on X-ray images.

### Feasibility of 4D Flow MRI for Quantification of Hepatic Outflow in Children After Liver Transplantation and Comparison with Color Doppler Ultrasound

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S402

Jan Moritz Seliger, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Assessment of the feasibility of 4D Flow MRI to quantify hepatic outflow in children after liver transplantation and comparison with current standard bedside color Doppler ultrasound (US).

#### METHODS AND MATERIALS

We retrospectively analyzed 11 children (median age 11 years, 1 - 17 years) who underwent liver transplantation (full organ, right lateral or left lateral). All children underwent quantitative color Doppler US assessment of the hepatic vessels and 4D flow MRI at 3T. Color Doppler US and b-Mode standard transverse and longitudinal planes were recorded with full liver coverage. Intrahepatic quantitative flow measurements were performed in the main hepatic vein 1-2 cm distant to the anastomosis. Flow measurements with Doppler US were performed with angle correction for assessment of maximum and minimum velocities (US-Vmax and US-Vmin). At corresponding anatomic positions, hepatic outflow was quantified on 4D flow MRI with through plane velocities (MR-Vmin and MR-Vmax). Doppler US-derived and 4D flow-derived parameters were compared using linear regression analyses and Wilcoxon rank tests.

#### RESULTS

In all cases, the hepatic venous outflow tract was detectable on both 4D flow MRI and Doppler US. US-Vmax and US-Vmin revealed no significant differences between 4D flow MRI and Doppler US (MR-Vmax  $31.8 \pm 14.1$  cm/s vs. mean US-Vmax  $31.5 \pm 10.0$  cm/s and mean MR-Vmin  $-4.3 \pm 5.0$  cm/s vs. mean US-Vmin  $3.7 \pm 16.4$  cm/s, both  $p > 0.05$ ). Maximum and minimum velocities showed weak correlations between 4D flow MRI and Doppler US (Vmax:  $R = 0.42$ ,  $p = 0.18$  and Vmin:  $R = 0.32$ ,  $p = 0.34$ ).

#### CONCLUSION

4D flow MRI is feasible for non-invasive quantification of hepatic outflow in children after liver transplantation. Our results suggest that 4D flow MRI and color Doppler US have comparable accuracy in measuring hepatic venous flow velocities.

#### CLINICAL RELEVANCE/APPLICATION

Establishing 4D flow MRI as supplement to US assessment may improve non-invasive postoperative monitoring after liver transplantation in children, warranting further evaluation in patients with post-transplant venous stenosis.

### Reader Confidence with Use of Ferumoxytol in Liver Tumor Staging

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S402

Mara O'Connor, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Magnetic Resonance Imaging (MRI) with hepatobiliary contrast agent is important in the evaluation of pediatric liver tumors. Staging includes extent of liver involvement and annotation factors for vessel involvement. While Gadoxetate disodium (Eovist, Bayer HealthCare) is advantageous in lesion characterization, it is not a dedicated blood pool contrast agent. Ferumoxytol (Feraheme, AMAG Pharmaceuticals) is an iron oxide nanoparticle with a long intravascular half-life and strong MRI signal. We hypothesize ferumoxytol (Fe) improves inter-reader reliability and reader confidence in evaluation for tumor involvement of the vasculature.

#### METHODS AND MATERIALS

We identified MRIs with dual contrast (Eovist (Eo) and Fe) performed for baseline liver tumor staging. Images were uploaded into an anonymous dicom viewer as a random mix of Eo and Fe cases. The Eo cases contained 3-phase axial dynamic, 2-minute axial, and 30-minute axial and coronal sequences. The Fe set contained coronal MR-angiogram (MRA) with axial and sagittal reformats. Four reviewers rated portal and hepatic venous and inferior vena cava (IVC) involvement and their confidence level for all image sets provided in random order. Cases were re-paired after review with tabulation of changes in scores between contrasts. Inter-reader reliability was calculated using paired Cohen's kappa, intraclass correlation coefficients, and Fleiss multirater kappa.

#### RESULTS

Eight cases (median age 3.4 (intraquartile range 0.8 - 10.3) years; 50% female; 2 hepatocellular carcinoma, 6 hepatoblastoma) were reviewed as 16 sets of images. Reviewers were unsure of 28 vessels with Eo and 2 with Fe. For Eovist cases, all 4 reviewers rated 1 case as nondiagnostic and were not confident in portal veins in 4 cases and hepatic veins in 6 cases. For Fe, 2 reviewers were not confident in portal veins in 1 case. On average, 2 reviewers changed their staging per venous structure. Reviewers changed from patent on Eo to invaded/thrombosed on Fe in 6 portal veins and 3 right hepatic veins. They changed from invaded/thrombosed on Eo to patent on Fe in 3 portal veins. Inter-reader reliability was significantly higher in all vessels with Fe ( $p < 0.003$ ). However, reliability was low in general, especially for the IVC and hepatic veins.

#### CONCLUSION

Ferumoxytol MRA appears to increase reader confidence and inter-reader reliability in vascular staging of liver tumors. However, overall inter-reader reliability was fair to moderate at best.

#### CLINICAL RELEVANCE/APPLICATION

Vessel assessment is important in pediatric liver tumor staging. Ferumoxytol MR angiography appears to increase inter-reader reliability and reader confidence and may be a useful addition to pediatric liver tumor staging.

### Implementation of a 4D Free-Breathing Variable Density Stack-Of-Stars Functional Magnetic Resonance Urography in Young Children Without Sedation

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S402

Jakob Spogis, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Functional magnetic resonance urography (MRU) has been well established in the diagnostic workup of urinary tract anomalies in children. However, standard dynamic contrast-enhanced (DCE) images acquired in Cartesian order of the k-space are prone to respiratory motion artifacts. The purpose of this study was to implement and compare a newly introduced 4D free-breathing high spatiotemporal resolution DCE-MRI with radial sampling order for functional MRU (4D MRU) in pediatric patients and to compare its image quality and analyzability with Standard Cartesian MRU.

#### METHODS AND MATERIALS

We retrospectively evaluated 4D MRU performed without general anesthesia between 09/2021 and 12/2022 and compared them with matched pairs (age, affected kidney, diagnosis) of Standard Cartesian MRU. Image analysis was performed by two radiologists independently regarding the following criteria using a 4-point Likert scale: overall image quality, diagnostic confidence, respiratory motion artifacts as well as sharpness and contrast of aorta, kidneys, and ureters. We also measured vertical kidney motion due to respiratory motion and compared the variance for each kidney using F-test. Both radiologists calculated the volume, split renal volume (vDRF), split renal Patlak function (pDRF), and split renal function considering the volume and Patlak function (vpDRF) for each kidney. Values were compared using Bland-Altman plots and F-test.

#### RESULTS

40 children (20 for 4D and Standard Cartesian) were enrolled. 10 children of each group were examined using the feed-and-sleep technique (median age 8.9 months), 10 were awake (median age 8.6 years). Overall image quality, diagnostic confidence, respiratory motion artifacts, and sharpness and contrast of the aorta, kidneys, and ureters were rated significantly better for 4D compared to Standard Cartesian by both readers (p ranging from <0.0001 to 0.005). Vertical kidney motion was significantly less pronounced in 4D for both kidneys (both  $p < 0.001$ ). There was a significantly lesser variance in the differences between the two readers for vpDRF in 4D MRU ( $p = 0.0003$ ). In contrast, no significant difference could be demonstrated for volume ( $p = 0.05$ ), vDRF ( $p = 0.93$ ), and pDRF ( $p = 0.14$ ).

#### CONCLUSION

We demonstrated the feasibility of applying a 4D free-breathing variable density stack-of-stars imaging for functional MRU in young pediatric patients with improved image quality, fewer motion artifacts, and improved functional analyzability.

#### CLINICAL RELEVANCE/APPLICATION

Respiratory motion artifacts often interfere with the analyzability of MRU in children. With 4D MRU we could implement a DCE MRI sequence with superb image quality despite free breathing significantly improving the diagnostic confidence in clinical routine.

### Feasibility of Renal Artery Flow Quantitation in Pediatric Patients Using 4D Flow MRI

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S402

Tammy Kim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To demonstrate feasibility of time-resolved flow-sensitive four-dimensional (4D) MRI for quantification of renal artery hemodynamics in a clinical pediatric population.

#### METHODS AND MATERIALS

Patients who underwent 4D flow MRI during work up of underlying abdominal pathology in the past 6 months were retrospectively identified. Flow was quantified using Arterys web-based flow analysis software in predefined anatomic regions of the abdominal aorta and renal arteries. Flow volumes and maximum velocities were recorded. Inter-observer variability was assessed using Bland-Altman and regression techniques.

#### RESULTS

15 patients (7 male, mean age 9.6 years, range [2, 17]) received 4D flow MRI. Flow averaged 0.28 L/min [0.05, 0.56], 0.29 L/min [0.07, 0.76], and 1.66 L/min [0.47, 3.29] in the left renal artery, right renal artery, and aorta respectively. Flow rate correlated moderately with age for the left renal artery ( $r=0.61$ ,  $p=0.0009$ ), right renal artery ( $r=0.41$ ,  $p=0.01$ ), and aorta ( $r=0.61$ ,  $p=0.006$ ). Bland-Altman analysis showed excellent inter-observer agreement, with mean difference of -0.01 L/min in the left renal artery, which was not significant on 1-tail t-test ( $p=0.3$ ) or regression analysis ( $r^2=0.04$ ,  $p=0.51$ ). Similarly, mean inter-observer difference was -0.03 L/min in the right renal artery, not significant on significant on 1-tail t-test ( $p=0.3$ ) or regression analysis ( $r^2=0.01$ ,  $p=0.68$ ). Finally, mean inter-observer difference was -0.02 L/min in the aorta, not significant on significant on 1-tail t-test ( $p=0.88$ ) or regression analysis ( $r^2=0$ ,  $p=0.85$ ).

#### CONCLUSION

4D flow MRI assessment of renal arteries is feasible in a pediatric population, with excellent inter-observer agreement.

#### CLINICAL RELEVANCE/APPLICATION

4D flow MRI provides anatomic and functional assessment of vascular flow, and allows for evaluation of smaller, tortuous vessels, which is less reliable on 2D phase contrast MRI. Feasibility has been shown in various vessels for adults; however, renal artery applications in the pediatric population have not yet been explored. Though more studies are required to determine the clinical utility of this modality, 4D flow MRI represents a promising noninvasive, non-ionizing method of comprehensive renal vascular flow assessment.

### The Differences in Diagnostic Models of NEC by Combining Radiomics Features and Non-radiomics Feature

Wednesday, Nov. 29 3:00PM - 4:00PM Room: S402

Chaogang Lu (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop a traditional radiomics model of abdominal X-ray images of NEC and a joint model of radiomics and non-radiomics feature to evaluate the differences in diagnostic efficacy of the different models on the entire data set.

#### METHODS AND MATERIALS

In this retrospective study, we collected images of 252 NEC patients ( $n = 131$ ) and non-NEC patients ( $n = 121$ ) who underwent abdominal X-ray in 2016-2022, and divided them into training set ( $n = 146$ ), testing set ( $n = 62$ ), and validation set ( $n = 44$ ). Non-radiomics feature called Abdominal Chest Ratio (ACR) was calculated by measuring the length diameter of the abdominal cavity and the thoracic cavity in the thoracoabdominal anteroposterior radiograph. Radiomics features were extracted by using traditional radiomics methods and were used to construct radiomics models. The models radiomics features combined with ACR and Radscore combined with ACR were built separately by logistic regression. The area under the receiver operating characteristic curve (AUC) was used to evaluate the models' performance for the diagnosis of NEC.

#### RESULTS

ACR and Radscore independently achieved an AUC of 0.682 versus 0.885 on the whole data set. The models ACR combined with Radscore and ACR combined with feature based on the training set both achieved an AUC of 0.893 on the entire data set; based on the testing set and validation set, the models achieved an AUC of 0.885 versus 0.868 and of 0.888 versus 0.757 respectively.

#### CONCLUSION

The diagnostic efficacy of the model which Radscore combined with the non-radiomics feature was superior to the model radiomics features combined with the non-radiomics feature.

#### CLINICAL RELEVANCE/APPLICATION

Necrotizing enterocolitis (NEC) is one of the most common gastrointestinal emergencies in neonates, and X-ray is its preferred imaging modality. Current X-ray image diagnostic or predictive models of the disease are mainly modeled using deep learning methods. #### Sub-Events

### W7-SSPH11-1 Unified Spectral Processing in Photon-counting-detector CT using Bayesian Deep Learning with Explicit Uncertainty and Bias Penalty

Hao Gong, PHD (*Presenter*) Nothing to Disclose

#### PURPOSE

Photon-counting-detector (PCD) CT provides high-quality spectral data to derive multiple image types (e.g., iodine maps, virtual monoenergetic (VMI), non-calcium (VNCa)), which assist diagnoses in many CT tasks. Conventional spectral processing methods are susceptible to amplified image noise and artifacts that impede reader interpretation. We aim to improve diagnostic image quality through unified spectral processing based on Bayesian deep learning with explicit uncertainty and bias penalty (BEACAN)

#### METHODS AND MATERIALS

BEACAN is based on a Bayesian dual-task neural network with bifurcated branches to classify types and quantify mass densities of basis materials. The network used probabilistic modeling of model likelihood and posterior distribution to re-balance its uncertainty and bias in training and characterize the statistical distribution of outputs for given inputs. Training used PCD-CT low-/high-threshold images of tissue-/contrast-mimicking inserts (e.g., hydroxyapatite (HA), iodine, muscle) and simulated random-shaped inserts. The predicted means of mass density maps were used to derive additional image types, due to improved robustness and detail preservation. Pixel-wise uncertainty was derived to support anomaly detection. Material quantification accuracy was assessed using root mean square error (RMSE) at 100% and 50% routine doses. For proof of concept, 5 patient CT cardiac angiograms were used to assess overall image quality, noise, and artifacts in material maps and VMIs. A prior-knowledge-assisted iterative material decomposition (Iter-MD; basis materials: HA, iodine, water) and commercial VMI software served as baseline methods

#### RESULTS

BEACAN improved quantification accuracy (e.g., RMSE of BEACAN vs Iter-MD: Iodinated blood 0.8 vs >1.6mgI/cc; HA <12 vs >14mgHA/cc; Fat <6 vs >70mgFat/cc), and generalized well in patients (e.g., little iodine residual in HA maps, reduced beam-hardening, and preserved details). Heteroscedastic uncertainty was observed, and tissue boundaries (e.g., plaque-lumen) tend to show higher variability. BEACAN-synthesized VMIs enhanced iodine signal, but reduced image noise (range 28% to 50% at 55keV) and blooming artifacts relative to commercial VMI. VNCa displayed at varying keVs can be derived from BEACAN, which is not commercially available on scanner

#### CONCLUSION

BEACAN provides high-quality spectral CT post-processing, showing improved material decomposition and VMI image quality in patient exams

#### CLINICAL RELEVANCE/APPLICATION

BEACAN is potential to accurately quantify target material in patients with dense calcified plaques, which could be undiagnostic in standard CT. It provides built-in uncertainty estimation to support anomaly detection and decision support

### W7-SSPH11-2 Improved Stenosis Assessment through AI-Enabled Virtual Monoenergetic Imaging on Photon Counting Detector CT in Ultra-High-Resolution Mode

Shaojie Chang, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Ultra-high-resolution (UHR) photon counting detector (PCD) CT has shown great potential in various clinical applications. However, the current commercial system lacks multi-energy capabilities in the UHR, ECG-gated cardiac scan mode. This study aims to use a convolutional neural network to generate virtual monoenergetic images (VMIs, Mono-CNN) in UHR mode to improve stenosis assessments in patients with dense calcifications.

## METHODS AND MATERIALS

Coronary CT angiography (cCTA) exams performed with standard (144x0.4 mm) multi-energy and UHR (120x0.2 mm) scan modes on a commercial dual-source PCD-CT (NAEOTOM Alpha, Siemens) were included for training and testing. VMIs at 100 keV and 70 keV (70 keV is effective energy of 120 kV beam) from the standard mode were reconstructed following the standard clinical protocol, using an iterative reconstruction (IR) algorithm at strength 4, Bv60 kernel, 0.6 mm slice thickness. A convolutional neural network (Mono-CNN) was trained using MSE loss with the 70 keV VMI as input and the 100 keV VMI as the label. The trained Mono-CNN was validated on independent multi-energy data sets (not used in training), with Mono-CNN VMI compared qualitatively and quantitatively to the true VMI. For testing, the Mono-CNN was applied to the single-energy-equivalent (T3D) cCTA patient cases (n=10) acquired with the UHR mode (no multi-energy capability), which were reconstructed using IR-4, Bv60 kernel, and 0.4 mm slice thickness. In addition to visual assessment, quantitative assessment of percent area stenosis was performed using commercial software (Syngo.Via CT Coronary Vascular Definition, Siemens). Stenosis quantification was performed for both T3D images and the Mono-CNN-generated 100 keV VMIs and the results were compared.

## RESULTS

The Mono-CNN generated high-quality images that closely resembled the true 100 keV VMIs. Mean HU differences between Mono-CNN and true VMI were 4.85 (1.6%), 8.82 (8.7%), and 1.37 (1.6%) HU for ROIs in the aorta, left ventricle, and myocardial fat, respectively. The UHR 100 keV VMIs produced by Mono-CNN demonstrated reduced blooming artifacts compared to standard T3D images. Quantitative analysis showed reduction of percent area stenosis in every patient involved in this study, with an average reduction of 12%, ranging from 4 to 20%.

## CONCLUSION

Mono-CNN provides VMI capabilities to the UHR cCTA in PCD-CT, enabling simultaneous high-resolution and multi-energy imaging, which can reduce blooming artifacts and improve stenosis assessment.

## CLINICAL RELEVANCE/APPLICATION

The Mono-CNN has the potential to improve the PCD-CT system's performance by decreasing cardiac blooming artifacts in the 100 keV images while also using the highest spatial resolution.

## W7-SSPH11-3 Deep Learning-based 4D CT and 4D CBCT Motion Compensation of Periodic and Non-Periodic Patient Motion with Single-View Temporal Resolution

Joscha Maier, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

To provide cardiac- and respiratory-compensated CT and cone-beam CT (CBCT) reconstructions showing the patient in any patient motion state that had occurred during the acquisition, i.e. at the time point of any given x-ray projection of the scan.

## METHODS AND MATERIALS

Some CT and several CBCT applications rely on 4D (3D+time) reconstructions that resolve organ motion. To do so, current strategies typically synchronize the scan with an external motion monitoring device such as a breathing belt or an ECG. Subsequently, projections sharing a similar motion phase are reconstructed together to derive a set of phase-correlated (gated) reconstructions that represent different phases of the motion cycle. This strategy, that is often followed by motion compensation (MoCo), which is the determination of motion vector fields (MVFs) and the warping of the phases according to these MVFs into a target phase, implicitly assumes periodic motion and fails in case of irregular and non-periodic motion patterns. Here, we also determine MVFs, but we do no gating. Instead, each individual projection is reconstructed into a separate volume, which is referred to as partial angle reconstruction (PAR). A deep neural network is trained on simulated data to derive the desired MVFs between any two PARs of the scan. With N projections, there will be N PARs and N(N-1) MVFs. The MVFs used for the simulation serve as training labels, i.e. as ground truth (GT). Since CT reconstruction is a linear operation, a MoCo for time point n (projection n) can be performed by warping all PARs with  $n' \neq n$  into time point n and summing up the warped PARs. To evaluate the performance of the proposed approach, it was tested on simulated data as well as on real measurements of patients scanned with the on-board CBCT of a Varian TrueBeam® system.

## RESULTS

For all simulated test cases, the estimated MVFs were in good agreement with the GT MVFs. MoCo volumes based on the estimated MVFs differed by less than 12 HU on average from the respective GT. In case of measured patient data, respiratory and cardiac motion could clearly be resolved for both regular and highly irregular motion patterns. In particular, the

displacement of the diaphragm extracted from the MoCo reconstructions showed a high correlation with external respiration signals.

## **CONCLUSION**

Using the proposed approach allows to derive accurate 4D reconstructions of patients with arbitrary motion patterns without the need for external gating signals. Thereby, the temporal resolution equals the acquisition time of a single projection.

## **CLINICAL RELEVANCE/APPLICATION**

The high temporal resolution may improve 4D CBCT applications such as radiation therapy planning or tumor tracking while not requiring external gating signals simplifies patient preparation.

## **W7-SSPH11-4 Fourier Diffusion Models for CT Denoising and Restoration for Known Image Properties**

Web W. Stayman, PhD (*Presenter*) Research Grant, Fischer Medical; Research Grant, General Electric Company; Research Grant, Canon Medical Systems Corporation; Research collaboration, Koninklijke Philips NV; Research collaboration, Siemens AG; Researcher, Varex Imaging Corporation

## **PURPOSE**

Diffusions models have found widespread application in imaging applications including denoising and restoration approaches. We modify the commonly used scalar diffusion model that relies on a relatively simple stochastic process of image fading and incremental independent Gaussian noise to a process that includes spatial blur and correlated noise. Such Fourier diffusion models permit matching of this model to the image properties (i.e., spatial resolution and noise distribution) produced by a CT system for improved performance.

## **METHODS AND MATERIALS**

The Fourier diffusion model is built upon a stochastic process where an incremental spatial blur and incremental correlated noise is applied at every time step. This forward process allows for the definition of a reverse stochastic differential equation that includes a score term that can be learned and applied in a discrete update equation. We implement a score-matching neural network that is conditioned on time samples and measurements. Specifically, we trained a UNet using Lung Image Database Consortium images comprised of 8000 slices of training data, 2000 validation slices, and with 10,000 epochs, uniform time sampling, and 32 images per batch. Blur and noise emulated the modulation transfer function and noise power spectrum of a typical CT image volume. The Fourier Diffusion model was compared with a scalar diffusion model using a varied number of time steps in the discrete update equation.

## **RESULTS**

We find that the Fourier diffusion model achieves a mean squared error reduction of greater than 25% across the range of time steps investigated. Moreover, the Fourier diffusion model achieves nearly optimal performance using only 16 time steps whereas scalar diffusion appears to require about 4 times the number of time steps to achieve its optimal performance.

## **CONCLUSION**

Fourier diffusion models allows for explicit modeling of the image properties in CT data. Integration of this information into the model permits both improved restoration of image data, but also a smaller number of time steps in the iterative update equation. This addresses a commonly cited disadvantage of diffusion models - namely, the increased computation time required by fine discretization of the reverse stochastic process.

## **CLINICAL RELEVANCE/APPLICATION**

While diffusion models have already shown great promise for dose reduction and resolution improvements in x-ray computed tomography, explicit modeling of CT image properties within the diffusion framework permits both faster implementation of the data processing as well as improved imaging performance.

## **W7-SSPH11-5 Iodine Map Generation from Single-kV Contrast-enhanced CT Scan using a Conditional Diffusion Probabilistic Machine Learning (CDPML) Model**

Ran Zhang, PhD (*Presenter*) Nothing to Disclose

## **PURPOSE**

Iodine maps generated from dual-energy CT (DECT) have numerous clinical and pathological applications in cardiothoracic and abdominal imaging. Using the iodine maps as input, various DECT image sets such as virtual monochromatic images, virtual unenhanced images, and effective atomic number images can be derived. However, it is highly desirable to generate corresponding iodine maps from contrast-enhanced CT data acquired from scanners without dual-energy functionality. This work aims to develop a conditional diffusion probabilistic machine learning (CDPML) model for generating iodine maps from single-kV CT data.

## METHODS AND MATERIALS

Diffusion probabilistic models can be applied to learn the statistical distribution of DECT-generated iodine maps. To generate the patient-specific iodine maps from single-kV contrast-enhanced CT scans, the diffusion-reverse-diffusion process was modified to incorporate the single-kV contrast-enhanced CT image as a conditional input in the iodine map generation process, resulting in a proposed CDPML model. The training dataset included 17,284 paired (140-kV image, iodine maps) image slices from 151 subjects who underwent DECT at a single clinical center. The testing dataset had 903 image slices from 12 subjects independent of the training set. The performance of the generated iodine maps was evaluated against the corresponding DECT reference using quantitative image quality metrics, including root mean square error (RMSE) and structural similarity index measure (SSIM). Bland-Altman analysis was employed to evaluate the mean differences between the generated iodine map and the DECT reference.

## RESULTS

(1). The median [25th, 75th percentiles] of RMSE for all the test cases is 0.58 [0.52, 0.66] mg/ml, and the median [25th, 75th percentiles] of SSIM is 0.979 [0.975, 0.982]. (2). Bland-Altman analysis shows the mean bias between DECT and CDPML over the entire test cohort is -0.02 mg/ml and the agreement limits are [-0.63 mg/ml, 0.59 mg/ml]. (3). The CDPML model also facilitates uncertainty estimation, essential for establishing trust in AI for medical imaging.

## CONCLUSION

Machine learning models trained using the proposed CDPML scheme offer a new approach to generating clinically relevant iodine maps from single-kV contrast-enhanced CT exams.

## CLINICAL RELEVANCE/APPLICATION

Using machine learning models to generate iodine maps from single-kV contrast-enhanced CT images can equip many lower-end CT scanners with dual-energy CT functionality to improve their diagnostic values in clinical practice.

## W7-SSPH11-6 Automatic Liver Tumor Screening and Differential Diagnosis in CT Using Pixel-Lesion-Patient Network with Reader Study and External Validation

Ling Zhang (*Presenter*) Nothing to Disclose

## PURPOSE

We aim to build an accurate tumor segmentation and classification model to screen for liver tumors in non-contrast (NC) CTs, as well as to diagnose tumor types in multiphase contrast-enhanced (CE) CTs.

## METHODS AND MATERIALS

Our cohort contains 1790 control cases without liver tumors and 1368 patients. Among them, 1749 from one hospital are used for model development, the other 1409 from three hospitals are used for internal and external validation. We consider full-spectrum liver tumors, including seven major types (HCC, ICC, metastasis, hepatoblastoma, hemangioma, FNH, cyst) and "others". A proportion of control cases have diffuse liver diseases such as hepatitis and steatosis. Each patient has three CT scans, i.e. NC, arterial, and venous phases. A radiologist with 10 years of experience in liver imaging annotated the 3D tumor masks and types in all patients according to pathological reports. A novel algorithm called pixel-lesion-patient network is proposed. It contains three branches with bottom-up cooperation. The pixel branch produces a pixel-wise segmentation map helping to initialize the lesion branch. The lesion branch focuses on lesion-wise segmentation and classification using a mask transformer to leverage liver context information and inter-lesion relationship. The patient branch aggregates features from the whole CT and predicts image-level labels.

## RESULTS

We conduct reader study to compare our model with two radiologists on an internal test set with 150 patients and 100 normal subjects. Using NC CT, our model achieves 96.7% in sensitivity and 98.0% in specificity in patient-level tumor screening (AUC=0.985). It is on par with a senior radiologist (SR) with 16 years of experience (94.1%, 99.0%), surpassing a junior radiologist (JR) with 2 years of experience (85.5%, 99.0%). Our model can also classify NC CTs into normal, benign, and malignant with 91.3% accuracy (SR: 90.8%, JR: 72.0%). Using CE CT, the model can distinguish 8 tumor types with 75.6% accuracy (SR: 75.6%, JR: 40.5%). We further evaluate on external NC CT test sets of 279 patients with HCC and 880 normal subjects, achieving 97% sensitivity and 96.4% specificity.

## CONCLUSION

The pixel-lesion-patient network can effectively detect liver tumor patients in NC CT and classify eight types of tumors in CE CT, with similar accuracy to a senior radiologist and better than a junior one. As far as we know, in the task of differential diagnosis on CE CT, it is the first model on par with a senior radiologist specialized in liver imaging. It also generalizes well to external datasets.

## **CLINICAL RELEVANCE/APPLICATION**

Our model can be applied to screen patients with liver tumor using NC CT for early detection and triage with high accuracy. It can also help clinicians differentiate major tumor types in CE CT.

### Unified Spectral Processing in Photon-counting-detector CT using Bayesian Deep Learning with Explicit Uncertainty and Bias Penalty

Wednesday, Nov. 29 3:00PM - 4:00PM Room: N227B

Hao Gong, PHD (*Presenter*) Nothing to Disclose

#### PURPOSE

Photon-counting-detector (PCD) CT provides high-quality spectral data to derive multiple image types (e.g., iodine maps, virtual monoenergetic (VMI), non-calcium (VNCa)), which assist diagnoses in many CT tasks. Conventional spectral processing methods are susceptible to amplified image noise and artifacts that impede reader interpretation. We aim to improve diagnostic image quality through unified spectral processing based on Bayesian deep learning with explicit uncertainty and bias penalty (BEACAN)

#### METHODS AND MATERIALS

BEACAN is based on a Bayesian dual-task neural network with bifurcated branches to classify types and quantify mass densities of basis materials. The network used probabilistic modeling of model likelihood and posterior distribution to re-balance its uncertainty and bias in training and characterize the statistical distribution of outputs for given inputs. Training used PCD-CT low-/high-threshold images of tissue-/contrast-mimicking inserts (e.g., hydroxyapatite (HA), iodine, muscle) and simulated random-shaped inserts. The predicted means of mass density maps were used to derive additional image types, due to improved robustness and detail preservation. Pixel-wise uncertainty was derived to support anomaly detection. Material quantification accuracy was assessed using root mean square error (RMSE) at 100% and 50% routine doses. For proof of concept, 5 patient CT cardiac angiograms were used to assess overall image quality, noise, and artifacts in material maps and VMIs. A prior-knowledge-assisted iterative material decomposition (Iter-MD; basis materials: HA, iodine, water) and commercial VMI software served as baseline methods

#### RESULTS

BEACAN improved quantification accuracy (e.g., RMSE of BEACAN vs Iter-MD: Iodinated blood 0.8 vs >1.6mgI/cc; HA <12 vs >14mgHA/cc; Fat <6 vs >70mgFat/cc), and generalized well in patients (e.g., little iodine residual in HA maps, reduced beam-hardening, and preserved details). Heteroscedastic uncertainty was observed, and tissue boundaries (e.g., plaque-lumen) tend to show higher variability. BEACAN-synthesized VMIs enhanced iodine signal, but reduced image noise (range 28% to 50% at 55keV) and blooming artifacts relative to commercial VMI. VNCa displayed at varying keVs can be derived from BEACAN, which is not commercially available on scanner

#### CONCLUSION

BEACAN provides high-quality spectral CT post-processing, showing improved material decomposition and VMI image quality in patient exams

#### CLINICAL RELEVANCE/APPLICATION

BEACAN is potential to accurately quantify target material in patients with dense calcified plaques, which could be undiagnostic in standard CT. It provides built-in uncertainty estimation to support anomaly detection and decision support

### Improved Stenosis Assessment through AI-Enabled Virtual Monoenergetic Imaging on Photon Counting Detector CT in Ultra-High-Resolution Mode

Wednesday, Nov. 29 3:00PM - 4:00PM Room: N227B

Shaojie Chang, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Ultra-high-resolution (UHR) photon counting detector (PCD) CT has shown great potential in various clinical applications. However, the current commercial system lacks multi-energy capabilities in the UHR, ECG-gated cardiac scan mode. This study aims to use a convolutional neural network to generate virtual monoenergetic images (VMIs, Mono-CNN) in UHR mode to improve stenosis assessments in patients with dense calcifications.

#### METHODS AND MATERIALS

Coronary CT angiography (cCTA) exams performed with standard (144x0.4 mm) multi-energy and UHR (120x0.2 mm) scan modes on a commercial dual-source PCD-CT (NAEOTOM Alpha, Siemens) were included for training and testing. VMIs at 100 keV and 70 keV (70 keV is effective energy of 120 kV beam) from the standard mode were reconstructed following the standard clinical protocol, using an iterative reconstruction (IR) algorithm at strength 4, Bv60 kernel, 0.6 mm slice thickness. A convolutional neural network (Mono-CNN) was trained using MSE loss with the 70 keV VMI as input and the 100 keV VMI as the label. The trained Mono-CNN was validated on independent multi-energy data sets (not used in training), with Mono-CNN VMI compared qualitatively and quantitatively to the true VMI. For testing, the Mono-CNN was applied to the single-energy-equivalent (T3D) cCTA patient cases (n=10) acquired with the UHR mode (no multi-energy capability), which were reconstructed using IR-4, Bv60 kernel, and 0.4 mm slice thickness. In addition to visual assessment, quantitative assessment of percent area stenosis was performed using commercial software (Syngo.Via CT Coronary Vascular Definition, Siemens). Stenosis quantification was performed for both T3D images and the Mono-CNN-generated 100 keV VMIs and the results were compared.

#### RESULTS

The Mono-CNN generated high-quality images that closely resembled the true 100 keV VMIs. Mean HU differences between Mono-CNN and true VMI were 4.85 (1.6%), 8.82 (8.7%), and 1.37 (1.6%) HU for ROIs in the aorta, left ventricle, and myocardial fat, respectively. The UHR 100 keV VMIs produced by Mono-CNN demonstrated reduced blooming artifacts compared to standard T3D images. Quantitative analysis showed reduction of percent area stenosis in every patient involved in this study, with an average reduction of 12%, ranging from 4 to 20%.

#### CONCLUSION

Mono-CNN provides VMI capabilities to the UHR cCTA in PCD-CT, enabling simultaneous high-resolution and multi-energy imaging, which can reduce blooming artifacts and improve stenosis assessment.

#### CLINICAL RELEVANCE/APPLICATION

The Mono-CNN has the potential to improve the PCD-CT system's performance by decreasing cardiac blooming artifacts in the 100 keV images while also using the highest spatial resolution.

### Deep Learning-based 4D CT and 4D CBCT Motion Compensation of Periodic and Non-Periodic Patient Motion with Single-View Temporal Resolution

Wednesday, Nov. 29 3:00PM - 4:00PM Room: N227B

Joscha Maier, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To provide cardiac- and respiratory-compensated CT and cone-beam CT (CBCT) reconstructions showing the patient in any patient motion state that had occurred during the acquisition, i.e. at the time point of any given x-ray projection of the scan.

#### METHODS AND MATERIALS

Some CT and several CBCT applications rely on 4D (3D+time) reconstructions that resolve organ motion. To do so, current strategies typically synchronize the scan with an external motion monitoring device such as a breathing belt or an ECG. Subsequently, projections sharing a similar motion phase are reconstructed together to derive a set of phase-correlated (gated) reconstructions that represent different phases of the motion cycle. This strategy, that is often followed by motion compensation (MoCo), which is the determination of motion vector fields (MVFs) and the warping of the phases according to these MVFs into a target phase, implicitly assumes periodic motion and fails in case of irregular and non-periodic motion patterns. Here, we also determine MVFs, but we do no gating. Instead, each individual projection is reconstructed into a separate volume, which is referred to as partial angle reconstruction (PAR). A deep neural network is trained on simulated data to derive the desired MVFs between any two PARs of the scan. With  $N$  projections, there will be  $N$  PARs and  $N(N-1)$  MVFs. The MVFs used for the simulation serve as training labels, i.e. as ground truth (GT). Since CT reconstruction is a linear operation, a MoCo for time point  $n$  (projection  $n$ ) can be performed by warping all PARs with  $n' \neq n$  into time point  $n$  and summing up the warped PARs. To evaluate the performance of the proposed approach, it was tested on simulated data as well as on real measurements of patients scanned with the on-board CBCT of a Varian TrueBeam® system.

#### RESULTS

For all simulated test cases, the estimated MVFs were in good agreement with the GT MVFs. MoCo volumes based on the estimated MVFs differed by less than 12 HU on average from the respective GT. In case of measured patient data, respiratory and cardiac motion could clearly be resolved for both regular and highly irregular motion patterns. In particular, the displacement of the diaphragm extracted from the MoCo reconstructions showed a high correlation with external respiration signals.

#### CONCLUSION

Using the proposed approach allows to derive accurate 4D reconstructions of patients with arbitrary motion patterns without the need for external gating signals. Thereby, the temporal resolution equals the acquisition time of a single projection.

#### CLINICAL RELEVANCE/APPLICATION

The high temporal resolution may improve 4D CBCT applications such as radiation therapy planning or tumor tracking while not requiring external gating signals simplifies patient preparation.

### W7-SSPH12-2 Feasibility Studies of an Ultra-low-dose, Stationary, Tomographic Molecular Breast Imaging System using 3D CZT Detectors

Alexander Cherlin, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Molecular Breast Imaging (MBI) has been shown to have high sensitivity in cancer detection, even in dense breast tissue. However, long imaging time and radiation dose that is higher than mammography impede its wide adoption. A novel ultra-low-dose stationary tomographic MBI system is being developed by Kromek and University College London. Comparing to planar MBI, the new system is expected to provide the patient dose reduction to the mammography level, better sensitivity, and improved diagnostic content by detecting smaller lesions and their 3D structure.

#### METHODS AND MATERIALS

The feasibility prototype has been built at Kromek with 2x2 array of 5 mm thick 2 mm pixel CZT detectors with 2x2 sub-pixelisation, and a densely packed multi-pinhole 3D printed tungsten collimator. The system delivers tomographic images with significant multiplexing. De-multiplexing algorithms utilise DOI information to mitigate the adverse multiplexing artefacts. GATE and MATLAB simulations were used to evaluate the design feasibility, develop new image reconstruction methods and to compare the performance of the new system to published planar MBI results. It is being evaluated using an "activity-painting" setup and a point  $^{57}\text{Co}$  source and  $^{99\text{m}}\text{Tc}$ -filled physical phantoms. Non-local means (NLM) noise filtering and a relaxation scheme were applied to the results to improve the contrast-to-noise ratio (CNR) and lesion detection uniformity across the field of view (FOV).

#### RESULTS

The images reconstructed in both simulations and phantom measurements demonstrate very effective reduction of multiplexing artefacts by using the detector DOI information. CNR of  $\sim 15$  was achieved after collimator design optimisation and image de-noising using NLM filtering. Multiple algorithms were implemented in both simulated and experimental data image reconstruction to compare their performance. The algorithms incorporating the multiplexing directly in the system matrix have shown better performance. The relaxation scheme demonstrated significant improvement of image reconstruction performance across the FOV. As the next step, Kromek is working with clinical partners on designing a full-size prototype and preparations for clinical trials.

#### CONCLUSION

Our results demonstrate the feasibility to decrease the injected patient dose to about 2 mCi/75 MBq (equiv. to mammography dose of  $\sim 0.5$  mSv), significantly decrease the scan time comparing to the current 40 min and decrease the lesion detection size to 5-6 mm across the whole FOV.

#### CLINICAL RELEVANCE/APPLICATION

The reduction of patient dose, scan time, and 3D localisation, aiding biopsy, should fulfil American College of Radiology's criteria (2018) for accepting MBI for cancer screening, especially for patients with dense breast tissue.

### W7-SSPH12-3 Development of a Novel Compton Camera for Low Dose Nuclear Medicine Imaging

Bill Kamtchou, MSc, BSc (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study is to develop a Compton camera for Nuclear Medicine imaging applications using Timepix technology. A Compton camera is an imaging device that can determine the direction of photons emitted by radioisotopes based on the kinematics of Compton scattering. Current gamma camera technology relies on the use of collimators to determine positional information of incident photons. Collimators, however, attenuate >99% of incident photons, requiring increased administered activities. The development of a Compton camera would negate the need for collimators, thus significantly reducing patient dose and potentially improving patient throughput.

## METHODS AND MATERIALS

A high spatial, high contrast resolution Timepix3 (55  $\mu\text{m}$  pixel pitch) device with a Cadmium Telluride sensor layer was used to acquire 2D image datasets for  $^{99\text{mTc}}$ ,  $^{131\text{I}}$  and  $^{137\text{Cs}}$  test objects. Analysis pipelines were established for identifying appropriate interaction events and clusters, with subsequent Compton cone data reconstructed onto single and multiple planes, using maximum likelihood expectation maximization (MLEM) techniques. A Monte Carlo (MC) simulation of the Timepix3 detector Compton camera was developed using the EGSnrc Monte Carlo software.

## RESULTS

The model, accounting for the Timepix3 spatial and energy resolution, in addition to Doppler broadening effects, was validated using the above experimental data. The spatial resolution, as measured by the full width half maximum (FWHM) of  $^{99\text{mTc}}$  and  $^{137\text{Cs}}$  point sources was found to be 6 and 6.6 mm, respectively, which is comparable to that of high resolution gamma cameras. Images of anthropomorphic thyroid phantoms will be presented and compared to conventional gamma cameras in terms of sensitivity and spatial resolution.

## CONCLUSION

A nuclear medicine Compton camera has been developed, with experimental data and simulations demonstrating its potential for Compton imaging applications. Future work will extend the use of the CdTe Timepix3 detector to more complex nuclear medicine imaging applications to investigate the technology's potential to significantly reduce administered patient activities and, hence, reduce patient dose.

## CLINICAL RELEVANCE/APPLICATION

The development of a Compton camera has the potential to significantly reduce the required patient radiation dose in nuclear medicine. The results demonstrate that Timepix can be effectively used for Compton imaging with a spatial resolution comparable to current state-of-the-art gamma cameras, but with an approximately 20-fold increased sensitivity. Further development of this technology could lead to a significant increase in patient throughput and the establishment of novel nuclear medicine imaging, such as low dose screening studies.

## W7- SSPH12-5 Risk Assessment for Fetal Dose

Christiane S. Burton, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Quantifying radiation risk is needed for optimizing personalized procedures involving imaging with radiation dose. There are various methods for characterizing radiation risk for CT and PET. Purpose We demonstrate the radiation risk for various tissue in fetuses for pregnant patients who underwent PET/CT examinations.

## METHODS AND MATERIALS

Nine pregnant patients underwent a PET/CT examination over an 11-year period at the University of Michigan. The gestational ages range from 12-36 weeks. The radiation risk index (RRI) was measured using the lifetime attributable risk (LAR) of cancer incidences in the US population from BEIR VII. For CT, the fetal organ tissue dose needed for RRI was calculated using the Monte Carlo simulations that utilizes the ICRP reference phantoms. For PET, the MIRD calculation was used for the RRI calculation using a low  $^{18\text{F}}$  activity of 3.5 mCi for fetuses at 12, 24 and 36 weeks of gestation.

## RESULTS

The RRI ranges from 2.1 to 85.5 cases per 100,000 patients per 100 mGy. There were also notable differences in risk index for various tissues between males and females, particularly lung and colon. The risk index for CTDIvol of 50 mGy and 100 mGy for fetuses was shown to decrease as gestational increases for 12, 24 and 36 weeks.

## CONCLUSION

The risk of PET/CT dose to fetus doses for various tissues have been reported. While maintaining fetal dose below 100 mGy is important, there are risks associated with different fetal tissues that should be considered should a pregnant patient need to undergo a diagnostic exam that involves radiation.

## CLINICAL RELEVANCE/APPLICATION

While clinical PET/CT scans are considered safe for fetuses, the SSDE is not a reliable risk estimate, and the radiation risk should be considered when modifying doses to a pregnant patient.

### W7-SSPH12-6 **Comparison of the Accuracy of an Optimised Planar Scintigraphy LSF Estimation Technique with SPECT-CT LSF: A Monte Carlo (MC) Study for a Range of Gamma Camera Systems**

Niamh McArdle, BSc, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Prior to 90Y selective internal radiation therapy (SIRT) treatment, planar 99mTc-MAA scintigraphy imaging is used in the estimation of the lung shunt fraction (LSF). Significant overestimations in the LSF using planar imaging has been well documented hence affecting the dosimetric accuracy. While this remains the manufacturer's recommended method for LSF estimation, it neglects to account for scatter radiation and respiratory motion. A scatter window based correction has been shown to significantly improve the LSF estimation accuracy. However, the technique has only been demonstrated for an average sized phantom, on a specific gamma camera type and has yet to be compared with SPECT-CT LSF estimations. Accordingly, the objective of this study was to compare the accuracy of the optimised planar LSF estimation (LSF<sub>planar</sub>) technique, with that of SPECT-CT (LSFSPECT), for a set of 4D virtual phantoms representative of a typical patient population, and applied to a range of gamma camera systems.

#### METHODS AND MATERIALS

SIMIND Monte Carlo (MC) modelling software was used to simulate planar scintigraphy and SPECT-CT images of the XCAT 4D digital anatomical phantom for clinically relevant LSFs (0-25%). MC image acquisition of different modelled anatomical phantoms (BMI of 21-38 kgm<sup>-2</sup>) were simulated on a range of systems including a GE NM gamma camera series including CZT technology, Phillips Brightspace and Siemens Symbia. The scatter corrected LSF<sub>planar</sub> technique was compared with the LSFSPECT for each gamma camera type.

#### RESULTS

The scatter correction technique significantly improved the LSF<sub>planar</sub> accuracy to within 28% across each gamma camera type, as compared with overestimations of up to 200% prior to scatter correction. The employment of an enhanced depth specific scatter correction, to account for varying patient size, further improved the LSF<sub>planar</sub> accuracy to within 19%. Spectral analysis showed a 114-126 keV scatter energy window to be optimal for sodium-iodide detectors with a scatter window of ~99-128 keV most applicable for CZT technology. A comparison between optimised LSF<sub>planar</sub> and that of LSFSPECT imaging datasets will be presented.

#### CONCLUSION

LSF<sub>planar</sub> with incorporated scatter correction can significantly improve the accuracy of the planar LSF estimation approaching that of LSF<sub>SPECT</sub>. The use of MC simulations and voxel based phantoms allowed for comparison between true and estimated LSFs in a range of phantom sizes representative of the patient population. This revised methodology facilitates improved accuracy in the dosimetry estimation using planar imaging and a more optimised prescribed patient therapy dose.

## CLINICAL RELEVANCE/APPLICATION

Accurate LSF estimations can improve the therapeutic dose calculations for SIRT patients.

### Feasibility Studies of an Ultra-low-dose, Stationary, Tomographic Molecular Breast Imaging System using 3D CZT Detectors

Wednesday, Nov. 29 3:00PM - 4:00PM Room: N229

Alexander Cherlin, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Molecular Breast Imaging (MBI) has been shown to have high sensitivity in cancer detection, even in dense breast tissue. However, long imaging time and radiation dose that is higher than mammography impede its wide adoption. A novel ultra-low-dose stationary tomographic MBI system is being developed by Kromek and University College London. Comparing to planar MBI, the new system is expected to provide the patient dose reduction to the mammography level, better sensitivity, and improved diagnostic content by detecting smaller lesions and their 3D structure.

#### METHODS AND MATERIALS

The feasibility prototype has been built at Kromek with 2x2 array of 5 mm thick 2 mm pixel CZT detectors with 2x2 sub-pixelisation, and a densely packed multi-pinhole 3D printed tungsten collimator. The system delivers tomographic images with significant multiplexing. De-multiplexing algorithms utilise DOI information to mitigate the adverse multiplexing artefacts. GATE and MATLAB simulations were used to evaluate the design feasibility, develop new image reconstruction methods and to compare the performance of the new system to published planar MBI results. It is being evaluated using an "activity-painting" setup and a point  $^{57}\text{Co}$  source and  $^{99\text{m}}\text{Tc}$ -filled physical phantoms. Non-local means (NLM) noise filtering and a relaxation scheme were applied to the results to improve the contrast-to-noise ratio (CNR) and lesion detection uniformity across the field of view (FOV).

#### RESULTS

The images reconstructed in both simulations and phantom measurements demonstrate very effective reduction of multiplexing artefacts by using the detector DOI information. CNR of  $\sim 15$  was achieved after collimator design optimisation and image de-noising using NLM filtering. Multiple algorithms were implemented in both simulated and experimental data image reconstruction to compare their performance. The algorithms incorporating the multiplexing directly in the system matrix have shown better performance. The relaxation scheme demonstrated significant improvement of image reconstruction performance across the FOV. As the next step, Kromek is working with clinical partners on designing a full-size prototype and preparations for clinical trials.

#### CONCLUSION

Our results demonstrate the feasibility to decrease the injected patient dose to about 2 mCi/75 MBq (equiv. to mammography dose of  $\sim 0.5$  mSv), significantly decrease the scan time comparing to the current 40 min and decrease the lesion detection size to 5-6 mm across the whole FOV.

#### CLINICAL RELEVANCE/APPLICATION

The reduction of patient dose, scan time, and 3D localisation, aiding biopsy, should fulfil American College of Radiology's criteria (2018) for accepting MBI for cancer screening, especially for patients with dense breast tissue.

### Development of a Novel Compton Camera for Low Dose Nuclear Medicine Imaging

Wednesday, Nov. 29 3:00PM - 4:00PM Room: N229

Bill Kamtchou, MSc, BSc (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study is to develop a Compton camera for Nuclear Medicine imaging applications using Timepix technology. A Compton camera is an imaging device that can determine the direction of photons emitted by radioisotopes based on the kinematics of Compton scattering. Current gamma camera technology relies on the use of collimators to determine positional information of incident photons. Collimators, however, attenuate >99% of incident photons, requiring increased administered activities. The development of a Compton camera would negate the need for collimators, thus significantly reducing patient dose and potentially improving patient throughput.

#### METHODS AND MATERIALS

A high spatial, high contrast resolution Timepix3 (55  $\mu\text{m}$  pixel pitch) device with a Cadmium Telluride sensor layer was used to acquire 2D image datasets for  $^{99\text{mTc}}$ ,  $^{131\text{I}}$  and  $^{137\text{Cs}}$  test objects. Analysis pipelines were established for identifying appropriate interaction events and clusters, with subsequent Compton cone data reconstructed onto single and multiple planes, using maximum likelihood expectation maximization (MLEM) techniques. A Monte Carlo (MC) simulation of the Timepix3 detector Compton camera was developed using the EGSnrc Monte Carlo software.

#### RESULTS

The model, accounting for the Timepix3 spatial and energy resolution, in addition to Doppler broadening effects, was validated using the above experimental data. The spatial resolution, as measured by the full width half maximum (FWHM) of  $^{99\text{mTc}}$  and  $^{137\text{Cs}}$  point sources was found to be 6 and 6.6 mm, respectively, which is comparable to that of high resolution gamma cameras. W7-STCE1

### Science Session (Sustainability in Imaging)

Wednesday, Nov. 29 2:30PM - 3:00PM Room: Learning Center Theater 1

#### Sub-Events

#### **W7-STCE1- Advancing sustainability and energy efficient MRI operations through Fast Imaging 1 Techniques**

Azadeh Tabari, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Using the latest MRI systems and accelerated MRI techniques can lead to significant energy savings in radiology by reducing active scan times and optimizing resource utilization. The goal of this study was to determine the acquisition time, energy, cost, and carbon savings that could be achieved through implementing fast MRI techniques in outpatient brain imaging.

#### **METHODS AND MATERIALS**

Acquisition time (i.e. net scan time: active mode - exam preparation time) were extracted from consecutive brain MRI examinations done on 4 outpatient 3T wide-bore scanners from the same vendor (all Magnetom Vida; Siemens Healthineers), during pre-implementation (3/1/2019-3/1/2020) and post-implementation periods (3/1/2022-3/1/2023). Expected acquisition times were compared for the most frequently performed brain MRI protocols: brain without contrast (BR-) and brain with and without contrast (BR+). Power measurement logs were extracted for these protocols. Data from the scanner system-on mode were acquired from the scanner log data and was segmented into exam preparation time, net scan time and swap time (idle) for each scanner. Per-examination energy consumption, cost (assuming a mean cost of \$0.252/kWh in Massachusetts) and carbon savings were retrospectively calculated.

#### **RESULTS**

210 examinations were done during the pre-implementation period and 571 examinations were done during the post-implementation period. The median acquisition time for BR- and BR+ protocols were 16:42 and 26:15 min:sec for the pre-implementation period and 9:22 and 17:12 min:sec for the post-implementation period, respectively. The expected net scan time reductions for BR- and BR+ protocols were 7:20 min:sec (44%) and 9:03 min:sec (34.5%) for net scan time in the post-implementation period. The per-examination energy consumption for BR- and BR+ protocols using accelerated MRI sequences during net scan time were reduced by 3.53 and 6.4 kWh, respectively, translating to a potential annual savings of 2,015.6 to 3,654.4 kWh, \$508 to \$921 and 1.4 to 2.6 MTCO<sub>2</sub>eq per year.

#### **CONCLUSION**

The implementation of fast brain MRI sequences significantly reduced the acquisition times for commonly performed outpatient brain MRI protocols, leading to less energy expenditure during active net scan time and system-on modes and ultimately substantial sustainability and cost-savings potential.

#### **CLINICAL RELEVANCE/APPLICATION**

The reduction in acquisition times provided by accelerated MRI sequences translates into less energy expenditure during active scanning and ultimately substantial sustainability and cost-savings potential.

#### **W7-STCE1- Shedding Light on Sustainability for Radiologists - A Comprehensive Life Cycle Assessment 2 (LCA) of a Diagnostic Radiology Department**

Cassandra L. Thiel, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Climate change negatively impacts peoples' health, and healthcare emits 8.5% of the US's total GHGs. The urgency of the climate crisis requires coordinated action from healthcare stakeholders, including radiology. Previous radiology studies

assessed emissions per scans or omitted the production and distribution of capital equipment. This study measures the emissions associated with an entire radiology unit in an academic medical center.

## **METHODS AND MATERIALS**

This study is a partnership between a major radiology equipment manufacturer and one of the largest academic medical centers/health systems in the Southeastern USA. This study uses ISO14040-based Life Cycle Assessment (LCA), including manufacturing and distribution of capital equipment, consumable goods, and durable supplies; energy during use phase; staff and patient commuting; laundering and durable supply reprocessing; capital equipment refurbishment; and waste disposal. Results are reported in GHG emissions in kilograms of carbon dioxide equivalents (kg CO<sub>2</sub>e).

## **RESULTS**

Initial results (which currently exclude non-scanner plug loads, HVAC, cooling loads, and disposable supplies) show that the MR suite, with 2, 1.5T and 1, 3T machine generate the most emissions at an estimated 2,160,800 kg CO<sub>2</sub>e/year. The CT suite generates approximately 61,100 kg CO<sub>2</sub>e/yr (four scanners), Fluoro (99,800 with two machines), US (109,100 with two machines), and Xray (72,800 with two machines). Within the MR and CT suite, the largest source of emissions appears to be electricity use of the scanners (81% and 74% respectively). For MR, linens use represents the next largest category of GHG emissions (11%, assuming a 30 use lifespan for reusable linens) with production of the scanner accounting for 8% of emissions. For US, the linens consumption dominates emissions (75% of total), followed by electricity use (15%).

## **CONCLUSION**

Previous healthcare LCAs often omitted manufacturing of capital equipment due to a lack of data and the assumption that its impact would be minimal per patient. Here, approximately 25% of a CT scanner's lifetime GHGs come from its production; it should not be excluded from LCA studies. This study is ongoing, and the case location may not be representative of other radiology units with variables including number of scanners, scheduling, use of idle modes, and electricity sources.

## **CLINICAL RELEVANCE/APPLICATION**

Fully mitigating these impacts will require partnerships between multiple healthcare stakeholders, including manufacturers. There are many possible interventions to mitigate these emissions; given the prevalence of electricity-associated emissions, measures should be taken to reduce electricity consumption and 'decarbonize' these sources.

## **W7-STCE1- Spinning Radiology Resources: Balancing environmental and economic considerations with circular business models including extending scanner lifespan, software upgrades, repair, refurbishment, and leases**

Cassandra L. Thiel, PhD (*Presenter*) Nothing to Disclose

## **PURPOSE**

Human consumption of natural resources has reached unsustainable levels, in part due to a make-use-trash, or linear, product life cycle. Healthcare uses 10% of materials used globally every year, and most of this just goes to waste. Manufacturers and healthcare providers are beginning to incorporate circularity in their business models and practices, which can enable the longer use of existing materials and decrease the extraction of new materials. This study assesses the emissions materials associated with the original production and maintenance of scanners in a diagnostic radiology unit at an academic medical center. We model the financial and environmental trade-offs between maintaining or upgrading an older scanner, buying a refurbished replacement, or buying brand new with leasing models.

## **METHODS AND MATERIALS**

This study is part of a partnership between a major radiology equipment manufacturer and one of the largest academic medical centers in the Southeastern USA. The diagnostic radiology unit maintains 4 CTs, 2 DX, 3 MR, 2 US, and 3 XRays, ranging in age from 18.5 years to 3 years. This study uses ISO14040-based Life Cycle Assessment (LCA) to estimate the Greenhouse Gas (GHG) emissions from the original manufacture and distribution of capital equipment; energy during use phase; and performance impact of software upgrades improving clinical performance, life-time extensions, refurbishment, and leases.

## **RESULTS**

Initial results demonstrate that applying circular practices can reduce the GHG emissions compared to a linear manufacturing and use cycle. For annual emissions, circular business models can reduce CT emissions 5%-7% and MR 6%-8%. Most gains come from extending the lifetime of existing equipment or replacing existing equipment with a refurbished or leased one. If the equipment were run on renewable energy, reductions would be significantly higher, with CT reduced by 29%-39% and MR 29%-41%. For per patient emissions, software upgrades show the highest potential for reduction in both CT and MR, because improved clinical performance helps treat more patients daily.

## **CONCLUSION**

This manufacturer offers a variety of circularity options for capital scanning equipment, including lease or service-based contracts, software and hardware upgrades which may affect performance efficiency, end-of-life extension services, and total

refurbishment. Compared to a baseline scenario of buying new and disposing after use, most scanners perform as good as new, but in line with the previous model of the scanner.

**CLINICAL RELEVANCE/APPLICATION**

Radiologists must select equipment that meets their needs; however, they should prioritize procuring refurbished models and extending the lifespan of the equipment already on site for lower cumulative emissions.

We model the financial and environmental trade-offs between maintaining or upgrading an older scanner, buying a refurbished replacement, or buying brand new with leasing models.

#### **METHODS AND MATERIALS**

This study is part of a partnership between a major radiology equipment manufacturer and one of the largest academic medical centers in the Southeastern USA. The diagnostic radiology unit maintains 4 CTs, 2 DX, 3 MR, 2 US, and 3 XRays, ranging in age from 18.5 years to 3 years. This study uses ISO14040-based Life Cycle Assessment (LCA) to estimate the Greenhouse Gas (GHG) emissions from the original manufacture and distribution of capital equipment; energy during use phase; and performance impact of software upgrades improving clinical performance, life-time extensions, refurbishment, and leases.

#### **RESULTS**

Initial results demonstrate that applying circular practices can reduce the GHG emissions compared to a linear manufacturing and use cycle. For annual emissions, circular business models can reduce CT emissions 5%-7% and MR 6%-8%. Most gains come from extending the lifetime of existing equipment or replacing existing equipment with a refurbished or leased one. If the equipment were run on renewable energy, reductions would be significantly higher, with CT reduced by 29%-39% and MR 29%-41%. For per patient emissions, software upgrades show the highest potential for reduction in both CT and MR, because improved clinical performance helps treat more patients daily.

#### **CONCLUSION**

This manufacturer offers a variety of circularity options for capital scanning equipment, including lease or service-based contracts, software and hardware upgrades which may affect performance efficiency, end-of-life extension services, and total refurbishment. Compared to a baseline scenario of buying new and disposing after use, most scanners perform as good as new, but in line with the previous model of the scanner.

#### **CLINICAL RELEVANCE/APPLICATION**

Radiologists must select equipment that meets their needs; however, they should prioritize procuring refurbished models and extending the lifespan of the equipment already on site for lower cumulative emissions.

## Abstract Archives of the RSNA, 2023

W7-STCE2

### Science Session (Generative AI)

Wednesday, Nov. 29 2:30PM - 3:00PM Room: Learning Center Theater 2

#### Sub-Events

#### **W7-STCE2- Clinical benefit of AI-based Chest X-ray Reading Support for non-radiology physicians in clinical routine** 1

Dr. Karsten Ridder (*Presenter*) Nothing to Disclose

#### **PURPOSE**

1. Research question: How can non-radiology physicians (NRP), e.g. internists, benefit from AI-based Chest X-ray reading, especially in times when a radiologist is not around?

#### **METHODS AND MATERIALS**

We installed an AI-based CXR reading support in clinical routine in a German multi-site medical supply centre. The MVZ for radiology connects 18 institutions including hospitals and private practices. 8 of these institutions are hospitals producing CXR images in a clinical routine set-up 24/7. In total more than 57.000 cases were processed in 2022 with a success rate > 99%. AI results are generated in less than 3 min. which fully suffices the clinical need. We use the AI Rad Companion Chest X-ray from Siemens Healthineers. The AI system identifies five abnormalities on CXRs: Pneumothorax, Pleural Effusion, Pulmonary Lesions, Consolidation, and Atelectasis.

#### **RESULTS**

Method 1: In more than 80% of the cases the ad-hoc decision of the physician was confirmed by the radiologist and by the AI. In 3 cases the AI showed a result which was not seen by the NRP: one benign lesion was overlooked, one consolidation and one pleural effusion detected. In all cases the clinical ad-hoc decision was unchanged. Method 2: The AI found only in 25% of the studies an abnormality. In 90% of these studies no actionable abnormality was found afterwards by the radiologist. In the remaining 10% following abnormalities were found: strong/chronic bronchiectasis, cardiomegaly, rib fracture, emphysema.

#### **CONCLUSION**

We tested the AI system regarding the clinical benefit for NRP. AI provides benefit for NRP: - In case the AI has not found an abnormality there is a high probability for no clinical actions required, i.e. an 'extra-check' with an expert might not be needed during night shifts or week-ends - AI-based diagnostic support plays an important role since often radiology services do not cover CXR reading in extra times. - The five findings of the used product (AI Rad Companion Chest X-ray) cover a large part of radiographic findings in clinical routine

#### **CLINICAL RELEVANCE/APPLICATION**

As one of the worldwide most taken X-ray procedures, chest X-ray (CXR) is one of the most important and most demanding modalities in daily medical imaging. Due to its accessibility and fast acquisition, chest radiographs are frequently used as a first diagnostic step, deciding on further patient treatment [1,2]. Beside the radiologist, NRP often need to interpret CXR images in a timely manner and decide about the next steps with the patient. While most of the research is focused on quantitative evaluations in a retrospective and synthetic environment [3,4], this abstract is focused on the implementation of such system in a real-world clinical setup.

#### **W7-STCE2- Grounding Large Language Models in Evidence: A Systematic Approach to Mitigate Hallucination Errors in Automated Radiology Question-Answering Systems** 2

Pouria Rouzrokh, MD, MPH (*Presenter*) Nothing to Disclose

## PURPOSE

Large Language Models (LLMs) have recently garnered considerable interest within the healthcare sector. The impressive performance of LLMs across various applications underlines their potential use for crucial tasks such as medical question answering. However, LLMs are subject to "hallucination" errors, which involve generating overly confident responses based on insufficient facts. Our study introduces a pipeline that leverages LLMs in automated radiology question-answering systems while firmly grounding their responses to user-specified evidence.

## METHODS AND MATERIALS

We gathered a total of 10 peer-reviewed articles pertaining to "brain tumors" from RadioGraphics, specifically from the journal website's "Core Exam" section. We then derived five low-level questions (Bloom's taxonomy level 1; memorizing tasks) and five high-level questions (Bloom's taxonomy level 4; clinical scenarios) from each article. Every question was formatted as multiple-choice and scrutinized for scientific validity. First, we divided the articles' raw text into 503 sections of 1500 characters, allowing for a 200-character overlap between consecutive parts. Using OpenAI models, we then converted these text sections into 1536-dimension vectors and stored them in an in-memory database. Each question was similarly embedded, with the cosine similarity distance between it and all reference vectors computed. The ten reference vectors most similar to the question vector were identified, and corresponding text chunks were retrieved. These and the index question were inputted into a ChatGPT-3.5-Turbo model, using a carefully crafted prompt instructing the model to generate answers solely based on the given context. We then compared the accuracy of this method with a baseline method of posting the same questions to the LLM without providing any retrieved evidence.

## RESULTS

The LLM yielded an average accuracy of 80% (88% and 72% for low- and high-level questions, respectively; used 358,445 tokens) within the knowledge retrieval pipeline, signifying a notable improvement compared to the baseline method with an average accuracy of 66% (70% and 62% for low- and high-level questions, respectively; used 27,758 tokens). Our demo is available online: <http://3.18.4.242:8090>

## CONCLUSION

Our proposed pipeline could markedly enhance the performance of LLMs in medical question-answering tasks, leveraging a scalable method for storing and querying scientific evidence.

## CLINICAL RELEVANCE/APPLICATION

Given the rapidly expanding application of LLMs, it is of utmost importance to ensure robust mechanisms are in place to mitigate hallucination risks associated with these models when responding to medical inquiries from patients and healthcare personnel.

## W7-STCE2- Report Generation of Chest Radiographs Utilizing a Multimodal Transformer Model

3

Yash S. Saboo (*Presenter*) Nothing to Disclose

## PURPOSE

While uncommon, radiologists can miss significant findings in reading chest X-rays due to burnout, anchoring bias, and a distracting reading-room environment. Thus, there is a need to implement artificial intelligence to assist radiologists with a comprehensive preliminary chest X-ray reading. Currently, research in radiologist report generation using AI techniques is limited. Our study aims to develop a multimodal transformer model that generates radiology reports comparable to those from professional radiologists.

## METHODS AND MATERIALS

We used the Reports and Eye-Tracking Data for Localization of Abnormalities in Chest X-rays (REFLACX) dataset, a de-identified dataset of 2616 chest X-rays from the Medical Information Mart for Intensive Care (MIMIC-III) dataset and corresponding free-text radiology reports. We employed ChatGPT 3.5 to segment each free-text report into seven sections: cardiomeastinal, pleural space, lungs, bones, soft tissue, lines and tubes, and other. The open-source Vision Image Transformer (ViT) was fine-tuned to encode each chest X-ray and RoBERTa was fine-tuned to decode the encoding into a text description of a particular section of the radiograph. The descriptions from the seven models were compiled into one report. Outcomes were measured utilizing common language model metrics including Rouge-1, Rouge-2, and Rouge-L F1 Scores. F1 scores were used because the wide distribution of possible tokens leads to class imbalance.

## RESULTS

On the test set, The ViT Roberta Model achieved a Rouge-1 F1 Score of 51.6%, Rouge 2 F1 Score of 10.4%, and Rouge L F1 Score of 51.4%. An interactive, robust website highlights the comparability of the ViT Roberta and radiologist-generated reports. On this website, the user attempts to identify the report that was AI-generated. The purpose of the website is to assess the similarity of AI-generated reports to human reports. The website URL is <http://aiormd.com>.

## **CONCLUSION**

Our study demonstrates the potential of multimodal transformer models in assisting radiologists with automatic reporting of chest X-rays. Traditional natural language processing metrics such as Rouge may not fully assess a model's ability, as they are generally inconsiderate to semantic meaning. Further validation with larger datasets and prospective clinical settings are needed to fully establish the clinical utility and reliability of this approach.

## **CLINICAL RELEVANCE/APPLICATION**

By generating instantaneous, accurate, and comprehensive reports of chest X-rays, this transformer model has the potential to alleviate radiologist workload and improve diagnostic accuracy.

BREE

### Breast Imaging Education Exhibits

All Day Room: Learning Center

#### Sub-Events

#### **BREE-1 Pathologic Nipple Discharge: Is Breast MRI a Good Option?**

Valeria Vidales (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Pathologic nipple discharge (PND) is unilateral, spontaneous, involves a single duct, and is serous or bloody in appearance. MRI is able to detect the etiology of nipple discharge in 56-61% of cases when initial imaging with mammogram and ultrasound are negative. To describe differential diagnosis and its classification in BIRADS system.

#### **TABLE OF CONTENTS/OUTLINE**

Description of the anatomy of the nipple and retroareolar Description of different types of lesions that could be found in patients with nipple discharge US, mammographic and RM principal findings and its correlations. Sample cases

#### **BREE-10 Single Duct Abnormalities: Multimodality Imaging and Assessment**

Juliana Sitta, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Ductal abnormalities entail a wide range of pathology that may present clinically or grow silently, ranging from benign to malignant processes. Solitary dilated duct is a rare mammographic finding with controversial clinical significance in the literature. Workup of the solitary dilated duct must include additional mammographic views and ultrasound to assess for additional findings that would raise suspicion for malignancy and provide a biopsy target. Ductal ectasia is the most common benign finding; however, atypical presentations such as peripheral location, wall thickening, and hypoechoic tissue should raise suspicion for secondary obstruction causes. In spissated secretions can mimic intraductal masses and may be seen in association or secondary to acute and chronic mastitis, ductal ectasia, and intraductal papilloma. Patients with papillomatosis often have associated high-risk lesions and an increased lifetime risk of breast malignancy. MRI is a great adjunct to evaluate nipple discharge, particularly when the initial workup is negative, and to exclude underlying DCIS or invasive ductal carcinoma.

#### **TABLE OF CONTENTS/OUTLINE**

Review and illustrate ductal anatomy, physiology, and normal findings on multimodality imaging, including mammography, ultrasound, galactogram, and MRI. Illustrate and discuss problem-solving for single duct findings and presentations commonly associated with single duct abnormality with interesting cases from our institution. Analyze the added value of multiple imaging modalities in assessing ductal pathology, including galactogram and MRI.

#### **BREE-100 The Leading Role of Ultrasound in Breast Implant Evaluation in Developing Countries**

Giannina M. Secco, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

To illustrate ultrasound findings in breasts with implants and their comparison with those in magnetic resonance imaging. To discuss the advantages and limitations of ultrasound for breast implant evaluation and why it remains a valuable and irreplaceable tool in underdeveloped and developing countries.

#### **TABLE OF CONTENTS/OUTLINE**

Detecting a broken breast implant is essential due to the potential physical discomfort, cosmetic deformity, and health risks associated with a ruptured implant. Early detection and prompt treatment of a broken implant are crucial to prevent further

complications and ensure optimal patient outcomes. Knowledge of a ruptured implant can help patients make informed decisions about implant replacement or removal. In order to acknowledge this, we believe breast implant ultrasound is a preferable choice to MRI for breast implant evaluation in underdeveloped and developing countries. Breast implant ultrasound is more cost-effective, with often portable machines, non-invasive procedure that does not require the use of contrast agents or ionizing radiation, provides real-time imaging, does not require anesthesia and is widely available in many healthcare facilities. Ultrasound imaging can be performed and interpreted quickly, allowing clinicians to make prompt treatment decisions. Furthermore, breast implant ultrasound is safe for patients with pacemakers or other implanted devices, while MRI may not be feasible for these patients. Although ultrasound has its limitations in some cases, it remains a valuable and irreplaceable tool for breast implant evaluation in underdeveloped and developing countries.

### **BREE-101 Cystic Breast Lesions Assessment and Management: An Educational Approach for Radiology Residents**

Karina Pesce, PhD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

To recognize the spectrum of cystic breast lesions. To learn tools and tips for the sonographic evaluation of cystic lesions. To understand the importance of distinguishing benign cystic lesions from potentially malignant cystic masses To learn skills in the assessment and management of cystic breast lesions

#### **TABLE OF CONTENTS/OUTLINE**

1-Introduction: Cystic breast lesions are a common finding in breast imaging studies. Accurate characterization and precise management of these lesions are essential to avoid unnecessary biopsies and tests, as well as to timely identify which of these lesions require further diagnostic evaluation. 2- Ultrasound parameters necessary for a correct evaluation of cystic lesions. 3- Tips and tricks in the ultrasound evaluation of cystic lesions. 4- Spectrum of cystic lesions. 5- Ultrasound appearance 6-Radiological appearance of cystic breast lesions on other imaging modalities such as mammography, MRI. 7- Management. 8- Interactive clinical cases for self-evaluation. 9- Conclusions

### **BREE-102 Radiological Signs in Breast Imaging: What Should the Radiology Resident Know?**

#### **Awards**

##### **Certificate of Merit**

Karina Pesce, PhD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1.To know recognize the different radiological signs in breast imaging.2.To learn the importance of accurate identification of the different radiological signs.

#### **TABLE OF CONTENTS/OUTLINE**

Introduction This educational poster reviews the importance of understanding breast radiological signs. Accurate identification of different radiological signs is critical for early diagnosis and effective treatment of various medical conditions, including breast cancer. Furthermore, knowledge of clinical and radiological signs in breast imaging can help prevent diagnostic errors and reduce the number of unnecessary medical tests. Description of the radiological signs in breast imaging. Tips and techniques for identifying these signs are also provided to assist residents in their interpretation of medical images. Interactive clinical cases for self-evaluation. These cases offer residents the opportunity to apply their knowledge and receive immediate feedback, thereby strengthening their diagnostic skills and decision-making abilities. Conclusion: Radiologists residents must be familiar with different radiological signs to accurately interpret medical images and provide an accurate diagnosis.

### **BREE-103 Peer Learning in Breast Imaging: Lessons Learned in Our Institution**

Marcela C. Lauer, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

It is estimated that medical diagnostic mistakes contribute to approximately 10% of patients deaths and 17% of adverse events in hospitals. Consequently, optimal patient care is related to recognizing and preventing such errors. Strategies were developed to ensure performance standards in radiology departments, including score-based second-reader peer review systems. However, this type of strategy may be associated with subjectivity, sampling bias, underreporting of errors due to peer relationships and fear of punitive action. It may have emotional impact for radiologists and lead to feelings like anxiety, shame, and humiliation, contributing to a culture of defensiveness. On the other hand, peer learning is an strategy focused on learning and improvement that has gained momentum, as a respectful nonpunitive collaborative culture improves performance in modern radiology practice. The objective of this presentation is to show how we established peer learning in our breast imaging department, the bias that were related to the mistakes we made, how we concluded they could have been avoided and our experience with peer learning as a group. We aim that this presentation may help and encourage other services to implement peer learning in their clinical practice, and also learn from the multimodality imaging cases we provide.

## TABLE OF CONTENTS/OUTLINE

Didactic case-based reviews of breast imaging exams (including mammography, ultrasound and magnetic resonance imaging performed in our service) that were discussed in our peer learning meetings in the last 5 years, with correlation of associated cognitive bias, how the cases could have been better managed and lessons learned that changed our daily practice.

### **BREE-104 Multimodality Surveillance of Breast Implants in Asymptomatic Patients and the Potential Challenges for the Radiologist in Light of the 2022 United States Food and Drug Administration (FDA) Guidelines**

H. Carisa Le-Petross, MD, FRCPC (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Recently the United States Food and Drug Administration (FDA) implemented changes to breast implant surveillance that radiologists may not be aware of<sup>1,2</sup>. At the end of this exhibit, the participant will:

- Be up-to-date on the 2022 FDA guidelines for breast implant screening.
- Learn the common signs of implant rupture on ultrasound (US).
- Learn the common signs of implant rupture on magnetic resonance imaging (MRI).
- Be familiar with implant complications and new technology to minimize some complications<sup>3</sup>.
- Be familiar with some key differences between updated FDA guidelines and the imaging recommendations from the American College of Radiology Appropriateness Criteria.

## TABLE OF CONTENTS/OUTLINE

- Discuss the changes in the 2022 FDA guidelines for breast implant screening, especially the addition of US as an alternative to MRI for initial imaging surveillance for silicone implant rupture in asymptomatic patients<sup>1-4</sup>.
- Discuss the 2022 FDA guidelines recommendation for the first screening imaging test at 5 years after implantation instead of 2 years after implantation, the lack of compliance from patients, and background behind this change<sup>1-5</sup>.
- Discuss the potential controversies regarding the imaging modality of choice to evaluate for implant rupture via case-based presentation<sup>4</sup>.
- Review the imaging signs of implant rupture on different modalities, focusing mainly on US and MRI. Review benefits and/or challenges of new implants, technology such as acellular dermal matrix (ADM), and new generation tissue expanders.

### **BREE-105 Abnormality of the Duct on Breast Ultrasound: Comparison with Multimodality, Correlation with Pathological Findings, and Assessment**

Ken Oba, MD, BArch (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The 6th edition of BI-RADS is expected to include nonmass lesions detected on breast ultrasound. In breast imaging, it is important to comprehend lesions such as ductal carcinoma in situ which do not form masses but appear as abnormalities of the ducts. Ultrasound is the best imaging tool for a detailed evaluation of the ducts. Although definitions and terminology for ductal abnormalities may vary in the literature, there is a growing interest among Asian countries regarding ultrasound findings of ductal abnormalities. In this review, we present a method for detecting and evaluating ductal abnormalities based on a detailed comparison with pathological findings. To understand and organize the terminology found in various literature and guidelines, as well as the corresponding findings. To become familiar with normal anatomy and identify findings accurately. To compare expected findings in other modalities with pathological findings. To discuss evidence-based assessment and management plan for each finding.

## TABLE OF CONTENTS/OUTLINE

Normal anatomy  
Methods of detection  
Terminology  
Comparison with multimodality and correlation with pathological findings  
Assessment and management plan of each pathological finding  
Case studies  
The included cases are as follows: Ultrasound findings  
Ductal dilatation  
Duct dilatation with internal echoes  
Duct wall thickening  
Irregularity of the ductal caliber  
Pathological diagnoses  
Duct ectasia  
Fibrocystic change  
Intraductal papilloma (IDP)  
Atypical ductal hyperplasia  
Ductal carcinoma in situ (DCIS)  
Ductal carcinoma in situ with invasive component  
Invasive ductal carcinoma (IDC)

### **BREE-106 A Review of Contrast-Enhanced Mammography in the Evaluation of Suspicious Breast Micro-Calcifications and Our Experience**

Felix Maimir Quadrado, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

- To outline a potential indication of contrast-enhanced mammography (CEM).  
- To review the contribution to date of CEM in the evaluation of suspicious breast microcalcifications.  
- To share and discuss our initial experience using CEM in the evaluation of suspicious breast microcalcifications and their histopathologic results.  
The interpretation and description of breast microcalcifications have always posed a great challenge to breast radiologists. Due to the intrinsic relation of microcalcifications with different breast lesions, and in the case of suspicious ones with breast carcinomas, CEM has been proposed as a promising technique because of its capability to assess neoangiogenesis. We present an up-to-date revision of CEM in the evaluation of suspicious breast microcalcifications and our center's initial experience.

## TABLE OF CONTENTS/OUTLINE

- Introduction- False-positive cases- False-negative cases- What the recent literature tells us- Our experience

### **BREE-107 Diagnostic Approach and Assessment of Cystic Breast Lesion**

Hyo Soon Lim, MD, PhD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Cystic masses are common findings on mammography, ultrasonography, and MR imaging and a thorough understanding of their imaging findings and management is important. 2. It is important to obtain US images with meticulous technique for accurate classification and assessment of cystic breast lesions. 3. Complex cystic and solid masses may have one or all of the following characteristics: a thick wall ( $\geq 0.5$  mm), thick internal septations, an intracystic mass, and both solid and cystic components. 4. Complex cystic and solid masses are usually assessed as suspicious (BI-RADS category 4) and accompanied by a recommendation for biopsy.

## TABLE OF CONTENTS/OUTLINE

A. Definition of cystic breast lesions 1. Simple cyst 2. Complicated cyst 3. Clustered microcysts 4. Complex cystic and solid mass B. Meticulous technique in evaluating cystic breast lesions on US C. Multimodality imaging findings with important differential diagnosis 1. Simple or complicated cyst vs. Nearly anechoic solid mass on US 2. Inflamed or ruptured cyst vs. Rim enhancing mass on breast MRI D. Imaging-pathologic correlation of complex cystic and solid mass E. Diagnostic approach and BI-RADS assessment of cystic breast lesions F. Management of cystic breast lesions

### **BREE-108 Breast Malignancy: Beyond Breast Carcinoma**

Alex Gil Ordonez, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- To provide the basis for recognizing morphological and functional imaging findings of non-epithelial and metastatic lesions of the breast (B5d, NHSBSP).- To review the most common B5d lesions through a pictorial review of our cases.- To describe the clinical management of B5d lesions and the role of the radiologist in these cases.

## TABLE OF CONTENTS/OUTLINE

1. Introduction 1.1. NHSBSP classification. 2. B5d lesions through a pictorial review of our cases. 2.1. Metastatic disease. 2.2. Oncohematological disease. 2.3. Sarcomas 3. Imaging features 4. Management 5. Conclusions The vast majority of malignant breast neoplasms are breast carcinomas. Nevertheless, some malignant breast lesions present different histologies, which are commonly less suspicious than carcinomas on imaging techniques. Their recognition is essential to an early diagnosis and therapeutic approach.

### **BREE-109 Vague and Nebulous: Non-Mass Ultrasound Lesions**

Craig Wilsen, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

(1.) To review descriptors of ultrasound (US) non-mass lesions. (2.) To illustrate US non-mass lesions identified as correlates for breast MRI non-mass enhancement. (3.) To demonstrate methods for locating US non-mass lesions as correlates for breast MRI non-mass enhancement.

## TABLE OF CONTENTS/OUTLINE

Introduction: Ultrasound (US) correlates of MRI-detected non-mass enhancement (NME) may have no defined mass-like sonographic margin or shape, or may show subtle disruptions of the background tissue pattern. A new US lexicon term, non-mass lesion (NML), better describes these US findings. Cases: This educational exhibit will show 10 cases of US NML corresponding to MRI NME. We will highlight methods of predicting the US appearance and location of the NML on MRI-directed US by the use of breast architecture, surrounding cysts/masses, and use of the MRI appearance to predict the size and shape of the NML. Histopathologies include breast cancer, radial scar, sclerosing adenosis, fibrocystic change and fat necrosis. Conclusion: The exhibit illustrates subtle US NML correlates to MRI NME. Techniques for successful MRI-directed ultrasound detection of these findings are described. Once correlation is confirmed, US-guided biopsy, which is more expeditious than MRI-guided biopsy, can be performed.

### **BREE-11 Male Breast Lesions: To Infinity and Beyond**

Camila F. Guimaraes, PhD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Teaching Points: Male breast disease encompasses both benign and malignant conditions that are hormonally influenced. Gynecomastia and skin lesions are the most common conditions in symptomatic men, referred for a palpable mass, with imaging patterns that can correlate with different histopathological phases. Other benign tumors in male breasts include lipoma, pseudoangiomatous stromal hyperplasia, granular cell tumor, fibromatosis, myofibroblastoma, schwannoma, and hemangioma. The incidence of breast cancer in men is rare but has increased and accounts for 1% of all breast carcinomas, with invasive ductal carcinoma being the most common type in adult males. Other tumors that may occur include papillary carcinoma, invasive lobular carcinoma, adenoid cystic carcinoma, liposarcoma, dermatofibrosarcoma, pleomorphic hyalinizing angiectatic tumor, basal cell carcinoma of the nipple, hematopoietic malignancies, and secondary tumors. Understanding the clinical and imaging characteristics of these tumors is important for their accurate diagnosis and optimal treatment.

## TABLE OF CONTENTS/OUTLINE

Table of Contents/Outline: This article examines the clinical, radiological, and pathological characteristics of both benign and malignant tumors of the male breast. Cases of male breast disease were selected from the file of the Breast Radiology group of our hospital showing some of these pathologies: 1. Complicated Cyst; 2. Dermoid Cyst; 3. Myxoid Liposarcoma; 4. Hybernoma.

## BREE-110 From Words to Images: Applying the Contrast Enhanced Mammography BI-RADS® Lexicon

### Awards

#### Certificate of Merit

Mitva J. Patel, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

The American College of Radiology Breast Imaging Reporting and Data System (ACR BI-RADS®) lexicon is widely used in clinical practice and is a standardized nomenclature used for mammographic reporting. Recently, an extension of the lexicon was developed for the interpretation and reporting of contrast-enhanced mammography (CEM) findings. Adopting the American College of Radiology (ACR) Contrast Enhanced Mammography (CEM) Lexicon is important as standardization reduces inter-observer variability and improves the accuracy and reliability of diagnostic reporting, which ultimately leads to better patient outcomes. Education on this new topic is essential as adoption of the lexicon is critical to assist standardize reporting, improve patient care, and facilitate communication between radiologists and clinicians.

## TABLE OF CONTENTS/OUTLINE

I. CEM Lexicon classification for recombined images?A. Background parenchymal enhancement?1. Level?2. Symmetry?B. Lesion conspicuity?C. Masses?-Internal enhancement characteristics?D. Non-mass enhancement?-Distribution?E. Enhancing asymmetry?II. Interpretation?A. Findings on low energy images only?B. Areas of enhancement seen on recombined images only?C. Low energy images with associated enhancement on recombined images

## BREE-111 The Power of Contrast: Contrast Enhanced Mammography in the Diagnostic Clinic

Mitva J. Patel, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

We hope that by highlighting the practical uses of CEM and its potential to enhance breast cancer detection in the diagnostic clinic, more practices will embrace this powerful technology. Contrast enhanced mammography (CEM) is an imaging technique that combines standard mammography with iodinated contrast to improve breast cancer detection. By highlighting areas of increased vascularity associated with malignancy, CEM has been shown to improve the sensitivity of mammography, particularly in women with dense breast tissue. Despite these well-known benefits, the adoption of CEM in clinical practice has been slow, owing primarily to the difficulties establishing a CEM program and reimbursement. Despite these challenges, we believe the benefits it brings to the diagnostic clinic outweigh the additional effort. CEM may be used to: -resolve equivocal findings on mammography, and to increase confidence prior to stereotactic biopsy for vague areas of architectural distortion. -as a more efficient, accessible alternative to MRI in pre-operative extent of disease and workup of highly suspicious findings identified on screening mammography. We hope that by highlighting the practical uses of CEM and its potential to enhance breast cancer detection in the diagnostic clinic, more practices will embrace this powerful technology.

## TABLE OF CONTENTS/OUTLINE

Examples provided will demonstrate how CEM impacted these patients' management and supports the notion that CEM has a place in the diagnostic clinic as a cost-effective and time-efficient alternative to breast magnetic resonance imaging (MRI) for select patients.

## BREE-112 Common Enough to Care - Young Women with Breast Cancer: Multidisciplinary Approach and Special Considerations

Grace DeWitt, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Breast cancer in young women, widely accepted as women under 40 years of age, has a worse prognosis compared to older patients as young age is an independent predictor of adverse breast-cancer specific outcomes, including morbidity, local and systemic recurrence, and death. Historically, young women have been underrepresented in clinical trials and undergo more aggressive therapy solely based on their young age. As it is important to recognize how these women differ from older patients, the teaching points of this presentation are to: 1. Describe the epidemiology, clinical presentation, and tumor biology of young women with breast cancer. 2. Define imaging guidelines in high-risk populations and in young women after diagnosis of breast cancer. 3. Explain surgical management and surgical risk reducing strategies. 4. Highlight the special considerations unique to young women including the effects of oncology treatment on fertility and lactation and describe fertility preservation techniques.

## TABLE OF CONTENTS/OUTLINE

1. Appearance of breast cancer in young women: Epidemiology and clinical presentation, Tumor biology; 2. Imaging guidelines: Risk factors and assessment, Genetics based or calculated lifetime risk, Diagnosis and staging; 3. Surgical management: Breast conserving vs. mastectomy, Cosmetic options, Risk reducing strategies; 4. Effects of oncology treatment on fertility: Chemotherapy, Hormone therapy; 5. Fertility Preservation Techniques

### **BREE-113 Breast US: A Guide for Beginners**

Erica E. Francolin Federicci, PhD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Ultrasonographic characterization of mammographic abnormalities and palpable lesions is indicated in the evaluation and management of breast diseases. Although in the United States breast ultrasounds (US) are performed by sonographers, in many countries it is performed by physicians. Considering that breast screening US as an adjunct to mammography will be more widely practiced in the United States, the Breast Imaging-Reporting and Data System (BI-RADS®) provides training and performance guidance as set forth in ACRIN 6666. Because the effective use of the US lexicon relies on excellent sonographic technique and understanding of breast anatomy, the objective of this presentation is to didactically illustrate how the BI-RADS® recommendations should be followed, including the most common findings, pitfalls and how to avoid them.

## TABLE OF CONTENTS/OUTLINE

We used ultrasonographic images (in correlation to mammography and magnetic resonance imaging, when appropriate) from our institution's digital archive, in order to provide a case-based didactic review of the most common findings in breast ultrasounds, including a review of the adequate technical parameters, lexicon and reporting system and tips to avoid common pitfalls, based on the BI-RADS® recommendations.

### **BREE-114 Pseudo-progression During Immunotherapy: A New Challenge for Breast Radiologists**

#### **Awards**

#### **Cum Laude**

Aline D. Guimaraes, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Immunotherapy has emerged as a promising treatment strategy for advanced breast tumors. Immune checkpoint inhibitors (ICI) such as blockades that target programmed death-1 (PD-1), programmed death-ligand 1 (PD-L1) and cytotoxic T-lymphocyte associated antigen (CTLA-4), are one of the most powerful tools in the immunotherapy armamentarium and offer a beneficial immunotherapeutic regimen for patients with breast cancer. The pattern of treatment with immunotherapy is totally different from other therapeutic modalities, thus bringing major challenges to clinicians and radiologists who are not familiar with it. One of these challenges is pseudoprogression, that can be characterized as a transient increase of tumor burden followed by tumor regression. Although rare, it is fundamental for the radiologist to be aware of this condition and to carry out studies in the direction of finding diagnostic tools that are capable of more accurately identify this phenomenon contributing for better patient outcomes. In this didactic exhibit, we will discuss the basis of immunotherapy in breast cancer, demonstrate imaging findings of cases of breast cancer pseudoprogression and discuss the current tools available to identify the possibility of this condition such as biomarkers, imaging techniques and biopsy.

## TABLE OF CONTENTS/OUTLINE

1) Basis of immunotherapy 2) Definition of pseudoprogression 3) Tools used to identify pseudoprogression 3.1) Biomarkers 3.2) Medical imaging 3.3) Biopsy 4) Cases of breast cancer pseudoprogression

### **BREE-115 Contrast-enhanced Mammography in Breast Cancers for Women with Dense Breasts: Accuracy, Value, Controversies and Solutions**

Bingmei Zhang, MBBS, MMedSc (*Presenter*) Nothing to Disclose

## TEACHING POINTS

The purpose of this exhibit is: 1. To familiarize the reader to what CESM implies as an emerging modality and its implementation for breast imaging. 2. To demonstrate diagnostic accuracy and correlation in lesion size estimation of CEM against DCE-MRI in dense breast patients. 3. To illustrate value of CEM in evaluating BI-RADS 4 microcalcifications including morphology, distribution and neovascularity of microcalcifications. 4. To discuss whether CEM can be an effective imaging tool in pre-surgical planning for women with dense breast parenchyma. 5. To highlight the benefits and deficits of CEM in women with dense breast who are at an increased risk of developing breast cancer.

## TABLE OF CONTENTS/OUTLINE

1. Brief overview about the different approaches in CEM and their features in imaging interpretation (temporal subtraction and dual energy technique). 2. Cancer evaluation in the dense breast and review of cases, comparing CESM with MRI in the assessment of disease extent in breast carcinomas. 3. Practical application of CEM with illustrated clinical examples in evaluating BI-RADS 4 microcalcifications in dense breast. 4. Is CESM adequate and accurate in pre-surgical planning for women with dense breast. 5. Advantages vs. drawbacks of CEM and potential pitfalls elucidation for high risk screening for women in dense breast. 6. The future applications of CEM in breast evaluation.

## BREE-116 Preoperative Wire and Wireless Localizations Gone Wrong: How to Get Out of Trouble

Sheila S. Enamandram, MD, MBA (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Accurate, thoughtful planning of preoperative image-guided wire or wireless localizations is critical for breast conservation surgery, especially in complex imaging scenarios. Target lesion visualization and localization may require more than one imaging modality and/or a non-routine approach for difficult marker/target localizations. Understanding the differences in size, appearance, and deployment techniques of localization devices is important in accurate placement and retrieval. Targeted markers may be found in unexpected places when not seen in the initial specimen radiograph. Clear communication with surgical colleagues is paramount.

## TABLE OF CONTENTS/OUTLINE

This case-based exhibit will highlight anatomic, procedural, and technical troubleshooting steps in the following scenarios: Biopsy marker, wire, or wireless device migration; Biopsy marker non-visualization; Target not marked at time of initial biopsy; Target obscured or visible on only one imaging modality; Wireless radar reflector malfunction; Alternative imaging modalities needed for localization; Biopsy marker not seen in the specimen and ultimately found in unexpected places; Incomplete retrieval of distal hook wire in the specimen.

## BREE-12 Nipple Discharge: In the Era of Multimodality Imaging

Astrid Orfali Camez, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

TEACHING POINTS 1. To remind the different etiologies responsible for nipple discharge 2. To recognize the worrisome signs of a nipple discharge that must lead to further investigation 3. To discuss imaging modalities and management

## TABLE OF CONTENTS/OUTLINE

TABLE OF CONTENTS 1. Clinical history and physical examination 2. Etiologies responsible for nipple discharge a. Extra-mammary causes :- Hyperprolactinemia- Drugs- Others b. Breast lesions :- Benign lesions (infections, galactophoritis, papillomas)- Malignant lesions (intra-ductal, inflammatory) 3. Multimodality imaging approach a. Gold standard of initial evaluation of nipple discharge- Mammography + Ultrasound b. Second level of investigation :- The role of MRI and contrast-enhanced mammography 4. Diagnosis a. Cytology of the nipple discharge b. US guided micro biopsy c. MRI guided core biopsy d. Emerging role of contrast-enhanced guided core biopsy 5. Patient management flowchart a. Follow-up, what? When? b. US guided macro biopsy, when? c. Surgery

## BREE-13 Staying Vigilant: Imaging Surveillance and Risk Prediction After Breast Cancer

### Awards

### Certificate of Merit

Beatriu Reig, MD, MPH (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. Patients with a personal history of breast cancer have 5-20% recurrence rates and are at increased risk of second breast cancers. 2. Risk factors for recurrent or second breast cancer include dense breasts, young age at diagnosis of the first breast cancer, omission of radiation after breast conserving therapy, and hormone receptor negative first breast cancer. 3. Imaging

biomarkers such as background parenchymal enhancement are under investigation and may permit personalized risk prediction and guide surveillance recommendations in the future.

#### **TABLE OF CONTENTS/OUTLINE**

1) Introduction (definition, statistics, localized vs metastatic recurrence, early vs late recurrence) 2) Risk factors for recurrence a) Association of molecular subtypes with risk for recurrence b) Effect of neoadjuvant chemotherapy c) Modifiable risk factors (aromatase inhibitor or tamoxifen after ER+ cancer, alcohol consumption, weight) 3) Screening methods for recurrence a) Mammography b) Ultrasound i) Inclusion of the axilla c) MRI i) Abbreviated vs full-protocol d) Contrast-enhanced mammography 4) What should be the imaging interval? 5) Post-mastectomy imaging 6) Risk models for individualized screening a) Clinicopathologic factors b) Imaging biomarkers c) Radiomics and artificial intelligence models

#### **BREE-14 Breast Cancer or Not? An Interactive Case-Based Review of FDG-PET/CT Positive Findings in the Breast**

##### **Awards**

##### **Certificate of Merit**

Emily O. Yoon, MD (*Presenter*) Nothing to Disclose

##### **TEACHING POINTS**

Background Interpretation of lesions with increased FDG uptake in the breast can be challenging due to nonspecific uptake in various benign and malignant processes involving the breasts. Knowledge of this wide spectrum is essential for accurate analysis of FDG-PET/CT in conjunction with a patient's symptomology. The purpose of this educational exhibit is to illustrate the multi-modality imaging appearance of various benign and malignant processes that demonstrate hypermetabolic activity within the breast on FDG-PET/CT. Teaching Points Differentiate various benign and malignant processes that can result in hypermetabolic lesions in the breast Understand sensitivity and specificity of FDG-PET/CT for breast cancer and metastatic breast lymphadenopathy Conclusion There is a wide range of benign and malignant conditions presenting as hypermetabolic breast lesions on FDG-PET/CT. Knowledge of the various imaging features is important for accurate diagnosis and patient management.

#### **TABLE OF CONTENTS/OUTLINE**

This presentation will be case-based with review of clinical history and imaging findings (mammogram, US, MRI, PET/CT) of patients with FDG-PET positive findings in the breast. Several benign and malignant pathologies will be reviewed, as outlined below. Teaching points with recent literature review will provide guidance when non-breast cancer pathology should be suspected in cases, while also highlighted when additional dedicated breast imaging is indicated. Breast implant capsule-associated squamous cell carcinoma Reactive lymphadenopathy Metastatic disease Granulomatous mastitis Fat necrosis Inflammatory breast cancer Gynecomastia Infectious/Inflammatory changes

#### **BREE-15 The Role of DBT-Guided Biopsy for MRI/CEM Detected Lesions**

Cesar Urtasun Iriarte I, MD (*Presenter*) Nothing to Disclose

##### **TEACHING POINTS**

To emphasize the need to correlate MRI/Contrast Enhanced Mammography (CEM) findings with DBT (Digital breast tomosynthesis). To show the advantages of DBT-guided biopsy compared to MRI-guided biopsy. To consider DBT-guided biopsy as an alternative for CEM-detected lesions.

#### **TABLE OF CONTENTS/OUTLINE**

INTRODUCTION: Both MRI and CEM are morphofunctional imaging techniques based on neoangiogenesis. These techniques are more sensitive than pure morphological techniques, such as DM or DBT. ASSESSMENT OF MASS ENHANCEMENTS: Second look US is of choice to evaluate these lesions. ASSESSMENT OF NON-MASS ENHANCEMENTS: These lesions are challenging. Although US plays an important role, in many cases it is inconclusive. DBT correlation is very important, specifically using the craneocaudal (CC) view. This view is easy to compare anatomical structures with both MRI (axial) and CEM. DBT GUIDED BIOPSY: This technique offers several advantages over MRI or CEM guided biopsies: Less time consuming, widely spread technique. Not all the vendors have dedicated units to perform CEM guided biopsies. Once the lesion is located with DBT, the performance of the biopsy is easy. Usually 10G vacuum assisted biopsy devices are used. CONCLUSION: DBT guided biopsy can offer a good alternative for MRI/CEM detected lesions, specially for non-mass enhancements.

#### **BREE-16 Male Breast: Common and Rare Conditions**

Carla Sitges, MD (*Presenter*) Nothing to Disclose

##### **TEACHING POINTS**

Teaching Points: To describe the spectrum of imaging features of benign and malignant lesions of the male breast from a review of pathologically-proved cases. To correlate imaging and pathological findings. To discuss the appropriate imaging workup of male breast cancer.

## TABLE OF CONTENTS/OUTLINE

Introduction  
Gynecomastia  
Benign lesions  
Imaging features on mammography, ultrasound and MRI. Radiologic-pathologic correlation.  
Malignant lesions  
Imaging features on mammography, ultrasound and MRI. Radiologic-pathologic correlation.  
Conclusions

### **BREE-17 Breast Ductal Disease: Multimodality Imaging Detection and Assessment**

Meng Hao, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Review normal ductal anatomy and its imaging features. Review the broad differential of benign and malignant ductal diseases, particularly in the setting of a single dilated duct. Recognize imaging abnormalities of ductal diseases and features associated with malignancy on DBT, US, and MRI. Describe appropriate diagnostic workups and management of ductal diseases.

## TABLE OF CONTENTS/OUTLINE

Breast ductal disease is an important aspect of breast imaging and often poses challenges in diagnosis and management, particularly in the setting of a single dilated duct. Thus, radiologists should be familiar with clinical presentations, diagnostic workup, imaging features, and differentials for ductal abnormalities. Patients may present with nipple discharge, palpable abnormalities, infectious symptoms, lactational issues, or be asymptomatic. Ductal pathologies range from ductal ectasia, periductal mastitis, intraductal papillomas, to ductal carcinoma in situ, invasive ductal carcinoma, and Paget's disease. Radiologists should recognize both normal and abnormal ductal imaging features on DBT (dilated ducts, masses, and/or calcifications), on US (cystic ductal dilation, ductal wall irregularities or arborization, intraductal masses or debris), and on MRI (clustered ring non-mass enhancement, abnormal linear or segmental NME). This educational exhibit will provide a comprehensive case-based review of benign and malignant ductal diseases, their multimodality imaging features, and associated management recommendations.

### **BREE-18 Breast Surgery: Changes and Findings Multimodal Diagnosis**

Maria Jose Chico (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Identify the different post-surgical changes of breast surgery.  
2. Learn to identify which findings are suspicious and which are not.  
3. Understand and integrate the findings in the different imaging modalities.  
4. Understand the differential diagnoses

## TABLE OF CONTENTS/OUTLINE

The accurate interpretation of images of the postsurgical breast depends on the availability of high-quality imaging. These changes should be interpreted in conjunction with the clinical and surgical history. They may correspond to benign or suspected changes. It is useful to analyze them in the different imaging modalities to support or rule out a suspected diagnosis. They can appear in the post-surgical period due to both malignant and benign conditions

### **BREE-19 Beyond the Lump: Navigating the Challenges of Cystic Breast Lesions**

Maria Vitoria D. Ludwig, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Our educational exhibit is directed to review the assessment and management of cystic breast lesions through the following points: review the pathologies presented as cystic breast lesions; understand how to identify and categorize breast cysts at ultrasonography; comprehend the appropriate management according to the imaging finding, correlating with clinical history and other imaging modalities if available; enlighten biopsy modalities, indication and technique; recognize the importance of subsequent histological analysis.

## TABLE OF CONTENTS/OUTLINE

The subject will be approached in the following sequence: pathologies presented as cystic breast lesions and their malignancy risk; diagnosis, initial evaluation and ultrasound classification of breast cysts, linked with drawing representations of each type of cyst; appropriate risk assessment and management according to the imaging finding considering correlation with clinical history and other imaging modalities, namely mammography and magnetic resonance imaging; how to choose the most suitable biopsy modality and possible pitfalls; correlation of radiological findings with histopathologic analysis, followed by revision of management if required; illustrative cases in the different imaging methods.

### **BREE-2 Lipofilling: What Does Breast Radiology Need to Know?**

Karen L. Caro, PhD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1.- Describe the imaging characteristics of the lesions in lipofilling2.- When should we consider that a lesion after a lipofilling procedure would need histological certification, in relation to the imaging findings?

## TABLE OF CONTENTS/OUTLINE

Currently fat transfer (lipofilling) is used in breast reconstruction. In this paper we will describe its advantages and how it is seen in the different imaging studies (ultrasound, mammography and MRI).It is important to identify which are the usual benign findings in the different methods and what Bi-Rads to assign, in this way we can define those cases in which their histological evaluation should be considered.Describe the advantages and disadvantages of this method in breast remodeling.The importance of recognizing radiological manifestations and the difficulties involved in detecting suspicious lesions.Knowing how to recognize that fat necrosis is a frequent lesion after lipofilling, which should be suspected in order to avoid other more complex studies such as MRI and even biopsies

## BREE-20 Not Every Ductal Ectasia Is Evil: Spectrum of Ductal Lesions

Raissa Soares, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

To review the imaging appearance of normal ductal anatomy; Illustrate imaging findings of ductal ectasias using different techniques, including mammography, ultrasound and magnetic resonance imaging, providing clinical images and histopathology correlation;To discuss the appropriate management of these lesions; Review a case series of benign ductal breast diagnoses from our institute, without associated malignancy;

## TABLE OF CONTENTS/OUTLINE

Identify imaging criteria that may help in the diagnosis of ductal ectasia and, eventually, in its management;Typical multimodality imaging findings (magnetic resonance imaging, ultrasound and mammography) from cases of our radiology department;Diagnostic challenges, main differentials, and key points suspicion of this pathology;Discuss the role of percutaneous biopsy (ultrasound-guided core biopsy and vacuum - assisted biopsy) in the diagnosis of ductal ectasias;Conclusion.

## BREE-21 Understanding the BI-RADS 3 Category

Summer Joyce Batasin (*Presenter*) Nothing to Disclose

## TEACHING POINTS

By the end of this educational exhibit, learners will:1. Accurately define BI-RADS 3 and appropriate use cases.2. Explain BI-RADS 3 radiographic features and diagnostic considerations for mammography, ultrasound, and MRI.3. Demonstrate proficiency in the assessment process of a BI-RADS 3 lesions, through a case-based review.

## TABLE OF CONTENTS/OUTLINE

1. What is BI-RADS 3?a. Definitionb. Appropriate use cases2. BI-RADS 3: Mammographya. Imaging featuresb. Diagnostic considerations3. BI-RADS 3: Ultrasounda. Imaging featuresb. Diagnostic considerations4. BI-RADS 3: MRIa. Imaging featuresb. Diagnostic considerations5. Identifying BI-RADS 3 Lesions: Case-Based Walkthrougha. Classic BI-RADS 3 casesb. Special cases

## BREE-22 Back to the Tumor: Navigating Breast Cancer Recurrence Like a Pro

### Awards

### Cum Laude

Vitor C. Zanetta, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Review the risk and pattern of tumor recurrence according to molecular subtypeProvide visual and data-driven insights into expected imaging changes following treatment.Highlight the role that multimodality plays in differentiating expected imaging findings from treatment and imaging findings indicative of recurrence or new breast cancer.Review current follow-up protocols after breast cancer and screening for intermediate risk patients.

## TABLE OF CONTENTS/OUTLINE

Review the influence of breast cancer subtype on the rate, timing and location of tumor recurrence.Expected imaging changes following treatment with visual and data-driven insights:Expected timeline of post-surgical changes.Details in the assessment of local recurrence in breast-conserving surgery and mastectomy.Possible changes in axillary and internal mammary lymph nodes.The role that multimodality imaging (mammogram, ultrasound, MRI and PET-CT) plays in differentiating recurrence or new breast cancer from post-treatment changes, including:Frequent dilemmas in clinical practice: evaluation of calcifications,

distortions, fat necrosis and enhancements in the surgical bed. How to deal with conflicting findings between different imaging methods to avoid unnecessary biopsies without losing sensitivity for early recognition of recurrence. Subtle recurrence and the importance of serial follow-up imaging. Examine the follow-up protocols after breast cancer and screening for intermediate-risk patients from the perspective of personalized medicine.

## **BREE-23 From Flat to Fabulous - A Radiological Guide to Breast Aesthetic Fillers and Biostimulators**

### **Awards**

#### **Certificate of Merit**

Heni D. Skaf, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

To expose, through cases from our institution, manifestations of different breast filling and biostimulator materials in the most diverse imaging methods, such as: free silicone, acrylates (PMMA, PAAG), hyaluronic acid, vitamin D, calcium hydroxyapatite and fat grafting. To familiarize the breast radiologist with the radiological presentation of these materials, avoiding false positives and unnecessary investigations. To discuss the usual topography in which they are injected, as well as possible local and systemic complications of using such materials.

#### **TABLE OF CONTENTS/OUTLINE**

Introduction: The demand for percutaneous aesthetic procedures is rising in medicine, especially in the context of facial harmonization. This also applies to the breast, both for use in cancer patients, with the increase in the incidence and in diagnosis of breast cancer, as well as for purely aesthetic purposes in the breast itself or even due to migration from other injection sites. Imaging findings: on mammography, ultrasonography and magnetic resonance as well as possible complications and usual injection sites of free silicone, acrylates (PMMA, PAAG), hyaluronic acid, vitamin D, calcium hydroxyapatite and fat grafting. For the most part, non-resorbable synthetic biomaterials, fat grafting, as well as resorbable materials used recently, have radiologic representation. Conclusion: The use of aesthetic breast fillers, whether in the oncological context or not, is on the rise. Often, the patient does not have knowledge of what was used, which can limit the clinical decision of the physician. Additionally, recognition of the radiological appearance of different fillers can avoid false positives and unnecessary biopsies.

## **BREE-24 Far Beyond The Axilla, What Else do We Need to See? Tips and Pitfalls of Lymph Nodes**

Raissa Soares, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Aspects of normal images of axillary and supraclavicular lymph nodes and internal mammary in different methods and mainly in ultrasound; To present imaging cases of normal lymph nodes, as well as differential diagnoses of axillary, supraclavicular and internal mammary lymph node enlargement, from our database; Image-guided procedures; Show the importance of the radiological-pathological correlation.

#### **TABLE OF CONTENTS/OUTLINE**

Review the main spots of mammary drainage; To show imaging cases of normal findings and our histological correlation; To present some differential cases of lymph node pathologies; Discuss the types of lesions and which ones require biopsy; Conclusion.

## **BREE-25 Axillary Lymphadenopathy Induced by COVID-19 Vaccination: What Have We Learned?**

Miguel Barrio Piqueras I, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- US features of reactive lymph nodes after COVID-19 vaccination in patients with and without previous COVID-19 infection- Nodal reactivity in young and middle-age patients vaccinated with different COVID-19 vaccine protocols- Association between the cortical thickness measurement of reactive post-vaccine lymphadenopathy and an effective humoral response in COVID-19-naïve patients

#### **TABLE OF CONTENTS/OUTLINE**

The COVID-19 pandemic led to the approval of an emerging vaccination program to contain coronavirus dissemination. One of the most commonly reported local side effects of COVID-19 vaccination has been the development of axillary lymphadenopathy. In this poster, we will discuss about this phenomenon: 1. Which ultrasound features should be evaluated? 2. Does nodal response differ if there exists a prior history of COVID-19 infection? 3. Do the ultrasound characteristics of reactive axillary nodes change depending on the administered COVID-19 vaccination? 4. What is the nodal reactivity to the COVID vaccination according to age? 5. How long does reactive lymphadenopathy last? 6. Does cortical thickness of reactive post-vaccine lymph nodes reflect a humoral response? Conclusions- Reactive lymphadenopathy is a common side effect of COVID-

19 vaccination- It is generally a harmless and temporary condition- Healthcare providers should be aware of this potential phenomenon to provide an appropriate guidance to patients

## **BREE-26 Cystic Carcinomas: Preventing Misdiagnosis and Lessons Learned**

Hemal Grover, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Simple cysts: well circumscribed isodense masses on mammogram; well circumscribed anechoic masses on ultrasound with a thin, smooth, imperceptible wall and posterior acoustic enhancement. Complicated cysts meet all criteria for simple cysts except they contain debris/echogenic intracystic contents. Necrotic tumors (rapidly growing) can present as cystic masses. They can be anechoic, demonstrate posterior acoustic enhancement and therefore often misdiagnosed as simple or complicated cysts. However, careful evaluation of the margins is imperative as it can reveal subtle irregularity and raise suspicion for malignancy. Correlation with mammogram (particularly spot compression views) can be helpful to reveal obscured or irregular margins. Cystic carcinomas often present as palpable masses. These cases should be viewed with a higher index of suspicion before being labeled as BIRADS 2. Real time physician directed ultrasound is recommended along with a bilateral mammogram with spot compression views (including in women 30-35 years old). Family history, genetic mutations and ancestry (eg Ashkenazi Jewish descent) should be considered while evaluating these patients.

### **TABLE OF CONTENTS/OUTLINE**

Imaging features of simple, complicated and complex cysts. Classification of complex cysts. Clinical history, diagnostic mammogram, ultrasound and MRI findings of authors' cases of cystic carcinomas. Errors of interpretation/misdiagnosis and lessons learnt. Differential Diagnoses.

## **BREE-27 Granulomatous Mastitis: Imaging Insights into a Benign Mimicker of Breast Infection and Malignancy**

Sravani Gampala, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. Understand the etiology and clinical presentation of granulomatous mastitis. 2. Recognize the imaging findings of granulomatous mastitis across mammography, ultrasound, and MRI. 3. Appreciate the importance of correlating imaging findings with the clinical picture. 4. Acknowledge the consequences of misdiagnosing granulomatous mastitis. 5. Emphasize the role of radiologists in considering granulomatous mastitis as a differential diagnosis. 6. Discuss the importance of a multidisciplinary approach in the accurate diagnosis of granulomatous mastitis.

### **TABLE OF CONTENTS/OUTLINE**

I. Introduction to Granulomatous Mastitis A. Etiology B. Clinical presentation II. Imaging Modalities A. Mammography 1. Findings 2. Differential diagnosis B. Ultrasound 1. Findings 2. Differential diagnosis C. MRI 1. Findings 2. Differential diagnosis III. Consequences of Misdiagnosis A. Unnecessary studies B. Patient anxiety C. Invasive procedures IV. Radiologist's Role in Diagnosis A. Considering granulomatous mastitis B. Biopsy and pathological challenges V. Multidisciplinary Approach A. Collaboration in diagnosis B. Improved diagnostic accuracy.

## **BREE-28 More Than Just a Pretty Cyst - Assessment and Management of Cystic Breast Lesions**

Vivian S. Ogata, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

- To discuss the ultrasound imaging parameters, from B-mode adjustments, Doppler imaging, to post-processing techniques, to properly evaluate cystic breast lesions.- To present the imaging findings of the listed cystic lesions according to the BI-RADS® lexicon such as: simple cyst, complicated cyst, clustered microcysts and complex solid and cystic masses, illustrating with multimodality imaging.- To discuss each subcategory of cystic lesions, its management and follow-up, illustrating with some challenging radiologic cases.- To habituate general radiologists with these findings in order to improve the diagnostic rate of such mammary lesions, reducing unnecessary biopsies.

### **TABLE OF CONTENTS/OUTLINE**

- Introduction and epidemiology: breast cystic lesions are a common diagnosis in women and include a wide spectrum of diseases, from a simple apocrine cyst to complex solid cystic carcinomas.- Scanning techniques, ultrasound adjustment, artifacts and post-processing imaging: adjustment of ultrasonographic basic parameters and adequate scanning techniques are essential for an accurate diagnosis. We can also employ Doppler, elastography, as well as use imaging artifacts to our advantage, patient's position changes more recent post-processing techniques (harmonic and spatial compounding imaging) to better characterize cystic lesions.- Cystic lesions subcategories, classification, histological representation and multimodality imaging depiction.- Management and follow-up: adequate ACR BI-RADS® categorization of each subtype of cystic lesion, illustrating with some challenging cases, exploring some related pitfalls and discussing benign and malignant differential diagnosis.

### **BREE-29 Can Aesthetic Procedures Interfere With Breast Cancer Screening?**

Leticia T. Oliveira, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

The incidence of dermatological procedures to modify aesthetics in body contouring, including post-surgical reconstructions, has been increasing every year, especially minimally invasive ones with injectables. Recognizing the imaging findings provoked by these procedures will avoid possible diagnostic pitfalls and allow the radiologist to alert the dermatologist about the possible loss of breast cancer screening caused by some of these previously unregistered procedures. Further, patients should be educated about the hazards associated with improper use of injectables from non-licensed individuals. Patients must be encouraged to seek out licensed physicians who use FDA-approved products for any medical and cosmetic care.

#### **TABLE OF CONTENTS/OUTLINE**

To review literature data on aesthetic dermatological procedures in the breast and axillary region, with cases from our institution, and illustrate with imaging findings found, based on different imaging methods

### **BREE-3 It's Not the Same As It Was: Multimodal Review of Breast Cancer Recurrence and What the Radiologist Needs to Know**

Leticia T. Oliveira, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- Breast cancer is the most common cancer in the female population worldwide and the number of patients underwent conservative surgery is growing; - The annual risk of recurrence disease varies between 2 to 5% in 5-20 years after diagnosis; - Locoregional recurrence is defined as the detection of lesions in the ipsilateral breast, chest wall or regional lymph node. If the other parts of the body are affected, it becomes a systemic recurrence; - Some factors related to breast cancer recurrence include failure in the first treatment and non-adherence to adjuvant therapy and surgical margins, but could be related to tumor size, aggressive biology of the primary tumor, young patient age at diagnosis and presence of familial or genetic risk factors; - Tumor recurrence may or may not be similar to the primary malignancy and can simulate benign conditions; - Imaging recurrence are variable and this knowledge becomes essential in radiological practice in order to improve the diagnosis and management of the patient.

#### **TABLE OF CONTENTS/OUTLINE**

- To review the factors associated to breast cancer recurrence and the epidemiology of these cases; - To show the most common findings in breast cancer recurrence using cases of our institution; - To teach how to evaluate the different methods of imaging (mammogram, ultrasound and MRI) in these cases and give tips that may help to differentiate sequelae of treatment from suspect lesion; - Easy-to-use take home messages to facilitate the handling of challenging cases.

### **BREE-30 Demystifying Gynecomastia: A Pictorial Review**

Rocio D. Cortes Quezada, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

\*Most male breast masses are benign and the most common reason is gynecomastia. \*Forms of breast imaging in male patients are used for diagnostic purposes. \*Pseudogynecomastia and cancer are the most common differential diagnoses. \*Mammography can show increased glandular tissue and ductal dilatation in cases of gynecomastia. Masses, calcifications or signs suggestive of malignancy can also be visualized. \*Ultrasound can help distinguish true gynecomastia from pseudogynecomastia (accumulation of fatty tissue in the breast region). \* Biopsy is the only method to determine if a breast mass in a man is benign or malignant. • \*Biopsy can be guided by ultrasound or mammography

#### **TABLE OF CONTENTS/OUTLINE**

1. Introduction 2. Definition 3. Epidemiology 4. Clinical presentation 5. Etiology 6. Anatomy and embryology of the male breast 7. Types of gynecomastia 8. Imaging tests of the male breast 9. Imaging findings (mammography, ultrasound) 10. Differential diagnoses 11. Cases: a. Pseudogynecomastia. b. Lipoma. c. Epidermal inclusion cyst of the breast. d. Duct ectasia. e. Fat necrosis f. Invasive ductal carcinoma 12. Conclusions

## **BREE-31 Breast Cancer Surveillance in Patients with Prior History of Breast Cancer: Updates and Controversies**

### **Awards**

#### **Certificate of Merit**

Sona A. Chikarmane, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Patients with a prior history of breast cancer (PHBC) are at increased risk of recurrent or second breast cancers. PHBC are also living longer due to improved screening and advances in treatment. Developing optimal screening regimens are critical in detecting breast cancers in these high-risk patients. Expected post-treatment changes include architectural distortion, edema, and skin thickening, which stabilize around two years post-treatment. Multimodality breast imaging surveillance is available, with screening mammography (full field digital mammography or digital breast tomosynthesis), whole breast ultrasound, contrast-enhanced mammography, and breast MRI. The purpose of this educational exhibit will be to review breast cancer surveillance in PHBC, highlighting updates and controversies in screening guidelines.

#### **TABLE OF CONTENTS/OUTLINE**

1. Review literature on risk of recurrent/second breast cancers in PHBC 2. Discuss optimal mammography screening regimens, including screening vs diagnostic mammography, cadence of screening, and batch vs immediate interpretation. 3. Review the current societal screening guidelines, including mammography and breast MRI. 4. Show multi-modality image-rich cases of recurrent breast cancer versus expected post-treatment changes. 5. Highlight controversies in breast cancer screening guidelines, including age when to stop screening, imaging the reconstructed breast, and compliance with screening.

## **BREE-32 Tales from the Breast: When Breast Problems Have Surprising Origins**

Natalia T. Lima (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Diseases that affect the breast, but do not originate from it, may include systemic, autoimmune, infectious or even tumoral conditions from other sites. They can cause inflammation in the breast tissue and manifest with pain, skin thickening, ulcerations and masses. It is essential to know each one of them to help the clinical practice of differentiating breast carcinoma from these pathologies.

#### **TABLE OF CONTENTS/OUTLINE**

Illustrated didactic cases from our Breast Radiology group showing some diseases and their presentation forms that can simulate breast carcinoma. They were classified into subgroups such as: 1. Related to the vasculonervous system (MAV and neurofibromatosis), 2. Systemic disorders (cutaneous lymphoma and congestive heart failure), 3. Metastasis to the breast (melanoma and adrenal cortical carcinoma), 4. Soft Tissue tumors (granular cell tumor and synovial sarcoma), 5. Infectious (tuberculosis and dermatobiosis).

## **BREE-33 Spectrum of Papillary Lesions of the Breast: Multimodality Imaging and Radiologic-Pathologic Correlation**

Janice Thai, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Papillary lesions represent a heterogeneous group of entity with histologic continuum from benign, atypical to invasive and non-invasive malignant lesions. 2. To review the multimodality imaging spectrum of papillary lesions. 3. To review the unique histopathologic patterns of lesions with papillary and micropapillary features. 4. To review the clinical management algorithm for different papillary lesions diagnosed on core needle biopsy.

#### **TABLE OF CONTENTS/OUTLINE**

- Multimodality imaging review of common and uncommon imaging features of papillary lesions.
- Review of classification system according to WHO 5th Edition Breast Tumors (2019)
- Review of histopathology of papillary lesions.
- Review of current evidence-based management algorithm for benign, atypical and malignant papillary lesions.

## **BREE-34 A Guide to Cystic Breast Lesions**

Christina Le, DO (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Breast imaging is often complex and can appear difficult to understand. It is rarely explored in depth throughout medical school training and can be rather limited throughout residency, especially for those pursuing other specialties for fellowship. The purpose of this exhibit is to provide a demystified review of cystic breast lesions. This is meant to supplement a resident's knowledge of breast pathology and present the information in a concise yet comprehensive manner. Throughout the presentation, the pathophysiology and patient presentation of each entity will be discussed. This will be followed by the often variable imaging findings that can be encountered on ultrasound, mammography, and MRI. Annotated pictorial examples are provided to facilitate visualization of the specific lesion characteristics. To conclude, the exhibit will discuss treatment options and the appropriate BIRADS criteria to help standardize the severity of these lesions.

## TABLE OF CONTENTS/OUTLINE

1. Overview/educational objectives 2. BIRADS categories 3. Simple Cyst 4. Galactocele 5. Fat necrosis/oil cyst 6. Hematoma 7. Abscess 8. Intracystic papilloma 9. Necrotic neoplasm 10. Conclusion 11. References

## BREE-35 Cryoablation Therapy for Breast Cancer: Procedural Technique and Imaging Review

Janice Thai, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. To review the procedural techniques for performing breast cancer cryoablation. 2. To review multimodality post procedural imaging features of cryoablation to identify normal and abnormal findings.

## TABLE OF CONTENTS/OUTLINE

- Review of proper patient selection in a multidisciplinary approach.
- Review of equipment, device and procedural technique.
- Review of post procedural imaging, including normal and abnormal findings on mammography, ultrasound, and MRI.
- Review of follow-up imaging protocol and strategies for detection of tumor recurrence.

## BREE-36 Exploding Jelly of the Breast: The Mucocele-Like Lesion (MLL)

Juan C. Vargas, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

<Mucocele-Like Lesions are considered risk injuries (B3a).Mucin in the stroma calcifies over time, showing up as such on mammography.By mammography the type of calcifications is variable.By ultrasound it appears as microcysts, complex cysts or irregular nodules.The treatment depends on the diagnostic biopsy method.>

## TABLE OF CONTENTS/OUTLINE

<Mucocele-Like Lesions were first described by Rosen in 1986 as a benign lesion "cysts containing mucin, lined by squamous or cuboid epithelium with or without extravasated mucin", currently considered a risk lesion.It is due to mucinous ducts that obstruct their contents, causing rupture with extravasation of the contents into the surrounding stroma, wich over time can form calcifications, wich are observed by mammography; less commonly, it present as a mass. By ultrasound they are observed as a cyst with thick, mucin-like content or microcystic conglomerates. The more complex the cystic lesion, the more likely it is to be associated with Ductal Carcinoma In Situ (DCIS).With core needle biopsy, the percentage of diagnostic underestimation is less than 4% if they are lesions without atypia, but amounts to approximately 20% if they are lesions with atypia, so removal by vacuum-assisted biopsy or surgery is preferred.>

## BREE-37 Rare Tumors of the Breast

Neftali A. Granados Flores, PhD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Rare tumors of the breast: Metaplastic carcinoma of the breast and Primary signet ring cell carcinoma of the breast.Epidemiology, image presentation of cases, clinical characteristics, imaging findings

## TABLE OF CONTENTS/OUTLINE

Metaplastic breast carcinoma is a rare type of neoplasm that resembles a high-grade histological carcinoma, presents a high incidence of recurrences, poor prognosis, difficulties at the time of diagnosis, the establishment of therapeutic guidelines, and controversy regarding its nomenclature. The bibliography is very limited and the published descriptive studies have a low number of cases, making it difficult to obtain definitive and extrapolated conclusions, especially when making therapeutic decisions.Primary signet ring cell carcinoma of the breast is a rare tumor of controversial histogenesis, aggressive behavior and unusual metastatic pattern to the gastrointestinal tract and serous surfaces, posing differential diagnosis problems with metastasis of signet ring cell carcinoma of the breast. other origins, preferably gastrointestinal.

## BREE-38 AI Advancements in Breast Imaging: Transforming Radiology for Improved Patient Care

Mancino, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

To explore the basic concepts of deep learning and machine learning in breast imaging. To examine AI-based tools and their applications in detection, diagnosis, and treatment planning for breast cancer. To assess AI performance compared to human experts. To discuss ethical considerations. To investigate AI future trends and developments for breast imaging.

### TABLE OF CONTENTS/OUTLINE

Introduction: presenting the fundamental principles of deep learning and machine learning in the context of breast imaging. 1. Workload to explore how AI algorithms can positively influence radiologists' workload, also triaging negative mammograms and potentially replacing second readers. 2. AI accuracy to discuss how AI-based solutions contribute to improve diagnostic accuracy in mammography and enable a more precise lesion classification. 3. Cancer-Prediction evaluating the ability of AI algorithms to identify cancer-predictive features in mammograms. 4. AI role in ultrasound and MRI to examine the development and performance of AI-based solutions for detecting and classifying breast lesions in ultrasound and MRI. 5. Ethical considerations Addressing the ethical concerns surrounding AI implementation, including data privacy, algorithm fairness, and potential biases in the development process. 6. Future trends to address the future trends of AI, contemplating the potential integration of AI with other imaging modalities, exploring the role of radiogenomics in breast imaging, and anticipating novel AI advancements.

### BREE-39 **Multimodal Imaging of Breast Tissue Expanders, Including Associated Complications and MRI Contraindications**

Almir Bitencourt, MD, PhD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

? To show the types of breast tissue expanders and MRI contraindications. ? To perform a multimodal review of the imaging aspects of breast tissue expanders. ? To illustrate complications associated to breast tissue expanders.

### TABLE OF CONTENTS/OUTLINE

Breast tissue expanders are temporary devices commonly used in two-stage breast reconstruction surgery. Tissue expanders are gradually filled with saline to stretch the skin and chest tissues to make room for breast reconstruction with a permanent implant. There are different types of breast tissue expanders depending on the number of lumens (one or two), filling (saline and/or silicone) and injection dome (remote or internal). Some types have metallic components that are not suitable for MRI imaging due to the potential for image distortion or dislocation. It is important to recognize the imaging features of breast tissue expanders, to avoid misdiagnosis, since tissue expanders with small filling may mimic implant rupture on imaging. Complications associated with breast tissue expanders are rare and include infection, hematoma, rupture, and displacement.

### BREE-4 **Code of Con-DUCT: An Algorithmic Approach to Multimodality Assessment and Management of Dilated Mammary Ducts**

Rajshree Singh, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

- The ACR BI-RADS® 5th Edition indicates that a SDD has a > 2% likelihood of malignancy, and therefore warrants a suspicious (BI-RADS 4A) assessment. Otherwise, there are few recommendations for evaluation and management of dilated ducts found at breast imaging.
- Further evaluation with MRI and/or tissue sampling may be warranted if ductal dilation (DD) is new or increasing, symptomatic, or associated with worrisome mammographic or ultrasound (US) features.
- We propose an algorithm-based approach to assessing dilated ducts, specifying worrisome features on mammogram and targeted US to guide further workup.
- This approach may potentially reduce radiologists' uncertainty, unnecessary biopsies, missed cancers, and healthcare expenditures.

### TABLE OF CONTENTS/OUTLINE

1. Ductal anatomy 2. Definition of DD 3. Etiologies of DD 4. DD requiring further evaluation: a. New or interval change b. Patient symptoms and/or clinical findings c. Suspicious mammographic findings 5. Worrisome US findings 6. Proposed algorithm for assessment and management 7. Identification of key findings that help guide diagnostic decisions. 8. Case-based application and examples 9. Role of ductography, US with elastography, and MR

### BREE-40 **Breast Imaging Disparities in the U.S**

Dami Olufosoye, BS, MPH (*Presenter*) Nothing to Disclose

### TEACHING POINTS

This educational exhibit is a call to action for radiologists to identify racial disparities in their own practice. We will review recent studies identifying disparities individuals of color face in breast imaging and discuss successful interventions. 1. Breast

cancer is the second leading cause of cancer deaths in women in the US but the leading cause in black women. 2. Black women have less access to screening mammography 3. Black and Hispanic women have lower rates of receiving adequate breast cancer treatment and post-treatment surveillance 4. Black women have increased rates of breast cancer recurrence 5. Imaging disparities based on race and other factors can be identified by radiologists and mitigated with outreach programs

#### **TABLE OF CONTENTS/OUTLINE**

1 US Epidemiologic breast cancer data 2 Racial disparities in breast cancer screening • Decreased access to mammography centers, advanced imaging equipment, specialized physicians, genetic testing • Additional limitations: § Patient distrust § Provider-patient relationship 3 Racial disparities in diagnostic work-up • Increased time to diagnostic work-up and to biopsy • Later stage at diagnosis 4 Racial disparities after breast cancer diagnosis • Lower rates of receiving adequate breast cancer care and post-treatment surveillance • Lower rates of 5-year breast cancer survival • Higher rates of cancer recurrence 5 How radiologists can help • Identification and mitigation of imaging disparities is part of our professional responsibility to our patients • Examples of successful initiatives

#### **BREE-41 Breast Cysts: A Pictorial Exhibit of Benign and Malignant Twists**

Flavia M. Starling, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Cystic breast lesions are the most common masses found in the female breast of any age group, mainly between 30 and 50 years of age. They are derived from the terminal lobular duct unit as a result of fibrocystic change and may contain isolated liquid or even associated solid component, thus comprising a wide spectrum of variable disease entities, including benign and malignant pathologies. Simple and complicated cysts are usually benign; but on the other hand, complex cystic masses containing mixed cystic and solid components are indeterminate. Therefore, knowing that cysts are common lesions and that up to approximately 31% of complex breast cysts are associated with malignancy, the radiologist must be familiar with the main pathologies and imaging characteristics that includes this category of lesions.

#### **TABLE OF CONTENTS/OUTLINE**

- Didactically review the main cystic lesions of the breast and their characteristics through different imaging methods and case-based revision obtained from the digital archive of our institution.
- Take home message
- References

#### **BREE-42 Molecular Classification of Breast Cancer: Guide for the Radiologist**

Sandra Lara (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Breast cancer is a disease that, despite having a histopathological classification, also includes molecular and genetic subtypes, being able to carry out a molecular classification that guides the clinical behavior, prognosis and different radiological characteristics based on the expression of biomarkers (HER2, ER, PR, Ki67), this classification complements the traditional classification and adds a very useful biological approach to disease management. That is why it is important for the radiologist to know and recognize the importance of classification, as well as to identify the most common imaging characteristics in the different diagnostic methods according to each molecular subtype.

#### **TABLE OF CONTENTS/OUTLINE**

Introduction· Breast molecular biomarkers· Revision of the classification of molecular subtypes of breast cancer· Imaging characteristics in the different methods according to each molecular subtype· Clinical cases· Conclusions

#### **BREE-43 Invasive Lobular Carcinoma (ILC): The Cancer With a Thousand Faces**

Adriana Alvarez, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

The Invasive Lobular Carcinoma (ILC) is the second most common type of invasive breast cancer. The incidence is increasing due to replacement therapy in postmenopausal women and diagnosis advances. There are two histologic variants: classic and pleomorphic. ILC is usually estrogen receptor positive and her2 negative. The loss of desmoplastic cell reaction and the low density of cells in this tumors make the clinical and the mammographic detection difficult. This entity has multiple imaging manifestations, being a challenge for the radiologist. ILC can be bilateral, multifocal or multicentric, with an unique metastatic pattern. Diagnosis is based in clinical and radiological tests. The most common manifestation is an irregular or spiculated mass in mammography and an hipococic irregular mass with posterior shadowing in US. MRI is the gold standard and it is used in the presence of multifocal, multicentric or bilateral disease as well as in the presence of lymphadenopathies.

#### **TABLE OF CONTENTS/OUTLINE**

This educational exhibit presents epidemiological and main ILC features. Tumor presentation and behaviour are explained. A multi-modality review of clinical and radiologic features through clinical cases, as well as pitfalls, are presented and they can help the radiologist in the diagnosis.

## **BREE-44 MRI-Detected US: How to Improve the Detection Rate of Non Mass Lesions Using Breast Anatomical Landmarks**

Ayumi Izumori (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Nonmass lesions on US are most often observed when US is used to target mammographic asymmetries, biopsy suspicious calcifications seen on screening mammography, and to biopsy abnormalities on MRI. In a meta-analysis of 2201 lesions, the success rate of targeted US after MRI was 58% (range, 23%-82%) and detection rates varied by lesion type. Nonmass enhancement lesions on MRI are less likely to be detected on targeted US than mass lesions (66% of all masses and 30% of nonmass enhancement lesions were seen). This review introduces a new viewpoint on breast ultrasound anatomy necessary to obtain a close correlation with MRI and describes a target US method with anatomical landmarks based on this viewpoint. 1. Some US images of MRI-detected lesions are more indistinct than surrounding benign lesions and need to be correlated with precision. 2. About effective anatomical landmarks for MRI correlation including surrounding tissues and vascular routes as a new anatomical landmark. 3. Pattern classification of mammary fat and mammary gland distribution for reading anatomic landmarks in MRI correlation. 4. The anatomical mechanism of deformity and how to decipher it on US. Breast deformity during ultrasound examination is not related to breast size, but varies from individual to individual.

### **TABLE OF CONTENTS/OUTLINE**

1. the identification rate of in each literature and its relationship to landmarks used 2. identification rates by anatomical landmarks and MRI images using those landmarks 3. classification of patterns of fat and mammary gland distribution in the breast based on anatomical understanding 4. anatomic mechanisms of breast deformity in MRI and US 5. US techniques considering breast deformity 6. case presentation

## **BREE-45 Unraveling the Enigma of DCIS: A Multimodality Imaging Journey**

Giselle G. Mello, PhD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

-Definition and classification of DCIS-Epidemiology and risk factors-Clinical presentation and symptoms Imaging modalities for DCIS detection and assessment

### **TABLE OF CONTENTS/OUTLINE**

-Interpretation of mammography, ultrasound, and MRI in DCIS diagnosis-The role of breast tomosynthesis in DCIS detection-Pathologic correlation and biopsy techniques-Management options: Discuss management options for DCIS, including surgery (lumpectomy or mastectomy), radiation therapy, hormonal therapy, and surveillance.-Discuss emerging imaging technologies for DCIS detection and assessment.-Future directions: Discuss future research directions and areas of innovation in the field of DCIS detection and assessment, such as the use of artificial intelligence and machine learning in radiology, and the development of more personalized approaches.

## **BREE-46 Unveiling the Mysteries of PASH in Breast Radiology: A Cutting-Edge Approach**

Andrea Di Ninno, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Definition and classification of PASH Imaging modalities for PASH detection and characterization Differential diagnosis of PASH with other breast lesions

### **TABLE OF CONTENTS/OUTLINE**

Definition and histopathology of PASH Clinical presentation and diagnostic workup of PASH Radiologic features of PASH on mammography, ultrasound, and MRI Differential diagnosis of PASH, including benign and malignant breast lesions Radiologic-pathologic correlation of PASH Management and follow-up of patients with PASH, including surveillance imaging and surgical options Association of PASH with other breast conditions, such as atypical ductal hyperplasia and breast cancer Multi-disciplinary approach to PASH management, involving radiologists, pathologists, and clinicians.

## **BREE-47 Imaging Review of Mammography and Ultrasound Findings in Uncommon Breast Lesions: A Trainee-Focused Guide**

Thurl Hugh C. Cledera, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Differentiating uncommon breast lesions from cancerous lesions in the breast is paramount to proper diagnosis, risk stratification, and treatment in patients presenting with a breast mass in imaging. Uncommon breast lesions may vary from those arising in the glandular parenchyma (phyllodes), inflammation (mastitis and abscess), autoimmune (granulomatous mastitis), and metabolic (diabetic mastopathy) etiologies. In centers where resources are limited, knowing the value of mammography and ultrasound findings may help guide biopsy, which in turn provides adequate treatment. At the end of this exhibit, the learner will be able to review the basic findings that are seen in breast lesions on imaging and understand the role of clinical and imaging correlation in the proper identification of these lesions.

## TABLE OF CONTENTS/OUTLINE

1. Introduction  
2. Brief review of histology of uncommon breast lesions  
3. Basic findings in mammography  
4. Basic findings in ultrasound  
5. Correlating findings in mammography and ultrasound  
6. Cases of uncommon breast lesions  
a. Lactating adenoma  
b. Intraductal papilloma  
c. Mastitis (bacterial)  
d. Granulomatous mastitis  
e. Diabetic mastopathy  
f. Mondor's disease  
g. Paget's disease  
h. Phyllodes tumor  
i. Dermatomyositis  
j. Foreign bodies

## BREE-48 Untangling the Mammary Ducts: Decoding the Complexity of Intraductal Pathology

Elsa Cecilia Molina Miranda, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

**Mammography:** Mammography can show intraductal lesions as grouped calcifications in a linear or branching pattern.  
**Breast ultrasound:** Ultrasound can identify intraductal lesions as masses or areas of ductal dilation.  
**Core needle biopsy (CNB):** This procedure is used to obtain a tissue sample from the lesion. CNB is performed guided by ultrasound or mammography.  
**Vacuum-assisted biopsy (VAB):** This procedure uses a suction device to obtain a tissue sample from the lesion. VAB is performed guided by ultrasound or mammography.  
**Contrast-enhanced mammography:** This exam uses a contrast medium to evaluate the vascularity of lesions in the breast, which may suggest the presence of a malignant lesion. Management of intraductal lesions depends on the definitive diagnosis obtained by biopsy. If the lesion is found to be malignant, treatment may include surgery, radiation therapy, and/or chemotherapy. If the lesion is benign, treatment may include observation or surgical removal.

## TABLE OF CONTENTS/OUTLINE

Table of contents: 1. Objectives 2. Anatomía y fisiopatología 3. Cases 4. Métodos diagnósticos 5. Approach 6. Conclusions  
Outline: Intraductal breast lesions are those that originate in the breast ducts and can be benign or malignant. These lesions can be detected by diagnostic methods such as mammography, breast ultrasound, core needle biopsy (CNB), vacuum-assisted biopsy (VAB), and contrast-enhanced mammography. The management of intraductal lesions depends on the definitive diagnosis obtained by biopsy, and treatment may include surgery, radiotherapy, and/or chemotherapy for malignant lesions, while benign lesions may be observed or surgically removed.

## BREE-49 Coming Out of the Bubble: Assessment and Management of Cystic Breast Lesions

Bruna P. Nantes, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

An approach to the evaluation and diagnosis of cystic lesions in the breast, with the aim of helping radiologists in their daily practice. Detail the different types of cystic breast lesions and their differential diagnoses, as well as the appropriate management of these lesions.

## TABLE OF CONTENTS/OUTLINE

**Brief introduction:** the prevalence of cystic breast lesions and the importance of adequate recognition and classification of these lesions.  
**Definition and descriptors:** detail the correct definition and description of the different types of cystic lesions.  
**Flowchart on the management of cystic breast lesions.**  
**Multiple clinical cases of the different differential diagnoses of each type of cystic breast lesion, that contemplate:**  
- Images from mammography, ultrasound and eventually MRI or CT scan;  
- Type of biopsy performed (if performed);  
- Recommendations on approaches to cystic lesions as per BI-RADS;  
- Recommendations on some special cases of cystic lesions;  
**Conclusion.**

## BREE-5 When Lightning Strikes the Same Place Twice: Detecting Ipsilateral Breast Cancer Recurrence in the Post Operative Breast

Aurela I. Clark, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Illustrate the imaging features suspicious of ipsilateral breast cancer recurrence in patients with prior lumpectomy or mastectomy. Review current literature for recommendations on adjunct imaging surveillance in women with prior history of breast cancer given their increased risk of a second breast cancer. Review imaging mimickers of breast cancer recurrence and

discuss management recommendations. Highlight teaching points for each case to increase confidence in making a timely diagnosis.

#### **TABLE OF CONTENTS/OUTLINE**

Case base review We will present an image rich exhibit depicting imaging findings in ipsilateral breast cancer recurrence in the post lumpectomy patients who present for annual surveillance mammography or breast MRI, and in patients who present with clinical concerns. Cases will illustrate imaging findings, histopathology and management at the initial diagnosis and at time of recurrence. Examples of imaging mimickers of breast cancer will familiarize the learner with benign conditions in the post-surgical breast. At the end of the exhibit, teaching points will be summarized. Summary: Women with a prior personal history of breast cancer are at an increased breast cancer risk. Cumulative incidence of ipsilateral breast tumor recurrence rate has been reported at 14.3%. The image appearance of the post operative breast can make the detection of breast cancer recurrence more challenging. As a result, radiologists should be familiar with common and uncommon imaging findings of ipsilateral breast cancer recurrence. This presentation will review the current screening recommendations in this setting, expected post operative changes, breast cancer mimics, and the imaging findings of recurrence.

#### **BREE-50 New Blossoms on the Old Tree: Advancing Ductography with Digital Breast Tomosynthesis (DBT) or Contrast-enhanced Mammography (CEM)**

Juan Tao (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Ductography is a useful tool for evaluating pathologic nipple discharge, allowing for identification and localization of intraductal lesions. 2. Ductography combined with DBT or CEM can eliminate masking of small filling defects caused by overlapping ductal branches and improve visualization of the entire ductal tree, enhancing the clarity of diagnosis. 3. Fine-tuning of the procedural steps and optimization of the contrast agent concentration are necessary for the successful implementation of ductography with DBT or CEM. 4. Potential additional risks of radiation exposure associated with combining DBT or CEM should be considered, and measures should be taken to minimize radiation dose to the patient in accordance with established protocols and guidelines for radiation safety in breast imaging.

#### **TABLE OF CONTENTS/OUTLINE**

I. The Old Tree: Overview of Ductography and Its Clinical Value in Evaluating PND. II. The New Bloom on the Tree: Clinical Cases Demonstrating the Utility of Ductography combined with DBT or CEM A. Sharper Sights Case: DBT-Ductography Increased Accuracy of Diagnosis. B. Wider Insights Case: CEM-Ductography Improved Visualization of the Entire Ductal Tree. III. Technical Aspects of Ductography combined with DBT or CEM. IV. Radiation Safety Considerations with Ductography and DBT or CEM A. Potential Additional Risks of Radiation Exposure B. Strategies to Minimize Radiation Dose to the Patient C. Importance of Adherence to Established Protocols and Guidelines for Radiation Safety in Breast Imaging. V. Conclusion A. Summary of the Key Points Regarding Ductography with DBT or CEM B. Future Directions and Potential Applications of Ductography with DBT or CEM. VI. References.

#### **BREE-51 Genetic Risk Assessment in the Radiology Setting: Our Nationwide Experience in 2023**

Sean D. Raj, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Review breast cancer risk assessment opportunities 2. Review key high-risk breast care and assessment considerations 3. Highlight key workflow, operational, and regulatory considerations from our practice's experience spanning multiple states on both coasts

#### **TABLE OF CONTENTS/OUTLINE**

I. Risk Assessment Guidelines a. Discuss often conflicting recommendation statements suggesting when to begin and which individuals to consider for cancer risk assessment, genetic testing, education/counseling, and modified medical management b. Spotlight recommendations for different demographics c. Examine benefits of supplemental screening II. Higher than average risk: Breast Screening Considerations a. Mammography sensitivities: general population with breakdown by demographics and women with intermediate risk, high risk, and women with genetic mutations b. ACR/SBI guidelines for those with genetically based [and/or family history and dense breast] increased risk III. Higher than average risk: Genetic Testing Considerations a. 32% of women qualify for genetic testing: a combination of hereditary and familial risk factors b. Simple multi-gene panel tests and risk assessment workflow can assess germline and polygenic risk for inherited cancer risk factors IV. Review development of Risk-Assessment ChatBot, Intake and Educational Workflow and discuss our nationwide practice's experience including pearls and pitfalls

#### **BREE-52 Vascular Mammary Lesions: Key Features to Make an Accurate Diagnosis and Avoid Unnecessary Biopsies**

Ladys J. Camargo, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. Review the normal vascular anatomy of the breast  
2. Know the most frequent vascular breast lesions  
3. Know and discuss the diagnostic modalities commonly used for the diagnosis of vascular lesions  
4. What is the imaging follow-up of vascular lesions?

## TABLE OF CONTENTS/OUTLINE

There are various vascular mammary lesions, ranging from chronic systemic processes, congenital malformations, post-traumatic sequelae, benign masses, to malignant tumors. Accurate diagnosis of vascular lesions in breast images is very risky due to overlapping characteristics. This is why radiologists must be aware of the key features in the different diagnostic methods for interpreting images of vascular lesions in order to make an accurate diagnosis and avoid unnecessary biopsies and finally be able to discuss management recommendations and guidance.

Outline-Introduction-Vascular anatomy of the breast-Imaging characteristics of the most frequent vascular mammary lesions-Diagnostic methods for the diagnosis of vascular lesions-Discussion of management and monitoring-Clinical cases.-Conclusions.-Bibliography

### **BREE-53 Cyst Breast Lesions: The Good, the Bad and the Ugly**

Tatiana C. Tucunduva, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Definition of cystic breast lesions and their prevalence  
Differentiation between simple cysts, complicated cysts, and complex cystic lesions  
Imaging modalities used for the assessment of cystic breast lesions, including mammography, ultrasound, and MRI

## TABLE OF CONTENTS/OUTLINE

Symptoms and clinical presentation  
Diagnostic imaging modalities for cystic breast lesions, including mammography, ultrasound, and MRI  
Imaging features of cystic breast lesions  
Differential diagnosis of cystic breast lesions, including benign and malignant conditions  
Role of imaging-guided percutaneous biopsy techniques in the diagnosis of cystic breast lesions, including fine-needle aspiration, core needle biopsy, and vacuum-assisted biopsy, and their advantages and limitations.  
Discussion of the importance of a multidisciplinary approach in selecting the most appropriate biopsy technique based on lesion characteristics, patient factors, and imaging findings.  
Follow-up and surveillance after diagnosis and treatment of cystic breast lesions

### **BREE-54 Everything We Need to Know About Papillary Breast Carcinoma**

Lisett N. Cruzado-Quiroz, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Papillary breast carcinoma is a rare subtype of invasive ductal carcinoma with infiltrative papillary growth representing about 0,5 -0,7% of all invasive breast cancers. It is usually seen in postmenopausal in their sixth to eight decade of life. Association with carcinoma in situ is uncommon. Typically presents with bloody nipple discharge or/with slow growing palpable tumors, frequently found in the periareolar region. In general, they have better prognosis than ductal carcinoma with a 100% 10 year survival rate following treatment. Lymph node involvement and distant metastases are rare except in the invasive form. Mammography usually shows a solitary round or oval mass with circumscribed margins. Rarely they associate poorly defined margins or spiculation, given the low occurrence of desmoplastic reaction. Ultrasound generally shows a complex mass with solid and cystic components with good sound transmission. MRI may demonstrate heterogeneous lesions with septations, mural nodule and intracystic haemorrhage, the solid components typically show washout kinetics. Intracystic papillary carcinomas can occur in a pure form or may be associated with ductal carcinoma in-situ or invasive ductal carcinoma. The authors will review the clinical manifestation, imaging features and pathology correlation of this rare breast carcinoma.

## TABLE OF CONTENTS/OUTLINE

Review of the pathophysiology of papillary breast cancers (histological and molecular aspect).  
Multimodal review of imaging features of papillary cancers (mammographic, ultrasonographic, and MR findings)  
To determine the Radiology-Pathology concordance/discordance by reviewing cases.  
Update on the treatment of papillary breast cancer.

### **BREE-55 Decoding Ductal Pathology: Multimodality Approach to Nipple Discharge and Management of the Solitary Duct**

Zoya M. Patni, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. Identify what differentiates physiologic nipple discharge from pathologic discharge  
2. Describe an approach to the diagnostic workup of patients with nipple discharge  
3. Discuss the clinical importance of a solitary dilated duct and describe an approach to management in these patients  
4. Implement new strategies for biopsy of hard-to-sample intraductal masses under both ultrasound and MRI-guidance

## TABLE OF CONTENTS/OUTLINE

Nipple discharge represents 2-5% of medical visits among women and is the third most common breast concern (pain > lump > nipple discharge). As radiologists our primary responsibility in assessment and management of these patients is to distinguish physiologic and pathologic causes of nipple discharge. This presentation will review the prevalence, epidemiology and pathologic subtypes of papillary lesions and other common pathologies resulting in pathologic nipple discharge and provide the reader with a diagnostic algorithm for management of these patients. Using a multimodality case-based approach, the reader will develop a differential diagnosis and management strategy for imaging findings in patients with nipple discharge, including management of the solitary dilated duct. We provide the reader with important tips and tricks for biopsy of intraductal lesions and solitary dilated ducts under ultrasound and MRI-guidance and address the potential challenges of radiology-pathology concordance in these cases.

### **BREE-56 Uncovering False Positive Lesions Through DBT**

Giovana O. D'Avila I, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Teaching Points Screening mammography using DBT is replacing digital mammography as the preferred imaging modality. Recognize that DBT and mammography together minimize the effects of overlapping breast tissue and improves lesion detection and localization. Identify that digital breast tomosynthesis showed lower recall, cancer detection rate, and biopsy rate. The ability to problem solve with DBT images reduces patient anxiety associated with a callback.

## TABLE OF CONTENTS/OUTLINE

Table of contents 1 - Advantages of screening mammography using DBT. 2 - Amorphous calcifications 3 - Left axillary lymphadenopathy 4 - Palpable finding 5 - Solid Mass

### **BREE-57 Ductal Carcinoma in Situ: Beyond First Impressions**

Hannah L. Chung, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

DCIS often co-exist with invasive cancers and 19-36% of DCIS after percutaneous needle biopsy are upstaged to an invasive cancer at surgical excision. Up to 3% of DCIS demonstrate axillary nodal metastases. The morphology of the calcifications are useful in predicting the nuclear grade. DCIS may also manifest as a noncalcified mass, asymmetry or distortion. Sonography demonstrates these findings as a mass, nonmass area or ductal change. MRI demonstrates the extent of DCIS better than other imaging modalities and findings correlate with high grade DCIS. Observed recurrences and lymph node metastases pose challenges to current evaluation and treatments of DCIS.

## TABLE OF CONTENTS/OUTLINE

Table of Contents 1. What is DCIS a. Significance of DCIS b. Biology and evolution of DCIS 2. Clinical Presentation of DCIS a. Asymptomatic b. Nipple discharge c. Paget's disease of the nipple d. Palpable lump 3. Imaging correlates with biology and pathology a. Mammographic i. Calcifications, mass, asymmetry, distortion b. Sonographic i. Nonmass findings 1. hypoechoic areas 2. echogenic foci 3. shadowing, 4. pseudomicrocyst ii. Ductal change c. MRI- MRI is useful to demonstrate extent of disease, exclude invasive disease, and correlates with high grade DCIS. i. nonmass enhancement ii. mass. 4. Special considerations a. Occult invasive cancers or misdiagnosis- Can imaging predict invasion? b. Axillary Staging- Is axillary ultrasound with biopsy and sentinel lymph node necessary? 5. Research: Past, now, and future endeavors a. NSABP, UKANZ, ECOG-ACRIN b. Active surveillance vs standard treatment - COMET, LORIS, LORD c. Advanced imaging techniques and artificial intelligence in both radiology and pathology

### **BREE-58 When Cysts Are Not So Simple: Tips for Complex Cystic Breast Masses Evaluation.**

Rosa M. Lorente-Ramos, MD, PhD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

-To review the different entities causing the sonographic appearance of a complex cyst. -To illustrate a series of cases of complex cystic benign and malignant lesions of the breast providing correlation with imaging (US, contrast-enhanced mammography, MRI) and pathology. - To discuss the specific management of those lesions including imaging and interventional procedures. -To emphasize pitfalls, diagnostic difficulties, and differential diagnosis.

## TABLE OF CONTENTS/OUTLINE

Cystic breast lesions are frequently detected on breast ultrasonography. Simple cysts, complicated cysts, and oil cysts do not require further invasive diagnostic procedures. However, malignant entities may present with complex cystic and solid masses. Through sample cases, a variety of imaging and pathology findings from complex cystic lesions with management discussion will be demonstrated. 1. Introduction. US findings and technical pitfalls. 2. Cystic lesions evaluation, useful findings that could be of significant diagnostic value to distinguish between confusing cysts. Classification of cysts and suspicious

findings. 3. Work-up of suspicious lesions on US: mammography/contrast-enhanced mammography (CEM) and MRI. Interventional procedures. 4. Typical benign and malignant lesions with their important findings on ultrasonography, contrast-enhanced mammography, and MRI: Benign: complicated/inflammatory cyst, seroma, oil cyst, epidermal inclusion cyst, galactocele, mucocele-like tumor, hematoma, abscess, fat necrosis, fibroadenoma, papilloma, benign Phyllodes tumor. Malignant: malignant Phyllodes tumor, papillary, medullary, colloid, and squamous cell carcinoma, sarcoma.

## **BREE-59 Differentiating Simple Cysts From Complicated Cysts, Complex Cystic and Solid Masses, and Other Cystic Breast Lesions**

Tara A. Retson, MD, PhD (*Presenter*) Research Consultant, CureMetrix, Inc Stock options, CureMetrix, Inc

### **TEACHING POINTS**

Cystic diseases of the breast are common, and confusion can occur regarding their appropriate classification and management. Distinguishing between benign cysts/cystic lesions and malignant cyst-like/fluid-containing cancers may be challenging. Specifically, triple negative breast cancers and intracystic papillary carcinomas should not be dismissed as benign/probably benign. Cystic lesions may be diagnosed accurately and managed appropriately using characteristic imaging findings. It is imperative to properly classify lesions as complex cystic and solid masses vs. complicated cysts since their management differs, and the differential of complex cystic and solid masses includes cancer. This educational exhibit will define simple cysts, teach radiologists about cystic lesions that may not be benign, review their imaging appearances, and recommend management options for complicated cysts, clustered microcysts, and complex cystic and solid breast masses.

### **TABLE OF CONTENTS/OUTLINE**

Introduction; Definitions/illustrations of simple cysts, complicated cysts, clustered microcysts and complex cystic and solid masses; Multimodality examples of cystic breast lesions, systematic approach to the characterization of cystic lesions; How to appropriately apply BI-RADS classification and management recommendations of cystic breast lesions; Utilization of a quiz at the end of the exhibit to test yourself on the systematic approach presented.

## **BREE-6 Get Your Ducts in a Row: Imaging and Management Considerations of Ductal Disease of the Breast**

### **Awards**

#### **Certificate of Merit**

Firouzeh K. Arjmandi, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

-In the imaging evaluation of spontaneous clear and/or bloody nipple discharge, negative diagnostic conventional imaging (mammogram and ultrasound) warrants further evaluation with breast MRI. -Nipple changes on physical exam even in the absence of imaging findings are suspicious. Clinical exam findings should guide next steps in management, and nipple tissue biopsy should be performed by the surgeon in the appropriate clinical setting. -In the setting of a small, subtle intraductal mass seen on diagnostic MRI and not well visualized at time of MR-guided biopsy, targeting the end of a blind-ending solitary duct can help to guide the biopsy. -The combination of findings of a palpable lump, nipple discharge, and nipple inversion, and the presence of associated coarse heterogeneous calcifications raises concern for malignancy, and biopsy should be recommended (despite the presence of more benign appearing rim calcifications). -Treatment of intraductal papillomas without atypia has become more conservative. Upgrade to DCIS or invasive carcinoma is more common in women >50 years, lesions >1 cm, palpable lesions and papillomas >5 cm from the nipple.

### **TABLE OF CONTENTS/OUTLINE**

-Overlapping imaging features of benign and malignant calcifications, including high grade versus low grade DCIS -Utility of MRI in the evaluation of extent of disease in intermediate to high grade DCIS -Multimodality imaging and clinical evaluation of pathologic nipple discharge and nipple changes (erythema and scaling) -Imaging assessment and clinical management of a solitary dilated duct and intraductal lesions -Accurate assessment of response to neoadjuvant chemotherapy in the setting of increasing calcifications post therapy

## **BREE-60 Test Your Knowledge: A Case Based Quiz of Contrast Enhanced Mammography BI-RADS Lexicon**

### **Awards**

#### **Certificate of Merit**

Daniel Sandoval, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

• To learn the descriptors published in the ACR 2022 BI-RADS supplement for contrast enhanced mammography by reviewing a series of daily case images. • As this supplement has only recently been published, this exhibit is intended to help

radiologists become familiar with the terminology and its representation on images, through an interactive and entertaining activity.

#### **TABLE OF CONTENTS/OUTLINE**

• Background Contrast enhanced mammography lexicon overview (categories, terms, features and definitions) • Illustrated case based quizzes  
Case #1: Background parenchymal enhancement - Level: Minimal, Mild, Moderate, Marked. - Symmetry: Symmetric, Asymmetric.  
Case #2: Masses - Shape: Oval, Round, Irregular.- Margin: Circumscribed, Irregular, Spiculated. - Internal enhancement characteristics: Homogeneous, Heterogeneous, Rim enhancement. - Distribution; Diffuse, Multiple regions, Regional, Focal, Linear, Segmental- Internal enhancement characteristics: Homogeneous, Heterogeneous, Clumped.  
Case #4: Enhancing asymmetry - Internal enhancement pattern: Homogeneous, Heterogeneous.  
Case #5: Lesion conspicuity - Low - Moderate - High• References

#### **BREE-61 Complex Cystic Breast Masses: An MR Imaging Review**

Jie Liu (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. To define the concept of complex cystic breast masses. 2. To categorize complex cystic breast masses into three types based on the percentage and spatial distribution of cystic and solid components in the contrast-enhanced MRI. 3. In comparison with US, MRI affords superior visualisation of the proportion and distribution characteristics of solid and cystic components within complex cystic breast masses, which facilitates their differential diagnosis. Moreover, multi-parametric MRI such as T2WI, dynamic contrast-enhanced MRI (DCE-MRI) and diffusion-weighted imaging (DWI) enables the recognition of the presence and distribution characteristics of cystic and solid components, the combination of which can serve as a complementary imaging aid for accurate diagnosis.

#### **TABLE OF CONTENTS/OUTLINE**

I. Introduction A. Overview of complex cystic breast masses B. Importance of accurate diagnosis II. Complex cystic breast masses A. Definition of complex cystic breast masses B. Etiology of complex cystic breast masses C. Clinical manifestations of complex cystic breast masses III. Categorization of complex cystic breast masses based on MRI features Group A : thick outer wall and/or thick internal septa (> 0.5 mm). Group B: predominantly cystic component(>50%)or intracystic mural nodule. Group C:predominantly solid component and cystic component=50% IV. Comparison of MRI and ultrasound in complex cystic breast masses A. Advantages of MRI over ultrasound B. Limitations of ultrasound C. Diagnostic value of multiparametric MRI in identifying cystic components V. Conclusion A. Summary of key points B. diagnostic flow chart of complex cystic breast masses C. Future directions for research VI. References

#### **BREE-62 Trial by Priors: When to Call Back a Stable Mammographic Finding**

Samantha H. Epstein, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Comparison with multiple prior studies can help identify slowly evolving malignancies.2. Mammographic findings that warrant further evaluation include increasing number of calcifications or suspicious distributions, evolving asymmetries, architectural distortions, and slow growing or spiculated masses.3. Early recognition of these suspicious findings allows for appropriate diagnostic workup and improved diagnosis of slow growing malignancies.

#### **TABLE OF CONTENTS/OUTLINE**

1. Introductory slide. This exhibit hopes to educate breast imagers about stable mammographic findings that require further evaluation. While stability of imaging findings over two years is often suggestive of benignity, comparison with multiple prior imaging studies can allow better evaluation of stability and identify features that are slowly evolving over time. There are also some imaging features that should be further evaluated and sampled regardless of apparent stability. This educational exhibit will discuss several cases of malignancy, highlighting the suspicious imaging features that prompted additional work up.2. List of teaching points to guide the upcoming case discussion.3. Anonymized cases demonstrating different examples of slow growing malignancies. Each case will include: Multiple prior studies to demonstrate evolution over time; Explanation of decision making that lead to diagnostic evaluation; Findings on diagnostic imaging; Pathology results after biopsy.4. Summary slide that reviews the teaching points.

#### **BREE-63 Indications and Outcomes of Cryoablation in Breast Malignancies: A Single Institution Case Review**

Sasha Kurumety, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

The goal of this presentation is to educate radiology trainees on the use of cryoablation as a treatment option for breast malignancies, when cryoablation may be appropriate, and expected short and long term outcomes of the procedure. Using a series of cases from our institution, we will describe selection criteria to identify patients that may benefit from this minimally invasive cancer treatment option and demonstrate post treatment imaging findings. After this presentation, learners will be

able to describe the utility of cryoablation in treating breast malignancies and mechanisms of action, as well as understand the complications, outcomes, and future directions/ongoing trials for cryoablation.

#### **TABLE OF CONTENTS/OUTLINE**

Background:- Current FDA approved indications for cryoablation and uses of cryoablation in breast cancer- Ongoing trials: discussion of ICE3, FROST, and home institution trials and preliminary outcomes Discussion of mechanism of action:- Direct freezing and cell death, indirect immune response activation- Advantages, disadvantages, and risks/complications of cryoablation Cryoablation at our institution:- Qualifying patient and tumor characteristics, preprocedural evaluation- Interdisciplinary decision-making Institutional cryoablation cases:- Preprocedural imaging, biopsy pathology results, imaging during procedure, and post cryoablation follow up imaging/pathology Future directions: pathway to FDA approval, Medicare coverage, and increasing accessibility.

#### **BREE-64 To Treat or Not to Treat: A Review of Papillary Lesions of the Breast**

Shadan Alwan, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Papillary breast lesions are a heterogeneous group of proliferative changes that occur within the epithelial lining of breast ducts. These lesions have varying presentations, pathological characteristics, and treatment options, requiring careful radiological evaluation for an accurate diagnosis. The spectrum of the lesions includes intraductal papilloma with/without atypia, intraductal papillary carcinoma, encapsulated papillary carcinoma, solid papillary carcinoma, and invasive papillary carcinoma. Radiologists must be aware of these variations to accurately identify, diagnose, and provide appropriate management recommendations. The primary objective of the exhibit is to present a comprehensive pictorial review of papillary breast lesions with radiological pathological images. We will also discuss the steps in the diagnosis and current management recommendations of these lesions. By the end of this exhibit, the audience will have a better understanding of the various papillary lesions and their clinical and imaging presentations, enabling them to provide appropriate radiologic-pathologic correlation and treatment recommendation for patients.

#### **TABLE OF CONTENTS/OUTLINE**

1) Introduction. 2) Definition of papillary breast lesions. 3) Pictorial review of the spectrum of papillary lesions. 4) Case examples of the spectrum of papillary lesions with pathological correlation. 5) Symptoms presentation of various papillary lesions. 6) Imaging techniques recommendations for diagnosis of papillary lesions. 7) Review of current BI-RADS terms in the description of these abnormalities. 8) Latest management recommendation for papillary lesions within the spectrum. 9) Conclusion/Summary.

#### **BREE-65 Case Based Review of the Modern Reconstructed Breast: Benign Imaging Findings and Complications**

Shelby Breit, BS, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Understand imaging findings associated with modern reconstruction techniques 2. Recognize uncommon and common benign findings 3. Discuss complications

#### **TABLE OF CONTENTS/OUTLINE**

Reconstruction Methods Implants Autologous Flaps (AF) Imaging after implant reconstruction Type: silicone vs saline implant Acellular dermal matrix (ADM) Benign complications: Rupture Gel bleed Abscess/infection Hematoma Siliconoma Implant associated mesenchymal tumors (fibromatosis) Imaging after AF reconstruction Type: pedicled, free, perforator flaps Venous coupler device Benign complications: Fat necrosis/lipografting Epidermal inclusion cyst

#### **BREE-66 Breast MRI: What the Surgeon Wants to Know**

Daniella Boros, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

As there is increasing need for a multidisciplinary approach to patient care, it is important for the radiologist to understand which MRI findings change clinical management. After this presentation, participants will understand: 1. Indications for breast MRI 2. Breast cancer staging 3. Indications for different types of breast cancer treatment, including surgery, radiation, and systemic 4. Breast MRI findings that change clinical/surgical management 5. MRI correlates on mammogram and ultrasound

#### **TABLE OF CONTENTS/OUTLINE**

A. Indications for MRI a. American College of Radiology Practice Parameter b. American Society of Breast Surgeons Consensus Guidelines B. Overview of breast cancer staging C. Surgical management a. Indications b. Mastectomy vs. lumpectomy c. Types of mastectomy D. Radiation a. Indications b. Whole vs. partial breast treatment E. Systemic a. Indications for neoadjuvant chemotherapy b. Types of systemic treatment (chemotherapy, hormone blockade, biologic

therapies) F. MRI findings that impact staging and management with multimodality case examples a. Multicentric/multifocal disease b. Nodal involvement (rotter's node, level I, level II, level III, internal mammary chain node) c. Nipple enhancement d. Skin enhancement e. Chest wall involvement f. Cancer in contralateral breast g. Metastatic disease - bone/lung involvement

## **BREE-67 The Not So Simple Cyst**

Daymara Deynes-Ramos, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Cystic breast lesions are frequently encountered on ultrasound, often incidentally with a broad differential diagnosis including both benign and malignant pathology. Accurate description and classification according to the BI-RADS Lexicon based on ultrasound characteristics are essential for appropriate estimation of risk for malignancy and in turn management guidance. Emphasis on optimal ultrasound techniques, BI-RADS classification based on imaging characteristics, and correlation with example cases will be given with the purpose of helping residents and radiologists feel confident on how to proceed when faced with a cystic breast lesion.

### **TABLE OF CONTENTS/OUTLINE**

I. Introduction II. Optimal Ultrasound Technique III. BI-RADS classification of cystic lesions 1. Simple cyst 2. Complicated cyst 3. Complex cystic and solid mass (classification of complex masses) IV. Sampling techniques V. Take Away Points

## **BREE-68 The Cures Act: Challenges and Benefits in Breast Imaging**

Neda Ghassemi, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

The 21st Century Cures Act is a federal law signed in 2016, aiming to remove barriers to health information exchange. The legislation includes a Final Rule, federally enforced as of April 2021, mandating patient access to electronic health information to increase transparency. Part of the mandate prohibits "information blocking," defined as a healthcare practice that is "likely to interfere with access, exchange, or use of electronic health information." For radiology practices, this means that reports are released to patients immediately when finalized. Immediate release allows for increased patient autonomy but reports often include sensitive information, especially in breast imaging, in addition to terminology that might be confusing to patients. Screening and diagnostic reports, previously held for a period of time at many institutions to allow time for direct patient communication, are now immediately released to patients. This educational exhibit reviews the impact of the Cures Act on breast imaging practices, including benefits, challenges, and potential solutions to navigate the legislation.

### **TABLE OF CONTENTS/OUTLINE**

I. Legislation II. Positive Implications and Challenges III. Evolution of Practice

## **BREE-69 How to Start Using Optoacoustic Imaging in Your Breast Practice: A Primer**

### **Awards**

#### **Certificate of Merit**

Berat Bersu Ozcan, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Optoacoustic imaging (OAI) is a novel technique that uses non-ionizing lasers to detect endogenous tissue contrast. Gray scale ultrasound (GUS) is fused with parametric maps of relative light absorption for oxy/deoxyHgb in real-time, enabling simultaneous functional and anatomic imaging. The most frequently tested interpretation schema involves dividing mass into 3 internal and 2 external features. The 3 internal scores include the number of individually resolved vessels and their relative deoxygenation (vessel score), tumor blush, representing volume-averaged vessels too small to resolve individually (blush score), and Hgb amount (hemoglobin score). The 2 external scores reflect the amount and relative oxygenation of hemoglobin and vessel morphology within the boundary zone (bz, immediately surrounding the tumor, analogous to the thick echogenic rim surrounding tumors on GUS images) and the peripheral zone (pz, territory beyond the bz). Combined evaluation of GSUS and OAI features to classify benign and malignant masses have consistently shown to increase significantly (43.0% vs 28.1%,  $p < 0.001$ ) diagnostic specificity with high interreader (7 readers) agreement (mean kappa = 0.55;  $p < 0.001$ ). A study combining decision support tools with 15 fellowship-trained radiologists showed that interreader agreement [intraclass correlation coefficient (ICC) 0.80, 95%CI: 0.78, 9.82] and agreement between reader and decision support tool (95.3% of all reads) was high.

### **TABLE OF CONTENTS/OUTLINE**

1. Optoacoustic Imaging Principles 2. Equipment Types and Current Status 3. Interpreting Optoacoustic Images: A Comprehensive Guide 4. Understanding system limitations 5. Case Demonstration 6. Test Your Knowledge

## **BREE-7 Non-Malignant Papillary Lesions of the Breast: Imaging Features and Management**

Antonio Morales Rosa, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

- To describe the characteristics of non-malignant papillary lesions of the breast (B3) on different imaging techniques: mammography, US and MR. - To review the therapeutic algorithm of papillary B3 lesions of the breast and the role of vacuum assisted excision biopsy (VAE).

### **TABLE OF CONTENTS/OUTLINE**

1. Introduction 1.1 Intraductal papiloma without atypia. 1.2 Intraductal papiloma with atypia. 2. Imaging features. 2.1 Mammography. 2.2 US. 2.3 MR. 3. Radiopathological correlation. 4. Management of B3 papillary breast lesions. Algorithm. Role of MR. Indications of VAE. 4.1 Follow-up. 4.2 Surgery. 4.3 Vacuum assisted excisional biopsy (VAE). 5. Conclusions

## **BREE-70 What You Need to Know About the Pediatric Breast: A Review of the Normal Breast and Diagnostic Approach of Pediatric Breast Disease.**

### **Awards**

#### **Certificate of Merit**

Ilany L. Valdivia I, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

The purpose of this exhibit is to: Describe the physiologic breast development and its variants from birth to adolescence. Review the optimal imaging modalities for evaluation of breast lesions in children and adolescents. Recognize imaging appearances of benign and malignant lesions that can affect the pediatric breast. Learn the recommendations for follow-up and management of pediatric breast lesions to avoid a delayed diagnosis or unnecessary interventions.

### **TABLE OF CONTENTS/OUTLINE**

We review: Utility of the different imaging modalities in the assessment of the pediatric breast. Breast physiologic development from birth to puberty and pathological conditions that can occur. Benign and malignant pediatric breast disease with illustrating cases. Non-mass findings: Asymmetrical breast development, accessory breast tissue, accessory nipple, pseudogynecomastia, gynecomastia, atypical ductal hyperplasia, surgical scar. Benign masses: Simple and complex cysts, retroareolar cyst, epidermal inclusion cyst, fibrocystic changes, mastitis and abscess, hematoma, intramammary lymph node, reactive lymph node to vaccines, fibroadenoma, pseudoangiomatous stromal hyperplasia, sclerosing adenosis, phyllodes tumor and tubular adenoma. Malignant masses: Metastasis and primary breast cancer. Diagnostic approach of pediatric breast disease with follow-up and management algorithm and indications for interventions such as biopsy or surgery.

## **BREE-71 Localization for Nonpalpable Breast Lesions. A Pictorial Review of Different Imaging-guided Preoperative Localization Procedures in the Breast and Axilla.**

Javier Azpeitia Arman, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

-To know the different devices employed for nonpalpable breast lesions localization. -To review the role of imaging techniques (mammogram, US, MR, CT, gamma detector) in the localization of breast lesions for breast conserving surgery. -To understand surgeon needs including technical factors of localization and communication of the relationship of the lesion and the marker. -To become familiar with the localization process, and different tips and tricks for each device.

### **TABLE OF CONTENTS/OUTLINE**

Breast-conserving surgery requires multidisciplinary communication and planning between the surgeon and the radiologist. Removal of the lesion with adequate surgical margins and avoiding resection of healthy breast tissue is essential. 1. History of wire localization, radioactive seed, and other non-needle-wire localization techniques 2. Advantages and disadvantages of using seed localization versus needle-wire localization. 3. Wire localization. 4. Non-wire devices: radioactive I125, magnetic, radar, and radiofrequency seeds 5. Technique and pitfalls. Before the procedure: review of the patient's imaging and histopathologic findings. Wire or seed placement. Preoperative detection. Operating room. Recovery. 6. Case examples of potential difficulties and problems and how to overcome them.

## **BREE-72 Is it Back? Multimodality Surveillance of Breast Cancer Recurrence: Literature Review and Case Presentation**

Mohammed A. Sabawi, MBChB (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Screening patients with previously treated breast cancer is challenging, because benign post treatment changes can obscure or resemble an underlying recurrence and due to technical limitations in performing a mammography on a treated breast. There are postoperative mammographic findings in a conservatively treated breast which follow expected time course. Any new mammographic finding (new masses, asymmetries or microcalcifications) should raise suspicion for recurrence. Abnormal screening mammogram is the most common presentation of breast cancer recurrence. Margin involvement and lack of radiotherapy and/ or chemotherapy are important prognostic factors of local recurrence. There is no clear guidelines to dictate ipsilateral breast screening after mastectomy and reconstruction with or without implant. Breast MRI is highly sensitive imaging modality to detect local recurrence in certain patient groups. It can be also utilized as problem solving to assess equivocal clinical or mammographic findings.

## TABLE OF CONTENTS/OUTLINE

Introduction Review of incidence, risk factors, diagnostic performance of multimodality surveillance and presentation of breast cancer recurrence. Review of post breast conserving treatment imaging findings and their time course of evolution. Review of available national guidelines for multimodality surveillance after curative treatment for locoregional breast cancer. Case based review of different and unusual presentations of breast cancer recurrence. Conclusion. References.

### **BREE-73 A Review of the Combined Score for Quantitative Shear Wave Elastography (SWE) and Superb Microvascular Image Vascular Index (SMI<sub>VI</sub>) to Evaluate Breast Masses**

NA YOUNG LEE (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. To differentiate between benign and malignant breast masses, we propose using the combined score of quantitative parameters for shear wave elastography (SWE) and superb microvascular image (SMI) with BI-RADS. We suggest using the combined score for SWEmax, SWERatio, and SMIVI and demonstrate how it can be used to differentiate between benign and malignant breast masses. 2. We calculated the combined score by adding the BI-RADS score and each quantitative parameter (SWEmax, SWERatio, and SMIVI). The BI-RADS categories were scored on a scale of 1 to 5 (C3:1, C4a:2, C4b:3, C4c:4, and C5:5), and SWEmax, SWERatio, and SMIVI were scored as 0 or 1 based on applied cutoff values. The summed score ranged from 1 to 8. We used a cutoff value of 4 for the combined score to discriminate between benign and malignant cases based on the reported AUC values. 3. The combined score of B-mode US and quantitative parameters can improve diagnostic performance and reduce unnecessary breast biopsy. However, the combined scores should be applied with caution, considering that the quantitative parameters have limitations in assessing small-sized, pure DCIS, or low-grade invasive cancer.

## TABLE OF CONTENTS/OUTLINE

1. Review the principles of quantitative parameters for SWE (SWEmax, SWERatio) and SMIVI. 2. Review the appropriate cut off value for quantitative parameters for SWEmax, SWERatio, and SMIVI and evaluate their diagnostic performance in differentiating between benign and malignant masses. 3. Showcase the various case of combined score and pathology reviews to demonstrate how combined scores are helpful for differential diagnosis of breast masses, and which cases will be carefully applied.

### **BREE-74 Threading the Needle: The Role of Breast Radiologists in Managing Suspicious Internal Mammary Lymph Nodes**

#### **Awards**

#### **Certificate of Merit**

Megan J. Kalambo, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. Examine Internal Mammary Lymph Nodes (IMLN) as an important component of breast lymphatic drainage. 2. Review the implications of metastatic IMLN adenopathy in the staging of breast cancer. 3. Provide an overview of IMLN basin anatomy, differential diagnosis of IM adenopathy, and the clinical indications for imaging and sampling. 4. Explain the tools and technical steps necessary for conducting a successful ultrasound biopsy of IMLNs. 5. Recognize ultrasound-guided Fine Needle Aspiration (FNA) biopsy as a feasible percutaneous sampling technique radiologists can use to provide treatment planning assistance to clinical teams.

## TABLE OF CONTENTS/OUTLINE

Based on our experiences at a tertiary oncologic referral center, we will provide an overview of internal mammary lymph nodes (IMLN) with regard to the anatomical, clinical, imaging and procedural considerations for radiologists. • Overview of IMLN nodal basin anatomy • Management of indeterminate and suspicious IMLNs • Differential diagnosis of abnormal/indeterminate IMLNs • Incidence and implications of IMLN adenopathy on breast cancer staging • Indications for imaging of IMLN • Multimodality identification of IMLN on Ultrasound, MRI, PET/CT • Biopsy considerations • Indications •

Tools • Technical steps • Case-based discussion of IMLNs • Tips for imaging and clinical management of patients with indeterminate/suspicious IMLN.

## **BREE-75 The State of Breast Imaging in the Caribbean**

Dami Olufosoye, BS, MPH (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. Provide an overview of the current trends in incidence and mortality of breast cancer in the Caribbean 2. Discuss the state of breast services with respect to breast exams and screening 3. Discuss the challenges in breast services including infrastructure and health workforce availability 4. Recognize patient-related barriers 5. Review main points of the global breast cancer initiative and goals for breast imaging in the Caribbean

### **TABLE OF CONTENTS/OUTLINE**

- Overview of breast cancer incidence, prevalence, mortality, and stage of diagnosis in the Caribbean compared globally and to the US
- State of breast services with respect to breast exams and testing
- National guidelines on breast exams and screening
- Self-breast exams
- Clinical breast exams
- Access to mammograms
- Discuss the state of breast services pertaining to the infrastructure and health workforce availability
- Number of equipment in the region
- Type of equipment available: digital mammography vs full film digital mammography vs tomosynthesis
- Maintenance/ Audit of equipment
- Health workforce: radiologists, oncologists, physicists
- Breast treatment services
- Barriers surrounding breast cancer
- Knowledge deficits
- Patient beliefs
- 2021 Global Breast Initiative
- Key messages
- Recommendations for implementing interventions

## **BREE-76 Breast Lesions Detected on CT: When to Refer for Triple Breast Assessment**

Sharmeen Jaffer, BMBS, FRCR (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

- Incidental breast lesions are a common finding on CT and unnecessary referrals can create a significant burden on the breast clinic.
- To evaluate imaging characteristics of incidental breast lesions identified on CT and suggest characteristics which warrant referral to the breast clinic.
- To identify imaging characteristics of breast lesion mimics or benign breast lesions; avoiding unnecessary referral to the breast clinic.
- To explore the limitations of CT with imaging breast lesions including post-contrast enhancement in benign and malignant lesions.

### **TABLE OF CONTENTS/OUTLINE**

- Variability of normal breast glandular tissue on CT including asymmetry and differences in density.
- Breast lesions with benign characteristics such as coarse or popcorn calcification or well defined cysts with homogenous fluid attenuation.
- Indeterminate breast lesions including intramammary lymph nodes, leiomyomas, papilloma, fat necrosis or lobular fibroadenomas which demonstrate post-contrast enhancement.
- Suspicious breast lesions and indicators of malignancy including irregular or spiculate margins and global or peripheral contrast enhancement; measured in Hounsfield units (HU).
- Mimics of breast malignancy including lymphoedema, post surgical changes or radiotherapy.
- Factors that negate an unnecessary referral to breast clinic include: long term stability, lesion previously assessed on mammography/ultrasound/biopsy proven benign lesion.

## **BREE-77 Multimodality Imaging of Recurrent and Residual Breast Cancer**

### **Awards**

#### **Certificate of Merit**

Victoria Domonkos (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

After this exhibit, the reader will be able to: 1. Describe the epidemiology and clinical implications of recurrent and residual breast cancer. 2. Demonstrate the importance of a multimodality approach to the detection, workup and diagnosis of recurrent and residual breast cancer. 3. Apply specific strategies to improve early detection to optimize patient outcomes.

### **TABLE OF CONTENTS/OUTLINE**

Recurrent and residual breast cancer remains a diagnostic challenge with significant clinical implications. Early and accurate detection is critical for optimizing patient outcomes. Using a case-based multi-modality approach, this exhibit will: 1. Review the epidemiology and clinical implications of recurrent and residual breast cancer. 2. Discuss current surveillance recommendations and supporting literature, including the importance of patient anxiety. 3. Review expected post-treatment findings, discussing the advantages and disadvantages of each modality (mammography, ultrasound and MRI). 4. Provide an approach to surveillance imaging and residual disease, with emphasis on the surgical pathology report, surgical margins and the importance of breast biopsy marker clips. 5. Provide tips and tricks to ensure early identification of recurrent/residual disease and avoid post-treatment surveillance pitfalls.

### **BREE-78 From Benign to Malignant: Understanding the Spectrum of Phyllodes Tumors**

Abel Gonzalez Huete, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. To provide an overview of Phyllodes tumors, including their pathology features, categories and clinical presentation. 2. To discuss the role of the different imaging in the diagnosis of Phyllodes tumors. 3. To review the differential diagnosis of Phyllodes tumors and how to differentiate them from other breast tumors. 4. To highlight the importance of accurate diagnosis in the management of Phyllodes tumors.

#### **TABLE OF CONTENTS/OUTLINE**

1. Introduction: Breast anatomy, Fibroepithelial tumors, Epidemiology, Pathogenesis, Categories of Phyllodes Tumors (Benign, Borderline, and Malignant) 2. Clinical Presentation 3. Pathology 4. Imaging Findings: - Benign Phyllodes tumor (Mammography, Ultrasound and MRI), - Borderline Phyllodes tumor (Mammography, Ultrasound and MRI), - Malignant Phyllodes tumor (Mammography, Ultrasound and MRI). 5. Differential Diagnosis: Fibroadenoma, Primary Sarcoma of the Breast, Periductal Stromal Tumor of the Breast, Other. 6. Benign vs Malignant Phyllodes Tumors: Key Differences 7. Management, Treatment and Prognosis 8. Conclusion 9. References

### **BREE-79 A Sheep in Wolf's Clothing: The Multiple Appearances of Local Breast Cancer Recurrence After Breast Mastectomy**

Agostina B. Peralta I (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

-Discuss the role of the different image modalities in the surveillance of breast cancer recurrence after breast mastectomy.-Recognizing the imaging and the normal anatomic changes depending on the type of breast mastectomy performed.-Illustrate the imaging findings corresponding to a breast cancer recurrence on different image modalities.-Differentiating post-surgical benign findings from a malignant relapse.

#### **TABLE OF CONTENTS/OUTLINE**

Studies have proven that the presence of local recurrence is an independent predictor for survival this is why radiologist should be familiarized to distinguish normal or benign findings after mastectomy from a recurrence. With the main objective of early detection and treatment. -Briefly review the different surveillance recommendations for these patients given by international societies. -Description of the different surgical breast reconstruction techniques used nowadays will be performed. These include the use of prosthetic implants, autologous tissue flaps, skin and fat flaps. -Illustrations will be shown of the expected anatomic changes after mastectomy on different image modalities depending on the surgical technique. -Images showing and differentiating benign findings from a post-surgical local breast cancer recurrence will be portrait.

### **BREE-8 Comparison of Indications, Reading Time, and Work Flow of FDA Approved Supplemental Screening Automated Whole Breast Ultrasound Tomography in Women With Dense Breasts**

Mary W. Yamashita, MD (*Presenter*) Research Grant, Delphinus Medical Technologies, Inc; Consultant, Delphinus Medical Technologies, Inc

#### **TEACHING POINTS**

- Ultrasound as adjunct to screening mammography for women with dense breasts increases cancer detection. - There are new ultrasound technologies available for same day supplemental dense breast screening. - Invenia ABUS from GE and SoftVue Automated Whole Breast Ultrasound Tomography (SV) from Delphinus Medical Technologies are both PMA-approved for screening and diagnostic purposes. - In clinical practice, ABUS is time-consuming and requires significant reading time. - SV offers benefits of same day supplemental screening with mammography and, unlike other ultrasound imaging, only adds 3-4 mins of reading time per case for the radiologist.

#### **TABLE OF CONTENTS/OUTLINE**

1. Why ultrasound is important in screening women with dense breasts 2. Overview of ultrasound technologies available for dense breast screening 3. Comparison of indications for use 4. Benefits and challenges with integrating ultrasound into

practice for adjunct screening for women with dense breasts: Workflow 5. Reading time: what makes reading ABUS and HHUS challenging in clinical practice, what are the main drivers of the time it takes for radiologist to interpret images including technique and training, number of images, image quality, and artifacts 6. Overview of SV automated whole breast ultrasound 7. Image sequence and reading protocol for SV 8. Example clinical cases demonstrating SV hanging protocol 9. SV reading time study and results 10. Conclusion

## **BREE-80 Do Not Miss Architectural Distortion!**

### **Awards**

#### **Certificate of Merit**

Haydee Ojeda-Fournier, MD (*Presenter*) Research Consultant, View Point Medical, Inc; Stock options, CureMetrix, Inc

### **TEACHING POINTS**

The BI-RADS 5th edition manual defines architectural distortion (AD) as “distortion of the breast parenchyma with no definite mass visible.” AD of the breast is an abnormality found in multimodality breast imaging and occurs with benign and malignant lesions. The most common cause of architectural distortion is a surgical scar. However, 4% of breast cancers present with AD. In addition to being a primary imaging finding, AD may also be an associated finding. In addition, AD is notorious for being a missed mammographic lesion. It is important for radiologists to “train their eyes” to identify AD and to know the differential considerations and pitfalls associated with AD evaluation to avoid potential missed breast cancer. The goals of this educational exhibit are to 1. recognize AD by 2D mammogram, digital breast tomosynthesis (DBT), ultrasound, and MRI, 2. review the differential considerations of AD, and 3. recommend management options and perform radiology-pathology concordance.

### **TABLE OF CONTENTS/OUTLINE**

Introduction; Definition of AD; Multimodality imaging examples of AD of the breast including mammography, sonography, and MRI; Learn a systematic approach to the characterization of AD; AD and DBT; How to appropriately apply the BI-RADS classification and management recommendations of AD; Challenging cases of AD; Pitfalls in evaluating AD: fat-containing, one view only, not seen at biopsy; Discordance in AD rad-path correlation; Sample cases; Conclusion.

## **BREE-81 Non-mass Lesion on Breast Ultrasound: Radiologic-Pathologic Correlation and a Guide to Approach**

Haejung Kim, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Unlike mass, non-mass lesion does not show a three-dimensional structure, so it is more difficult than mass to detect and make an accurate diagnosis on breast ultrasound. For this reason, non-mass lesion evaluation on breast ultrasound often follows the detection of abnormality on other imaging modalities, such as mammography or MRI. This educational exhibit was prepared to increase understanding of non-mass lesions seen on breast ultrasound and to help accurately diagnose benign and malignant non-mass lesions. 1. Review the definition of non-mass lesion on breast ultrasound, 2. Correlate radiologic and pathological findings of benign and malignant non-mass lesions, and 3. Discuss a guide to approach for evaluating non-mass lesions on breast ultrasound.

### **TABLE OF CONTENTS/OUTLINE**

1. Definition of non-mass lesion on breast ultrasound A. True non-mass lesion vs. Normal variants 2. Correlation between radiologic and pathologic findings of non-mass lesions on US A. Imaging features of non-mass lesions on US B. Pathologic features correlated with benign and malignant non-mass lesions 3. Approach for evaluating non-mass lesion on breast ultrasound

## **BREE-82 The Cyst Bang Theory: When to Biopsy**

Claudia L. Ruano, MSc (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. Explain the epidemiology and pathogenesis of breast cyst. 2. Recognize the characteristics by image of breast cysts. The complex cyst is uncommon, but are suspicious of malignancy and merit biopsy. 3. Recognize criteria that will help identify a complex cyst. 4. Identify intraductal papillary nodule. Benign papillomas constitute 85% and 90%, intracystic papillary carcinomas 6% to 7%. 5. Points to help distinguish real from artifacts (echos) on ultrasonography images. 6. Recognize the most important differences in images between complicated and complex cyst. The true papillary nodules are anchored to the wall and do not move with the postural changes of the patient. 7. Analyze when to suspect malignancy in the breast cysts and categorize them based on the BIRADS.

### **TABLE OF CONTENTS/OUTLINE**

1. Introduction 2. Epidemiology and pathogenesis 3. What are complex cysts 4. What should birads assign to a complex cyst 5. Review the spectrum of findings (mammography, us and contrast-enhanced mammography) 6. When to decide biopsy, a

complex cyst 7. Let's practice (illustrative cases) 8. Conclusions

### **BREE-83 Solitary Dilated Duct in the Breast: A Multimodality Pictorial Review**

Zachary R. Zaniewski, DO (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Solitary dilated duct is associated with benign and malignant findings and the BI-RADS classification has varied over previous editions. Solitary dilated duct has characteristic imaging features on multiple modalities. Recognizing the imaging features, particularly if new, is important for management.

#### **TABLE OF CONTENTS/OUTLINE**

Background Review of solitary dilated duct and BIRADS classification. Pictorial Review: Cases illustrating benign and malignant lesions with multiple modalities. Case 1: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound. Pathology: Papilloma without atypia. Case 2: History: Presenting with breast pain. Imaging: Mammogram, ultrasound. Pathology: Invasive ductal carcinoma. Case 3: History: 60-year-old female presenting for screening mammogram. Imaging: Mammogram, ultrasound. Pathology: Papilloma without atypia. Case 4: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound, MRI. Pathology: Papilloma with high-risk features. Case 5: History: Presenting for screening mammogram. Imaging: Mammogram, ultrasound. Pathology: Intraductal papilloma. Case 6: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound, ductogram. Pathology: DCIS. Case 7: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound, ductogram, MRI. Pathology: Multifocal DCIS with intraductal papillomatosis. Conclusion Review pearls for solitary dilated duct findings and management.

### **BREE-84 MRI Detected Lesion in Women with a Personal History of Breast Cancer, and Then?**

Ga-Eun Park, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- Screening is still important for women with a history of breast cancer, because of high risk for future breast cancer. Breast MRI shows impressive resolution with high sensitivity, but specificity is relatively low.
- Second look ultrasound is a well-established approach for MRI detected lesions, and lesions found on subsequent ultrasound have a high probability of malignancy. However, second look ultrasound has limitations, such as operator dependence and the possibility of false negatives. Follow-up is required, and re-biopsy should be considered in case of image-pathology discordant.
- Correlation with mammography can sometimes be helpful. In particular, new or increasing calcifications can be objective evidence for lesion detection and confirmation of biopsy results.
- MR-guided biopsy must be considered in lesions with suspicious MRI features but occult on US or mammography.

#### **TABLE OF CONTENTS/OUTLINE**

<Representative cases of new enhancing lesion on breast MRI>• According to surgical method: op site after BCS, ipsilateral and contralateral breast after BCS, after mastectomy• According to detection modality: second look ultrasound (successful and missed), mammography, MR-guided biopsy for occult lesion• According to biopsy results: recurrence, false positive (benign), false negative (missed)

### **BREE-85 5 Years of False Negative Review from the Mammography Audit: Observations and Lessons Learned**

#### **Awards**

**Magna Cum Laude**

Heather V. Garrett, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

-Review of false negative (FN) cases can refine your mammography practice.-Sensitivity of mammography is limited in dense breasts.-BCT changes can make mammography difficult to interpret. ACR recommends annual screening MRI in patients with a prior history of BCT and dense breasts.-Screening MRI is more sensitive than mammography in the detection of breast cancer. High-risk patients should obtain annual mammography and annual screening MRI alternating at 6 month intervals.-Clinical symptoms (palpable breast lump, nipple discharge, skin changes and focal breast pain) should be evaluated using a multi-modality imaging approach.-BIRADS 3 cases are included in the FN review of diagnostic mammography. 0-2% of these cases may be cancers.

#### **TABLE OF CONTENTS/OUTLINE**

Background: False negative (FN) case review is mandated part of the annual mammography radiologist audit (MQSA/ACR). We are a large academic practice with dedicated breast imagers. We analyzed 135 FN cases from 5 years (2016-2020).Observations: -FN cases tended to be in patients with dense breasts, personal history of breast cancer, prior BCT, elevated life-time risk for breast cancer.-FN cases were mostly detected by presenting clinical symptom or screening MRI.-

Some FN cases were women who had been given the assessment of BIRADS 3 in the diagnostic setting. Cases: 5-10 cases to illustrate teaching points. Lessons Learned: Overall, we found that there are many reasons for FN studies, the minority of which involved "missed cancers." Review of FN cases can refine your mammography practice.

## **BREE-86 Don't Forget About the Nipple: Overview of the Anatomy and Different Lesions Involving the Nipple-areolar Complex**

Maria Guerra, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

To describe the normal anatomy and some anatomic variants of the nipple-areolar complex (NAC). To review imaging anatomy of the NAC by different techniques. To present a pictorial review of commonly known benign and malignant NAC lesions.

### **TABLE OF CONTENTS/OUTLINE**

Anatomy of the nipple-areolar complex  
Retraction  
Inversion  
Imaging anatomy: mammogram, ultrasound, magnetic resonance  
Different lesions:  
Dermal lesions: nipple calcifications, Epidermal inclusion cyst  
Inflammatory lesions: duct ectasia, retroareolar cyst, periductal mastitis, abscess, Zuska disease  
Benign Tumors: Nipple adenoma  
Malignant tumors: papilloma, carcinoma, Paget's disease

## **BREE-87 The Many Faces of Invasive Lobular Carcinoma**

### **Awards**

#### **Cum Laude**

Miral M. Patel, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. Invasive lobular carcinoma accounts for 5-15% of all breast cancers. 2. ILC is characterized by the lack of E-cadherin function, which explains the discohesive growth pattern and the subtle findings in imaging. 3. A review of radiologic and pathologic correlation of invasive lobular carcinoma and its morphologic variants can aid radiologists in recognizing patterns in the imaging presentation of invasive lobular carcinoma to facilitate early detection.

### **TABLE OF CONTENTS/OUTLINE**

This educational exhibit reviews: 1- Basic review of invasive lobular carcinoma 2- Case based discussion of the radiologic presentation and pathologic correlation of the variants of invasive lobular carcinoma including classic, solid, signet ring cell, and pleomorphic 3- Pattern recognition in the presentation of invasive lobular carcinoma

## **BREE-88 Breast Cancer Recurrence: Incidence and Imaging Appearance**

### **Awards**

#### **Certificate of Merit**

Haydee Ojeda-Fournier, MD (*Presenter*) Research Consultant, View Point Medical, Inc; Stock options, CureMetrix, Inc

### **TEACHING POINTS**

Locoregional recurrence has been estimated to occur in 5-25% of breast cancer (BC) survivors, defined as the reappearance of the tumor at the surgical site or metastases in the regional lymph nodes. Even after mastectomy, there is a 2-10% reported lifetime risk of recurrence. Recurrence varies by molecular subtypes of BC, triple negative BC at 2-5 years after and other types at 5-15 years after treatment. Mammography remains the primary imaging modality for post-BCT surveillance. Breast MRI has the highest accuracy for differentiating post-surgical scar from recurrence. By the end of this educational exhibit, the learner will: 1. Learn the incidence, risk factors, and clinical presentation of breast cancer recurrence, 2. Review imaging recommendations for patients with a history of breast cancer and those with suspected breast cancer recurrence, 3. Recognize the common imaging appearance of recurrent breast cancer on multimodality imaging, 4. Distinguish the appearance of recurrent breast cancer from expected post-surgical changes and other differential diagnoses

### **TABLE OF CONTENTS/OUTLINE**

Introduction; Incidence and definition of breast cancer recurrence; Expected recurrence rates based on molecular subtypes of BC; Clinical presentation of breast cancer recurrence; Review imaging recommendations for patients with a history of breast cancer; Review diagnostic workup for patients with suspected breast cancer recurrence; Differential considerations of in-breast recurrence and regional nodal recurrence; A pictorial review of multimodality imaging in BC recurrence; Clinical management of recurrent BC; Algorithm for imaging patients with suspected recurrence; Conclusion

## **BREE-89 AI in Breast Imaging: Current Status and Future Directions**

Berat Bersu Ozcan, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

- Artificial intelligence (AI) in breast imaging is being used for lesion classification, breast density and cancer risk assessment. In screening mammography setting, stand-alone sensitivity of commercially available AI system range 75-85% at radiologists' specificity of 49-79%. This indicates comparable results with radiologist performance (AUC, 0.84 vs 0.81, respectively).
- Beyond screening, a deep learning model trained on uses mammograms and traditional risk factors showed superior performance in predicting 5 year breast cancer risk compared to the Tyrer-Cuzick model. (AUC, 0.70 vs 0.62,  $p < 0.001$ ).
- Model drift is a concept that describes degradation of AI model performance as the data it is used on changes. This raises concerns regarding the performance and reliability of AI models in real-life clinical settings.
- The FDA requires manufacturers of Artificial Intelligence/Machine Learning (AI/ML)-Based Software as a Medical Device (SaMD) to be transparent and monitor the real-world performance of their products to ensure the algorithm meets the standards after deployment.
- In a recent Dutch patient survey most patients (77.8%) did not support stand-alone use of AI in screening interpretation. Furthermore, 41.7% opposed the idea of using AI to select cases for second reading and 17% objected to AI as a second reader.
- The reimbursement for breast imaging AI has not yet been established, and several proposed frameworks are currently under discussion.

## TABLE OF CONTENTS/OUTLINE

Integrating AI Tools to Breast Imaging Workflow: Opportunities, Challenges and Potential Impact Patient Engagement Ethical and Regulatory Perspectives The Future of AI in Breast Imaging

### BREE-9 Navigating Mammary Ducts Pathologies and Anatomy: A Radiological Handbook

#### Awards

#### Certificate of Merit

Giovanna Andreani, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

The breast is an apocrine gland that contains different types of tissue: glandular, fibrous or connective, and fatty tissue. The glandular tissue is composed of mammary lobules and ducts, the latter being a tubular structure with the function of carrying the milk produced by the gland to the nipple. There are several pathologies and variations that can affect the mammary duct, ranging from benign alterations such as ductal ectasia or papilloma to even malignant ones (ductal carcinoma in situ or invasive ductal carcinoma, among others). Knowing that the majority of breast cancer arises from the ductal epithelium, it is crucial in the diagnosis and treatment of breast cancer by detecting intraductal lesions at an early stage. The objective of this study is to didactically review the anatomy and embryology of mammary ducts, as well as the main pathologies that affect this very important structure.

## TABLE OF CONTENTS/OUTLINE

Review of the anatomy and discussion of the radiological findings in the mammary ducts, whether in their normal appearance or pathological changes through the different imaging methods obtained from the digital archive of our institution.

### BREE-90 Beyond the Norm: An Exploration of Extramammary Metastases to the Breast

Berat Bersu Ozcan, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

- Metastases to the breast are rare, comprising 0.5-6.6% of all malignancies in the breast, and typically indicate widely disseminated disease and poor prognosis.
- Lymphoma (17-38.3%), melanoma (8.3-23.4%), lung (8-15%), gynecological carcinomas (8-12.8%), and sarcomas (2%-12%) are the most common primary tumors to metastasize to the breast.
- Imaging features can vary depending on the primary neoplasm and route of dissemination, hematogenous (more common) or lymphatic.
- Typically, metastases present as well-defined masses without calcifications or distortion on mammography and round hypoechoic masses on ultrasound. Hematogenous metastases present as solitary or multiple breast masses located in the skin, subcutaneous tissue, or the breast parenchyma.
- Breast findings should be characterized according to the BI-RADS lexicon and managed according to the most suspicious features. If metastatic disease to the breast is in the differential diagnosis based on patient history and/or clinical presentation, early confirmation of secondary involvement with pre-operative biopsy of breast lesions is crucial to direct appropriate management.
- Breast metastases can be highly vascular, and ultrasound technique should be optimized to not confuse with pseudoaneurysms or aneurysms, which could result in a delay of diagnosis.

## TABLE OF CONTENTS/OUTLINE

1. Literature review 2. Diagnostic algorithm 3. Key clinical and imaging features 4. The diagnostic and prognostic role of imaging modalities 5. Case demonstration and pathologic correlation

### BREE-91 Optimizing DWI for Improved Imaging in Breast Cancer and Beyond

Sheida Ebrahimi, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Diffusion weighted imaging (DWI) is an advanced MRI technique that reflects water diffusion in tissues of interest and has been shown predicting pathologic response to neoadjuvant chemotherapy. It assists radiologists in better detecting and characterizing breast lesions. DWI can be challenging due to the breast morphology and introduction of artifacts. This exhibit reviews current state of DWI in breast cancer imaging including the physics of DWI, protocols utilized, advanced DWI techniques, and current indications. Strategies for optimizing DWI to improve image quality, diagnostic accuracy, and clinical utility will also be reviewed. At the end of this educational exhibit, learners will: 1. Recall the fundamentals of DWI and ADC Values; 2. Describe the correlation between ADC values and breast cancer prognostic factors; 3. Understand DWI challenges and limitations, and strategies for enhancing standard DWI; 4. Classify advanced DWI.

## TABLE OF CONTENTS/OUTLINE

1. Introduction: Overview of DWI and its importance in breast cancer; 2. Fundamentals of DWI: Explanation of water diffusion in tissues; ADC values and their significance in DWI; 3. ADC Values and prognostic factors in breast cancer; 4. Benefits and applications of DWI in breast cancer; 5. Quality control and factors influencing repeatability and reproducibility of ADC measure: Techniques to improve the quality of ADC measurements; 6. Comparison of DWI protocols: QIBA recommendations vs. our institute's approach; 7. Technical challenges and limitations of DWI: Techniques to Improve standard DWI; 8. Classification of advanced DWI: Overview of subtypes of advanced DWI, their differences, and advantages; 9. Conclusion.

## **BREE-92    Swipe Left or Right? The Multimodality Imaging Detection and Assessment of the Solitary Dilated Duct**

### Awards

#### Cum Laude

Tanya W. Moseley, MD, PhD (*Presenter*) Consultant, Hologic, Inc; Consultant, Merit Medical Systems, Inc; Owner, TW Moseley, LLC; CEO, TW Moseley, LLC

## TEACHING POINTS

- Review ductal anatomy and the epidemiology of ductal disease.
- Discuss imaging findings of benign and malignant ductal disease.
- Discuss the solitary dilated duct (SDD) and review the BI-RADS® 5th edition's recommendations for classifying and managing ductal lesions.
- Describe the role of imaging in the screening and diagnosing of ductal disease including mammography/tomosynthesis, ultrasound, magnetic resonance imaging, and galactography/ductography.
- Review methods and challenges specific to the sampling of ductal abnormalities.

## TABLE OF CONTENTS/OUTLINE

-Introduction-Anatomy-Benign ductal findings-Malignant ductal findings-Solitary dilated duct (SDD) BI-RADS® 5th edition's recommendation-Imaging's role in screening and diagnosis and the correlation with prognosis-Imaging Techniques to evaluate the ductal anatomy and pathology-Methods to sample ductal abnormalities and tips to overcome the challenges that may be encountered-Conclusion

## **BREE-93    Idiopathic Granulomatous Mastitis: A Case-Based Review**

Layne Kelley, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. Idiopathic granulomatous mastitis (IGM) is estimated to affect 2.4/100,000 women, at median age of 36.5 years, and bilateral involvement in 8.8%. 2. Common symptoms are pain, erythema, palpable lump, and less frequently, fistulous drainage or nipple discharge. 3. The most common ultrasound findings are hypoechoic collection (75.9%) and skin involvement (53.5%). Mammography is often nonspecific, but common findings include focal asymmetry (51.6%), global asymmetry (18.3%), mass (17.2%), abnormal lymph nodes (8.6%). 4. IGM can mimic infectious mastitis or breast cancer on imaging and clinically. 5. Biopsy is usually required to confirm diagnosis and guide management. Often biopsy is necessary to exclude malignancy, especially inflammatory or triple-negative subtypes. Suspected IGM may be tentatively diagnosed by clinically assessing treatment response, but given overlap of imaging features and different treatment for IGM and infectious mastitis, biopsy is often needed. 6. Imaging findings often persist after resolution of clinical symptoms, thus clinical follow-up should be the mainstay for surveillance.

## TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Typical imaging findings on mammography and ultrasound 3. Other entities that mimic IGM 4. Case-based review of biopsy-proven cases using key images with descriptions, treatment and clinical outcome data 5. Biopsy and management considerations

## **BREE-94    Don't Be Fooled: Not Every Late-Onset Peri-Implant Effusion is Seroma! A Case-Based Review of Breast Implant-Associated Anaplastic Large Cell Lymphoma (BIA-ALCL)**

Larissa L. Botelho, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

We report the case of a female patient, with a history of mammoplasty six years ago, reporting sudden enlargement of the left breast. Imaging exams showed the presence of peri-implant fluid in the same breast, with the analysis of the fluid confirming the BIA-ALCL. Breast Implant-associated Anaplastic Large Cell Lymphoma (BIA-ALCL) is characterized by a late-onset peri-implant effusion, appearing on average 10 years after exposure to breast implants. The pathogenesis is not completely identified, but it is known that cases of BIA-ALCL are related to textured prostheses, with the surface of the prosthesis being the most important factor in inducing the disease. It may present only with the effusion (subtype of effusion) or associated with a peri-implant mass (mass-forming disease). The main associated symptoms are sudden edema secondary to the peri-implant effusion and, in case of mass-forming disease, the presence of a palpable nodule. Multiple imaging methods can be used in the evaluation of patients with suspected BIA-ALCL. However, diagnostic confirmation depends on the analysis of the fluid found. The diagnosis of BIA-ALCL is made with the characterization of morphologically atypical lymphocytes, with CD30 expression and negativity for ALK-1. The differential diagnosis of the effusion subtype is made with late seroma. Distant disease is rare, being a neoplasm with a high potential for cure, if identified in the early stages and when not associated with masses, with a surgical approach as a curative technique, in the case of the subtype of effusion.

### **TABLE OF CONTENTS/OUTLINE**

Introduction; Definition and Subtypes; Pathogenesis; Symptoms; Image Methods; Diagnosis; Differential diagnoses

### **BREE-95 Cystic Breast Lesions- What to Do When It's Not Simple**

#### **Awards**

#### **Certificate of Merit**

Laura K. Harper, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Imaging features of benign and malignant cystic lesions may overlap, causing misclassification with the potential to produce diagnostic delay and harm. The purpose of this exhibit is to review ultrasound features of benign and malignant cystic breast masses to guide appropriate characterization and management. The Breast Imaging Reporting and Data System (BIRADS) assessment categories will be reviewed as it pertains to cystic breast masses, including review of appropriate utilization of the BIRADS-3 (probably benign) assessment category. Emphasis will be placed on recognizing suspicious imaging features warranting further evaluation with percutaneous biopsy. Teaching Points: 1. Examine imaging features of various cystic breast masses (Simple cysts, complicated cysts, and complex cystic and solid mass). 2. Discuss overlap of benign and malignant complex cystic and solid masses (ex: hematoma, abscess, cancer). 3. Review appropriate BI-RADS category assessment and management for various cystic lesions

### **TABLE OF CONTENTS/OUTLINE**

1. Introduction of the prevalence, clinical presentation and patient factors associated with cystic breast masses 2. Review distinguishing features and BI-RADS category assessments for various cystic masses 3. Multimodality (mammography, contrast-enhanced mammography, ultrasound, and magnetic resonance imaging) case-based review of benign and malignant cystic breast masses 4. Conclusion (summary of key educational points)

### **BREE-96 Patterns of Breast Cancer Recurrence in the Post-Mastectomy Breast with or without Reconstruction: A Case-Based Review**

Shannon Lanzo, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. Women treated for breast cancer with mastectomy with or without reconstruction are at risk of developing loco-regional recurrence along the suture line or within residual tissue. 2. Benign post-operative findings include edema, seroma, hematoma, fat necrosis, post-operative scarring and fibrosis, which evolve over time. 3. Recurrence may be difficult to distinguish from these benign findings. 4. Biopsy is warranted when imaging findings are equivocal.

### **TABLE OF CONTENTS/OUTLINE**

1. This case-based exhibit will review the expected post-operative appearance post mastectomy without or with reconstruction using autologous tissue flaps (pedicled or free flap), and/or prosthetic implants. 2. We will illustrate typical imaging features of benign post treatment changes (fat necrosis, fibrosis, edema, skin thickening, etc.) and malignant findings on mammogram, ultrasound, and MRI. 3. We will review appropriate use of combined imaging and biopsy methods when imaging findings are equivocal.

### **BREE-98 Diagnostic Potential of Photon-Counting Detector Computed Tomography to Evaluate Breast Cancer Patients**

Misugi Urano, MD, PhD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Photon-counting detector computed tomography (PCD-CT) has several advantages over energy-integrating computed tomography (EID-CT). It provides high spatial resolution and improves image contrast, resulting in precise visualization of soft tissue and microstructures while reducing radiation dose. In addition, a simultaneous multi-energy acquisition offers further qualitative and quantitative information in a single scan. These benefits make PCD-CT a valuable tool for systemic staging, preoperative planning, and post-treatment monitoring of breast cancer patients due to its ability to precisely depict the local extent of tumors and the presence of small lesions. This presentation will focus on PCD-CT in initial staging workup, treatment response assessment, or recurrences monitoring in breast cancer patients, comparing to EID-CT, other image modalities, and pathological results. We will also discuss the advantages and pitfalls of PCD-CT.

## TABLE OF CONTENTS/OUTLINE

1. Current CT recommendation for breast cancer patients in guidelines 2. The potential of PCD-CT for breast cancer workup 3. Case-based review of PCD-CT in breast cancer patients compared to EID-CT, other image modalities, and pathological results. 4. Discussion of the utilities of PCD-CT for breast cancer patients, including advantages, disadvantages, and pitfalls.

## BREE-99 Breast Ultrasound Tomography: The Essentials for the Breast Radiologist

Yu Zhao, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

This educational exhibit will review the essentials of breast ultrasound tomography. 1. Understand basic concepts of breast ultrasound tomography including essential physics, the basic imaging sequences, and keys to imaging interpretation. 2. Describe the advantages of breast ultrasound tomography for evaluation of the breasts, especially in those with dense breasts. 3. Describe the specific imaging appearance on ultrasound tomography of various breast entities, benign and malignant. 4. Discuss the future practice considerations and limitations of ultrasound tomography.

## TABLE OF CONTENTS/OUTLINE

-This educational exhibit reviews the essentials of breast ultrasound tomography for the breast radiologist. This is a new imaging modality with enormous potential to add new value to breast imaging by improving diagnostic accuracy especially in patients with dense breasts. -We will describe in simple terms the physics of breast ultrasound tomography and the basic imaging sequences including Waveform Enhanced Reflection (Wafer), Reflection, Sound Speed, and Stiffness Fusion sequences in a breast ultrasound tomographic examination.-We will review with illustrative case examples of high-yield breast lesions including cysts, fibroadenomas, and cancers comparing the distinctive imaging appearance on ultrasound tomography versus other breast imaging modalities.-This will be followed by a discussion of the specific advantages of ultrasound tomography relative to other imaging modalities, such as improved lesion localization and lesion characterization. Finally, we will present the limitations of ultrasound tomography and general considerations for future practice.

### Pathologic Nipple Discharge: Is Breast MRI a Good Option?

All Day Room: Learning Center

Valeria Vidales (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Pathologic nipple discharge (PND) is unilateral, spontaneous, involves a single duct, and is serous or bloody in appearance. MRI is able to detect the etiology of nipple discharge in 56-61% of cases when initial imaging with mammogram and ultrasound are negative. To describe differential diagnosis and its classification in BIRADS system.

#### TABLE OF CONTENTS/OUTLINE

Description of the anatomy of the nipple and retroareolar Description of different types of lesions that could be found in patients with nipple discharge US, mammographic and RM principal findings and its correlations. Sample cases

Printed on: 08/22/24

## Abstract Archives of the RSNA, 2023

BREE-10

### Single Duct Abnormalities: Multimodality Imaging and Assessment

All Day Room: Learning Center

Juliana Sitta, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Ductal abnormalities entail a wide range of pathology that may present clinically or grow silently, ranging from benign to malignant processes. Solitary dilated duct is a rare mammographic finding with controversial clinical significance in the literature. Workup of the solitary dilated duct must include additional mammographic views and ultrasound to assess for additional findings that would raise suspicion for malignancy and provide a biopsy target. Ductal ectasia is the most common benign finding; however, atypical presentations such as peripheral location, wall thickening, and hypoechoic tissue should raise suspicion for secondary obstruction causes. Inspissated secretions can mimic intraductal masses and may be seen in association or secondary to acute and chronic mastitis, ductal ectasia, and intraductal papilloma. Patients with papillomatosis often have associated high-risk lesions and an increased lifetime risk of breast malignancy. MRI is a great adjunct to evaluate nipple discharge, particularly when the initial workup is negative, and to exclude underlying DCIS or invasive ductal carcinoma.

#### TABLE OF CONTENTS/OUTLINE

Review and illustrate ductal anatomy, physiology, and normal findings on multimodality imaging, including mammography, ultrasound, galactogram, and MRI. Illustrate and discuss problem-solving for single duct findings and presentations commonly associated with single duct abnormality with interesting cases from our institution. Analyze the added value of multiple imaging modalities in assessing ductal pathology, including galactogram and MRI.

BREE-100

### The Leading Role of Ultrasound in Breast Implant Evaluation in Developing Countries

All Day Room: Learning Center

Giannina M. Secco, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

To illustrate ultrasound findings in breasts with implants and their comparison with those in magnetic resonance imaging. To discuss the advantages and limitations of ultrasound for breast implant evaluation and why it remains a valuable and irreplaceable tool in underdeveloped and developing countries.

#### TABLE OF CONTENTS/OUTLINE

Detecting a broken breast implant is essential due to the potential physical discomfort, cosmetic deformity, and health risks associated with a ruptured implant. Early detection and prompt treatment of a broken implant are crucial to prevent further complications and ensure optimal patient outcomes. Knowledge of a ruptured implant can help patients make informed decisions about implant replacement or removal. In order to acknowledge this, we believe breast implant ultrasound is a preferable choice to MRI for breast implant evaluation in underdeveloped and developing countries. Breast implant ultrasound is more cost-effective, with often portable machines, non-invasive procedure that does not require the use of contrast agents or ionizing radiation, provides real-time imaging, does not require anesthesia and is widely available in many healthcare facilities. Ultrasound imaging can be performed and interpreted quickly, allowing clinicians to make prompt treatment decisions. Furthermore, breast implant ultrasound is safe for patients with pacemakers or other implanted devices, while MRI may not be feasible for these patients. Although ultrasound has its limitations in some cases, it remains a valuable and irreplaceable tool for breast implant evaluation in underdeveloped and developing countries.

### Radiological Signs in Breast Imaging: What Should the Radiology Resident Know?

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Karina Pesce, PhD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1.To know recognize the different radiological signs in breast imaging.2.To learn the importance of accurate identification of the different radiological signs.

#### TABLE OF CONTENTS/OUTLINE

Introduction This educational poster reviews the importance of understanding breast radiological signs. Accurate identification of different radiological signs is critical for early diagnosis and effective treatment of various medical conditions, including breast cancer. Furthermore, knowledge of clinical and radiological signs in breast imaging can help prevent diagnostic errors and reduce the number of unnecessary medical tests. Description of the radiological signs in breast imaging. Tips and techniques for identifying these signs are also provided to assist residents in their interpretation of medical images. interactive clinical cases for self-evaluation. These cases offer residents the opportunity to apply their knowledge and receive immediate feedback, thereby strengthening their diagnostic skills and decision-making abilities. Conclusion: Radiologists residents must be familiar with different radiological signs to accurately interpret medical images and provide an accurate diagnosis.

### Peer Learning in Breast Imaging: Lessons Learned in Our Institution

All Day Room: Learning Center

Marcela C. Lauer, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

It is estimated that medical diagnostic mistakes contribute to approximately 10% of patients deaths and 17% of adverse events in hospitals. Consequently, optimal patient care is related to recognizing and preventing such errors. Strategies were developed to ensure performance standards in radiology departments, including score-based second-reader peer review systems. However, this type of strategy may be associated with subjectivity, sampling bias, underreporting of errors due to peer relationships and fear of punitive action. It may have emotional impact for radiologists and lead to feelings like anxiety, shame, and humiliation, contributing to a culture of defensiveness. On the other hand, peer learning is an strategy focused on learning and improvement that has gained momentum, as a respectful nonpunitive collaborative culture improves performance in modern radiology practice. The objective of this presentation is to show how we established peer learning in our breast imaging department, the bias that were related to the mistakes we made, how we concluded they could have been avoided and our experience with peer learning as a group. We aim that this presentation may help and encourage other services to implement peer learning in their clinical practice, and also learn from the multimodality imaging cases we provide.

#### TABLE OF CONTENTS/OUTLINE

Didactic case-based reviews of breast imaging exams (including mammography, ultrasound and magnetic resonance imaging performed in our service) that were discussed in our peer learning meetings in the last 5 years, with correlation of associated cognitive bias, how the cases could have been better managed and lessons learned that changed our daily practice.

### Multimodality Surveillance of Breast Implants in Asymptomatic Patients and the Potential Challenges for the Radiologist in Light of the 2022 United States Food and Drug Administration (FDA) Guidelines

All Day Room: Learning Center

H. Carisa Le-Petross, MD, FRCPC (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Recently the United States Food and Drug Administration (FDA) implemented changes to breast implant surveillance that radiologists may not be aware of<sup>1,2</sup>. At the end of this exhibit, the participant will:

- Be up-to-date on the 2022 FDA guidelines for breast implant screening.
- Learn the common signs of implant rupture on ultrasound (US).
- Learn the common signs of implant rupture on magnetic resonance imaging (MRI).
- Be familiar with implant complications and new technology to minimize some complications<sup>3</sup>.
- Be familiar with some key differences between updated FDA guidelines and the imaging recommendations from the American College of Radiology Appropriateness Criteria.

#### TABLE OF CONTENTS/OUTLINE

- Discuss the changes in the 2022 FDA guidelines for breast implant screening, especially the addition of US as an alternative to MRI for initial imaging surveillance for silicone implant rupture in asymptomatic patients<sup>1-4</sup>.
- Discuss the 2022 FDA guidelines recommendation for the first screening imaging test at 5 years after implantation instead of 2 years after implantation, the lack of compliance from patients, and background behind this change<sup>1-5</sup>.
- Discuss the potential controversies regarding the imaging modality of choice to evaluate for implant rupture via case-based presentation<sup>4</sup>.
- Review the imaging signs of implant rupture on different modalities, focusing mainly on US and MRI. Review benefits and/or challenges of new implants, technology such as acellular dermal matrix (ADM), and new generation tissue expanders.

### Abnormality of the Duct on Breast Ultrasound: Comparison with Multimodality, Correlation with Pathological Findings, and Assessment

All Day Room: Learning Center

Ken Oba, MD, BArch (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The 6th edition of BI-RADS is expected to include nonmass lesions detected on breast ultrasound. In breast imaging, it is important to comprehend lesions such as ductal carcinoma in situ which do not form masses but appear as abnormalities of the ducts. Ultrasound is the best imaging tool for a detailed evaluation of the ducts. Although definitions and terminology for ductal abnormalities may vary in the literature, there is a growing interest among Asian countries regarding ultrasound findings of ductal abnormalities. In this review, we present a method for detecting and evaluating ductal abnormalities based on a detailed comparison with pathological findings. To understand and organize the terminology found in various literature and guidelines, as well as the corresponding findings. To become familiar with normal anatomy and identify findings accurately. To compare expected findings in other modalities with pathological findings. To discuss evidence-based assessment and management plan for each finding.

#### TABLE OF CONTENTS/OUTLINE

Normal anatomy Methods of detection Terminology Comparison with multimodality and correlation with pathological findings Assessment and management plan of each pathological finding Case studies The included cases are as follows: Ultrasound findings Ductal dilatation Duct dilatation with internal echoes Duct wall thickening Irregularity of the ductal caliber Pathological diagnoses Duct ectasia Fibrocystic change Intraductal papilloma (IDP) Atypical ductal hyperplasia Ductal carcinoma in situ (DCIS) Ductal carcinoma in situ with invasive component Invasive ductal carcinoma (IDC)

### Diagnostic Approach and Assessment of Cystic Breast Lesion

All Day Room: Learning Center

Hyo Soon Lim, MD, PhD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Cystic masses are common findings on mammography, ultrasonography, and MR imaging and a thorough understanding of their imaging findings and management is important. 2. It is important to obtain US images with meticulous technique for accurate classification and assessment of cystic breast lesions. 3. Complex cystic and solid masses may have one or all of the following characteristics: a thick wall ( $\geq 0.5$  mm), thick internal septations, an intracystic mass, and both solid and cystic components. 4. Complex cystic and solid masses are usually assessed as suspicious (BI-RADS category 4) and accompanied by a recommendation for biopsy.

#### TABLE OF CONTENTS/OUTLINE

A. Definition of cystic breast lesions 1. Simple cyst 2. Complicated cyst 3. Clustered microcysts 4. Complex cystic and solid mass B. Meticulous technique in evaluating cystic breast lesions on US C. Multimodality imaging findings with important differential diagnosis 1. Simple or complicated cyst vs. Nearly anechoic solid mass on US 2. Inflamed or ruptured cyst vs. Rim enhancing mass on breast MRI D. Imaging-pathologic correlation of complex cystic and solid mass E. Diagnostic approach and BI-RADS assessment of cystic breast lesions F. Management of cystic breast lesions

BREE-108

### Breast Malignancy: Beyond Breast Carcinoma

All Day Room: Learning Center

Alex Gil Ordonez, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

- To provide the basis for recognizing morphological and functional imaging findings of non-epithelial and metastatic lesions of the breast (B5d, NHSBSP).- To review the most common B5d lesions through a pictorial review of our cases.- To describe the clinical management of B5d lesions and the role of the radiologist in these cases.

#### TABLE OF CONTENTS/OUTLINE

1.Introduction 1.1. NHSBSP classification. 2. B5d lesions through a pictorial review of our cases. 2.1. Metastatic disease. 2.2. Oncohematological disease. 2.3. Sarcomas 3. Imaging features 4. Management 5. ConclusionsThe vast majority of malignant breast neoplasms are breast carcinomas. Nevertheless, some malignant breast lesions present different histologies, which are commonly less suspicious than carcinomas on imaging techniques. Their recognition is essential to an early diagnosis and therapeutic approach.

## Abstract Archives of the RSNA, 2023

BREE-109

### Vague and Nebulous: Non-Mass Ultrasound Lesions

All Day Room: Learning Center

Craig Wilsen, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

(1.) To review descriptors of ultrasound (US) non-mass lesions. (2.) To illustrate US non-mass lesions identified as correlates for breast MRI non-mass enhancement. (3.) To demonstrate methods for locating US non-mass lesions as correlates for breast MRI non-mass enhancement.

#### TABLE OF CONTENTS/OUTLINE

Introduction: Ultrasound (US) correlates of MRI-detected non-mass enhancement (NME) may have no defined mass-like sonographic margin or shape, or may show subtle disruptions of the background tissue pattern. A new US lexicon term, non-mass lesion (NML), better describes these US findings. Cases: This educational exhibit will show 10 cases of US NML corresponding to MRI NME. We will highlight methods of predicting the US appearance and location of the NML on MRI-directed US by the use of breast architecture, surrounding cysts/masses, and use of the MRI appearance to predict the size and shape of the NML. Histopathologies include breast cancer, radial scar, sclerosing adenosis, fibrocystic change and fat necrosis. Conclusion: The exhibit illustrates subtle US NML correlates to MRI NME. Techniques for successful MRI-directed ultrasound detection of these findings are described. Once correlation is confirmed, US-guided biopsy, which is more expeditious than MRI-guided biopsy, can be performed.

Printed on: 08/22/24

### Male Breast Lesions: To Infinity and Beyond

All Day Room: Learning Center

Camila F. Guimaraes, PhD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Teaching Points: Male breast disease encompasses both benign and malignant conditions that are hormonally influenced. Gynecomastia and skin lesions are the most common conditions in symptomatic men, referred for a palpable mass, with imaging patterns that can correlate with different histopathological phases. Other benign tumors in male breasts include lipoma, pseudoangiomatous stromal hyperplasia, granular cell tumor, fibromatosis, myofibroblastoma, schwannoma, and hemangioma. The incidence of breast cancer in men is rare but has increased and accounts for 1% of all breast carcinomas, with invasive ductal carcinoma being the most common type in adult males. Other tumors that may occur include papillary carcinoma, invasive lobular carcinoma, adenoid cystic carcinoma, liposarcoma, dermatofibrosarcoma, pleomorphic hyalinizing angiectatic tumor, basal cell carcinoma of the nipple, hematopoietic malignancies, and secondary tumors. Understanding the clinical and imaging characteristics of these tumors is important for their accurate diagnosis and optimal treatment.

#### TABLE OF CONTENTS/OUTLINE

Table of Contents/Outline: This article examines the clinical, radiological, and pathological characteristics of both benign and malignant tumors of the male breast. Cases of male breast disease were selected from the file of the Breast Radiology group of our hospital showing some of these pathologies: 1. Complicated Cyst; 2. Dermoid Cyst; 3. Myxoid Liposarcoma; 4. Hybernoma.

### From Words to Images: Applying the Contrast Enhanced Mammography BI-RADS® Lexicon

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Mitva J. Patel, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The American College of Radiology Breast Imaging Reporting and Data System (ACR BI-RADS®) lexicon is widely used in clinical practice and is a standardized nomenclature used for mammographic reporting. Recently, an extension of the lexicon was developed for the interpretation and reporting of contrast-enhanced mammography (CEM) findings. Adopting the American College of Radiology (ACR) Contrast Enhanced Mammography (CEM) Lexicon is important as standardization reduces inter-observer variability and improves the accuracy and reliability of diagnostic reporting, which ultimately leads to better patient outcomes. Education on this new topic is essential as adoption of the lexicon is critical to assist standardize reporting, improve patient care, and facilitate communication between radiologists and clinicians.

#### TABLE OF CONTENTS/OUTLINE

I. CEM Lexicon classification for recombined images?A. Background parenchymal enhancement?1. Level?2. Symmetry?B. Lesion conspicuity?C. Masses?-Internal enhancement characteristics?D. Non-mass enhancement?-Distribution?E. Enhancing asymmetry?II. Interpretation?A. Findings on low energy images only?B. Areas of enhancement seen on recombined images only?C. Low energy images with associated enhancement on recombined images

Printed on: 08/22/24

BREE-111

### The Power of Contrast: Contrast Enhanced Mammography in the Diagnostic Clinic

All Day Room: Learning Center

Mitva J. Patel, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

We hope that by highlighting the practical uses of CEM and its potential to enhance breast cancer detection in the diagnostic clinic, more practices will embrace this powerful technology. Contrast enhanced mammography (CEM) is an imaging technique that combines standard mammography with iodinated contrast to improve breast cancer detection. By highlighting areas of increased vascularity associated with malignancy, CEM has been shown to improve the sensitivity of mammography, particularly in women with dense breast tissue. Despite these well-known benefits, the adoption of CEM in clinical practice has been slow, owing primarily to the difficulties establishing a CEM program and reimbursement. Despite these challenges, we believe the benefits it brings to the diagnostic clinic outweigh the additional effort. CEM may be used to: -resolve equivocal findings on mammography, and to increase confidence prior to stereotactic biopsy for vague areas of architectural distortion. -as a more efficient, accessible alternative to MRI in pre-operative extent of disease and workup of highly suspicious findings identified on screening mammography. We hope that by highlighting the practical uses of CEM and its potential to enhance breast cancer detection in the diagnostic clinic, more practices will embrace this powerful technology.

#### TABLE OF CONTENTS/OUTLINE

Examples provided will demonstrate how CEM impacted these patients' management and supports the notion that CEM has a place in the diagnostic clinic as a cost-effective and time-efficient alternative to breast magnetic resonance imaging (MRI) for select patients.

### **Common Enough to Care - Young Women with Breast Cancer: Multidisciplinary Approach and Special Considerations**

All Day Room: Learning Center

Grace DeWitt, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Breast cancer in young women, widely accepted as women under 40 years of age, has a worse prognosis compared to older patients as young age is an independent predictor of adverse breast-cancer specific outcomes, including morbidity, local and systemic recurrence, and death. Historically, young women have been underrepresented in clinical trials and undergo more aggressive therapy solely based on their young age. As it is important to recognize how these women differ from older patients, the teaching points of this presentation are to: 1. Describe the epidemiology, clinical presentation, and tumor biology of young women with breast cancer. 2. Define imaging guidelines in high-risk populations and in young women after diagnosis of breast cancer. 3. Explain surgical management and surgical risk reducing strategies. 4. Highlight the special considerations unique to young women including the effects of oncology treatment on fertility and lactation and describe fertility preservation techniques.

#### **TABLE OF CONTENTS/OUTLINE**

1. Appearance of breast cancer in young women: Epidemiology and clinical presentation, Tumor biology; 2. Imaging guidelines: Risk factors and assessment, Genetics based or calculated lifetime risk, Diagnosis and staging; 3. Surgical management: Breast conserving vs. mastectomy, Cosmetic options, Risk reducing strategies; 4. Effects of oncology treatment on fertility: Chemotherapy, Hormone therapy; 5. Fertility Preservation Techniques

Printed on: 08/22/24

### Breast US: A Guide for Beginners

All Day Room: Learning Center

Erica E. Francolin Federicci, PhD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Ultrasonographic characterization of mammographic abnormalities and palpable lesions is indicated in the evaluation and management of breast diseases. Although in the United States breast ultrasounds (US) are performed by sonographers, in many countries it is performed by physicians. Considering that breast screening US as an adjunct to mammography will be more widely practiced in the United States, the Breast Imaging-Reporting and Data System (BI-RADS®) provides training and performance guidance as set forth in ACRIN 6666. Because the effective use of the US lexicon relies on excellent sonographic technique and understanding of breast anatomy, the objective of this presentation is to didactically illustrate how the BI-RADS® recommendations should be followed, including the most common findings, pitfalls and how to avoid them.

#### TABLE OF CONTENTS/OUTLINE

We used ultrasonographic images (in correlation to mammography and magnetic resonance imaging, when appropriate) from our institution's digital archive, in order to provide a case-based didactic review of the most common findings in breast ultrasounds, including a review of the adequate technical parameters, lexicon and reporting system and tips to avoid common pitfalls, based on the BI-RADS® recommendations.

### Pseudo-progression During Immunotherapy: A New Challenge for Breast Radiologists

All Day Room: Learning Center

#### Awards

##### Cum Laude

Aline D. Guimaraes, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Immunotherapy has emerged as a promising treatment strategy for advanced breast tumors. Immune checkpoint inhibitors (ICI) such as blockades that target programmed death-1 (PD-1), programmed death-ligand 1 (PD-L1) and cytotoxic T-lymphocyte associated antigen (CTLA-4), are one of the most powerful tools in the immunotherapy armamentarium and offer a beneficial immunotherapeutic regimen for patients with breast cancer. The pattern of treatment with immunotherapy is totally different from other therapeutic modalities, thus bringing major challenges to clinicians and radiologists who are not familiar with it. One of these challenges is pseudoprogression, that can be characterized as a transient increase of tumor burden followed by tumor regression. Although rare, it is fundamental for the radiologist to be aware of this condition and to carry out studies in the direction of finding diagnostic tools that are capable of more accurately identify this phenomenon contributing for better patient outcomes. In this didactic exhibit, we will discuss the basis of immunotherapy in breast cancer, demonstrate imaging findings of cases of breast cancer pseudoprogression and discuss the current tools available to identify the possibility of this condition such as biomarkers, imaging techniques and biopsy.

#### TABLE OF CONTENTS/OUTLINE

1) Basis of immunotherapy 2) Definition of pseudoprogression 3) Tools used to identify pseudoprogression 3.1) Biomarkers 3.2) Medical imaging 3.3) Biopsy 4) Cases of breast cancer pseudoprogression

### **Contrast-enhanced Mammography in Breast Cancers for Women with Dense Breasts: Accuracy, Value, Controversies and Solutions**

All Day Room: Learning Center

Bingmei Zhang, MBBS, MMedSc (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

The purpose of this exhibit is: 1. To familiarize the reader to what CESM implies as an emerging modality and its implementation for breast imaging. 2. To demonstrate diagnostic accuracy and correlation in lesion size estimation of CEM against DCE-MRI in dense breast patients. 3. To illustrate value of CEM in evaluating BI-RADS 4 microcalcifications including morphology, distribution and neovascularity of microcalcifications. 4. To discuss whether CEM can be an effective imaging tool in pre-surgical planning for women with dense breast parenchyma. 5. To highlight the benefits and deficits of CEM in women with dense breast who are at an increased risk of developing breast cancer.

#### **TABLE OF CONTENTS/OUTLINE**

1. Brief overview about the different approaches in CEM and their features in imaging interpretation (temporal subtraction and dual energy technique). 2. Cancer evaluation in the dense breast and review of cases, comparing CESM with MRI in the assessment of disease extent in breast carcinomas. 3. Practical application of CEM with illustrated clinical examples in evaluating BI-RADS 4 microcalcifications in dense breast. 4. Is CESM adequate and accurate in pre-surgical planning for women with dense breast. 5. Advantages vs. drawbacks of CEM and potential pitfalls elucidation for high risk screening for women in dense breast. 6. The future applications of CEM in breast evaluation.

### Preoperative Wire and Wireless Localizations Gone Wrong: How to Get Out of Trouble

All Day Room: Learning Center

Sheila S. Enamandram, MD, MBA (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Accurate, thoughtful planning of preoperative image-guided wire or wireless localizations is critical for breast conservation surgery, especially in complex imaging scenarios. Target lesion visualization and localization may require more than one imaging modality and/or a non-routine approach for difficult marker/target localizations. Understanding the differences in size, appearance, and deployment techniques of localization devices is important in accurate placement and retrieval. Targeted markers may be found in unexpected places when not seen in the initial specimen radiograph. Clear communication with surgical colleagues is paramount.

#### TABLE OF CONTENTS/OUTLINE

This case-based exhibit will highlight anatomic, procedural, and technical troubleshooting steps in the following scenarios: Biopsy marker, wire, or wireless device migration; Biopsy marker non-visualization; Target not marked at time of initial biopsy; Target obscured or visible on only one imaging modality; Wireless radar reflector malfunction; Alternative imaging modalities needed for localization; Biopsy marker not seen in the specimen and ultimately found in unexpected places; Incomplete retrieval of distal hook wire in the specimen.

### Staying Vigilant: Imaging Surveillance and Risk Prediction After Breast Cancer

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Beatriu Reig, MD, MPH (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Patients with a personal history of breast cancer have 5-20% recurrence rates and are at increased risk of second breast cancers. 2. Risk factors for recurrent or second breast cancer include dense breasts, young age at diagnosis of the first breast cancer, omission of radiation after breast conserving therapy, and hormone receptor negative first breast cancer. 3. Imaging biomarkers such as background parenchymal enhancement are under investigation and may permit personalized risk prediction and guide surveillance recommendations in the future.

#### TABLE OF CONTENTS/OUTLINE

1) Introduction (definition, statistics, localized vs metastatic recurrence, early vs late recurrence) 2) Risk factors for recurrence a) Association of molecular subtypes with risk for recurrence b) Effect of neoadjuvant chemotherapy c) Modifiable risk factors (aromatase inhibitor or tamoxifen after ER+ cancer, alcohol consumption, weight) 3) Screening methods for recurrence a) Mammography b) Ultrasound i) Inclusion of the axilla c) MRI i) Abbreviated vs full-protocol d) Contrast-enhanced mammography 4) What should be the imaging interval? 5) Post-mastectomy imaging 6) Risk models for individualized screening a) Clinicopathologic factors b) Imaging biomarkers c) Radiomics and artificial intelligence models

### **Breast Cancer or Not? An Interactive Case-Based Review of FDG-PET/CT Positive Findings in the Breast**

All Day Room: Learning Center

#### **Awards**

##### **Certificate of Merit**

Emily O. Yoon, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Background Interpretation of lesions with increased FDG uptake in the breast can be challenging due to nonspecific uptake in various benign and malignant processes involving the breasts. Knowledge of this wide spectrum is essential for accurate analysis of FDG-PET/CT in conjunction with a patient's symptomology. The purpose of this educational exhibit is to illustrate the multi-modality imaging appearance of various benign and malignant processes that demonstrate hypermetabolic activity within the breast on FDG-PET/CT. Teaching Points Differentiate various benign and malignant processes that can result in hypermetabolic lesions in the breast Understand sensitivity and specificity of FDG-PET/CT for breast cancer and metastatic breast lymphadenopathy Conclusion There is a wide range of benign and malignant conditions presenting as hypermetabolic breast lesions on FDG-PET/CT. Knowledge of the various imaging features is important for accurate diagnosis and patient management.

#### **TABLE OF CONTENTS/OUTLINE**

This presentation will be case-based with review of clinical history and imaging findings (mammogram, US, MRI, PET/CT) of patients with FDG-PET positive findings in the breast. Several benign and malignant pathologies will be reviewed, as outlined below. Teaching points with recent literature review will provide guidance when non-breast cancer pathology should be suspected in cases, while also highlighted when additional dedicated breast imaging is indicated. Breast implant capsule-associated squamous cell carcinoma Reactive lymphadenopathy Metastatic disease Granulomatous mastitis Fat necrosis Inflammatory breast cancer Gynecomastia Infectious/Inflammatory changes

BREE-15

### The Role of DBT-Guided Biopsy for MRI/CEM Detected Lesions

All Day Room: Learning Center

Cesar Urtasun Iriarte I, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

To emphasize the need to correlate MRI/Contrast Enhanced Mammography (CEM) findings with DBT (Digital breast tomosynthesis). To show the advantages of DBT-guided biopsy compared to MRI-guided biopsy. To consider DBT-guided biopsy as an alternative for CEM-detected lesions.

#### TABLE OF CONTENTS/OUTLINE

INTRODUCTION: Both MRI and CEM are morphofunctional imaging techniques based on neoangiogenesis. These techniques are more sensitive than pure morphological techniques, such as DM or DBT. ASSESSMENT OF MASS ENHANCEMENTS: Second look US is of choice to evaluate these lesions. ASSESSMENT OF NON-MASS ENHANCEMENTS: These lesions are challenging. Although US plays an important role, in many cases it is inconclusive. DBT correlation is very important, specifically using the craneocaudal (CC) view. This view is easy to compare anatomical structures with both MRI (axial) and CEM. DBT GUIDED BIOPSY: This technique offers several advantages over MRI or CEM guided biopsies: Less time consuming, widely spread technique. Not all the vendors have dedicated units to perform CEM guided biopsies. Once the lesion is located with DBT, the performance of the biopsy is easy. Usually 10G vacuum assisted biopsy devices are used. CONCLUSION: DBT guided biopsy can offer a good alternative for MRI/CEM detected lesions, specially for non-mass enhancements.

### Male Breast: Common and Rare Conditions

All Day Room: Learning Center

Carla Sitges, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Teaching Points: To describe the spectrum of imaging features of benign and malignant lesions of the male breast from a review of pathologically-proved cases. To correlate imaging and pathological findings. To discuss the appropriate imaging workup of male breast cancer.

#### TABLE OF CONTENTS/OUTLINE

Introduction Gynecomastia Benign lesions Imaging features on mammography, ultrasound and MRI. Radiologic-pathologic correlation. Malignant lesions Imaging features on mammography, ultrasound and MRI. Radiologic-pathologic correlation. Conclusions

Printed on: 08/22/24

## Abstract Archives of the RSNA, 2023

BREE-17

### Breast Ductal Disease: Multimodality Imaging Detection and Assessment

All Day Room: Learning Center

Meng Hao, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Review normal ductal anatomy and its imaging features. Review the broad differential of benign and malignant ductal diseases, particularly in the setting of a single dilated duct. Recognize imaging abnormalities of ductal diseases and features associated with malignancy on DBT, US, and MRI. Describe appropriate diagnostic workups and management of ductal diseases.

#### TABLE OF CONTENTS/OUTLINE

Breast ductal disease is an important aspect of breast imaging and often poses challenges in diagnosis and management, particularly in the setting of a single dilated duct. Thus, radiologists should be familiar with clinical presentations, diagnostic workup, imaging features, and differentials for ductal abnormalities. Patients may present with nipple discharge, palpable abnormalities, infectious symptoms, lactational issues, or be asymptomatic. Ductal pathologies range from ductal ectasia, periductal mastitis, intraductal papillomas, to ductal carcinoma in situ, invasive ductal carcinoma, and Paget's disease. Radiologists should recognize both normal and abnormal ductal imaging features on DBT (dilated ducts, masses, and/or calcifications), on US (cystic ductal dilation, ductal wall irregularities or arborization, intraductal masses or debris), and on MRI (clustered ring non-mass enhancement, abnormal linear or segmental NME). This educational exhibit will provide a comprehensive case-based review of benign and malignant ductal diseases, their multimodality imaging features, and associated management recommendations.

### **Breast Surgery: Changes and Findings Multimodal Diagnosis**

All Day Room: Learning Center

Maria Jose Chico (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Identify the different post-surgical changes of breast surgery<sup>2</sup>. Learn to identify which findings are suspicious and which are not.<sup>3</sup> Understand and integrate the findings in the different imaging modalities.<sup>4</sup> Understand the differential diagnoses

#### **TABLE OF CONTENTS/OUTLINE**

The accurate interpretation of images of the postsurgical breast depends on the availability of high-quality imaging. These changes should be interpreted in conjunction with the clinical and surgical history. They may correspond to benign or suspected changes. It is useful to analyze them in the different imaging modalities to support or rule out a suspected diagnosis. They can appear in the post-surgical period due to both malignant and benign conditions

### **Beyond the Lump: Navigating the Challenges of Cystic Breast Lesions**

All Day Room: Learning Center

Maria Vitoria D. Ludwig, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Our educational exhibit is directed to review the assessment and management of cystic breast lesions through the following points: review the pathologies presented as cystic breast lesions; understand how to identify and categorize breast cysts at ultrasonography; comprehend the appropriate management according to the imaging finding, correlating with clinical history and other imaging modalities if available; enlighten biopsy modalities, indication and technique; recognize the importance of subsequent histological analysis.

#### **TABLE OF CONTENTS/OUTLINE**

The subject will be approached in the following sequence: pathologies presented as cystic breast lesions and their malignancy risk; diagnosis, initial evaluation and ultrasound classification of breast cysts, linked with drawing representations of each type of cyst; appropriate risk assessment and management according to the imaging finding considering correlation with clinical history and other imaging modalities, namely mammography and magnetic resonance imaging; how to choose the most suitable biopsy modality and possible pitfalls; correlation of radiological findings with histopathologic analysis, followed by revision of management if required; illustrative cases in the different imaging methods.

### **Lipofilling: What Does Breast Radiology Need to Know?**

All Day Room: Learning Center

Karen L. Caro, PhD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1.- Describe the imaging characteristics of the lesions in lipofilling  
2.- When should we consider that a lesion after a lipofilling procedure would need histological certification, in relation to the imaging findings?

#### **TABLE OF CONTENTS/OUTLINE**

Currently fat transfer (lipofilling) is used in breast reconstruction. In this paper we will describe its advantages and how it is seen in the different imaging studies (ultrasound, mammography and MRI). It is important to identify which are the usual benign findings in the different methods and what Bi-Rads to assign, in this way we can define those cases in which their histological evaluation should be considered. Describe the advantages and disadvantages of this method in breast remodeling. The importance of recognizing radiological manifestations and the difficulties involved in detecting suspicious lesions. Knowing how to recognize that fat necrosis is a frequent lesion after lipofilling, which should be suspected in order to avoid other more complex studies such as MRI and even biopsies

BREE-20

### **Not Every Ductal Ectasia Is Evil: Spectrum of Ductal Lesions**

All Day Room: Learning Center

Raissa Soares, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

To review the imaging appearance of normal ductal anatomy; Illustrate imaging findings of ductal ectasias using different techniques, including mammography, ultrasound and magnetic resonance imaging, providing clinical images and histopathology correlation; To discuss the appropriate management of these lesions; Review a case series of benign ductal breast diagnoses from our institute, without associated malignancy;

#### **TABLE OF CONTENTS/OUTLINE**

Identify imaging criteria that may help in the diagnosis of ductal ectasia and, eventually, in its management; Typical multimodality imaging findings (magnetic resonance imaging, ultrasound and mammography) from cases of our radiology department; Diagnostic challenges, main differentials, and key points suspicion of this pathology; Discuss the role of percutaneous biopsy (ultrasound-guided core biopsy and vacuum - assisted biopsy) in the diagnosis of ductal ectasias; Conclusion.

### Understanding the BI-RADS 3 Category

All Day Room: Learning Center

Summer Joyce Batasin (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

By the end of this educational exhibit, learners will: 1. Accurately define BI-RADS 3 and appropriate use cases. 2. Explain BI-RADS 3 radiographic features and diagnostic considerations for mammography, ultrasound, and MRI. 3. Demonstrate proficiency in the assessment process of a BI-RADS 3 lesions, through a case-based review.

#### TABLE OF CONTENTS/OUTLINE

1. What is BI-RADS 3? a. Definition b. Appropriate use cases  
2. BI-RADS 3: Mammography a. Imaging features b. Diagnostic considerations  
3. BI-RADS 3: Ultrasound a. Imaging features b. Diagnostic considerations  
4. BI-RADS 3: MRI a. Imaging features b. Diagnostic considerations  
5. Identifying BI-RADS 3 Lesions: Case-Based Walkthrough a. Classic BI-RADS 3 cases b. Special cases

### Back to the Tumor: Navigating Breast Cancer Recurrence Like a Pro

All Day Room: Learning Center

#### Awards

##### Cum Laude

Vitor C. Zanetta, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Review the risk and pattern of tumor recurrence according to molecular subtype. Provide visual and data-driven insights into expected imaging changes following treatment. Highlight the role that multimodality plays in differentiating expected imaging findings from treatment and imaging findings indicative of recurrence or new breast cancer. Review current follow-up protocols after breast cancer and screening for intermediate risk patients.

#### TABLE OF CONTENTS/OUTLINE

Review the influence of breast cancer subtype on the rate, timing and location of tumor recurrence. Expected imaging changes following treatment with visual and data-driven insights: Expected timeline of post-surgical changes. Details in the assessment of local recurrence in breast-conserving surgery and mastectomy. Possible changes in axillary and internal mammary lymph nodes. The role that multimodality imaging (mammogram, ultrasound, MRI and PET-CT) plays in differentiating recurrence or new breast cancer from post-treatment changes, including: Frequent dilemmas in clinical practice: evaluation of calcifications, distortions, fat necrosis and enhancements in the surgical bed. How to deal with conflicting findings between different imaging methods to avoid unnecessary biopsies without losing sensitivity for early recognition of recurrence. Subtle recurrence and the importance of serial follow-up Imaging. Examine the follow-up protocols after breast cancer and screening for intermediate-risk patients from the perspective of personalized medicine.

### From Flat to Fabulous - A Radiological Guide to Breast Aesthetic Fillers and Biostimulators

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Heni D. Skaf, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

To expose, through cases from our institution, manifestations of different breast filling and biostimulator materials in the most diverse imaging methods, such as: free silicone, acrylates (PMMA, PAAG), hyaluronic acid, vitamin D, calcium hydroxyapatite and fat grafting. To familiarize the breast radiologist with the radiological presentation of these materials, avoiding false positives and unnecessary investigations. To discuss the usual topography in which they are injected, as well as possible local and systemic complications of using such materials.

#### TABLE OF CONTENTS/OUTLINE

Introduction: The demand for percutaneous aesthetic procedures is rising in medicine, especially in the context of facial harmonization. This also applies to the breast, both for use in cancer patients, with the increase in the incidence and in diagnosis of breast cancer, as well as for purely aesthetic purposes in the breast itself or even due to migration from other injection sites. Imaging findings: on mammography, ultrasonography and magnetic resonance as well as possible complications and usual injection sites of free silicone, acrylates (PMMA, PAAG), hyaluronic acid, vitamin D, calcium hydroxyapatite and fat grafting. For the most part, non-resorbable synthetic biomaterials, fat grafting, as well as resorbable materials used recently, have radiologic representation. Conclusion: The use of aesthetic breast fillers, whether in the oncological context or not, is on the rise. Often, the patient does not have knowledge of what was used, which can limit the clinical decision of the physician. Additionally, recognition of the radiological appearance of different fillers can avoid false positives and unnecessary biopsies.

### **Axillary Lymphadenopathy Induced by COVID-19 Vaccination: What Have We Learned?**

All Day Room: Learning Center

Miguel Barrio Piqueras I, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- US features of reactive lymph nodes after COVID-19 vaccination in patients with and without previous COVID-19 infection- Nodal reactivity in young and middle-age patients vaccinated with different COVID-19 vaccine protocols- Association between the cortical thickness measurement of reactive post-vaccine lymphadenopathy and an effective humoral response in COVID-19-naïve patients

#### **TABLE OF CONTENTS/OUTLINE**

The COVID-19 pandemic led to the approval of an emerging vaccination program to contain coronavirus dissemination. One of the most commonly reported local side effects of COVID-19 vaccination has been the development of axillary lymphadenopathy. In this poster, we will discuss about this phenomenon: 1. Which ultrasound features should be evaluated? 2. Does nodal response differ if there exists a prior history of COVID-19 infection? 3. Do the ultrasound characteristics of reactive axillary nodes change depending on the administered COVID-19 vaccination? 4. What is the nodal reactivity to the COVID vaccination according to age? 5. How long does reactive lymphadenopathy last? 6. Does cortical thickness of reactive post-vaccine lymph nodes reflect a humoral response? Conclusions- Reactive lymphadenopathy is a common side effect of COVID-19 vaccination- It is generally a harmless and temporary condition- Healthcare providers should be aware of this potential phenomenon to provide an appropriate guidance to patients

### Cystic Carcinomas: Preventing Misdiagnosis and Lessons Learned

All Day Room: Learning Center

Hemal Grover, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Simple cysts: well circumscribed isodense masses on mammogram; well circumscribed anechoic masses on ultrasound with a thin, smooth, imperceptible wall and posterior acoustic enhancement. Complicated cysts meet all criteria for simple cysts except they contain debris/echogenic intracystic contents. Necrotic tumors (rapidly growing) can present as cystic masses. They can be anechoic, demonstrate posterior acoustic enhancement and therefore often misdiagnosed as simple or complicated cysts. However, careful evaluation of the margins is imperative as it can reveal subtle irregularity and raise suspicion for malignancy. Correlation with mammogram (particularly spot compression views) can be helpful to reveal obscured or irregular margins. Cystic carcinomas often present as palpable masses. These cases should be viewed with a higher index of suspicion before being labeled as BIRADS 2. Real time physician directed ultrasound is recommended along with a bilateral mammogram with spot compression views (including in women 30-35 years old). Family history, genetic mutations and ancestry (eg Ashkenazi Jewish descent) should be considered while evaluating these patients.

#### TABLE OF CONTENTS/OUTLINE

Imaging features of simple, complicated and complex cysts. Classification of complex cysts. Clinical history, diagnostic mammogram, ultrasound and MRI findings of authors' cases of cystic carcinomas. Errors of interpretation/misdiagnosis and lessons learnt. Differential Diagnoses.

### More Than Just a Pretty Cyst - Assessment and Management of Cystic Breast Lesions

All Day Room: Learning Center

Vivian S. Ogata, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

- To discuss the ultrasound imaging parameters, from B-mode adjustments, Doppler imaging, to post-processing techniques, to properly evaluate cystic breast lesions.- To present the imaging findings of the listed cystic lesions according to the BI-RADS® lexicon such as: simple cyst, complicated cyst, clustered microcysts and complex solid and cystic masses, illustrating with multimodality imaging.- To discuss each subcategory of cystic lesions, its management and follow-up, illustrating with some challenging radiologic cases.- To habituate general radiologists with these findings in order to improve the diagnostic rate of such mammary lesions, reducing unnecessary biopsies.

#### TABLE OF CONTENTS/OUTLINE

- Introduction and epidemiology: breast cystic lesions are a common diagnosis in women and include a wide spectrum of diseases, from a simple apocrine cyst to complex solid cystic carcinomas.- Scanning techniques, ultrasound adjustment, artifacts and post-processing imaging: adjustment of ultrasonographic basic parameters and adequate scanning techniques are essential for an accurate diagnosis. We can also employ Doppler, elastography, as well as use imaging artifacts to our advantage, patient's position changes more recent post-processing techniques (harmonic and spatial compounding imaging) to better characterize cystic lesions.- Cystic lesions subcategories, classification, histological representation and multimodality imaging depiction.- Management and follow-up: adequate ACR BI-RADS® categorization of each subtype of cystic lesion, illustrating with some challenging cases , exploring some related pitfalls and discussing benign and malignant differential diagnosis.

### Can Aesthetic Procedures Interfere With Breast Cancer Screening?

All Day Room: Learning Center

Leticia T. Oliveira, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The incidence of dermatological procedures to modify aesthetics in body contouring, including post-surgical reconstructions, has been increasing every year, especially minimally invasive ones with injectables. Recognizing the imaging findings provoked by these procedures will avoid possible diagnostic pitfalls and allow the radiologist to alert the dermatologist about the possible loss of breast cancer screening caused by some of these previously unregistered procedures. Further, patients should be educated about the hazards associated with improper use of injectables from non-licensed individuals. Patients must be encouraged to seek out licensed physicians who use FDA-approved products for any medical and cosmetic care.

#### TABLE OF CONTENTS/OUTLINE

To review literature data on aesthetic dermatological procedures in the breast and axillary region, with cases from our institution, and illustrate with imaging findings found, based on different imaging methods

Printed on: 08/22/24

### **It's Not the Same As It Was: Multimodal Review of Breast Cancer Recurrence and What the Radiologist Needs to Know**

All Day Room: Learning Center

Leticia T. Oliveira, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- Breast cancer is the most common cancer in the female population worldwide and the number of patients underwent conservative surgery is growing; - The annual risk of recurrence disease varies between 2 to 5% in 5-20 years after diagnosis; - Locoregional recurrence is defined as the detection of lesions in the ipsilateral breast, chest wall or regional lymph node. If the other parts of the body are affected, it becomes a systemic recurrence; - Some factors related to breast cancer recurrence include failure in the first treatment and non-adherence to adjuvant therapy and surgical margins, but could be related to tumor size, aggressive biology of the primary tumor, young patient age at diagnosis and presence of familial or genetic risk factors; - Tumor recurrence may or may not be similar to the primary malignancy and can simulate benign conditions; - Imaging recurrence are variable and this knowledge becomes essential in radiological practice in order to improve the diagnosis and management of the patient.

#### **TABLE OF CONTENTS/OUTLINE**

- To review the factors associated to breast cancer recurrence and the epidemiology of these cases; - To show the most common findings in breast cancer recurrence using cases of our institution; - To teach how to evaluate the different methods of imaging (mammogram, ultrasound and MRI) in these cases and give tips that may help to differentiate sequelae of treatment from suspect lesion; - Easy-to-use take home messages to facilitate the handling of challenging cases.

### Breast Cancer Surveillance in Patients with Prior History of Breast Cancer: Updates and Controversies

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Sona A. Chikarmane, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Patients with a prior history of breast cancer (PHBC) are at increased risk of recurrent or second breast cancers. PHBC are also living longer due to improved screening and advances in treatment. Developing optimal screening regimens are critical in detecting breast cancers in these high-risk patients. Expected post-treatment changes include architectural distortion, edema, and skin thickening, which stabilize around two years post-treatment. Multimodality breast imaging surveillance is available, with screening mammography (full field digital mammography or digital breast tomosynthesis), whole breast ultrasound, contrast-enhanced mammography, and breast MRI. The purpose of this educational exhibit will be to review breast cancer surveillance in PHBC, highlighting updates and controversies in screening guidelines.

#### TABLE OF CONTENTS/OUTLINE

1. Review literature on risk of recurrent/second breast cancers in PHBC 2. Discuss optimal mammography screening regimens, including screening vs diagnostic mammography, cadence of screening, and batch vs immediate interpretation. 3. Review the current societal screening guidelines, including mammography and breast MRI. 4. Show multi-modality image-rich cases of recurrent breast cancer versus expected post-treatment changes. 5. Highlight controversies in breast cancer screening guidelines, including age when to stop screening, imaging the reconstructed breast, and compliance with screening.

### Tales from the Breast: When Breast Problems Have Surprising Origins

All Day Room: Learning Center

Natalia T. Lima (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Diseases that affect the breast, but do not originate from it, may include systemic, autoimmune, infectious or even tumoral conditions from other sites. They can cause inflammation in the breast tissue and manifest with pain, skin thickening, ulcerations and masses. It is essential to know each one of them to help the clinical practice of differentiating breast carcinoma from these pathologies.

#### TABLE OF CONTENTS/OUTLINE

Illustrated didactic cases from our Breast Radiology group showing some diseases and their presentation forms that can simulate breast carcinoma. They were classified into subgroups such as: 1. Related to the vasculonervous system (MAV and neurofibromatosis), 2. Systemic disorders (cutaneous lymphoma and congestive heart failure) , 3. Metastasis to the breast (melanoma and adrenal cortical carcinoma), 4. Soft Tissue tumors (granular cell tumor and synovial sarcoma), 5. Infectious (tuberculosis and dermatobiosis).

### A Guide to Cystic Breast Lesions

All Day Room: Learning Center

Christina Le, DO (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Breast imaging is often complex and can appear difficult to understand. It is rarely explored in depth throughout medical school training and can be rather limited throughout residency, especially for those pursuing other specialties for fellowship. The purpose of this exhibit is to provide a demystified review of cystic breast lesions. This is meant to supplement a resident's knowledge of breast pathology and present the information in a concise yet comprehensive manner. Throughout the presentation, the pathophysiology and patient presentation of each entity will be discussed. This will be followed by the often variable imaging findings that can be encountered on ultrasound, mammography, and MRI. Annotated pictorial examples are provided to facilitate visualization of the specific lesion characteristics. To conclude, the exhibit will discuss treatment options and the appropriate BIRADS criteria to help standardize the severity of these lesions.

#### TABLE OF CONTENTS/OUTLINE

1. Overview/educational objectives 2. BIRADS categories 3. Simple Cyst 4. Galactocele 5. Fat necrosis/oil cyst 6. Hematoma 7. Abscess 8. Intracystic papilloma 9. Necrotic neoplasm 10. Conclusion 11. References

### Exploding Jelly of the Breast: The Mucocele-Like Lesion (MLL)

All Day Room: Learning Center

Juan C. Vargas, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

<Mucocele-Like Lesions are considered risk injuries (B3a). Mucin in the stroma calcifies over time, showing up as such on mammography. By mammography the type of calcifications is variable. By ultrasound it appears as microcysts, complex cysts or irregular nodules. The treatment depends on the diagnostic biopsy method.>

#### TABLE OF CONTENTS/OUTLINE

<Mucocele-Like Lesions were first described by Rosen in 1986 as a benign lesion "cysts containing mucin, lined by squamous or cuboid epithelium with or without extravasated mucin", currently considered a risk lesion. It is due to mucinous ducts that obstruct their contents, causing rupture with extravasation of the contents into the surrounding stroma, which over time can form calcifications, which are observed by mammography; less commonly, it presents as a mass. By ultrasound they are observed as a cyst with thick, mucin-like content or microcystic conglomerates. The more complex the cystic lesion, the more likely it is to be associated with Ductal Carcinoma In Situ (DCIS). With core needle biopsy, the percentage of diagnostic underestimation is less than 4% if they are lesions without atypia, but amounts to approximately 20% if they are lesions with atypia, so removal by vacuum-assisted biopsy or surgery is preferred.>

### Rare Tumors of the Breast

All Day Room: Learning Center

Neftali A. Granados Flores, PhD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Rare tumors of the breast: Metaplastic carcinoma of the breast and Primary signet ring cell carcinoma of the breast. Epidemiology, image presentation of cases, clinical characteristics, imaging findings

#### TABLE OF CONTENTS/OUTLINE

Metaplastic breast carcinoma is a rare type of neoplasm that resembles a high-grade histological carcinoma, presents a high incidence of recurrences, poor prognosis, difficulties at the time of diagnosis, the establishment of therapeutic guidelines, and controversy regarding its nomenclature. The bibliography is very limited and the published descriptive studies have a low number of cases, making it difficult to obtain definitive and extrapolated conclusions, especially when making therapeutic decisions. Primary signet ring cell carcinoma of the breast is a rare tumor of controversial histogenesis, aggressive behavior and unusual metastatic pattern to the gastrointestinal tract and serous surfaces, posing differential diagnosis problems with metastasis of signet ring cell carcinoma of the breast. other origins, preferably gastrointestinal.

### AI Advancements in Breast Imaging: Transforming Radiology for Improved Patient Care

All Day Room: Learning Center

Matteo Mancino, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

To explore the basic concepts of deep learning and machine learning in breast imaging. To examine AI-based tools and their applications in detection, diagnosis, and treatment planning for breast cancer. To assess AI performance compared to human experts. To discuss ethical considerations. To investigate AI future trends and developments for breast imaging.

#### TABLE OF CONTENTS/OUTLINE

Introduction: presenting the fundamental principles of deep learning and machine learning in the context of breast imaging. 1. Workload to explore how AI algorithms can positively influence radiologists' workload, also triaging negative mammograms and potentially replacing second readers. 2. AI accuracy to discuss how AI-based solutions contribute to improve diagnostic accuracy in mammography and enable a more precise lesion classification. 3. Cancer-Prediction evaluating the ability of AI algorithms to identify cancer-predictive features in mammograms. 4. AI role in ultrasound and MRI to examine the development and performance of AI-based solutions for detecting and classifying breast lesions in ultrasound and MRI. 5. Ethical considerations Addressing the ethical concerns surrounding AI implementation, including data privacy, algorithm fairness, and potential biases in the development process. 6. Future trends to address the future trends of AI, contemplating the potential integration of AI with other imaging modalities, exploring the role of radiogenomics in breast imaging, and anticipating novel AI advancements.

### **Multimodal Imaging of Breast Tissue Expanders, Including Associated Complications and MRI Contraindications**

All Day Room: Learning Center

Almir Bitencourt, MD, PhD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

? To show the types of breast tissue expanders and MRI contraindications. ? To perform a multimodal review of the imaging aspects of breast tissue expanders. ? To illustrate complications associated to breast tissue expanders.

#### **TABLE OF CONTENTS/OUTLINE**

Breast tissue expanders are temporary devices commonly used in two-stage breast reconstruction surgery. Tissue expanders are gradually filled with saline to stretch the skin and chest tissues to make room for breast reconstruction with a permanent implant. There are different types of breast tissue expanders depending on the number of lumens (one or two), filling (saline and/or silicone) and injection dome (remote or internal). Some types have metallic components that are not suitable for MRI imaging due to the potential for image distortion or dislocation. It is important to recognize the imaging features of breast tissue expanders, to avoid misdiagnosis, since tissue expanders with small filling may mimic implant rupture on imaging. Complications associated with breast tissue expanders are rare and include infection, hematoma, rupture, and displacement.

### **Code of Con-DUCT: An Algorithmic Approach to Multimodality Assessment and Management of Dilated Mammary Ducts**

All Day Room: Learning Center

Rajshree Singh, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- The ACR BI-RADS® 5th Edition indicates that a SDD has a > 2% likelihood of malignancy, and therefore warrants a suspicious (BI-RADS 4A) assessment. Otherwise, there are few recommendations for evaluation and management of dilated ducts found at breast imaging.
- Further evaluation with MRI and/or tissue sampling may be warranted if ductal dilation (DD) is new or increasing, symptomatic, or associated with worrisome mammographic or ultrasound (US) features.
- We propose an algorithm-based approach to assessing dilated ducts, specifying worrisome features on mammogram and targeted US to guide further workup.
- This approach may potentially reduce radiologists' uncertainty, unnecessary biopsies, missed cancers, and healthcare expenditures.

#### **TABLE OF CONTENTS/OUTLINE**

1. Ductal anatomy
2. Definition of DD
3. Etiologies of DD
4. DD requiring further evaluation:
  - a. New or interval change
  - b. Patient symptoms and/or clinical findings
  - c. Suspicious mammographic findings
5. Worrisome US findings
6. Proposed algorithm for assessment and management
7. Identification of key findings that help guide diagnostic decisions.
8. Case-based application and examples
9. Role of ductography, US with elastography, and MR

### Breast Imaging Disparities in the U.S

All Day Room: Learning Center

Dami Olufosoye, BS, MPH (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

This educational exhibit is a call to action for radiologists to identify racial disparities in their own practice. We will review recent studies identifying disparities individuals of color face in breast imaging and discuss successful interventions. 1. Breast cancer is the second leading cause of cancer deaths in women in the US but the leading cause in black women. 2. Black women have less access to screening mammography 3. Black and Hispanic women have lower rates of receiving adequate breast cancer treatment and post-treatment surveillance 4. Black women have increased rates of breast cancer recurrence 5. Imaging disparities based on race and other factors can be identified by radiologists and mitigated with outreach programs

#### TABLE OF CONTENTS/OUTLINE

1 US Epidemiologic breast cancer data 2 Racial disparities in breast cancer screening • Decreased access to mammography centers, advanced imaging equipment, specialized physicians, genetic testing • Additional limitations: § Patient distrust § Provider-patient relationship 3 Racial disparities in diagnostic work-up • Increased time to diagnostic work-up and to biopsy • Later stage at diagnosis 4 Racial disparities after breast cancer diagnosis • Lower rates of receiving adequate breast cancer care and post-treatment surveillance • Lower rates of 5-year breast cancer survival • Higher rates of cancer recurrence 5 How radiologists can help • Identification and mitigation of imaging disparities is part of our professional responsibility to our patients • Examples of successful initiatives

### Breast Cysts: A Pictorial Exhibit of Benign and Malignant Twists

All Day Room: Learning Center

Flavia M. Starling, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Cystic breast lesions are the most common masses found in the female breast of any age group, mainly between 30 and 50 years of age. They are derived from the terminal lobular duct unit as a result of fibrocystic change and may contain isolated liquid or even associated solid component, thus comprising a wide spectrum of variable disease entities, including benign and malignant pathologies. Simple and complicated cysts are usually benign; but on the other hand, complex cystic masses containing mixed cystic and solid components are indeterminate. Therefore, knowing that cysts are common lesions and that up to approximately 31% of complex breast cysts are associated with malignancy, the radiologist must be familiar with the main pathologies and imaging characteristics that includes this category of lesions.

#### TABLE OF CONTENTS/OUTLINE

- Didactically review the main cystic lesions of the breast and their characteristics through different imaging methods and case-based revision obtained from the digital archive of our institution.
- Take home message
- References

### **Molecular Classification of Breast Cancer: Guide for the Radiologist**

All Day Room: Learning Center

Sandra Lara (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Breast cancer is a disease that, despite having a histopathological classification, also includes molecular and genetic subtypes, being able to carry out a molecular classification that guides the clinical behavior, prognosis and different radiological characteristics based on the expression of biomarkers (HER2, ER, PR, Ki67), this classification complements the traditional classification and adds a very useful biological approach to disease management. That is why it is important for the radiologist to know and recognize the importance of classification, as well as to identify the most common imaging characteristics in the different diagnostic methods according to each molecular subtype.

#### **TABLE OF CONTENTS/OUTLINE**

Introduction· Breast molecular biomarkers· Revision of the classification of molecular subtypes of breast cancer· Imaging characteristics in the different methods according to each molecular subtype· Clinical cases· Conclusions

Printed on: 08/22/24

### **Invasive Lobular Carcinoma (ILC): The Cancer With a Thousand Faces**

All Day Room: Learning Center

Adriana Alvarez, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

The Invasive Lobular Carcinoma (ILC) is the second most common type of invasive breast cancer. The incidence is increasing due to replacement therapy in postmenopausal women and diagnosis advances. There are two histologic variants: classic and pleomorphic. ILC is usually estrogen receptor positive and her2 negative. The loss of desmoplastic cell reaction and the low density of cells in this tumors make the clinical and the mammographic detection difficult. This entity has multiple imaging manifestations, being a challenge for the radiologist. ILC can be bilateral, multifocal or multicentric, with a unique metastatic pattern. Diagnosis is based in clinical and radiological tests. The most common manifestation is an irregular or spiculated mass in mammography and an hypoechoic irregular mass with posterior shadowing in US. MRI is the gold standard and it is used in the presence of multifocal, multicentric or bilateral disease as well as in the presence of lymphadenopathies.

#### **TABLE OF CONTENTS/OUTLINE**

This educational exhibit presents epidemiological and main ILC features. Tumor presentation and behaviour are explained. A multi-modality review of clinical and radiologic features through clinical cases, as well as pitfalls, are presented and they can help the radiologist in the diagnosis.

### **MRI-Detected US: How to Improve the Detection Rate of Non Mass Lesions Using Breast Anatomical Landmarks**

All Day Room: Learning Center

Ayumi Izumori (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Nonmass lesions on US are most often observed when US is used to target mammographic asymmetries, biopsy suspicious calcifications seen on screening mammography, and to biopsy abnormalities on MRI. In a meta-analysis of 2201 lesions, the success rate of targeted US after MRI was 58% (range, 23%-82%) and detection rates varied by lesion type. Nonmass enhancement lesions on MRI are less likely to be detected on targeted US than mass lesions (66% of all masses and 30% of nonmass enhancement lesions were seen). This review introduces a new viewpoint on breast ultrasound anatomy necessary to obtain a close correlation with MRI and describes a target US method with anatomical landmarks based on this viewpoint.

1. Some US images of MRI-detected lesions are more indistinct than surrounding benign lesions and need to be correlated with precision.
2. About effective anatomical landmarks for MRI correlation including surrounding tissues and vascular routes as a new anatomical landmark.
3. Pattern classification of mammary fat and mammary gland distribution for reading anatomic landmarks in MRI correlation.
4. The anatomical mechanism of deformity and how to decipher it on US. Breast deformity during ultrasound examination is not related to breast size, but varies from individual to individual.

#### **TABLE OF CONTENTS/OUTLINE**

1. the identification rate of in each literature and its relationship to landmarks used
2. identification rates by anatomical landmarks and MRI images using those landmarks
3. classification of patterns of fat and mammary gland distribution in the breast based on anatomical understanding
4. anatomic mechanisms of breast deformity in MRI and US
5. US techniques considering breast deformity
6. case presentation

### Imaging Review of Mammography and Ultrasound Findings in Uncommon Breast Lesions: A Trainee-Focused Guide

All Day Room: Learning Center

Thurl Hugh C. Cledera, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Differentiating uncommon breast lesions from cancerous lesions in the breast is paramount to proper diagnosis, risk stratification, and treatment in patients presenting with a breast mass in imaging. Uncommon breast lesions may vary from those arising in the glandular parenchyma (phyllodes), inflammation (mastitis and abscess), autoimmune (granulomatous mastitis), and metabolic (diabetic mastopathy) etiologies. In centers where resources are limited, knowing the value of mammography and ultrasound findings may help guide biopsy, which in turn provides adequate treatment. At the end of this exhibit, the learner will be able to review the basic findings that are seen in breast lesions on imaging and understand the role of clinical and imaging correlation in the proper identification of these lesions.

#### TABLE OF CONTENTS/OUTLINE

1. Introduction
2. Brief review of histology of uncommon breast lesions
3. Basic findings in mammography
4. Basic findings in ultrasound
5. Correlating findings in mammography and ultrasound
6. Cases of uncommon breast lesions
  - a. Lactating adenoma
  - b. Intraductal papilloma
  - c. Mastitis (bacterial)
  - d. Granulomatous mastitis
  - e. Diabetic mastopathy
  - f. Mondor's disease
  - g. Paget's disease
  - h. Phyllodes tumor

### Untangling the Mammary Ducts: Decoding the Complexity of Intraductal Pathology

All Day Room: Learning Center

Elsa Cecilia Molina Miranda, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

**Mammography:** Mammography can show intraductal lesions as grouped calcifications in a linear or branching pattern. **Breast ultrasound:** Ultrasound can identify intraductal lesions as masses or areas of ductal dilation. **Core needle biopsy (CNB):** This procedure is used to obtain a tissue sample from the lesion. CNB is performed guided by ultrasound or mammography. **Vacuum-assisted biopsy (VAB):** This procedure uses a suction device to obtain a tissue sample from the lesion. VAB is performed guided by ultrasound or mammography. **Contrast-enhanced mammography:** This exam uses a contrast medium to evaluate the vascularity of lesions in the breast, which may suggest the presence of a malignant lesion. Management of intraductal lesions depends on the definitive diagnosis obtained by biopsy. If the lesion is found to be malignant, treatment may include surgery, radiation therapy, and/or chemotherapy. If the lesion is benign, treatment may include observation or surgical removal.

#### TABLE OF CONTENTS/OUTLINE

Table of contents: 1. Objectives 2. Anatomia y fisiopatologia 3. Cases 4. Metodos diagnosticos 5. Approach 6. Conclusions  
Outline: Intraductal breast lesions are those that originate in the breast ducts and can be benign or malignant. These lesions can be detected by diagnostic methods such as mammography, breast ultrasound, core needle biopsy (CNB), vacuum-assisted biopsy (VAB), and contrast-enhanced mammography. The management of intraductal lesions depends on the definitive diagnosis obtained by biopsy, and treatment may include surgery, radiotherapy, and/or chemotherapy for malignant lesions, while benign lesions may be observed or surgically removed.

### When Lightning Strikes the Same Place Twice: Detecting Ipsilateral Breast Cancer Recurrence in the Post Operative Breast

All Day Room: Learning Center

Aurela I. Clark, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Illustrate the imaging features suspicious of ipsilateral breast cancer recurrence in patients with prior lumpectomy or mastectomy. Review current literature for recommendations on adjunct imaging surveillance in women with prior history of breast cancer given their increased risk of a second breast cancer. Review imaging mimickers of breast cancer recurrence and discuss management recommendations. Highlight teaching points for each case to increase confidence in making a timely diagnosis.

#### TABLE OF CONTENTS/OUTLINE

Case base review We will present an image rich exhibit depicting imaging findings in ipsilateral breast cancer recurrence in the post lumpectomy patients who present for annual surveillance mammography or breast MRI, and in patients who present with clinical concerns. Cases will illustrate imaging findings, histopathology and management at the initial diagnosis and at time of recurrence. Examples of imaging mimickers of breast cancer will familiarize the learner with benign conditions in the post-surgical breast. At the end of the exhibit, teaching points will be summarized. Summary: Women with a prior personal history of breast cancer are at an increased breast cancer risk. Cumulative incidence of ipsilateral breast tumor recurrence rate has been reported at 14.3%. The image appearance of the post operative breast can make the detection of breast cancer recurrence more challenging. As a result, radiologists should be familiar with common and uncommon imaging findings of ipsilateral breast cancer recurrence. This presentation will review the current screening recommendations in this setting, expected post operative changes, breast cancer mimics, and the imaging findings of recurrence.

### **Vascular Mammary Lesions: Key Features to Make an Accurate Diagnosis and Avoid Unnecessary Biopsies**

All Day Room: Learning Center

Ladys J. Camargo, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Review the normal vascular anatomy of the breast  
2. Know the most frequent vascular breast lesions  
3. Know and discuss the diagnostic modalities commonly used for the diagnosis of vascular lesions  
4. What is the imaging follow-up of vascular lesions?

#### **TABLE OF CONTENTS/OUTLINE**

There are various vascular mammary lesions, ranging from chronic systemic processes, congenital malformations, post-traumatic sequelae, benign masses, to malignant tumors. Accurate diagnosis of vascular lesions in breast images is very risky due to overlapping characteristics. This is why radiologists must be aware of the key features in the different diagnostic methods for interpreting images of vascular lesions in order to make an accurate diagnosis and avoid unnecessary biopsies and finally be able to discuss management recommendations and guidance.

### Everything We Need to Know About Papillary Breast Carcinoma

All Day Room: Learning Center

Lisett N. Cruzado-Quiroz, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Papillary breast carcinoma is a rare subtype of invasive ductal carcinoma with infiltrative papillary growth representing about 0,5 -0,7% of all invasive breast cancers. It is usually seen in postmenopausal in their sixth to eight decade of life. Association with carcinoma in situ is uncommon. Typically presents with bloody nipple discharge or/with slow growing palpable tumors, frequently found in the periareolar region. In general, they have better prognosis than ductal carcinoma with a 100% 10 year survival rate following treatment. Lymph node involvement and distant metastases are rare except in the invasive form. Mammography usually shows a solitary round or oval mass with circumscribed margins. Rarely they associate poorly defined margins or spiculation, given the low occurrence of desmoplastic reaction. Ultrasound generally shows a complex mass with solid and cystic components with good sound transmission. MRI may demonstrate heterogeneous lesions with septations, mural nodule and intracystic haemorrhage, the solid components typically show washout kinetics. Intracystic papillary carcinomas can occur in a pure form or may be associated with ductal carcinoma in-situ or invasive ductal carcinoma. The authors will review the clinical manifestation, imaging features and pathology correlation of this rare breast carcinoma.

#### TABLE OF CONTENTS/OUTLINE

Review of the pathophysiology of papillary breast cancers (histological and molecular aspect).Multimodal review of imaging features of papillary cancers (mammographic, ultrasonographic, and MR findings)To determine the Radiology-Pathology concordance/discordance by reviewing cases.Update on the treatment of papillary breast cancer.

### **Decoding Ductal Pathology: Multimodality Approach to Nipple Discharge and Management of the Solitary Duct**

All Day Room: Learning Center

Zoya M. Patni, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Identify what differentiates physiologic nipple discharge from pathologic discharge 2. Describe an approach to the diagnostic workup of patients with nipple discharge 3. Discuss the clinical importance of a solitary dilated duct and describe an approach to management in these patients 4. Implement new strategies for biopsy of hard-to-sample intraductal masses under both ultrasound and MRI-guidance

#### **TABLE OF CONTENTS/OUTLINE**

Nipple discharge represents 2-5% of medical visits among women and is the third most common breast concern (pain > lump > nipple discharge). As radiologists our primary responsibility in assessment and management of these patients is to distinguish physiologic and pathologic causes of nipple discharge. This presentation will review the prevalence, epidemiology and pathologic subtypes of papillary lesions and other common pathologies resulting in pathologic nipple discharge and provide the reader with a diagnostic algorithm for management of these patients. Using a multimodality case-based approach, the reader will develop a differential diagnosis and management strategy for imaging findings in patients with nipple discharge, including management of the solitary dilated duct. We provide the reader with important tips and tricks for biopsy of intraductal lesions and solitary dilated ducts under ultrasound and MRI-guidance and address the potential challenges of radiology-pathology concordance in these cases.

Hannah L. Chung, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

DCIS often co-exist with invasive cancers and 19-36% of DCIS after percutaneous needle biopsy are upstaged to an invasive cancer at surgical excision. Up to 3% of DCIS demonstrate axillary nodal metastases. The morphology of the calcifications are useful in predicting the nuclear grade. DCIS may also manifest as a noncalcified mass, asymmetry or distortion. Sonography demonstrates these findings as a mass, nonmass area or ductal change. MRI demonstrates the extent of DCIS better than other imaging modalities and findings correlate with high grade DCIS. Observed recurrences and lymph node metastases pose challenges to current evaluation and treatments of DCIS.

#### TABLE OF CONTENTS/OUTLINE

Table of Contents 1. What is DCIS a. Significance of DCIS b. Biology and evolution of DCIS 2. Clinical Presentation of DCIS a. Asymptomatic b. Nipple discharge c. Paget's disease of the nipple d. Palpable lump 3. Imaging correlates with biology and pathology a. Mammographic i. Calcifications, mass, asymmetry, distortion b. Sonographic i. Nonmass findings 1. hypoechoic areas 2. echogenic foci 3. shadowing, 4. pseudomicrocyst ii. Ductal change c. MRI- MRI is useful to demonstrate extent of disease, exclude invasive disease, and correlates with high grade DCIS. i. nonmass enhancement ii. mass. 4. Special considerations a. Occult invasive cancers or misdiagnosis- Can imaging predict invasion? b. Axillary Staging- Is axillary ultrasound with biopsy and sentinel lymph node necessary? 5. Research: Past, now, and future endeavors a. NSABP, UKANZ, ECOG-ACRIN b. Active surveillance vs standard treatment - COMET, LORIS, LORD c. Advanced imaging techniques and artificial intelligence in both radiology and pathology

### When Cysts Are Not So Simple: Tips for Complex Cystic Breast Masses Evaluation.

All Day Room: Learning Center

Rosa M. Lorente-Ramos, MD, PhD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

-To review the different entities causing the sonographic appearance of a complex cyst.-To illustrate a series of cases of complex cystic benign and malignant lesions of the breast providing correlation with imaging (US, contrast-enhanced mammography, MRI) and pathology. - To discuss the specific management of those lesions including imaging and interventional procedures. -To emphasize pitfalls, diagnostic difficulties, and differential diagnosis.

#### TABLE OF CONTENTS/OUTLINE

Cystic breast lesions are frequently detected on breast ultrasonography. Simple cysts, complicated cysts, and oil cysts do not require further invasive diagnostic procedures. However, malignant entities may present with complex cystic and solid masses. Through sample cases, a variety of imaging and pathology findings from complex cystic lesions with management discussion will be demonstrated. 1. Introduction. US findings and technical pitfalls. 2.Cystic lesions evaluation, useful findings that could be of significant diagnostic value to distinguish between confusing cysts. Classification of cysts and suspicious findings. 3.Work-up of suspicious lesions on US: mammography/contrast-enhanced mammography (CEM) and MRI. Interventional procedures. 4. Typical benign and malignant lesions with their important findings on ultrasonography, contrast-enhanced mammography, and MRI: Benign: complicated/inflammatory cyst, seroma, oil cyst, epidermal inclusion cyst, galactocele, mucocele-like tumor, hematoma, abscess, fat necrosis, fibroadenoma, papilloma, benign Phyllodes tumor. Malignant: malignant Phyllodes tumor, papillary, medullary, colloid, and squamous cell carcinoma, sarcoma.

### **Differentiating Simple Cysts From Complicated Cysts, Complex Cystic and Solid Masses, and Other Cystic Breast Lesions**

All Day Room: Learning Center

Tara A. Retson, MD, PhD (*Presenter*) Research Consultant, CureMetrix, IncStock options, CureMetrix, Inc

#### **TEACHING POINTS**

Cystic diseases of the breast are common, and confusion can occur regarding their appropriate classification and management. Distinguishing between benign cysts/cystic lesions and malignant cyst-like/fluid-containing cancers may be challenging. Specifically, triple negative breast cancers and intracystic papillary carcinomas should not be dismissed as benign/probably benign. Cystic lesions may be diagnosed accurately and managed appropriately using characteristic imaging findings. It is imperative to properly classify lesions as complex cystic and solid masses vs. complicated cysts since their management differs, and the differential of complex cystic and solid masses includes cancer. This educational exhibit will define simple cysts, teach radiologists about cystic lesions that may not be benign, review their imaging appearances, and recommend management options for complicated cysts, clustered microcysts, and complex cystic and solid breast masses.

#### **TABLE OF CONTENTS/OUTLINE**

Introduction; Definitions/illustrations of simple cysts, complicated cysts, clustered microcysts and complex cystic and solid masses; Multimodality examples of cystic breast lesions, systematic approach to the characterization of cystic lesions; How to appropriately apply BI-RADS classification and management recommendations of cystic breast lesions; Utilization of a quiz at the end of the exhibit to test yourself on the systematic approach presented.

### Get Your Ducts in a Row: Imaging and Management Considerations of Ductal Disease of the Breast

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Firouzeh K. Arjmandi, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

-In the imaging evaluation of spontaneous clear and/or bloody nipple discharge, negative diagnostic conventional imaging (mammogram and ultrasound) warrants further evaluation with breast MRI.-Nipple changes on physical exam even in the absence of imaging findings are suspicious. Clinical exam findings should guide next steps in management, and nipple tissue biopsy should be performed by the surgeon in the appropriate clinical setting.-In the setting of a small, subtle intraductal mass seen on diagnostic MRI and not well visualized at time of MR-guided biopsy, targeting the end of a blind-ending solitary duct can help to guide the biopsy.-The combination of findings of a palpable lump, nipple discharge, and nipple inversion, and the presence of associated coarse heterogeneous calcifications raises concern for malignancy, and biopsy should be recommended (despite the presence of more benign appearing rim calcifications).-Treatment of intraductal papillomas without atypia has become more conservative. Upgrade to DCIS or invasive carcinoma is more common in women >50 years, lesions >1 cm, palpable lesions and papillomas >5 cm from the nipple.

#### TABLE OF CONTENTS/OUTLINE

-Overlapping imaging features of benign and malignant calcifications, including high grade versus low grade DCIS-Utility of MRI in the evaluation of extent of disease in intermediate to high grade DCIS-Multimodality imaging and clinical evaluation of pathologic nipple discharge and nipple changes (erythema and scaling)-Imaging assessment and clinical management of a solitary dilated duct and intraductal lesions-Accurate assessment of response to neoadjuvant chemotherapy in the setting of increasing calcifications post therapy

### Test Your Knowledge: A Case Based Quiz of Contrast Enhanced Mammography BI-RADS Lexicon

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Daniel Sandoval, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

- To learn the descriptors published in the ACR 2022 BI-RADS supplement for contrast enhanced mammography by reviewing a series of daily case images.
- As this supplement has only recently been published, this exhibit is intended to help radiologists become familiar with the terminology and its representation on images, through an interactive and entertaining activity.

#### TABLE OF CONTENTS/OUTLINE

- Background Contrast enhanced mammography lexicon overview (categories, terms, features and definitions)
- Illustrated case based quizzes
  - o Case #1: Background parenchymal enhancement - Level: Minimal, Mild, Moderate, Marked. - Symmetry: Symmetric, Asymmetric.
  - o Case #2: Masses - Shape: Oval, Round, Irregular.- Margin: Circumscribed, Irregular, Spiculated. - Internal enhancement characteristics: Homogeneous, Heterogeneous, Rim enhancement.
  - o Case #3: Non mass enhancement - Distribution; Diffuse, Multiple regions, Regional, Focal, Linear, Segmental- Internal enhancement characteristics: Homogeneous, Heterogeneous, Clumped.
  - o Case #4: Enhancing asymmetry - Internal enhancement pattern: Homogeneous, Heterogeneous.
  - o Case #5: Lesion conspicuity - Low - Moderate - High

### Complex Cystic Breast Masses: An MR Imaging Review

All Day Room: Learning Center

Jie Liu (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. To define the concept of complex cystic breast masses. 2. To categorize complex cystic breast masses into three types based on the percentage and spatial distribution of cystic and solid components in the contrast-enhanced MRI. 3. In comparison with US, MRI affords superior visualisation of the proportion and distribution characteristics of solid and cystic components within complex cystic breast masses, which facilitates their differential diagnosis. Moreover, multi-parametric MRI such as T2WI, dynamic contrast-enhanced MRI (DCE-MRI) and diffusion-weighted imaging (DWI) enables the recognition of the presence and distribution characteristics of cystic and solid components, the combination of which can serve as a complementary imaging aid for accurate diagnosis.

#### TABLE OF CONTENTS/OUTLINE

I. Introduction A. Overview of complex cystic breast masses B. Importance of accurate diagnosis II. Complex cystic breast masses A. Definition of complex cystic breast masses B. Etiology of complex cystic breast masses C. Clinical manifestations of complex cystic breast masses III. Categorization of complex cystic breast masses based on MRI features Group A : thick outer wall and/or thick internal septa (> 0.5 mm). Group B: predominantly cystic component(>50%)or intracystic mural nodule. Group C:predominantly solid component and cystic component=50% IV. Comparison of MRI and ultrasound in complex cystic breast masses A. Advantages of MRI over ultrasound B. Limitations of ultrasound C. Diagnostic value of multiparametric MRI in identifying cystic components V. Conclusion A. Summary of key points B. diagnostic flow chart of complex cystic breast masses C. Future directions for research VI. References

### Trial by Priors: When to Call Back a Stable Mammographic Finding

All Day Room: Learning Center

Samantha H. Epstein, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Comparison with multiple prior studies can help identify slowly evolving malignancies. 2. Mammographic findings that warrant further evaluation include increasing number of calcifications or suspicious distributions, evolving asymmetries, architectural distortions, and slow growing or spiculated masses. 3. Early recognition of these suspicious findings allows for appropriate diagnostic workup and improved diagnosis of slow growing malignancies.

#### TABLE OF CONTENTS/OUTLINE

1. Introductory slide. This exhibit hopes to educate breast imagers about stable mammographic findings that require further evaluation. While stability of imaging findings over two years is often suggestive of benignity, comparison with multiple prior imaging studies can allow better evaluation of stability and identify features that are slowly evolving over time. There are also some imaging features that should be further evaluated and sampled regardless of apparent stability. This educational exhibit will discuss several cases of malignancy, highlighting the suspicious imaging features that prompted additional work up. 2. List of teaching points to guide the upcoming case discussion. 3. Anonymized cases demonstrating different examples of slow growing malignancies. Each case will include: Multiple prior studies to demonstrate evolution over time; Explanation of decision making that lead to diagnostic evaluation; Findings on diagnostic imaging; Pathology results after biopsy. 4. Summary slide that reviews the teaching points.

### Indications and Outcomes of Cryoablation in Breast Malignancies: A Single Institution Case Review

All Day Room: Learning Center

Sasha Kurumety, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The goal of this presentation is to educate radiology trainees on the use of cryoablation as a treatment option for breast malignancies, when cryoablation may be appropriate, and expected short and long term outcomes of the procedure. Using a series of cases from our institution, we will describe selection criteria to identify patients that may benefit from this minimally invasive cancer treatment option and demonstrate post treatment imaging findings. After this presentation, learners will be able to describe the utility of cryoablation in treating breast malignancies and mechanisms of action, as well as understand the complications, outcomes, and future directions/ongoing trials for cryoablation.

#### TABLE OF CONTENTS/OUTLINE

Background:- Current FDA approved indications for cryoablation and uses of cryoablation in breast cancer- Ongoing trials: discussion of ICE3, FROST, and home institution trials and preliminary outcomes  
Discussion of mechanism of action:- Direct freezing and cell death, indirect immune response activation- Advantages, disadvantages, and risks/complications of cryoablation  
Cryoablation at our institution:- Qualifying patient and tumor characteristics, preprocedural evaluation- Interdisciplinary decision-making  
Institutional cryoablation cases:- Preprocedural imaging, biopsy pathology results, imaging during procedure, and post cryoablation follow up imaging/pathology  
Future directions: pathway to FDA approval, Medicare coverage, and increasing accessibility.

### To Treat or Not to Treat: A Review of Papillary Lesions of the Breast

All Day Room: Learning Center

Shadan Alwan, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Papillary breast lesions are a heterogeneous group of proliferative changes that occur within the epithelial lining of breast ducts. These lesions have varying presentations, pathological characteristics, and treatment options, requiring careful radiological evaluation for an accurate diagnosis. The spectrum of the lesions includes intraductal papilloma with/without atypia, intraductal papillary carcinoma, encapsulated papillary carcinoma, solid papillary carcinoma, and invasive papillary carcinoma. Radiologists must be aware of these variations to accurately identify, diagnose, and provide appropriate management recommendations. The primary objective of the exhibit is to present a comprehensive pictorial review of papillary breast lesions with radiological pathological images. We will also discuss the steps in the diagnosis and current management recommendations of these lesions. By the end of this exhibit, the audience will have a better understanding of the various papillary lesions and their clinical and imaging presentations, enabling them to provide appropriate radiologic-pathologic correlation and treatment recommendation for patients.

#### TABLE OF CONTENTS/OUTLINE

1) Introduction. 2) Definition of papillary breast lesions. 3) Pictorial review of the spectrum of papillary lesions. 4) Case examples of the spectrum of papillary lesions with pathological correlation. 5) Symptoms presentation of various papillary lesions. 6) Imaging techniques recommendations for diagnosis of papillary lesions. 7) Review of current BI-RADS terms in the description of these abnormalities. 8) Latest management recommendation for papillary lesions within the spectrum. 9) Conclusion/Summary.

### Case Based Review of the Modern Reconstructed Breast: Benign Imaging Findings and Complications

All Day Room: Learning Center

Shelby Breit, BS, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Understand imaging findings associated with modern reconstruction techniques
2. Recognize uncommon and common benign findings
3. Discuss complications

#### TABLE OF CONTENTS/OUTLINE

Reconstruction Methods  
Implants  
Autologous Flaps (AF)  
Imaging after implant reconstruction  
Type: silicone vs saline  
implant  
Acellular dermal matrix (ADM)  
Benign complications:  
Rupture  
Gel bleed  
Abscess/infection  
Hematoma  
Siliconoma  
Implant associated mesenchymal tumors (fibromatosis)  
Imaging after AF reconstruction  
Type: pedicled, free, perforator flaps  
Venous coupler device  
Benign complications:  
Fat necrosis/lipografting  
Epidermal inclusion cyst

### Breast MRI: What the Surgeon Wants to Know

All Day Room: Learning Center

Daniella Boros, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

As there is increasing need for a multidisciplinary approach to patient care, it is important for the radiologist to understand which MRI findings change clinical management. After this presentation, participants will understand: 1. Indications for breast MRI 2. Breast cancer staging 3. Indications for different types of breast cancer treatment, including surgery, radiation, and systemic 4. Breast MRI findings that change clinical/surgical management 5. MRI correlates on mammogram and ultrasound

#### TABLE OF CONTENTS/OUTLINE

A. Indications for MRI a. American College of Radiology Practice Parameter b. American Society of Breast Surgeons Consensus Guidelines B. Overview of breast cancer staging C. Surgical management a. Indications b. Mastectomy vs. lumpectomy c. Types of mastectomy D. Radiation a. Indications b. Whole vs. partial breast treatment E. Systemic a. Indications for neoadjuvant chemotherapy b. Types of systemic treatment (chemotherapy, hormone blockade, biologic therapies) F. MRI findings that impact staging and management with multimodality case examples a. Multicentric/multifocal disease b. Nodal involvement (rotter's node, level I, level II, level III, internal mammary chain node) c. Nipple enhancement d. Skin enhancement e. Chest wall involvement f. Cancer in contralateral breast g. Metastatic disease - bone/lung involvement

### The Not So Simple Cyst

All Day Room: Learning Center

Daymara Deynes-Ramos, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Cystic breast lesions are frequently encountered on ultrasound, often incidentally with a broad differential diagnosis including both benign and malignant pathology. Accurate description and classification according to the BI-RADS Lexicon based on ultrasound characteristics are essential for appropriate estimation of risk for malignancy and in turn management guidance. Emphasis on optimal ultrasound techniques, BI-RADS classification based on imaging characteristics, and correlation with example cases will be given with the purpose of helping residents and radiologists feel confident on how to proceed when faced with a cystic breast lesion.

#### TABLE OF CONTENTS/OUTLINE

I. Introduction II. Optimal Ultrasound Technique III. BI-RADS classification of cystic lesions 1. Simple cyst 2. Complicated cyst 3. Complex cystic and solid mass (classification of complex masses) IV. Sampling techniques V. Take Away Points

Printed on: 08/22/24

BREE-68

### The Cures Act: Challenges and Benefits in Breast Imaging

All Day Room: Learning Center

Neda Ghassemi, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The 21st Century Cures Act is a federal law signed in 2016, aiming to remove barriers to health information exchange. The legislation includes a Final Rule, federally enforced as of April 2021, mandating patient access to electronic health information to increase transparency. Part of the mandate prohibits "information blocking," defined as a healthcare practice that is "likely to interfere with access, exchange, or use of electronic health information." For radiology practices, this means that reports are released to patients immediately when finalized. Immediate release allows for increased patient autonomy but reports often include sensitive information, especially in breast imaging, in addition to terminology that might be confusing to patients. Screening and diagnostic reports, previously held for a period of time at many institutions to allow time for direct patient communication, are now immediately released to patients. This educational exhibit reviews the impact of the Cures Act on breast imaging practices, including benefits, challenges, and potential solutions to navigate the legislation.

#### TABLE OF CONTENTS/OUTLINE

I. Legislation II. Positive Implications and Challenges III. Evolution of Practice

Printed on: 08/22/24

### How to Start Using Optoacoustic Imaging in Your Breast Practice: A Primer

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Berat Bersu Ozcan, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Optoacoustic imaging (OAI) is a novel technique that uses non-ionizing lasers to detect endogenous tissue contrast. Gray scale ultrasound (GUS) is fused with parametric maps of relative light absorption for oxy/deoxyHgb in real-time, enabling simultaneous functional and anatomic imaging. The most frequently tested interpretation schema involves dividing mass into 3 internal and 2 external features. The 3 internal scores include the number of individually resolved vessels and their relative deoxygenation (vessel score), tumor blush, representing volume-averaged vessels too small to resolve individually (blush score), and Hgb amount (hemoglobin score). The 2 external scores reflect the amount and relative oxygenation of hemoglobin and vessel morphology within the boundary zone (bz, immediately surrounding the tumor, analogous to the thick echogenic rim surrounding tumors on GUS images) and the peripheral zone (pz, territory beyond the bz). Combined evaluation of GSUS and OAI features to classify benign and malignant masses have consistently shown to increase significantly (43.0% vs 28.1%,  $p < 0.001$ ) diagnostic specificity with high interreader (7 readers) agreement (mean kappa = 0.55;  $p < 0.001$ ). A study combining decision support tools with 15 fellowship-trained radiologists showed that interreader agreement [intraclass correlation coefficient (ICC) 0.80, 95%CI: 0.78, 9.82] and agreement between reader and decision support tool (95.3% of all reads) was high.

#### TABLE OF CONTENTS/OUTLINE

1. Optoacoustic Imaging Principles 2. Equipment Types and Current Status 3. Interpreting Optoacoustic Images: A Comprehensive Guide 4. Understanding system limitations 5. Case Demonstration 6. Test Your Knowledge

### What You Need to Know About the Pediatric Breast: A Review of the Normal Breast and Diagnostic Approach of Pediatric Breast Disease.

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Ilany L. Valdivia I, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The purpose of this exhibit is to: Describe the physiologic breast development and its variants from birth to adolescence. Review the optimal imaging modalities for evaluation of breasts lesions in children and adolescents. Recognize imaging appearances of benign and malignant lesions that can affect the pediatric breast. Learn the recommendations for follow-up and management of pediatric breast lesions to avoid a delayed diagnosis or unnecessary interventions.

#### TABLE OF CONTENTS/OUTLINE

We review: Utility of the different imaging modalities in the assessment of the pediatric breast. Breast physiologic development from birth to puberty and pathological conditions that can occur. Benign and malignant pediatric breast disease with illustrating cases. Non-mass findings: Asymmetrical breast development, accessory breast tissue, accessory nipple, pseudogynecomastia, gynecomastia, atypical ductal hyperplasia, surgical scar. Benign masses: Simple and complex cysts, retroareolar cyst, epidermal inclusion cyst, fibrocystic changes, mastitis and abscess, hematoma, intramammary lymph node, reactive lymph node to vaccines, fibroadenoma, pseudoangiomatic stromal hyperplasia, sclerosing adenosis, phyllodes tumor and tubular adenoma. Malignant masses: Metastasis and primary breast cancer. Diagnostic approach of pediatric breast disease with follow-up and management algorithm and indications for interventions such as biopsy or surgery.

### **Localization for Nonpalpable Breast Lesions. A Pictorial Review of Different Imaging-guided Preoperative Localization Procedures in the Breast and Axilla.**

All Day Room: Learning Center

Javier Azpeitia Arman, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

-To know the different devices employed for nonpalpable breast lesions localization. -To review the role of imaging techniques (mammogram, US, MR, CT, gamma detector) in the localization of breast lesions for breast conserving surgery. -To understand surgeon needs including technical factors of localization and communication of the relationship of the lesion and the marker. -To become familiar with the localization process, and different tips and tricks for each device.

#### **TABLE OF CONTENTS/OUTLINE**

Breast-conserving surgery requires multidisciplinary communication and planning between the surgeon and the radiologist. Removal of the lesion with adequate surgical margins and avoiding resection of healthy breast tissue is essential. 1. History of wire localization, radioactive seed, and other non-needle-wire localization techniques 2. Advantages and disadvantages of using seed localization versus needle-wire localization. 3. Wire localization. 4. Non-wire devices: radioactive I125, magnetic, radar, and radiofrequency seeds 5. Technique and pitfalls. Before the procedure: review of the patient's imaging and histopathologic findings. Wire or seed placement. Preoperative detection. Operating room. Recovery. 6. Case examples of potential difficulties and problems and how to overcome them.

BREE-72

### Is it Back? Multimodality Surveillance of Breast Cancer Recurrence: Literature Review and Case Presentation

All Day Room: Learning Center

Mohammed A. Sabawi, MBChB (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Screening patients with previously treated breast cancer is challenging, because benign post treatment changes can obscure or resemble an underlying recurrence and due to technical limitations in performing a mammography on a treated breast. There are postoperative mammographic findings in a conservatively treated breast which follow expected time course. Any new mammographic finding (new masses, asymmetries or microcalcifications) should raise suspicion for recurrence. Abnormal screening mammogram is the most common presentation of breast cancer recurrence. Margin involvement and lack of radiotherapy and/ or chemotherapy are important prognostic factors of local recurrence. There is no clear guidelines to dictate ipsilateral breast screening after mastectomy and reconstruction with or without implant. Breast MRI is highly sensitive imaging modality to detect local recurrence in certain patient groups. It can be also utilized as problem solving to assess equivocal clinical or mammographic findings.

#### TABLE OF CONTENTS/OUTLINE

Introduction Review of incidence, risk factors, diagnostic performance of multimodality surveillance and presentation of breast cancer recurrence. Review of post breast conserving treatment imaging findings and their time course of evolution. Review of available national guidelines for multimodality surveillance after curative treatment for locoregional breast cancer. Case based review of different and unusual presentations of breast cancer recurrence. Conclusion. References.

### **A Review of the Combined Score for Quantitative Shear Wave Elastography (SWE) and Superb Microvascular Image Vascular Index ( $SMI_{VT}$ ) to Evaluate Breast Masses**

All Day Room: Learning Center

NA YOUNG LEE (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. To differentiate between benign and malignant breast masses, we propose using the combined score of quantitative parameters for shear wave elastography (SWE) and superb microvascular image (SMI) with BI-RADS. We suggest using the combined score for SWEmax, SWERatio, and SMIVI and demonstrate how it can be used to differentiate between benign and malignant breast masses. 2. We calculated the combined score by adding the BI-RADS score and each quantitative parameter (SWEmax, SWERatio, and SMIVI). The BI-RADS categories were scored on a scale of 1 to 5 (C3:1, C4a:2, C4b:3, C4c:4, and C5:5), and SWEmax, SWERatio, and SMIVI were scored as 0 or 1 based on applied cutoff values. The summed score ranged from 1 to 8. We used a cutoff value of 4 for the combined score to discriminate between benign and malignant cases based on the reported AUC values. 3. The combined score of B-mode US and quantitative parameters can improve diagnostic performance and reduce unnecessary breast biopsy. However, the combined scores should be applied with caution, considering that the quantitative parameters have limitations in assessing small-sized, pure DCIS, or low-grade invasive cancer.

#### **TABLE OF CONTENTS/OUTLINE**

1. Review the principles of quantitative parameters for SWE (SWEmax, SWERatio) and SMIVI. 2. Review the appropriate cut off value for quantitative parameters for SWEmax, SWERatio, and SMIVI and evaluate their diagnostic performance in differentiating between benign and malignant masses. 3. Showcase the various case of combined score and pathology reviews to demonstrate how combined scores are helpful for differential diagnosis of breast masses, and which cases will be carefully applied.

### Threading the Needle: The Role of Breast Radiologists in Managing Suspicious Internal Mammary Lymph Nodes

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Megan J. Kalambo, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Examine Internal Mammary Lymph Nodes (IMLN) as an important component of breast lymphatic drainage. 2. Review the implications of metastatic IMLN adenopathy in the staging of breast cancer. 3. Provide an overview of IMLN basin anatomy, differential diagnosis of IM adenopathy, and the clinical indications for imaging and sampling. 4. Explain the tools and technical steps necessary for conducting a successful ultrasound biopsy of IMLNs. 5. Recognize ultrasound-guided Fine Needle Aspiration (FNA) biopsy as a feasible percutaneous sampling technique radiologists can use to provide treatment planning assistance to clinical teams.

#### TABLE OF CONTENTS/OUTLINE

Based on our experiences at a tertiary oncologic referral center, we will provide an overview of internal mammary lymph nodes (IMLN) with regard to the anatomical, clinical, imaging and procedural considerations for radiologists. • Overview of IM nodal basin anatomy • Management of indeterminate and suspicious IMLNs • Differential diagnosis of abnormal/indeterminate IMLNs • Incidence and implications of IMLN adenopathy on breast cancer staging • Indications for imaging of IMLN • Multimodality identification of IMLN on Ultrasound, MRI, PET/CT • Biopsy considerations • Indications • Tools • Technical steps • Case-based discussion of IMLNs • Tips for imaging and clinical management of patients with indeterminate/suspicious IMLN.

### The State of Breast Imaging in the Caribbean

All Day Room: Learning Center

Dami Olufosoye, BS, MPH (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Provide an overview of the current trends in incidence and mortality of breast cancer in the Caribbean 2. Discuss the state of breast services with respect to breast exams and screening 3. Discuss the challenges in breast services including infrastructure and health workforce availability 4. Recognize patient-related barriers 5. Review main points of the global breast cancer initiative and goals for breast imaging in the Caribbean

#### TABLE OF CONTENTS/OUTLINE

- Overview of breast cancer incidence, prevalence, mortality, and stage of diagnosis in the Caribbean compared globally and to the US
- State of breast services with respect to breast exams and testing
- National guidelines on breast exams and screening
- Self-breast exams
- Clinical breast exams
- Access to mammograms
- Discuss the state of breast services pertaining to the infrastructure and health workforce availability
- Number of equipment in the region
- Type of equipment available: digital mammography vs full film digital mammography vs tomosynthesis
- Maintenance/ Audit of equipment
- Health workforce: radiologists, oncologists, physicists
- Breast treatment services
- Barriers surrounding breast cancer
- Knowledge deficits
- Patient beliefs
- 2021 Global Breast Initiative
- Key messages
- Recommendations for implementing interventions

### Breast Lesions Detected on CT: When to Refer for Triple Breast Assessment

All Day Room: Learning Center

Sharmeen Jaffer, BMBS, FRCR (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

- Incidental breast lesions are a common finding on CT and unnecessary referrals can create a significant burden on the breast clinic.
- To evaluate imaging characteristics of incidental breast lesions identified on CT and suggest characteristics which warrant referral to the breast clinic.
- To identify imaging characteristics of breast lesion mimics or benign breast lesions; avoiding unnecessary referral to the breast clinic.
- To explore the limitations of CT with imaging breast lesions including post-contrast enhancement in benign and malignant lesions.

#### TABLE OF CONTENTS/OUTLINE

- Variability of normal breast glandular tissue on CT including asymmetry and differences in density.
- Breast lesions with benign characteristics such as coarse or popcorn calcification or well defined cysts with homogenous fluid attenuation.
- Indeterminate breast lesions including intramammary lymph nodes, leiomyomas, papilloma, fat necrosis or lobular fibroadenomas which demonstrate post-contrast enhancement.
- Suspicious breast lesions and indicators of malignancy including irregular or speculate margins and global or peripheral contrast enhancement; measured in Hounsfield units (HU).
- Mimics of breast malignancy including lymphoedema, post surgical changes or radiotherapy.
- Factors that negate an unnecessary referral to breast clinic include: long term stability, lesion previously assessed on mammography/ultrasound/biopsy proven benign lesion.

### Multimodality Imaging of Recurrent and Residual Breast Cancer

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Victoria Domonkos (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

After this exhibit, the reader will be able to: 1. Describe the epidemiology and clinical implications of recurrent and residual breast cancer. 2. Demonstrate the importance of a multimodality approach to the detection, workup and diagnosis of recurrent and residual breast cancer. 3. Apply specific strategies to improve early detection to optimize patient outcomes.

#### TABLE OF CONTENTS/OUTLINE

Recurrent and residual breast cancer remains a diagnostic challenge with significant clinical implications. Early and accurate detection is critical for optimizing patient outcomes. Using a case-based multi-modality approach, this exhibit will: 1. Review the epidemiology and clinical implications of recurrent and residual breast cancer. 2. Discuss current surveillance recommendations and supporting literature, including the importance of patient anxiety. 3. Review expected post-treatment findings, discussing the advantages and disadvantages of each modality (mammography, ultrasound and MRI). 4. Provide an approach to surveillance imaging and residual disease, with emphasis on the surgical pathology report, surgical margins and the importance of breast biopsy marker clips. 5. Provide tips and tricks to ensure early identification of recurrent/residual disease and avoid post-treatment surveillance pitfalls.

Printed on: 08/22/24

### From Benign to Malignant: Understanding the Spectrum of Phyllodes Tumors

All Day Room: Learning Center

Abel Gonzalez Huete, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. To provide an overview of Phyllodes tumors, including their pathology features, categories and clinical presentation. 2. To discuss the role of the different imaging in the diagnosis of Phyllodes tumors. 3. To review the differential diagnosis of Phyllodes tumors and how to differentiate them from other breast tumors. 4. To highlight the importance of accurate diagnosis in the management of Phyllodes tumors.

#### TABLE OF CONTENTS/OUTLINE

1. Introduction: Breast anatomy, Fibroepithelial tumors, Epidemiology, Pathogenesis, Categories of Phyllodes Tumors (Benign, Borderline, and Malignant) 2. Clinical Presentation 3. Pathology 4. Imaging Findings: - Benign Phyllodes tumor (Mammography, Ultrasound and MRI), - Borderline Phyllodes tumor (Mammography, Ultrasound and MRI), - Malignant Phyllodes tumor (Mammography, Ultrasound and MRI). 5. Differential Diagnosis: Fibroadenoma, Primary Sarcoma of the Breast, Periductal Stromal Tumor of the Breast, Other. 6. Benign vs Malignant Phyllodes Tumors: Key Differences 7. Management, Treatment and Prognosis 8. Conclusion 9. References

### **A Sheep in Wolf's Clothing: The Multiple Appearances of Local Breast Cancer Recurrence After Breast Mastectomy**

All Day Room: Learning Center

Agostina B. Peralta I (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

-Discuss the role of the different image modalities in the surveillance of breast cancer recurrence after breast mastectomy.- Recognizing the imaging and the normal anatomic changes depending on the type of breast mastectomy performed.-Illustrate the imagen findings corresponding to a breast cancer recurrence on different image modalities.-Differentiating post-surgical benign findings from a malignant relapse.

#### **TABLE OF CONTENTS/OUTLINE**

Studies have proven that the presence of local recurrence is an independent predictor for survival this is why radiologist should be familiarized to distinguish normal or benign findings after mastectomy form a recurrence. With the main objective of early detection and treatment. -Briefly review the different surveillance recommendations for these patients given by international societies. -Description of the different surgical breast reconstruction techniques used nowadays will be performed. These include the use of prosthetic implants, autologous tissue flaps, skin and fat flaps. -Illustrations will be shown of the expected anatomic changes after mastectomy on different image modalities depending on the surgical technique. -Images showing and differentiating benign findings from a post-surgical local breast cancer recurrence will be portrait.

### Comparison of Indications, Reading Time, and Work Flow of FDA Approved Supplemental Screening Automated Whole Breast Ultrasound Tomography in Women With Dense Breasts

All Day Room: Learning Center

Mary W. Yamashita, MD (*Presenter*) Research Grant, Delphinus Medical Technologies, Inc; Consultant, Delphinus Medical Technologies, Inc

#### TEACHING POINTS

- Ultrasound as adjunct to screening mammography for women with dense breasts increases cancer detection. - There are new ultrasound technologies available for same day supplemental dense breast screening. - Invenia ABUS from GE and SoftVue Automated Whole Breast Ultrasound Tomography (SV) from Delphinus Medical Technologies are both PMA-approved for screening and diagnostic purposes. - In clinical practice, ABUS is time-consuming and requires significant reading time. - SV offers benefits of same day supplemental screening with mammography and, unlike other ultrasound imaging, only adds 3-4 mins of reading time per case for the radiologist.

#### TABLE OF CONTENTS/OUTLINE

1. Why ultrasound is important in screening women with dense breasts 2. Overview of ultrasound technologies available for dense breast screening 3. Comparison of indications for use 4. Benefits and challenges with integrating ultrasound into practice for adjunct screening for women with dense breasts: Workflow 5. Reading time: what makes reading ABUS and HHUS challenging in clinical practice, what are the main drivers of the time it takes for radiologist to interpret images including technique and training, number of images, image quality, and artifacts 6. Overview of SV automated whole breast ultrasound 7. Image sequence and reading protocol for SV 8. Example clinical cases demonstrating SV hanging protocol 9. SV reading time study and results 10. Conclusion

BREE-80

### Do Not Miss Architectural Distortion!

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Haydee Ojeda-Fournier, MD (*Presenter*) Research Consultant, View Point Medical, Inc; Stock options, CureMetrix, Inc

#### TEACHING POINTS

The BI-RADS 5th edition manual defines architectural distortion (AD) as “distortion of the breast parenchyma with no definite mass visible.” AD of the breast is an abnormality found in multimodality breast imaging and occurs with benign and malignant lesions. The most common cause of architectural distortion is a surgical scar. However, 4% of breast cancers present with AD. In addition to being a primary imaging finding, AD may also be an associated finding. In addition, AD is notorious for being a missed mammographic lesion. It is important for radiologists to “train their eyes” to identify AD and to know the differential considerations and pitfalls associated with AD evaluation to avoid potential missed breast cancer. The goals of this educational exhibit are to 1. recognize AD by 2D mammogram, digital breast tomosynthesis (DBT), ultrasound, and MRI, 2. review the differential considerations of AD, and 3. recommend management options and perform radiology-pathology concordance.

#### TABLE OF CONTENTS/OUTLINE

Introduction; Definition of AD; Multimodality imaging examples of AD of the breast including mammography, sonography, and MRI; Learn a systematic approach to the characterization of AD; AD and DBT; How to appropriately apply the BI-RADS classification and management recommendations of AD; Challenging cases of AD; Pitfalls in evaluating AD: fat-containing, one view only, not seen at biopsy; Discordance in AD rad-path correlation; Sample cases; Conclusion.

BREE-81

### Non-mass Lesion on Breast Ultrasound: Radiologic-Pathologic Correlation and a Guide to Approach

All Day Room: Learning Center

Haejung Kim, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Unlike mass, non-mass lesion does not show a three-dimensional structure, so it is more difficult than mass to detect and make an accurate diagnosis on breast ultrasound. For this reason, non-mass lesion evaluation on breast ultrasound often follows the detection of abnormality on other imaging modalities, such as mammography or MRI. This educational exhibit was prepared to increase understanding of non-mass lesions seen on breast ultrasound and to help accurately diagnose benign and malignant non-mass lesions. 1. Review the definition of non-mass lesion on breast ultrasound, 2. Correlate radiologic and pathological findings of benign and malignant non-mass lesions, and 3. Discuss a guide to approach for evaluating non-mass lesions on breast ultrasound.

#### TABLE OF CONTENTS/OUTLINE

1. Definition of non-mass lesion on breast ultrasound A. True non-mass lesion vs. Normal variants 2. Correlation between radiologic and pathologic findings of non-mass lesions on US A. Imaging features of non-mass lesions on US B. Pathologic features correlated with benign and malignant non-mass lesions 3. Approach for evaluating non-mass lesion on breast ultrasound

Printed on: 08/22/24

### The Cyst Bang Theory: When to Biopsy

All Day Room: Learning Center

Claudia L. Ruano, MSc (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Explain the epidemiology and pathogenesis of breast cyst. 2. Recognize the characteristics by image of breast cysts. The complex cyst is uncommon, but are suspicious of malignancy and merit biopsy. 3. Recognize criteria that will help identify a complex cyst. 4. Identify intraductal papillary nodule. Benign papillomas constitute 85% and 90%, intracystic papillary carcinomas 6% to 7%. 5. Points to help distinguish real from artifacts (echos) on ultrasonography images. 6. Recognize the most important differences in images between complicated and complex cyst. The true papillary nodules are anchored to the wall and do not move with the postural changes of the patient. 7. Analyze when to suspect malignancy in the breast cysts and categorize them based on the BIRADS.

#### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Epidemiology and pathogenesis 3. What are complex cysts 4. What should birads assign to a complex cyst 5. Review the spectrum of findings (mammography, us and contrast-enhanced mammography) 6. When to decide biopsy, a complex cyst 7. Let's practice (illustrative cases) 8. Conclusions

Printed on: 08/22/24

BREE-83

### Solitary Dilated Duct in the Breast: A Multimodality Pictorial Review

All Day Room: Learning Center

Zachary R. Zaniewski, DO (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Solitary dilated duct is associated with benign and malignant findings and the BI-RADS classification has varied over previous editions. Solitary dilated duct has characteristic imaging features on multiple modalities. Recognizing the imaging features, particularly if new, is important for management.

#### TABLE OF CONTENTS/OUTLINE

Background Review of solitary dilated duct and BIRADS classification. Pictorial Review: Cases illustrating benign and malignant lesions with multiple modalities. Case 1: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound. Pathology: Papilloma without atypia. Case 2: History: Presenting with breast pain. Imaging: Mammogram, ultrasound. Pathology: Invasive ductal carcinoma. Case 3: History: 60-year-old female presenting for screening mammogram. Imaging: Mammogram, ultrasound. Pathology: Papilloma without atypia. Case 4: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound, MRI. Pathology: Papilloma with high-risk features. Case 5: History: Presenting for screening mammogram. Imaging: Mammogram, ultrasound. Pathology: Intraductal papilloma. Case 6: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound, ductogram. Pathology: DCIS. Case 7: History: Presenting with bloody nipple discharge. Imaging: Mammogram, ultrasound, ductogram, MRI. Pathology: Multifocal DCIS with intraductal papillomatosis. Conclusion Review pearls for solitary dilated duct findings and management.

BREE-84

### **MRI Detected Lesion in Women with a Personal History of Breast Cancer, and Then?**

All Day Room: Learning Center

Ga-Eun Park, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- Screening is still important for women with a history of breast cancer, because of high risk for future breast cancer. Breast MRI shows impressive resolution with high sensitivity, but specificity is relatively low.
- Second look ultrasound is a well-established approach for MRI detected lesions, and lesions found on subsequent ultrasound have a high probability of malignancy. However, second look ultrasound has limitations, such as operator dependence and the possibility of false negatives. Follow-up is required, and re-biopsy should be considered in case of image-pathology discordant.
- Correlation with mammography can sometimes be helpful. In particular, new or increasing calcifications can be objective evidence for lesion detection and confirmation of biopsy results.
- MR-guided biopsy must be considered in lesions with suspicious MRI features but occult on US or mammography.

#### **TABLE OF CONTENTS/OUTLINE**

<Representative cases of new enhancing lesion on breast MRI>• According to surgical method: op site after BCS, ipsilateral and contralateral breast after BCS, after mastectomy• According to detection modality: second look ultrasound (successful and missed), mammography, MR-guided biopsy for occult lesion• According to biopsy results: recurrence, false positive (benign), false negative (missed)

Printed on: 08/22/24

BREE-85

### 5 Years of False Negative Review from the Mammography Audit: Observations and Lessons Learned

All Day Room: Learning Center

#### Awards

##### Magna Cum Laude

Heather V. Garrett, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

-Review of false negative (FN) cases can refine your mammography practice.-Sensitivity of mammography is limited in dense breasts.-BCT changes can make mammography difficult to interpret. ACR recommends annual screening MRI in patients with a prior history of BCT and dense breasts.-Screening MRI is more sensitive than mammography in the detection of breast cancer. High-risk patients should obtain annual mammography and annual screening MRI alternating at 6 month intervals.-Clinical symptoms (palpable breast lump, nipple discharge, skin changes and focal breast pain) should be evaluated using a multi-modality imaging approach.-BIRADS 3 cases are included in the FN review of diagnostic mammography. 0-2% of these cases may be cancers.

#### TABLE OF CONTENTS/OUTLINE

Background: False negative (FN) case review is mandated part of the annual mammography radiologist audit (MQSA/ACR). We are a large academic practice with dedicated breast imagers. We analyzed 135 FN cases from 5 years (2016-2020).Observations: -FN cases tended to be in patients with dense breasts, personal history of breast cancer, prior BCT, elevated life-time risk for breast cancer.-FN cases were mostly detected by presenting clinical symptom or screening MRI.-Some FN cases were women who had been given the assessment of BIRADS 3 in the diagnostic setting.Cases: 5-10 cases to illustrate teaching points.Lessons Learned: Overall, we found that there are many reasons for FN studies, the minority of which involved "missed cancers." Review of FN cases can refine your mammography practice.

### **Don't Forget About the Nipple: Overview of the Anatomy and Different Lesions Involving the Nipple-areolar Complex**

All Day Room: Learning Center

Maria Guerra, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

To describe the normal anatomy and some anatomic variants of the nipple-areolar complex (NAC). To review imaging anatomy of the NAC by different techniques. To present a pictorial review of commonly known benign and malignant NAC lesions.

#### **TABLE OF CONTENTS/OUTLINE**

Anatomy of the nipple-areolar complex  
Retraction  
Inversion  
Imaging anatomy: mammogram, ultrasound, magnetic resonance  
Different lesions:  
Dermal lesions: nipple calcifications, Epidermal inclusion cyst  
Inflammatory lesions: duct ectasia, retroareolar cyst, periductal mastitis, abscess, Zuska disease  
Benign Tumors: Nipple adenoma  
Malignant tumors: papilloma, carcinoma, Paget's disease

### The Many Faces of Invasive Lobular Carcinoma

All Day Room: Learning Center

#### Awards

##### Cum Laude

Miral M. Patel, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Invasive lobular carcinoma accounts for 5-15% of all breast cancers. 2. ILC is characterized by the lack of E-cadherin function, which explains the discohesive growth pattern and the subtle findings in imaging. 3. A review of radiologic and pathologic correlation of invasive lobular carcinoma and its morphologic variants can aid radiologists in recognizing patterns in the imaging presentation of invasive lobular carcinoma to facilitate early detection.

#### TABLE OF CONTENTS/OUTLINE

This educational exhibit reviews: 1- Basic review of invasive lobular carcinoma 2- Case based discussion of the radiologic presentation and pathologic correlation of the variants of invasive lobular carcinoma including classic, solid, signet ring cell, and pleomorphic 3- Pattern recognition in the presentation of invasive lobular carcinoma

### Breast Cancer Recurrence: Incidence and Imaging Appearance

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Haydee Ojeda-Fournier, MD (*Presenter*) Research Consultant, View Point Medical, Inc; Stock options, CureMetrix, Inc

#### TEACHING POINTS

Locoregional recurrence has been estimated to occur in 5-25% of breast cancer (BC) survivors, defined as the reappearance of the tumor at the surgical site or metastases in the regional lymph nodes. Even after mastectomy, there is a 2-10% reported lifetime risk of recurrence. Recurrence varies by molecular subtypes of BC, triple negative BC at 2-5 years after and other types at 5-15 years after treatment. Mammography remains the primary imaging modality for post-BCT surveillance. Breast MRI has the highest accuracy for differentiating post-surgical scar from recurrence. By the end of this educational exhibit, the learner will: 1. Learn the incidence, risk factors, and clinical presentation of breast cancer recurrence, 2. Review imaging recommendations for patients with a history of breast cancer and those with suspected breast cancer recurrence, 3. Recognize the common imaging appearance of recurrent breast cancer on multimodality imaging, 4. Distinguish the appearance of recurrent breast cancer from expected post-surgical changes and other differential diagnoses

#### TABLE OF CONTENTS/OUTLINE

Introduction; Incidence and definition of breast cancer recurrence; Expected recurrence rates based on molecular subtypes of BC; Clinical presentation of breast cancer recurrence; Review imaging recommendations for patients with a history of breast cancer; Review diagnostic workup for patients with suspected breast cancer recurrence; Differential considerations of in-breast recurrence and regional nodal recurrence; A pictorial review of multimodality imaging in BC recurrence; Clinical management of recurrent BC; Algorithm for imaging patients with suspected recurrence; Conclusion

Printed on: 08/22/24

BREE-89

### AI in Breast Imaging: Current Status and Future Directions

All Day Room: Learning Center

Berat Bersu Ozcan, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

- Artificial intelligence (AI) in breast imaging is being used for lesion classification, breast density and cancer risk assessment. In screening mammography setting, stand-alone sensitivity of commercially available AI system range 75-85% at radiologists' specificity of 49-79%. This indicates comparable results with radiologist performance (AUC, 0.84 vs 0.81, respectively).
- Beyond screening ,a deep learning model trained on uses mammograms and traditional risk factors showed superior performance in predicting 5 year breast cancer risk compared to the Tyrer-Cuzick model. (AUC, 0.70 vs 0.62,  $p < 0.001$ ).
- Model drift is a concept that describes degradation of AI model performance as the data it is used on changes. This raises concerns regarding the performance and reliability of AI models in real-life clinical settings.
- The FDA requires manufacturers of Artificial Intelligence/Machine Learning (AI/ML)-Based Software as a Medical Device (SaMD) to be transparent and monitor the real-world performance of their products to ensure the algorithm meets the standards after deployment.
- In a recent Dutch patient survey most patients (77.8%) did not support stand-alone use of AI in screening interpretation. Furthermore, 41.7% opposed the idea of using AI to select cases for second reading and 17% objected to AI as a second reader.
- The reimbursement for breast imaging AI has not yet been established, and several proposed frameworks are currently under discussion.

### Navigating Mammary Ducts Pathologies and Anatomy: A Radiological Handbook

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Giovanna Andreani, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The breast is an apocrine gland that contains different types of tissue: glandular, fibrous or connective, and fatty tissue. The glandular tissue is composed of mammary lobules and ducts, the latter being a tubular structure with the function of carrying the milk produced by the gland to the nipple. There are several pathologies and variations that can affect the mammary duct, ranging from benign alterations such as ductal ectasia or papilloma to even malignant ones (ductal carcinoma in situ or invasive ductal carcinoma, among others). Knowing that the majority of breast cancer arises from the ductal epithelium, it is crucial in the diagnosis and treatment of breast cancer by detecting intraductal lesions at an early stage. The objective of this study is to didactically review the anatomy and embryology of mammary ducts, as well as the main pathologies that affect this very important structure.

#### TABLE OF CONTENTS/OUTLINE

Review of the anatomy and discussion of the radiological findings in the mammary ducts, whether in their normal appearance or pathological changes through the different imaging methods obtained from the digital archive of our institution.

Printed on: 08/22/24

## Abstract Archives of the RSNA, 2023

BREE-90

### **Beyond the Norm: An Exploration of Extramammary Metastases to the Breast**

All Day Room: Learning Center

Berat Bersu Ozcan, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- Metastases to the breast are rare, comprising 0.5-6.6% of all malignancies in the breast, and typically indicate widely disseminated disease and poor prognosis.
- Lymphoma (17-38.3%), melanoma (8.3-23.4%), lung (8-15%), gynecological carcinomas (8-12.8%), and sarcomas (2%-12%) are the most common primary tumors to metastasize to the breast.
- Imaging features can vary depending on the primary neoplasm and route of dissemination, hematogenous (more common) or lymphatic.
- Typically, metastases present as well-defined masses without calcifications or distortion on mammography and round hypoechoic masses on ultrasound. Hematogenous metastases present as solitary or multiple breast masses located in the skin, subcutaneous tissue, or the breast parenchyma.
- Breast findings should be characterized according to the BI-RADS lexicon and managed according to the most suspicious features. If metastatic disease to the breast is in the differential diagnosis based on patient history and/or clinical presentation, early confirmation of secondary involvement with pre-operative biopsy of breast lesions is crucial to direct appropriate management.
- Breast metastases can be highly vascular, and ultrasound technique should be optimized to not confuse with pseudoaneurysms or aneurysms, which could result in a delay of diagnosis.

#### **TABLE OF CONTENTS/OUTLINE**

1. Literature review 2. Diagnostic algorithm 3. Key clinical and imaging features 4. The diagnostic and prognostic role of imaging modalities 5. Case demonstration and pathologic correlation

### Optimizing DWI for Improved Imaging in Breast Cancer and Beyond

All Day Room: Learning Center

Sheida Ebrahimi, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Diffusion weighted imaging (DWI) is an advanced MRI technique that reflects water diffusion in tissues of interest and has been shown predicting pathologic response to neoadjuvant chemotherapy. It assists radiologists in better detecting and characterizing breast lesions. DWI can be challenging due to the breast morphology and introduction of artifacts. This exhibit reviews current state of DWI in breast cancer imaging including the physics of DWI, protocols utilized, advanced DWI techniques, and current indications. Strategies for optimizing DWI to improve image quality, diagnostic accuracy, and clinical utility will also be reviewed. At the end of this educational exhibit, learners will: 1. Recall the fundamentals of DWI and ADC Values; 2. Describe the correlation between ADC values and breast cancer prognostic factors; 3. Understand DWI challenges and limitations, and strategies for enhancing standard DWI; 4. Classify advanced DWI.

#### TABLE OF CONTENTS/OUTLINE

1. Introduction: Overview of DWI and its importance in breast cancer;
2. Fundamentals of DWI: Explanation of water diffusion in tissues; ADC values and their significance in DWI;
3. ADC Values and prognostic factors in breast cancer;
4. Benefits and applications of DWI in breast cancer;
5. Quality control and factors influencing repeatability and reproducibility of ADC measure: Techniques to improve the quality of ADC measurements;
6. Comparison of DWI protocols: QIBA recommendations vs. our institute's approach;
7. Technical challenges and limitations of DWI: Techniques to Improve standard DWI;
8. Classification of advanced DWI: Overview of subtypes of advanced DWI, their differences, and advantages;
9. Conclusion.

### Idiopathic Granulomatous Mastitis: A Case-Based Review

All Day Room: Learning Center

Layne Kelley, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Idiopathic granulomatous mastitis (IGM) is estimated to affect 2.4/100,000 women, at median age of 36.5 years, and bilateral involvement in 8.8%. 2. Common symptoms are pain, erythema, palpable lump, and less frequently, fistulous drainage or nipple discharge. 3. The most common ultrasound findings are hypoechoic collection (75.9%) and skin involvement (53.5%). Mammography is often nonspecific, but common findings include focal asymmetry (51.6%), global asymmetry (18.3%), mass (17.2%), abnormal lymph nodes (8.6%). 4. IGM can mimic infectious mastitis or breast cancer on imaging and clinically. 5. Biopsy is usually required to confirm diagnosis and guide management. Often biopsy is necessary to exclude malignancy, especially inflammatory or triple-negative subtypes. Suspected IGM may be tentatively diagnosed by clinically assessing treatment response, but given overlap of imaging features and different treatment for IGM and infectious mastitis, biopsy is often needed. 6. Imaging findings often persist after resolution of clinical symptoms, thus clinical follow-up should be the mainstay for surveillance.

#### TABLE OF CONTENTS/OUTLINE

1. Introduction  
2. Typical imaging findings on mammography and ultrasound  
3. Other entities that mimic IGM  
4. Case-based review of biopsy-proven cases using key images with descriptions, treatment and clinical outcome data  
5. Biopsy and management considerations

### **Don't Be Fooled: Not Every Late-Onset Peri-Implant Effusion is Seroma! A Case-Based Review of Breast Implant-Associated Anaplastic Large Cell Lymphoma (BIA-ALCL)**

All Day Room: Learning Center

Larissa L. Botelho, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

We report the case of a female patient, with a history of mammoplasty six years ago, reporting sudden enlargement of the left breast. Imaging exams showed the presence of peri-implant fluid in the same breast, with the analysis of the fluid confirming the BIA-ALCL. Breast Implant-associated Anaplastic Large Cell Lymphoma (BIA-ALCL) is characterized by a late-onset peri-implant effusion, appearing on average 10 years after exposure to breast implants. The pathogenesis is not completely identified, but it is known that cases of BIA-ALCL are related to textured prostheses, with the surface of the prosthesis being the most important factor in inducing the disease. It may present only with the effusion (subtype of effusion) or associated with a peri-implant mass (mass-forming disease). The main associated symptoms are sudden edema secondary to the peri-implant effusion and, in case of mass-forming disease, the presence of a palpable nodule. Multiple imaging methods can be used in the evaluation of patients with suspected BIA-ALCL. However, diagnostic confirmation depends on the analysis of the fluid found. The diagnosis of BIA-ALCL is made with the characterization of morphologically atypical lymphocytes, with CD30 expression and negativity for ALK-1. The differential diagnosis of the effusion subtype is made with late seroma. Distant disease is rare, being a neoplasm with a high potential for cure, if identified in the early stages and when not associated with masses, with a surgical approach as a curative technique, in the case of the subtype of effusion.

### Cystic Breast Lesions- What to Do When It's Not Simple

All Day Room: Learning Center

#### Awards

##### Certificate of Merit

Laura K. Harper, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Imaging features of benign and malignant cystic lesions may overlap, causing misclassification with the potential to produce diagnostic delay and harm. The purpose of this exhibit is to review ultrasound features of benign and malignant cystic breast masses to guide appropriate characterization and management. The Breast Imaging Reporting and Data System (BIRADS) assessment categories will be reviewed as it pertains to cystic breast masses, including review of appropriate utilization of the BIRADS-3 (probably benign) assessment category. Emphasis will be placed on recognizing suspicious imaging features warranting further evaluation with percutaneous biopsy. Teaching Points: 1. Examine imaging features of various cystic breast masses (Simple cysts, complicated cysts, and complex cystic and solid mass). 2. Discuss overlap of benign and malignant complex cystic and solid masses (ex: hematoma, abscess, cancer). 3. Review appropriate BI-RADS category assessment and management for various cystic lesions

#### TABLE OF CONTENTS/OUTLINE

1. Introduction of the prevalence, clinical presentation and patient factors associated with cystic breast masses 2. Review distinguishing features and BI-RADS category assessments for various cystic masses 3. Multimodality (mammography, contrast-enhanced mammography, ultrasound, and magnetic resonance imaging) case-based review of benign and malignant cystic breast masses 4. Conclusion (summary of key educational points)

### **Patterns of Breast Cancer Recurrence in the Post-Mastectomy Breast with or without Reconstruction: A Case-Based Review**

All Day Room: Learning Center

Shannon Lanzo, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Women treated for breast cancer with mastectomy with or without reconstruction are at risk of developing loco-regional recurrence along the suture line or within residual tissue.2. Benign post-operative findings include edema, seroma, hematoma, fat necrosis, post-operative scarring and fibrosis, which evolve over time.3. Recurrence may be difficult to distinguish from these benign findings.4. Biopsy is warranted when imaging findings are equivocal.

#### **TABLE OF CONTENTS/OUTLINE**

1. This case-based exhibit will review the expected post-operative appearance post mastectomy without or with reconstruction using autologous tissue flaps (pedicled or free flap), and/or prosthetic implants.2. We will illustrate typical imaging features of benign post treatment changes (fat necrosis, fibrosis, edema, skin thickening, etc.) and malignant findings on mammogram, ultrasound, and MRI.3. We will review appropriate use of combined imaging and biopsy methods when imaging findings are equivocal.

Printed on: 08/22/24

## Abstract Archives of the RSNA, 2023

BREE-98

### Diagnostic Potential of Photon-Counting Detector Computed Tomography to Evaluate Breast Cancer Patients

All Day Room: Learning Center

Misugi Urano, MD, PhD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Photon-counting detector computed tomography (PCD-CT) has several advantages over energy-integrating computed tomography (EID-CT). It provides high spatial resolution and improves image contrast, resulting in precise visualization of soft tissue and microstructures while reducing radiation dose. In addition, a simultaneous multi-energy acquisition offers further qualitative and quantitative information in a single scan. These benefits make PCD-CT a valuable tool for systemic staging, preoperative planning, and post-treatment monitoring of breast cancer patients due to its ability to precisely depict the local extent of tumors and the presence of small lesions. This presentation will focus on PCD-CT in initial staging workup, treatment response assessment, or recurrences monitoring in breast cancer patients, comparing to EID-CT, other image modalities, and pathological results. We will also discuss the advantages and pitfalls of PCD-CT.

#### TABLE OF CONTENTS/OUTLINE

1. Current CT recommendation for breast cancer patients in guidelines
2. The potential of PCD-CT for breast cancer workup
3. Case-based review of PCD-CT in breast cancer patients compared to EID-CT, other image modalities, and pathological results.
4. Discussion of the utilities of PCD-CT for breast cancer patients, including advantages, disadvantages, and pitfalls.

Printed on: 08/22/24

## Abstract Archives of the RSNA, 2023

BREE-99

### **Breast Ultrasound Tomography: The Essentials for the Breast Radiologist**

All Day Room: Learning Center

Yu Zhao, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

This educational exhibit will review the essentials of breast ultrasound tomography. 1. Understand basic concepts of breast ultrasound tomography including essential physics, the basic imaging sequences, and keys to imaging interpretation. 2. Describe the advantages of breast ultrasound tomography for evaluation of the breasts, especially in those with dense breasts. 3. Describe the specific imaging appearance on ultrasound tomography of various breast entities, benign and malignant. 4. Discuss the future practice considerations and limitations of ultrasound tomography.

#### **TABLE OF CONTENTS/OUTLINE**

-This educational exhibit reviews the essentials of breast ultrasound tomography for the breast radiologist. This is a new imaging modality with enormous potential to add new value to breast imaging by improving diagnostic accuracy especially in patients with dense breasts. -We will describe in simple terms the physics of breast ultrasound tomography and the basic imaging sequences including Waveform Enhanced Reflection (Wafer), Reflection, Sound Speed, and Stiffness Fusion sequences in a breast ultrasound tomographic examination.-We will review with illustrative case examples of high-yield breast lesions including cysts, fibroadenomas, and cancers comparing the distinctive imaging appearance on ultrasound tomography versus other breast imaging modalities.-This will be followed by a discussion of the specific advantages of ultrasound tomography relative to other imaging modalities, such as improved lesion localization and lesion characterization. Finally, we will present the limitations of ultrasound tomography and general considerations for future practice.

Printed on: 08/22/24

## Abstract Archives of the RSNA, 2023

CAEE

### Cardiac Imaging Education Exhibits

All Day Room: Learning Center

#### Sub-Events

#### **CAEE-1 Is It Possible to Assess Left Atrial Remodeling Using Deep Learning? An Attempt to Classify Atrial Fibrillation Types Using Contrast-Enhanced CT Images.**

Hina Kotani (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Catheter ablation therapy is one of the curative treatments for atrial fibrillation (AF). It is generally known that the recurrence rate after treatment increases as attacks persist, and the factor is related to structural remodeling of the left atrium. However, standard evaluation is difficult, and the indication for catheter ablation therapy is currently determined by the surgeon's empirical judgment and the duration of disease obtained from the patient's self-report. Therefore, this study demonstrates the possibility of assessing remodeling of the left atrium from the results of the visualization of the classification basis of the two models. The major teaching points of this exhibit are 1. Evaluation of AF types using contrast-enhanced CT imaging is difficult only for experienced physicians 2. Deep learning enables evaluation of the left atrium using features such as the structure of the left atrium and pulmonary veins obtained from images. 3. Evaluation of structural remodeling of the left atrium may be useful for AF types

#### TABLE OF CONTENTS/OUTLINE

1. About Atrial Fibrillation -Classification of Atrial Fibrillation Types -Structural remodeling of the left atrium 2. Treatment options for Atrial Fibrillation -Relationship between seizure duration and treatment outcome 3. Results of experiments -How well did you recognize the shape of the left atrium?

#### **CAEE-10 Seeing Beyond the Surface: A Radiological Exploration of Pacemakers, CRT, and ICDs**

#### Awards

#### Cum Laude

Lucas Ortiz, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

- Review the relevant cardiac anatomy, the different types of devices (pacemakers, CRT, and ICDs), and the positioning and integrity of the different elements of the devices.
- Understand the importance of X-ray imaging in the diagnosis and follow-up of patients with pacemakers, CRT, and ICDs.
- Identify the normal and abnormal X-ray findings for these devices, including lead placement, device positioning, and associated complications.
- Understand how X-ray imaging is used to evaluate the function of pacemakers, CRT, and ICDs, including pacing and electrical leads, and common X-ray findings associated with device malfunction.
- Recognize the potential limitations associated with X-ray imaging of these devices and the troubleshooting strategies for addressing those limitations.

#### TABLE OF CONTENTS/OUTLINE

1. Introduction 2. Overview of cardiac devices (pacemakers, CRT, and ICDs) 3. Anatomy and positioning of cardiac devices 4. Importance of X-ray imaging in diagnosis and follow-up 5. Differentiating between pacemakers, CRT, and ICDs on chest radiography 6. Normal and abnormal X-ray findings for pacemakers, CRT, and ICDs a. Device type and differences b. Device positioning c. Internal elements d. Lead placement e. Lead integrity f. Associated complications 7. Troubleshooting strategies for technical limitations of X-ray 8. Take home points

#### **CAEE-11 AI-Assisted Autonomous Aortic Aneurysm Analysis - Status, Strengths, Slants, and Stresses: Ut Nos Ibi Nunc?**

Roshan Fahimi, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

The exhibit will help the audience understand the following aspects of multiple AI algorithms pertaining to triage, measurement, detection, and report creation for aortic aneurysm and dissection. 1. 1. Aortic evaluation with CT: Intentional and incidental 2. 2. Scientific evidence for aortic evaluation with AI 3. 3. Multi-vendor AI for aortic evaluation 4. 4. Status, strengths, slants, and stresses of AI models

## TABLE OF CONTENTS/OUTLINE

We use our multi-vendor AI experience to organize and present the exhibit content into following brackets: 1. 1. Aortic Diseases: Incidence, importance, and imaging 2. 2. AI for aortic aneurysm and dissection: Evidence in literature 3. 3. Approach of multiple AI algorithms in aortic aneurysm and dissection 4. 4. Screening and AI-based new metrics for aorta 5. 5. Status, weaknesses, and stresses of AI algorithms 6. 6. Autonomy for AI-assisted analysis: Should we be there now?

## CAEE-12 **Boost Your Imaging Skills and Help Your Interventional Cardiologists Before and After Left Atrial Appendage Occlusion**

Syedali Nabipoorashrafi, MD, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Familiarize radiologists with available LAAO devices and their clinical applications. Review the required pre-procedural measurements for LAAO. Educate radiologists with post LAAO complications and ideal imaging techniques for their detection. Review spectrum of normal post procedural findings that should be differentiated from complications.

## TABLE OF CONTENTS/OUTLINE

1. Review the different LAAO devices (Watchman, Watchman FLX, Amulet, and Lariat), their unique features, and patient selection criteria. 2. Recognize the importance of preprocedural Image based planning in guiding device selection and placement. 3. Pictorial review of LAAO complications A) peri-device leak B) off-axis placement, and C) device-related thrombosis. 4. Review of the clinical importance of post procedural complications with focus on the role of imaging. 5. Review of the management of device-related complications with emphasis on the role of imaging. 6. Comparison between CT and other imaging modalities (Echocardiography and MRI) for LAAO planning and surveillance.

## CAEE-13 **Fibromuscular Dysplasia: a Multifaceted Vascular Disease**

Frances D. Ferreira De Deus, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

- Provide an overview of the pathophysiology and clinical manifestations of fibromuscular dysplasia (FMD). less prevalent, but more commonly underdiagnosed as related to this pathology.- To describe the role of imaging in the diagnosis and prevention of complications.

## TABLE OF CONTENTS/OUTLINE

Fibromuscular dysplasia (FMD) is a non-inflammatory, non-atherosclerotic, idiopathic arterial disease that primarily affects Caucasian women and medium-sized vessels. The classic finding is the beaded appearance and tortuosity of the affected vessel. However, FMD also predisposes to aneurysm formation, dissection, and stenosis, which are not always suspected to be related to FMD by the imaging community. We describe and illustrate with schematic figures and cases the main sites of vessel involvement, the variable radiological findings and the complications related to the disease. The most affected sites are the renal and cerebrovascular arteries, although the aorta and other arteries may also be involved. FMD can predispose to important complications, such as stroke, myocardial or renal infarction, aneurysm rupture and progressive dissection. FMD is often a subclinical and underdiagnosed arteriopathy with catastrophic complications. The radiological community should be familiar with the different phenotypic appearances. Invasive angiography and non-invasive vascular imaging by CT and MRI play an important role in the diagnosis and prevention of complications.

## CAEE-16 **Calcium in the Heart: A Guide to Interpret Like an Expert**

Syedali Nabipoorashrafi, MD, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1- Reviewing various calcified cardiac lesions, including calcification of the pericardium, vascular structures, myocardium, valves, and valve annuli. 2- Reviewing the morphology, location, and extent of calcification, which are often pathognomonic features that aid in identifying each type of calcified lesion as well as conditions associated with them. 3- Exploring the clinical significance of various calcified lesions and outlining a structured clinical approach for their management. 4- Discussing differential diagnosis of cardiac calcification and evaluation of their etiologies

## TABLE OF CONTENTS/OUTLINE

1- Introduction to a systematic evaluation of calcified cardiac lesions  
2- Identifying:  
A) Pathognomonic features of pericardial calcifications and considering their underlying causes  
B) Pathognomonic features of valvular and annular calcifications based on underlying causes  
C) Myocardial calcifications associated with tumors (such as endothelioma and rhabdomyoma), trauma, or infarction.  
D) Papillary muscle calcification.  
E) Left atrial calcifications related to atrial fibrillation, congestive heart failure, and endocarditis.  
F) Intracavitary calcifications in the atria and ventricles.

### CAEE-17 Medical Terminology in Cardiothoracic Radiology

Evgenia Efthymiou, MBBS (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Medical terminology includes words and phrases aiming to accurately describe anatomical structures, processes, conditions, medical procedures, and treatments. In cardiothoracic radiology, there is a plethora of words originating from Greek and they may be misused and misspelled in everyday practice. To aid colleagues in fluent and effective use of these terms, we have derived a radiologically illustrated glossary of the most frequent terms, their definitions and explanations of their origin and meaning. Typically, medical terms stemming from Greek adhere to a fixed structure of a prefix, a root, and a suffix. The prefix appears at the beginning of a medical term and usually indicates a location, direction, type, quality, or quantity. The root gives a term its essential meaning whereas the suffix appears at the end of a term and may indicate a specialty, test, procedure, function, disorder, or status.

## TABLE OF CONTENTS/OUTLINE

In a comprehensive and schematic way, words are presented alphabetically divided in two sections: anatomy and pathology and illustrated with representative radiology images, relevant findings and key imaging references. For each word the correct orthography is demonstrated along with a brief review of its history and etymology.

### CAEE-18 The One Ring to Rule Them Out: Deciphering Differential Diagnosis of Left Ventricular Ring-Like Late Gadolinium Enhancement

Andre Vaz (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Despite being initially described as a diagnostic marker for arrhythmogenic cardiomyopathy (ACM), ring-like LGE has been increasingly reported in non-genetic heart disease  
Ring-like LGE secondary to ACM may be accompanied by inverted T-waves in left precordial leads, ventricular arrhythmia with left bundle branch block morphology, and family history of premature sudden death  
Ring-like LGE secondary to Chagas disease may be accompanied by residency in south america, positive serology, right bundle branch block and left anterior fascicular block, and apical aneurysm  
Ring-like LGE secondary to viral myocarditis may be accompanied by prodromal manifestations (e.g fever, flu-like symptoms and diarrhea), and myocardial edema  
Ring-like LGE secondary to Keshan disease may be accompanied by residency in China, disabsortive syndrome, and selenium deficiency  
Ring-like LGE secondary to sarcoidosis may be accompanied by extracardiac findings, right bundle branch block, 2nd- and 3rd-degree heart block, and right ventricular free wall LGE

## TABLE OF CONTENTS/OUTLINE

Introduction: definition of left ventricular ring-like LGE, clinical significance, and objectives  
Differential diagnosis between genetic causes: left-dominant CMADifferential diagnosis between endemic causes: Chagas disease, and Keshan disease  
Differential diagnosis between inflammatory causes: viral myocarditis, sarcoidosis, and heart transplant rejection  
Differential diagnosis between causes of non-ring-like circumferential LGE: myocardial infarction, amyloidosis, and dystrophin cardiomyopathies  
Discussion: table with distinctive features of ring-like LGE differential diagnosis

### CAEE-19 Understanding Transesophageal Echocardiography: A Radiologist's Guide

#### Awards

#### Certificate of Merit

Zaid H. Khan, MBBS (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

TEACHING POINTS  
1. To understand the complimentary role of transesophageal echocardiography in multi-modality cardiac imaging including indications, contra-indications and potential complications.  
2. To have an understanding of the standard trans-esophageal examination  
3. Using cross modality reference be able to identify specific pathologies on TEE, CT and MRI.

## TABLE OF CONTENTS/OUTLINE

TABLE OF CONTENTS/OUTLINE  
1. Introduction: Overview of the role of TEE in multimodality cardiac imaging including indications, contraindications, and complications.  
2. The standard transesophageal examination with cross modality reference

with CT and MRI3. Specific roles of TEE in acute aortic syndromes, cardiac source of emboli, infective endocarditis and valvular assessment. Pathological appearances on TEE with cross modality reference.4. Summary.

## **CAEE-2 Role of Cardiac MRI in the Follow Up of Postoperative Congenital Heart Disease**

Harold Goerne, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

To review congenital heart diseases that require imaging follow up after surgical or endovascular repair. To discuss the role of cardiac MRI in the evaluation of postoperative findings in CHD repair. To demonstrate the importance of follow up imaging for detection of postoperative complications.

### **TABLE OF CONTENTS/OUTLINE**

1) Introduction 2) Congenital heart diseases - Clinical features; embryology; pathophysiology; treatment 3) Advantages and disadvantages of imaging modalities- Echo, CT, MRI. 4) MRI 5) Discussion, illustration with case examples of postoperative findings in repaired congenital heart diseases a) TOF: 1) Total repair (Pulmonary valve regurgitation, RV dilatation, RVOT wall fibrosis/aneurysms) b) TGA: 1) Jatene / Atrial switch (stenosis, thrombosis) 2) Banding (stenosis) c) DORV 1) Jatene (coronary ostia stenosis, PA stenosis) 2) MBT 3) Rastelli (leaking, regurgitation) 6) Discussion, illustration with case examples of postoperative complications in the repair of congenital heart diseases. I. Pulmonary valve insufficiency II. Aneurysmal dilatation of patch III. Myocardial dysfunction (Structural alterations, hypertrophy and remodeling) IV. Right ventricular dysfunction

## **CAEE-20 Multimodality Imaging of the Pericardium**

Nilo Fernandes Leca Junior, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

To discuss the strengths and limitations of different imaging techniques in the exploration of the pericardium. To highlight the radiological aspects of the normal pericardium and the spectrum of pathological entities such as developmental anomalies, inflammation/infection, effusion, neoplasms, iatrogenic conditions and pericardial constriction.

### **TABLE OF CONTENTS/OUTLINE**

Pericardial diseases are conditions that involve the membrane that surrounds the heart. Imaging plays a pivotal role in the assessment, which is performed by multiple non-invasive methods such as x-ray, echocardiography, CT and MRI. Echo remains as the first modality in most clinical scenarios. The most common conditions involving the pericardium are inflammation, effusions and constriction. Pericarditis is classified by symptom duration and by etiology (infection, idiopathic, neoplastic, drug related, iatrogenic and autoimmune). Pericardial constriction is a rare complication. Pericardial effusion is related to varying degrees of abnormal fluid accumulation into the pericardial space, and can evolve to tamponade. Primary and secondary masses are commonly accessed by CT and MRI. Secondary involvement is far more common than primary pericardial tumors. Congenital anomalies are relatively uncommon entities and may range from pericardial cysts to partial or total agenesis. Cardiovascular imaging plays an important role on the management of pericardial pathologies, which should be promptly recognized to help guide timely treatment.

## **CAEE-21 Utility of CT Coronary Angiography in Septal Vascular Mapping Prior to Alcohol Ablation in Hypertrophic Obstructive Cardiomyopathy**

Anjuna Reghunath, MD, FRCR (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. Alcohol septal ablation (ASA), an established treatment in hypertrophic obstructive cardiomyopathy (HOCM), iatrogenically induces an infarct of the target basal septum- the site of contact of mitral valve leaflet on the septum during systolic anterior motion (SAM). 2. Invasive angiography provides information about the course and size of coronary arteries but not their territorial distribution. Inaccurate infarct localisation due to alcohol injection into right ventricular side of septum and inability to identify the target vessel on invasive angiography leads to failure of ASA. 3. Computed tomography (CT) angiography has the dual benefit of detailing vascular anatomy and providing information on myocardial distribution. Mapping the septal vascular anatomy with CT coronary angiography prior to ASA improves localisation of infarct with predictable outcome and procedural success at the first attempt compared to traditional methods. The authors describe a new 5-step method of creating a CT navigational map for planning selective sub-branch micro-catheterisation.

### **TABLE OF CONTENTS/OUTLINE**

1. Mechanism and principle of ASA. 2. CT angiography protocol and 5-step mapping technique of the target basal septal vasculature. 3. Checklist of CT reporting points including the distance and angulation of the septal arteries. 4. Illustration of variant CT septal vascular anatomy. 5. Causes and demonstration of failed procedures in pre-CT traditional ASA. 6. Clinical utility of CT-guided ASA in terms of symptomatic, functional and haemodynamic improvement.

## CAEE-22 Gray Blood and Applications

### Awards

#### Certificate of Merit

Paula Terra M. Amaral, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The purpose of this exhibition is: ? Review the concept and indications of the gray blood myocardial delayed enhancement (MDE) technique? Highlight the ease of execution and applicability of the method? Understand the benefits of applying gray blood in the investigation of myocardial fibrosis? Identify the radiological findings that will help in the diagnosis as well as pitfalls of this technique

#### TABLE OF CONTENTS/OUTLINE

Gray blood is a sequence in cardiac magnetic resonance imaging (CMR) obtained by partial blood signal suppression that increases the ability to identify and localize myocardial scarring near the cavity. A pictorial essay based on cases from our collection allows for a comprehensive assessment and understanding: ? Grayblood MDE technique with a tutorial video? Main indications of grayblood MDE images? Grayblood MDE radiological findings in cases of subendocardial enhancement and papillary muscles? Grayblood MDE radiological findings in cases of post-cardiac transplantation, cardiac tumor, myocarditis and hypertrophic cardiomyopathy? Cases in which grayblood MDE did not help in the diagnosis

## CAEE-23 Imaging of the Ductus Arteriosus

Kaustav Bera, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. 1. To know the embryology, physiology and modalities for evaluation of the ductus arteriosus 2. 2. To learn about the pathologies of the ductus going beyond patent ductus arteriosus 3. To review the clinical and imaging findings of the above-mentioned entities with case examples

#### TABLE OF CONTENTS/OUTLINE

1. Embryologic development of ductus arteriosus 2. Physiological significance of ductus arteriosus 3. Modalities for evaluation of pathologies of ductus arteriosus : USG, CT, MR, Invasive angiogram 4. Pathologies of Ductus: - Normal variants - Congenital/developmental o PDA § Risk factors and pathophysiology § Classification § Causes § Maintaining patency post birth for some Congenital Heart diseases § Closure of PDA o Aneurysm of DA o Congenital vascular ring o Significance in Coarctation of aorta ( Preductal versus post ductal) - Post traumatic o Mechanism of and incidence of ductal injury o Minimal aortic injury (MAI) o Ductal Pseudoaneurysm o Penetrating ulcer o Aortic dissection - Miscellaneous o Infective aortitis associated with the nonpatent remnant of a ductus arteriosus o Atherosclerotic penetrating ulcer/ pseudoaneurysm of aortic ductus. 5. Differential diagnosis/mimics: - Aortic spindle mimicking aortic ductus pseudoaneurysm/MAI - Type III ductal diverticulum mimicking Aortic ductus pseudoaneurysm - Infundibula of the aortic branch vessels mimicking Aortic ductus pseudoaneurysm - Technical mimics of MAI :Breathing, arterial pulsation and other motion artefacts, streaming/streaking of contrast mimic minimal aortic injuries) - Anatomical mimics of MAI : Noncalcified and partially calcified atheroma

## CAEE-24 The Space Between: A Roadmap to Cardiac Recesses & Grooves

Katherine A. Cheng, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The recesses, grooves, and potential spaces around the heart are defined by the vasculature and supporting fibrous structures; these areas can easily be overlooked by the radiologist. Changes in configuration and appearance of these spaces can occur with pathological processes and can be more readily identified using a standard search pattern. A structured search pattern using a vascular and fibro-skeletal based review can help the radiologist identify and differentiate pathology from normal spaces and structures.

#### TABLE OF CONTENTS/OUTLINE

1. Review the normal anatomy of the heart including the recesses and grooves as well as the supporting vascular and fibro-skeleton of the heart.2. Illustrate the common pathology that can occur in these spaces including thrombus, tumor, abscesses, and pseudoaneurysm.3. Highlight the importance of variant and abnormal processes in these spaces and the impact on medical and surgical management.

## CAEE-25 The Role of Imaging in Cardio-Oncology: Detecting, Preventing, and Managing Cardiovascular Disease in Cancer Patients and Survivors

Osamu Manabe, MD, PhD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Cardio-oncology is a new specialty that focuses on detecting, preventing, treating, and following up on cardiovascular disease (CVD) in cancer patients and survivors. Cancer and CVD share many risk factors, such as aging, smoking, diabetes mellitus, and genetic predisposition. Furthermore, some cancer treatments have negative effects on the cardiovascular system, leading to an increased burden of cardiac complications in survivors. Cardio-oncology aims to minimize cardiovascular complications in patients with cancer and requires close collaboration between oncologists, cardiologists, and radiologists. In this presentation, we will discuss the usefulness of various imaging modalities in the field of cardio-oncology, taking into account the latest technology available.

## TABLE OF CONTENTS/OUTLINE

Cardio-oncology is a new multidisciplinary field to institute appropriate surveillance, treatment, and follow-up strategies for CVD in patients with cancer (Fig.1). Imaging modalities such as MRI (Fig.2), CT (Fig.3), and nuclear medicine including PET (Fig.4) play a crucial role in diagnosing and monitoring CVD in cancer patients. These non-invasive methods can be used to assess cardiac function, tissue characteristics, metabolic activity, and also tumor size and extent. Using novel imaging technologies is essential for early detection, treatment, risk stratification, and survivorship in cardio-oncology (Fig 5).

### CAEE-26 Whole-body Assessment of Vasculitis and Its Complications Using CT, FDG-PET, and MRI

Noriko Oyama-Manabe, MD, PhD (*Presenter*) Grant, DAIICHI SANKYO Group; Grant, Bayer AG; Grant, Eisai Co, Ltd; Grant, Canon Medical Systems Corporation

## TEACHING POINTS

1. Overview of the etiology, pathophysiology, clinical presentation, diagnostic criteria, and therapeutic approaches for primary and secondary vasculitis 2. To compare image characteristics of specific vasculitis and its complications with CT, MRI and FDG-PET/CT 3. To describe the role of multimodality imaging in the quantitative evaluation of inflammation for the initial diagnosis and during follow-up after treatment

## TABLE OF CONTENTS/OUTLINE

Vasculitis manifests in various clinical presentations, morphologies, and prognoses, requiring a multimodal imaging approach. Radiologists can aid in the accurate diagnosis of vasculitis and its complications, treatment planning, and patient care with multimodality imaging. In this presentation, we will cover both primary and secondary vasculitis, which can be caused by various factors, including infections and drug-induced reactions. Knowledge of systemic clinical manifestations in affected patients may help establish a specific diagnosis. 1. To review the clinical features and imaging findings of the different types of vasculitis including those that primarily involve large, medium-sized, or small vessels. 2. Tips for scanning with adequate timing and reconstruction for various complications due to infectious vasculitis including secondary to TEVAR and EVAR. 3. To describe the role of these imaging modalities in the quantitative evaluation of inflammation for the initial diagnosis and during follow-up after treatment, with an emphasis on monitoring therapeutic response using quantitative parameters.

### CAEE-27 Unveiling Cardiac Intracavitary 4D flow MRI

Jordi Broncano, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Reliable analysis of intracardiac flow provides important insight for the interpretation and management of cardiovascular diseases. Recently, non-invasive evaluation of intracardiac hemodynamics by 4D flow CMR constitute a reliable, robust, and reproducible method for the analysis of flow patterns in valvular diseases, cardiomyopathies, or congenital heart diseases (CHD). Furthermore, in virtue of its multidimensional/multidirectional capabilities it allows to calculate common (flow, velocities, and volumes) and advanced (kinetic energy and turbulent kinetic energy, vortical flow imaging and particle tracing) intracardiac chamber flow hemodynamic parameters. Recently, some of them have been shown to have important prognostic implications. Teaching points 1. To describe the physical basis of 4D flow, the main acquisition process, optimization techniques and advanced post-processing methods 2. To analyze the current and potential clinical applications of intracavitary 4D flow in cardiac imaging.

## TABLE OF CONTENTS/OUTLINE

1. 4D flow physical basis 2. 4D flow acquisition technique and protocol 3. Conventional intracavitary flow analysis 4. Advanced intracavitary 4D flow analysis - Kinetic Energy and Turbulent Kinetic Energy - Viscous energy loss - Vortical Flow Imaging - Particle tracing 5. Current and potential clinical applications intracavitary 4D flow - Dilated cardiomyopathy - Ischemic heart disease - Atrial fibrillation and heart failure - Valvular heart disease - Hypertrophic cardiomyopathy - Congenital heart diseases 6. Intracavitary 4D flow prognostic biomarkers: Ready to primetime? 7. Take home points

### CAEE-28 CT Imaging in Ischemic Heart Disease and Complications

Takashi Norikane, MD, PhD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Cardiac imaging plays a pivotal role in the diagnosis of ischemic heart disease. Echocardiogram, coronary angiography, nuclear medicine imaging and magnetic resonance imaging are common imaging modalities. However, conventional CT can provide important information about ischemic heart disease and complications. This presentation introduces the basic approaches of CT in ischemic heart disease and complications and follows with an overview of normal heart and coronary anatomy and frequently encountered pathologic conditions.

## TABLE OF CONTENTS/OUTLINE

Normal anatomy Coronary artery and territories Heart chambers Pericardium Myocardial infarction Atherosclerosis, Air embolism, Coronary artery anomaly, IgG4-related disease, Aortic dissection, thromboembolism due to essential thrombocythemia, Diaphragmatic hernia (post CABG), Post aortic valve replacement Complications Myocardial rupture, ventricular septal rupture, Dressler's syndrome, Ventricular aneurysm, Calcification Myocardial persistent enhancement after percutaneous coronary intervention Differential diagnosis Myocarditis, Takotsubo-myocardiopathy

### CAEE-29 Unravelling the Mitral Valve on CT

Vidushi Gupta JR, MD, MBBS (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. Assessment of normal valvular morphology and basic physiology of mitral valve on MDCT2. Discuss the pearls and pitfalls relevant to planning, acquisition and interpretation of cardiac CT images3. Enumerate various structural and functional abnormalities4. Describe the role of CT in pre and post-procedural imaging in patients with TMVR (Transcatheter mitral valve replacement).

## TABLE OF CONTENTS/OUTLINE

1. Introduction2. ECG placement with proper planning and acquisition protocol3. Pearls and pitfalls4. Post processing 5. Normal mitral valvular anatomy and function6. Assessing Structural abnormalities7. Assessing Functional abnormalities8. Role of CT in pre and post procedural imaging in TMVR9. Take home message

### CAEE-3 Robotic and Minimally Invasive Mitral Valve Surgery: Radiological Assessment and Surgery Correlation

Omer Onder, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. Robotic and minimally invasive mitral valve surgery is a safe and less traumatic surgical approach compared to the open cardiac surgery. Besides, it can be regarded as a widely accepted technique given the volume of publications from numerous institutions. 2. Multimodality imaging assessment conducted before to surgery are essential for selecting appropriate patients, anatomical evaluation, surgical planning, and optimal patient outcomes. 3. Radiologists can assist in patient treatment by being knowledgeable about the variety of anticipated postoperative findings and potential complications following robotic and minimally invasive mitral valve surgery.

## TABLE OF CONTENTS/OUTLINE

A. Overview of surgical techniques: Ministernotomy, minithoracotomy, robotically assisted B. Indications and contraindications C. CT angiography for pre-operative assessment 1. Scan protocol and postprocessing technique 2. Preoperative checklist 1) Aorta and iliofemoral arteries 2) Evaluation of lung, pleural plaques 3) Chest wall, diaphragm 4) Pericardium, mediastinum 5) Aorta diameter, pulmonary artery diameter, ascending aortic calcification 6) Mitral valve geometry, calcification 7) Central veins (vena cavae, coronary sinus) 8) Coronary arteries D. Procedural considerations E. Case examples F. Postoperative assessment G. Conclusion

### CAEE-30 Need for Speed: Fast MRI in Cardiac Imaging

Jordi Broncano, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Cardiac MRI has become versatile technique for normal and diseased heart. However this results in complex and slow CMR examinations, raising the perception of CMR as a high-cost imaging method. Therefore, a more rationale and question-driven protocols are increasing acceptance in order to reduce the amount of acquisition time, increase patient acceptance and clinical value of this well-known game-changer imaging method. Teaching points 1. To describe the current technical advances, drawbacks, tips and tricks available for providing fast MRI protocols in clinical practice. 2. To detail the different proposals described in the literature for optimizing CMR protocols (fast MRI) in a "question - driven" scenario and with a "building - blocks" strategy.

## TABLE OF CONTENTS/OUTLINE

1. Fast MRI concept and rationale 2. Conventional CMR protocoling problems: Knowing what I need to fix. 3. Fast MRI strategies in cardiac imaging • 3.1. Cine SSFP o Free - breathing EKG gated cine SSFP o Post-contrast cine SSFP o Sparse acquisition cine SSFP o Deep Learning (DL) cine SSFP o 3D cine SSFP • 3.2 Tissue characterization/parametric mapping o Single-Shot black blood imaging o DL acquisition and reconstruction o 3D single parameter mapping o Accelerated T1 T2 mapping • 3.3. 4D flow imaging o 4D flow EPI o Accelerated 4D flow • 3.4. MR angiography o Compressed sensing o Other strategies o Non - contrast MRA • 3.5. Late Gadolinium Enhancement o Free breathing single-shot LGE o Breathold 3D LGE o 3D PSIR LGE o DL LGE 5. Fast CMR protocols in the clinical practice: The “building - blocks” strategy - Ischemic heart disease - Non-ischemic heart disease - Valvular heart disease - Arrhythmogenic cardiomyopathy - Congenital heart disease 6. Take home points

### CAEE-31 Pulmonary Vein Anomalies Made Easy

Juliana S. Da Silveira, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

To overview the embryology and normal anatomy of the pulmonary veins. To discuss the spectrum of anomalous pulmonary venous connections (APVCs). To describe and illustrate with schematic figures and cases the types of APVCs. To discuss the importance of the diagnosis to allow timely treatment and a better prognosis.

## TABLE OF CONTENTS/OUTLINE

The normal PV anatomy consists of four PVs, which drain oxygenated blood from the lungs to the left atrium (LA). The LA and PVs initially develop separately, and get progressively connected during fetal development. If there is failure in any step of this embryonic process, APVCs will happen. Anomalous pulmonary venous connections are a group of abnormal drainage of one or more PVs outside of the LA and can be classified either as partial or total, depending on the number of the veins involved. We describe and illustrate with schematic figures and cases the types of anomalous pulmonary venous connections, whether partial or total, common or rare, depending on the site of pulmonary vein drainage, the number of veins involved, and the presence or absence of vein obstruction. Common and rare anatomical variations will also be demonstrated. The clinical syndromes related to abnormal pulmonary venous returns will be discussed, ranging from dramatic neonatal emergency to subclinical presentation and late development of pulmonary hypertension.

### CAEE-32 The Changing Face of Myocarditis

Matthew R. McCann, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

COVID-19 ushered in a dramatic rise in public awareness of myocarditis and related complications. Mirroring this, an unprecedented utilization of imaging for assessment of cardiac events followed. Utilization of imaging for vaccine-related cardiotoxicity has similarly risen. Synchronously, other previously unrecognized causes of myocarditis are now increasingly encountered, including drug-related cardiotoxicity, as seen with new oncologic agents. Clinical history, lab assessment, and imaging remain central to establishing a diagnosis of myocarditis. Cardiac MRI plays an integral role in diagnosis, stratification, and monitoring of recovery from this changing face of myocarditis. Recognition of the evolving etiologies, imaging techniques and revised diagnostic criteria are paramount for appropriate diagnosis.

## TABLE OF CONTENTS/OUTLINE

This exhibit outlines the timeline of awareness, specific entities and imaging features which comprise the “changing face of myocarditis” including cardiotoxicity related to COVID-19, COVID-19 vaccination, drug reactions including immune checkpoint inhibitors, and cardiotoxicity related to environmental contaminants and other exposures. Cardiac MR plays a key role in diagnosis, stratification, and monitoring of cardiotoxicity in these entities. The specific imaging features and diagnostic considerations are outlined and described in order that the radiologist gains a better understanding of this evolving diagnosis, allowing for appropriate utilization of imaging and improved diagnostic accuracy of this complex disease.

### CAEE-33 New CAD-RADS 2.0: What Has Changed from CAD-RADS 1.0

Janio De Paula Santos, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

To reinforce the importance of applying the CAD-RADS classification for a better communication with the healthcare providers. To describe the differences between CAD-RADS versions 1.0 and 2.0. To demonstrate with cases how to apply the CAD-RADS 2.0 classification.

## TABLE OF CONTENTS/OUTLINE

The Coronary Artery Disease Reporting and Data System (CAD-RADS) is a standardized guide created to categorize coronary CT angiography findings and to facilitate communication between the radiological community and referring physicians. A new

CAD-RADS classification was recently published with the objective of adding anatomical and functional data, which may offer stronger prognostic value other than just describing the presence or absence of anatomical lesions. What's the same? The main categories (0,1, 2, 3, 4, 5) based on stenosis severity (0, 1-24%, 25-49%, 50-69% 70-99%, occlusion) were maintained. Complementary modifiers "G", "S" and "N" standing for the presence of Grafts, Stents, or a Non-diagnostic study were maintained. What has changed? A grading scale for calcific plaque burden was added (P1, P2, P3 and P4). For plaques with features indicating high risk of rupture, the modifier "V" was replaced to "HRP" -> high-risk plaque. An "I" modifier was added if the investigation of ischemia was performed, either by perfusion or FFR-CT. The use of CAD-RADS to report findings provides a clinically useful categorization of CAD and standardizes the way of providing results across imaging sites, which is additionally useful for research purposes.

### **CAEE-34 Multimodality Review of Common Mitral Valve Pathology and the Current Surgical Interventions**

#### **Awards**

#### **Certificate of Merit**

Alexander Phan, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

As the treatments for valvular disease have evolved over the years, the assessment of cardiac valves now often requires multiple imaging modalities, including cardiac CT, cardiac MRI, and echocardiography. The aim of this exhibit is to review the normal appearance as well as common pathologies involving the mitral valve on the various modalities discussed above. Lastly, the current available treatments for mitral valve disease will be reviewed including repairs (such as annuloplasty, valvuloplasty, and mitral valve clips) and replacements (such as surgical valve replacement and transcatheter mitral valve replacement).

#### **TABLE OF CONTENTS/OUTLINE**

1. Review of the normal appearance of mitral valve on CT, MRI, and Echo. 2. Review of common mitral valve disease including mitral regurgitation, mitral stenosis, mitral prolapse, mitral annular disjunction, flail leaflet, parachute mitral valve, mitral cleft, mitral masses (fibroelastoma, vegetations, thrombus), and mitral annular calcification. 3. Review of the current treatments. Mitral valve repairs include annuloplasty, valvuloplasty, and mitral valve clips. Mitral valve replacements including surgical and more minimally invasive techniques, such as robot-assisted or transcatheter-based TMVR.

### **CAEE-35 Visualizing the Mitral: An Imager Approach to Mitral Valve Disorders**

Mohamed K. Ibrahim, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- Overview on clinical burden of Mitral valve diseases (MVDs) and pertinent anatomy.
- Familiarity with the current imaging approach to MVDs.
- Understand the role of imaging in the management of MVDs.

#### **TABLE OF CONTENTS/OUTLINE**

- Mitral valve diseases burden and pertinent anatomy
  - o Mitral valve anatomy
  - o Clinical burden of MVDs
- Current imaging approach to MVDs:
  - o Role of Echo as the main modality for early detection
  - o Complementary role of CT and MR
  - o Comprehensive evaluation of MVDs (Mechanism of abnormality, Quantification, Ventricular remodeling, Vascular changes, Risk stratification, Valve morphology)
- Where does imaging fit in MVDs management?
  - o Assessing etiology, mechanism, and grading
  - o Pre-procedural planning: § Surgery vs Transcatheter intervention § Repair vs replacement
- Surgical replacement: sternotomy vs Robotic, and the role of CTA and CMR
- Transcatheter replacement: transapical vs trans-septal approaches, and the role of Echo and CT
  - § Favorable anatomical markers, predictors of challenging procedures and contraindications
  - o Intra-procedural guidance and monitoring
  - o Post-procedural Follow up; Devices (stability, leaflet motion, leaks, vegetations/thrombus), Hemodynamics, and chamber size and function)

### **CAEE-36 Left Ventricular Hypertrophy: An Approach to Differential Diagnosis**

Rafael Perez Milan, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

- Left ventricular hypertrophy (LVH) is a common finding in cardiac magnetic resonance (CMR) with multiple diagnostic considerations.- LVH is an independent predictor of future cardiovascular events regardless of its etiology.- LVH can be defined as follows.- LV myocardial thickness more 12 mm.- Increased LV mass: Body surface area - indexed LV mass (over 95th percentile - 91 g/m<sup>2</sup> in males; 77 g/m<sup>2</sup> in females)

#### **TABLE OF CONTENTS/OUTLINE**

- To understand basic anatomy and embryology of the left ventricle.- To define left ventricular hypertrophy (LVH) and clinical implications.- To describe the differential diagnosis of LVH.- Role of cardiac magnetic resonance (CMR) in narrowing the

differential diagnosis.

### **CAEE-37 Complications of Acute Myocardial Infarction: Infrequent but Lethal**

Francisca Aliaga, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Acute Myocardial Infarction (AMI) is a frequent pathology and one of the leading causes of death in the world. Early revascularization has become a standard of care, thus reducing the high associated morbi-mortality. 2. Although infrequent, several secondary complications can occur, particularly when treatment is delayed or inadequate. 3. These are divided into mechanical, inflammatory, arrhythmic, thrombotic, and embolic. 4. CT, and especially MRI, help us to adequately assess cardiac function, ventricular volumes and structure, myocardial viability and possible associated complications.

#### **TABLE OF CONTENTS/OUTLINE**

- Introduction- General characteristics of AMI and its complications.- Complications are divided into categories, with cases to illustrate each Mechanical complications are most frequently evaluated through CT and MR. In the acute phase, the most frequent are left ventricular free wall rupture, septal ventricular defect, and papillary muscle rupture. In a chronic phase, pseudoaneurysms and ventricular aneurysms are found.- Conclusions. Complications of AMI are infrequent, but they can be potentially lethal. An accurate and early diagnosis significantly improves the prognosis. CT and MRI are the main imaging modalities used after echocardiography.

### **CAEE-38 Imaging Features and Mimics of Primary and Metastatic Pericardial Tumors**

Aparna Singh, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Understand the role of imaging modalities in the diagnosis and management of primary and metastatic pericardial tumors and their mimics. 2. Review the imaging features of pericardial tumors and their mimics on echocardiography, CT, MRI, and PET/CT. 3. Discuss the limitations of imaging in the diagnosis and management of pericardial tumors and their mimics.

#### **TABLE OF CONTENTS/OUTLINE**

I. Introduction A. Epidemiology and clinical presentation of pericardial tumors and their mimics II. Role of Imaging Modalities A. Echocardiography B. Computed Tomography (CT) C. Magnetic Resonance Imaging (MRI) D. Positron Emission Tomography/Computed Tomography (PET/CT) III. Imaging Features of Pericardial Tumors and Their Mimics A. Primary pericardial tumors B. Metastatic pericardial tumors C. Pericardial cysts D. Lipomatous hypertrophy E. Pericardial fat pad F. Hemangioma G. Thymoma IV. Limitations of Imaging in the Diagnosis and Management of Pericardial Tumors and Their Mimics V. Conclusion

### **CAEE-39 Mitral Valve Diseases 101: A Comprehensive Case-Based Review for Radiology Trainees**

Mangun Randhawa, MBBS (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

1. Describe the normal anatomy of the mitral valve and imaging modalities used for its evaluation 2. Discuss various pathologies of native and prosthetic mitral valves, their implications, and their differential diagnoses 3. Review role of imaging for mitral valve interventions

#### **TABLE OF CONTENTS/OUTLINE**

1. Morphologic anatomy of the mitral valve 2. Congenital mitral valve abnormalities : parachute mitral valve, parachute-like mitral valve, Shone complex 3. Mitral valve prolapse (various types) and mitral annular dysjunction 4. Mitral annular calcifications, and complications 5. Infective endocarditis 6. Mass (different histopathologies) 7. Pre-procedural and Post-procedural evaluation of mitral valve implantation including prediction of left ventricular outflow tract obstruction post transcatheter implantation.

### **CAEE-4 It's All About the Pericardium**

Felipe Aluja, MD, MEd (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Discuss the anatomy of the pericardium and the pericardial recesses with emphasis on CT and MRI. Identify selected entities affecting the pericardium, from benign to malignant, with a brief description of their clinical characteristics. Provide a deep review of the imaging findings from the conventional radiology to MRI, with emphasis in the ancillary findings that aid in the differential diagnosis approach. Describe the pitfalls and mimics of pericardial disease in conventional radiology, CT, MRI and PET/CT.

## TABLE OF CONTENTS/OUTLINE

• Introduction • Anatomy of the pericardium and pericardial recesses: from the schemes to the imaging. • The pericardium in conventional radiology, CT, MRI and PET/CT. • Conditions of the pericardium: o Air, collections, hemorrhage, and pericardial tamponade o Acute and chronic inflammation (including constrictive pericarditis) o Benign neoplasms o Malignant primary and secondary neoplasms o Congenital lesions • Try your best? Take home points

### CAEE-40 Artificial Intelligence in Cardiac MRI- Applications, Pitfalls & Challenges

Prabhakar Rajiah, MD, FRCR (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. To review the principles of Artificial Intelligence (AI) techniques relevant to cardiac MRI(CMR); 2. To discuss how AI can be applied to the different steps of the CMR; 3. To illustrate common applications of AI in CMR

## TABLE OF CONTENTS/OUTLINE

1. AI, MACHINE LEARNING, DEEP LEARNING; 2. CHALLENGES OF CMR- complex anatomy, pathology, planes, sequences 3. AI NETWORKS- Convolutional neuronal network (CNN), general adversarial network (GAN); 4. ILLUSTRATION OF CLINICAL APPLICATIONS OF AI IN CARDIAC MRI WITH CASE EXAMPLES AND TECHNIQUES USED A. Upstream- Protocolling, workflow management/prioritization B. Image acquisition- Plane prescription; Patient positioning; Automated cardiac MRI planes; Automated selection of inversion time; B. Image reconstruction- Decreased artifacts; Decreased noise; Decreased acquisition time; Improved resolution- Super resolution ; Virtual Native Enhancement without contrast (VNE); Synthetic strain; C. Segmentation of structures- Ventricular volumes, function, mass in SSFP, Vascular anatomy in MRA; D. Automated quantification- Volumes, mass, function, LGE, parametric mapping (T1, T2, ECV), flow, strain, aortic diameter; E. Automated post-processing- perfusion, 4D flow; F. Classification of disease- Scar from non-contrast cine, Cardiomyopathies, CAD, myocardial infarction, atherosclerotic plaque, valvular disease, heart failure G. Prognostic factors- Risk stratification- Predictive models; H. Radiomics /Textural analysis I. Automated reporting J. Automated CMR pipeline 5. CHALLENGES- Small, biased training datasets, black box, quality criteria for algorithm design; 6. PITFALLS - Inaccuracies; 7. FUTURE DIRECTIONS- Good Machine learning practices.

### CAEE-41 Emerging Applications of Non-Contrast Cardiac CT: Beyond Coronary Score

Masafumi Kidoh, MD, PhD (*Presenter*) Endowed Chair, Koninklijke Philips NV

#### TEACHING POINTS

Teaching Points 1. Non-contrast cardiac CT is widely used to detect and quantify coronary and heart valve calcium. On the other hand, detection of fat, myocardial edema, thrombus/hematoma, and subtle myocardial calcification beyond coronary and heart valve calcification using non-contrast cardiac CT has not been widely performed, possibly due to poor image quality. 2. Recent advances in CT technology (such as model-based iterative reconstruction and dual-layer spectral/photon-counting CT) have drastically improved the low-contrast resolution of CT images, allowing the detection of small differences in CT values within soft tissue on non-contrast and delayed phase cardiac CT images. Side-by-side viewing of non-contrast cardiac CT images and delayed (or arterial) phase cardiac CT images may be useful in differentiating various pathologies. 3. In this exhibit, we report that non-contrast cardiac CT is useful for the detection and characterization of cardiac low-contrast lesions (soft tissue lesions) beyond coronary and heart valve calcification.

## TABLE OF CONTENTS/OUTLINE

Table of Contents/Outline 1. Scan and reconstruction techniques for non-contrast cardiac CT - Single-energy CT - Dual-energy CT - Photon-counting CT 2. Principle of CT number in non-contrast cardiac CT 3. Clinical applications: beyond coronary score - Calcification - Thrombus/hematoma - Anemia - Water/myocardial edema - Fat 4. Future directions 5. Summary

### CAEE-42 From Cyan to Cinnabar - The Radiologist's Role in Operative Management of Single Ventricle Congenital Heart Disease

#### Awards

#### Cum Laude

Shravan Sridhar, MD, MS (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Single ventricle congenital heart diseases are rare and challenging to manage. While historically, outcomes have been poor, recent advancements in surgical management have improved post-operative outcomes and long-term prognosis. Imaging has also advanced from morphologic characterization to assessment of function and flow dynamics. Here, we present a framework for understanding the pathophysiology of the single ventricle state and 3-stage palliation repair, review important imaging-informed decision points along the course of operative management, and present metrics important to long-term outcome and management.

## TABLE OF CONTENTS/OUTLINE

1. Title slide, disclosures  
2. Abbreviations  
3. Table of contents  
4. Normal physiology  
5. Single ventricle physiology  
6. Norwood/DKS  
7. mBTT and RV-PA conduit  
8. Glenn procedure, mention of Kawashima  
9. Fontan procedure  
10. Operative management, main decisions  
11. Single (SVR), biventricular (BiVR), or 1.5 ventricle (1.5VR) repair?  
12. SVR Ex) AV canal  
13. CT/MRI evaluation  
14. BiVR Ex) DORV  
15. CT/MRI evaluation  
16. 1.5VR Ex) Tricuspid atresia  
17. CT/MRI evaluation  
18. 1.5VR Ex) Ebstein anomaly  
19. CT/MRI evaluation  
20. Safe for hybrid/bridge-to-Norwood?  
21. Example  
22. Hybrid procedure, relevance of HLHS, and risk factors for retrograde aortic arch obstruction  
23. CT/MRI evaluation  
24. Safe for Glenn?  
25. Example  
26. CT/MRI evaluation  
27. What features may change Fontan approach?  
28. Pre-Fontan operative planning example  
29. CT/MRI evaluation prior to Fontan  
30. Failing Fontan and BiVR or 1.5VR conversion surgery  
31. Preop. Items (e.g. LVOT widening, valvuloplasty)  
32. CT/MRI evaluation prior to conversion surgery  
33. Summary  
34. References

### CAEE-43 Myocardial Strain Analysis Using Feature Tracking

Masaya Kisohara, MD, PhD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Myocardial strain refers to the deformation of the walls and chambers of the heart from a relaxed to a contracted state.  
2. Feature tracking is a technique that enables the analysis of myocardial strain.  
3. Strain analysis performed in the left ventricle and the left atrium is a better prognostic indicator for heart failure than left ventricular ejection fraction.  
4. Strain analysis by feature tracking might apply to 4D-CT images.

## TABLE OF CONTENTS/OUTLINE

1. The concept of myocardial strain and its types: Myocardial strain using feature tracking is an alteration of length in one dimension or spatial orientation. Left ventricular strain is classified as radial, circumferential, and longitudinal strain. Left atrial strain is obtained as global longitudinal strain.  
2. The principle of features tracking: Template matching is a technique that follows similar templates during the process of myocardial contraction.  
3. The importance of myocardial strain for patients with heart failure.  
4. What is left atrial strain? The left atrial strain is an index that reflects the diastolic and contractile capacity of the left atrium. Similar to the left ventricular global longitudinal strain, it is helpful in predicting prognosis in heart failure with preserved left ventricular ejection fraction.  
5. An experiment using 4D-CT for myocardial strain analysis

### CAEE-44 The Role of Gadolinium Enhancement Patterns in Diagnosing Myocardial Diseases at Cardiac MR - Enhancing Residents' Knowledge

Otavio Augusto Ferreira Dalla Pria, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

The abnormal myocardium can depict different patterns of gadolinium contrast enhancement depending on the cause of the injury. Therefore, assessing enhancement patterns in Cardiac MR plays a pivotal role in diagnosing diverse myocardium diseases. Ischemic cardiomyopathies produce delayed vascular-distributed gadolinium enhancement, and non-ischemic patterns are not limited to vascular territories. Patterns of enhancement distribution are crucial in differentiating between ischemic and non-ischemic heart pathologies and narrowing differential etiologic diagnostics in both. This exhibit aims: 1. To review myocardium gadolinium enhancement MR patterns. 2. To illustrate differential diagnostics based on the type of enhancement. 3. To discuss challenges and confounder factors.

## TABLE OF CONTENTS/OUTLINE

1- Introduction/Objectives: Cardiac MRI can help diagnose a plethora of myocardial dysfunction. The gadolinium enhancement pattern is one of the characteristics that can help identify differential diagnostics. In this presentation, we summarize and illustrate the 5 types of cardiac MRI enhancement patterns and correlate findings with main differential diagnostics.  
2- Case-based approach: Present 5 Patterns of Enhancement in Cardiac MRI (Subendocardial, subepicardial, transmural, patchy, mid-myocardial/mesocardial), correlating with primary differential diagnostics through didactical cases illustration in both ischemic and non-ischemic cardiomyopathies.  
3- Limitations, Conclusion, and Take-home messages.

### CAEE-45 Role of Multi-Modality Imaging in Cardio-Obstetrics

Prabhakar Rajiah, MD, FRCR (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Cardio-obstetrics is an expanding subspecialty that focuses on prevention, early detection, and management of cardiovascular disease (CVD) in pregnancy. 1. To review the cardiovascular complications in pregnancy; 2. To understand disease processes exacerbated by pregnancy; 3. To discuss the role of imaging in cardiovascular complications of pregnancy and pre-conception planning; 4. To understand the concept of pregnancy heart team and risk stratification

## TABLE OF CONTENTS/OUTLINE

1. INTRODUCTION ;2.PHYSIOLOGICAL CARDIOVASCULAR CHANGES OF PREGNANCY;3. ROLE OF IMAGING IN PREGNANCY;4. IMAGING MODALITIES;5. COMPLICATIONS RELATED TO PREGNANCY (Discussion, clinical features, imaging findings and differential diagnosis with case examples)-Cardiac- Heart failure, arrhythmia, thromboembolism;Obstetrics- hypertension, Preeclampsia, hemorrhage;Perinatal-miscarriage, premature delivery, restricted growth;Venous thromboembolism including PE;Amniotic fluid embolism;Peri-partum cardiomyopathy;Spontaneous coronary artery dissection;Pulmonary hypertension;Hypertensive disorders (Eclampsia/Pre-eclampsia);Heart failure and arrhythmias;6.EXACERBATION OF PRE-EXISTING CVD DURING PREGNANCY (Illustration with case examples)-Inherited aortic diseases;Congenital heart disease;Hereditary hemorrhagic telangiectasia;Valvular disorders;7. PRECONCEPTION PLANNING- Risk stratification;8. CARDIOVASCULAR CHANGES IN ABDOMINAL DISEASES;9. ISSUES RELATED TO IMAGING IN PREGNANCY;- CT- Radiation, contrast agents- MRI- Gadolinium10. APPROPRIATENESS CRITERIA for imaging in pregnancy; 11. FLOW-CHART SHOWING systematic approach to imaging pregnant patients.

### CAEE-46 Single Ventricle: A Radiology Primer for Pre-Procedural Evaluation

#### Awards

#### Certificate of Merit

Prabhakar Rajiah, MD, FRCR (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. To review the spectrum of lesions that result in a single ventricle 2. To discuss the surgical options in the management of single ventricle 3. To illustrate the different types of single ventricle using case examples 4. To highlight critical imaging parameters necessary for pre-procedural planning

## TABLE OF CONTENTS/OUTLINE

1. SINGLE VENTRICLE- Definition, types 2. ROLE OF MULTIMODALITY IMAGING- Echo, CT, MRI, Cardiac cath, nuclear medicine 3. CT AND MRI- Indications, protocols, tips and tricks 4. REVIEW AND ILLUSTRATION OF PHENOTYPES OF SINGLE VENTRICLE Right dominant- Hypoplastic left heart syndrome, mitral atresia, double inlet/outlet RV; Left dominant- Hypoplastic right heart syndrome, Tricuspid atresia, Double inlet LV ; Either- unbalanced AV canal (Right/left); Functional single ventricle- TOF with pulmonary atresia, truncus, TAPVR, Severe Ebsteins anomaly, Tricuspid atresia, Double inlet LV/RV, AV canal defect (balanced/unbalanced), heterotaxy 5. ANATOMICAL CHARACTERIZATION- Atrial situs, ventricular situs, great artery relationship, morphologic LV vs RV, functioning/rudimentary ventricles 6. CRITICAL PARAMETERS NECESSARY FOR SURGICAL/INTERVENTIONAL MANAGEMENT - Ventricular function- Poor prognosis if low - Atrial septal restriction - Bulboventricular foramen in DILV or tricuspid atresia with TGA - Atrioventricular valve- Obstruction or regurgitation - Outlet obstruction- Presence and nature - Vascular resistance- Pulmonary and systemic - Patency of ductus arteriosus - Patency of aortic arch - Pulmonary artery anatomy - Venous connections 7. MIMICS- Criss-cross heart; Superior/inferior ventricle

### CAEE-47 Generating Cardiac Segmentation Datasets: Automated Segmentation and Tool-Based Manual Correction

Hirohisa Oda, PhD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

Easy label generation for custom AI: Manual correction tool for cardiac segmentation

## TABLE OF CONTENTS/OUTLINE

- Application-specific custom AI for cardiac segmentation\* Our application: Modeling patient-specific therapeutic instrument- Outline\* Step 1: AI-based segmentation with a very limited number of cases for automated segmentation on other cases\* Step 2: Manual correction with our original tool- Step 1: AI-based segmentation\* Innovations from the "U-Net era"\* Trainable with limited training datasets as "seeds" of dataset generation\* Key technologies: Swin Transformer Self-supervised training [1]\* Examples of automatic segmentation- Step 2: Manual correction with our original tool\* HeartCorrect: Our original plugin for an image visualization tool MITK-Workbench\* Utilizing MITK's interpolation feature\* Automated correction for obeying the anatomical relationships of chambers- Comparison with MONAI Label[1] Hatamizadeh, Ali, et al. "Swin UNETR: Swin transformers for semantic segmentation of brain tumors in MRI images." BrainLes 2021, LNCS 12962, 2022.

### CAEE-48 Myocardial Delayed Enhancement By Spectral CT: Our Experience

Almudena Gil Boronat, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Role of Late enhancement in cardiac dual-CT2. Show the protocol we are using in our centre.3. Present CT-MRI correlation in several pathologies, mainly in myocarditis

## TABLE OF CONTENTS/OUTLINE

1. Background Quick review of the pathophysiology and usefulness of late enhancement in cardiological studies.2. Spectral CT and acquisition protocol used in our center.3. Representative cases of different diagnoses with CT-MRI correlation.4. Conclusions.5. Bibliography.

### CAEE-49 **Mitral Valve Disjunction: The Great Unknown**

Almudena Gil Boronat, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. To review mitral valve disjunction (MVD)2. Role of MRI in the evaluation of radiological features associated with and pitfalls.

## TABLE OF CONTENTS/OUTLINE

1. Background Revision of mitral valve disjunction • Definition • Pathology • Classification • Location 2. Representative cases of different disjunction types. 3. Representative cases of different radiological features associated with and pitfalls. 4. Conclusion. 5. Bibliography.

### CAEE-5 **All “In Vein”? Anatomy, Variations and Abnormalities of Coronary Venous System with an Emphasis on CT Findings and Clinical Importance**

#### Awards

##### Certificate of Merit

Firat Atak, MD (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. Cardiac CT can provide substantial information regarding cardiac venous anatomy and anomalies although it is mainly used for the evaluation of coronary arterial system. 2. Radiologists can more readily identify cardiac venous anomalies on CT by having a basic knowledge of the normal venous anatomy, adding venous anomalies to the standard checklist, and being aware of the conditions in which these anomalies may be clinically significant. 3. Cardiac venous system anomalies may be vital in percutaneous interventions and surgical procedures as they may fundamentally influence the course of the procedure or change the operation plan.

## TABLE OF CONTENTS/OUTLINE

A. Overview of normal cardiac venous anatomy B. Scan protocol and postprocessing C. Coronary sinus (CS) variations and anomalies with case examples D. Other cardiac vein variations with case examples E. Clinical importance of the cardiac venous system -Cardiac shunts -Cardiac resynchronization therapy -Coronary sinus pacing -Retrograde cardioplegia - Percutaneous mitral anuloplasty -Percutaneous atriotomy (Levoatrial-to-coronary sinus shunting) for heart failure - Percutaneous in situ coronary venous arterialization (PICVA) -Enlargement of CS and clinical importance of PLSVC - Radiofrequency catheter ablation - Central venous interventions F. Conclusion

### CAEE-50 **State-of-the-Art Multimodality Imaging of Cardiac Transplant and Complications: A Practical Update**

Prabhakar Rajiah, MD, FRCR (*Presenter*) Nothing to Disclose

#### TEACHING POINTS

1. To discuss the normal appearances of cardiac transplant 2. To optimize the CT and MRI protocols for evaluation of patients with cardiac transplant 3. To illustrate the imaging appearances of various complications following cardiac transplant

## TABLE OF CONTENTS/OUTLINE

1.Introduction 2. Indications- Heart failure, intractable angina or arrhythmia, cardiomyopathies, congenital heart disease, cardiac tumor) 3. Cardiac transplant techniques- Orthotopic vs heterotopic, bicaval vs biatrial 4. Role of imaging in evaluation of cardiac transplant 5. Imaging techniques- Echo, CT, MRI, Cardiac catheterization, Intravascular ultrasound, Optical coherence tomography, nuclear medicine 6. Cardiac transplant follow up diagnostic pathway 7. Imaging protocols for follow up= CT-No premedications, Photon counting CT; MRI- Quantitative techniques, T2, T1 mapping; 8. Complications- Review of the following complications with illustrative case examples- Post procedural graft dysfunction; Post surgical- pericardial effusion, mediastinal hematoma; Cardiac Allograft Vasculopathy (CAV) - Diffuse, more aggressive, microvasculature-angiography vs CTA; Acute cellular rejection; Chronic rejection; Accelerated coronary atherosclerosis; Infections; Post-transplant lymphoproliferative disorder; Gout; Osteoporosis; Chronic kidney disease;

### CAEE-51 **The Heart of the Matter: Pearls and Pitfalls in Cardiac CT**

Katherine Chung, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Cardiac CT imaging is a valuable diagnostic resource for physicians to evaluate cardiac anatomy and function. The indications for CT imaging include evaluation of the coronary vessels for anomalies, presence of coronary artery disease (CAD) and calcium score, pre-TAVR evaluation, pre-ablation study for atrial fibrillation, and observing the patency of grafts, amongst other reasons as well. Although radiologists regularly read these types of images, radiologists-in-training may have variable levels of exposure and can come across cases that lead to confusion. The goal of this presentation is to elucidate the essential pearls of acquiring and evaluating cardiac CT scans, so radiologists-in-training are comfortable and confident with evaluating CT scans and providing appropriate recommendations. Furthermore, we will highlight the common areas of confusion through case-based examples of common pitfalls that may occur.

### TABLE OF CONTENTS/OUTLINE

1) Introduction 2) Indications and contraindications (Efficacy in disease diagnosis) 3) Definitions and Anatomy 4) Protocols and Techniques for acquiring images 5) Pearls and Pitfalls (Pre-ablation study for atrial fibrillation, Pre-TAVR study, Calcium Score, Coronary Artery Disease, Thoracic aortic aneurysm) 6) Artifacts (Stair Step artifact, Streak artifact from CABG or TAVR patients, Motion) 7) Conclusion

### CAEE-52 From Pumps to Waves: Understanding the Impact of Mechanical Circulatory Assist Devices on Spectral Doppler Ultrasound Analysis

Mateus K. Soares (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Heart failure (HF) is a syndrome resulting from impaired ventricular filling or ejection. Many patients with HF progress to a refractory state, regardless of advanced therapies. Cardiac transplantation remains the definitive treatment for end-stage disease. Mechanical circulatory assist devices (CAD) help support patients with cardiogenic shock or end-stage HF. It may be used as a short-term device to support hemodynamically unstable patients, including those with the possibility of heart function recovery, or as long-term device usually as a bridge to transplantation. CAD are mechanical pumps that help an impaired ventricle maintain hemodynamics and preserve satisfactory end-organ blood flow. There are commercially available devices to support both the left and right ventricle. In most cases, the spectral Doppler waveform is altered in the setting of a CAD, reflecting systemic hemodynamic changes. Despite the increasing use of these devices, there is not much information in the radiological literature about spectral Doppler changes in these patients. Accurate diagnosis requires a better understanding of CAD mechanisms and associated Doppler ultrasound findings, as well as possible vascular complications.

### TABLE OF CONTENTS/OUTLINE

Review the normal arterial Doppler waveforms in patients with preserved cardiac function. Describe the mechanisms of various CAD and their hemodynamic impacts on arterial spectral Doppler waveforms. Discuss the main vascular-related complications and the use of ultrasound in diagnosis.

### CAEE-53 Blood-Flow Volume Quantification Using Phase-contrast MRI in Congenital Heart Disease: Pre- and Post-surgical Evaluation

#### Awards

#### Certificate of Merit

Nobuko Tanitame, MD (*Presenter*) Nothing to Disclose

### TEACHING POINTS

Phase-contrast (PC) MRI can be used to measure blood flow in patients with congenital heart disease (CHD). Although Doppler echocardiography can provide shunt flow velocities in patients with common CHD such as atrial or ventricular septal defects, it may be limited by natural or surgical variations. On the other hand, PC MRI can provide precise blood flow analysis non-invasively for patients with complex CHDs and post-surgical anatomy. We demonstrate the principles and potential pitfalls of blood flow volume quantification using PC MRI and present some cases such as a coronary fistula, anomalous origin of one pulmonary artery from the aorta, and a patient who underwent a Blalock-Taussig shunt operation.

### TABLE OF CONTENTS/OUTLINE

1. Principles of PC flow volume measurement - A review of PC MRI technique, semi-automatically flow volume measurements 2. Pitfalls of PC flow volume measurement - Velocity encoding (VENC) selection considering aliasing and low phase shift value, spatial and temporal resolution, image plane setting, respiratory motion artifact, validation strategies 3. Blood flow volumes commonly measured in our hospital - Ascending aorta, main/right/left pulmonary artery, superior/inferior vena cava, the cross-section of mitral/tricuspid valve, right/left pulmonary vein 4. Representative cases - Right coronary artery to left ventricular fistula, right pulmonary artery from the descending aorta, post-surgical patients (modified Blalock-Taussig shunt, Glenn procedure, cardiac plug implantation, balloon angioplasty etc.)

CAEE-54 Takayoshi Yamaguchi (*Presenter*) Nothing to Disclose

## **A Novel Coronary CT Imaging Technique that Further Improves the Spatial Resolution of Super Resolution Deep Learning Reconstruction**

### **TEACHING POINTS**

1. Review the current status in coronary CT image evaluation and summarize its limitations 2. Summarize the relationship between spatial resolution and image noise in the current various CT image reconstruction methods 3. Explain the features of the new super resolution deep learning reconstruction (SR-DLR) algorithm trained using the data acquired by the super resolution CT system 4. Proposal of a new imaging method that further improves the spatial resolution of the SR-DLR algorithm and improves the visualization capabilities of coronary arteries, stent lumens, and calcified lesions 5. Comparison of image quality and exposure dose between conventional and new imaging methods

### **TABLE OF CONTENTS/OUTLINE**

1. Introduction 2. Summarize the limitations of assessment of STENT lumens and calcified lesions using current CT imaging 3. Explains the features and usefulness of the new super resolution deep learning reconstruction (SR-DLR) algorithm trained using data acquired by a super-resolution CT system 4. Limitations of coronary CT imaging under normal scanning conditions using the SR-DLR algorithm 5. Proposal of a new imaging method that further improves the spatial resolution of the SR-DLR algorithm 6. Description of focal spot sizes used in coronary CT for super-resolution and conventional CT systems 7. Presenting the spatial resolution and image noise of small-focus imaging combined with the SR-DLR in conventional CT systems 8. Comparison of images with different focal spot size for stents and calcified lesions in the same cases, presenting the usefulness of small-focus imaging 9. Comparison of exposure dose in imaging at each focal spot size

## **CAEE-55 Cardiac CT Pearls and Pitfalls: What You Should Know About Anatomy to Avoid Catastrophes**

Amalia Aranaz Murillo, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. Understanding the different visual axes in cardiac imaging is crucial for interpreting cardiac anatomy. 2. Familiarity with the characteristics and structures of the atriums and ventricles is essential for accurate diagnosis and assessment of cardiac function. 3. Knowledge of main coronary arteries and their pathways and bifurcations is vital for accurate assessment of coronary artery disease. 4. Understanding the anatomy and branches of the coronary and pulmonary veins is essential for evaluating cardiac function and assessing for potential blockages.

### **TABLE OF CONTENTS/OUTLINE**

We sometimes read a poster or a review and feel quite deceived because what you expect to learn you already know. For that reason, this poster will have at the beginning a QA. If you know all the answers, please, do not waste time on it, if not, it might teach you some anatomy tricks. It will be divided into seven blocks that detail the anatomy and structures of the heart in CT. The first block describes the different visualization axes of the heart and evaluates structures such as the anterior and inferior wall of the myocardium, the left atrial appendage, and the coronary sinus. The second block focuses on the characteristics of the right atrium and its different structures. The third describes the components of the ventricles and their structure. The fourth focuses on the major arteries of the heart, including the aorta and pulmonary artery. The fifth block details the four main coronary arteries and their paths and bifurcations. In the sixth, the coronary veins and their tributaries are explained, and finally, the anatomy of the pulmonary veins and their variability in the number and arrangement of drainage orifices to the left atrium is described.

## **CAEE-56 Complications After Cardiac and Ascending Aorta Surgery**

Maria Guerrero Martin (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. To understand and distinguish the different types of ascending aorta surgeries 2. To evaluate the pathological findings after cardiovascular surgery, in order to differentiate them from the usual ones 3. To discern the most typical complications in relation to their chronological onset and their follow-up 4. To show the possible options in the management of patients with these complications 5. To emphasize the role of CT in the diagnosis of these conditions

### **TABLE OF CONTENTS/OUTLINE**

1. Background and methods 2. Findings 2.1. Techniques used to evaluate postoperative patients 2.2. Common findings after cardiovascular surgery 2.3. Complication following aortic surgery 2.3.1. Early complications: periprosthetic haematomas, pseudoaneurysm formation, distal malperfusion 2.3.2. Late complications: aortic valve regurgitation, infection, anastomotic stenosis 2.4. Complications following cardiac valve surgery: valvular/paravalvular regurgitation, endocarditis, hypoattenuating leaflet thickening, prosthesis-patient mismatch 2.5. Complications following coronary artery procedures: stenosis, thrombosis 3. Our experience 4. Conclusion

## **CAEE-57 Cardiac MRI in Adult Orthotopic Heart Transplant**

Sandra Quinn (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. Outline unique CMR tissue characteristics of the transplanted heart 2. Discuss tissue characteristics suggestive of acute cardiac allograft rejection in the transplanted heart 3. Outline the role of quantitative myocardial stress perfusion in detection of epicardial and microvascular cardiac allograft vasculopathy 4. Provide an overview of the published data with respect to CMR and adult heart transplant

## TABLE OF CONTENTS/OUTLINE

1. Cardiac MRI in Orthotopic Heart Transplant· Overview of structural and functional CMR and its role in major complications of heart transplant, i.e., acute cardiac allograft rejection and cardiac allograft vasculopathy.2. CMR Tissue Characterization in Orthotopic Heart Transplant· Describes the general considerations and overview of published values regarding CMR myocardial tissue characterization of the transplant heart.3. Acute Cardiac Allograft Rejection (ACAR)· Outline the published CMR myocardial tissue characterization values for patients with active ACAR and ACAR previous history.4. Cardiac Allograft Vasculopathy (CAV)· Illustrate with a representative clinical case the role of CMR quantitative perfusion in the identification of CAV· Describe expected resting and stress myocardial blood flow and myocardial perfusion reserve in heart transplant recipients vs healthy volunteers· Identify the role of myocardial perfusion reserve for identification of CAV· 5. The Key Evidence in Summary· Summary table outlining the published evidence for CMR in heart transplant and complications of heart transplant.

## CAEE-58 Pre and Postoperative CT Evaluation for Robotic and Minimally Invasive Coronary Artery Bypass

Omer Onder, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Teaching points: 1. Robotic and minimally invasive coronary artery bypass is a safe and less traumatic surgical technique than open-heart surgery. It is considered the first-choice therapy for selected patients although the adoption has been slow in some institutions. 2. Imaging assessment prior to the surgery and providing relevant information to the surgeons is crucial for identifying suitable patients, anatomic assessment, surgical planning, and predicting outcomes. 3. Being familiar with the spectrum of expected postsurgical findings and complications following robotic and minimally invasive coronary artery bypass surgery is essential for radiologists to contribute to proper patient management.

## TABLE OF CONTENTS/OUTLINE

Table of Contents/Outline: A. Overview of surgical techniques: TECAB, MIDCAB, robotic assisted B. Indications and contraindications C. CT angiography for preoperative evaluation 1. Scan protocol and postprocessing techniques 2. Preoperative checklists 1) Aorta and iliofemoral arteries 2) Evaluation of lung, pleural plaques 3) Chest wall, diaphragm 4) Heart, pericardium, mediastinum 5) Aorta diameter, pulmonary artery diameter, ascending aortic calcification 6) Internal mammary arteries 7) LAD and other coronary arteries D. Procedural considerations E. Postoperative CCTA assessment, complications F. Conclusion

## CAEE-59 Navigating the Vortex: Advancements in Turbulent Flow Detection Using Cardiovascular 4D Flow MRI

Tetsuro Sekine, MD, PhD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

4D flow MRI has revolutionized the assessment of in vivo flow dynamics, leading to a better understanding of physiological flow in healthy subjects and those with thoracic aortic aneurysms, chronic aortic dissection complications, and aortic prostheses. A key finding related to altered blood flow is turbulence, which can be visually detected through vortices in 4D flow MRI. However, visual assessment is subjective, prompting the need for quantitative evaluations. Recent advancements have facilitated the quantification of turbulent parameters such as vorticity, energy loss, and turbulent kinetic energy using 4D flow MRI. This presentation will explore clinical evaluation methods for these turbulence indices while discussing specific diseases as examples.

## TABLE OF CONTENTS/OUTLINE

1. The background of flow analysis a. Clinical demands for flow analysis b. 4D Flow MRI technique for flow analysis c. Primary and secondary flow in a healthy aorta d. Quantification of turbulence - vorticity, energy loss, and turbulent kinetic energy2. Thoracic aneurysm a. Helical flows in patients with bicuspid aortic valve b. Association between aneurysmal development and wall shear stress3. Aortic dissection a. Blood flow volume quantification - forward and backward flow in the false lumen b. Vortices in the false lumen4. Post-prosthetic graft replacement a. Quantification of turbulent blood flow induced by artificial aorta b. Mechanical hemolytic anemia due to aortic arch graft stenosis5. Hypertrophic cardiomyopathy a. Vortex flow in the ascending aorta b. Association between turbulent kinetic energy elevation and left ventricular mass increase

## CAEE-6 Beyond Coronary Artery Calcium: Cardiovascular Findings in Non-Gated Chest CT Scans

Miguel Barrio Piqueras I, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. To review the most common incidental cardiac findings on routine chest CT examinations. 2. To recognize which cardiac findings are relevant and can alter the clinical course and outcome of patients.

## TABLE OF CONTENTS/OUTLINE

1. Coronary arteries: a). Anatomical variants (dominance) b). Coronary anomalies (origin)-Benign-Malignant c). Coronary artery calcium d). Coronary aneurysm e). Coronary artery fistula 2. Cardiac chambers: a). Intracavitary thrombus 3. Myocardium: a). Myocardial infarction -Acute-Chronic b). Cardiomyopathy-Dilated-Hypertrophic c). Primary tumors-Fibroma-Myxoma d). Metastases-Chordoma-Lymphoma-Lung carcinoma-Melanoma e). Pseudotumors -Lipomatous hypertrophy of the interatrial septum 4. Valvular heart disease: a). Anatomical variants -Bicuspid aortic valve b). Calcifications -Mitral annulus-Aortic valve 5. Congenital heart disease and thoracic vascular disorders: a). Atrial septal defects b). Patent ductus arteriosus c). Persistent left superior vena cava d). Aortic arch anomalies-Right sided -Double aortic arch e). Anomalous pulmonary venous drainage 6. Pericardial diseases: a). Pericarditis -Infectious-Iatrogenic-Autoimmune-Constrictive b). Pericardial effusion and hematoma c). Pericardial cysts d). Malignant pericardial involvement-Direct invasion-Metastases-Venous extension e). Pericardial fat necrosis

## CAEE-60 Quantitative Stress Perfusion Cardiac Magnetic Resonance: Why, How and When?

### Awards

#### Certificate of Merit

Fai Wang Fong (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. Understand differences between qualitative, semi-quantitative and quantitative stress perfusion. 2. Understand how quantitative stress cardiac MRI (QuantCMR) is performed and calculated as well as how to interpret myocardial blood flow/myocardial perfusion reserve. 3. Demonstrate clinical role of cardiac MRI quantitative stress perfusion. 4. Illustrate different pathologies and their appearances on cardiac MRI quantitative stress perfusion.

## TABLE OF CONTENTS/OUTLINE

This exhibit will explain the recent interest and development of QuantCMR and how this differs from qualitative and semi-quantitative stress perfusion. Technical details of how QuantCMR is performed and quantified will be demonstrated along with tips/ tricks of how to get high quality perfusion maps. The exhibit will explain differences between dual bolus and dual sequence techniques and issues to be aware of with different stress agents. The exhibit will discuss how QuantCMR is being increasingly recognised as being useful in patients with ischaemia and non-obstructive coronary arteries (INOCA) to diagnose coronary microvascular dysfunction (CMD) as well in standard assessment of obstructive coronary artery disease. Clinical examples of these pathologies will be illustrated. In addition, other cardiac diseases will also be demonstrated to illustrate how QuantCMR perfusion maps appear in different disease entities such as dilated cardiomyopathy and hypertrophic cardiomyopathy. Knowledge gaps and future directions will also be discussed.

## CAEE-61 State of the Art on Acute Coronary Syndrome with Negative Coronary Angiography

Cesar Urtasun Iriarte I, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

To learn the definition of MINOCA and review the spectrum of causes that manifest as acute coronary syndrome with non-obstructive coronary arteries. To understand the role of cardiovascular imaging, learn about the management and, outline CT and MRI protocols.

## TABLE OF CONTENTS/OUTLINE

A. Background, diagnosis, and management B. Assessment: CT and MRI protocols C. Acute coronary syndrome with negative coronary angiography a. MINOCA entities - Coronary plaque disruption- Coronary artery vasospasm- Coronary artery dissection- Coronary artery thrombosis/embolism- Coronary microvascular disorder- Myocardial oxygen demand-supply imbalance b. MINOCA-like entities Myocardial location (Tako-Tsubo, myocarditis, hypertrophic cardiomyopathy, dilated cardiomyopathy, infiltrative cardiomyopathy) Other non-cardiac mimickers (Vasculitis, pulmonary embolism, aortic dissection) D. Take-home messages

## CAEE-62 Development in Free-Breathing Coronary CTA for Patients With High Heart Rate: Using Non-Device Respiratory Gating Method

Nobuyuki Akiyama, RT (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Technological advances make Free-Breathing Coronary CTA (FB-CCTA) possible, but there are challenges for patients with higher heart rate (HR). We have developed a protocol of FB-CCTA at high HR using a non-device respiratory gating method.

## TABLE OF CONTENTS/OUTLINE

We have developed a method to reduce motion artifacts even at high HR from free-breathing images. Since multi-segment reconstruction can improve image quality and diagnostic accuracy at higher HR, Scans and post-processing were performed to allow the segment reconstruction from free breathing images. After electrocardiogram gated Dynamic Volume Scan, to avoid motion artifacts due to breathing, the non-device respiratory gating was performed. The respiratory arrest phase was analyzed using Time-Density-Curve (TDC) plotted from the region of interest drawn on the chest wall of the dynamic image. Multi-segment reconstruction used data from multiple cardiac cycles during respiratory arrest time analyzed from the TDC was performed. In addition, the reconstruction type was applied with full-iterative model-based reconstruction algorithms for improved Signal-To-Noise ratio (SNR). The resulting image was reduced motion artifacts and improved SNR. This method is feasible to provide acceptable image quality and diagnostic performance in CCTA with free-breathing and high HR.

### **CAEE-63 Effectiveness of a Contrast Enhancement Boost Technique in Cardiac CT: Improved Detection of Late Iodine Enhancement (LIE) in Non-Ischemic Cardiomyopathy**

Nobuaki Hasegawa, RT (*Presenter*) Nothing to Disclose

## TEACHING POINTS

- To learn about issues of myocardial evaluation with Single-Energy CT.
- To learn about a subtraction technique with non-rigid registration, that can be used to represent an image of the myocardium.
- To learn the principles of the contrast enhancement boost technique (CE-boost) with non-rigid registration.
- To learn about the contrast-improving effects of CE-boost and its diagnostic value in non-ischemic cardiomyopathy.

## TABLE OF CONTENTS/OUTLINE

A. Comparison of CNR between Single-Energy CT and other imaging techniques for non-ischemic cardiomyopathy. B. Advantages of non-rigid registration compared to rigid registration in subtraction techniques. C. Usefulness of non-rigid registration subtraction technique with CE-boost in LIE-CT. D. Clinical case of LIE-CT using CE-boost for preoperative CT examination for TAVI. E. Advantages of CE-boost in non-ischemic cardiomyopathy and its application in clinical imaging.

### **CAEE-64 Cardiac MRI for the Beginner: A Step by Step Approach**

Rebekah Lee, MBBS, FRCR (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Cardiac MRI is a non-invasive modality for anatomical, functional and myocardial tissue evaluation of the heart for a variety of cardiovascular diseases. It holds immense diagnostic potential and despite its relative high cost, it is becoming more increasingly mainstay in cardiac evaluation. Some conditions that cardiac MR renders benefits to include ischaemic heart disease, cardiomyopathy, valvular disease, congenital disease, pericardial disease and characterization of cardiac masses. It supplements the initial cardiac work-up by providing an unobstructed field of view, myocardial tissue assessment and remains the gold standard for RV and LV volumetric assessment. It is a complex study and includes an arsenal of MRI sequences including cine, myocardial perfusion, parametric mapping and flow sensitive sequences, all tailored to the specific clinical indication or question. Reading a Cardiac MR for the novice radiologist/cardiologist can be a daunting task. With the need for more Cardiac MR readers and to demystify this process, this poster will aim to provide a basic navigational chart for the novice reader which will provide a foundation for them to build upon. Teaching points: An overview of cardiac MRI sequences, basic principles and utility of each sequence An basic approach to interpreting a cardiac study An algorithm approach to common cardiac conditions with case based examples.

## TABLE OF CONTENTS/OUTLINE

Basic cardiac MR sequences and their purpose How to approach a Cardiac MR Basic techniques on qualitative and quantitative assessment with tips and tricks Algorithm for common conditions Case based discussion

### **CAEE-65 Late Iodine Enhancement of Myocardial with Deep Learning Reconstruction Under Low Radiation Doses and Low Contrast Doses: How to Get the Best Image Quality**

Yuuta Yasunaga (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Late Iodine Enhancement (LIE) of myocardium in cardiac CT has been reported to reflect fibrotic lesions in myocardium similar to Late Gadolinium Enhancement (LGE) in cardiac MRI, but requires a higher contrast dose and radiation dose due to contrast enhancement and noise effects. To solve this problem, we propose three new points in using imaging, reconstruction and subtraction technology. 1. Imaging technology: Low-voltage imaging according to BMI. 2. Reconstruction technology:

Deep Learning Reconstruction (Contrast enhancement parameters "AiCE"). 3. Subtraction technology: special contrast-enhancing subtraction technology "CE-Boost". Using the above three methods enables significant contrast enhancement and noise reduction, even with LIE at low radiation doses and low contrast doses. In addition, using DLR provides stability in the uniformity of CT values required for myocardial Extra Cellular Volume (ECV) quantification.

#### **TABLE OF CONTENTS/OUTLINE**

(1) Combination of three special technologies (2) Reconstruction and subtraction technologies (3) Deep learning reconstruction and special subtraction (4) Stable noise reduction with DLR (5) Combination of three special technologies

### **CAEE-66 Success Within Your Grasp: Planning for Mitral Valve Transcatheter Edge-to-Edge Repair**

Hyun Jung Koo, MD, PhD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

To recap the evidence of mitral edge-to-edge repair in both primary and secondary mitral regurgitation To demonstrate preprocedural imaging modalities to help appropriate patient selection and interventional guide To understand intraprocedural imaging and post-procedural imaging findings

#### **TABLE OF CONTENTS/OUTLINE**

1. Evaluation of mitral regurgitation (MR) 1) Etiology of MR - Primary mitral regurgitation - Secondary (functional) mitral regurgitation 2) Quantification of MR 2. Types of percutaneous mitral valve repair 3. Patient selection for M-TEER - AHA/ACC Guidelines for M-TEER - Review of Trials: EVEREST II trial, COAPT trial, MITRA-FR trial - Anatomically suitable mitral valve morphology 4. Pre-procedural planning for M-TEER - Echocardiography and cardiac CT - Evaluation parameters 5. Intra-/Post-TEER imaging of M-TEER 6. Potential complications after M-TEER

### **CAEE-67 Multimodality Imaging in Sports Cardiology: New Kid on the Block**

#### **Awards**

#### **Cum Laude**

Prabhakar Rajiah, MD, FRCR (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Although athletes' have low prevalence of coronary artery disease (CAD), they are prone for other cardiovascular disorders, which should be evaluated prior to suitability for athletic activity. 1. To review the role of Sports Cardiology, a relatively new subspecialty focused on athletes 2. To discuss the role of imaging, particularly MRI in the diagnosis of athlete's heart which is a structural adaptive change that overlaps with cardiomyopathies. 3. To illustrate with case examples the various entities that are encountered in athletes.

#### **TABLE OF CONTENTS/OUTLINE**

1. SPORTS CARDIOLOGY- INTRODUCTION a. Pre-athletic activity screening for diseases that may be worsened with sports activities b. Evaluation of diseases that cause adverse events in athletes 2. ROLE OF IMAGING- Echo, MRI, CT 3. MRI SEQUENCES AND PROTOCOL 4. ADAPTIVE CHANGES IN ATHLETES= Endurance- Volume overload, increased wall stress, eccentric hypertrophy; Strength- Pressure overload, increased wall stress, concentric hypertrophy 5. MYOCARDIAL FIBROSIS IN ATHLETES- Prevalence and pattern 6. ATHLETE'S HEART (WITH CASE EXAMPLES)- Diagnostic criteria controversies; Distinguishing from mimics (Grey zone) a. Hypertrophic cardiomyopathy b. Dilated cardiomyopathy c. LV non compaction d. Arrhythmogenic cardiomyopathy 7. DISEASES CAUSING SUDDEN CARDIAC DEATH IN ATHLETES (with case examples) a. HCM b. ARVD C. Anomalous coronary arteries d. Commotio cordis e. Myocarditis 8. SCREENING STRATEGIES WITH IMAGING IN PROFESSIONAL ATHLETES 9. CTA IN RISK STRATIFICATION OF CORONARY ARTERY DISEASE 10. VETERAN ATHLETES AND MYOCARDIAL FIBROSIS- ARRHYTHMIA 11. ATHLETES AND COVID-19 12. MANAGEMENT OF INCIDENTAL FINDINGS IN ATHLETES

### **CAEE-68 The Minimal Essence of Machine Learning for Cardiovascular Diagnosis**

Ryo Ogawa, PhD, MD (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**

Various information related to medical data can be obtained by machine learning. We explain how machine learning are used to cardiovascular diagnosis. 1. To review the role of machine learning. 2. To explain the application of machine learning in cardiovascular diagnosis. 3. To explain the principle of machine learning.

#### **TABLE OF CONTENTS/OUTLINE**

1. Linear regression; overview, algorithm, example (heart failure) 2. Logistic regression; overview, algorithm, example (history of heart disease) 3. Support vector machine; overview, algorithm, example (Differentiation of cardiomyopathy) 4. Random forest; overview, algorithm, example (Differentiation of cardiomyopathy) 5. Neural network; overview, algorithm,

example (Classification of myocardial infarction)6. Explainable AI; overview, algorithm, example (Gradient-weighted class activation mapping, Guided gradient-weighted class activation mapping)7. Generative AI; overview, algorithm, example (Deep convolutional generative adversarial network)

## **CAEE-69 Denoise to Visualize: The AI-Driven Post-Hoc Denoising for High-Fidelity Cardiac CT**

Tatsuya Nishii, MD, PhD (*Presenter*) Speakers Bureau, Guerbet SA;Speakers Bureau, General Electric Company;Speakers Bureau, Siemens AG;Research Grant, Canon Medical Systems Corporation

### **TEACHING POINTS**

In cardiac CT, maintenance the increased image noise from photon insufficiency is crucial while upholding high resolution. CT manufacturers have developed iterative and deep-learning reconstruction methods, but disparities exist. Advancements in AI enable image restoration, such as denoising through post-processing allowing radiologists to develop image-processing AI promoting the "democratization" of technology.This exhibit presents the development of a denoising method for high-fidelity cardiac CT using image-based deep learning and its clinical applications. Participants will learn about democratized image-processing AI and engage in its development and clinical application. In enhancement, we showcase cardiac CT images with the application of noise reduction technology, aiming to generate new ideas for diagnostic and prognostic imaging.

### **TABLE OF CONTENTS/OUTLINE**

1. Importance of noise reduction in cardiac CT 1.1 Cardiac CT imaging techniques 1.2 Noise's adverse effects2. AI denoising method differences 2.1 Deep-learning image reconstruction 2.2 Deep-learning post hoc denoising3. Denoising AI development Process 3.1 Optimal network selection 3.2 Data preparation essentials 3.3 Training, validation, and testing 3.4 Implementation highlights4. Clinical Showcases 4.1Exposure Reduction 4.1.1 1/4 dose coronary CT angiography 4.1.2 1/3 dose myocardial delayed enhancement CT 4.1.3 Low-dose pediatric cardiac CT 4.2 Image quality enhancements 4.2.1 Improved diagnostic performance of coronary CT angiography 4.2.2 Enhanced myocardial delayed enhancement CT 4.2.3 Enhanced 3D rendering images

## **CAEE-7 Atrial Septal Defects: A Multimodality Case-Based Approach**

David Gonzalez, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

Outline the most common atrial septal defects and their associations.Demonstrate the role of cardiac MRI and CT in the diagnosis of atrial septal defects. Illustrate, through case reviews, the imaging findings of atrial septal defects.Discuss treatment options and morphological characteristics to treatment decisions.

### **TABLE OF CONTENTS/OUTLINE**

This review presents a multimodality case-based approach to the diagnosis of Atrial Septal Defects (ASDs).ASDs are the most common congenital cardiac anomaly.Ostium secundum is the most common ASD. Some congenital syndromes, including Holt Oram Syndrome and Lutembacher Syndrome, have ostium secundum type septal defects as part of their spectrum.Sinus venosus can present as a superior or inferior defect, each with different anatomical associations.Ostium primum is within the spectrum of atrioventricular septal defects and is associated with endocardial cushion defects and Trisomy 21.Coronary sinus atrial septal defect is a rare disease presenting as permeability of the coronary sinus. Raghbi syndrome is a type of coronary sinus ASD defined as a PLSVC draining to an unroofed coronary sinus.The roles of CT and MRI offer information on coronary and pulmonary diseases, as well as other anatomical variations that can impact the patient's treatment. MRI also enables functional assessment of the flow, cardiac function, and myocardial tissue characterization.Ostium primum/atrioventricular septal defects, coronary sinus defects, and sinus venosus defects are often treated surgically, while septum secundum type defects can be treated with transcatheter closure. The decision is based on the size, number, and shape of the defects.

## **CAEE-70 Quantitative Myocardial Perfusion MR: State-of-the-Art**

### **Awards**

#### **Magna Cum Laude**

Roberta Catania, MD (*Presenter*) Institutional Research Grant, Siemens AG

### **TEACHING POINTS**

1. Quantitative perfusion MR is an objective and more reproducible tool to identify myocardial perfusion defects and differentiate artifacts compared to only qualitative assessment. 2. Quantitative perfusion MR is a non-invasive tool that can add significant value in the work-up of patients with suspected coronary artery disease and surveillance of post heart transplant patients.

### **TABLE OF CONTENTS/OUTLINE**

Introduction - Physiology of myocardial circulation at rest and stress and autoregulation - Overview of current noninvasive imaging techniques for coronary artery disease assessment and their accuracy - Clinical applications of myocardial perfusion

imaging including assessment for epicardial and microvascular coronary artery disease and heart transplant surveillance  
Imaging techniques - Pharmaceutical stress agents: mechanism of action and contraindications - Cardiac perfusion MR: physical principles, imaging sequences and protocol - Quantitative analysis:  $\emptyset$  Current quantification techniques (automated pixel-wise and dual sequence approach)  $\emptyset$  Absolute quantification and myocardial perfusion reserve (MPR)  
Imaging interpretation and case study- How to interpret quantitative perfusion and key information to be provided in radiology report - Normal quantitative myocardial perfusion MR - Atlas of different radiologic findings - Troubleshooting interpretations of complicated quantitative perfusion MR findings

## **CAEE-71 Utility of Non-contrast MRI for Preprocedural Assessment in Patients Undergoing TAVI**

Naoki Hosoda (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

To learn about the pre-procedural assessment for transcatheter aortic valve implantation. To learn about the validity of non-contrast MRI assessment. To learn about non-contrast MRI imaging protocols. To learn about the benefit patient gain by alternative non-contrast MRI.

### **TABLE OF CONTENTS/OUTLINE**

A. Non-contrast MRI can be used as an alternative to contrast CT for patients with CKD and contrast allergies. B. Usefulness of non-contrast MRI to measure in the same way as contrast CT. C. Short imaging protocol focused on pre-procedural assessment of TAVI. D. Non-contrast MRI not only allows assessment comparable to contrast CT, but also avoids risks for patients with CKD and contrast allergy and allows radiation free imaging.

## **CAEE-72 Pulmonary Artery: Showcase of Congenital and Acquired Pathologies You Should Know**

Pedro L. Murra Falla, MD (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

1. To review the normal anatomy of the of the pulmonary artery and their branches. 2. To review the acquired and congenital causes. 3. To show the frequent findings in congenital pathologies. 4. To show the repercussion of the long-term affection of the pulmonary artery.

### **TABLE OF CONTENTS/OUTLINE**

1. introduccion. 2. Normal anatomy of the pulmonary artery and their branches. 3. Acquired pathologies: Complications of chronic Pulmonary embolism, Dilated arteries secondary to pulmonary hypertension, Pulmonary Artery Stenosis and Pulmonary Veno-occlusive Disease. 4. Congenital pathologies: Pulmonary artery agenesis associated with aortopulmonary collateral arteries (MAPCAs), Pulmonary atresia with intact ventricular septum, Anomalous Aortic Origin of Pulmonary Arteries, Aneurysm, Absent pulmonary valve syndrome, Double-Outlet Right Ventricle, Dextro-Transposition of the Great Arteries, Anomalous left coronary artery from the pulmonary artery (ALCAPA), Pulmonary Artery Sling, pulmonary arteriovenous malformations. 5. Long term repercussion in the cardiac chambers and great vessels. 6. Review of the most commons surgical options and outcomes. 7. Discussion. 8. Conclusion

## **CAEE-73 Dual-energy Late Iodine Enhancement Cardiac CT: What is Necessary to Achieve with Dual-Layer Spectral CT?**

Junji Mochizuki, MSc, RT (*Presenter*) Nothing to Disclose

### **TEACHING POINTS**

A. To learn about late iodine enhancement (LIE): Imaging technique with dual-layer spectral CT. B. To learn how spectral imaging solves conventional imaging problems. C. To learn about the use of iodine density image for myocardial extracellular volume (ECV). D. To illustrate various clinical applications of these techniques by presenting clinical images.

### **TABLE OF CONTENTS/OUTLINE**

A. Methods of scanning and contrasting late iodine enhancement (LIE) using dual-slice spectral CT. And their advantages and disadvantages. B. Advantage of spectral images over conventional CT for LIE. C. LIE image analysis. LIE by image subtraction and myocardial extracellular volume (ECV) by iodine concentration images. D. Evaluation of myocardial viability by LIE. Evaluation of OMI by subtraction-LIE. E. LIE myocardial viability evaluation. Evaluation of cardiomyopathies by ECV.

## **CAEE-74 The ABC's of ECG - Practical Tips and Tricks for Salvaging ECG-Gated Cardiac CT**

### **Awards**

#### **Certificate of Merit**

Prabhakar Rajiah, MD, FRCR (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. Distinguish the various artifacts commonly encountered in ECG-gated cardiac CT 2. Recognize whether the artifact can be repaired, reduced, or read around 3. Employ ECG sync point editing and composing to salvage cardiac CTs degraded by artifacts from heart rate rhythm, and ECG-gating error

## TABLE OF CONTENTS/OUTLINE

1. Introduction Basics of ECG interpretation; ECG-gating techniques, trade-offs, applications; 2. Distinguishing respiratory/patient motion vs. gating artifact 3. ECG Gating Error: Missing Data (interpolation artifact)- Pitch too high on retro helical - data gaps; Missing Sync Points; 4. ECG Gating Error: Misplaced Data (duplication artifact)- Peaked T-waves; 5. Gating Artifact with correct ECG Gating: Tachycardia or Arrhythmia- PVCs; PACs; Long pause (PVC, PAC, dropped beat); Afib other beat-to-beat Irregularity; 6. ECG-editing options- Sync point editing-Missed a beat/tagged wrong thing/helical; Sync point composing: R wave tagged, manipulation of reconstructions to read-around; 7. A systematic approach for troubleshooting ECG-gating errors and artifacts including case examples- Respiratory motion artifact- Normal ECG; Sinus tachycardia- Multisegment reconstruction; Heart rate change- Can sometimes be read-around; PVC without pause- Eliminate PVC sync; PVC with long pause- Eliminate PVC sync; Add evenly spaced sync points in pause; PAC- eliminate PAC sync or retain it extra, even sync points in best systolic phase; Atrial tachycardia- Sync in best systolic phase; Severe bradycardia- Two separate syncs in diastole; Atrial fibrillation- Artificially space sync points at each R-R interval so they line up each beat;

## CAEE-75 Tumors of the Heart: From the Right Side to the Left Side

Felipe Aluja, MD, MEd (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Discuss the most common cardiac masses, including their typical manifestations and associations, and a brief discussion of clinical scenarios. Describe the imaging signs of cardiac tumors in computed tomography, magnetic resonance imaging and PET/CT. Identify selected cardiac tumors commonly encountered in daily practice and integrate them with the clinical manifestations.

## TABLE OF CONTENTS/OUTLINE

- Introduction
- Classification with brief but concise clinical presentation
- Imaging signs of cardiac tumors in computed tomography, magnetic resonance imaging and PET/CT.
- Selected cardiac tumors:
  - o Primary: § Myxoma § Fibroelastoma § Atrial hemangioma § Lipoma § Rhabdomyoma § Fibroma § Angiosarcoma § Lymphoma § Paraganglioma
  - o Secondary: § Metastasis
- Pitfalls in cardiac tumors:
  - o Vegetations
  - o Intracavitary thrombus
  - o Lipomatous hypertrophy
- Take a guess?
- Take home points

## CAEE-76 Solving the Mystery: Cardiac Devices on Chest Radiographs

Justin Little, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Heart disease is the leading cause of mortality in the United States. Advances in clinical care leading to new devices and treatments allow patients to live longer. Radiologists encounter chest radiographs daily, many with cardiac devices. On radiographs, devices will typically be visible, and it is essential for radiologists to recognize them, know appropriate positioning, and understand complications related to the devices to provide appropriate patient management. Inaccurate interpretation may lead to inappropriate management, delayed diagnosis, and delay of necessary or harmful interventions. The purpose of this exhibit is to walk through common and uncommon cardiac devices, their appropriate positioning, and complications related to mispositioned devices, as well as discuss pathophysiology of some devices. Cardiac rhythmic controlled devices, cardiovascular support devices, stroke prevention devices, cardiac valve support and prosthetic valves, and miscellaneous devices will be reviewed.

## TABLE OF CONTENTS/OUTLINE

1. Introduction to common cardiac devices 2. Classification of these devices 3. Expected positioning of cardiac devices 4. Visible and barely visible devices on CXR 5. Pathophysiological mechanisms of these devices 6. Examples of mispositioned devices 7. Complications related to incorrectly positioned devices 8. Less common/miscellaneous devices and their positioning 9. Flowchart of what to do with a mispositioned devices (urgent versus emergent) 10. What cardiologist expects from radiology report?

## CAEE-77 Simplifying Semantic Segmentation in Cardiac MR: An Intuitive Guide for Radiologists using Transfer Learning

A Ankush, MBBS, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Understanding the importance of semantic segmentation in cardiac MR imaging  
Review of available solutions for segmentation and evaluation metrics  
Introduction to approaches for segmentation using Transfer learning  
Guided approach to a simplified segmentation process using high-level API for low-code development.  
Best practices for achieving accurate segmentation

## TABLE OF CONTENTS/OUTLINE

I. Introduction to Segmentation in Cardiac MRI Imaging  
Definition of image segmentation and its types.  
Need for segmentation in cardiac MRI imaging  
Available solutions for image segmentation and metrics for assessing accuracy  
II. Introduction to TorchIO, MONAI and FAST AI Libraries for Medical Image Analysis  
Overview of libraries.  
Understanding the Data to Model pipeline.  
Importance of Using Transfer Learning.  
Use of High-level APIs for low-code model development. III. Step-by-Step Demonstration of Segmentation using Google Colab and the Heart MRI Dataset  
Setting up the Google Colab environment  
Introduction to the Heart MRI dataset from the Medical Segmentation Decathlon challenge provided by King's College London  
Step-by-step demonstration of target segmentation of the left atrium with minimal lines of code  
IV. Best Practices for Achieving Accurate Segmentation  
Tips for optimising segmentation accuracy  
Strategies for addressing common segmentation challenges  
V. Conclusion  
Summary of key teaching points  
Future directions in semantic segmentation in cardiac MR imaging (like use of generative adversarial network (GAN))

## CAEE-78 A Precarious Path - Complications of 3-stage Palliative Surgery for Single Ventricle Congenital Heart Disease

### Awards

#### Certificate of Merit

Shravan Sridhar, MD, MS (*Presenter*) Nothing to Disclose

## TEACHING POINTS

Single ventricle congenital heart diseases are most commonly managed with 3-stage palliation which culminates in the Fontan procedure. Post-operative imaging has been instrumental in assessing for complications both in the short term and long term and ensuring patient longevity. Here, we present some of the most commonly encountered complications associated with 3-stage palliation including early post-operative complications, features of physiologic decompensation, and late-stage downstream effects attributed to the unique physiology in these patients. Where appropriate, we review practical tips and pitfalls in imaging this unique set of patients.

## TABLE OF CONTENTS/OUTLINE

1. Title, disclosures  
2. Abbreviations  
3. Complications overview  
4. Clinical scenarios  
5. Potential workup  
6. Recent operation  
a. Mediastinal hematoma  
b. Pitfall: Surgical packing material  
c. Shunt/conduit occlusion  
d. Pitfall: Un/intentional occlusion  
7. Acute SOB/desaturation/chest pain  
a. PE  
b. MI  
c. CHF  
8. Chronic non-cyanotic SOB/desaturation  
a. Fontan thrombosis  
b. Pitfall: Pseudothrombosis  
c. Systemic AV valve dysfunction  
d. Peri-anastomotic PA stenosis  
e. Pitfall: Morphology/flow discrepancy  
9. RPA/LPA  
f. Diaphragmatic paralysis  
g. Post-Glenn SVC syndrome  
10. Recurrent cyanosis  
a. Pulmonary AVM  
b. Systemic-pulmonary venous collaterals  
c. Practical tip: Quantifying collateral circulation  
d. Patent fenestration  
e. Baffle leak  
11. Arrhythmia  
a. Myocardial LGE  
12. Weight gain  
a. Liver failure  
13. Weight loss  
a. HCC  
b. Protein-losing enteropathy  
14. Chronic cough  
a. Plastic bronchitis  
15. Unexplained pleural effusion  
a. Chylous pleural effusion  
16. Potentially helpful clinical tests  
17. References

## CAEE-8 Coronary Artery Vasculitis, Encasement, and Mimics

### Awards

#### Certificate of Merit

Claire F. Woodworth, MD (*Presenter*) Nothing to Disclose

## TEACHING POINTS

1. Coronary artery vasculitis is an inflammatory process that is often distinguished from coronary artery encasement from benign and malignant neoplasms, although imaging appearances can overlap.  
2. Coronary artery vasculitis is rare but represents an important diagnostic consideration, especially for acute coronary syndrome (ACS) patients with no traditional cardiovascular risk factors or systemic illness.  
3. There are several mimics of coronary artery vasculitis, demanding careful attention to multi-organ findings and clinical presentation.

## TABLE OF CONTENTS/OUTLINE

1. Introduction.2. Spectrum of coronary artery vasculitis and encasement.3. Review and illustration of coronary artery vasculitis, including: polyarteritis nodosa, Kawasaki's disease, Takayasu's arteritis, giant cell arteritis, HIV.4. Review and illustration of coronary artery encasement, including: malignant neoplasms (lymphoma, angiosarcoma), IgG4-related disease, Histiocytic disorders (Erdheim-Chester disease, Rosai Dorfman).5. Complications of coronary artery vasculitis: aneurysms, stenosis, CHF.5. Mimics of coronary artery vasculitis: spontaneous coronary artery dissection (SCAD), acute plaque rupture, vasospasm.

### **CAEE-80 Women's Heart: Role of Cardiac Imaging in Early Detection and Prognostication of Heart Diseases- A Primer for Cardiac Imagers**

Barun Bagga, MBBS (*Presenter*) Nothing to Disclose

#### **TEACHING POINTS**
