Extracting procedure-specific cancer progression patterns across multiple organ systems in heavily treated patients is challenging. With the volume rapidly growing, additional reviewing of all images for research and quality control purposes may not be feasible. The original reports of these scans already contain rich information and can be used to flag sentinel scans for elective review to extract procedure specific outcomes. However, these reports may not be structured in favor of the current research protocol. The proposed text-based method could overcome this barrier and be adopted to build procedure specific registries, allowing radiologists to identify and review critical scans more efficiently.

### Machine learning approaches to CT and MRI protocol assignment: comparison of foundation and fine-tuned large language models with a conventional classifier.

Thursday, Nov. 30 12:15PM - 12:45PM Room: Learning Center Theater 2

Timothy Sotman, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Imaging protocol assignment for CT and MRI studies is critical for high quality radiology care. Correct determination of specialized protocols requires time and expertise. Machine learning (ML) techniques in natural language processing (NLP) may be used to automate this process. This study sought to compare the performance of a conventional ML classifier and large language models (LLM) in protocol assignment.

#### METHODS AND MATERIALS

Protocols assigned to CT and MRI exams during routine clinical care were extracted for all exams between April 2022 and April 2023. The free text protocols were mapped to 189 standardized protocol classes using pattern matching and manual review to produce a dataset of 68,610 exams and protocols. The dataset was normalized using the Natural Language Toolkit Python package and vectorized using the term frequency-inverse document frequency vectorizer from the scikit-learn Python package. A classification model was trained on 80% of the dataset using a stochastic gradient descent classifier from scikit-learn. The model was evaluated on 20% of the data withheld as a test set. The text-bison-001 large language model from Google PaLM 2 was fine-tuned by providing 9839 prompts containing examination code, type, and indication and example responses containing the correct protocol assignment. Each class was represented by at least 20 examples. The model was evaluated with 100 prompts withheld from training. The performance of the foundation GPT-4 model via the Azure OpenAI Service was evaluated using 100 prompts providing a list of protocol classes to select from along with the examination type and clinical indication. Class weighted F1 scores were calculated for each model.

#### RESULTS

The classifier demonstrated an F1 score of 0.898. The fine-tuned PaLM 2 model demonstrated an F1 score of 0.861. Foundation GPT-4 without any additional fine-tuning demonstrated an F1 score of 0.718. The models performed worse for protocols that appeared infrequently in the training set due to class imbalance.

#### CONCLUSION

Imaging protocol assignment is a multilabel classification problem that can be approached using several ML techniques. A fine-tuned LLM performed similarly well in this task to a bespoke classifier trained on a much larger dataset. A foundation LLM also performed reasonably well without any additional information about our institutional protocols. These results suggest that a further fine-tuned large language model may achieve expert level performance. Fine-tuning and evaluation of LLMs with larger data sets is ongoing.

#### CLINICAL RELEVANCE/APPLICATION

Correct imaging protocol assignment is critical for optimal patient care as CT and MRI protocols are highly tailored to address the clinical question at hand.

#### Sub-Events

#### **R6-SSBR11-1 Supplemental Optoacoustic Imaging of Breast Masses: A Cost-Effectiveness Analysis**

Berat Bersu Ozcan, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Optoacoustic Ultrasound (OA/US) is a novel imaging method that utilizes tissue's intrinsic contrast to demonstrate real-time oxygenation and can be co-registered with gray-scale ultrasound (US). Prior prospective trials demonstrated that OA/US significantly improves diagnostic specificity with a slight decrease in sensitivity when used as a supplemental technique to US alone. In our study, we aimed to evaluate the cost-effectiveness of using OA/US versus US to differentiate benign and malignant breast masses in a diagnostic setting.

#### METHODS AND MATERIALS

We created a decision-tree model based on potential diagnostic results to compare the cost-effectiveness of OA/US and US from the perspective of the U.S. Healthcare system. We utilized diagnostic test performance parameters from the PIONEER-01 (NCT01943916) and the MAESTRO (NCT02364388) clinical trials and cost parameters (USD) from the Truven Health MarketScan® Databases. Utility (quality-adjusted life in years, QALY) assumptions were made following published patient-reported outcomes. Diagnostic outcomes were designed as true positive, true negative, false positive, and false negative to represent certain relations between health states and related costs. Cost effectiveness was calculated through incremental cost-effectiveness ratio (USD per QALY gain, ICER) and net monetary benefit (USD, NMB) calculations. One-way and two-way deterministic and probabilistic sensitivity analyses were performed to determine the significance of variation in input parameters. A willingness-to-pay (WTP) threshold of \$100,000 per QALY gain was used for the study. All analyses were performed using TreeAge Pro Healthcare 2022 (Williamstown, MA).

#### RESULTS

OA/US had a total cost of \$1,784.58 and 0.80 QALYs in the base case, whereas US had a total cost of \$2,018.84 and 0.79 QALYs. The incremental NMB for OA/US was \$1,452.86, and the ICER was -\$19,223.77 per QALY, indicating that OA/US was more cost-effective than US. Tornado analysis revealed the greatest sensitivity to variation in the disutility caused by biopsy and follow-up visits, followed by the cost of OA/US and US, respectively. The estimated variation in input parameters for the analyzed ranges did not produce an ICER higher than the \$100,000/QALY WTP threshold. According to probabilistic sensitivity analysis, OA/US was the better strategy in 100% of 10,000 iterations.

#### CONCLUSION

OA/US is more cost-effective than US for evaluating breast masses. It can reduce costs while improving patients' quality of life, primarily by reducing false-positive results with consequent benign biopsies.

#### CLINICAL RELEVANCE/APPLICATION

Evaluating breast masses with OA/US in a diagnostic setting is economically feasible and can increase patients' quality of life.

#### **R6-SSBR11-2 Photon-counting CT for the Diagnosis of Degenerative Changes and Rupture of Silicone Breast Implants: A Comprehensive Evaluation of Diagnostic Accuracy and Imaging Features**

Jakob Neubauer, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

The purpose of this study was to evaluate the diagnostic accuracy of photon-counting CT (PC-CT) in detecting degenerative changes and rupture of silicone breast implants. Accurate detection and diagnosis of these complications are important for appropriate clinical management.

## **METHODS AND MATERIALS**

Over a period of one year, we prospectively included all patients with silicone breast implants who received thoracic PC-CT (NAEOTOM Alpha, Siemens Healthineers) and breast MRI. Monoenergetic reconstructions and material decomposition reconstructions were obtained. Two radiologists (5 and 10 years of experience in breast imaging) independently evaluated the images for the presence of folds of the membrane, peri-implant fluid collections and silicone collections, intra-implant fluid, keyhole and linguini sign, and capsular calcifications. The reference standard was a consensus reading by two radiologists (11 and 25 years of experience in breast imaging) of all imaging examinations. Cohen's kappa for inter-rater reliability and pooled measures for diagnostic accuracy were calculated.

## **RESULTS**

We included 19 patients with 31 implants and found that the diagnostic accuracy of PC-CT was high for detecting peri-implant silicone collections, the linguini sign, intra-implant fluid, the keyhole sign, capsular calcifications, and folds of the membrane, with accuracy values ranging from 0.91 to 0.99. Also, sensitivities ranged from 0.88-0.99 and specificities from 0.75-0.99. Inter-rater reliability was observed to be nearly perfect ( $\kappa > 0.80$ ) for all imaging features, with the exception of peri-implant fluid collections where inter-rater reliability was determined to be fair (0.39).

## **CONCLUSION**

We found PC-CT to be highly accurate in detecting various signs of degenerative changes and rupture of silicone breast implants.

## **CLINICAL RELEVANCE/APPLICATION**

Our findings suggest that PC-CT could be a feasible imaging modality for the evaluation of implant ruptures.

## **R6-SSBR11-3 A Radiomics Approach Based on Machine Learning in Distinguishing Benign and Malignant Breast Lesions Using T2 Weighted and Diffusion Weighted Imaging: A Multicenter Study**

Yulu Liu (*Presenter*) Nothing to Disclose

## **PURPOSE**

Breast Magnetic Resonance Imaging (BMRI) has been recommended as supplemental screening tool of breast cancer by international guidelines, but its long examination time and use of contrast material remains to be concerned. Thus, the purpose of this study is to develop an unenhanced radiomics model using machine learning techniques based on T2W and DW sequences to identify benign and malignant breast lesions.

## **METHODS AND MATERIALS**

A total of 1760 patients were enrolled in this multicenter study to develop, validate and test a radiomics model. 1293 continuous patients were randomly divided into two groups at a ratio of 6:4 for model construction. (training cohort,  $n=775$ ; validation cohort,  $n=518$ ). After MR image segmentation, feature extraction and selection, we used the machine learning Gaussian Process (GP), Support Vector Machine (SVM) and Logistic algorithm to differentiate breast cancer. Afterwards, models' diagnostic performance was tested on three independent testing cohorts (internal retrospective test,  $n=167$ ; internal perspective test,  $n=188$ ; external retrospective test,  $n=112$ ). Model performance was evaluated using AUC to compare with the model combining Postcontrast Phase I images, and the diagnosis of radiologists. Subgroup analysis was performed to assess the performance in different categories, including lesion types (mass and no-mass), background parenchymal enhancement (minimal, mild, moderate, and marked), age ( $\geq 50$  and  $< 50$ ), and pathological types of malignancy.

## **RESULTS**

The unenhanced model performed best based on GP classifier (AUC, training: 0.893, validation: 0.848), and showed favorable prediction in testing cohorts (AUCs, 0.818-0.840). The AUC values for unenhanced model were not statistically different from the combined model ( $p > 0.05$ ). There was no significant difference in performance between the unenhanced model with two readers ( $p > 0.05$ ). The unenhanced model demonstrated favorable performance in diagnosing tumors with different lesion types, background parenchymal enhancement, and ages. The model performed worst in identifying ductal carcinoma in situ, whereas showed favorable competence in identifying other types of malignancies ( $p=0.0054$ ).

## **CONCLUSION**

The model utilizing the unenhanced sequences based on T2WI and DWI, has displayed excellent diagnostic accuracy, comparable to radiologists. These findings indicate that our model could potentially help the screening of breast cancer in the future.

## CLINICAL RELEVANCE/APPLICATION

Our study showed that a machine learning unenhanced radiomics model using T2WI and DWI is effective in distinguishing breast lesions, which suggests this approach could potentially assist in screening of breast cancers in the future.

### R6-SSBR11-4 **Assessment of Nonmass Lesions Detected by Screening Breast US: A Multicenter Study**

Su Min Ha, MD, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To analyze US features of non-mass lesions (NMLs) detected by screening US and determine the predictive features. In addition, to investigate application of classification system for validating screening US detected NMLs.

#### METHODS AND MATERIALS

This retrospective, multicenter study included 993 asymptomatic women who were referred for screening US. Eligible women had NMLs detected at US. Three radiologists interpreted and assessed the final Breast Imaging Reporting and Data System (BI-RADS) category. Univariable and multivariable logistic regression was used to identify independent clinical and imaging factors associated with malignancy. We applied the classification system and calculated the positive predictive value for biopsy recommendations (PPV2) and conversion rate of BI-RADS 4A to 3 category. Inter-reader agreements between readers were analyzed with weighted kappa values.

#### RESULTS

Among 993 patients (mean age  $49.7 \pm 8.6$  years, range, 30-80 years) with 993 NMLs, 885 (89.1%) were benign, 29 (2.9%) were high risk lesion, and 79 (8.0%) were malignant lesions. The mean size of malignant NMLs was significantly larger than benign NMLs ( $2.6 \pm 1.1$  vs  $1.9 \pm 0.8$  cm,  $P < .001$ ). In the multivariable analysis, mixed echogenicity (OR, 4.95;  $P < .001$ ), segmental distribution (OR, 5.52;  $P < .001$ ), presence of calcification (OR, 22.87;  $P < .001$ ), presence of posterior shadowing (OR, 7.22;  $P < .001$ ) and size on US (OR, 1.56;  $P = .009$ ) were independent factors associated with malignant NMLs. The presence of multiple small cysts was not negatively associated with malignant NMLs (OR, 0.59;  $P = .290$ ). Among the features showing statistical significance on multivariable analysis, presence of calcification showed PPV of 44.3%, segmental distribution (PPV of 22.9%), presence of posterior shadowing (PPV of 21.8%) and mixed echogenicity (PPV of 16.5%). Utilizing the classification system showed PPV2 of 16.7% (95% CI: 13.6, 20.3) and conversion rate of BI-RADS 4A to 3 were 42.8% (reader 1 and reader 2) and 40.0% (reader 3). Inter-observer agreement for NMLs was excellent with kappa values ranging from 0.83 to 0.90.

#### CONCLUSION

When breast NMLs are detected on screening US, suspicious malignant US features may be applicable for diagnosing clinically occult malignant NMLs.

## CLINICAL RELEVANCE/APPLICATION

No prior study has investigated US features of NMLs detected on screening US. Our study provides data regarding US features that may improve the utility of screening US in asymptomatic women in accurate diagnosis of NML.

### R6-SSBR11-5 **Keynote Speaker: Potential Role of Breast DWI in Breast Cancer Screening and Diagnosis**

Savannah C. Partridge, PhD (*Presenter*) Research Grant, General Electric Company; Research support, Koninklijke Philips NV; Consultant, Guerbet SA

### R6-SSBR11-6 **Different Downstream Outcomes After Consensus Discussion Related to Which Readers, AI or Radiologist, Flagged the Screening Mammography as Abnormal - In the Prospective Interventional Screentrustcad Trial**

Karin Dembrower, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

ScreenTrustCAD (NCT04778670) was the first prospective interventional study of AI in population-based breast cancer screening with a total of 55,581 women included. Based on a paired-reader design, it was found that in a double-reading and consensus workflow, AI plus one reader achieved superior cancer detection to two readers, without increasing recalls. The purpose of the current sub-study was to analyze differences in consensus recall decisions depending on whether AI or radiologists had initially flagged the exam as abnormal.

#### METHODS AND MATERIALS

The current study was performed within the ScreenTrustCAD trial, which employed an index test of paired reading between two human readers and Lunit INSIGHT MMG (AI). The three readers of each exam were blinded to the reads of others. An exam flagged by any reader was forwarded to the consensus discussion. In this sub-study, women who reported lumps at

time of screening were excluded since AI did not consider that information. For each combination of readers who flagged the exam, we calculated the proportion of recalled women, cancers detected and positive predictive value (PPV).

## **RESULTS**

There were 55,581 women included in the ScreenTrustCAD trial with 269 women diagnosed with breast cancer. After excluding women reporting a lump, there were 53,865 women overall, of whom 238 with breast cancer. In total, 5515 exams were flagged for consensus discussion, of which AI, reader 1 and reader 2 each flagged 3014 (55%), 2255 (41%) and 2424 (44%) respectively. 1358 (2.47%) women were recalled, of whom 238 (17.5%) were diagnosed with breast cancer and 1120 (82.5%) were not. Among 2501 consensus cases which had not been flagged by AI (but by one or two radiologists), the consensus discussion decided to recall 626 (25%) and for 21 (0.8%) cancer was detected, resulting in 3.4% PPV. Among 3014 consensus cases which had been flagged by AI (and zero to two radiologists), the consensus discussion decided to recall 732 (24%) and for 217 (7.2%) cancer was detected, resulting in 29% PPV. See Figure 1 for further breakdown of results.

## **CONCLUSION**

For the exams that the radiologists in the consensus discussion decided to recall, the PPV for exams previously flagged by AI, compared to those only flagged by radiologists, was nearly 10 times higher.

## **CLINICAL RELEVANCE/APPLICATION**

Radiologists involved in the consensus discussions in screening mammography should be made aware of their bias of overcalling non-AI-flagged exams and possibly undercalling AI-flagged exams. The consensus discussion may need to be re-designed for optimal use of AI reads.

### Supplemental Optoacoustic Imaging of Breast Masses: A Cost-Effectiveness Analysis

Thursday, Nov. 30 1:30PM - 2:30PM Room: E450B

Berat Bersu Ozcan, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Optoacoustic Ultrasound (OA/US) is a novel imaging method that utilizes tissue's intrinsic contrast to demonstrate real-time oxygenation and can be co-registered with gray-scale ultrasound (US). Prior prospective trials demonstrated that OA/US significantly improves diagnostic specificity with a slight decrease in sensitivity when used as a supplemental technique to US alone. In our study, we aimed to evaluate the cost-effectiveness of using OA/US versus US to differentiate benign and malignant breast masses in a diagnostic setting.

#### METHODS AND MATERIALS

We created a decision-tree model based on potential diagnostic results to compare the cost-effectiveness of OA/US and US from the perspective of the U.S. Healthcare system. We utilized diagnostic test performance parameters from the PIONEER-01 (NCT01943916) and the MAESTRO (NCT02364388) clinical trials and cost parameters (USD) from the Truven Health MarketScan® Databases. Utility (quality-adjusted life in years, QALY) assumptions were made following published patient-reported outcomes. Diagnostic outcomes were designed as true positive, true negative, false positive, and false negative to represent certain relations between health states and related costs. Cost effectiveness was calculated through incremental cost-effectiveness ratio (USD per QALY gain, ICER) and net monetary benefit (USD, NMB) calculations. One-way and two-way deterministic and probabilistic sensitivity analyses were performed to determine the significance of variation in input parameters. A willingness-to-pay (WTP) threshold of \$100,000 per QALY gain was used for the study. All analyses were performed using TreeAge Pro Healthcare 2022 (Williamstown, MA).

#### RESULTS

OA/US had a total cost of \$1,784.58 and 0.80 QALYs in the base case, whereas US had a total cost of \$2,018.84 and 0.79 QALYs. The incremental NMB for OA/US was \$1,452.86, and the ICER was -\$19,223.77 per QALY, indicating that OA/US was more cost-effective than US. Tornado analysis revealed the greatest sensitivity to variation in the disutility caused by biopsy and follow-up visits, followed by the cost of OA/US and US, respectively. The estimated variation in input parameters for the analyzed ranges did not produce an ICER higher than the \$100,000/QALY WTP threshold. According to probabilistic sensitivity analysis, OA/US was the better strategy in 100% of 10,000 iterations.

#### CONCLUSION

OA/US is more cost-effective than US for evaluating breast masses. It can reduce costs while improving patients' quality of life, primarily by reducing false-positive results with consequent benign biopsies.

### Different Downstream Outcomes After Consensus Discussion Related to Which Readers, AI or Radiologist, Flagged the Screening Mammography as Abnormal - In the Prospective Interventional ScreenTrustcad Trial

Thursday, Nov. 30 1:30PM - 2:30PM Room: E450B

Karin Dembrower, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

ScreenTrustCAD (NCT04778670) was the first prospective interventional study of AI in population-based breast cancer screening with a total of 55,581 women included. Based on a paired-reader design, it was found that in a double-reading and consensus workflow, AI plus one reader achieved superior cancer detection to two readers, without increasing recalls. The purpose of the current sub-study was to analyze differences in consensus recall decisions depending on whether AI or radiologists had initially flagged the exam as abnormal.

#### METHODS AND MATERIALS

The current study was performed within the ScreenTrustCAD trial, which employed an index test of paired reading between two human readers and Lunit INSIGHT MMG (AI). The three readers of each exam were blinded to the reads of others. An exam flagged by any reader was forwarded to the consensus discussion. In this sub-study, women who reported lumps at time of screening were excluded since AI did not consider that information. For each combination of readers who flagged the exam, we calculated the proportion of recalled women, cancers detected and positive predictive value (PPV).

#### RESULTS

There were 55,581 women included in the ScreenTrustCAD trial with 269 women diagnosed with breast cancer. After excluding women reporting a lump, there were 53,865 women overall, of whom 238 with breast cancer. In total, 5515 exams were flagged for consensus discussion, of which AI, reader 1 and reader 2 each flagged 3014 (55%), 2255 (41%) and 2424 (44%) respectively. 1358 (2.47%) women were recalled, of whom 238 (17.5%) were diagnosed with breast cancer and 1120 (82.5%) were not. Among 2501 consensus cases which had not been flagged by AI (but by one or two radiologists), the consensus discussion decided to recall 626 (25%) and for 21 (0.8%) cancer was detected, resulting in 3.4% PPV. Among 3014 consensus cases which had been flagged by AI (and zero to two radiologists), the consensus discussion decided to recall 732 (24%) and for 217 (7.2%) cancer was detected, resulting in 29% PPV. See Figure 1 for further breakdown of results.

#### CONCLUSION

For the exams that the radiologists in the consensus discussion decided to recall, the PPV for exams previously flagged by AI, compared to those only flagged by radiologists, was nearly 10 times higher.

#### CLINICAL RELEVANCE/APPLICATION

Radiologists involved in the consensus discussions in screening mammography should be made aware of their bias of overcalling non-AI-flagged exams and possibly undercalling AI-flagged exams. The consensus discussion may need to be re-designed for optimal use of AI reads.

### Cardiac Imaging (Advanced Imaging in Congenital and Inherited Diseases)

Thursday, Nov. 30 1:30PM - 2:30PM Room: N226

Hildo J. Lamb, MD, PhD (*Moderator*) Consultant, Koninklijke Philips NV  
Cristina Fuss, MD, PhD (*Moderator*) Nothing to Disclose

#### Sub-Events

#### **R6-SSCA11-1 Ventricular Interdependence in Repaired Tetralogy of Fallot Patients with Right Ventricular Heart Failure**

Li Jiang, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Individuals with repaired tetralogy of Fallot (rTOF) are still at high risk for worsening cardiac function, and understanding the underlying pathophysiological mechanism is important for exploring disease progression and management options. This study aims to investigate ventricular interdependence in rTOF patients prior to and following right ventricular (RV) heart failure.

#### METHODS AND MATERIALS

118 rTOF patients and 34 controls that underwent cardiac magnetic resonance (CMR) analyses were retrospectively analyzed, with rTOF patients being further subdivided into those with preserved RV function ( $n = 54$ ) and those that experienced RV heart failure ( $n = 64$ ). CMR-derived feature tracking techniques were used to assess RV, left ventricular (LV) and septal strain. Interventricular interdependence in different patient subgroups was analyzed through the use of correlation and multivariate backward linear regression models.

#### RESULTS

Progressive reductions in RV, LV and septal strain were evident from controls, through patients with preserved RV function, to patients with RV heart failure ( $P < 0.01$ ), but LV and septal longitudinal strain increased slightly in patients with preserved RV function relative to controls ( $P > 0.05$ ). Correlations between LV and RV strain were found to gradually change with RV function, and were the closest in rTOF patients with RV heart failure ( $r = |-0.270| - 0.506$ , all  $P < 0.05$ ). Correlations between RV volume and septal strain is nonlinear with different disease state. Subsequent multivariate analyses revealed the RV longitudinal strain is independently correlated with LV strain in three directions in rTOF patients with RV heart failure (Radial  $-0.70 [-1.33, -0.06]$ ,  $P = 0.032$ ; Circumferential  $0.44 [0.17, 0.72]$ ,  $P = 0.002$ , Longitudinal  $0.54 [0.26, 0.81]$ ,  $P < 0.001$ ).

#### CONCLUSION

Our study indicates the nonlinear effect of RV volume load on septal deformation with different disease state and RV functionality in rTOF patients, and emphasizes the effect of RV on LV deformation is greatest when RV function decreased significantly.

#### CLINICAL RELEVANCE/APPLICATION

This research preliminarily describes that RV-LV interdependencies varies and LV adaptation to RV dysfunction in rTOF patients, and non-invasively analyzes the interventricular physiological association, offering a valuable foundation for further studies exploring disease progression and the mechanisms underlying interventricular interaction in this patient population.

#### **R6-SSCA11-3 Assessment of Global Longitudinal Strain in the Human Fetus using Feature-Tracking MRI and Doppler Ultrasound Gating**

Bjoern Schoennagel, MD (*Presenter*) Co-founder, North Medical GmbH; Stockholder, North Medical GmbH

## PURPOSE

To evaluate the feasibility of Feature-Tracking MRI (FT-MRI) for the assessment of global longitudinal strain (GLS) of the left (LV) and right ventricle (RV) using cardiac Doppler ultrasound gating in human fetuses.

## METHODS AND MATERIALS

This retrospective study included 47 human fetuses (gestational age: 28+3 - 37+6 weeks) with or without congenital heart disease (CHD) who underwent fetal cardiac MRI at 3T. The local ethics committee approved the study and pregnant women gave written informed consent prior to MR examination. Fetal cardiac MRI was performed using Doppler ultrasound (SmartSync, northh medical, Germany) for gating of a cine balanced steady-state free-precession sequence (FOV 246 x 246 mm<sup>2</sup>, matrix size 164 x160, slices 12, slice thickness 5 mm, slice gap -1 mm, TR 4.1 ms, TE 2.0 ms, FA = 60°, echo train length 9, shot duration 36.7 ms). GLS of the LV and RV was derived from four-chamber views and determined by manual delineation of endo- and epicardial contours on end-diastolic images followed by automated propagation using dedicated feature-tracking software (Segment, Medviso, Sweden). GLS between healthy fetuses and fetuses with CHD were compared by Student's t-Test (level of significance = 0.05).

## RESULTS

GLS of 38/47 fetuses (81 %) was successfully analyzed. 21 fetuses had known CHD (e.g. Coarctation, Ebstein anomaly, Tetralogy of Fallot) and 17 were healthy. Nine fetuses were excluded due to reduced image quality or misregistration of myocardial wall motion by the feature-tracking software. One fetus had univentricular left heart, so determination of RV GLS was not possible in this case. Mean LV GLS of all 38 fetuses was -14.5 % (SD ± 6.7 %) and mean RV GLS was -11.9 % (SD ± 5.8). Fetuses with CHD revealed significantly reduced LV GLS (-11.7 % vs. -17.8 %,  $p < 0.004$ ) and RV GLS (-9.3 % vs. -15.2 %,  $p < 0.001$ ) when compared to healthy fetuses.

## CONCLUSION

Our study revealed significantly reduced LV and RV GLS values for fetuses with CHD compared to healthy fetuses. FT-MRI using Doppler ultrasound gating in the human fetus provides a new quantitative approach for evaluation of fetal cardiac function and may serve as a new tool to improve the understanding of fetal cardiac function.

## CLINICAL RELEVANCE/APPLICATION

FT-MRI using Doppler ultrasound gating warrants further quantitative investigation to assess fetal cardiac function.

## R6-SSCA11-5 Aortic Diameters in Marfan Syndrome: Intraindividual Comparison of Transthoracic Echocardiography (TTE) and 3D Modified Relaxation-Enhanced Angiography without Contrast and Triggering (REACT)

Carsten H. Gietzen, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To compare the measurement of aortic diameters using a novel flow-independent MR-Angiography (3D modified Relaxation-Enhanced Angiography without Contrast and Triggering (modified REACT)) and transthoracic echocardiography (TTE) in Marfan syndrome (MFS) patients.

## METHODS AND MATERIALS

This was a retrospective, single-center study that included 46 examinations of 32 MFS patients (mean age 37.5 ± 11.3 years, 17 women, no prior aortic surgery) who received TTE and REACT (ECG- and respiratory-triggering, Compressed SENSE 9, 1.5 T) of the thoracic aorta (January 2018 - April 2022). Aortic diameters (sinuses of Valsalva (SV), sinotubular junction (STJ), and ascending aorta (AoA)) were independently measured by two radiologists (inner-edge, using multiplanar reconstruction) in REACT and two cardiologists in TTE (leading-edge). Intraclass correlation coefficient (ICC), Pearson correlation coefficient (r), Bland-Altman analyses, and t-test were employed to assess agreement between imaging modalities and observers.

## RESULTS

The mean time between TTE and modified REACT was 28 ± 45 days. Modified REACT yielded an average total acquisition time of 05:06 min ± 02:47 min. Interobserver correlation at the SV, STJ, and AoA were excellent for REACT (ICC=0.98-0.99) and TTE (ICC=0.90-0.97). There was no significant difference between REACT and TTE for diameters determined at the SV (39.6 ± 3.8 mm vs. 39.2 ± 3.2 mm;  $r=0.78$ ,  $p=0.26$ ) and the STJ (35.3 ± 4.7 mm vs. 35.2 ± 4.5 mm;  $r=0.87$ ,  $p=0.552$ ). AoA diameters measured by REACT were smaller than in TTE (30.6 ± 5.3 mm vs. 34.3 ± 5.3 mm;  $r=0.74$ ,  $p<0.01$ ).

## CONCLUSION

There was a strong correlation between REACT and TTE at all levels of measurement. At the AoA, diameters were significantly larger using TTE. This difference is mostly due to different heights of measurements since AoA measurements were measured closer to the aortic valve in TTE due to the limited field of view whereas in REACT, measurement of the AoA is performed at the level of the bifurcation of the pulmonary trunk.

## CLINICAL RELEVANCE/APPLICATION

Given its fast acquisition time and strong agreement with TTE, modified REACT represents an attractive and fast technique to depict the thoracic aorta in Marfan syndrome patients. Patients who receive repetitive aortic imaging throughout their lives may benefit from this technique free of gadolinium contrast.

### **R6-SSCA11-6 Monitoring Marfan Syndrome and Related Disorders: Updated 2022 ACC/AHA Guideline Improves Concordance between TTE and CT but Relevant Measurements Differences Remain Frequent**

Nick Lasse Beetz, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Patients with Marfan syndrome and related syndromes require repetitive aortic imaging with TTE and CT being most widely used. Aortic measurements should provide high accuracy as in patients with progressive aortic enlargement of as little as > 2 mm surgical aortic repair is usually recommended. However, there is few scientific evidence as to which imaging modality should be performed in this young patient population. Recently, the 2022 ACC/AHA Guideline for the Diagnosis and Management of Aortic Disease was published. This study aims at comparing the updated imaging recommendations.

## METHODS AND MATERIALS

In this retrospective study we included 137 patients diagnosed with Marfan syndrome. All patients underwent TTE and ECG-triggered CT. Aortic diameter measurement at the aortic sinus and the ascending aorta were taken - first, according to the old 2010 ACC/AHA guideline (TTE: inner edge to inner edge, CT: external diameter), and second, according to the new 2022 ACC/AHA guideline (TTE: leading edge to leading edge, CT: internal diameter). Differences between the two methods for measuring aortic diameters were compared using Bland-Altman plots. The acceptable clinical limit of agreement for the difference between the two methods was predefined as < +/-2 millimeters.

## RESULTS

Using the updated 2022 ACC/AHA guideline the frequency of measurement differences outside the acceptable clinical agreement limit of difference was significantly reduced from 49% to 26% for the aortic sinus and from 41% to 29% for the ascending aorta. The systematic measurement error (bias) decreased from -0.3 mm for the aortic sinus and +1.1 mm for the ascending aorta using the new 2022 guideline, compared to a bias of -2.7 mm for the aortic sinus and +1.2 mm for the ascending aorta using the old 2010 guideline.

## CONCLUSION

For the first time this study shows that the updated imaging recommendations of the 2022 ACC/AHA can improve the concordance between ECG-triggered CT and TTE measurements in patients with Marfan syndrome who require accurate monitoring to prevent life-threatening aortic dissection and rupture. Unfortunately, the frequency of measurement differences between CT and TTE outside the acceptable clinical agreement limit of difference remains high.

## CLINICAL RELEVANCE/APPLICATION

Highly accurate measurement of aortic diameters in patients at risk for fatal aortic rupture and dissection is warranted. Although the updated 2022 guidelines shows improved concordance between the different imaging modalities, there is still a high frequency of measurement differences > 2 mm, which may lead to relevant clinical implications regarding aortic repair. Therefore, the risk of repetitive radiation exposure by the clinically accepted "gold-standard" ECG-triggered CT can be justified.

### **Aortic Diameters in Marfan Syndrome: Intraindividual Comparison of Transthoracic Echocardiography (TTE) and 3D Modified Relaxation-Enhanced Angiography without Contrast and Triggering (REACT)**

Thursday, Nov. 30 1:30PM - 2:30PM Room: N226

Carsten H. Gietzen, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To compare the measurement of aortic diameters using a novel flow-independent MR-Angiography (3D modified Relaxation-Enhanced Angiography without Contrast and Triggering (modified REACT)) and transthoracic echocardiography (TTE) in Marfan syndrome (MFS) patients.

#### **METHODS AND MATERIALS**

This was a retrospective, single-center study that included 46 examinations of 32 MFS patients (mean age  $37.5 \pm 11.3$  years, 17 women, no prior aortic surgery) who received TTE and REACT (ECG- and respiratory-triggering, Compressed SENSE 9, 1.5 T) of the thoracic aorta (January 2018 - April 2022). Aortic diameters (sinuses of Valsalva (SV), sinotubular junction (STJ), and ascending aorta (AoA)) were independently measured by two radiologists (inner-edge, using multiplanar reconstruction) in REACT and two cardiologists in TTE (leading-edge). Intraclass correlation coefficient (ICC), Pearson correlation coefficient (r), Bland-Altman analyses, and t-test were employed to assess agreement between imaging modalities and observers.

#### **RESULTS**

The mean time between TTE and modified REACT was  $28 \pm 45$  days. Modified REACT yielded an average total acquisition time of  $05:06 \text{ min} \pm 02:47 \text{ min}$ . Interobserver correlation at the SV, STJ, and AoA were excellent for REACT (ICC=0.98-0.99) and TTE (ICC=0.90-0.97). There was no significant difference between REACT and TTE for diameters determined at the SV ( $39.6 \pm 3.8 \text{ mm}$  vs.  $39.2 \pm 3.2 \text{ mm}$ ;  $r=0.78$ ,  $p=0.26$ ) and the STJ ( $35.3 \pm 4.7 \text{ mm}$  vs.  $35.2 \pm 4.5 \text{ mm}$ ;  $r=0.87$ ,  $p=0.552$ ). AoA diameters measured by REACT were smaller than in TTE ( $30.6 \pm 5.3 \text{ mm}$  vs.  $34.3 \pm 5.3 \text{ mm}$ ;  $r=0.74$ ,  $p<0.01$ ).

#### **CONCLUSION**

There was a strong correlation between REACT and TTE at all levels of measurement. At the AoA, diameters were significantly larger using TTE. This difference is mostly due to different heights of measurements since AoA measurements were measured closer to the aortic valve in TTE due to the limited field of view whereas in REACT, measurement of the AoA is performed at the level of the bifurcation of the pulmonary trunk.

#### **CLINICAL RELEVANCE/APPLICATION**

Given its fast acquisition time and strong agreement with TTE, modified REACT represents an attractive and fast technique to depict the thoracic aorta in Marfan syndrome patients. Patients who receive repetitive aortic imaging throughout their lives may benefit from this technique free of gadolinium contrast.

### **R6-SSGI19- Noninvasive Quantification of Hepatic Steatosis using Ultrasound-derived Fat Fraction with MRI-derived Proton Density Fat Fraction as the Reference Standard (CHESS 2303): A Multicenter Prospective Study**

Yi Dong, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To prospectively assess the role of ultrasound-derived fat fraction (UDFF) in the detection of hepatic steatosis using MRI-derived proton density fat fraction (PDFF) as the reference standard.

#### METHODS AND MATERIALS

Participants with or suspected of having nonalcoholic fatty liver disease (NAFLD) were prospectively recruited by an international multicenter between January 2023 to April 2023. All participants underwent UDFF and MRI-derived PDFF measurements on the same day. Demographic, clinical, and laboratory data were gathered. An MRI-derived PDFF cutoff of 5% was used for the definition of NAFLD. The correlation between UDFF (%) and MRI-derived PDFF (%) was calculated using the Pearson correlation coefficient. The area under the receiver operating characteristic curve (AUC) was calculated to assess the accuracy of UDFF in the diagnosis of hepatic steatosis.

#### RESULTS

A total of 113 participants were included: 46.0% (52/113) were male, mean age was 45 years  $\pm$  12 (SD); mean body mass index was 25.5 kg/m<sup>2</sup>  $\pm$  4.2 (SD); median alanine aminotransferase was 21.0 IU/L (IQR: 15.3, 34.8), median aspartate aminotransferase was 20.0 IU/L (IQR: 16.0, 27.0), median albumin was 4.6 md/dL (IQR: 4.3, 4.9), median total bilirubin was 1.1 md/dL (IQR: 0.8, 1.4), median prothrombin time international normalized ratio was 1.0 (IQR: 0.9, 1.0), and median platelet was 227.0  $\times$  10<sup>9</sup>/L (IQR: 188.0, 258.8). Overall, 34.5% (39/113) had type 2 diabetes mellitus, and 67.3% (76/113) had NAFLD (MRI-derived PDFF of 5% or more). The median UDFF was 9.2% (IQR: 4.8, 15.2). The Pearson correlation coefficient between UDFF and MRI-derived PDFF was good ( $r = 0.764$ ,  $P < 0.001$ ). Using MRI-derived PDFF as a reference, UDFF had good accuracy for the diagnosis of NAFLD (AUC was 0.865 [95% CI: 0.797, 0.932], with a sensitivity of 67.1%, and a specificity of 89.2%). The interobserver agreement of UDFF was excellent (ICC = 0.948,  $P < 0.001$ ). The intraobserver agreement of UDFF was excellent (ICC = 0.904-0.969,  $P < 0.001$ ).

#### CONCLUSION

The UDFF was useful for assessing hepatic steatosis when using MRI-derived PDFF as the reference standard.

#### CLINICAL RELEVANCE/APPLICATION

This multicenter prospective study highlights the practicality of ultrasound-derived fat fraction as a potential alternative tool for magnetic resonance imaging for detecting nonalcoholic fatty liver disease.

### **R6-SSGI19- Disease Progression and Tissue Inhomogeneity affect Fibrosis Staging Discordance between Hepatic MRE and Liver Biopsy in Nonalcoholic Fatty Liver Disease**

Yiyang Sheng (*Presenter*) Nothing to Disclose

## PURPOSE

In this study, our objective is to investigate the hypothesis that discrepancies between MR elastography (MRE) based fibrosis staging and biopsy staging may be linked to the heterogeneity of liver tissue that develops during chronic liver diseases (CLD) and is associated with other histopathological characteristics.

## METHODS AND MATERIALS

In this retrospective study, we analyzed 3D vector MRE exams from 175 individual patients with diagnosed nonalcoholic fatty liver disease (NAFLD) who underwent MRE and liver biopsy exams between Oct. 2015 and Oct. 2021 (227 total data sets). First, we determined the MRE diagnostic stage using the Youden Index, and calculated the discordance between MRE and biopsy-based fibrosis stages. Then, we performed feature extraction on pixel-wise liver stiffness (LS) measurements, including histogram-based distribution features and position-based shape features (129 total features). Next, we employed multivariate logistic regression with lasso regularization and correlation analysis to identify independent features contributing to the discordance in fibrosis staging. Finally, we examined the associations between inhomogeneity features and NAFLD progression, as assessed by MRI-assessed proton-density fat fraction (PDFF) and MRE-assessed mean LS.

## RESULTS

The top six features impacting the discordance in fibrosis staging, ordered from high to low normalized impact, were ballooning, PDFF, sex, maximum 2D diameter, gray-level run length matrix (GLRLM) run variance, and minimum LS. Using logistic regression that incorporated these six features, we were able to differentiate discordant cases with an overall accuracy of 0.83, based on a train-to-test ratio of 7:3. We observed that elevated ballooning grade, increased PDFF, male sex, and high minimum LS were associated with increased values of pixel-wise high-rank features metrics (maximum 2D diameter, GLRLM run variance). Steatosis and ballooning may be the primary drivers in more discordant cases, while pixel-wise high-rank features metrics might represent secondary factors related to these primary drivers.

## CONCLUSION

This study highlights that ballooning and steatosis (PDFF) are the two most significant factors leading to discordant readings between MRE and biopsy in fibrosis staging. The discordance may stem from subjective histologic staging influenced by steatosis and ballooning, or it could result from histogram and position-related inhomogeneity caused by these primary factors.

## CLINICAL RELEVANCE/APPLICATION

Findings highlight the importance of factors like PDFF, ballooning in NAFLD diagnosis monitoring. MRE is a reliable substitute of biopsy in cases with mild steatosis and ballooning, serving as a high-value screening tool.

## R6-SSGI19- Three-Dimensional MR Elastography Identifies Portal Hypertension in Cirrhosis: A Prospective Multicenter Study

Yu Shi, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To develop a non-invasive multivariate models based on Three-dimensional MR elastography (3D-MRE) to determine portal hypertension (PH), particularly to diagnose clinically significant portal hypertension (CSPH, HVPG>10mmHg) and severe portal hypertension (SPH, HVPG>12mmHg), using HVPG as the gold standard.

## METHODS AND MATERIALS

This prospective, multicenter study enrolled patients with cirrhosis scheduled for HVPG, and who intended to undergo MR imaging (including 3D-MRE and diffusion-, T1-, and T2-weighted imaging) before the HVPG procedure. A total of 57 patients were recruited from five institutions. Multiple viscoelastic parameters of the liver and spleen, as well as shear stiffness (SS) ratios and subtraction values, were evaluated independently by two radiologists. Univariable and multivariable linear regression analyses were conducted to assess the associations between mechanical parameters and HVPG. Univariable and multivariable logistic regression analyses were used to predict CSPH and SPH, respectively.

## RESULTS

HVPG showed the strongest positive correlation with splenic SS at 60Hz ( $r = 0.785$ ;  $P < .001$ ), followed by hepatic SS at 30Hz ( $r = 0.631$ ;  $P < .001$ ), splenic SS at 30Hz ( $r = 0.612$ ;  $P < .001$ ), hepatic SS at 60Hz ( $r = 0.547$ ;  $P < .001$ ). Multivariable linear regression analysis showed splenic SS at 60Hz ( $\beta = 1.017$ ; 95% CI: 0.71, 1.325;  $P < .001$ ), liver SS ratio ( $\beta = -2.359$ ; 95% CI: -4.477, -0.241;  $P = .03$ ), and liver stiffness difference ( $\beta = 1.169$ ; 95% CI: 0.251, 2.087;  $P = .001$ ) was the independent factors determining HVPG. Approximately 56.5% of the total variability in HVPG was explained by these 3 variables (adjusted  $R^2 = 0.565$ ). Logistic regression analysis showed splenic SS at 60Hz (OR = 2.217 [95% CI: 1.292, 3.803];  $P = 0.004$ ) and liver SS at 30Hz (OR = 6.211 [95% CI: 1.218, 31.669];  $P = 0.028$ ) were independently associated with CSPH, establishing a model with excellent performance in diagnosing CSPH (area under the receiver operating characteristic curve [AUC], 0.975 [95% CI: 0.79, 0.99]). As for SPH, it showed splenic SS at 60Hz (OR = 1.65 [95%

CI:1.25,2.16]; P = .001) were independently associated with HVPG, also with better performance (AUC, 0.969 [95% CI: 0.81, 0.98]).

## **CONCLUSION**

3D-MRE with dual frequencies is a very promising method in both predicting HVPG and diagnosing the presence CSPH and SPH. Splenic stiffness at 60Hz, combining liver stiffness ratio (60Hz/30Hz) and differences (60Hz-30Hz), was the independent parameters associating HVPG.

## **CLINICAL RELEVANCE/APPLICATION**

3D-MRE is a non-invasive, rapid, and highly accurate tool for predicting PH. This indicates that the use of 3D-MR elastography can provide more personalized evaluation and better medical experience for patients with cirrhosis.

## **R6-SSGI19- Practical Application of Multivendor MRI-based R2\* Mapping for Liver Iron Quantification at 1.5T and 3.0T**

Gregory Simchick, PhD (*Presenter*) Nothing to Disclose

## **PURPOSE**

To determine the practical applicability of MRI vendor-provided R2\* maps for liver iron concentration (LIC) quantification.

## **METHODS AND MATERIALS**

In this prospective study, participants with suspected iron overload were recruited at four academic medical centers. Each participant underwent MRI of the liver at 1.5T and 3.0T using clinical MRI systems from one of three vendors (GE Healthcare, Philips Healthcare, and Siemens Healthineers). At each field strength, 3D multiecho gradient echo data were acquired for R2\* mapping. A standardized 2D multiecho single spin-echo acquisition was performed at 1.5T to obtain reference LIC measurements using an FDA-approved LIC estimation algorithm (FerriScan, Resonance Health). Recent multicenter, multivendor R2\* versus LIC linear calibrations with wide dynamic LIC ranges have been published (i.e., MCMV calibrations). However, the MCMV calibrations were derived using a non-commercial, centralized R2\* reconstruction, and their applicability with vendor-provided R2\* maps remains unknown. R2\* ranges of agreement comparing the centralized and vendor reconstructions were determined by evaluating coefficient of variation as a function of vendor R2\* range. Within the determined R2\* ranges of agreement, R2\*-LIC linear calibrations were derived for each site, field strength, and reconstruction. Calibrations were compared using F tests and multiple comparison testing.

## **RESULTS**

207 participants (mean age  $37.6 \pm 19.6$  [SD] years; 117 male and 90 female) were recruited. R2\* ranges of agreement were determined with upper limits of approximately 500, 375, and 330 s<sup>-1</sup> (corresponding to LICs of approximately 12.9, 9.6, and 8.4 mg/g [Fe/dry tissue]) for the GE, Philips, and Siemens reconstructions, respectively, at 1.5T and approximately 700 and 800 s<sup>-1</sup> (corresponding to LICs of approximately 9.4 and 10.8 mg/g) for GE and Philips, respectively, at 3.0T. Within the R2\* ranges of agreement, no significant differences were observed in the R2\*-LIC calibrations when comparing across all sites and reconstructions ( $p = 0.06$ ) or when comparing the calibrations pairwise ( $p = 0.24$ ). Joint (including all sites) vendor R2\*-LIC calibrations ( $LIC = 0.0256 R2^* - 0.02$  mg/g and  $LIC = 0.0137 R2^* + 0.06$  mg/g at 1.5T and 3.0T, respectively) agreed with the MCMV calibrations.

## **CONCLUSION**

R2\* measurements obtained from vendor-provided R2\* maps can be reliably and practically used with the published MCMV calibrations to quantify LIC less than approximately 8.4-12.9 mg/g [Fe/dry tissue].

## **CLINICAL RELEVANCE/APPLICATION**

This work may facilitate widespread clinical dissemination of R2\*-based LIC quantification over a range of LIC values that cover the optimal range for chelation therapy, thereby reducing the need to perform liver biopsy.

## **R6-SSGI19- Identification of Super-high-risk Group for Developing Hepatocellular Carcinoma in Ultrasound Surveillance**

Yeun-Yoon Kim, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

To develop and validate a model to predict super-high-risk group of incident hepatocellular carcinoma (HCC) in patients with chronic hepatitis B or C under ultrasound (US) surveillance who are potentially eligible for surveillance with alternative imaging modality.

## **METHODS AND MATERIALS**

This retrospective study included 17,557 treatment-naïve patients with chronic hepatitis B or C from three institutions who underwent US surveillance for HCC between 2005 and 2015. All patients were in Child-Pugh class A, and aged 40 to 75 years.

For model establishment, 11,311 patients from one institution were identified, and randomly assigned to development (n = 7,918) or internal validation (n = 3,393) datasets. In the development dataset, clinical characteristics and US features (presence of cirrhosis, fatty liver, splenomegaly, ascites and cirrhotic nodules) were recorded based on the review of electronic medical chart. Significant factors were identified by multivariable Cox regression analysis, and the prediction model was established. The model performance was compared to existing HCC development risk models in validation dataset (n = 3,393) and test dataset from two other institutions (n = 6,246).

## **RESULTS**

The 5-year cumulative incidence rates of HCC were 7.6%, 7.4% and 4.3% in the development, validation, and external test datasets, respectively. Multivariable Cox regression revealed that age, sex, diabetes mellitus, serum albumin and alanine aminotransferase levels, platelet counts, cirrhotic parenchymal echotexture on US, and multiple cirrhotic nodules on US were independently associated with HCC risk. Using a cut-off for annual HCC incidence rate of 2.5% or higher, the 5-year cumulative HCC incidence rates in the validation and external test datasets were 24.1% and 15.5%, respectively. The Uno concordance index was significantly higher than those of aMAP, THRI, ADDRESS-HCC, Velazquez score index, and modified PAGE-B in the validation dataset (0.747 vs. 0.686, 0.662, 0.584, 0.582, and 0.668, respectively; all P <0.001) and external test dataset (0.791 vs. 0.740, 0.668, 0.658, 0.650, and 0.740, respectively; all P <0.001).

## **CONCLUSION**

Our model integrating clinical and surveillance US features was useful to discriminate the super-high-risk group for HCC in chronic hepatitis B or C, and showed superior performance than previously reported risk scoring systems. Alternative surveillance imaging modality may be considered in the super-high-risk group to facilitate early detection of HCC.

## **CLINICAL RELEVANCE/APPLICATION**

Given that the use of alternative imaging modality is limited in HCC surveillance, our prediction model would help focus on super-high-risk group for developing HCC, and potentially individualize surveillance imaging modality.

### Noninvasive Quantification of Hepatic Steatosis using Ultrasound-derived Fat Fraction with MRI-derived Proton Density Fat Fraction as the Reference Standard (CHESS 2303): A Multicenter Prospective Study

Thursday, Nov. 30 1:30PM - 2:30PM Room: E352

Yi Dong, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To prospectively assess the role of ultrasound-derived fat fraction (UDFF) in the detection of hepatic steatosis using MRI-derived proton density fat fraction (PDFF) as the reference standard.

#### METHODS AND MATERIALS

Participants with or suspected of having nonalcoholic fatty liver disease (NAFLD) were prospectively recruited by an international multicenter between January 2023 to April 2023. All participants underwent UDFF and MRI-derived PDFF measurements on the same day. Demographic, clinical, and laboratory data were gathered. An MRI-derived PDFF cutoff of 5 % was used for the definition of NAFLD. The correlation between UDFF (%) and MRI-derived PDFF (%) was calculated using the Pearson correlation coefficient. The area under the receiver operating characteristic curve (AUC) was calculated to assess the accuracy of UDFF in the diagnosis of hepatic steatosis.

#### RESULTS

A total of 113 participants were included: 46.0 % (52/113) were male, mean age was 45 years  $\pm$  12 (SD); mean body mass index was 25.5 kg/m<sup>2</sup>  $\pm$  4.2 (SD); median alanine aminotransferase was 21.0 IU/L (IQR: 15.3, 34.8), median aspartate aminotransferase was 20.0 IU/L (IQR: 16.0, 27.0), median albumin was 4.6 md/dL (IQR: 4.3, 4.9), median total bilirubin was 1.1 md/dL (IQR: 0.8, 1.4), median prothrombin time international normalized ratio was 1.0 (IQR: 0.9, 1.0), and median platelet was 227.0 $\times$ 10<sup>9</sup>/L (IQR: 188.0, 258.8). Overall, 34.5 % (39/113) had type 2 diabetes mellitus, and 67.3 % (76/113) had NAFLD (MRI-derived PDFF of 5% or more). The median UDFF was 9.2 % (IQR: 4.8, 15.2). The Pearson correlation coefficient between UDFF and MRI-derived PDFF was good ( $r = 0.764$ ,  $P < 0.001$ ). Using MRI-derived PDFF as a reference, UDFF had good accuracy for the diagnosis of NAFLD (AUC was 0.865 [95 % CI: 0.797, 0.932], with a sensitivity of 67.1 %, and a specificity of 89.2 %). The interobserver agreement of UDFF was excellent (ICC = 0.948,  $P < 0.001$ ). The intraobserver agreement of UDFF was excellent (ICC = 0.904-0.969,  $P < 0.001$ ).

#### CONCLUSION

The UDFF was useful for assessing hepatic steatosis when using MRI-derived PDFF as the reference standard.

#### CLINICAL RELEVANCE/APPLICATION

This multicenter prospective study highlights the practicality of ultrasound-derived fat fraction as a potential alternative tool for magnetic resonance imaging for detecting nonalcoholic fatty liver disease.

### **Disease Progression and Tissue Inhomogeneity affect Fibrosis Staging Discordance between Hepatic MRE and Liver Biopsy in Nonalcoholic Fatty Liver Disease**

Thursday, Nov. 30 1:30PM - 2:30PM Room: E352

Yiyang Sheng (*Presenter*) Nothing to Disclose

#### **PURPOSE**

In this study, our objective is to investigate the hypothesis that discrepancies between MR elastography (MRE) based fibrosis staging and biopsy staging may be linked to the heterogeneity of liver tissue that develops during chronic liver diseases (CLD) and is associated with other histopathological characteristics.

#### **METHODS AND MATERIALS**

In this retrospective study, we analyzed 3D vector MRE exams from 175 individual patients with diagnosed nonalcoholic fatty liver disease (NAFLD) who underwent MRE and liver biopsy exams between Oct.2015 and Oct. 2021 (227 total data sets). First, we determined the MRE diagnostic stage using the Youden Index, and calculated the discordance between MRE and biopsy-based fibrosis stages. Then, we performed feature extraction on pixel-wise liver stiffness (LS) measurements, including histogram-based distribution features and position-based shape features(129 total features).. Next, we employed multivariate logistic regression with lasso regularization and correlation analysis to identify independent features contributing to the discordance in fibrosis staging. Finally, we examined the associations between inhomogeneity features and NAFLD progression, as assessed by MRI-assessed proton-density fat fraction (PDFF) and MRE-assessed mean LS.

#### **RESULTS**

The top six features impacting the discordance in fibrosis staging, ordered from high to low normalized impact, were ballooning, PDFF, sex, maximum 2D diameter, gray-level run length matrix (GLRLM) run variance, and minimum LS. Using logistic regression that incorporated these six features, we were able to differentiate discordant cases with an overall accuracy of 0.83, based on a train-to-test ratio of 7:3. We observed that elevated ballooning grade, increased PDFF, male sex, and high minimum LS were associated with increased values of pixel-wise high-rank features metrics (maximum 2D diameter, GLRLM run variance). Steatosis and ballooning may be the primary drivers in more discordant cases, while pixel-wise high-rank features metrics might represent secondary factors related to these primary drivers.

#### **CONCLUSION**

This study highlights that ballooning and steatosis (PDFF) are the two most significant factors leading to discordant readings between MRE and biopsy in fibrosis staging. The discordance may stem from subjective histologic staging influenced by steatosis and ballooning, or it could result from histogram and position-related inhomogeneity caused by these primary factors.

#### **CLINICAL RELEVANCE/APPLICATION**

Findings highlight the importance of factors like PDFF, ballooning in NAFLD diagnosis monitoring. MRE is a reliable substitute of biopsy in cases with mild steatosis and ballooning, serving as a high-value screening tool.

### Three-Dimensional MR Elastography Identifies Portal Hypertension in Cirrhosis: A Prospective Multicenter Study

Thursday, Nov. 30 1:30PM - 2:30PM Room: E352

Yu Shi, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop a non-invasive multivariate models based on Three-dimensional MR elastography (3D-MRE) to determine portal hypertension (PH), particularly to diagnose clinically significant portal hypertension (CSPH, HVPG>10mmHg) and severe portal hypertension (SPH, HVPG>12mmHg), using HVPG as the gold standard.

#### METHODS AND MATERIALS

This prospective, multicenter study enrolled patients with cirrhosis scheduled for HVPG, and who intended to undergo MR imaging (including 3D-MRE and diffusion-, T1-, and T2-weighted imaging) before the HVPG procedure. A total of 57 patients were recruited from five institutions. Multiple viscoelastic parameters of the liver and spleen, as well as shear stiffness (SS) ratios and subtraction values, were evaluated independently by two radiologists. Univariable and multivariable linear regression analyses were conducted to assess the associations between mechanical parameters and HVPG. Univariable and multivariable logistic regression analyses were used to predict CSPH and SPH, respectively.

#### RESULTS

HVPG showed the strongest positive correlation with splenic SS at 60Hz ( $r = 0.785$ ;  $P < .001$ ), followed by hepatic SS at 30Hz ( $r = 0.631$ ;  $P < .001$ ), splenic SS at 30Hz ( $r = 0.612$ ;  $P < .001$ ), hepatic SS at 60Hz ( $r = 0.547$ ;  $P < .001$ ). Multivariable linear regression analysis showed splenic SS at 60Hz ( $\beta = 1.017$ ; 95% CI: 0.71, 1.325;  $P < .001$ ), liver SS ratio ( $\beta = -2.359$ ; 95% CI: -4.477, -0.241;  $P = .03$ ), and liver stiffness difference ( $\beta = 1.169$ ; 95% CI: 0.251, 2.087;  $P = .001$ ) was the independent factors determining HVPG. Approximately 56.5% of the total variability in HVPG was explained by these 3 variables (adjusted  $R^2 = 0.565$ ). Logistic regression analysis showed splenic SS at 60Hz (OR = 2.217 [95% CI: 1.292, 3.803];  $P = 0.004$ ) and liver SS at 30Hz (OR = 6.211 [95% CI: 1.218, 31.669];  $P = 0.028$ ) were independently associated with CSPH, establishing a model with excellent performance in diagnosing CSPH (area under the receiver operating characteristic curve [AUC], 0.975 [95% CI: 0.79, 0.99]). As for SPH, it showed splenic SS at 60Hz (OR = 1.65 [95% CI: 1.25, 2.16];  $P = .001$ ) were independently associated with HVPG, also with better performance (AUC, 0.969 [95% CI: 0.81, 0.98]).

#### CONCLUSION

3D-MRE with dual frequencies is a very promising method in both predicting HVPG and diagnosing the presence CSPH and SPH. Splenic stiffness at 60Hz, combining liver stiffness ratio (60Hz/30Hz) and differences (60Hz-30Hz), was the independent parameters associating HVPG.

#### CLINICAL RELEVANCE/APPLICATION

3D-MRE is a non-invasive, rapid, and highly accurate tool for predicting PH. This indicates that the use of 3D-MR elastography can provide more personalized evaluation and better medical experience for patients with cirrhosis.

### Practical Application of Multivendor MRI-based R2\* Mapping for Liver Iron Quantification at 1.5T and 3.0T

Thursday, Nov. 30 1:30PM - 2:30PM Room: E352

Gregory Simchick, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To determine the practical applicability of MRI vendor-provided R2\* maps for liver iron concentration (LIC) quantification.

#### METHODS AND MATERIALS

In this prospective study, participants with suspected iron overload were recruited at four academic medical centers. Each participant underwent MRI of the liver at 1.5T and 3.0T using clinical MRI systems from one of three vendors (GE Healthcare, Philips Healthcare, and Siemens Healthineers). At each field strength, 3D multiecho gradient echo data were acquired for R2\* mapping. A standardized 2D multiecho single spin-echo acquisition was performed at 1.5T to obtain reference LIC measurements using an FDA-approved LIC estimation algorithm (FerriScan, Resonance Health). Recent multicenter, multivendor R2\* versus LIC linear calibrations with wide dynamic LIC ranges have been published (i.e., MCMV calibrations). However, the MCMV calibrations were derived using a non-commercial, centralized R2\* reconstruction, and their applicability with vendor-provided R2\* maps remains unknown. R2\* ranges of agreement comparing the centralized and vendor reconstructions were determined by evaluating coefficient of variation as a function of vendor R2\* range. Within the determined R2\* ranges of agreement, R2\*-LIC linear calibrations were derived for each site, field strength, and reconstruction. Calibrations were compared using F tests and multiple comparison testing.

#### RESULTS

207 participants (mean age  $37.6 \pm 19.6$  [SD] years; 117 male and 90 female) were recruited. R2\* ranges of agreement were determined with upper limits of approximately 500, 375, and 330 s<sup>-1</sup> (corresponding to LICs of approximately 12.9, 9.6, and 8.4 mg/g [Fe/dry tissue]) for the GE, Philips, and Siemens reconstructions, respectively, at 1.5T and approximately 700 and 800 s<sup>-1</sup> (corresponding to LICs of approximately 9.4 and 10.8 mg/g) for GE and Philips, respectively, at 3.0T. Within the R2\* ranges of agreement, no significant differences were observed in the R2\*-LIC calibrations when comparing across all sites and reconstructions ( $p = 0.06$ ) or when comparing the calibrations pairwise ( $p = 0.24$ ). Joint (including all sites) vendor R2\*-LIC calibrations ( $LIC = 0.0256 R2^* - 0.02$  mg/g and  $LIC = 0.0137 R2^* + 0.06$  mg/g at 1.5T and 3.0T, respectively) agreed with the MCMV calibrations.

#### CONCLUSION

R2\* measurements obtained from vendor-provided R2\* maps can be reliably and practically used with the published MCMV calibrations to quantify LIC less than approximately 8.4-12.9 mg/g [Fe/dry tissue].

#### CLINICAL RELEVANCE/APPLICATION

This work may facilitate widespread clinical dissemination of R2\*-based LIC quantification over a range of LIC values that cover the optimal range for chelation therapy, thereby reducing the need to perform liver biopsy.

### Identification of Super-high-risk Group for Developing Hepatocellular Carcinoma in Ultrasound Surveillance

Thursday, Nov. 30 1:30PM - 2:30PM Room: E352

Yeun-Yoon Kim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop and validate a model to predict super-high-risk group of incident hepatocellular carcinoma (HCC) in patients with chronic hepatitis B or C under ultrasound (US) surveillance who are potentially eligible for surveillance with alternative imaging modality.

#### METHODS AND MATERIALS

This retrospective study included 17,557 treatment-naïve patients with chronic hepatitis B or C from three institutions who underwent US surveillance for HCC between 2005 and 2015. All patients were in Child-Pugh class A, and aged 40 to 75 years. For model establishment, 11,311 patients from one institution were identified, and randomly assigned to development (n = 7,918) or internal validation (n = 3,393) datasets. In the development dataset, clinical characteristics and US features (presence of cirrhosis, fatty liver, splenomegaly, ascites and cirrhotic nodules) were recorded based on the review of electronic medical chart. Significant factors were identified by multivariable Cox regression analysis, and the prediction model was established. The model performance was compared to existing HCC development risk models in validation dataset (n = 3,393) and test dataset from two other institutions (n = 6,246).

#### RESULTS

The 5-year cumulative incidence rates of HCC were 7.6%, 7.4% and 4.3% in the development, validation, and external test datasets, respectively. Multivariable Cox regression revealed that age, sex, diabetes mellitus, serum albumin and alanine aminotransferase levels, platelet counts, cirrhotic parenchymal echotexture on US, and multiple cirrhotic nodules on US were independently associated with HCC risk. Using a cut-off for annual HCC incidence rate of 2.5% or higher, the 5-year cumulative HCC incidence rates in the validation and external test datasets were 24.1% and 15.5%, respectively. The Uno concordance index was significantly higher than those of aMAP, THRI, ADDRESS-HCC, Velazquez score index, and modified PAGE-B in the validation dataset (0.747 vs. 0.686, 0.662, 0.584, 0.582, and 0.668, respectively; all P <0.001) and external test dataset (0.791 vs. 0.740, 0.668, 0.658, 0.650, and 0.740, respectively; all P <0.001).

#### CONCLUSION

Our model integrating clinical and surveillance US features was useful to discriminate the super-high-risk group for HCC in chronic hepatitis B or C, and showed superior performance than previously reported risk scoring systems. Alternative surveillance imaging modality may be considered in the super-high-risk group to facilitate early detection of HCC.

#### CLINICAL RELEVANCE/APPLICATION

Given that the use of alternative imaging modality is limited in HCC surveillance, our prediction model would help focus on super-high-risk group for developing HCC, and potentially individualize surveillance imaging modality.

### **R6-SSGI20- Income, Racial/Ethnic, and Urbanicity Differences for Screening CT Colonography Use 1 Among Medicare Beneficiaries**

Eric W. Christensen, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Colorectal cancer (CRC) screening is associated with reduced mortality, yet almost one-third of the U.S. population is not current with CRC screening guidelines. These guidelines include various screening strategies, with multiple options being provided to increase the adherence to these guidelines. Of these screening strategies, the Centers for Medicare and Medicaid Services provides reimbursement for all except CT colonography (CTC). Given these reimbursement differences, the purpose is to examine the association of income, racial/ethnic, and urbanicity differences in the use of CTC relative to other CRC screening strategies.

#### METHODS AND MATERIALS

This was a multiyear (January 2011 to December 2020) retrospective study of individuals aged 45-85 years with Medicare fee-for-service insurance. Data were obtained using a 5% research identifiable sample of all Medicare fee-for-service beneficiaries. Income, racial/ethnic, and urbanicity differences for screening CTC use were assessed with multivariable logistic regression and adjusted for sex, age, race/ethnicity, Charlson comorbidity index, year, and related conditions. Like logistic regressions models were estimated for other CRC screening strategies.

#### RESULTS

Between 2011 and 2020, there were 10,027,439 beneficiary years (mean age, 69.8 +/- 8.2 [SD]). The odds ratio (OR) of beneficiaries residing in communities with a per capita income of \$100,000 or more having a screening CTC was 6.06 (95%CI: 3.96, 9.27) compared with those residing in communities with a per capita income of less than \$25,000. The like odds for other CRC screening strategies were 1.35 (95%CI: 1.30, 1.39) for optical colonoscopy, 1.01 (95%CI: 0.67, 1.54) for sigmoidoscopy, 1.44 (95%CI: 1.42, 1.46) for guaiac fecal-occult blood test/fecal immunochemical test, and 1.32 (95%CI: 1.26, 1.37) for stool DNA..

#### CONCLUSION

While higher income was associated with higher odds for most screening strategies, the positive income effect was many orders of magnitude larger for screening CTC. The lack of reimbursement for screening CTC may be associated with income-based access differences.

#### CLINICAL RELEVANCE/APPLICATION

Among the CRC screening strategies, optical colonoscopy offers higher detection sensitivity and allows for lesion biopsy or resection, but it is the most invasive, which for some individuals, may hinder compliance with the CRC screening guidelines. Hence, while optical colonoscopy is the gold standard, if some individuals are reluctant to undergo it due to its invasiveness, the need for anesthesia, or risk of complications, reimbursement for CTC may be beneficial if it increases compliance with screening guidelines.

### Income, Racial/Ethnic, and Urbanicity Differences for Screening CT Colonography Use Among Medicare Beneficiaries

Thursday, Nov. 30 1:30PM - 2:30PM Room: E351

Eric W. Christensen, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Colorectal cancer (CRC) screening is associated with reduced mortality, yet almost one-third of the U.S. population is not current with CRC screening guidelines. These guidelines include various screening strategies, with multiple options being provided to increase the adherence to these guidelines. Of these screening strategies, the Centers for Medicare and Medicaid Services provides reimbursement for all except CT colonography (CTC). Given these reimbursement differences, the purpose is to examine the association of income, racial/ethnic, and urbanicity differences in the use of CTC relative to other CRC screening strategies.

#### METHODS AND MATERIALS

This was a multiyear (January 2011 to December 2020) retrospective study of individuals aged 45-85 years with Medicare fee-for-service insurance. Data were obtained using a 5% research identifiable sample of all Medicare fee-for-service beneficiaries. Income, racial/ethnic, and urbanicity differences for screening CTC use were assessed with multivariable logistic regression and adjusted for sex, age, race/ethnicity, Charlson comorbidity index, year, and related conditions. Like logistic regressions models were estimated for other CRC screening strategies.

#### RESULTS

Between 2011 and 2020, there were 10,027,439 beneficiary years (mean age, 69.8 +/- 8.2 [SD]). The odds ratio (OR) of beneficiaries residing in communities with a per capita income of \$100,000 or more having a screening CTC was 6.06 (95%CI: 3.96, 9.27) compared with those residing in communities with a per capita income of less than \$25,000. The like odds for other CRC screening strategies were 1.35 (95%CI: 1.30, 1.39) for optical colonoscopy, 1.01 (95%CI: 0.67, 1.54) for sigmoidoscopy, 1.44 (95%CI: 1.42, 1.46) for guaiac fecal-occult blood test/fecal immunochemical test, and 1.32 (95%CI: 1.26, 1.37) for stool DNA..

#### CONCLUSION

While higher income was associated with higher odds for most screening strategies, the positive income effect was many orders of magnitude larger for screening CTC. The lack of reimbursement for screening CTC may be associated with income-based access differences.

#### CLINICAL RELEVANCE/APPLICATION

Among the CRC screening strategies, optical colonoscopy offers higher detection sensitivity and allows for lesion biopsy or resection, but it is the most invasive, which for some individuals, may hinder compliance with the CRC screening guidelines. Hence, while optical colonoscopy is the gold standard, if some individuals are reluctant to undergo it due to its invasiveness, the need for anesthesia, or risk of complications, reimbursement for CTC may be beneficial if it increases compliance with screening guidelines.

#### Sub-Events

#### R6-SSGU07-1 **Spatial Characterization of Multiparametric MRI Performance using a Standardized Prostate Segmentation Model**

Sohaib Naim, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

We aim to evaluate the performance of multiparametric MRI (mpMRI) to accurately detect clinically significant prostate cancer (csPCa) lesions through spatial characterization across different regions within the prostate gland.

#### METHODS AND MATERIALS

Our HIPAA-compliant, IRB-approved study group consisted of 1,143 consecutive men at our single institution that underwent mpMRI prior to radical prostatectomy between 2010 and 2022. Genitourinary (GU) radiologists and GU pathologists performed matching workflows with the prostate sector map model to identify true positive (TP), false negative (FN), and false positive (FP) lesions for all subjects. All TP, FN, and FP lesions were used to illustrate cancer prevalence (CP), detection rate (DR), and positive predictive values (PPV), each of which was sorted within a standardized prostate segmentation model, the prostate sector map. Using a weighted chi-square test we correlated statistical differences for DR and PPV for sectors established within the transition zone (TZ) vs. peripheral zone (PZ), anterior vs. posterior, base-gland (Base) vs. mid-gland (Mid) vs. apex-gland (Apex), and left vs. right prostate.

#### RESULTS

Our findings are presented across different sector regions for both DR and PPV. From our 1,143 subject cohort, we identified 2,152 PCa lesions, of which 1060 were csPCa lesions. We analyzed differences by stratifying laterality, anterior vs. posterior, and Base, Mid, and Apex levels within TZ and PZ. Our statistical findings show a significantly lower DR for the anterior vs. posterior regions (67.3% vs. 75.6%;  $p < 0.001$ ) for PZ sectors as well as right vs. left hemispheres (69.4% vs. 75.7%;  $p < 0.05$ ) for TZ sectors. We also identify a significantly lower DR in the Apex region vs. Base and Mid regions (71.5%;  $p < 0.01$ ). For our statistical findings with lower PPV values, we observe a significantly lower PPV for TZ vs. PZ sectors (75.8% vs. 82.4%;  $p < 0.001$ ) and the Base region vs. Mid and Apex regions (77.1%;  $p < 0.01$ ) for PZ sectors. These findings inform us how underdiagnosis occurs for lesions within anterior and Apex regions for PZ sectors, and often overdiagnoses occur for lesions which classify under PZ sectors in the Base region.

#### CONCLUSION

From 1,143 subjects, we identified significantly lower DRs for lesions in the anterior and apex regions of the prostate within PZ, along with significantly lower PPVs in the base prostate region and TZ compared to PZ. These findings, indicate that further attention to these locations would better resolve these shortcomings and benefit PCa diagnosis.

#### CLINICAL RELEVANCE/APPLICATION

Spatial-based mpMRI performance in detecting lesions can improve the identification of prostate cancer and reduce the need for biopsies in at-risk men.

#### R6-SSGU07-2 **Equivalence of nnU-Net Based and Manual T-index for Assessing Surgical Difficulty in Patients with Small Renal Mass**

Dongkyu An, MD (*Presenter*) Nothing to Disclose

## PURPOSE

We proposed a novel nephrometry index called T-index for small renal mass based on three-dimensional topology, which represents the degree of intraparenchymal extension and peripherality of the renal cell carcinoma (RCC). Despite the usefulness of the novel nephrometry index predicting the difficulty of the partial nephrectomy (PNx), some opinions suggested that it might be difficult to apply clinically due to the time-consuming manual segmentation process of extracting the values. To overcome this limitation, we aimed to demonstrate the equivalent performance of the automatically extracted T-index based on nnU-Net, a deep-learning based segmentation program, compared to the manually extracted one.

## METHODS AND MATERIALS

This retrospective, single-center study included 215 patients who underwent PNx for clear cell RCC (less than 5cm) between September 2007 and December 2019. Then, 125 cases were sorted as a training set for nnU-Net to label the kidney, tumor and renal sinus. The rest of 90 cases were sorted as a test set for the automatic segmentation. T-index was calculated by adding up the reciprocals of the distances from all points on the tumor-parenchyma and tumor-sinus (if tumor invades renal sinus) interface to renal sinus. The intraclass correlation coefficient between manually (mT-index) and automatically extracted T-index (auT-index) was measured. Spearman's correlation and logistic regression were used to analyze the efficacy of T-index.

## RESULTS

The mean±SD of mT-index and auT-index for the 90 patients in the test set was 117.30±101.24 and 105.23±95.71 (1/mm), respectively. T-index showed an excellent intraclass correlation coefficient (0.970, 95% confidence interval 0.928-0.985) regardless of its extracting methods. Also, T-index showed a significant correlation with perioperative factors reflecting surgical difficulty, regardless of the extracting methods: immediate postoperative creatinine difference (mT-index  $r=0.343$ ;  $p=0.001$ , auT-index  $r=0.331$ ;  $p=0.0015$ ) and warm ischemia time (mT-index  $r=0.615$ ;  $p<0.001$ , auT-index  $r=0.624$ ;  $p<0.001$ ). In the entire patient population, the T-index significantly predicted the immediate post-operative complications compared to preexisting nephrometry indices, and these results were consistent with our previous study.

## CONCLUSION

auT-index extracted from the nnU-Net based segmentation showed an excellent correlation and equivalent performance of predicting surgical difficulty and post-operative complications in PNx compared to the manually extracted one.

## CLINICAL RELEVANCE/APPLICATION

Using an automatically extracted T-index could be a reliable method for preoperative prediction of prognosis in PNx without requiring labor-intensive manual processes by experts.

## R6-SSGU07-4 Deep Learning based on ResNet-18 for Intelligent Classification of PI-RADS 3 Lesions

Liang Wang (*Presenter*) Nothing to Disclose

## PURPOSE

To explore the intelligent classification and prediction efficacy of deep learning model for benign prostate lesions, non-clinically significant prostate cancer (non-csPCa) and clinically significant prostate cancer (csPCa) in PI-RADS 3 lesions.

## METHODS AND MATERIALS

From January 2015 to December 2021, lesions diagnosed with PI-RADS 3 by multi-parametric MRI or bi-parametric MRI were retrospectively included. They were classified as benign, non-csPCa, and csPCa according to the pathologic results of biopsy, transurethral resection or radical prostatectomy specimens. T2WI images of the lesions were saved in JPEG format and were divided into a training set and a test set according to 8:2. The preprocessing of the training set included scaling, clipping, image enhancement, tensor conversion and normalization. The preprocessing of the test set included scaling, clipping, tensor conversion and normalization. ResNet-18 architecture was used for model training, and all layers were trained. The GPU used was Tesla T4 and the computing device architecture version was v11.2. All statistical analyses were performed using Python open-source libraries such as numpy, pandas, matplotlib, seaborn, plotly requests, tqdm, opencv-python, pillow, wandb, etc. The trained model was saved as pth file and evaluated in the test set. The receiver operating curve was used to evaluate the predictive effectiveness of the model. t-NSE was used for image semantic feature visualization. The class activation mapping was used to visualize the area focused by the model.

## RESULTS

A total of 428 benign prostate lesion images, 158 non-csPCa images and 273 csPCa images were included. 685 images were used for training and 169 images for testing. The best accuracy of the model in test set was 0.787. The precision in predicting benign prostate disease, non-csPCa and csPCa were 0.882, 0.681 and 0.851, and the area under ROC curve were 0.875, 0.89 and 0.929, respectively. Semantic feature analysis shows strong classification separability between csPCa and benign diseases. The class activation map shows that the deep learning model can focus on the area of the prostate or the location of PI-RADS 3 lesions.

## CONCLUSION

Deep learning model based on ResNet-18 architecture can realize intelligent classification of PI-RADS 3 lesions.

## CLINICAL RELEVANCE/APPLICATION

Deep learning based on ResNet-18 network provides a new method and basis for accurately classifying ambiguous PI-RADS 3 lesions and is helpful for formulating management strategies for PI-RADS 3 lesions.

### R6-SSGU07-5 **Using 3D Swin UnetR Architecture and 3D Hinge Forest Architecture for Automatically Segmenting all Subtypes of Renal Cell Masses, Kidney, and Cysts on MRI**

Pouria Yazdian, MD (*Presenter*) Nothing to Disclose

## PURPOSE

This study explores the potential of convolutional neural networks (CNN) for automating renal cell carcinoma (RCC) mass, cyst, and healthy kidney tissue segmentation, addressing the time-consuming manual segmentation process traditionally performed by expert radiologists.

## METHODS AND MATERIALS

We utilized a retrospectively maintained dataset consisting of 326 patients, 1034 complex masses (approximately three tumors per kidney), and 2171 cysts. All patients underwent an MRI between 2015 and 2021, with surgically removed tumors being pathologically confirmed. Lesions were manually segmented using ITK-SNAP on the excretory phase of MRI and co-registered on all other contrast-enhanced T1 sequences (pre-, arterial, and venous). The patient population was randomly divided into training (65%), testing (25%), and validation (10%) groups, stratified by tumor count, pathology, tumor volume, and kidney size. We trained ten benchmark models using 3D SwinUNETR and a differentiable decision forest, Hinge Forest, to segment lesions and kidney tissue, evaluating their performance with the Dice Similarity Coefficient (DSC) score.

## RESULTS

The best 3D Swin UnetR models achieved DSC scores of 0.81 for AML, 0.89 for chromophobe, 0.54 for ccRCC, 0.48 for HLRCC, 0.77 for hybrid, 0.71 for oncocytoma, 0.76 for papillary, 0.94 for kidney, and 0.48 for cysts. Overall performance of all the 10 benchmarked test sets was  $0.55 \pm 0.21$  for Swin UnetR tumor segmentation. The best 3D HF model scored 0.65 for AML, 0.72 for chromophobe, 0.50 for ccRCC, 0.46 for HLRCC, 0.65 for hybrid, 0.72 for oncocytoma, 0.65 for papillary, 0.92 for kidney, and 0.4 for cysts. Overall performance of all the 10 benchmarked test sets was  $0.51 \pm 0.8$  tumor segmentation.

## CONCLUSION

Advanced CNN architectures, such as 3D SwinUNET and hinge forest, show promise for automating renal mass subtypes, cyst, and kidney tissue segmentation on MRI. The 3D SwinUNET outperformed the 3D HF model, potentially reducing radiologist workload and enhancing diagnostic accuracy. Future research should refine these models, investigate their clinical application, and externally validate them for improving patient care.

## CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of advanced CNN architectures to revolutionize renal cancer diagnosis by automating RCC subtype, cyst, and kidney tissue segmentation on MRI, potentially reducing radiologist workload, improving diagnostic accuracy, and facilitating efficient treatment planning.

### R6-SSGU07-6 **A Multicenter Validation of Prediction Uncertainty to Triage Patients for Prostate Cancer AI Diagnosis**

Stefan J. Fransen, MSc (*Presenter*) Grant, Siemens AG; Grant, Health~Holland

## PURPOSE

AI prediction uncertainty can identify cases at risk of AI failure, enabling reliable automatic AI triaging. This study validates an uncertainty-based triage for prostate cancer patients, to improve diagnostic accuracy of AI and improve the clinical workflow.

## METHODS AND MATERIALS

A multi-center dataset of patients undergoing MRI triage for prostate cancer and an existing state-of-the-art AI algorithm for prostate cancer detection was used. The algorithm was previously trained on 7756 prostate bpMRI examinations (T2, ADC, and high b-value DWI) from Institute A (Siemens scanner) and provides 15 heatmaps with voxel-level likelihoods of malignant tissues (PIRADS=4). The trained algorithm was used to predict 561 unseen cases from Institute B (Philips scanner) and 200 unseen cases from Institute C (Siemens scanner). The variability in patient-level likelihood scores was used to measure prediction uncertainty. Predictions with a low variability were considered certain whereas predictions with a high variability were considered uncertain, at risk of AI failure. Multiple splits (20%, 40%, 60%, and 80%) were used to make certain and uncertain groups. The ability of AI to triage patients was assessed by comparing the AUROC of certain cases with

uncertain cases. Furthermore, a comparison was made with the radiologist by comparing the true positive rate (TPR) of certain cases and the TPR of the radiologist at the false positive rate (FPR) operating point of the radiologist. Statistical significance was assessed by using DeLong's test.

## **RESULTS**

AUROC of AI prediction was significantly higher for certain cases compared to uncertain cases, in both test sets up to 40% AI diagnosis ( $p < 0.05$ ). The highest AI performance was achieved by only selecting the 20% most certain cases (0.85 AUROC Institute B, 0.97 AUROC Institute C), indicating that AI prediction with a high level of certainty is more reliable. Compared to the overall radiologist performance, the AI can predict with a higher sensitivity in 20% of the cases from institute B (0.96 vs. 0.87 TPR at 0.45 FPR) and 60% of the cases from institute C (0.98 vs. 0.96 TPR at 0.22 FPR).

## **CONCLUSION**

Prediction uncertainty can triage patients for which AI diagnosis is reliable and identify patients at risk of AI failure in external test sets including other MRI vendors. This technique could improve the clinical workflow by implementing AI diagnosis for cases with high certainty, while only redirecting patients at risk of AI failure to a radiologist worklist for reporting.

## **CLINICAL RELEVANCE/APPLICATION**

AI detection for prostate cancer approaches expert-level performance, making automatic patient triaging possible. Using AI prediction uncertainty enables a reliable selection of patients fit for AI diagnosis.

### Spatial Characterization of Multiparametric MRI Performance using a Standardized Prostate Segmentation Model

Thursday, Nov. 30 1:30PM - 2:30PM Room: S502

Sohaib Naim, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

We aim to evaluate the performance of multiparametric MRI (mpMRI) to accurately detect clinically significant prostate cancer (csPCa) lesions through spatial characterization across different regions within the prostate gland.

#### METHODS AND MATERIALS

Our HIPAA-compliant, IRB-approved study group consisted of 1,143 consecutive men at our single institution that underwent mpMRI prior to radical prostatectomy between 2010 and 2022. Genitourinary (GU) radiologists and GU pathologists performed matching workflows with the prostate sector map model to identify true positive (TP), false negative (FN), and false positive (FP) lesions for all subjects. All TP, FN, and FP lesions were used to illustrate cancer prevalence (CP), detection rate (DR), and positive predictive values (PPV), each of which was sorted within a standardized prostate segmentation model, the prostate sector map. Using a weighted chi-square test we correlated statistical differences for DR and PPV for sectors established within the transition zone (TZ) vs. peripheral zone (PZ), anterior vs. posterior, base-gland (Base) vs. mid-gland (Mid) vs. apex-gland (Apex), and left vs. right prostate.

#### RESULTS

Our findings are presented across different sector regions for both DR and PPV. From our 1,143 subject cohort, we identified 2,152 PCa lesions, of which 1060 were csPCa lesions. We analyzed differences by stratifying laterality, anterior vs. posterior, and Base, Mid, and Apex levels within TZ and PZ. Our statistical findings show a significantly lower DR for the anterior vs. posterior regions (67.3% vs. 75.6%;  $p < 0.001$ ) for PZ sectors as well as right vs. left hemispheres (69.4% vs. 75.7%;  $p < 0.05$ ) for TZ sectors. We also identify a significantly lower DR in the Apex region vs. Base and Mid regions (71.5%;  $p < 0.01$ ). For our statistical findings with lower PPV values, we observe a significantly lower PPV for TZ vs. PZ sectors (75.8% vs. 82.4%;  $p < 0.001$ ) and the Base region vs. Mid and Apex regions (77.1%;  $p < 0.01$ ) for PZ sectors. These findings inform us how underdiagnosis occurs for lesions within anterior and Apex regions for PZ sectors, and often overdiagnoses occur for lesions which classify under PZ sectors in the Base region.

#### CONCLUSION

From 1,143 subjects, we identified significantly lower DRs for lesions in the anterior and apex regions of the prostate within PZ, along with significantly lower PPVs in the base prostate region and TZ compared to PZ. These findings, indicate that further attention to these locations would better resolve these shortcomings and benefit PCa diagnosis.

#### CLINICAL RELEVANCE/APPLICATION

Spatial-based mpMRI performance in detecting lesions can improve the identification of prostate cancer and reduce the need for biopsies in at-risk men.

### A Multicenter Validation of Prediction Uncertainty to Triage Patients for Prostate Cancer AI Diagnosis

Thursday, Nov. 30 1:30PM - 2:30PM Room: S502

Stefan J. Fransen, MSc (*Presenter*) Grant, Siemens AG; Grant, Health~Holland

#### PURPOSE

AI prediction uncertainty can identify cases at risk of AI failure, enabling reliable automatic AI triaging. This study validates an uncertainty-based triage for prostate cancer patients, to improve diagnostic accuracy of AI and improve the clinical workflow.

#### METHODS AND MATERIALS

A multi-center dataset of patients undergoing MRI triage for prostate cancer and an existing state-of-the-art AI algorithm for prostate cancer detection was used. The algorithm was previously trained on 7756 prostate bpMRI examinations (T2, ADC, and high b-value DWI) from Institute A (Siemens scanner) and provides 15 heatmaps with voxel-level likelihoods of malignant tissues (PIRADS=4). The trained algorithm was used to predict 561 unseen cases from Institute B (Philips scanner) and 200 unseen cases from Institute C (Siemens scanner). The variability in patient-level likelihood scores was used to measure prediction uncertainty. Predictions with a low variability were considered certain whereas predictions with a high variability were considered uncertain, at risk of AI failure. Multiple splits (20%, 40%, 60%, and 80%) were used to make certain and uncertain groups. The ability of AI to triage patients was assessed by comparing the AUROC of certain cases with uncertain cases. Furthermore, a comparison was made with the radiologist by comparing the true positive rate (TPR) of certain cases and the TPR of the radiologist at the false positive rate (FPR) operating point of the radiologist. Statistical significance was assessed by using DeLong's test.

#### RESULTS

AUROC of AI prediction was significantly higher for certain cases compared to uncertain cases, in both test sets up to 40% AI diagnosis ( $p < 0.05$ ). The highest AI performance was achieved by only selecting the 20% most certain cases (0.85 AUROC Institute B, 0.97 AUROC Institute C), indicating that AI prediction with a high level of certainty is more reliable. Compared to the overall radiologist performance, the AI can predict with a higher sensitivity in 20% of the cases from institute B (0.96 vs. 0.87 TPR at 0.45 FPR) and 60% of the cases from institute C (0.98 vs. 0.96 TPR at 0.22 FPR).

#### CONCLUSION

Prediction uncertainty can triage patients for which AI diagnosis is reliable and identify patients at risk of AI failure in external test sets including other MRI vendors. This technique could improve the clinical workflow by implementing AI diagnosis for cases with high certainty, while only redirecting patients at risk of AI failure to a radiologist worklist for reporting.

#### CLINICAL RELEVANCE/APPLICATION

AI detection for prostate cancer approaches expert-level performance, making automatic patient triaging possible. Using AI prediction uncertainty enables a reliable selection of patients fit for AI diagnosis.

#### R6-SSMK12-1 **High Frequency Ultrasound in Assessment of Nail Psoriasis and Onychomycosis: A Comparative Study**

Chhavi Gupta, MBBS, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Differentiation between psoriatic onychopathy and onychomycosis is a diagnostic challenge. The differentiation is critical as both these entities have long term prognostic and clinical implications and encompass long-course therapies. Currently, differentiation is based on clinical and histopathological examination like biopsies (wherein they share common features) and fungal culture. The special stains may not be readily available and are costly. Ultrasound (USG), a low cost, non-invasive and readily available modality has been used for evaluation of nail unit in recent studies, where changes in nail structure have been observed. This study compares the nail USG features in psoriasis and onychomycosis.

#### METHODS AND MATERIALS

After ethical clearance and informed consent, 185 dystrophic nails with psoriasis (105) and onychomycosis (82) were enrolled. 30 control nail units were examined. The opposite side nail served as control in focal disease and age and sex matched control was assessed in global disease. USG examination of the nail unit was performed using high frequency linear transducer (3-16 MHz). Qualitative examination of nail plate, ventral and dorsal nail plate contours, nail bed, nail matrix, extensor tendon, enthesi and distal interphalangeal joint (DIP) was performed. The quantitative parameters recorded were thickening of nail plate, nail bed, nail matrix and extensor tendon. Colour and power doppler was used to assess the vascularity of nail bed and DIP joint.

#### RESULTS

Both psoriasis and onychomycosis showed increased nail plate and nail bed thickness with wavy nail plate contour. The nail matrix thickness was significantly more in psoriatic nails of the hand ( $3.54 \pm 0.75$  vs  $3.17 \pm 0.63$ ;  $p=0.0086$ ) compared to onychomycosis. Psoriatic nails had increased thickness of extensor tendon ( $0.81 \pm 0.25$  vs  $0.54 \pm 0.12$ ;  $p=0.0001$  in hands,  $0.75 \pm 0.19$  vs  $0.55 \pm 0.13$ ;  $p=0.0001$  in feet;  $1.17 \pm 0.33$  vs  $0.7 \pm 0.16$ ;  $p=0.001$  in great toe) viz a viz onychomycosis. Psoriatic nails had a higher associated presence of DIP enthesopathies such as enthesophytes (20.4 vs 2.4 %;  $p=0.0002$ ); bony erosions (7.8 vs 1.2%;  $p=0.039$ ); raised enthesi vascularity (54.3 vs 1.2%;  $p=0.00001$ ) and raised nail bed vascularity (13.6 vs 4.9%;  $p=0.046$ ) compared to onychomycotic counterparts. The interplate space was preserved more commonly in psoriasis viz a viz onychomycosis (23.3 vs 11%;  $p=0.029$ ).

#### CONCLUSION

Nail USG emerged as a useful non-invasive technique for differentiating psoriatic and onychomycotic nails.

#### CLINICAL RELEVANCE/APPLICATION

USG can aid in differentiating nail psoriasis and onychomycosis which is a diagnostic challenge clinically and after biopsy. Its easy availability, low cost, ability to image multiple nails repeatedly makes it a lucrative modality.

#### R6-SSMK12-2 **Diagnostic Value of Hand Ultrasound in Early Detection of Rheumatoid Arthritis**

Mahyar Daskareh, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Rheumatoid arthritis (RA) is now considered to be a multistep process and a continuum of disease, rather than a distinct phenotype. In this study, we aimed to investigate the diagnostic value and predictive role of hand ultrasound (US) in the early stages of RA and to identify the characteristics that contribute to predicting the development of clinical RA in the long-term follow up.

## METHODS AND MATERIALS

Patients complaining of non-traumatic pain in their hand joints who did not meet the ACE-EULAR 2010 criteria for RA diagnosis were recruited and followed for 24 months. After initial clinical and laboratory examinations, we evaluated the hands' joints and tendons using greyscale and power doppler US techniques. Supervised machine learning (ML) methods were implemented to identify the characteristics that have high value in predicting future RA development.

## RESULTS

Of the 326 patients, 123 (37.7%) progressed to clinical RA. Laboratory parameters, including WBC (OR:1.23, 95%CI: 1.02-1.50, P=0.035), RF (OR:1.08, 95%CI: 1.04-1.12, P=<0.0001), and Anti CCP (OR:1.04, 95%CI: 1.02-1.07, P=0.002) were the strongest independent predictors of RA progression. Additionally, baseline greyscale US findings, such as radiocarpal synovial thickening (OR: 39.8, 95%CI: 15.86-100.20, P=<0.0001), PIP synovitis, (OR: 68, 95%CI: 12.62-365.91, P=<0.0001), MCP synovitis (OR: 39, 95%CI: 3.34-454.1, P=0.003), and wrist effusion (OR:12.56, 95%CI: 2.22-70.95, P=0.004) were significantly associated with developing RA. ML results suggested that the best model with the highest F1-score was the random forest with 80 trees, and radiocarpal synovial thickening, MCP and PIP synovitis in addition to RF, and anti-CCP were the most important predictive features.

## CONCLUSION

Our study suggests that US examination is a sensitive method for detecting and predicting clinical RA at early stages and can facilitate treatment decision-makings in earlier course of the disease. Radiocarpal synovial thickening, PIP, and MCP synovitis at baseline were the most valuable predictors for RA development when added to clinical and laboratory evaluations.

## CLINICAL RELEVANCE/APPLICATION

Using ultrasound to evaluate and predict the risk of clinical RA during pre-clinical phases could help with the early initiation of management strategies and improve patients' prognosis.

## R6-SSMK12-4 Fast Elbow MRI with Deep Learning Reconstruction: Assessment of Image Quality and Visualization of Anatomy Compared to Standard Imaging

Sebastian Werner (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study was to evaluate a deep learning (DL) reconstruction for turbo spin echo (TSE) sequences of the elbow regarding image quality and visualization of anatomy.

## METHODS AND MATERIALS

Between October 2020 and June 2021, seventeen participants (8 patients, 9 healthy subjects; mean age: 43±16 [20-70] years, 8 men) were prospectively included in this study. Each patient underwent two examinations: standard MRI, including TSE sequences reconstructed with a generalized autocalibrating partial parallel acquisition reconstruction (TSES), and prospectively undersampled TSE sequences reconstructed with a DL reconstruction (TSEDL). The images were evaluated concerning image quality, noise, edge sharpness, artifacts, diagnostic confidence, and delineation of anatomical structures using a 5-point Likert scale.

## RESULTS

Image quality was significantly improved in TSEDL (4.35, IQR 4-5) compared to TSES (3.76, IQR 3-4, p=0.008). Moreover, TSEDL showed decreased noise (4.29, IQR 3.5-5) compared to TSES (3.35, IQR 3-4, p=0.004). Ratings for delineation of anatomical structures, artifacts, edge sharpness, and diagnostic confidence did not differ significantly between TSEDL and TSES (p > 0.05). Inter- and intra-reader agreement was substantial to almost perfect (?=0.628-0.904). Using DL, the acquisition time could be reduced by more than 35% compared to TSES.

## CONCLUSION

TSE<sub>DL</sub> provided improved image quality and decreased noise while receiving equal ratings for edge sharpness, artifacts, delineation of anatomical structures, and diagnostic confidence compared to TSE<sub>S</sub>.

## CLINICAL RELEVANCE/APPLICATION

Providing more than a 35% reduction of acquisition time, TSEDL may be clinically relevant for elbow imaging due to increased patient comfort and higher patient throughput.

## **R6-SSMK12-5 Clinical and Radiological Predictors of Delayed Union or Non-Union of Scaphoid Fractures**

Gianluca Folco, MD (*Presenter*) Nothing to Disclose

### **PURPOSE**

The purpose of our study was to review the role of different clinical and radiological variables from X-ray images of the hand in patients with scaphoid fractures on potential delayed union or non-union.

### **METHODS AND MATERIALS**

We retrospectively reviewed all patients who underwent at least one X-ray examination of the hand at our institution for a scaphoid fracture, excluding those who were referred for surgical treatment. Patients' clinical variable such as age and sex, and radiological data such as fracture dislocation, site on the scaphoid bone, articular involvement and side were collected, to then construct a multivariate model to predict delayed union or non-union of said fractures.

### **RESULTS**

Our final population was composed by 105 patients, 75 (71%) of whom males, with a median age of 39 years (interquartile range, 27-63 years). Overall, 26 (25%) patients developed a delayed union or non-union of their scaphoid fracture. At multiple regression, fracture displacement ( $p < 0.001$ ), and patients' age ( $p = 0.046$ ) and sex ( $p = 0.038$ ) yielded a significant impact on delayed union or non-union, with an overall R-squared of 0.479 for such predictive model. Site fracture on the scaphoid bone displayed a borderline significance on delayed union or non-union rates ( $p = 0.079$ ).

### **CONCLUSION**

A higher age, male sex, fracture dislocation or fracture sites different than the middle third of the scaphoid bone are predictors of higher rates of delayed union or non-union of scaphoid fractures.

### **CLINICAL RELEVANCE/APPLICATION**

Such data could be considered when planning clinical pathways for patients presenting with scaphoid fractures.

## **R6-SSMK12-6 MRI Findings in the Elbow Among Pediatric Baseball Players Based on Skeletal Maturity**

Vandan Patel, BS (*Presenter*) Nothing to Disclose

### **PURPOSE**

To characterize the spectrum of MRI findings in the elbow among youth baseball players with respect to regional skeletal maturity and surgical intervention.

### **METHODS AND MATERIALS**

This IRB-approved, HIPAA-compliant retrospective study analyzed consecutive baseball players (<18 years), who underwent elbow MRI at our free-standing children's hospital in the past 11 years (2010-2021). Two radiologists reviewed each examination independently to categorize regional skeletal maturity and findings within the medial, lateral, and posterior elbow. Findings were compared between maturation groups and logistic regression models were used to identify predictors of surgery.

### **RESULTS**

This study group of 136 children (115 boys, 21 girls) included 89 skeletally immature ( $12.7 \pm 2.3$  years) and 47 skeletally mature children ( $16.2 \pm 1.0$  years,  $p < 0.01$ ). Kappa coefficient ranged 0.64-0.96 and percent agreement ranged 86%-99%. Elbow effusion (27% vs 9%,  $p = 0.02$ ), medial epicondyle marrow edema (52% vs 15%,  $p < 0.01$ ), avulsion fractures (19% vs 2%,  $p = 0.01$ ), and osteochondritis dissecans (OCD, 24% vs 6%,  $p = 0.02$ ) were significantly more common among skeletally immature children whereas sublime tubercle marrow edema (10% vs 47%,  $p < 0.01$ ) and triceps tendinosis (19% vs 38%,  $p = 0.03$ ) were more common among skeletally mature children. Presence of intra-articular body (OR=22.8, 95% CI 2.2-466.8,  $p = 0.02$ ) and OCD (OR=6.6, 95% CI 1.6-29.3,  $p = 0.01$ ) were independent predictors for surgery.

### **CONCLUSION**

Differential patterns of MRI findings were observed in the elbow in our study group of symptomatic pediatric baseball players, which correlated with regional skeletal maturity. The presence of intra-articular body and OCD, but not skeletal maturity, were independent predictors of surgery.

### **CLINICAL RELEVANCE/APPLICATION**

With increasing sports participation and prevalence of elbow injuries among youth baseball players, a comprehensive assessment of various sites of stress in the context of functional anatomy and regional skeletal maturity can improve

diagnostic accuracy, ensure timely intervention, and reduce long-term morbidity.

### High Frequency Ultrasound in Assessment of Nail Psoriasis and Onychomycosis: A Comparative Study

Thursday, Nov. 30 1:30PM - 2:30PM Room: N228

Chhavi Gupta, MBBS, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Differentiation between psoriatic onychopathy and onychomycosis is a diagnostic challenge. The differentiation is critical as both these entities have long term prognostic and clinical implications and encompass long-course therapies. Currently, differentiation is based on clinical and histopathological examination like biopsies (wherein they share common features) and fungal culture. The special stains may not be readily available and are costly. Ultrasound (USG), a low cost, non-invasive and readily available modality has been used for evaluation of nail unit in recent studies, where changes in nail structure have been observed. This study compares the nail USG features in psoriasis and onychomycosis.

#### METHODS AND MATERIALS

After ethical clearance and informed consent, 185 dystrophic nails with psoriasis (105) and onychomycosis (82) were enrolled. 30 control nail units were examined. The opposite side nail served as control in focal disease and age and sex matched control was assessed in global disease. USG examination of the nail unit was performed using high frequency linear transducer (3-16 MHz). Qualitative examination of nail plate, ventral and dorsal nail plate contours, nail bed, nail matrix, extensor tendon, enthesis and distal interphalangeal joint (DIP) was performed. The quantitative parameters recorded were thickening of nail plate, nail bed, nail matrix and extensor tendon. Colour and power doppler was used to assess the vascularity of nail bed and DIP joint.

#### RESULTS

Both psoriasis and onychomycosis showed increased nail plate and nail bed thickness with wavy nail plate contour. The nail matrix thickness was significantly more in psoriatic nails of the hand ( $3.54 \pm 0.75$  vs  $3.17 \pm 0.63$ ;  $p=0.0086$ ) compared to onychomycosis. Psoriatic nails had increased thickness of extensor tendon ( $0.81 \pm 0.25$  vs  $0.54 \pm 0.12$ ;  $p=0.0001$  in hands,  $0.75 \pm 0.19$  vs  $0.55 \pm 0.13$ ;  $p=0.0001$  in feet;  $1.17 \pm 0.33$  vs  $0.7 \pm 0.16$ ;  $p=0.001$  in great toe) viz a viz onychomycosis. Psoriatic nails had a higher associated presence of DIP enthesopathies such as enthesophytes (20.4 vs 2.4 %;  $p=0.0002$ ); bony erosions (7.8 vs 1.2%;  $p=0.039$ ); raised enthesis vascularity (54.3 vs 1.2%;  $p=0.00001$ ) and raised nail bed vascularity (13.6 vs 4.9%;  $p=0.046$ ) compared to onychomycotic counterparts. The interplate space was preserved more commonly in psoriasis viz a viz onychomycosis (23.3 vs 11%;  $p=0.029$ ).

#### CONCLUSION

Nail USG emerged as a useful non-invasive technique for differentiating psoriatic and onychomycotic nails.

#### CLINICAL RELEVANCE/APPLICATION

USG can aid in differentiating nail psoriasis and onychomycosis which is a diagnostic challenge clinically and after biopsy. Its easy availability, low cost, ability to image multiple nails repeatedly makes it a lucrative modality.

### Fast Elbow MRI with Deep Learning Reconstruction: Assessment of Image Quality and Visualization of Anatomy Compared to Standard Imaging

Thursday, Nov. 30 1:30PM - 2:30PM Room: N228

Sebastian Werner (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to evaluate a deep learning (DL) reconstruction for turbo spin echo (TSE) sequences of the elbow regarding image quality and visualization of anatomy.

#### METHODS AND MATERIALS

Between October 2020 and June 2021, seventeen participants (8 patients, 9 healthy subjects; mean age:  $43 \pm 16$  [20-70] years, 8 men) were prospectively included in this study. Each patient underwent two examinations: standard MRI, including TSE sequences reconstructed with a generalized autocalibrating partial parallel acquisition reconstruction (TSES), and prospectively undersampled TSE sequences reconstructed with a DL reconstruction (TSEDL). The images were evaluated concerning image quality, noise, edge sharpness, artifacts, diagnostic confidence, and delineation of anatomical structures using a 5-point Likert scale.

#### RESULTS

Image quality was significantly improved in TSEDL (4.35, IQR 4-5) compared to TSES (3.76, IQR 3-4,  $p=0.008$ ). Moreover, TSEDL showed decreased noise (4.29, IQR 3.5-5) compared to TSES (3.35, IQR 3-4,  $p=0.004$ ). Ratings for delineation of anatomical structures, artifacts, edge sharpness, and diagnostic confidence did not differ significantly between TSEDL and TSES ( $p > 0.05$ ). Inter- and intra-reader agreement was substantial to almost perfect ( $\kappa=0.628-0.904$ ). Using DL, the acquisition time could be reduced by more than 35% compared to TSES.

#### CONCLUSION

TSE<sub>DL</sub> provided improved image quality and decreased noise while receiving equal ratings for edge sharpness, artifacts, delineation of anatomical structures, and diagnostic confidence compared to TSE<sub>S</sub>.

#### CLINICAL RELEVANCE/APPLICATION

Providing more than a 35% reduction of acquisition time, TSEDL may be clinically relevant for elbow imaging due to increased patient comfort and higher patient throughput.

#### **R6-SSNMMI08-1 Lesion Based Dosimetric Analysis of Response to 177Lu-Psma Therapy in McRpc Patients**

**1** Surekha Yadav, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To perform lesion-based dosimetry to evaluate the tumor dose absorbed per lesion and to evaluate the relation between the absorbed tumor dose and the response to RLT.

#### METHODS AND MATERIALS

25 patients with progressive mCRPC who presented for RLT therapy were consecutively sampled for inclusion in this retrospective study. Semi-quantitative analysis of 24-hour post-treatment SPECT was performed using MRT Dosimetry Software (MIM Software Inc., Cleveland, US) after cycle 1 (C1) and cycle 2 (C2). Lesion segmentation used a 42% threshold. The change in the absorbed dose of a lesion from C1 to C2 was evaluated to assess the response:  $\text{Response} = 1 - \frac{\text{Mean Absorbed dose C1} - \text{Mean Absorbed dose C2}}{\text{Mean Absorbed dose C1}}$

#### RESULTS

103 lesions evaluated at two time points. The decrease in the average radiation absorbed dose was 41%. Out of the 21 patients, 10 (47%) achieved a PSA50 response after C2. Responders who achieved PSA50 showed a significantly higher decrease in average absorbed dose as compared to the patients who did not achieve a PSA50 (54.32% in PSA50 versus 28.9% in non-PSA50,  $p=0.0047$ ). There was no difference in baseline absorbed dose between the two groups (5.7 Gray in PSA50 versus 3.9 Gray in non-PSA50,  $p=0.1678$ ). Skeletal lesions in the responders showed a decrease of 55%, while nodal lesions showed a decrease of 51%. Non-responders who did not achieve PSA50 concurrently showed a lower decrease in average absorbed dose from C1 to C2 for both the skeletal (26%) as well as the nodal lesions (40%).

#### CONCLUSION

Patients demonstrating a higher decrease in absorbed dose are more likely to have a PSA50 response after C2, although there was no relationship between baseline absorbed dose and PSA response.

#### CLINICAL RELEVANCE/APPLICATION

Lesion based dosimetry will potentially lead to optimal disease control by targeting high radiation doses to patient who need it, while reducing radiation toxicity and delaying therapy resistance in others.

#### **R6-SSNMMI08-2 AI-based Prediction of Treatment Response in Patients with Metastatic Castration-resistant Prostate Cancer using <sup>18</sup>F-DCFpYl PSMA PET/CT**

Andrew F. Voter (*Presenter*) Nothing to Disclose

## PURPOSE

Despite widespread adoption of prostate-specific membrane antigen (PSMA) PET/CT imaging for prostate cancer, prognostication of patient outcomes remains challenging. The primary goal of this work was to evaluate the feasibility of a deep learning (DL) model to identify patients at risk for progression based on baseline PSMA PET imaging.

## METHODS AND MATERIALS

PSMA-PET/CT scans of 128 patients (Age 71.7±8.4years, PSA 19.4±42.7) with metastatic castration-resistant prostate cancer (mCRPC) on the index PSMA PET/CT scans were used for the training set. A total of 1624 PSMA-avid foci suspicious for malignancy were labeled and reassessed on follow-up PSMA PET/CT or other imaging modalities. Lesions were classified as either progressive or non-progressive based on increased radiotracer avidity or greater than 2mm size increase. A deep multi-modal fusion 3D convolutional neural network (CNN) based on the index PSMA PET/CT was trained to predict lesion-wise treatment response on follow up imaging. The model was validated using an independent test set comprising 105 lesions from 19 patients (Age 72.2±7.1 years, PSA 18.5±16.1). Then, patient-wise CNN features were obtained by averaging lesion-wise CNN features, and a random survival forest model was trained to predict PFS. Then, patients were stratified into low-versus high-risk groups by Kaplan Meier analysis and the log rank test.

## RESULTS

The model based on PET/CT achieved an accuracy of 0.819, AUC of 0.615, F1-score of 0.899, precision of 0.838 and recall of 0.970 in classifying lesions as progressive versus non-progression. The time to event survival analysis yielded a C index of 0.61. Our algorithm was able to identify a high-risk population in the testing set with significantly reduced median survival (26.1 months) relative to the remaining population (57.4 months, P=0.04).

## CONCLUSION

We developed a DL model to predict lesion and patient-level treatment response using PSMA PET/CT scans. Our DL model was able to identify mCRPC patients at high risk for progression. Further studies are warranted to determine the clinical implications of our deep learning model.

## CLINICAL RELEVANCE/APPLICATION

PSMA PET/CT is an invaluable tool for the management of mCRPC. We demonstrated its value in prognostication by stratifying patient outcomes and identifying a high risk subgroup of patients who may benefit from focused care or alternative therapies.

## R6-SSNMMI08-3 Salvage Radiotherapy Guidance with <sup>18</sup>F-Fluciclovine PET/CT and <sup>68</sup>Ga-PSMA PET/CT in Patients with Biochemical Recurrence Postprostatectomy: A Planned Secondary Endpoint from a Randomized Trial

Olayinka A. Abiodun-Ojo, MD, MPH (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the impact of 18F-fluciclovine and 68Ga-PSMA PET on salvage radiotherapy (RT) management decisions in patients with biochemical recurrence after radical prostatectomy.

## METHODS AND MATERIALS

Prospectively enrolled men with rise in prostate-specific antigen (PSA) postprostatectomy were randomized in an intention-to-treat clinical trial to PET/CT imaging with 18F-fluciclovine (arm A) or 68Ga-PSMA with 20 mg Lasix unless contraindicated (arm B), to guide treatment planning. Initial RT decisions based on conventional imaging and clinicopathologic findings were compared with final RT decisions based on PET findings: extrapelvic nodal/bone uptake - no RT; pelvic nodal uptake - RT to prostate bed+pelvis; no uptake or prostate bed only uptake - RT to prostate bed. Clopper-Pearson binomial method was used to determine the significance of decision changes.

## RESULTS

6/140 patients withdrew from the trial before PET scanning. Of the remaining 134 patients, 65 (median PSA 0.28 ng/mL) received 18F-fluciclovine PET and 69 (median PSA 0.35 ng/mL) received 68Ga-PSMA PET. Patient-based analysis showed a significantly higher positivity rate for prostate cancer recurrence with 18F-fluciclovine (95.4%) than 68Ga-PSMA (60.9%; p<0.001). Local recurrence was detected on 18F-fluciclovine in 72.3% and on 68Ga-PSMA in 37.7% (p<0.001). Positivity rates on 18F-fluciclovine and 68Ga-PSMA were comparable for pelvic lymph node recurrence and extrapelvic metastases (Table 1). Overall RT decision change was 30.7% in arm A vs 42.0% in arm B. 5/65 (7.7%) in arm A and 8/69 (11.6%) patients in arm B had the decision to offer radiotherapy withdrawn due to extrapelvic uptake on PET. Among patients with final decision to receive RT, treatment fields were changed in 15/60 (25.0%) in arm A vs 21/61 (34.4%) in arm B. 1/60 (1.7%) in arm A vs 2/61 (3.3%) in arm B had field increased from prostate bed only to prostate bed and pelvis, while 14/60 (23.3%) in arm A vs 19/61 (31.1%) in arm B had field reduced from RT to prostate bed and pelvis to prostate bed only. Changes in the decision to offer RT, treatment fields, and overall RT decisions were statistically significant for arms A B.

## CONCLUSION

We report significantly higher positivity rates on <sup>18</sup>F-fluciclovine than <sup>68</sup>Ga-PSMA PET for whole body and local recurrence. <sup>18</sup>F-fluciclovine and <sup>68</sup>Ga-PSMA had significant impact on salvage radiotherapy management decisions in postprostatectomy patients with recurrent prostate cancer. Further analysis to determine the effect of management decision change on failure-free survival is ongoing.

## CLINICAL RELEVANCE/APPLICATION

<sup>18</sup>F-fluciclovine and <sup>68</sup>Ga-PSMA significantly influenced radiotherapy management decisions in prostate cancer patients with biochemical recurrence postprostatectomy.

## R6-SSNMMI08- Early Adverse Events, Emergency Room Visits and Hospitalizations After PSMA Based RLT: A Retrospective Analysis from Real World Theranostics Practice

Ahmad Abdelrazek (*Presenter*) Nothing to Disclose

## PURPOSE

Lutetium-177-PSMA (Lu-PSMA) is an effective treatment for metastatic castration-resistant prostate cancer (mCRPC) patients, even though the immediate side effects that can occur during or right after treatment administration are not heavily investigated. Herein, we aimed to report on all adverse events occurring during or shortly after treatment.

## METHODS AND MATERIALS

We reviewed 185 patients between April and November 2022. The primary goal of our study is to outline the early side effects reported in the clinical notes, and the secondary goal is to report the emergency room visits and hospitalizations within 30 days following a Lu-PSMA administration. We investigated independent variables in univariable and multivariable logistic regression analyses

## RESULTS

The median (IQR) age at the time of the first Lu-PSMA cycle was 70 years (67-76), with a median (IQR) PSA of 11.8 ng/ml (2.3-76.4) and an Eastern Cooperative Oncology Group (ECOG) performance status of 0,1,2,3 was 114 (61.6%) 59 (31.9%) 10 (5.4%) 2 (1.1%), respectively. At the time of the first Lu-PSMA cycle, 123 (66.5%) patients had lymph node metastasis, 164 (88.6%) had bone metastasis, and 54 (32.4%) had visceral metastasis, as detected by <sup>68</sup>Ga or <sup>18</sup>F PSMA-targeted PET/CT. Among known side effects attributed to Lu-PSMA, the most observed during or shortly after therapy were gastrointestinal in origin, including nausea 36 (19.5%), vomiting 36 (19.5%), abdominal pain 17 (9.2%), constipation 16 (8.6%), and diarrhea 9 (4.9%). Other adverse effects included fatigue 54 (29.2%), decreased appetite 15 (8.1%), unintentional weight loss 10 (5.4%), and dry mouth 9 (4.9%). In all, 16 (8.6%) patients had visited the emergency room after receiving Lu-PSMA. Out of those 16 patients, 2 (1.1%) patients were due to anemia and thrombocytopenia, 2 (1.1%) patients had pneumonia, pleural effusion, and acute respiratory failure, 2 (1.1%) patients were due to abdominal pain and vomiting, 2 (1.1%) patients presented with sepsis and septic shock, and one (0.5%) patient was due to intestinal obstruction and perforated appendicitis. Additionally, 2 (1.1%) patients were hospitalized, one (0.5%) due to severe anemia, and the other one (0.5%) due to pathological spinal fracture. A high ECOG performance score was associated with an increased number of emergency department visits ( $p= 0.017$ ) and hospital admissions ( $p= 0.007$ )

## CONCLUSION

Mild to moderate short-term side effects secondary to treatment with Lu-PSMA are not uncommon, but most patients can be managed in an outpatient setting

## CLINICAL RELEVANCE/APPLICATION

In the current era of treatment of metastatic castrate-resistant prostate cancer with <sup>177</sup>-PSMA Lutetium, we gave the physicians a broad view of the common side effects that we faced from real-world data

### Lesion Based Dosimetric Analysis of Response to 177Lu-Psma Therapy in mCRpc Patients

Thursday, Nov. 30 1:30PM - 2:30PM Room: S403A

Surekha Yadav, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To perform lesion-based dosimetry to evaluate the tumor dose absorbed per lesion and to evaluate the relation between the absorbed tumor dose and the response to RLT.

#### METHODS AND MATERIALS

25 patients with progressive mCRPC who presented for RLT therapy were consecutively sampled for inclusion in this retrospective study. Semi-quantitative analysis of 24-hour post-treatment SPECT was performed using MRT Dosimetry Software (MIM Software Inc., Cleveland, US) after cycle 1 (C1) and cycle 2 (C2). Lesion segmentation used a 42% threshold. The change in the absorbed dose of a lesion from C1 to C2 was evaluated to assess the response:  $\text{Response} = 1 - \frac{\text{Mean Absorbed dose C2} - \text{Mean Absorbed dose C1}}{\text{Mean Absorbed dose C1}}$

#### RESULTS

103 lesions evaluated at two time points. The decrease in the average radiation absorbed dose was 41%. Out of the 21 patients, 10 (47%) achieved a PSA50 response after C2. Responders who achieved PSA50 showed a significantly higher decrease in average absorbed dose as compared to the patients who did not achieve a PSA50 (54.32% in PSA50 versus 28.9% in non-PSA50,  $p=0.0047$ ). There was no difference in baseline absorbed dose between the two groups (5.7 Gray in PSA50 versus 3.9 Gray in non-PSA50,  $p=0.1678$ ). Skeletal lesions in the responders showed a decrease of 55%, while nodal lesions showed a decrease of 51%. Non-responders who did not achieve PSA50 concurrently showed a lower decrease in average absorbed dose from C1 to C2 for both the skeletal (26%) as well as the nodal lesions (40%).

#### CONCLUSION

Patients demonstrating a higher decrease in absorbed dose are more likely to have a PSA50 response after C2, although there was no relationship between baseline absorbed dose and PSA response.

#### CLINICAL RELEVANCE/APPLICATION

Lesion based dosimetry will potentially lead to optimal disease control by targeting high radiation doses to patient who need it, while reducing radiation toxicity and delaying therapy resistance in others.

### AI-based Prediction of Treatment Response in Patients with Metastatic Castration-resistant Prostate Cancer using $^{18}\text{F}$ -DCFPyL PSMA PET/CT

Thursday, Nov. 30 1:30PM - 2:30PM Room: S403A

Andrew F. Voter (*Presenter*) Nothing to Disclose

#### PURPOSE

Despite widespread adoption of prostate-specific membrane antigen (PSMA) PET/CT imaging for prostate cancer, prognostication of patient outcomes remains challenging. The primary goal of this work was to evaluate the feasibility of a deep learning (DL) model to identify patients at risk for progression based on baseline PSMA PET imaging.

#### METHODS AND MATERIALS

PSMA-PET/CT scans of 128 patients (Age  $71.7 \pm 8.4$  years, PSA  $19.4 \pm 42.7$ ) with metastatic castration-resistant prostate cancer (mCRPC) on the index PSMA PET/CT scans were used for the training set. A total of 1624 PSMA-avid foci suspicious for malignancy were labeled and reassessed on follow-up PSMA PET/CT or other imaging modalities. Lesions were classified as either progressive or non-progressive based on increased radiotracer avidity or greater than 2mm size increase. A deep multi-modal fusion 3D convolutional neural network (CNN) based on the index PSMA PET/CT was trained to predict lesion-wise treatment response on follow up imaging. The model was validated using an independent test set comprising 105 lesions from 19 patients (Age  $72.2 \pm 7.1$  years, PSA  $18.5 \pm 16.1$ ). Then, patient-wise CNN features were obtained by averaging lesion-wise CNN features, and a random survival forest model was trained to predict PFS. Then, patients were stratified into low-versus high-risk groups by Kaplan Meier analysis and the log rank test.

#### RESULTS

The model based on PET/CT achieved an accuracy of 0.819, AUC of 0.615, F1-score of 0.899, precision of 0.838 and recall of 0.970 in classifying lesions as progressive versus non-progression. The time to event survival analysis yielded a C index of 0.61. Our algorithm was able to identify a high-risk population in the testing set with significantly reduced median survival (26.1 months) relative to the remaining population (57.4 months,  $P=0.04$ ).

#### CONCLUSION

We developed a DL model to predict lesion and patient-level treatment response using PSMA PET/CT scans. Our DL model was able to identify mCRPC patients at high risk for progression. Further studies are warranted to determine the clinical implications of our deep learning model.

#### CLINICAL RELEVANCE/APPLICATION

PSMA PET/CT is an invaluable tool for the management of mCRPC. We demonstrated its value in prognostication by stratifying patient outcomes and identifying a high risk subgroup of patients who may benefit from focused care or alternative therapies.

### Salvage Radiotherapy Guidance with <sup>18</sup>F-Fluciclovine PET/CT and <sup>68</sup>Ga-PSMA PET/CT in Patients with Biochemical Recurrence Postprostatectomy: A Planned Secondary Endpoint from a Randomized Trial

Thursday, Nov. 30 1:30PM - 2:30PM Room: S403A

Olayinka A. Abiodun-Ojo, MD, MPH (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the impact of <sup>18</sup>F-fluciclovine and <sup>68</sup>Ga-PSMA PET on salvage radiotherapy (RT) management decisions in patients with biochemical recurrence after radical prostatectomy.

#### METHODS AND MATERIALS

Prospectively enrolled men with rise in prostate-specific antigen (PSA) postprostatectomy were randomized in an intention-to-treat clinical trial to PET/CT imaging with <sup>18</sup>F-fluciclovine (arm A) or <sup>68</sup>Ga-PSMA with 20 mg Lasix unless contraindicated (arm B), to guide treatment planning. Initial RT decisions based on conventional imaging and clinicopathologic findings were compared with final RT decisions based on PET findings: extrapelvic nodal/bone uptake - no RT; pelvic nodal uptake - RT to prostate bed+pelvis; no uptake or prostate bed only uptake - RT to prostate bed. Clopper-Pearson binomial method was used to determine the significance of decision changes.

#### RESULTS

6/140 patients withdrew from the trial before PET scanning. Of the remaining 134 patients, 65 (median PSA 0.28 ng/mL) received <sup>18</sup>F-fluciclovine PET and 69 (median PSA 0.35 ng/mL) received <sup>68</sup>Ga-PSMA PET. Patient-based analysis showed a significantly higher positivity rate for prostate cancer recurrence with <sup>18</sup>F-fluciclovine (95.4%) than <sup>68</sup>Ga-PSMA (60.9%;  $p < 0.001$ ). Local recurrence was detected on <sup>18</sup>F-fluciclovine in 72.3% and on <sup>68</sup>Ga-PSMA in 37.7% ( $p < 0.001$ ). Positivity rates on <sup>18</sup>F-fluciclovine and <sup>68</sup>Ga-PSMA were comparable for pelvic lymph node recurrence and extrapelvic metastases (Table 1). Overall RT decision change was 30.7% in arm A vs 42.0% in arm B. 5/65 (7.7%) in arm A and 8/69 (11.6%) patients in arm B had the decision to offer radiotherapy withdrawn due to extrapelvic uptake on PET. Among patients with final decision to receive RT, treatment fields were changed in 15/60 (25.0%) in arm A vs 21/61 (34.4%) in arm B. 1/60 (1.7%) in arm A vs 2/61 (3.3%) in arm B had field increased from prostate bed only to prostate bed and pelvis, while 14/60 (23.3%) in arm A vs 19/61 (31.1%) in arm B had field reduced from RT to prostate bed and pelvis to prostate bed only. Changes in the decision to offer RT, treatment fields, and overall RT decisions were statistically significant for arms A B.

#### CONCLUSION

We report significantly higher positivity rates on <sup>18</sup>F-fluciclovine than <sup>68</sup>Ga-PSMA PET for whole body and local recurrence. <sup>18</sup>F-fluciclovine and <sup>68</sup>Ga-PSMA had significant impact on salvage radiotherapy management decisions in postprostatectomy patients with recurrent prostate cancer. Further analysis to determine the effect of management decision change on failure-free survival is ongoing.

#### CLINICAL RELEVANCE/APPLICATION

<sup>18</sup>F-fluciclovine and <sup>68</sup>Ga-PSMA significantly influenced radiotherapy management decisions in prostate cancer patients with biochemical recurrence postprostatectomy.

### Early Adverse Events, Emergency Room Visits and Hospitalizations After PSMA Based RLT: A Retrospective Analysis from Real World Theranostics Practice

Thursday, Nov. 30 1:30PM - 2:30PM Room: S403A

Ahmad Abdelrazek (*Presenter*) Nothing to Disclose

#### PURPOSE

Lutetium-177-PSMA (Lu-PSMA) is an effective treatment for metastatic castration-resistant prostate cancer (mCRPC) patients, even though the immediate side effects that can occur during or right after treatment administration are not heavily investigated. Herein, we aimed to report on all adverse events occurring during or shortly after treatment.

#### METHODS AND MATERIALS

We reviewed 185 patients between April and November 2022. The primary goal of our study is to outline the early side effects reported in the clinical notes, and the secondary goal is to report the emergency room visits and hospitalizations within 30 days following a Lu-PSMA administration. We investigated independent variables in univariable and multivariable logistic regression analyses

#### RESULTS

The median (IQR) age at the time of the first Lu-PSMA cycle was 70 years (67-76), with a median (IQR) PSA of 11.8 ng/ml (2.3-76.4) and an Eastern Cooperative Oncology Group (ECOG) performance status of 0,1,2,3 was 114 (61.6%) 59 (31.9%) 10 (5.4%) 2 (1.1%), respectively. At the time of the first Lu-PSMA cycle, 123 (66.5%) patients had lymph node metastasis, 164 (88.6%) had bone metastasis, and 54 (32.4%) had visceral metastasis, as detected by 68Ga or 18F PSMA-targeted PET/CT. Among known side effects attributed to Lu-PSMA, the most observed during or shortly after therapy were gastrointestinal in origin, including nausea 36 (19.5%), vomiting 36 (19.5%), abdominal pain 17 (9.2%), constipation 16 (8.6%), and diarrhea 9 (4.9%). Other adverse effects included fatigue 54 (29.2%), decreased appetite 15 (8.1%), unintentional weight loss 10 (5.4%), and dry mouth 9 (4.9%). In all, 16 (8.6%) patients had visited the emergency room after receiving Lu-PSMA. Out of those 16 patients, 2 (1.1%) patients were due to anemia and thrombocytopenia, 2 (1.1%) patients had pneumonia, pleural effusion, and acute respiratory failure, 2 (1.1%) patients were due to abdominal pain and vomiting, 2 (1.1%) patients presented with sepsis and septic shock, and one (0.5%) patient was due to intestinal obstruction and perforated appendicitis. Additionally, 2 (1.1%) patients were hospitalized, one (0.5%) due to severe anemia, and the other one (0.5%) due to pathological spinal fracture. A high ECOG performance score was associated with an increased number of emergency department visits ( $p= 0.017$ ) and hospital admissions ( $p= 0.007$ )

#### CONCLUSION

Mild to moderate short-term side effects secondary to treatment with Lu-PSMA are not uncommon, but most patients can be managed in an outpatient setting

#### CLINICAL RELEVANCE/APPLICATION

In the current era of treatment of metastatic castrate-resistant prostate cancer with 177-PSMA Lutetium, we gave the physicians a broad view of the common side effects that we faced from real-world data

### **R6-SSNR16-1 Increased Relative Risk of Delayed Hemorrhage in Patients Taking Anticoagulant and Antiplatelet Medications with Concurrent Aspirin Therapy: Clinical Recommendations Based on Five Year Retrospective Analysis in a Large Health System**

Warren Chang, MD, MBA (*Presenter*) Nothing to Disclose

#### PURPOSE

The incidence of delayed posttraumatic intracranial hemorrhage (DH) in patients on anticoagulant (AC) and antiplatelet (AP) medications, including direct oral anticoagulants (DOACs) is not well defined, especially in patients taking AC/AP agents with concurrent aspirin. Studies have reported disparate results with 1-10% risk of DH and 0-3% mortality and few examined risk of concurrent aspirin. We seek to provide guidelines for clinical management for patients taking AC/AP agents with or without aspirin in the ED (Emergency Department) setting.

#### METHODS AND MATERIALS

1642 patients taking AP and AC agents presenting to network EDs from 2017-2023 with head trauma were included. Repeat CT scans were recommended for patients taking AP/AC medications that had head trauma. Repeat CTs were typically performed within 24 hours (average follow-up was 21 hours and 99% were within 3 days). Average time to DH was 20 hours. Patients with repeat exams were included if their initial CT was read as negative and there was no trauma between the scans. All positive cases were reviewed by two board certified neuroradiologists. Patients were excluded if hemorrhage (ICH) was retrospectively identified on the initial examination. Cases were reclassified as negative if ICH on the follow-up CT was thought to be absent or artifactual. Cases were positive if the initial CT was considered negative and the follow-up CT demonstrated new ICH.

#### RESULTS

There was 1.88% overall incidence (31 cases) of DH and 0.4% overall mortality (6 patients). Patients taking concurrent aspirin had increased risk of DH (RR 5.2, 3.8% vs 0.8%,  $p < 0.001$ ). The group of patients taking warfarin or AP agents demonstrated higher rate of DH (3.6% compared to 0.7%, RR 5.1,  $p < 0.01$ ) and higher mortality (0.9% compared to 0.0%) compared to the DOAC group. There was increased risk in the warfarin/AP group both with and without aspirin therapy (6.0% vs 1.7% with aspirin, 1.5% vs 0.2% without aspirin). Patients taking DOACs had markedly increased risk of DH while taking concurrent aspirin (1.7% vs 0.16%, RR 10.8,  $p < 0.01$ ).

#### CONCLUSION

The risk of DH was increased in patients taking aspirin in addition to AC/AP medications (3.9%, 1 per 26 scans). Repeat imaging should be obtained for patients with head trauma taking AC/AP agents along with aspirin. Repeat examination should be strongly considered on patients taking warfarin or AP agents even without aspirin given moderate risk (1.5% 1/66 scans). Patients taking DOACs alone have low risk of DH (0.16%, 1 / 603 scans) and repeat imaging can be deferred unless patients have external signs of trauma or a dangerous mechanism of injury.

#### CLINICAL RELEVANCE/APPLICATION

Patients taking both AC/AP medications and aspirin have high relative risk of DH and repeat CT scan to evaluate for DH is recommended.

### **R6-SSNR16-2 Soccer Heading Over 2 Years is Associated with Change in Frontal White Matter Microstructure That Varies by Exposure Magnitude**

Lipton, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Repetitive head impacts (RHI) in soccer have been associated with adverse cognitive and neuroimaging outcomes in cross-sectional studies. However, few have reported on the longitudinal effects of soccer RHI on neuroimaging and cognitive performance. The objective of this study was to assess the association of soccer heading over two years with change in brain microstructure and cognitive performance in adult amateur players (n=148, mean age 26.7 years, 25.6% female).

## METHODS AND MATERIALS

Two-year heading exposure was categorized as low (0-556 total headers), moderate (564-1,512 total headers), or high (1,538-23,462 total headers) using the HeadCount-12m questionnaire. Diffusion tensor imaging (3T, 32 encoding directions, b=800 s/mm<sup>2</sup>, 2mm<sup>3</sup> isotropic resolution), neurite orientation dispersion and density imaging (same parameters as above except three shells instead of one: 6 directions at b = 300 s/mm<sup>2</sup>, 32 at b = 800 s/mm<sup>2</sup>, and 60 at b = 2,000 s/mm<sup>2</sup>), and the Cogstate battery were acquired at the initial study visit and two years later. Mixed-effects models accounted for age, concussion history, sex, and education. Significant findings survived false discovery rate of 0.05 (actual p-values 0.001-0.004).

## RESULTS

The high heading exposure group, over two years, demonstrated an increase of mean diffusivity (MD), radial diffusivity (RD), and axial diffusivity (AD) in frontal WM regions, and a decrease of orientation-dispersion index (ODI) in the right superior frontal white matter and superior corona radiata. Low and moderate heading was associated with a decrease of MD, RD, and AD, and increase of ODI over the same period. High heading was associated with decline of verbal learning performance over two years, whereas low and moderate heading exposure was associated with improvement in verbal learning, but these findings did not reach statistical significance.

## CONCLUSION

These results suggest greater heading exposure over two years is associated with adverse effects on white matter microstructure in young adult amateur soccer players. Our results are suggestive of a subclinical effect, given the sub-significant pattern of verbal learning changes. Larger longitudinal studies in diverse cohorts are needed to determine the potential for adverse microstructural and functional change over the longer term to better guide intervention and policy.

## CLINICAL RELEVANCE/APPLICATION

Decline of brain microstructure over 2 years in soccer players who head at high levels, with trends toward decline of cognitive performance, suggests potential subclinical injury, which could affect long-term brain health.

## R6-SSNR16-3 Functional Connectivity Changes Observed Using Resting-State Functional Magnetic Resonance Imaging Following Mild Traumatic Brain Injury: A Systematic Review

Siddhant Dogra, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Mild traumatic brain injury (mTBI) remains a relatively common diagnosis that nevertheless often poses diagnostic and therapeutic challenges. Advanced neuroimaging has been used to great effect over the last decade to characterize post-mTBI neurological changes. In particular, a large number of studies have investigated resting-state functional MRI changes following mTBI, across a diverse set of brain areas and time periods, using a variety of methods. We performed a systematic review to summarize common and discordant findings among the literature.

## METHODS AND MATERIALS

This study was performed as per PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses of Diagnostic Test Accuracy) guidelines. Five databases ("PubMed," "Embase," "Cochrane Central," "Scopus," "Web of Science") were searched for research published since 2010. The search strategy used keywords of "functional magnetic resonance imaging" and "mild traumatic brain injury" as well as related terms. All results were screened at the abstract and title level by four reviewers according to predefined inclusion and exclusion criteria. Two reviewers performed full-text data screening and extraction. The following categories were extracted: article characteristics, cohort demographics, MRI technical parameters, data processing, statistical analysis, and data characteristics.

## RESULTS

Data extraction was performed for 66 studies. On average, these studies included 41.2 subjects (average age 36.6 years, 48% females) in the mTBI group and 32.6 (average age 36.6 years, 45% females) in the control group. The most common analysis method was seed-to-voxel (n=25) followed by independent component analysis (ICA, n=19). 62 studies used 3T tesla MRI scanners. The whole brain (n=28) was the most common subject of analysis followed by the default mode network (n=23). Inconsistent patterns of functional connectivity changes were reported, even when the same method was used to study the same region or network.

## CONCLUSION

Although studies of functional connectivity changes following mTBI have similar patient demographics among mTBI and control groups, there is significant heterogeneity in reported analysis methods, regions and networks of interest, and reported functional connectivity changes.

## CLINICAL RELEVANCE/APPLICATION

We provide a systematic review of the diverse literature regarding functional connectivity changes, observed via resting-state functional MRI, following mild traumatic brain injury. We hope the results highlight unsettled questions and guide further investigation.

### R6-SSNR16-4 **Adverse Association of Soccer Heading with Verbal Learning is Mediated by Microstructure of the Orbitofrontal Gray Matter-White Matter Interface**

Joan Song (*Presenter*) Nothing to Disclose

#### PURPOSE

Repetitive head impacts (RHI) from soccer heading are an integral part of the sport. High RHI exposure is associated with worse verbal learning (VL). Adverse associations of RHI with white matter (WM) microstructure have also been identified using diffusion tensor MRI (DTI). The orbitofrontal region and the gray matter (GM) - WM interface (GWI) are known predilection sites for head impact shear force trauma, but DTI investigations have been restricted to deeper WM regions. Moreover, studies have not yet tested the causal role of imaging findings in the pathway from RHI exposure to worse cognitive function. We tested the mediating role of orbitofrontal GWI microstructure in a known association of RHI with worse VL. We hypothesized the natural sharp transition from high WM fractional anisotropy (FA) to low GM FA is attenuated as a function of RHI and this attenuation mediates the association of RHI with VL.

#### METHODS AND MATERIALS

We analyzed RHI (12-month heading from HeadCount, a validated instrument), DTI (3.0T; 32 directions; b=800; voxel size 2mm<sup>3</sup>) and VL (International Shopping List) from 353 amateur soccer players (18-53, 27% female). To overcome limitations (e.g., misregistration and partial volume effects) we interrogated the transition from low GM FA to high WM FA by computing the slope of FA orthogonal to the GWI (defined by FreeSurfer) over the entire orbitofrontal region, as follows: we binned all orbitofrontal voxels by distance to the GWI and computed average FA within each bin. Average FA was plotted vs. distance to the GWI and fit to a 7th order polynomial. FA slope across the GWI is defined as the maximum slope magnitude of the polynomial fit. To test mediation by GWI microstructure, we fitted linear models to test the associations of (1) RHI with VL, (2) RHI with FA slope and (3) RHI and FA slope with VL, with age and sex as covariates. Mediation by FA slope was calculated as the product of RHI effect size in model (2) and FA slope effect size in model (3). Mediation significance was tested using the Sobel test.

#### RESULTS

We confirmed an association of higher RHI with worse VL ( $p=0.0305$ ). High RHI was associated with lower orbitofrontal GWI FA slope ( $p=0.00745$ ). The orbitofrontal GWI FA slope was a significant mediator ( $p=0.0186$ ) of the association of higher RHI with worse VL.

## CONCLUSION

GWI microstructure integrity in the orbitofrontal region, as quantified by FA slope, mediates the association of RHI with VL. These results support a mechanistic role for juxtacortical white matter in adverse associations of soccer RHI with worse cognitive performance.

## CLINICAL RELEVANCE/APPLICATION

GWI microstructure findings support a causal role in the adverse association of RHI with cognitive performance and may serve as a complementary biomarker of trauma-related brain pathology.

### R6-SSNR16-5 **Identification of Subarachnoid Lymphatic-Like Membranes in Patients with Severe Head Trauma**

Toshiteru Miyasaka, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Recently, subarachnoid lymphatic-like membranes (SLYMs) have been identified, and subarachnoid space (SAS) is subdivided into outer SAS and inner SAS. A traumatic brain injury could bring physical rupture of SLYMs, altering CSF flow patterns. Therefore, we investigated how much abnormal outer SAS is found in severe head trauma patients.

## METHODS AND MATERIALS

Of 63 patients hospitalized for severe head trauma between April 1, 2021, and March 31, 2023, 48 patients were analyzed retrospectively, excluding three patients with significant artifacts and 12 patients who did not have T2-weighted images. The mean age of the patients was 55.6 years (8-89 years), with 18 females and 30 males. The mean GCS on admission was 9.4 points, and the head MRI was taken between 1 and 26 days, averaging 9.4 days after admission. Of the 48 patients, T2WI was taken in transverse and coronal sections except for two patients whose T2WI was taken only in a transverse section, and susceptibility weighted image (SWI) was taken in all patients. On T2WI, membrane-like structures that appear to be accompanied by superficial veins in SAS were assumed to be SLYMs. For patients with disproportionately enlarged outer SAS in the fornix, its thickness was observed in T2WI transverse and coronal sections on the left and right sides, respectively. The thickest part of the outer SAS was measured. MRI, including SWI, was also examined concerning abnormal findings in the brain parenchyma, such as cerebral contusions and diffuse axonal injury (DAI).

## RESULTS

Disproportionate fluid retention of outer SAS was found in 29 unilateral fornices of 18 patients (37.5%). The mean thickness was 5 mm, with a standard deviation of 1.87. Subdural hematomas were found in 13 unilateral fornices of 10 patients (20.8%), and SLYMs could not be identified. Of the 18 patients with abnormal outer SAS, 13 (72.2%) had either cerebral contusion or DAI, or both, and 2 (11.1%) had fat emboli. Thirty patients with no identifiable outer SAS had a cerebral contusion, DAI, or both in 21 patients (70%).

## CONCLUSION

Outer SAS was identified in a low frequency of patients with severe head trauma. There was no correlation between the presence of abnormal outer SAS and cerebral contusion or DAI. 2 patients, a small number, but both patients with fat emboli had abnormal outer SAS. The limitation of this study is that it is challenging to distinguish SLYMs from subdural hematomas.

## CLINICAL RELEVANCE/APPLICATION

The rupture of SLYMs could be associated with the prolonged suppression of glymphatic flow and heightened risk of Alzheimer's disease after traumatic brain injury. It is essential to identify SLYMs by imaging.

## R6-SSNR16-6 Quantitative Volumetry of Ventricles in Association to Clinical Assessment in MTBI

Thomas Knoblauch, MS (*Presenter*) Nothing to Disclose

## PURPOSE

This study aimed to investigate trends in ventricular volume in patients with mild traumatic brain injury (mTBI) and explore clinical associations.

## METHODS AND MATERIALS

We conducted a chart review of clinical and radiological data for a diverse group of 540 patients ( $42 \pm 15$  years; 229 male) with diagnosed mTBI, excluding those with prior head injury or neurological comorbidities. We documented loss of consciousness (LOC) at the time of injury and recorded occurrence and improvement of seven clinical mTBI symptoms (i.e., headache, balance difficulties, cognitive impairment, fatigue, anxiety, depression, and emotional lability) on a survival timeline. A brain MRI protocol with a 3.0T MR scanner sequencing T1, T2, FLAIR, gradient echo imaging, susceptibility weighted imaging, diffusion tensor imaging (DTI), dynamic whole brain perfusion, and functional MRI was performed on each patient. A 3D T1-weighted image (0.93mm x 0.93mm x 1.2mm) was subsequently analyzed using NeuroQuant V.3 software to provide normative percentile volume of ventricles (NPVV) and normalized value of ventricles volume to the intracranial volume (VV). MRI normalcy was defined by the absence of atypical white matter hyperintensities, hippocampal atrophy or asymmetry, abnormal fractional anisotropy in DTI, MR perfusion anomaly, and atypical auditory functional MRI during a word listening task. We conducted t-tests and a machine learning analysis using the random forest algorithm to examine the association between NPVV, VV, and clinical and demographic measures, including age, sex, MRI normalcy, LOC, occurrence and improvement of seven mTBI symptoms, time of examination of the symptoms, time until first reported improvement of any symptoms, and time of MRI scan.

## RESULTS

Female patients had greater NPVV ( $P < 0.0073$ ). The only clinical measure significantly associated with NPVV was MRI normalcy ( $P < 0.00041$ ), with patients with abnormal MRI having significantly larger ventricle volume than those with normal MRI. As expected, age was the top feature ranked by the random forest in the prediction of the VV (%IncMSE = 57.1 and %IncNodePurity = 83.4). The MRI normalcy was ranked second by the random forest regarding '%IncMSE' for the prediction of the VV.

## CONCLUSION

Our study suggests that increased ventricular volumes may be reflective of the underlying neuropathology of disparate imaging abnormalities in head trauma and relate to the associated atrophy of these processes.

## **CLINICAL RELEVANCE/APPLICATION**

This study provides insights into potential diagnostic and clinical applications of quantitative ventricular volume assessment in mTBI. Quantitative volumetric software may assist radiologic interpretation and offer value to the imaging assessment of mTBI subjects.

### Increased Relative Risk of Delayed Hemorrhage in Patients Taking Anticoagulant and Antiplatelet Medications with Concurrent Aspirin Therapy: Clinical Recommendations Based on Five Year Retrospective Analysis in a Large Health System

Thursday, Nov. 30 1:30PM - 2:30PM Room: N229

Warren Chang, MD, MBA (*Presenter*) Nothing to Disclose

#### PURPOSE

The incidence of delayed posttraumatic intracranial hemorrhage (DH) in patients on anticoagulant (AC) and antiplatelet (AP) medications, including direct oral anticoagulants (DOACs) is not well defined, especially in patients taking AC/AP agents with concurrent aspirin. Studies have reported disparate results with 1-10% risk of DH and 0-3% mortality and few examined risk of concurrent aspirin. We seek to provide guidelines for clinical management for patients taking AC/AP agents with or without aspirin in the ED (Emergency Department) setting.

#### METHODS AND MATERIALS

1642 patients taking AP and AC agents presenting to network EDs from 2017-2023 with head trauma were included. Repeat CT scans were recommended for patients taking AP/AC medications that had head trauma. Repeat CTs were typically performed within 24 hours (average follow-up was 21 hours and 99% were within 3 days). Average time to DH was 20 hours. Patients with repeat exams were included if their initial CT was read as negative and there was no trauma between the scans. All positive cases were reviewed by two board certified neuroradiologists. Patients were excluded if hemorrhage (ICH) was retrospectively identified on the initial examination. Cases were reclassified as negative if ICH on the follow-up CT was thought to be absent or artifactual. Cases were positive if the initial CT was considered negative and the follow-up CT demonstrated new ICH.

#### RESULTS

There was 1.88% overall incidence (31 cases) of DH and 0.4% overall mortality (6 patients). Patients taking concurrent aspirin had increased risk of DH (RR 5.2, 3.8% vs 0.8%,  $p < 0.001$ ). The group of patients taking warfarin or AP agents demonstrated higher rate of DH (3.6% compared to 0.7%, RR 5.1,  $p < 0.01$ ) and higher mortality (0.9% compared to 0.0%) compared to the DOAC group. There was increased risk in the warfarin/AP group both with and without aspirin therapy (6.0% vs 1.7% with aspirin, 1.5% vs 0.2% without aspirin). Patients taking DOACs had markedly increased risk of DH while taking concurrent aspirin (1.7% vs 0.16%, RR 10.8,  $p < 0.01$ ).

#### CONCLUSION

The risk of DH was increased in patients taking aspirin in addition to AC/AP medications (3.9%, 1 per 26 scans). Repeat imaging should be obtained for patients with head trauma taking AC/AP agents along with aspirin. Repeat examination should be strongly considered on patients taking warfarin or AP agents even without aspirin given moderate risk (1.5% 1/66 scans). Patients taking DOACs alone have low risk of DH (0.16%, 1 / 603 scans) and repeat imaging can be deferred unless patients have external signs of trauma or a dangerous mechanism of injury.

#### CLINICAL RELEVANCE/APPLICATION

Patients taking both AC/AP medications and aspirin have high relative risk of DH and repeat CT scan to evaluate for DH is recommended.

### Soccer Heading Over 2 Years is Associated with Change in Frontal White Matter Microstructure That Varies by Exposure Magnitude

Thursday, Nov. 30 1:30PM - 2:30PM Room: N229

Michael L. Lipton, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Repetitive head impacts (RHI) in soccer have been associated with adverse cognitive and neuroimaging outcomes in cross-sectional studies. However, few have reported on the longitudinal effects of soccer RHI on neuroimaging and cognitive performance. The objective of this study was to assess the association of soccer heading over two years with change in brain microstructure and cognitive performance in adult amateur players (n=148, mean age 26.7 years, 25.6% female).

#### METHODS AND MATERIALS

Two-year heading exposure was categorized as low (0-556 total headers), moderate (564-1,512 total headers), or high (1,538-23,462 total headers) using the HeadCount-12m questionnaire. Diffusion tensor imaging (3T, 32 encoding directions, b=800 s/mm<sup>2</sup>, 2mm<sup>3</sup> isotropic resolution), neurite orientation dispersion and density imaging (same parameters as above except three shells instead of one: 6 directions at b = 300 s/mm<sup>2</sup>, 32 at b = 800 s/mm<sup>2</sup>, and 60 at b = 2,000 s/mm<sup>2</sup>), and the Cogstate battery were acquired at the initial study visit and two years later. Mixed-effects models accounted for age, concussion history, sex, and education. Significant findings survived false discovery rate of 0.05 (actual p-values 0.001-0.004).

#### RESULTS

The high heading exposure group, over two years, demonstrated an increase of mean diffusivity (MD), radial diffusivity (RD), and axial diffusivity (AD) in frontal WM regions, and a decrease of orientation-dispersion index (ODI) in the right superior frontal white matter and superior corona radiata. Low and moderate heading was associated with a decrease of MD, RD, and AD, and increase of ODI over the same period. High heading was associated with decline of verbal learning performance over two years, whereas low and moderate heading exposure was associated with improvement in verbal learning, but these findings did not reach statistical significance.

#### CONCLUSION

These results suggest greater heading exposure over two years is associated with adverse effects on white matter microstructure in young adult amateur soccer players. Our results are suggestive of a subclinical effect, given the sub-significant pattern of verbal learning changes. Larger longitudinal studies in diverse cohorts are needed to determine the potential for adverse microstructural and functional change over the longer term to better guide intervention and policy.

#### CLINICAL RELEVANCE/APPLICATION

Decline of brain microstructure over 2 years in soccer players who head at high levels, with trends toward decline of cognitive performance, suggests potential subclinical injury, which could affect long-term brain health.

### Functional Connectivity Changes Observed Using Resting-State Functional Magnetic Resonance Imaging Following Mild Traumatic Brain Injury: A Systematic Review

Thursday, Nov. 30 1:30PM - 2:30PM Room: N229

Siddhant Dogra, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Mild traumatic brain injury (mTBI) remains a relatively common diagnosis that nevertheless often poses diagnostic and therapeutic challenges. Advanced neuroimaging has been used to great effect over the last decade to characterize post-mTBI neurological changes. In particular, a large number of studies have investigated resting-state functional MRI changes following mTBI, across a diverse set of brain areas and time periods, using a variety of methods. We performed a systematic review to summarize common and discordant findings among the literature.

#### METHODS AND MATERIALS

This study was performed as per PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses of Diagnostic Test Accuracy) guidelines. Five databases ("PubMed," "Embase," "Cochrane Central," "Scopus," "Web of Science") were searched for research published since 2010. The search strategy used keywords of "functional magnetic resonance imaging" and "mild traumatic brain injury" as well as related terms. All results were screened at the abstract and title level by four reviewers according to predefined inclusion and exclusion criteria. Two reviewers performed full-text data screening and extraction. The following categories were extracted: article characteristics, cohort demographics, MRI technical parameters, data processing, statistical analysis, and data characteristics.

#### RESULTS

Data extraction was performed for 66 studies. On average, these studies included 41.2 subjects (average age 36.6 years, 48% females) in the mTBI group and 32.6 (average age 36.6 years, 45% females) in the control group. The most common analysis method was seed-to-voxel (n=25) followed by independent component analysis (ICA, n=19). 62 studies used 3T tesla MRI scanners. The whole brain (n=28) was the most common subject of analysis followed by the default mode network (n=23). Inconsistent patterns of functional connectivity changes were reported, even when the same method was used to study the same region or network.

#### CONCLUSION

Although studies of functional connectivity changes following mTBI have similar patient demographics among mTBI and control groups, there is significant heterogeneity in reported analysis methods, regions and networks of interest, and reported functional connectivity changes.

#### CLINICAL RELEVANCE/APPLICATION

We provide a systematic review of the diverse literature regarding functional connectivity changes, observed via resting-state functional MRI, following mild traumatic brain injury. We hope the results highlight unsettled questions and guide further investigation.

### Adverse Association of Soccer Heading with Verbal Learning is Mediated by Microstructure of the Orbitofrontal Gray Matter-White Matter Interface

Thursday, Nov. 30 1:30PM - 2:30PM Room: N229

Joan Song (*Presenter*) Nothing to Disclose

#### PURPOSE

Repetitive head impacts (RHI) from soccer heading are an integral part of the sport. High RHI exposure is associated with worse verbal learning (VL). Adverse associations of RHI with white matter (WM) microstructure have also been identified using diffusion tensor MRI (DTI). The orbitofrontal region and the gray matter (GM) - WM interface (GWI) are known predilection sites for head impact shear force trauma, but DTI investigations have been restricted to deeper WM regions. Moreover, studies have not yet tested the causal role of imaging findings in the pathway from RHI exposure to worse cognitive function. We tested the mediating role of orbitofrontal GWI microstructure in a known association of RHI with worse VL. We hypothesized the natural sharp transition from high WM fractional anisotropy (FA) to low GM FA is attenuated as a function of RHI and this attenuation mediates the association of RHI with VL.

#### METHODS AND MATERIALS

We analyzed RHI (12-month heading from HeadCount, a validated instrument), DTI (3.0T; 32 directions; b=800; voxel size 2mm<sup>3</sup>) and VL (International Shopping List) from 353 amateur soccer players (18-53, 27% female). To overcome limitations (e.g., misregistration and partial volume effects) we interrogated the transition from low GM FA to high WM FA by computing the slope of FA orthogonal to the GWI (defined by FreeSurfer) over the entire orbitofrontal region, as follows: we binned all orbitofrontal voxels by distance to the GWI and computed average FA within each bin. Average FA was plotted vs. distance to the GWI and fit to a 7th order polynomial. FA slope across the GWI is defined as the maximum slope magnitude of the polynomial fit. To test mediation by GWI microstructure, we fitted linear models to test the associations of (1) RHI with VL, (2) RHI with FA slope and (3) RHI and FA slope with VL, with age and sex as covariates. Mediation by FA slope was calculated as the product of RHI effect size in model (2) and FA slope effect size in model (3). Mediation significance was tested using the Sobel test.

#### RESULTS

We confirmed an association of higher RHI with worse VL ( $p=0.0305$ ). High RHI was associated with lower orbitofrontal GWI FA slope ( $p= 0.00745$ ). The orbitofrontal GWI FA slope was a significant mediator ( $p= 0.0186$ ) of the association of higher RHI with worse VL.

#### CONCLUSION

GWI microstructure integrity in the orbitofrontal region, as quantified by FA slope, mediates the association of RHI with VL. These results support a mechanistic role for juxtacortical white matter in adverse associations of soccer RHI with worse cognitive performance.

#### CLINICAL RELEVANCE/APPLICATION

GWI microstructure findings support a causal role in the adverse association of RHI with cognitive performance and may serve as a complementary biomarker of trauma-related brain pathology.

### Identification of Subarachnoid Lymphatic-Like Membranes in Patients with Severe Head Trauma

Thursday, Nov. 30 1:30PM - 2:30PM Room: N229

Toshiteru Miyasaka, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Recently, subarachnoid lymphatic-like membranes (SLYMs) have been identified, and subarachnoid space (SAS) is subdivided into outer SAS and inner SAS. A traumatic brain injury could bring physical rupture of SLYMs, altering CSF flow patterns. Therefore, we investigated how much abnormal outer SAS is found in severe head trauma patients.

#### METHODS AND MATERIALS

Of 63 patients hospitalized for severe head trauma between April 1, 2021, and March 31, 2023, 48 patients were analyzed retrospectively, excluding three patients with significant artifacts and 12 patients who did not have T2-weighted images. The mean age of the patients was 55.6 years (8-89 years), with 18 females and 30 males. The mean GCS on admission was 9.4 points, and the head MRI was taken between 1 and 26 days, averaging 9.4 days after admission. Of the 48 patients, T2WI was taken in transverse and coronal sections except for two patients whose T2WI was taken only in a transverse section, and susceptibility weighted image (SWI) was taken in all patients. On T2WI, membrane-like structures that appear to be accompanied by superficial veins in SAS were assumed to be SLYMs. For patients with disproportionately enlarged outer SAS in the fornix, its thickness was observed in T2WI transverse and coronal sections on the left and right sides, respectively. The thickest part of the outer SAS was measured. MRI, including SWI, was also examined concerning abnormal findings in the brain parenchyma, such as cerebral contusions and diffuse axonal injury (DAI).

#### RESULTS

Disproportionate fluid retention of outer SAS was found in 29 unilateral fornices of 18 patients (37.5%). The mean thickness was 5 mm, with a standard deviation of 1.87. Subdural hematomas were found in 13 unilateral fornices of 10 patients (20.8%), and SLYMs could not be identified. Of the 18 patients with abnormal outer SAS, 13 (72.2%) had either cerebral contusion or DAI, or both, and 2 (11.1%) had fat emboli. Thirty patients with no identifiable outer SAS had a cerebral contusion, DAI, or both in 21 patients (70%).

#### CONCLUSION

Outer SAS was identified in a low frequency of patients with severe head trauma. There was no correlation between the presence of abnormal outer SAS and cerebral contusion or DAI. 2 patients, a small number, but both patients with fat emboli had abnormal outer SAS. The limitation of this study is that it is challenging to distinguish SLYMs from subdural hematomas.

#### CLINICAL RELEVANCE/APPLICATION

The rupture of SLYMs could be associated with the prolonged suppression of glymphatic flow and heightened risk of Alzheimer's disease after traumatic brain injury. It is essential to identify SLYMs by imaging.

### Quantitative Volumetry of Ventricles in Association to Clinical Assessment in MTBI

Thursday, Nov. 30 1:30PM - 2:30PM Room: N229

Thomas Knoblauch, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aimed to investigate trends in ventricular volume in patients with mild traumatic brain injury (mTBI) and explore clinical associations.

#### METHODS AND MATERIALS

We conducted a chart review of clinical and radiological data for a diverse group of 540 patients ( $42 \pm 15$  years; 229 male) with diagnosed mTBI, excluding those with prior head injury or neurological comorbidities. We documented loss of consciousness (LOC) at the time of injury and recorded occurrence and improvement of seven clinical mTBI symptoms (i.e., headache, balance difficulties, cognitive impairment, fatigue, anxiety, depression, and emotional lability) on a survival timeline. A brain MRI protocol with a 3.0T MR scanner sequencing T1, T2, FLAIR, gradient echo imaging, susceptibility weighted imaging, diffusion tensor imaging (DTI), dynamic whole brain perfusion, and functional MRI was performed on each patient. A 3D T1-weighted image (0.93mm x 0.93mm x 1.2mm) was subsequently analyzed using NeuroQuant V.3 software to provide normative percentile volume of ventricles (NPVV) and normalized value of ventricles volume to the intracranial volume (VV). MRI normalcy was defined by the absence of atypical white matter hyperintensities, hippocampal atrophy or asymmetry, abnormal fractional anisotropy in DTI, MR perfusion anomaly, and atypical auditory functional MRI during a word listening task. We conducted t-tests and a machine learning analysis using the random forest algorithm to examine the association between NPVV, VV, and clinical and demographic measures, including age, sex, MRI normalcy, LOC, occurrence and improvement of seven mTBI symptoms, time of examination of the symptoms, time until first reported improvement of any symptoms, and time of MRI scan.

#### RESULTS

Female patients had greater NPVV ( $P < 0.0073$ ). The only clinical measure significantly associated with NPVV was MRI normalcy ( $P < 0.00041$ ), with patients with abnormal MRI having significantly larger ventricle volume than those with normal MRI. As expected, age was the top feature ranked by the random forest in the prediction of the VV (%IncMSE = 57.1 and %IncNodePurity = 83.4). The MRI normalcy was ranked second by the random forest regarding '%IncMSE' for the prediction of the VV.

#### CONCLUSION

Our study suggests that increased ventricular volumes may be reflective of the underlying neuropathology of disparate imaging abnormalities in head trauma and relate to the associated atrophy of these processes.

#### CLINICAL RELEVANCE/APPLICATION

This study provides insights into potential diagnostic and clinical applications of quantitative ventricular volume assessment in mTBI. Quantitative volumetric software may assist radiologic interpretation and offer value to the imaging assessment of mTBI subjects.

### R6-SSPD05-1 Neonatal Pulmonary MRI at Term-Equivalent Age for Defining Bronchopulmonary Dysplasia Severity and Its Relationship with Short-Term Respiratory Outcomes

Francesco Rizzetto, MD (*Presenter*) Travel support, Bracco Group

#### PURPOSE

This retrospective study aims to evaluate the potential of neonatal pulmonary magnetic resonance imaging (MRI), using commercially available sequences, to identify and quantify lung parenchymal injury associated with bronchopulmonary dysplasia (BPD) and predict short-term respiratory outcomes.

#### METHODS AND MATERIALS

Pulmonary MRI, using turbo spin echo and gradient echo sequences during natural sleep, was performed in premature infants, including infants with and without a clinical diagnosis of BPD. Lung MRIs were scored independently by two pediatric radiologists and one 4th year radiology resident, using the modified Ochiai scoring system and a new proposed score, the Bronchopulmonary Dysplasia Magnetic Resonance Index (BPDMRI), based on four hyperaeration (hyperexpansion, emphysema, cysts, mosaic pattern) and four parenchymal variables (triangular subpleural opacities, fibrous stripes and bands, edema and atelectasis, distortion of bronchovascular bundles). Both the modified Ochiai score and the BPDMRI were correlated with two short-term respiratory outcomes: the length of mechanical ventilation and the length of any respiratory support until discharge. The BPDMRI was also compared with the clinical definition of BPD between the severity groups. Intra- and inter-reader reproducibility of the BPDMRI were calculated.

#### RESULTS

The study included 25 premature infants (9 no-BPD and 16 BPD subjects). Pulmonary MRI showed a wide variety in appearance of pulmonary parenchyma among BPD patients and revealed significant structural differences across the range of MRI scores. Both the modified Ochiai score and the BPDMRI resulted positively correlated to the length of mechanical ventilation ( $r = 0.828$ ,  $p < 0.001$ ;  $r = 0.900$ ,  $p < 0.001$ ) and the length of any respiratory support until discharge ( $r = 0.897$ ,  $p < 0.001$ ;  $r = 0.953$ ,  $p < 0.001$ ). In the severe disease group, the length of respiratory support showed a smaller IQR when related with the BPDMRI rather than when related with the clinical definition. The BPDMRI had almost perfect intra-reader reproducibility and good inter-reader reproducibility.

#### CONCLUSION

Pulmonary MRI identified and objectively quantified lung parenchymal abnormalities associated with BPD, showing a strong correlation with the length of mechanical ventilation and the length of any respiratory support until discharge.

#### CLINICAL RELEVANCE/APPLICATION

Lung MRI may help identify infants with more serious disease and likely at greater risk for respiratory morbidities better than the severity stratification based on the clinical definition, proving its potential to contribute to a new definition of BPD based on the underlying pulmonary pathology and to predict short-term respiratory outcomes.

### R6-SSPD05-2 Assessment of 3D Hemi-Diaphragmatic Motion via Free-Breathing Dynamic MRI in Pediatric Thoracic Insufficiency Syndrome

Mahdie Hosseini, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Thoracic insufficiency syndrome (TIS) is a condition that affects respiratory function due to spinal and thoracic deformities in pediatric subjects. When progressive deformities limit lung development, reconstructive surgery is performed to promote growth. We present a novel method for the analysis of the 3D motion of each hemi-diaphragm (HD) surface via free-breathing thoracic dynamic magnetic resonance imaging (dMRI) toward understanding lung function, evaluating the effect of surgical intervention, and long-term follow up.

## METHODS AND MATERIALS

In a study of 49 children with TIS who underwent VEPTR surgery and 150 healthy children, we constructed 4D dMRI images from free-breathing dMRI acquisitions and manually delineated the diaphragm at end-expiration (EE) and end-inspiration (EI) time points. We automatically selected 25 points uniformly on each HD surface, obtained their velocities based on their inferior-superior displacements between the EE and EI time points, and derived mean velocities in 13 homologous regions for each HD surface to provide a measure of regional 3D HD motion. We compared between the motion of right HD (RHD) and left HD (LHD) in homologous regions in normal subjects and patients and before and after operation for patients via a paired T-test.

## RESULTS

The normal group comprised of 49.4% males and 50.6% females, while the TIS group had 55.1% males and 44.9% females. The mean age was  $11.7 \pm 3.6$  years for the normal group and  $3.5 \pm 3.5$  and  $5.9 \pm 3.6$  years for the pre-op and post-op TIS subjects, respectively. In the normal group, the RHD exhibited a statistically significantly higher velocity compared to its homologous regions in LHD, and the posterior regions showed higher velocity than other regions in both RHD and LHD. In the TIS group, the velocities were generally significantly lower than in normal subjects, although the velocities generally increased post-operatively, particularly in RHD in posterior, central, and medial regions with statistical significance.

## CONCLUSION

It is feasible to quantify the regional motion of the 3D diaphragm surface in normal subjects and TIS patients via free-breathing dMRI. Using this method, regional motion of the 3D HD surface can be assessed in comparison to normal subjects to study TIS and its corrective surgery.

## CLINICAL RELEVANCE/APPLICATION

The proposed free-breathing 4D dynamic MRI method can be used to quantify the motion of the individual 3D hemi-diaphragm surface to assess deviation from normal and alteration due to corrective surgery in TIS.

## R6-SSPD05-3 Right Atrial Remodeling In Pediatric Patients with Repaired of Tetralogy of Fallot: A CMR Study

Rong-Zhen Ouyang, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

This study aims to evaluate the RA remodeling and atrioventricular interaction in young pediatric patients with repaired tetralogy of Fallot (rTOF) using cardiovascular magnetic resonance imaging (CMR).

## METHODS AND MATERIALS

A total of 146 consecutive pediatric patients with rTOF & 9;(Table 1) who underwent clinically indicated CMR were included and 56 normal controls were recruited as control group according to the inclusion and exclusion criteria. On routine two and four chamber cine images, right atrial (RA) maximum volume (Vmax), passive volume (Vpac), and minimum volume (Vmin) as well as the corresponding ejection fraction (EF), including RA total EF, passive EF, and booster EF, were measured (Figure 1A). CMR biplane feature tracking of RA was performed to derive RA strain, including total strain (es), passive strain (ee) and active strain (ea), and the corresponding strain rate (SRs, SRe, SRa) (Figure 1B). Right atrioventricular coupling index (RAVCI) was & 9;defined for each participant by the ratio between RA volume and RV volume at end-diastole. GLS, GRS and FAC of RA were also derived from CMR feature tracking. Transthoracic echocardiography was performed on the same day to determine right ventricular (RV) diastolic function.

## RESULTS

Patients with rTOF had higher RA volume and lower reservoir, conduit and booster function as well as GLS, GCS and FAC, compared to controls (Table 2). Patients with RV diastolic dysfunction (DD) had larger RA size and lower partial function than patients without RV DD (Table 3). RA Vmax, Vpac and Vmin index were all negatively associated with RA reservoir and conduit function (Figure 1C). RA volumetric data was positively associated with RV end-diastolic volume index (EDVi) and RV end-systolic volume index (ESVi) (Figure 1D). RA SRs and SRa were positively correlated with RV ESVi. The association of parameters between RV diastolic function and RA function were also found. RAVCI increased while LACVI decreased in patients with rTOF. LA Vmax, SV and function were lower in patients than in controls (Table 2).

## CONCLUSION

RA three phasic structure and function demonstrated earlier remodeling than RV diastolic and systolic function impairment. There was atrioventricular interaction between RA and RV and atrial interaction between RA and LA. RA evaluation is clinically important in the management of patients with rTOF.

## CLINICAL RELEVANCE/APPLICATION

This study comprehensively assessed RA structure and function remodeling using CMR in patient with rTOF. RA three phasic volume increased while function impaired, which were prior to remodeling of RV and associated with RV and LA function, highlighting a need for CMR assessment of RA remodeling.

## R6-SSPD05-4 Myocardial Native T1 Mapping in Children with Kawasaki Disease: Correlation with Disease Phase and Coronary Artery Dilation

Shengkun Peng, MD (*Presenter*) Nothing to Disclose

### PURPOSE

To assess myocardial abnormalities using native T1 mapping based on cardiac magnetic resonance (CMR) and investigate their relationship with disease phase and coronary artery (CA) dilation in children with Kawasaki disease (KD).

### METHODS AND MATERIALS

Fifty-eight KD patients in the acute phase group (within 40 days of onset), 72 KD patients in the chronic phase group (onset >40 days, and 40 age- and sex-matched normal controls underwent a 3.0 T CMR examination. Each phase group was subdivided by Coronary Artery (CA) dilation. Z-score of >2 was defined as coronary artery dilation (CA dilation). In the CA dilation group, CA dilation was further stratified (subgroup: mid- to large-size aneurysms,  $2 < Z\text{-score} < 5$ , dilation only and/or small aneurysm Z-score = 5.0). Global, regional (base, middle, and apex), and segments (territory of CA dilation) native T1 values in 16 American Heart Association segmentation were measured and compared among groups.

### RESULTS

The global T1 value of KD patients in acute phase was the highest, followed by that of patients in chronic phase, and the global T1 value of controls was the lowest ( $1404.32 \pm 71.28$  vs  $1376.96 \pm 64.72$  vs  $1304.31 \pm 62.10$  ms,  $P < 0.01$ ). No significant difference in global and segmental native T1 values were observed between KD patients with and without CA dilation in acute and chronic phase, respectively (all  $P > 0.05$ ). No correlation was found between the Z-score and native T1 values of the corresponding coronary territories both in the acute and chronic phase (all  $P > 0.05$ ). Only in the chronic phase, global and segmental (territory of CA) T1 values of KD patients with mid- to large-size aneurysms were higher than that of dilation-only to small aneurysms. After adjusting for clinical characteristics, the multivariate analysis demonstrated that disease phase and age were associated with global T1 in KD patients ( $\beta = -0.223$ ,  $P = 0.007$ ;  $\beta = -0.346$ ,  $P = 0.001$ , model  $R^2 = 0.146$ ). Compared to controls, ROC curves showed the optimal cutoff value of global T1 value was 1369.53 ms (AUC 0.857) in the acute phase and 1344.32 ms (AUC 0.795) in the chronic phase.

## CONCLUSION

Native T1 mapping can quantitatively assess myocardial abnormalities in KD. Myocardial damage in KD patients exists in both acute and chronic phases, and is more severe in the acute phase. Native T1-quantified myocardial injury exists independently of CA dilation in the acute phase.

## CLINICAL RELEVANCE/APPLICATION

Based on these findings, the understanding of the pathogenesis of KD can be further improved.

## R6-SSPD05-5 Evolution of Diffusivity and Anisotropy in the Fetal Brain in the Second and Third Trimesters

Camilo A. Calixto, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Evaluate changes in fractional anisotropy (FA) and mean diffusivity (MD) in the cortical plate (CP) and subcortical white matter (scWM) of fetuses between 23 and 36 weeks of gestational age (GA).

### METHODS AND MATERIALS

Women aged 18-45 years with normal pregnancies were prospectively recruited. Subjects underwent 3T fetal MRI. We acquired DTI using 12 directions and b-values of 0 and 500 s/mm<sup>2</sup>. Each subject had 2-8 acquisitions along orthogonal planes, and data were reconstructed using a motion-tracked slice-to-volume registration algorithm. We used a spatiotemporal DTI atlas of fetal brain as a template for automatic segmentation. This template included labels for CP and scWM, parcellated to pre-frontal, posterior parietal, temporal, and occipital lobes, and motor and sensory cortex. We propagated labels to individual fetuses using a tensor-based registration algorithm and multiple-template-based fusion of probabilistic segmentations (STAPLE). Different models were fitted, and based on the Akaike information criterion, FA was evaluated using

an exponential model and MD using a quadratic one. For each model, we defined a point of change. For FA, this point was set where there was a decrease of less than 2% in two consecutive weeks; for MD, it was the parabola's vertex. Confidence intervals for these estimates were obtained via bootstrapping. We examined differences between hemispheres using a t-test over the bootstrapped samples.

## RESULTS

We included 44 fetuses with median GA of 32.1 weeks (IQR; 30.1, 34.4). FA in all CP and scWM parcellations followed an exponential decay trend. The scWM parcellations of frontal and temporal lobe, cingulum, and sensory cortex had a point of slow decay in FA before 36 weeks of GA. The sensory cortex had the earliest point of slow decay at 32.7 weeks. None of the CP parcellations had a point of slow decay in FA in our study period. We only found differences in points of slow decay between left and right hemispheres in the sensory cortex, cingulum, and temporal lobe scWM parcellations. MD in all CP and scWM parcellation followed a downward opened parabolic trend. Most ROIs showed a peak of MD between 27 and 29 weeks of GA. The sensory cortex had the earliest peak in both CP and aWM. We only found differences in change points between the left and right hemispheres in the motor cortex and cingulum CP parcellations.

## CONCLUSION

Our work utilized motion-corrected DTI to perform the first non-invasive evaluation of microstructural development of the CP and scWM in live fetuses. FA in the CP and scWM follows exponential decay, while MD in the CP and scWM has a parabolic trend.

## CLINICAL RELEVANCE/APPLICATION

These data provide insights into cytoarchitectonic changes at this critical period in human life and could enable earlier detection of abnormalities.

## R6-SSPD05-6 A New Quantitative Approach for Prenatal Diagnosis of Esophageal Atresia on Fetal MRI

Yukiko Michishita, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the diagnostic accuracy of a quantitative index for esophageal atresia (EA), and to calculate cutoff values for fetal MRI to distinguish fetuses with EA from those without, identified by a distended pharynx.

## METHODS AND MATERIALS

From our radiology database, we extracted 32 fetuses diagnosed with suspected EA from radiology reports over the past 20 years. Of these, 20 cases, excluding 12 cases in which esophageal atresia was ruled out after birth, were included [mean GA wks; 33 (range: 29-36), Gross EA classification; type C (n=17) and A (n=3)]. Similarly, 47 fetuses diagnosed as normal on the radiology report were selected for comparison [mean GA wks; 32 (range: 25-38)]. As a conventional qualitative diagnosis, the presence or absence of an esophageal pouch (EP) was determined. The anteroposterior diameters of the pharynx (P) and upper cervical spinal canal (SC) were measured and the P/SC ratio was calculated as a quantitative indicator. Two radiologists performed both evaluations independently based on sagittal images obtained using a bSSFP or SSTSE. We calculated sensitivity and specificity as indicators of the diagnostic performance. The mean P/SC ratio calculated by the two raters was used to compare the P/SC ratio between fetuses with/without EA. The optimal cutoff point of the P/SC ratio, suggesting EA, was analyzed by ROC-AUC, and was subjected to 2000 bootstrap resamples for internal validation. Inter-rater reliability was confirmed by k coefficient for EP and ICC for P/SC ratio. P-values less than 0.05 were considered statistically significant.

## RESULTS

The sensitivity and specificity for EP were 90.0% and 98.9%. The median P/SC ratio in fetuses with EA was 1.2 (IQR: 1.0-1.3) and those without EA was 0.9 (IQR: 0.8-1.1), and the P/SC ratio was significantly higher in fetuses with EA. Estimated cutoff value for EA in our data was 1.1. Analysis of the internal validation cohort yielded the best diagnostic P/SC ratio of 1.1 with AUC of 0.85 (95%CI; 0.73-0.95), sensitivity and specificity of 79.9% and 83.9%, respectively. K coefficient of EP, ICC(2,1) of P/SC ratio was 0.89, 0.95 (95%CI, 0.92-0.97).

## CONCLUSION

Addition of the objective P/SC ratio to the subjective findings (EP) could improve the diagnostic performance of fetal MRI for EA.

## CLINICAL RELEVANCE/APPLICATION

Esophageal pouch is the only direct sign of esophageal atresia, but cannot always be seen. Adding the P/SC ratio, a new quantitative index, to conventional qualitative assessment may improve the fetal diagnosis of esophageal atresia.

### Neonatal Pulmonary MRI at Term-Equivalent Age for Defining Bronchopulmonary Dysplasia Severity and Its Relationship with Short-Term Respiratory Outcomes

Thursday, Nov. 30 1:30PM - 2:30PM Room: N230B

Francesco Rizzetto, MD (*Presenter*) Travel support, Bracco Group

#### PURPOSE

This retrospective study aims to evaluate the potential of neonatal pulmonary magnetic resonance imaging (MRI), using commercially available sequences, to identify and quantify lung parenchymal injury associated with bronchopulmonary dysplasia (BPD) and predict short-term respiratory outcomes.

#### METHODS AND MATERIALS

Pulmonary MRI, using turbo spin echo and gradient echo sequences during natural sleep, was performed in premature infants, including infants with and without a clinical diagnosis of BPD. Lung MRIs were scored independently by two pediatric radiologists and one 4th year radiology resident, using the modified Ochiai scoring system and a new proposed score, the Bronchopulmonary Dysplasia Magnetic Resonance Index (BPDMRI), based on four hyperaeration (hyperexpansion, emphysema, cysts, mosaic pattern) and four parenchymal variables (triangular subpleural opacities, fibrous stripes and bands, edema and atelectasis, distortion of bronchovascular bundles). Both the modified Ochiai score and the BPDMRI were correlated with two short-term respiratory outcomes: the length of mechanical ventilation and the length of any respiratory support until discharge. The BPDMRI was also compared with the clinical definition of BPD between the severity groups. Intra- and inter-reader reproducibility of the BPDMRI were calculated.

#### RESULTS

The study included 25 premature infants (9 no-BPD and 16 BPD subjects). Pulmonary MRI showed a wide variety in appearance of pulmonary parenchyma among BPD patients and revealed significant structural differences across the range of MRI scores. Both the modified Ochiai score and the BPDMRI resulted positively correlated to the length of mechanical ventilation ( $r = 0.828$ ,  $p < 0.001$ ;  $r = 0.900$ ,  $p < 0.001$ ) and the length of any respiratory support until discharge ( $r = 0.897$ ,  $p < 0.001$ ;  $r = 0.953$ ,  $p < 0.001$ ). In the severe disease group, the length of respiratory support showed a smaller IQR when related with the BPDMRI rather than when related with the clinical definition. The BPDMRI had almost perfect intra-reader reproducibility and good inter-reader reproducibility.

#### CONCLUSION

Pulmonary MRI identified and objectively quantified lung parenchymal abnormalities associated with BPD, showing a strong correlation with the length of mechanical ventilation and the length of any respiratory support until discharge.

#### CLINICAL RELEVANCE/APPLICATION

Lung MRI may help identify infants with more serious disease and likely at greater risk for respiratory morbidities better than the severity stratification based on the clinical definition, proving its potential to contribute to a new definition of BPD based on the underlying pulmonary pathology and to predict short-term respiratory outcomes.

### Assessment of 3D Hemi-Diaphragmatic Motion via Free-Breathing Dynamic MRI in Pediatric Thoracic Insufficiency Syndrome

Thursday, Nov. 30 1:30PM - 2:30PM Room: N230B

Mahdie Hosseini, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Thoracic insufficiency syndrome (TIS) is a condition that affects respiratory function due to spinal and thoracic deformities in pediatric subjects. When progressive deformities limit lung development, reconstructive surgery is performed to promote growth. We present a novel method for the analysis of the 3D motion of each hemi-diaphragm (HD) surface via free-breathing thoracic dynamic magnetic resonance imaging (dMRI) toward understanding lung function, evaluating the effect of surgical intervention, and long-term follow up.

#### METHODS AND MATERIALS

In a study of 49 children with TIS who underwent VEPTR surgery and 150 healthy children, we constructed 4D dMRI images from free-breathing dMRI acquisitions and manually delineated the diaphragm at end-expiration (EE) and end-inspiration (EI) time points. We automatically selected 25 points uniformly on each HD surface, obtained their velocities based on their inferior-superior displacements between the EE and EI time points, and derived mean velocities in 13 homologous regions for each HD surface to provide a measure of regional 3D HD motion. We compared between the motion of right HD (RHD) and left HD (LHD) in homologous regions in normal subjects and patients and before and after operation for patients via a paired T-test.

#### RESULTS

The normal group comprised of 49.4% males and 50.6% females, while the TIS group had 55.1% males and 44.9% females. The mean age was  $11.7 \pm 3.6$  years for the normal group and  $3.5 \pm 3.5$  and  $5.9 \pm 3.6$  years for the pre-op and post-op TIS subjects, respectively. In the normal group, the RHD exhibited a statistically significantly higher velocity compared to its homologous regions in LHD, and the posterior regions showed higher velocity than other regions in both RHD and LHD. In the TIS group, the velocities were generally significantly lower than in normal subjects, although the velocities generally increased post-operatively, particularly in RHD in posterior, central, and medial regions with statistical significance.

#### CONCLUSION

It is feasible to quantify the regional motion of the 3D diaphragm surface in normal subjects and TIS patients via free-breathing dMRI. Using this method, regional motion of the 3D HD surface can be assessed in comparison to normal subjects to study TIS and its corrective surgery.

#### CLINICAL RELEVANCE/APPLICATION

The proposed free-breathing 4D dynamic MRI method can be used to quantify the motion of the individual 3D hemi-diaphragm surface to assess deviation from normal and alteration due to corrective surgery in TIS.

### Right Atrial Remodeling In Pediatric Patients with Repaired of Tetralogy of Fallot: A CMR Study

Thursday, Nov. 30 1:30PM - 2:30PM Room: N230B

Rong-Zhen Ouyang, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aims to evaluate the RA remodeling and atrioventricular interaction in young pediatric patients with repaired tetralogy of Fallot (rTOF) using cardiovascular magnetic resonance imaging (CMR).

#### METHODS AND MATERIALS

A total of 146 consecutive pediatric patients with rTOF & 9;(Table 1) who underwent clinically indicated CMR were included and 56 normal controls were recruited as control group according to the inclusion and exclusion criteria. On routine two and four chamber cine images, right atrial (RA) maximum volume (Vmax), passive volume (Vpac), and minimum volume (Vmin) as well as the corresponding ejection fraction (EF), including RA total EF, passive EF, and booster EF, were measured (Figure 1A). CMR biplane feature tracking of RA was performed to derive RA strain, including total strain (es), passive strain (ee) and active strain (ea), and the corresponding strain rate (SRs, SRe, SRa) (Figure 1B). Right atrioventricular coupling index (RAVCI) was & 9;defined for each participant by the ratio between RA volume and RV volume at end-diastole. GLS, GRS and FAC of RA were also derived from CMR feature tracking. Transthoracic echocardiography was performed on the same day to determine right ventricular (RV) diastolic function.

#### RESULTS

Patients with rTOF had higher RA volume and lower reservoir, conduit and booster function as well as GLS, GCS and FAC, compared to controls (Table 2). Patients with RV diastolic dysfunction (DD) had larger RA size and lower partial function than patients without RV DD (Table 3). RA Vmax, Vpac and Vmin index were all negatively associated with RA reservoir and conduit function (Figure 1C). RA volumetric data was positively associated with RV end-diastolic volume index (EDVi) and RV end-systolic volume index (ESVi) (Figure 1D). RA SRs and SRa were positively correlated with RV ESVi. The association of parameters between RV diastolic function and RA function were also found. RAVCI increased while LACVI decreased in patients with rTOF. LA Vmax, SV and function were lower in patients than in controls (Table 2).

#### CONCLUSION

RA three phasic structure and function demonstrated earlier remodeling than RV diastolic and systolic function impairment. There was atrioventricular interaction between RA and RV and atrial interaction between RA and LA. RA evaluation is clinically important in the management of patients with rTOF.

#### CLINICAL RELEVANCE/APPLICATION

This study comprehensively assessed RA structure and function remodeling using CMR in patient with rTOF. RA three phasic volume increased while function impaired, which were prior to remodeling of RV and associated with RV and LA function, highlighting a need for CMR assessment of RA remodeling.

### Myocardial Native T1 Mapping in Children with Kawasaki Disease: Correlation with Disease Phase and Coronary Artery Dilation

Thursday, Nov. 30 1:30PM - 2:30PM Room: N230B

Shengkun Peng, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess myocardial abnormalities using native T1 mapping based on cardiac magnetic resonance (CMR) and investigate their relationship with disease phase and coronary artery (CA) dilation in children with Kawasaki disease (KD).

#### METHODS AND MATERIALS

Fifty-eight KD patients in the acute phase group (within 40 days of onset), 72 KD patients in the chronic phase group (onset>40 days, and 40 age- and sex-matched normal controls underwent a 3.0 T CMR examination. Each phase group was subdivided by Coronary Artery(CA)dilation. Z-score of >2 was defined as coronary artery dilation (CA dilation). In the CA dilation group, CA dilation was further stratified (subgroup: mid- to large-size aneurysms, $2 < Z\text{-score} < 5$ , dilation only and/or small aneurysm  $Z\text{-score} = 5.0$ ). Global, regional (base, middle, and apex), and segments (territory of CA dilation) native T1 values in 16 American Heart Association segmentation were measured and compared among groups.

#### RESULTS

The global T1 value of KD patients in acute phase was the highest, followed by that of patients in chronic phase, and the global T1 value of controls was the lowest ( $1404.32 \pm 71.28$  vs  $1376.96 \pm 64.72$  vs  $1304.31 \pm 62.10$ ms,  $P < 0.01$ ). No significant difference in global and segmental native T1 values were observed between KD patients with and without CA dilation in acute and chronic phase, respectively (all  $P > 0.05$ ). No correlation was found between the Z-score and native T1 values of the corresponding coronary territories both in the acute and chronic phase (all  $P > 0.05$ ). Only in the chronic phase, global and segmental(territory of CA)T1 values of KD patients with mid- to large-size aneurysms were higher than that of dilation-only to small aneurysms. After adjusting for clinical characteristics, the multivariate analysis demonstrated that disease phase and age were associated with global T1 in KD patients ( $\beta = -0.223$ ,  $P = 0.007$ ;  $\beta = -0.346$ ,  $P = 0.001$ , model  $R^2 = 0.146$ ). Compared to controls, ROC curves showed the optimal cutoff value of global T1 value was 1369.53 ms (AUC 0.857) in the acute phase and 1344.32 ms (AUC 0.795) in the chronic phase.

#### CONCLUSION

Native T1 mapping can quantitatively assess myocardial abnormalities in KD. Myocardial damage in KD patients exists in both acute and chronic phases, and is more severe in the acute phase. Native T1-quantified myocardial injury exists independently of CA dilation in the acute phase.

#### CLINICAL RELEVANCE/APPLICATION

Based on these findings, the understanding of the pathogenesis of KD can be further improved.

### Evolution of Diffusivity and Anisotropy in the Fetal Brain in the Second and Third Trimesters

Thursday, Nov. 30 1:30PM - 2:30PM Room: N230B

Camilo A. Calixto, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Evaluate changes in fractional anisotropy (FA) and mean diffusivity (MD) in the cortical plate (CP) and subcortical white matter (scWM) of fetuses between 23 and 36 weeks of gestational age (GA).

#### METHODS AND MATERIALS

Women aged 18-45 years with normal pregnancies were prospectively recruited. Subjects underwent 3T fetal MRI. We acquired DTI using 12 directions and b-values of 0 and 500 s/mm<sup>2</sup>. Each subject had 2-8 acquisitions along orthogonal planes, and data were reconstructed using a motion-tracked slice-to-volume registration algorithm. We used a spatiotemporal DTI atlas of fetal brain as a template for automatic segmentation. This template included labels for CP and scWM, parcellated to pre-frontal, posterior parietal, temporal, and occipital lobes, and motor and sensory cortex. We propagated labels to individual fetuses using a tensor-based registration algorithm and multiple-template-based fusion of probabilistic segmentations (STAPLE). Different models were fitted, and based on the Akaike information criterion, FA was evaluated using an exponential model and MD using a quadratic one. For each model, we defined a point of change. For FA, this point was set where there was a decrease of less than 2% in two consecutive weeks; for MD, it was the parabola's vertex. Confidence intervals for these estimates were obtained via bootstrapping. We examined differences between hemispheres using a t-test over the bootstrapped samples.

#### RESULTS

We included 44 fetuses with median GA of 32.1 weeks (IQR; 30.1, 34.4). FA in all CP and scWM parcellations followed an exponential decay trend. The scWM parcellations of frontal and temporal lobe, cingulum, and sensory cortex had a point of slow decay in FA before 36 weeks of GA. The sensory cortex had the earliest point of slow decay at 32.7 weeks. None of the CP parcellations had a point of slow decay in FA in our study period. We only found differences in points of slow decay between left and right hemispheres in the sensory cortex, cingulum, and temporal lobe scWM parcellations. MD in all CP and scWM parcellation followed a downward opened parabolic trend. Most ROIs showed a peak of MD between 27 and 29 weeks of GA. The sensory cortex had the earliest peak in both CP and scWM. We only found differences in change points between the left and right hemispheres in the motor cortex and cingulum CP parcellations.

#### CONCLUSION

Our work utilized motion-corrected DTI to perform the first non-invasive evaluation of microstructural development of the CP and scWM in live fetuses. FA in the CP and scWM follows exponential decay, while MD in the CP and scWM has a parabolic trend.

#### CLINICAL RELEVANCE/APPLICATION

These data provide insights into cytoarchitectonic changes at this critical period in human life and could enable earlier detection of abnormalities.

### A New Quantitative Approach for Prenatal Diagnosis of Esophageal Atresia on Fetal MRI

Thursday, Nov. 30 1:30PM - 2:30PM Room: N230B

Yukiko Michishita, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the diagnostic accuracy of a quantitative index for esophageal atresia (EA), and to calculate cutoff values for fetal MRI to distinguish fetuses with EA from those without, identified by a distended pharynx.

#### METHODS AND MATERIALS

From our radiology database, we extracted 32 fetuses diagnosed with suspected EA from radiology reports over the past 20 years. Of these, 20 cases, excluding 12 cases in which esophageal atresia was ruled out after birth, were included [mean GA wks; 33 (range: 29-36), Gross EA classification; type C (n=17) and A (n=3)]. Similarly, 47 fetuses diagnosed as normal on the radiology report were selected for comparison [mean GA wks; 32 (range: 25-38)]. As a conventional qualitative diagnosis, the presence or absence of an esophageal pouch (EP) was determined. The anteroposterior diameters of the pharynx (P) and upper cervical spinal canal (SC) were measured and the P/SC ratio was calculated as a quantitative indicator. Two radiologists performed both evaluations independently based on sagittal images obtained using a bSSFP or SSTSE. We calculated sensitivity and specificity as indicators of the diagnostic performance. The mean P/SC ratio calculated by the two raters was used to compare the P/SC ratio between fetuses with/without EA. The optimal cutoff point of the P/SC ratio, suggesting EA, was analyzed by ROC-AUC, and was subjected to 2000 bootstrap resamples for internal validation. Inter-rater reliability was confirmed by k coefficient for EP and ICC for P/SC ratio. P-values less than 0.05 were considered statistically significant.

#### RESULTS

The sensitivity and specificity for EP were 90.0% and 98.9%. The median P/SC ratio in fetuses with EA was 1.2 (IQR: 1.0-1.3) and those without EA was 0.9 (IQR: 0.8-1.1), and the P/SC ratio was significantly higher in fetuses with EA. Estimated cutoff value for EA in our data was 1.1. Analysis of the internal validation cohort yielded the best diagnostic P/SC ratio of 1.1 with AUC of 0.85 (95%CI; 0.73-0.95), sensitivity and specificity of 79.9% and 83.9%, respectively. K coefficient of EP, ICC(2,1) of P/SC ratio was 0.89, 0.95 (95%CI, 0.92-0.97).

#### CONCLUSION

Addition of the objective P/SC ratio to the subjective findings (EP) could improve the diagnostic performance of fetal MRI for EA.

#### CLINICAL RELEVANCE/APPLICATION

Esophageal pouch is the only direct sign of esophageal atresia, but cannot always be seen. Adding the P/SC ratio, a new quantitative index, to conventional qualitative assessment may improve the fetal diagnosis of esophageal atresia.

### R6-SSPH15-1 Cone-beam CT Imaging of Knee Fractures with a Super Short Scan

Dell P. Dunn, MD (*Presenter*) Research Grant, Samsung Electronics Co, Ltd;

#### PURPOSE

Cone-beam CT with flat panel detector is playing an increasingly important role in radiology. To get complete data for theoretically exact image reconstruction, the X-ray source trajectory must be non-planar and the detector wide enough to avoid transaxial data truncation. In practice, such conditions are very constraining: acquiring data on a circular arc is much easier, and data truncation cannot always be avoided depending on scanned anatomy and detector size. Ideally, the circular arc would at least cover 180 degrees plus the fan angle subtended by the region-of-interest, thereby defining a short scan. If the arc length is shorter, the data is only partially complete for theoretically exact reconstruction in the plane of the trajectory. We aim to show that such a super short scan with truncated projection data scan can nevertheless be of strong diagnostic value for knee imaging.

#### METHODS AND MATERIALS

23 patients referred from the Emergency Department with high suspicion for knee fracture were evaluated with super short scans and conventional radiographs (CR). All data were acquired on a twin-robotic X-ray system (Siemens Healthineers, Germany). The geometry of the system limits the scan angle for lying knee acquisitions to 171 degrees, and the data is transaxially truncated as the knee of interest is covered in each view while the other knee moves in and out of the field-of-view during the scan. The data was analyzed in a retrospective study with three radiologists of 1, 4, and 12 years of experience. They rated the 23 sets of images from the super short scans in terms of diagnostic value for inspection of both osseous structures and soft tissue (including effusion, a sign of fracture). They also provided confidence levels for detection of a tibial plateau fracture, of which 5 were present based on an adjudicating reader panel and review of medical records.

#### RESULTS

On a scale of 1 to 4 corresponding to "inadequate, somewhat adequate, adequate, more than adequate", the reader-averaged score of diagnostic value was  $3.39 \pm 0.06$  for inspection of osseous structures and  $3.32 \pm 0.09$  for soft tissue. Reader average AUC for detection of a tibial plateau fracture was 0.96 (80% confidence interval: [0.85, 0.99]), while AUC for detection of a tibial plateau fracture from CR was 0.8 (80% CI: [0.67, 0.89]). Given our paired study design, the difference was statistically significant with a p value of 0.056.

#### CONCLUSION

Despite inherent cone-beam and limited angle artifacts, super short scans of cone-beam data can be of high diagnostic value for evaluation for fracture in the knee.

#### CLINICAL RELEVANCE/APPLICATION

Advanced developments in cone-beam imaging have strong potential to improve patient healthcare through early detection of fractures otherwise missed on conventional radiographs.

### R6-SSPH15-2 The New Kid on the Block: Comparison Between Dynamic Digital Radiography (DDR) with Perfusion Assessment and CT Pulmonary Angiography (CTPA) in Evaluation of Suspected Pulmonary Thromboembolism

Anmol Dhawan, MBBS, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

To evaluate the findings of dynamic digital radiography (DDR) in patients with suspected pulmonary thromboembolism (PTE) and compare them with findings of CT pulmonary angiography (CTPA) in patients with suspected PTE; and to define the role of DDR in patients with suspected or proven PTE.

## **METHODS AND MATERIALS**

Study design: Prospective analytical study. Population: Patients referred to the radiology department for a CTPA study to rule out PTE. Sample size: 24 (currently ongoing). Exclusion criteria: unstable and intubated patients. Equipment used: Shimadzu RadSpeed Pro Radiography System with Konica-Minolta DDR technology, Philips Incisive Pro 128-slice MDCT machine.

## **RESULTS**

This is an interim analysis of an ongoing pilot study. We currently have a comparison of 24 patients who underwent both CT pulmonary angiography (CTPA) and dynamic digital radiography (DDR) studies for evaluation of suspected pulmonary thromboembolism (PTE). We have used both qualitative and quantitative assessment of lung perfusion as provided by the DDR system. The primary quantitative parameter that we have used for assessment is the difference in the percentage share of total perfusion between both lungs, and correlating it with the presence or absence of thromboembolism on a CTPA study. In the interim analysis of our study, we have found a greater mean difference in inter-lung perfusion in patients with PTE (21%) than in patients without PTE (13%). However, a larger sample size is required to determine true statistical significance.

## **CONCLUSION**

To our knowledge, this is the first study comparing dynamic digital radiography (DDR) and CT pulmonary angiography for the assessment of pulmonary thromboembolism (PTE). So far in our study, DDR has shown promising results in evaluation of lung perfusion in patients with suspected pulmonary thromboembolism and may have a role in ruling out PTE and following up patients being treated for PTE. However, a larger sample size is required to determine true statistical significance.

## **CLINICAL RELEVANCE/APPLICATION**

Pulmonary thromboembolism (PTE) is an important cause of mortality in today's world. CT pulmonary angiography (CTPA) remains the gold standard for evaluation of these patients. However, it does have drawbacks such as requirement of intravenous iodinated contrast, significant radiation exposure and higher cost. Dynamic digital radiography (DDR) with perfusion assessment is an upcoming modality to evaluate patients with suspected PTE, and it offers a promising use in circumstances precluding the use of CTPA or for follow-up of patients, limiting exposure to ionizing radiation and iodinated contrast as well as saving cost.

## **R6-SSPH15-3 Quantification of Thoracic Duct Lymphatic Flow using Dynamic Contrast Enhanced CT Lymphangiography**

Sabee Y. Molloy, PhD (*Presenter*) Research Grant, Canon Medical Systems Corporation

## **PURPOSE**

The thoracic duct is the largest lymphatic vessel in the human body and is responsible for draining lymphatic fluid from the lower limbs, abdomen, and thorax. The flow rate of lymphatic fluid through the thoracic duct is an important diagnostic parameter for a variety of medical conditions, including lymphedema, protein losing enteropathy, and heart failure. Currently, there is no reliable method for measuring the thoracic duct lymphatic flow rate. The purpose of this study was to develop and validate a non-invasive method for quantifying the thoracic duct lymphatic flow rate using dynamic contrast enhanced CT lymphangiography.

## **METHODS AND MATERIALS**

Initially an ultrasound flow probe was surgically implanted on the thoracic duct and used as the reference standard. Angiotensin II was infused in a subset of animals to increase the lymphatic flow rate. CT lymphangiography was acquired at 100 kV and 200 mA using a fast-pitched helical scan mode covering the entire thoracic duct following water-soluble iodinated contrast injection into bilateral inguinal lymph nodes. Specifically, two helical scans, acquired at the base and peak contrast enhancement of the thoracic duct, were used to measure CT lymphatic flow rate. Both first pass analysis and thresholding techniques for lymphatic flow measurement using dynamic contrast enhanced CT lymphangiography were validated. CT lymphatic flow measurements were compared to the reference flow probe measurements using regression, root-mean-square error (RMSE) and root-mean-square deviation (RMSD) analysis.

## **RESULTS**

Eleven swine (10 male; mean weight, 43.6±2.6 kg) were evaluated with 71 dynamic CT acquisitions. The lymphatic flow measurement using a first pass analysis (QFPA) and thresholding (QTHR) techniques were related to the reference flow measurements (QREF) by  $QFPA=1.01QREF+0.02$ ,  $r=0.98$ ,  $RMSE=0.13$  mL/min and  $RMSD=0.36$  mL/min and  $QTHR=0.84QREF+0.40$ ,  $r=0.87$ ,  $RMSE=0.28$  mL/min and  $RMSD=0.34$  mL/min.

## CONCLUSION

The study results showed that the first pass analysis and thresholding techniques could be used to accurately quantify lymphatic flow rate using dynamic contrast-enhanced CT lymphangiography. These techniques can potentially be used to noninvasively assess lymphatic flow rate in different disease states affecting the lymphatic system, including lymphedema, protein losing enteropathy, and heart failure.

## CLINICAL RELEVANCE/APPLICATION

This study can potentially provide important information about the flow rate of the thoracic duct in patients with suspected lymphatic abnormalities. The non-invasive method we develop for quantifying the thoracic duct lymphatic flow rate will have significant clinical implications for the diagnosis and treatment of lymphatic disorders.

## R6-SSPH15-4 Spectral Breast Computed Tomography (CT) Based on a CdTe Photon-counting Detector: Quantitative Contrast Imaging

Sabee Y. Molloy, PhD (*Presenter*) Research Grant, Canon Medical Systems Corporation

### PURPOSE

To investigate the feasibility of iodine contrast quantification using dual-energy material decomposition with a dedicated cone beam breast Computed Tomography (CT) system based on a CdTe photon-counting detector in a postmortem breast study.

### METHODS AND MATERIALS

This study was performed with a prototype bench-top breast CT system, consisting of a tungsten target x-ray tube, a rotational platform controlled by a high precision stepper motor, and a prototype CdTe photon-counting 2D array detector. The CdTe energy-resolved detector has a pixel pitch of 75  $\mu\text{m}$  and a matrix size of 2070 by 514. The photon-counting detector has two energy thresholds, which can be used to acquire low and high energy images simultaneously within a single scan. Iodine contrast quantification is achieved through dual-energy material decomposition based on experimental phantom calibrations. Liquid iodine solutions of various iodine concentrations were used in the calibration. A non-linear fitting function was used to determine the iodine decomposition coefficients based on the phantom calibrations. Solid iodine disks, with concentrations ranging from 2 to 20 mg/ml, were inserted into postmortem breast for a validation study. The breast was shaped into a cylindrical shape, approximately 12 cm in diameter, and was imaged using 70 kVp and 114 mAs. The average glandular dose at this setting was estimated to be approximately 6 mGy based on a previously developed breast CT dose simulation package. Iodine signals from the low and high energy images were measured and used to derive the iodine concentrations using the iodine decomposition coefficients obtained in the calibration.

### RESULTS

The measured iodine concentrations from dual-energy material decomposition showed a good linear correlation with the known values (Pearson's  $R = 0.99$ ). The slope and the intercept from the linear fitting were derived to be 1.03 and -0.59 mg/ml, respectively. The root-mean-square (RMS) error and the standard error of estimate (SEE) were determined to be 0.97 mg/ml and 0.89 mg/ml.

## CONCLUSION

The results from this study show the feasibility of accurate iodine quantification in breast contrast imaging using the proposed CdTe photon-counting breast CT at a dose level equivalent to that of a standard two-view mammography.

## CLINICAL RELEVANCE/APPLICATION

The capability of iodine quantification in breast contrast imaging at a clinically relevant dose level with breast CT can significantly improve the predictive power of malignancy in breast cancer diagnosis.

## R6-SSPH15-5 Assessment of Diagnostic Quality of a Low-dose Dynamic CT Myocardial Perfusion Technique in a High-Fat Diet Swine Animal Model

Alireza Shojazadeh, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study was to evaluate the capability of a low-dose single-volume myocardial CT perfusion technique to assess changes in myocardial perfusion and coronary flow reserve (CFR) over the duration of a high-fat diet in a swine animal model.

### METHODS AND MATERIALS

Ten Swine (39.2 kg  $\pm$  11.0) fed a high-fat diet (HFD) between May 2022 and February 2023 were imaged using a 320-slice CT scanner under rest and stress (IV adenosine: 240  $\mu\text{g}/\text{mg}/\text{kg}/\text{min}$ ) conditions at 3, 4, 4.3, 4.7, 4.8 and 5.8 months of HFD. Twenty pairs of repeated CT measurements were made with approximately 10-minute delay between each acquisition under rest and stress conditions. Peripheral injection of contrast (0.5 mL/kg; 370 mgI/mL) and a diluted contrast/saline chaser (0.5

mL/kg; 30:70 contrast/saline) at 5 mL/s was followed by bolus tracking and a single volume scan acquired at the peak of the aortic enhancement (100kVp, 200 mA). Following image acquisition, myocardium segmentation was performed, and a first pass analysis model was used to derive perfusion in mL/min/g using the bolus-tracking and single volume scan data. Subsequently, rest and stress perfusion measurements were used for CFR computation. All volume scans were used for rest perfusion measurement (PREST), and sixteen volume scans were available for stress perfusion measurement (PSTRESS) and CFR computation. Correlation between the HFD duration and changes in both stress-induced myocardial perfusion and CFR were assessed via regression analysis. The CT dose index for the volume scans was also determined.

## RESULTS

Starting at 3 months following HFD, stress-induced myocardial perfusion measurements (PSTRESS) and CFR were correlated to HFD duration (T), as follows:  $PSTRESS = -0.19T + 2.35$  ( $r = -0.99$ ) and  $CFR = -0.25T + 3.04$  ( $r = -0.96$ ). The first (P1) and second (P2) single-volume CT perfusion measurements were related by  $P2 = 0.97 P1 + 0.05$  ( $r = 0.99$ , RMSE = 0.03 mL/min/g). The average CT dose index of the technique was only 7.4 mGy.

## CONCLUSION

A strong negative correlation was found between high-fat diet time duration and both CFR and stress-induced myocardial perfusion measurements using the low-dose single-volume myocardial CT perfusion technique. This technique can potentially assess myocardial perfusion and CFR for early diagnosis of coronary artery disease.

## CLINICAL RELEVANCE/APPLICATION

This low-dose dynamic CT perfusion technique can potentially allow for efficient treatment planning and preventive care as it allows can provide accurate, low-dose physiologic assessment of coronary artery disease.

## R6- SSPH15-6 Impact of a Novel Silicon-based Photon-counting CT Prototype on Plaque Burden, Plaque Composition and Blooming: An ex Vivo Phantom Study

Emma Verelst, MSc (*Presenter*) Nothing to Disclose

## PURPOSE

To characterize vascular plaques with a silicon-based photon-counting CT prototype (Si-PCCT) in comparison with a conventional energy-integrating detector CT (EIDCT) system.

## METHODS AND MATERIALS

Ethical approval was obtained for the use of three human resected and formol-fixed arteries (carotid, femoral and iliac), which were centrally embedded in a cylindrical phantom ( $d = 20$  cm) filled with a 2% agar-water mixture. In one sample (iliac artery), a stainless steel covered stent (Atrium Advanta V12, Atrium Medical Corporation) was introduced. The arteries were filled with an iodine-based contrast solution (15 mg/mL with 0.9% saline). Helical scans were acquired using a prototype Si-PCCT and a conventional EIDCT system (Revolution CT, GE Healthcare) at similar scans parameters (120 kV, 40 mm collimation, 0.9 pitch, 1 s rotation and 17 mGy CTDIvol). Images were reconstructed with a bone kernel and ASIR0, a 15 cm field-of-view (FOV) and a slice thickness of 0.42 mm (Si-PCCT) and 0.63 mm (EIDCT). The plaques were characterized by evaluation of 1) plaque area, 2) area-based plaque burden, and 3) calcified plaque region, i.e. the area with CT-values  $> 1000$  HU. In addition, to evaluate the appearance of the plaque-stent interface, 4) blooming artefacts were quantified as the ratio between inner and outer stent diameter. Differences between Si-PCCT and EIDCT were tested using a paired sample t-test.

## RESULTS

On average, Si-PCCT resulted in 50% smaller plaque areas ( $p = 0.001$ ), a 9.6% reduction in plaque burden ( $p = 0.005$ ), and a 25.7% increase of heavily calcified regions ( $HU > 1000$ ) within plaques ( $p < 0.001$ ), when compared to EIDCT. The evaluation of the stented sample resulted in an average blooming reduction of 27.3% (Si-PCCT:  $34.6\% \pm 2\%$ ; EIDCT:  $61.9\% \pm 6\%$ ;  $p < 0.001$ ).

## CONCLUSION

This study demonstrated an improved spatial resolution of a novel Si-PCCT prototype for the characterization of plaques, based on plaque area, plaque burden, plaque composition and blooming, when compared to EIDCT.

## CLINICAL RELEVANCE/APPLICATION

EIDCT is prone to blooming and beam hardening artefacts, compromising plaque characterization. This study evaluated the impact of a Si-PCCT prototype on plaque characterization using an ex vivo vascular phantom.

### Cone-beam CT Imaging of Knee Fractures with a Super Short Scan

Thursday, Nov. 30 1:30PM - 2:30PM Room: S501

Dell P. Dunn, MD (*Presenter*) Research Grant, Samsung Electronics Co, Ltd;

#### PURPOSE

Cone-beam CT with flat panel detector is playing an increasingly important role in radiology. To get complete data for theoretically exact image reconstruction, the X-ray source trajectory must be non-planar and the detector wide enough to avoid transaxial data truncation. In practice, such conditions are very constraining: acquiring data on a circular arc is much easier, and data truncation cannot always be avoided depending on scanned anatomy and detector size. Ideally, the circular arc would at least cover 180 degrees plus the fan angle subtended by the region-of-interest, thereby defining a short scan. If the arc length is shorter, the data is only partially complete for theoretically exact reconstruction in the plane of the trajectory. We aim to show that such a super short scan with truncated projection data scan can nevertheless be of strong diagnostic value for knee imaging.

#### METHODS AND MATERIALS

23 patients referred from the Emergency Department with high suspicion for knee fracture were evaluated with super short scans and conventional radiographs (CR). All data were acquired on a twin-robotic X-ray system (Siemens Healthineers, Germany). The geometry of the system limits the scan angle for lying knee acquisitions to 171 degrees, and the data is transaxially truncated as the knee of interest is covered in each view while the other knee moves in and out of the field-of-view during the scan. The data was analyzed in a retrospective study with three radiologists of 1, 4, and 12 years of experience. They rated the 23 sets of images from the super short scans in terms of diagnostic value for inspection of both osseous structures and soft tissue (including effusion, a sign of fracture). They also provided confidence levels for detection of a tibial plateau fracture, of which 5 were present based on an adjudicating reader panel and review of medical records.

#### RESULTS

On a scale of 1 to 4 corresponding to "inadequate, somewhat adequate, adequate, more than adequate", the reader-averaged score of diagnostic value was  $3.39 \pm 0.06$  for inspection of osseous structures and  $3.32 \pm 0.09$  for soft tissue. Reader average AUC for detection of a tibial plateau fracture was 0.96 (80% confidence interval: [0.85, 0.99]), while AUC for detection of a tibial plateau fracture from CR was 0.8 (80% CI: [0.67,0.89]). Given our paired study design, the difference was statistically significant with a p value of 0.056.

#### CONCLUSION

Despite inherent cone-beam and limited angle artifacts, super short scans of cone-beam data can be of high diagnostic value for evaluation for fracture in the knee.

#### CLINICAL RELEVANCE/APPLICATION

Advanced developments in cone-beam imaging have strong potential to improve patient healthcare through early detection of fractures otherwise missed on conventional radiographs.

### Assessment of Diagnostic Quality of a Low-dose Dynamic CT Myocardial Perfusion Technique in a High-Fat Diet Swine Animal Model

Thursday, Nov. 30 1:30PM - 2:30PM Room: S501

Alireza Shojazadeh, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to evaluate the capability of a low-dose single-volume myocardial CT perfusion technique to assess changes in myocardial perfusion and coronary flow reserve (CFR) over the duration of a high-fat diet in a swine animal model.

#### METHODS AND MATERIALS

Ten Swine (39.2 kg  $\pm$  11.0) fed a high-fat diet (HFD) between May 2022 and February 2023 were imaged using a 320-slice CT scanner under rest and stress (IV adenosine: 240  $\mu$ g/mg/kg/min) conditions at 3, 4, 4.3, 4.7, 4.8 and 5.8 months of HFD. Twenty pairs of repeated CT measurements were made with approximately 10-minute delay between each acquisition under rest and stress conditions. Peripheral injection of contrast (0.5 mL/kg; 370 mgI/mL) and a diluted contrast/saline chaser (0.5 mL/kg; 30:70 contrast/saline) at 5 mL/s was followed by bolus tracking and a single volume scan acquired at the peak of the aortic enhancement (100kVp, 200 mA). Following image acquisition, myocardium segmentation was performed, and a first pass analysis model was used to derive perfusion in mL/min/g using the bolus-tracking and single volume scan data. Subsequently, rest and stress perfusion measurements were used for CFR computation. All volume scans were used for rest perfusion measurement (PREST), and sixteen volume scans were available for stress perfusion measurement (PSTRESS) and CFR computation. Correlation between the HFD duration and changes in both stress-induced myocardial perfusion and CFR were assessed via regression analysis. The CT dose index for the volume scans was also determined.

#### RESULTS

Starting at 3 months following HFD, stress-induced myocardial perfusion measurements (PSTRESS) and CFR were correlated to HFD duration (T), as follows:  $PSTRESS = -0.19T + 2.35$  ( $r = -0.99$ ) and  $CFR = -0.25T + 3.04$  ( $r = -0.96$ ). The first (P1) and second (P2) single-volume CT perfusion measurements were related by  $P2 = 0.97 P1 + 0.05$  ( $r = 0.99$ , RMSE = 0.03 mL/min/g). The average CT dose index of the technique was only 7.4 mGy.

#### CONCLUSION

A strong negative correlation was found between high-fat diet time duration and both CFR and stress-induced myocardial perfusion measurements using the low-dose single-volume myocardial CT perfusion technique. This technique can potentially assess myocardial perfusion and CFR for early diagnosis of coronary artery disease.

#### CLINICAL RELEVANCE/APPLICATION

This low-dose dynamic CT perfusion technique can potentially allow for efficient treatment planning and preventive care as it allows can provide accurate, low-dose physiologic assessment of coronary artery disease.

### Impact of a Novel Silicon-based Photon-counting CT Prototype on Plaque Burden, Plaque Composition and Blooming: An ex Vivo Phantom Study

Thursday, Nov. 30 1:30PM - 2:30PM Room: S501

Emma Verelst, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

To characterize vascular plaques with a silicon-based photon-counting CT prototype (Si-PCCT) in comparison with a conventional energy-integrating detector CT (EIDCT) system.

#### METHODS AND MATERIALS

Ethical approval was obtained for the use of three human resected and formol-fixated arteries (carotid, femoral and iliac), which were centrally embedded in a cylindrical phantom (d = 20 cm) filled with a 2% agar-water mixture. In one sample (iliac artery), a stainless steel covered stent (Atrium Advanta V12, Atrium Medical Corporation) was introduced. The arteries were filled with an iodine-based contrast solution (15 mg/mL with 0.9% saline). Helical scans were acquired using a prototype Si-PCCT and a conventional EIDCT system (Revolution CT, GE Healthcare) at similar scans parameters (120 kV, 40 mm collimation, 0.9 pitch, 1 s rotation and 17 mGy CTDIvol). Images were reconstructed with a bone kernel and ASIR0, a 15 cm field-of-view (FOV) and a slice thickness of 0.42 mm (Si-PCCT) and 0.63 mm (EIDCT). The plaques were characterized by evaluation of 1) plaque area, 2) area-based plaque burden, and 3) calcified plaque region, i.e. the area with CT-values > 1000 HU. In addition, to evaluate the appearance of the plaque-stent interface, 4) blooming artefacts were quantified as the ratio between inner and outer stent diameter. Differences between Si-PCCT and EIDCT were tested using a paired sample t-test.

#### RESULTS

On average, Si-PCCT resulted in 50% smaller plaque areas ( $p = 0.001$ ), a 9.6% reduction in plaque burden ( $p = 0.005$ ), and a 25.7% increase of heavily calcified regions (HU > 1000) within plaques ( $p < 0.001$ ), when compared to EIDCT. The evaluation of the stented sample resulted in an average blooming reduction of 27.3% (Si-PCCT: 34.6%  $\pm$  2%; EIDCT: 61.9%  $\pm$  6%;  $p < 0.001$ ).

#### CONCLUSION

This study demonstrated an improved spatial resolution of a novel Si-PCCT prototype for the characterization of plaques, based on plaque area, plaque burden, plaque composition and blooming, when compared to EIDCT.

#### CLINICAL RELEVANCE/APPLICATION

EIDCT is prone to blooming and beam hardening artefacts, compromising plaque characterization. This study evaluated the impact of a Si-PCCT prototype on plaque characterization using an ex vivo vascular phantom.

#### PURPOSE

Large language models (LLMs) have recently become popular for general-purpose use and are helpful for various tasks, including patient support. In this study, we present the PromptWise (Prompt engineering for Well-structured, Interactive, and Supportive Education) paradigm to focus on the applications of LLMs specifically in patient education, and explore how prompt engineering can improve patient interactions with LLMs for medical education. By crafting specific and context-rich prompts, patients can receive more accurate and relevant information, enhancing their understanding of medical conditions and facilitating better decision-making.

#### METHODS AND MATERIALS

Our study focuses on the development of a prompt engineering guideline (PromptWise) and the assessment of 25 paired radiology prompt scenarios. The PromptWise guidelines were derived through input from medical experts, a literature review, and iterative refinement. Each scenario featured a pair of prompts asking the same radiology-related query, with one prompt constructed following our PromptWise guidelines and the other not. Scenarios were focused on medical education and not clinical decision-making. Patient education aims to empower patients to be more involved in their condition or diagnosis by helping them make more informed decisions regarding their health. The responses generated by the LLM (OpenAI's GPT3.5) were recorded systematically for each pair. This data collection process facilitates a comprehensive analysis of the LLM's performance based on the varying prompt quality and development.

#### RESULTS

We developed six key pointers for the PromptWise guidelines and assessed them using 25 paired radiology prompt scenarios. The results demonstrate the tangible impact of prompt engineering on patient-LLM interactions. Prompts following our guidelines yielded accurate and relevant responses from the LLM (GPT3.5). In contrast, inconsistent prompts, which lacked essential details, led to inaccurate or irrelevant responses. The findings underline the potential of prompt engineering to enhance patient education and improve medical decision-making.

#### CONCLUSION

PromptWise will transform patient-LLM interactions by crafting specific, context-rich prompts; patients can receive accurate and relevant information, leading to an improved understanding of medical conditions, better decision-making, and increased patient empowerment. Well-structured prompts also reduce the risk of misinformation, support medical professionals, and offer tailored healthcare guidance.

#### CLINICAL RELEVANCE/APPLICATION

PromptWise guidelines will enable patients to access information, bridge knowledge gaps efficiently, and actively participate in their healthcare.

### **PromptWise: Introducing Prompt Engineering Paradigm for Enhanced Patient-Large Language Model Interactions Towards Medical Education**

Thursday, Nov. 30 1:30PM - 2:00PM Room: Learning Center Theater 1

Satvik Tripathi (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Large language models (LLMs) have recently become popular for general-purpose use and are helpful for various tasks, including patient support. In this study, we present the PromptWise (Prompt engineering for Well-structured, Interactive, and Supportive Education) paradigm to focus on the applications of LLMs specifically in patient education, and explore how prompt engineering can improve patient interactions with LLMs for medical education. By crafting specific and context-rich prompts, patients can receive more accurate and relevant information, enhancing their understanding of medical conditions and facilitating better decision-making.

#### **METHODS AND MATERIALS**

Our study focuses on the development of a prompt engineering guideline (PromptWise) and the assessment of 25 paired radiology prompt scenarios. The PromptWise guidelines were derived through input from medical experts, a literature review, and iterative refinement. Each scenario featured a pair of prompts asking the same radiology-related query, with one prompt constructed following our PromptWise guidelines and the other not. Scenarios were focused on medical education and not clinical decision-making. Patient education aims to empower patients to be more involved in their condition or diagnosis by helping them make more informed decisions regarding their health. The responses generated by the LLM (OpenAI's GPT3.5) were recorded systematically for each pair. This data collection process facilitates a comprehensive analysis of the LLM's performance based on the varying prompt quality and development.

#### **RESULTS**

#### Sub-Events

#### R6-STCE2-1 Artificial Intelligence Enabled Acceleration Reduces the Carbon Footprint of MRI

Sean A. Woolen, MD, MS (*Presenter*) Research Grant, Siemens AG; Investigator, Siemens AG

##### PURPOSE

Deep learning (DL) powered MRI acceleration algorithms enable practices to reduce scanning time while reducing noise, keeping the same resolution, and preserving image quality. Our objective was to assess the potential energy, cost, and carbon savings resulting from DL acceleration.

##### METHODS AND MATERIALS

In this retrospective evaluation, an MRI was equipped with a power meter (1-Hz sampling rate). A phantom was scanned using traditional acquisition and a single vendor technique for DL acceleration for MRI head, cervical spine, and knee. Power measurement logs were extracted for exams. Data were segmented into individual sequences and total sequence energy consumption. Energy, time, cost (assuming a mean cost of \$0.14 per kilowatt hour), and carbon savings were calculated for the DL acceleration model. The projected annual savings were calculated using current procedure terminology codes for 2022 studies at a single institution. Data were summarized using descriptive statistics.

##### RESULTS

The standard protocol energy and duration for active scanning ranged from 5.3-9.3 kWh and 9.3-13.8 min. Compared to the standard protocols, DL acceleration reduced active scan time for brain MRI by 3.9 min (-41.8%), cervical spine MRI by 6.3 min (-45.7%), and knee MRI by 8.2 min (-66.3%). The decreased time resulted in 36.4% to 67.7% lower energy consumption between the protocols, translating to MRI exam savings ranging from 2.0-6.3 kWh, \$0.28-\$0.88, and 1.4-4.5 kilograms of carbon dioxide equivalent (Kg CO<sub>2</sub>eq). Applying these results to our institution's annual imaging volume, DL acceleration would save 31,362 kWh, \$4,391, and 22,226 Kg CO<sub>2</sub>eq for brain MRI; 9,240 kWh, \$1,294, and 6,548 Kg CO<sub>2</sub>eq for cervical spine MRI; and 7,812 kWh, \$1,094, and 5,536 Kg CO<sub>2</sub> eq for knee MRI.

##### CONCLUSION

Accelerated protocols using DL acceleration can result in more sustainable, energy-efficient, faster and lower cost MRI.

##### CLINICAL RELEVANCE/APPLICATION

It is crucial for radiologists and scientists to understand how deep learning acceleration can serve to mitigate energy consumption in medical imaging. This data will help institutions make informed decisions regarding Radiology operations and develop strategies to maximize the positive contributions of new acceleration methods.

#### R6-STCE2-2 Abbreviated MRI for Hepatocellular Carcinoma Screening Reduces Carbon Footprint

Sean A. Woolen, MD, MS (*Presenter*) Research Grant, Siemens AG; Investigator, Siemens AG

##### PURPOSE

Abbreviated MRI for hepatocellular carcinoma (HCC) screening enables practices to reduce scanning time while maintaining high sensitivity and specificity for early-stage cancer. We aimed to assess the potential energy, cost, time, and carbon savings resulting from an abbreviated MRI HCC screening exam with dynamic extracellular gadolinium-based contrast media.

##### METHODS AND MATERIALS

This is an IRB-approved retrospective single-center energy and time study. Inclusion criteria were hepatocellular carcinoma screening patients with an MRI. Exclusion criteria were studies with MRCP, Eovist, or pelvic imaging and incomplete studies.

Ten prospective observations were performed to determine differences between HCC screening exams. MRIs were equipped with a power meter (1-Hz sampling rate). Power measurement logs were extracted for a phantom and five patient exams for the abbreviated and full HCC screening protocol. Energy, time, cost (assuming a mean cost of \$0.14 per kilowatt hour), and carbon savings were calculated for the abbreviated HCC screening protocol. Exam duration for the larger dataset from November 2019 to June 2021 was extracted for 318 abbreviated MRIs and 169 full MRI screening studies. DICOM header data of total times were extracted using Quantivly. Mean full and abbreviated protocol times were assessed with a Welch's t-test. Energy data were summarized using descriptive statistics.

## **RESULTS**

The process map revealed the only differences between the full and abbreviated MRI exams were the study duration and energy consumption. The duration for the abbreviated protocol was 12.0 min +/- 4.3 min, compared with 29.7 +/- 8.8 min (mean +/- SD) for the full protocol (difference, 17.7 min; P < 0.0001). The study durations for the power-metered exams were similar to the times extracted from the DICOM files. The decreased study duration from the abbreviated protocol resulted in a 60.6% decrease in energy consumption, translating to MRI exam savings of 7.7 kWh, \$1.08, and 5.5 Kg CO<sub>2</sub>eq. Applying these results to the 318 abbreviated exams performed from Nov 2019 to June 2021 at our institution estimates a saving of 2,448.6 kWh, \$343.44, and 1,749 Kg CO<sub>2</sub>eq compared to the full protocol.

## **CONCLUSION**

Abbreviated protocols for hepatocellular screening can result in more sustainable, energy-efficient, faster, and lower-cost MRI. The amount of energy savings is nearly identical to time savings.

## **CLINICAL RELEVANCE/APPLICATION**

Radiology policymakers must understand the benefits of abbreviated versus full protocol for hepatocellular screening. This data will help institutions make informed decisions to optimize their radiology operations and policies.

## **R6-STCE2-3 Comparison of the carbon footprint of CT and wide-angle tomosynthesis**

Alan H. Zhao, BS (*Presenter*) Nothing to Disclose

## **PURPOSE**

Carbon emissions are a significant contributor to global climate changes. As a result, there is a need for a low carbon footprint, efficacious imaging method. The wide-angle carbon nanotube x-ray enabled stationary digital chest tomosynthesis system has unique traits that may make it a more sustainable and energy efficient imaging modality than computerized tomography (CT).

## **METHODS AND MATERIALS**

We reviewed the power usage of CT from multiple studies and compared them to our measured power usage of our wide-angle tomosynthesis system.

## **RESULTS**

A 2020 Swiss study found that a CT scanner that scanned 7904 patients over 1 year found that the CT scanner used 26226 kWh in total (active + idle/off time). This is comparable to 5 Swiss households of 4 people. Each scan required 3.32 kWh or 1.4 kg of CO<sub>2</sub> emissions equivalent. A 2022 Australian study found similar results, with each scan requiring 3.72 kWh or 1.6 kg of CO<sub>2</sub> emissions equivalent (active + idle/off time). For the wide-angle tomosynthesis system, each scan requires 0.005 kWh during active scan time or 0.002 kg of CO<sub>2</sub> emissions equivalent. Assuming an annual CT scan load of 7904 patients, the wide-angle tomosynthesis system requires 1000 kWh (active + idle/off time).

## **CONCLUSION**

For each active scan, the wide-angle tomosynthesis system requires 4% electricity. Using an average of 3.52 kWh per CT scan of the two studies and assuming an annual CT scan load of 7904 patients, the total CO<sub>2</sub> emissions equivalent saved is comparable to 2.4 years of an average gasoline-powered car. Alternatively, it is equivalent to the carbon sequestered by 13 acres of forest in one year. These energy savings are due to the fact that the wide-angle tomosynthesis system requires much less electricity and therefore has a lower carbon footprint than CT. To maximize imaging acquisition speed, CT machines are often placed in standby for hours at a time, increasing their electricity demands, especially as gantry rotation is maintained. The wide-angle tomosynthesis system does not require these high load standby periods and can be utilized to replace CT scans when clinically appropriate, such as lung nodule screening, calcium scoring and fracture evaluation.

## **CLINICAL RELEVANCE/APPLICATION**

Given the need to reduce carbon emissions, low carbon footprint imaging methods are necessary. The stationary digital tomosynthesis system has a lower carbon footprint than that of CT.

### Science Session (Theranostics)

Thursday, Nov. 30 2:30PM - 3:00PM Room: Learning Center Theater 1

#### Sub-Events

### R7-STCE1-3 Deciphering the Disruption of Abnormal Functional Gradient Distribution and Brain Network Connectivity Decoupling in Spinocerebellar Ataxia Type 3

Heiko Meyer (*Presenter*) Employee, Siemens AG

#### PURPOSE

Purpose: To explore the functional and structural connectivity changes in the cerebellum and cerebrum in spinocerebellar ataxia type 3 (SCA3) patients,<sup>1</sup> using a novel gradient-based resting-state functional connectivity (FC) analysis approach and to examine their relationships with clinical factors as well as to identify potential therapeutic targets and theoretical foundations for SCA3 intervention

#### METHODS AND MATERIALS

We recruited 51 SCA3 patients and 59 healthy controls who underwent T1-MPRAGE, resting-state fMRI and diffusion tensor imaging (DTI) examination. We computed the FC gradients in the cerebellum and cerebrum to map the functional hierarchy from sensorimotor to supramodal regions. We also performed coupling analysis of FC and structural connectivity (SC) among regions of interest (ROIs) in the brain. We then correlated the quantitative values of ROIs with clinical variables such as CAG repeats, disease duration, ataxia scales, and cognitive tests.

#### RESULTS

SCA3 patients showed compression of the primary sensory-motor and supramodal gradient, indicating a loss of functional differentiation and integration in the cerebellum and cerebrum. They also exhibited disruption in the coupling of FC and SC, suggesting impaired communication between brain regions. Moreover, we found that FC gradient values in right calcarine were negatively associated with CAG repeats, ataxia severity, and cognitive impairment; FC values in left cerebellum crus I and right cerebellum crus II were positively associated with disease duration and verbal memory.

#### CONCLUSION

These findings propose a possible mechanism involving gradient abnormalities that explains the co-occurrence and interaction of low-level and high-level functional abnormalities in SCA3. On the other hand, the clarification of the pathophysiological significance of connectivity abnormalities in SCA3 hinges on a more comprehensive comprehension of how network architecture shapes and restricts functional processes.

#### CLINICAL RELEVANCE/APPLICATION

Our findings suggest that FC gradient analysis is a potential biomarker for SCA3 diagnosis and treatment evaluation.

Printed on: 08/22/24

#### R7-STCE2-1 Large language model improves detection of negated expressions in radiology reports

Yvonne Su, BA (*Presenter*) Nothing to Disclose

##### PURPOSE

Named-entity recognition (NER) and negation detection are crucial to extract structured information from unstructured text. The extracted information can provide meaningful insights for clinical decision-making, patient care, and medical research. Large Language Models (LLMs), such as the Bidirectional Encoder Representations from Transformers (BERT), may improve understanding of text. This study compared the ability of a rule-based NLP system and an LLM—both trained for the medical domain—to correctly detect negated concepts in radiology reports.

##### METHODS AND MATERIALS

This HIPAA-compliant, IRB-approved study used a convenience sample of 1000 consecutive de-identified radiology reports from a large U.S.-based academic health system. Duplicate reports were excluded to yield the study cohort of 984 reports. The rule-based medspaCy system was applied to identify terms in the report text corpus from RadLex, the Unified Medical Language System (UMLS), and the Radiology Gamuts Ontology. An LLM, the Clinical Assertion and Negation Classification BERT (CAN-BERT), had been trained using MIMIC III and patient data from the i2b2/VA challenge. We compared medspaCy and CAN-BERT to detect negations of the identified entities. Power analysis determined a sample size of 382 pairs to achieve  $\alpha=0.05$ ,  $\beta=0.8$  for McNemar's test; based on 15% negated terms, 2800 randomly selected terms were annotated manually as affirmative or negative. The two models were compared with ground-truth annotations using McNemar's test. Precision, recall, and F1 were computed.

##### RESULTS

Of the 2800 terms, 387 (13.8%) were negated. For negation detection, medspaCy attained recall of 0.795, precision of 0.356, and F1 of 0.492. CAN-BERT achieved recall of 0.785, precision of 0.768, and F1 of 0.777. Although the models' recall was not significantly different, CAN-BERT had significantly better precision ( $\chi^2 = 304.64$ ;  $p < 0.001$ ).

##### CONCLUSION

The CAN-BERT LLM detected negated terms in radiology reports with high precision and recall; its precision significantly exceeded that of a rule-based system.

##### CLINICAL RELEVANCE/APPLICATION

Detection of negated expressions is crucial to accurately annotate radiology reports to: (1) improve training of image-based AI models and (2) enable discovery of causal relationships among diseases and findings in radiology reports.

#### R7-STCE2-2 Glioblastoma Monitoring using GPT-4 for Summarization of Radiological Reports

Robert Terzis, MD (*Presenter*) Nothing to Disclose

##### PURPOSE

Disease monitoring in patients with glioblastoma typically involves numerous consecutive cranial MRI scans, making the longitudinal evaluation of these patients a complex and resource-intensive task. The advent of large language models (LLMs) presents an opportunity to facilitate physician support by summarizing radiological results and disease tracking data. The purpose of this study was to evaluate this possibility, particularly focusing on the capacity of LLMs to extract meaningful information from complex textual input.

## METHODS AND MATERIALS

We retrospectively included 225 MRI examinations from 45 patients with biopsy-confirmed glioblastoma who were treated at our institution. The large language model, GPT-4, was supplied with the five most recent MRI reports, including clinical information in text form. The model's task was to synthesize the disease course, present the current state, and produce the R-code for a suitable graphic representation. Summaries generated by GPT-4 were evaluated by two experts in neuro-oncology with >20 and >8 years of experience, respectively. The evaluation categories included: (1) accuracy and logical-semantic representation, determined by assessing four distinct items on a binomial scale of "yes" or "no"; (2) overall quality; and (3) utility in patient monitoring and clinical decision-making, assessed using a 5-point Likert scale, with higher scores indicating more favorable results.

## RESULTS

The summaries derived from GPT-4 aligned with expert consensus about the disease course 86.7% of the time. GPT-4's disease course summaries received a median score of 4 in terms of quality and were perceived to have a median utility score of 3.

## CONCLUSION

GPT-4 efficiently summarized the course of the disease and pinpointed essential events with considerable accuracy, quality, and relevant usefulness for treating physicians.

## CLINICAL RELEVANCE/APPLICATION

Our results underline the potential of large language models for radiological and medical workflow optimization.

## R7-STCE2-3 Adapting Large Language Models for Personalized Impression Generation in PET reports: Expert Evaluation

Xin Tie, MS (*Presenter*) Nothing to Disclose

## PURPOSE

While large language models (LLMs) have been used in generating impressions for X-ray, CT, and MRI reports, adapting them for whole-body PET reports introduces new challenges: (1) the lengthy and complex PET findings, and (2) the necessity for impressions to be tailored to each physician's reporting style. In this study, we evaluated the performance of an LLM in generating personalized impressions for PET reports and identified remaining performance gaps.

## METHODS AND MATERIALS

In previous work, we developed a PEGASUS-based LLM on a corpus of 37,590 whole-body PET reports. The model, trained to generate impressions in the styles of different dictating physicians, outperformed 11 other state-of-the-art LLMs, including LLaMA and GPT2. In this work, we performed a reader study to evaluate different aspects of the model's performance. Three nuclear medicine physicians independently reviewed a total of 72 PET reports along with model-generated impressions. Each physician assessed 12 impressions originally dictated by themselves and generated in their own style, and 12 impressions dictated by other physicians; readers were blinded to dictating physicians during this assessment. These impressions were evaluated on 6 quality dimensions (3-point scale) and an overall utility score (5-point scale). The quality categories comprised (1) unnecessary additions; (2) important omissions; (3) factual correctness; (4) clarity and organization; (5) appropriate interpretations; and (6) valid recommendations for patient management. The overall utility score gauged the extent of changes needed to render an impression suitable for clinical use.

## RESULTS

When physicians reviewed their own reports, 72% (26/36) of the PEGASUS-generated impressions were clinically acceptable with minor or no changes and none received the lowest possible score, with a mean utility score of 4.08 out of 5. This score was significantly lower than the mean utility score (4.75) of clinical impressions originally dictated by the physicians themselves. The discrepancy was primarily attributed to "factual correctness" (Clinical vs. LLM: 2.97 vs. 2.58), "interpretations" (2.94 vs. 2.78), and "recommendations" (3.00 vs. 2.69). However, the physicians favored LLM impressions generated in their own style over the impressions dictated by other physicians.

## CONCLUSION

Our model produced clinically-useful and personalized PET impressions. However, model-generated impressions fell short in terms of factual accuracy, interpretation, and providing recommendations.

## CLINICAL RELEVANCE/APPLICATION

LLMs could expedite PET reporting by automatically drafting impressions based on the findings. The identified challenges provide directions for future research efforts.

### Large language model improves detection of negated expressions in radiology reports

Thursday, Nov. 30 2:30PM - 3:00PM Room: Learning Center Theater 2

Yvonne Su, BA (*Presenter*) Nothing to Disclose

#### PURPOSE

Named-entity recognition (NER) and negation detection are crucial to extract structured information from unstructured text. The extracted information can provide meaningful insights for clinical decision-making, patient care, and medical research. Large Language Models (LLMs), such as the Bidirectional Encoder Representations from Transformers (BERT), may improve understanding of text. This study compared the ability of a rule-based NLP system and an LLM—both trained for the medical domain—to correctly detect negated concepts in radiology reports.

#### METHODS AND MATERIALS

This HIPAA-compliant, IRB-approved study used a convenience sample of 1000 consecutive de-identified radiology reports from a large U.S.-based academic health system. Duplicate reports were excluded to yield the study cohort of 984 reports. The rule-based medspaCy system was applied to identify terms in the report text corpus from RadLex, the Unified Medical Language System (UMLS), and the Radiology Gamuts Ontology. An LLM, the Clinical Assertion and Negation Classification BERT (CAN-BERT), had been trained using MIMIC III and patient data from the i2b2/VA challenge. We compared medspaCy and CAN-BERT to detect negations of the identified entities. Power analysis determined a sample size of 382 pairs to achieve  $\alpha=0.05$ ,  $\beta=0.8$  for McNemar's test; based on 15% negated terms, 2800 randomly selected terms were annotated manually as affirmative or negative. The two models were compared with ground-truth annotations using McNemar's test. Precision, recall, and F1 were computed.

#### RESULTS

Of the 2800 terms, 387 (13.8%) were negated. For negation detection, medspaCy attained recall of 0.795, precision of 0.356, and F1 of 0.492. CAN-BERT achieved recall of 0.785, precision of 0.768, and F1 of 0.777. Although the models' recall was not significantly different, CAN-BERT had significantly better precision ( $\chi^2 = 304.64$ ;  $p < 0.001$ ).

#### CONCLUSION

The CAN-BERT LLM detected negated terms in radiology reports with high precision and recall; its precision significantly exceeded that of a rule-based system.

#### CLINICAL RELEVANCE/APPLICATION

Detection of negated expressions is crucial to accurately annotate radiology reports to: (1) improve training of image-based AI models and (2) enable discovery of causal relationships among diseases and findings in radiology reports.

### Glioblastoma Monitoring using GPT-4 for Summarization of Radiological Reports

Thursday, Nov. 30 2:30PM - 3:00PM Room: Learning Center Theater 2

Robert Terzis, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Disease monitoring in patients with glioblastoma typically involves numerous consecutive cranial MRI scans, making the longitudinal evaluation of these patients a complex and resource-intensive task. The advent of large language models (LLMs) presents an opportunity to facilitate physician support by summarizing radiological results and disease tracking data. The purpose of this study was to evaluate this possibility, particularly focusing on the capacity of LLMs to extract meaningful information from complex textual input.

#### METHODS AND MATERIALS

We retrospectively included 225 MRI examinations from 45 patients with biopsy-confirmed glioblastoma who were treated at our institution. The large language model, GPT-4, was supplied with the five most recent MRI reports, including clinical information in text form. The model's task was to synthesize the disease course, present the current state, and produce the R-code for a suitable graphic representation. Summaries generated by GPT-4 were evaluated by two experts in neuro-oncology with >20 and >8 years of experience, respectively. The evaluation categories included: (1) accuracy and logical-semantic representation, determined by assessing four distinct items on a binomial scale of "yes" or "no"; (2) overall quality; and (3) utility in patient monitoring and clinical decision-making, assessed using a 5-point Likert scale, with higher scores indicating more favorable results.

#### RESULTS

The summaries derived from GPT-4 aligned with expert consensus about the disease course 86.7% of the time. GPT-4's disease course summaries received a median score of 4 in terms of quality and were perceived to have a median utility score of 3.

#### CONCLUSION

GPT-4 efficiently summarized the course of the disease and pinpointed essential events with considerable accuracy, quality, and relevant usefulness for treating physicians.

#### CLINICAL RELEVANCE/APPLICATION

Our results underline the potential of large language models for radiological and medical workflow optimization.

### Adapting Large Language Models for Personalized Impression Generation in PET reports: Expert Evaluation

Thursday, Nov. 30 2:30PM - 3:00PM Room: Learning Center Theater 2

Xin Tie, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

While large language models (LLMs) have been used in generating impressions for X-ray, CT, and MRI reports, adapting them for whole-body PET reports introduces new challenges: (1) the lengthy and complex PET findings, and (2) the necessity for impressions to be tailored to each physician's reporting style. In this study, we evaluated the performance of an LLM in generating personalized impressions for PET reports and identified remaining performance gaps.

#### METHODS AND MATERIALS

In previous work, we developed a PEGASUS-based LLM on a corpus of 37,590 whole-body PET reports. The model, trained to generate impressions in the styles of different dictating physicians, outperformed 11 other state-of-the-art LLMs, including LLaMA and GPT2. In this work, we performed a reader study to evaluate different aspects of the model's performance. Three nuclear medicine physicians independently reviewed a total of 72 PET reports along with model-generated impressions. Each physician assessed 12 impressions originally dictated by themselves and generated in their own style, and 12 impressions dictated by other physicians; readers were blinded to dictating physicians during this assessment. These impressions were evaluated on 6 quality dimensions (3-point scale) and an overall utility score (5-point scale). The quality categories comprised (1) unnecessary additions; (2) important omissions; (3) factual correctness; (4) clarity and organization; (5) appropriate interpretations; and (6) valid recommendations for patient management. The overall utility score gauged the extent of changes needed to render an impression suitable for clinical use.

#### RESULTS

When physicians reviewed their own reports, 72% (26/36) of the PEGASUS-generated impressions were clinically acceptable with minor or no changes and none received the lowest possible score, with a mean utility score of 4.08 out of 5. This score was significantly lower than the mean utility score (4.75) of clinical impressions originally dictated by the physicians themselves. The discrepancy was primarily attributed to "factual correctness" (Clinical vs. LLM: 2.97 vs. 2.58), "interpretations" (2.94 vs. 2.78), and "recommendations" (3.00 vs. 2.69). However, the physicians favored LLM impressions generated in their own style over the impressions dictated by other physicians.

#### CONCLUSION

Our model produced clinically-useful and personalized PET impressions. However, model-generated impressions fell short in terms of factual accuracy, interpretation, and providing recommendations.

#### CLINICAL RELEVANCE/APPLICATION

LLMs could expedite PET reporting by automatically drafting impressions based on the findings. The identified challenges provide directions for future research efforts.

### S1-SSCH01-Radiological-Histological Correlation on Photon-Counting-Detector CT Using Cadaveric Human Lungs: Nodule and Airway Analysis<sup>1</sup>

Akinori Hata, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the performance of photon-counting-detector CT (PCD-CT) to evaluate nodules and airways (bronchioles and bronchi) compared with energy-integrating-detector CT (EID-CT) using cadaveric human lungs.

#### METHODS AND MATERIALS

Image data of 20 cadaveric lungs were acquired by both EID-CT and PCD-CT at radiation dose with a noise level equivalent to the diagnostic reference level image (CTDIvol: 9.0mGy). EID-CT images were reconstructed with 512 matrix and 0.6-mm thickness. PCD-CT images were reconstructed with two settings; PCD-512: same as C-CT; PCD-1024: 1024 matrix and 0.2-mm thickness. Two specimens per lung were obtained and examined using hematoxylin and eosin stains. The CT images were evaluated for nodules and airways on a 5-point scale comparing with histology (1=Not identifiable, 2=Barely identifiable, 3=Identifiable, but difficult to assess detail, 4=Partially consistent with histology, 5=Nearly consistent with histology). For identifiable nodules, the error rates were calculated as the absolute difference between the diameters on CT and the true diameters on histology divided by the true diameters. Objective noise in the lung parenchyma was evaluated by measuring standard deviation. The Wilcoxon signed-rank test with Bonferroni correction was used for statistical analyses.

#### RESULTS

In total, 70 nodules (median 1195  $\mu\text{m}$ , range 235 - 8803  $\mu\text{m}$ ) and 91 airways (median 855  $\mu\text{m}$ , range 204 - 3324  $\mu\text{m}$ ) in 40 specimens were evaluated. In terms of nodules, PCD-1024, PCD-512, and EID-CT scored significantly higher in that order (EID-CT,  $2.6 \pm 1.1$ ; PCD-512,  $2.8 \pm 1.1$ ; PCD-1024,  $3.7 \pm 1.4$ ; all  $p < 0.002$ ). The error rate on PCD-1024 tended to be lower than the others, but there was no significant difference (EID-CT,  $0.17 \pm 0.12$ ; PCD-512,  $0.18 \pm 0.16$ ; PCD-1024,  $0.14 \pm 0.11$ ; all  $p > 0.05$ ). In terms of airways, PCD-1024, PCD-512, and EID-CT scored significantly higher in that order (EID-CT,  $1.8 \pm 1.3$ ; PCD-512,  $2.0 \pm 1.4$ ; PCD-1024,  $2.6 \pm 1.7$ ; all  $p < 0.005$ ). Objective noise was significantly larger for PCD-1024, EID-CT and PCD-512 in that order (EID-CT,  $37 \pm 5\text{HU}$ ; PCD-512,  $27 \pm 5\text{HU}$ ; PCD-1024,  $44 \pm 7\text{H}$ ; all  $p < 0.001$ ).

#### CONCLUSION

This study histologically confirmed that PCD-CT images outperformed EID-CT in the assessment of nodules and airways, especially in the high-resolution setting with 1024 matrix and 0.2-mm thickness.

#### CLINICAL RELEVANCE/APPLICATION

PCD-CT is suitable for the assessment of nodules and airways in detail and has the potential to evaluate submillimeter nodules and bronchioles.

### S1-SSCH01-Photon Counting CT in the Chest: Improvements in Contrast-to-Noise Ratio and Radiation Dose Compared to Energy Integrating CT<sup>2</sup>

Pooyan Khalighinejad, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To evaluate the use of Photon Counting Detector CT (PCD-CT) for dose-to-noise ratio and radiation dose improvements in chest CT imaging. This study compares PCD-CT to Energy Integrating Detector CT (EID-CT) by measuring radiation dose, image noise, and contrast-to-noise ratios (CNR) for four vital chest anatomy structures within the same patient cohort.

## METHODS AND MATERIALS

In this institutional review board (IRB)-approved, single-center, multi-vendor study 30 consecutive patients referred for routine chest CT underwent PCD-CT (NAEOTOM Alpha, Siemens) and had a previous EID-CT within the last two years. EID-CT systems included GE Optima CT660 and Revolution EVO (n = 17), Siemens SOMATOM Force (n = 6), Canon Aquilion (n = 6), and Philips IQon (n = 1). PCD-CT scans used 120 kVp, automated exposure control (AEC), 0.8 pitch, and 0.25 s rotation time; with images reconstructed using 2-mm thick slices at 60 keV (Br44 kernel, QIR 3). EID-CT scans followed standard clinical protocols with 100-120 kVp based on BMI and AEC; with images reconstructed using 2-mm or 2.5-mm thick slices and manufacturer-recommended kernels. A radiology resident measured CT numbers at three non-consecutive levels in the 1) right lung, 2) aorta, 3) pulmonary artery, 4) thyroid, 5) right latissimus dorsi, and 6) mediastinal fat. All regions of interest (ROIs) were approximately 1-cm<sup>2</sup> in area. The CT dose index volume (CTDIvol) and dose length product (DLP) were recorded for each scan. Image noise was defined as the standard deviation of CT numbers within the mediastinal fat. CNR was calculated as the difference between the mean CT number at each anatomical site and the latissimus dorsi muscle mean CT number, divided by image noise.

## RESULTS

The 30 patients included 15 females and 15 males with mean age of 61 years (range: 30-81 years) and mean BMI of 26.5 kg/m<sup>2</sup>. The median interval between the PCD-CT and EID-CT scans was 123 days (range: 38-425 days). Mean CTDIvol and DLP values were significantly smaller in PCD-CT as compared with EID-CT (P < 0.01 and P < 0.05, respectively). Image noise and CNR in the lung parenchyma were not significantly different. CNR in the aorta, pulmonary artery, and thyroid were significantly higher in PCD-CT compared to EID-CT (P < 0.001, P < 0.05, and P < 0.001, respectively).

## CONCLUSION

These findings reveal that PCD-CT significantly enhances the CNR of vascular and iodine-rich structures in chest CT while using a lower radiation dose compared to EID-CT.

## CLINICAL RELEVANCE/APPLICATION

Photon counting detector CT (PCD-CT) is an innovative technology that delivers enhanced contrast-to-noise ratio (CNR) of vital chest structures with reduced radiation exposure.

## S1-SSCH01-Super-High-Resolution Chest Imaging using CZT-Based Photon Counting CT: Performance Characterization and First Clinical Trial

Keiichi Nomura, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Recently, first clinical studies of CZT-based photon counting detector CT (CZT-PCD-CT) has started in Japan. Due to its small detector pixel design, CZT-PCD-CT provides super-high-resolution (SHR) imaging mode, and has potential to improve diagnostic quality for CT chest imaging. Deep learning reconstruction can also be used together with SHR mode to reduce the noise in high resolution imaging. This study aims to 1) quantify resolution benefits of the CZT-PCD-CT SHR mode in comparison to normal resolution mode (NR); 2) evaluate clinical image quality and potential clinical benefits of SHR mode in chest imaging.

## METHODS AND MATERIALS

The prototype CZT-PCD-CT is built based on a Aquilion Precision system (Canon Medical Systems, Japan). The beam coverage of the CZT-PCD-CT system is 40 mm. Catphan600 (The Phantom Laboratory, U.S) and patient scans were acquired in helical mode at 120 kVp, 250 mA (9.7 mGy), 0.5s rotation and pitch factor 0.8. The focal spot size is 0.4 mm\*0.5 mm. NR images were reconstructed using a 512-matrix size, and a hybrid-iterative reconstruction (Hybrid-IR). SHR images were reconstructed using a 1024-matrix size, and both Hybrid-IR and deep learning reconstruction method (DLR). The image thickness is 1.2 mm, lung kernel was used for all images. Visual evaluation and profile measurements are performed on Catphan with slit modules, and task-based transfer functions (TTF) are measured using Teflon module. Clinical chest images were assessed for NR and SHR image noise (SD) and anatomical structures in the lung fields.

## RESULTS

Slit profiles were visible up to 10 lp/cm in NR, 12 lp/cm in SHR and 12 lp/cm in SHR with DLR. TTF value at 10% was NR 1.1, SHR1.5 and SHR with DLR 2.5 cycles/mm. From the clinical images, the image noise levels of SHR and NR are acceptable for diagnostic tasks. The SHR mode with DLR shows the lowest noise level in all three methods (SD was 52.6 HU for NR, 73.4 HU for SHR and 45.5 HU for SHR with DLR). For chest imaging, ground glass opacity and bronchioles are better defined, and chest wall undershoot artifacts are significantly reduced in SHR images.

## CONCLUSION

The CZT-PCD-CT with super-high-resolution imaging mode has significantly improved spatial resolution and has potential in improving diagnostic accuracy for chest imaging.

## CLINICAL RELEVANCE/APPLICATION

The high-resolution images in the SHR mode of CZT-PCD-CT contribute to improved diagnostic performance in chest imaging.

## S1-SSCH01-Ultra-High-Resolution Spectral Characterization of Lung Airways with Deep-Silicon Photon-Counting CT: A Phantom Study

Amir Pourmorteza, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

CT scanners with photon-counting detectors (PCDs) show significant potential for enhancing diagnostic value and image quality. Potential advantages of PCD-CT include reduced radiation exposure, always-on spectral capability, and spatial resolution of 150  $\mu\text{m}$  or better. A recently developed technology, edge-on-irradiated deep-Si PCD, has the potential to provide improved simultaneous spectral and spatial resolution compared to current CdTe/CdZnTe PCDs, which exhibit reduced energy resolution due to K-escape fluorescence and charge-sharing. Higher combined spatial and spectral resolution could improve visualization of small lung airways by resolving these in task-optimal virtual monoenergetic images (VMIs). This study aims to explore the benefits of deep-Si PCD-CT in chest CT for evaluating the airway walls and lumens.

## METHODS AND MATERIALS

We 3D-print seven airway models with different inner-wall diameters (0.75-2 mm) and wall thicknesses (0.75-1 mm) which are placed inside a 20 cm-diameter phantom filled with ballistic gel. We scan the phantom on a clinical prototype deep-Si PCD-CT scanner with the following parameters: 120 kVp, 300 mAs, 8 energy thresholds, 1 s rotation time. VMIs at 40, 70, and 140 keV are reconstructed using a filtered-backprojection algorithm with a prototype sharp kernel (10% modulation transfer function cutoff at 21.2 lp/cm) with  $125 \times 125 \times 417 \mu\text{m}^3$  voxel size. We measure airway lumen diameter and wall thickness through a series of line profiles ( $N = 63$ ), and contrast-to-noise ratio (CNR) between airway wall and air in the VMIs. The Wilcoxon signed rank test is used for all comparisons with  $p < 0.05$  being considered statistically significant.

## RESULTS

CNR is significantly lower for 40 keV images compared to 70 and 140 keV, with medians of 16.1, 19.8, and 20.1, respectively. The 70 keV images show significantly more accurate estimation of airway wall thickness (error 19-110  $\mu\text{m}$ ) and lumen diameter (error 30-105  $\mu\text{m}$ ) compared to the 40 keV and 140 keV images.

## CONCLUSION

Ultra-high-resolution (UHR) spectral imaging of the lung airways with deep-Si PCD realized subpixel ( $< 150 \mu\text{m}$ ) accuracy in measuring airway lumen and wall thickness in 70 keV VMIs. This is a small phantom study on a prototype scanner without any denoising algorithms applied. Additional algorithms may further improve the CNR and accuracy of airway measurements.

## CLINICAL RELEVANCE/APPLICATION

UHR PCD-CT improves visualization of small lung airways, and the spectral information used to generate VMIs can be utilized to maximize the CNR between airway walls and the lumen. The combined UHR VMI information may help improve characterization of changes in airways which may be of value in monitoring the treatment of diseases such as cystic fibrosis.

## S1-SSCH01-Investigating the Small Pixel Effect in Ultra-High-Resolution Photon-Counting CT of the Lung

Henner Huflage, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate potential benefits in image quality and radiation dose of ultra-high resolution (UHR) collimation over standard macro mode in ultra-low-dose photon-counting detector CT (PCD-CT) of the lung.

## METHODS AND MATERIALS

Six cadaveric specimens were examined with 5 dose settings using tin prefiltration, each with UHR ( $120 \times 0.2 \text{ mm}$ ) and standard collimation ( $144 \times 0.4 \text{ mm}$ ), with a first-generation PCD-CT scanner. Image quality was evaluated quantitatively by noise comparisons in the trachea and both main bronchi. Additionally, 16 readers (14 radiologists and 2 internal medicine physicians) independently completed a browser-based pairwise forced-choice comparison task for assessment of subjective image quality. Kendall's rank coefficient ( $W$ ) was calculated to assess interrater agreement, and Pearson's correlation coefficient ( $r$ ) was used to analyse the relationship between noise measurements and image quality rankings.

## RESULTS

Across all dose levels, image noise in UHR mode was lower than in macro mode for scan protocols matched by CTDIvol ( $p < 0.001$ ). UHR examinations exhibited noise levels comparable to the next higher dose setting in macro mode ( $p = 0.275$ ). Subjective ranking of protocols based on 5760 pairwise tests showed high interrater agreement ( $W = 0.99$ ;  $p = 0.001$ ) with UHR mode being preferred by readers in the majority of comparisons. Irrespective of scan mode, a substantial indirect correlation was observed between image noise and subjective image quality ranking ( $r = -0.97$ ;  $p < 0.001$ ).

## CONCLUSION

In PCD-CT of the lung, UHR collimation reduces image noise considerably over macro mode with standard collimation. This so-called "small pixel effect" allows for superior image quality in ultra-low-dose examinations with associated considerable potential for radiation dose reduction.

## CLINICAL RELEVANCE/APPLICATION

Exploiting the small pixel effect in UHR lung imaging by means of PCD-CT allows for both superior image quality and considerable radiation dose reduction.

## S1-SSCH01-Deep Learning Reconstruction vs. Hybrid-Type Iterative Reconstruction: Capability for Image Quality Improvement and Lung Finding Evaluation on Standard-, Reduced- and Ultra-Low-Dose High-Definition CTs

Daisuke Takenaka, MD (*Presenter*) Canon Medical Systems Corporation

## PURPOSE

High definition CTs (HDCTs) with and without a photon counting system have been clinically applied, although image noise for thinner section thickness is one of the drawbacks on HDCT. Moreover, deep learning reconstruction (DLR) has been introduced and compared with iterative reconstruction (IR) methods. The purpose of this study was to compare the capabilities of DLR for image quality improvement and lung finding evaluation with those of hybrid-type IR for standard-, reduced- and ultra-low dose CTs (SDCT, RDCT and ULDC) obtained with HDCT in patients with various pulmonary diseases.

## METHODS AND MATERIALS

Forty patients with various pulmonary diseases underwent SDCT (CT dose index volume  $<CTDIvol>$ : mean $\pm$ standard deviation,  $9.0 \pm 1.8$  mGy), RDCT ( $CTDIvol$ :  $1.7 \pm 0.2$  mGy) and ULDC ( $CTDIvol$ :  $0.8 \pm 0.1$  mGy) at a HDCT. All CT data set were then reconstructed at 0.25, 0.5 and 1mm section thicknesses with  $512 \times 512$  or  $1024 \times 1024$  matrixes by hybrid-type IR and DLR. SNR of lung parenchyma was assessed by ROI measurement. Probabilities of presence of major lung finding were independently evaluated by 5-point scoring system by two board-certified chest radiologists for each CT data set. SNR and detection performance of each lung finding were then compared between DLR and hybrid-type IR by paired t-tests and ROC analyses for all CT data at each section thickness. Inter-observer agreement for each lung finding was evaluated by  $\kappa$  statistics followed by  $\chi^2$  test.

## RESULTS

SNR of DLR was significantly higher than that of hybrid-type IR on each CT data ( $p < 0.0001$ ). Assessments of all findings except consolidation and nodules or masses, areas under the curve (AUCs) for ULDC with IR for each section thickness ( $0.91 = AUC = 0.97$ ) were significantly smaller than those of all CT data with DLR ( $0.97 = AUC = 1$ ,  $p < 0.05$ ) and the SDCT with hybrid-type IR ( $0.98 = AUC = 1$ ,  $p < 0.05$ ). All inter-observer agreements were determined to be substantial or almost perfect ( $0.72 = \kappa = 0.93$ ,  $p < 0.0001$ ).

## CONCLUSION

DLR is potentially more effective for image quality improvement and lung finding evaluation than hybrid-type IR on all radiation dose CTs obtained at HDCT in patients with a variety of pulmonary diseases.

## CLINICAL RELEVANCE/APPLICATION

DLR is potentially more effective for image quality improvement and lung finding evaluation than hybrid-type IR on all radiation dose CTs obtained at HDCT in patients with various pulmonary diseases.

### **Radiological-Histological Correlation on Photon-Counting-Detector CT Using Cadaveric Human Lungs: Nodule and Airway Analysis**

Sunday, Nov. 26 9:00AM - 10:00AM Room: S401

Akinori Hata, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To investigate the performance of photon-counting-detector CT (PCD-CT) to evaluate nodules and airways (bronchioles and bronchi) compared with energy-integrating-detector CT (EID-CT) using cadaveric human lungs.

#### **METHODS AND MATERIALS**

Image data of 20 cadaveric lungs were acquired by both EID-CT and PCD-CT at radiation dose with a noise level equivalent to the diagnostic reference level image (CTDIvol: 9.0mGy). EID-CT images were reconstructed with 512 matrix and 0.6-mm thickness. PCD-CT images were reconstructed with two settings; PCD-512: same as C-CT; PCD-1024: 1024 matrix and 0.2-mm thickness. Two specimens per lung were obtained and examined using hematoxylin and eosin stains. The CT images were evaluated for nodules and airways on a 5-point scale comparing with histology (1=Not identifiable, 2=Barely identifiable, 3=Identifiable, but difficult to assess detail, 4=Partially consistent with histology, 5=Nearly consistent with histology). For identifiable nodules, the error rates were calculated as the absolute difference between the diameters on CT and the true diameters on histology divided by the true diameters. Objective noise in the lung parenchyma was evaluated by measuring standard deviation. The Wilcoxon signed-rank test with Bonferroni correction was used for statistical analyses.

#### **RESULTS**

In total, 70 nodules (median 1195  $\mu$ m, range 235 - 8803  $\mu$ m) and 91 airways (median 855  $\mu$ m, range 204 - 3324  $\mu$ m) in 40 specimens were evaluated. In terms of nodules, PCD-1024, PCD-512, and EID-CT scored significantly higher in that order (EID-CT, 2.6 $\pm$ 1.1; PCD-512, 2.8 $\pm$ 1.1; PCD-1024, 3.7 $\pm$ 1.4; all  $p$ <0.002). The error rate on PCD-1024 tended to be lower than the others, but there was no significant difference (EID-CT, 0.17 $\pm$ 0.12; PCD-512, 0.18 $\pm$ 0.16; PCD-1024, 0.14 $\pm$ 0.11; all  $p$ >0.05). In terms of airways, PCD-1024, PCD-512, and EID-CT scored significantly higher in that order (EID-CT, 1.8 $\pm$ 1.3; PCD-512, 2.0 $\pm$ 1.4; PCD-1024, 2.6 $\pm$ 1.7; all  $p$ <0.005). Objective noise was significantly larger for PCD-1024, EID-CT and PCD-512 in that order (EID-CT, 37 $\pm$ 5HU; PCD-512, 27 $\pm$ 5HU; PCD-1024, 44 $\pm$ 7H; all  $p$  <0.001).

#### **CONCLUSION**

This study histologically confirmed that PCD-CT images outperformed EID-CT in the assessment of nodules and airways, especially in the high-resolution setting with 1024 matrix and 0.2-mm thickness.

#### **CLINICAL RELEVANCE/APPLICATION**

PCD-CT is suitable for the assessment of nodules and airways in detail and has the potential to evaluate submillimeter nodules and bronchioles.

### Photon Counting CT in the Chest: Improvements in Contrast-to-Noise Ratio and Radiation Dose Compared to Energy Integrating CT

Sunday, Nov. 26 9:00AM - 10:00AM Room: S401

Pooyan Khalighinejad, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the use of Photon Counting Detector CT (PCD-CT) for dose-to-noise ratio and radiation dose improvements in chest CT imaging. This study compares PCD-CT to Energy Integrating Detector CT (EID-CT) by measuring radiation dose, image noise, and contrast-to-noise ratios (CNR) for four vital chest anatomy structures within the same patient cohort.

#### METHODS AND MATERIALS

In this institutional review board (IRB)-approved, single-center, multi-vendor study 30 consecutive patients referred for routine chest CT underwent PCD-CT (NAEOTOM Alpha, Siemens) and had a previous EID-CT within the last two years. EID-CT systems included GE Optima CT660 and Revolution EVO ( $n = 17$ ), Siemens SOMATOM Force ( $n = 6$ ), Canon Aquilion ( $n = 6$ ), and Philips IQon ( $n = 1$ ). PCD-CT scans used 120 kVp, automated exposure control (AEC), 0.8 pitch, and 0.25 s rotation time; with images reconstructed using 2-mm thick slices at 60 keV (Br44 kernel, QIR 3). EID-CT scans followed standard clinical protocols with 100-120 kVp based on BMI and AEC; with images reconstructed using 2-mm or 2.5-mm thick slices and manufacturer-recommended kernels. A radiology resident measured CT numbers at three non-consecutive levels in the 1) right lung, 2) aorta, 3) pulmonary artery, 4) thyroid, 5) right latissimus dorsi, and 6) mediastinal fat. All regions of interest (ROIs) were approximately 1-cm<sup>2</sup> in area. The CT dose index volume (CTDIvol) and dose length product (DLP) were recorded for each scan. Image noise was defined as the standard deviation of CT numbers within the mediastinal fat. CNR was calculated as the difference between the mean CT number at each anatomical site and the latissimus dorsi muscle mean CT number, divided by image noise.

#### RESULTS

The 30 patients included 15 females and 15 males with mean age of 61 years (range: 30-81 years) and mean BMI of 26.5 kg/m<sup>2</sup>. The median interval between the PCD-CT and EID-CT scans was 123 days (range: 38-425 days). Mean CTDIvol and DLP values were significantly smaller in PCD-CT as compared with EID-CT ( $P < 0.01$  and  $P < 0.05$ , respectively). Image noise and CNR in the lung parenchyma were not significantly different. CNR in the aorta, pulmonary artery, and thyroid were significantly higher in PCD-CT compared to EID-CT ( $P < 0.001$ ,  $P < 0.05$ , and  $P < 0.001$ , respectively).

#### CONCLUSION

These findings reveal that PCD-CT significantly enhances the CNR of vascular and iodine-rich structures in chest CT while using a lower radiation dose compared to EID-CT.

#### CLINICAL RELEVANCE/APPLICATION

Photon counting detector CT (PCD-CT) is an innovative technology that delivers enhanced contrast-to-noise ratio (CNR) of vital chest structures with reduced radiation exposure.

### Super-High-Resolution Chest Imaging using CZT-Based Photon Counting CT: Performance Characterization and First Clinical Trial

Sunday, Nov. 26 9:00AM - 10:00AM Room: S401

Keiichi Nomura, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Recently, first clinical studies of CZT-based photon counting detector CT (CZT-PCD-CT) has started in Japan. Due to its small detector pixel design, CZT-PCD-CT provides super-high-resolution (SHR) imaging mode, and has potential to improve diagnostic quality for CT chest imaging. Deep learning reconstruction can also be used together with SHR mode to reduce the noise in high resolution imaging. This study aims to 1) quantify resolution benefits of the CZT-PCD-CT SHR mode in comparison to normal resolution mode (NR); 2) evaluate clinical image quality and potential clinical benefits of SHR mode in chest imaging.

#### METHODS AND MATERIALS

The prototype CZT-PCD-CT is built based on a Aquilion Precision system (Canon Medical Systems, Japan). The beam coverage of the CZT-PCD-CT system is 40 mm. Catphan600 (The Phantom Laboratory, U.S) and patient scans were acquired in helical mode at 120 kVp, 250 mA (9.7 mGy), 0.5s rotation and pitch factor 0.8. The focal spot size is 0.4 mm\*0.5 mm. NR images were reconstructed using a 512-matrix size, and a hybrid-iterative reconstruction (Hybrid-IR). SHR images were reconstructed using a 1024-matrix size, and both Hybrid-IR and deep learning reconstruction method (DLR). The image thickness is 1.2 mm, lung kernel was used for all images. Visual evaluation and profile measurements are performed on Catphan with slit modules, and task-based transfer functions (TTF) are measured using Teflon module. Clinical chest images were assessed for NR and SHR image noise (SD) and anatomical structures in the lung fields.

#### RESULTS

Slit profiles were visible up to 10 lp/cm in NR, 12 lp/cm in SHR and 12 lp/cm in SHR with DLR. TTF value at 10% was NR 1.1, SHR 1.5 and SHR with DLR 2.5 cycles/mm. From the clinical images, the image noise levels of SHR and NR are acceptable for diagnostic tasks. The SHR mode with DLR shows the lowest noise level in all three methods (SD was 52.6 HU for NR, 73.4 HU for SHR and 45.5 HU for SHR with DLR). For chest imaging, ground glass opacity and bronchioles are better defined, and chest wall undershoot artifacts are significantly reduced in SHR images.

#### CONCLUSION

The CZT-PCD-CT with super-high-resolution imaging mode has significantly improved spatial resolution and has potential in improving diagnostic accuracy for chest imaging.

#### CLINICAL RELEVANCE/APPLICATION

The high-resolution images in the SHR mode of CZT-PCD-CT contribute to improved diagnostic performance in chest imaging.

### Ultra-High-Resolution Spectral Characterization of Lung Airways with Deep-Silicon Photon-Counting CT: A Phantom Study

Sunday, Nov. 26 9:00AM - 10:00AM Room: S401

Amir Pourmorteza, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

CT scanners with photon-counting detectors (PCDs) show significant potential for enhancing diagnostic value and image quality. Potential advantages of PCD-CT include reduced radiation exposure, always-on spectral capability, and spatial resolution of 150  $\mu\text{m}$  or better. A recently developed technology, edge-on-irradiated deep-Si PCD, has the potential to provide improved simultaneous spectral and spatial resolution compared to current CdTe/CdZnTe PCDs, which exhibit reduced energy resolution due to K-escape fluorescence and charge-sharing. Higher combined spatial and spectral resolution could improve visualization of small lung airways by resolving these in task-optimal virtual monoenergetic images (VMIs). This study aims to explore the benefits of deep-Si PCD-CT in chest CT for evaluating the airway walls and lumens.

#### METHODS AND MATERIALS

We 3D-print seven airway models with different inner-wall diameters (0.75-2 mm) and wall thicknesses (0.75-1 mm) which are placed inside a 20 cm-diameter phantom filled with ballistic gel. We scan the phantom on a clinical prototype deep-Si PCD-CT scanner with the following parameters: 120 kVp, 300 mAs, 8 energy thresholds, 1 s rotation time. VMIs at 40, 70, and 140 keV are reconstructed using a filtered-backprojection algorithm with a prototype sharp kernel (10% modulation transfer function cutoff at 21.2 lp/cm) with  $125 \times 125 \times 417 \mu\text{m}^3$  voxel size. We measure airway lumen diameter and wall thickness through a series of line profiles ( $N = 63$ ), and contrast-to-noise ratio (CNR) between airway wall and air in the VMIs. The Wilcoxon signed rank test is used for all comparisons with  $p < 0.05$  being considered statistically significant.

#### RESULTS

CNR is significantly lower for 40 keV images compared to 70 and 140 keV, with medians of 16.1, 19.8, and 20.1, respectively. The 70 keV images show significantly more accurate estimation of airway wall thickness (error 19-110  $\mu\text{m}$ ) and lumen diameter (error 30-105  $\mu\text{m}$ ) compared to the 40 keV and 140 keV images.

#### CONCLUSION

Ultra-high-resolution (UHR) spectral imaging of the lung airways with deep-Si PCD realized subpixel ( $< 150 \mu\text{m}$ ) accuracy in measuring airway lumen and wall thickness in 70 keV VMIs. This is a small phantom study on a prototype scanner without any denoising algorithms applied. Additional algorithms may further improve the CNR and accuracy of airway measurements.

#### CLINICAL RELEVANCE/APPLICATION

UHR PCD-CT improves visualization of small lung airways, and the spectral information used to generate VMIs can be utilized to maximize the CNR between airway walls and the lumen. The combined UHR VMI information may help improve characterization of changes in airways which may be of value in monitoring the treatment of diseases such as cystic fibrosis.

### Investigating the Small Pixel Effect in Ultra-High-Resolution Photon-Counting CT of the Lung

Sunday, Nov. 26 9:00AM - 10:00AM Room: S401

Henner Huflage, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate potential benefits in image quality and radiation dose of ultra-high resolution (UHR) collimation over standard macro mode in ultra-low-dose photon-counting detector CT (PCD-CT) of the lung.

#### METHODS AND MATERIALS

Six cadaveric specimens were examined with 5 dose settings using tin prefiltration, each with UHR (120 x 0.2 mm) and standard collimation (144 x 0.4 mm), with a first-generation PCD-CT scanner. Image quality was evaluated quantitatively by noise comparisons in the trachea and both main bronchi. Additionally, 16 readers (14 radiologists and 2 internal medicine physicians) independently completed a browser-based pairwise forced-choice comparison task for assessment of subjective image quality. Kendall's rank coefficient (W) was calculated to assess interrater agreement, and Pearson's correlation coefficient (r) was used to analyse the relationship between noise measurements and image quality rankings.

#### RESULTS

Across all dose levels, image noise in UHR mode was lower than in macro mode for scan protocols matched by CTDIvol ( $p < 0.001$ ). UHR examinations exhibited noise levels comparable to the next higher dose setting in macro mode ( $p = 0.275$ ). Subjective ranking of protocols based on 5760 pairwise tests showed high interrater agreement ( $W = 0.99$ ;  $p = 0.001$ ) with UHR mode being preferred by readers in the majority of comparisons. Irrespective of scan mode, a substantial indirect correlation was observed between image noise and subjective image quality ranking ( $r = -0.97$ ;  $p < 0.001$ ).

#### CONCLUSION

In PCD-CT of the lung, UHR collimation reduces image noise considerably over macro mode with standard collimation. This so-called "small pixel effect" allows for superior image quality in ultra-low-dose examinations with associated considerable potential for radiation dose reduction.

#### CLINICAL RELEVANCE/APPLICATION

Exploiting the small pixel effect in UHR lung imaging by means of PCD-CT allows for both superior image quality and considerable radiation dose reduction.

### Deep Learning Reconstruction vs. Hybrid-Type Iterative Reconstruction: Capability for Image Quality Improvement and Lung Finding Evaluation on Standard-, Reduced- and Ultra-Low-Dose High-Definition CTs

Sunday, Nov. 26 9:00AM - 10:00AM Room: S401

Daisuke Takenaka, MD (*Presenter*) Canon Medical Systems Corporation

#### PURPOSE

High definition CTs (HDCTs) with and without a photon counting system have been clinically applied, although image noise for thinner section thickness is one of the drawbacks on HDCT. Moreover, deep learning reconstruction (DLR) has been introduced and compared with iterative reconstruction (IR) methods. The purpose of this study was to compare the capabilities of DLR for image quality improvement and lung finding evaluation with those of hybrid-type IR for standard-, reduced- and ultra-low dose CTs (SDCT, RDCT and ULDC) obtained with HDCT in patients with various pulmonary diseases.

#### METHODS AND MATERIALS

Forty patients with various pulmonary diseases underwent SDCT (CT dose index volume <CTDIvol>: mean±standard deviation, 9.0±1.8mGy), RDCT (CTDIvol: 1.7±0.2mGy) and ULDC (CTDIvol: 0.8±0.1mGy) at a HDCT. All CT data set were then reconstructed at 0.25, 0.5 and 1mm section thicknesses with 512×512 or 1024×1024 matrixes by hybrid-type IR and DLR. SNR of lung parenchyma was assessed by ROI measurement. Probabilities of presence of major lung finding were independently evaluated by 5-point scoring system by two board-certified chest radiologists for each CT data set. SNR and detection performance of each lung finding were then compared between DLR and hybrid-type IR by paired t-tests and ROC analyses for all CT data at each section thickness. Inter-observer agreement for each lung finding was evaluated by ? statistics followed by ?2 test.

#### RESULTS

SNR of DLR was significantly higher than that of hybrid-type IR on each CT data ( $p<0.0001$ ). Assessments of all findings except consolidation and nodules or masses, areas under the curve (AUCs) for ULDC with IR for each section thickness (0.91=AUC=0.97) were significantly smaller than those of all CT data with DLR (0.97=AUC=1,  $p<0.05$ ) and the SDCT with hybrid-type IR (0.98=AUC=1,  $p<0.05$ ). All inter-observer agreements were determined to be substantial or almost perfect (0.72=?=0.93,  $p<0.0001$ ).

#### CONCLUSION

DLR is potentially more effective for image quality improvement and lung finding evaluation than hybrid-type IR on all radiation dose CTs obtained at HDCT in patients with a variety of pulmonary diseases.

#### CLINICAL RELEVANCE/APPLICATION

DLR is potentially more effective for image quality improvement and lung finding evaluation than hybrid-type IR on all radiation dose CTs obtained at HDCT in patients with various pulmonary diseases.

### Genitourinary Imaging (AI for Detection and Characterization of Genitourinary Cancers)

Sunday, Nov. 26 9:00AM - 10:00AM Room: S404

Baris Turkbey, MD (*Moderator*) Nothing to Disclose  
Jessica G. Fried, MD (*Moderator*) Nothing to Disclose

#### Sub-Events

#### S1-SSGU01-2 Evaluation of a Cascaded Deep Learning-Based Algorithm for Prostate Lesion Detection on Biparametric MRI

Yue Lin, BA (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate a deep learning-based AI algorithm for intraprostatic lesion detection and segmentation and to compare its performance with radiologist and biopsy results.

#### METHODS AND MATERIALS

This retrospective study included consecutive participants who were imaged with mpMRI and subsequently received MRI/ultrasound fusion-guided targeted and systematic biopsy from April 2019 to September 2022. All lesions were prospectively evaluated using PI-RADSv2.1. A previously developed deep learning-based AI algorithm was evaluated, the algorithm inputs included biparametric MRI sequences and the outputs included prostate organ and intraprostatic lesion segmentations. Algorithm performance was compared to a radiologist at both lesion- and participant-level using sensitivity, positive predictive value (PPV), false discovery rate (FDR), and Dice similarity coefficient (DSC). Gleason Grade Groups 2 and higher were considered as clinically significant prostate cancer. The algorithm performance was also examined using the histopathological outcomes, and the Wald test was used to compare the performance of the algorithm and the radiologist for cancer detection.

#### RESULTS

A total of 658 participants (median age, 67 years; interquartile range, 61-71 years) with 1029 MRI visible lesions were evaluated. On participant-level analysis using the radiologist as ground truth, the detection sensitivity of the AI was 93% (519/559; 95% confidence interval [CI]: 90, 95), PPV was 88% (519/594; 95% CI: 85, 90), and FDR was 13% (75/594; 95% CI: 10, 15). Mean number of false positive lesions per participant was 0.61 (range 0-3). DSC for lesion segmentation was 0.34. On histopathologic analysis, the algorithm identified 96% (282/294; 95% CI: 94, 98) of all participants with clinically significant prostate cancer versus 98% (287/294; 95% CI: 96, 99) identified by the radiologist ( $P = 0.23$ ). The algorithm detected 84% (103/122), 96% (152/159), 96% (47/49), 95% (38/40), and 98% (45/46) of participants with Gleason Grade Groups of 1, 2, 3, 4, and 5 lesions, respectively.

#### CONCLUSION

Validation of AI algorithms in clinical scenarios is critical for their translation, demonstrated here in a fully automated cascaded deep learning-based AI algorithm which can detect lesions suspicious for cancer on MRI with a reasonable performance comparable to a well-trained radiologist. Moreover, it was able to reliably predict clinically significant lesions on histopathology.

#### CLINICAL RELEVANCE/APPLICATION

A deep-learning AI can detect prostate cancer with radiologist-like performance on MRI and reliably predict clinically significant lesions on histopathology, which may aid in prostate cancer detection and reduce interpretation variability.

#### S1-SSGU01-3 Multiple Centre External Validation of an AI Solution for Prostate Cancer Diagnostic Imaging

Francesco Giganti, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Clinical translation of AI solutions for detection of clinically significant prostate cancer (csPCa) has been limited by the lack of validation on multi-centre datasets including multiple MRI scanners, vendors, field strengths and imaging protocols. Here, we evaluate the ability of an AI solution to generalise to real-world external validation data including blinded validation on an unseen site.

## METHODS AND MATERIALS

AI-based software was developed using PROSTATEx and retrospective data from five sites (794 patients, 34% csPCa). The software was evaluated on a blinded external validation set (252 patients - 42 per site, 31% csPCa, 9% with prior negative biopsy) of multiparametric (mpMRI) data obtained from six sites; one site was unseen during development, and data from other sites was from later time periods than the development set. This external data included six scanner models from two vendors, with different field strengths (1.5T/3.0T) and acquisition protocols. The software automatically outputs scores intended to identify Gleason score (GS)=3+4 csPCa per-patient. csPCa was confirmed by biopsy (GS=3+4 / PI-RADS =3), with PI-RADS 1/2 patients that did not receive a biopsy assumed negative. Exclusion criteria included quality issues such as severe motion and metal prostheses, active surveillance, prior prostate or bladder surgery or treatment including brachytherapy, TURP, prostatectomy, ablation, HIFU/focal therapy, or water vapour therapy. Performance was evaluated using ROC analysis, with 95% confidence intervals estimated by bootstrapping.

## RESULTS

For selecting patients for biopsy, the AI identified patients with csPCa with sensitivity 94% (95% CI 88-99%), specificity 57% (49-64%), NPV 95% (90-99%), and AUC 0.85 (0.80-0.90) using mpMRI data from the blinded external validation set. Comparing between sites, the AUC ranged from 0.70-0.98, with a pooled AUC of  $0.86 \pm 0.11$ . On the unseen site, the AUC was 0.95 (0.87-1.00). Reporting radiologists had per-patient sensitivity 99% (95% CI 96-100%) due to the assumed ground truth, specificity 73% (67-80%), NPV 99% (98-100%), and AUC 0.95 (0.92-0.97). In a 2019 Cochrane meta-analysis of 12 major studies (37% csPCa), radiologists identified patients with GS=3+4 csPCa with sensitivity 86% and specificity 42%.

## CONCLUSION

The proposed AI solution shows comparable performance to radiologists in major expert studies, on a large real-world, multi-centre, external validation dataset with different cs scanners, vendors, field strengths and imaging protocols.

## CLINICAL RELEVANCE/APPLICATION

AI could support prostate cancer detection in clinical practice, generalises to multiple sites, scanners and imaging protocols, and is robust to novel data.

## S1-SSGU01-5 Discerning Benign and Malignant T1a Renal Mass in CT Images using an End-to-end Deep Learning based Pipeline

Aakanksha Rana, PhD, MSc (*Presenter*) Nothing to Disclose

## PURPOSE

This study aims to evaluate the effectiveness of an end-to-end deep learning-based pipeline that can be used to assist physicians in pre-operatively diagnosing the malignancy of T1a renal masses. The pipeline functions by taking a preoperative CT scan as input, localizing the tumor region by segmenting it, and predicting the probability of malignancy in a fully automated fashion without requiring manual intervention.

## METHODS AND MATERIALS

This T1a-focused retrospective study was performed on 289 kidney cancer cases where malignancy was confirmed by histopathology; consisting of 224 malignant (82% clear cell, 9% papillary, 5% chromophobe, 1% multilocular, 1% tubulocystic) and 65 benign (51% oncocytoma, 13% angiomyolipoma, 3% mest, and 32% simple cysts). This T1a group was selected from a larger cohort of 697 RCC patients of all stages, collected from multiple centers in United States and Europe which were a part of a private and two publicly available datasets (Kidney Tumor Segmentation Challenge and TCGA-KIRC). Data from 289 T1a patients were used to train and validate the deep learning-based pipeline. A cascade of convolutional neural networks (CNNs) is used to segment the tumor for localization, and classify the segmented tumor region as benign or malignant. Validation metrics included dice scores for precise localization, and accuracy and area under the curve for malignancy at optimal output data cutoff values.

## RESULTS

A total of 289 patients with T1a RCC (224 malignant and 65 benign, median age 48 years; (12-79 years), 59% male and 41% female) were used to train and validate the pipeline following a five-fold cross validation process. The deep learning pipeline used a split of 80:20 for defining training and validation sets, respectively. For the first localization stage, a segmentation dice score of 0.83 was achieved. Then, for classification stage, an average area under the curve of 0.87 was observed with an accuracy of 0.82, a specificity of 0.81 (58 out of 65 patients) and sensitivity of 0.89 (180 out of 224 patients).

## **CONCLUSION**

An end-to-end "Localize-to-Classify" convolutional neural network-based framework demonstrates potential in the differentiation of T1a renal masses as benign or malignant using pre-op CT scans.

## **CLINICAL RELEVANCE/APPLICATION**

T1a Renal Cell Carcinoma (RCC) is the earliest stage of kidney cancer accounting for approximately 40% of kidney cancer cases in the United States. The diagnosis of T1a RCC is difficult due to its small size ( $\leq 40\text{mm}$ ), often resulting in over- or under-treatment of patients. Prior studies using tumors up to 70mm reported that radiologists could only correctly diagnose half of the malignant tumors pre-operatively.

Validation metrics included dice scores for precise localization, and accuracy and area under the curve for malignancy at optimal output data cutoff values.

#### RESULTS

A total of 289 patients with T1a RCC (224 malignant and 65 benign, median age 48 years; (12-79 years), 59% male and 41% female) were used to train and validate the pipeline following a five-fold cross validation process. The deep learning pipeline used a split of 80:20 for defining training and validation sets, respectively. For the first localization stage, a segmentation dice score of 0.83 was achieved. Then, for classification stage, an average area under the curve of 0.87 was observed with an accuracy of 0.82, a specificity of 0.81 (58 out of 65 patients) and sensitivity of 0.89 (180 out of 224 patients).

#### CONCLUSION

An end-to-end "Localize-to-Classify" convolutional neural network-based framework demonstrates potential in the differentiation of T1a renal masses as benign or malignant using pre-op CT scans.

#### CLINICAL RELEVANCE/APPLICATION

T1a Renal Cell Carcinoma (RCC) is the earliest stage of kidney cancer accounting for approximately 40% of kidney cancer cases in the United States. The diagnosis of T1a RCC is difficult due to its small size (= 40mm), often resulting in over- or under-treatment of patients. Prior studies using tumors up to 70mm reported that radiologists could only correctly diagnose half of the malignant tumors pre-operatively.

### S1-SSHNO1-1 Oral Cavity Ultrasonography: Our Preliminary Experience

Vittorio Patane' (*Presenter*) Nothing to Disclose

#### PURPOSE

Ultra-high Frequency Ultrasound (UHFUS) is a recent-evolving technique used to study oral lesions. This study aims to assess potential role of intraoral UHFUS in evaluating parameters such as Tumor Thickness (TT) and Depth of Invasion (DOI) in Oral Squamous Cell Carcinoma (OSCC).

#### METHODS AND MATERIALS

Twelve patients, aged 48 to 74 years, presenting with oral cavity, gum, or tongue lesions between January 2022 and April 2023 suspected of having OSCC were examined by a skilled examiner using intraoral UHFUS prior to surgery. Subsequently, an anatomopathological examination was performed. UHFUS features were then compared to the histological findings.

#### RESULTS

Ten patients were diagnosed with several oral pathologies including infiltrating squamous carcinoma, fibrous dysplasia, candidiasis, squamous carcinoma, and post-traumatic fibroma. Ultrasonographic assessment revealed hypoechoic structures with irregular, stellate borders and increased vascularity around the infiltrating squamous mucosal and submucosal regions in cases of infiltrating squamous carcinoma. Candidiasis with ulceration appeared as a hyper-echoic gap with frayed margins and heterogeneous submucosal involvement. Sublingual fibroma presented as an isoechoic esophytic lesion with well-defined margins. All lesions were pathologically confirmed except for a recurrent lesion involving the posterior gingival angle and both the soft and hard palate regions. The study found a positive correlation between UHFUS measurements and histology for both TT and DOI, although UHFUS slightly overestimated the latter. The site of the lesion did not significantly affect echogenicity or vascularization.

#### CONCLUSION

Emerging as a non-invasive method, UHFUS has proven useful for investigating both endo- and exophytic lesions within the oral cavity. The main limitation lies in the inability to image lesions located in the posterior aspect of the hard palate or soft palate. Our preliminary experience, although limited in samplesize, has demonstrated consistent correspondence between UHFUS and pathological anatomy. These findings highlight the potential of UHFUS as a valuable technique for evaluating oral lesions and offer guidance for its inclusion within diagnostic and surgical management protocols. In conclusion, intraoral UHFUS has presented promising potential for OSCC due to its significant correlation with histology.

#### CLINICAL RELEVANCE/APPLICATION

These findings highlight the potential of UHFUS as a valuable technique for evaluating oral lesions and offer guidance for its inclusion within diagnostic and surgical management protocols. In conclusion, intraoral UHFUS has presented promising potential for OSCC due to its significant correlation with histology.

### S1-SSHNO1-3 An AI-driven end-to-end Segmentation Tool for Extraocular Muscles Affecting Thyroid Eye Disease (TED)

Vikash Gupta, PhD, MS (*Presenter*) Nothing to Disclose

## PURPOSE

Thyroid Eye Disease (TED), also known as Graves' ophthalmopathy or orbitopathy, is a condition that affects patients with autoimmune hyperthyroidism. It is caused by the activation of orbital fibroblasts by thyroid autoantibodies leading to their proliferation, differentiation, and the deposition of glycosaminoglycans, ultimately leading to varying degrees of enlargement of the extraocular muscles and an increase in orbital fat. The resulting symptoms of TED can include exophthalmos, lagophthalmos, diplopia, and periorbital edema as well as compressive optic neuropathy which can lead to permanent blindness. We developed a system for automated segmentation of 10 non-osseous structures in the orbit for the purpose of longitudinal morphological monitoring as the disease progresses or responds to treatment.

## METHODS AND MATERIALS

We identified neuroradiologist-verified CT scans of normal orbits (n=32) and 10 orbits affected by TED (n=32). Orbital structures (globe, optic nerve, fat, lacrimal gland, and 6 extraocular muscles) were manually segmented on each orbit by trained raters using ITKSnap. For binary segmentation, a 3D-UNet-based method (5 encoding layers of 16, 32, 62, 128, and 256 channels and 5 decoding layers of matching channels) was used. First, the relevant image quadrant (top-left or top-right depending on the eye) was cropped and the images were resized to a size of 256, 256, and 96 slices. A binary image was created from each of the 10 labels. The model was trained 2000 epochs using 44 training and 10 validation image-label pairs; a separate segmentation model was employed for each label. Testing was performed on 10 new image-label pairs, and performance was quantified using the dice coefficient.

## RESULTS

Dice scores for each label were: globe 0.913, optic nerve 0.729, medial rectus 0.606, inferior rectus 0.693, lateral rectus 0.586, superior rectus 0.670, superior oblique 0.488, inferior oblique 0.512, fat 0.820, lacrimal gland 0.416.

## CONCLUSION

This is one of the first attempts to study the segmentation of the orbital tissues in the setting of TED. The ability to automatically segment these structures will facilitate large-scale statistical analyses of the individual compartment shapes and volumes to detect early TED, its progression, and/or its response to therapy.

## CLINICAL RELEVANCE/APPLICATION

Segmenting the aforementioned muscles is a labor-intensive task, which prevents large-scale morphological statistical study in this domain. An automated end-to-end process will help in evaluating the effects of therapy in long-term patient care.

## S1-SSHN01-4 Two Heterogeneous Growth and Prognosis Patterns of Metastatic Cervical Lymph Node Among Nasopharyngeal Carcinoma: Is it True that the Bigger the Lymph Node the Worse the Prognosis

Shuqi Li, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Anti-tumor immunity and metastatic ability are presented in metastatic cervical lymph node (mCLN) simultaneously. However, for patients with nasopharyngeal carcinoma (NPC), there is currently no simple and feasible radiological indicator that can distinguish the dominant effect of mCLN, making it difficult to guide further management. Here, we investigated the cervical lymph node-to-primary tumor ratio of the maximum diameter (maxCLN/maxPT) in indicating prognostic value and growth patterns for mCLN among NPC patients.

## METHODS AND MATERIALS

Totally 866 non-metastatic NPC patients with N1-N3 staging were retrospectively included from two centers. Scatter plot with polynomial fitting curve, Kaplan-Meier survival analysis and multivariable Cox proportional hazard model with or without interaction effect were carried out to analyze the association between maxCLN and maxPT and their dominant prognostic value in OS. Three methods including receiver operating characteristic curve, restricted cubic spline and maximally selected rank statistics were used to calculate the cutoff value of maxCLN/maxPT. Random matched-pair analysis was used to analyze the treatment outcomes. A violin plot with Chi-square test was used to show the difference of Ki-67 expressions between the two groups from biopsy samples of primary tumor and mCLN.

## RESULTS

The maxCLN was not an independent prognostic factor in OS among NPC until considering the interaction item of maxCLN/maxPT (HR: 0.14, 95% CI: 0.04-0.46, P=0.001). With the optimal cutoff value of 0.8 for maxCLN/maxPT, which was proved by three kinds of methods, patients were divided into two groups: the 5-year OS of CLN-protect group (maxCLN/maxPT=0.8) was better than those of CLN-damage group (maxCLN/maxPT<0.8) (all P and adjusted P<0.05). Better 5-year OS was achieved for CLN-protect group treated with additional induction chemotherapy comparing to concurrent chemoradiotherapy alone (82.6% vs. 93.3%, P and adjusted P<0.05). The maxCLN/maxPT indicated two types of growth patterns: the maxCLN grew faster than maxPT in CLN-protect group, which is opposite in CLN-damage group. The

expression of Ki-67 in mCLN was lower in CLN-protect group than those in CLN-damage group, supporting the favorable prognosis of maxCLN/maxPT.

## **CONCLUSION**

With the cutoff of 0.8, maxCLN/maxPT, which is a positive prognostic indicator and IC-sensitive marker, enable the identification for two types of growth patterns and prognostic value for mCLN among patients with NPC.

## **CLINICAL RELEVANCE/APPLICATION**

The introduction of maxCLN/maxPT reveals interaction association between mCLN and primary tumor, and visualizes intrinsic tumor activity. It provides a novel tool for accurate prognostic prediction among NPC patients with mCLN.

## **S1-SSHN01-5 A Comparative Analysis of Two Machine Learning-Based Diagnostic Patterns with Thyroid Imaging Reporting and Data System for Thyroid Nodules: Diagnostic Performance and Unnecessary Biopsy Rate**

Chong-Ke Zhao, PhD (*Presenter*) Nothing to Disclose

## **PURPOSE**

The risk stratification system of the American College of Radiology Thyroid Imaging Reporting and Data System (ACR TI-RADS) for thyroid nodules is affected by low diagnostic specificity. Machine learning (ML) methods can optimize the diagnostic performance in medical image analysis. However, it is unknown which ML-based diagnostic pattern is more effective in improving diagnostic performance for thyroid nodules and reducing nodule biopsies. Therefore, we compared ML-assisted visual approaches and radiomics approaches with ACR TI-RADS in diagnostic performance and unnecessary fine-needle aspiration biopsy (FNAB) rate for thyroid nodules.

## **METHODS AND MATERIALS**

This retrospective study evaluated a data set of ultrasound(US) and shear wave elastography (SWE) images in patients with biopsy-proven thyroid nodules ( $\geq 1$  cm) from the Hospital A (743 nodules in 720 patients from September 2017 to January 2019) and an independent test data set from the Hospital B (106 nodules in 102 patients from February 2019 to April 2019). Six US features and five SWE parameters from the radiologists' interpretation were used for building the ML-assisted visual approaches. The radiomics features extracted from the US and SWE images were used with ML methods for developing the radiomics approaches. The diagnostic performance for differentiating thyroid nodules and the unnecessary FNAB rate of the ML-assisted visual approaches and the radiomics approaches were compared with ACR TI-RADS.

## **RESULTS**

The ML-assisted US visual approach had the best diagnostic performance than the US radiomics approach and ACR TI-RADS (area under the curve [AUC]: 0.900 vs. 0.789 vs. 0.689 for the validation data set, 0.917 vs. 0.770 vs. 0.681 for the test data set). After adding SWE, the ML-assisted visual approach had a better diagnostic performance than US alone (AUC: 0.951 vs. 0.900 for the validation data set, 0.953 vs. 0.917 for the test data set). When applying the ML-assisted US+SWE visual approach, the unnecessary FNAB rate decreased from 30.0% to 4.5% in the validation data set and from 37.7% to 4.7% in the test data set in comparison to ACR TI-RADS.

## **CONCLUSION**

The ML-assisted dual modalities visual approach can assist radiologists to diagnose thyroid nodules more effectively and considerably reduce the unnecessary FNAB rate in the clinical management of thyroid nodules.

## **CLINICAL RELEVANCE/APPLICATION**

The application of the ML-assisted dual modalities visual approach can improve diagnostic for thyroid nodules and meaningful reduction in unnecessary FNAB rate of thyroid nodules. The ML method has significant potential for enhancing the ability of radiologists to determine the optimal clinical management of thyroid nodules.

##### S1-SSNMMI01-3 **Final Analysis of a Prospective, Single-center, Phase II/III Imaging Trial of <sup>68</sup>Ga-RM2 PET/MRI in Patients with Biochemical Recurrence of Prostate Cancer**

Heying Duan, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The recent NCCN guideline has included prostate-specific membrane antigen (PSMA)-targeted PET for the detection of biochemical recurrent (BCR) prostate cancer (PC). However, up to 10% of PC do not express PSMA, and given the high intratumor heterogeneity, targeting a single tumor characteristic might not be sufficient to reflect full extent of disease. Gastrin releasing peptide receptors (GRPR) have shown to be overexpressed in PC and can be targeted with <sup>68</sup>Ga-RM2. In this study, we evaluated the diagnostic performance of <sup>68</sup>Ga-RM2 PET/MRI in BCR PC.

#### METHODS AND MATERIALS

This prospective, single-center, open-label, single-arm, phase II/III trial was performed at Stanford University. Patients =18 years with Karnofsky performance =50, rising PSA =0.2 ng/mL after prostatectomy, or =2 ng/mL above nadir after radiotherapy, and non-contributory conventional imaging (negative CT and/or bone scan) were eligible. The primary outcome was to assess diagnostic performance of <sup>68</sup>Ga-RM2 PET/MRI vs MRI alone. Each PET scan was interpreted by three independent masked readers using a standardized evaluation criteria. This study is registered with ClinicalTrials.gov NCT02624518 and is complete.

#### RESULTS

Between December 12, 2015 and July 27, 2021, 209 patients were screened for eligibility, of whom 100 were included. The primary endpoint was met; <sup>68</sup>Ga-RM2 PET/MRI showed significantly higher detection rates than MRI alone (143 vs 96 lesions, respectively; P<0.001) and sensitivity (85.2%; 95% CI 75.6, 92.1 vs 49.4%; 95% CI 38.1, 60.7, respectively; P<0.001) while specificity was comparably high (100.0%; 95% CI 82.4, 100.0 vs 94.7%; 95% CI 74.0, 99.9, respectively; P=0.303).

#### CONCLUSION

<sup>68</sup>Ga-RM2 PET/MRI showed better diagnostic performance than MRI alone in BCR PC with significantly higher detection rates, sensitivity, and accuracy. Therefore, <sup>68</sup>Ga-RM2 PET should be considered in BCR PC patients in aiding disease detection and management decision. Further prospective comparative studies with PSMA-targeted PET are needed to gain a better understanding of GRPR and PSMA expression patterns in BCR PC.

#### CLINICAL RELEVANCE/APPLICATION

The collective findings of this comparative imaging trial and other published studies provide compelling evidence that <sup>68</sup>Ga-RM2 PET/MRI not only outperforms conventional imaging with MRI but also shows higher reliability and number of lesions

detected which could potentially affect subsequent patient management. Thus, GRPR-targeted PET imaging is a valuable tool in the imaging armamentarium of prostate cancer at biochemical recurrence.

## **S1-SSNMMI01-4 Correlation between PSMA PET/CT and Prostate MRI in Newly Diagnosed Prostate Cancer**

Sean Gharai, MD (*Presenter*) Nothing to Disclose

### **PURPOSE**

To compare prostate cancer mpMRI PIRADS score with 68Gallium Gozetotide Prostate Specific Membrane Antigen (68Ga PSMA) PET/CT lesion uptake in newly diagnosed prostate cancer. 68Ga PSMA PET/CT which was approved by the FDA for use in detection of metastatic disease in patients with castrate-resistant prostate cancer, has primarily been used to evaluate disease involvement following initial treatment with surgery or radiation therapy. To our knowledge, there are few studies directly comparing the correlation between 68Ga PSMA PET/CT and prostate MRI in newly diagnosed prostate cancer prior to definitive treatment. We aim to evaluate the complementary role of these studies in this patient group.

### **METHODS AND MATERIALS**

15 newly diagnosed biopsy proven prostate cancer patients who underwent prostate MRI with and without contrast and 68Ga PSMA PET/CT are included in our retrospective analysis. All patients underwent prostate MRI, followed by 68Ga PSMA PET/CT. After injection of 68Ga PSMA, emission and transmission scans of the whole body from the head to mid-thigh as well as a low-dose spiral CT scan from the lower head to mid-thigh for anatomical localization were obtained. The maximum standardized uptake values (SUVmax) were calculated using the patient's body weight and injected dose. The lesion's PIRADS score and zonal location was correlated with 68Ga PSMA lesion location and SUVmax.

### **RESULTS**

One patient was diagnosed with a PIRADS 3 lesion, six patients with a PIRADS 4 lesion, and eight patients with a PIRADS 5 lesion. SUVmax values ranged from 3.3 to 29.9. The prostate zonal location of the 68Ga PSMA and mpMRI lesions were concordant in 14 of 15 patients. Out of these 14 patients, 12 had a relatively high lesion SUVmax (6.2-29.9) and a high PIRADS score (4 or 5). In the remaining two patients, one had a relatively low SUVmax (3.3) and low PIRADS score (3) and one had high SUVmax (22.7) and low PIRADS score (3).

### **CONCLUSION**

Our findings demonstrate correlation between SUVmax of lesions on 68Ga PSMA PET/CT and corresponding PIRADS score on MRI in newly diagnosed prostate cancer patients. Further studies with higher sample sizes are warranted to establish a statistically significant relationship between the degree of uptake and PIRADS score. Based on our findings, future investigation of the correlation between SUVmax, PIRADS score, and pathologic Gleason score may aid in treatment planning.

### **CLINICAL RELEVANCE/APPLICATION**

68Ga PSMA PET/CT and prostate MRI may be complementary in both initial diagnosis and therapy planning, including guiding radiation where it may be the appropriate therapeutic approach.

## **S1-SSNMMI01-5 Comparison of the Pattern of Local Prostate Cancer Recurrence on <sup>68</sup>Ga-PSMA PET/CT Versus <sup>18</sup>F-fluciclovine PET/CT in Post-prostatectomy, Pre-radiotherapy Patients: Analysis of a Randomized Controlled Trial**

Ismahel Lawal, MD, PhD (*Presenter*) Nothing to Disclose

### **PURPOSE**

Local recurrence in the prostate bed region (PBR) is the earliest and commonest form of prostate cancer (PCa) recurrence. We investigated the detection rate and pattern of local recurrence of prostate cancer (PCa) on 68Ga-PSMA PET/CT versus 18F-fluciclovine PET/CT in post-prostatectomy patients to see if the differences in the excretory patterns of these tracers influence lesion detection in the prostate bed region (PBR).

### **METHODS AND MATERIALS**

We evaluated PET/CT images of patients recruited into a phase 2 trial that randomized post-prostatectomy patients with detectable PSA to imaging with either 68Ga-PSMA PET/CT with 20 mg furosemide at radiotracer injection or routine 18F-fluciclovine PET/CT for guiding salvage radiotherapy decision. Two experienced Nuclear Medicine Physicians read the scans independently. We identified patients with PBR recurrence and categorized the sites of recurrence as (i) vesicourethral anastomotic (VUA) site, (ii) seminal vesicle lateral resection margin region (SVLR), (ii) retrovesical (RV) region, and (iv) other regions, including recurrence in the urethral, bladder and rectal walls. We compared the pattern of recurrent lesions seen on 68Ga-PSMA PET/CT versus 18F-fluciclovine PET/CT using Chi-square test.

## RESULTS

Sixty-nine and 66 patients completed 68Ga-PSMA PET/CT and 18F-fluciclovine PET/CT, respectively. Median PSA was not different between the 68Ga-PSMA arm and 18F-fluciclovine arms [0.39 (IQR=0.19 - 1.13) ng/mL and 0.28 (IQR=0.13 - 0.79) ng/mL, respectively,  $p=0.276$ ]. 18F-fluciclovine PET/CT detected more PBR recurrence than 68Ga-PSMA PET/CT (87.88% versus 37.68%,  $p<0.001$ ). Among the 26 patients with PBR recurrence on 68Ga-PSMA PET/CT, 35 recurrent lesions were detected versus 58 patients with 104 PBR lesions detected on 18F-fluciclovine. Fourteen VUA lesions were detected on 68Ga-PSMA PET/CT and 52 on 18F-fluciclovine PET/CT,  $p<0.001$ . Twelve SVLR lesions were detected on 68Ga-PSMA versus 40 on 18F-fluciclovine,  $p=0.081$ . One recurrent lesion was seen each on 68Ga-PSMA PET/CT and 18F-fluciclovine PET/CT in the RV region. Eight recurrent lesions at other sites were seen on 68Ga-PSMA PET/CT versus 11 on 18F-fluciclovine PET/CT,  $p=0.361$ .

## CONCLUSION

<sup>18</sup>F-fluciclovine PET/CT has a higher detection rate at the VUA post-prostatectomy compared to <sup>68</sup>Ga-PSMA, despite the use of furosemide with <sup>68</sup>Ga-PSMA. Differences in detection rate at other prostate bed sites did not reach statistical significance.

## CLINICAL RELEVANCE/APPLICATION

18F-fluciclovine PET/CT for PCa recurrence improves lesion detection at the vesicourethral anastomosis versus 68Ga-PSMA with furosemide likely due to lower bladder activity, allowing better visualization of bladder contiguous structures.

## S1- SSNMMI01- Improvement of Gleason Grading Prediction in Prostate Cancer Stratification for Radical Prostatectomy: A Machine Learning- based Theranostic Multi-omics Study

Jing Ning, MD (Presenter) Nothing to Disclose

## PURPOSE

We aim to improve the predictive performance of the whole mount Gleason grading in prostate cancer for a smart and better stratification for radical prostatectomy by deploying a high-throughput machine learning model to merge multiple omics.

## METHODS AND MATERIALS

**Study Design** A total of 146 patients with histologically confirmed prostate cancer were enrolled in this study, all of whom underwent 68Ga-PSMA-11 PET/MR scans before radical prostatectomy between May 2014 to April 2020 in the nuclear medicine department of our hospital. After the surgery, all patients were followed up until 1st December 2022. **Radiomics Data Acquisition** Volumes of Interest (VOIs) were delineated 68Ga-PSMA-11 PET/MR images on Hermes, from whom radiomics features were computed using the PyRadiomics. **Genomics Data Acquisition** DNA was isolated from FFPE samples of radical prostatectomy. Whole exome sequencing (WES) analysis was conducted. Functional pathway states were quantified using multiple established in silico tools. **Clinical endpoints** were defined as BCR status and death status. **Pathomics Data Acquisition** Tissue microarray were constructed from RP specimens and immunohistochemical analysis was performed on 2-5- $\mu$ m-thick sections from FFPE samples. PSMA, AR, Ki-67, PSA, FASN, IL6ST, CDK2, CD3, STAT3, NKX3.1, TBb have already been selected as potential biomarkers and stained in TMA slides. **ML-based Data Integration** We established 5 ML-based models including KNN, RF, SVM, IGR, and XGB. These ML algorithms were applied to the integration of clinical parameters, radiomics data, genomics data and pathomics data. The classification results were validated using 100-fold Monte Carlo cross-validation.

## RESULTS

The AUC, ACC, SNS, SPC, PPV and NPV of 5 ML-based approaches were respectively calculated and the resulting RF classification algorithm gave the best performance with 0.87, 0.78, 0.83, 0.72, 0.80, 0.80. Compared to needle biopsy, the performance of machine learning algorithm to predict Gleason grading is better. The specificity, positive predictive value, accuracy and the area under curve were elevated by 18% (0.61 vs 0.72), 7% (0.75 vs 0.80), 1% (0.77 vs 0.78) and 11% (0.75 vs 0.87) respectively while the sensitivity and negative predictive value were decreased by 7% (0.89 vs 0.83) and 1% (0.81 vs 0.80).

## CONCLUSION

Our findings suggest that our multi-omics machine learning model has the better performance for the prediction of Gleason grading than the current clinical baseline, which potentially facilitate the clinical decision-making and personalized management of prostate cancer.

## CLINICAL RELEVANCE/APPLICATION

To facilitate precise prostate cancer patient stratification for radical prostatectomy.

### Final Analysis of a Prospective, Single-center, Phase II/III Imaging Trial of <sup>68</sup>Ga-RM2 PET/MRI in Patients with Biochemical Recurrence of Prostate Cancer

Sunday, Nov. 26 9:00AM - 10:00AM Room: E350

Heying Duan, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The recent NCCN guideline has included prostate-specific membrane antigen (PSMA)-targeted PET for the detection of biochemical recurrent (BCR) prostate cancer (PC). However, up to 10% of PC do not express PSMA, and given the high intratumor heterogeneity, targeting a single tumor characteristic might not be sufficient to reflect full extent of disease. Gastrin releasing peptide receptors (GRPR) have shown to be overexpressed in PC and can be targeted with <sup>68</sup>Ga-RM2. In this study, we evaluated the diagnostic performance of <sup>68</sup>Ga-RM2 PET/MRI in BCR PC.

#### METHODS AND MATERIALS

This prospective, single-center, open-label, single-arm, phase II/III trial was performed at Stanford University. Patients =18 years with Karnofsky performance =50, rising PSA =0.2 ng/mL after prostatectomy, or =2 ng/mL above nadir after radiotherapy, and non-contributory conventional imaging (negative CT and/or bone scan) were eligible. The primary outcome was to assess diagnostic performance of <sup>68</sup>Ga-RM2 PET/MRI vs MRI alone. Each PET scan was interpreted by three independent masked readers using a standardized evaluation criteria. This study is registered with ClinicalTrials.gov NCT02624518 and is complete.

#### RESULTS

Between December 12, 2015 and July 27, 2021, 209 patients were screened for eligibility, of whom 100 were included. The primary endpoint was met; <sup>68</sup>Ga-RM2 PET/MRI showed significantly higher detection rates than MRI alone (143 vs 96 lesions, respectively;  $P<0.001$ ) and sensitivity (85.2%; 95% CI 75.6, 92.1 vs 49.4%; 95% CI 38.1, 60.7, respectively;  $P<0.001$ ) while specificity was comparably high (100.0%; 95% CI 82.4, 100.0 vs 94.7%; 95% CI 74.0, 99.9, respectively;  $P=0.303$ ).

#### CONCLUSION

<sup>68</sup>Ga-RM2 PET/MRI showed better diagnostic performance than MRI alone in BCR PC with significantly higher detection rates, sensitivity, and accuracy. Therefore, <sup>68</sup>Ga-RM2 PET should be considered in BCR PC patients in aiding disease detection and management decision. Further prospective comparative studies with PSMA-targeted PET are needed to gain a better understanding of GRPR and PSMA expression patterns in BCR PC.

#### CLINICAL RELEVANCE/APPLICATION

The collective findings of this comparative imaging trial and other published studies provide compelling evidence that <sup>68</sup>Ga-RM2 PET/MRI not only outperforms conventional imaging with MRI but also shows higher reliability and number of lesions detected which could potentially affect subsequent patient management. Thus, GRPR-targeted PET imaging is a valuable tool in the imaging armamentarium of prostate cancer at biochemical recurrence.

### Correlation between PSMA PET/CT and Prostate MRI in Newly Diagnosed Prostate Cancer

Sunday, Nov. 26 9:00AM - 10:00AM Room: E350

Sean Gharai, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare prostate cancer mpMRI PIRADS score with 68Gallium Gozetotide Prostate Specific Membrane Antigen (68Ga PSMA) PET/CT lesion uptake in newly diagnosed prostate cancer. 68Ga PSMA PET/CT which was approved by the FDA for use in detection of metastatic disease in patients with castrate-resistant prostate cancer, has primarily been used to evaluate disease involvement following initial treatment with surgery or radiation therapy. To our knowledge, there are few studies directly comparing the correlation between 68Ga PSMA PET/CT and prostate MRI in newly diagnosed prostate cancer prior to definitive treatment. We aim to evaluate the complementary role of these studies in this patient group.

#### METHODS AND MATERIALS

15 newly diagnosed biopsy proven prostate cancer patients who underwent prostate MRI with and without contrast and 68Ga PSMA PET/CT are included in our retrospective analysis. All patients underwent prostate MRI, followed by 68Ga PSMA PET/CT. After injection of 68Ga PSMA, emission and transmission scans of the whole body from the head to mid-thigh as well as a low-dose spiral CT scan from the lower head to mid-thigh for anatomical localization were obtained. The maximum standardized uptake values (SUVmax) were calculated using the patient's body weight and injected dose. The lesion's PIRADS score and zonal location was correlated with 68Ga PSMA lesion location and SUVmax.

#### RESULTS

One patient was diagnosed with a PIRADS 3 lesion, six patients with a PIRADS 4 lesion, and eight patients with a PIRADS 5 lesion. SUVmax values ranged from 3.3 to 29.9. The prostate zonal location of the 68Ga PSMA and mpMRI lesions were concordant in 14 of 15 patients. Out of these 14 patients, 12 had a relatively high lesion SUVmax (6.2-29.9) and a high PIRADS score (4 or 5). In the remaining two patients, one had a relatively low SUVmax (3.3) and low PIRADS score (3) and one had high SUVmax (22.7) and low PIRADS score (3).

#### CONCLUSION

Our findings demonstrate correlation between SUVmax of lesions on 68Ga PSMA PET/CT and corresponding PIRADS score on MRI in newly diagnosed prostate cancer patients. Further studies with higher sample sizes are warranted to establish a statistically significant relationship between the degree of uptake and PIRADS score. Based on our findings, future investigation of the correlation between SUVmax, PIRADS score, and pathologic Gleason score may aid in treatment planning.

#### CLINICAL RELEVANCE/APPLICATION

68Ga PSMA PET/CT and prostate MRI may be complementary in both initial diagnosis and therapy planning, including guiding radiation where it may be the appropriate therapeutic approach.

### Comparison of the Pattern of Local Prostate Cancer Recurrence on $^{68}\text{Ga}$ -PSMA PET/CT Versus $^{18}\text{F}$ -fluciclovine PET/CT in Post-prostatectomy, Pre-radiotherapy Patients: Analysis of a Randomized Controlled Trial

Sunday, Nov. 26 9:00AM - 10:00AM Room: E350

Ismaheel Lawal, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Local recurrence in the prostate bed region (PBR) is the earliest and commonest form of prostate cancer (PCa) recurrence. We investigated the detection rate and pattern of local recurrence of prostate cancer (PCa) on  $^{68}\text{Ga}$ -PSMA PET/CT versus  $^{18}\text{F}$ -fluciclovine PET/CT in post-prostatectomy patients to see if the differences in the excretory patterns of these tracers influence lesion detection in the prostate bed region (PBR).

#### METHODS AND MATERIALS

We evaluated PET/CT images of patients recruited into a phase 2 trial that randomized post-prostatectomy patients with detectable PSA to imaging with either  $^{68}\text{Ga}$ -PSMA PET/CT with 20 mg furosemide at radiotracer injection or routine  $^{18}\text{F}$ -fluciclovine PET/CT for guiding salvage radiotherapy decision. Two experienced Nuclear Medicine Physicians read the scans independently. We identified patients with PBR recurrence and categorized the sites of recurrence as (i) vesicourethral anastomotic (VUA) site, (ii) seminal vesicle lateral resection margin region (SVLR), (ii) retrovesical (RV) region, and (iv) other regions, including recurrence in the urethral, bladder and rectal walls. We compared the pattern of recurrent lesions seen on  $^{68}\text{Ga}$ -PSMA PET/CT versus  $^{18}\text{F}$ -fluciclovine PET/CT using Chi-square test.

#### RESULTS

Sixty-nine and 66 patients completed  $^{68}\text{Ga}$ -PSMA PET/CT and  $^{18}\text{F}$ -fluciclovine PET/CT, respectively. Median PSA was not different between the  $^{68}\text{Ga}$ -PSMA arm and  $^{18}\text{F}$ -fluciclovine arms [0.39 (IQR=0.19 - 1.13) ng/mL and 0.28 (IQR=0.13 - 0.79) ng/mL, respectively,  $p=0.276$ ].  $^{18}\text{F}$ -fluciclovine PET/CT detected more PBR recurrence than  $^{68}\text{Ga}$ -PSMA PET/CT (87.88% versus 37.68%,  $p<0.001$ ). Among the 26 patients with PBR recurrence on  $^{68}\text{Ga}$ -PSMA PET/CT, 35 recurrent lesions were detected versus 58 patients with 104 PBR lesions detected on  $^{18}\text{F}$ -fluciclovine. Fourteen VUA lesions were detected on  $^{68}\text{Ga}$ -PSMA PET/CT and 52 on  $^{18}\text{F}$ -fluciclovine PET/CT,  $p<0.001$ . Twelve SVLR lesions were detected on  $^{68}\text{Ga}$ -PSMA versus 40 on  $^{18}\text{F}$ -fluciclovine,  $p=0.081$ . One recurrent lesion was seen each on  $^{68}\text{Ga}$ -PSMA PET/CT and  $^{18}\text{F}$ -fluciclovine PET/CT in the RV region. Eight recurrent lesions at other sites were seen on  $^{68}\text{Ga}$ -PSMA PET/CT versus 11 on  $^{18}\text{F}$ -fluciclovine PET/CT,  $p=0.361$ .

#### CONCLUSION

$^{18}\text{F}$ -fluciclovine PET/CT has a higher detection rate at the VUA post-prostatectomy compared to  $^{68}\text{Ga}$ -PSMA, despite the use of furosemide with  $^{68}\text{Ga}$ -PSMA. Differences in detection rate at other prostate bed sites did not reach statistical significance.

#### CLINICAL RELEVANCE/APPLICATION

$^{18}\text{F}$ -fluciclovine PET/CT for PCa recurrence improves lesion detection at the vesicourethral anastomosis versus  $^{68}\text{Ga}$ -PSMA with furosemide likely due to lower bladder activity, allowing better visualization of bladder contiguous structures.

### Physics (Photon Counting Detector CT I)

Sunday, Nov. 26 9:00AM - 10:00AM Room: E353C

Cynthia H. McCollough, PhD (*Moderator*) Research Grant, Siemens AG  
Ke Li, PhD (*Moderator*) Research Consultant, Pulmera Inc.

#### Sub-Events

#### S1-SSPH01-1 Scatter Estimation and Correction in Photon Counting Detector CT

Ran Zhang, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Scattered radiation in multi-row detector CT (MDCT) and cone-beam CT (CBCT) can lead to image artifacts, contrast reduction, and quantification errors. Multi-row photon counting detector CT (PCD-CT) is a promising technology that can potentially improve clinical CT imaging. This work aimed to develop a real-time and effective method for scatter estimation and correction using the energy-discriminating capability of PCD-CT.

#### METHODS AND MATERIALS

Monte Carlo simulations and experimental measurements were conducted to investigate the impact of energy thresholds on the scatter-to-primary ratio (SPR) in PCD-CT. A benchtop PCD-CT system with a 120 kVp spectrum and 4-cm z-coverage was utilized. The energy threshold of the PCD (T) was changed from 40 keV to 110 keV, creating a low-energy bin [20 keV, T] and a high-energy bin [T, 120 keV]. The SPR in low-energy and high-energy bins was measured as a function of the energy threshold. A novel data acquisition mode called MoHi-PoLo was proposed, which combines a quasi-Monochromatic High-energy bin and a Polychromatic Low-energy bin. A scatter correction method was then proposed to leverage the benefits of the MoHi-PoLo acquisition. Physical phantom experiments were conducted to demonstrate the effectiveness and robustness of the proposed method.

#### RESULTS

The SPR measurements showed that 1) high-energy bin data in PCD-CT always have a lower SPR compared to the corresponding low-energy bin data; 2) the SPR of the high-energy bin decreased significantly as the energy threshold increased; and 3) when the energy threshold approached the maximum keV of the spectrum, MoHi bin data was nearly free of scatter artifacts. Moreover, MoHi bin data was effective in estimating and correcting scatter in the PoLo bin.

#### CONCLUSION

Scatter decreases significantly in higher energy bins of PCD-CT. By utilizing the energy-discriminating capability offered by PCD-CT, the proposed MoHi-PoLo data acquisition scheme provides a new opportunity to address the scatter problem in CT.

#### CLINICAL RELEVANCE/APPLICATION

Scatter has a significant impact on the accuracy of HU number and material quantification. A real-time and low-cost scatter correction method can benefit many applications in interventional radiology and radiation therapy.

#### S1-SSPH01-2 Quantitative Knee Imaging using High-resolution Photon-counting Detector CT

Kishore Rajendran, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To demonstrate the feasibility of simultaneous, quantitative cartilage and subchondral bone imaging using ultra-high-resolution (UHR) multi-energy photon-counting detector (PCD) CT.

## METHODS AND MATERIALS

After approval from our institutional review board, four cadaveric knees were scanned on a clinical PCD-CT system (Siemens NAEOTOM Alpha) using the UHR collimation (120 x 0.2 mm) at 120 kV, 20 mGy CTDIvol mimicking the routine knee arthrography protocol used in our clinical practice. A 50 mL bolus of 50-75% diluted anionic iodine contrast (Conray, Guerbet LLC) was injected into the intraarticular space under sonographic guidance approximately 10 minutes prior to CT acquisition. UHR PCD-CT images (0.2-mm thickness, "T3D" images using 20-120 keV, Br96 kernel with cutoff frequency at 40 lp/cm), and low- and high-energy threshold images (0.4 mm thickness, 20-120 keV and 65-120 keV, Qr76 kernel with cutoff frequency at 28 lp/cm) were reconstructed for trabecular bone morphometry and quantitative iodine decomposition, respectively. A material decomposition algorithm was applied to the Qr76 images to quantify iodine diffusion in the articular cartilage, while the UHR Br96 images were used to quantify trabecular thickness (Tb.Th), spacing (Tb.Sp) and bone volume fraction (BV/TV) in distal femur and proximal tibia of each knee. Additionally, a multi-energy CT phantom (Gammex, Sun Nuclear, WI) containing iodine at 2, 5, 10, 15 mg/cc was scanned on the PCD-CT system to assess iodine quantification accuracy using root-mean-squared-error (RMSE).

## RESULTS

Iodine decomposition in the articular cartilage showed contrast diffusion up to 15 mg/mL in the superficial zone and between 0 and 5 mg/mL in the deep zone. Bone morphometry measurements showed Tb.Th ranging from 0.43 to 0.54 mm, Tb.Sp ranging from 1.14 to 2.95 mm, and BV/TV ranging from 0.12 to 0.2. The RMSE for iodine quantification was 0.19 mg/cc in the multi-energy phantom.

## CONCLUSION

The UHR mode of the PCD-CT system facilitates simultaneous assessment of bone trabecular architecture and iodine quantification in intraarticular cartilage of the knee joint from a single arthrographic exam.

## CLINICAL RELEVANCE/APPLICATION

Contrast diffusion in cartilage, and trabecular microarchitecture are crucial markers of overall joint health relevant to diagnosis and management of osteoarthritis.

## S1- SSPH01-3 High z-axis Resolution Imaging using CZT Based Photon Counting CT: Quantitative Study and First Clinical Trial

Saeko Mochinaga, RT (*Presenter*) Nothing to Disclose

## PURPOSE

First clinical studies have been performed on CZT-based photon counting CT (CZT-PCD-CT). Due to its small detector pixel design, CZT-PCD-CT can provide super high-resolution (SHR) mode with 0.2mm slice thickness. Its z-axis resolution stands out from conventional scintillator-based CT systems. This study aims to characterize z-resolution improvements of CZT-PCD-CT using phantom studies and explore its potential clinical benefits in thoracic and spine imaging.

## METHODS AND MATERIALS

The prototype CZT-PCD-CT is built based on a Aquilion Precision system (Canon Medical Systems, Japan). The beam coverage of the system is 40 mm, and the focus size is 0.4\*0.5 mm. To evaluate z-axis resolution, comb-shaped phantom of 0.3, 0.4, 0.5, 0.6 mm intervals were scanned with helical-mode, 120 kVp, 100 mA, 0.5 s/rotation, pitch factor of 0.8. Normal resolution (NR) and SHR images were reconstructed with standard kernel with filtered back projection. NR images were 512-matrix size and 0.6 mm slice thickness, and SHR images were 1024-matrix size and 0.2 mm slice thickness. Coronal NR and SHR images of the comb phantom were obtained for the visibility evaluation and profile measurement. In addition, the visibility of bone and lung structures and the image noise (noise SD) was evaluated with sagittal images of the thoracic spine and coronal images of the lung. These clinical images were reconstructed using NR mode with hybrid-iterative reconstruction and SHR mode with hybrid-iterative reconstruction and deep learning reconstruction (DLR).

## RESULTS

For the comb phantom images, 0.3 mm gap on the SHR images was visible while gap of 0.5 mm or less on the NR images was not visible. Cortical and cancellous bone on sagittal images of the thoracic spine was more sharply delineated in SHR images. The noise SD of the intervertebral disc was 10.2 HU for the NR images, 13.1 HU for the SHR images with IR, and 11.1 HU for the SHR images with DLR. The interlobar pleura, bronchioles, and ground glass opacity on the coronal lung images were also more visible on the SHR images. The noise SD of the lung field was 52.6 HU for the NR images, 73.4 HU for the SHR images with IR, and 45.5 HU for the SHR images with DLR. These results showed that SHR images has higher Z-axis spatial resolution than NR images, and improved image quality of CT images obtained with multi planar reconstruction.

## CONCLUSION

SHR provides higher Z-axis spatial resolution and MPR images with higher sharpness compared to NR. Furthermore, DLR algorithm is expected to maintain resolution and further reduce noise.

## CLINICAL RELEVANCE/APPLICATION

Z-axis spatial resolution is important for the evaluation of sharpness MPR images, and the SHR modes of PCD-CT contribute to the improvement of the image quality of MPR images.

### **S1-SSPH01-4 Initial Investigation of Metal Artifact Reduction Performance on a Prototype Deep Silicon Based Photon Counting CT System**

Jonathan L. Troville, PhD (*Presenter*) Research support, Canon Medical Systems Corporation

#### **PURPOSE**

To compare the efficacy of metal artifact reduction using a prototype deep silicon based photon counting CT system with energy-integrating detector (EID) CT.

#### **METHODS AND MATERIALS**

A prototype deep silicon based photon counting CT scanner and an EID CT scanner (GE Discovery CT750 HD) were used to acquire images of a surgical screw. The screw was placed in a 20 cm-diameter water bath. 140 keV virtual monochromatic images were acquired with the deep silicon prototype at 120 kV, 290 mA, 0.5 second rotation time, and 0.417 mm slice thickness. 140 kV polychromatic and 140 keV virtual monochromatic images were acquired on the EID scanner at 140 kV/80 mA/1 second rotation time/0.625 mm slice thickness, and 80-140 kV/260 mA/0.8 seconds rotation time/0.625 mm slice thickness respectively. All images were reconstructed at 100 mm reconstruction diameter. ROIs were manually placed over the regions containing the largest magnitude hypo and hyper dense artifacts for each scan mode. Additionally, ROIs were placed over water background regions approximately 20 mm from the center of the surgical screw. HU values averaged over the background ROIs, standard deviations of the averages, and integral uniformity of background ROI values were compared between acquisition types.

#### **RESULTS**

Deep silicon photon counting images exhibited the smallest magnitude hyper/hypo dense artifacts with values of 130/-194 HU, compared to 367/-305 and 332/-451 HU for polychromatic and GSI scan types, respectively. The background water range of average HU values was -20.81 to 16.42 (SD: 17.53), -78.48 to 14.94 (SD: 50.77), and -132.7 to 20.67 (SD: 79.59) for deep silicon, polychromatic, and GSI modes respectively.

#### **CONCLUSION**

This study indicates that deep silicon photon counting outperforms polychromatic and dual energy for reduction of metal artifacts of a surgical screw model. Deep silicon provided better reduction of artifact near the surgical screw, and in regions further away from the screw.

## CLINICAL RELEVANCE/APPLICATION

Visualization near the surface of surgical screws is important to assess for screw loosening and infection but is impeded by artifact which was less severe with deep silicon photon counting compared to energy integrating and dual energy CT.

### **S1-SSPH01-5 Universal 120 kV Dual-Source Ultra-High Pitch Protocol on the Emerging Photon Counting CT System for Pediatric Abdomen of All Sizes: A Phantom Investigation**

Wei Zhou, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To test the hypothesis if a universal 120 kV ultra-high pitch and virtual monoenergetic image (VMI) on photon counting CT (PCCT) can provide equivalent or better quality for pediatric abdominal imaging, regardless of size, compared to single kV energy-integrating CT (EICT).

#### **METHODS AND MATERIALS**

3 iodine (2, 5, 10 mgI/cc) and 1 solid water inserts were attached to phantoms of variable sizes (Dw of 11.7, 17.3, 19.2, 32cm), simulating abdomen of a newborn, 5-year-old, 10-year-old, and adult size pediatric patients. Each phantom setting was scanned on a EICT (Siemens Drive) using clinical size specific kV (e.g. 80kV for newborn, 120kV for adult size), pitch 3 abdomen protocol. The CTDIvol of each phantom was determined by clinical CareDose on, while all scans were later performed with fixed mA and matched to pre-determined CTDIvol on EICT. Each phantom was then scanned on a PCCT (Siemens Alpha) using 120kV, pitch 3, and CTDI values matched to EICT scans. VMIs were generated from PCCT scans between 40 and 80keV with a 5keV interval. Reconstructions were matched between PCCT and EICT. Image noise was measured as standard deviation of solid water. Iodine CNR was measured as 10mgI/cc vs. water. NPS was measured in uniform phantom regions. Image quality metrics were compared between PCCT VMIs and EICT.

## RESULTS

The noise level of PCCT VMIs decreases with increased keV while CNR decreases with increased keV. The noise level (HU) of PCCT VMIs at 65keV ( $7.8\pm 0.9$ ) for newborn, 70keV ( $8.8\pm 1.1$ ) for 5 years, 55keV ( $12.0\pm 0.8$ ) for 10 years, and 65keV ( $15.8\pm 1.8$ ) for adult size are comparable or lower than ( $P<0.05$ , T-Test) corresponding EICT acquisitions with size specific kV (newborn:  $7.8\pm 0.8$ , 5 years:  $7.6\pm 1.0$ , 10 years:  $12.2\pm 0.7$ , adult size:  $15.3\pm 1.5$ ). The CNR of PCCT VMI at 50keV ( $51.1\pm 10.2$ ) for newborn, 55keV ( $42.5\pm 3.8$ ) for 5 years, 70keV ( $27.5\pm 1.0$ ) for 10 years, and 80keV ( $14.1\pm 1.4$ ) for adult size is comparable or higher than ( $P<0.05$ ) EICT acquisitions with size specific kV (newborn:  $55.8\pm 5.4$ , 5 years:  $40.6\pm 6.2$ , 10 years:  $25.4\pm 0.7$ , adult size:  $13.4\pm 1.4$ ). The peak noise frequency (mm<sup>-1</sup>) of PCCT VMIs at 65 or 70keV (newborn: 0.18, 5 years: 0.15, 10 years: 0.19, adult size: 0.16) is almost identical to EICT images (newborn: 0.18, 5 years: 0.15, 10 years: 0.19, adult size: 0.17).

## CONCLUSION

Compared to size specific kV EICT, PCCT 120kV and post-processed VMIs can provide equivalent or better quality for pediatric abdominal CT, regardless of patient size.

## CLINICAL RELEVANCE/APPLICATION

Our findings provide the first evidence that all (contrast or non-contrast) pediatric abdominal CT can be scanned by a universal ultra-fast protocol on PCCT, which reduces complexity of pediatric CT protocols to accommodate diverse patient sizes while avoiding sub-optimal acquisition parameters based on size.

## S1- SSPH01-6 Simultaneous Multi-energy High-pitch CT Pulmonary Angiography using a Dual-source Photon-counting-detector CT: A Phantom Experiment

Jelena Mihailovic, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

A dual-source CT system can be operated in a high pitch (3.2) helical mode (FLASH) to provide a temporal resolution as fast as 66 milliseconds, which is beneficial to reduce motion artifacts in CT pulmonary angiography (CTPA). A dual-source CT can also be operated in a multi-energy (ME) mode (including dual-energy) to provide pulmonary perfused blood volume (PBV) information, beneficial in the evaluation of pulmonary embolism (PE). Currently, no energy-integrating detector (EID) CT can perform ME acquisition at a temporal resolution as fast as in the high-pitch scan mode. The purpose of this phantom study is to evaluate the ability of a dual-source photon-counting-detector (PCD) CT to perform simultaneous ME and high-pitch imaging for CTPA.

## METHODS AND MATERIALS

Two plastic tubes filled with iodine solution were made to mimic two different shapes of emboli in a pulmonary vessel. These tubes, along with 3 solid iodine samples at various concentrations (5, 10 and 15 mg/mL), were placed on a motion arm to mimic the motion of vessels during breathing (20 and 30 rpm). These were scanned inside a semi-anthropomorphic chest phantom (25x35 cm) on both a clinical dual-source PCD-CT (Naeotom Alpha, Siemens) and a dual-source EID CT (Force, Siemens) without and with motion of the vascular PE phantom, each scan repeated twice. EID-CT scans were performed separately using both ME and high pitch modes. PCD scans were performed using the ME high-pitch mode. Iodine maps were generated from the ME scans, and iodine concentrations measured centrally inside each sample.

## RESULTS

When there was no motion, measured iodine concentrations agreed well with the ground truth for both EID-CT at ME mode and PCD-CT (EID:  $5.4\pm 0.5$ ,  $10.3\pm 0.6$ ,  $15.6\pm 0.8$  mg/mL; PCD:  $5.1\pm 0.2$ ,  $10.6\pm 0.6$ ,  $15.3\pm 0.3$  mg/ml, for the 3 iodine samples, respectively). When there was motion, EID-CT at ME mode suffered from significant artifacts on the two tubes mimicking PEs and distortions on the 3 iodine samples. The measured iodine concentrations on PCD-CT were more stable than on EID-CT at ME mode (Range of percent error: EID: [-13.0%, 6.4%] and [-22.2%, 20.4%]; PCD: [-0.9%, 3.9%] and [0.9%, 5.9%] for 20 and 30 rpm, respectively). Although EID-CT at high-pitch mode has the same temporal resolution as PCD-CT, it does not provide spectral information for iodine quantification.

## CONCLUSION

The combined ME and high-pitch acquisition mode in dual-source PCD-CT enables simultaneous accurate iodine quantification and high-pitch motion-free imaging of pulmonary arteries and emboli.

## CLINICAL RELEVANCE/APPLICATION

ME high-pitch PCD-CT may improve detection of pulmonary emboli over EID-CT by providing images with reduced motion artifacts and improved accuracy for iodine quantification.

### Scatter Estimation and Correction in Photon Counting Detector CT

Sunday, Nov. 26 9:00AM - 10:00AM Room: E353C

Ran Zhang, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Scattered radiation in multi-row detector CT (MDCT) and cone-beam CT (CBCT) can lead to image artifacts, contrast reduction, and quantification errors. Multi-row photon counting detector CT (PCD-CT) is a promising technology that can potentially improve clinical CT imaging. This work aimed to develop a real-time and effective method for scatter estimation and correction using the energy-discriminating capability of PCD-CT.

#### METHODS AND MATERIALS

Monte Carlo simulations and experimental measurements were conducted to investigate the impact of energy thresholds on the scatter-to-primary ratio (SPR) in PCD-CT. A benchtop PCD-CT system with a 120 kVp spectrum and 4-cm z-coverage was utilized. The energy threshold of the PCD (T) was changed from 40 keV to 110 keV, creating a low-energy bin [20 keV, T] and a high-energy bin [T, 120 keV]. The SPR in low-energy and high-energy bins was measured as a function of the energy threshold. A novel data acquisition mode called MoHi-PoLo was proposed, which combines a quasi-Monochromatic High-energy bin and a Polychromatic Low-energy bin. A scatter correction method was then proposed to leverage the benefits of the MoHi-PoLo acquisition. Physical phantom experiments were conducted to demonstrate the effectiveness and robustness of the proposed method.

#### RESULTS

The SPR measurements showed that 1) high-energy bin data in PCD-CT always have a lower SPR compared to the corresponding low-energy bin data; 2) the SPR of the high-energy bin decreased significantly as the energy threshold increased; and 3) when the energy threshold approached the maximum keV of the spectrum, MoHi bin data was nearly free of scatter artifacts. Moreover, MoHi bin data was effective in estimating and correcting scatter in the PoLo bin.

#### CONCLUSION

Scatter decreases significantly in higher energy bins of PCD-CT. By utilizing the energy-discriminating capability offered by PCD-CT, the proposed MoHi-PoLo data acquisition scheme provides a new opportunity to address the scatter problem in CT.

#### CLINICAL RELEVANCE/APPLICATION

Scatter has a significant impact on the accuracy of HU number and material quantification. A real-time and low-cost scatter correction method can benefit many applications in interventional radiology and radiation therapy.

### Quantitative Knee Imaging using High-resolution Photon-counting Detector CT

Sunday, Nov. 26 9:00AM - 10:00AM Room: E353C

Kishore Rajendran, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To demonstrate the feasibility of simultaneous, quantitative cartilage and subchondral bone imaging using ultra-high-resolution (UHR) multi-energy photon-counting detector (PCD) CT.

#### METHODS AND MATERIALS

After approval from our institutional review board, four cadaveric knees were scanned on a clinical PCD-CT system (Siemens NAEOTOM Alpha) using the UHR collimation (120 x 0.2 mm) at 120 kV, 20 mGy CTDIvol mimicking the routine knee arthrography protocol used in our clinical practice. A 50 mL bolus of 50-75% diluted anionic iodine contrast (Conray, Guerbet LLC) was injected into the intraarticular space under sonographic guidance approximately 10 minutes prior to CT acquisition. UHR PCD-CT images (0.2-mm thickness, "T3D" images using 20-120 keV, Br96 kernel with cutoff frequency at 40 lp/cm), and low- and high-energy threshold images (0.4 mm thickness, 20-120 keV and 65-120 keV, Qr76 kernel with cutoff frequency at 28 lp/cm) were reconstructed for trabecular bone morphometry and quantitative iodine decomposition, respectively. A material decomposition algorithm was applied to the Qr76 images to quantify iodine diffusion in the articular cartilage, while the UHR Br96 images were used to quantify trabecular thickness (Tb.Th), spacing (Tb.Sp) and bone volume fraction (BV/TV) in distal femur and proximal tibia of each knee. Additionally, a multi-energy CT phantom (Gammex, Sun Nuclear, WI) containing iodine at 2, 5, 10, 15 mg/cc was scanned on the PCD-CT system to assess iodine quantification accuracy using root-mean-squared-error (RMSE).

#### RESULTS

Iodine decomposition in the articular cartilage showed contrast diffusion up to 15 mg/mL in the superficial zone and between 0 and 5 mg/mL in the deep zone. Bone morphometry measurements showed Tb.Th ranging from 0.43 to 0.54 mm, Tb.Sp ranging from 1.14 to 2.95 mm, and BV/TV ranging from 0.12 to 0.2. The RMSE for iodine quantification was 0.19 mg/cc in the multi-energy phantom.

#### CONCLUSION

The UHR mode of the PCD-CT system facilitates simultaneous assessment of bone trabecular architecture and iodine quantification in intraarticular cartilage of the knee joint from a single arthrographic exam.

#### CLINICAL RELEVANCE/APPLICATION

Contrast diffusion in cartilage, and trabecular microarchitecture are crucial markers of overall joint health relevant to diagnosis and management of osteoarthritis.

### High z-axis Resolution Imaging using CZT Based Photon Counting CT: Quantitative Study and First Clinical Trial

Sunday, Nov. 26 9:00AM - 10:00AM Room: E353C

Saeko Mochinaga, RT (*Presenter*) Nothing to Disclose

#### PURPOSE

First clinical studies have been performed on CZT-based photon counting CT (CZT-PCD-CT). Due to its small detector pixel design, CZT-PCD-CT can provide super high-resolution (SHR) mode with 0.2mm slice thickness. Its z-axis resolution stands out from conventional scintillator-based CT systems. This study aims to characterize z-resolution improvements of CZT-PCD-CT using phantom studies and explore its potential clinical benefits in thoracic and spine imaging.

#### METHODS AND MATERIALS

The prototype CZT-PCD-CT is built based on a Aquilion Precision system (Canon Medical Systems, Japan). The beam coverage of the system is 40 mm, and the focus size is 0.4\*0.5 mm. To evaluation z-axis resolution, comb-shaped phantom of 0.3, 0.4, 0.5, 0.6 mm intervals were scanned with helical-mode, 120 kVp, 100 mA, 0.5 s/rotation, pitch factor of 0.8. Normal resolution (NR) and SHR images were reconstructed with standard kernel with filtered back projection. NR images were 512-matrix size and 0.6 mm slice thickness, and SHR images were 1024-matrix size and 0.2 mm slice thickness. Coronal NR and SHR images of the comb phantom were obtained for the visibility evaluation and profile measurement. In addition, the visibility of bone and lung structures and the image noise (noise SD) was evaluated with sagittal images of the thoracic spine and coronal images of the lung. These clinical images were reconstructed using NR mode with hybrid-iterative reconstruction and SHR mode with hybrid-iterative reconstruction and deep learning reconstruction (DLR).

#### RESULTS

For the comb phantom images, 0.3 mm gap on the SHR images was visible while gap of 0.5 mm or less on the NR images was not visible. Cortical and cancellous bone on sagittal images of the thoracic spine was more sharply delineated in SHR images. The noise SD of the intervertebral disc was 10.2 HU for the NR images, 13.1 HU for the SHR images with IR, and 11.1 HU for the SHR images with DLR. The interlobar pleura, bronchioles, and ground glass opacity on the coronal lung images were also more visible on the SHR images. The noise SD of the lung field was 52.6 HU for the NR images, 73.4 HU for the SHR images with IR, and 45.5 HU for the SHR images with DLR. These results showed that SHR images has higher Z-axis spatial resolution than NR images, and improved image quality of CT images obtained with multi planar reconstruction.

#### CONCLUSION

SHR provides higher Z-axis spatial resolution and MPR images with higher sharpness compared to NR. Furthermore, DLR algorithm is expected to maintain resolution and further reduce noise.

#### CLINICAL RELEVANCE/APPLICATION

Z-axis spatial resolution is important for the evaluation of sharpness MPR images, and the SHR modes of PCD-CT contribute to the improvement of the image quality of MPR images.

### Initial Investigation of Metal Artifact Reduction Performance on a Prototype Deep Silicon Based Photon Counting CT System

Sunday, Nov. 26 9:00AM - 10:00AM Room: E353C

Jonathan L. Troville, PhD (*Presenter*) Research support, Canon Medical Systems Corporation

#### PURPOSE

To compare the efficacy of metal artifact reduction using a prototype deep silicon based photon counting CT system with energy-integrating detector (EID) CT.

#### METHODS AND MATERIALS

A prototype deep silicon based photon counting CT scanner and an EID CT scanner (GE Discovery CT750 HD) were used to acquire images of a surgical screw. The screw was placed in a 20 cm-diameter water bath. 140 keV virtual monochromatic images were acquired with the deep silicon prototype at 120 kV, 290 mA, 0.5 second rotation time, and 0.417 mm slice thickness. 140 kV polychromatic and 140 keV virtual monochromatic images were acquired on the EID scanner at 140 kV/80 mA/1 second rotation time/0.625 mm slice thickness, and 80-140 kV/260 mA/0.8 seconds rotation time/0.625 mm slice thickness respectively. All images were reconstructed at 100 mm reconstruction diameter. ROIs were manually placed over the regions containing the largest magnitude hypo and hyper dense artifacts for each scan mode. Additionally, ROIs were placed over water background regions approximately 20 mm from the center of the surgical screw. HU values averaged over the background ROIs, standard deviations of the averages, and integral uniformity of background ROI values were compared between acquisition types.

#### RESULTS

Deep silicon photon counting images exhibited the smallest magnitude hyper/hypo dense artifacts with values of 130/-194 HU, compared to 367/-305 and 332/-451 HU for polychromatic and GSI scan types, respectively. The background water range of average HU values was -20.81 to 16.42 (SD: 17.53), -78.48 to 14.94 (SD: 50.77), and -132.7 to 20.67 (SD: 79.59) for deep silicon, polychromatic, and GSI modes respectively.

#### CONCLUSION

This study indicates that deep silicon photon counting outperforms polychromatic and dual energy for reduction of metal artifacts of a surgical screw model. Deep silicon provided better reduction of artifact near the surgical screw, and in regions further away from the screw.

#### CLINICAL RELEVANCE/APPLICATION

Visualization near the surface of surgical screws is important to assess for screw loosening and infection but is impeded by artifact which was less severe with deep silicon photon counting compared to energy integrating and dual energy CT.

### Universal 120 kV Dual-Source Ultra-High Pitch Protocol on the Emerging Photon Counting CT System for Pediatric Abdomen of All Sizes: A Phantom Investigation

Sunday, Nov. 26 9:00AM - 10:00AM Room: E353C

Wei Zhou, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To test the hypothesis if a universal 120 kV ultra-high pitch and virtual monoenergetic image (VMI) on photon counting CT (PCCT) can provide equivalent or better quality for pediatric abdominal imaging, regardless of size, compared to single kV energy-integrating CT (EICT).

#### METHODS AND MATERIALS

3 iodine (2, 5, 10 mgI/cc) and 1 solid water inserts were attached to phantoms of variable sizes (Dw of 11.7, 17.3, 19.2, 32cm), simulating abdomen of a newborn, 5-year-old, 10-year-old, and adult size pediatric patients. Each phantom setting was scanned on a EICT (Siemens Drive) using clinical size specific kV (e.g. 80kV for newborn, 120kV for adult size), pitch 3 abdomen protocol. The CTDIvol of each phantom was determined by clinical CareDose on, while all scans were later performed with fixed mA and matched to pre-determined CTDIvol on EICT. Each phantom was then scanned on a PCCT (Siemens Alpha) using 120kV, pitch 3, and CTDI values matched to EICT scans. VMIs were generated from PCCT scans between 40 and 80keV with a 5keV interval. Reconstructions were matched between PCCT and EICT. Image noise was measured as standard deviation of solid water. Iodine CNR was measured as 10mgI/cc vs. water. NPS was measured in uniform phantom regions. Image quality metrics were compared between PCCT VMIs and EICT.

#### RESULTS

The noise level of PCCT VMIs decreases with increased keV while CNR decreases with increased keV. The noise level (HU) of PCCT VMIs at 65keV ( $7.8 \pm 0.9$ ) for newborn, 70keV ( $8.8 \pm 1.1$ ) for 5 years, 55keV ( $12.0 \pm 0.8$ ) for 10 years, and 65keV ( $15.8 \pm 1.8$ ) for adult size are comparable or lower than ( $P < 0.05$ , T-Test) corresponding EICT acquisitions with size specific kV (newborn:  $7.8 \pm 0.8$ , 5 years:  $7.6 \pm 1.0$ , 10 years:  $12.2 \pm 0.7$ , adult size:  $15.3 \pm 1.5$ ). The CNR of PCCT VMI at 50keV ( $51.1 \pm 10.2$ ) for newborn, 55keV ( $42.5 \pm 3.8$ ) for 5 years, 70keV ( $27.5 \pm 1.0$ ) for 10 years, and 80keV ( $14.1 \pm 1.4$ ) for adult size is comparable or higher than ( $P < 0.05$ ) EICT acquisitions with size specific kV (newborn:  $55.8 \pm 5.4$ , 5 years:  $40.6 \pm 6.2$ , 10 years:  $25.4 \pm 0.7$ , adult size:  $13.4 \pm 1.4$ ). The peak noise frequency (mm<sup>-1</sup>) of PCCT VMIs at 65 or 70keV (newborn: 0.18, 5 years: 0.15, 10 years: 0.19, adult size: 0.16) is almost identical to EICT images (newborn: 0.18, 5 years: 0.15, 10 years: 0.19, adult size: 0.17).

#### CONCLUSION

Compared to size specific kV EICT, PCCT 120kV and post-processed VMIs can provide equivalent or better quality for pediatric abdominal CT, regardless of patient size.

#### CLINICAL RELEVANCE/APPLICATION

Our findings provide the first evidence that all (contrast or non-contrast) pediatric abdominal CT can be scanned by a universal ultra-fast protocol on PCCT, which reduces complexity of pediatric CT protocols to accommodate diverse patient sizes while avoiding sub-optimal acquisition parameters based on size.

Printed on: 08/22/24

### Simultaneous Multi-energy High-pitch CT Pulmonary Angiography using a Dual-source Photon-counting-detector CT: A Phantom Experiment

Sunday, Nov. 26 9:00AM - 10:00AM Room: E353C

Jelena Mihailovic, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

A dual-source CT system can be operated in a high pitch (3.2) helical mode (FLASH) to provide a temporal resolution as fast as 66 milliseconds, which is beneficial to reduce motion artifacts in CT pulmonary angiography (CTPA). A dual-source CT can also be operated in a multi-energy (ME) mode (including dual-energy) to provide pulmonary perfused blood volume (PBV) information, beneficial in the evaluation of pulmonary embolism (PE). Currently, no energy-integrating detector (EID) CT can perform ME acquisition at a temporal resolution as fast as in the high-pitch scan mode. The purpose of this phantom study is to evaluate the ability of a dual-source photon-counting-detector (PCD) CT to perform simultaneous ME and high-pitch imaging for CTPA.

#### METHODS AND MATERIALS

Two plastic tubes filled with iodine solution were made to mimic two different shapes of emboli in a pulmonary vessel. These tubes, along with 3 solid iodine samples at various concentrations (5, 10 and 15 mg/mL), were placed on a motion arm to mimic the motion of vessels during breathing (20 and 30 rpm). These were scanned inside a semi-anthropomorphic chest phantom (25x35 cm) on both a clinical dual-source PCD-CT (Naeotom Alpha, Siemens) and a dual-source EID CT (Force, Siemens) without and with motion of the vascular PE phantom, each scan repeated twice. EID-CT scans were performed separately using both ME and high pitch modes. PCD scans were performed using the ME high-pitch mode. Iodine maps were generated from the ME scans, and iodine concentrations measured centrally inside each sample.

#### RESULTS

When there was no motion, measured iodine concentrations agreed well with the ground truth for both EID-CT at ME mode and PCD-CT (EID:  $5.4 \pm 0.5$ ,  $10.3 \pm 0.6$ ,  $15.6 \pm 0.8$  mg/mL; PCD:  $5.1 \pm 0.2$ ,  $10.6 \pm 0.6$ ,  $15.3 \pm 0.3$  mg/ml, for the 3 iodine samples, respectively). When there was motion, EID-CT at ME mode suffered from significant artifacts on the two tubes mimicking PEs and distortions on the 3 iodine samples. The measured iodine concentrations on PCD-CT were more stable than on EID-CT at ME mode (Range of percent error: EID: [-13.0%, 6.4%] and [-22.2%, 20.4%]; PCD: [-0.9%, 3.9%] and [0.9%, 5.9%] for 20 and 30 rpm, respectively. Although EID-CT at high-pitch mode has the same temporal resolution as PCD-CT, it does not provide spectral information for iodine quantification.

#### CONCLUSION

The combined ME and high-pitch acquisition mode in dual-source PCD-CT enables simultaneous accurate iodine quantification and high-pitch motion-free imaging of pulmonary arteries and emboli.

#### CLINICAL RELEVANCE/APPLICATION

ME high-pitch PCD-CT may improve detection of pulmonary emboli over EID-CT by providing images with reduced motion artifacts and improved accuracy for iodine quantification.

Printed on: 08/22/24

S1-STCE1

### Science Session (Generative AI)

Sunday, Nov. 26 9:30AM - 10:00AM Room: Learning Center Theater 1

#### Sub-Events

### S1-STCE1-1 Virtual Reality and AI Chatbot Improve Radiology On-Call Training

Yusuf Alibrahim, BMedSc, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This research project aims to evaluate the use of artificial intelligence (AI) chatbot tools when integrated in a virtual reality (VR) setting to teach radiology on call topics to radiology residents.

#### METHODS AND MATERIALS

Three first year radiology residents in Guyana are enrolled in an 8 week radiology course. Each resident was provided with a VR headset. Before the sessions, the residents completed an assessment related to the topics to be taught that week. In the sessions, the residents and the preceptor, a senior resident from the University of Toronto, join a shared room in the application. The sessions start with a presentation about the topics followed by cases with scrollable CT images and 3D reconstructions. This is followed by a discussion where each resident utilizes the conversational AI chatbot to gather information about a topic and teach it to other residents. After each session, the residents repeated the assessment and completed a survey rating their subjective experience of the sessions in VR and the AI chatbot.

#### RESULTS

The preliminary findings of our study showed that residents were able to see the imaging findings in VR and interact with others in a seamless fashion. The residents noted that there is minimal chance of distractions in VR and that the 3D reconstructions helped to quickly identify the pathologies. Further data is being collected with regards to integrating imaging findings of specific cases to the AI chatbot, accuracy of the information, and realism of chatting with the AI chatbot compared to people. Additional data about the seamless interaction with the AI chatbot and using voice recognition compared to traditional methods of typing to search are being collected. There were technical challenges in the earlier sessions with minor undesirable physical effects (nausea, headache, etc.) but those eventually improved with improvement in VR controls, session timing, and improvements in the application through updates.

#### CONCLUSION

These findings suggest that the use of AI and VR-based training are promising for teaching radiology on call topics to radiology residents. The integration of AI into VR leads to synergistic results with a more immersive and interactive learning experience than traditional methods, such as lectures or textbooks. Furthermore, the 3D reconstructions of CT scans are especially helpful in VR due to the sense of depth and scale provided by this modality.

#### CLINICAL RELEVANCE/APPLICATION

Artificial intelligence and VR-based training could be used to develop new and accessible ways of teaching a variety of radiology topics in a seamless and cost-effective way. This could be especially useful in supporting radiology education remotely in regions which lack local radiology expertise.

### S1-STCE1-2 Generation of Radiology Report's Impression from Findings' description on Pediatric Abdomen Ultrasound

Dana Alkhulaifat, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Training and validation of artificial intelligence (AI) models require annotated data. Annotation is challenging due to the need for well-defined search criteria (e.g., inclusion and exclusion), domain-specific knowledge and expertise, budget, and time. Additionally, since establishing well-defined annotation rules poses numerous challenges, manually curated datasets can be

subjective and inconsistent. Natural language processing has demonstrated utility in the identification of diagnoses from radiology reports. These reports could also be used to annotate images, thereby improving the speed and accuracy of data curation for model building. In this research, we trained an AI model to generate an impression from the findings section on pediatric ultrasound reports. We examined whether a generative deep learning (DL) model can construct an accurate impression from findings similar to a radiologist in pediatric ultrasound reports.

## **METHODS AND MATERIALS**

After receiving IRB exemption, a total of 16891 reports of pediatric complete abdominal ultrasound were obtained from our institution (51% female, 47% male, 2% unknown), from 2015 to 2022 (age range (0, 43 years), mean of 7y8m, std of 6y4m). The findings and impression sections of each report were extracted. The dataset was divided into (60%, 20%, 20%) for the training, validation, and testing of a generative DL model, respectively. Recall-Oriented Understudy for Gisting Evaluation (Rouge) 1, 2, L, and Lsum were used as performance metrics. Three outcomes were established to measure the interpretability performance: "human impression is more complete", "human and machine impressions are similar", and "model impression is more complete." These outcomes were assigned to 300 random reports from the test dataset and results were computed and declared with 95% confidence level.

## **RESULTS**

The Rouge 1, 2, L, and Lsum metrics were (0.61, 0.49, 0.57, 0.6) (0.52, 0.38, 0.48, 0.5) on the train and validation datasets, and (0.51, 0.37, 0.46, 0.49) on the blind test dataset. The average completeness scores of the generated impressions were (36.6%, 59.7%, 3.7%) which indicates that 63.4% of generated impressions are similar or better than human impressions with confidence interval of (0.5857, 0.6943). Table 1 demonstrates an example of a radiologist's impression and an AI-generated impression.

## **CONCLUSION**

The Rouge and human scores indicate that a generative DL model fine-tuned on the reports of pediatric complete abdominal ultrasounds can be a valuable and time-saving tool for annotating datasets for the purpose of building AI models in radiology.

## **CLINICAL RELEVANCE/APPLICATION**

The utilization of radiology reports to annotate images improves the speed and accuracy of large dataset curation for model building.

## **S1-STCE1-3 Impact of an AI-Based Workflow in Interpretation of Chest Radiographs**

Charu Arora, MBBS, MBA (*Presenter*) Nothing to Disclose

## **PURPOSE**

To assess the impact of an artificial intelligence (AI) based radiology tool on the efficiency and accuracy of radiologists with varying experience in interpreting chest radiographs.

## **METHODS AND MATERIALS**

50 normal chest radiographs (CXR) confirmed by a panel of United States board certified radiologists were given blinded for interpretation to 11 radiologists with 1 to 17 years of experience (mean + SD: 3.8 + 4.7, median: 3) Radiographs were randomised into two groups, one interpreted unaided (U) and one aided by an AI tool (A). Radiologists were asked to (a) create a brief report (in group A, the artificial intelligence tool created a report which could be edited), (b) classify the CXR as normal or abnormal, (c) if abnormal, make a management decision based on a standardised protocol (critical attention, follow-up, no follow-up), (d) indicate confidence in their interpretation on a 10 point scale. Sensitivity, false positivity rate (FPR), turnaround time (TAT) from the time the study was opened to the time the report was submitted and reader confidence were calculated.

## **RESULTS**

275 reads each were received in groups U and A. Mean sensitivity in U was 64% and A was 85.4% ( $p < 0.001$ ). FPR reduced by 0.21 ( $p < 0.001$ ) in A as compared to U. Percent reduction in FPR was highest for less experienced readers (62.2%) as compared to more experienced readers (57.5%). 47 (17%) and 20 (7%) were recommended follow up while 5 (2%) and 1 (0.4%) were classified as critical in groups U and A respectively. Median TAT was 39 and 18 seconds respectively in groups U and A. Mean confidence of readers in classifying cases as normal increased by 25% in group A as compared to group U.

## **CONCLUSION**

An AI-based tool can improve sensitivity, TAT, and reader confidence while also reducing FPR. The improvement is more significant in less experienced readers. This is part of a larger multi-reader multi-case (MRMC) study including normal and abnormal radiographs which will be completed and presented by November 2023.

## **CLINICAL RELEVANCE/APPLICATION**

AI tools have a significant impact on radiologist efficiency and accuracy in interpretation of chest radiographs which may be more evident in less experienced radiologists. The full effect of this needs further evaluation.

### Virtual Reality and AI Chatbot Improve Radiology On-Call Training

Sunday, Nov. 26 9:30AM - 10:00AM Room: Learning Center Theater 1

Yusuf Alibrahim, BMedSc, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This research project aims to evaluate the use of artificial intelligence (AI) chatbot tools when integrated in a virtual reality (VR) setting to teach radiology on call topics to radiology residents.

#### METHODS AND MATERIALS

Three first year radiology residents in Guyana are enrolled in an 8 week radiology course. Each resident was provided with a VR headset. Before the sessions, the residents completed an assessment related to the topics to be taught that week. In the sessions, the residents and the preceptor, a senior resident from the University of Toronto, join a shared room in the application. The sessions start with a presentation about the topics followed by cases with scrollable CT images and 3D reconstructions. This is followed by a discussion where each resident utilizes the conversational AI chatbot to gather information about a topic and teach it to other residents. After each session, the residents repeated the assessment and completed a survey rating their subjective experience of the sessions in VR and the AI chatbot.

#### RESULTS

The preliminary findings of our study showed that residents were able to see the imaging findings in VR and interact with others in a seamless fashion. The residents noted that there is minimal chance of distractions in VR and that the 3D reconstructions helped to quickly identify the pathologies. Further data is being collected with regards to integrating imaging findings of specific cases to the AI chatbot, accuracy of the information, and realism of chatting with the AI chatbot compared to people. Additional data about the seamless interaction with the AI chatbot and using voice recognition compared to traditional methods of typing to search are being collected. There were technical challenges in the earlier sessions with minor undesirable physical effects (nausea, headache, etc.) but those eventually improved with improvement in VR controls, session timing, and improvements in the application through updates.

#### CONCLUSION

These findings suggest that the use of AI and VR-based training are promising for teaching radiology on call topics to radiology residents. The integration of AI into VR leads to synergistic results with a more immersive and interactive learning experience than traditional methods, such as lectures or textbooks. Furthermore, the 3D reconstructions of CT scans are especially helpful in VR due to the sense of depth and scale provided by this modality.

#### CLINICAL RELEVANCE/APPLICATION

Artificial intelligence and VR-based training could be used to develop new and accessible ways of teaching a variety of radiology topics in a seamless and cost-effective way. This could be especially useful in supporting radiology education remotely in regions which lack local radiology expertise.

### Generation of Radiology Report's Impression from Findings' description on Pediatric Abdomen Ultrasound

Sunday, Nov. 26 9:30AM - 10:00AM Room: Learning Center Theater 1

Dana Alkhulaifat, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Training and validation of artificial intelligence (AI) models require annotated data. Annotation is challenging due to the need for well-defined search criteria (e.g., inclusion and exclusion), domain-specific knowledge and expertise, budget, and time. Additionally, since establishing well-defined annotation rules poses numerous challenges, manually curated datasets can be subjective and inconsistent. Natural language processing has demonstrated utility in the identification of diagnoses from radiology reports. These reports could also be used to annotate images, thereby improving the speed and accuracy of data curation for model building. In this research, we trained an AI model to generate an impression from the findings section on pediatric ultrasound reports. We examined whether a generative deep learning (DL) model can construct an accurate impression from findings similar to a radiologist in pediatric ultrasound reports.

#### METHODS AND MATERIALS

After receiving IRB exemption, a total of 16891 reports of pediatric complete abdominal ultrasound were obtained from our institution (51% female, 47% male, 2% unknown), from 2015 to 2022 (age range (0, 43 years), mean of 7y8m, std of 6y4m). The findings and impression sections of each report were extracted. The dataset was divided into (60%, 20%, 20%) for the training, validation, and testing of a generative DL model, respectively. Recall-Oriented Understudy for Gisting Evaluation (Rouge) 1, 2, L, and Lsum were used as performance metrics. Three outcomes were established to measure the interpretability performance: "human impression is more complete", "human and machine impressions are similar", and "model impression is more complete." These outcomes were assigned to 300 random reports from the test dataset and results were computed and declared with 95% confidence level.

#### RESULTS

The Rouge 1, 2, L, and Lsum metrics were (0.61, 0.49, 0.57, 0.6) (0.52, 0.38, 0.48, 0.5) on the train and validation datasets, and (0.51, 0.37, 0.46, 0.49) on the blind test dataset. The average completeness scores of the generated impressions were (36.6%, 59.7%, 3.7%) which indicates that 63.4% of generated impressions are similar or better than human impressions with confidence interval of (0.5857, 0.6943). Table 1 demonstrates an example of a radiologist's impression and an AI-generated impression.

#### CONCLUSION

The Rouge and human scores indicate that a generative DL model fine-tuned on the reports of pediatric complete abdominal ultrasounds can be a valuable and time-saving tool for annotating datasets for the purpose of building AI models in radiology.

#### CLINICAL RELEVANCE/APPLICATION

The utilization of radiology reports to annotate images improves the speed and accuracy of large dataset curation for model building.

### Science Session (Theranostics)

Sunday, Nov. 26 9:30AM - 10:00AM Room: Learning Center Theater 2

#### Sub-Events

### **S1-STCE2-2 Assessment of a Syndecan-1 targeted theranostic nanoparticle for improved detection and treatment of pancreatic cancer**

Lacey R. McNally, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Pancreatic cancer is a recalcitrant cancer that is both difficult to detect at early stage and generally resistant to standard of care therapy. As such, we have developed a tumor-targeted nanoparticle that has the capability to serve as a contrast agent or to deliver a therapeutic agent to block the autophagic survival mechanism. We synthesized a tumor-targeted nanoparticle to IGF1-R via syndecan-1 peptide to deliver dye or echinomycin for detection and treatment of pancreatic cancer.

#### **METHODS AND MATERIALS**

Using microwave chemistry, we synthesized a Syndecan-1 peptide and conjugated it to a 100 nm liposome using standard techniques. We loaded either IR-800 dye or echinomycin, an antibiotic, into the nanoparticle to facilitate tumor detection and treatment. In vitro testing of nanoformulated echinomycin and mechanism of action were assessed. Syndecan-1 targeted theranostic nanoparticles were iv injected into orthotopic pancreatic (S2VP10 or S2013) xenografts. Biodistribution and efficacy were tracked using Multispectral Optoacoustic Tomography or bioluminescence imaging.

#### **RESULTS**

In vivo, biodistribution of syndecan-1-targeted nanoparticles indicated preferential uptake in orthotopic pancreatic tumors (S2VP10 or S2CP9) compared to the liver and kidney (S2VP10  $p = 0.0016$ ,  $p = 0.00004$  and S2CP9  $p = 0.0009$ ,  $p = 0.0001$ ). Syndecan-1 targeted nanodelivered echinomycin resulted in significant survival increases compared to gemcitabine (S2VP10  $p = 0.0003$ , S2CP9  $p = 0.0017$ ) or echinomycin only (S2VP10  $p = 0.0096$ , S2CP9  $p = 0.0073$ ). The mechanism of action of echinomycin treatment demonstrated autophagic cell death based upon high levels of LC3-II among other autophagy markers, but without hallmarks of apoptosis, e.g., caspase activation and chromatin fragmentation, or necrosis, e.g., plasma membrane degradation and chromatin condensation/degrading.

#### **CONCLUSION**

We demonstrate that actively targeted nanodelivery of echinomycin results in autophagic cell death in pancreatic and potentially other high-autophagy, apoptosis-resistant tumors. Collectively, these findings support syndecan-1-targeted delivery of echinomycin and dysregulation of autophagy to induce cell death in pancreatic cancer.

#### **CLINICAL RELEVANCE/APPLICATION**

Neither improved detection or neoadjuvant treatment of pancreatic cancer have substantially changed in decades. Our theranostic nanoparticle demonstrates both successful detection via MSOT and treatment via blocking of autophagy. As this treatment targets non-apoptosis pathways, it has the potential to translate into clinical trials as a complementary therapy.

### **S1-STCE2-3 Leveraging serial quantitative imaging for treatment response monitoring and dosimetry of <sup>177</sup>Lu-PSMA-617 therapy**

Catherine Meyer, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

While <sup>177</sup>Lu-PSMA-617 is a promising treatment option for metastatic castration-resistant prostate cancer, not all patients respond equally to treatment. <sup>177</sup>Lu SPECT/CT imaging offers an opportunity to assess response dynamics while the therapy

is ongoing. In this work, we evaluate the value of baseline and interim  $^{177}\text{Lu}$  SPECT/CT imaging after cycles 1 and 3 of treatment. We also report patient-specific dosimetry based on serial SPECT/CT imaging following the first cycle of therapy.

## **METHODS AND MATERIALS**

To date, 23 patients (age  $\pm$  SD,  $72 \pm 7.9$ ) underwent quantitative SPECT/CT imaging from vertex to mid-thighs 24h following administration of the 1st and 3rd cycles of  $^{177}\text{Lu}$ -PSMA-617. Total tumor burden (TTB) was evaluated on the initial PET and cycles 1 and 3 SPECT scans using an SUV threshold of 3 with removal of physiologic uptake. TTB was assessed longitudinally and correlated to PSA values and clinical measures. Additionally, dosimetry was performed retrospectively based on SPECT/CT at 4 time points (4h, 24h, 48h, 72h) in 5 patients selected predominantly for concerns of exceeding dose limits with the standard administered activity. Normal organs were segmented using a neural-network algorithm and manual contouring. Tumor lesions were segmented using a patient-specific SUV threshold. Image and dosimetry analysis were performed using commercial software to generate 3D voxelized dose maps.

## **RESULTS**

Three representative patients were included in this preliminary retrospective analysis exhibiting response, progression, and a mixed response. In all cases, the TTB volume kinetics were well-correlated with serum PSA values and clinical measures. Dosimetry in 5 patients revealed tolerable mean doses to the kidneys, parotid glands, and bone marrow of  $3.5 \pm 1.8$  Gy,  $1.5 \pm 1.0$  Gy, and  $0.2 \pm 0.06$  Gy, respectively. However, in one patient with a single kidney, the mean kidney dose was 5.2 Gy, indicating a possible cumulative 6 cycle dose exceeding the commonly used 23 Gy tolerance dose limit. In total, 46 lesions were contoured with an overall mean tumor dose of  $5.6 \pm 4.4$  Gy.

## **CONCLUSION**

Post-therapy SPECT/CT images provide a quantitative metric by which response can be systematically measured and early detection of progression confirmed. Voxelized dosimetry for a patient with a single kidney revealed a kidney dose possibly contraindicating the standard activity dosing regimen, as well as a high degree of heterogeneity in tumor doses across all patients.

## **CLINICAL RELEVANCE/APPLICATION**

This work demonstrates the added value of serial SPECT/CT imaging throughout the course of  $^{177}\text{Lu}$ -PSMA-617 treatment for earlier response detection and dose estimation. Post-therapy imaging may provide additional imaging biomarkers and absorbed doses may predict treatment efficacy.

### S2-SSBR01-The Optimal Timepoint for Lesion Evaluation in Ultrafast DCE MRI: Correlation With Background Parenchymal Enhancement and Lesion Characteristics

Masako Y. Kataoka, MD, PhD (*Presenter*) Speaker, Siemens AG Speaker, Bayer AG Speaker, Devicor Medical Products, Inc Speaker, Guerbet SA

#### PURPOSE

Ultrafast Dynamic contrast MRI (UF-DCE MRI) scan multiple frames of images just after contrast agent injection, visualizing lesions before background parenchymal enhancement (BPE) appears. Knowing the optimal time frame of the lesion evaluation helps in interpretation and improvement of the UF-DCE protocol. Thus, we aimed to investigate the optimal timing for lesion evaluation on UF-DCE MRI in relation to BPE and lesion characteristics.

#### METHODS AND MATERIALS

We retrospectively analyzed patients who underwent UF-DCE MRI in our hospital from 2018 to 2021, and had at least one target enhanced lesion suspected of malignancy. Those with post neoadjuvant chemotherapy and poor image quality were excluded. 3T-MRI (Prisma, Siemens, Erlangen) with a 18-ch breast coil was used. The UF-DCE protocol used a 3D gradient-echo VIBE with compressed sensing. Gadobutrol was injected at 2 ml/s. UF-DCE MRI (from 15 sec before to 60 sec after contrast injection, 2 sec preparation time followed by 3.65 sec/frame x 20 frames) were obtained. Axial subtracted MIP images (2nd -20th frames) were computed. An experienced breast radiologist evaluated the serial MIP images and evaluated conspicuity (score 1-5, 5 as best) and the first and last frames of optimal timing. The frame number is used as a proxy to time (sec) from the contrast injection. BPE and lesion size were also recorded. Wilcoxon rank-sum test was used for comparison.

#### RESULTS

In total 419 patients (mean age 56) were included (with 402 patients with timing information) The first and the last frames of optimal timing was the 12.6 and 19.6 (31 sec and 57 sec after contrast injection respectively). For those with marked BPE (n = 59), the first and the last frames of optimal timing was the 12.0 and 18.5 frames (29 and 53 sec) and significantly earlier than those with non-marked BPE (12.7 and 19.7,  $p=0.009$  and  $p<0.0001$  respectively). For those with a lesion size > 20mm (n=195), the first frame of optimal timing was the 12.4 frame (30 sec), slightly earlier than those with a smaller lesion (12.8,  $p=0.029$ ). For benign lesions (n=66), the first frame of optimal timing was significantly later than malignant lesions (n=336) (13.4 vs 12.4, 34 vs 30 sec,  $P=0.0003$ ). Conspicuity score was higher in invasive carcinoma (n=296) than non-invasive carcinoma and benign lesions (score 4.8 vs 3.7  $p<0.0001$ )

#### CONCLUSION

Optimal timing of breast lesion evaluation on UF-DCE MRI can be earlier for those with marked BPE and later for benign disease / smaller lesions. Conspicuity is excellent for invasive carcinoma.

#### CLINICAL RELEVANCE/APPLICATION

The current data helps in interpreting various breast lesions on UF-DCE MRI. Information of optimal timing can be used to develop simpler and more efficient UF-DCE MRI protocol focusing on best timing for lesion evaluation.

## **S2-SSBR01-Voxelwise Mapping of DCE-MRI Time-Intensity-Curve Profiles Enables Visualizing and Quantifying Hemodynamic Heterogeneity in Breast Lesions**

Zhou Liu, MD, PhD (*Presenter*) Nothing to Disclose

### **PURPOSE**

To propose a novel model-free data-driven approach based on the voxelwise mapping of DCE-MRI time-intensity-curve (TIC) profiles for quantifying and visualizing hemodynamic heterogeneity and to validate its potential clinical applications.

### **METHODS AND MATERIALS**

From December 2018 to July 2022, 259 patients with 325 pathologically confirmed breast lesions who underwent breast DCE-MRI were retrospectively enrolled. Based on the manually segmented breast lesions, the TIC of each voxel within the 3D whole lesion was classified into 19 subtypes based on wash-in rate (nonenhanced, slow, medium, and fast), wash-out enhancement (persistent, plateau, and decline), and wash-out stability (steady and unsteady), and the composition ratio of these 19 subtypes for each lesion was calculated as a new feature set (Type-19). Compared with the three-type TIC classification and semiquantitative parameters, Type-19 features were used to build a machine learning model to differentiate lesion malignancy and classify histologic grades, proliferation status, and molecular subtypes.

### **RESULTS**

The Type-19 feature-based model significantly outperformed models based on the three-type TIC method and semiquantitative parameters both in distinguishing lesion malignancy (AUC = 0.875 vs. 0.831,  $P = 0.01$  and 0.875 vs. 0.804,  $P = 0.03$ ), predicting tumor proliferation status (AUC = 0.890 vs. 0.548,  $P = 0.006$  and 0.890 vs. 0.596,  $P = 0.020$ ), and classifying molecular subtypes (AUC = 0.697 vs. 0.548,  $P = 0.009$  and 0.697 vs. 0.534,  $P < 0.001$ ), but not in predicting histologic grades ( $P = 0.820$  and 0.970).

### **CONCLUSION**

In addition to conventional methods, the proposed computational approach provides another novel model-free data-driven approach to quantify and visualize hemodynamic heterogeneity.

### **CLINICAL RELEVANCE/APPLICATION**

Voxelwise intra-lesion mapping of TIC profiles allows for visualization of hemodynamic heterogeneity and its composition ratio for differentiation of malignant and benign breast lesions.

## **S2-SSBR01-Super-resolution Deep-learning K-space-to-image Reconstruction in Diffusion-weighted Breast MRI at 3.0 Tesla**

Stephanie Sauer, MD (*Presenter*) Nothing to Disclose

### **PURPOSE**

Diffusion-weighted imaging (DWI) in breast MRI is time-consuming and often associated with suboptimal spatial resolution. This study investigated a k-space-to-image reconstruction approach for scan time reduction and a deep-learning based interpolation-algorithm for improved spatial resolution in single-shot echo planar imaging for breast DWI at 3.0 Tesla.

### **METHODS AND MATERIALS**

A total of 133 women (age  $49.7 \pm 12.1$  years) who received multiparametric breast MRI including DWI between November 2022 and January 2023 were enrolled. The acquired DWI raw data (standard DWI) was retrospectively processed using deep-learning image reconstruction (DL-DWI) and an additional interpolation algorithm referred to as "super resolution" (SRDL-DWI). All datasets included b values of 800  $\text{s/mm}^2$ , 1600  $\text{s/mm}^2$  (calculated), and ADC maps. Overall image quality was ranked by three blinded readers, while SNR and ADC values were compared. To quantify structural variations caused by image quality alterations, we employed a range of quantitative similarity and error metrics.

### **RESULTS**

Compared to standard DWI, both DL- and SRDL-DWI allowed for a 39% reduction in simulated scan time (5:26 vs. 3:20 min). Highest image quality rankings were assigned to SRDL-DWI (all  $p < 0.001$ ). Interreader agreement was good, indicated by an ICC of 0.780 (95% confidence interval 0.758-0.801;  $p < 0.001$ ). Irrespective of b value, both standard and DL-DWI produced superior SNR compared to interpolated SRDL-DWI in the pectoral muscle (all  $p = 0.050$ ) and fibroglandular tissue (all  $p < 0.001$ ), while no significant difference was ascertained between the two standard-resolution DWI datasets (all  $p > 0.999$ ). ADC values in fibroglandular tissue were higher in SRDL-DWI (+0.5%) and DL-DWI (+3.4%) compared to standard DWI (both  $p = 0.001$ ). Structural similarity index metrics (SSIM = 0.86) revealed high concordance between the undersampled reconstructions (with and without super resolution) and the acquired standard DWI images for all b values. Accordingly, calculation of error metrics (NRMSE = 0.05, SMAPE = 0.02, LOGAC = 0.04) supported the assumption of low voxel-wise error. Of note, similarity was highest and error metrics were lowest for b values of 800  $\text{s/mm}^2$ .

## CONCLUSION

Deep-learning based k-space-to-image reconstruction reduced simulated scan time by 39% without influencing structural similarity in breast DWI at 3.0 Tesla. Additionally employing a SRDL interpolation algorithm allows for subjective improvement of image quality.

## CLINICAL RELEVANCE/APPLICATION

DWI constitutes a promising technique for non-contrast breast MRI, e.g., for screening purposes. The assessed deep-learning approaches facilitate a significant reduction of acquisition time without compromising image quality.

## S2-SSBR01-Diffusion-Weighted MRI for Breast Cancer Screening in High-Risk Women: Analysis of First 4 Year Outcome for Invasive and In Situ Cancer Detection

Hee Jung Shin, MD (*Presenter*) Nothing to Disclose

### PURPOSE

Interest in unenhanced magnetic resonance imaging (MRI) screening for breast cancer is growing due to concerns about gadolinium deposition in the brain and the high cost of contrast-enhanced MRI. The purpose of this study was to analyze the outcomes of the data obtained during the first year of enrollment in DWIST (Diffusion-Weighted Magnetic Resonance Imaging Screening Trial; <https://ClinicalTrials.gov, NCT03835897>), which is a prospective, multicenter, intraindividual comparative cohort study designed to compare the performance of mammography, ultrasonography, dynamic contrast-enhanced (DCE) MRI, and diffusion-weighted (DW) MRI screening in women at high risk of developing breast cancer.

### METHODS AND MATERIALS

A total of 1046 women with BRCA mutation or family history of breast cancer and lifetime risk = 20% underwent the first-year breast screenings with digital mammography, ultrasonography, DCE MRI, and DW MRI (b=0, 800, 1200 sec/mm<sup>2</sup> and ADC map) at 3.0 T. Images are independently interpreted by trained radiologists at each institution. As for the interim results, pathology served as the reference standard. Each image modality and their combination was compared in terms of invasive and in situ cancer detection.

### RESULTS

In the first year, a total of 39 cancers (3.7%, 39/1046) were detected, with one of them being an interval cancer. Among them, 28 (72%) were invasive cancers, and 11 (28%) were in situ cancers. Overall cancer detection rate (CDR) was 43.6% (95% confidence interval, 29.3%-59.0%) on mammography, 59.0% (95% CI, 43.4%-72.9%) on US, 74.4% (95% CI, 58.9%-85.4%) on DW-MRI, and 92.3% (95% CI, 79.7%-97.3%) on DCE-MRI. CDR of invasive cancer was 53.6% (95% CI, 35.8%-70.5%) on mammography, 67.9% (95% CI, 49.3%-82.1%) on US, 82.1% (95% CI, 64.4%-92.1%) on DW-MRI, and 92.9% (95% CI, 77.4%-98.0%) on DCE-MRI, whereas CDR of in situ cancer was 18.2% (95% CI, 5.1%-47.7%) on mammography, 36.4% (95% CI, 15.2%-64.6%) on US, 54.5% (95% CI, 28.0%-78.7%) on DW-MRI, and 90.9% (95% CI, 62.3%-98.4%) on DCE-MRI. Cancer detection rate of combined mammography and DW-MRI was 85.7% (95% CI, 68.5%-94.3%) for invasive cancer and 63.6% (95% CI, 35.4%-84.8%) for in situ cancer.

### CONCLUSION

DW-MRI showed a higher invasive and in situ cancer detection rate than mammography and ultrasound, but a lower one than DCE-MRI.

### CLINICAL RELEVANCE/APPLICATION

DW-MRI is expected to be used as a supplemental screening tool to mammography, which has shown higher performance compared to ultrasound.

## S2-SSBR01-Reduced Acquisition Time of Deep-Learning Accelerated T2-Weighted Breast MR Imaging at 6 3T With Super-Resolution: A Prospective Study on Image Quality

Caroline Wilpert, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The study aimed to compare a deep-learning accelerated T2-weighted Dixon sequence with super resolution (DL-T2) to a standard T2-weighted Dixon sequence (T2) for breast MRI with evaluation of overall image quality features in intra-individual comparison.

### METHODS AND MATERIALS

Prospective monocentric pseudo-anonymized study on 140 women (mean age 52 years  $\pm$  14 SD [range:24-82]) who underwent 3T breast MRI with a standard breast imaging protocol and a novel DL reconstructed T2-weighted research application sequence with doubled acceleration factor (4 vs. 2), reduced phase resolution (53%vs.100%) and identical spatial resolution of 0.6 x 0.6 x 3.0 mm. The signal-to-noise ratio (SNR) was employed for quantitative analysis. Two

radiologists rated the image data for qualitative analysis (image quality, noise, anatomic subregions, artifacts, conspicuity of 85 cystic lesions) with intra-individual comparisons and 5-point Likert-Scales (1 = non-diagnostic to 5 = excellent).

## **RESULTS**

The mean acquisition time was 01:50 min for DL-T2 compared to 04:29 min for T2 ( $p < 0.001$ ). There was a significant difference in SNR in DL-T2 and T2 ( $51 \pm 26$  vs.  $40 \pm 19$ ,  $p < 0.001$ ). Image quality was significantly higher in DL-T2 with excellent quality in 127/140 vs. 5/140 cases for conventional T2 ( $p < 0.001$ ). Good image quality (Likert = 4) was reported in 12/140 cases for DL-T2 vs. 113/140 cases for T2 ( $p < 0.001$ ). A higher assessability of all anatomic regions was noted in DL-T2 ( $p < 0.001$ ) with the exception of the image quality of bone marrow, which was better in T2 ( $4.9 \pm 0.3$  vs.  $4.1 \pm 0.2$ ,  $p < 0.001$ ). Conspicuity of cysts was rated higher in DL-T2 ( $p < 0.001$ ). No additional artifacts were observed in DL-T2.

## **CONCLUSION**

DL-T2 for breast imaging results in a reduction of acquisition time of 59 % compared to standard T2 with improved SNR, image quality and conspicuity of cystic lesions compared to standard T2.

## **CLINICAL RELEVANCE/APPLICATION**

Application of DL-T2 may improve cost- and time-effectiveness of breast MR protocols with advantage of improved image quality. To analyse diagnostic accuracy is aim of future studies.

### The Optimal Timepoint for Lesion Evaluation in Ultrafast DCE MRI: Correlation With Background Parenchymal Enhancement and Lesion Characteristics

Sunday, Nov. 26 10:30AM - 11:30AM Room: S401

Masako Y. Kataoka, MD, PhD (*Presenter*) Speaker, Siemens AG Speaker, Bayer AG Speaker, Devicor Medical Products, Inc Speaker, Guerbet SA

#### PURPOSE

Ultrafast Dynamic contrast MRI (UF-DCE MRI) scan multiple frames of images just after contrast agent injection, visualizing lesions before background parenchymal enhancement (BPE) appears. Knowing the optimal time frame of the lesion evaluation helps in interpretation and improvement of the UF-DCE protocol. Thus, we aimed to investigate the optimal timing for lesion evaluation on UF-DCE MRI in relation to BPE and lesion characteristics.

#### METHODS AND MATERIALS

We retrospectively analyzed patients who underwent UF-DCE MRI in our hospital from 2018 to 2021, and had at least one target enhanced lesion suspected of malignancy. Those with post neoadjuvant chemotherapy and poor image quality were excluded. 3T-MRI (Prisma, Siemens, Erlangen) with a 18-ch breast coil was used. The UF-DCE protocol used a 3D gradient-echo VIBE with compressed sensing. Gadobutrol was injected at 2 ml/s. UF-DCE MRI (from 15 sec before to 60 sec after contrast injection, 2 sec preparation time followed by 3.65 sec/frame x 20 frames) were obtained. Axial subtracted MIP images (2nd -20th frames) were computed. An experienced breast radiologist evaluated the serial MIP images and evaluated conspicuity (score 1-5, 5 as best) and the first and last frames of optimal timing. The frame number is used as a proxy to time (sec) from the contrast injection. BPE and lesion size were also recorded. Wilcoxon rank-sum test was used for comparison.

#### RESULTS

In total 419 patients (mean age 56) were included (with 402 patients with timing information) The first and the last frames of optimal timing was the 12.6 and 19.6 (31 sec and 57 sec after contrast injection respectively). For those with marked BPE (n = 59), the first and the last frames of optimal timing was the 12.0 and 18.5 frames (29 and 53 sec) and significantly earlier than those with non-marked BPE (12.7 and 19.7, p=0.009 and p<0.0001 respectively). For those with a lesion size > 20mm (n=195), the first frame of optimal timing was the 12.4 frame (30 sec), slightly earlier than those with a smaller lesion (12.8, p=0.029). For benign lesions (n=66), the first frame of optimal timing was significantly later than malignant lesions (n=336) (13.4 vs 12.4, 34 vs 30 sec, P=0.0003). Conspicuity score was higher in invasive carcinoma (n=296) than non-invasive carcinoma and benign lesions (score 4.8 vs 3.7 p<0.0001)

#### CONCLUSION

Optimal timing of breast lesion evaluation on UF-DCE MRI can be earlier for those with marked BPE and later for benign disease / smaller lesions. Conspicuity is excellent for invasive carcinoma.

#### CLINICAL RELEVANCE/APPLICATION

The current data helps in interpreting various breast lesions on UF-DCE MRI. Information of optimal timing can be used to develop simpler and more efficient UF-DCE MRI protocol focusing on best timing for lesion evaluation.

### Voxelwise Mapping of DCE-MRI Time-Intensity-Curve Profiles Enables Visualizing and Quantifying Hemodynamic Heterogeneity in Breast Lesions

Sunday, Nov. 26 10:30AM - 11:30AM Room: S401

Zhou Liu, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To propose a novel model-free data-driven approach based on the voxelwise mapping of DCE-MRI time-intensity-curve (TIC) profiles for quantifying and visualizing hemodynamic heterogeneity and to validate its potential clinical applications.

#### METHODS AND MATERIALS

From December 2018 to July 2022, 259 patients with 325 pathologically confirmed breast lesions who underwent breast DCE-MRI were retrospectively enrolled. Based on the manually segmented breast lesions, the TIC of each voxel within the 3D whole lesion was classified into 19 subtypes based on wash-in rate (nonenhanced, slow, medium, and fast), wash-out enhancement (persistent, plateau, and decline), and wash-out stability (steady and unsteady), and the composition ratio of these 19 subtypes for each lesion was calculated as a new feature set (Type-19). Compared with the three-type TIC classification and semiquantitative parameters, Type-19 features were used to build a machine learning model to differentiate lesion malignancy and classify histologic grades, proliferation status, and molecular subtypes.

#### RESULTS

The Type-19 feature-based model significantly outperformed models based on the three-type TIC method and semiquantitative parameters both in distinguishing lesion malignancy (AUC = 0.875 vs. 0.831,  $P = 0.01$  and 0.875 vs. 0.804,  $P = 0.03$ ), predicting tumor proliferation status (AUC = 0.890 vs. 0.548,  $P = 0.006$  and 0.890 vs. 0.596,  $P = 0.020$ ), and classifying molecular subtypes (AUC = 0.697 vs. 0.548,  $P = 0.009$  and 0.697 vs. 0.534,  $P < 0.001$ ), but not in predicting histologic grades ( $P = 0.820$  and 0.970).

#### CONCLUSION

In addition to conventional methods, the proposed computational approach provides another novel model-free data-driven approach to quantify and visualize hemodynamic heterogeneity.

#### CLINICAL RELEVANCE/APPLICATION

Voxelwise intra-lesion mapping of TIC profiles allows for visualization of hemodynamic heterogeneity and its composition ratio for differentiation of malignant and benign breast lesions.

### Super-resolution Deep-learning K-space-to-image Reconstruction in Diffusion-weighted Breast MRI at 3.0 Tesla

Sunday, Nov. 26 10:30AM - 11:30AM Room: S401

Stephanie Sauer, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Diffusion-weighted imaging (DWI) in breast MRI is time-consuming and often associated with suboptimal spatial resolution. This study investigated a k-space-to-image reconstruction approach for scan time reduction and a deep-learning based interpolation-algorithm for improved spatial resolution in single-shot echo planar imaging for breast DWI at 3.0 Tesla.

#### METHODS AND MATERIALS

A total of 133 women (age  $49.7 \pm 12.1$  years) who received multiparametric breast MRI including DWI between November 2022 und January 2023 were enrolled. The acquired DWI raw data (standard DWI) was retrospectively processed using deep-learning image reconstruction (DL-DWI) and an additional interpolation algorithm referred to as "super resolution" (SRDL-DWI). All datasets included b values of 800 s/mm<sup>2</sup>, 1600 s/mm<sup>2</sup> (calculated), and ADC maps. Overall image quality was ranked by three blinded readers, while SNR and ADC values were compared. To quantify structural variations caused by image quality alterations, we employed a range of quantitative similarity and error metrics.

#### RESULTS

Compared to standard DWI, both DL- and SRDL-DWI allowed for a 39% reduction in simulated scan time (5:26 vs. 3:20 min). Highest image quality rankings were assigned to SRDL-DWI (all  $p < 0.001$ ). Interreader agreement was good, indicated by an ICC of 0.780 (95% confidence interval 0.758-0.801;  $p < 0.001$ ). Irrespective of b value, both standard and DL-DWI produced superior SNR compared to interpolated SRDL-DWI in the pectoral muscle (all  $p = 0.050$ ) and fibroglandular tissue (all  $p < 0.001$ ), while no significant difference was ascertained between the two standard-resolution DWI datasets (all  $p > 0.999$ ). ADC values in fibroglandular tissue were higher in SRDL-DWI (+0.5%) and DL-DWI (+3.4%) compared to standard DWI (both  $p = 0.001$ ). Structural similarity index metrics (SSIM = 0.86) revealed high concordance between the undersampled reconstructions (with and without super resolution) and the acquired standard DWI images for all b values. Accordingly, calculation of error metrics (NRMSE = 0.05, SMAPE = 0.02, LOGAC = 0.04) supported the assumption of low voxel-wise error. Of note, similarity was highest and error metrics were lowest for b values of 800 s/mm<sup>2</sup>.

#### CONCLUSION

Deep-learning based k-space-to-image reconstruction reduced simulated scan time by 39% without influencing structural similarity in breast DWI at 3.0 Tesla. Additionally employing a SRDL interpolation algorithm allows for subjective improvement of image quality.

#### CLINICAL RELEVANCE/APPLICATION

DWI constitutes a promising technique for non-contrast breast MRI, e.g., for screening purposes. The assessed deep-learning approaches facilitate a significant reduction of acquisition time without compromising image quality.

### Diffusion-Weighted MRI for Breast Cancer Screening in High-Risk Women: Analysis of First Year Outcome for Invasive and In Situ Cancer Detection

Sunday, Nov. 26 10:30AM - 11:30AM Room: S401

Hee Jung Shin, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Interest in unenhanced magnetic resonance imaging (MRI) screening for breast cancer is growing due to concerns about gadolinium deposition in the brain and the high cost of contrast-enhanced MRI. The purpose of this study was to analyze the outcomes of the data obtained during the first year of enrollment in DWIST (Diffusion-Weighted Magnetic Resonance Imaging Screening Trial; <https://ClinicalTrials.gov, NCT03835897>), which is a prospective, multicenter, intraindividual comparative cohort study designed to compare the performance of mammography, ultrasonography, dynamic contrast-enhanced (DCE) MRI, and diffusion-weighted (DW) MRI screening in women at high risk of developing breast cancer.

#### METHODS AND MATERIALS

A total of 1046 women with BRCA mutation or family history of breast cancer and lifetime risk = 20% underwent the first-year breast screenings with digital mammography, ultrasonography, DCE MRI, and DW MRI ( $b=0$ , 800, 1200 sec/mm<sup>2</sup> and ADC map) at 3.0 T. Images are independently interpreted by trained radiologists at each institution. As for the interim results, pathology served as the reference standard. Each image modality and their combination was compared in terms of invasive and in situ cancer detection.

#### RESULTS

In the first year, a total of 39 cancers (3.7%, 39/1046) were detected, with one of them being an interval cancer. Among them, 28 (72%) were invasive cancers, and 11 (28%) were in situ cancers. Overall cancer detection rate (CDR) was 43.6% (95% confidence interval, 29.3%-59.0%) on mammography, 59.0% (95% CI, 43.4%-72.9%) on US, 74.4% (95% CI, 58.9%-85.4%) on DW-MRI, and 92.3% (95% CI, 79.7%-97.3%) on DCE-MRI. CDR of invasive cancer was 53.6% (95% CI, 35.8%-70.5%) on mammography, 67.9% (95% CI, 49.3%-82.1%) on US, 82.1% (95% CI, 64.4%-92.1%) on DW-MRI, and 92.9% (95% CI, 77.4%-98.0%) on DCE-MRI, whereas CDR of in situ cancer was 18.2% (95% CI, 5.1%-47.7%) on mammography, 36.4% (95% CI, 15.2%-64.6%) on US, 54.5% (95% CI, 28.0%-78.7%) on DW-MRI, and 90.9% (95% CI, 62.3%-98.4%) on DCE-MRI. Cancer detection rate of combined mammography and DW-MRI was 85.7% (95% CI, 68.5%-94.3%) for invasive cancer and 63.6% (95% CI, 35.4%-84.8%) for in situ cancer.

#### CONCLUSION

DW-MRI showed a higher invasive and in situ cancer detection rate than mammography and ultrasound, but a lower one than DCE-MRI.

#### CLINICAL RELEVANCE/APPLICATION

DW-MRI is expected to be used as a supplemental screening tool to mammography, which has shown higher performance compared to ultrasound.

### Reduced Acquisition Time of Deep-Learning Accelerated T2-Weighted Breast MR Imaging at 3T With Super-Resolution: A Prospective Study on Image Quality

Sunday, Nov. 26 10:30AM - 11:30AM Room: S401

Caroline Wilpert, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The study aimed to compare a deep-learning accelerated T2-weighted Dixon sequence with super resolution (DL-T2) to a standard T2-weighted Dixon sequence (T2) for breast MRI with evaluation of overall image quality features in intra-individual comparison.

#### METHODS AND MATERIALS

Prospective monocentric pseudo-anonymized study on 140 women (mean age 52 years  $\pm$  14 SD [range:24-82]) who underwent 3T breast MRI with a standard breast imaging protocol and a novel DL reconstructed T2-weighted research application sequence with doubled acceleration factor (4 vs. 2), reduced phase resolution (53%vs.100%) and identical spatial resolution of 0.6 x 0.6 x 3.0 mm. The signal-to-noise ratio (SNR) was employed for quantitative analysis. Two radiologists rated the image data for qualitative analysis (image quality, noise, anatomic subregions, artifacts, conspicuity of 85 cystic lesions) with intra-individual comparisons and 5-point Likert-Scales (1 = non-diagnostic to 5 = excellent).

#### RESULTS

The mean acquisition time was 01:50 min for DL-T2 compared to 04:29 min for T2 ( $p < 0.001$ ). There was a significant difference in SNR in DL-T2 and T2 ( $51 \pm 26$  vs.  $40 \pm 19$ ,  $p < 0.001$ ). Image quality was significantly higher in DL-T2 with excellent quality in 127/140 vs. 5/140 cases for conventional T2 ( $p < 0.001$ ). Good image quality (Likert = 4) was reported in 12/140 cases for DL-T2 vs.113/140 cases for T2 ( $p < 0.001$ ). A higher assessability of all anatomic regions was noted in DL-T2 ( $p < 0.001$ ) with the exception of the image quality of bone marrow, which was better in T2 ( $4.9 \pm 0.3$  vs.  $4.1 \pm 0.2$ ,  $p < 0.001$ ). Conspicuity of cysts was rated higher in DL-T2 ( $p < 0.001$ ). No additional artifacts were observed in DL-T2.

#### CONCLUSION

DL-T2 for breast imaging results in a reduction of acquisition time of 59 % compared to standard T2 with improved SNR, image quality and conspicuity of cystic lesions compared to standard T2.

#### CLINICAL RELEVANCE/APPLICATION

Application of DL-T2 may improve cost- and time-effectiveness of breast MR protocols with advantage of improved image quality. To analyse diagnostic accuracy is aim of future studies.

### S2-SSCA01-Opportunistic Screening for Cardiomegaly on Chest or Abdominal CT using Fully Automated AI

Steven A. Rothenberg, MD (*Presenter*) Founder, Empower Therapeutics Inc ;Member, Translation Holdings LLC;Consultant, Radiostics LLC

#### PURPOSE

To validate the accuracy of a fully-automated artificial intelligence (AI) algorithm designed to opportunistically screen for cardiomegaly on routine chest or abdomen CT exams to predict future major cardiovascular disease (CVD) events.

#### METHODS AND MATERIALS

The heart and inner chest were manually segmented on a multi-institutional set of chest and abdominal CT exams without or with IV contrast (N=1200 routine and 300 with difficult technical and clinical features). A fully-automated AI algorithm (AI Cardiomegaly v0.9) was developed to quantify the area-based cardiothoracic ratio (CTR). For this single-center retrospective clinical validation study, the AI algorithm was run on 13,387 consecutive routine chest or abdominal CT exams from January 1 to June 30, 2016. The CTR (adjusted for age and gender) was statistically associated with the time of first major CVD event derived from a search of the electronic medical records for relevant ICD10 and CPT codes.

#### RESULTS

The cohort included 52% females with 65% white, 30% black, and 5% other/unknown. Mean age was 55.3. Mean BMI was 29.2. Compared to the lowest 50th percentile for the CTR, the top 10th percentile (with cardiomegaly) had increased risk of 2.3x for arrhythmia (HR: 2.3, 95%CI: 1.2-1.5, p<.001), 2.4x for valvular heart disease (HR: 2.4, 95%CI: 2.1-2.9, p<.001), 3.0x for heart failure (HR: 3.0, 95%CI: 2.5-3.6, p<.001), 4.9x for coronary event (HR: 4.9, 95%CI: 4.2-5.7, p<.001), 2.0x for stroke (HR: 2.0, 95%CI: 1.7-2.5, p<.001), and 1.7x for death (HR: 1.7, 95%CI: 1.5-1.9, p<.001).

#### CONCLUSION

A fully-automated AI algorithm designed to opportunistically screen for cardiomegaly on routine chest or abdomen CT exams was highly predictive of future major CVD events.

#### CLINICAL RELEVANCE/APPLICATION

The heart is imaged in 40 million annual chest and abdominal CT exams in the U.S., and unmanaged cardiomegaly is present in approximately 2 million of these patients. Opportunistic screening for cardiomegaly on routine chest and abdominal CT scans adds no patient cost or radiation and can be followed by appropriate care coordination and management that has the potential to markedly reduce the public health burden of CVD.

### S2-SSCA01-Ultra-High-Resolution Photon-Counting-Detector Coronary CT Angiography Using a Dedicated Denoising Convolutional Neural Network for Patients with Dense Calcifications and Stents

Shaojie Chang, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Patients with stents or dense calcifications pose considerable challenges to coronary CT angiography (cCTA) due to blooming artifacts. Ultra-high-resolution (UHR) photon-counting-detector (PCD) CT offers superior spatial resolution for cardiac imaging but significantly increases image noise. This study aims to develop a deep convolution neural network (CNN) for UHR PCD-CT to improve the quality of cCTA for patients with stent and dense calcification.

## METHODS AND MATERIALS

With IRB approval, a CNN was trained on clinical cCTA exams to reduce noise, and subsequently tested on a cohort (n=31; 26 male; mean age 74.2) of challenging coronary CTA cases including dense calcifications (24) and stents (7). All exams were performed using the UHR mode on a dual source PCD-CT (NAEOTOM Alpha, Siemens Healthcare). Images were reconstructed using both filtered back projection (FBP) and iterative reconstruction algorithms with strength 4 (QIR4), 0.2 mm slice thickness, a clinical routine kernel (Bv48), and a sharp kernel (Bv72). The trained CNN was applied to the 0.2 mm FBP images with Bv72 kernel. For each of the 31 testing cases, three blinded image series (Bv48-QIR4, Bv72-QIR4, and Bv72-CNN) were displayed side-by-side in a randomized order and reviewed by an experienced cardiac radiologist. The reader was asked to use a 5-point Likert score for overall image quality (1-nondiagnostic, 2-questionably/barely diagnostic for lumen evaluation, 3-fair/reasonable image quality but diagnostic for lumen evaluation, 4-good image quality, fully diagnostic for lumen evaluation, 5-excellent image quality, fully diagnostic), rate their confidence level on a scale of 1-100 (1 being not confident, and 100 being very confident), assess the degree of stenosis and provide the overall CAD-RADS score.

## RESULTS

The trained CNN substantially reduced image noise by approximately 50% compared to that of QIR images, making the noise of Bv72 images similar to that of Bv48 QIR images. The overall image quality for Bv72-CNN ( $4.22 \pm 0.56$ ) was significantly ( $p < 0.002$ ) higher than Bv48-QIR4 ( $3.96 \pm 0.41$ ) and Bv72-QIR4 ( $2.35 \pm 0.55$ ). CNN significantly improved mean reader confidence in stenosis assessment (Bv72-CNN/Bv48-QIR4/Bv72-QIR4: 94.1/92.3/82.4,  $p < 0.002$ ). For the overall CAD-RADS score, two studies deemed as non-diagnostic using the Bv72 kernel were scored and became diagnostic after applying the CNN denoising.

## CONCLUSION

The UHR PCD-CT combined with a CNN denoising effectively enhanced the diagnostic image quality and improved reader confidence in stenosis assessment.

## CLINICAL RELEVANCE/APPLICATION

The proposed CNN has the potential to improve diagnostic quality and reader confidence and promote clinical adoption of UHR PCD-CT by substantially reducing image noise.

## S2-SSCA01-Deep Learning Analysis of Cardiac Volumetry and Function with Real-Time MRI

5

Amin Mahmoodi, BS (*Presenter*) Nothing to Disclose

## PURPOSE

Electrocardiogram (ECG)-gated cine steady-state free-precession (SSFP) is the standard pulse sequence for assessment of ventricular volumetry and function in cardiac MRI. Yet, it's susceptible to respiratory motion, and it's sensitive to arrhythmia because it does not image a physiological heartbeat but collages snapshots from multiple beats. Real-time (RT) SSFP without ECG-gating has potential for assessing ventricular function, but is challenging to use clinically due to the need for manual identification of cardiac phase across multiple slices and heartbeats. We propose a deep learning strategy to automate phase and slice detection to enable volumetry from RT-SSFP.

## METHODS AND MATERIALS

Short-axis (SAX) cine SSFP images from 241 cardiac MRI exams were spatially and temporally downsampled to simulate RT SSFP to train two Xception-style convolutional neural networks (CNNs). Data were split 80/10/10 into training/validation/test to 1) provide end-diastolic (ED) and end-systolic (ES) phase estimation and 2) classify cardiac slices as atrial, ventricular, or apical. Both CNNs were evaluated for accuracy and recall for ED and ES phase and slice location. CNNs were then applied to RT SSFP acquisitions from 11 patients, for whom RT-SSFP was acquired as part of routine clinical care. CNNs were combined to generate pseudo-cine SSFP series from RT SSFP between detected ED-ED intervals, and compared against cine SSFP for ventricular volumetry measured with clinical cardiac MRI software (Cardio AI [version 29.8.3] Arterys, Redwood Shores, CA). Statistics include Pearson correlation and Bland-Altman.

## RESULTS

The phase estimation CNN detected ED and ES phases with accuracy of 91% and 88%, and recall of 0.82 and 0.74. The slice classification CNN achieved accuracy of 93-97%, and recall of 0.86-0.96. There was strong correlation between ventricular volumes obtained from RT SSFP and paired cine SSFP for ED ( $r=0.98$ ) and ES ( $r=0.97$ ). RT-SSFP slightly underestimated EDV ( $-8.80\text{mL}$ , LOA  $\pm 27.64\text{mL}$ ) and overestimated ESV ( $13.36\text{mL}$ , LOA  $\pm 25.59\text{mL}$ ). There was a lower correlation of calculated ejection fraction ( $r=0.68$ ) between RT-SSFP and cine SSFP.

## CONCLUSION

CNNs are capable of inferring cardiac phase and slice location from RT SSFP to enable measurements of cardiac volumetry, which were comparable to cine SSFP. Future improvements of RT SSFP may improve reliability of this method for quantification of cardiac function.

## CLINICAL RELEVANCE/APPLICATION

Deep learning algorithms may enable measurement of cardiac function from RT SSFP, which is less susceptible to motion and artifacts than traditional cine SSFP. This may enable more reliable cardiac MRI for patients with arrhythmia or who are unable to breath-hold.

## S2-SSCA01-Harnessing Deep Learning to Identify Type 2 Diabetes from Frontal Chest Radiographs: A 6 Prospective Study with External Validation

Ayis T. Pyrros, MD (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study is to explore the efficacy of a deep learning (DL) model, developed using a combination of ambulatory chest radiographs (CXRs) and electronic health records (EHRs), for the opportunistic detection of type 2 diabetes (T2D) from a prospective cohort.

## METHODS AND MATERIALS

In this IRB-approved study, we utilized a dataset of 271,065 CXRs from 160,244 unique patients, obtained between 2010 to 2021. The multi-task DL model was built using PyTorch and ResNet34, and trained on the following variables: age, BMI, HbA1c (%), diabetes status, and select comorbidities (CHF, cardiac arrhythmias, morbid obesity, COPD, and vascular disease) extracted from the EHR. Ground truth labels for diabetes were based on ICD10 and HbA1c data. The model's discriminatory ability was assessed with area under the receiver operating characteristic curve (ROC AUC) in prospective and external cohorts. For comparison, we developed logistic regression (LR) models that used only EHR data. To understand the model's decision-making process, CXR occlusion maps were generated and an autoencoder technique was employed.

## RESULTS

Our DL model, using only CXR data, predicted prevalent T2D in a 7-month (2022) prospective cohort of 9,943 patients, 5,641 females (57%), with an average age of 54.04 years (SD=18.17). The model achieved an AUC of 0.84 (95% CI: 0.83, 0.85), surpassing the EHR-based LR model with an AUC of 0.79 (95% CI: 0.77, 0.80;  $P < 0.001$ ). The DL model consistently outperformed the LR model: 0.85 vs. 0.74 for poorly controlled T2D patients, 0.89 vs. 0.77 for T2D patients with BMI<25 (ages 35-70), and 0.80 vs. 0.74 for T2D patients with BMI=25 (ages 35-70), all with  $P < 0.001$ . External validation at a geographically distinct institution (n=5,026) yielded a AUC of 0.77 (95% CI: 0.75, 0.78). In the prospective cohort, our model identified 1,381 (14%) patients as high-risk for T2D who were previously undiagnosed, suggesting screening opportunities. This included 147 individuals who would not meet criteria for T2D screening (BMI<25). Using explainable AI techniques, we found correlations between specific adiposity features and high DL scores.

## CONCLUSION

Our study showcases a DL model's ability, trained on CXRs and EHR data, to predict T2D. Outperforming a traditional LR model, it illustrates the advantage of using imaging data in disease prediction. Importantly, the model identified numerous high-risk, previously undiagnosed individuals, offering enhanced opportunities for early detection and intervention.

## CLINICAL RELEVANCE/APPLICATION

DL methods can utilize common CXRs for opportunistic disease screening, potentially improving healthcare outcomes, particularly as T2D, a major cardiovascular risk factor, can be identified through this approach.

### Opportunistic Screening for Cardiomegaly on Chest or Abdominal CT using Fully Automated AI

Sunday, Nov. 26 10:30AM - 11:30AM Room: N228

Steven A. Rothenberg, MD (*Presenter*) Founder, Empower Therapeutics Inc ;Member, Translation Holdings LLC;Consultant, Radiostics LLC

#### PURPOSE

To validate the accuracy of a fully-automated artificial intelligence (AI) algorithm designed to opportunistically screen for cardiomegaly on routine chest or abdomen CT exams to predict future major cardiovascular disease (CVD) events.

#### METHODS AND MATERIALS

The heart and inner chest were manually segmented on a multi-institutional set of chest and abdominal CT exams without or with IV contrast (N=1200 routine and 300 with difficult technical and clinical features). A fully-automated AI algorithm (AI Cardiomegaly v0.9) was developed to quantify the area-based cardiothoracic ratio (CTR). For this single-center retrospective clinical validation study, the AI algorithm was run on 13,387 consecutive routine chest or abdominal CT exams from January 1 to June 30, 2016. The CTR (adjusted for age and gender) was statistically associated with the time of first major CVD event derived from a search of the electronic medical records for relevant ICD10 and CPT codes.

#### RESULTS

The cohort included 52% females with 65% white, 30% black, and 5% other/unknown. Mean age was 55.3. Mean BMI was 29.2. Compared to the lowest 50th percentile for the CTR, the top 10th percentile (with cardiomegaly) had increased risk of 2.3x for arrhythmia (HR: 2.3, 95%CI: 1.2-1.5,  $p < .001$ ), 2.4x for valvular heart disease (HR: 2.4, 95%CI: 2.1-2.9,  $p < .001$ ), 3.0x for heart failure (HR: 3.0, 95%CI: 2.5-3.6,  $p < .001$ ), 4.9x for coronary event (HR: 4.9, 95%CI: 4.2-5.7,  $p < .001$ ), 2.0x for stroke (HR: 2.0, 95%CI: 1.7-2.5,  $p < .001$ ), and 1.7x for death (HR: 1.7, 95%CI: 1.5-1.9,  $p < .001$ ).

#### CONCLUSION

A fully-automated AI algorithm designed to opportunistically screen for cardiomegaly on routine chest or abdomen CT exams was highly predictive of future major CVD events.

#### CLINICAL RELEVANCE/APPLICATION

The heart is imaged in 40 million annual chest and abdominal CT exams in the U.S., and unmanaged cardiomegaly is present in approximately 2 million of these patients. Opportunistic screening for cardiomegaly on routine chest and abdominal CT scans adds no patient cost or radiation and can be followed by appropriate care coordination and management that has the potential to markedly reduce the public health burden of CVD.

### Ultra-High-Resolution Photon-Counting-Detector Coronary CT Angiography Using a Dedicated Denoising Convolutional Neural Network for Patients with Dense Calcifications and Stents

Sunday, Nov. 26 10:30AM - 11:30AM Room: N228

Shaojie Chang, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Patients with stents or dense calcifications pose considerable challenges to coronary CT angiography (cCTA) due to blooming artifacts. Ultra-high-resolution (UHR) photon-counting-detector (PCD) CT offers superior spatial resolution for cardiac imaging but significantly increases image noise. This study aims to develop a deep convolution neural network (CNN) for UHR PCD-CT to improve the quality of cCTA for patients with stent and dense calcification.

#### METHODS AND MATERIALS

With IRB approval, a CNN was trained on clinical cCTA exams to reduce noise, and subsequently tested on a cohort ( $n=31$ ; 26 male; mean age 74.2) of challenging coronary CTA cases including dense calcifications (24) and stents (7). All exams were performed using the UHR mode on a dual source PCD-CT (NAEOTOM Alpha, Siemens Healthcare). Images were reconstructed using both filtered back projection (FBP) and iterative reconstruction algorithms with strength 4 (QIR4), 0.2 mm slice thickness, a clinical routine kernel (Bv48), and a sharp kernel (Bv72). The trained CNN was applied to the 0.2 mm FBP images with Bv72 kernel. For each of the 31 testing cases, three blinded image series (Bv48-QIR4, Bv72-QIR4, and Bv72-CNN) were displayed side-by-side in a randomized order and reviewed by an experienced cardiac radiologist. The reader was asked to use a 5-point Likert score for overall image quality (1-nondiagnostic, 2-questionably/barely diagnostic for lumen evaluation, 3-fair/reasonable image quality but diagnostic for lumen evaluation, 4-good image quality, fully diagnostic for lumen evaluation, 5-excellent image quality, fully diagnostic), rate their confidence level on a scale of 1-100 (1 being not confident, and 100 being very confident), assess the degree of stenosis and provide the overall CAD-RADS score.

#### RESULTS

The trained CNN substantially reduced image noise by approximately 50% compared to that of QIR images, making the noise of Bv72 images similar to that of Bv48 QIR images. The overall image quality for Bv72-CNN ( $4.22\pm 0.56$ ) was significantly ( $p<0.002$ ) higher than Bv48-QIR4 ( $3.96\pm 0.41$ ) and Bv72-QIR4 ( $2.35\pm 0.55$ ). CNN significantly improved mean reader confidence in stenosis assessment (Bv72-CNN/Bv48-QIR4/Bv72-QIR4: 94.1/92.3/82.4,  $p < 0.002$ ). For the overall CAD-RADS score, two studies deemed as non-diagnostic using the Bv72 kernel were scored and became diagnostic after applying the CNN denoising.

#### CONCLUSION

The UHR PCD-CT combined with a CNN denoising effectively enhanced the diagnostic image quality and improved reader confidence in stenosis assessment.

#### CLINICAL RELEVANCE/APPLICATION

The proposed CNN has the potential to improve diagnostic quality and reader confidence and promote clinical adoption of UHR PCD-CT by substantially reducing image noise.

### Deep Learning Analysis of Cardiac Volumetry and Function with Real-Time MRI

Sunday, Nov. 26 10:30AM - 11:30AM Room: N228

Amin Mahmoodi, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Electrocardiogram (ECG)-gated cine steady-state free-precession (SSFP) is the standard pulse sequence for assessment of ventricular volumetry and function in cardiac MRI. Yet, it's susceptible to respiratory motion, and it's sensitive to arrhythmia because it does not image a physiological heartbeat but collages snapshots from multiple beats. Real-time (RT) SSFP without ECG-gating has potential for assessing ventricular function, but is challenging to use clinically due to the need for manual identification of cardiac phase across multiple slices and heartbeats. We propose a deep learning strategy to automate phase and slice detection to enable volumetry from RT-SSFP.

#### METHODS AND MATERIALS

Short-axis (SAX) cine SSFP images from 241 cardiac MRI exams were spatially and temporally downsampled to simulate RT SSFP to train two Xception-style convolutional neural networks (CNNs). Data were split 80/10/10 into training/validation/test to 1) provide end-diastolic (ED) and end-systolic (ES) phase estimation and 2) classify cardiac slices as atrial, ventricular, or apical. Both CNNs were evaluated for accuracy and recall for ED and ES phase and slice location. CNNs were then applied to RT SSFP acquisitions from 11 patients, for whom RT-SSFP was acquired as part of routine clinical care. CNNs were combined to generate pseudo-cine SSFP series from RT SSFP between detected ED-ED intervals, and compared against cine SSFP for ventricular volumetry measured with clinical cardiac MRI software (Cardio AI [version 29.8.3] Arterys, Redwood Shores, CA). Statistics include Pearson correlation and Bland-Altman.

#### RESULTS

The phase estimation CNN detected ED and ES phases with accuracy of 91% and 88%, and recall of 0.82 and 0.74. The slice classification CNN achieved accuracy of 93-97%, and recall of 0.86-0.96. There was strong correlation between ventricular volumes obtained from RT SSFP and paired cine SSFP for ED ( $r=0.98$ ) and ES ( $r=0.97$ ). RT-SSFP slightly underestimated EDV (-8.80mL, LOA  $\pm 27.64$ mL) and overestimated ESV (13.36mL, LOA  $\pm 25.59$ mL). There was a lower correlation of calculated ejection fraction ( $r=0.68$ ) between RT-SSFP and cine SSFP.

#### CONCLUSION

CNNs are capable of inferring cardiac phase and slice location from RT SSFP to enable measurements of cardiac volumetry, which were comparable to cine SSFP. Future improvements of RT SSFP may improve reliability of this method for quantification of cardiac function.

#### CLINICAL RELEVANCE/APPLICATION

Deep learning algorithms may enable measurement of cardiac function from RT SSFP, which is less susceptible to motion and artifacts than traditional cine SSFP. This may enable more reliable cardiac MRI for patients with arrhythmia or who are unable to breath-hold.

### Harnessing Deep Learning to Identify Type 2 Diabetes from Frontal Chest Radiographs: A Prospective Study with External Validation

Sunday, Nov. 26 10:30AM - 11:30AM Room: N228

Ayis T. Pyrros, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study is to explore the efficacy of a deep learning (DL) model, developed using a combination of ambulatory chest radiographs (CXRs) and electronic health records (EHRs), for the opportunistic detection of type 2 diabetes (T2D) from a prospective cohort.

#### METHODS AND MATERIALS

In this IRB-approved study, we utilized a dataset of 271,065 CXRs from 160,244 unique patients, obtained between 2010 to 2021. The multi-task DL model was built using PyTorch and ResNet34, and trained on the following variables: age, BMI, HbA1c (%), diabetes status, and select comorbidities (CHF, cardiac arrhythmias, morbid obesity, COPD, and vascular disease) extracted from the EHR. Ground truth labels for diabetes were based on ICD10 and HbA1c data. The model's discriminatory ability was assessed with area under the receiver operating characteristic curve (ROC AUC) in prospective and external cohorts. For comparison, we developed logistic regression (LR) models that used only EHR data. To understand the model's decision-making process, CXR occlusion maps were generated and an autoencoder technique was employed.

#### RESULTS

Our DL model, using only CXR data, predicted prevalent T2D in a 7-month (2022) prospective cohort of 9,943 patients, 5,641 females (57%), with an average age of 54.04 years (SD=18.17). The model achieved an AUC of 0.84 (95% CI: 0.83, 0.85), surpassing the EHR-based LR model with an AUC of 0.79 (95% CI: 0.77, 0.80;  $P < 0.001$ ). The DL model consistently outperformed the LR model: 0.85 vs. 0.74 for poorly controlled T2D patients, 0.89 vs. 0.77 for T2D patients with BMI<25 (ages 35-70), and 0.80 vs. 0.74 for T2D patients with BMI=25 (ages 35-70), all with  $P < 0.001$ . External validation at a geographically distinct institution (n=5,026) yielded a AUC of 0.77 (95% CI: 0.75, 0.78). In the prospective cohort, our model identified 1,381 (14%) patients as high-risk for T2D who were previously undiagnosed, suggesting screening opportunities. This included 147 individuals who would not meet criteria for T2D screening (BMI<25). Using explainable AI techniques, we found correlations between specific adiposity features and high DL scores.

#### CONCLUSION

Our study showcases a DL model's ability, trained on CXRs and EHR data, to predict T2D. Outperforming a traditional LR model, it illustrates the advantage of using imaging data in disease prediction. Importantly, the model identified numerous high-risk, previously undiagnosed individuals, offering enhanced opportunities for early detection and intervention.

#### CLINICAL RELEVANCE/APPLICATION

DL methods can utilize common CXRs for opportunistic disease screening, potentially improving healthcare outcomes, particularly as T2D, a major cardiovascular risk factor, can be identified through this approach.

#### Sub-Events

#### S2-SSGI01- Abbreviated Liver MRI with Gd-EOB-DTPA ( Eovist ) Compared to Complete MRI for Follow up of Colorectal Liver Metastases

Maria El Homsy, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare between abbreviated liver MRI and complete liver MRI for assessment of response in patients with colorectal liver metastases.

#### METHODS AND MATERIALS

This retrospective IRB approved study included consecutive patients with colorectal liver metastases between 1/1/2012 and 12/3/2021 on chemotherapy with at least one follow up MRI performed with Gd-EOB-DTPA (Eovist). A baseline MRI was designated by the study coordinator and a follow-up MRI was chosen and separated into two sets of images: a complete MRI with all sequences and an abbreviated MRI (AMRI) including Coronal and axial hepatobiliary phase, axial DWI and coronal T2W. 7 readers reviewed the sets of images with a month break in between to assess RECIST1.1 response and detection of new lesions. To assess interrater agreement (3 readers read each follow-up), Fleiss kappa was computed for variables with 2 levels and Light's averaged pairwise kappa was computed for variables with > 2 levels. To assess intra-rater agreement, simple kappa was computed for variables with 2 levels and weighted kappa was computed for variables with >2 levels.

#### RESULTS

195 patients (135M/60F, median 54y) were included. There was substantial intra-reader agreement for RECIST 1.1 response (Kappa between 0.66-0.89) and for detection of new lesions (Kappa between 0.63-0.81). There was substantial inter-reader agreement for RECIST1.1 response using complete MRI and AMRI with kappa = 0.68 [0.61, 0.74] and 0.72 [0.65, 0.78] respectively. There was moderate inter-reader agreement for detection of new lesion using complete MRI and AMRI with kappa of 0.49 [0.36, 0.64] and 0.56 [0.42, 0.71] respectively.

#### CONCLUSION

Inter-reader agreement between complete and abbreviated MRI was substantial for RECIST1.1 response assessment, thus AMRI can be considered as substitute for follow-up of patients with colorectal liver metastases.

#### CLINICAL RELEVANCE/APPLICATION

AMRI may be considered as an adequate substitute to a complete MRI liver for patients with colorectal liver metastases when the goal is to assess treatment response in the liver. The potential benefit of AMRI is reduced scan time for the patient, increased patient throughput, and decreased interpretation time for the radiologist.

#### S2-SSGI01- Predicting the Chemotherapeutic Response of Colorectal Cancer Liver Metastasis using Shear-Wave Elastography

Jae Seok Bae, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the prognostic role of shear-wave velocity (SWV) value for predicting chemotherapeutic response and progression-free survival (PFS) in patients with colorectal cancer liver metastases (CRLMs).

## METHODS AND MATERIALS

In this prospective, single-center study, participants with CRLM who were scheduled to undergo chemotherapy were enrolled between May 2018 and June 2021. SWV value measurements by using shear-wave elastography were performed at the CRLM before and after starting chemotherapy. Based on the Response Evaluation Criteria in Solid Tumors, the chemotherapeutic response of the participants was categorized into two categories: responders including complete remission and partial remission, and nonresponders including stable disease and progressive disease. Receiver operating characteristic (ROC) curve analysis was performed to evaluate the performance of changes in SWV values in predicting the chemotherapeutic response of CRLM. In addition, Cox proportional hazard model was used to identify variables associated with PFS.

## RESULTS

In total, 67 participants (40 men; mean age, 62.3 years  $\pm$  10.1) were enrolled, of which 34 were responders and 33 were nonresponders. The area under the ROC curve, sensitivity, and negative predictive value of SWV value in predicting nonresponders were 0.840, 97.0%, and 95.2%, respectively, with a cutoff value of 13% decrease. The change in SWV value was also independently associated with PFS (hazard ratio, 1.020) as well as being a nonresponder and number of CRLM=5.

## CONCLUSION

The change in SWV values measured after chemotherapy demonstrated a meaningful diagnostic performance to predict nonresponders in patients with CRLM. The change in SWV value was also independently associated with PFS.

## CLINICAL RELEVANCE/APPLICATION

In patients with CRLM, ARFI elastography performed early in the course of chemotherapy may help in the selection of chemotherapy regimen by predicting chemo-responsiveness of CRLM.

## S2-SSGI01- Efficacy of Contrast Enhanced Ultrasound Compared to Hepatobiliary MRI for Differentiation of FNH and Hepatic Adenoma: Preliminary Results of Prospective Clinical Trial (NCT03652636)

Jordan K. Swensson, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Focal nodular hyperplasia (FNH) and hepatic adenoma (HA) are hepatic lesions that occur in similar patient demographics but have markedly different risks and treatments. Because of overlapping morphologic and enhancement features, they are often difficult to differentiate on routine ultrasound, CT, or MR imaging. MR imaging with hepatobiliary agents such as gadoxetate disodium (Eovist/Primovist) utilizes physiologic and anatomic differences in FNH and HA uptake and biliary excretion of contrast to distinguish between these two entities and is the standard imaging approach with published accuracies of >90%. However, MRI may be time consuming, expensive, and at times poorly tolerated. This study presents preliminary data from a prospective clinical trial designed to evaluate if contrast enhanced ultrasound (CEUS) can be used to differentiate FNH from HA with similar accuracy compared to hepatobiliary agent MRI.

## METHODS AND MATERIALS

38 patients with lesions consistent with FNH or HA on hepatobiliary agent MRI within the previous 12 months were identified and consented. 7 chose to withdraw without any intervention, leaving 31 patients to undergo a one-time prospective CEUS of up to two hepatic lesions. Limited grayscale and post contrast sonographic images were obtained following intravenous administration of 2 mL sulfur hexafluoride lipid-type A microspheres (Lumason) per lesion for a total of 47 separate lesions. Images were anonymized and two blinded radiologists provided a diagnosis of FNH or HA for each individual lesion.

## RESULTS

A total of 29 female and 2 male patients were included in the analysis, with average age of 37 years and average body mass index of 32.3. A total of 21 FNH and 26 HA were characterized by MRI then evaluated with CEUS. For all 47 lesions, the two readers demonstrated sensitivity and specificity for FNH of 66.7% / 76.9% and 66.7% / 92.3% with overall accuracy of 72.3% and 80.8%. For lesions greater than or equal to 2 cm in size (12 FNH, 16 HA) the two readers demonstrated sensitivity and specificity for FNH of 75.0% / 100% and 91.4% / 89.3%, each with an overall accuracy of 89.3%. Kappa score for interobserver variability was 0.28 for all lesions and 0.71 for lesions greater than or equal to 2 cm in size.

## CONCLUSION

Contrast enhanced ultrasound demonstrates a high degree of accuracy compared to hepatobiliary agent MRI in differentiating FNH from HA lesions that are greater than 2 cm in size, with moderate inter-observer agreement. Smaller lesions are less reliably differentiated using CEUS.

## CLINICAL RELEVANCE/APPLICATION

Contrast enhanced ultrasound has utility in differentiating FNH from hepatic adenomas, with accuracy approaching that of hepatobiliary agent MRI for lesions greater than 2cm in size.

## Abstract Archives of the RSNA, 2023

### **Predicting the Chemotherapeutic Response of Colorectal Cancer Liver Metastasis using Shear-Wave Elastography**

Sunday, Nov. 26 10:30AM - 11:30AM Room: S405

Jae Seok Bae, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To assess the prognostic role of shear-wave velocity (SWV) value for predicting chemotherapeutic response and progression-free survival (PFS) in patients with colorectal cancer liver metastases (CRLMs).

#### **METHODS AND MATERIALS**

In this prospective, single-center study, participants with CRLM who were scheduled to undergo chemotherapy were enrolled between May 2018 and June 2021. SWV value measurements by using shear-wave elastography were performed at the CRLM before and after starting chemotherapy. Based on the Response Evaluation Criteria in Solid Tumors, the chemotherapeutic response of the participants was categorized into two categories: responders including complete remission and partial remission, and nonresponders including stable disease and progressive disease. Receiver operating characteristic (ROC) curve analysis was performed to evaluate the performance of changes in SWV values in predicting the chemotherapeutic response of CRLM. In addition, Cox proportional hazard model was used to identify variables associated with PFS.

#### **RESULTS**

In total, 67 participants (40 men; mean age, 62.3 years  $\pm$  10.1) were enrolled, of which 34 were responders and 33 were nonresponders. The area under the ROC curve, sensitivity, and negative predictive value of SWV value in predicting nonresponders were 0.840, 97.0%, and 95.2%, respectively, with a cutoff value of 13% decrease. The change in SWV value was also independently associated with PFS (hazard ratio, 1.020) as well as being a nonresponder and number of CRLM=5.

#### **CONCLUSION**

The change in SWV values measured after chemotherapy demonstrated a meaningful diagnostic performance to predict nonresponders in patients with CRLM. The change in SWV value was also independently associated with PFS.

#### **CLINICAL RELEVANCE/APPLICATION**

In patients with CRLM, ARFI elastography performed early in the course of chemotherapy may help in the selection of chemotherapy regimen by predicting chemo-responsiveness of CRLM.

### **Efficacy of Contrast Enhanced Ultrasound Compared to Hepatobiliary MRI for Differentiation of FNH and Hepatic Adenoma: Preliminary Results of Prospective Clinical Trial (NCT03652636)**

Sunday, Nov. 26 10:30AM - 11:30AM Room: S405

Jordan K. Swensson, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Focal nodular hyperplasia (FNH) and hepatic adenoma (HA) are hepatic lesions that occur in similar patient demographics but have markedly different risks and treatments. Because of overlapping morphologic and enhancement features, they are often difficult to differentiate on routine ultrasound, CT, or MR imaging. MR imaging with hepatobiliary agents such as gadoxetate disodium (Eovist/Primovist) utilizes physiologic and anatomic differences in FNH and HA uptake and biliary excretion of contrast to distinguish between these two entities and is the standard imaging approach with published accuracies of >90%. However, MRI may be time consuming, expensive, and at times poorly tolerated. This study presents preliminary data from a prospective clinical trial designed to evaluate if contrast enhanced ultrasound (CEUS) can be used to differentiate FNH from HA with similar accuracy compared to hepatobiliary agent MRI.

#### **METHODS AND MATERIALS**

38 patients with lesions consistent with FNH or HA on hepatobiliary agent MRI within the previous 12 months were identified and consented. 7 chose to withdraw without any intervention, leaving 31 patients to undergo a one-time prospective CEUS of up to two hepatic lesions. Limited grayscale and post contrast sonographic images were obtained following intravenous administration of 2 mL sulfur hexafluoride lipid-type A microspheres (Lumason) per lesion for a total of 47 separate lesions. Images were anonymized and two blinded radiologists provided a diagnosis of FNH or HA for each individual lesion.

#### **RESULTS**

A total of 29 female and 2 male patients were included in the analysis, with average age of 37 years and average body mass index of 32.3. A total of 21 FNH and 26 HA were characterized by MRI then evaluated with CEUS. For all 47 lesions, the two readers demonstrated sensitivity and specificity for FNH of 66.7% / 76.9% and 66.7% / 92.3% with overall accuracy of 72.3% and 80.8%. For lesions greater than or equal to 2 cm in size (12 FNH, 16 HA) the two readers demonstrated sensitivity and specificity for FNH of 75.0% / 100% and 91.4% / 89.3%, each with an overall accuracy of 89.3%. Kappa score for interobserver variability was 0.28 for all lesions and 0.71 for lesions greater than or equal to 2 cm in size.

#### **CONCLUSION**

Contrast enhanced ultrasound demonstrates a high degree of accuracy compared to hepatobiliary agent MRI in differentiating FNH from HA lesions that are greater than 2 cm in size, with moderate inter-observer agreement. Smaller lesions are less reliably differentiated using CEUS.

#### **CLINICAL RELEVANCE/APPLICATION**

Contrast enhanced ultrasound has utility in differentiating FNH from hepatic adenomas, with accuracy approaching that of hepatobiliary agent MRI for lesions greater than 2cm in size.

#### **S2-SSGI02- Image Quality of Abdominal Photon-Counting CT with Reduced Contrast Media Dose: Evaluation of Reduced Contrast Media Protocols during the COVID-19 Pandemic Supply Shortage**

Yannik Christian Layer, MD (*Presenter*) Research grant by Siemens Healthcare

#### PURPOSE

Due to iodinated contrast media supply shortages caused by the COVID-19 pandemic in summer 2022, patients received reduced CT contrast media doses (CMD) at our institute. Aim of this study was to assess the impact of CMD reduction on diagnostic quality of photon-counting detector CT (PCD-CT) and energy-integrating detector CT (EID-CT).

#### METHODS AND MATERIALS

Clinical CT scans of the abdominal region acquired in portal venous phase between June and July 2022 on a PCD-CT were included and virtual monoenergetic images (VMI) with 50, 60 and 70 keV reconstructed. CT scans performed on an EID-CT were analyzed for comparison. Diagnostic quality and contrast intensity were rated by two radiologists using a 5-point Likert grading scale qualitatively. Additionally, the blinded readers had to assign the CT scans to reduced or regular CMD. For quantitative assessment regions-of-interest (ROIs) were placed in defined segments of the abdominal aorta, the inferior vena cava, the portal vein, liver, spleen, kidneys and muscular tissue. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated for each organ.

#### RESULTS

Overall 158 CT scans (100% CMD: 75; 70% CMD: 24; 50% CMD: 42) performed on a PCD-CT and 68 examinations (100% CMD: 57; 50% CMD: 11) on an EID-CT were analyzed. Overall diagnostic quality scored 5 (5-5) for PCD-CT with standard CMD (PCD-CT 50% CMD: 4 (4-5); EID-CT 100%: 4 (4-5); EID-CT 50% CMD: 3 (2-3)) and contrast intensity scored 5 (4-5) (PCD-CT 50% CMD: 4 (3-4); EID-CT 100% CMD: 4 (4-4.75); EID-CT 50% CMD: 2.5 (1-3)). For PCD-CT 71.69% of the examinations with reduced CMD were assigned 100% CMD by the readers (Reader 1: 71.08%; Reader 2: 72.29%), for EID-CT 9.09% (Reader 1: 0%; Reader 2: 18.18%). Averaged for all measurements SNR for 50% CMD was reduced by 19% in PCD-CT (EID-CT 34%) and CNR by 48% (EID-CT 56%). VMI at 50 keV increased SNR averaged for all measurements at 50% CMD by 72% and CNR by 153%.

#### CONCLUSION

Diagnostic interpretability of photon-counting detector computed tomography examinations with reduction of up to 50% CMD is maintained. PCD-CT deducted scans with 70% CMD were often not recognized as CMD reduced scans. Compared to EID-CT less decline in SNR and CNR is observed for CMD reduced PCD-CT images. Reducing CMD by 30% on PCD-CT does not decrease overall objective image quality and is therefore recommended for abdominal CT. By reconstruction of low-keV images for example at 50 keV, a significant increase in SNR and CNR can be achieved, which even exceeds the effects of the CMD reduction.

#### CLINICAL RELEVANCE/APPLICATION

The study demonstrates the potential of contrast media reduction of PCD-CT in clinical routine. This can benefit patients with renal impairment, for example, and reduce negative effects of iodinated contrast media on the environment.

## **S2-SSGI02- Benefits of Photon Counting CT for Liver Lesion Detection Compared to Conventional Scanners: A Pilot Reader Study Using Virtual Imaging Trials**

Benjamin Wildman-Tobriner, MD (*Presenter*) Nothing to Disclose

### **PURPOSE**

Photon counting CT (PCCT) has potential for increased spatial resolution and decreased noise compared to traditional energy integrating CT (EICT). The purpose of this study was to compare PCCT to EICT for detection of liver lesions, particularly for challenging conditions: small lesions or larger patients.

### **METHODS AND MATERIALS**

A virtual imaging trial framework was employed using human models and scanner-specific, validated CT simulators. 25 anthropomorphic virtual phantoms (BMI from 20.0-38.8 kg/m<sup>2</sup>) were included, and between 1-6 liver lesions were inserted into each phantom. The lesions' size and contrast ranged from 0.4-1.5 cm, and 51-95 HU, respectively. The phantoms were then scanned, modeling commercial PCCT (Alpha) and EICT (Flash) scanners (Siemens) under a variety of acquisition and clinical reconstruction settings (CTDI<sub>vol</sub> of 1.5 6.0 mGy, reconstruction kernels of Br36/Br32, Br40/Br40, Br56/Br54). Ultimately 100 scans were produced. All scans were then independently evaluated by 3 subspecialty-trained abdominal radiologists using a web-based platform for image viewing and grading. Readers marked all identifiable liver lesions in each scan, assigned a confidence rating (0-100) for every detected lesion, and gave an overall image quality score (range 0-100). Reader detection of liver lesions was compared to the known ground truth of the inserted lesions, and performance metrics (sensitivity and precision) and image quality scores were evaluated across all imaging conditions.

### **RESULTS**

Mean sensitivity across all readers for lesion detection at 6 mGy was 91.8% for PCCT and 87.7% for EICT (p=0.05). At the lower dose of 1.5 mGy, mean sensitivities were 80.8% and 75.6% for PCCT and EICT, respectively (p=0.03). For lesions <1.0 cm at 1.5 mGy, sensitivity on PCCT was 84.9% compared to 73.5% for EICT (p=0.01). Precision between PCCT and EICT was not significantly different, and the overall image quality scores averaged 52.9 for PCCT and 48.3 for EICT.

### **CONCLUSION**

Detection of liver lesions was improved using a photon counting CT platform compared to a traditional energy integrating CT system. This performance increase was more pronounced at lower doses and for smaller lesions.

### **CLINICAL RELEVANCE/APPLICATION**

Detection of small liver lesions such as early metastasis is crucial for accurate staging and surgical planning. Our study suggests that photon counting CT may improve detection of small lesions compared to traditional scanners.

## **S2-SSGI02- Comparison of Image Quality of Abdominal CT Examinations and Virtual Noncontrast Images Between Photon-Counting and Energy-Integrating Detector CT**

Ludovica Lofino, MD (*Presenter*) Nothing to Disclose

### **PURPOSE**

To compare image quality of portal venous phase (PVP) abdominal CT examinations and virtual non-contrast (VNC) images between photon-counting CT (PCCT) and energy-integrating Detector CT (EID).

### **METHODS AND MATERIALS**

In this HIPAA compliant, IRB-approved, retrospective study, multi-phase CT scans from one commercially available PCCT (NAEOTOM Alpha, Siemens Healthineers) and two EID dual-source dual-energy CT systems (SOMATOM Definition Flash and SOMATOM Force, Siemens Healthineers) were retrieved. A total of 45 BMI-matched patients (21 women, 24 men; mean age 58.5 ± 15.3 years, range 19-81 years; mean BMI 29.0 ± 6.8 kg/m<sup>2</sup>, range 13-47 kg/m<sup>2</sup>) were included: 15 for PCCT and 15 for each EID system. In vivo image quality parameters (MTFF<sub>10</sub>, noise magnitude, Fav, Fpeak, NPSf<sub>10</sub>) were measured and compared between PCCT and EID for standard PVP and VNC images. A subset analysis was also performed in the overweight patient population (BMI>25 kg/m<sup>2</sup>). CTDI<sub>vol</sub> values were recorded for the three scanners. Because scanner tube current modulation adapts to patient size, radiation dose was compared among scanners accounting for BMI using a figure of merit: FOM=1/(BMI\*lnCTDI<sub>vol</sub>). A five-point scale (1=best and 5=worst) was used to assess reader perception of noise, visibility of small structures, and overall image quality.

### **RESULTS**

Compared to the two EID systems, PCCT yielded significantly improved resolution and noise magnitude for both PVP (MTFF<sub>10</sub> = 0.55 ± 0.08 for PCCT vs. 0.50 ± 0.04 and 0.49 ± 0.03 for Flash and Force, P=0.02; noise = 9.76 ± 3.10 vs. 15.35 ± 4.14 and 10.70 ± 1.34, P=0.02) and VNC images (MTFF<sub>10</sub> = 0.56 ± 0.01 for PCCT vs. 0.51 ± 0.05 and 0.51 ± 0.03 for Flash and Force, P=0.02; noise = 9.59 ± 2.77 vs. 13.90 ± 3.57 and 10.83 ± 2.83, P=0.02). A similar statistically significant trend was confirmed in the smaller subset of overweight patients. Our FOM analysis suggests that, for equal radiation exposure levels

and comparable patient size, PCCT yields 20% noise reduction compared to the two EID systems, with 18% reduction in overweight patients. Reader's perceived image noise was significantly lower for PCCT compared to EID for both PVP ( $1.85 \pm 0.88$  vs.  $2.60 \pm 0.88$  and  $2.70 \pm 0.80$ ) and VNC images ( $1.95 \pm 0.83$  vs.  $3.0 \pm 0.97$  and  $2.90 \pm 0.85$ ). Of note, overall image quality improved significantly for PCCT compared to EID ( $1.35 \pm 0.67$  vs.  $2.60 \pm 0.82$  and  $2.45 \pm 0.69$  for PVP and  $1.50 \pm 0.67$  vs  $2.85 \pm 0.81$  and  $2.55 \pm 0.60$  for VNC).

## **CONCLUSION**

Compared to conventional EID systems, PCCT yields significantly lower radiation dose along with improved image quality on PVP and VNC images of abdominal CT examinations.

## **CLINICAL RELEVANCE/APPLICATION**

PCCT has a lower radiation dose compared to EID CT, with better image quality parameters and lower noise magnitude.

## **S2-SSGI02- Deep-learning CT Reconstruction in the Abdomen: A Systematic Review and Meta-Analysis** **4**

Mostafa A. Shehata, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

Deep-learning image reconstruction (DLR) provides a unique opportunity to overcome current reconstruction modalities' restrictions. We conducted this systematic review of the literature and meta analysis to evaluate the two most common commercially available deep learning algorithms for CT reconstruction in abdominal imaging and determine their effectiveness.

## **METHODS AND MATERIALS**

We used PubMed, Scopus, Embase, and Web of Science to conduct systematic searches for studies assessing the most common commercially available deep learning CT reconstruction algorithms: True Fidelity (TF) and Advanced intelligent Clear-IQ Engine (AiCE) in the abdomen of human participants.

## **RESULTS**

Forty-four articles fulfilled inclusion criteria. 32 studies evaluated TF and 12 studies assessed AiCE. DLR algorithms produced images with significantly less noise (22-57.3% less than IR) but preserved a desirable noise texture with increased contrast-to-noise ratios and improved lesion detectability on conventional CT. These improvements with DLR were similarly noted in dual-energy CT which was only assessed for a single vendor. Reported radiation reduction potential was 35.1-78.5%. Nine studies assessed observer performance with the two dedicated liver lesion studies being performed on the same vendor reconstruction (TF). These two studies indicate preserved low contrast liver lesion detection (>5mm) at CTDIvol 6.8 mGy (BMI 23.5 kg/m<sup>2</sup>) to 12.2 mGy (BMI 29 kg/m<sup>2</sup>). If smaller lesion detection and improved lesion characterization is needed, a CTDIvol of 13.6 mGy - 34.9 mGy is needed in a normal weight to obese population. Mild signal loss and blurring have been reported at high DLR reconstruction strengths.

## **CONCLUSION**

Deep learning reconstructions significantly improve image quality in CT of the abdomen. Assessment of other dose levels and clinical indications is necessary. Careful choice of radiation dose levels is necessary, particularly for small liver lesion assessment.

## **CLINICAL RELEVANCE/APPLICATION**

The use of DLR reconstruction techniques could lead to more accurate diagnosis and treatment planning, while also reducing the risks associated with radiation exposure during CT imaging. However, careful selection of appropriate radiation doses is necessary to avoid signal loss and blurring at high DLR reconstruction strengths.

## **S2-SSGI02- AI-aided Contrast Augmentation of Abdominal-Pelvis CT Examinations: Multi-site, External** **5 Validation Study of Impact on Hepatic Lesions, Vessels, and Parenchyma**

Emiliano Garza Frias, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

Liver lesions can be difficult to detect and assess on abdomen-pelvis CT due to their low contrast and high noise in the liver parenchyma. We assessed the qualitative and quantitative effect of AI-aided, iodine-related contrast augmentation of abdominal-pelvis CT examinations on hepatic lesions, vessels, and parenchyma.

## **METHODS AND MATERIALS**

The study received IRB approval with the waiver of informed consent. Our study included 100 contrast-enhanced abdomen-pelvis CT exams from 100 adult patients (mean age 59 +/- 14 years, M:F 48:52 ) who were imaged to evaluate primary or metastatic liver lesions. The thin-section deidentified DICOM images were exported offline from PACS and processed with an AI algorithm (ClariACE, ClariPi, South Korea) for selective iodine-related contrast augmentation in CT images. The algorithm

allows users to set their preferred contrast augmentation intensity (fixed at 0.70 for the study purpose) and simultaneous image denoising (fixed at 0.20). We performed a side-by-side comparison of baseline (CT-B) and contrast augmentation (CT-CA) images for liver lesion conspicuity, detection, image noise, and artifacts. We also measured attenuation values on CT-B and CT-CA in abdominal fat, gall bladder, muscles, liver parenchyma, liver lesion, common hepatic artery, and right portal vein. Data were assessed using paired t-test and Wilcoxon rank sum test with a corrected p-value of < 0.0125 for statistical significance.

## RESULTS

There was a significant subjective improvement in hepatic and vascular enhancement as well as in the image noise on CT-CA versus CT-B images. There were no major artifacts on CT-CA images. Most CT exams had between 1-20 liver lesions with improved lesion conspicuity on CT-CA images compared to CTB. Likewise, there was a significant increase in HU values of liver, liver vessels, and liver lesions on CT-CA (HU increase of 15-80 HU,  $p < 0.001$ ), without any change in CT numbers of abdominal fat, muscles, and gall bladder (0-2 HU change;  $p > 0.9$ ).

## CONCLUSION

The AI-aided, iodine-related contrast augmentation of abdominal-pelvis CT examinations resulted in improvement in liver lesion conspicuity and quantitative lesion and vascular enhancement.

## CLINICAL RELEVANCE/APPLICATION

AI-aided, iodine-related contrast augmentation can help improve lesion detection and evaluation while denoising the CT images.

## S2-SSGI02- Super-High-Resolution Abdominal Imaging using CZT based Photon Counting CT with Deep Learning Reconstruction: Quantitative Study and First Clinical Impression

Ken Hirayama (*Presenter*) Nothing to Disclose

## PURPOSE

Recently, first clinical studies of CZT-based photon counting detector CT (CZT-PCD-CT) has started in Japan. Due to its small pixel design, CZT-PCD-CT can generate super-high-resolution (SHR) image and has potential to improve the diagnostic quality of abdominal imaging. To mitigate the noise in SHR imaging, a deep learning based reconstruction can also be applied in SHR mode. In this study, we aim to 1) quantify the resolution benefits of the CZT-PCD-CT for abdominal imaging in comparison to normal resolution mode (NR); 2) evaluate diagnostic image quality with patient scan and explore potential clinical benefits of SHR mode in abdominal imaging.

## METHODS AND MATERIALS

The prototype CZT-PCD-CT is built based on a Aquilion Precision system (Canon Medical Systems, Japan). The beam coverage of the CZT-PCD-CT system is 40 mm, and the focal spot size is 0.4 mm\*0.5 mm. Catphan600 (The Phantom Laboratory, U.S) and patients were scanned in helical mode at 120 kVp, 250 mA (9.7 mGy), 0.5 s rotation and pitch factor 0.8. NR images were reconstructed using a 512-matrix size, and a hybrid-iterative reconstruction (Hybrid-IR). SHR images were reconstructed using a 1024-matrix size with both Hybrid-IR and deep learning reconstruction (DLR). The image thickness is 1.2 mm, and standard kernel was used for all images. Visual evaluation and profile measurement are performed on Catphan with slit modules, task-based transfer functions (TTF) were measured at Polystyrene module. Clinical abdomen images were assessed for NR and SHR image noise (SD) and anatomical structures in the upper abdomen.

## RESULTS

Slit profiles were visible up to 8 lp/cm in NR, 10 lp/cm in SHR and 10 lp/cm in SHR with DLR. 10% TTF values were 0.7 cycles/mm for NR images, 1.0 cycles/mm for SHR images with IR, and 0.9 cycles/mm for SHR images with DLR. Spatial resolution with SHR mode was higher compared to NR mode. For abdominal NR and SHR images, the image noise levels were acceptable for diagnostic tasks. The noise SD was 10.2 HU for NR images, 13.1 HU for SHR images with IR and 11.1 HU for SHR images with DLR, and the SHR images with DLR showed low noise level with high spatial resolution. Pancreatic duct and vessels were more visible and blooming artifacts from calcification were significantly reduced on SHR images.

## CONCLUSION

The CZT PCD-CT with super-high-resolution imaging mode offers significant improvements in spatial resolution and has potential in improving diagnostic quality of abdominal imaging.

## CLINICAL RELEVANCE/APPLICATION

The high-resolution images in the SHR mode of CZT-PCD-CT contribute improved diagnostic performance in abdominal imaging.

## Abstract Archives of the RSNA, 2023

S2-SSGI02-1

### Image Quality of Abdominal Photon-Counting CT with Reduced Contrast Media Dose: Evaluation of Reduced Contrast Media Protocols during the COVID-19 Pandemic Supply Shortage

Sunday, Nov. 26 10:30AM - 11:30AM Room: S404

Yannik Christian Layer, MD (*Presenter*) Research grant by Siemens Healthcare

#### PURPOSE

Due to iodinated contrast media supply shortages caused by the COVID-19 pandemic in summer 2022, patients received reduced CT contrast media doses (CMD) at our institute. Aim of this study was to assess the impact of CMD reduction on diagnostic quality of photon-counting detector CT (PCD-CT) and energy-integrating detector CT (EID-CT).

#### METHODS AND MATERIALS

Clinical CT scans of the abdominal region acquired in portal venous phase between June and July 2022 on a PCD-CT were included and virtual monoenergetic images (VMI) with 50, 60 and 70 keV reconstructed. CT scans performed on an EID-CT were analyzed for comparison. Diagnostic quality and contrast intensity were rated by two radiologists using a 5-point Likert grading scale qualitatively. Additionally, the blinded readers had to assign the CT scans to reduced or regular CMD. For quantitative assessment regions-of-interest (ROIs) were placed in defined segments of the abdominal aorta, the inferior vena cava, the portal vein, liver, spleen, kidneys and muscular tissue. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated for each organ.

#### RESULTS

Overall 158 CT scans (100% CMD: 75; 70% CMD: 24; 50% CMD: 42) performed on a PCD-CT and 68 examinations (100% CMD: 57; 50% CMD: 11) on an EID-CT were analyzed. Overall diagnostic quality scored 5 (5-5) for PCD-CT with standard CMD (PCD-CT 50% CMD: 4 (4-5); EID-CT 100%: 4 (4-5); EID-CT 50% CMD: 3 (2-3)) and contrast intensity scored 5 (4-5) (PCD-CT 50% CMD: 4 (3-4); EID-CT 100% CMD: 4 (4-4.75); EID-CT 50% CMD: 2.5 (1-3)). For PCD-CT 71.69% of the examinations with reduced CMD were assigned 100% CMD by the readers (Reader 1: 71.08%; Reader 2: 72.29%), for EID-CT 9.09% (Reader 1: 0%; Reader 2: 18.18%). Averaged for all measurements SNR for 50% CMD was reduced by 19% in PCD-CT (EID-CT 34%) and CNR by 48% (EID-CT 56%). VMI at 50 keV increased SNR averaged for all measurements at 50% CMD by 72% and CNR by 153%.

#### CONCLUSION

Diagnostic interpretability of photon-counting detector computed tomography examinations with reduction of up to 50% CMD is maintained. PCD-CT deducted scans with 70% CMD were often not recognized as CMD reduced scans. Compared to EID-CT less decline in SNR and CNR is observed for CMD reduced PCD-CT images. Reducing CMD by 30% on PCD-CT does not decrease overall objective image quality and is therefore recommended for abdominal CT. By reconstruction of low-keV images for example at 50 keV, a significant increase in SNR and CNR can be achieved, which even exceeds the effects of the CMD reduction.

#### CLINICAL RELEVANCE/APPLICATION

The study demonstrates the potential of contrast media reduction of PCD-CT in clinical routine. This can benefit patients with renal impairment, for example, and reduce negative effects of iodinated contrast media on the environment.

### Benefits of Photon Counting CT for Liver Lesion Detection Compared to Conventional Scanners: A Pilot Reader Study Using Virtual Imaging Trials

Sunday, Nov. 26 10:30AM - 11:30AM Room: S404

Benjamin Wildman-Tobriner, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Photon counting CT (PCCT) has potential for increased spatial resolution and decreased noise compared to traditional energy integrating CT (EICT). The purpose of this study was to compare PCCT to EICT for detection of liver lesions, particularly for challenging conditions: small lesions or larger patients.

#### METHODS AND MATERIALS

A virtual imaging trial framework was employed using human models and scanner-specific, validated CT simulators. 25 anthropomorphic virtual phantoms (BMI from 20.0-38.8 kg/m<sup>2</sup>) were included, and between 1-6 liver lesions were inserted into each phantom. The lesions' size and contrast ranged from 0.4-1.5 cm, and 51-95 HU, respectively. The phantoms were then scanned, modeling commercial PCCT (Alpha) and EICT (Flash) scanners (Siemens) under a variety of acquisition and clinical reconstruction settings (CTDI<sub>vol</sub> of 1.5 6.0 mGy, reconstruction kernels of Br36/Br32, Br40/Br40, Br56/Br54). Ultimately 100 scans were produced. All scans were then independently evaluated by 3 subspecialty-trained abdominal radiologists using a web-based platform for image viewing and grading. Readers marked all identifiable liver lesions in each scan, assigned a confidence rating (0-100) for every detected lesion, and gave an overall image quality score (range 0-100). Reader detection of liver lesions was compared to the known ground truth of the inserted lesions, and performance metrics (sensitivity and precision) and image quality scores were evaluated across all imaging conditions.

#### RESULTS

Mean sensitivity across all readers for lesion detection at 6 mGy was 91.8% for PCCT and 87.7% for EICT ( $p=0.05$ ). At the lower dose of 1.5 mGy, mean sensitivities were 80.8% and 75.6% for PCCT and EICT, respectively ( $p=0.03$ ). For lesions <1.0 cm at 1.5 mGy, sensitivity on PCCT was 84.9% compared to 73.5% for EICT ( $p=0.01$ ). Precision between PCCT and EICT was not significantly different, and the overall image quality scores averaged 52.9 for PCCT and 48.3 for EICT.

#### CONCLUSION

Detection of liver lesions was improved using a photon counting CT platform compared to a traditional energy integrating CT system. This performance increase was more pronounced at lower doses and for smaller lesions.

#### CLINICAL RELEVANCE/APPLICATION

Detection of small liver lesions such as early metastasis is crucial for accurate staging and surgical planning. Our study suggests that photon counting CT may improve detection of small lesions compared to traditional scanners.

### Comparison of Image Quality of Abdominal CT Examinations and Virtual Noncontrast Images Between Photon-Counting and Energy-Integrating Detector CT

Sunday, Nov. 26 10:30AM - 11:30AM Room: S404

Ludovica Lofino, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare image quality of portal venous phase (PVP) abdominal CT examinations and virtual non-contrast (VNC) images between photon-counting CT (PCCT) and energy-integrating Detector CT (EID).

#### METHODS AND MATERIALS

In this HIPAA compliant, IRB-approved, retrospective study, multi-phase CT scans from one commercially available PCCT (NAEOTOM Alpha, Siemens Healthineers) and two EID dual-source dual-energy CT systems (SOMATOM Definition Flash and SOMATOM Force, Siemens Healthineers) were retrieved. A total of 45 BMI-matched patients (21 women, 24 men; mean age  $58.5 \pm 15.3$  years, range 19-81 years; mean BMI  $29.0 \pm 6.8$  kg/m<sup>2</sup>, range 13-47 kg/m<sup>2</sup>) were included: 15 for PCCT and 15 for each EID system. In vivo image quality parameters (MTF<sub>f10</sub>, noise magnitude, Fav, Fpeak, NPS<sub>f10</sub>) were measured and compared between PCCT and EID for standard PVP and VNC images. A subset analysis was also performed in the overweight patient population (BMI > 25 kg/m<sup>2</sup>). CTDI<sub>vol</sub> values were recorded for the three scanners. Because scanner tube current modulation adapts to patient size, radiation dose was compared among scanners accounting for BMI using a figure of merit:  $FOM = 1 / (BMI * \ln CTDI_{vol})$ . A five-point scale (1=best and 5=worst) was used to assess reader perception of noise, visibility of small structures, and overall image quality.

#### RESULTS

Compared to the two EID systems, PCCT yielded significantly improved resolution and noise magnitude for both PVP (MTF<sub>f10</sub> =  $0.55 \pm 0.08$  for PCCT vs.  $0.50 \pm 0.04$  and  $0.49 \pm 0.03$  for Flash and Force,  $P=0.02$ ; noise =  $9.76 \pm 3.10$  vs.  $15.35 \pm 4.14$  and  $10.70 \pm 1.34$ ,  $P=0.02$ ) and VNC images (MTF<sub>f10</sub> =  $0.56 \pm 0.01$  for PCCT vs.  $0.51 \pm 0.05$  and  $0.51 \pm 0.03$  for Flash and Force,  $P=0.02$ ; noise =  $9.59 \pm 2.77$  vs.  $13.90 \pm 3.57$  and  $10.83 \pm 2.83$ ,  $P=0.02$ ). A similar statistically significant trend was confirmed in the smaller subset of overweight patients. Our FOM analysis suggests that, for equal radiation exposure levels and comparable patient size, PCCT yields 20% noise reduction compared to the two EID systems, with 18% reduction in overweight patients. Reader's perceived image noise was significantly lower for PCCT compared to EID for both PVP ( $1.85 \pm 0.88$  vs.  $2.60 \pm 0.88$  and  $2.70 \pm 0.80$ ) and VNC images ( $1.95 \pm 0.83$  vs.  $3.0 \pm 0.97$  and  $2.90 \pm 0.85$ ). Of note, overall image quality improved significantly for PCCT compared to EID ( $1.35 \pm 0.67$  vs.  $2.60 \pm 0.82$  and  $2.45 \pm 0.69$  for PVP and  $1.50 \pm 0.67$  vs  $2.85 \pm 0.81$  and  $2.55 \pm 0.60$  for VNC).

#### CONCLUSION

Compared to conventional EID systems, PCCT yields significantly lower radiation dose along with improved image quality on PVP and VNC images of abdominal CT examinations.

#### CLINICAL RELEVANCE/APPLICATION

PCCT has a lower radiation dose compared to EID CT, with better image quality parameters and lower noise magnitude.

### Deep-learning CT Reconstruction in the Abdomen: A Systematic Review and Meta-Analysis

Sunday, Nov. 26 10:30AM - 11:30AM Room: S404

Mostafa A. Shehata, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Deep-learning image reconstruction (DLR) provides a unique opportunity to overcome current reconstruction modalities' restrictions. We conducted this systematic review of the literature and meta analysis to evaluate the two most common commercially available deep learning algorithms for CT reconstruction in abdominal imaging and determine their effectiveness.

#### METHODS AND MATERIALS

We used PubMed, Scopus, Embase, and Web of Science to conduct systematic searches for studies assessing the most common commercially available deep learning CT reconstruction algorithms: True Fidelity (TF) and Advanced intelligent Clear-IQ Engine (AiCE) in the abdomen of human participants.

#### RESULTS

Forty-four articles fulfilled inclusion criteria. 32 studies evaluated TF and 12 studies assessed AiCE. DLR algorithms produced images with significantly less noise (22-57.3% less than IR) but preserved a desirable noise texture with increased contrast-to-noise ratios and improved lesion detectability on conventional CT. These improvements with DLR were similarly noted in dual-energy CT which was only assessed for a single vendor. Reported radiation reduction potential was 35.1-78.5%. Nine studies assessed observer performance with the two dedicated liver lesion studies being performed on the same vendor reconstruction (TF). These two studies indicate preserved low contrast liver lesion detection (>5mm) at CTDIvol 6.8 mGy (BMI 23.5 kg/m<sup>2</sup>) to 12.2 mGy (BMI 29 kg/m<sup>2</sup>). If smaller lesion detection and improved lesion characterization is needed, a CTDIvol of 13.6 mGy - 34.9 mGy is needed in a normal weight to obese population. Mild signal loss and blurring have been reported at high DLR reconstruction strengths.

#### CONCLUSION

Deep learning reconstructions significantly improve image quality in CT of the abdomen. Assessment of other dose levels and clinical indications is necessary. Careful choice of radiation dose levels is necessary, particularly for small liver lesion assessment.

#### CLINICAL RELEVANCE/APPLICATION

The use of DLR reconstruction techniques could lead to more accurate diagnosis and treatment planning, while also reducing the risks associated with radiation exposure during CT imaging. However, careful selection of appropriate radiation doses is necessary to avoid signal loss and blurring at high DLR reconstruction strengths.

### AI-aided Contrast Augmentation of Abdominal-Pelvis CT Examinations: Multi-site, External Validation Study of Impact on Hepatic Lesions, Vessels, and Parenchyma

Sunday, Nov. 26 10:30AM - 11:30AM Room: S404

Emiliano Garza Frias, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Liver lesions can be difficult to detect and assess on abdomen-pelvis CT due to their low contrast and high noise in the liver parenchyma. We assessed the qualitative and quantitative effect of AI-aided, iodine-related contrast augmentation of abdominal-pelvis CT examinations on hepatic lesions, vessels, and parenchyma.

#### METHODS AND MATERIALS

The study received IRB approval with the waiver of informed consent. Our study included 100 contrast-enhanced abdomen-pelvis CT exams from 100 adult patients (mean age 59 +/- 14 years, M:F 48:52 ) who were imaged to evaluate primary or metastatic liver lesions. The thin-section deidentified DICOM images were exported offline from PACS and processed with an AI algorithm (ClariACE, Claripi, South Korea) for selective iodine-related contrast augmentation in CT images. The algorithm allows users to set their preferred contrast augmentation intensity (fixed at 0.70 for the study purpose) and simultaneous image denoising (fixed at 0.20). We performed a side-by-side comparison of baseline (CT-B) and contrast augmentation (CT-CA) images for liver lesion conspicuity, detection, image noise, and artifacts. We also measured attenuation values on CT-B and CT-CA in abdominal fat, gall bladder, muscles, liver parenchyma, liver lesion, common hepatic artery, and right portal vein. Data were assessed using paired t-test and Wilcoxon rank sum test with a corrected p-value of < 0.0125 for statistical significance.

#### RESULTS

There was a significant subjective improvement in hepatic and vascular enhancement as well as in the image noise on CT-CA versus CT-B images. There were no major artifacts on CT-CA images. Most CT exams had between 1-20 liver lesions with improved lesion conspicuity on CT-CA images compared to CTB. Likewise, there was a significant increase in HU values of liver, liver vessels, and liver lesions on CT-CA (HU increase of 15-80 HU,  $p < 0.001$ ), without any change in CT numbers of abdominal fat, muscles, and gall bladder (0-2 HU change;  $p > 0.9$ ).

#### CONCLUSION

The AI-aided, iodine-related contrast augmentation of abdominal-pelvis CT examinations resulted in improvement in liver lesion conspicuity and quantitative lesion and vascular enhancement.

#### CLINICAL RELEVANCE/APPLICATION

AI-aided, iodine-related contrast augmentation can help improve lesion detection and evaluation while denoising the CT images.

### Super-High-Resolution Abdominal Imaging using CZT based Photon Counting CT with Deep Learning Reconstruction: Quantitative Study and First Clinical Impression

Sunday, Nov. 26 10:30AM - 11:30AM Room: S404

Ken Hirayama (*Presenter*) Nothing to Disclose

#### PURPOSE

Recently, first clinical studies of CZT-based photon counting detector CT (CZT-PCD-CT) has started in Japan. Due to its small pixel design, CZT-PCD-CT can generate super-high-resolution (SHR) image and has potential to improve the diagnostic quality of abdominal imaging. To mitigate the noise in SHR imaging, a deep learning based reconstruction can also be applied in SHR mode. In this study, we aim to 1) quantify the resolution benefits of the CZT-PCD-CT for abdominal imaging in comparison to normal resolution mode (NR); 2) evaluate diagnostic image quality with patient scan and explore potential clinical benefits of SHR mode in abdominal imaging.

#### METHODS AND MATERIALS

The prototype CZT-PCD-CT is built based on a Aquilion Precision system (Canon Medical Systems, Japan). The beam coverage of the CZT-PCD-CT system is 40 mm, and the focal spot size is 0.4 mm\*0.5 mm. Catphan600 (The Phantom Laboratory, U.S) and patients were scanned in helical mode at 120 kVp, 250 mA (9.7 mGy), 0.5 s rotation and pitch factor 0.8. NR images were reconstructed using a 512-matrix size, and a hybrid-iterative reconstruction (Hybrid-IR). SHR images were reconstructed using a 1024-matrix size with both Hybrid-IR and deep learning reconstruction (DLR). The image thickness is 1.2 mm, and standard kernel was used for all images. Visual evaluation and profile measurement are performed on Catphan with slit modules, task-based transfer functions (TTF) were measured at Polystyrene module. Clinical abdomen images were assessed for NR and SHR image noise (SD) and anatomical structures in the upper abdomen.

#### RESULTS

Slit profiles were visible up to 8 lp/cm in NR, 10 lp/cm in SHR and 10 lp/cm in SHR with DLR. 10% TTF values were 0.7 cycles/mm for NR images, 1.0 cycles/mm for SHR images with IR, and 0.9 cycles/mm for SHR images with DLR. Spatial resolution with SHR mode was higher compared to NR mode. For abdominal NR and SHR images, the image noise levels were acceptable for diagnostic tasks. The noise SD was 10.2 HU for NR images, 13.1 HU for SHR images with IR and 11.1 HU for SHR images with DLR, and the SHR images with DLR showed low noise level with high spatial resolution. Pancreatic duct and vessels were more visible and blooming artifacts from calcification were significantly reduced on SHR images.

#### CONCLUSION

The CZT PCD-CT with super-high-resolution imaging mode offers significant improvements in spatial resolution and has potential in improving diagnostic quality of abdominal imaging.

#### CLINICAL RELEVANCE/APPLICATION

The high-resolution images in the SHR mode of CZT-PCD-CT contribute improved diagnostic performance in abdominal imaging.

##### S2-SSPD01-AI-Thyroid: Pilot Results for Evaluating Thyroid Malignancy in Children

6

Eun Ju Ha, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Although less common in children compared to adults, thyroid cancer represents the most common pediatric endocrine malignancy. Prior studies have shown feasibility of AI models for predicting malignant thyroid nodules in the adult population. Studies on AI model performance and validation on the pediatric population are presently lacking. Here, we examine applicability of AI in the evaluation of thyroid nodules in children.

#### METHODS AND MATERIALS

Pediatric cohorts (N = 123; mean age,  $15.4 \pm 2.4$  years; 99 female) who obtained ultrasound (US) for thyroid nodule(s) and had histological confirmation were retrospectively identified from two independent institutions (Ajou University Medical Center, South Korea; Stanford Lucile Packard Children's Hospital, USA). AI-Thyroid, a deep learning model for identifying malignant thyroid nodules and learned on adult population, was tested on the pediatric cohorts on the following scenarios: (a) scenario 1: nodules, with axial US images; (b) scenario 2, nodules, with longitudinal US images; and (c) scenario 3, nodules, with both axial and longitudinal US images together. Model performance was compared against blinded expert radiologist performance using the American College of Radiology-, American Thyroid Association-, and Korean-Thyroid Imaging Reporting and Data Systems (TIRADSs) interpretation.

#### RESULTS

A total of 150 thyroid nodules were analyzed, 44 (29.3%) comprising malignant nodules. Based on the radiologists' TIRADSs interpretation, the sensitivity and specificity were 86.4-93.2% and 45.3-78.3%, respectively. Using AI-Thyroid, the area under the receiver operating characteristic (AUROC), sensitivity, and specificity were: (a) scenario 1: 0.894, 72.7%, and 86.7%; (b) scenario 2: 0.927, 77.3%, and 89.5%; (c) scenario 3: 0.904, 86.4%, and 79.1%. The AUROC did not differ significantly between the pediatric cohorts from the two institutions ( $p = 0.410$ ).

#### CONCLUSION

We present high performance of AI-Thyroid on the pediatric population. Future investigations could include additional approaches to optimizing AI-Thyroid tailored to pediatric population, such as transfer learning from adult population, fine-tuning on pediatric cohorts, and, image synthesis, as well as implications of AI as an adjunct tool alongside tissue sampling in the ENT clinics.

#### CLINICAL RELEVANCE/APPLICATION

1. The diagnostic performances of the adult-based AI model were acceptable in the pediatric population. 2. It is necessary to optimize AI-Thyroid tailored to pediatric population, such as transfer learning from adult population, fine-tuning on pediatric cohorts, and, image synthesis, as well as implications of AI as an adjunct tool alongside tissue sampling in the ENT clinics.

### S2-SSR001-3 **Graph-Based Spatially-Aware Radiomics Improves Prediction of Locoregional Recurrence in Radiotherapy-Treated Head and Neck Squamous Cell Carcinoma**

Joseph Bae, MS, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Most radiomic analyses calculate a single number for each feature studied. Each of these values captures the global expression of a single textural component within a region of interest (ROI), but cannot holistically represent the spatial distribution of that feature (i.e. pixel or voxel-wise values). Nonetheless, radiomic analysis has been largely successful in numerous contexts and has been applied to multiple tasks including the prediction of treatment response to radiotherapy (RT) in head and neck squamous cell carcinoma (HNSCC). HNSCC treated via RT results in locoregional recurrence (LR) in up to 30% of cases, which can result in negative outcomes for patients. Here we propose a novel method leveraging computational graphs to more thoroughly exploit the spatial expression of radiomic features from pre-treatment CT to improve LR prediction for RT-treated HNSCC.

#### METHODS AND MATERIALS

A de-identified dataset containing 492 HNSCC patient CTs and RT structures was identified from the Cancer Imaging Archive. 70 patients experienced LR. Voxel-wise radiomic features were extracted from each CT from within RT gross target volume (GTV) ROIs. Supervoxel clustering was used to segment ROIs within GTVs into 50 subregions. Computational graphs were built by creating 50 nodes with each containing radiomic feature expression from one GTV subregion. Edges were created between nodes by calculating the Euclidean distance between mean radiomic feature values of each pair of nodes, thereby capturing the relationship in radiomic expression between each pair of subregions. One graph was created for each image studied. A graph attention neural network (GAT) was trained for the LR prediction task. 80% of the data was randomly used for training and the remaining for testing. Comparisons were made with a previously published radiomic signature and standard clinical predictors including patient age, smoking history, sex, and tumor stage.

#### RESULTS

Graph radiomics resulted in an AUC of 0.775, a sensitivity of 83.8% and a specificity of 55.6% on the test set, outperforming both clinical (AUC=0.520, sensitivity=81.5%, specificity=29.4%) and traditional radiomic (AUC=0.495, sensitivity=65.5%, specificity=41.2%) approaches.

#### CONCLUSION

Graph radiomics more effectively leverages information contained in voxel-level radiomic feature expression, improving LR prediction for HNSCC patients. Graph radiomics may expand the potential for radiomic analysis of medical imaging datasets complementary to deep learning analyses.

#### CLINICAL RELEVANCE/APPLICATION

The prediction of LR for HNSCC patients from pre-treatment imaging might inform alternative or more aggressive treatment paradigms for at-risk patients, hopefully improving patient outcomes and quality of life.

### S2-SSR001-4 **Structured Reporting and Deep Learning to Reduce Miss Rate of Radiation-Induced Temporal Lobe Injury on MRI of Patients With Nasopharyngeal Carcinoma**

Linmei Zhao (*Presenter*) Nothing to Disclose

## PURPOSE

To develop a structured report (SR) and deep learning (DL) model for the reduction of miss rate of radiation-induced temporal lobe injury (RTLTI) on magnetic resonance imaging (MRI) of patients with nasopharyngeal carcinoma (NPC).

## METHODS AND MATERIALS

A total of 2043 NPC patients from four academic centers in China were included. All patients underwent radiotherapy and follow-up MRIs. RTLTI was diagnosed if any of white matter finger-like lesions, contrast-enhanced lesions, cysts, or hemorrhages appeared in the index (N) and follow-up MRI images (N+1) but no lesion on prior MRI(N-1). The index MRI, defined as the one in which the temporal lobe findings that meet the diagnostic criteria for RTLTI first appeared, was reviewed blindly by two radiologists (L.Z and Y.Z) using the original report (OR) and SR. A DL model based on the Efficient Net B4 architecture was trained for RTLTI classification. A cohort of 476 patients (293 non-RTLTI and 183 RTLTI) from one hospital was divided into training and testing set at a ratio of 8:2. Then, the model was externally tested on MRI scans of 1567 patients (1353 non-RTLTI and 214 RTLTI) from 3 other hospitals. Model performance was evaluated by accuracy, area under the receiver operator curve (AUC), sensitivity, and specificity. Images were evaluated again by two radiologists (L.Z and Y.Z) using the output of the DL model as a reference. Performance was evaluated by calculating the miss rates, accuracy, specificity, and sensitivity for radiologists using OR (OR), radiologist using SR (SR), DL model alone (Artificial intelligence [AI]) and radiologists with DL assistance (AI-assisted).

## RESULTS

The miss rates of RTLTI for OR, SR, AI and AI-assisted were 46.3% (99 of 214), 26.6% (57 of 214), 9.8% (21 of 214) and 7.5% (16 of 214), respectively. Figure 1 demonstrates the performance of the four approaches in classifying RTLTI. Compared with OR, radiologists assisted by SR had significantly improved diagnostic accuracy (95.5% vs. 93.7%,  $P=0.002$ ) and sensitivity (73.6% vs. 53.7%,  $P<0.001$ ). The AI model outperformed SR in sensitivity (90.3 vs. 53.7%,  $P<0.001$ ), but accuracy or specificity were not improved. Assisted with the AI model, the radiologists achieved a higher accuracy (by 1.5%,  $P<0.001$ ) and specificity (by 1.3%,  $P<0.001$ ).

## CONCLUSION

The implementation of SR and AI improved radiologist performance in detecting RTLTI on conventional MRI. Moreover, the AI model outperformed radiologists using SR in RTLTI detection.

## CLINICAL RELEVANCE/APPLICATION

Our study plays an important role in promoting the integration of SR and AI into routine clinical workflow to assist radiologists in the early diagnosis of RTLTI, improving diagnostic capabilities and health outcomes

## S2-SSR001-5 Radiomics Approaches for Predicting Non-iodine-Avid Status of Lung Metastases in Patients With Differentiated Thyroid Cancer Based on CT: A Prospective, Observational Study

Xinyi Gao, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Identifying non-iodine-avid status of lung metastases (LMs) in time is crucial to avoid radioactive I131 treatment for patients with differentiated thyroid cancer (DTC) who will not benefit from it. In this study, we speculated that vivid radiomics features and deep learning features of routine chest CT scans may reflect different tumor heterogeneity between noniodine-avid and iodine-avid LMs. To evaluate this hypothesis, different radiomics models were built with machine learning, deep learning and novel integration of radiomics features and deep learning features to discriminate non-iodine-avid LMs from iodine-avid LMs in patients with DTC.

## METHODS AND MATERIALS

Models were built in 1445 pretreated LMs of 270 consecutive DTC patients with pretreated initially diagnosed LMs who underwent both chest CT and diagnostic radioiodine whole-body scanning between January 2010 and December 2019 in A Cancer Hospital. Integration models based on machine learning were built with selected radiomics features and deep learning features and compared with classic machine learning models (Random Forest, K-Nearest Neighbor, Logistic Regression, and Support Vector Machine), or deep learning models to predict non-iodine-avid status of lung metastases. To validate these radiomics approaches prospectively, we recruited 244 consecutive patients with 876 LMs between January 2020 to October 2022.

## RESULTS

Among all the machine learning models, the Support Vector Machine showed the best discrimination, with a 0.815 area under the curve (AUC), a 0.754 sensitivity and a 0.730 specificity. The deep learning model reached a 0.869 AUC, a 0.794 sensitivity and a 0.798 specificity. All the integration models were significantly better than classic machine learning or deep learning alone, with the best AUC of 0.904, sensitivity of 0.812, specificity of 0.823.

## CONCLUSION

Radiomics features and deep learning features of routine chest CT scans can reflect different tumor heterogeneity between noniodine-avid and iodine-avid LMs. Specially, we found that the novel integration models combining traditional radiomics features and deep learning features could further improve the prediction ability comparing with classic machine learning or deep learning alone. Our study highlights a possible role of radiomics approaches from routine chest CT as a noninvasive, less radioactive and cost-effective way to evaluate iodine-avid status of LMs in DTC.

## CLINICAL RELEVANCE/APPLICATION

Radiomics approaches based on routine chest CT scans can predict iodine-avid status of LMs in patients with DTC and aid in treatment strategy in advance before radioactive I131 therapy, noninvasively and less radioactively.

## S2-SSR001-6 Assessment of Skin Changes and Recovery Following Radiotherapy Using High Frequency Ultrasound

Vittorio Patane' (*Presenter*) Nothing to Disclose

## PURPOSE

Radiation therapy (RT) results as an effective and safe treatment for cutaneous non-melanoma skin cancer (NMSC). Although surgery is the gold standard, in cases of inoperability or patient choice RT is used for radical intent; in high-risk disease, RT in adjuvant setting is preferred. In the case of positive margins, the indication for RT remains undisputed; for other risk factors (PNI invasion, T3, G3 degree of differentiation), the indication for adjuvant therapy remains at the discretion of the radiation oncologist, as the adverse effects could be greater than the benefit. HFUS (US ultra-high frequency, 48MHZ) as the latest generation ultrasound that allows, thanks to the use of high frequency ultrasound, to study the skin accurately and reliably, compared to the traditional ultrasound (10-20MHZ). It allows to have greater detail of the skin layers from the epidermis to the hypodermis, to better characterize the thickness and size of skin oncological lesions. Aims: The aim of this study is to evaluate skin structures after RT treatment clinically and with HFUS to record adverse effects and grade of severities and eventually studying disease recurrences that would not be clinically evident.

## METHODS AND MATERIALS

Between July 2022 to April 2023, we enrolled 20 patients (pts) who underwent RT to evaluate toxicities clinically and with HFUS. 13 patients had the histological diagnosis of Squamous cell carcinoma (cSCC), while 7 had a diagnosis of Basal cell carcinoma (BCC); 10 pts performed RT for radical purpose, the remaining 10 received adjuvant RT treatment. Follow-up (fup) was performed every 3 months after the end of RT by clinical examination and HFUS.

## RESULTS

At the first fup, at 3 months after the end of RT, 4 patients presented erythema G1 according to CTCAE toxicity scale. Only 1 patient had erythema G1 at the 2nd fup at 6 months after treatment. Remaining patients had no acute toxicities in fup at 3/6/9 months. HFUS showed alterations in the echogenicity of the skin layers, most evident immediately after radiotherapy treatment. The most frequently documented lesions were bands and areolas of hypoechogenicity in the radiotreated area which showed a slight increase in the vascular signal on Color Doppler, especially in more superficial layers of the skin, in agreement with the clinical findings of dyschromia and erythema in the treated area. In all cases after 3-month, we documented the restitutio ad integrum of the treated skin region.

## CONCLUSION

RT for NMSC is confirmed as a safe and well-tolerated treatment clinically and by ultrasound evaluation, both in the radical and adjuvant modality.

## CLINICAL RELEVANCE/APPLICATION

Resulting minimal toxicities, RT should always be considered in the case of adjuvant therapy in the treatment of high-risk of NMSC.

Printed on: 08/22/24

Graph radiomics resulted in an AUC of 0.775, a sensitivity of 83.8% and a specificity of 55.6% on the test set, outperforming both clinical (AUC=0.520, sensitivity=81.5%, specificity=29.4%) and traditional radiomic (AUC=0.495, sensitivity=65.5%, specificity=41.2%) approaches.

#### CONCLUSION

Graph radiomics more effectively leverages information contained in voxel-level radiomic feature expression, improving LR prediction for HNSCC patients. Graph radiomics may expand the potential for radiomic analysis of medical imaging datasets complementary to deep learning analyses.

#### CLINICAL RELEVANCE/APPLICATION

The prediction of LR for HNSCC patients from pre-treatment imaging might inform alternative or more aggressive treatment paradigms for at-risk patients, hopefully improving patient outcomes and quality of life.

### Structured Reporting and Deep Learning to Reduce Miss Rate of Radiation-Induced Temporal Lobe Injury on MRI of Patients With Nasopharyngeal Carcinoma

Sunday, Nov. 26 10:30AM - 11:30AM Room: S402

Linmei Zhao (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop a structured report (SR) and deep learning (DL) model for the reduction of miss rate of radiation-induced temporal lobe injury (RTLI) on magnetic resonance imaging (MRI) of patients with nasopharyngeal carcinoma (NPC).

#### METHODS AND MATERIALS

A total of 2043 NPC patients from four academic centers in China were included. All patients underwent radiotherapy and follow-up MRIs. RTLI was diagnosed if any of white matter finger-like lesions, contrast-enhanced lesions, cysts, or hemorrhages appeared in the index (N) and follow-up MRI images (N+1) but no lesion on prior MRI(N-1). The index MRI, defined as the one in which the temporal lobe findings that meet the diagnostic criteria for RTLI first appeared, was reviewed blindly by two radiologists (L.Z and Y.Z) using the original report (OR) and SR. A DL model based on the Efficient Net B4 architecture was trained for RTLI classification. A cohort of 476 patients (293 non-RTLI and 183 RTLI) from one hospital was divided into training and testing set at a ratio of 8:2. Then, the model was externally tested on MRI scans of 1567 patients (1353 non-RTLI and 214 RTLI) from 3 other hospitals. Model performance was evaluated by accuracy, area under the receiver operator curve (AUC), sensitivity, and specificity. Images were evaluated again by two radiologists (L.Z and Y.Z) using the output of the DL model as a reference. Performance was evaluated by calculating the miss rates, accuracy, specificity, and sensitivity for radiologists using OR (OR), radiologist using SR (SR), DL model alone (Artificial intelligence [AI]) and radiologists with DL assistance (AI-assisted).

#### RESULTS

The miss rates of RTLI for OR, SR, AI and AI-assisted were 46.3% (99 of 214), 26.6% (57 of 214), 9.8% (21 of 214) and 7.5% (16 of 214), respectively. Figure 1 demonstrates the performance of the four approaches in classifying RTLI. Compared with OR, radiologists assisted by SR had significantly improved diagnostic accuracy (95.5% vs. 93.7%,  $P=0.002$ ) and sensitivity (73.6% vs. 53.7%,  $P<0.001$ ). The AI model outperformed SR in sensitivity (90.3 vs. 53.7%,  $P<0.001$ ), but accuracy or specificity were not improved. Assisted with the AI model, the radiologists achieved a higher accuracy (by 1.5%,  $P<0.001$ ) and specificity (by 1.3%,  $P<0.001$ ).

#### CONCLUSION

The implementation of SR and AI improved radiologist performance in detecting RTLI on conventional MRI. Moreover, the AI model outperformed radiologists using SR in RTLI detection.

#### CLINICAL RELEVANCE/APPLICATION

Our study plays an important role in promoting the integration of SR and AI into routine clinical workflow to assist radiologists in the early diagnosis of RTLI, improving diagnostic capabilities and health outcomes

### **Radiomics Approaches for Predicting Non-iodine-Avid Status of Lung Metastases in Patients With Differentiated Thyroid Cancer Based on CT: A Prospective, Observational Study**

Sunday, Nov. 26 10:30AM - 11:30AM Room: S402

Xinyi Gao, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Identifying non-iodine-avid status of lung metastases (LMs) in time is crucial to avoid radioactive I131 treatment for patients with differentiated thyroid cancer (DTC) who will not benefit from it. In this study, we speculated that vivid radiomics features and deep learning features of routine chest CT scans may reflect different tumor heterogeneity between noniodine-avid and iodine-avid LMs. To evaluate this hypothesis, different radiomics models were built with machine learning, deep learning and novel integration of radiomics features and deep learning features to discriminate non-iodine-avid LMs from iodine-avid LMs in patients with DTC.

#### **METHODS AND MATERIALS**

Models were built in 1445 pretreated LMs of 270 consecutive DTC patients with pretreated initially diagnosed LMs who underwent both chest CT and diagnostic radioiodine whole-body scanning between January 2010 and December 2019 in A Cancer Hospital. Integration models based on machine learning were built with selected radiomics features and deep learning features and compared with classic machine learning models (Random Forest, K-Nearest Neighbor, Logistic Regression, and Support Vector Machine), or deep learning models to predict non-iodine-avid status of lung metastases. To validate these radiomics approaches prospectively, we recruited 244 consecutive patients with 876 LMs between January 2020 to October 2022.

#### **RESULTS**

Among all the machine learning models, the Support Vector Machine showed the best discrimination, with a 0.815 area under the curve (AUC), a 0.754 sensitivity and a 0.730 specificity. The deep learning model reached a 0.869 AUC, a 0.794 sensitivity and a 0.798 specificity. All the integration models were significantly better than classic machine learning or deep learning alone, with the best AUC of 0.904, sensitivity of 0.812, specificity of 0.823.

#### **CONCLUSION**

Radiomics features and deep learning features of routine chest CT scans can reflect different tumor heterogeneity between noniodine-avid and iodine-avid LMs. Specially, we found that the novel integration models combining traditional radiomics features and deep learning features could further improve the prediction ability comparing with classic machine learning or deep learning alone. Our study highlights a possible role of radiomics approaches from routine chest CT as a noninvasive, less radioactive and cost-effective way to evaluate iodine-avid status of LMs in DTC.

#### **CLINICAL RELEVANCE/APPLICATION**

Radiomics approaches based on routine chest CT scans can predict iodine-avid status of LMs in patients with DTC and aid in treatment strategy in advance before radioactive I131 therapy, noninvasively and less radioactively.

### Assessment of Skin Changes and Recovery Following Radiotherapy Using High Frequency Ultrasound

Sunday, Nov. 26 10:30AM - 11:30AM Room: S402

Vittorio Patane' (*Presenter*) Nothing to Disclose

#### PURPOSE

Radiation therapy (RT) results as an effective and safe treatment for cutaneous non-melanoma skin cancer (NMSC). Although surgery is the gold standard, in cases of inoperability or patient choice RT is used for radical intent; in high-risk disease, RT in adjuvant setting is preferred. In the case of positive margins, the indication for RT remains undisputed; for other risk factors (PNI invasion, T3, G3 degree of differentiation), the indication for adjuvant therapy remains at the discretion of the radiation oncologist, as the adverse effects could be greater than the benefit. HFUS (US ultra-high frequency, 48MHZ) as the latest generation ultrasound that allows, thanks to the use of high frequency ultrasound, to study the skin accurately and reliably, compared to the traditional ultrasound (10-20MHZ). It allows to have greater detail of the skin layers from the epidermis to the hypodermis, to better characterize the thickness and size of skin oncological lesions. Aims: The aim of this study is to evaluate skin structures after RT treatment clinically and with HFUS to record adverse effects and grade of severities and eventually studying disease recurrences that would not be clinically evident.

#### METHODS AND MATERIALS

Between July 2022 to April 2023, we enrolled 20 patients (pts) who underwent RT to evaluate toxicities clinically and with HFUS. 13 patients had the histological diagnosis of Squamous cell carcinoma (cSCC), while 7 had a diagnosis of Basal cell carcinoma (BCC); 10 pts performed RT for radical purpose, the remaining 10 received adjuvant RT treatment. Follow-up (fup) was performed every 3 months after the end of RT by clinical examination and HFUS.

#### RESULTS

At the first fup, at 3 months after the end of RT, 4 patients presented erythema G1 according to CTCAE toxicity scale. Only 1 patient had erythema G1 at the 2nd fup at 6 months after treatment. Remaining patients had no acute toxicities in fup at 3/6/9 months. HFUS showed alterations in the echogenicity of the skin layers, most evident immediately after radiotherapy treatment. The most frequently documented lesions were bands and areolas of hypoechogenicity in the radiotreated area which showed a slight increase in the vascular signal on Color Doppler, especially in more superficial layers of the skin, in agreement with the clinical findings of dyschromia and erythema in the treated area. In all cases after 3-month, we documented the restitutio ad integrum of the treated skin region.

#### CONCLUSION

RT for NMSC is confirmed as a safe and well-tolerated treatment clinically and by ultrasound evaluation, both in the radical and adjuvant modality.

#### CLINICAL RELEVANCE/APPLICATION

Resulting minimal toxicities, RT should always be considered in the case of adjuvant therapy in the treatment of high-risk of NMSC.

S2-STCE1

### Science Session (Sustainability in Imaging)

Sunday, Nov. 26 10:30AM - 11:00AM Room: Learning Center Theater 1

#### Sub-Events

#### **S2-STCE1-2 Energy and greenhouse gas emission savings from power down of CT scanners in non-operational hours in a large regional practice**

Maura J. Brown, MD, FRCPC (*Presenter*) Synthesis Health Inc - research collaboration, no financial relationship at this time (Nov 2022).

#### **PURPOSE**

To assess the clinical practicality of placing CT scanners in low power mode our group gathered CT scanner use data from practice settings over a multi-hospital region serving 3.1 million people. Using vendor provided energy use data, we modeled energy, cost and greenhouse gas (GHG) savings which could be obtained switching to a lower power mode without impact on patient care

#### **METHODS AND MATERIALS**

CT scanner usage data was pulled from the RIS systems of four healthcare organizations. Exclusion criteria included lack of a practical low power mode or lack of data from the manufacturer regarding power consumption. Scanners were classified based on clinical usage pattern: "Low-use" scanners are minimally used outside standard daytime hours. "Medium-use" scanners are staffed and always available, however usage is less than one scan every two hours outside of daytime hours. "Heavy-use" scanners are in use 24 hours a day with no opportunity to lower power consumption level. For low- and medium-use scanners, we model energy savings during a 6-hour period from 7 pm to 1 am (evening) or 1 am to 7 am (night):  $E = P(6 \text{ hours} - nt)$  Where  $P$  = difference in power consumption between stand-by and lower power modes,  $n$  = the average number of scans done in the time period, and  $t$  is time estimate the scanner will be out of sleep mode when one patient is scanned ( $t = 25$  minutes). A 12-hour daytime period (7 am to 7 pm) was considered on weekends in addition to evening/night

#### **RESULTS**

Of the 37 CT scanners, 20 were excluded. Of the 17 eligible scanners 7 were low-use, 5 medium-use and 5 heavy-use. In total, for the 12 scanners in low-use and medium-use clinical settings, the energy savings are 251,022 kWh/year if all were switched to lower power mode when not in use, equivalent to 456,042 miles driven in a gasoline powered car and US \$30,876 saved in electricity costs. The heavy-use scanners were in use greater than one scan every two hours 24 hours per day, therefore switching to lower power mode for energy savings was not performed

#### **CONCLUSION**

Placing CT scanners in lower power mode in non-operational hours in low-use and medium-use clinical settings results in substantial energy and GHG savings

#### **CLINICAL RELEVANCE/APPLICATION**

Results of this modeling study suggest that efforts should be targeted to switching CT scanners to lower power mode outside standard daytime hours in low-use and medium-use clinical settings

#### **S2-STCE1-3 Exposing Sustainable Imaging Strategies: The Role of Practitioners in Reducing Carbon Footprint**

Diana E. Carver, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Diagnostic radiology is a crucial component of medicine and must be "decarbonized" for public health and safety. Healthcare emits an estimated 4.4% of global greenhouse gases (GHG) and 8.5% of the US's total GHGs. The climate crisis requires

coordinated action from everyone, including radiologists and healthcare systems. This study estimates emissions associated with a radiology department in an academic medical center and aims to identify and implement interventions to reduce environmental impact by focusing on rescan rates.

## **METHODS AND MATERIALS**

This study is part of a collaboration between a major radiology equipment manufacturer and a large academic medical center in the southeastern US that sees more than 2.6M patients annually. The manufacturer makes radiology equipment such as MR, CT, X-ray, and US; software; and provides sustainability program services. Our scope included 14 pieces of radiology equipment, performing an average 15,000 exams per month with 24-hr operations. We performed an ISO14040-based Life Cycle Assessment, including capital equipment manufacturing and distribution, consumable and durable supplies, energy use, staff and patient commuting, laundering and supply reprocessing, equipment refurbishment, and waste disposal. Using the electronic medical record, we assessed rescan rates by modality and anatomy, in addition to turnover and flow rates.

## **RESULTS**

Initial results from one month of data show rescan rates vary by modality, with an average exam per patient ranging from 1 to 1.78. CT showed the highest average number of exams per patient, followed by X-Ray, US, and MR. Total energy consumption of 4 CTs over one month was 7263 kWh, resulting in an estimated 3744 kg CO<sub>2</sub>e. Annual total emissions could reach up to 44,927 kg CO<sub>2</sub>e. Energy consumption was 74% of the total CO<sub>2</sub>e related to the life cycle emissions of the equipment. Based on energy consumption alone, CO<sub>2</sub>e was estimated to be 0.6 kg CO<sub>2</sub>e per exam. Reducing repeat scans from 1.78 to 1 exam per patient could lead to 78% less energy consumption and emissions, assuming the repeated scans do not have a clinical indication.

## **CONCLUSION**

Reducing unnecessary or repeated scans provides substantial GHG emission reductions and improves health equity. Several factors impact the rescan rate, including procedure and disease type, technical errors, staff expertise, and operational factors. Technology innovations, such as AI, can perform scans faster and reduce rescans of MR and CT images when patients are moving. Optimal utilization of equipment may reduce per-scan or per-patient GHGs but may increase cumulative GHGs.

## **CLINICAL RELEVANCE/APPLICATION**

Health system policies for decarbonized energy sources can reduce GHGs in an aging patient population and growing demand for medical imaging.

### Science Session (Imaging of Immunotherapy)

Sunday, Nov. 26 10:30AM - 11:00AM Room: Learning Center Theater 2

#### Sub-Events

#### **S2-STCE2-1 Combo or mono-immunotherapy in patients with metastatic MSI colorectal cancer: The role of radiologists in clinical decision-making.**

Remy Barbe, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The goal is to determine the response to mono vs combo immunotherapy for patients with metastatic microsatellite instability colorectal cancer (MSI mCRC), using quantitative imaging features from baseline CT-scans and clinical factors.

#### **METHODS AND MATERIALS**

This retrospective study included a training cohort of 105 patients and a validation cohort of 45 patients treated either with a single immunotherapy (mono) or a combination of immunotherapies (combo). Chest-abdomen-pelvis baseline CT-scans were collected and annotated by 6 radiologists. Annotations were made manually in 2D on the axial plane slice where the tumor was largest. Total tumor volume (TTV) was computed by summing the approximate volume of each lesion. Reproducibility was assessed using Intra-correlation coefficient (ICC2k) on 10 patients. Cox models were used to predict overall survival (OS). Progression free survival (PFS) was evaluated. Recursive feature elimination (RFE) was used to reduce the number of variables using bootstrap and the concordance-index. A cutoff was selected for each continuous feature and a risk score was built using Hazard ratios. The final model was modified to exclude the type of treatment (mono-combo).

#### **RESULTS**

In total, 2258 lesions were annotated. ICC2k was equal to 0.95, 0.91 and 0.88 for TTV, number of lesions and number of metastatic sites. Of the 14 variables studied, 4 were selected after the RFE: age, presence of peritoneal carcinomatosis (PC), number of lesions and TTV. Type of treatment was excluded from the feature selection process. The cutoffs for TTV, number of lesions and age were 73cm<sup>3</sup>, 20 lesions and 60 years old. The log HR for TTV, number of lesions, age and PC were 1.13, 0.96, 0.91 and 0.38 and the cutoff of the risk score was 1.36. Patients with a low risk score had similar OS and PFS independently of treatment, while those with a high score had significantly worse OS and PFS if treated with monotherapy (HR=3.68, p=0.006 and HR=5.68, p<0.001 respectively). In the validation cohort, a significant difference in PFS was observed for the high score population (HR=8.487, p=0.046).

#### **CONCLUSION**

Total tumor volume combined with number of lesions and presence of peritoneal carcinomatosis could guide immunotherapy treatment for MSI mCRC. This score would allow radiologists to identify patients who will benefit from combo immunotherapy, thus limiting drug-overuse and its increased risk of serious adverse effects. TTV had the highest HR, highlighting the value of calculating total tumor burden in selected cases.

#### **CLINICAL RELEVANCE/APPLICATION**

Imaging is able to identify criteria that may play a role in therapeutic decision-making in patients with mCRC MSI, identifying those who benefit from combo-immunotherapy, enabling personalized treatment.

### Performance of an Artificial Intelligence System on Screening Breast Tomosynthesis Cases

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Roger S. Yang, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the performance of artificial intelligence (AI) on screening tomosynthesis mammograms

#### METHODS AND MATERIALS

This retrospective study included 28,278 DBT screening exams and the subsequent BIRADS 0 workups, consecutively collected from February to July 2022 from multiple outpatient imaging centers within a private practice. The screening exams (Hologic) were evaluated by 36 MQSA radiologists and scored according to the Breast Imaging Reporting and Data Classification System (BIRADS). BIRADS 0 cases were recalled for additional evaluation and potential biopsy. All DBT screening exams were analyzed by an AI system (Transpara 1.7.1, ScreenPoint Medical), which assigned an exam score between 1-10 indicating an increasing likelihood of malignancy. The positive predictive value (PPV) of radiologists and the performance of the AI system were evaluated.

#### RESULTS

Out of 28,278 screening exams, 4170 exams were labeled as BIRADS 0, resulting in a recall rate of 14.75%. Of the 4,170 patients recalled, 3,531 returned to one of our facilities for diagnostic imaging. There were 581 diagnostic exams labeled as BIRADS 4-5 and recommended for biopsy. Biopsy results were available for 335 cases at the time of analysis, revealing 70 biopsy-proven cancers. A BIRADS-0 rating corresponded to a PPV of 3.4%. A BIRADS 4-5 rating based on DBT and subsequent workup yielded a PPV of 20.9%. AI identified 92.9% of cancers (65/70) with an exam score between 8 and 10, 84.3% of cancers (59/70) were flagged with the highest AI score of 10.

#### CONCLUSION

AI score 8-10 has a strong predictive value for cancer. This system can be used to aid radiologists when evaluating screening mammograms.

#### CLINICAL RELEVANCE/APPLICATION

An AI tool that reliably indicates the probability of malignancy on the initial mammogram could serve as clinical decision support reducing biopsy and recall rates and increasing cancer detection rates.

### Improving Video-Based Ultrasound Diagnostic Performance for Breast Cancer to Expert-Level Using Deep Learning: A Retrospective, Multicenter, Diagnostic Study

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Fajin Dong JR, MD,MD (*Presenter*) Nothing to Disclose

#### PURPOSE

we aim to propose and validate a new automated deep learning framework based on standard video recordings of ultrasound examination.

#### METHODS AND MATERIALS

We designed a video-based framework for breast screening cineclips and integrated three classic AI models, DenseNet121, MobileNet, and Xception as backbones. For comparison, image-based framework is also constructed using the same three backbones with physician selected images, since image-based diagnosis is the current standard practice. In total, 3907 patients from two major medical centers were enrolled between July 2015 and January 2022. Both images and videos of the patients are utilized to train and evaluate models, including retrospective real-world data and prospective test data. Cineclip model tests, image model tests, and reader studies with human experts are performed on both retrospective and prospective data.

#### RESULTS

The accuracy of cineclip models is 87.40 to 92.59%, exceeding the accuracy of 76.00 to 85.60% achieved by all physicians with 7 to 10 years of experience in reader studies. In both real-world and prospective tests, cineclip models surpass image models among all evaluation metrics, including accuracy (87.40-92.59% vs. 80.80-85.83%), sensitivity (86.00-93.33% vs. 80.00-91.07%), specificity (83.10-92.00% vs. 78.87-86.67%), F1 (0.876-0.927 vs. 0.807-0.861) and AUROC (Area under Receiver Operating Characteristic Curve, 0.926-0.962 vs. 0.843-0.936). The difference in AUROC between cineclip models and image models with DenseNet121 and Xception backbone is statistically significant in real-world test under significance level ( $p=0.049$  for DenseNet backbone, and  $p=0.008$  for Xception backbone).

#### CONCLUSION

Cineclip models can achieve higher accuracy along with better robustness than image-based models, outperforming human experts. Our video-based AI framework might better aid breast cancer diagnosis and alleviate the scarcity of experienced physicians.

#### CLINICAL RELEVANCE/APPLICATION

Ultrasound is one of the most widely used methods for breast cancer screening. However, its popularity is prohibited by its high operator dependence and the scarcity of skilled ultrasound specialists. This study can reduce the skill requirement and inter-operator variations.

### Deep Learning-Based MRI Model to Predict Pathologic Complete Response After Neoadjuvant Chemotherapy in HER2-Positive and Triple-Negative Breast Cancer

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Sooyeon Kim, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

There are limited studies on the prediction of pathologic complete response (pCR) after neoadjuvant chemotherapy (NAC) using deep learning technique. We aimed to develop a deep learning-based MRI model to predict pCR in women with human epidermal growth factor receptor 2 (HER2)-positive or triple-negative breast cancers.

#### METHODS AND MATERIALS

In this IRB-approved single center retrospective study, a total of 852 women (mean age $\pm$ standard deviation, 51 $\pm$ 10 years old) with HER2-positive or triple negative breast cancer who underwent NAC followed by surgery between 2017 and 2021 were included. They were divided into a training set (n=724) and a validation set (n=128) in a ratio of 8.5:1.5. Post-NAC dynamic contrast-enhanced (DCE)-MRI data (subtraction images of the 1st, 3rd, and 5th dynamic phase) and clinical data (age, clinical T stage, clinical N stage, estrogen receptor, progesterone receptor, HER2, Ki-67, histologic grade, histologic type, and initial MRI size) were collected. pCR was defined as the absence of both invasive and in-situ residuals in the breast in the surgical specimen. For each woman, tumor bed or residual enhancing lesions on post-NAC MRI were annotated using the three rectangular region-of-interests for the initial, intermediate (center), and endpoints, respectively. After pre-processing, the deep learning models were developed using 3D ResNet 50 architecture, 5-fold cross validation, and Python 3.6. Clinical data model, each phase model of DCE-MRI, and the combined model were developed, and each performance was evaluated using an area under the receiver operating characteristics curve (AUC). DeLong method was used to compare AUCs.

#### RESULTS

The AUCs of the 1st, 3rd, and 5th dynamic MRI model were 0.63, 0.70, and 0.67, respectively. Compared to the 3rd dynamic MRI model with the highest AUC value of 0.70, the combined MRI model obtained from all dynamic images showed a lower AUC value of 0.66 albeit without statistical significance (0.70 vs 0.66, P=0.09). The AUC of the clinical data model was 0.57. The combined model of the clinical data and all dynamic MR images showed an AUC value of 0.65, which was significantly lower than that of the 3rd dynamic MRI model (0.65 vs 0.70, P=0.02).

#### CONCLUSION

The deep learning model based on the 3<sup>rd</sup> dynamic phase of DCE-MRI showed the best performance in predicting pCR in women with HER2-positive or triple-negative breast cancers.

#### CLINICAL RELEVANCE/APPLICATION

Our deep-learning based MRI model demonstrates the potential to predict pCR in women with HER2-positive or triple-negative breast cancer. This information, after careful validation in further studies, can be utilized in a prospective trial to omit breast cancer surgery for women with a high possibility of pCR.

### Combining with Convolution Neural Network and Graph Convolution Network for Predicting Axillary Lymph Node Metastasis in Breast Cancer Based on DCE-MRI: A Multicenter Study

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Yi Dai, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aims to develop a deep learning model combining convolution neural network (CNN) and graph convolution network (GCN) based on dynamic contrast-enhanced (DCE)-MRI for predicting axillary nodal status in breast cancer as well as to explore the biological mechanism by employing gene analysis of RNA-sequencing data.

#### METHODS AND MATERIALS

A total of 935 patients with breast cancer who underwent preoperative DCE-MRI from four institutes were retrospectively analyzed. 742, 83 and 110 patients were grouped into the training, internal test and independent external test sets, respectively. The regions of interest of the breast lesions were cropped manually by two radiologists. Three conventional CNNs, namely, 3D ResNet, 3D-Xception and HRNet (high-resolution Net) were used as the backbone architecture for axillary lymph node (ALN) metastasis identification based on the tumor, ALN, and combined tumor-ALN regions on the images. The feature maps obtained by CNNs are globally pooled and fused with the spatial structure features obtained by high resolution GCN. RNA-sequencing data from 11 patients were used to explore the underlying biological basis of the AI prediction. To select the most powerful CNN or CNN-GCN model for ALN-metastasis prediction, the performance of three CNN models and three CNN-GCN models was compared with area under the receiver operating characteristic (ROC) curve (AUC), accuracy, sensitivity and specificity. The performance of these models was compared with radiomics models, the Memorial Sloan-Kettering Cancer Center (MSKCC) model, and three radiologists.

#### RESULTS

The optimal HRNet-GCN\_tumor+ALN model, achieved an AUC of 0.873 in the internal test cohort, as well as an AUC of 0.870 in the external test cohort, which was better than the best performing radiomics model (logistic regression, AUC: 0.790) and MSKCC model (AUC: 0.752). Additionally, with the assistance of HRNet-GCN\_tumor+ALN, the radiologists' performance was improved (external test cohort,  $P < 0.05$ ). In the biological basis exploration, the high-risk group was associated with the downregulation of pathways mediating tumor proliferation and the promotion of anti-tumor immune cell infiltration in the microenvironment.

#### CONCLUSION

The proposed GCN-CNN fusion deep learning model could effectively predict ALN status preoperatively in breast cancer patients.

#### CLINICAL RELEVANCE/APPLICATION

This study successfully demonstrated a CNN-GCN model base on DCE-MRI, which could non-invasively and preoperatively predict ALN metastasis of breast cancer with high accuracy. This model may assist and guide for radiologists to make more precise evaluation of ALN status.

### Patient Race Impacts the Screening Mammogram False Positive Rate of a Commercially Available AI Algorithm

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Derek L. Nguyen, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate a commercially available AI algorithm's ability to accurately interpret negative screening mammograms and the impact of patient demographics on its performance.

#### METHODS AND MATERIALS

This retrospective cohort study identified 27,681 negative screening tomosynthesis mammograms from our academic institution from 1/1/16 to 12/31/19. All patients had two years of follow up without a diagnosis of atypia or malignancy. Patients with prior breast surgery or implant augmentation were excluded. A subset of unique patients was randomly selected to provide a broad distribution of race/ethnicity. This final cohort was interpreted by an FDA approved, commercially available AI algorithm (ProFound AI 3.0, iCAD, Inc) which was trained prior to the study using an enriched multi-vendor screening population dataset from at least 20 institutions. The algorithm generated case and risk scores for each mammogram. Per vendor, case scores > 49 (range 0-100) have a high certainty for malignancy and risk scores > 0.8 (range 0-1) are at high-risk for developing a malignancy on the subsequent screening mammogram (1-year cancer risk). Patient demographics (age, race/ethnicity, and breast density) were compared with case and risk scores using bivariate and multivariate logistic regression.

#### RESULTS

4855 unique patients (median age: 54 years [46-63]) were included. The false positive rate for case and risk scores was 17% (816/4855) and 5% (240/4855), respectively. Every patient demographic was significantly associated with patients' case and risk scores on bivariate analysis,  $p < 0.001$ . On multivariate analysis, Black patients were significantly more likely (OR: 1.45, 95% CI 1.19-1.77) to have case scores > 49 compared to White patients. Asian patients were significantly less likely (OR: 0.68, 95% CI 0.54-0.86) to have case scores > 49 when compared to White patients. Breast density did not influence case scores after adjusting for age and race. On multivariate analysis, only Black patients were significantly more likely (OR: 1.46, 95% CI 1.05-2.03) to have risk scores > 0.8 compared to White patients. Increased breast density was associated with risk scores > 0.8 (fatty - reference; scattered - OR: 1.99, 95% CI 1.33-3.05; heterogeneous - OR: 2.00, 95% CI 1.25-3.55; extremely - OR: 2.80, 95% CI 1.26-5.84).

#### CONCLUSION

Patient race influenced the performance of a commercially available AI algorithm analyzing negative screening mammograms. False positive rates for suspicious case and risk scores were 17% and 5%, respectively.

#### CLINICAL RELEVANCE/APPLICATION

Radiologists should be aware that the performance of FDA approved, commercially available AI software will vary by patient demographics and efforts to train on diverse datasets are needed.

### AI for Diffusion-Weighted Breast MRI

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Dimitrios Bounias, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Diffusion-weighted imaging (DWI) is a rapidly emerging MRI technique in oncologic breast imaging that requires no contrast agent administration, rendering it an attractive potential future supplement or even alternative to mammography and dynamic contrast-enhanced MRI. Artificial intelligence (AI) has the potential to assist radiological decisions on this emerging MR technique, facilitating a quicker adoption into clinical routine. In this work, we utilized nnDetection, a state-of-the-art self-configuring Retina U-Net based object detection model, with certain breast cancer-specific extensions to create a robust model trained on a large dataset of unenhanced breast MRI acquisitions.

#### METHODS AND MATERIALS

The IRB approved study included n=818 patients. Histopathologically proven malignant lesions accounted for n=618 lesions in n=268 patients. All patients underwent a clinically indicated multiparametric breast 3T MRI examination, including a multi-b-value DWI acquisition (50,750,1500). The nnDetection AI model was trained with the following extensions: (i) Apparent Diffusion Coefficient (ADC) as additional input, (ii) random bias field, random spike, and random ghosting augmentations, (iii) a size-balanced data loader to ensure that the fewer large lesions were given an equal chance to be picked in a mini-batch and (iv) replacement of the loss function with a size-adjusted focal loss, that increases as false positive predictions get smaller or as true positive predictions get larger. This adapted loss function prioritizes finding the primary lesion while disincentivizing small indeterminate false positives. The Area Under the Receiver Operating Characteristic (AUROC) was used as the metric for patient-level performance in 5-fold cross-validation.

#### RESULTS

The nnDetection AI model was able to achieve an AUROC of 0.88 using only the abbreviated unenhanced DWI MRI acquisition, and compares favorably against multireader performance metrics reported for mammography ((i)0.81, (ii) 0.87, (iii) 0.81). The model was also able to achieve 0.70 FROC (Free-response Receiver Operating Characteristic) for primary lesions, indicating a relevant localization ability.

#### CONCLUSION

This study shows that AI has the ability to complement the assessment of breast MRI in abbreviated unenhanced examinations based on DWI, even before radiologists are involved in the diagnostic process.

#### CLINICAL RELEVANCE/APPLICATION

This work supports personalization in breast cancer screening by enabling radiologists to use advanced imaging techniques such as abbreviated diffusion-weighted imaging (DWI), potentially supplementing the diagnostic toolbox.

### Risk-aware AI for Lesion Detection and Characterization in Breast MRI

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Dimitrios Bounias, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

AI methods for medical object detection revolve around discovering and rating structures of potential relevance to the patient. Performance is commonly calculated with Free-response Receiver Operating Characteristic (FROC) analysis, which calculates sensitivity at predefined thresholds of false positives (FPs) per case. FROC weighs all lesions equally, but in practice not all lesions might be considered as having identical instantaneous impact for the further clinical pathway of a patient, revealing a risk imbalance. Here we describe the development and evaluation of such a risk-aware model for breast cancer using diffusion-weighted imaging (DWI) MR acquisitions.

#### METHODS AND MATERIALS

For this IRB approved study we used a dataset with  $n=818$  women undergoing clinically indicated 3T breast MRI including multi-b-value DWI (50,750,1500), containing  $n=618$  histopathologically verified malignant lesions in  $n=268$  patients. The risk function was calculated using reported 15-year breast cancer mortality based on lesion size, from a multi-year study involving  $n=819,647$  patients from Sopik et al, 2018. A risk-adjusted adaptation of FROC (raFROC) is proposed, where true positive predictions and ground truth samples are weighted by the associated risk. FPs are weighted by  $1/\text{risk}$ , due to the desire to minimize unneeded biopsies and the lower value of low risk lesions. To accommodate for the metric, we also propose a risk-adjusted focal loss (raFocal) that applies similar weighting. A focal loss and a raFocal model were trained using 5-fold cross validation. Evaluation took place using traditional methods and raFROC.

#### RESULTS

The risk-aware (raFocal) model improved both the AUROC (Area Under the Receiver Operating Characteristic curve) and AP (Average Precision) patient-level performance (AUROC/AP 0.86/0.77) compared to the standard "focal" model (0.84/0.70). The proposed raFROC portrays a difference (focal 0.60, raFocal 0.65) between the models across all FP thresholds, being able to better mirror patient-level improvement. In contrast, a lesser difference was present for regular FROC (focal 0.50, raFocal 0.52), appearing only in lower thresholds.

#### CONCLUSION

This work showcases a first step for risk-aware AI model training and validation in medical object detection. Accounting for clinical risk and outcome is very important in medical diagnosis, as it allows balancing the trade off between FP findings and missing pathologies, significantly influencing the clinical outcome of the individual patient.

#### CLINICAL RELEVANCE/APPLICATION

This work showcases how to incorporate risk into the training and evaluation of object detection models for breast cancer screening, which previously considered all lesions equal, bringing AI closer to clinical needs.

### Chat GPT: How Far Has It Gone Yet?

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Marcela C. Lauer, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Chat GPT is an artificial intelligence (AI) language model trained on a dataset of human language, making it capable of understanding and generating complex sentences and paragraphs, including medical literature. The objective of this study is to analyze Chat GPT's accuracy and reproducibility in answering questions about breast radiology.

#### METHODS AND MATERIALS

Questions were gathered from nationally regarded professional societies, as well as elaborated from breast radiologists with over 15 years of experience. We formulated 10 questions that were answered by medical residents (12 from the 1st/2nd year and 12 from the 3rd/4th year) and 12 professionals specialized in breast imaging. All questions had only one correct answer. The alternatives included the options of "more than one alternative is correct" and "all alternatives are incorrect", for the cases in which Chat GPT could not provide one correct answer for the question. Reproducibility was determined by asking the model each question ten times from at least 5 different devices in at least 3 different locations.

#### RESULTS

The mean average of the residents in the 1st and 2nd years was 40% of correct answers, for 3rd and 4th years residents it was 60%, for breast imaging specialists it was 80% and the average of correct responses by Chat GPT-4 was 45%, and varied from 30% to 60% correct answers. Chat-GPT did not demonstrate an increasing or decreasing pattern of number of correct answers thought time that would allow us to infer that it was learning through the questions. Concerning reproducibility, Chat GPT answered the same item in all 10 attempts for only 4 questions.

#### CONCLUSION

ChatGPT could provide accurate responses in 45% of questions related to breast imaging, which is more than a 1st or 2nd year radiology resident but less than a 3rd or 4th year resident. Although it is expected that it will evolve over time, we could not state that in our study. We encourage future studies to further examine how trustworthy are the information provided by it and to analyze if this technology will continue evolving over time, as we hope this technology may improve education for medical doctors, and even patient's outcomes and quality of life.

#### CLINICAL RELEVANCE/APPLICATION

ChatGPT is an AI language model launched in November 2022, trained on a dataset covering a broad range of topics, including the medical literature. Discussion regarding the potential of ChatGPT in all fields of academia is ongoing, and its applicability is under investigation. Although there is one study that tests how Chat GPT would answer questions about screening breast cancer recommendations (Haver et. al), there are currently no studies examining Chat GPT's applicability as a learning tool for professionals consult.

### **Preliminary Interim Analysis of AI-STREAM (Artificial Intelligence for Breast Cancer Screening in Mammography): A Prospective Multicenter Study Design in Korea Using AI-based CADe/x**

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Yun Woo Chang, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study is to compare the diagnostic accuracy of radiologists with and without the use of AI-based CADe/x in mammography reading for breast cancer screening of Korean women with average breast cancer risk.

#### **METHODS AND MATERIALS**

Total of 24,601 participants were enrolled between February 2021 and December 2022 at six study sites in Korea. The mammograms were read by breast imaging radiologist (BR) without using AI-based CADe/x through single reading, and results were recorded on the study platform (BEST image). Then, the radiologists reviewed the mammograms with the assistance of AI-based CADe/x and recorded the results on the study platform based on the radiologist's decision after considering both with and without AI-based CADe/x. These BR were experts in breast imaging at an academic hospital for over ten years. If a recall was required, further diagnostic workup was conducted to confirm the cancer detected on screening. In the simulation study, the same participants' mammograms were read by general radiologists (GR) in the same setting of the reading process, without and with use of AI-based CADe/x. GR are radiologists not specializing in breast imaging. The diagnostic accuracy of GR and BR, with or without the use of AI-based CADe/x was compared with AI-based CADe/x for mammography reading for breast cancer screening.

#### **RESULTS**

By the end of patient enrollment, breast cancer was confirmed in 131 patients. GR without AI found 86 cancers, GR with AI found 110 cancers, BR without AI found 110 cancers, and BR with AI found 124 cancers. When a 10% cutoff was applied to AI, it detected 118 cancers. Stand-alone AI-based CADe/x detected significantly higher cancer detection than GR without AI. AI detected slightly more cancer than BR without AI or GR with AI, but there was no statistical significance. BR with AI had the highest cancer detection rate compared with AI stand-alone, BR without AI, or GR with AI, but there was no statistical significance. There was no difference between GR and AI in the recall, but recall in BR was significantly lower.

#### **CONCLUSION**

AI-based CAD e/x could be helpful for radiologists with less experience in mammography reading. BR with AI had the highest accuracy in cancer detection and a lower recall rate compared with other situations. This is a preliminary interim analysis of the prospective study as cancer registry data will be available at least 26 months after the year of interest.

#### **CLINICAL RELEVANCE/APPLICATION**

This prospective multicenter cohort study aims to generate real-world evidence to compare the diagnostic accuracy of radiologists with and without AI-based CADe/x in mammography reading for breast cancer screening.

Printed on: 08/22/24

S3A-SPCA-1

### Total Cardiac Volume Segmentation Model for Pediatric Heart Transplant Donors and Patients using Transfer Learning

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Elanchezhian Somasundaram, PhD, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop an optimized model to predict total cardiac volumes (TCV) in donors and pediatric heart transplant patients using transfer learning techniques on pretrained models predicting individual heart segments.

#### METHODS AND MATERIALS

An internal, clinical chest computed tomography (CT) dataset (n=275), consisting of non-contrast and contrast-enhanced exams, was included for the study. 251 exams were used for model training while 27 were retained for model testing. TCV was segmented as part of clinical workflow using Mimics (Materialize NV, Leuven, Belgium). Additionally, heart chamber segments from a large public dataset (n= 866) curated by the University Hospital Radiology Department (Basel, Switzerland) was included for transfer learning. A dynamic U-net (DynUNET) architecture within the MONAI framework was first pre-trained on the public dataset for 100 epochs, using a 0.8/0.2 split for training/validation respectively, and then trained on the internal TCV dataset. Another DynUNET model was trained only on the internal TCV dataset. Experiment tracking and hyperparameter search tools were used to find the training parameters that produced the best validation dice score. Both models were tested on the internal test dataset (n=27) as well as 20 adult, chest CT scans from multiple institutions, shared by UNOS (United Network for Organ Sharing) through a formal research agreement. UNOS exams were segmented for TCV using 3D Slicer. Relative volume error (RVE) and Dice coefficients (DSC) were calculated for model performance evaluation and comparison.

#### RESULTS

The most optimal DynUNET model trained with pre-trained weights had an initial learning rate of 0.0005 with an exponential learning rate scheduler and an Adam optimizer. The mean ( $\pm$  standard deviation) RVE and DSC was 3.3 ( $\pm$  3.0%) and 0.95 ( $\pm$  0.02) respectively for the internal dataset and 6.9 ( $\pm$  10%) and 0.90 ( $\pm$  0.10) respectively for the UNOS dataset. The most optimal DynUNET model trained only on the internal TCV dataset had an initial learning rate of 0.003 using a cosine learning rate scheduler and Adam optimizer. The mean ( $\pm$  standard deviation) RVE and DSC was 5.3 ( $\pm$  5.5%) and 0.93 ( $\pm$  0.02) respectively for the internal dataset and 11 ( $\pm$  16%) and 0.87 ( $\pm$  0.15) for the UNOS dataset.

#### CONCLUSION

Transfer learning using pre-trained weights from a large public dataset improved model performance for prediction of TCV in an internal clinical dataset as well as a set from UNOS, where exams span various institutions, scanner manufacturers, and protocols.

#### CLINICAL RELEVANCE/APPLICATION

Total cardiac volume (TCV) is an important metric for recipient-donor organ matching for organ transplantation. A clinically deployable, optimized deep learning TCV segmentation model is useful for such organ size matching.

### Comparison of Prognostic Value Between CAD-RADS 1.0 and CAD-RADS 2.0 Evaluated by Convolutional Neural Networks Based CCTA

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Zengfa Huang (*Presenter*) Nothing to Disclose

#### PURPOSE

The aim of the present study was to investigate the prognostic value of the novel coronary artery disease reporting and data system (CAD-RADS) 2.0 compared with CAD-RADS 1.0 in patients with suspected CAD evaluated by convolutional neural networks (CNN) based coronary computed tomography angiography (CCTA).

#### METHODS AND MATERIALS

A total of 2131 consecutive inpatients with suspected CAD were evaluated by CCTA for CAD-RADS 1.0 and CAD-RADS 2.0 classifications. Kaplan-Meier and multivariate Cox models were used to estimate major adverse cardiovascular events (MACE) inclusive of all-cause mortality or myocardial infarction (MI). The C-statistic was used to assess the discriminatory ability of the two classifications.

#### RESULTS

In total, 94 (5.2%) MACE occurred over the median follow-up of 45.25 months (interquartile range 43.53 to 46.63 months). The annualized MACE rate was 0.014 (95% CI: 0.011-0.017). Kaplan-Meier survival curves indicated that the Coronary Artery Disease Reporting and Data System (CAD-RADS) classification, segment involvement score (SIS) grade, and Computed Tomography Fractional Flow Reserve (CT-FFR) classification were all significantly associated with the increase in the cumulative MACE (all  $P < 0.001$ ). CAD-RADS classification, SIS grade, and CT-FFR classification were significantly associated with endpoint in univariate and multivariate Cox analysis. CAD-RADS 2.0 showed a further incremental increase in the prognostic value in predicting MACE (c-statistic 0.702, 95% CI: 0.641-0.763,  $P = 0.047$ ), compared with CAD-RADS 1.0.

#### CONCLUSION

The novel CAD-RADS 2.0 evaluated by CNN-based CCTA showed higher prognostic value of MACE than CAD-RADS 1.0 in patients with suspected CAD.

#### CLINICAL RELEVANCE/APPLICATION

The novel CAD-RADS 2.0 evaluated by CNN-based CCTA showed good performance for predicting major adverse cardiac events (MACE) in patients with suspected CAD and may serve as a non-invasive imaging marker for risk stratification in future clinical practice.

### Diagnostic Utility of Artificial Intelligence in Detecting Coronary Artery Disease on CT Coronary Calcium Score Using Manual Calcium Scoring as Reference Standard- A Meta-Analysis

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Sarah Agnes Mary R. Lim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The amount of coronary artery calcification is said to be a strong and independent predictor of coronary heart disease events. Calcium scoring is a non-invasive procedure wherein calcifications within the coronary arteries are quantified and this is interpreted by trained radiologists. However, this is known to be tedious and time-consuming. Artificial intelligence (AI) is now being used as an adjunct tool in cardiovascular imaging. "Machine learning or deep-learning algorithm is a subset of AI that utilizes algorithms to combine voluminous data comprising clinical information and coronary anatomical variables for optimal prediction of major adverse cardiac events" (Wang, 2019). The aim of this study is to determine the accuracy of AI in detecting coronary artery disease on CT coronary calcium score using manual counting as reference standard.

#### METHODS AND MATERIALS

We searched PUBMED, Google Scholar for studies on AI in detecting CT coronary calcium using manual counting as the reference standard. Pooled sensitivity, specificity, positive and negative likelihood ratios were calculated. Two investigators (ISB and SRL) independently extracted the data.

#### RESULTS

Out of 45 articles, three (3) were included in the study. A total of 769 calcium score procedures were included in the analysis. Overall pooled sensitivity of 0.952 (CI=95%, 0.926-0.970), pooled specificity of 0.949 (CI=95%, 0.921-0.970), positive likelihood ratio of 12.1 (CI=95%, 2.304-63.636) and negative likelihood ratio of 0.055 (CI=95%, 0.036-0.084).

#### CONCLUSION

Deep learning A.I. on coronary artery calcium score can be used to detect coronary artery disease. Further study to compare utility of machine learning with deep learning using manual counting as reference standard.

#### CLINICAL RELEVANCE/APPLICATION

Artificial intelligence is now used in a myriad of applications not only in medicine but also in daily life. AI has a potential to improve the workflow in radiology through automation of CT coronary calcium score determination, a task which is known to be time-consuming. If A.I. may be used in the clinical setting, more people may be screened for coronary artery disease in a given amount of time. This may also help in improving the efficiency of radiologists.

### Accuracy of Machine Learning Algorithms for Calcium Scores on Chest Computed Tomography: A Systematic Review and Meta-analysis

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Pedro A. Pereira, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the diagnostic accuracy of artificial intelligence (AI) algorithms for quantifying coronary artery calcium (CAC) on chest computed tomography (CT) images.

#### METHODS AND MATERIALS

PubMed, EMBASE, and Cochrane Central databases were systematically searched for studies published up to April 1st. Studies were included if they compared ML-derived calcium score categories (Agatston score) with expert manual analysis in gated and non-gated studies. The main outcome was the percentage of agreement between automatic and manual analyses of the Agatston score categories. We also calculated the rates of the underestimated and overestimated categories using automatic analysis. Heterogeneity was examined using  $I^2$  statistics. A random effects model was used to perform the meta-analysis. The study protocol was registered a priori in the International Prospective Register of Systematic Reviews (Prospero Protocol CRD42023407318).

#### RESULTS

A total of 23 studies comprising 9788 subjects with gated CT and 4967 with non-gated CT were included. The mean age of the sample was 58.9 years. The percentage of Agatston score agreement between automatic and manual analyses for gated studies was 93.1% (95% CI, 90.8-94.8%). Automatic analysis overestimated the Agatston category by 4.2% (95% CI, 2.8-6.2%) and underestimated it by 2.3% (95% CI, 1.8-2.9%). The percentage agreement for non-gated studies was 79.8% (95%CI, 68.0-88.0%). Automatic models overestimated or underestimated the Agatston category by 10% (95%CI, 4.7-20.0%) and 5% (95%CI, 2.1-11.1%), respectively. Significant heterogeneity was observed in the analyzed outcomes ( $I^2 > 50\%$ ).

#### CONCLUSION

Our findings demonstrate a high degree of agreement in calcium score analysis using machine learning algorithms, particularly in gated studies.

#### CLINICAL RELEVANCE/APPLICATION

The use of AI algorithms could improve CT interpretation workflow, offering automatic quantification coronary calcium with high accuracy to both cardiac-gated and non-cardiac-gated chest CTs.

### Deep Learning-Based Measurement of Left Atrial Volume on Calcium Scoring CT: Observations in the Dallas Heart Study

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Fernando U. Kay, MD, PhD (*Presenter*) Research Grant, Edwards Lifesciences Corporation

#### PURPOSE

Coronary calcium scoring CT (CAC-CT) imaging data is currently underutilized. Left atrial (LA) enlargement is associated with atrial arrhythmias and stroke. In this study, we aimed to evaluate the accuracy of an AI-based segmentation algorithm for estimating LA volumes on CAC-CT and compare the results with other clinical variables in the Dallas Heart Study phase 2 (DHS2).

#### METHODS AND MATERIALS

Participants with both CAC-CT and cardiac MRI (CMRI) were eligible for inclusion. We developed a 3D Unet Deep Learning model using a semi-supervised approach with nested cross-validation. A cardiac imager created reference cardiac chamber segmentation on CAC-CT for 70 randomly selected participants, using epicardial margins. This initial model generated synthetic segmentations in 1,931 additional scans, which were utilized for model refinement. LA volume was derived using Pyradiomics. In 749 participants, maximum LA volume was independently assessed on CMRI via the biplane method. Clinical variables were collected for analysis. We included a subset of 735 participants without prior events for a Kaplan-Meier analysis of incident atrial fibrillation, stroke, or transient ischemic attack.

#### RESULTS

The segmentation model achieved a Dice score of  $0.93 \pm 0.01$  (mean  $\pm$  SD) when compared to manual segmentation. The cohort consisted of 445 females and 304 males with a median age of 50 years (IQR: 43 - 57). The intraclass correlation coefficient between CAC-CT-derived LA volume and maximum LA volume on CMRI was 0.67 (95% CI: 0.63 - 0.71). CAC-CT LA volume had an AUC curve of 0.82 (95% CI: 0.78 - 0.86) for detecting participants in the 4th quartile of maximum LA volume on CMRI. In multivariable linear analysis, CAC-CT LA volume indexed to BSA was significantly associated with male sex (Beta coefficient: 1.6\*\*), age (0.3\*\*\*), smoking habit (-0.7\*), and hypertension (2.9\*\*\*) (P: \* $<0.1$ , \*\* $<0.05$ , \*\*\* $<0.01$ ). The 4th percentile of indexed LA volume on CAC-CT was associated with incident composite events (N = 15) during follow-up when compared to the 1st-3rd percentiles (P = 0.01).

#### CONCLUSION

We developed a segmentation model capable of extracting LA volume from CAC-CT, demonstrating moderate correlation with LA maximum values derived from CMRI. This CAC-CT biomarker was significantly associated with clinical variables, including incident atrial fibrillation and cerebrovascular events in the DHS2.

#### CLINICAL RELEVANCE/APPLICATION

AI-derived segmentation algorithms have the potential to enhance the extraction of LA volume from CAC-CT, enabling more comprehensive risk stratification beyond traditional calcium scoring.

### Right Ventricular Strain and Abnormal Muscle Formation on Cardiac CT: To Identify Pulmonary Hypertension in Repaired Tetralogy of Fallot

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Yamato Shimomiya (*Presenter*) Employee, Ziosoft, Inc

#### PURPOSE

In the long-term period of repaired tetralogy of Fallot (TOF), right ventricular (RV) volume augmentation due to pulmonary regurgitation is frequent, and right heart failure due to its aggravation is prognostic. Transcatheter pulmonary valve implantation (TPVI) is becoming increasingly popular as a minimally invasive treatment, but it must be carefully indicated in cases of RV pressure overload. We used multi-phase cardiac CT to assess RV volumetry, strain, and morphology to identify pulmonary hypertension in patients with repaired TOF scheduled for TPVI.

#### METHODS AND MATERIALS

Forty-four patients with repaired TOF scheduled for TPVI were enrolled to undergo cardiac CT, MRI, and right heart catheterization. Pulmonary hypertension (PH) was defined as a mean pulmonary artery pressure of 25 mmHg or greater by right heart catheterization. CT-RV strain was calculated using ECG-gated CT data with motion coherence image processing. The association of PH with RV strain and abnormal muscle bundles in the right ventricular outflow tract on cardiac CT was evaluated. Additionally, RV volumetry was compared between cardiac cine MRI and CT.

#### RESULTS

Eleven of the 44 patients had PH. CT-RV strain was significantly lower patients with PH than those without PH ( $-8.7 \pm 1.6$  % vs.  $-11.3 \pm 2.33$  %;  $p < 0.001$ ). Receiver-operating-characteristic curve analysis revealed that with optimal RV strain  $-10.4$  %, patients with PH can be diagnosed with an area under the curve 0.97, sensitivity 100%, and specificity 89%. The frequency of formation of abnormal muscle bundles in the RV outflow tract was significantly greater in patients with PH (7/11, 64%) than in patients without PH (11/33, 35%). RV volumes calculated from CT and MRI showed a strong positive correlation, but CT tended to increase volume more than MRI (RV-EDVi: CT vs. MRI,  $176.2 \pm 47.9$  ml/m<sup>2</sup> vs.  $147.0 \pm 42.1$  ml/m<sup>2</sup>; Pearson  $r = 0.90$ ; RV-ESVi: CT vs. MR:  $98.7 \pm 36.9$  ml/m<sup>2</sup> vs.  $79.8 \pm 28.4$  ml/m<sup>2</sup>; Pearson  $r = 0.91$ ).

#### CONCLUSION

The reduction of RV strain and the presence of abnormal muscle bundles in the RV outflow tract obtained from multi-phase CT indicate PH in repaired TOF and should make one cautious about the indication for TPVI.

#### CLINICAL RELEVANCE/APPLICATION

Cardiac CT provides not only accurate anatomical information from the RV to the pulmonary artery, but also noninvasive evaluation of pulmonary hypertension.

### Assessment of Solitary Pulmonary Nodules Using Dual-layer Spectral Detector Computed Tomography

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Ko Tsepang, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

With lung cancer being the most common malignancy diagnosed worldwide, differentiating between malignant solitary pulmonary nodules (SPNs) and other lung diseases remained a substantial challenge. The aim of this study was to examine the usefulness of Dual-layer Spectral Detector Computed Tomography in solitary pulmonary nodule (SPN) assessment.

#### METHODS AND MATERIALS

Between September 2021 and December 2022, dual-layer spectral images of 71 patients confirmed by pathology were retrospectively analyzed in the venous phase. Patients were classified into the malignant group and the benign group. The iodine concentration (IC) values of the SPN, normalized IC of the SPN to aorta/pulmonary artery/pulmonary vein (NICa/NICpa/NICpv), CT values of 40 keV (HU40keV) and 80keV (HU80keV) monochromatic images, and the slope of spectral HU curve were calculated and compared between the benign and malignant groups. ROC curve analysis was performed to assess the diagnostic performance of the above parameters.

#### RESULTS

IC, NICpa, HU40keV, and slope HU had significantly higher values in the malignant group than in the benign group (all  $P < 0.05$  in Mann-Whitney U test). Iodine density (AUC = 0.78) of 1.74 mg/ml yielded a sensitivity of 95% and a specificity of 57%. Slope HU (AUC = 0.79) of 2.9 yielded a sensitivity of 95% and a specificity of 57%.

#### CONCLUSION

Both virtual monochromatic images and iodine concentration maps prove to be highly useful in differentiating benign and malignant pulmonary nodules.

#### CLINICAL RELEVANCE/APPLICATION

Dual-layer Spectral Detector Computed Tomography can help to differentiate benign from malignant SPNs.

### Combination of Clinical and Spectral CT Parameters for Predicting Lymphovascular Invasion in N0 Stage Non-small Cell Lung Cancer

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Liangna Deng (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the predictive value of spectral CT quantitative parameters for lymphovascular invasion in N0 stage non-small cell lung cancer, a diagnostic model was constructed and visualized as a nomogram to assist clinical preoperative treatment decisions.

#### METHODS AND MATERIALS

107 patients with N0 stage non-small cell lung cancer underwent spectral CT before surgery and were divided into two groups: positive group and negative group. Clinical baseline characteristics included age, gender, biochemical markers, serum tumor markers and Immunohistochemical markers. Imaging features included lobe location, tumor boundary, lobulation sign, spiculation, bubblelike lucency, air bronchogram, vascular convergence and pleural retraction. A radiologist delineated the regions of interest on the layer of maximum tumor diameter and the nearest upper and lower layers in axial enhanced images and calculated the average value. Monoenergetic CT value, effective atomic number (Eff-Z), iodine concentration (IC) of tumor and artery were acquired to calculate normalized iodine concentration (NIC,  $NIC = IC_{tumor} / IC_{artery}$ ).  $\chi^2$  test, t-test and U test were used for calculated differences between groups. Then, least absolute shrinkage and selection operator (LASSO) regression and multivariate logistic regression were used to select the most discriminating features, build a predictive model and visualize the model as a nomogram. ROC curves, calibration curves and decision curves analysis (DCA) were used to evaluate prediction performance and clinical utility.

#### RESULTS

41 patients had lymphovascular invasion in 107 N0 stage non-small cell lung cancer patients. The gender, TIF-1 and lymphocyte count differed between the two groups ( $P < 0.05$ ). After feature selection, the six variables included 70keV, 90keV and Eff-Z in the dual phase were screened by LASSO regression to construct the nomogram. The AUC of the clinical-spectral CT model were 0.93 (95%CI: 0.88~0.98). The sensitivity and specificity were 0.89 and 0.88, respectively. The model showed good calibration, and the DCA demonstrated that the model has a higher net benefit than the best single variable.

#### CONCLUSION

There were differences in gender, TIF-1 and lymphocyte count and spectral CT parameters in lymphovascular invasion status. The nomogram based on Clinical characteristics and 70keV, 90keV and Eff-Z in the dual phase is helpful for the preoperative determination of lymphovascular invasion status in non-small cell lung cancer.

#### CLINICAL RELEVANCE/APPLICATION

The nomogram is helpful for the preoperative determination of lymphovascular invasion status in N0 stage non-small cell lung cancer, which can assist in clinical preoperative decision-making and patient risk stratification.

### Quantitative Lung and Lobar Perfusion from Dual-source, Dual-energy CTPA in Chronic Thromboembolic Pulmonary Hypertension and Acute Pulmonary Embolism

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Jacob V. Hansen, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the differences in quantitative lung and lobar perfusion metrics between patients with chronic thromboembolic pulmonary hypertension (CTEPH) and acute pulmonary embolism (PE).

#### METHODS AND MATERIALS

Under IRB approval, 162 adult patients (>21 years) diagnosed with acute PE or CTEPH were scanned clinically using dual-source, dual-energy CT (Siemens SOMATOM Flash) pulmonary angiography (DE-CTPA) between 2019 and 2023. De-identified, thin-section DE-CTPA images from 81 PE patients (M:F 45:36; median age 69 years [60; 76]) and 81 CTEPH patients (M:F 46:35; median age 71 [61; 78]) were processed using the automated, machine-learning based eXamine DE Lung Isolation software (Siemens Healthineers) to obtain quantitative lung and lobar perfusion data. Clinical data was retrieved from electronic patient journals. Statistical analysis was performed using R (RStudio) with Mann-Whitney U test (individual perfusion parameters), PERMANOVA (for multivariate comparison) and multiple logistic regression (for correlation between perfusion parameters and clinical data and biomarkers).

#### RESULTS

Whole lung blood volume was lower ( $p < 0.001$ ) in PE patients (median 3399 mL [2554, 4284]) than in CTEPH patients (median 4094 mL [3397, 4818]). The same was observed at single lung and lobar level (figure 1A). The multivariate comparison encompassing all perfusion variables (figure 1A-C) showed a difference between the two groups ( $F = 6.15$ ,  $Pr > (F) = 0.004$ ) after testing for homogeneity of variance. We found poor correlation ( $r < 0.3$ ) between perfusion parameters and right heart catheterization parameters, 6-minute walking distance, and tricuspid annular plane systolic excursion (TAPSE) in CTEPH patients as well as with TAPSE, mean arterial blood pressure, and saturation in PE patients. In CTEPH, right upper lobe contrast uptake (CU), left upper lobe volume and CU, and left and lower lobe contrast concentration (CC) predicted whether patients had high ( $> 4$  L/min) cardiac output (CO) ( $p = 0.01 - 0.03$ ).

#### CONCLUSION

Lung and lobar perfusion are lower in patients with acute PE than patients with CTEPH as highlighted by differences in DECT-derived pulmonary blood volume parameters. This might be explained by the differences between an acute, decompensated disease phenotype and a chronic, compensated disease phenotype. Perfusion parameters correlate poorly with hemodynamic and clinical parameters in both diseases, but might predict severity.

#### CLINICAL RELEVANCE/APPLICATION

Fully automatic estimation of quantitative pulmonary perfusion from dual-source, dual-energy CTPA can help assess differences in patients CTEPH and PE.

### Application Value of Spectral CT Multi-Parameter Imaging in the Detection of Emboli and Assessment of Thrombus Burden in Acute Pulmonary Embolism

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Weimeng Cao (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aims to investigate the efficacy of spectral CT multi-parameter (Spectral Based Image) imaging compared to regular CT (rCT) imaging in the detection of emboli and assessment of thrombus burden in acute pulmonary embolism (PE).

#### METHODS AND MATERIALS

102 suspected pulmonary embolism (PE) patients who underwent dual-layer spectral CT (DLCT) pulmonary angiography (CTPA) were prospectively enrolled. Spectral data were reconstructed into conventional images (CI), iodine density maps (ID), effective atomic number (Zeff) maps, and ID-Zeff fusion maps (ID-Zeff). The detection rate of acute PE in each group was evaluated, and the diagnostic efficiency for PE was assessed using receiver operating characteristic (ROC) curves and area under the curve (AUC) for each type of image. The diagnostic efficiency for PE was evaluated separately in pulmonary lobes and main pulmonary arteries, pulmonary segmental arteries, and subsegmental pulmonary arteries. In diagnosed acute PE patients, the total number of thrombi and the number of thrombi detected in three level of pulmonary artery were counted, and the thrombus burden was compared among groups using the Qanadli (Q) score. Independent sample t-tests and chi-square tests were used for quantitative and qualitative data, respectively.

#### RESULTS

Among the 102 suspected PE patients, a total of 63 cases were diagnosed based on imaging, laboratory tests, and clinical data. Among them, the CI, ID, Zeff, and ID-Zeff respectively diagnosed 53, 55, 60, and 60 cases. The ID-Zeff image (AUC: 0.989, sensitivity: 97%, specificity: 100%) significantly improved the detection rate of PE compared to the CI image (AUC: 0.892, sensitivity: 84%, specificity: 94%). The total number of thrombi detected by the CI image and each spectral image group in each three level of pulmonary artery were as follows: CI (172, 25, 75, 72), ID (217, 25, 82, 100), Zeff (222, 25, 85, 112), and ID-Z-eff (230, 25, 85, 120). The Q scores for each spectral image group were as follows: CI (15.64±5.28), ID (19.25±6.42), Zeff (19.87±6.86), and ID-Zeff (20.46±6.6). The Q scores in each spectral image group were statistically significant compared to the CI group ( $p < 0.001$ ).

#### CONCLUSION

DLCT multi-parameter ID-Zeff maps exhibit better detection rates and thrombus detecting efficacy in PE compared to CI images, especially in subsegmental PE. Additionally, the ID-Zeff map provides more accurate Q scores.

#### CLINICAL RELEVANCE/APPLICATION

ID-Zeff imaging can use the wedge-shaped perfusion defect region to detect subsegmental and micro thrombi, significantly improving the detection efficacy of peripheral micro emboli in PE. This provides more accurate imaging data for the precise assessment of thrombus burden, risk stratification, and prognosis prediction.

### CT-based Automated Measure of Vertebral Fracture Associates with COPD Severity, Sex and Age in Smokers

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Syed Ahmed Nadeem, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Osteoporosis is a major comorbidity of chronic obstructive pulmonary disease (COPD) contributing to high prevalence of vertebral compression fractures (VCF). Alteration in spine morphology due to VCF reduces rib-cage mobility and chest space, hinders lung expansion and function, and adversely impacts mobility, quality of life, and clinical outcomes. This retrospective study examines the association of VCF with COPD severity, sex, and age using a CT-based automated method.

#### METHODS AND MATERIALS

Twelve thoracic and the first lumbar vertebrae were automatically segmented and labeled from chest CT scans using a previously validated deep learning-based method. Following the Genant's principle, an automated VCF assessment method was developed and applied to individual vertebral volume. Inspiratory or total lung capacity chest CT scans from the Iowa cohort of the Genetic Epidemiology of COPD (COPDGene) study at baseline visits were used. Four COPD severity groups were defined—(1) preserved lung function (GOLD 0), (2) mild COPD (PRISm and GOLD 1), (3) moderate COPD (GOLD 2), and (4) severe COPD (GOLD 3 and 4). A generalized linear model of the VCF count with age, sex, height, weight, smoking history, and COPD severity was developed.

#### RESULTS

Study participants (n=1221; age (mean±SD): 59.29±8.98 years; 581 female) in the preserved lung function and mild, moderate, and severe COPD groups had 0.61±1.27, 0.66±1.37, 0.85±1.53, and 1.03±1.75 VCF counts, respectively. As compared to the preserved lung function group, moderate and severe COPD were associated with significantly higher VCF counts (p=0.047 and p=0.00048, respectively), while the observed higher VCF counts in mild COPD were not significant (p=0.084). Females (p<0.0001) were associated with lower VCF counts. Aging was positively correlated with the VCF count (p<0.0001).

#### CONCLUSION

A CT-based automated measure of VCF is presented, and its association with COPD severity, sex, and age is demonstrated. Automation of the CT-based method will facilitate its application to nationwide repositories chest CT scans exploring associations of demographic, lifestyle, and clinical factors on osteoporosis and VCF and their impacts in COPD and other lung diseases.

#### CLINICAL RELEVANCE/APPLICATION

The new method offers CT-based automated quantification of VCF, which may be useful to investigate the osteoporosis comorbidity in COPD and its impact on lung function and clinical outcomes.

### Deep Neural Network to Detect Emphysema on Chest Radiographs.

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Seowoo Lee, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Chronic obstructive lung disease (COPD) remains underdiagnosed globally, and chest radiographs are typically obtained for patients with respiratory symptoms. This study aimed to develop a deep neural network to detect emphysema on chest radiographs.

#### METHODS AND MATERIALS

We retrospectively collected chest radiographs and CT scans between 2009 and 2020 from patients with emphysema, as identified in CT reports, at a single tertiary referral center for the model development. The emphysema index was calculated from the CT scans and dichotomized at a cutoff of 10% to determine the presence of CT-defined emphysema. A U-Net-based deep neural network was trained to predict CT-defined emphysema on chest radiographs. Chest radiographs were processed to generate three-channel images, consisting of a native chest radiograph, a segmented lung image, and a pulmonary vessel map. Lung segmentation and pulmonary vessel map extraction guided the model to focus on anatomical structures relevant to emphysema pathophysiology. The diagnostic performance of the model was evaluated using the area under the receiver operating characteristic curve (AUC) in the temporally separated internal test set and two external test sets. The prognostic value of model-defined emphysema on chest radiographs for overall survival was assessed using a Cox proportional hazards model in an independent internal set of patients with COPD.

#### RESULTS

A total of 2,579 chest radiographs and 11,284 chest computed tomography (CT) scans from 9,192 adult patients were included in the training. The deep neural network achieved AUCs of 0.90, 0.90, and 0.87 in the internal test set (n=184), external test set 1 (n=491) and external test set 2 (n=559), respectively. In an independent internal set (n=4,919), survival analysis demonstrated that the presence of emphysema, as predicted by the deep learning model, was associated with worse overall survival on multivariable analysis (adjusted hazard ratio: 1.3; 95% confidence interval: 1.2-1.5;  $P < .01$ ).

#### CONCLUSION

The deep neural network accurately detected emphysema presence on chest radiographs.

#### CLINICAL RELEVANCE/APPLICATION

The deep neural network can help overcome the global underdiagnosis of COPD using chest radiographs.

### Detection of Pooled Intracavitary Torso Hemorrhage on CT with Deep Learning

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Nathan Sarkar, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Internal hemorrhage caused by traumatic injury is a potentially life-threatening condition requiring rapid treatment. Hemorrhage accounts for 30-40% of all trauma-related deaths, and approximately 50,000 people die from trauma-related hemorrhage in the US annually. WBCT reports are time consuming, and automated algorithms that detect hemorrhage could be used for early notification, however to our knowledge, no such methods have been described. We develop and test DL algorithms for detection of three forms of pooled hemorrhage at CT- hemothorax, hemoperitoneum, and pelvic hematoma.

#### METHODS AND MATERIALS

Three datasets of patients with hemothorax (n=77), hemoperitoneum (n=150), and pelvic hematoma (n=253) served as positive cases for each feature and 373 negative WBCT scans were used as controls in three separate experiments using a ResNeXt-101 architecture with fully connected layer pre-trained on ImageNet. Positive slices were identified using existing label masks. All scans were resampled to a uniform slice thickness of 1.5 mm, and pre-processed using an abdominal/mediastinal window [HU -175, 250]. Data augmentation was performed using rotation, translation, scaling, and shear transformations. 3 consecutive slices were used as input. Training, validation, and testing was conducted using a 70:10:20 split of the data. Models were trained on an NVIDIA Titan RTX graphics card with 24GB memory. Decision thresholds were optimized for high sensitivity for this screening task. If a single slice was determined to be positive for a given feature, the patient was predicted to be positive. Performance was measured using standard accuracy metrics. Grad-CAM saliency maps were used for explainability.

#### RESULTS

Patient level accuracies in the test sets were as follows: 1. For pelvic hematoma (test n=125 CTs), accuracy, precision (PPV), recall (sensitivity), and NPV were 97%, 93%, 100%, and 100%, respectively. 2. For hemoperitoneum (n=105), these were 97%, 97%, 93%, and 97%, and 3. For hemothorax (n=90), these were 99%, 94%, 100%, and 100%. Hemoperitoneum was the only feature with false negatives and both occurred at low segmented volumes (18 and 23 mL). Saliency maps showed that attention corresponded with areas of pooled blood.

#### CONCLUSION

Our models were highly accurate and could be used to accelerate the activation of life-saving treatment protocols in patients at risk for exsanguination.

#### CLINICAL RELEVANCE/APPLICATION

In future work, these classification algorithms can be scaled to larger datasets and included in a pipeline with segmentation algorithms to serve combined early notification (CADt) and precision medicine (CADx) purposes, thus reducing time to diagnosis and assisting with surgical decision-making in positive patients.

### **Predictive Value of a Radiomics Nomogram Model Based on Contrast-enhanced Computed Tomography for KIT Exon 9 Gene Mutation in Gastrointestinal Stromal Tumors**

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Yuze Wei (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To establish and validate a radiomics nomogram model for predicting the KIT exon 9 mutation status of gastrointestinal stromal tumors (GISTs) before surgery.

#### **METHODS AND MATERIALS**

All imaging and clinicopathological data of 87 patients diagnosed with pathologically confirmed GISTs were retrospectively collected and randomly assigned to the training set ( $n = 60$ ) and test set ( $n = 27$ ) at a ratio of 7:3. Based on contrast-enhanced CT (CE-CT) arterial and venous period images, the region of interest (ROI) of the tumors were manually drawn layer by layer, and the radiomics features were extracted. The ICC (intra-class correlation coefficient) was used to test the consistency between observers and least absolute shrinkage and selection operator regression (LASSO) was used to further screen the features. The nomogram of integrated radiomics score (Rad-Score) and clinical risk factors (extra-gastric location and distant metastasis) was drawn on the basis of multivariate logistic regression. The area under the receiver operating characteristic curve (AUC) and the correction curve were used to evaluate the predictive efficiency of the nomogram, and the clinical benefits that the decision curve evaluation model might bring to patients.

#### **RESULTS**

The AUC, sensitivity, specificity, and accuracy in the nomogram model were 0.902 (95% confidence interval [CI]: 0.798-0.964), 85.7%, 86.9%, and 91.7% for the training group, and 0.907 (95% CI: 0.732-0.984), 77.8%, 94.4%, and 88.9% for the test group.

#### **CONCLUSION**

The radiomics nomogram model based on CE-CT can effectively predict the KIT exon 9 mutation status of GISTs and may be used for selective gene analysis in the future, which is of great significance for the accurate treatment of GISTs.

#### **CLINICAL RELEVANCE/APPLICATION**

Our models show that radiomics has great potential for predicting GIST gene mutations, which may enable clinicians to optimize clinical decisions in patients with GIST.

### Identification of Macrotrabecular-massive Hepatocellular Carcinoma (MTM-HCC) using Gadoteric Acid-enhanced MRI and User-friendly Radiomics Analysis Suite

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Jongjin Yoon, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Radiomics analysis is often challenging for radiologists due to time-consuming pre-processing, tumor segmentation, and complex analysis. The purpose of this study was to attempt to develop a radiomics model for identifying macrotrabecular-massive HCCs (MTM-HCCs) using radiomics analysis suite that provides semi-automatic segmentation and user-friendly analysis tools, and to compare the model's performance to that of conventional radiomics analysis.

#### METHODS AND MATERIALS

We enrolled 3 independent cohorts from 2 tertiary care centers. The 3 cohorts consisted of a total of 464 patients who underwent gadoteric acid-enhanced MRI and surgical resection for treatment-naïve single HCCs between December 2007 and December 2014. Independent review of histopathology by two pathologists was performed for each cohort. The arterial phase images were semi-automatically segmented by reviewer 1 (faculty radiologist) in training set, and by reviewer 1, reviewer 2 (resident radiologist), and reviewer 3 (research assistant) in validation cohorts. Inter-observer agreement was evaluated using intraclass correlation coefficient (ICC). A commercial radiomics suite (syngo.via, Siemens Healthineers) was used to calculate and analyze 1,234 radiomics features. Additionally, the same radiomics features were analyzed using conventional radiomics analysis method. Area under a receiver operating characteristic curve (AUROC) was the performance metric.

#### RESULTS

ICC values in internal and external validation sets mostly exhibited excellent agreement. The training cohort AUROC for the radiomics suite random forest model was 0.72 for reviewer 1. The internal validation cohort AUROC values were 0.63, 0.71, and 0.73, while external validation set values were 0.72, 0.75, and 0.73 for reviewer 1, 2, and 3, respectively. The radiomics suite model demonstrated comparable or superior AUROC values compared to conventional techniques. In the pooled internal and external validation cohort (n=250), the predicted MTM-HCC by radiomics suite was significantly associated with frequent early recurrence and extrahepatic metastasis, and poor overall survival for all reviewers ( $P < 0.05$  for all)

#### CONCLUSION

We developed radiomics models to classify histopathologic subtypes of HCCs using a user-friendly radiomics suite. The models' diagnostic performance was comparable to conventional methods and consistent across varying user experience levels. The model showed potential in predicting prognostic factors in a pooled validation cohort.

#### CLINICAL RELEVANCE/APPLICATION

This simple, user-friendly approach of developing radiomics models is expected to make radiomics more accessible to radiologists and facilitate real-world application.

### Deep Learning of Two- Dimensional Shear Wave Elastography for Assessment of Clinically Significant Portal Hypertension

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Youngseo Cho, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

We aimed to make a deep-learning model of 2D-shear wave elastography (SWE) images to detect clinically significant portal hypertension (CSPH) [DL-CSPH] using long short-term memory (LSTM) architecture, and to compare the diagnostic performance with conventional diagnostic method.

#### METHODS AND MATERIALS

A retrospective study was conducted using 2D-SWE image data collected in a single center, and the subject were divided into training (n=168) and test (n=113) sets. CSPH was diagnosed by hepatic venous pressure gradient measurement. With the training set, the DL-CSPH model using convolution neural network (CNN) and long short-term memory (LSTM) architecture of the 2D-SWE measurement image was derived. Especially, sequential order of liver stiffness (LS) measurement was applied into the LSTM model and compared with the LSTM model with random selection. As a conventional diagnostic method, the cut-off value of LS was calculated via a receiver operating curve analysis in the training set and applied the cut-off value in the test set.

#### RESULTS

In the prediction of CSPH using the deep-learning model, the LSTM model with sequential order showed better performance than the CNN model (sensitivity: 94.3% VS 85.7%, specificity: 86.1% VS 79.1%, accuracy: 91.2% VS 83.2%, AUC: 0.824 VS 0.902). The difference in AUC value was statistically significant. (P=0.03) Although the DL-CSPH model in sequential order performed better in predicting CSPH compared to the LS or APRI cutoff values, this difference was not statistically significant (P=0.53, 0.19, respectively). However, the DL-CSPH model in sequential order exhibited a significant improvement over FIB4 in predicting CSPH (P=0.01).

#### CONCLUSION

DL-CSPH model in sequential order demonstrates excellent overall performance in predicting CSPH.

#### CLINICAL RELEVANCE/APPLICATION

The DL-CSPH model has practical value as it enables non-invasive, automated monitoring of portal pressure in patients with chronic liver disease in a robust and reproducible manner.

### Identification of a Radiomic Signature to Predict the Risk of Hepatocellular Carcinoma in Cirrhotic Patients

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Olimpia Bazzini (*Presenter*) Nothing to Disclose

#### PURPOSE

Patients with cirrhosis are at increased risk of Hepatocellular Carcinoma (HCC); currently, clinical and radiological scores for an accurate early prediction of the development of HCC are lacking. The study aims to assess if radiomics can assist in accurately identifying cirrhotic patients at risk of HCC.

#### METHODS AND MATERIALS

98 patients (M:F=64:34; mean age 67 years  $\pm$ 9,81) were included in this retrospective monocentric study. Two groups were identified: group (a) with 49 patients (M:F=31:18; mean age 67,4 years  $\pm$ 9,12) who had a baseline CT with radiological signs of cirrhosis, without evidence of HCC in follow-up CT (LI-RADS 1-3); group (b) with 49 patients (M:F=33:16; mean age 67,5 years  $\pm$ 10,5) who had a baseline CT with radiological signs of cirrhosis and evidence of HCC in one follow-up CT scan (LI-RADS 4/5). Four radiologists (3 years of experience) provided complete liver segmentations, manually drawing volumes of interest (VOI) on non-enhanced baseline CT scans. 851 radiomic features (RF) were extracted from each VOI. Redundant RF (Spearman correlation coefficient = 0.99) were removed. The dataset was split into train:test set (70%:30%). Decision Tree classification algorithm and a 3-fold cross-validation were performed on train dataset to explore different cost complexity parameters to set the best pruning. The final model was validated on the test set in terms of accuracy, sensibility, sensitivity, precision, areas under the receiver operating characteristic (ROC) curve and under the precision-recall curve (PRC).

#### RESULTS

The tree-based model included the "wavelet-LLH\_glcm\_DifferenceAverage" RF, classifying patients as positive when higher than 0.97. The final model predicted the risk of developing HCC with an accuracy, sensitivity, specificity and precision of 0.73, 0.93, 0.56, and 0.65, respectively. Areas under ROC curve and PRC were 0.74 and 0.81.

#### CONCLUSION

A radiomic model identified a RF for stratification of cirrhotic patients at risk of developing HCC, showing high sensitivity. To increase the specificity of the model, we aim to integrate this radiomic approach with clinical and radiological parameters.

#### CLINICAL RELEVANCE/APPLICATION

Radiomics can non-invasively predict the development of HCC in cirrhotic patients and may assist clinicians in creating a tailored monitoring path for each patient.

### Added Value of Diffusion-weighted MR Imaging in the Diagnosis of Cholangiocarcinoma Recurrence

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Keiichiro Yamada, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the added value of magnetic resonance (MR) imaging including diffusion-weighted imaging (DWI) in the diagnostic performance of contrast-enhanced computed tomography (CECT) for diagnosis of cholangiocarcinoma recurrence.

#### METHODS AND MATERIALS

Thirty-three consecutive patients who underwent follow-up CECT and MR imaging after cholangiocarcinoma resection were included: 20 with recurrence and 13 without recurrence. Two observers independently reviewed CECT and subsequently reviewed combined CECT and MR imaging including DWI (b value, 1000 s/mm<sup>2</sup>). A five-point scale rating for the likelihood of cholangiocarcinoma recurrence was assessed. Both observers reviewed each image set twice. Diagnostic performance (receiver operating characteristic [ROC] curve analysis), accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were evaluated. To evaluate the intra-observer and inter-observer agreement with regard to the correct diagnosis of recurrence, kappa statistics were used.

#### RESULTS

For both observers, diagnostic performance (area under curve [AUC] of ROC) improved after additional review of MR imaging including DWI; AUC improved from 0.614 to 0.918 ( $P < 0.01$ ) in the first reading session of Observer A, and from 0.820 to 0.928 ( $P = 0.20$ ) in the second reading session of Observer A, from 0.566 to 0.858 ( $P < 0.01$ ) in the first reading session of Observer B, from 0.753 to 0.930 ( $P < 0.01$ ) in the second reading session of Observer B. Diagnostic accuracy, sensitivity, specificity, PPV, and NPV were higher than CECT alone in the first reading session of Observer A and both reading session of Observer B. Intra-observer agreement of confidence levels improved after the addition of MR imaging: kappa value improved from 0.423 to 0.636 for Observer A, from 0.199 to 0.479 for Observer B. Inter-observer agreement of confidence levels also improved after the addition of MR images: kappa value improved from 0.093 to 0.230 for the first reading session, from 0.140 to 0.460 for the second reading session.

#### CONCLUSION

The addition of MR imaging including DWI to CECT, improves the detection of cholangiocarcinoma recurrence when compared with CECT alone.

#### CLINICAL RELEVANCE/APPLICATION

The addition of MR imaging including DWI to CECT, helps to detect early-stage resectable recurrence lesions of cholangiocarcinoma.

Printed on: 08/22/24

### To Predict Hepatic Decompensation Status using Computed Tomography-Based Radiomics Signature with the Body Composition Model

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Yashbir Singh, PhD, MEng (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The purpose of this study was to investigate the potential value of computational radiomics in predicting hepatic decompensation using body-composition model in the patients with Primary Sclerosing Cholangitis (PSC), a chronic cholestatic liver disease that can lead to hepatic decompensation.

#### **METHODS AND MATERIALS**

A total of 220 patients diagnosed with PSC and with an available abdomen CT acquired during the portal venous phase were included in the study. We used an in-house developed U-Net model that assesses body composition using the subcutaneous adipose tissue (SAT), skeletal muscle (SKM), visceral adipose tissue (VAT), and intermuscular adipose tissue (IMAT). The PyRadiomics library was used to extract radiomic features on the region of interest (ROI) created by the body composition model. Out of 100 radiomics features, 23 features were identified to be significant using statistical analysis (t-test). We aimed to develop a classification model using radiomics features based on a traditional machine learning approach (random forest classification).

#### **RESULTS**

The machine learning model achieved a prediction accuracy of 97% in the validation set, which was evaluated in terms of the AUC. This study is a first step in this proof-of-concept application of combining Radiomics Signature and the Body Composition Model with imaging data and the model was designed to predict short-term outcomes.

#### **CONCLUSION**

The study revealed the potential for prognostic features for hepatic decompensation patients in PSC and provided hidden information that may help in discovering new differentiating imaging features. This methodological approach may also have the potential for detecting other PSC-related complications such as cholangiocarcinoma and applications in other chronic liver diseases such as non-alcoholic fatty liver disease.

#### **CLINICAL RELEVANCE/APPLICATION**

The use of radiomics with Body composition model in predicting hepatic decompensation in PSC patients may aid in early detection and intervention. The approach may also be useful in detecting other complications associated with PSC and other chronic liver diseases, thereby contributing to better clinical management and improved patient outcomes.

### Prediction of Bladder Cancer Based on Biparametric MRI Radiomics: Comparison with Traditional MRI

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Li Zhang (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare biparametric (bp) MRI radiomics signatures and traditional MRI model for the preoperative prediction of bladder cancer (BCa) grade.

#### METHODS AND MATERIALS

This retrospective study included 255 consecutive patients with pathologically confirmed 113 low-grade and 142 high-grade BCa who underwent preoperative MRI, including T2-weighted imaging (T2WI) and apparent diffusion coefficient (ADC). The traditional MRI nomogram model was developed using univariate and multivariate logistic regression by the mean apparent diffusion coefficient (mADC), vesical imaging reporting and data system (VI-RADS) scoring, tumor size and number of tumors. Volumes of interest were manually drawn on T2WI and ADC maps by two radiologists. Using ANOVA, correlation and LASSO methods to select features. Then, a logistic regression (LR) classifier was used to develop the radiomics signatures in the training set and assessed in the validation set. Receiver operating characteristic (ROC) analysis was used to compare the diagnostic abilities of the radiomics and traditional MRI models by the DeLong test. Finally, decision curve analysis (DCA) was performed by estimating the clinical usefulness of the two models in both the training and validation sets.

#### RESULTS

The areas under the ROC curves (AUCs) of the traditional MRI model were 0.841 in the training cohort and 0.806 in the validation cohort. The AUCs of the three groups of radiomics model [ADC, T2WI, bp-MRI (ADC and T2WI)]-based logistic regression analysis algorithms were 0.888, 0.875 and 0.899 in the training cohort and 0.863, 0.805 and 0.867 in the validation cohort, respectively. The combined radiomics model achieved higher AUCs than the traditional MRI model and was compared using the DeLong test ( $P = 0.026$  and  $0.023$  in the training and validation cohorts, respectively). DCA indicated that the radiomics model had higher net benefits than the traditional MRI model.

#### CONCLUSION

The bp-MRI radiomics model may be helpful for distinguishing high-grade and low-grade BCa and outperformed the traditional MRI model. Multicenter validation is needed to acquire high-level evidence for its clinical application.

#### CLINICAL RELEVANCE/APPLICATION

Our study shows that the bp-MRI radiomics model presented superior diagnostic performance to the traditional MRI model. This may assist doctors in obtaining the preoperative histological grading of the tumor, which is convenient for determining the treatment strategy for BCa.

### Comparison of Single-shot EPI, Multi-shot EPI, and Reduced Field-of-view in Bladder DWI at 3.0 T

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Tsutomu Tamada, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare the image quality of single-shot echo-planar diffusion-weighted imaging (SS-EPI DWI), multi-shot EPI DWI (MS-EPI DWI), and reduced field-of-view DWI (rFOV DWI) in bladder cancer and their diagnostic ability for muscle invasion.

#### METHODS AND MATERIALS

Seventy-three patients who had a multiparametric MRI including SS-EPI DWI, MS-EPI DWI, and rFOV DWI as a preoperative examination for bladder cancer between August 2020 and February 2023 were included in the study. Qualitative image quality was evaluated by three radiologists. Regarding the SS-EPI DWI, MS-EPI DWI, and rFOV DWI, the three items of distortion, wall clarity, and lesion conspicuity were graded in four stages: 1: poor, 2: fair, 3: good, and 4: excellent. Quantitative image quality assessment was performed by a radiologist. The signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and signal intensity ratio (SIR) were used as measures of quantitative evaluation. The control was set to the iliopsoas muscle. Three radiologists assessed the presence of muscle invasion of bladder cancer using Vesical Imaging-Reporting and Data System. Clinical information and pathology results were not known to the readers. The Wilcoxon matched pairs signed ranks test was used to compare qualitative and quantitative scores. The McNemar test and ROC analysis were used to compare diagnostic performance. A p-value < 0.05 was considered significant.

#### RESULTS

The qualitative scores for distortion were MS-EPI DWI (2.95 to 3.42), rFOV DWI (2.74 to 3.18), and SS-EPI DWI (2.33 to 3.00) in descending order, with significant differences for all combinations. The wall clarity scores were MS-EPI DWI (3.00 to 3.34), SS-EPI DWI (2.86 to 3.16), and rFOV DWI (2.44 to 2.86) in descending order, and the three readers were in agreement, with significant differences between rFOV DWI and the other two types of DWI. Quantitative evaluation showed no significant difference in SNR and CNR between each test. SIR was higher for MS-EPI DWI (average, 10.5; SD, 4.4), rFOV DWI (average, 6.5; SD, 2.1), and SS-EPI DWI (average, 5.6; SD, 1.5), in that order, with significant differences between each DWI. The diagnostic performance of muscle invasion was good for all DWIs. AUC values were 0.83 to 0.88 for SS-EPI DWI, 0.85 to 0.90 for MS-EPI DWI, and 0.83 to 0.93 for rFOV DWI. There was no significant difference between sequences.

#### CONCLUSION

MS-EPI DWI and rFOV DWI reduced image distortion and MS-EPI DWI improved bladder wall visibility compared to SS-EPI DWI, but did not contribute to improve diagnostic performance of muscle layer invasion.

#### CLINICAL RELEVANCE/APPLICATION

If distortion or bladder wall obscuration is seen on SS-EPI DWI during examination, additional MS-EPI DWI can improve image quality.

### **Osteogenesis Imperfecta: Implications of Using Micro-CT for Visualizing Developmental Variation in the Middle and Inner Ear of OIM Mice**

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Dallin Judd (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The purpose of our research is to visualize and document anatomic variation in the ears of mice bred to have the Type III OI genetic variant in order to better understand the cause of OI-related hearing loss.

#### **METHODS AND MATERIALS**

3D models of the middle and inner ears were created from micro-CT scans that also employed two new contrast-enhanced methods to visualize the cochlea and middle ear (malleus, incus, and stapes). All CT scanning were done using the new Small Animal Imaging Facility (SAIF). The scan resolution was approximately 20 $\mu$ m. The studied WT and OIM mouse samples include three time points intended to capture a developmental sequence: 0-day-old (WT=20, OIM=29), 7-day-old (WT=23, OIM=23), and 14-day-old mice (WT=22, OIM=18). The visualization software Avizo was then used to digitally segment the bone of the inner ear and middle ear.

#### **RESULTS**

In OIM inner ears, the surrounding otic capsule tended to be more demineralized, exhibiting lower threshold values than WT. This contrasts with WT specimens, where the ossified bone was more distinct from the hollow space of the inner ear. Intrusions in the vestibule were observed in both the 2D slices and the reconstructed 3D models of the OIM inner ears. Comparison of volumes for the right OI and WT inner ears and left OI and WT inner ears indicated statistically significant differences between the genotypes.?

#### **CONCLUSION**

Bony intrusions observed in the vestibules of OIM mice may negatively affect fluid movement within the semicircular canals and vestibule (utricle and saccule), possibly altering the balancing and body positioning abilities of OI mice. This is ongoing research employing additional contrast enhanced CT (CE-CT) methods to visualize not only the bony labyrinths, but also soft tissue, including muscle and cartilage. In addition, more age-points are currently being collected with the aim of elucidating the pathogenesis of osteogenesis imperfecta during different stages of ear development.

#### **CLINICAL RELEVANCE/APPLICATION**

This research uses micro-CT imaging designed to capture a developmental sequence, giving us the potential to elucidate how and when the bony intrusions are impacting surrounding structures. Insight into this anatomical damage may help disambiguate the OI-related pathology, including the distinction between sensorineural vs. mixed hearing loss, unilateral vs. bilateral pathology, and the asymmetric nature of the disease in the ear. Upon completion, this research will demonstrate the efficacy of using these new imaging approaches for studying minute structures of the ear and may markedly advance our understanding of the pathogenesis of OI-related hearing loss.

### **Magnetic Resonance Neurography of Peripheral Trigeminal Nerves: Correlation of Sunderland Class of Nerve Injury on Imaging versus Clinical Neurosensory Testing and its Diagnostic Efficacy**

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Shuda Xia (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Iatrogenic or traumatic injuries to the peripheral trigeminal nerve (PTN) can cause loss of sensation and neuropathic pain in the face and oral cavity. Clinical neurosensory testing (NST) is currently the reference standard for diagnosis but is less reliable within the first 3 months following injury and cannot precisely identify the location of the nerve injury. MR neurography (MRN) has been studied for PTN injury diagnosis but with small sample sizes. The aim of this cross-sectional study was to evaluate the correlation between Sunderland class of nerve injury on MRN and NST and obtain diagnostic efficacy with surgical findings as reference standard.

#### **METHODS AND MATERIALS**

An Institutional Review Board approved this retrospective cross-sectional study of adult patients of all genders with suspected injury of PTN who had both clinical NST by an experienced oral maxillofacial surgeon and MRN interpreted by an expert radiologist. A total of 297 patient records with a chief complaint of PTN neuralgia were identified from the university database. All patient charts were reviewed to identify Sunderland injury class on NST and MRN, previous surgeries, whether surgery was performed after the MRN, and surgical outcomes. Of the cohort, 87 patients had both NST injury grade and Sunderland class injury in their records, and 45 of these patients had surgery. Pearson correlation was obtained and the accuracy of NST and MRI was obtained with surgical and histopathology findings as reference standards. Cohen's weighted Kappa was also calculated.

#### **RESULTS**

There were 20 men and 67 women with an age range of 15 to 81 years. Most (69/87, 79%) injuries resulted from tooth extractions and implants. On MRN, there were no class I injuries, 26 class II injuries, 26 class III injuries, 26 class IV injuries, and 9 class V injuries. There was a very strong positive correlation between injury grade on MRN and the NST injury class ( $p < .001$ ). There were substantial agreements between NST, MRN, and surgical findings.

#### **CONCLUSION**

The results of this study confirm that MRN adequately provides the injury grade better than NST with improved diagnostic accuracy.

#### **CLINICAL RELEVANCE/APPLICATION**

Prompt non-invasive and accurate diagnostic evaluation of suspected PTN injury is critical for successful management. MRN provides the needed pre-operative information on injury grade and its anatomic localization.

### Relationship Between MRI and Clinical Findings of Anatomic Risk Factors in Adult Patients Affected by Obstructive Sleep Apnea/hypopnea Syndrome (OSAHS)

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Maria Paola Belfiore (*Presenter*) Nothing to Disclose

#### PURPOSE

Identify specific anatomical abnormalities associated with Obstructive Sleep Apnea/hypopnea syndrome (OSAHS), and establish a correlation between the pathological condition and the anatomical changes and enhance treatment planning for future management

#### METHODS AND MATERIALS

This case-control study conducted in 2022 investigated the potential of MRI in identifying the causes of upper airway obstruction in OSAHS patients. The study included 30 participants diagnosed with OSAHS and 16 healthy subjects enrolled as a control group, matched for gender, age, height, and weight. All participants underwent MRI examination of the cervical maxillofacial district in the bore of the same 1.5 T magnet. MRI exams revealed significant differences in the upper airway volume, midsagittal nasopharyngeal antero-posterior distance, axial CSA of the nasopharyngeal airway, midsagittal tongue area, soft palatal length, midsagittal soft palatal area, and axial volume of the right and left parapharyngeal adipose tissue in patients with OSAHS compared to controls. Furthermore, the study analyzed the correlation between cephalometric and anatomical measurements and OSAHS severity.

#### RESULTS

The results showed a significant association between the severity of OSAHS and soft palate length, soft palate area, Hyoid-Sella distance, and Hyoid-Nasion distance. Soft palate length was closely associated with Hyoid-Sella distance, Hyoid-Nasion distance, and tongue area. The study also evaluated the facial skeletal structure, showing significant differences in intermandibular distance, mandibular depth, and the position of both the maxilla and mandible between the two groups.

#### CONCLUSION

Multiple soft tissue and skeletal structures surrounding the upper airways may contribute to the symptoms and clinical severity of OSAHS; in some cases, they may even play a dominant role. MRI has enormous potential in evaluating the three compartments of obstruction: air lumen, soft tissues, and facial skeleton.

#### CLINICAL RELEVANCE/APPLICATION

This study highlights the potential of MRI in identifying the causes of upper airway obstruction in adult OSAHS patients. While polysomnography remains the gold standard for OSAHS diagnosis, MRI can offer a valuable alternative method for evaluating the craniomaxillofacial morpho-volumetric characteristics contributing to airway size reduction. This information can assist in determining the most appropriate therapeutic approach and surgical intervention, ultimately improving OSAHS patient outcomes.

### Cochlea-carotid Dehiscence: An Underappreciated Condition

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Charles Tandler, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Cochlea-carotid artery dehiscence (CCD) is the erosion of the bony plate between the cochlea and the petrous segment of the internal carotid artery. In one study of 1,000 temporal bones, there is a histologic prevalence of cochlea-carotid artery dehiscence of 7.7%. It has been reported to be associated with pulsatile tinnitus, conductive hearing loss, sensorineural hearing loss, vertigo, and other otologic disorders. However, the clinical significance of cochlea-carotid artery dehiscence is unknown. Other than a small number of case reports, no large-scale study investigates the radiographic prevalence of CCD and its clinical significance. This study hopes to highlight its clinical significance by retrospectively reviewing a large volume of temporal bone computed tomography (CT) exams and patients' symptoms.

#### METHODS AND MATERIALS

This retrospective single-center cross-sectional study was conducted after the institution's IRB approved the study. Consecutive 1,000 patients (2,000 ears) who underwent CT temporal bones were reviewed. CT images were obtained with 0.625 mm thick and 0.3 mm reconstruction interval. First, a radiology resident reviewed all exams for possible CCD. Then, selected cases were reviewed by two board-certified neuroradiologists independently. The discrepancy was resolved by consensus. Possible CCD ears were divided into three categories: 1) dehiscence, 2) thinning/possible dehiscence, and 3) no dehiscence. The location of the dehiscence or thinning/possible dehiscence was recorded. The results were correlated with clinical findings. Duplicated exams and age less than 18 years old were excluded.

#### RESULTS

Thirteen temporal bones with CCD were identified in twelve patients, including one patient with bilateral CCD (8 men, 4 women, age: 36-78). The basal turn was affected in eleven ears, and the apical turn was affected in two ears. One patient had progressive sensorineural hearing loss of high frequency of the affected ear. Another patient had bilateral hearing loss, more profound in the affected ear, with episodic dizziness. One patient had no documented otological finding in the chart. Other patients did not have symptoms that might be associated with CCD.

#### CONCLUSION

CCD is a rare condition, as reported in the literature. Its clinical significance is still unknown, although pulsatile tinnitus, conductive hearing loss, sensorineural hearing loss, vertigo, and other otologic disorders have been reported in the literature.

#### CLINICAL RELEVANCE/APPLICATION

CCD is a rare condition as reported in the literature. Its clinical significance is still unknown, although pulsatile tinnitus, conductive hearing loss, sensorineural hearing loss, vertigo, and other otologic disorders have been reported.

### Combining Virtual Monoenergetic Imaging and Iterative Metal Artifact Reduction in Photon-counting CT of Patients with Dental Implants

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Theresa Sophie Patzer, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Virtual monoenergetic imaging (VMI) and iterative metal artifact reduction (MAR) are established techniques in energy-integrating detector (EID) CT. The artifact suppressing effect of both approaches is not thoroughly investigated in photon-counting detector (PCD) CT. This study aims to evaluate the potential of VMI, MAR, and combinations thereof in PCD-CT for metal artifact reduction in patients with dental implants.

#### METHODS AND MATERIALS

In 50 patients with dental implants (25 women; mean age  $62 \pm 9.92$  years), conventional 120 kVp imaging (T3D), VMI, T3DMAR and VMIMAR were compared. VMI datasets were reconstructed at 40, 70, 110, 150 and 190 keV. Objective image quality was assessed by ROI-based measurements of attenuation and respective standard deviations in the most hyper- and hypodense artifacts, as well as in artifact-impaired soft tissue of the mouth floor. Three readers evaluated artifact extent and soft tissue interpretability separately on a five-point scale. The introduction of new artifacts and/or overcorrection of pre-existing artifacts was assessed subjectively.

#### RESULTS

MAR substantially reduced hyperdense and hypodense artifacts (T3D 1305.0/-1418.4 HU; T3DMAR 103.2/-46.9 HU), soft tissue impairment (T3D 106.7 HU; T3DMAR 39.7 HU) and image noise (T3D 16.9 HU; T3DMAR 5.2 HU) compared to non-MAR datasets (all  $p=0.001$ ). While VMIMAR =150 keV did not enhance artifact reduction over T3DMAR objectively (all  $p=0.081$ ), VMIMAR =110 keV received superior subjective ratings (all  $p=0.023$ ). Without MAR, VMI displayed no measurable artifact extent reduction (all  $p=0.186$ ). However, VMI =110 keV reduced soft tissue impairment over T3D (all  $p=0.009$ ). VMI facilitated no significant denoising over T3D with or without MAR (all  $p=0.366$ ). VMIMAR =110 keV resulted in less overcorrection than T3DMAR (all  $p=0.001$ ).

#### CONCLUSION

While VMI alone presented only minimal metal artifact reduction potential, post-processing using MAR enabled a substantial reduction of hyperdense and hypodense artifacts. The combination of both provided a considerable benefit in subjective artifact reduction compared to MAR alone.

#### CLINICAL RELEVANCE/APPLICATION

Combining iterative MAR with VMI represents a potent tool for maxillofacial PCD-CT with dental implants achieving substantial artifact reduction. Thus, these approaches allow for improved image quality, improving delicate detection and evaluation of oral pathologies.

### Application of parotid gland ASL and T2 mapping MRI in Sjögren's syndrome

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Zhang Gaozhengbo, MA (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aims to explore the application value of ASL and T2 mapping techniques in the assessment and early diagnosis of parotid gland injury in Sjögren's syndrome(SS) patients.

#### METHODS AND MATERIALS

This study prospectively included 54 first-time confirmed SS patients and 30 healthy volunteers from a tertiary hospital from August 2021 to October 2022. Non parametric Mann Whitney U test was used to compare various parameters between SS patients and healthy volunteers. LSD test was used to compare the differences in parameters between adjacent MRI morphological grading. Spearman rank correlation test was used to analyze the correlation between parotid gland MRI morphological grading and various parameters of SS patients. The combination of logistic regression and receiver operating characteristics is used to evaluate the diagnostic efficacy of various parameters and their combination in distinguishing healthy volunteers from early SS patients and all SS patients.

#### RESULTS

The parotid gland BF of all SS patients and 0-3 grade SS patients was higher than that of healthy volunteers. There was no statistically significant difference in BF between grade 4 SS patients and healthy volunteers. The T2 value and standard deviation of T2 value in the parotid gland of all SS patients and 0-4 grade SS patients were higher than those of healthy volunteers. The morphological grading of parotid gland MRI (0-3 grades) showed a strong positive correlation with BF ( $r=0.785$ ,  $P<0.001$ ), a moderate positive correlation with T2 value ( $r=0.547$ ,  $P<0.001$ ), and a moderate positive correlation with T2 standard deviation ( $r=0.622$ ,  $P<0.001$ ). The area under the curve of BF is 0.813; The AUC of T2 value is 0.810; The AUC of T2 standard deviation is 0.649. The AUC of the combined diagnosis of BF, T2 value, and T2 value standard deviation is 0.842. The diagnostic efficacy of BF, T2 value, and combined diagnosis is higher than the T2 value standard deviation, while the diagnostic efficacy of combined diagnosis is higher than BF or T2 value.

#### CONCLUSION

The BF, T2 values, and standard deviation of T2 values of the parotid gland can distinguish between healthy volunteers and SS patients, reflecting the corresponding changes in the parotid gland of SS patients at different stages. The combination of the three can improve diagnostic efficiency. ASL technology and T2 mapping technology have certain significance in the evaluation and early diagnosis of parotid gland injury in SS patients, and are important supplementary tools for routine MRI diagnosis.

#### CLINICAL RELEVANCE/APPLICATION

ASL technology and T2 mapping technology have certain significance in the evaluation and early diagnosis of parotid gland injury in SS patients, and are important supplementary tools for routine MRI diagnosis.

### Development of a Three-Dimensional Expression Method for Ultrasound Images Using Mixed Reality Head-Mounted Displays

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Do Hyung Lee (*Presenter*) Nothing to Disclose

#### PURPOSE

This research aimed to develop a real-time three-dimensional (3D) expression of ultrasound images in mixed reality (MR) space to enhance the intuitiveness and understanding of ultrasound images, and to compare its performance with conventional two-dimensional (2D) ultrasound.

#### METHODS AND MATERIALS

An MR ultrasound system was developed using the Microsoft HoloLens 2™ MR head-mounted display (HMD), incorporating a 3D camera for SLAM (Simultaneous Localization and Mapping) of the ultrasound transducer. Technical performance was evaluated for MR 2D and MR 3D ultrasound modalities. User evaluation involved 20 healthcare workers (10 medical doctors (MD) group, and 10 non-MD group; 4 nurses, and 6 radiology technicians) who assessed elapsed time, target object position identification score (both of horizontal and vertical position), and shape identification score for every three modalities: 1) conventional 2D ultrasound, 2) MR 2D ultrasound, and 3) MR 3D ultrasound. For each correct identification of the position and shape for a single target object, a score of 1 point was given. The user satisfaction assessment was also conducted regarding the intuitiveness of shape recognition, location recognition, and ease of use in the 3D accumulation process on a scale of 5.

#### RESULTS

User evaluation revealed no significant difference in elapsed time, and position identification among the three modalities. Shape identification score was significantly improved with MR 3D ultrasound compared to conventional 2D and MR 2D ultrasound (conventional 2D:  $1.05 \pm 0.76$  [average  $\pm$  standard deviation], MR 2D:  $1.30 \pm 1.13$ , MR 3D:  $3.00 \pm 0.00$ ,  $p < 0.001$ ). All evaluators identified the correct shapes of all target objects, eliminating differences between groups in using MR 3D ultrasound. User satisfaction score in the intuitiveness of shape identification with MR 3D ultrasound was as high as  $4.85 \pm 0.37$ .

#### CONCLUSION

Incorporating 2D ultrasound into the MR space and expressing it in three dimensions through a user-driven 3D accumulation process were both technically feasible to implement. Moreover, the MR 3D ultrasound display was superior to both conventional 2D and MR 2D ultrasound in discerning the shape of the target object, providing a more intuitive visualization.

#### CLINICAL RELEVANCE/APPLICATION

HoloLens offers the function for multiple users to simultaneously share the same MR space, which can be implemented when several users are each wearing their own HoloLens device. By employing the technology developed in this study to reconstruct and display the images as 3D MR, it is expected to facilitate sharing of examination contents and promote intuitive understanding among patients with limited anatomical knowledge and clinical support staff.

### A Novel 18F-FDG-PET Based Signature for Non-Small Cell Lung Cancer Prognostication

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Mitchell Chen, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop a novel 18F-fluorodeoxyglucose-positron emission tomography (FDG-PET) radiomics predictive model combined with metabolic hotspot to centroid (HOC) metric for patient prognostication in non-small cell lung cancer (NSCLC).

#### METHODS AND MATERIALS

Pre-therapy FDG-PET scans from 301 NSCLC patients (age:  $69.1 \pm 9.8$ , male: female (M: F) = 183:118) were acquired between July 2009 and November 2018 and included as the training data. Independent external FDG-PET data were acquired from five centers ( $n = 257$ ) and used for model validation. Two board-certified clinical radiologists with 8 and 13 years of professional experience segmented the primary tumor using metabolic tumor volume 40% (MTV40) threshold. Additional regions of interests (ROI) were acquired from the peri-tumoral penumbra as annular shells of 1cm in thickness, and from the background lung parenchyma as spheres of 3cm in diameter. Following pre-processing, radiomics features compliant with the Image Biomarker Standardization Initiative (IBSI) were extracted using PyRadiomics from each ROI, normalized and aggregated to form a feature space. Non-reproducible features with an inter-class correlation (ICC) of less than 0.8 were excluded. Cox regression with elastic net regularization was performed to develop a radiomics model with patients' 3-year overall survival as the response vector. Using multivariable regression, this was combined with a novel PET metric developed based on the clonal driver mutation theory of cancer growth, namely the FDG HOC distance, to develop a composite radiomics predictive vector (RPV). Model performance for disease prognostication was tested by stratifying the patients into a high and low risk group using k-means clustering based on RPV.

#### RESULTS

In all external testing cohorts, statistically significant stratification of the patients into high and low risk groups was achieved using RPV ( $p$ -value  $< 0.05$ ).

#### CONCLUSION

A model developed based on PET radiomics and HOC can achieve patient prognostication in NSCLC. Comparing to models based on CT or PET radiomics alone, this novel signature captures explainable information on tumour growth, and demonstrates a role of the latter for predicting patient survival in NSCLC.

#### CLINICAL RELEVANCE/APPLICATION

Imaging-based metrics such as FDG-PET radiomics and HOC offer a non-invasive way of assessing neoplasms at the time of diagnosis. This can aid in clinical decision making, particularly in cases where tissue sampling is challenging or shows inconclusive results. The information presented by these measurements can additionally give insight into tumor composition and metabolism, thereby advancing an understanding of cancer biology that is not otherwise achievable in vivo.

### AI-assisted Volumetric Segmentation for Metastases in Follow-up CT Scans: A Multi-institutional Reader Study

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Alessa Hering, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

AI-assisted techniques for lesion registration and segmentation have the potential to make CT-based tumor follow-up assessment faster and less reader-dependent. However, empirical evidence on the advantages of AI assistance for lymph node and soft tissue metastases in follow-up CT scans is lacking. Therefore, the aim of this study was to assess the efficiency, quality and inter-reader variability of an AI-assisted workflow for volumetric segmentation of lymph node and soft tissue metastases in follow-up CT scans. Three hypotheses were tested: (H1) Assessment time for follow-up lesion segmentation is reduced using an AI-assisted workflow. (H2) The quality of the AI-assisted segmentation is non-inferior to the quality of fully manual segmentation. (H3) The inter-reader variability of the resulting segmentations is reduced with AI assistance.

#### METHODS AND MATERIALS

This multi-institutional reader study retrospectively analyzed 126 lymph nodes and 135 soft tissue metastases from 55 patients diagnosed with stage IV melanoma. Given segmentations of these lesions on the baseline scan, three experienced readers from two institutions performed both AI-assisted and manual segmentations on the follow-up scans. The results were then statistically analyzed and compared to a manual segmentation reference standard to assess the quality and accuracy of the AI-assisted workflow.

#### RESULTS

AI-assisted segmentation reduced user interaction time significantly by a third (222s vs 336s per patient), achieved similar Dice scores (0.80-0.84 vs 0.81-0.82) and decreased inter-reader variability (median Dice 0.85-1.0 vs 0.80-0.82), compared to manual segmentation. In over 50% of the segmentation propositions within the AI-assisted workflow, two radiologists accepted the results without any further corrections.

#### CONCLUSION

AI-assisted segmentation reduced user interaction time significantly by a third, achieved similar Dice scores and decreased inter-reader variability, compared to manual segmentation. In over 50% of the segmentation propositions within the AI-assisted workflow, two radiologists accepted the results without any further corrections.

#### CLINICAL RELEVANCE/APPLICATION

AI-assisted lesion segmentation makes accurate quantification of volumetric tumor growth and other characteristics feasible in clinical routine, enabling earlier and better response assessment.

### Graph-Theoretic Automatic Lesion Tracking and Detection of Patterns of Lesion Changes in Longitudinal CT Studies

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Leo Joskowicz, PhD (*Presenter*) Officer, HighRAD Ltd

#### PURPOSE

To evaluate the performance of a novel generic method for tracking individual lesion changes and detecting patterns in liver and lung metastatic lesions in longitudinal CT.

#### METHODS AND MATERIALS

We define seven individual lesion change classes: new, disappeared, unique, lone, merged, split, and complex lesion and five lesion change patterns: single, linear, merged, split, and complex pattern to summarize the evolution of lesions over time. The method automatically computes the lesion matchings, the labels of the changes in individual lesions, and the patterns of the lesion changes. It uses a graph-based technique where lesions are vertices and edges are pairings of matched lesions. The inputs are the scans and the organ and lesion segmentations in each scan. It performs pairwise deformable registration of consecutive scans, organs and lesion segmentations, matches overlapping lesions, and computes the changes from the resulting graph. The method was evaluated on lung and liver metastases datasets with 83 scans from 19 patients (mean  $126 \pm 81$  days apart) and 77 scans from 19 patients (mean  $109 \pm 93$  days apart). Ground truth manual lesion segmentations, matchings and changes classification were obtained by an expert radiologist.

#### RESULTS

The lung and liver metastases overall individual lesion change class accuracy is 97% and 87%. The patterns of lesion changes were identified with an accuracy of 94% and 80%. The highlighting of unusual lesion labels and lesion change patterns helped the radiologist find missed lesions (57 lungs, 52 liver) and wrongly annotated lesions (1 lungs, 18 liver), accounting for 4.9% and 8.7% of the original ground-truth lesions.

#### CONCLUSION

Our method accurately classifies changes in individual lesion and reliably identifies patterns of lesion changes in liver and lung longitudinal CT studies.

#### CLINICAL RELEVANCE/APPLICATION

Automatic lesion change classification and pattern detection in longitudinal CT studies may improve the accuracy and efficiency of radiological interpretation and disease status evaluation.

### Accurate Coverage Assessment in MRI using Deep Learning-Based Landmark Detection

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Ryan Chamberlain, PhD (*Presenter*) Employee, ImBio, LLC

#### PURPOSE

This study aims to develop a deep learning-based MRI coverage detection model. By introducing key points to define coverage, using self-supervised learning to overcome annotation challenges, the model addresses crucial coverage detection obstacles and promotes patient-centered care.

#### METHODS AND MATERIALS

**Datasets:** We used three datasets for train and evaluate the model: Lumbar Spine Open dataset1 (464 T1 and T2-weighted lumbar spine MRI images); IXI MRA dataset2 (nearly 600 MR images from healthy subjects); and TubeTK MRA dataset (100 T1-weighted MRA images from healthy patients). No manual annotations of key points needed. **Model:** Adapted from Frueh et al.'s paper<sup>3</sup>, we employed the Template Matching Network (TMN) with separate feature encoders for the source image and augmented extracted patch. The stacked feature vectors feed into three fully connected layers, the localizer. We added a detector branch for coverage detection, sharing the localizer's architecture, but yielding binary results (Figure). **Augmentation:** Techniques include affine transformation, gamma adjustment, and Gaussian blurring. Images and patches are cropped before resizing to the model's input size of 224x224, ensuring flexible image scope and dynamic image/patch size ratios, enhancing model robustness and adaptability. **Training:** Loss functions comprise log negative likelihood loss for the localizer and cross-entropy loss for the detector, using multi-purpose optimization. StepLR manages learning rate scheduling, and early stopping ensures an efficient training strategy.

#### RESULTS

We evaluated our deep learning-based coverage detection model in spine and MRA scenarios. The spine model demonstrated a 4.84mm mean distance in localizing key points, and correctly identified vertebral levels in 55% of cross subject test cases. The model achieved an F1 score of 0.799 in detecting coverage in partial lumbar spine images. The MRA model achieved a 6.65mm mean distance in localization, and qualitatively identified correct locations in two randomly selected cross subject images (see figure).

#### CONCLUSION

Our coverage detection model exhibits strong performance in spine imaging and MRA studies, with promising results in localizing random or manually labeled key points as well as detecting coverage in partial images.

#### CLINICAL RELEVANCE/APPLICATION

By ensuring accurate coverage of relevant anatomical structures, our deep learning-based model has the potential to reduce repeat imaging and patient revisits, conserving resources and minimizing risks for patients. By automating the coverage assessment process, the model alleviates the burden on clinicians to manually review images. This innovation ultimately boosts efficiency, and promotes better patient care.

### Discrimination of the Pulmonary Nodules Using the Chest CT Image Features by Homology Method

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Akira Sato, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

The degree of lung adenocarcinoma (LAc) invasion is important in determining treatment strategy, but it is not revealed until the pathological diagnosis at surgical treatment. So, we developed a method to determine it from preoperative CT images, but it is also necessary to discriminate the lesion of LAc from normal tissues. Homology is one of the topological concepts and quantifies contact. Homology-based image analysis (HA) can explain the reason for inference based on mathematics. So, we have aimed to discriminate LAc and normal tissues in CT image based on HA.

#### METHODS AND MATERIALS

This study uses chest CT images of patients with LAc. Fifty ROIs (regions of interest) were created for each LAc lesion, lung field (no lesion), blood vessels in the lung field, bronchi, and ribs. Next, binarized images were created while varying the CT value. The Betti numbers ( $b_0$ ,  $b_1$ : the number of isolated areas and holes) in the ROI were measured and normalized with the area of ROI. These indices were used as imaging features and compared using Mann-Whitney U test. The relationship between HU and imaging features was plotted as a homology profile. Moreover, we developed a binary classification model based on the support vector machine (SVM) that classifies the ROI for LAc or normal tissue, and five-fold cross-validation was used.

#### RESULTS

U test showed that each normal tissue significantly differed for nodules ( $p < 0.05$ ). The performances of SVM-based model are as follows (mean  $\pm$  SD). The discrimination between lung fields and LAc had an accuracy of  $1.00 \pm 0.00$  and area under the ROC curve (AUROC) of  $1.00 \pm 0.00$ , while the discrimination between ribs and LAc had an accuracy of  $0.99 \pm 0.01$  and AUROC  $1.00 \pm 0.00$  were the best results. For the best discrimination between blood vessels and LAc, an accuracy of  $0.91 \pm 0.03$  and AUROC of  $0.97 \pm 0.01$  were obtained, while for the discrimination between bronchi and LAc, an accuracy of  $0.97 \pm 0.01$  and AUROC  $1.00 \pm 0.00$ .

#### CONCLUSION

The results suggest that it is possible to extract image features for each tissue by using HA, and that the classification model using those features can classify with excellent performance. Therefore, we will discriminate the ROIs obtained from the automatic contouring technique using the multi-classification model in the future. In conclusion, we succeeded in discriminating the ROI obtained from chest CT images for LAc and normal tissues using the SVM-based model that discriminates the image features by HA.

#### CLINICAL RELEVANCE/APPLICATION

We will develop the hybrid model, including this proposed model and our developed model that classifies the invasiveness degree of LAc on preoperative CT images. The hybrid model may not only help in early diagnosis and predicting prognosis but also lead to the discovery of novel valuable indices.

### Comparison of Micro Flow Imaging and Contrast Enhanced Ultrasound in Microwave Ablation of Benign Thyroid Nodules

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Min Zhuang (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the application value of micro-flow imaging (MFI) in microwave ablation (MWA) of thyroid nodules by comparing it with contrast-enhanced ultrasound (CEUS).

#### METHODS AND MATERIALS

From January 2020 to March 2022, 50 patients with 55 thyroid nodules who underwent MWA in the ultrasound department of our hospital were included. According to the different ablation evaluation methods, they were divided into the CEUS group and the MFI group. Before the operation, CEUS and MFI were used to evaluate the consistency of blood flow inside the nodule. Immediately after ablation, CEUS or MFI was used to evaluate whether the ablation was complete. Follow-up was conducted at 1, 3, and 6 months after the operation and every 6 months thereafter to record the diameter and volume of the nodule, CEUS and MFI were used to evaluate the suspected recurrent nodules.

#### RESULTS

There was no significant difference between MFI and CEUS in assessing the internal blood flow of nodules ( $P > 0.05$ ), and the consistency between them was very strong (kappa value = 0.81). All nodules showed complete ablation. At 1, 3, 6, and 12 months after the operation, the VRR in the CEUS group was 41%, 61%, 78%, and 89% respectively, and in the MFI group was 41%, 55%, 71%, and 83% respectively, there was no significant statistical difference between the two groups ( $p > 0.05$ ). No serious complications occurred after the operation.

#### CONCLUSION

The application effect of MFI in MWA of benign thyroid nodules is consistent with CEUS, and when CEUS cannot be used or unconditionally to use, MFI can be an alternative.

#### CLINICAL RELEVANCE/APPLICATION

CEUS can sensitively display the micro blood perfusion in tissues and can be used to differentiate benign and malignant tumors, it plays an essential role in the whole ablation process, which can determine the ablation area before ablation and evaluate the therapeutic effect after ablation. However, CEUS is an invasive and expensive examination, and not suitable for patients with severe cardiopulmonary dysfunction or hypersensitivity to ultrasound contrast agents. Explore a new, non-invasive way to evaluate the efficacy of thyroid nodule ablation will not only help to reduce the cost of patients. Micro-flow imaging (MFI) is a new ultrasound technology that can eliminate tissue motion artifacts while maintaining sensitivity to low-speed blood flow signals by using effective algorithms to visualize microvascular, it has the advantages of being non-invasive, fast, and convenient. In recent years, MFI has gradually been widely used in clinical practice. There are only a few studies on the application of MFI in the thermal ablation process of thyroid nodules. This paper aims to further study the application value of MFI in the MWA process of thyroid nodules by comparing it with CEUS.

### Reperfusion of Pulmonary Arteriovenous Malformations Treated by Catheter Embolization

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Guenther K. Schneider, MD, PhD (*Presenter*) Research Grant, Siemens AG;Speakers Bureau, Siemens AG;Speakers Bureau, Bracco Group;Research Grant, Bracco Group

#### PURPOSE

339 patients with HHT (Osler disease) underwent screening for manifestation of the disease in the brain, the lung and the liver by one CE MRI study. In 144 patients at least one pulmonary AVM was found and catheter embolization using platinum coils or vascular plugs was performed with initial complete occlusion of the PAVM. However, especially in the lung reperfusion may occur due to reopening of the treated vessel itself or newly developed collateral vessels. The aim of our study was to evaluate patients post treatment of pulmonary AVM's for possible reperfusion.

#### METHODS AND MATERIALS

Of 144 patients with previous treatment of PAVMs 117 patients underwent follow-up studies to detect reperfused PAVM by CE MRA. The mean follow-up period was 4 yrs and 8 month. For follow-up a time-resolved MRA was used with injection of a small CM bolus (0.025 mmol/kg BW MultiHance, Bracco). The temporal resolution of the sequence was < 3 sec/dataset with a total number of 72 slices. Thereafter a high resolution CE MRA (0.075 mmol/kg BW MultiHance) was performed. Images were evaluated regarding enhancement of the AVM and if detected, time of enhancement of the draining vein.

#### RESULTS

In 77 of 117 patients no reperfusion in follow-up studies was found. In 35 patients reperfusion of the treated vessel and in 5 patients reperfusion of the PAVM was detected due to collateral vessels supplying the PAVM. In one patient reperfusion occurred due to systemic arterial supply from collaterals arising from the intercostal arteries. The mean time between embolization and detection of reperfusion in patients treated at our department was 6 years. 36 of 40 patients with reperfused PAVM were confirmed by DSA and underwent reembolization. In 4 cases supplying vessels were < 2mm and only further follow-up studies were performed. Reperfusion was detected both after coil embolization and implantation of Amplatzer vascular plug 4. The mean diameter of reperfused vessels was 4.6 mm (SD 1.4).

#### CONCLUSION

Reperfusion of initially completely occluded PAVMs might even occur after longer time intervals thus regular follow-up studies are mandatory. CE MR-Angiography can reliably depict reperfusion of PAVM and evaluation of the enhancement kinetics of the draining vein was helpful to distinguish between retrograde filling, filling of the still dilated draining vein via normal lung tissue and reperfusion by reopening of shunt vessels or new collateral supply.

#### CLINICAL RELEVANCE/APPLICATION

Reperfusion of embolized PAVM can occur in up to 35 percent of patients and early detection is mandatory to avoid complications e.g. stroke. Dynamic CE MRA directly depicts early enhancement of the draining vein as a sign of reperfusion and thus can give important additional information not gained in conventional acquisitions or CT.

### Comparative Prospective Analysis of Digital Variance Angiography and Digital Subtraction Angiography in Prostatic Artery Embolization: A Potential Solution for Radiation Dose Reduction

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Leona Alizadeh, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Prostatic Artery Embolization (PAE) is a complex vascular intervention that requires the use of X-ray angiography imaging with high doses of radiation and iodinated contrast agent. The purpose of this study was to compare the performance of Digital Variance Angiography (DVA) with standard Digital Subtraction Angiography (DSA) in PAE and to evaluate the potential of DVA to reduce radiation exposure and contrast agent use.

#### METHODS AND MATERIALS

A prospective observational study was conducted on 26 patients (mean age 72, SD 14.6, range 49-89) in two groups (n=13): Group 1: standard CARE imaging protocol and Group 2: reduced detector dose and image quality pre-settings. All patients underwent PAE at our institution between January and December 2022. The study included a total of 107 acquisitions, from which DSA and DVA images were generated from the same raw series. The Contrast-to-Noise Ratio (CNR) values were calculated, and the image quality was assessed by four experienced readers using a 5-grade-Likert-scale in a randomized blinded survey. Radiation dose data was evaluated by assessment of dose-area-product (DAP) reference point air-kerma (RP), fluoroscopy times and image frames.

#### RESULTS

The DVA images provided significantly higher CNR values compared to DSA images, with a median CNR of  $32.2 \pm 9.5$  in Group 1 and  $24.8 \pm 9.9$  for Group 2 vs.  $8.1 \pm 11.1$  for Group 1 DSA and  $7.3 \pm 9.3$  for Group 2 DSA,  $p < 0.001$ . Furthermore, the DVA images received significantly higher Likert scores compared to DSA images, with a median (IQR) value of 4.52 (4-5) for Group 1 DVA 4.12 (3-5) for Group 2 and 3.24 (3-4) for Group 1 DSA and 2.9 (2-4) for Group 2,  $p < 0.001$ . Mean radiation burden in Group 1 was significantly higher by -49% / -45% with a DAP  $17.85 \mu\text{Gy} \cdot \text{m}^2 / \text{frame}$  and RP 0.89 / frame compared to Group 2 with a DAP  $9.62 \mu\text{Gy} \cdot \text{m}^2 / \text{frame}$  and RP 0.49 / frame ( $p < 0.001$ ).

#### CONCLUSION

The results of this study demonstrate that DVA has significantly higher CNR compared to DSA for both Groups in PAE procedures. The use of DVA could potentially provide a quality reserve that can be utilized for significant reduction of radiation exposure and iodinated contrast agent in PAE, up to 50-70% without compromising image quality. This may have a significant impact on patient safety during complex procedures such as PAE.

#### CLINICAL RELEVANCE/APPLICATION

The implementation of DVA in PAE can significantly reduce radiation exposure, which is a critical factor for improving patient safety during complex vascular interventions. These findings suggest that DVA should be considered as an alternative to DSA in PAE and other similar procedures that require high-quality imaging while minimizing the risk of radiation exposure and potentially also contrast agent use.

### Quantitative MRI-based Volumetric Analysis of Percutaneous Sclerotherapy Outcomes in Peripheral Extremity Venous Malformations

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Amanda Laguna, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

To study the changes in MRI radiomic features occurring in peripheral venous malformations (VMs) after treatment using percutaneous sclerotherapy (PS).

#### METHODS AND MATERIALS

Our vascular anomalies database was searched for patients with peripheral extremity VMs who were treated by image-guided PS and had completed their treatment plan, and clinical and imaging follow-up between 2005-2022. VMs were manually segmented on pre- and post-treatment T2-weighted (T2-WI) MRI using 3D Slicer software to assess changes in lesion volume and signal intensity (SI). To account for signal parameter differences between pre- and post-treatment T2-WI, the post-treatment T2-WI MRI signal was re-scaled to the pre-treatment T2-WI volume using a simple histogram matching algorithm, which allowed for precise and true calculation of SI change after PS. Therapeutic response was categorized as 0=worse or unchanged, and 1=improvement based on clinical evolution after treatment. Clinical outcome assessment was also scored on a 7-point scale, ranging from -3 (worst) to +3 (maximum improvement), based on patient's perception of symptom improvement. Spearman's rank correlation coefficient (?) and Paired t-test were used for statistical analysis.

#### RESULTS

Eighty-one patients (mean age: 20±14 years; 47 females) with upper (23 lesions) and lower (58) extremity VMs underwent 125 PS treatments (range: 1-6). Different sclerosants were used: alcohol (52 sessions), bleomycin (38), and sotradecol (35). Most patients (77) reported clinical improvement following PS, including mild (8 patients), moderate (22), and significant (47) improvement. The mean change in lesion volume was  $-7.9 \pm 24.6 \text{ cm}^3$  ( $P=.005$ ) and in mean SI was  $-123.1 \pm 162.9$  ( $P<.001$ ). Overall, there was a significant correlation between change in lesion volume and treatment response ( $r=-.3$ ,  $P=.004$ ). On subgroup analysis, SI change correlated with clinical outcomes of VMs treated in one session ( $n=51$ ;  $r=-.3$ ,  $P=.01$ ), and VMs treated with bleomycin ( $n=22$ ;  $r=-.4$ ,  $P=.04$ ). While lesion volume change correlated with clinical outcomes of pediatric patients ( $n=50$ ;  $r=-.3$ ,  $P=.03$ ), VMs treated with sotradecol ( $n=17$ ;  $r=-.5$ ,  $P=.02$ ), and VMs located in the foot ( $n=10$ ;  $r=-.6$ ,  $P=.04$ ).

#### CONCLUSION

MRI radiomic features including lesion volume and signal intensity correlate with the clinical outcomes for peripheral VMs treated using PS.

#### CLINICAL RELEVANCE/APPLICATION

This study is first to investigate the relationship between signal intensity change of VMs and clinical outcome after PS. The study represents first step for application of complex, comprehensive radiomics in vascular malformations.

### **Efficacy of 50% Acetic Acid Sclerotherapy for Treatment of Simple Renal Cysts - Comparison of 5-Minutes Dwell time Technique and 3-Minutes Dwell Time Technique**

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

INKEON YEO, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To compare long term follow-up treatment results of single-session sclerotherapy for renal cyst using 50% acetic acid 3-minute dwell technique with those using 50% acetic acid 5-minute dwell technique.

#### **METHODS AND MATERIALS**

Total 101 simple renal cysts of 97 patients (M:F = 43:54, mean age -  $63 \pm 12.8$  years) underwent single-session 50% acetic acid sclerotherapy using less than 5 minutes (35 cysts, Group I) or 3 minutes (66 cysts, Group II) dwell technique in our institution. An acetic acid volume corresponding to a 5 ~ 40% (mean percentage- 13%) of the aspirated cyst volume was injected into the cysts and removed in less than 5 minutes or 3 minutes with position changes. Follow-up examination was performed using ultrasound or CT images at 3 to 6-months intervals for a minimum of 1 year. All patients were retrospectively reviewed on the therapeutic response and complications. The response was classified as either complete remission (volume reduction, = 95%), partial remission (volume reduction, 50-95%), or failure (volume reduction, = 50%).

#### **RESULTS**

In 97 simple renal cysts, complete remission on follow-up was observed in 22 of 35 cysts (62.9%) in group I and 46 of 66 cysts (69.7%) in group II. The partial remission on follow-up was observed in 11 of 35 cysts (37.1%) in group I and 20 of 66 cysts (30.3%) in group II. There was no failure in both groups. There were no statistically significant differences in the complete remission and partial remission between the two groups. There was mild post procedure complication in 25 patients, but no major procedure related complication.

#### **CONCLUSION**

Single-session 50% acetic acid sclerotherapy for the treatment of simple renal cysts using less than 3 minutes dwell technique is an effective and safe therapeutic option for simple renal cyst. 50% acetic acid sclerotherapy with a 3 minutes dwell time, using a volume of about 10% of the aspirated volume, is sufficient for satisfactory results of simple renal cyst sclerotherapy when compared with 50% acetic acid sclerotherapy using 5 minutes dwell time.

#### **CLINICAL RELEVANCE/APPLICATION**

50% acetic acid sclerotherapy show higher complete remission rate than any other ethanol one session sclerotherapy and, also show acetic acid sclerotherapy with 3 minute dwell time is sufficient for complete remission of renal cysts.

### Quantification and Analysis of Radiation Dose from Fluoroscopically Guided Prostate Artery Embolization Procedures

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Rasha S. Makkia, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To quantify patient radiation exposure during PAE and provide radiometric data to inform clinical decision-making regarding the radiation-related deterministic and stochastic risks versus the relative benefits of PAE.

#### METHODS AND MATERIALS

121 PAE procedures were performed between 2018 and 2021 at Yale New Haven Hospital, CT. The collected patient data followed an IRB-approved protocol, including age, height, body weight, and metal implants or contrast in the bladder during the procedure. Dosimetric data included total procedure time, total fluoroscopy time, Cumulative-Air-Kerma (CAK), Kerma-Area-Product (KAP) from fluoroscopy, and total KAP. These dosimetric data were analyzed using Radimetrics software (Bayer HealthCare, NJ). As a surrogate for stochastic risk, the effective dose from each PAE was computed by multiplying the total KAP using a conversion factor of  $0.11\text{mSv.Gy}^{-1}\text{.cm}^{-2}$  derived from values in published literature. PAE effective doses were then compared to abdominal-pelvic CT exams for patients who had individual abdominal-pelvic CTs. The CT effective dose was calculated by multiplying the DLP using the standard conversion factor of  $0.015\text{mSv.Gy}^{-1}\text{.cm}^{-1}$ . To account for patient size, for each patient, a ratio was derived between the effective dose from PAE and that from abdominal-pelvic CT. To examine the likelihood of deterministic effects, peak skin dose (PSD) calculations were performed for PAE patients with a CAK greater than 3Gy using an in-house Matlab algorithm (MathWorks, MA).

#### RESULTS

The average PAE procedure and fluoroscopy took 150 minutes and 37.1 minutes, accordingly. KAP and CAK had a mean value of  $280\text{Gy.cm}^2$ , and  $2.145\text{Gy}$ . The average effective dose from PAE fluoroscopy was 30.8 mSv and the effective dose from CT was 9.1mSv. The average ratio was 4.1; however, patients with CTs had a higher average PAE dose than patients without CTs due to greater use of CBCT, DSA, and larger field sizes in earlier patients. PSD was calculated for any PAE exam with a CAK greater than 3Gy. 12 exams had a CAK between 3 and 4Gy, 6 had a CAK between 4 and 5Gy and only 2 had a CAK greater than 5Gy. The maximum PSD calculations were 4Gy and 4.1Gy. There were no deterministic complications reported within 90 days after PAE.

#### CONCLUSION

This quantification data helps provide a standard for which clinicians can draw accurate judgments regarding the risks of PAE and can provide a standard for interventionalists to compare their own procedural radiation dosages during PAE.

#### CLINICAL RELEVANCE/APPLICATION

Benign prostatic hyperplasia is a worldwide health problem that significantly impacts men's quality of life. When radiation safety guidelines are followed, it offers effective treatment with a low risk of deterministic or stochastic radiation-related injuries.

### Shear Wave Elastosonography Applied to Synovitis: A Preliminary Study

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Salvatore Marsico (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aims to evaluate the utility of shear wave elastosonography (SWE) to identify synovitis in patients who had a history of arthritis within the diagnosis of a defined rheumatological disease.

#### METHODS AND MATERIALS

We performed a B-mode and SWE (US) to a total number of 58 participants divided in 2 groups: group 1 included 29 patients with confirmed active wrist and/or hand synovitis; group 2 included 29 healthy volunteers without suspicion of synovitis. In a subset of patients (n=8), the joint count and the rest of the disease evaluation were performed to the elastosonography to study the correlation between the clinical and radiological findings.

#### RESULTS

The difference in both the mean maximum kPa value and the average joint kPa value was statistically significant between cases and controls: maximum kPa value cases  $38.14 \pm 35.08$  kPa, controls  $4.72 \pm 5.93$  kPa; average joint value cases  $29.77 \pm 26.07$ , controls  $4.17 \pm 5.22$ . The most frequent place to find joint effusion in both cases and controls was the dorsal radiocarpal joint: 41.4% of controls, mean kPa value of  $7.66 \pm 5.39$  kPa, 58.6% of cases, mean kPa value  $40.61 \pm 40.76$  kPa (p-value 0.004). kPa values correlated with disease activity measurements in the 8 patients clinically evaluated at the moment of the SWE.

#### CONCLUSION

SWE is a promising technique that may have a role in the diagnosis and assessment of synovial inflammatory activity.

#### CLINICAL RELEVANCE/APPLICATION

New semiquantitative ultrasound technique in the diagnosis and in monitoring of therapy of synovitis.

### Zero Time-to-Echo Imaging of the Hand and Wrist in Patients with Rheumatoid Arthritis: Comparison with Radiography and Conventional MRI using CT as Gold Standard

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Jun Tsukamoto, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Zero echo time (ZTE) imaging has been developed to detect signals from the objects with extremely short T2\* value, and this sequence can generate CT-like images from MRI after gray-scale inversion. The aim of this study is to compare ZTE imaging with radiography for the detection of hand and wrist bone erosions in patients with rheumatoid arthritis (RA), using CT as the reference method.

#### METHODS AND MATERIALS

The study was approved by the local ethics committee, and written consent was obtained from all patients. From December 2022 to April 2023, nine consecutive patients with RA were included in this prospective study. They underwent radiography, MRI at 3T (conventional T1-weighted and fat-suppressed T2-weighted imaging, and ZTE imaging), and CT of the bilateral hand and wrist on within 2 weeks. MRI evaluation was performed according to the Outcome Measures in Rheumatology Clinical Trials (OMERACT) recommendations. Two certificated radiologists evaluated the images from the three imaging modalities. Bone erosion on images was independently reviewed by the 2 certificated radiologists with a four-point scale (0; normal, 1; discrete erosion, 2; less than 50% of the joint surface, 3; more than 50% of the joint surface). The images were evaluated for bone erosion in 25 sites in each finger and wrist, including the distal radius, the distal ulna, the 8 carpal bones, the first through fifth bases of metacarpal bones, and the proximal and distal aspects of first through fifth metacarpophalangeal joints. One experienced musculoskeletal radiologist performed the CT evaluation and set the findings as gold standard.

#### RESULTS

With CT as the reference method for bone erosions, the sensitivity and specificity of plain radiography, conventional MRI, and ZTE were 51.6/95.3%, 71.1/90.4%, and 93.8/96.3%, respectively. Overall diagnostic performance was significantly better at ZTE than at radiography and conventional MRI images ( $P < .01$ ). Interobserver agreement on bone erosion assessment was excellent for ZTE imaging ( $\kappa$  value of 0.815) but was not excellent for radiography ( $\kappa$  value of 0.496) and conventional MRI ( $\kappa$  value of 0.648).

#### CONCLUSION

Zero time-to-echo imaging can provide reliable bone erosion assessment in RA patients.

#### CLINICAL RELEVANCE/APPLICATION

Zero time-to-echo imaging is superior to plain radiography and almost comparable to CT for the detection of bone erosion in RA patients. It can be readily incorporated into the clinical workflow in addition to conventional MRI.

### Ultra-high-resolution Photon-counting Detector CT Arthrography of the Ankle: A Feasibility Study

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Karsten S. Luetkens, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Assessing the stability of chondral lesions represents a crucial diagnostic imaging task in musculoskeletal imaging, as chondral delamination and subchondral pathologies may not be visible in direct arthroscopy but impact therapeutic concepts. This study was designed to investigate the image quality of ultra-high-resolution ankle arthrography employing photon-counting detector CT.

#### METHODS AND MATERIALS

A board-certified radiologist with nine years of experience in musculoskeletal imaging performed bilateral ankle arthrographies in all four cadaveric specimens using ultrasound for guidance. Bilateral arthrograms were acquired in four cadaveric specimens with full-dose (10 mGy) and low-dose (3 mGy) scan protocols. Three convolution kernels with different spatial frequencies were utilized for image reconstruction (?50; Br98: 39.0, Br84: 22.6, Br76: 16.5 lp/cm). Seven radiologists subjectively assessed image quality regarding the depiction of bone, hyaline cartilage, and ligaments. Additional quantitative assessment comprised the measurement of noise and computation of contrast-to-noise ratios (CNR).

#### RESULTS

While optimal depiction of bone tissue was achieved with the ultra-sharp Br98 kernel ( $p=0.043$ ), visualization of cartilage improved with lower modulation transfer functions at each dose level ( $p=0.014$ ). Interrater reliability was good to excellent for all assessed tissues (intraclass correlation coefficient = 0.805). Noise levels in subcutaneous fat decreased with reduced spatial frequency ( $p<0.001$ ). Notably, low-dose Br76 matched CNR of full-dose Br84 ( $p>0.999$ ) and superseded Br98 ( $p<0.001$ ) in all tissues. No dose-dependent difference was ascertained for any of the tissues with Br98 ( $p > 0.999$ ).

#### CONCLUSION

Based on the reported results, photon-counting detector CT arthrography of the ankle with ultra-high-resolution collimation offers stellar image quality and tissue assessability. While bone depiction was found to be superior in combination with an ultra-sharp convolution kernel, soft tissue evaluation benefited from employing lower spatial frequency.

#### CLINICAL RELEVANCE/APPLICATION

Photon-counting detector CT arthrography is feasible and allows for depicting even minute anatomy at low radiation dose. The inherent advantages regarding imaging of thin layers of hyaline cartilage ought to be pursued further.

S3A-SPMK-6

### Frequency of Peroneal Compartment Pathology in a Large Series of Ankle MRIs from a Tertiary Care County US Hospital: Imaging-based Epidemiological Study

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Muhammad R. Akram, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Peroneal compartment pathology is a frequently misdiagnosed finding or underdiagnosed as simple ankle ligament sprains in patients presenting to the healthcare system with ankle injuries. High-resolution magnetic resonance imaging allows timely identification of these injuries for outlining appropriate treatment. However, these lesions have been studied in only a few small case series, convenient samples, or review articles. The aim of this study was to elucidate the frequency of peroneal compartment pathology in a large series of patients presenting for ankle MRIs with ankle pain and/or injury in our tertiary care county system with the hypothesis that peroneal lesions are a frequent finding.

#### METHODS AND MATERIALS

A consecutive series of 373 patients with suspected ankle internal derangement at a tertiary care county hospital (ages 13-87 years, all genders) were included. All had undergone 3 Tesla ankle MR imaging with standardized institutional MR imaging protocols. The structured reports were data-mined, and all scans were re-reviewed by a fellowship-trained musculoskeletal radiologist. Any scans performed for tumors or infections were excluded. The scans were re-analyzed for peroneal longus (PL) and peroneal brevis (PB) tenosynovitis and tendinopathy using previously described criteria for pathology in the literature. Descriptive statistics were performed.

#### RESULTS

There were 404 MRIs from 373 patients, with 292 MRIs (72.3%) from 267 females and 112 MRIs (27.7%) from 106 males. Only 98 (24.3%) MRIs had normal peroneal compartments, and 306 MRIs (75.7%) had ankles with peroneal findings. There were 51 (12.6%) cases of PB tenosynovitis, 57 (14.1%) cases of PL tenosynovitis, 148 (36.6%) cases of PB tendinopathy, 239 (59.2%) cases of PL tendinopathy, 95 (23.5%) partial PB tendon tears, 8 (2.0%) partial PL tendon tears, 2 (0.5%) complete PB tendon tears, and 1 (0.2%) complete PL tendon tear. Peroneal longus tendinopathy was the most common finding.

#### CONCLUSION

Peroneal compartment pathology is frequent on high-resolution 3T ankle MRIs performed for internal derangements.

#### CLINICAL RELEVANCE/APPLICATION

The ankle MRI reader should pay close attention to peroneal compartment lesions while evaluating for ankle derangement, as these lesions are frequent.

### Clinical Application of a Deep Learning Model for Osteoporosis Screening using Chest X-rays Taken During Lung Cancer Screening

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

YOICHI SATO, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The number of patients suffering from age-related osteoporosis is increasing worldwide. In Japan, osteoporosis screening is conducted in municipalities throughout the country for early detection and treatment, but the screening uptake rate remains at around 5%. To address this issue, we developed a deep learning model to test for osteoporosis from chest X-rays as a new screening method. In Japan, approximately 40 million people undergo lung cancer screening annually, which includes chest X-rays. We focused on this point and conducted a demonstration experiment, believing that it would be possible to screen a large number of citizens for osteoporosis by simultaneously assessing osteoporosis using chest X-rays taken during lung cancer screening.

#### METHODS AND MATERIALS

The demonstration was conducted in a medium-sized city in Japan with a population of 80,000 from Apr 2022 to Apr 2023. In this city, a medical association was contracted by the local government to conduct lung cancer screening. The examinees had chest X-rays taken at 25 clinics in the city. The chest X-rays are then sent to the medical association's health checkup center for secondary reading. We installed an AI algorithm at the center and performed AI analysis on the chest X-rays of the examinees who had given their consent in advance. The examinees who were found to be in need of further examination (YAM<80%) visited an orthopedic hospital in the city and underwent a bone density test using the DEXA method. Based on the examination and test results, medication was started for those examinees who needed therapeutic intervention. The study obtained the number of people who underwent lung cancer screening, the number of people who consented to AI analysis, the number of people who required inspection, the number of people who visited orthopaedic clinics, and the number of people diagnosed and treated for osteoporosis.

#### RESULTS

5,290 patients underwent lung cancer screening. Of these, 3,324 patients consented to AI analysis, excluding those already undergoing osteoporosis treatment. Of these, 1,848 patients required further examination. After examination and DEXA, 497 patients were diagnosed with osteoporosis, and treatment was initiated.

#### CONCLUSION

The study suggested the usefulness of screening for osteoporosis using chest X-rays taken during lung cancer screening.

#### CLINICAL RELEVANCE/APPLICATION

The conventional osteoporosis screening examined 185 individuals yearly. By utilizing chest radiographs for screening, 3,324 people could be screened, roughly 18 times more. This method detected about 497 osteoporosis patients, enabling treatment initiation. It's estimated that this approach could prevent 16 hip fractures and reduce medical and nursing care costs by about 29 million yen.

### Application of a Deep Learning Algorithm in Detection of Hardware Complications for the Post-Operative Hip

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Jin Rong Tan, MD, FRCR (*Presenter*) Nothing to Disclose

#### PURPOSE

The most common mechanical failure in the internal fixation of trochanteric hip fractures is the cutout of the sliding screw through the femoral head, with the incidence ranging from 0 to 16.5%. Radiography remains the mainstay for evaluation, both in the immediate postoperative period and at long-term follow-up. The clinical and radiological progression of hardware complications including cutout is often insidious, and can be missed especially in limited resource settings. There is relatively limited literature on the application of deep learning to assess hardware complications on radiographs. Hence, we aim to evaluate the performance of a deep convolutional neural network (DCNN) in detecting and localising implant cutout on plain frontal pelvic radiographs.

#### METHODS AND MATERIALS

A DCNN was developed using 32,152 pelvic radiographs containing fixation hardware acquired from the emergency department and orthopaedic clinics between January 2016 and December 2020, of which 24,114 and 8,038 were allocated for training (75%) and validation (25%) sets respectively. Presence of cutout was defined as protrusion of the fixation hardware beyond the cortical margins. To determine ground truth labels (cutout present or absent), all radiographs were individually read by 2 board-certified consultant musculoskeletal subspecialty radiologists blinded to the accompanying radiology reports. In doubtful cases, the accompanying report and all imaging performed in the following 6 months were reviewed. Final decision was made by consensus between the 2 musculoskeletal radiologists. Algorithm performance was evaluated with a hold-out test dataset of 8,039 radiographs of which 53 (0.66%) were positive for cutout. The authors also used the visualization algorithm gradient-weighted class activation mapping (Grad-CAM) to assess localization accuracy.

#### RESULTS

The algorithm achieved an accuracy of 99.5%, a sensitivity of 83%, a specificity of 99.6%, and an AUC of 0.992 for identifying implant cutout. The visualization algorithm showed an accuracy of 25%. Of the 44 true positive cases accurately predicted, there were 11 (25%) instances where the model correctly identified an activation site.

#### CONCLUSION

A DCNN can detect implant cutout on PXR with a high accuracy and might assist clinicians to assess the presence of post-operative hardware complications including implant cutout. However, the visualization algorithm is unable to accurately localize the site of cutout; this is work in progress at time of abstract submission

#### CLINICAL RELEVANCE/APPLICATION

A DCNN can detect implant cutout on PXR with a high accuracy and might assist clinicians to assess the presence of post-operative hardware complications including implant cutout.

### Metabolic Outcomes of Aging and Obesity: A Longitudinal Study of the Dallas Heart Study Cohort

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Parker Davis, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aims to examine the metabolic risk factors in the longitudinal Dallas Heart Study (DHS) cohort. The baseline exam (DHS1) was conducted in 1999-2000, and the current 3rd phase exam (DHS3) has been enrolling since 2020.

#### METHODS AND MATERIALS

Subjects underwent a multi-2D axial T2-weighted spin-echo abdominal MRI (10mm axial section) in DHS1 on Philips 1.5T Intera at the baseline exam and a 3D volumetric T1-weighted gradient-echo whole-body MRI (5mm axial section) in DHS3 on Siemens 3T Prisma. Based on the DHS1 data, manual fat segmentation was previously completed on a single slice at L2-L3 measuring subcutaneous (SAT) and visceral (VAT) cross-sectional areas. On the DHS3 images, fat segmentations were performed on the same slice location corresponding with the subject's DHS1 segmentation. Changes in the segmented SAT and VAT areas between DHS1 and DHS3 were calculated. Subjects' height, weight, and serum laboratory values (lipids, cholesterol, glucose, and insulin) were collected for DHS1 and -3 exams, from which metabolic syndrome (MetS) risk factors were recorded (waist circumference  $\geq 88$ in for women,  $\geq 102$ in for men; blood pressure  $\geq 130/85$ ; LDL  $\geq 130$ ; HDL  $\leq 50$  for women,  $\leq 40$  for men; total cholesterol  $\geq 200$ ; triglycerides  $\geq 150$ ; fasting glucose  $\geq 100$ ; HOMA-IR  $\geq 2.73$ ) for both time points, and metabolic health was categorized as unhealthy ( $\geq 3$  risk factors) or healthy ( $\leq 3$  risk factors). The association between metabolic health and abdominal adiposity (SAT and VAT) was assessed using logistic regression, adjusting for age and sex as covariates.

#### RESULTS

192 subjects from the original DHS1 cohort have thus far returned for DHS3 examination. The median age of this interim cohort is 64 years (43 years at baseline). Over the 21 years, the median weight gain was +3.2 [interquartile range, -3.3, +9.3]kg, BMI gain +1.3 [-0.6, +3.6]kg/m<sup>2</sup>, SAT change +82 [18, 154]cm<sup>2</sup>, VAT change +33 [-9, +69]cm<sup>2</sup>. The prevalence of MetS increased from 53.6% to 63.3%, with 53.9% of previously metabolically healthy subjects becoming metabolically unhealthy in the interim, whereas 29.1% of previously metabolically unhealthy subjects became metabolically healthy. After adjustment for age and sex, VAT, but not SAT, was consistently associated with MetS over 20 years of aging. Gain in VAT was also associated with interval development of MetS in previously metabolically healthy subjects.

#### CONCLUSION

Visceral fat, rather than subcutaneous fat, is consistently associated with MetS through aging, and the gain in visceral fat is associated with the development of MetS.

#### CLINICAL RELEVANCE/APPLICATION

Our preliminary finding in this 20-year longitudinal cohort further strengthens the evidence that visceral fat is implicated in metabolic health.

### Clinical Impact of Digital PET/CT Compared to Conventional PET/CT in Patients with Malignant Tumor for Initial Staging

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Naoto Kawaguchi, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Digital PET/CT (dPET) systems have improved the detection of small lesions by increasing spatial and temporal resolution and have the potential to allow for accurate staging in patients with malignant tumor. The purpose of this study is to compare <sup>18</sup>F-fluorodeoxyglucose (FDG) uptake of lesions and the diagnostic performance for initial disease staging of the dPET with conventional PET/CT (cPET).

#### METHODS AND MATERIALS

Between April and August 2020, 60 patients (mean age, 66±13 years; 31 males) with malignant tumors underwent a single FDG injection and both dPET and conventional cPET with a randomized scan order. We measured the maximum standardized uptake values (SUVmax) in up to 5 FDG-positive lesions per patients and compared them between the two scanners. Furthermore, two experienced readers independently diagnosed the initial disease staging using the TNM score (The eighth edition of the Union for International Cancer Control) or Lugano classification on both PET imaging. Cases of inconsistency between the two readers were finally determined by the third experienced reader. The final staging results for the two PET modalities were compared with the pathological diagnosis. The institutional ethics committee approved this study protocol in accordance with the ethical guidelines of the Declaration of Helsinki, and all patients provided informed consent.

#### RESULTS

One hundred and twenty-three lesions were analyzed. 14 lesions could only be measured only with dPET. In the remaining 109 lesions, SUVmax was significantly higher on the dPET compared to the cPET (12.0±7.8 vs. 8.5±7.0, p<0.01). Especially in 36 lesions less than 10 mm in diameter, the SUVmax with the dPET was higher in all lesions. 8 of the 60 cases showed differences in staging between the two PET modalities. dPET detected new lymph node metastases in five cases and bone metastasis in one case compared to cPET, four were true positives and two were false positives. Otherwise, the N-factor was changed in two cases on dPET compared to cPET, but one was true negative, and one could not be judged pathologically.

#### CONCLUSION

Our study showed that the dPET can better detect small lesions compared to cPET. dPET can have an impact on the diagnosis of metastasis in the initial staging of malignant tumor compared to cPET.

#### CLINICAL RELEVANCE/APPLICATION

New digital PET/CT can have a big impact on the diagnosis of metastasis in the initial staging of malignant tumor.

### **Increasing Cost-effectiveness of CT-based Mobile Stroke Units in Germany: A Model-based Economic Analysis**

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Johann S. Rink, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To analyze the design of Computed Tomography (CT) based Mobile Stroke Unit (MSU) programs and operating modes in order to identify major determinants and cut-offs that help improve cost-effectiveness and enable large-scale implementation of MSUs.

#### **METHODS AND MATERIALS**

Costs of different possible operating modes, varying operating hours including weekend and non-weekend coverage, and personnel were simulated for the German healthcare system. Ischemic stroke incidence, circadian distribution, rates of alternative diagnoses and stroke mimics were included as well as missed cases to model case coverage and patient-level costs in acute stroke care. Based on internationally reported stroke outcomes, a 5-year Markov-Model was used to analyze cost-effectiveness outcomes for varying catchment zone populations.

#### **RESULTS**

For a catchment zone of 400,000 inhabitants, the 7-day/16-hour MSU coverage resulted in the lowest cost of MSU deployment per ischemic stroke (USD 5,667) whereas the 7-day/24-hour model caused the highest costs (USD 8,285). Comparing stroke care delivered by MSU to regular emergency medical services, MSU achieved an incremental 0.06 quality-adjusted life years (QALY) on average, with an incremental cost-effectiveness ratio of USD 37,348 per QALY. Sensitivity analyses revealed that a catchment zone population below 400,000 inhabitants together with the effect of missing stroke cases at dispatch significantly increased patient-level costs of MSU care.

#### **CONCLUSION**

When setting up prospective MSU programs, cost-effectiveness can be addressed by taking into account major determinants of MSU operation: For the German healthcare system, the catchment zone should cover at least 400,000 inhabitants and operating modes should include weekend coverage and 12 to 16 hour daytime coverage. Measures to reduce the rate of missed strokes are advised.

#### **CLINICAL RELEVANCE/APPLICATION**

The economic evaluation of MSU programs aiming at identifying major determinants and thresholds could optimize efficient resource allocation and maximize MSU cost-effectiveness.

### Economic Impact in the MRI Department using Artificial Intelligence in MRI Acquisitions

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Patricia M. Carrascosa, MD, PhD (*Presenter*) Speakers Bureau, General Electric Company

#### PURPOSE

The objective of this work is to project the economic impact of the use of Artificial Intelligence (AI) in an MRI scanner of our institution that has a high demand of scheduled studies between 8 AM to 8 PM. We previously performed an optimization of protocols and validated the new algorithm with AI in terms of image quality and diagnostic accuracy versus conventional studies determining the new time duration of the studies.

#### METHODS AND MATERIALS

During one month we worked with AI system (AIR Recon DL, GE) in two 3T MRI scanners (Signa Architect; GE) in order to obtain the best sequences in terms of image quality, signal to noise and time duration of the studies. After finishing that phase we performed a research comparing the new length time for the sequences and agenda times for each study type, image quality and diagnostic accuracy between two experienced observers to analyzed AI and conventional studies of the same patient respectively. Results have shown no differences regarding diagnosis and image quality but with a significant reduction in scanning times. With that information we will project the economic impact of using AI system in the two scanners per month. The time reduction of the studies varied according to the region. We calculated according to the normal distribution of studies the total minutes regarding each type, we projected the new duration time applying AI, the gained difference in minutes and the additional studies that could be carried out. We calculated the increment in the percentage regarding the number of studies performed in the same time range and also in relation to the total number of patients.

#### RESULTS

The most required studies at our centers were selected for the projection (knee, spine and brain MRI scans). Both scanning times and the assigned agenda time were reduced significantly using AI. The mean scan time without AI technology was 10.3 minutes, while using AI technology was 5.7 minutes. The mean assigned agenda time without AI technology was 16.6 minutes, while using AI technology was 10 minutes. The time reduction in the projected studies allowed to be able to perform a 638,5 more studies in both scanners in the same time that only 1111 were done. This corresponds to an increment of 57,64% .The global impact regarding the total scanners production would be a 36,6%.

#### CONCLUSION

AI in MR is an excellent opportunity to increment the number of studies in centers with high demand and delayed accessibility .In this projection selecting only the more frequent studies required we could project an increment of 35 % in our monthly billing.

#### CLINICAL RELEVANCE/APPLICATION

Artificial intelligence in MRI scan opens new horizons in terms of image quality, patients experience and cost effectiveness of the MRI department

### Testing the Ability of ChatGPT to Generate Differential Diagnoses from Transcribed Radiological Findings in Chest and Cardiac Imaging

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Shawn H. Sun, MD, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the accuracy and reliability of ChatGPT3.5 and ChatGPT4 in producing a differential diagnosis from transcribed radiological findings of specific chest and cardiac radiology cases.

#### METHODS AND MATERIALS

A sample of 52 cases from adult and pediatric chest and cardiac imaging were evaluated. Cases were selected from a radiology textbook, from which the answers were used as the gold standard. The case images and history were converted into standardized prompts that contained purely descriptive language of the cases and a query for the most likely diagnosis, top three differential diagnoses, and the corresponding explanations and references from the medical literature. These prompts were fed into the ChatGPT3.5 and ChatGPT4 algorithms. Generated responses were analyzed for accuracy by comparison with the original literature and reliability through manual verification of the generated explanations and citations. The top 1 accuracy and the top 3 accuracy were defined as the percentage of generated responses that matched the original diagnosis and the complete differential provided by the original literature. An additional differential diagnosis score was defined as the proportion of differentials that matched the original literature's answers for each case. Comparisons were made between the results of the two algorithms using a one-tailed two proportion z-test method.

#### RESULTS

The top 1 accuracy and top 3 accuracy, for ChatGPT3.5 versus ChatGPT4 were 57.7% compared to 69.2% ( $p=0.11$ ) and 11.5% compared to 15.4% ( $p=0.28$ ), respectively. The average differential diagnosis score of ChatGPT3.5 versus ChatGPT4 was 48.1% compared to 55.8% ( $p=0.21$ ). ChatGPT3.5 and ChatGPT4 hallucinated 34.2% versus 9.6% ( $p=0.001$ ) of the references provided and generated 10 total false statements versus 4 total false statements, respectively.

#### CONCLUSION

The two generations of ChatGPT were able to generate a differential diagnosis for prompts containing descriptive radiological findings. The contents of these responses matched the expert literature from which the cases originated a minority of the time, though a non-statistically significant improvement was made in the accuracy categories from 3.5 to the 4th generation algorithm. The well-known hallucination effect was encountered more commonly in citations produced than in statements made by the algorithm, both of which improved with the newest generation.

#### CLINICAL RELEVANCE/APPLICATION

ChatGPT and Large Language Models (LLM) have a large potential to impact clinical and educational medicine. Knowledge of the accuracy and erroneous possibilities of these algorithms will provide a better understanding of the limitations of these new tools.

### Causal Associations of Genetically Determined Tinnitus with Neuroimaging Traits: Evidence from a Mendelian Randomization Study

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Jing Sun, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Potential reverse causality and unmeasured confounding factors are common biases in previous studies of the relationship between tinnitus and neuroanatomical features. Additionally, the causal association between neuroimaging features and the presence of tinnitus is unclear. The aim of this study was to investigate the causal role of tinnitus in the alteration of brain volumetric measures using Mendelian randomization (MR).

#### METHODS AND MATERIALS

Summary-level data from a genome-wide association study (GWAS) of tinnitus were derived from the UK Biobank ( $n = 117,882$ ). GWAS summary statistics for total brain volume, white and gray matter volume and cerebrospinal fluid volume were also obtained ( $n = 33,224$ ). A bidirectional MR analysis was performed to investigate the causal relationship between tinnitus and neuroanatomical features.

#### RESULTS

Genetic susceptibility to tinnitus was causally associated with increased white matter volume (odds ratio [OR] = 2.36, 95% confidence interval [CI] 1.03-5.39,  $p = 0.04$ ) and total brain volume (OR = 2.39, 95% CI 1.05-5.46,  $p = 0.04$ ) but inversely associated with cerebrospinal fluid volume (OR = 0.36, 95% CI 0.16-0.83,  $p = 0.02$ ). However, no causal effect of total brain volume, white matter volume, gray matter volume, or cerebrospinal fluid volume on the presence of tinnitus was detected in the reverse MR study.

#### CONCLUSION

The genetically predicted risk of tinnitus was causally associated with higher white matter volume and total brain volume, independent of any confounding factors, while neuroanatomical features were not causally associated with the presence of tinnitus. Our findings provide evidence supporting the hypothesis that tinnitus has a neurodevelopmental origin at the genetic level.

#### CLINICAL RELEVANCE/APPLICATION

Our findings provide evidence supporting the hypothesis that tinnitus has a neurodevelopmental origin at the genetic level, further elucidating the underlying pathophysiological mechanisms of tinnitus-related brain anatomical impairment.

### Improving Image Quality of Skull Base with Volume High Definition Reconstruction in a Wide-detector CT System

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Yanan Zhu (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the image quality improvement for the skull base with a volume high definition (VHD) reconstruction algorithm on a 16cm wide-detector 256-row CT.

#### METHODS AND MATERIALS

Prospectively enrolled 40 adults (Group 1) for non-enhanced head CT on a 16cm wide-detector 256-row Revolution CT scanner. The CT numbers and their standard deviation (SD) of Medulla Oblongata, cerebellum, brain stem, basal frontal lobe and centrum ovale (used as background) were measured to calculate signal to noise ratio (SNR) and artifact index (AI):  $AI = \sqrt{SD^2(ROI) - SD^2(\text{centrum ovale})}$ . These values were compared with those of 40 adults in Group 2 who underwent a non-enhanced head CT on a 64-row VCT. All subjects were scanned with a protocol of 120 kVp, and 1.0s rotation time. The tube currents were adjusted to have similar CT dose index (CTDI) for the two systems.

#### RESULTS

There was no statistical difference in the age, thickness of occipital tuberosity, anteroposterior or trans diameters between the two groups. Compared with 64-row CT, the image noise (in HU) with the 256-row CT was reduced by 27% ( $4.39 \pm 0.68$  vs.  $6.00 \pm 1.10$ ) at the Medulla Oblongata, 24% ( $4.48 \pm 0.51$  vs.  $5.86 \pm 0.57$ ) at cerebellum, 33% ( $4.14 \pm 0.51$  vs.  $6.17 \pm 0.74$ ) at brain stem, 39% ( $3.84 \pm 0.58$  vs.  $6.30 \pm 1.19$ ) at the basal frontal lobe and 28% ( $3.16 \pm 0.37$  vs.  $4.36 \pm 0.42$ ) at centrum ovale. This resulted in an increase of 43%, 42%, 76% and 65% in SNR in the four regions, respectively. In addition, the artifacts index was significantly reduced with 256-row CT by 25% ( $2.95 \pm 0.95$  vs.  $3.93 \pm 1.61$ ) at Medulla Oblongata, 20% ( $3.05 \pm 0.93$  vs.  $3.83 \pm 0.88$ ) at cerebellum, 40% ( $2.54 \pm 0.92$  vs.  $4.26 \pm 1.14$ ) at brain stem, and 54% ( $2.00 \pm 1.14$  vs.  $4.33 \pm 1.83$ ) at the basal frontal lobe.

#### CONCLUSION

The CT image quality of the skull base in terms of noise and artifacts was significantly improved on a 256-row wide-detector CT with VHD reconstruction algorithm, compared with a 64-row system at similar radiation dose.

#### CLINICAL RELEVANCE/APPLICATION

Improved images of the skull base can be obtained on a wide-detector CT with VHD to overcome physical challenges such as cone beam and scattering, when keeping similar dose to 64-row CT.

S3A-SPNR-11

### Geniculate Ganglion Diverticulum: A Novel MRI Finding in Patient with Idiopathic Intracranial Hypertension

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Ahmed Abdelmonem, MD, MBBS (*Presenter*) Nothing to Disclose

#### PURPOSE

While patients with idiopathic intracranial hypertension (IIH) typically present with headache and/or visual disturbance, pulse-synchronous tinnitus (PST) and hearing loss can be the primary manifestations of this condition in a group of patients. The correct diagnosis for this group can be delayed. Although several MRI signs have been previously described to be associated with IIH, none have been proven to have a high positive predictive value (PPV). In this study, we tested the hypothesis that the presence of the geniculate ganglion diverticulum (GD) is a novel marker for the detection of IIH.

#### METHODS AND MATERIALS

This is an IRB-approved single institution retrospective observational study. Brain MRI exams of patients referred by Otolaryngology division over the period of 10 years were reviewed. 400 MRI exams fulfilling inclusion and exclusion criteria were screened for presence of GD by two Neuroradiology fellows independently. In cases of discrepancy in image interpretation, an agreement was reached by reviewing images jointly. A matched control group of cases without GD was compiled. Brain MRI studies of all patients in this study were reviewed for presence of an "empty" sella appearance (ES), a known MRI sign of IIH. Electronic medical records of patients in this study were reviewed for presence of clinical manifestations of IIH. Receiver operator characteristic (ROC) curves were generated to estimate accuracy of each covariate in diagnosing IIH. Area under each ROC curve (AUC) was calculated to identify an accurate prognostic covariate. Statistical analysis was done using R programming language V 4.2.2.

#### RESULTS

GD was visualized in MRI exams of 41 patients. GD was not present in the MRI exams of 359 patients. 61 patients were randomly selected from group of 359 patients that did not have GD. A total of 102 patients were included in this study. Studied groups had no significant differences in terms of age, gender, and BMI. GD and ES have a statistically significant correlation with IIH (P-value: < 0.001). There was no correlation between PST and GD (P-value: 0.83). Presence of unilateral or bilateral GD has a similar correlation with IIH (P-value: < 0.001). AUC based on GD for predicting IIH was 0.84 (0.79- 0.89) and based on ES was 0.93 (0.89- 0.96). Negative predictive value of both GD and ES for IIH was 100%. PPV of GD for IIH was 31% and this value for ES was 52%.

#### CONCLUSION

There was a statistically significant correlation between the presence of GD and the presence of IIH. There was no statistically significant correlation between the presence of GD and the presence of PST.

#### CLINICAL RELEVANCE/APPLICATION

The presence of GD should raise the possibility of IIH, particularly in patients presenting with otologic manifestations such as PST and low-frequency hearing loss.

### Treatment Response Prediction in Major Depressive Disorder using Brain Magnetic Resonance Imaging: A Systematic Review and Meta-analysis

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Fenghua Long (*Presenter*) Nothing to Disclose

#### PURPOSE

To quantify the value of brain magnetic resonance imaging (MRI) in predicting major depressive disorder (MDD) treatment efficacy and to assess performance variations among interventions and biomarkers.

#### METHODS AND MATERIALS

We searched eligible studies in PubMed, Embase, Web of Science, and Science Direct databases before March 22, 2023, using keywords "depress\*", "major depress\*", "MDD", "treatment outcome", "remission", "response", and "MRI". Information including individuals as responders/remitters or non-responders/non-remitters, sensitivity, and specificity were extracted. Logarithm of diagnostic odds ratios [log(DOR)] was summarized, and forest plot was drawn. Sensitivity and specificity were conducted using Reitsma's random effect model. Area under curve (AUC) of summary receiver operating characteristic (SROC) curve was calculated. We conducted Deek's funnel plot asymmetry test to evaluate impact of publication bias. Subgroup analyses were conducted based on MRI modalities (structural MRI [sMRI], resting-state functional MRI [rs-fMRI], task-based fMRI [tb-fMRI]) and interventions (antidepressant and electroconvulsive therapy [ECT]). Antidepressants were subdivided into selective serotonin reuptake inhibitors (SSRI) and mixed medication groups. Meta-regression was conducted among subgroups.

#### RESULTS

We included 44 studies with 2623 MDD participants. Overall, the SROC AUC was 0.875, sensitivity was 77.1%, specificity was 74.1%, and log(DOR) was 2.381. Deek's test indicated a negative correlation between effective sample size and log(DOR) ( $P = 0.008$ ). Rs-fMRI subgroup had higher predictive performance (79.3% sensitivity, 78.2% specificity, AUC 0.891) than tb-fMRI subgroup (74.9% sensitivity, 68.9% specificity, AUC 0.854) in terms of specificity in predicting treatment efficacy ( $P = 0.01$ ). No significant difference was found between sMRI and other modalities. No significant predicting differences were found in antidepressants and ECT, or among ECT, SSRI, and mixed group. Brain biomarkers located in limbic system and frontal were more frequently revealed contributing to prediction in antidepressant subgroup, such as functional connectivity between amygdala and anterior cingulate cortex, while those for ECT were often located in limbic system.

#### CONCLUSION

Brain MRI has potential to predict MDD treatment efficacy, with rs-fMRI showing higher predictive performance. No significant difference were found between different interventions, but brain biomarkers located in limbic system and frontal lobe may provide clinical relevance.

#### CLINICAL RELEVANCE/APPLICATION

Brain MRI biomarkers can predict treatment efficacy of MDD, reducing the financial burden, time of trial, and poor prognosis for patients.

S3A-SPNR-14

### Comparative Analysis of Normative Brain Structural Volumes Between Singapore (SG) and Caucasian Population

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Chi Long Ho, MD, FRCR (*Presenter*) Nothing to Disclose

#### PURPOSE

Structural brain volumes vary due to differences in age, gender [males(M), females(F)], geographical location and ethnicity. Currently, MNI is most widely used brain template but it is limited to young/healthy Western population and not representative of other populations. We aim to compare differences between SG Chinese and Caucasian (Cau) brain volumes to address the need for age, gender-and-ethnicity-specific brain templates for accurate stereotactic standardization across structural brains from different individuals. Our aim is also to build a brain volumetry database for SG Chinese population (for now), which is currently lacking in Singapore.

#### METHODS AND MATERIALS

Retrospective T1W MPRAGE brain (N:248) gathered from Parkinson's Progression Markers Initiative (PPMI-Caucasian) database and SG data (N:360) obtained from Sengkang General Hospital. FastSurfer (v2.0.4) used for brain segmentation into 21 regions (some left and right regions combined); brain volumes were normalized using total intracranial volume. Subjects divided into 5 age-groups: 31-40, 41-50, 51-60, 61-70, 71-80 years. If > 2 outliers were present, subjects were removed while the rest of outliers imputed with median (age-and-gender-matched). Wilcoxon tests (Bonferroni corrected) used for comparisons between SG and Cau.

#### RESULTS

In 41-50 age-group, SG(M) have significantly greater cerebral white-matter than Cau(M), but the reversed is true for lateral ventricular volumes, while SG(F) have greater thalamus than Cau(F). SG(M+F) 51-60 age-group have significantly greater 3rd ventricle while SG(M) 71-80 age-group have greater inferior lateral ventricle and CSF compared to Cau(M). In SG 41-50 age-group, M have significantly smaller caudate, pallidum, sub-cortical gray matter, cortex, cerebellum white matter, corpus callosum, cerebellum cortex, total gray matter, hippocampus, putamen, and thalamus than F. In SG 51-60 age-group, M have significantly greater 3rd ventricles than F while reversed is true for cerebellum white matter. In SG 71-80 age-group, M have significantly smaller caudate than F.

#### CONCLUSION

There are differences in brain structure/volumes between SG and Cau across ages and gender. Building an age, gender-and-population-specific brain volumetry database is paramount to ensure accurate comparison and greater accuracy during brain registration, especially if comparison to neurological diseased states has to be made.

#### CLINICAL RELEVANCE/APPLICATION

Normative brain volumetry database for specific age-group, gender and ethnicity ensures reliable differentiation of healthy from neurological diseased brains for early diagnosis and interventions.

### Brain Functional Connectivity Alterations in the Depressed Adolescents with Suicide Behaviors

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Wei Peng (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate abnormalities of brain functional connectivity (FC) in both gray matter (GM) and white matter (WM) of depressed adolescents with suicide behaviors.

#### METHODS AND MATERIALS

Participants included 38 depressed adolescents with suicide behaviors (SA) and 28 healthy control (HC) subjects. FC differences in both gray and white matters between the two groups were identified at whole brain level with FDR corrected, based on resting-state blood oxygenation level-dependent signals. Correlation analyses were further conducted to explore the relationships between FCs and cognitive ability reflected by Wisconsin card sorting test.

#### RESULTS

Age and gender were well matched between two groups (SA mean age =14.8, HC mean age =15.0; 6males and 32 females in SA, 8 males and 20 females in HC). Compared to HC, SA group presented lower FCs in left orbitofrontal area-middle cerebellar peduncle (GM10WM22,  $t=5.43$ ), left orbitofrontal area-right superior cerebellar peduncle (GM10WM45,  $t=5.28$ ), left orbitofrontal area-right corticospinal tract (GM10WM48,  $t=5.18$ ), left ventral posterior cingulate cortex-left sagittal stratum (GM18GM13,  $t=4.47$ ), right ventral posterior cingulate cortex-left sagittal stratum (GM65WM13,  $t=4.55$ ), right associative visual cortex-left sagittal stratum (GM69WM13,  $t=3.57$ ), right primary visual cortex-left sagittal stratum (GM71WM13,  $t=4.79$ ), right superior temporal gyrus-left internal capsule (GM66WM8,  $t=4.00$ ), left middle temporal gyrus-left superior corona radiata (GM16WM10,  $t=6.91$ ), right anterior prefrontal cortex-right tapetum (GM73WM28,  $t=3.56$ ), left cingulate gyrus-right tapetum (WM15WM28,  $t=3.47$ ), and left orbitofrontal area-right tapetum (GM10WM28,  $t=4.95$ ). Correlation analyses further revealed that, FCs in GM18WM13 and GM65WM13 were positively associated with the percentage of correct response and negatively correlated with the perseverative response; FC in GM18WM13 was negatively associated with the percentage of perseverative errors; FC in GM71WM13 was positively associated with the percentage of correct response, and negatively associated with the perseverative response and the percentage of perseverative errors; FC in GM69WM13 was negatively correlated with the perseverative response and the percentage of perseverative errors.

#### CONCLUSION

This study identified reduced FCs in essential brain areas of depressed adolescents with suicide behaviors, mainly located in the default mode network and visual network, which was related with impaired cognition.

#### CLINICAL RELEVANCE/APPLICATION

The findings suggested the pathophysiology of suicide behaviors in depressed adolescents and might imply targeted brain areas for future treatment of suicide.

Printed on: 08/22/24

S3A-SPNR-3

### Concurrent Structural and Perfusion Changes in the Brain in Migraineurs with Patent Foramen Ovale: A Perfusion Functional Magnetic Resonance Imaging Study

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Xiangcao Li, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the structural and perfusion alterations in the brain and their neural mechanisms in migraineurs with patent foramen ovale (PFO) by jointly applying magnetic resonance imaging in both structural and perfusion modalities.

#### METHODS AND MATERIALS

Participants included migraineurs with PFO (n=20) and healthy controls (n=28), matched for age and gender. MRI data acquisition for all subjects was performed on a GE Discovery MR750W 3.0T. Scans were performed during the interictal period of headache attacks in patients. The scanned sequences included T1 Flair, T2 Flair, T2 Propeller, 3D T1 Bravo, 3D pcASL sequences. Magnetic resonance image preprocessing and statistical analysis were performed on SPM8, SPM12, CAT12 in MATLAB 2018b. CAT12 and BrainNetViewer software were used to present the results.

#### RESULTS

1. There was no statistical difference between the two groups of subjects in terms of gender and age composition ( $P > 0.05$ ). 2. VBM analysis was performed using total intracranial volume (TIV), gender, and age as covariates. The gray matter density was found to be reduced in the midbrain and the precuneus in the left inferior temporal gyrus, left middle temporal gyrus, left middle occipital gyrus, left lingual gyrus, left inferior occipital gyrus, and left hippocampus in the patient group ( $P > 0.05$ ). 3. SBM analysis was performed using age and gender as covariates. The depth of the sulcus in the insula, superior temporal gyrus, inferior frontal gyrus triangle, temporal pole, lateral prefrontal cortex, internal olfactory cortex, lingual gyrus, hippocampal gyrus, and talar parietal gyrus was found to be reduced in the patient group. The gyrification was reduced in the lateral occipital lobe, superior parietal lobule, cuneus, and precuneus ( $P > 0.05$ ). Comparisons between CBF groups were made using age and sex as covariates. CBF values were found to be elevated in the cerebellum as well as in the left perirhinal cortex, left lingual gyrus, and right lingual gyrus in the patient group. CBF values were decreased in the right middle frontal gyrus, right superior temporal gyrus, and right insula ( $P > 0.05$ ).

#### CONCLUSION

Migraineurs with PFO were found to have multiple eigenvalue changes in brain structure and perfusion, and the brain regions with two or more eigenvalue changes were mainly located in the temporal lobe, frontal lobe, occipital lobe, insula, cuneus, precuneus, and cerebellum. It is suggested that subsequent studies could focus on observing the relevant brain regions.

#### CLINICAL RELEVANCE/APPLICATION

This study lays the foundation for the pathological mechanism of the disease and the discovery of relevant imaging markers. It provides a basis for further research on the relatively specific brain mechanisms as well as the treatment of migraineurs with PFO.

S3A-SPNR-6

### Schizophrenia and Gray Matter Heterotopia in the Frontal Lobe: A Finding with Hitherto Little Attention Despite Nowadays High Resolution 3D MR Imaging

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Christophe Arendt, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Only a handful of cases with gray matter heterotopia (GMH) in schizophrenia are described in the literature from the late '90s through MRI. Yet, postmortem studies detected heterotopic neurons in the white matter (WM) more frequently. The aim was to demonstrate their prevalence using images with higher spatial resolution than before.

#### METHODS AND MATERIALS

Inpatients with schizophrenia and an institutional MRI were included in this retrospective study, and consecutive data sets of non-schizophrenic persons served as controls. Two independent radiologists, trained for neuroimaging and blinded to any clinical information, evaluated 3D T1-weighted gradient echo sequences (1 mm<sup>3</sup> voxel size; 1.5 and 3.0 T) to look for GMH. Number and location (periventricular/deeper WM; frontal, parietal, temporal or occipital) of GMH were assessed. Presence of periventricular cysts (PVC), enlarged caves of the septum pellucidum (ECSP), dysgenesis of the corpus callosum (DCC), focal cortical dysplasia (FCD) and polymicrogyria (PMG) were noted, if present. A consensus for cases with disagreements was made in a second read. Fisher's exact and Pearson's  $\chi^2$  test were used to test for differences and relationships, respectively.

#### RESULTS

From 01/2013 till 07/2021, MR scans of 214 cases (mean age, 42 yrs; 69% males) and 141 controls (mean age, 46 yrs; 50% males) were analyzed. There was a prevalence of 2.8% (n=6/214) of GMH in the patient cohort versus 0% in non-schizophrenic persons (p=0.046). All seven lesions were located in the frontal lobe; two of them on both sides in one patient and two patients with GMH in the deeper and not in the periventricular WM. Another finding that was found solely in the patient cohort was the presence of PVC (n=3/214, 1.4%; p=0.218). ECSP were detected in both groups (n=6/214, 2.8% vs. n=4/141, 2.8%; p=0.613). Raters did not detect DCC, FCD or PMG in both cohorts. There were no relationships between GMH and PVC ( $\chi^2=0.052$ ; p=0.950), GMH and ECSP ( $\chi^2=0.177$ ; p=0.841), and PVC and ECSP ( $\chi^2=0.088$ ; p=0.918). No associations between GMH and baseline characteristics or pre-existing conditions could be made.

#### CONCLUSION

GMH in schizophrenia were found more frequently than expected, as indicated by a prevalence of 2.8%, which might be due to the nowadays higher resolution of structural MRI. All lesions were found in the frontal lobe and even in the deeper WM. Other findings were PVC and ECSP, the latter being also present in controls with almost the same frequency. Interestingly, there were no associations between GMH and epilepsy.

#### CLINICAL RELEVANCE/APPLICATION

High resolution 3D T1-weighting detected GMH in 2.8% of schizophrenic patients. These findings may inform personalized approaches to intervention such as in treatment-resistance despite good compliance.

### Multiclass Radiomics-based Models for Pediatric Low-Grade Neuroepithelial Tumors Molecular Subtype Identification Based on Open-Radiomics Protocol

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Khashayar Namdar, MSc, MEng (*Presenter*) Nothing to Disclose

#### PURPOSE

Pediatric Low-Grade Neuroepithelial Tumor (PLGNT) is the most common type of brain tumor in children, and radiomics-based machine learning (ML) models have been shown to be effective for classifying BRAF fusion and BRAF V600E mutation PLGNT molecular subtypes. We investigate the effect of MRI sequence, image normalization, and radiomics extraction hyperparameters using the Open-Radiomics protocol to provide reproducible results.

#### METHODS AND MATERIALS

Our REB-approved retrospectively acquired study cohort consisted of 339 children with PLGNT including 143 with BRAF fusion, 71 with BRAF V600E mutation, and 125 tumors with other molecular subtypes. MRI sequences included Fluid-Attenuated Inversion Recovery (FLAIR), T1-weighted (T1), gadolinium-based contrast agent (GBCA) enhanced T1-weighted (T1CE), and T2-weighted (T2) sequences images. Tumor segmentations were provided by a pediatric neuroradiology fellow and verified by a senior pediatric neuroradiologist. PyRadiomics was used for extracting the radiomics features from the regions of interest. We created 72 radiomics datasets using a combination of 4 sequences, 3 sets of radiomics extraction hyperparameters (binWidth of 15, 25, 35), and 6 image normalization methods (NoNormalization, MinMax, ZScore, Histogram Equalization, Gamma normalization with 0.5 and 1.5 as gamma coefficient). We used Random Forest classifiers. For each radiomics dataset, we repeated the train-validation-test (60/20/20) experiment with different data splits and model random states 100 times (7200 tests) and calculated the Area Under ROC Curve (AUC).

#### RESULTS

We achieved a test AUC of 0.880 with 95% Confidence Interval (CI) [0.879, 0.882] for BRAF fusion vs BRAF V600E mutation binary classification. The highest average test performance for a specific dataset was achieved using MinMax normalization and binWidth of 25 on T1CE (AUC: 0.890). For 3-class classification, the average one-vs-the-rest (OvR) AUC was 0.789 with 95% CI [0.786, 0.792]. The top-performing dataset was ZScore, binWidth 15, FLAIR, with an average test AUC of 0.816. Unlike binWidth and image normalization, different imaging sequences resulted in statistically significant differences in AUC in both binary and multiclass scenarios.

#### CONCLUSION

Among the four imaging sequences in the dataset, T1CE was the best for separating BRAF fusion from V600E mutation. However, radiomic features extracted from FLAIR images outperformed other sequences at differentiating BRAF fusion and mutation from the other subtypes.

#### CLINICAL RELEVANCE/APPLICATION

Identification of the molecular subtype of PLGNT is important for treatment planning. Our comprehensive approach ensures that we capture best-performing and reproducible models.

S3A-SPNR-8

### Multiclass Radiomics-based Machine Learning Models for Medulloblastoma Molecular Subtype Identification

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Khashayar Namdar, MSc, MEng (*Presenter*) Nothing to Disclose

#### PURPOSE

Medulloblastoma (MB) is an aggressive brain tumor in children and qualitative MR imaging features including tumor location within the cerebellum have been shown to differentiate MB subtypes. We develop radiomics-based machine learning (ML) models using MRI Fluid-Attenuated Inversion Recovery (FLAIR) images to classify four MB molecular subtypes (WNT, SHH, group 3, group 4). We follow the Open-Radiomics protocol to achieve reproducible results.

#### METHODS AND MATERIALS

Our REB-approved and retrospective study includes 104 pediatric patients with an age range of 1 to 17.2 years (mean age  $7.8 \pm 3.95$  years, 71 males, 68%). Tumor segmentations were provided by two pediatric neuroradiologists. PyRadiomics was used for extracting the radiomics features from the regions of interest (ROIs). The four MB molecular subgroups were identified based on next-generation sequencing panels, fluorescence in situ hybridization, and specialized testing (including RNA methylation array and DNA methylation array). The dataset included 44, 28, 20, and 12 cases of the WNT, SHH, group 3, and group 4 subgroups, respectively. We created 18 radiomics datasets using 3 sets of radiomics extraction hyperparameters (binWidth of 15, 25, 35), and 6 image normalization methods (NoNormalization, MinMax, ZScore, Histogram Equalization, Gamma normalization with 0.5 and 1.5 as gamma coefficient). We used Random Forests as classifiers. For each radiomics dataset, we repeated the experiment with different data splits and model random state 100 times (1800 tests) and calculated the Area Under Receiver Operating Characteristic Curve (AUC).

#### RESULTS

When classifying group 3 versus all other subgroups, we achieved an overall test AUC of 0.619 with 95% confidence interval (CI) [0.607, 0.631]. On 4-class classification, the average one-vs-the-rest AUC was 0.703 with 95% CI [0.690, 0.716]. The top-performing dataset was ZScore with binWidth 25, where we achieved average test AUC of 0.750. Analyzing per-class AUCs on the top-performing setting, the highest performance was noted for SHH vs others, where we achieved an average test AUC of 0.845. We also observed significantly higher AUC for group 3 vs others when switched to multiclass classification (0.668).

#### CONCLUSION

Performance of radiomics-based ML models for identifying MB subtypes using MR images depends on the subtype, how the model is trained, and how the image is normalized. Our results show ZScore is the best image normalization technique and multiclass classification can improve per-class performance of the models.

#### CLINICAL RELEVANCE/APPLICATION

Pretherapeutic identification of MB subtype is important for treatment planning for which we train and evaluate reproducible machine learning models.

### Nodal Properties of Resting-State Brain Functional Network in Childhood and Adolescence

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Yu Tian (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aimed to describe and compare the characteristics of changes in the nodal properties of brain functional networks during childhood and adolescence, revealing the developmental trajectories of different brain structures during development.

#### METHODS AND MATERIALS

In this study, 42 healthy volunteers aged 6-18 years were right-handed primary and middle school students were recruited, and the subgroup analysis included children (6-12 years,  $n = 19$ ) and adolescents (13-18 years,  $n = 23$ ). Resting-state functional magnetic resonance imaging (fMRI) data were collected using a 3.0T MRI scanner. The topological properties of the functional brain network were analyzed using graph theory.

#### RESULTS

Compared with the children group, the nodal efficiency of the superior frontal gyrus, middle frontal gyrus, left dorsolateral fusiform gyrus, and other brain regions in the adolescent group was significantly increased ( $P < 0.05$ , FDR correction) and positively correlated with age. The degree of centrality of the superior frontal gyrus, bilateral inferior frontal gyrus operculum, left medioventral fusiform gyrus, and other brain regions increased significantly ( $P < 0.05$ , FDR correction) and were positively correlated with age. The degree of centrality of the left dorsolateral fusiform gyrus, left rostral cuneus gyrus, and right medial superior occipital gyrus was significantly reduced ( $P < 0.05$ , FDR correction) and negatively correlated with age. The nodal shortest paths in the superior frontal gyrus, left ventrolateral fusiform gyrus, right superior parietal lobule, and other brain regions were significantly reduced ( $P < 0.05$ , FDR correction) and negatively correlated with age.

#### CONCLUSION

The transmission efficiency of the brain core network gradually increased, and the subnetwork function gradually improved in children and adolescents with age. the functional development of each brain area in the occipital visual cortex was uneven and internally functionally differentiated.

#### CLINICAL RELEVANCE/APPLICATION

Changes in the topological properties of brain functional network nodes during childhood and adolescence can provide more detailed and intuitive information on the rules of brain development. We believe that our study makes a significant contribution to the literature because it provides evidence-based findings that clinicians and healthcare providers can adopt in actual clinical settings.

### Value Addition of Subspecialty Trained Experienced Readers for O-RADS MRI Scoring and Guiding Management for Patients with Adnexal Mass Referred to Gynecology Oncology Multidisciplinary Rounds in a Tertiary Center

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Ankush Jajodia, MBBS, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Assess the diagnostic accuracy, interobserver variability, and common lexical errors of the ACR O-RADS scoring system in staff radiologists with less experience and non-fellowship trained.

#### METHODS AND MATERIALS

Patients with an adnexal mass on standard post-contrast pelvic MRI and referred after initial interpretation by a staff radiologist (R3-lacking experience and fellowship experience) to gynec-oncology rounds in a tertiary center. Two fellowship-trained radiologists with different experience levels, R2 (2 years) and R1 (10 years), assigned O-RADS MRI scores independently. Diagnostic accuracies (ROC curve analysis) and agreement between readers were analyzed for each reader. Scores 4 and 5 were assigned malignant. R1 independently assigned misclassification if a malignant lesion scored = 3, a benign lesion scored = 4, or a non-adnexal mass was incorrectly categorized as benign or malignant.

#### RESULTS

Twelve malignant and 36 benign lesions included in the study were assigned O-RADS MRI score malignant (4,5) and benign (1,2,3) in 10 (20.8%) and 38 (79.2%), 15 (31.2%) and 33 (68.8%) and 45 (93.7%) and 3 (6.3%) by R1, R2, and R3 respectively. MR O-RADS score (4,5) associated with malignancy with diagnostic efficacy and areas under the curve values of 0.942 (95 % CI, 0.834-0.989), 0.579 (95 % CI, 0.428-0.720), and 0.553 (95 % CI, 0.403-0.697) obtained for readers R1, R2, and R3 respectively, with statistically significantly different between R1-R2 and R2-R3. Two and eleven lesions were incorrectly classified as benign by R1 and R3 readers. Inter-observer agreement interpretation obtained k values was fair between all readers; 0.435 (95 % CI, 0.224-0.646) for R1-R2, 0.441 (95 % CI, 0.238-0.645) for R2-R3, and 0.440 (95 % CI, 0.192-0.687) for R2-R3 respectively. There were nine correct upgrades and seven correct downgrades to malignant and benign categories by experienced R1 readers. Misclassification in nonexperienced readers was due to misinterpretation of solid tissue (n=14), incorrect interpretation of diffusion images (n=10), and incorrect interpretation of non-dynamic contrast enhancement (n=7).

#### CONCLUSION

Additional interpretation by experienced readers provides incremental diagnostic accuracies in the MR O-RADS score.

#### CLINICAL RELEVANCE/APPLICATION

Experienced readers correctly upgraded 18% malignant lesions with fair inter-observer agreement among readers with various experiences, although the diagnostic accuracies were significantly different between readers. Unnecessary biopsy was avoided in 14.5% by correct downgrading by experienced readers. Incorrect classification of 16% of lesions by experienced readers potentially highlights need to simplify the existing scoring system.

### Accuracy of the Characterization of Adnexal Masses, Indeterminate at Ultrasonography, Using a Magnetic Resonance Imaging (MRI) Protocol without Contrast: External Validation of the Non-contrast MRI Adnex Score in a Multicentre setting

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Camilla Panico, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The characterization of adnexal masses is critical to guide appropriate patient management. Up to 20% of adnexal masses remain uncharacterized after ultrasound and MRI is needed. The O-RADS MRI score relies on gadolinium-based contrast; however, avoiding contrast is sometimes preferable due to logistical and patient factors. A recent study proposed an alternative (Non-contrast MRI Adnex Score -NCMAS). The purpose of our study is to show the preliminary data of a multicentric prospective evaluation of the NCMAS in characterizing the adnexal masses.

#### METHODS AND MATERIALS

A multicenter observational prospective study has been set up including 16 standing Italian Centers. NCMAS is the Index Test; its aim is to predict the malignancy of the ovarian lesions on the basis of a NCMAS. The score is based on 5 categories. Two radiologists for each center (one senior and one junior) read the images, blinded to the clinical information of the patients except for age. The diagnostic end-point (absence/presence of the malignant tumor) is verified through histopathology after surgery or through radiological follow-up at 12 months. The diagnostic accuracy of NCMAS is evaluated by measuring sensitivity, specificity, positive and negative predictive values, and ROC curve with area under the curve (AUC). To measure agreement between senior and junior radiologist Kappa statistics is performed. This preliminary analysis includes 45 patients representing about 15% of the total patients to be recruited.

#### RESULTS

Fifteen out of the 45 patients were classified as malignant using the NCMAS. Comparing these diagnoses with the gold standard we found: sensitivity of 85.71% (95% Conf. Int. 66.13%-98.22%), specificity of 90.32% (Conf. Int. 78,58%-97.96%), positive predictive value of 80% (Conf. Int. 59.54%-95.67%), negative predictive value 93.33% (Conf. Int: 52.78%-99.18%). The malignant lesions correctly classified were 88.89% (Conf. Int. 77.78%-96.29%). The AUC was 88.02% (Conf. Int. 77.14%-98.90%). As to the comparison between senior and junior radiologists, for a diagnosis of a malignant lesion, the agreement was 90.24%, with a Kappa statistic of 0.79 (Conf. Int. 0.59-0.985).

#### CONCLUSION

The performance of NCMAS score was externally and prospectively confirmed. Even if found in about 15% of the total calculated sample size, the results are promising. If confirmed, the use of NCMAS may add an important tool in clinical practice when contrast imaging cannot be used for logistic or patient factors.

#### CLINICAL RELEVANCE/APPLICATION

The results of this study may represent a confident support to the clinical use of non-contrast MRI in diagnosing adnexal masses, undetermined at ultrasonography

### Cardiac Computed Tomography Angiography with and without Bolus Tracking Methods in Infants with Congenital Heart Disease

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Takayuki Yoshiura, BA, RT (*Presenter*) Nothing to Disclose

#### PURPOSE

Cardiac computed tomography angiography (CCTA) is useful in congenital heart disease (CHD) diagnosis and plays a major role in treatment. The bolus tracking (BT) methods can accurately predict the optimal scan delay that reflects the hemodynamics of the individual, but the drawback is the increased radiation dose due to pre-monitoring scans. This study aimed to compare the radiation dose, vascular CT number, and image quality of CCTA with and without BT methods for infants with CHD.

#### METHODS AND MATERIALS

This study retrospectively studied 72 consecutive patients with suspected CHD who underwent infant CCTA from December 2017 to April 2022, divided into groups with and without BT methods, in our information system. All scans were performed using a 64-detector row CT scanner (Lightspeed VCT; GE Healthcare, Milwaukee, Wisconsin) with the following parameters: rotation: 0.4 s, helical pitch: 1.375, slice thickness: 0.625 mm, tube voltage: 80 kVp, and automatic tube current modulation with a noise index of 40, iterative reconstruction (IR, blending of 30% of ASIR with FBP) algorithms under the standard kernel/filter reconstruction. Volume CT dose index (CTDI<sub>vol</sub>) and dose length product (DLP) were recorded for all CT scanning, and an effective dose was obtained using conversion factors. The CT number of the ascending aorta (AO) and pulmonary artery (PA), image noise of muscle tissue, and contrast-to-noise ratio (CNR) were measured and calculated.

#### RESULTS

The median values in the groups with and without BT were 2.20 mGy vs. 0.44 mGy for CTDI<sub>vol</sub>, 8.10 mGy·cm vs. 6.20 mGy·cm for DLP, and 0.66 mSv vs. 0.51 mSv for effective dose. The mean values in the groups with and without BT were 471.2 Hounsfield units (HU) and 515.6 HU for AO and 463.2 HU and 512.5 HU for PA, respectively. The mean image noise was 17.3 HU and 17.0 HU in the groups with and without BT ( $p = 0.76$ ), and the mean CNR was 23.9 and 26.5 in both groups ( $p = 0.21$ ).

#### CONCLUSION

CCTA for infants with CHD without BT methods can reduce the radiation dose while maintaining the CT enhancement of the vessels and image quality compared to CCTA with BT methods.

#### CLINICAL RELEVANCE/APPLICATION

CCTA for infants with CHD can ensure good image quality and reduce radiation dose without using the BT method.

### Improved Single-Shot GRASE with Flyback Variable Density Sampling and Deep Neural-Network

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Zheng Zhong, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To enable highly accelerated (12X) single shot gradient and spin echo (ss-GRASE) sequence without appreciable image artifacts by incorporating flyback variable density sampling coupled to a deep neural network.

#### METHODS AND MATERIALS

**SS-GRASE with flyback variable density sampling:**The sequence diagram was shown in Figure A, where a 3-fold acceleration was achieved using three gradient echoes after each refocusing pulse. This was coupled with variable density sampling for a total of 12-fold acceleration. To minimize phase inconsistency among the gradient echoes, flyback acquisition was employed with three echoes each grouped into different regions of the k-space.**Data Acquisition:**With IRB approval, images were acquired using ss-GRASE on phantom and human brains on a GE 3T Premier scanner. Key sequence parameters were: TR/TE=300/100ms, slice thickness=3mm, FOV=28cm<sup>2</sup>, matrix=256×224, slices=30 to 40, parallel imaging factor=3. A total of 90 slices of phantom and 320 slices of the human brain were acquired. The experiment was repeated using variable density sampling SSFSE with the same parameters except for TR=700ms.**Image Reconstruction:**The acquired data from both ss-GRASE and SSFSE was reconstructed using the parallel imaging compressive sensing (PICS) algorithm provided by BART and fed into the neural network as input and output, respectively. A U-Net architecture was tailored to further remove artifacts from PICS reconstruction. The U-Net consists of a downsampling encoder and an upsampling decoder network with a mirrored and reversed encoder structure (Figure B). The network was trained on an NVIDIA Titan Xp 16GB graphics card. To avoid overfitting, weight-decay (0.01) and random rotation for data augmentation were applied. Adam optimizer was used with a learning rate of 0.0005 for 1000 epochs guided by MSE loss until convergence.

#### RESULTS

The second column of Figure C illustrates the artifacts of PICS reconstruction arising from the phase inconsistency of the three gradient echoes in ss-GRASE. The artifacts can be largely removed using the deep neural network, as evidenced by the improved image quality from both phantom and human brain images (third column).

#### CONCLUSION

The performance of the ss-GRASE sequence was substantially improved with a combination of flyback variable density sampling and a deep neural network. The deep neural network enables reduction of the artifacts which PICS reconstruction fails to address in ss-GRASE.

#### CLINICAL RELEVANCE/APPLICATION

The proposed approach of ss-GRASE enables improved acquisition speed (300ms/slice) and less SAR issue as compared to conventional SSFSE, implying further applications of the technique in freezing motion such as bowel imaging, and SAR-sensitive situations such as pediatric imaging.

### Unpaired MR-CT Translation using Diffusion Model and Cross-modality Structure Extractor

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Junghyun Roh, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

For the breast cancer patients after surgery, MRI scans are required to identify the surgical site and determine the treatment plan, but radiotherapy planning requires extra CT scans. By developing the deep learning model to synthesize CT from MRI images, physicians can reduce the time consumption and do treatment efficiently. Since a dataset containing paired MR and CT images with registration is difficult to be retrieved because of anatomical changes, unpaired MR-CT translation is the key to solve this problem. However, due to the information difference within MRI and CT, unpaired translation across the modalities is still a hard task to be done. In this paper, we propose a novel structure using a cycle-structured diffusion model and an extra algorithm for structure preservation.

#### METHODS AND MATERIALS

The dataset we used is composed of 2D MRI (T2) and CT scans of the patients who underwent partial resection for breast cancer or did radiation therapy. Train set is composed of 3,606 MR scans and 2,770 CT scans from 62 patients, and 543 pairs of MRI and CT from 15 patients were used for test. The proposed model is composed of two generators: Diffusive and Non-Diffusive. Non-diffusive generator  $G'$  is used to make a reference for the diffusive generator  $G$ . Using the image  $G'(x)$  and noisy input  $x_t$ , the diffusive generator focuses on learning the target domain's structure and reconstructing the input image  $x$ . The Modality independent neighborhood descriptor (MIND) algorithm extracts the structural information using the similarity among adjacent patches. This descriptor makes a similar output for the same object regardless of its modality, so it can guide the unsupervised model to keep the structure. We compared our model's result with other unsupervised translation models by quantitative metrics: MSE, PSNR, and SSIM.

#### RESULTS

By the metrics, we can know that our proposed model generates the most similar result with ground truth for both sides: MR to CT and CT to MR. The resulting image shows that the diffusive generator contributed well to build realistic images. Also, the MIND loss helped to solve the structure deformation problem, especially in CT to MR conversion.

#### CONCLUSION

In this study, we showed bidirectional MR-CT unpaired translation functionality can be raised by adapting a diffusive generator as translation model. In addition, the proposed loss function in this paper can help maintain the structural information and compensate for the essential problem of unpaired translation.

#### CLINICAL RELEVANCE/APPLICATION

The synthetic CT image generated by the proposed model and MRI can be used for dose calculation in radiation treatment planning for breast cancer. This method can help physicians to reduce the time consumption and establish precise treatment regions.

### The Superiority of Low-kV Renal Triphasic-enhanced CT with Deep Learning Image Reconstruction in Patient Care over the Conventional Enhanced CT Exam

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Xiaobo Ding, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate whether the deep learning image reconstruction (DLIR) can provide more patient care through the reduction of radiation dose and contrast agent volume for renal enhanced CT exam.

#### METHODS AND MATERIALS

148 patients suspicious of renal lesion were included, 118 patients in the DLIR group and 30 in the conventional enhanced CT (CECT) group. The parameters for DLIR group: rotation speed of 0.5 s, collimation of 128×0.625 mm, pitch of 0.992:1, 50% ASIR-V, noise index (NI) of 9, automatic current modulation, standard kernel, 100 kV and mA range of 100-550 in the arterial phase (AP) and excretion phase (EP) and 120 kV and mA range of 150-500 in the parenchymal phase (PP); retrospective algorithm of DLIR. The volume and injection rate of contrast agent (320 mgI/ml) were 0.9 ml/kg and 3 ml/s. In CECT group: 120 kV, 281 mAs, collimation of 128×0.625 mm, pitch of 0.914:1, level 3 of iDose4, standard(B) filter for all phases. The volume and injection rate of contrast agent (320 mgI/ml) were 1.2 ml/kg and 2.7 ml/s. CT values and standard deviation (SD) of cortex, medulla, subcutaneous adipose tissue (SAT) on AP, parenchyma, pelvis and psoas muscle (PM) and SAT on PP, middle calyx (MC), upper ureter and middle ureter on EP were measured to calculate signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR). SD of SAT was lower in DLIR group, compared to CECT (9.08 vs. 11.11,  $p<0.001$ ). No differences in subjective scores were observed between two groups.

#### RESULTS

There was no difference in BMI between two groups (24.4 vs. 23.4,  $p>0.05$ ). CTDI, DLP and contrast agent volume of DLIR group were significantly lower than those of CECT group (23.7 vs. 70.8 mGy,  $p<0.001$ ; 744.1 vs. 2197.4 mGy[[Unsupported Character - Symbol Font #158;]]cm,  $p<0.001$ ; 62.4 vs. 77.8 ml,  $p<0.001$ ). SNR of parenchyma and upper ureter and CNR of cortex to medulla in DLIR group were significantly higher than those in CECT group (10.83 vs. 7.52; 19.45 vs. 7.12; 11.83 vs. 6.59;  $p<0.001$  each). The SD of SAT was lower in DLIR group, compared to CECT (9.08 vs. 11.11,  $p<0.001$ ). No differences in subjective scores were observed between two groups.

#### CONCLUSION

Low-kV enhanced CT exam combined with DLIR algorithm is a feasible method for better patient care, compared to conventional enhanced CT exam.

#### CLINICAL RELEVANCE/APPLICATION

The scan speed is faster and image quality is better for the deep learning algorithm of low-dose renal three-phase scan of GE revolution 256 row CT than that of conventional renal three-phase scan of Philips 128 row CT, which could significantly reduce the radiation dose and contrast agent dosage of patients, and reduce the burden of liver and kidney of patients.

### Performance of an Artificial Intelligence-Based Real-time System for Breast Positioning Evaluation and Image Quality Control in Mammography

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Ying Guo (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the effectiveness of an artificial intelligence (AI) system for automated assessment of breast positioning and image quality in mammography.

#### METHODS AND MATERIALS

Assessment of breast positioning and image quality was performed by AI system and by two radiographers on 360 images of 90 women. Nine image quality criteria evaluating the appearance of the nipple, breast rotation, pectoral muscle, inframammary fold, pectoral nipple line, shoulder overlap shadow, abdominal skin, contralateral breast and foreign body were used for craniocaudal and mediolateral-oblique views. Image quality of cases were also evaluated with the standards of Mammography Quality Standards Act (MQSA) as grade "adequate" or "inadequate". Intraclass correlation and Cohen's kappa coefficient ( $\kappa$ ) were used to investigate the correlation and agreement between the radiographer's assessments and AI. The performance of the AI system was evaluated using accuracy, sensitivity, and specificity.

#### RESULTS

The AI algorithm demonstrated high accuracy in distinguishing between adequate and inadequate images, with an overall accuracy of 93%, sensitivity of 94% and specificity of 92%. In terms of breast positioning, the AUC of poor imaging quality prediction by AI system according to incomplete gland, incomplete pectoralis muscle, over or insufficient exposure was (0.903 vs 0.937 vs 0.982). Overall accuracy of AI system was 0.958. Inter-observer agreement for breast positioning assessment indicating substantial agreement between the radiographers and AI system ( $\kappa=0.75$ ). A substantial to almost perfect agreement was observed between the radiographers and AI on the nipple in profile ( $\kappa = 0.93$ ) and contralateral breast criterion ( $\kappa = 0.82$ ). We observed a slight to moderate agreement for the other criteria ( $\kappa = 0.55-0.79$ ).

#### CONCLUSION

The AI algorithm demonstrated high accuracy in distinguishing between high and low-quality images and detecting suboptimal breast positioning in mammography. The results showed a high level of agreement between the AI system and the radiographers.

#### CLINICAL RELEVANCE/APPLICATION

The high accuracy, sensitivity, and specificity of an AI system for quality control in mammography suggest its potential as a valuable tool for radiologists and technologists in the clinical setting, particularly in low-resource areas where access to experienced radiologists may be limited.

### Artificial Intelligence-based Triage of Breast Cancer Screening Mammograms in a Swiss Region: Possible Impact of AI Region's Score Cutoff on Radiologist Workload

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Federica Zanca, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To identify the optimal region's score cutoff when using an artificial intelligence (AI) cancer-detection software to triage negative screening examinations into a one-click reporting radiologist work stream, e.g. reader validation of the AI negative result.

#### METHODS AND MATERIALS

This prospective multi-center simulation study aims at collecting about 10000 exams from a Swiss screening program. Preliminary data includes 3 months of screening mammograms. AI cancer-detection software (Transpara, Screenpoint Medical, v1.7.1) was used as a concurrent reading to detect potential abnormalities, for all exams collected. The software computes a region score for every marked area (soft tissue lesions and microcalcifications), indicating the likelihood of cancer on a scale from 0-98. Higher scores represent a higher likelihood of cancer. Based on these AI prediction scores, various cutoff points for the highest region score at the exam level (42, 49, 60, 74) were evaluated as thresholds to potentially channel women to the one-click reporting work stream. The different cutoff points were assessed in terms of missed abnormalities. Mean, median and variance of the AI scores were calculated. Data were also stratified per lesion type and breast density.

#### RESULTS

500 exams were examined, of which 12 were recalled for further examination (recall rate: 2.4%). Of these, 4 did not return, 5 were benign and 3 were diagnosed as cancer (biopsy proven), resulting in a 0.6% cancer incidence over one screening interval of 2 years. The mean, median and variance of AI scores were, respectively, 13, 0 and 564. There were respectively 0,1,2 and 2 missed cancers in case an AI score cutoff of 42, 49, 60 and 74 was used, corresponding to 0%, 0.2%, 0.4% and 0.4% of all screen-detected cancers in the population. The cutoffs of 42/49/60/74 correspond to 79%/87%/93%/99% of the workload. More data collection and stratification per lesion type and breast density is ongoing.

#### CONCLUSION

Preliminary data suggests that a cutoff score of 42 would allow triaging breast cancer screening mammograms with a 99.9% negative predicted value (NPV) into a one-click reporting.

#### CLINICAL RELEVANCE/APPLICATION

Using commercial AI software to triage mammogram workflow based on a 99.9% NPV could reduce radiologist workload by 78%.

### Development of a Machine Learning Algorithm for Fat-free Mass Estimation: Application to Personalized Contrast Injection in Computed Tomography

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Natalie Heracleous, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Using fat-free mass (FFM) to personalize i.v. contrast volume injection enables reproducible target liver enhancement. However, measuring FFM requires expensive equipment and is time-consuming, limiting its applicability in clinical practice. This study aims at developing a Machine Learning (ML) model to accurately estimate the patient FFM.

#### METHODS AND MATERIALS

Previously collected abdominal CT data from 689 adult patients referred for liver lesion characterization or cancer follow-up was used (11 centers, different CT vendors, 2018-2022). This dataset includes various patient characteristics and measurements such as age, gender, weight, height, Body Mass Index (BMI), Size Specific Dose Estimate (SSDE), and FFM measured with Bioelectrical Impedancemeter (ground truth (GT)). A multivariate linear regression model was developed for FFM estimation. The correlations of the investigated variables with measured FFM were studied, and the most correlating variables were retained in the final model. The data was divided into training and test sets following the 80/20 rule and were validated using the K-fold technique. The model's performance was evaluated against the GT using Mean Absolute Percentage Error (MAPE), Root Mean Squared Error (RMSE) and R-squared. Our algorithm was also benchmarked against models already existing in the literature by comparing the distributions of the relative differences between theoretical and measured FFM values when applied to our data.

#### RESULTS

Preliminary results show a very good performance in predicting the FFM for our patient data sample. The cross-validation results showed the model to be robust for the typical patient profiles in our clinical settings. Specifically, the model showed low MAPE (0.033 +/- 0.003), high R2 (0.91 +/- 0.02) and relatively low standard deviation of residuals RMSE (2.13 +/- 0.23).

#### CONCLUSION

Our model can reliably and efficiently estimate the patient FFM to personalize i.v. contrast volume in adult abdominal CT examinations, reducing the time required for its measurement and avoiding the need for expensive equipment.

#### CLINICAL RELEVANCE/APPLICATION

The ability to accurately estimate FFM enables effortless personalization of contrast volume injection for a reproducible liver enhancement in clinical practice.

### Evaluation of Unsupervised Low-dose Digital Breast Tomosynthesis Denoising using Cycle-consistent Generative Adversarial Network

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Tsutomu Gomi, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aimed to evaluate the image quality improvement in digital breast tomosynthesis (DBT) with unsupervised cycle-consistent generative adversarial networks (cycle-GANs) during pre-reconstruction processing under low radiation exposure.

#### METHODS AND MATERIALS

The cycle-GAN pre-reconstruction manipulation with filtered back projection (FBP) was compared with and without relative GAN techniques (unsupervised image-to-image translation: UNIT and supervised image-to-image translation: pix2pix). The peak signal-to-noise ratio (PSNR), mean square error (MSE), structural similarity (SSIM), and detectability index ( $d'$ ) in the in-focus plane and artifact spread function (ASF) in the longitudinal direction using a phantom (training; BR3D [model 020, CIRS Inc.], testing; DBT quality control [model 021, CIRS Inc.] and TOR-MAM [Leeds Test Objects Inc.]) at various radiation doses (automatic exposure control reference dose: 1.36 mGy: approximately 50% reduction of reference dose: 0.66 mGy; approximately 75% reduction of reference dose: 0.31 mGy) were used to compare noise reduction and preserved contrast rates.

#### RESULTS

PSNR and MSE were similar to the references with cycle-GAN at 75% and pix2pix at 50% radiation dose reductions of reference, respectively (PSNR: cycle-GAN: 25.19 and 25.81, UNIT: 23.81 and 18.68, pix2pix: 26.46 and 25.92, without GAN (w/o-GAN): 26.03 and 24.07; MSE: cycle-GAN: 0.003 and 0.002, UNIT: 0.004 and 0.013, pix2pix: 0.002 and 0.002, w/o-GAN: 0.002 and 0.003, at 50% and 75% reduced radiation dose, respectively). The SSIM of the images generated by the cycle-GAN model at a 50% reduced radiation dose was similar to that of the reference images acquired at full radiation dose (cycle-GAN: 0.66 and 0.64, UNIT: 0.62 and 0.59, pix2pix: 0.64 and 0.62, w/o-GAN: 0.61 and 0.50 at 50% and 75% reduced radiation dose, respectively).  $d'$  was similar to the reference in cycle-GAN and pix2pix at 50% radiation dose reduction of reference (reference: 2.79, cycle-GAN: 2.80 and 2.71, UNIT: 2.64 and 2.46, pix2pix: 2.82, and 2.58, w/o-GAN: 2.73 and 1.89 at 50% and 75% reduced radiation dose, respectively). ASF revealed a similar distribution (symmetry) to the reference, except for pix2pix. Pix2pix spread the distribution and became asymmetric.

#### CONCLUSION

This phantom experiment revealed the highest usefulness of cycle-GAN in low-dose conditions considering the image quality in the in-focus plane and longitudinal direction, as well as a 50% reduction in the reference.

#### CLINICAL RELEVANCE/APPLICATION

The cycle-GAN pre-reconstruction manipulation with FBP can significantly reduce noise with preserved contrast and radiation dose reduction in clinical practice.

### MRI Image Generation from CT Images for Cerebral Ischemic Stroke Patients Using Deep Learning

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Zhihua LI (*Presenter*) Nothing to Disclose

#### PURPOSE

Cerebral ischemic stroke is a leading cause of death and disability worldwide, and timely diagnosis and treatment are crucial for improving patient outcomes. Computed tomography (CT) and magnetic resonance imaging (MRI) are both widely used imaging modalities for diagnosing stroke. However, CT is often the first choice due to its accessibility and speed, while MR provides higher sensitivity and specificity. This study aims to investigate the feasibility of converting CT images of cerebral ischemic stroke patients to MRI using deep learning techniques.

#### METHODS AND MATERIALS

The proposed method utilizes a Cycle Generative Adversarial Network (Cycle-GAN) raised by Jun et al. to learn the mapping between the two modalities and generate synthetic MRI from CT scans. We have added a new attribute to the network, based on the observation that stroke lesions are highly discernible on MR images. The dataset used in this study consists of CT and MR images from 120 patients at Longgang Central Hospital of Shenzhen. Only the MRI input contains attribute information, where the presence or absence of lesions is encoded as one-hot codes. To address the challenge of detecting lesions in CT images and improve the network's feature extraction capabilities, we adjusted the window width and center of the original CT image to 60 and 35, respectively.

#### RESULTS

Experimental results demonstrate that the proposed approach can effectively generate high-quality MRI from CT scans, achieving a peak signal-to-noise ratio (PSNR) of 24.4 dB and a structural similarity index (SSIM) of 0.78. Furthermore, our method outperforms existing image-to-image translation methods in terms of visual quality and quantitative evaluation metrics.

#### CONCLUSION

Deep learning has shown promising results in extracting subtle lesion features from CT images, although the outcomes may differ from those of the original MRI. Nonetheless, the algorithm can still provide valuable insights to medical professionals. While some progress has been made in this area, there is still significant room for improvement. Future research will focus on refining the algorithm and conducting comparative studies with related algorithms.

#### CLINICAL RELEVANCE/APPLICATION

Timely diagnosis of Cerebral ischemic stroke is critical. However, traditional MRI scans are time-consuming, while CT imaging is widely available. By using deep learning to convert CT images to MRI, medical professionals can diagnose the condition more quickly and develop appropriate treatment plans.

### Semi-Automatic Segmentation of Thymic Epithelial Tumors using U-Net

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Nathan S. Lay, PhD (*Presenter*) Inventor, ScanMed

#### PURPOSE

Volumetric analysis of thymic epithelial lesions can be more informative than RECIST for oncologic follow up but requires laborious segmentation with low reproducibility when done manually. To propose and quantify performance of a U-Net artificial intelligence (AI) model for segmenting thymic epithelial tumors in CT scans with user-provided 3D regions-of-interest.

#### METHODS AND MATERIALS

A consecutive cohort comprised of 85 CT scans from 60 thymoma patients (mean age: 55 range: 32-75) was queried from a single institution database. Thymic tumors in the thorax were then manually segmented slice-by-slice on axial CT images by trainees or volunteers under the supervision of an expert cardiothoracic radiologist. The cohort was then partitioned into training and validation sets containing 63 CT scans from 45 patients and 22 CT scans from 15 patients respectively. A 2D U-Net was then trained on cropped image slices from 141 tumors over 1000 epochs. Performance was measured using the arithmetic mean and standard deviation of Dice similarity coefficient (DSC) over 3D manual segmentation masks of the whole image. DSC produces a similarity score ranging from 0 to 1 with 1 being a perfect match.

#### RESULTS

U-Net model snapshots were validated every 10 epochs on cropped image slices coming from 49 validation tumors. The method achieved a peak overall validation Dice similarity coefficient of 0.59 +/- 0.17. This corresponds to validation tumor DSCs of 0.60 +/- 0.09 for thymoma lesions located in the lung parenchyma, 0.68 +/- 0.14 for pleural and 0.57 +/- 0.19 for mediastinal thymoma lesions.

#### CONCLUSION

The current DSC results of our U-net AI model show promise for volumetric analysis of thymic tumors. Thymic tumors present a complicated and often unnoticed appearance in CT and a larger dataset is likely to produce a more generalizable and performant U-Net model over our current results.

#### CLINICAL RELEVANCE/APPLICATION

Thymic tumor progression is currently tracked using RECIST v1.1. RECIST is used because it is simple and reproducible, but it is not suitable for some types of pleural thymic tumors. Automatic volumetric analysis can be simple, reproducible and accurate for all thymic tumors.

S3A-SPPH-6

### Reproducibility of a Deep Learning COVID-19 Classification Model Based on Image Acquisition Dates and Data Resampling

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Mena Shenouda, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the impact of (1) image acquisition date and (2) data resampling, which was performed to create new training and test sets, on the ability of a deep learning (DL) model to predict COVID-19 diagnosis from chest radiographs (CXRs).

#### METHODS AND MATERIALS

A DL model using the DenseNet-121 architecture was trained on an original dataset of 9860 COVID+/- patients (disease prevalence: 15.5%) from a single institution. The model was validated on a more current cohort of 5893 patients (disease prevalence: 12.4%) from the same institution but achieved significantly lower performance as evaluated using area under the receiver operating characteristic curve (AUC). To investigate this performance discrepancy, this work (1) compared the International Classification of Diseases 10 (ICD-10) codes between the original dataset and current test set, (2) limited the image acquisition date range of the current test set to that of the original and compared COVID severity scores and age, and (3) retrained the model using a resampling of the original dataset to evaluate whether the original results were due to a statistical anomaly. No training was performed using the current test set.

#### RESULTS

The original dataset and current test set shared the same top-three ICD-10 codes: (1) screening for other viral disease, (2) age-related osteoporosis, and (3) unspecified osteoarthritis. COVID severity scores of patients with images obtained during the overlap of dates between the test sets failed to achieve a significant difference ( $p=0.06$ ); however, the DL prediction scores indicated more "obvious" cases within the original test set, thus correctly labeling a greater portion of true-positive and true-negative CXRs. There was a significant difference ( $p<0.001$ ) between cohort age, with the current test set having a larger mean ( $57.9 \text{ years} \pm 18.3$ ) than the original dataset ( $54.7 \text{ years} \pm 18.9$ ). Lastly, retraining the model by resampling the original dataset resulted in an AUC value [95% CI] of 0.71 [0.67, 0.74], significantly lower than the original AUC value of 0.76 [0.73, 0.79]. Importantly, the AUC value of the current test set was no longer statistically less than the AUC value obtained with this resampled original dataset ( $p=0.11$ ).

#### CONCLUSION

This work examined potential factors that may impact model performance. Resampling the dataset resulted in significantly lower performance, which may explain how different partitions of a dataset (or an entirely new dataset) may yield variable performance.

#### CLINICAL RELEVANCE/APPLICATION

With the rise of DL use in medical applications, interpretability of models is essential for proper deployment, ensuring an understanding of how various factors may impact model performance and that results are comprehensible.

### Model Calibration by Temperature Scaling of a U-Net Deep Learning Model Trained for the Segmentation of Mesothelioma Tumor: A Pilot Study

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Mena Shenouda, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

To produce calibrated pixel-wise label probabilities in the task of mesothelioma segmentation, which will ensure proper generation of probability maps.

#### METHODS AND MATERIALS

Temperature scaling (TS) is a post-processing probability calibration method to be used for multi-class classification. For medical image semantic segmentation tasks, the two classes would be "disease" or "no disease." TS estimates a single scalar parameter temperature  $T > 0$ , using the logit  $z_i$  vector as input, where  $i$  is the  $i$ -th image. The temperature is typically optimized only on the validation images and using the negative log-likelihood cost function, as was performed in this work. The calculated temperature "softens" the output of the last activation layer with  $T > 1$  reducing model confidence (i.e., probability predictions),  $T = 1$  indicating no change to the original probability, and  $T < 1$  increasing model confidence. The temperature was calculated for four separate validation sets: left or right hemithorax displaying either tumor only or tumor plus effusion. For the left hemithorax, 275 sections displayed tumor only, and 97 sections displayed tumor plus effusion. For the right hemithorax, 216 sections displayed tumor only, and 101 sections displayed tumor plus effusion.

#### RESULTS

The calculated temperatures for tumor only on the left hemithorax, tumor plus effusion on the left hemithorax, tumor only on the right hemithorax, and tumor plus effusion on the right hemithorax were  $T = 3.7, 3.4, 2.3, 2.1$ , respectively. All temperature values were greater than unity, which demonstrated the model's overconfidence prior to calibration.

#### CONCLUSION

This work demonstrated the overconfidence of the initial model, as all temperatures were greater than one. This finding is consistent with the literature, since modern neural networks have been reported to be overconfident in their predictions. With a correctly calibrated model, accurate probability maps can be generated, thus streamlining automation of the mesothelioma segmentation task.

#### CLINICAL RELEVANCE/APPLICATION

Due to the widespread use of neural networks for medical image classification and segmentation tasks, there is a need to ensure that model outputs are properly calibrated so that the resulting probabilities are indicative of the model's true confidence.

### Adaptive Multimodality Medical Image Translation with Total-Body PET

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Yuxi Jin (*Presenter*) Nothing to Disclose

#### PURPOSE

To dynamically generate specified modality images from nonattenuation-corrected PET images according to user requirements.

#### METHODS AND MATERIALS

To dynamically translate nonattenuation corrected (NAC) PET images to user-specified modality images, we embed a switch layer after each skip connection in the decoder of UNet. The switch layer learns the scale and offset parameters by two fully connected layers from the switch code. The switch codes are 001/010/100 for attenuation corrected (AC) PET/CT/MRI, respectively, and are coded by one-hot coding. The proposed model can adaptively output the specified modality image by normalizing the input features into the specified modality with the scale and offset parameters. A total of 119 patients scanned with the uEXPLORER scanner and 225 patients scanned with the uPMR scanner were retrospectively enrolled. We selected 13 patient cases as an external validation set for quantitative analysis, and the remaining 108 PET/CT cases and 215 PET/MR cases were used as experimental data to train the proposed network. To better train the proposed model, we mix and slice these data along the axial orientation to obtain two-dimensional images. After excluding 6547 slices for negative samples, we obtained 104286 slice samples in total. We randomly select 83429 samples for training, 10428 samples for validation, and 10429 samples for testing. The quantitative performance is evaluated by PSNR, MAE, and SSIM. The qualitative performance is measured by the error map between the model output and the ground truth.

#### RESULTS

Our results achieved small quantification errors (low bias), good image quality (high PSNR), and high similarity (high SSIM) in the different body regions. All modal translation results have a similar appearance as the ground truth. Qualitative and quantitative analyses demonstrated the outstanding performance of the proposed model.

#### CONCLUSION

We design a novel deep learning model to realize adaptatively multimodality translation. This work can complete one-to-many modality translation, including direct PET attenuation correction (NAC-AC), CT synthesis (PET-CT), and MRI synthesis (PET-MRI). The simulated multimodality images have small qualification errors, good image quality, and high image similarity, which demonstrates that the proposed method is a promising tool in preclinical research, such as tumor contouring, anatomical localization, and dose calculation of radiotherapy.

#### CLINICAL RELEVANCE/APPLICATION

The proposed adaptive multimodality medical image translation model can provide more comprehensive and integrated image information, aiding doctors in better understanding a patient's physical condition and making more accurate diagnoses and treatment plans.

### Large Language Model (LLM) Passes the Radiology Physics Quiz

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Shakthi K. Ramasamy, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

With the recent advances in natural language processing, large language models (LLMs) such as GPT-4 have become increasingly powerful in their ability to understand and generate natural language. This study aims to assess the knowledge quiz-taking capacity of GPT-4 and GPT-3.5 for the Radiology Physics quiz.

#### METHODS AND MATERIALS

An IRB approval is not required. The study was conducted on a set of 62 multiple-choice questions compiled from the Radiology Core Physics App, which is used by radiology residents for their board preparations, and the sample questions for the Diagnostic, Nuclear, and Therapeutic content of the Initial Certification for Medical Physics from the American Board of Radiology (ABR) ([theabr.org](http://theabr.org)) website. Image-based questions were excluded from the study due to the limitations of the current GPT models. The questions were typed into the prompt of [chat.openai.com](https://chat.openai.com) models GPT-4 (subscription required) and GPT-3.5 (freely available to the public). The answers were correlated with the respective answer keys. The performance of the models was evaluated for a passing score of 75%. The performance of GPT-4 vs GPT-3.5 was compared using a two-proportion z-test.

#### RESULTS

GPT-4 and GPT-3.5 took the Radiology Physics quiz, with GPT-4 achieving a success rate of 79% (49 correct) and GPT-3.5 achieving a success rate of 55% (34 correct). A two-proportion z-test was conducted to compare the performances of the two models. The calculated z-score is approximately 2.863, and the p-value is approximately 0.0042. Since the p-value (0.0042) is less than the significance level of 0.05, there is a statistically significant difference between the performances of GPT-4 and GPT-3.5 on the Radiology Physics quiz.

#### CONCLUSION

The results indicate a significant difference between the performances of GPT-4 and GPT-3.5 on the Radiology Physics quiz. GPT-4 demonstrated a higher success rate, scoring above the passing score. GPT-3.5 had a notably lower success rate, indicating that the newer GPT-4 model has improved knowledge and understanding of radiology core physics compared to its predecessor.

#### CLINICAL RELEVANCE/APPLICATION

The performance of GPT-4 in the Radiology Physics quiz highlights the potential application of large language models in medical education and training. GPT-4 could be a valuable resource for radiology residents, medical physicists, and other healthcare professionals seeking to enhance their understanding of radiology core physics principles. Additionally, the significant improvement in performance between GPT-3.5 and GPT-4 demonstrates the rapid advancements in natural language processing, indicating a promising future for LLMs in the medical field.

### Ten-Year Experience of 5-Fraction Lung Stereotactic Body Radiotherapy (SBRT) for Biopsy-Proven Non-Small Cell Lung Carcinoma (NSCLC)

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

John M. Watkins, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Describe the local control (LC) and correlative clinicopathologic prognostic factors in patients treated with 5-fraction lung SBRT for biopsy-proven NSCLC.

#### METHODS AND MATERIALS

Intradepartmental quality assurance database of SBRT patients was utilized to identify patients with biopsy-proven NSCLC treated with 5-fraction SBRT at a single institution. Overall survival (OS), disease-free survival (DFS), and LC were measured from SBRT completion to last clinical follow-up or death (with DFS/LC backdated to last clinical follow-up if death occurred more than 3 months after last imaging). Regression analyses were performed on clinical (age, gender, race, tobacco use), radiographic (maximal tumor dimension, T-stage), pathologic (histology), and treatment (target coverage by dose, frequency of SBRT, SBRT start to completion) factors for association with LC. Kaplan-Meier method was employed for survival estimation.

#### RESULTS

Between 2011-2021, 107 patients were identified for inclusion in the present analysis. There were 112 total NSCLC targets, 60 (54%) being adenocarcinoma. Median age at the time of treatment was 75 years old (range, 38-93). Median SBRT dose was 5000 cGy (4500-6000 cGy) delivered over a median treatment time of 9 days (4-45). Median maximal internal target volume (ITV) dose (D 0.1 cc) was 6554 cGy (4497-7660), with median ITV receiving 5000 cGy (V50) and 5500 cGy (V55) of 100% (0-100%) and 98.8% (0-100%), respectively. Median planning target volume (PTV) V50 and V55 were 96.6% (0-100%) and 67.4% (0-99.7%), respectively. At median follow-up of 21 months (1-139), 75 (70%) patients had died. Median survivor follow-up was 39 months (7-139) with an estimated 3-year overall survival of 42.6% (32.6-52.6%). Forty-three patients experienced disease recurrence, of whom 8 had local failures (4 biopsy-proven). Estimated 3-year local control was 86.2% (76.2-96.2%). Univariate analysis of factors associated with LC identified only ITV V50 and PTV V50 as being significantly associated with LC. Estimated 3-year LC for ITV V50 > 98% versus < 98% was 88% and 79%, respectively. Estimated 3-year LC for PTV V50 > 95% versus < 95% was 91% and 75%, respectively.

#### CONCLUSION

ITV V50 and PTV V50 were the most strongly associated factors with LC after 5-fraction lung SBRT in the present population.

#### CLINICAL RELEVANCE/APPLICATION

SBRT for early-stage NSCLC is an excellent option for inoperable patients or those who decline lobectomy. The present study demonstrates the importance of minimum target coverage on local control in a large population with mature follow-up.

### **Perivascular Fat Attenuation on CT Angiography is a Biomarker to Identify the Inflammation of Culprit Plaques in Internal Carotid Atherosclerosis**

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Ziyu Tian (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Our study aimed to evaluate the value of FAI as a tool for measuring plaque inflammation and identifying culprit plaques in internal carotid atherosclerosis.

#### **METHODS AND MATERIALS**

We analysed patients with internal carotid atherosclerosis who underwent neck CTA examination. The culprit plaque group and nonculprit plaque group were divided based on the clinical diagnosis. We compared the CTA characteristics, and baseline data between the two groups, as well as the FAI at the maximum stenosis, nonstenosis site and the whole ICA. A receiver operating characteristic (ROC) curve was used to determine the diagnostic accuracy of FAI for classifying culprit plaques in patients with bilateral ICA atherosclerotic stenosis.

#### **RESULTS**

In total, 101 and 94 patients were included in the culprit plaque (mean age, 64.78 years  $\pm$ 8.17; 84 men) and nonculprit plaque groups, respectively (mean age, 66.72 years  $\pm$ 7.51; 80 men). In the nonculprit plaque group, the perivascular FAI around the maximum stenosis site and around the whole ICA were lower than those in the culprit plaque group ( $P < 0.05$ ). In patients with bilateral extracranial ICA stenosis, ROC analysis of atherosclerotic stenosis in combination with FAI performed well in predicting the culprit plaque (AUC=0.863,  $P < 0.001$ ).

#### **CONCLUSION**

The perivascular FAI may be useful in identifying inflammation and the culprit plaque from ICA atherosclerosis and provides a new monitoring method for risk stratification.

#### **CLINICAL RELEVANCE/APPLICATION**

To our best knowledge, we first use the novel biomarker perivascular FAI to measure plaque inflammation and identify culprit plaques in internal carotid atherosclerosis. Our study first demonstrated that patients in the culprit plaque group had a higher level of perivascular inflammation measured by FAI than those in the nonculprit group. The noninvasive measurement of FAI can be used to evaluate and identify the local inflammation of culprit plaques in the ICA, which may help to monitor the inflammation progression of atherosclerotic plaques. Furthermore, FAI at the maximum stenosis site combined with stenosis can noninvasively predict the ICA culprit plaques, which enables the recognition of stroke risk patients and guides targeted treatments.

### Dark Blood Computed Tomography Angiography Combined with Deep Learning Reconstruction for Thickened Carotid Artery Wall Imaging in Takayasu Arteritis Patients

Sunday, Nov. 26 11:45AM - 12:15PM Room: Learning Center

Tong Su, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the capability of a newly developed dark-blood CTA imaging, combined with deep learning reconstruction (DLR), to visualize the thickened carotid artery wall of Takayasu arteritis (TAK) patients, compared with conventional CTA images.

#### METHODS AND MATERIALS

This prospective study continuously recruited fifty-three patients with TAK who underwent neck CTA scans. All acquisitions were performed with a 320 row-detector CT scanner (Aquilion ONE Genesis Edition). Arterial and Delayed phase images were reconstructed using HIR (Adaptive Iterative Dose Reduction [AIDR] 3D) and DLR (Advanced Intelligent Clear-IQ Engine [AiCE]). Afterward, these two groups of images processed with a dedicated software (SURESubtraction) to generate dark-blood images. Therefore, four groups of images were produced for analysis: Delayed-HIR, Delayed-DLR, Dark-blood-HIR, Dark-blood-DLR. Qualitative parameters, including overall image quality, vessel wall visualization ability, and diagnostic confidence index, were rated by two radiologists independently according to a five-point scale. Quantitative parameters, including SNR of vessel wall, CNR between the vessel wall and lumen, were computed and compared. The vessel wall thickness of thickened common carotid artery was measured and the inter-rater variability was evaluated.

#### RESULTS

The qualitative scores of overall image quality presented Delayed-DLR was superior to Delayed-HIR and Dark-blood-DLR was superior to Dark-blood-HIR (all  $p < 0.001$ ). CTA images processed with dark-blood technique presented higher qualitative scores in terms of vascular wall display ability and diagnostic confidence index, superior to conventional CTA images (all  $p < 0.001$ ). For brachiocephalic trunk, bilateral subclavian arteries and common carotid arteries, the SNRs and the CNR of Dark-blood-DLR images were significantly higher than those of Dark-blood-HIR images. And for bilateral common carotid arteries, the CNR of DLR presented higher quantitative scores than HIR for both delayed and dark-blood phases (all  $p < 0.001$ ). CTA images processed with dark-blood technique presented higher quantitative scores superior to conventional CTA images (all  $p < 0.001$ ). The average vessel wall thickness of carotid arteries measured on dark-blood phases were thicker than delayed phases (all  $p < 0.001$ ). And the highest ICC value between two raters was obtained on Dark-blood-DLR image (ICC 0.958).

#### CONCLUSION

Compared to HIR, dark blood method combined with DLR reconstruction improved CTA image quality, and enhanced the visualization of thickened vessel wall of TAK patients.

#### CLINICAL RELEVANCE/APPLICATION

Dark blood method combined with DLR reconstruction is conducive to rapid and accurate measurement of vessel wall thickness.

### Evaluation of a Deep-Learning Based Software Tool to Automatically Detect and Quantify Breast Arterial Calcifications on Digital Mammography

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Bilel Ben Jedidia (*Presenter*) Nothing to Disclose

#### PURPOSE

Breast arterial calcification (BAC) has been identified as an independent cardiovascular risk factor but is not routinely documented in mammography reports, partially because manually scoring by radiologists can be time-consuming. The aim of this study was to evaluate an artificial intelligence (AI) software that automatically detects and quantifies BAC.

#### METHODS AND MATERIALS

Women who underwent both 2D mammography and thoracic CT from 2009 to 2018 were retrospectively included in this single-center study. A deep learning based software (iCAD, Nashua, NH, USA) was used to automatically detect and quantify BAC with a 0 to 10 point BAC AI score. Results were compared with a previously described BAC manual score based on radiologists' visual quantification of BAC on the mammogram. Coronary Artery Calcium (CAC) score was manually evaluated using a 12-point scale on CT. Diagnostic performance of marked BAC AI score (defined as a BAC AI score = 5) for the detection of marked CAC (CAC score = 4) was analyzed. R software version 4.0.2 was used to perform the analysis.

#### RESULTS

502 women (mean age: 62 years  $\pm$  16) were included. BAC AI score was highly correlated with BAC manual score (Spearman's correlation 0.83,  $p < 0.01$ ). Marked BAC AI score for the detection of marked CAC had a sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of 32.7%, 96.1%, 71.2%, 83.1% and 81.9%, respectively. Marked BAC AI score was associated with marked CAC with an adjusted odds ratio of 12.139, (95% CI 11.92-12.35,  $p < 0.001$ ).

#### CONCLUSION

Automatic BAC AI score shows a very strong correlation to manual BAC scoring. Marked BAC AI score is associated with marked CAC (CAC score  $\geq 4$ ).

#### CLINICAL RELEVANCE/APPLICATION

Automatic BAC AI score could be a useful tool to promote the integration of BAC in the mammography report and improve awareness of a woman's cardiovascular risk status.

### Comparison of Supplemental Screening with Artificial Intelligence and Breast Ultrasound in Women with Dense Breast

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Su Min Ha, MD, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Whether using artificial intelligence (AI) system for screening mammography in women with dense breasts can replace supplemental breast ultrasound (US) is not well known. This study aimed to assess the value of supplemental US and AI with screening mammography in women with dense breasts.

#### METHODS AND MATERIALS

A retrospective database search identified consecutive asymptomatic women who underwent digital mammography (DM) and supplemental screening US between January 2017 and December 2018. AI software was applied for mammography, and four-view heat maps with a representative abnormality score per breast were evaluated. A BI-RADS category =3 on US and maximum abnormality score =10 on AI were considered positive results. The cancer detection rate (CDR) per 1000 examinations, sensitivity, specificity, and abnormal interpretation rate (AIR) were estimated and compared.

#### RESULTS

Among 5708 women (mean age±standard deviation: 52.4±7.9), 33 cancers (13 ductal carcinoma in situ and 20 invasive carcinoma) were found. DM alone showed CDR of 2.8 (16/5708; 95% CI: 1.7, 4.5), sensitivity of 48.5% (16/33; 95% CI: 32.5, 64.8), specificity of 94.3% (5350/5675; 95% CI: 93.6, 94.9) and AIR of 6.0% (341/5708; 95% CI: 5.4, 6.6). DM combined with AI showed a CDR of 3.2 per 1000 examinations (18/5708; 95% CI: 1.9, 4.9), sensitivity of 54.5% (18/33; 95% CI: 38.0, 70.2), specificity of 95.3% (5409/5675; 95% CI: 94.7, 95.8) and AIR of 5.0% (284/5708; 95% CI: 4.4, 5.6). DM combined with US yielded a CDR of 5.3 per 1000 examinations (30/5708; 95% CI: 3.6, 7.5), sensitivity of 90.9% (95% CI: 30/33; 95% CI: 76.4, 96.9), specificity of 77.6% (4401/5675; 95% CI: 76.5, 78.6), and AIR of 22% (1304/5708; 95% CI: 21, 24). CDR and sensitivity of DM with supplemental US were significantly higher than that of DM alone ( $P < .001$ ), but with higher AIR and lower specificity ( $P < .001$ ). DM with AI showed higher specificity ( $P = .001$ ) with lower AIR ( $P = .002$ ) than DM alone, however with comparable CDR and sensitivity ( $P = .157$ ). AI correctly identified one invasive lobular cancer missed by DM and US. US alone detected additional 10 cancers, of which 90% were stage 0 ( $n=4$ ) and stage I ( $n=5$ ) invasive cancers, all node negative.

#### CONCLUSION

DM with supplemental US showed higher cancer detection ability than with supplemental AI in women with dense breasts. Supplemental US detected additional early-stage cancers in women with dense breasts without AI recall.

#### CLINICAL RELEVANCE/APPLICATION

The combined use of digital mammography with artificial intelligence cannot replace supplemental breast US in women with dense breasts yet.

### **Bias-Free Artificial Intelligence: Developing a Deep Learning Algorithm for Diverse Racial Populations in Breast Cancer Diagnosis**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Dogan S. Polat, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study aimed to develop a deep learning (DL) algorithm to facilitate automated diagnosis of breast cancer using mammography.

#### **METHODS AND MATERIALS**

The algorithm was trained on a total of 136,172 mammograms that includes an isolated partition of Optimam (n=103472), DDSM (n=2812), and multiple single and multi-institution datasets across southeast Asia, Africa, South America, and Europe (n=29888). The algorithm was then tested on 9304 cases [Optimam (n=8980) and independent blinded single institution (n=324)]. Cancers comprised 34.7% (n=3226) of 9304 mammograms (23.6% invasive, 8.7% DCIS and 2.5% unknown types), while 65.3% (n=6078) were benign/negative. Race was stratified into five categories: white (n=6943, 74.6%), Asian (n=555, 6%), black (n=411, 4.4%), other (n=235, 2.5%), and unavailable/withheld (n=1160, 12.5%). Chi-square tests compared categorical variables, while t-tests and ANOVA compared area under the curve (AUC) of the model for different groups and means. ROC curves are compared in pairwise manner using pROC library in R.

#### **RESULTS**

Mean patient age was 61.1 (SD±7.7). While lesion type information either was not available or negative for 5604 (60.2%) patients, 2544(27.3%) presented as soft tissue abnormality and 1156 (12.4%) as calcifications. The algorithm achieved AUC of 0.91, 0.95 sensitivity, 0.55 specificity, 0.92 negative predictive value (NPV) and 0.66 positive predictive value (PPV). When stratified by lesion type, the algorithm performed better in characterizing soft tissue lesions [compared to calcification and other lesion types with following parameters AUC, sensitivity, specificity, NPV and PPV: 0.87, 0.9, 0.59, 0.48, 0.93 vs 0.71, 0.8, 0.49, 0.55, 0.76, 0.71 (p<0.001)]. Similarly, better diagnostic performance was achieved in detecting invasive cancer than DCIS (AUC 0.87 vs. 0.72, p<0.001), and cancer size >20mm vs <5mm (AUC 0.87 vs 0.77, respectively p<0.001). Performance was comparable across racial groups with the following AUC, sensitivity, specificity, NPV, and PPV: White (0.90, 0.86, 0.76, 0.92, 0.63), Black (0.92, 0.89, 0.75, 0.96, 0.54), Asian (0.89, 0.86, 0.75, 0.94, 0.54), Other (0.91, 0.85, 0.82, 0.95, 0.59), and Unknown (0.90, 0.90, 0.75, 0.82, 0.86). All racial groups were compared to global AUC and found no significant difference (p=1 for each).

#### **CONCLUSION**

The algorithm's performance on datasets comprising diverse racial populations is comparable to that of breast radiologists, tested on datasets that include cases representative of real-world clinical settings.

#### **CLINICAL RELEVANCE/APPLICATION**

The mammography DL algorithm showed high diagnostic performance across diverse datasets, comparable to US screening benchmarks, promising for large-scale screening triaging.

### Simulating Synthetic Post-contrast Breast MRI from Single Pre-contrast MRI Sequence Using Deep Learning Model

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Su Min Ha, MD, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the feasibility of deep learning model for simulated post-contrast T1-weighted breast MR images generated using single pre-contrast MR image in patients with breast cancer. In addition, to validate the deep model network implemented with five pre-contrast sequences including T2-weighted and diffusion-weighted imaging.

#### METHODS AND MATERIALS

In this retrospective study, 363 women with breast cancer and contrast-enhanced breast MRI were identified between June 2019 and December 2019 at a single academic institution. An Extra-Dimensional U-net with visual geometry group was developed to simulate T1-weighted post-contrast images from single pre-contrast T1-weighted images. A total of 330 cases were used for the training set and 24 cases were used for validation set. In addition, we externally validated the deep learning model using five pre-contrast sequences (T1-weighted non-fat suppressed [FS], T1-weighted FS, T2-weighted FS, apparent diffusion coefficient, and diffusion-weighted imaging) [[https://github.com/ecalabr/breast\\_simulated\\_gad](https://github.com/ecalabr/breast_simulated_gad)]. Performance was evaluated qualitatively regarding lesion visibility and five point scale (5: excellent, 4: good, 3: acceptable, 2: poor and 1: unacceptable), and also quantitatively with metrics including peak signal to noise ratio (PSNR) and SSIM (structural similarity index).

#### RESULTS

The validation set of 24 MRI examinations in 24 women (mean age, 56 years; range, 43-73 years) were evaluated. There were 23 invasive ductal carcinoma, 1 ductal carcinoma in situ; 19 masses and 1 non-mass, 4 mass with nonmass lesions (mean size, 2.2cm; range, 1.1-7.0cm). With our model, 63% (15/24) were visible and were rated 50% (12/24) good or excellent or acceptable and 50% (12/24) unacceptable or poor. In comparison, with the open-source deep model, 70% (17/24) lesions were visible and rated 46% (11/24) good or excellent or acceptable, and 54% (13/24) unacceptable or poor. With our developed model, simulated post-contrast T1-weighted breast MR images showed PSNR of 27.10 and SSIM of 0.87.

#### CONCLUSION

Our developed model using single pre-contrast T1-weighted imaging is capable of producing the simulated post-contrast MR image, and is comparable to outcomes using suggested deep learning model.

#### CLINICAL RELEVANCE/APPLICATION

There is increasing need for non-contrast breast MRI for cancer detection due to gadolinium retention and more accessibility of breast MRI.

### Machine Learning-based Texture Analysis of Axillary LNs Using 3-T MRI for Predicting LN Metastasis in Breast Cancer

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Na Lae Eun, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aimed to determine whether texture analysis for 3-T magnetic resonance imaging (MRI) in axillary lymph nodes (LNs) can predict LN metastasis in breast cancer.

#### METHODS AND MATERIALS

This retrospective study included 204 patients who underwent breast and axillary surgery for breast cancer between March 2022 and December 2022. We assessed common features of axillary LNs, including clinicopathologic features and MRI assessment by radiologists, as well as texture features of axillary LNs on contrast-enhanced T1-weighted images using commercial software based on PyRadiomics. The index LN was determined as the LN with the largest cortical thickness. Logistic regression with feature selection was used to reduce the dimensionality of the data (14 clinicopathologic and 869 texture features). Using the selected features, we trained an XGBoost classifier to build common, radiomics, and combined common and radiomics models for predicting LN metastasis. The diagnostic performance of predictive models for LN metastasis was compared by using generalized estimating equation analysis.

#### RESULTS

Of the 204 women, 47 (23%) were diagnosed with LN metastases. The XGBoost classifier with common features, including clinicopathologic and MRI assessment, showed the lowest diagnostic performance (accuracy and area under the receiver operating characteristic curve [AUC], 73.81% and 0.846). The radiomics and combined common and radiomics model with the XGBoost classifier showed better diagnostic performance than that of the analysis of common features alone (accuracy and AUC, 90.48% and 0.939, 90.48% and 0.939 vs. 73.81% and 0.846,  $p < 0.05$ ). In addition, the combined common and radiomics model showed a positive predictive value of 100% for predicting LN metastasis.

#### CONCLUSION

Texture analysis using an XGBoost classifier for axillary LNs on 3-T MRI may be a useful tool in predicting LN metastasis in patients with breast cancer.

#### CLINICAL RELEVANCE/APPLICATION

Machine learning-based texture analysis of axillary LNs using 3T-MRI can help predict axillary LN metastasis and potentially de-escalate axillary surgery in patients with breast cancer.

### Artificial Intelligence Helps General Radiologists and Breast Imaging Specialists Find Challenging-to-Detect Cancers

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Bryan Haslam, PhD (*Presenter*) Employee, RadNet, Inc

#### PURPOSE

There is growing evidence that AI helps radiologists detect more breast cancers in screening mammography. However, there has been little explanation of how AI helps radiologists with varying levels of specialty. Here, we investigated how AI for DBT helps general radiologists and breast imaging specialists detect breast cancer lesions with varying degrees of how challenging the cancers are to detect.

#### METHODS AND MATERIALS

Following an IRB approved protocol, a reader study was conducted to evaluate the interpretative performance of 18 radiologists including 9 general radiologists and 9 breast imaging specialists. Each reader read 240 retrospectively collected DBT screening exams (100 cancers and 140 non-cancers) once with and once without the aid of AI. General radiologists' and breast imaging specialists' performance, as measured by AUC, were examined with vs without AI. Additionally, cancer exams were sorted by degree of difficulty in two different ways. First, the cancer exams were grouped by the BIRADS assessment given at the time of original clinical interpretation: a) recalled cancers (n = 67) were those given a BIRADS 0 and b) non-recalled cancers (n = 33) were those given a BIRADS 1 or 2. The non-recalled exams are considered more difficult given that these are the clinically "missed" exams where the interpreting radiologist at the time of exam acquisition deemed there were no suspicious findings for a recall. Second, the cancer exams were subdivided into a) harder (n = 16), b) medium (n = 11) and c) easier (n = 73) cancer cases based on the proportion of the readers in the study that recalled the exam when reading without the aid of AI (< 50% recalled, 50% to 75% recalled, and > 75% recalled, respectively).

#### RESULTS

Overall, both general radiologists (AUC increase of 0.075) and breast imaging specialists (AUC increase of 0.050) demonstrated improved performance when reading with AI than without AI. Across both methods of sorting the cancer exams by difficulty, there were greater improvements with AI when radiologists interpreted more challenging (AUC increase for non-recalled: 0.100, harder: 0.176 and medium: 0.110) than less challenging cancers (recalled: 0.040 and easier: 0.027). The largest boost in performance was observed for general radiologists on the harder cancers with an AUC improvement of 0.186.

#### CONCLUSION

AI helped both general radiologists and breast imaging specialists improve cancer detection performance overall and to a greater extent for the more challenging cancer cases.

#### CLINICAL RELEVANCE/APPLICATION

AI for screening DBT helps radiologists with varying levels of specialty, especially on difficult to detect cancers that would likely go undetected until a future exam, suggesting that AI may help detect these cancers earlier.

### Examining the Potential of ChatGPT to Derive Differential Diagnoses from Transcribed Radiological Findings in Breast and Ultrasound Imaging

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Shawn H. Sun, MD, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the accuracy and reliability of ChatGPT3.5 and ChatGPT4 in producing a differential diagnosis from transcribed radiological findings of breast and ultrasound radiology cases.

#### METHODS AND MATERIALS

A sample of 25 breast and ultrasound imaging cases were selected from a radiology textbook, from which the answers were used as the gold standard. The case images and history were converted into standardized prompts that contained purely descriptive language of the cases and a query for the most likely diagnosis, top three differential diagnoses, and the corresponding explanations and references from the medical literature. These prompts were fed into the ChatGPT3.5 and ChatGPT4 algorithms. Generated responses were analyzed for accuracy by comparison with the original literature and reliability through manual verification of the generated explanations and citations. The top 1 accuracy and the top 3 accuracy were defined as the percentage of generated responses that matched the original diagnosis and the complete differential provided by the original literature. An additional differential diagnosis score was defined as the proportion of differentials that matched the original literature's answers for each case. Comparisons were made between the results of the two algorithms using a one-tailed two proportion z-test method.

#### RESULTS

The top 1 accuracy and top 3 accuracy, for ChatGPT3.5 versus ChatGPT4 were 32% compared to 40% ( $p=0.28$ ) and 8.0% compared to 12.0% ( $p = 0.32$ ), respectively. The average differential diagnosis score of ChatGPT3.5 versus ChatGPT4 was 38.9% compared to 45.2% ( $p=0.33$ ). ChatGPT3.5 and ChatGPT4 hallucinated 32.0% versus 8.0% ( $p=0.017$ ) of the references provided and generated 6 total false statements versus 2 total false statements, respectively.

#### CONCLUSION

The ChatGPT algorithms were able to produce a differential diagnosis for prompts containing descriptive radiological findings. The responses matched the expert literature from which the cases originated a minority of the time, though a non-statistically significant improvement was made in the accuracy categories from 3.5 to the 4th generation algorithm. The renowned hallucination effect appeared more frequently in generated citations compared to algorithm-produced statements, with both showing improvement in the latest generation.

#### CLINICAL RELEVANCE/APPLICATION

ChatGPT and Large Language Models (LLM) possess considerable potential to transform clinical and educational medicine. Awareness of their accuracy and potential for mistakes will contribute to a more comprehensive understanding of the limitations of such new tools.

### Improving Artificial Intelligence (AI) Risk Assessment with Multiple Imaging Modalities and Prior Imaging Data

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Eliana Goldberg, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study is to evaluate the efficacy of multimodal AI algorithms (full field digital mammography (FFDM)/digital breast tomosynthesis (DBT), breast ultrasound (US) and prior imaging) into breast cancer risk assessment models

#### METHODS AND MATERIALS

Our IRB-approved research utilized a multimodal AI system trained on a dataset of FFDM, DBT, and US exams. These exams were conducted between 2010 and 2020, involving 1,964,416 exams on 324,978 patients. We used a patient-based 60-10-30 split for training/validation/testing. The testing dataset comprised FFDM/DBT/US from patients not included in the training/validation sets, with histopathology/imaging stability as reference standard. The AI risk model was designed to predict cancer risk at multiple time points: 1 year, 3 years, 5 years, and 10 years based on imaging alone. We compared the model's AUROC, sensitivity, and specificity for each risk assessment interval. We also compared 10-year risk assessments to Tyrer-Cuzick (TC) scores.

#### RESULTS

On a test set of 29,845 patients (average age 59.1, standard deviation 11.09, 74,024 exams), 3.05% (910/29845) were diagnosed with breast cancer within 10 years. The AI model achieved AUROC for breast cancer risk assessment as follows: 0.888 (1 year), 0.804 (3 years), 0.770 (5 years), and 0.760 (10 years). Sensitivity was 71.5% (1 year), 52.3% (3 years), 44.0% (5 years), and 40.7% (10 years). For women with dense breasts, AI model AUROC was 0.876 (1 year), 0.779 (3 years), 0.750 (5 years), and 0.739 (10 years). Sensitivity was 69.8% (1 year), 50% (3 years), 42.7% (5 years), and 39.8% (10 years). For women with non-dense breasts, model AUROC was 0.896 (1 year), 0.822 (3 years), 0.781 (5 years), and 0.774 (10 years). Sensitivity was 72.2% (1 year), 52.8% (3 years), 43.1% (5 years), and 39.5% (10 years). Specificity was held constant at 90% for model binarization thresholds. On a random subset of 134 patients with cancer and non-cancer patients, model AUROC was 0.826 (10 years), while TC scores was 0.644 (10 years). When patients were binarized into high or low risk, AI was more informative than was TC. For example, patients who were assessed as TC high risk but AI low risk had a low incidence of cancer (18.9%; 7/37), whereas patients who were assessed as TC low risk and AI high risk had a high incidence of cancer (89.1%; 33/37).

#### CONCLUSION

Multimodal breast cancer risk assessment based on FFDM/DBT, US imaging and prior examinations outperforms standardized risk cancer assessment.

#### CLINICAL RELEVANCE/APPLICATION

Integrating multiple imaging modalities and prior imaging into AI breast cancer risk assessment models enhances performance, enabling the development of a personalized, data-driven, and evolving screening schedule based on an individual's risk profile over time.

### Self-Supervised Pretrained Vision Transformers for Breast Ultrasound Classification

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

George Zhou, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Develop a deep learning model for automated breast ultrasound classification. For computer vision tasks such as this one, convolutional neural networks (CNN) have been the gold standard. Here we study the application of Vision Transformers (ViT) for breast ultrasound classification. Specifically, we examine how the performance of ViT can be improved with self-supervised pretraining.

#### METHODS AND MATERIALS

A total of 647 breast ultrasound images were collected. A label of either benign or malignant was given to each image by radiologists. Malignant cases were validated with histopathologic results from subsequent fine needle aspiration biopsies. The final dataset included 437 benign and 210 malignant US images (PMID: 31867417). The ViT explored in this study consists of 12 transformer encoder layers with 12 multi-attention heads. First the images are tokenized into patches. The patches are linearly projected and combined with positional encodings before input into the sequence of transformer encoders. We study three pretraining paradigms: random weight initialization, supervised pretraining on ImageNet, and self-supervised pretraining on ImageNet. In supervised learning, annotated labels are used during pretraining. In self-supervised learning, representations are learned without any explicit labels; instead, supervisory signals are derived from the data itself. After the models are pretrained, one fully connected layer is added on top of each model and trained to perform binary classification.

#### RESULTS

We evaluate our models using five-fold cross validation. The ViT with random weight initialization achieves an AuROC of  $0.67 \pm 0.08$ . The supervised pretrained ViT achieves an AuROC of  $0.88 \pm 0.04$ . The self-supervised pretrained ViT achieves an AuROC of  $0.92 \pm 0.02$ . Visualization of the self-attention heat maps show that the self-supervised ViT can learn semantic segmentation information without any explicit segmentation masks.

#### CONCLUSION

We show that self-supervised pretraining offers a performance boost compared to supervised pretraining ViT for breast ultrasound classification. Overall, our results show that with the advances being made in deep learning, it may be worthwhile to renew the discussion on the role of ultrasound in screening for breast cancer.

#### CLINICAL RELEVANCE/APPLICATION

In the context of breast cancer screening, mammography is the gold standard. Breast ultrasound, despite being widely available and posing no radiation risk, is limited by a high rate of false positives, operator dependency, and a growing shortage of (breast) radiologists. However, advances in deep learning can potentially mitigate these limitations.

S3B-SPCA-1

### Inferior Left Atrial Diverticulum Communicating with the Right Atrium or Inferior Vena Cava: CT and Clinical Features

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Hae Jin Kim (*Presenter*) Nothing to Disclose

#### PURPOSE

Interatrial communications in atypical locations are found at CT. However, information on imaging findings of atypical or nonseptal communications between two cardiac atria has not been known to dates. The purpose of this study was to evaluate the prevalence, location, size and morphological characteristics of left trial (LA) diverticula communicated with right atrium on cardiac CT.

#### METHODS AND MATERIALS

This retrospective study included 222 consecutive patients who underwent cardiac computed tomography and showed incidental inferior LA diverticula (ILAD). The prevalence, number, size, morphological characteristics and location of ILAD communicating with the right atrium or inferior vena cava were analyzed. Shunts were defined as anatomical defects between the two structures with or without visible contrast flow or attenuation step up.

#### RESULTS

The prevalence of ILAD with shunt was 9.9% (22/222) among ILADs. Shapes of ILAD with shunt were tubular (n = 12, 54.5%), saccular (n = 8, 36.3%), and network-like appearance (n = 2, 9.1%). Mean ostial diameter of ILAD and mean size of shunt were 6.4 mm, 4.9 mm, respectively. Of the 22 patients, 7 (31.8%) had two or more shunts.

#### CONCLUSION

Cardiac CT helps to detect a new type of interatrial communications which can mimic classical atrial septal defects. Although their clinical significance remains unclear, radiologists should be aware of them and report their findings.

#### CLINICAL RELEVANCE/APPLICATION

Our study is the first study to visually assess the category using ECG gated cardiac CT for LA diverticulum with shunt to RA.

Printed on: 08/22/24

## Abstract Archives of the RSNA, 2023

S3B-SPCA-2

### Cardiac CT-derived Global and Regional Epicardial Adipose Tissue Contributes to Atrial Fibrillation in Patients without Left Atrial Myopathy as Defined by Endocardial Voltage Mapping

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Aqeel Umar, MBCh (*Presenter*) Nothing to Disclose

#### PURPOSE

Atrial myopathy contributes to the pathogenesis of atrial fibrillation (AF), but many AF patients have no obvious atrial myopathy. Epicardial adipose tissue (EAT) has recently been shown to be greater in AF patients than those without AF. Our aim was to assess the relationship of EAT in AF patients with/without atrial myopathy defined by endocardial voltage mapping.

#### METHODS AND MATERIALS

75 AF patients with cardiac CT prior to pulmonary vein ablation were prospectively enrolled. Left atrial (LA) endocardial voltage mapping was performed in all patients. Left atrial myopathy was defined as the sum of all low voltage ( $<0.5\text{mV}$ ) areas (LVA) exceeding 5% of total LA surface area. AF patients were assigned to either LVA- ( $<5\%$  LVA) or LVA+ ( $\geq 5\%$  LVA) groups. 48 age-, sex- and BMI-matched patients without AF and structural heart disease/coronary artery disease, who had undergone cardiac CT, were identified as a control group. Total, LA and right atrial (RA) EAT were quantified on CT using fat density thresholding ( $-195$  to  $-30$  HU) after segmenting areas of interest using standard 3D post-processing software. Differences between groups were assessed using one-way ANOVA and relationships were assessed using correlation analysis. Inter-observer variability of EAT analysis was assessed with correlation analysis and Coefficient of Variance (CV) using random subset of 35 AF patients.

#### RESULTS

LVA- patients ( $n=50$ ; 6% f) were younger than LVA+ patients ( $n=25$ ; 44% f). BMI correlated with total EAT (Spearman  $r$  0.50;  $p<.01$ ), LA EAT ( $r$  0.47;  $p<.01$ ) and RA EAT ( $r$  0.41;  $p<.01$ ) in AF patients and similarly in controls. Between LVA+ and LVA- AF patients, there was no significant difference for total EAT ( $89.1\pm 41.1\text{cm}^3$  vs  $83.5\pm 31.1\text{cm}^3$ ;  $P=.5$ ), LA EAT ( $9.9\pm 5.8\text{cm}^3$  vs  $8.9\pm 3.5\text{cm}^3$ ;  $P=.6$ ) and RA EAT ( $7.4\pm 3.8\text{cm}^3$  vs  $7.5\pm 3.1\text{cm}^3$ ;  $P=.9$ ). Compared to controls, LVA- patients had greater total EAT ( $80.1\pm 29.3\text{cm}^3$  vs  $56.5\pm 22.1\text{cm}^3$ ;  $p<.001$ ), greater LA EAT ( $8.9\pm 3.5\text{cm}^3$  vs  $4.5\pm 1.9\text{cm}^3$ ;  $p<.001$ ) and greater RA EAT ( $7.5\pm 3.1\text{cm}^3$  vs  $4.9\pm 2.0\text{cm}^3$ ;  $p<.001$ ). There was good agreement for total EAT ( $r=0.99$ ), LA EAT ( $r=0.98$ ) and RA EAT ( $r=0.98$ ) between observers (all  $p<.001$ ) with CV of 3.5%, 6.4% and 6.2% respectively.

#### CONCLUSION

EAT does not differ between AF patient with or without LA myopathy, but EAT is significantly greater among AF patients without LA myopathy compared to controls without AF. These findings suggest that EAT may contribute to the pathogenesis of AF even in the absence of LA myopathy. Strategies to monitor and reduce EAT may help to improve rhythm control in these patients.

#### CLINICAL RELEVANCE/APPLICATION

Increased EAT volume may play an important role in AF pathogenesis in patients without LA myopathy; further studies should analyse the effect of EAT reducing treatment and downstream effects on AF incidence.

### **Metabolic Syndrome is Associated with Impaired Left Atrial and Left Ventricular Deformation and Abnormal Atrioventricular Interaction in Patients with Myocardial Infarction**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Jing Liu, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Metabolic syndrome (MetS) is a cluster of cardiovascular risk factors that predicts poor short- or long-term outcomes in patients with myocardial infarction (MI). However, the potential mechanisms influencing prognosis are still unclear. Thus, this study aimed to determine the effect of MetS on left atrial (LA) and left ventricular (LV) deformation and abnormal atrioventricular interactions in MI patients.

#### **METHODS AND MATERIALS**

A total of 181 MI patients, including 119 without MetS (MI [MetS-]) and 62 with MetS (MI [MetS+]), and 58 controls who underwent 3.0 T cardiac magnetic resonance (CMR) were included. LA ejection fraction [LAEF] and deformation indices (reservoir, conduit, and booster pump function) and LV deformation parameter (global peak radial, circumferential, and longitudinal strain [PS]) based on CMR three-dimensional feature tracking were measured and compared among groups. Correlations of MetS and LV deformation and geometry with LA functional indices were assessed by multivariable linear regression analysis.

#### **RESULTS**

LA reservoir function (total EF and total strain) and conduit function (passive strain) and LV deformation parameters (radial, circumferential, and longitudinal PS) significantly decreased from the control group, through the MI (MetS-), to MI (MetS+) group (all  $P < 0.05$ ). Compared with controls, the booster pump function (active EF and active strain) was decreased in the MI (MetS+) group (all  $P < 0.05$ ) but preserved in the MI (MetS-) group. Furthermore, multivariate linear regression demonstrated that MetS was independently associated with total and active LAEF, total and passive strain ( $\beta = -0.172$  to  $-0.200$ , all  $P < 0.05$ ) in MI patients; LA reservoir and conduit function were independently associated with LV circumferential PS ( $\beta = 0.230$  to  $0.394$ , all  $P < 0.05$ ) and longitudinal PS ( $\beta = 0.189$  to  $0.354$ , all  $P < 0.05$ ), LA passive strain and strain rate were independently associated with LV mass ( $\beta = -0.178$  and  $-0.298$ , all  $P < 0.05$ ).

#### **CONCLUSION**

Coexisting MetS may exacerbate the adverse effects of MI on LA and LV dysfunction. LV circumferential and longitudinal PS are stable predictors of LA three-phasic function; LV hypertrophy is independently associated with LA conduit function.

#### **CLINICAL RELEVANCE/APPLICATION**

These results suggest that metabolic disorders may be important in managing patients with myocardial infarction.

### **MRI Evaluation by T1 Mapping of the Post Myocardial Infarction Left Ventricular Thrombus**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Samer Abi Khalil, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The objective of this study is to evaluate the post myocardial infarction left ventricular thrombus on cardiac MRI by measuring its T1 mapping value, thus to determine the age of thrombus.

#### **METHODS AND MATERIALS**

This observational retrospective study was performed on all patients scheduled for 3.0 Tesla cardiac MRI post myocardial infarction on our institution from January 2015 to December 2022. 35 patients with a left ventricular thrombus that may be measurable on T1 mapping sequence were included. They were separated in two groups depending on the period of time between the infarct and the MRI - less than three months: group A; more than three months: group B. T1 mapping value was measured for all thrombi.

#### **RESULTS**

T1 of thrombi was  $1098 \pm 61$  ms in group A and  $1316 \pm 75$  ms in group B,  $p < 10^{-4}$ . T1 of the myocardium was  $1224 \pm 73$  ms in group A and  $1254 \pm 48$  ms in group B,  $p = 0.139$ . T1 of the blood pool was  $1934 \pm 137$  ms in group A and  $2008 \pm 124$  ms in group B,  $p = 0.135$ .

#### **CONCLUSION**

Recent thrombi had shorter mapping T1 than old thrombi.

#### **CLINICAL RELEVANCE/APPLICATION**

This method represents a new approach for the age and the maturity of left ventricular thrombus. It provides complementary information for the recommendations of imaging control and anticoagulation therapy.

### STEMI Patients: Who Gets What Imaging

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Alex Zhang, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Our study aims to determine if hospital and patient characteristics affect what type of imaging modality ST elevated myocardial infarction (STEMI) patients receive.

#### METHODS AND MATERIALS

The National Emergency Department Sample (NEDS) database was retrospectively queried for patients with a primary diagnosis of STEMI. Logistic regression was used to determine the likelihood of receiving ultrasound and fluoroscopy based cardiac imaging with respect to hospital characteristics such as region, teaching status, and trauma level designations. We also looked at patient characteristics including hypertension, hyperlipidemia, and tobacco usage.

#### RESULTS

Of the 175,700 patients with a primary diagnosis of STEMI, most were white (74.1%), seen at a non-trauma hospital (49.7%), and insured through medicare (44.8%). Female patients were less likely to get fluoroscopy imaging (OR: .927, 95%CI .871 - .987) than male patients. Black patients were also less likely to get fluoroscopy imaging relative to white patients (OR: .711, 95%CI .583 - .869). Patients with private insurance and patients at teaching hospitals were more likely to get fluoroscopy relative to medicare patients (OR: 1.211, 95%CI 1.069 -1.371) and patients at non teaching hospitals (OR: 1.563, 95%CI 1.133 - 2.155). Patients at trauma hospitals level 1-3 were more likely to get fluoroscopic cardiac imaging compared to non trauma hospitals: Level 1 (OR: 1.593, 95%CI 1.022 - 2.486), Level 2 (OR: 2.489??, 95%CI 1.813 - 3.417), Level 3 (OR: 2.216 95%CI 1.544 - 3.180) Patients with private insurance were more likely to get ultrasound cardiac imaging compared to medicare patients (OR: 1.165, 95%CI 1.025 - 1.325). Trauma level had no effect on patients receiving ultrasound cardiac imaging compared to non trauma: Level 1 (OR: 1.548, 95%CI 0.856 - 2.801), Level 2 (OR: 1.548, 95%CI 0.796 - 2.266), Level 3 (OR: 0.941 95%CI .559 - 1.583)

#### CONCLUSION

We found that females and black patients are less likely to receive fluoroscopy imaging relative to male and white patients, respectively. While ongoing gender and race disparities may play a role in these findings, further studies are needed to fully elucidate this relationship. Additionally, private insurance beneficiaries are more likely to get imaged with fluoroscopy. Proximity to hospitals with imaging capabilities and better access to resources may play a role in our findings

#### CLINICAL RELEVANCE/APPLICATION

Hospitals and clinicians need to re-evaluate their imaging algorithm for black and female patients. We also found that type of insurance and teaching hospital drastically affects likelihood of receiving fluoroscopy. These findings indicate a deeper health inequality that hospitals and physicians should address together in order to make healthcare more equitable

### STEMI Patients: Can Imaging Predict Cost of Stay and Mortality?

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Alex Zhang, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Our study aims to determine if imaging modality can predict cost of stay and mortality in patients who have a primary diagnosis of ST elevated myocardial infarction (STEMI).

#### METHODS AND MATERIALS

The national emergency department sample (NEDS) database was retrospectively queried for patients who had a primary diagnosis of STEMI. A multivariate linear regression model was used to account for key clinical covariates including age, sex, race, insurance status, income quartile, teaching status, trauma level, and cardiac risk factors such as tobacco use, coronary artery disease, and hyperlipidemia to determine cost associated with cardiac imaging. Primary outcomes focused on cost associated with use of CT, MRI, fluoroscopy, and ultrasound. A secondary analysis, with the same multivariate model, was performed to determine if certain imaging corresponded to increased odds of death.

#### RESULTS

Of the 175,700 patients, in our analysis, that presented to the emergency department with a primary diagnosis of a STEMI, most were female (69.3%), white (74.1%), and had a median income in the 1st quartile (29.4%). There was increased cost associated with all cardiac imaging modalities (relative to patients who did not receive an imaging modality); fluoroscopy (B: 27,630, 95%CI 15,748-39,311), CT (B: 32,757, 95%CI 4,036-61,478), MRI (B: 397,766 380980-414,751), x-ray (24,740, 95%CI 6,426-43,055) and ultrasound (B: 25,492, 95%CI 14,150-36,834). Patients who got imaging with ultrasound (OR: 0.76, 95%CI 0.64-0.90) or fluoroscopy (OR: 0.45 95%CI 0.39-0.53) were less likely to die relative to patients who did not get imaged by those modalities. There was no difference in death rate in patients who were imaged with X-ray (OR:0.79, 95%CI 0.47-1.35) or CT scan (OR: 0.62, 95%CI 0.37-0.1.04).

#### CONCLUSION

STEMI patients who get imaging pay significantly more than patients who do not get imaging. However, the use of x-ray or CT scan imaging does not necessarily lead to better outcomes, as shown in the death rates we have found. Each imaging modality is found to increase cost of stay in the tens of thousands of dollars, with MRI, being the exception, increasing cost of stay by hundreds of thousands of dollars.

#### CLINICAL RELEVANCE/APPLICATION

Hospitals and clinicians should be encouraged to rethink what type of imaging they order for STEMI patients. Our study shows that CT and X-ray do not decrease mortality rate, while increasing cost of stay for patients by tens of thousands of dollars.

### Diagnostic Accuracy of Dynamic Stress CT Myocardial Perfusion with Regadenoson for the Detection of Hemodynamically Significant Coronary Artery Disease

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Cesar Urtasun Iriarte I, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the diagnostic performance of dynamic stress CT myocardial perfusion imaging (CT-MPI) in combination with coronary CT angiography (CCTA) to accurately identify hemodynamically significant coronary artery disease (CAD) compared to the gold standard (invasive coronary angiography, ICA; and invasive fractional flow reserve, iFFR).

#### METHODS AND MATERIALS

Between December 2019 and February 2023, 141 patients with suspected or known CAD underwent CCTA and dynamic stress CT-MPI employing regadenoson as stressor. The presence of hemodynamically significant coronary lesions was determined by CCTA (CAD-RADS=3) and CT-MPI (myocardial blood flow relative to remote myocardium <0.85) compared to CCTA alone, using angiographic severity and a iFFR of =0.80 as reference.

#### RESULTS

A total of 141 patients (113 males, mean 64.8±10.1 years old, 24 with prior stent implantation) were evaluated. CCTA and CT-MPI were positive in 67 (47.5%) and 50 (35.5%) patients, respectively. 43 patients (32 males, 65.6±11.1 years old; 93.3% with CAD-RADS =3) who underwent ICA were retained for the statistical analysis. Compared to ICA, the patient-based analysis of CCTA showed a sensitivity of 100%; specificity of 50%, negative predictive value (NPV) of 100% and a positive predictive value (PPV) of 92.5%. The approach comprising CCTA and dynamic stress CT-MPI increased the specificity (97.4%) and PPV (97.4%). The accuracy of the combination of the anatomical and functional techniques was also higher (97.7% vs 93%). Receiver operating curve (ROC) analysis showed improved discrimination accuracy for the combination of CCTA and CT-MPI (0.92; CI 0.74-1; p=0.001) compared with CCTA alone (0.75; CI 0.49-1; p=0.052).

#### CONCLUSION

Dynamic stress CT-MPI with regadenoson offers incremental diagnostic value over CCTA alone for the detection of hemodynamically significant CAD.

#### CLINICAL RELEVANCE/APPLICATION

Dynamic stress CT-MPI is an easy-to-perform diagnostic examination technique which increases the specificity and diagnostic accuracy of CCTA alone for the detection of hemodynamically significant CAD.

### Quantitative Analysis for Bronchiectasis using Artificial Intelligence-based Bronchial Tapering Ratio in Patients with Chronic Obstructive Pulmonary Disease

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Hyejin Park (*Presenter*) Nothing to Disclose

#### PURPOSE

Bronchiectasis (BE) is associated with loss of lung function and increased morbidity and mortality. CT is the standard method used to assess bronchiectasis but current imaging methods are limited in assessing the extent of bronchiectasis on CT scans. This study aimed to automatically quantify the extent of bronchiectasis based on an artificial intelligence (AI)-based analysis of bronchial tapering ratio on chest CT and assess the association of quantified bronchiectasis score and exacerbations in patients with chronic obstructive pulmonary disease (COPD).

#### METHODS AND MATERIALS

We analyzed the longitudinal cohort data of COPD patients from the Korean Obstructive Lung Disease (KOLD) cohort. The bronchiectasis score accounting the extent of abnormal tapering of inner lumen compared with the proximal airway (bronchial tapering ratio = 1.1, a measure of airway dilatation) in each patients on chest CT scans was analyzed. Quantified bronchiectasis score was correlated with visual analysis by two thoracic radiologists. Multivariable logistic analysis was performed to assess the association between the bronchiectasis score and pulmonary exacerbations on follow-up adjusted by demographics, pulmonary functional measure, and airway CT parameters.

#### RESULTS

Total 337 patients (median age, 66 years; 328 men [97%]) were included. Among the 337 patients, 210 (62%) had a history of a least one exacerbation. Bronchiectasis was present based on visual analysis in 148 (43.9%) patients and bronchiectasis score significantly increased as extent of bronchiectasis on visual analysis increased ( $P = .02$ ). During a median 5-year follow-up, the bronchiectasis score was a significant independent predictor of acute exacerbation (adjusted odds ratio [OR], 1.12 [95%CI: 1.03-1.22];  $P = .007$ ) along with wall area percentage on CT (OR, 1.03 [1.01-1.06];  $P = 0.02$ ) and forced expiratory volume in 1 s (OR, 0.98 [0.97-0.99];  $P = 0.002$ ) in multivariable analysis.

#### CONCLUSION

In COPD, artificial intelligence-based CT measures of bronchiectasis based on bronchial tapering ratio were significant predictors for acute exacerbation.

#### CLINICAL RELEVANCE/APPLICATION

Evaluation of extent of bronchiectasis on chest CT using artificial intelligence-based bronchial tapering ratio were reliable and automatically quantified extent of bronchiectasis on CT had prognostic implications for COPD exacerbations.

### **Lymphatic Bubble Sign in Lung and Mediastinum: Special CT Feature for the Diagnosis of Pulmonary Lymphatic Malformation with Lymphatic-airway Leakage**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

MENGKE LIU (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the special CT feature of lymphatic bubble sign (LBS) on HRCT for the diagnosis of pulmonary lymphatic malformation (PLM) with lymphatic-airway or alveolar leakage.

#### **METHODS AND MATERIALS**

Eight hundred and ten patients diagnosed as PPL were collected in this retrospective study from January of 2006 to December of 2022, of which 62 cases with chylous phlegm and plastic bronchitis showed LBS in lung and/or mediastinum on HRCT or CT lymphography. The imaging features of LBS were blinded reviewed by two chest radiologists respectively, including the position, size, quantity, morphology, and dynamic changes of bubbles. All patients were followed up for HRCT within 1-6 months.

#### **RESULTS**

LBS was seen in 62 (7.7%) of 810 patients with PPL, which was located in pulmonary interstitium in 30 cases, paraloobar-fissure with thickening in 5 and mediastinal fat area in 12, both in 20 patients. ALL the LBS manifested multiple lesions, no wall or thin wall and round-like with smooth edges with a size of 3-10mm. A dynamic changes of this sign was showed in all patients with obvious improvement in 56 cases, aggravation 6 and recurrent occurrence in 25 patients on the 1-6 months follow-up CT. In addition, similar lesions were showed in chest wall, ribs and pleural cavity, respectively. The associated-accompanying lesions include ground glass opacity, interlobular septal thickening, tree-in-bud, chylothorax, chylo-pericardium and mediastinal opacity. All the lesions is not related to thoracic puncture drainage or direct lymphangiography, but patients often have long-term medical history of dyspnea and chronic cough.

#### **CONCLUSION**

This sign indicates the formation of lymphatic and airway leaks in the lungs, with chylous leakage leading to chylous pneumonia and plastic bronchitis. However, the air in the airway pours back into the lymphatic vessels due to pressure changes and other reasons, forming the LBS. Chest CT has important value in displaying this sign and helps to determine PLMs and chylous leakage and providing strong evidence for clinical treatment.

#### **CLINICAL RELEVANCE/APPLICATION**

LBS strongly favors a diagnosis of pulmonary lymphedema and lymphatic dilatation with lymphatic-airway or alveolar leakage and plastic bronchitis.

### Template Matching Method for Accurate Quantification of Cystic Tissue Volume in CT Scans of Diffuse Cystic Lung Disease

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Katie J. Noonan, BEng, MEng (*Presenter*) Nothing to Disclose

#### PURPOSE

Diffuse Cystic Lung Disease (DCLD) is a broad term used to describe rare lung diseases characterised by the presence of air-filled cysts within the parenchyma of the lungs. Due to their relative scarcity and visual similarity to more prevalent diseases such as emphysema, DCLDs are frequently mis-diagnosed, leading to significantly worse clinical outcomes and a higher burden on the healthcare system. Our research presents a method which accurately identifies cystic regions within DCLD CT scans, achieving a similar standard to expert defined manually annotated cases. Furthermore, the method quantifies cystic tissue volume in the sample, providing a reliable and efficient means of assessment.

#### METHODS AND MATERIALS

Template matching methods involve the extraction of image features, such as shape, texture and colour, and correlates them with a pre-defined image template to identify regions of interest. In the context of a Lymphangioliomyomatosis CT scan, circular regions of low attenuation that exhibit high correlation to a black circle template were isolated and defined as potential cystic regions. The detected regions were then compared with related manually annotated cases which had previously outlined the presence of cystic regions as identified by an expert radiologist.

#### RESULTS

The method's performance was evaluated by comparing its results with that of the manual annotations of an expert radiologist. The assessment yielded a Dice Similarity Coefficient of 86%, Precision of 79%, Specificity of 99% and an F1 Score of 88%.

#### CONCLUSION

The high correlation observed between the template matching method and the manually annotated cases outlines the potential of semi-automated feature extraction methods as a faster and less labour-intensive method to quantifying cystic tissue volume across numerous cases. By computing the ratio between cystic and lung tissue volume, this method provides a reliable means of assessing the overall health of lung tissue. The use of such methods has broad implications in clinical settings, where accurate and efficient evaluation of numerous cases is essential.

#### CLINICAL RELEVANCE/APPLICATION

The semi-automated method outlined identifies cystic regions comparably to expert radiologists, allowing development of a lung health score based on cystic/lung tissue volume ratio.

### Clinical Course and Risk Factors for Development and Progression of Interstitial Lung Disease in Primary Sjögren's Syndrome

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Eunseo Lee (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the long-term course and prognostic factors of patients with primary Sjögren syndrome-associated interstitial lung disease (pSS-ILD).

#### METHODS AND MATERIALS

This single-center, retrospective study included 120 pSS patients who underwent at least two high-resolution computed tomography (HRCT) scans between March 2013 and February 2021. Clinical symptoms, laboratory data, HRCT findings, and pulmonary function test results were collected. HRCT were scored blindly by two expert thoracic radiologists: extent of ground glass opacities (GGO), fine/coarse reticulations, and honeycombing, and coarseness score of fibrosis.

#### RESULTS

In patients with pSS without ILD at baseline (n=81), no development of ILD was found on follow-up (median, 2.8 years). In patients with pSS-ILD (n=39), total disease extent, extent of coarse reticulation, and traction bronchiectasis increased on HRCT, whereas the extent of GGO decreased at follow-up (median, 3.2 years) (each  $p < 0.001$ ). In progressive group of pSS-ILD (n=19/39, 48.7%), the extent of coarse reticulation and coarseness score of fibrosis were increased at follow-up ( $p < 0.05$ ). Multivariate logistic regression analysis showed that LDH (OR, 1.012) and diffusing capacity for carbon monoxide (OR, 0.922) were independent risk factors for pSS-ILD at baseline. Usual interstitial pneumonia (UIP) pattern on CT (OR, 15.237) and follow-up duration (OR, 1.403) were independent risk factors for disease progression in patients with pSS-ILD. In response to glucocorticoid and/or immunosuppressants, GGO decreased, whereas the extent of fibrosis increased even after treatment.

#### CONCLUSION

In pSS patients with no ILD during baseline evaluation, no newly developed ILD was identified during follow-up over two years. Progression occurred in approximately half of the pSS-ILD patients with slow gradual deterioration. UIP pattern on CT and follow-up duration were independent risk factors for progression of pSS-ILD.

#### CLINICAL RELEVANCE/APPLICATION

HRCT is a crucial modality for determining the progression of lung fibrosis in patients with pSS, in addition to the initial screening evaluation for ILD.

### Chest Radiography, Computed Tomography and Magnetic Resonance in Evaluation of Pulmonary Sarcoidosis in Assessment of Disease Progression and Comparison with Pulmonary Function Tests

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Stephan Altmayer, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare radiography, high resolution computed tomography (HRCT), and magnetic resonance imaging (MRI) in the assessment of disease progression in pulmonary sarcoidosis in comparison to pulmonary function tests.

#### METHODS AND MATERIALS

In this prospective study of 77 adults diagnosed with sarcoidosis, all subjects underwent baseline pulmonary function testing, chest radiography, HRCT and MRI. Chest radiographs were categorized using the Siltzbach classification system. HRCT and MRI were scored using the Scleroderma Lung Study I system. Pulmonary function was reassessed after 12 months, with progressive disease defined by  $\geq 5\%$  reduction of forced vital capacity (FVC). Differences in median imaging scores were assessed with Student's t-test and Wilcoxon rank-sum test. Correlation between imaging and pulmonary function was investigated using Pearson's and Spearman's rank correlation coefficients. FVC decline was the gold standard on multivariate analysis used to calculate the odds ratios (OR) for progression of disease predicted by imaging, with score thresholds determined by maximum Youden's index. The area under the curve (AUC) of the receiver operating characteristic plot was calculated for each imaging modality.

#### RESULTS

There is a strong correlation between chest radiography and MRI ( $r=0.649$ ,  $P < 0.001$ ), and CT and MRI scores ( $r=0.851$ ,  $P < 0.05$ ). CT and MRI scores correlated with FVC (MRI:  $r = -0.584$ ,  $P < 0.001$ ; CT:  $r = -0.308$ ,  $P = 0.049$ ) and diffusing capacity of the lung for carbon monoxide (MRI:  $r = -0.564$ ,  $P = 0.004$ ; CT  $r = -0.216$ ,  $P = 0.017$ ). The AUCs for Radiography, MRI and CT scores were 0.70 (0.49-0.85), 0.51 (0.32-0.75), and 0.76 (0.56-0.90), respectively. Multivariate analysis demonstrated significant prediction of progressive disease by CT (OR = 1.236,  $p = 0.044$ ) and MRI (OR = 1.594,  $p = 0.021$ ).

#### CONCLUSION

MRI may be a viable alternative to HRCT in lung assessment and prediction of disease progression in patients with pulmonary sarcoidosis.

#### CLINICAL RELEVANCE/APPLICATION

MRI may be a viable tool for the assessment of disease progression in patients with pulmonary sarcoidosis, although further studies are necessary to validate this tool.

### To Evaluate the Role of the F FDG PET CT in the Idiopathic Pulmonary Fibrosis and Diffuse Parenchymal Lung Disease

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Sikandar M. Shaikh, DMRD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to evaluate the role of the (18)F-FDG PET/CT in patients with idiopathic pulmonary fibrosis (IPF) and diffuse parenchymal lung disease (DPLD).

#### METHODS AND MATERIALS

Seventy-two patients (62 men and 10 women; mean age +/- SD, 68.7 +/- 9.4 y) with IPF (n = 36) or other forms of DPLD (n = 36) were advised whole body PET/CT and also high-resolution CT (HRCT), which were acquired simultaneously. 18 F FDG was done after injecting the radiotracer and whole-body PET-CT was done after 60 minutes of FDG administration. The amount of the uptake in the pulmonary (18)F-FDG metabolism was quantified as a standardized uptake value (SUV(max)). Along with this scan the HRCT lung was done for each patient and further analysis of the various HRCT patterns of parenchymal involvement as ground-glass opacities or reticulation/honeycombing. Along with this the patients underwent a global health assessment and pulmonary function tests.

#### RESULTS

The pulmonary uptake metabolism in 72 of 72 patients was evaluated. The parenchymal pattern of the HRCT is seen as the maximal (18)F-FDG metabolism which was seen predominantly in ground-glass (14/72), reticulation/honeycombing (52/72), and mixed (6/72). The mean SUV(max) in patients with ground-glass and mixed patterns was 2.0 +/- 0.4, and in reticulation/honeycombing it was 3.0 +/- 1.0 (Mann-Whitney U test, P = 0.007). The mean SUV(max) in patients with IPF was 2.9 +/- 1.1, and in other DPLD it was 2.7 +/- 0.9 (Mann-Whitney U test, P = 0.862). The mean mediastinal lymph node SUV(max) (2.7 +/- 1.3) correlated with pulmonary SUV(max) (r = 0.63, P < 0.001). Pulmonary (18)F-FDG uptake correlated with the global health score (r = 0.50, P = 0.004), forced vital capacity (r = 0.41, P = 0.014), and transfer factor (r = 0.37, P = 0.042).

#### CONCLUSION

The increased pulmonary (18)F-FDG metabolism is seen in all the patients with IPF and also other forms of DPLD was observed. Pulmonary (18)F-FDG uptake shows significant changes in the measurements of health and lung physiology in these patients. The analysis showed that the (18)F-FDG metabolism is higher at the site of maximal uptake which corresponds to the areas of reticulation/honeycombing on the HRCT scans other than with ground-glass patterns.

#### CLINICAL RELEVANCE/APPLICATION

The role of the Whole body PET-CT is important in various forms of ILD and other pathologies in the chest

### Predictors of Progressive Pulmonary Fibrosis: A Radiologic-Pathologic Correlation Study

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Hyeong Ryun Cho, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Progressive pulmonary fibrosis (PPF), which is treatable with anti-fibrotic therapy, is defined as interstitial lung disease (ILD) other than idiopathic pulmonary fibrosis (IPF) that manifests progressive features regardless of standard management. This study evaluates the radiologic-pathologic correlations of PPF and identifies predictors associated with disease progression and survival.

#### METHODS AND MATERIALS

Between January 2004 and December 2020, 75 patients diagnosed with ILD other than IPF who underwent surgical lung biopsy were retrospectively included. Three chest radiologists reviewed chest computed tomography (CT) features and fibrosis extent on baseline and follow-up CT, and patients were subdivided into PPF and non-PPF based on progression. Two pathologists reviewed cases for pathologic features and the presence of usual interstitial pneumonia (UIP). Overall and progression-free survival were calculated using the Kaplan-Meier method, and the Cox proportional hazard method was used to examine predictors for progressive pulmonary fibrosis and survival.

#### RESULTS

Regarding radiologic-pathologic correlations, when the pathologic UIP pattern was present in the specimen, it was associated with radiologic honeycombing, traction bronchiectasis, and reticulation ( $p < 0.001$ ). Progression was seen in 42.7% (32/75) of non-IPF ILD patients, with a median progression time of 44 months. Radiologic traction bronchiectasis was identified as the only predictive factor of PPF on the multivariate Cox-proportional hazard method (hazard ratio [HR], 6.54;  $p = 0.003$ ). PPF (HR, 3.96;  $p = 0.013$ ) and advanced age (HR, 1.13,  $p < 0.001$ ) were associated with an increased risk of death in non-IPF ILD patients. The median survival time of PPF was 120 months.

#### CONCLUSION

A radiologic pattern of traction bronchiectasis was a predictor of PPF, while PPF and advanced age were risk factors for low survival in non-IPF ILD patients.

#### CLINICAL RELEVANCE/APPLICATION

Recognition of traction bronchiectasis is crucial for predicting PPF in patients with non-IPF ILD, emphasizing the importance of timely initiation of anti-fibrotic therapy in improving patient outcomes.

### **Granulomatous and Lymphocytic Interstitial Lung Disease in Common Variable Immunodeficiency: CT Findings and Association with Pulmonary Function Tests**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Nicholas Landini, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Common Variable Immunodeficiency (CVID) may be complicated by Granulomatous and Lymphocytic Interstitial Lung Disease (GL-ILD). GL-ILD includes a wide spectrum of ILD abnormalities, worsening CVID prognosis. We aimed to characterize chest Computed Tomography (CT) findings of GL-ILD, in comparison with CVID patients without GL-ILD, and their association with PFT worsening.

#### **METHODS AND MATERIALS**

Patients with CVID followed from 2018 to 2021 were retrospectively evaluated. Inclusion criteria were: GL-ILD diagnosis, CT and PFT performed within one week. Patients on GL-ILD therapy or with the clinical suspicion of infection were excluded. Age and sex matched non GL-ILD subjects were searched. CT findings, evaluated in consensus by two chest radiologists, were: bronchiectasis, bronchial wall thickening, mucous plugs, tree in bud, mosaic perfusion, small nodules ( $\leq 10$ mm) and big nodules (multiple  $\geq 3$ ), consolidation, ground glass opacities (GGO), reticulation, fibrotic ILD, cavitation/necrosis and bands. Small nodules main distribution (centrilobular, perilymphatic or random) was noted. CT abnormalities were assessed in upper, lower fields and whole lungs, describing disease predominance. Presence of enlarged nodes (axis  $\geq 10$  mm), pleural or pericardial effusion was also assessed. Fisher exact test was computed, assessing Odds Ratios (OR) for GL-ILD against non GL-ILD. A significant p-value was set as  $\leq 0.05$ , with Bonferroni correction for the following PFT: TLC, FEV1, FVC and DLCO, % predicted.

#### **RESULTS**

38 GL-ILD subjects and 38 controls were identified. Most common GL-ILD CT findings in GL-ILD ( $\geq 50\%$  patients) were: bronchiectasis, multiple non-perilymphatic small nodules, GGO, consolidations, bands and enlarged nodes. The disease was usually predominant in lower fields (92%). Bronchiectasis, GGO, reticulations, fibrosis and bands were more frequent in lower fields. GGO was associated with TLC worsening, reticulation with all PFT worsening, fibrotic ILD with DLCO (p-value  $\leq 0.0125$ ). Considering whole lungs analysis, small nodules, consolidations, reticulations and fibrosis had an OR  $\geq 10$  in identifying GL-ILD versus non GL-ILD patients.

#### **CONCLUSION**

GL-ILD usually manifests with bronchiectasis, non-perilymphatic nodules, GGO, consolidations, bands and enlarged mediastinal lymph nodes, with a lower field predominance. Reticulation is the main CT finding associated with functional worsening. Small nodules, consolidations, reticulations and fibrotic ILD are highly suggestive of GL-ILD in CVID subjects.

#### **CLINICAL RELEVANCE/APPLICATION**

These results provide CT characteristics of GL-ILD that may be helpful in the diagnosis of a such polymorphic disease, verifying their relationships with PFT worsening

### Self-Supervised Machine Learning to Triage Acute Chest Syndrome in Pediatric Patients with SCD

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Syed M. Anwar, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Children with sickle cell disease (SCD) are at a high risk of poor outcome if they develop pneumonia or acute chest syndrome (ACS). We have developed a machine learning model for ACS prediction using chest radiographs (CXR), hence triaging children for treatment presented to the emergency department.

#### METHODS AND MATERIALS

We performed a retrospective analysis of children with SCD who had a CXR performed at an urban pediatric emergency department between July 2015 and March 2023. A query of our clinical registry identified 1,115 pediatric SCD patients with "likely ACS" (n=601) or "likely not ACS" (n=514), based on diagnosis code and disposition. We manually reviewed the radiologist impression for each CXR and excluded 28.4% (n=171) of patients in the "likely ACS" group and 5.1% (n=26) of patients initially labeled "likely not ACS". A pre-trained, self-supervised machine learning model was fine-tuned using manually reviewed CXR impressions to predict ACS in future radiographic images. Our deep learning model used a vision transformer and was pre-trained on 400,000 CXRs from publicly available data. The model and was earlier tested on other clinical conditions such as covid-19, age, and sex prediction. We report machine learning inference time and the time required to complete the radiologic assessment, reporting timing for both daytime and overnight studies because an attending radiologist is available to review new studies during daytime and evening hours but only reviews images overnight if they are paged directly with a question.

#### RESULTS

The average accuracy of our ACS prediction model was 0.85 with sensitivity of 0.77, specificity of 0.91, and AUC of 0.89. Machine learning inference time was 0.0068 (median) seconds (IQR:0.0065-0.0072) running on machine with NVIDIA RTX A5000 GPU with half-precision (FP16). Daytime studies, completed between 06:00 and 22:00 h, were read by a radiologist within 55.0 (median) minutes (IQR:23.0-115.0). Overnight studies, completed between 22:00 and 06:00 h, were read within 401.5 (median) minutes (IQR:245.25-535.75).

#### CONCLUSION

The model for ACS prediction from CXR has the potential to identify high risk SCD patients in the emergency department in a timely manner with clinically acceptable performance. Our inference time is real-time, allowing for prediction of ACS as soon as a CXR is recorded in the PACS.

#### CLINICAL RELEVANCE/APPLICATION

ACS is associated with mortality and severe morbidity in children with SCD and requires rapid recognition and intervention. At our single site, real-time machine learning prediction has the greatest potential to expedite diagnosis during overnight hours.

### Clinical and Imaging Features of Focal Intrahepatic Biliary Stricture Visualized Only as Duct Dilatation

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Byoungje Kim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The percentage of patients with precursor lesions or malignancy due to focal intrahepatic stricture (FIHS) without radiographically demonstrable bile duct abnormality, visualized only as duct dilatation, is currently unknown. Moreover, it is unknown whether there is a variable to differentiate malignant or precursor lesions from non-precursor benign lesions. Therefore, we studied the proportion of patients with FIHSs that were precursor lesions or malignancies. Additionally, we evaluated the clinical variables and MRI features that may discriminate between non-premalignant benign and premalignant/malignant FIHSs.

#### METHODS AND MATERIALS

This retrospective study assessed patients who underwent surgery for FIHS between January 2010 and March 2022. The number and proportion of non-precursor benign lesions, precursors, and malignancies were calculated. Clinical variables and MRI features were compared between non-premalignant benign and premalignant/malignant FIHSs using independent t-tests and chi-square tests for continuous and categorical variables, respectively.

#### RESULTS

Twenty-five patients with confirmed histopathological diagnoses were identified. The study included 13 men (52.0%) and 12 women (48.0%). The median age of all the patients at the first imaging diagnosis was 65 years (range, 43-78 years). Of the 25 FIHS patients, 9 (36%) were diagnosed with cholangiocarcinoma and 6 (24%) were diagnosed with precursor lesions. Among the precursor lesions, five were intraductal papillary neoplasms of the bile duct, and one was biliary intraepithelial neoplasia. Therefore, 15 (60%) had malignant or precursor lesions, and 10 (40%) were diagnosed with non-precursor benign lesions. None of the clinical variables and imaging features used for analysis showed a statistically significant difference between the non-premalignant benign and premalignant/malignant FIHS groups ( $p < .05$ ).

#### CONCLUSION

More than half of FIHSs were malignant or precursor lesions. There were no predictive values for the clinical and imaging parameters. Therefore, a more active strategy for the diagnosis and follow-up imaging should be considered.

#### CLINICAL RELEVANCE/APPLICATION

Patients with FIHS require active treatment including surgical treatment and careful imaging follow-up.

### **MRI Screening with Machine Learning-supported Post-processing and Genetics of Multiple Biliary Hamartomas**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Philipp Schindler, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Multiple biliary hamartomas (MBH), also known as "von Meyenburg complexes", are benign and asymptomatic malformations of dilated bile ducts embedded in fibrous stroma, usually smaller than 10 mm. A detailed knowledge of these malformative cystic-like lesions is crucial because they may be misdiagnosed as malignant. The aim of this study was to investigate the feasibility of magnetic resonance imaging (MRI) screening for the detection of MBH with machine learning-supported post-processing and to explore the genetic characteristics of this rare condition.

#### **METHODS AND MATERIALS**

Five consecutive patients with MBH were prospectively enrolled in this study. All patients underwent high-resolution (3.0 Tesla) contrast-enhanced hepatobiliary MRI and magnetic resonance cholangiopancreatography (MRCP) at baseline to provide a structured report of imaging features of MBH and at 12-month follow-up to exclude progression. A pipeline of 3D k-means clustering based image segmentation was used for detection of cystic-like lesions. Eccentricity was calculated to identify round and oval objects in the cluster and to exclude the biliary tree. Customized next-generation sequencing (NGS) was used to identify the underlying genetic cause of MBH.

#### **RESULTS**

Baseline MRI showed innumerable small hepatic cystic lesions without contrast enhancement, even in the hepato-biliary phase, and without communication with the biliary tree, allowing the diagnosis of MBH. K-means clustering based image segmentation was feasible for annotation of MBH. Total liver lesion volume remained stable over time (mean volume: 104.8 ml; mean proportion of total liver volume: 8.1%). All patients had a heterozygous missense, truncating, or frameshift mutation in the polycystic kidney and hepatic disease 1 (PKHD1) gene encoding the multidomain integral membrane protein fibrocystin.

#### **CONCLUSION**

This preliminary data suggests that machine learning-augmented MRI screening can be used for quantification of MBH. The genetic analysis revealed a potential association between multiple biliary hamartomas and mutations in the PKHD1 gene. These findings provide important insights into the diagnosis of this rare condition.

#### **CLINICAL RELEVANCE/APPLICATION**

Knowledge of MRI findings and genetics of MBH is helpful for a prompt and correct diagnosis, avoiding unnecessary invasive procedures and/or an excessive number of radiological investigations.

S3B-SPGI-3

### A Comparison of the Diagnostic Accuracies of Ultrasound and CT in 82 Proven Cases of Acute Cholecystitis

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Joshua Thurgood (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare the efficacies of US imaging vs CT imaging in the diagnosis of acute cholecystitis in aiming to improve the diagnosis and treatment of patients with acute cholecystitis.

#### METHODS AND MATERIALS

We retrospectively collected data on 100 patients with suspected acute cholecystitis and 100 control patients with studies occurring between 3/1/2015 and 3/31/2020. Of the 100 suspected acute cholecystitis patients, 50 had US imaging and 50 had CT imaging done. To be included as a proven case of acute cholecystitis, cases were then screened for cholecystectomy. Due to this, 7 US subjects and 11 CT subjects were removed as they did not undergo cholecystectomy or were treated via a different method. In the control group, 50 patients had US imaging and 50 had CT imaging. All studies were then reviewed by three radiologists of differing experience levels. The data from each reviewer was then combined and tabulated. One reviewer also tabulated data for patients that had both US and CT studies done, which amounted to 47 of the patients with confirmed acute cholecystitis.

#### RESULTS

The sensitivity of CT for diagnosing acute cholecystitis was greater than the sensitivity of US, with these being 66.67% and 53.49% respectively. The negative predictive value of CT was also greater than that of US, which were 75.93% and 64.91% respectively. There were no false positives by any of the reviewers, so the specificities and positive predictive values were 100% for both CT and US modalities. Among the 47 patients who had both US and CT studies done, 24 had both positive US and CT for acute cholecystitis, 9 patients had a positive CT and negative US, 4 patients had a positive US and negative CT, and 10 patients had both negative US and CT studies.

#### CONCLUSION

CT was significantly more sensitive and had a higher negative predictive value than US. However, both modalities had lower sensitivities and negative predictive values than what is found in the literature. All three reviewers performed better on CT than US with two performing significantly better with sensitivities improving by 20.63% and 15.98% respectively. The results of our study showed significantly higher performance using CT imaging over US imaging when evaluating for acute cholecystitis. However, we still suggest US as our first imaging test in patients with suspected AC. If the US is negative, CT should be performed. If the CT is negative and there is still strong clinical suspicion for AC, a HIDA scan should be done.

#### CLINICAL RELEVANCE/APPLICATION

The research being conducted is significant because time to treatment of acute cholecystitis is most often imaging dependent and understanding the relative efficacies of the two most common initial imaging modalities will lead to increased efficiency and time to treatment of these patients.

### Ultra-high-resolution Drip-infusion CT Cholangiography with Deep Learning-based Reconstruction: Comparison with Normal-resolution Simulation

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Atsushi Nakamoto, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the image quality and bile duct delineation of drip-infusion CT cholangiography (DIC-CT) using an ultra-high-resolution CT (UHR CT) with a 1024 x 1024 matrix combined with a deep learning-based reconstruction algorithm in comparison with simulated normal-resolution (NR) images.

#### METHODS AND MATERIALS

Twenty-five potential liver transplant donors (13 men and 12 women, age range, 21 to 61 years; mean age, 36.3 years) who underwent DIC-CT using the super-high-resolution (SHR) mode of a UHR CT scanner for preoperative evaluation were included in this retrospective study. SHR images were reconstructed with a 1024 x 1024 matrix and 0.25-mm slice thickness using a deep learning-based reconstruction algorithm. Simulated NR images were reconstructed from the same raw data with a 512 x 512 matrix and 0.5-mm slice thickness using a hybrid iterative reconstruction algorithm. Maximum CT value and contrast-to-noise ratio (CNR) of the common bile duct were compared between SHR and NR images using the paired t-test. Two radiologists independently reviewed the maximum intensity projection images and graded the image quality for delineation of the peripheral bile ducts, image sharpness, image noise, and the overall image quality using a 5-point scale, and the results were compared using the Wilcoxon signed-rank test.

#### RESULTS

The maximum CT number of the common bile duct was significantly higher on SHR images than on NR images ( $451.6 \pm 65.0$  vs.  $382.5 \pm 67.4$ ,  $P < .001$ ). CNR was significantly lower on SHR images than on NR images ( $19.8 \pm 4.0$  vs.  $38.9 \pm 12.4$ ,  $P < .001$ ). In qualitative analysis, NR scored significantly higher (i.e. less noise) than SHR for noise ( $4.0 \pm 0.2$  and  $4.1 \pm 0.3$  vs.  $2.0 \pm 0.2$  and  $1.9 \pm 0.3$ ,  $P < .001$ ), whereas SHR scored significantly higher for peripheral bile duct delineation ( $3.6 \pm 0.8$  and  $3.8 \pm 0.5$  vs.  $2.4 \pm 0.8$  and  $2.2 \pm 0.5$ ,  $P < .01$ ), sharpness ( $3.8 \pm 0.6$  and  $3.9 \pm 0.7$  vs.  $2.2 \pm 0.6$  and  $2.1 \pm 0.7$ ,  $P < .001$ ), and overall image quality ( $4.0 \pm 0.6$  and  $3.6 \pm 0.8$  vs.  $2.0 \pm 0.6$  and  $2.4 \pm 0.8$ ,  $P < .01$ ) for both readers.

#### CONCLUSION

UHR CT combined with a deep learning-based reconstruction provided drip-infusion CT cholangiography images with higher spatial resolution and improved the delineation of the peripheral bile duct, despite increased image noise and decreased CNR.

#### CLINICAL RELEVANCE/APPLICATION

Ultra-high-resolution CT combined with a deep learning-based reconstruction provides high-quality drip-infusion CT cholangiography and improves peripheral bile duct delineation.

### Breath-hold 3D Gradient- and Spin-echo (GRASE) MRCP Compared to Compressed-sensing Highly Accelerated Respiratory-triggered Technique

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Nobuyuki Kawai, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate breath-hold 3D gradient- and spin-echo (GRASE) MRCP compared to respiratory-triggered 3D turbo spin-echo (TSE) MRCP highly accelerated with the compressed sensing-sensitivity encoding (C SENSE).

#### METHODS AND MATERIALS

Fifty-eight consecutive patients (30 men, 28 women, mean age 67.2 years) with suspicious having pancreaticobiliary diseases underwent MRCP on a 3-T clinical scanner. All patients underwent breath-hold 3D GRASE MRCP with sensitivity encoding (SENSE) (BH-MRCP; SENSE factor, 2) and respiratory-triggered 3D TSE MRCP highly accelerated with the C SENSE (RT-MRCP; C SENSE factor, 11.6) in a random order. For quantitative image analyses, signal intensity (SI) of biliary ducts and main pancreatic duct (MPD), peribiliary ductal tissue, and peripancreatic ductal tissue were measured. The relative duct-to-periductal contrast ratios (RCs) of each pancreaticobiliary segments were calculated as  $(SI_{duct} - SI_{periduct}) / (SI_{duct} + SI_{periduct})$ , respectively. For qualitative image analyses, two radiologists coincidentally graded conspicuity of biliary ducts, MPD, and pancreatic cystic lesion, and overall image quality between the two sequences using a five-point rating scale. Artifacts were also graded using a four-point rating scale.

#### RESULTS

Mean acquisition times in BH-MRCP and RT-MRCP sequence were 23 and 29 seconds, respectively. RCs of all three segments of MPD in BH-MRCP were slightly lower than those in RT-MRCP ( $P = 0.002$ ). Conspicuity of central and peripheral segments of right and left hepatic duct, cystic duct, and common bile duct in BH-MRCP were significantly higher than those in RT-MRCP ( $P = 0.015$ ). Conspicuity of MPD and pancreatic cystic lesion was comparable between the two sequences. Overall image quality in BH-MRCP was significantly higher than that in RT-MRCP ( $P = 0.038$ ). In BH-MRCP, the number of scans with the poor or non-diagnostic image quality (score = 2) in overall image quality was decreased compared with that in RT-MRCP [3.4% (2/58) vs. 8.6% (5/58),  $P = 0.242$ ].

#### CONCLUSION

BH-MRCP provided better image quality and a reduced number of poor or non-diagnostic images compared to RT-MRCP.

#### CLINICAL RELEVANCE/APPLICATION

Breath-hold 3D gradient- and spin-echo MRCP provided better image quality compared to respiratory-triggered 3D turbo spin echo MRCP highly accelerated with the compressed sensing-sensitivity encoding.

Printed on: 08/22/24

### Ultra-High Resolution T2-weighted PROPELLER MRI of the Rectum with Deep Learning Reconstruction: Assessment of the Image Quality and Diagnostic Performance

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Takahiro Tsuboyama, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to evaluate the impact of ultra-high resolution acquisition with a slice thickness of 1.2 mm and deep learning reconstruction (DLR) on the image quality and diagnostic performance of T2-weighted periodically rotated overlapping parallel lines with enhanced reconstruction (PROPELLER) images for rectal cancer.

#### METHODS AND MATERIALS

This prospective study included 34 patients who underwent MRI for the assessment of pretreatment or post-chemoradiotherapy rectal cancer. Written informed consent was obtained. The following four types of axial T2-weighted PROPELLER imaging perpendicular to the tumor were obtained: a slice thickness of 3 mm with conventional reconstruction (3-CR) and DLR (3-DLR), and a slice thickness of 1.2 mm with CR (1.2-CR) and DLR (1.2-DLR). Three radiologists independently evaluated the image quality and assessed the extramural tumor spread, extramural venous invasion (EMVI), lymph node metastasis, and response to chemoradiotherapy if applicable by using a 5-point scoring system. The image quality was compared with Friedman's test. Agreement of the scores obtained with the four types of PROPELLER imaging was assessed by the intraclass correlation coefficient. The diagnostic performance by the three readers were compared with Friedman's test in 22 patients who underwent surgery after MRI.

#### RESULTS

In the image quality assessment, 1.2-DLR yielded significantly the best sharpness, rectal and tumor conspicuity, and overall image quality ( $P < 0.05$ ) for all readers. In the diagnostic performance, perfect agreement (ICC value  $> 0.80$ ) was not seen among the four PROPELLER images in all readers regarding extramural tumor spread, EMVI, and complete response. For the diagnosis of extramural tumor spread, specificity and accuracy were significantly lower with 3-DLR (mean, 0.64 and 0.74) and 1.2-DLR (mean, 0.58 and 0.74) than with 3-CR (mean, 0.75 and 0.79) and 1.2-CR (mean, 0.78 and 0.83) ( $P < 0.05$ ). For the diagnosis of venous invasion, sensitivity and accuracy were significantly higher with 1.2-CR (mean, 0.42 and 0.67) and 1.2-DLR (mean, 0.55 and 0.71) than with 3-CR (mean, 0.30 and 0.59) and 3-DLR (mean, 0.36 and 0.56) ( $P < 0.05$ ). There were no significant differences in the diagnostic accuracies of lymph node metastases and complete response.

#### CONCLUSION

Ultra-high resolution PROPELLER T2-weighted MRI using DLR could provide high image quality and accurate detection of venous invasion although it increased false-positive diagnoses of extramural tumor extension.

#### CLINICAL RELEVANCE/APPLICATION

Although DLR can provide thin-slice T2-weighted PROPELLER MRI with high image quality, extramural tumor spread should be carefully interpreted because DLR may increase false-positive results.

### Deep Learning Segmentation and Radiomics for Automatic Identification and Activity Assessment of CTE Lesions in Crohn's Disease

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Yankun Gao (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this paper is to develop a deep learning automatic segmentation model for the segmentation of Crohn's Disease (CD) lesions in CTE images. Additionally, the radiomics features extracted from the segmented CD lesions will be analyzed, and multiple machine learning classifiers will be built to distinguish CD activity.

#### METHODS AND MATERIALS

This retrospective study includes two sets of CTE image data (segmentation dataset and classification dataset). The CD lesions in the segmentation dataset were manually segmented by radiologists, and a deep learning automatic segmentation model based on nnU-Net neural network was developed. The CTE images in the classification dataset were processed using the automatic segmentation model to obtain segmentation results and extract radiomics features. The most optimal features were then selected to build five machine learning classifiers to distinguish CD activity. The performance of the automatic segmentation model was evaluated using the Dice similarity coefficient (DSC), while the performance of the machine learning classifier was evaluated using the area under the curve (AUC), sensitivity, specificity and accuracy.

#### RESULTS

The segmentation dataset consisted of 84 CTE examinations of CD patients (60 males) and the classification dataset included a total of 193 CTE examinations of CD patients (136 males). The deep learning segmentation model achieved a DSC value of 0.824 on the testing set. Among the five machine learning classifiers, the Logistic Regression (LR) model showed the highest classification performance in the testing set, with an AUC, sensitivity, specificity and accuracy of 0.862, 0.697, 0.840 and 0.759, respectively.

#### CONCLUSION

Our study demonstrates that a deep learning segmentation model based on the nnU-Net neural network can accurately segment CD lesions in CTE images and build a machine learning classifier to distinguish CD activity based on the extracted radiomics features. This approach can help clinicians assess the severity of patient's disease with greater accuracy.

#### CLINICAL RELEVANCE/APPLICATION

Helps radiologists aid in diagnosis and improve diagnostic efficiency, which in turn helps clinicians assess a patient's condition and provide an idea for the next step in treatment.

### Predicting Renal Allograft Dysfunction using Shear-wave Dispersion Slope

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Taekmin Kim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the role of shear-wave dispersion slope for predicting renal allograft dysfunction.

#### METHODS AND MATERIALS

We retrospectively reviewed 126 kidney transplant recipients (median age 57 years [interquartile range 47-62 years], 60 women) who underwent kidney biopsy for allograft evaluation from November 2022 to February 2023. All patients underwent shear-wave elastography (SWE) examination just before biopsy, and parenchymal stiffness and dispersion slope were obtained in cortex. To reduce subject-to-subject variations, we performed SWE in renal sinus fat for reference tissue. Clinical and pathologic factors related to renal stiffness and dispersion slope were evaluated by multivariable linear regression analysis. We conducted univariate and multivariate analysis to predict acute rejection using imaging parameters including SWE. Diagnostic performance of significant parameters in detecting acute rejection was evaluated by area under the receiver operating curve (AUC) values.

#### RESULTS

Acute rejection was found in 31 out of 126 (24.6%) of the patients. The median cortex-to-sinus stiffness ratio (SR) did not differ between the patients with acute rejection and without rejection (1.21 vs. 1.20,  $P=0.47$ ), while median cortex-to-sinus dispersion slope ratio (DSR) was higher in patients with acute rejection than in those without rejection (1.4 vs. 1.21,  $P<0.01$ ). Grade of interstitial fibrosis and tubular atrophy (IFTA) was the only determinant factor for both SR (coefficient, 0.13 per grade;  $P<0.01$ ) and DSR (coefficient, 0.10 per grade,  $P=0.01$ ). In multivariate analysis, mean resistive index (OR 1.06, 95% CI 1.02-1.15,  $P<0.01$ ) and DSR (OR 18.3, 95% CI 3.3-101.6,  $P<0.001$ ) were independent factors for predicting acute rejection. The AUC of resistive index, DSR, and combined two parameters were 0.64, 0.68, and 0.74, respectively.

#### CONCLUSION

Shear-wave dispersion slope obtained at SWE may be helpful for identifying renal allograft dysfunction.

#### CLINICAL RELEVANCE/APPLICATION

Shear-wave dispersion slope, which reflects the viscosity of tissue, might be used as a reliable noninvasive imaging modality that can help differentiate acute dysfunction from stable graft.

### Fluoroscopic Function in Cone-beam CT Provides Video Fluorographic Swallowing Study

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Yukihiro Iida, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Videofluoroscopic swallowing study (VFSS) is a gold-standard radiological examination for dysphagic patients. Usually, VFSS is performed using whole-body x-ray fluoroscopic unit. This prevents oral radiologists without a whole-body x-ray fluoroscopic unit from performing VFSS. Recently, a cone-beam CT unit equipped with x-ray fluoroscopy has been put into practical use. In this study, we evaluated the cone-beam CT unit's fluoroscopic function whether it is suitable for VFSS.

#### METHODS AND MATERIALS

A cone-beam CT unit for maxillofacial region (VGi evo Evolved 3D Imaging, NewTom, Inc.) was used to take fluoroscopic images. The temporal resolution was 20 and 15 frames per second. The tube current was fixed at 3 mA and tube voltage at 110 kV. The contrast and gamma values of the images were adjusted to clearly observe. First, a phantom modeled living body was subjected. A 4 mm diameter tube was attached to the inside of the phantom and a 40w/v% barium solution (Barytgen HD, FUSHIMI Pharmaceutical Co., Ltd.) was through. Two 2 mm diameter iron balls were also attached to the pharynx of the phantom. One was on the epiglottic valley, and one on the piriform sinus. Then, two healthy adults with no history of dysphagia were subjected. Saliva (with no contrast media), a 40w/v% barium solution, a paste with barium solution (Fruche, House Foods Corp.), and a gelatin jelly with barium solution (Jelly Ace, House Foods Corp.) were used as test foods. Two subjects swallowed a spoonful or 3 ml of each test food. The subject's VFSS images were evaluated using the checking items in the VFSS guideline of the Japanese Society of Dysphagia Rehabilitation.

#### RESULTS

The image of barium solution passed through the tube and 2 mm iron balls were clear observed in the phantom's VFSS images. Swallowing movements without contrast medium allowed clear observation of the anatomical structures these were tongue, pharynx, soft palate, and others. All target evaluation items including the movement of the test food into the epiglottic valley, the piriform sinus, and the esophagus could be observed. The VFSS image of the phantom and two subjects were clear observed in both 20 and 15 frames per second.

#### CONCLUSION

Although there are restrictions on the body position of the subject, a cone-beam CT unit equipped with x-ray fluoroscopy could be applied for practical VFSS examination. It allows the oral radiologists to perform VFSS in minimal clinics. Then, the accurate diagnosis of swallowing function, treatment effects, and the progress of recovery of swallowing function will be possible.

#### CLINICAL RELEVANCE/APPLICATION

This method allows performing VFSS in minimal clinics. The accurate diagnosis of swallowing function, treatment effects, and the progress of recovery of swallowing function will be possible.

### Application of Multidimensional Diffusion MRI in Nasopharyngeal Carcinoma: An Exploratory Cross-sectional Study

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Yingying Chen (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the potential of multidimensional diffusion MRI (Mdd-MRI) in assessing the microscopic diffusion characteristics of nasopharyngeal carcinoma (NPC) and explore its potential application in diagnosing and differentiating tumor pathological subtypes and TNM stage, as well as determining Epstein-Barr virus (EBV) infection status.

#### METHODS AND MATERIALS

Sixty-six patients with histologically-confirmed NPC were included in the study. Mdd-MRI was performed with multiple b values to obtain five microscopic diffusion metrics: anisotropic mean kurtosis (MKa), isotropic mean kurtosis (MKi), total mean kurtosis (MKt), and microscopic fractional anisotropy ( $\mu$ FA). For comparison with macroscopic diffusion characteristics, apparent diffusion coefficient (ADC) was obtained through conventional diffusion weighted imaging sequence. Diffusion-related measurements were compared using student t test between NPC tissue and normal nasopharyngeal tissue, among different histopathology, TNM stage, and EBV infection status. Spearman correlation analysis was performed between diffusion-related measurements and T stage.  $P < 0.05$  (two-tailed) indicates significant difference.

#### RESULTS

Significant difference was found in ADC between tumor tissue and normal nasopharyngeal tissue ( $P = 6.023e-11$ ). Microscopic metrics and ADC showed significant differences among different primary tumor stages (T1-T4) and a significant correlation with T stage ( $\mu$ FA:  $\rho = 0.52$ ,  $P = 0.00001$ ; MKa:  $\rho = 0.38$ ,  $P = 0.002$ ; MKi:  $\rho = 0.27$ ,  $P = 0.03$ ; MKt:  $\rho = 0.32$ ,  $P = 0.009$  and ADC:  $\rho = -0.36$ ,  $P = 0.003$ ). However, no significant differences were observed in other subgroups, including histopathology, N stage, and M stage, and EBV infection status (all  $P > 0.05$ ).

#### CONCLUSION

Mdd-MRI is a valuable tool for assessing the microscopic diffusion characteristics of NPC. However, it has limited value in diagnosing NPC, differentiating tumor pathological subtypes, N stage, and M stage, and predicting EBV infection status.

#### CLINICAL RELEVANCE/APPLICATION

Mdd-MRI can be a useful technique in assessing the microscopic diffusion characteristics of NPC, providing insights into tumor heterogeneity from a novel diffusion perspective.

### Demonstrating the Facial Nerve in the Parotid Gland using 3 Dimension Fast Field Echo Imaging

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Yihua Wang (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the performance of three-dimension fast field echo imaging (T2WI-3D-FFE) in displaying the intraparotid facial nerve (IFN) and localizing the tumor.

#### METHODS AND MATERIALS

Seventy-nine patients with parotid tumors who underwent T2WI-3D-FFE were retrospectively enrolled (Table 1). The T2WI-3D-FFE images were reconstructed with curvilinear planar reconstruction (CPR) by two radiologists independently. The identification certainty of IFN was scored with an arbitrary scale of 0-3. The tumor locations were categorized as deep or superficial on the basis of direct and 2 indirect methods (the facial nerve line (FNL) and retromandibular vein (RMVL)). Surgical localization was considered as the criterion standard. The diagnostic accuracy, sensitivity and specificity for localizing parotid lesions using each method were calculated and compared using the McNemar tests.

#### RESULTS

The main trunk, temporofacial division, and cervicofacial division of IFN were visualized in 100%, 52% and 46% of patients, respectively on the reconstructed T2WI-3D-FFE images. The diagnostic accuracy, sensitivity, specificity, positive predictive value, and negative predictive value for localizing deep lobe lesions using direct method were 96.2%, 88.9%, 91.7%, 80%, 98.6%, respectively. These findings were significantly higher than FNL and RMVL in sensitivity ( $P < 0.05$ ). The relationship between the tumor and the main trunk of the facial nerve was correctly predicted in 93.67% (74/79) of images (Table 3).

#### CONCLUSION

T2WI-3D-FFE can provide detailed morphological information on the nerve relative to adjacent structures preoperatively.

#### CLINICAL RELEVANCE/APPLICATION

Intraparotid facial nerve (IFN) imaging is a clinical challenge in MRI that it is difficult to differentiate parotid gland tumors from facial nerve on conventional MRI. It is great demand to develop new diagnostic technology to accurately display peripheral nerve and tumor for avoiding intraoperative injury.

### Multi-parametric MRI Brain Tumor Diagnosis with Memorizing Transformer

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Yiqing Shen (*Presenter*) Nothing to Disclose

#### PURPOSE

Deep learning has been widely utilized in MRI diagnosis. Among them, transformers have gained increasing popularity due to their ability to handle multiple modalities. However, its application has been hindered because acquiring large-scale multimodal MR data is expensive and time-consuming. To narrow the gap, we designed a transformer architecture with external memory, which memorizes the attention from the historical training process to reduce the reliance on large-scale dataset.

#### METHODS AND MATERIALS

During training, the external memory stores a paired query and value from each attention head. Importantly, this design is efficient and does not incur any additional computation cost. During inference, the cached memory is used to enhance local attention through K nearest neighbor lookup. This improves the overall performance of the model. We implemented this external memory design on an 8-layer vision transformer with 8 attention heads in each layer and the dimension of the tokens were set to 256, but it can be incorporated into any transformer-based model (Fig. a). Evaluations were performed on a dataset of 147 brain post-treatment malignant glioma cases, each of which included five MRI sequences, T1-weighted (T1w), T2-weighted (T2w), fluid-attenuated inversion recovery (FLAIR), gadolinium-enhanced T1w (GdT1w), and amide proton transfer-weighted (APTw) MR images, for classifying treatment effect and tumor recurrence. For each scan, the 3D APTw MRI protocol provided 15 slices, so all volumetric MR images had 15 instances. Each instance included T1w, T2w, FLAIR, GdT1w, and APTw images with the matrix shape of 5 (sequences)  $\times$  256 (pixels)  $\times$  256 (pixels). A proportion of 80% on the case-level was split as the training set (n=118) and the remaining 20% as the test set.

#### RESULTS

The baseline was the ViT without external memory. Our method achieved an AUC of 0.848 ( $p < 0.001$ ), which improves 5.15% of the plain ViT's AUC of 0.806 ( $p < 0.001$ ). The accuracy is 0.779, the precision is 0.625, the sensitivity is 0.818, the specificity is 0.818 and the F1-score is 0.709 (Fig. b).

#### CONCLUSION

In this work, we propose a memorizing transformer for the small-scale multi-parametric MR image analysis. The method stores the attention in the training process and applies them to the inference stage with KNN lookup, which thus costs no extra GPU run-in memory. The method can increase the plain transformer AUC by 5.15%, which confirms the effectiveness of our method.

#### CLINICAL RELEVANCE/APPLICATION

We propose a memorizing transformer for the small-scale multi-parametric MR image analysis that can increase the plain transformer AUC.

S3B-SPIN-2

### Consistent and Efficient Image Segmentation in the German Nationwide RACOON Consortium

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Bianca C. Lassen-Schmidt, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Multi-center studies, including large cohorts, require software tools that ensure consistent and efficient segmentation of image data. In the RACOON project, all German university hospitals jointly work with identical software systems. Here we analyze the segmentation tool of the first RACOON trial retrospectively and discuss the requirements for such a tool.

#### METHODS AND MATERIALS

In this study, a cohort of 14,023 patients (47% female, mean age 54.6 years, mean BMI 23.4) from 36 German university hospitals was collected and evaluated by radiologists. The datasets included chest CT with 22 different disease groups. Of the total cohort, 20% (2394 datasets) were randomly selected and processed using the segmentation and annotation toolkit SATORI. This client-server application is highly configurable and was utilized to provide a guided lung segmentation workflow, including automated segmentation of the lungs, lung lobes, and ground glass opacities. Additionally, other anatomical structures and pathologies could be manually or semi-automatically segmented.

#### RESULTS

The overall performance of SATORI was evaluated by 35 radiologists with varying levels of experience using the tool, ranging from 1 (less use) to 5 (frequent use) on a Likert scale of 1 (poor) to 5 (excellent). The mean overall performance rating for SATORI was 2.7. Analysis of the ratings from the different user groups, based on their intensity of use (IoU), revealed that 5/5/6/8/10 radiologists with an IoU 1/2/3/4/5 rated the performance as 1.8/2.2/2.3/2.9/3.4, respectively. A Wilcoxon rank sum test was performed to compare the ratings between inexperienced (IoU 1-3) and experienced (IoU 4-5) readers, and a difference was found ( $P = 0.01$ ). Seven radiologists reported occasional freezing or slowness as the reason for a negative rating.

#### CONCLUSION

SATORI showed promise in achieving consistent image segmentation in the RACOON project. Users with more experience rated it higher, likely due to a learning effect. SATORI is being prepared for three more RACOON studies, with improvements to usability and network connection logging to address occasional freezing. Future enhancements include individual worklists for readers and a review tool for communication between reader and reviewer. Three key requirements for segmentation software in large multi-center studies to ensure consistent and efficient image segmentation are guided workflows, simultaneous use by multiple users, and highly automatic segmentation tools. "Funded by „NUM 2.0“ (FKZ: 01KX2121)".

#### CLINICAL RELEVANCE/APPLICATION

Multi-center studies provide heterogeneous data, more readers, and enough data for studies with rare pathologies. Nonetheless, segmentation software needs to meet specific requirements.

### Clinical Study of Low Radiation Dose Combined with Deep Learning Image Reconstruction Algorithm for Detection of Liver Metastases

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Nana Liu (*Presenter*) Nothing to Disclose

#### PURPOSE

The aim was to investigate whether low radiation doses combined with DLIR algorithms improve liver image quality and liver metastasis detection compared with ASiR-V algorithms.

#### METHODS AND MATERIALS

195 patients with suspected liver lesions who needed abdominal enhanced CT scans were collected. Conventional radiation dose examination (tube current of 400 mA) was performed during the first venous phase and low radiation dose examination (200 mA or 120 mA) was performed during the second venous phase. Patients were divided into a 50% radiation dose reduction group and a 70% radiation dose reduction group according to the different tube currents at the second venous phase. All images were reconstructed with ASiR-V50%, DLIR-L, DLIR-M and DLIR-H. Quantitative parameters including subcutaneous fat noise, CT values and SNR of liver, pancreas, portal vein and muscle, and contrast-noise ratio of liver metastases were compared with one way ANOVA test. Qualitative parameters including image quality, noise, contrast, lesion conspicuity, and diagnostic confidence score were compared with Kruskal-Wallis H test. The number and size of liver metastases detected by the ASiR-V50% algorithm at standard radiation doses were used as a reference standard, and the detection rates of liver metastases of different sizes were calculated for each algorithm under low radiation dose conditions.

#### RESULTS

Objective evaluation: The noise and SNR of ASiR-V50% at standard dose were comparable to DLIR-M at 50% lower dose and 70% lower dose, while DLIR-H at 50% lower dose and 70% lower dose had lower noise and higher SNR and CNR. Subjective evaluation: Compared with the ASiR-V50% of standard dose, both DLIR-M and DLIR-H with 50% reduced dose could maintain the image quality, and DLIR-M and DLIR-H with 70% reduced dose had reduced image quality but still met the diagnostic requirements with a subjective score >3. Lesion detection rate: The lesion detection rates for ASiR-V50%, DLIR-L, DLIR-M, and DLIR-H at 50% lower doses were 90.2%, 89.2%, 91.4%, and 89.9%, respectively. All algorithms were able to detect all lesions larger than 1 cm. The lesion detection rates were 69.4%, 70.5%, 73.3%, and 71.3% for ASiR-V50%, DLIR-L, DLIR-M, and DLIR-H at 70% lower doses, respectively.

#### CONCLUSION

Compared to ASiR-V50%, DLIR can improve the objective and subjective image quality, as well as lesion conspicuity and diagnostic confidence of liver metastases. DLIR can maintain or improve image quality at 50% radiation dose reduction while preserving the detection of liver metastases larger than 1 cm.

#### CLINICAL RELEVANCE/APPLICATION

DLIR can maintain or improve image quality at 50% radiation dose reduction while preserving the detection of liver metastases larger than 1 cm.

S3B-SPIN-5

### **Prediction of T2DM using MRI Fat Fraction Maps of Ectopic Fat Deposition, Abdominal Wall Muscle Fat and Bone Marrow Adipose Tissue**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Qi An (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The purpose of our study was to quantitatively assess the abdominal wall muscle adipose tissue (AMAT) and bone marrow adipose tissue (BMAT) content and ectopic adipose deposition in patients with Type 2 diabetes mellitus (T2DM) by MRI fat fraction maps to explore independent risk factors that can predict T2DM.

#### **METHODS AND MATERIALS**

A total of 345 participants who underwent 1.5 T or 3.0 T MRI examination of upper abdomen were included in our study. The MRI images of all patients included IDEAL-IQ or mDixon Quant sequence. The fat fraction (FF) and area of visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), AMAT were obtained at the level of the L1 and L2 vertebral bodies by Image J (National Institutes of Health, USA), and the FF and area of BMAT were automatically calculated at the level of the T12 and L1 vertebral bodies by the software where the mean of BMAT were computed. The hepatic fat fraction (HFF) and pancreatic fat fraction (PFF) were semi-automatically measured by Smart ROI on the post-processing platform (Intellispace Portal, ISP, Philips, Holland). The binary Logistic regression analysis and receiver operating characteristic (ROC) curve were used to evaluate the predictive ability of independent risk factors for T2DM.

#### **RESULTS**

VAT area, VAT FF, HFF, PFF, BMAT FF, AMAT area and AMAT FF of the T2DM group were higher than the non-T2DM group and SAT FF was lower ( $P < 0.05$ ). However there was no statistically significant difference in SAT area of two groups ( $P > 0.05$ ). The binary logistic regression model analysis showed that SAT FF, VAT area and PFF were independent risk factors for T2DM, and OR values were 0.920, 1.007 and 1.073, respectively. The ROC curve showed that area under the curve (AUC) values of SAT FF, VAT area and PFF were 0.609, 0.681 and 0.786 respectively, and the sensitivity were 0.441, 0.676 and 0.750 respectively, and the specificity were 0.798, 0.625 and 0.773. The AUC values predicted by SAT FF combined with VAT area and PFF for T2DM were 0.787, with the sensitivity of 0.853 and the specificity of 0.661. The differences of AUC values were compared by Delong test, and the results showed that the AUC values of PFF and their combination were higher than those of SAT FF and VAT area ( $P < 0.05$ ).

#### **CONCLUSION**

In this study, we found that SAT FF, VAT area and PFF are independent risk factors for T2DM, and PFF is a better predictor of T2DM than SAT FF and VAT area.

#### **CLINICAL RELEVANCE/APPLICATION**

Our findings further deepened our understanding of the relationship among ectopic fat deposition, AMAT and BMAT. In addition, we found that PFF is a better independent risk factor for T2DM, so quantitative evaluation of PFF fat content in patients with T2DM by non-invasive MRI fat maps can better predict and evaluate the occurrence, progress and prognosis of T2DM.

S3B-SPIN-6

### Cardiac CT to MR Image Conversion Using Generative Diffusion Models

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Albert S. Song, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate whether 1) a generative diffusion model, trained exclusively with cardiac MRI data, could be used to perform intermodality image conversion from cardiac CTA to cine SSFP MRI and 2) if these synthesized SSFP images can be used as inputs for other MRI-specific CNNs.

#### METHODS AND MATERIALS

With HIPAA compliance and IRB approval, we retrospectively collected 222 cardiac MRIs to train a diffusion model to synthesize SSFP images from image edges. MRI exams were split 70/15/15 for training, validation, and testing. To evaluate cross-modality image conversion, we retrospectively identified an additional 30 patients who underwent both cardiac CTA and MRI within  $7 \pm 8$  months, between 4/2020 and 3/2023 (age  $47 \pm 20$  years, 13 male). The diffusion CNN was used to synthesize SSFP images from CTA. To show that synthesized SSFP images are superior inputs for MRI-specific CNNs, we used an existing MRI-trained 2D UNet to segment the synthetic SSFP and source CTA images and compared them against manual segmentations. Cardiac volumes were then compared between synthetic and real cine SSFP images. Statistical analyses included comparison of segmentation overlap using Dice and comparison of cardiac volumetry using Pearson correlation and paired t-test with a type I error threshold of 0.05.

#### RESULTS

For the following results, segmentation Dice scores are presented in order of epicardium, myocardium, and endocardium. For short axis CTA images, median Dice was 0.900 (IQR:0.844-0.932), 0.689 (0.597-0.752), and 0.906 (0.853-0.938), respectively. For synthesized-SSFP images, median Dice was 0.926 (IQR: 0.893 - 0.945), 0.757 (0.682 - 0.812), and 0.920 (0.866 - 0.948), respectively. Mean Dice scores were significantly higher for synthetic SSFP images relative to CTA images ( $p < 0.001$  for each task, paired t-test). Volumetric measurements from synthesized and real SSFP images correlated well for EDV ( $r=0.77$ ), ESV ( $r=0.83$ ), and EF ( $r=0.88$ ).

#### CONCLUSION

Diffusion models can be used to perform intermodality image conversion, including synthesizing SSFP images from CTA. Volumetric measurements of cardiac function using synthetic SSFP images generated from cardiac CTA correlated well with direct measurements from cardiac MRI.

#### CLINICAL RELEVANCE/APPLICATION

Diffusion models may enable intermodality image conversion to facilitate cross-modality image quantification, segmentation, and comparison for cardiac CTA and MRI.

### AI Enhancement: Emulating Radiologists' Approach for Automated Contrast Phase Detection in Abdominal CT Scans

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Eduardo P. Reis, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The accurate determination of contrast phases in abdominal CT scans is essential for the deployment of downstream artificial intelligence (AI) applications and reliable quantification of imaging biomarkers. DICOM tags are often used to identify contrast phases, but they can be unreliable. To address this challenge, we present an image-based AI algorithm that emulates how radiologists visually assess the enhancement patterns of key anatomical structures to determine the contrast phase. Our goal is to enhance the reliability and generalizability of contrast phase detection, independent of DICOM tags, and to facilitate its integration into clinical workflows by open sourcing the tool through an easy-to-use AI pipeline.

#### METHODS AND MATERIALS

We obtained 739 abdominal CT exams, and included 1545 axial series, split into a 1183 and 362 for training and testing. Each patient's data was exclusively allocated to one set. The series were labeled as non-contrast, arterial, venous, or delayed using the "Series Description" DICOM tag. A radiologist reviewed each series to confirm or correct labels. Key anatomical structures, such as aorta, portal vein, inferior vena cava, renal parenchyma, and renal pelvis, were segmented using our open-source AI toolbox and radiomic features were extracted. An Extreme Gradient Boosting (XGBoost) classifier was trained to classify CT images into four contrast phases. The performance was evaluated using accuracy, sensitivity, specificity and F1 scores on internal and external validation datasets. External validation was performed on 209 scans (582 series) from "VinDr-Multiphase CT", a publicly available dataset that included non-contrast, arterial and venous scans.

#### RESULTS

In internal validation, we achieved an overall accuracy of 92% and F1 scores of 97% for non-contrast, 79% for arterial, 92% for venous, and 95% for delayed phases. In external validation, we achieved an accuracy of 89%, and F1 scores of 97% for non-contrast, 87% for arterial, and 81% for venous phases. The performance improvement of the arterial class on external validation shows generalization capability despite limited training examples for this class. The algorithm was made publicly available through an open-source platform.

#### CONCLUSION

The proposed AI-based algorithm accurately detects contrast phases in abdominal CT scans independent of DICOM tags. The successful external validation demonstrates the algorithm's generalizability and robustness.

#### CLINICAL RELEVANCE/APPLICATION

Contrast detection is crucial for deploying AI methods and ensuring the reliability of quantitative imaging biomarkers. The proposed algorithm serves as a valuable tool for enhancing AI applicability in medical imaging, allowing integration with other AI algorithms.

### Shear Wave Elastography Evaluates the Efficacy of Microwave Ablation on Thyroid Nodules

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Shishi Wang (*Presenter*) Nothing to Disclose

#### PURPOSE

As a minimally invasive technique, percutaneous microwave ablation (MWA) has been applied as an alternative to thyroid surgery for benign thyroid nodules. Coagulation necrosis occurs and stiffness changes in thyroid tissue after ablation. Shear wave elastography (SWE) has been used to differentiate the malignant thyroid from benign nodules. But it has seldom been applied to monitor the change of thyroid nodules after ablation. The study aimed to investigate the efficacy of MWA on thyroid nodules and the effect of stiffness on the efficacy of MWA.

#### METHODS AND MATERIALS

Sixty-seven thyroid nodules treated with MWA were included between June 2021 and April 2023. All nodules were pathologically confirmed benign, and the maximum diameter was within 3 cm. SWE was performed to quantify the stiffness of nodules. The size, volume, volume reduction rate (VRR), and stiffness value of thyroid nodules were recorded before and at one, three, and six months after ablation. Thyroid nodules are classified as hard nodules or soft nodules according to the value of SWE. Compare the VRR between hard and soft nodules during post-ablation follow-up.

#### RESULTS

All nodules were completely ablated, and no complications occurred. The VRR of thyroid nodules gradually increased after ablation, and the VRR at one, three, and six months after ablation were 52.3% [interquartile range (IQR): 35.6-74.1%], 57.6% (IQR: 37.2-78.4%), and 74.9% (IQR: 50.4-90.2%), respectively ( $P < 0.05$ ). The study showed that the stiffness of the nodules increased post-ablation compared with pre-ablation ( $P < 0.05$ ). The stiffness value peaked one month after ablation and then gradually decreased ( $P < 0.05$ ). The mean of SWE before ablation, and at one, three, and six months after ablation were  $36.7 \pm 9.5$  KPa,  $76.5 \pm 10.2$  KPa,  $62.8 \pm 11.4$  KPa, and  $46.9 \pm 9.5$  KPa, respectively ( $P < 0.05$ ). Compared with soft nodules, hard nodules have a lower VRR after ablation ( $P < 0.05$ ).

#### CONCLUSION

SWE is a noninvasive, sensitive and repeatable technique which can be applied to evaluate the efficacy of MWA of thyroid nodules and postoperative follow-up.

#### CLINICAL RELEVANCE/APPLICATION

SWE has been used for noninvasive and quantitative evaluation of the efficacy of MWA on thyroid nodules and postoperative follow-up.

### The Role of Contrast-enhanced Ultrasound in the Biopsies of Peripheral Pulmonary Lesions: A Retrospective Multicenter Study by using Propensity Score Analysis

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Xue-Yan Wang (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare the performance of conventional US and contrast-enhanced US (CEUS) as guiding tools in percutaneous transthoracic needle biopsy (PTNB) and evaluate the role of CEUS in PTNB for peripheral pulmonary lesions (PPLs).

#### METHODS AND MATERIALS

Patients with PPLs who received PTNB between 2017 and 2022 were retrospectively enrolled at four medical centers. According to whether pre-biopsy CEUS was performed, patients were divided into CEUS and US groups. The sampling success rate and the diagnostic accuracy of PTNB stratified by lesion size were analyzed. One-to-one propensity score-matching (PSM) analysis was performed using the nearest-neighbor matching method.

#### RESULTS

A total of 1027 lesions were analyzed: there were 634 in US group (mean age, 59 years  $\pm$  13 [standard deviation], 413 men) and 393 in CEUS group (mean age, 61 years  $\pm$  13 [standard deviation], 270 men). The CEUS group produced more acceptable samples than the US group (98.2% vs. 95.7%,  $p = .03$ ) and improved diagnostic accuracy (96.9% vs. 94.2%,  $p = .042$ ), and sensitivity (96.9% vs. 94.0%,  $p = .03$ ). PSM and stratified analyses ( $n = 358$  per group) indicated that the sample success rate (99.0% vs. 95.7%,  $p = .04$ ) and diagnostic accuracy (98.5% vs. 92.9%,  $p = .006$ ) of the CEUS group was higher than that of the US group for 2-7cm PPLs but not for lesions larger than 7cm (sample success rate: 96.9% vs. 97.1%,  $p = .93$ ; diagnostic accuracy: 95.0% vs. 99.0%,  $p = .08$ ).

#### CONCLUSION

CEUS-guided PTNB has a higher sampling success rate and diagnostic accuracy than US in 2-7cm PPLs. For PPLs larger than 7cm, consistent diagnostic accuracy can be achieved by well-trained biopsy operators whether using US or CEUS as the guide tool.

#### CLINICAL RELEVANCE/APPLICATION

This study aims to investigate the role of CEUS in guiding PTNB of PPLs. The findings of this study can provide a detailed reference for selecting biopsy imaging guidance with a stratification criterion.

### Comparison Between Percutaneous Transthoracic Co-axial Needle CT-guided Biopsy and Transbronchial Lung Biopsy for the Diagnosis of Persistent Pulmonary Consolidation

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Juan Wang (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study is to compare the diagnostic yield and the complication rate between percutaneous transthoracic CT-guided co-axial needle biopsy (PTCNB) and transbronchial lung biopsy (TBLB) in persistent pulmonary consolidation.

#### METHODS AND MATERIALS

From January 1, 2016 to December 31, 2020, we have retrospectively enrolled a total of 155 consecutive patients with persistent pulmonary consolidation who underwent both TBLB and PTCNB. The diagnostic accuracy, specificity, sensitivity and complication rate of the two biopsy methods for persistent lung consolidation has been compared. According to histopathological and microbiological analysis, the results of biopsy specimens were categorized as follows: malignant, specific benign, non-specific benign and non-diagnostic. The final diagnosis was established by surgical resection or clinicoradiological follow-up for at least 12 months following biopsy. Diagnostic yield of PTCNB/TBLB was defined as the percentage of the true diagnosis from biopsy as malignant and specific benign lesions.

#### RESULTS

According to the standard reference, the final biopsy diagnoses of 11 cases were confirmed true malignant based on the surgical resections, the remaining were confirmed by clinical and imaging follow-up for at least 12 months. The overall diagnostic accuracy, sensitivity and specificity of PTCNB for malignant diagnosis were 91.61%, 72.34% and 100%, whereas of TBLB were 87.74%, 59.57% and 100%. At the same time, the overall diagnostic accuracy, sensitivity and specificity of PTCNB for specific benign diagnosis were 84.25%, 64.71% and 100%, whereas of TBLB were 63.23%, 16.18% and 100%. The diagnostic yield of PTCNB and TBLB were 50.32% and 25.16% respectively. For the TBLB-based negative cases, PTCNB provided a definite diagnostic yield of 37.93%. There were 45(45/155, 29.03%), 22(22/155, 14.19%) and 13(13/155, 8.39%) patients who experienced pneumothorax, intrapulmonary hemorrhage and hemoptysis respectively in PTCNB, while there were only 5(5/155, 3.22%) cases of mild intraprocedural bleeding occurring in TBLB.

#### CONCLUSION

PTCNB is an effective and safe modality, associated with higher diagnostic yield and better diagnostic accuracy compared to TBLB for persistent consolidation, especially as the complementary method for TBLB-based negative lung lesions.

#### CLINICAL RELEVANCE/APPLICATION

In this study, we compared the diagnostic yield and the complication rate between percutaneous transthoracic CT-guided coaxial needle biopsy (PTCNB) and transbronchial lung biopsy (TBLB) of persistent pulmonary consolidation. Clinical physicians may choose appropriate biopsy method according to our study.

### **PI3K $\delta$ Inhibitor PI-3065 Induces Apoptosis in Hepatocellular Carcinoma Cells by Targeting Survivin**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Yuze Wei (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors worldwide, and its clinical treatment remains challenging. The development of new treatment regimens is important for effective HCC treatment. This research design to explore the anti-tumor function of PI3K  $\delta$  inhibitor PI-3065 on HCC and its potential mechanism.

#### **METHODS AND MATERIALS**

CCK8 and flow cytometry were used to determine the activity of HCC cells treated with PI-3065. Apoptosis of HCC cells treated with PI-3065 were evaluated by hoechst staining and western blot. Mitochondrial staining and extraction were used to detect the mitochondrial state of HCC cells. SK-HEP-1 cells effectively transfected with survivin siRNA and plasmid overexpressed with survivin were treated with PI-3065, and then the apoptosis level of cells was evaluated by hoechst staining and western blot. The effects of PI-3065 on migration and colony formation of HCC cells were evaluated by wound-healing assay and colony formation assay. SK-HEP-1-derived xenograft tumor model in nude mice were constructed and administered by intragastric administration for 14 days. The control group were given the same dose of placebo. At the end point, the anti-hepatoma activity of PI-3065 in vivo was evaluated according to the volume, weight and protein changes of transplanted tumor.

#### **RESULTS**

We found that PI-3065 dose- and time-dependently reduced HCC cell viability and induced apoptosis while posing no obvious apoptotic toxicity in normal liver cells. Further mechanistic analysis showed that PI-3065 induced apoptosis mainly by inhibiting survivin protein expression, decreasing mitochondrial membrane potential, and promoting cytochrome C release. Simultaneously, PI-3065 markedly suppressed the colony formation, migration, and epithelial-mesenchymal transition abilities of HCC cells. Furthermore, transplantation of nude mice with HCC tumors showed that PI-3065 inhibits HCC tumor growth in vivo by targeting survivin.

#### **CONCLUSION**

PI-3065 specifically inhibited survivin expression and exerted anti-HCC activity in vivo and in vitro, suggesting that it may serve as an effective antitumor drug for HCC treatment, which warrants further study.

#### **CLINICAL RELEVANCE/APPLICATION**

In this study, we confirmed for the first time that PI-3065 can exert anti-HCC activity by inducing cell apoptosis in vivo and in vitro, which indicated that PI-3065 has great potential in clinical practice. Further studies have confirmed that PI-3065 has no toxicity to normal hepatocytes, and its safety and efficacy may provide a new choice for the treatment of HCC patients.

### **Sono-activated Oxygen/Sulfate Dual-Radical Nanotherapy for Combined Cancer Suppression & Infected Wound Repair**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Xiaohui Qiao (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To explore an all-in-one therapy for cooperatively fighting cancer, infection and boosting wound repair for patients with advanced superficial cancers or after surgical intervention to avoid multiple drug abuse and resultant adverse effects.

#### **METHODS AND MATERIALS**

The ultrasound-activated nanosensitizer PHMP was dexterously designed for combined therapy of cancer and infected wound based on oxygen/sulfate dual-radical nanotherapy. Firstly, the *in vitro* cancer cell killing action was proved using CCK-8 assay and fluorescence staining after the cells being treated with PHMP + US. Then, the *in vitro* migration promoting and bacteriostatic action was assessed through scratch test and detecting the bacteria viability respectively. Finally, the *in vivo* tumor-suppressive effect and repair function to the infected skin defect of PHMP + US was evaluated by constructing the subcutaneous melanoma and full thickness *S. aureus* infected skin wound model, and then monitoring tumor size, wound area as well as analyzing histological characteristics.

#### **RESULTS**

In the PHMP + US group, the descended cell viability and apparent cell death were observed, and the narrower scratch gap and fewer bacterial colonies were displayed. Simultaneously, the tumors undergoing PHMP + US disposal exhibited poor growth, distinct cell apoptosis and lower proliferation ability. In addition, the infected wounds in the PHMP + US group healed the fastest and demonstrated well-organized collagen fiber and skin structure.

#### **CONCLUSION**

The *in vitro* and *in vivo* results suggests that US-activated PHMP can effectively inhibit tumor and promote infected wound repair.

#### **CLINICAL RELEVANCE/APPLICATION**

This study highlights the overall treatment of later stage or postoperative cancers accompanied by infectious wounds with a single US-activated multifunctional intervention which bypasses the side effects of polypharmacy and systemic administration of anticancer drugs/antibiotics. Such a conception delves the maximum capacity of each member and meanwhile reduces the harm to the minimum, which is of vast prospect in clinical transformation.

### Elucidation of the Microvascular Embolization Effects of Imipenem/Cilastatin; Evaluation at the Level of Microvessels using Monochromatic X-ray in Vivo Study

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Hiroki Nakamura (*Presenter*) Nothing to Disclose

#### PURPOSE

To elucidate the characteristics of Imipenem/Cilastatin (IPM/CS) as an embolic material in vivo.

#### METHODS AND MATERIALS

Three healthy Japanese white rabbits (approximately 3 kg each) were used. A portion of one ear of each rabbit was injected subcutaneously with picibanil (0.5 KE) to create an inflammation-induced model. High spatial resolution microangiography was performed using monochromatic X-rays extracted from synchrotron radiation facility (Super Photon ring-8; SPring-8). Under anesthesia, an elastomer needle (26 G) was placed in the intermediate branch of the auricular artery, and pre-embolization angiography was performed. Then, embolization was performed from the intermediate branch of the auricular artery using a mixture of IPM/CS (0.2 g) and non-ionic contrast agent (2 ml). Angiography was performed during embolization, and at 3, 10, 20, 30, 40, 50, 60, 70, 80, and 90 minutes after embolization. The embolized vascular diameter was evaluated from the images during embolization, and the recanalization time was defined as after embolization time of "total artery area of post embolization / total artery area of pre embolization  $\times$  100" was  $\geq$ 100 %. ROIs were set in both normal (n=3) and inflammation-induced (n=3) sites, and comparisons were made between the two groups.

#### RESULTS

The mean diameter of the embolized vessels immediately after embolization was  $267 \pm 58.35 \mu\text{m}$ , with a range of 174-363  $\mu\text{m}$ . In the follow-up observations after embolization, the normal vessels recanalized at an average of 70 minutes (case1: 101% on 70 min later, case2: 100% on 90 min later and case3: 101% on 50min later). In contrast, the vessels in the inflammation-induced areas did not show recanalization during the 90 minutes observation period.

#### CONCLUSION

The characteristics of IPM/CS as an embolic material in vivo were elucidated. In vivo, much larger vessels are embolized than the actual particle size. It was also suggested that the embolization effect duration might differ between normal and inflammation-induced areas.

#### CLINICAL RELEVANCE/APPLICATION

The analgesic effect of IPM/CS embolization for pain associated with chronic arthritis has been clinically confirmed, and it may potentially become a basic data for the development of new embolic materials as alternatives to IPM/CS.

### Feasibility Study on Classification of Meniscus Damage Based on MRI Radiomics

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Hongxing Fan (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the value of machine learning(ML)models based on MRI radiomics features in predicting the degree of meniscus injury.

#### METHODS AND MATERIALS

MRI images of 732 knee menisci were retrospective analyzed. The menisci were randomly divided into a training group (n=512) and a validation group (n=220) at a ratio of 7:3. Radiomic features were extracted from the sagittal and coronal proton density-weighted fat suppression images. The Minimum redundancy maximum relevance (mRMR) and least absolute shrinkage and selection operator (LASSO) were used for data dimension reduction and feature selection. Then, based on the optimal features, we constructed a four-category classification model with different ML methods, and its diagnostic performance was quantified by the the area under the receiver operating characteristic curve (AUC).

#### RESULTS

Eighteen significant radiomic features (10 from sagittal and 8 from coronal images) were selected for model construction. The Macro AUC of support vector machine, logistic regression, Gaussian process, random forest, quadratic discriminant analysis and Bagging decision tree model were 0.876, 0.871, 0.870, 0.869, 0.868 and 0.868, respectively. The best-performing models for each lesion grade were: random forest for normal meniscus (AUC=0.948), logistic regression for grade 1 meniscus injury (AUC=0.833), Bagging decision tree for grade 2 (AUC=0.805) and random forest (AUC=0.902) for grade 3 meniscus injury.

#### CONCLUSION

The ML models based on MRI radiomics features can accurately assess the type of meniscal injury.

#### CLINICAL RELEVANCE/APPLICATION

By accurately assessing the type of meniscal injury, ML can enhance the reliability and reproducibility of the diagnosis and help radiologists make clinical decisions.

### Enhancing Patient-Centered Radiology Reports with Generative Artificial Intelligence: Adding Value to Radiology Reporting

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Jiwoo Park, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the efficacy of AI-generated radiology reports in terms of report processing and providing high-quality, easily understandable reports that can address patient questions and to estimate the accuracy and artificial hallucination of AI-generated radiology reports.

#### METHODS AND MATERIALS

A total of 100 spine MRI reports were retrieved from our hospital database, all of which had been approved by fellowship-trained board-certified radiologists with 6 to 18 years of experience. To ensure compliance with HIPAA regulations, all reports were deidentified by removing unique identifying information. Using generative AI, AI-generated radiology reports were then produced by inputting the original reports into a new session without any prior questions having been posed. The reports were generated in four formats: (1) structured reports, (2) summary reports, (3) recommendations, and (4) patient-friendly reports. To evaluate the quality and accuracy of the AI-generated reports, they were compared with the original reports by a panel of radiologists in terms of: (1) the quality of the structured report, (2) the quality of the summary, (3) the concordance of the recommendations with those made by the radiologists, (4) the compatibility of the patient-friendly reports, and (5) the occurrence of artificial hallucinations. Two radiologists conducted qualitative and quantitative studies, independently (five-point scale).

#### RESULTS

The scoring of the AI-generated radiology reports were  $4.95 \pm 0.24$  for structured report and  $4.69 \pm 0.67$  for summary. The agreements of radiologist recommendations and generative-AI recommendations was 95.96% (score  $4.88 \pm 0.54$ ). The compatibility for patient-friendly reports was 83 % (score  $4.71 \pm 0.71$ ). There were 3% artificial hallucinations in patient-friendly reports. This amounted to 3.6 times higher prevalence of easy understandable for the generative-AI powered patient friendly reports ( $P < .001$ ).

#### CONCLUSION

Generative AI was employed to reproduce radiology reports in various useful formats. The potential benefits of using AI assistants to generate these reports include improved report quality, greater efficiency in radiology workflows for producing structured reports, summaries, and recommendations, and a move toward patient-centered radiology.

#### CLINICAL RELEVANCE/APPLICATION

The use of large language model in radiology reports can have a significant impact on the quality and efficiency of radiology workflows. By producing high-quality, easily understandable reports that can address patient questions, AI-generated reports can improve patient care and satisfaction, moving towards patient-centered radiology, which places a greater emphasis on meeting the needs and expectations of patients.

### Performance of Deep Learning based Vertebral Compression Fracture Detection Algorithm in Patients with Acute and Chronic Fractures

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Jemyoung LEE, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Although deep learning algorithms (DL) show promising detecting lesions, the robustness of DL in detecting vertebral compression fractures (VCFs) in patients with acute and chronic fractures was less well known. Therefore, the aim of this study was to investigate the robustness of a DL for detecting VCFs in patients with acute and chronic fractures.

#### METHODS AND MATERIALS

We included 178 patient CT cases (excluding those who underwent surgery with cement or screw) diagnosed with VCF at a tertiary medical center (KUMC, Seoul). Each vertebra's reference standard was established by two radiologists. A total of 1200 vertebral bodies (VBs) were labeled for use in the evaluation of which 1000 VBs were normal, 104 chronic and 171 acute. We utilized a deep learning-based quantitative spine analysis program (ClariVCF, ClariPi Inc., Seoul) in which the vertebral body was segmented automatically by using a pre-trained CNN model followed by measurement of vertebral heights at anterior, middle, and posterior portions of each vertebra. Vertebral height loss was then calculated by measuring the ratio of height at the anterior or middle portion to that of the posterior portion. In addition, a formula was used to compare the vertebral heights between the consecutive vertebra above and below. We evaluated the detection performance of DL for acute and chronic VCFs with sensitivity and specificity by using a criterion of 20% height loss ratio according to the Genant classification.

#### RESULTS

The detection performance of DL for the chronic VCFs was shown to be 94.23% (87.87-97.85%, 95% CI) in sensitivity and 86.91% (84.65-88.94%, 95% CI) in specificity. The performance was reduced for acute VCFs (N=171) to 78.95% (72.07-84.80%, 95% CI) in sensitivity and 86.91% (84.65-88.94%, 95% CI) in specificity. For the overall dataset, which included both acute and chronic VCFs, the sensitivity was 84.56% (79.71-88.64%, 95% CI) and the specificity was 86.91% (84.65-88.94%, 95% CI).

#### CONCLUSION

The deep learning-based VCFs detection algorithm was more sensitive in detecting chronic VCFs than acute VCFs. However, the specificity remained unchanged for both chronic and acute.

#### CLINICAL RELEVANCE/APPLICATION

It might be necessary to take cortical disruption or cortical step-off into account for acute VCFs, where some vertebral height loss might not be noticeable. This demonstrates the necessity for techniques other than height loss measurement. Additionally, a unique height loss measurement approach is necessary for each spinal location while taking into account the physiologic wedging of each vertebral level in order to prevent false positive results.

### Describing the Effects of IV Contrast on CT Abdominal Body Composition Biomarkers

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Alexander D. Weston, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Automated measures of body composition from abdominal CT images are becoming more common to quantify frailty, obesity, and to predict disease outcomes. However, measures may be biased by the presence of intravenous (IV) contrast, possibly leading to prior studies avoiding reporting skeletal muscle density measurements (e.g., Magudia 2021, Radiology). We evaluated the effect of IV contrast phase on six biomarkers of abdominal body composition.

#### METHODS AND MATERIALS

We randomly sampled 244 persons with 258 abdominal CT radiologic exams (479 series) from a cohort representative of the general population. Series were manually annotated for IV contrast phase (noncontrast, arterial, venous, delayed, or nephrographic). We applied a deep-learning model to segment abdominal body composition centered at the L3 transverse process (previously validated mean Dice scores for subcutaneous fat area 0.98, visceral fat area 0.94, muscle area 0.96, and bone area 0.98). Muscle and bone density were defined as mean Hounsfield units (HU) of the segmented tissues. All available CT series were segmented and multiple acceptable series acquired at different IV contrast phases were used to calculate the difference in each body composition biomarker relative to the noncontrast CT series. Values are reported in scatter plots and significance was assessed using 2-sided paired-sample t-tests.

#### RESULTS

Based on manual review, 256/258 CT studies (99%) had one or more series with acceptable quality for body composition analysis and 95/256 studies (37%) had a noncontrast series for comparison. Skeletal muscle density measurements were higher in venous phase versus noncontrast (difference of 5.9HU, 95% CI: 4.72 - 7.15HU) and delayed phase versus noncontrast (difference of 8.5HU, 95% CI: 7.35 - 9.69HU), significant after Bonferroni correction. Vertebral bone density measurements were higher in venous phase versus noncontrast (difference of 8.2HU, 95% CI: 4.9 - 11.5HU) and delayed phase versus noncontrast (difference of 11.5HU, 95% CI: 7.5 - 15.6). No significant differences were observed between arterial phase versus noncontrast series.

#### CONCLUSION

Skeletal muscle density and vertebral bone density measurements on abdomen CT are slightly higher in the presence of IV contrast.

#### CLINICAL RELEVANCE/APPLICATION

A correction factor may be needed to account for IV contrast phase when measuring skeletal muscle density and vertebral bone density biomarkers in CT-based body composition analysis.

### **Distal Radius Fracture: Competent Radiology Reports Generated by ChatGPT Integrating RSNA Template Items and AO Classifier**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Wolfram A. Bosbach, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

While demand for radiology imaging grows worldwide, novel information technology tools promise an increase of reporting quality and as well quantity. Text report drafting tools are part of this development.

#### **METHODS AND MATERIALS**

In the present study, cases of distal radius fracture are defined. Command files for the writing of a report following a template of the Radiological Society of North America (RSNA) and Arbeitsgemeinschaft Osteosynthese (AO) are given to the natural language processing tool ChatGPT.

#### **RESULTS**

An overall high appraisal of ChatGPT radiology reports is obtained in an assessment by human radiologists. ChatGPT is able to adjust output files in response to minor changes in input command files. Shortcomings are the dealing with technical terminology and medical interpretation of findings.

#### **CONCLUSION**

In the future, text drafting tools might well support the clinical work of radiologists. ChatGPT is seen by us as a substantial step forward toward that aim.

#### **CLINICAL RELEVANCE/APPLICATION**

The amount of clinical imaging is growing because of reasons such as demographics and more complex imaging modalities. Tools which draft a text report allow the radiologist to increase output efficiency and to focus time on patient pathology.

### The Value of Incorporating Additional Carpal Tunnel Sequences in the Hand MRI for Patients Presenting with Trigger Finger Symptoms

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

NA YOUNG LEE (*Presenter*) Nothing to Disclose

#### PURPOSE

To determine the prevalence of carpal tunnel syndrome (CTS) in trigger finger patients and identify the MRI criteria necessary for its diagnosis, particularly in cases requiring surgical intervention by obtaining additional two sequence MRI of the carpal tunnel.

#### METHODS AND MATERIALS

Fifty-five hands in 49 patients underwent MRI for evaluation of trigger finger prior to surgery. The dataset included variables such as age, sex, patients' symptoms, and measurements of median nerve signal intensity (SI) and shape, cross-sectional area of the median nerve (MNA), and retinacular bowing. Patients who underwent carpal tunnel release were classified as having severe CTS. The statistical analysis of these factors was conducted using a suite of methods including the independent Student's t-test, Chi-square test, and logistic regression. ROC curves were also drawn to evaluate the precision of CTS diagnosis and to predict severe CTS.

#### RESULTS

A total of 22 hands underwent carpal tunnel release surgery for CTS with concomitant pulley release for trigger finger. The incidence of severe CTS in patients with trigger finger was observed to be 40%. One third of patients diagnosed with severe CTS exhibit the classical symptoms associated with CTS, including tingling sensations in their fingers. However, the remaining patients present with symptoms primarily related to trigger finger, such as pain in the fingers. Statistically significant differences were observed between patients with trigger finger and severe CTS, and those with trigger finger only groups, in relation to several key factors, including MNA, median nerve SI and shape, and retinacular bowing at the outlet ( $p < 0.001 \sim 0.005$ ). Among these factors, only MNA of proximal to inlet level (MNA-pi) and increased median nerve SI with nerve fascicle swelling exhibited a positive correlation with odds ratio of 1.657. Further analysis of ROC curves demonstrated a sensitivity, specificity, and accuracy of MNA-pi  $> 15 \text{ mm}^2$  of 77.27%, 72.73%, and 84.5%, and MNA of distal to outlet (MNA-do)  $> 13 \text{ mm}^2$  of 81.82%, 75.76%, and 84.8%.

#### CONCLUSION

MRI is a highly accurate diagnostic modality for detecting severe CTS, which often requires surgical intervention.

#### CLINICAL RELEVANCE/APPLICATION

Incorporating two additional sequences of MRI of the carpal tunnel with hand MRI for preoperative evaluation of trigger finger has the potential to aid in the detection of severe CTS and in facilitating optimal surgical planning.

### Usefulness of the Floating Fat Sign in the Extensor Tendon Sheath for Predicting Extensor Pollicis Longus Tendon Rupture in Distal Radius Fracture

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Bo Mi Chung, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the usefulness of the floating fat sign for predicting extensor pollicis longus (EPL) rupture in distal radius fracture (DRF).

#### **METHODS AND MATERIALS**

This retrospective study included patients with DRF, consisting of the EPL rupture ( $n = 9$ ) and non-rupture ( $n = 340$ ) groups. The floating fat sign was visually graded on a semi-quantitative Likert scale (0 to 2) for the second and third extensor compartments separately. The presence of bone fragment, Lister's tubercle fracture type, fracture gap, and presence of intra-articular fracture were assessed. Fisher's exact test was conducted to assess the correlation between the floating fat sign and EPL rupture. Univariate and multivariate analyses were performed, followed by ROC curve analysis.

#### **RESULTS**

The sum of floating fat sign scores of the second and third compartments was significantly correlated with the odds of EPL rupture ( $p = 0.001$ ). Male sex, conservative treatment, floating fat sign score of the second and third extensor compartments, and sum of floating fat sign scores of the second and third extensor compartments were significant variables associated with EPL rupture. The floating fat sign in the third compartment was an independent predictive indicator for EPL rupture ( $p = 0.002$ ). ROC curve analysis revealed that the AUC was the highest (0.835) for the multivariate model, followed by the univariate model of the sum of floating fat sign scores of the second and third compartments.

#### **CONCLUSION**

The floating fat sign in DRF could be a predictive indicator for EPL rupture.

#### **CLINICAL RELEVANCE/APPLICATION**

The presence of the floating fat sign in distal radius fracture may assist in predicting the risk of extensor pollicis longus tendon rupture, which could aid in developing a treatment plan or providing warning of potential tendon rupture.

### Investigation of Buffer Thickness for Reducing Artifacts from the Table in Computed Tomography Examinations During the Extremities Three-Dimensional Imaging

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Yoshiki Kamihoriuchi (*Presenter*) Nothing to Disclose

#### PURPOSE

If the hand is directly positioned on the computed tomography (CT) table mat, it is often difficult to separate the hand from the CT table mat due to artefacts from the CT table mat at the three-dimensional (3D) imaging. The objective of this investigation was to determine the optimal thickness of the buffer material utilized for 3D imaging, to alleviate artifact generation consequent to hand separation from the CT table mat.

#### METHODS AND MATERIALS

The wrist phantom was placed on a CT table mat. Styrofoam and medical non-woven gauze were used as buffers, and 10 scans were acquired each with no buffer (none), one piece of gauze (gauze) and 1, 2, 3, 4 and 5 mm of Styrofoam. The scan parameter was following (tube voltage 135 kV, tube current 100 mA, rotation time 1.0 second, helical pitch 0.637, slice thickness 1.0 mm, field of view 150). For the 3D image, we utilized images with a reconstruction interval of 0.5 mm and reconstructed them using three different bone functions (FC30 AIDR3D mild: FC30, Aice Bone mild: BM, and Aice Bone standard: BS). Three regions of interest (ROIs) were set up within an identical image section, both in the absence of buffer and with a 5 mm Styrofoam buffer. Subsequently, profile curves were measured and the maximum CT values at the phantom edge were compared. A comparative analysis of the full-width at half-maximum (FWHM) was conducted among three scenarios: no buffer, gauze, and 1 mm buffer. Visualization scores were evaluated at three levels to assess the degree of artifacts caused by the CT table mat during 3D image creation.

#### RESULTS

The results obtained indicate statistically significant differences between the scenarios without buffer and with gauze, gauze and 1 mm buffer for all cases. In terms of the maximum CT values at the phantom edges, the following comparisons were made: FC30 (none: 340 (229-348) HU, 5 mm: 289 (282-295) HU), BM (none: 446 (358-451) HU, 5 mm: 380 (366-387) HU), and BS (none: 269 (227-275) HU, 5 mm: 219 (215-222) HU) ( $p < 0.05$  for all). Furthermore, the full-width at half-maximum (FWHM) was analyzed for FC30 (gauze: 0.77 (0.71-0.85) mm, 1 mm: 1.08 (1.07-1.18) mm), Bone Mild (gauze: 0.72 (0.63-0.81) mm, 1 mm: 1.00 (0.99-1.08) mm), and Bone Standard (gauze: 0.77 (0.71-0.85) mm, 1 mm: 1.08 (1.07-1.18) mm) ( $p < 0.05$  for all).

#### CONCLUSION

By inserting a buffer material with a thickness of at least 1mm between the hand and the CT table mat at creating 3D imaging, the separation of the hand and the CT table mat can be achieved easier for regardless of the conditions.

#### CLINICAL RELEVANCE/APPLICATION

It was confirmed that using a buffer material of 1 mm or more can significantly reduce the effects of artifacts from the CT table mat, which can improve the quality of 3D imaging of the hand and increase flexibility in positioning.

### **STIR-based Volume Measurement Methods for Staging Primary Lower Extremity Lymphedema: A Single-center Study of Asymmetric Volume Difference**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

MENGKE LIU (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The staging of lower extremity lymphedema (LEL) is hard in clinical work. The perfect soft tissue contrast of Short Term Inversion Recovery (STIR) sequence of MRI enables quantitatively assess the clinical staging of primary LEL. This study aims to explore the clinical value of MRI-based asymmetric volume measurement in the clinical staging of primary LEL.

#### **METHODS AND MATERIALS**

92 patients with unilateral primary LEL underwent Short Term Inversion Recovery (STIR) sequence of MRI. The volume of the middle calf was calculated using the clinical dermatome method (VCl). Two radiologists measure the total volume (V), musculoskeletal volume (VM), and subcutaneous volume (VS) in the middle calves on MRI. The difference between the affected and unaffected calf regarding V (DV) and VS (DVS) was obtained. DV and DVS were defined as asymmetric volume difference. The volume of the middle calf (Vcl) and difference in volume (DVcl) were calculated using the clinical circumferential method. The relationship between asymmetric volume difference and clinical staging was evaluated. Interobserver consistency was assessed through intraclass correlation coefficient (ICC). Volume comparisons were performed using one-way analysis of variance (ANOVA) analysis or Kruskal-Wallis test among three groups. Spearman's correlation analysis was used to assess volume and clinical stage correlation. The receiver operating characteristic (ROC) curve was drawn to assess the value of asymmetric volume difference for clinical staging.

#### **RESULTS**

The asymmetric volume difference was statistically significant in stage I compared to stages II and III ( $p < 0.05$ ). The asymmetric volume difference (DV:  $r = 0.753$ ; DVS:  $r = 0.759$ ) correlated more with the clinical stage than the affected Vcl ( $r = 0.581$ ), V ( $r = 0.628$ ), VS ( $r = 0.743$ ) and DVcl ( $r = 0.718$ ). The area under ROC curve (AUC) for identifying the clinical stage by the asymmetric volume difference was greater than that for the affected Vcl, V, VS and DVcl, with DVS (AUC=0.951) having the highest area under the curve to distinguish between stages I and II.

#### **CONCLUSION**

STIR-based asymmetric volume difference can be used as an adjunctive measure for clinical staging of LEL with good reproducibility, and DVS could be the best indicator for differentiating between stages I and II.

#### **CLINICAL RELEVANCE/APPLICATION**

STIR can quantitatively assess the severity of primary lower extremity lymphedema, facilitating clinical decision making and improving prognosis.

### PSMA PET/CT for Localization of Prostate Cancer after Focal Therapy

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Mahbod Jafarvand, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

PSMA-ligand PET has become the first-line imaging tool for staging and re-staging patients with prostate cancer. However its role in patients with prostate cancer who underwent focal therapy (HIFU, irreversible electroporation, photodynamic therapy, cryoablation, and laser therapy) is still unknown. In this study, we aimed to investigate the diagnostic performances of PSMA PET/CT to detect and localize biochemical recurrence after focal therapy.

#### METHODS AND MATERIALS

This was a retrospective single center study. Patients with the following inclusion criteria were included: focal treatment for prostate cancer, 68Ga-PSMA-11 PET with contrast enhanced CT performed for biochemical recurrence, and no therapy between focal therapy and PET. Three independent blinded readers performed the PET image analysis and a per-region (T, N, M1a, M1b, M1c) centralized majority rule was applied (positivity rate). Inter-reader agreement of the positivity rates was calculated with Fleiss' kappa. In a sub-cohort of patients with a MRI and biopsy performed within 3 months of PSMA PET, diagnostic accuracy was evaluated on a per-patient and per-segment analysis on standard WB +60 min and the delayed +90 min pelvic images. A single radiologist blinded to PSMA and pathology performed MRI interpretation. Twelve prostatic segments were defined, and for every segment, suspicion for recurrence was assessed.

#### RESULTS

Of the 3329 patients with either a PSMA PET scan or focal therapy performed at UCLA, 100 patients met the inclusion criteria. PSMA-PET positivity rate per majority rule was 85/100 (85%) for prostate, 17/100 (17%) for pelvic lymph nodes and 20/100 (20%) for distant metastases. The inter-reader agreement for positivity rate by region was moderate ( $\kappa=0.5$ ). 29 patients had MRI and post-therapy biopsy data available. In these, Per-patient analysis showed a sensitivity of 92% for PSMA and 88% for MRI. Per-segment analysis performed on 297 validated segments resulted in a sensitivity, specificity, positive predictive value and negative predictive value of 53%, 90%, 74% and 78% for PSMA at +60 min, 55%, 92%, 79% and 79% for PSMA at +90 min and 29%, 92%, 72% and 65% for MRI ( $p<0.01$ ), respectively. All Patients with PSMA SUV<sub>max</sub> = 10 had GG =3 disease.

#### CONCLUSION

In this retrospective study of 100 patients treated with focal treatment for prostate cancer the PSMA-PET positivity rate was 85% for prostate. The sensitivity per-segment was 55% on delayed +90 min pelvic PSMA PET vs 29% for MRI with a similar specificity of 92%. results suggest that PSMA PET/CT has potential for localization of recurrent prostate cancer after focal therapy.

#### CLINICAL RELEVANCE/APPLICATION

PSMA PET appears promising for localization of biochemical recurrence after focal therapy.

### Manufacturing Iodine-loaded Polymeric Microcapsules: Proof-of-Concept for Theranostics in Peritoneal Carcinomatosis

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Nils Grosse Hokamp, MD, PhD (*Presenter*) Research Grant, Koninklijke Philips NV; Speakers Bureau, Koninklijke Philips NV; Consultant, Bristol-Myers Squibb Company

#### PURPOSE

Peritoneal carcinomatosis refers to shedding of tumor cells to the peritoneal cavity and often is indicative of incurable and/or end stage disease. Treatment options at this advanced stage include hyperthermic intraperitoneal chemotherapy (HIPEC) alongside cytoreductive surgery. Aiming for continuous chemotherapeutic delivery options, this study intended to provide proof-of-concept of polymeric microcapsules that allow incorporation of chemotherapeutic agents and that are furthermore loaded with iodine in order to allow in-vivo tracing using computed tomography.

#### METHODS AND MATERIALS

For synthesis a solvent-emulsion evaporation technique has been used. Hydrophobic iodinated oils (e.g. Lipiodol) were used as inner phase of the capsule. A biodegradable polymer [poly(lactic-co-glycolic acid), PGLA] was used as outer shell material. A fluorescent dye was added for direct visualisation. Incorporation of hydrophilic drugs, was shown with an aqueous iodinated compound (iohexol), using a water-oil-water emulsion process. Light/fluorescence microscopy, UV/Vis spectroscopy and size distribution using a Coulter Counter were conducted in addition to spectral detector CT based quantification of iodine content (SDCT).

#### RESULTS

The synthesis yielded polymeric capsules containing CT-imageable iodinated compounds with tuneable diameter. The obtained particle diameters were in the range of 0.1 - 15  $\mu\text{m}$ . Iodide concentration was further quantified using UV/vis spectroscopy. Here, Iodine to polymer ratio varied between 23 to 125 mg I/g corresponding to 0.01 to 0.03  $\mu\text{g}$  I/capsule; similar results were obtained using SDCT. In addition cytostatic drugs could be incorporated into the particles.

#### CONCLUSION

Controlled formation of iodine-loaded polymeric microcapsules can be achieved. The capsules can be visualized using SDCT which furthermore allows for quantification of their iodine content (consistent with UV/vis-based measurements as standard of reference). Furthermore, cytotoxic drugs can be incorporated into these particles.

#### CLINICAL RELEVANCE/APPLICATION

The described syntheses provide proof-of-concept for in-vivo traceable and quantifiable microcapsules. Attempts to alter longevity of these systems might allow for a continuous therapy of peritoneal carcinomatosis. Alternatively, advanced manufacturing might allow for targeted drug delivery, e.g. by incorporating receptors into the outer shell.

### **Disability, an Often-Overlooked Aspect of Equity, Diversity, and Inclusion Among Radiology Departments in Canada and the United States**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Ali Abbas, BS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Despite nearly a quarter of Canadians and Americans reported to be living with a disability, persons with disabilities continue to face both structural and cultural barriers with respect to careers in medicine. Equity, diversity, and inclusivity (EDI) statements can act as a first step in deconstruction of these cultural barriers. However, when compared to other EDI initiatives focused on gender, race, and ethnicity, persons with disabilities receive little attention.

#### **METHODS AND MATERIALS**

We conducted a cross-sectional analysis of all radiology residency program websites in Canada and the United States (US). Data was collected from each radiology department website including the presence or absence of an EDI statement or page; if present, we determined whether mention was made of persons with disabilities.

#### **RESULTS**

We reviewed the websites of 16 Canadian and 181 US radiology residency programs. Seven (44%) Canadian institutions had an EDI statement, with one (14%) mentioning persons with disabilities. In the US, 103 (57%) institutions had an EDI statement, with 42 (41%) mentioning persons with disabilities.

#### **CONCLUSION**

There were a significant proportion of radiology departments without EDI statements on their websites and an even smaller proportion that acknowledged persons with disabilities. Persons with disabilities are underrepresented in the medical profession and are often left out of radiology department EDI statements. This population faces many barriers to careers in medicine, underscoring the importance of physical and cultural accommodations.

#### **CLINICAL RELEVANCE/APPLICATION**

Patients with disabilities often report that healthcare providers lack understanding of their condition; thus, inclusion of persons with disabilities among the physician workforce may result in improved patient care. In recent years, there has been an increase in recruitment of medical students with disabilities. Therefore, it is important that post-graduate medical training programs implement the changes necessary to welcome and accommodate these individuals. An institution's public commitment to EDI, and specifically to patients and providers with disabilities, is central to implementing inclusive change going forward.

### Gender-specific Differences in Aspired Academic Qualification and Perceived Research Opportunities: Excerpts from a Nationwide German Survey

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Isabel Molwitz, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess gender-specific differences in aspired academic qualifications and perceived research opportunities.

#### METHODS AND MATERIALS

Questionnaires were sent to radiologists of different career levels via the German Roentgen Society, the European Society of Radiology's Radiological Trainee Forum, the Radiological Society of North America's Resident and Fellow Committee, and manually to 4500 radiologists of the largest German hospitals. Statistical analyses were conducted with age-adjusted regression analyses only for participants from Germany, as international responses were scarce.

#### RESULTS

Of 510 radiologists with German affiliations (female: 237, 46%, mean age 42 ±10 years) men were four times more likely to have a higher academic degree (PD, habilitation) than women (odds ratio 4.39 [95%-confidence interval 2.22-8.67]) and twice as likely to pursue such a degree (2.87 [1.47-5.61]). Stated reasons to pursue further academic qualification (PD) more frequently found among male participants were: to be eligible for a position as leading physician (2.56 [1.07-6.15]) and a research interest (2.36 [1.0-5.57]). There were no gender differences in motivations occurring from an interest in teaching (1.86 [0.84-4.14]), the wish for more opportunities (1.62 [0.73-3.59]), or a higher independency (0.95 [0.44-2.05]). Most male (84%) and female (74%) radiologists were satisfied with possibilities of congress participation. The odds for dissatisfaction were slightly smaller among men than among women (0.62 [0.39-0.98]). Among both genders, dissatisfaction was high concerning time off clinical duties for research purposes (women: 64%, men 57%; 0.69 [0.41-1.16]). Most female respondents (51%) were dissatisfied with options to be involved in research projects, while most men (61%) were satisfied with them. Differences between both genders were not significant (0.60 [0.35-1.01]). Likewise, dissatisfaction with possibilities to develop their own projects and apply for funding was slightly higher among women (48% vs. 40%) but differences not of statistical significance (0.77 [0.45-1.35]).

#### CONCLUSION

Among German radiologists, men pursue academic qualification more frequently, with eligibility for a position as leading physician being a gender-specific motivational difference. Dissatisfaction with research opportunities tend to be higher among women.

#### CLINICAL RELEVANCE/APPLICATION

To achieve gender equality in science and among leading academic positions, it is essential to understand differences in motivation and integration in research among male and female radiologists. Women may want more support than currently provided, in terms of integration into research projects, developing their own projects, and applying for funding.

### Gender Representation in Radiology Practices in the United States

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Elizabeth H. Dibble, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate gender representation in radiology practices in the United States

#### METHODS AND MATERIALS

The ACR Human Resources Commission fielded the 2022 Workforce Survey 11/2022-12/2022. The sample drew from the ACR members (35,601), non-members (12,551), and RBMA members (1,482). Structured closed-end questions were used, consistent with earlier surveys. Responses were group practice deduplicated and weighted and compared to 2021 survey results.

#### RESULTS

524 fully qualified (decision-maker) respondents completed the survey: 77% male and 20% female. 1278 partially qualified respondents completed it: 65% male, 29% female, and .002% nonbinary. Significantly fewer partially qualified respondents preferred not to self-report gender in 2022 vs 2021 (5% vs 8%,  $p=0.0046$ ). 325 respondents answered questions about practice size and gender composition. The median number of non-practice-leader radiologists per practice was 15 (interquartile range (IQR) 7,30); full-time 13 (IQR 6,24), part-time 2 (IQR 0,5). The median number of practice-leader radiologists was 4 (IQR 1,7); full-time 4 (IQR 2,7), part-time 0 (IQR 0,0). These numbers were not different from 2021 ( $p>0.05$ ). Of full-time non-practice-leader radiologists per practice, the median number of females age  $<40=0$  (IQR 0, 1),  $40-65=1$  (IQR 0, 3), and  $>65=0$  (IQR 0,0); the median number of males age  $<40=2$  (IQR 0,4),  $40-65=6$  (IQR 3,12), and  $66+=0$  (IQR 0,1). The mean number of non-practice-leader radiologists increased slightly from 2021 to 2022 across all ages and represented genders, although this did not reach significance ( $p>0.05$ ). Of full-time practice-leader radiologists, the median number of females age  $<40=0$  (IQR 0, 0),  $40-65=0$  (IQR 0,1), and  $66+=0$  (IQR 0,0); the median number of males age  $<40=0$  (IQR 0,0),  $40-65=3$  (IQR 1,5), and  $66+=0$  (IQR 0,0). The mean number of practice-leader females increased slightly across all age groups from 2021 to 2022. The mean number of practice-leader males increased for age  $<40$  ( $p=0.0458$ ), decreased for  $40-65$  ( $p>0.05$ ), and increased for  $66+$  ( $p>0.05$ ). The mean and median number of radiologists identifying as nonbinary was 0 for all queries.

#### CONCLUSION

Female and nonbinary radiologists are underrepresented in radiology practices. Significantly fewer respondents in 2022 preferred not to self-report gender compared to 2021. The median number of female and nonbinary radiologist practice leaders is 0. The mean number of female practice leaders increased slightly across all age groups from 2021 to 2022, although this did not reach significance.

#### CLINICAL RELEVANCE/APPLICATION

Female and nonbinary radiologists are underrepresented in US radiology practices in both leadership and non-leadership roles.

### Association of Body Mass Index and Waist Circumference with Multimodal Magnetic Resonance Imaging Indicators of Brain Health in 9- to 10-year-olds in the US

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Simone Kaltenhauser, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the relationship of pre-adolescents' Body Mass Index (BMI) and waist circumference (WC) with magnetic resonance imaging (MRI) indicators of brain health (cortical morphometry, resting-state functional connectivity, white matter (WM) micro- and cytostructure) over two years.

#### METHODS AND MATERIALS

We retrieved baseline and two-year follow-up clinical and neuroimaging information of a sociodemographic diverse cohort of 11,878 9- to 10-year-olds enrolled in the Adolescent Brain Cognitive Development (ABCD) study across 21 centers in the US. Inclusion required absence of neurodevelopmental/psychiatric diagnoses and traumatic brain injury. T1- and T2-weighted structural MRI, diffusion tensor imaging, resting-state functional MRI, and restriction spectrum imaging were quantified in a region-of-interest based approach. At both time points, cross-sectional linear regression determined the association of BMI/WC with fractional anisotropy (FA), neurite density (ND), cortical thickness and resting-state functional connectivity, after correction for age, gender, puberty, race/ethnicity, handedness, socioeconomic status and scanner device. In longitudinal analyses, multivariate regression was used to examine associations of baseline BMI with interval changes in neuroimaging metrics.

#### RESULTS

At baseline, 4,576 children (48.3% female) at an average age of 10.0 years (7.6 months) were included. 1,567 enrollees aged 12.0 years (7.7 months) had complete follow-up. At both point in time analyses, higher BMI/WC were associated with pervasive bilateral reductions of FA ( $P < .001$ ) as well as ND ( $P < .03$ ). With higher BMI/WC, especially prefrontal cortical thickness was reduced in both hemispheres ( $P < .04$ ). We found predominantly negative associations of BMI/WC with intra- and inter-network functional coupling of salience and cingulo-opercular networks ( $P < .005$ ). Over a mean follow-up period of 23.8 (1.6) months, we observed overall interval cortical thinning and increase in averaged FA and ND. Higher BMI at baseline was associated with lower interval increment in FA and ND of several commissural, projection and association WM tracts as well as reduced interval cortical thinning of prefrontal regions.

#### CONCLUSION

Higher BMI and waist circumference among children are associated with reduced WM micro- and cytostructural integrity, cortical thickness, and functional connectivity. Our longitudinal analysis suggests contribution of higher BMI to hindered interval development of WM micro- and cytostructure and cortex morphology.

#### CLINICAL RELEVANCE/APPLICATION

Our findings highlight the neurodevelopmental implications of pre-adolescents' higher weight and point to the need for early targeting of brain health indicators.

### Spatiotemporal Discoordination of Brain Spontaneous Activity in Major Depression Disorder

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Qunjun Liang (*Presenter*) Nothing to Disclose

#### PURPOSE

Major depressive disorder (MDD) is a world-wide debilitating mental illness. Despite extensive research, the pathogenesis of MDD remains unknown. Spatiotemporal psychopathology (STPP) posits that the symptoms of MDD arise from aberrant spatiotemporal experiences in a patient's inner world, which may be reflected by their brain spontaneous activity. In the present study, we aim at determining the spatiotemporal discoordination of MDD patient's brain spontaneous activity using fMRI.

#### METHODS AND MATERIALS

91 MDD and 91 demography-matched HC were recruited in this study. The fMRI data were preprocessed via fMRIPrep and the timeseries were extracted over Schaefer400 parcels. Spatiotemporal topology (SPT) of the brain activity was measured by the Euclidean distance of each pair of parcels in a 3-dimension coordinate composed by two functional gradients (Margulies et al., 2016) and time delay (Mitra et al., 2014). SPT was then averaged across Yeo's 7 network atlas, resulting in 7 intra- and 21 inter-network SPT. Repeated measures ANOVA was performed to test the mean difference of the SPTs between MDD and HC. A machine learning approach was employed to investigate the efficacy of SPT in discerning between HC and individuals with MDD.

#### RESULTS

A significant difference in network-specific features between MDD and HC was found ( $F(27, 5040) = 2.9, p < .001$ ). Simple-effect test identified four inter-network SPT that showed a significant group effect, including control-somatomotor distance ( $F = 7.3, p = .007$ ), salience-dorsal attention distance ( $F = 11.1, p < .001$ ), salience-visual distance ( $F = 19.2, p < .001$ ), and somatomotor-visual distance ( $F = 19.2, p < .001$ ). The logistic model yielded an accuracy of 0.73 in predicting the group label, and the ROC curve showed an AUC value of 0.86.

#### CONCLUSION

SPT may reflect the homeostatic fluctuation of neuronal activity in the brain, and it is a theoretical-driven measure inspired by STPP. The significant difference in SPT were found in the visual and somatomotor network. The machine learning approach demonstrated the effectiveness of SPT features in differentiating between individuals with MDD and HC. While SPT topology presents theoretical validity and potential clinical value, it is no more than a general evaluation of the current state of the brain. As a result, the precise interpretation of its magnitude and direction is not yet apparent.

#### CLINICAL RELEVANCE/APPLICATION

In the long run, SPT topology may serve as an important reference index in diagnosing MDD using low-cost fMRI scans. In addition, SPT topology could potentially function as a prognostic marker for MDD intervention. However, in its current stage, its main value lies in fundamental research, such as enhancing our understanding of the neural abnormalities of MDD.

### **Mild Cognitive Impairment in Non-alcoholic Fatty Liver Disease is Associated with Abnormal Resting-state Functional Connectivity Between the Default Mode Network and Regions within the Reward System**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Jie Li, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Mild cognitive impairment (MCI) is commonly seen in patients with nonalcoholic fatty liver disease (NAFLD), but the neural mechanisms have not been elucidated. In this study, we used resting-state fMRI (RS-fMRI) to investigate the characteristics of spontaneous neural activity in NAFLD patients with MCI.

#### **METHODS AND MATERIALS**

A total of 74 NAFLD patients and 62 demographic-matched healthy controls (HC) were enrolled. According to the Montreal Cognitive Assessment (MoCA) score, the patients were divided into two groups: 43 patients with MCI\_NAFLD and 31 patients with nonMCI\_NAFLD. All participants underwent 3.0T RS-fMRI scan and neurocognitive psychological assessment, and patients underwent liver MRI proton density fat fraction (PDFF) and blood biochemical indexes measurement. DPABI software was used to process the RS-fMRI data and obtain the whole brain amplitude of low-frequency fluctuations (ALFF) map. One-way analysis of covariance and post-hoc tests were used to compare the differences in ALFF maps among the three groups. The abnormal regions were selected as the regions of interest (ROI) to compare the differences in whole-brain seed-based functional connectivity (FC) between the two patient groups, and the correlation between abnormal FC values and clinical variables was analyzed.

#### **RESULTS**

Compared with nonMCI\_NAFLD patients, MCI\_NAFLD patients had reduced ALFF values in the right cerebellum and right cuneus, and increased ALFF values in the left posterior cingulate gyrus (PCC), and the ALFF values in these different regions were significantly correlated with MoCA scores. Compared with nonMCI\_NAFLD patients, MCI\_NAFLD patients had enhanced FC between the left PCC and the left lingual gyrus, left parahippocampal gyrus, left medial orbitofrontal gyrus, left middle frontal gyrus, left postcentral gyrus and right postcentral gyrus, and reduced FC between the left PCC and the left insula and right supplementary motor area. Among them, the FC values between the left PCC and the regions related to the reward system were correlated with cognitive function, emotional symptoms, PDFF values and insulin function in NAFLD patients. In particular, the ALFF values of the PCC completely mediated the correlation between the FC values between the PCC and the orbitofrontal cortex and MoCA scores.

#### **CONCLUSION**

The development of cognitive impairment in patients with NAFLD may be closely related to the dysfunction of the default mode network and dopamine pathway, in which visceral fat accumulation and insulin dysfunction also play a crucial role.

#### **CLINICAL RELEVANCE/APPLICATION**

These special neuroanatomical abnormalities may help to shed light on the underlying pathophysiology and manifestations of MCI in patients with NAFLD.

### Altered Functional Connectivity of Olfactory Neural Circuits in Subjective Cognitive Decline under Odor Stimulation

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Yajing Zhu (*Presenter*) Nothing to Disclose

#### PURPOSE

Olfactory involvement is an early feature of Alzheimer's disease. The purpose of this study was to investigate the functional connectivity(FC) changes of olfactory neural circuits in subjective cognitive decline (SCD) in olfactory task fMRI under specific odor stimulation.

#### METHODS AND MATERIALS

A total 56 normal controls(NC) and 57 SCD were included.All subjects were tested with cognitive scale, olfactory behavior assessment, and olfactory task fMRI. The FC difference of olfactory neural circuits between the two groups was analyzed by the method of generalized psychophysiological interaction (gPPI).

#### RESULTS

There was no significant difference in olfactory behavior between the two groups. In olfactory task-fMRI with specific odor stimulation, the FC from bilateral POCs to the right parahippocampal area in the SCD group was significantly reduced; while the FC from the right hippocampus to the right frontal lobe was significantly enhanced. The connectivities from bilateral POCs to the right parahippocampal area, the right parahippocampal, and the right hippocampal were significantly positively correlated with the memory cognitive threshold; the connectivities from bilateral POCs to the right parahippocampal area, the right parahippocampal, and the right fusiform gyrus were significantly positively correlated with the global cognitive function.

#### CONCLUSION

The olfactory behavior reflects the comprehensive performance of the olfactory function, while the olfactory task-fMRI reflects the FC of the olfactory neural circuits. The results of this study indicate that although the olfactory behavior of SCD is at a normal level, the FC of olfactory neural circuits(POC-hippocampus-frontal lobe) has changed.

#### CLINICAL RELEVANCE/APPLICATION

The results of this study suggest that the FC changes of olfactory nerve circuits in SCD subjects under specific odor stimulation conditions, and the correlation between the connectivity of olfactory nerve circuits and the global cognitive function and memory function, prove that the FC changes of olfactory nerve circuits in SCD patients may be used as an early identification marker of high AD risk.

### Altered Hippocampal Intra-networks in Mild Cognitive Impairment: A Structural MRI Study in a General Elderly Japanese Population

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Sera Kasai (*Presenter*) Nothing to Disclose

#### PURPOSE

Although altered networks inside the hippocampus (hippocampal intra-networks) have been observed in dementia, the evaluation of hippocampal intra-networks using MRI is challenging. We employed conventional structural imaging and incident component analysis (ICA) to investigate the structural covariance of the hippocampal intra-networks. To our knowledge, there have been no population-based studies with large sample sizes to assess the association between MCI status and hippocampal intra-network connectivity. Our aim was to assess whether individuals with MCI have altered hippocampal intra-network connectivity as measured using source-based morphometry (SBM) that is a type of structural network when compared with cognitively normal older adults (CNOA).

#### METHODS AND MATERIALS

This was a cross-sectional study of 2122 residents who participated in a population-based prospective study of cerebro- and cardiovascular diseases and dementia in a large population of older Japanese individuals with 3T MRI (median age 69 years, 60.9% female). The participants were divided into 218 patients with MCI and 1904 cognitively normal older adults (CNOA). By employing 3D T1-weighted imaging and ICA, we extracted the structural covariance intra-networks in the hippocampus.

#### RESULTS

The ICA extracted 16 intra-networks from the hippocampal structural images, which were divided into two bilateral networks and 14 ipsilateral networks. Of the 16 intra-networks, four (one bilateral network and three ipsilateral networks) were significant predictors of MCI from the CNOA after adjusting for age, sex, education, disease history, and hippocampal volume/total intracranial volume ratio (Figure) ( $p < 0.01$ ). In addition, the networks predicted MCI independent of hippocampal volume ( $p < 0.01$ ), although hippocampal volume was also a predictor of MCI ( $p < 0.01$ ).

#### CONCLUSION

In this population-based study with a large sample size, we extracted four MCI-related hippocampal intra-networks based on SBM, which can be estimated using conventional structural imaging with 3T MRI. These hippocampal intra-networks predicted MCI independently of hippocampal volume, suggesting the altered networks may reflect a different pathology from that of brain atrophy.

#### CLINICAL RELEVANCE/APPLICATION

By using conventional structural imaging and ICA, we found that the relationship between hippocampal intra-networks and MCI was independent from the hippocampal volume. This method provides additional information for understanding cognitive impairment.

### Clinical Quantitative Brain MRI: Quantifying Age-related Changes in Tissue Volume

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Artem Kaliaev, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The volumes of the brain and substructures change continuously throughout the human lifespan. Establishing normal development patterns can be useful for detecting abnormal developmental pathways by comparison. Our goal is to study the pattern of normal brain development for the general population of our hospital as stratified by sex using the high geometrical accuracy and precision of turbo spin echo-based quantitative MRI.

#### METHODS AND MATERIALS

This retrospective single-center cross-sectional study was conducted on healthy, ethnically diverse patients with normal brain imaging. The institution's IRB approved the study, and participants were imaged by 3.0-T MRI. Dual-echo turbo spin echo (DE-TSE; PD/T2-weighted) and single-echo turbo spin echo (SE-TSE; T1-weighted) images were used for the MRI parameter calculation. The image processing pipeline (IPP) consisted of a qMRI-based segmentation process that was programmed with Python (version 3.8.11) and the Anaconda Navigator (version 2.2.4). The IPP required a Fiji-based preparation step (version 2.1.1) to edit intracranial matter (ICM), which includes the in toto brain tissue and cerebrospinal fluid (CSF). Then, the IPP was applied consecutively for all subjects' MRIs. Finally, the mean volume for the ICM, brain, white matter (WM), gray matter (GM), and CSF were calculated. Statistical significance and Pearson correlation methods were used for the statistical analysis.

#### RESULTS

A total of 277 patients (146 females) with normal brain radiological reports were included in this study leading to 7 decadal age groups. The ICM, brain, GM, and CSF and CSF ventricles volumes were significantly different between the age groups ( $p$ -value 0.019,  $<0.001$ ,  $<0.001$ ,  $<0.001$ ,  $<0.001$  respectively). There was a significant negative association between age and the ICM, brain, and GM volumes ( $p$ -value 0.008,  $<0.001$ , and  $<0.001$ , respectively), while there was a significant positive association between age and CSF and CSF ventricles volume ( $p$ -value  $<0.001$  and  $<0.001$ ). Furthermore, the significant correlation between ICM, brain, GM, and CSF, CSF ventricle volumes, and age groups was different for male and female cohorts (0.028 and  $<0.001$ s, respectively).

#### CONCLUSION

In an ethnically diverse cohort of 277 patients without neurological findings, we find that the volume of total GM decreases with age and appears to be largely replaced by CSF as the WM volume stays constant after twenty years of age.

#### CLINICAL RELEVANCE/APPLICATION

Clinical quantitative brain MRI is a valuable tool for quantifying age-related changes in brain tissue volume, characteristic of normal development, which can aid in early diagnosis and monitoring of age-related neurodegenerative diseases.

### Evaluation of Brain Stiffness Change According to Brain Development using Virtual MR Elastography Based on DWI

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

You Na Kim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Viscoelastic property of brain have been demonstrated to be affected by aging and various neurological disease. Based on the knowledge that measured mechanical properties of brain reflect the microstructure composition and organization of neural tissue, magnetic resonance elastography (MRE) parameters representing mechanical properties can be a potential imaging marker for brain development. However, conventional MRE acquisition has been limited in children due to its invasive property and long scan time. The virtual MRE (vMRE) is a non-invasive and novel technique to measure tissue mechanical property based on diffusion weighted imaging (DWI). The purpose of this study was to evaluate change of brain stiffness according to brain development in children and young adults using vMRE.

#### METHODS AND MATERIALS

We retrospectively reviewed 247 children and young adults (6 months~30 years, 119 females, 128 males) without structural brain abnormality. Shifted apparent diffusion coefficient was calculated from DWI ( $b=200$  and  $1500\text{sec}/\text{mm}^2$ ) and converted to DWI-based virtual shear modulus ( $\mu$ ). Brain stiffness was measured in whole brain and thirteen brain regions; cerebrum, cerebral gray/white matter, basal ganglia, thalamus, frontal/ parietal/temporal/occipital lobe, cerebellum, middle cerebellar peduncle, hippocampus, amygdala. Multiple comparison test and linear regression were conducted to investigate changes in brain stiffness according to brain development.

#### RESULTS

Sexual dimorphism was not observed in any brain region. The virtual shear modulus ( $\mu$ ) of whole brain increased until the age of 16 years and then reached plateau. The DWI based mechanical property parameter of whole brain was increased 1.15% per year ( $R^2=0.642$ ,  $P < 0.001$ ) until 16-year-old. The change of brain stiffness according to brain development showed regional differences. Changes of brain stiffness showed the earliest plateau (8-year-old) in cerebral gray matter and continued to increase in the basal ganglia until 30-year-old. Although steepest increase in occipital lobe (1.85% increase/year,  $R^2=0.659$ ,  $P < 0.001$ ), there was no significant difference in pattern of stiffness change according to brain lobar area.

#### CONCLUSION

DWI-based brain stiffness parameters increased with brain development in pediatrics period with differences by region.

#### CLINICAL RELEVANCE/APPLICATION

DWI-based brain stiffness parameters increased with brain development until 16-year-old and reached plateau. The change of stiffness showed different pattern across the regions.

### Comparing the Clinical Utility of Linear Versus Volumetric MRI in Enlarged Vestibular Aqueduct Syndrome Patients

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Amit Gupta, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Presently CT is established method (Cincinnati criteria) for diagnosis of EVAS. Recently studies showed that linear measurement on MR are similar to CT in terms of confidence of diagnosis and correlation with audiometric data. The purpose of this study was to confirm validity of linear MR measurements and explore role of volumetric MRI measurements in predicting the hearing outcomes in patients with EVAS.

#### METHODS AND MATERIALS

A retrospective study design was used including 30 patients that fit the inclusion criteria for a total of 46 ears. Linear measurements were made using the vestibular aqueduct (VA) midpoint and VA opercular widths for determination of EVAS. Semiautomatic volumetric measurements were calculated from all slices containing both the VA and endolymphatic sac (VA-ELS) using MIM Software Platform (MIM Software Inc.). Air and bone conduction data was collected from medical records. Univariate and multivariate analyses were performed to assess for a correlation between volumetric measurements and audiometric hearing outcomes.

#### RESULTS

Of the study population, 16 patients demonstrated bilateral EVA (53.3%). Average VA volume estimated by volumetric MRI analysis was 0.19 mm<sup>3</sup>; sd = 0.17 mm<sup>3</sup>. Volumetric MRI measurements significantly correlated to both midpoint length and operculum size for EVAS diagnosis. Univariate analysis and multivariate analyses adjusting for age, race, and gender did not reveal significant correlations between volumetric MRI measurements and audiometric hearing outcomes. Midpoint size and operculum size correlated only weakly with low frequency bone conduction hearing outcomes.

#### CONCLUSION

These results suggests an excellent correlation between the liner and volumetric measurements for diagnosis of EVAS, however, with an unclear role for both MRI measurements in the predicting hearing outcomes. In our study, neither linear nor volumetric measurements showed strong correlations with audiometric hearing data.

#### CLINICAL RELEVANCE/APPLICATION

Given the 3D structure of the VA-ELS, volumetric measurements may improve MRI diagnostic utility in EVAS. This study warrants further research into the relationship VA-ELS structure and hearing outcomes, and questions the previously published results on this topic.

### A Normative Model of the Brain from the Adult Colombian Population

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Jon Duque-Grajales, MEng (*Presenter*) Nothing to Disclose

#### PURPOSE

The brain changes throughout life. There is an increasing interest in development of normative models based on anatomical brain features, which are related to the genetics of the population (Elliott et al. *Nature*, 2018). However, the normative models published so far have been mostly based on European descent population (Bethlehem et al. *Nature*, 2022, Rutherford et al. *Elife*, 2022). Here, we propose a normative model of brain aging in a Colombian adult population based on their brain volumes.

#### METHODS AND MATERIALS

2256 healthy participants (age range: 18 - 80 years; 1058 females) were selected based on their radiological report in a retrospective cross-sectional study. This study was approved by the institution's ethical committee. Brain anatomical T1w MR were processed using FSL (V.5) (Smith et al. *Neuroimage*, 2004). The preprocessing included tissue segmentation and subcortical structures extraction. Additionally, we aggregate all the volumes in a new parameter, the delta age, defined as the deviation of the predicted age by a multiple linear model between the age and the volume of all brain structures. Participants with volumes above or below five mean absolute deviations from the mean population for the same sex were discarded. Six different models were evaluated as normative models based on their standardized mean squared error (SMSE) derived from a random five-fold cross-validation: centiles, locally estimated scatterplot smoothing (LOESS), Gaussian process (GP), generalized additive models of location shape and scale (GAMLSS) and linear quantile regression (quant).

#### RESULTS

We derived one normative model per sex due to gender differences in 7 out of the 10 brain structures analyzed ( $p < 0.05$ ). Besides the GP model, all models had similar SMSE values for every structure (SMSE range, female: 0.684 - 1.136, male: 0.698 - 1.165). However, the LOESS model showed a consistent minimum SMSE across structures, having the best performance with the delta age.

#### CONCLUSION

The LOESS model provided a consistent minimum SMSE across all brain structures. Nevertheless, the use of a composed metric aggregating the volumes from all brain structures, the delta age, outperformed the performance of the model on individual brain structures. Therefore, we propose a normative model of brain aging in a Colombian adult population based on a LOESS model in terms of the delta age, that could be evaluated on a larger dataset.

#### CLINICAL RELEVANCE/APPLICATION

We derived a normative model of brain aging in a Colombian adult population based on the brain volume of different structures, providing a reference of brain aging which could highlight deviations from it in neurodegenerative and mental disorders.

### Can fMRI be Used to Develop Neuroimaging Biomarkers for the Risk of Developing Schizophrenia? A fMRI Study Investigating Neural Context-adaptation in Visual Perception, Object Categorization, and Reward Processing Across the Schizotypy Spectrum

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Anna O. Giarratana, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Schizophrenia can be understood to exist on a spectrum; from non-clinical individuals with higher levels of schizotypal personality traits to patients with schizophrenia. Studying schizotypy in non-clinical populations can be extremely informative, given that schizotypy is positively correlated with an increased liability for the eventual development of a schizophrenia spectrum disorder. By studying schizotypy, researchers may be able to detect biomarkers for early detection of psychosis and identify brain regions that may be targets for treatment. Our lab previously found using fMRI, that neural adaptation to reward range is impaired in both healthy individuals with stronger schizotypal personality traits and in patients with schizophrenia. However, it remained unclear whether these deficits are limited to the reward domain, or extend to other domains as well. To this end, we undertook the larger fMRI study described here.

#### METHODS AND MATERIALS

We recruited 98 participants who scored within the top 10%, bottom 10%, and middle 20% of the schizotypy scale as assessed by the Schizotypal personality questionnaire - brief revised (BPQ-BRU). Participants underwent three different tasks while in the fMRI. We investigated reward processing, utilizing a variant of the Monetary Incentive Delay task previously used in our lab. We investigated visual processing, using a task previously used in a collaborators lab based on the concept of surround suppression. Finally, we investigated object categorization, using a novel face-house identification task we developed for this purpose.

#### RESULTS

We find that participants exhibit neural adaptation in the context of reward, visual processing, and object categorization. However, while our previous studies showed that reward range adaptation is impaired in individuals with higher schizotypy, we find no such deficit in visual processing or object categorization.

#### CONCLUSION

Our findings suggest that the inability of those on the schizophrenia spectrum to adapt to the range seen in reward tasks does not generalize to the visual domain. These results may indicate that the deficits seen are specific to the dopamine reward pathways of the brain.

#### CLINICAL RELEVANCE/APPLICATION

These findings highlight reward adaptation as a possible functional neuroimaging biomarker, and a potential target for future studies to investigate interventions (i.e. behavioral interventions or brain stimulation) in an effort to decrease progression along the schizophrenia spectrum.

### Multi-site rTMS Combined with Cognitive Training Modulates Effective Connectivity in Patients with Alzheimer's Disease

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Yuan-Yuan Qin, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Alzheimer's disease (AD) is an irreversible neurodegenerative disorder with recent understanding as a disconnection syndrome. As pharmacotherapy for AD is currently limited, attention has been paid to non-drug adjuvant interventions such as repetitive transcranial magnetic stimulation (rTMS). Multi-site rTMS associated with cognitive training (rTMS-COG) therapy has been shown to be probably effective for AD patients at early-stage. rTMS has been approved to be able to modulate local activity in a remote area that is functionally connected to cortical stimulation targets. However, the causal interactions between the stimulation targets and other brain regions has yet to be explored. The purpose of this study is to investigate the effective connectivity (EC) changes after multi-site rTMS-COG therapy.

#### METHODS AND MATERIALS

Written informed consent of all participants were obtained according to the declaration of Helsinki before enrollment. 10Hz rTMS over left dorsal lateral prefrontal cortex (DLPFC) and lateral temporal lobe (LTL) were delivered for 4 weeks with COG. AD patients were divided into real (real rTMS+COG, n=11) or sham (sham rTMS+COG, n=8) group to undergo neuropsychological assessment, resting-state fMRI and 3D brain structural imaging before (T0), immediately at the end of (T4), and 4 weeks after treatment (T8). A 2x3 factorial design with "time" as within-subject factor (3 levels: T0, T4, T8) and "group" as between-subject factor (2 levels) were used to investigate the EC changes related to stimulation targets on the rest of brain, as well as the causal interactions among 7 resting state networks based on granger causality analysis (GCA).

#### RESULTS

At voxel-level, the EC changes from left DLPFC out to left inferior parietal lobe and left superior frontal gyrus, as well as from left LTL out to left orbital frontal cortex had significant group x time interaction effect. At network level, significant interaction effect has been identified on the EC increment from limbic network out to default mode network. The EC decrease at voxel level and EC increase at network level were all associated with better functioning in the ability of daily living and cognition.

#### CONCLUSION

Multi-site rTMS combined with cognitive training could modulate effective connectivity in patients with AD, doing better for the ability of daily living and cognitive function. Due to the longitudinal design, the sample size is limited. Further multi-center cohort study was further needed to validate our pilot study.

#### CLINICAL RELEVANCE/APPLICATION

This study provides a novel explanation for the neurobiological mechanisms of multisite rTMS-COG therapy in AD patients and further shed light on the direction of targeted brain network modulation in future.

### **Risk of Malignancy in Ovarian-Adnexal Imaging Reporting & Data System (O-RADS) Ultrasound (US) version 2022 Score 2 Unilocular and Bilocular, Smooth Ovarian Cysts Without Solid Components**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Luyao Shen, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Ovarian-Adnexal Imaging Reporting Data System (O-RADS) Ultrasound (US) version 2022 (v2022) downgraded smooth bilocular cysts without solid components <10 cm to the O-RADS US 2 with a lower expected risk of malignancy (ROM) of <1% based on results from IOTA5 trial (Timmerman et al. JAMA Oncol. 2023;9(2):225-233). We aim to assess the ROM of unilocular and bilocular, smooth cysts without solid components <10 cm in a non-selected patient population presenting to academic radiology departments in the United States.

#### **METHODS AND MATERIALS**

In this IRB-approved, retrospective study from 6 institutions, pelvic US over 5 years were consecutively reviewed to include exams with ovarian cystic lesions. Lesions without surgical, imaging, or clinical follow-up were excluded. Malignant lesions were diagnosed by histopathology, and benignity determined by histopathology, diagnostic on CT/MRI, resolution, decreased size >10%, or stability by imaging or normal clinical exam >2 years. Investigators blinded to the final outcome recorded imaging features and scores per the O-RADS US. Mann-Whitney and Fisher's exact tests were performed (two-tailed  $p < 0.05$  significant).

#### **RESULTS**

Of 14302 pelvic US reviewed, 913 patients had cystic ovarian lesions. Of those, 319 patients with 337 cystic lesions with smooth walls and septations without solid components <10 cm were included. The median age was 45 years (interquartile range 35-53), and there were 212 (66%) pre-menopausal and 107 (34%) post-menopausal patients. There were 292 unilocular cysts (275 patients) and 45 bilocular cysts (45 patients). Differences in patient age, menstrual status, and lesion size were not statistically significant between the 2 groups ( $p=0.633$ ,  $0.865$ , and  $0.845$ , respectively). The ROM was 0.3% (1/292) for unilocular cysts and 2% (1/45) for bilocular cysts. ROM was not statistically significant between the 2 groups ( $p=0.250$ ). The 2 malignant tumors (1 unilocular, premenopausal patient, and 1 bilocular cyst, postmenopausal patient) were both borderline serous tumors.

#### **CONCLUSION**

A 2% ROM was noted with bilocular cysts in our cohort, which is higher than expected range for O-RADS US v2022 score 2 (<1%). ROM difference between unilocular and bilocular, smooth ovarian cysts without solid components <10 cm is not statistically different. Further investigations in a larger cohort should be undertaken to confirm these initial results.

#### **CLINICAL RELEVANCE/APPLICATION**

In bilocular, smooth cysts without solid components, measuring less than 10 cm, the ROM is greater than the O-RADS US v2022 expected range of <1%. Borderline tumors can have this morphology. Our results suggest further investigation in a larger cohort is needed to help determine the appropriate risk categorization for bilocular cysts.

### Ovarian-Adnexal Reporting and Data System (O-RADS) MRI Score Effects of DWI and ADC Values

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Marco Gennarini (*Presenter*) Nothing to Disclose

#### PURPOSE

The aim of this study is to evaluate the potential of integrating diffusion-weighted imaging (DWI) and quantitative assessment of apparent diffusion coefficient (ADC) into the O-RADS MRI system for prognostic purposes. Subsequently, to evaluate the validity and reproducibility of this approach among operators with different levels of experience in female pelvic imaging and to identify any correlations between the histology of malignant lesions and ADC values.

#### METHODS AND MATERIALS

The study included 173 patients with 213 indeterminate masses in the adnexa that underwent MRI examination between January 2015 and June 2022. 140 patients with 172 masses met the inclusion criteria, which required them to be over 18 years old, have undergone a standard MRI exam, have no acute symptoms, and have had subsequent surgery with histopathological examination or stable follow-up for at least one year. Two radiologists with 4 and 1 year of experience in female pelvic imaging, respectively, blindly evaluated all masses according to the O-RADS MRI score system. To perform a quantitative analysis, a circular ROI was placed on the ADC map obtained from single-exponential DWI. If the lesion had multiple solid components, 4 to 6 ROIs were placed, and the ROI with the lowest ADC value was recorded. Lesions without enhanced solid tissue, with fluid, adipose, blood or fibrotic content, were considered benign (O-RADS 2) and excluded.

#### RESULTS

The study showed excellent agreement between the two radiologists in classifying adnexal masses according to the O-RADS MRI score system ( $K = 0.936$ ; 95% CI). Two ROC curves were used to determine the best cut-off value for the ADC between O-RADS MRI categories 3-4 and 4-5, which allowed for some masses to be upgraded or downgraded compared to their original classification. The AUC for O-RADS MRI scores 3 and 4 was 0.951, with an optimal ADC cut-off value of  $1.411 \times 10^{-3}$  mm<sup>2</sup>/sec. Three adnexal masses originally classified as O-RADS MRI score 3 were upgraded to score 4, and four lesions with an ROI ADC  $> 1.411 \times 10^{-3}$  mm<sup>2</sup>/sec were downgraded to score 3. All 30 adnexal lesions classified as O-RADS MRI score 5 remained in that category. The AUC for O-RADS MRI scores 4 and 5 was 0.630, with an optimal ADC cut-off value of  $0.849 \times 10^{-3}$  mm<sup>2</sup>/sec. Twenty-two adnexal masses originally classified as O-RADS MRI score 4 were upgraded to score 5, and 36 adnexal lesions, in accordance with TIC type 2, remained in O-RADS MRI score 4. There was a significant correlation between ADC values and the histotype of ovarian carcinoma ( $p$  value  $< 0.001$ ).

#### CONCLUSION

Our research reveals how DWI and ADC values can provide valuable prognostic information for the O-RADS MRI classification, leading to improved standardization and characterization of adnexal masses.

S3B-SPOB-3

### Comparison of O-RADS and Simple Rules Ultrasound Classifications to Predict Adnexal Malignancy

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Andrew Nanapragasam, FRCPC, FRCR (*Presenter*) Nothing to Disclose

#### PURPOSE

This study compares performance of US O-RADS (version 2022) and Simple Rules (SR) criteria in a cohort of asymptomatic pathology-proven adnexal masses and evaluates O-RADS and SR inter-observer agreement in a subset of patients.

#### METHODS AND MATERIALS

We conducted retrospective analysis in consecutive patients who underwent surgical resection between January 2008 and December 2018 at two adult university hospitals. US cine clips were available for all examinations. One experienced radiologist, blinded to diagnosis, categorized all US imaging by O-RADS and SR criteria. SR assessment assigned the following features as benign: unilocular/multilocular cyst with uniform thin septa irrespective of cyst content/size; cystic or solid mass with attenuating component; cystic mass with <3 mm nodule(s) or completely calcified nodule(s). Malignant features included: non-attenuating solid mass; cystic mass with non-attenuating nodule, nodule(s) =3 mm; multilocular cysts with septa too close to be distinctly seen. A subset of cohort was randomly selected and reviewed by two blinded radiologists with fewer years of experience. Chi-square testing was used for comparison of ratios, and Kappa statistic for inter-observer agreement.

#### RESULTS

791 adnexal masses in 762 patients were assessed, aged 18-92 ( $44 \pm 15$ ); 628 benign, 49 LMP, 114 malignant, measuring 1 to 39 cm ( $7.9 \text{ cm} \pm 4.2$ ). O-RADS categories were 2 (n=309), 3 (n=165), 4 (n=181), 5 (n=136) with malignant rates of 0.3%, 3%, 25%, and 82% respectively. Application of simple rules criteria identified 561 masses as benign and 230 as malignant. Combining O-RADS 4 and 5 categories as being malignant, sensitivity, specificity, NPV, PPV, and accuracy to detect invasive/LMP masses were 96% (CI:92-99%), 75% (CI:71-78%), 99% (CI:97-100%), 49% (CI:44-55%), and 79% (CI:76-82%). Corresponding results for SR were 96% (CI:91-98%), 89% (CI:85-91%), 99% (CI:98-100%), 68% (CI:61-74%), and 90% (CI:87-92%) with specificity, PPV, accuracy of SR being statistically significantly higher than O-RADS ( $p < 0.0001$ ). Inter-observer agreement between the three readers were 0.89, 0.91, and 0.93 for SR benign versus malignant categories and 0.71, 0.75, and 0.75 for O-RADS 2/3 from O-RADS 4/5.

#### CONCLUSION

Adnexal mass ultrasound assessment with SR performs significantly better than O-RADS classification for specificity, PPV, and accuracy with similarly high sensitivity and NPV. High inter-observer agreement was found with both SR and O-RADS.

#### CLINICAL RELEVANCE/APPLICATION

US risk stratification by experienced radiologists using SR criteria outperforms O-RADS and can result in a better triaging of patients to gynecologists versus gynecologists by predicting a more precise rate of malignancy.

### Automated Reconstruction and Segmentation of High-isotropic-resolution Fetal Brain MRI Data for Quantitative Brain Morphological Analysis

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Haoxiang Li (*Presenter*) Nothing to Disclose

#### PURPOSE

Fetal MRI has gained increasing importance in prenatal diagnosis because of its superior soft tissue contrast. To compensate for fetal and maternal motion and limited spatial resolution, two-dimensional (2D) images are acquired across each anatomical direction. In this study, we develop and present an automated pipeline that reconstructs a high-isotropic-resolution fetal brain volume from three 2D thick-slice images and segments it into multiple brain structures using state-of-the-art MR image analysis methods. The accuracy of the pipeline is validated by evaluating the correlation between brain structure volumes and gestational age.

#### METHODS AND MATERIALS

Sixty pregnant women with normal fetal brain, aged between 20 to 36 weeks of gestation, were enrolled with informed written consent and IRB approval to obtain T2-weighted images along axial, coronal, and sagittal directions using a turbo spin echo (TSE) sequence. The NiftyMIC method was employed to perform slice-to-volume motion correction and reconstruct a single fetal brain volume at 0.8 mm isotropic spatial resolution from the three 2D TSE images. The reconstruction process included brain masking, bias-field correction, volumetric reconstruction in each subject's native space, and transformation to the template space. A deep learning-based segmentation neural network named FetalBrainParcellation was then utilized to segment each high-resolution brain volume into eight brain structures, including cortical grey matter, deep grey matter, white matter, corpus callosum, brainstem, cerebellum, intra-axial cerebrospinal fluid (CSF), and extra-axial CSF. Finally, the Pearson correlation coefficient between the volume of each brain structure and the gestational age was computed.

#### RESULTS

The quality of reconstruction and segmentation results of all 60 subjects were visually confirmed by two expert pediatric radiologists. The volume of each brain structure was highly ( $r > 0.9$  for five structures,  $r > 0.8$  for seven structures) and significantly ( $p < 0.001$ ) correlated with the gestational age, which was consistent with previous studies.

#### CONCLUSION

This study introduced a pipeline that automatically reconstructed and segmented fetal brain volumes and validated its robustness and accuracy for quantitative morphological analysis of normal fetal brains.

#### CLINICAL RELEVANCE/APPLICATION

The automated pipeline developed for reconstructing and segmenting fetal brain MRI data provides a novel tool for quantitative morphological analysis of fetal brains, which can aid in diagnosis and prognosis. Further research will assess its validity for fetal brains with pathologies and explore its potential clinical applications.

### Evaluating ChatGPT's Performance on a Radiology-physics Question Set

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Jaydev K. Dave, PhD (*Presenter*) Research Grant, Koninklijke Philips NV; Equipment support, Lantheus Medical Imaging; Equipment support, General Electric Company; Research Consultant, Curvebeam LLC; Consultant, Rayscan, Inc.

#### PURPOSE

Recent reports have evaluated ChatGPT's (OpenAI, San Francisco, CA) performance on several standardized examinations. The purpose of this work was to evaluate the performance of this text-based AI language model on a radiology-physics question set.

#### METHODS AND MATERIALS

A radiology-physics question set with 135 questions (RAPHEX, Radiological and Medical Physics Society of New York) was used to assess ChatGPT's performance. All questions were in the multiple-choice format with single correct answer and three to four distractors. The questions covered different imaging modalities, and included questions with images ( $n = 27$ ), calculations ( $n = 36$ ), and regulatory limits/accreditation requirements ( $n = 17$ ). Freely available, March 23, 2023 version of ChatGPT was used in this study. The questions were entered in multiple choice format with the stem and the options into the chat dialogue box. The responses were evaluated and scored. The justification provided in the ChatGPT responses was also reviewed for correctness.

#### RESULTS

Out of 27 image-based question, there were 8 questions in which interpretation of images was required and given that images are not accepted as input in ChatGPT, there were no responses for these questions. Thus, these 8 questions were not considered in the scoring. Other image-based questions either included description of artifacts/image content in the question stem or images with tabulated data. For these questions, responses were provided by ChatGPT and so these were included for assessment. From the 127 questions included in the analysis, correct responses/explanation were obtained for 79 (62.2%). For 2 questions the correct responses were obtained; however, the justification was incorrect. Evaluating the proportion of correct responses as a function of question type revealed that correct responses were obtained for 63.2% of the questions with images (12/19), 50.0% of the questions that involved calculations (18/36), and 35.3% of the questions involving regulatory limits/accreditation requirements (6/17). Modality-wise, the proportion of correct cases was 88% for radiography, 50% for mammography, 36% for fluoroscopy, 60% for computed tomography, 83% for ultrasound, 67% for magnetic resonance imaging, 43% for nuclear medicine, and 72% for fundamental questions including safety and radiobiology.

#### CONCLUSION

Leaving aside questions that rely on image interpretation, ChatGPT scored 62.2% on a radiology-physics question set covering different modalities and question categories. Image-interpretation questions remain unanswered.

#### CLINICAL RELEVANCE/APPLICATION

Analyzing the performance of chatbots will help target evaluation criteria for maintenance of certification/online longitudinal assessment.

### Opportunistic Osteoporosis Screening with Bone Mineral Density Estimation on Computed Tomography using Multi-View Semi-Supervised Learning

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Heng Guo, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

Computed tomography (CT) scans, which are widely used for other indications, can provide added-value for osteoporosis screening. We propose a novel method for estimating bone mineral density (BMD) using routine CT scans.

#### METHODS AND MATERIALS

We proposed DeepBMD that consists of automatic spine vertebrae instance segmentation and BMD regression in this work. Patients who underwent both a routine CT and a Dual-energy X-ray Absorptiometry (DXA) examination within one month between December 2020 and December 2022 were retrospectively included. This led to 3,586 CT scans (81% chest CT, 19% abdomen CT) and 3,805 DXA results with lumbar BMD values (L1 - L4). After excluding scans with low quality, metal implants and bone fractures, a dataset of 2,633 CT-DXA pairs in patient-level were obtained. An automated vertebrae instance segmentation tool was developed to distinguish vertebrae with DXA gold-standard or not. Finally, we got 4,889 vertebrae with DXA gold-standard, and 30,400 not. The paired dataset was randomly split into 60%, 10%, and 30% for training, validation, and testing. We developed a multi-view semi-supervised learning framework for BMD regression. Specifically, 3D and 2.5D vertebrae patches were extracted under different augmentation parameters. A hybrid network consisting of a CNN and a Vision Transformer was used to extract features. For vertebrae without gold-standard, pseudo BMDs would be generated. An experienced clinical expert specialized in orthopedics checked the vertebrae identification results. The Pearson correlation coefficient, sensitivity, specificity, area under receiver operating characteristics (AUC) are reported.

#### RESULTS

There are 1,005 osteoporotic patients (group A) and 1,628 non-osteoporotic patients (group B) in our dataset. Females account for 68.6% in group A and 48.6% in group B. The average ages of group A and group B are 65.56( $\pm$ 8.59) and 62.17( $\pm$ 9.12). For vertebrae identification, DeepBMD achieves a success rate of 98.7%, indicating that it is robust and reliable. DeepBMD achieves a great correlation coefficient of 0.909 on the testing set. According to the literature that a T-score of less than or equal to -2.5 is considered to be osteoporotic, DeepBMD achieves a sensitivity of 0.87, specificity of 0.90, and AUC of 0.96 for osteoporosis screening.

#### CONCLUSION

The predictions of the proposed algorithm exhibit a strong correlation with DXA and can facilitate opportunistic osteoporosis screening.

#### CLINICAL RELEVANCE/APPLICATION

Using routine CT for BMD estimation can provide the added-value for opportunistic osteoporosis screening. Beyond evaluating BMD in the lumbar vertebrae, our method can also assess the thoracic vertebrae, providing patients with a more comprehensive evaluation of their spine health.

### Development of a TOPAS Monte Carlo Model of a C-arm Cone Beam CT (CBCT) for Organ Dose Estimation

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Nina McWilliams, BSc, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

C-arm cone beam computed tomography (CBCT) used in an interventional radiology (IR) setting provides the radiologist with cross sectional images to assist in performing and verifying a radiological intervention. To accurately estimate the radiation dose to the patient, knowledge of the doses delivered to major radiosensitive organs is required. However, the current approaches for CBCT dosimetry are still under development. Replication of system specific complexities such as automatic exposure control (AEC), rotational geometries, beam hardening and scatter contributions make the simulation and estimation of CBCT radiation doses challenging. The main aim of this research was to develop a novel TOPAS Monte Carlo (MC) dosimetry model of a C-arm CBCT incorporating AEC, and validate it with measurements using an anthropomorphic phantom.

#### METHODS AND MATERIALS

A MC model of a Siemens Artis Q C-arm CBCT system [Siemens, Erlangen, Germany] was developed in TOPAS, version 3.9. A TOPAS extension to incorporate AEC functionality was implemented into the MC model. The system's energy spectrum, CBCT rotational parameters, system geometry and tube filtration were simulated according to manufacturer specifications. Experimental data was obtained using the Body CBCT protocol and a physical CIRS ATOM® adult female anthropomorphic phantom. Verification of the dose distribution and AEC functionality of the MC model was carried out using thermoluminescent dosimeters (TLDs) placed in the tissue-equivalent organ sections of the phantom mimicking patient organs. Measured doses were compared with MC simulated doses for different sites within the phantom acquisitions.

#### RESULTS

This study presents details of the development of a novel AEC module in TOPAS MC simulations for incorporation into a C-arm CBCT MC model. The AEC module, the first of its kind, will shortly be released for public use in TOPAS. The CBCT MC model has been applied to abdominal acquisition protocols in IR and validated through anthropomorphic phantom dose distributions and organ dose measurements.

#### CONCLUSION

A novel AEC module has been successfully developed in TOPAS which can be easily incorporated into other imaging application models that employ such dose modulation. The MC model allows for a more realistic dosimetry estimation, advancing the current CBCT dosimetry approaches.

#### CLINICAL RELEVANCE/APPLICATION

Few studies have documented radiation doses from C-arm CBCT exposures in adults. The novel AEC module developed in this research, and its validation using an anthropomorphic phantom, is a step towards personalised dosimetry in CBCT.

### Development of an Ultra-high-Resolution Dental Cone-beam CT System

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Riku Koda (*Presenter*) Nothing to Disclose

#### PURPOSE

The dental cone-beam computed tomography (DCBCT) systems have been clinically used since early 2000s. They provide detailed images that can help dentists diagnose and plan treatment for different dental conditions. The spatial resolutions of DCBCTs are generally higher than those of multi-slice CT systems; however, the spatial frequency limits evaluated by 5% modulation transfer function (5%MTF) are approximately 2 mm<sup>-1</sup> and those are not necessarily sufficient for observing micro structural abnormalities in oral region. This study aimed to develop a new DCBCT (DCBCT<sub>new</sub>) that achieves a 5%MTF significantly higher than that of conventional DCBCT (DCBCT<sub>c</sub>) without increasing the radiation dose.

#### METHODS AND MATERIALS

A contact geometry, in which the X-ray detector is close to the object, for reducing the focus penumbra was adopted in this system. Furthermore, since the dentition is generally located anteriorly in the head, a half scan orbit was used to prevent collisions between the occipital region and the detector. The scan duration was 6.5 s; during that, projection data with 520 views were obtained using a CsI-based detector with 1488 × 660 pixels. The pixel size at the iso-center was 0.081 mm. For the DCBCT<sub>new</sub> and a DCBCT<sub>c</sub>, MTFs were measured from images obtained by scanning a copper wire with a diameter of 0.1 mm. The radiation dose of DCBCT<sub>new</sub> was measured according to the standard method for the weighted CT dose index (CTDI<sub>w</sub>); then, the effective dose was estimated from the result. An oral region in an anthropomorphic head phantom was scanned using both DCBCT<sub>new</sub> and DCBCT<sub>c</sub>.

#### RESULTS

The 5%MTF of DCBCT<sub>new</sub> was 3.80 mm<sup>-1</sup>, which was more than twice that of DCBCT<sub>c</sub> (1.65 mm<sup>-1</sup>). The estimated effective dose of DCBCT<sub>new</sub> was 0.084 mSv which was significantly lower than reported ones (around 0.2 mSv) of the DCBCT<sub>c</sub>. The phantom images of DCBCT<sub>new</sub> were remarkably sharper and clearer compared to those of DCBCT<sub>c</sub>.

#### CONCLUSION

The developed DCBCT presented significantly higher spatial resolution and more suitable dental CT images to observe micro structures with a lower radiation dose, compared to a conventional DCBCT.

#### CLINICAL RELEVANCE/APPLICATION

The developed DCBCT was able to provide high-resolution images with low dose scanning. This result suggested that there are sufficient rooms to improve the image quality of current clinical DCBCT systems.

### A Dose Based Method to Optimize Virtual Monoenergetic Cone-beam Computed Tomography Imaging Parameters for Image-guided Radiotherapy

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Hyejoo Kang, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aims to optimize Virtual Monoenergetic (VM) cone-beam computed tomography (CBCT) protocols for Image Guided Radiation Therapy (IGRT) as functions of exposure and single frame acquisition rate while minimizing patient imaging dose.

#### METHODS AND MATERIALS

First, 7 CBCT sets acquired at 80 kVp and 140 kVp with various exposures and frame rates were used to determine the average normalized Air Kerma ( $K_{air}$ ) per exposure (mAs) for the X-ray Imaging (XI) system of a Truebeam linac (Varian Medical System, CA) with a calibrated 0.6cc air Kerma Farmer chamber. Then, 6 combined dual (80 and 140 kVp) energy CBCT protocols were optimized, ensuring that their estimated cumulative  $K_{air}$  resulted in a lower imaging dose than  $K_{air}$  of the default 140 kVp-Pelvis CBCT protocol ( $K_{air} = 133$  mGy). VM-CBCT projection images of a Catphan 604 (Phantomlab, NY) at specific energies were generated from DE-CBCT, and then were reconstructed using the Feldkamp-Davis-Kress (FDK) algorithm within an open-source TIGRE toolbox. The quality of VM-CBCT images at 50 keV were evaluated using quantitative metrics such as Hounsfield units (HU), contrast-to-noise ratios (CNR), and noise-level using in-house scripts.

#### RESULTS

The average difference between estimated and measured cumulative  $K_{air}$  for all combined DE-CBCT protocols was  $2.2 \pm 2.1\%$ . Qualitative evaluation of VM-CBCT images at 50 keV showed comparable image quality between those with high- and low- $K_{air}$ . The HU of 20% bone material in the all low- $K_{air}$  VM-CBCT with were within 35 HU of the theoretical value of 298 HU. Additionally, the CNR and noise level between high- and low-  $K_{air}$  VM-CBCT images were within 1.6 ( $16.0 \pm 0.9$ ) and 3 HU ( $19.3 \pm 1.0$  HU) respectively.

#### CONCLUSION

The proposed method of optimizing DE-CBCT acquisition parameters based on  $K_{air}$  provides imaging dose estimate within 3%. VM-CBCT generated from optimized DE-CBCT with reduced  $K_{air}$  showed comparable image quality to VM-CBCT generated from the highest  $K_{air}$  DE-CBCT based on both qualitative and quantitative assessments. Ongoing research aims to explore the impact of further reducing the framerates in CBCT acquisition and evaluating the use of iterative reconstruction to determine imaging parameters with reduced imaging dose while maintaining image quality for clinical applications.

#### CLINICAL RELEVANCE/APPLICATION

VM-CBCT has shown promise in improving visualization of soft tissues compared to standard CBCT. However, the increased imaging dose associated with VM-CBCT remains a concern. We propose to determine imaging parameters using air Kerma measurement-based approaches of optimizing DE-CBCT imaging parameters. This approach has the potential to substantially reduce imaging dose for VM-CBCT without deteriorating image quality for clinical applications.

### Adaptive Deep Learning MR Image Enhancement for Flexible Rapid MR Protocol Design

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Zechen Zhou (*Presenter*) Nothing to Disclose

#### PURPOSE

Deep Learning (DL) based image enhancement approaches can restore the image quality for accelerated Magnetic Resonance (MR) scans. However, a single DL model might not allow flexible MR protocol setup to achieve higher acceleration and resolution. In this work, we propose a Proximal Gradient Descent based unrolled Network (PGDNet) that can adaptively resolve different levels of noise amplification and image blurring. Preliminary performance evaluations were compared with traditional DL methods on various acquisition tasks.

#### METHODS AND MATERIALS

PGDNet (Fig. A, PGDNet) incorporates the image degradation model into the image restoration process to jointly estimate the degradation kernel and the high quality image, which maintains the data consistency with the acquired image while performing adaptive image enhancement. 356 MR acquisitions with paired fully sampled and undersampled (i.e. fewer number of phase encodings [NPE] or signal averages [NSA]) images were collected for training (#pairs for reduced NPE: 101, #pairs for reduced NSA: 193, #pairs for both: 18) and testing (#pairs for reduced NPE: 11, #pairs for reduced NSA: 29, #pairs for both: 4). Three different models were trained: 1) Enhanced Deep Residual Networks (EDSR) (Fig. A, EDSR) trained with all data pairs; 2) EDSR model fine-tuned with the reduced NPE data pairs as the super-resolution expert (SRE) model; 3) PGDNet trained with all data pairs. Quantitative PSNR and SSIM metrics were used to evaluate the accuracy of the model outputs on 3 acquisition tasks.

#### RESULTS

In denoising tasks (Fig. B, reduced NSA scans), PGDNet can better preserve small structures, and prevent over-smoothing, particularly the trabecular bone textures in MSK cases. In deblurring tasks (Fig. B, reduced NPE scans), PGDNet can still achieve similar/superior performance compared to the EDSR SRE model, and show improved structural consistency with the reference image. Compared to EDSR and EDSR SRE, PGDNet demonstrates its adaptation and robustness in the joint denoising and deblurring tasks (Fig. B, scans with reduced NSA and NPE). Quantitative measurements also supported the qualitative assessment.

#### CONCLUSION

By explicitly leveraging the image degradation model, PGDNet outperforms the conventional DL methods in various acquisition tasks, particularly filling the gaps in acquisitions with both reduced NPE and NSA. This allows more flexible MR protocol design to achieve highly accelerated clinical exams or improved image quality for clinical diagnosis.

#### CLINICAL RELEVANCE/APPLICATION

DL based image enhancement methods supporting different types of fast MR acquisitions allow more flexible rapid protocol design to achieve more efficient clinical workflow or improved image quality for clinical diagnosis.

### Assessing Racial and Age-Related Fairness in Chest X-Ray Classification Algorithms

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Yonghan Ting, FRCR (*Presenter*) Nothing to Disclose

#### PURPOSE

Evaluate bias in two commercial (AI1, AI2) and one academic (AI3) chest x-ray classification algorithms. Estimate the fairness of these algorithms for different age and racial groups using the Aequitas package.

#### METHODS AND MATERIALS

- 500 anonymized chest x-rays were collected from patients aged above 18, across 6 races at an academic hospital center in Singapore.
- Ground truth was established by an experienced radiologist.
- X-rays were analyzed by two commercial and one academic CXR classification model for normal-abnormal classification on the CARPL.AI platform
- Aequitas package preloaded on this platform was used to evaluate algorithm performance on metadata classes, including age group and race, with reference groups selected based on the majority population characteristics.
- False negative rate (FNR) metric was used to calculate inter-class scores of bias.

#### RESULTS

- For age, AI1 showed FNR disparity for patients aged 48-99; AI2 showed FNR disparity for patients aged 19-31 and 48-99; AI3 showed FNR disparity across all age groups.
- For race, at a 60% disparity intolerance, FNR parity was observed for Chinese and Indian populations in AI1 and AI2, respectively; AI3 demonstrated FNR parity for Chinese and Malay groups.

#### CONCLUSION

The study found the AI algorithms to have racial parity but at a reduced tolerance range. Both algorithms showed a certain degree of FNR disparity for certain age groups. We propose including bias evaluation as a core component of every AI solutions' validation pipeline.

#### CLINICAL RELEVANCE/APPLICATION

By identifying disparities in the performance of these algorithms across different age groups and racial backgrounds, our findings can inform clinicians, healthcare institutions, and algorithm developers about the limitations and potential risks associated with the current AI-based diagnostic tools.

### Improving Reconstruction in Accelerated MRI via Transferable Deep Learning

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Yuxiang Zhou, PHD (*Presenter*) Nothing to Disclose

#### PURPOSE

The objective of this study is to develop an attentive feature refinement-based transfer learning approach for vendor transfer in medical image, which will allow any pre-trained model to transfer knowledge across domains and adapt to novel domains with relatively limited datasets.

#### METHODS AND MATERIALS

Variational Feedback Network (VFN) was adopted as the base architecture to conduct and evaluate the effectiveness of our proposed transfer learning strategy. We extend the transfer learning capability of VFN beyond existing transfer learning methods (i.e., pretrained weights finetuning) by selecting pretrained features that benefit reconstruction quality. To enable knowledge transfer from the source dataset to refine target tasks, we exploit the high-level features of reconstructions from VFN network. To refine the subsampled k-space, we propose a feature extraction and refinement (FER) module. We use more than 400 T1-weighted MRI ACR phantom images collected from MAGNETOM Skyra 3.0T (SIEMENS Healthcare) and Discovery 750W 3.0T (General Electric HealthCare) scanners as our two domains and analyze the transfer in both directions.

#### RESULTS

The images were reconstructed with an acceleration factor of 4. Five AI models were development in this studied and tested on GE phantom dataset. The first model was trained with SIEMENS ACR data (400 samples) using the basic VFN network. The second model was trained with GE ACR data (100 samples) using the basic VFN network. The third model was trained with SIEMENS + GE ACR data (500 samples) using the basic VFN network. The fourth model was trained based model 1 but fine-tuned with GE dataset without feature supervision. The fifth model was trained based model 1 but fine-tuned with GE dataset with a feature extractor. The reconstruction quality is compared across implicit and explicit transfer learning methods. The testing results for GE 5 dataset of PSNR are 35.7 +/- 13.05, 43.73 +/- 15.6, 44.16 +/- 13.06, 42.61 +/- 13.76, 44.72 +/- 16.38, and SSIM 0.9024 +/- 0.12, 0.9718 +/- 0.06, 0.9806 +/- 0.03, 0.9631 +/- 0.08, 0.9893 +/- 0.09 for the above 5 models.

#### CONCLUSION

Our study indicates that the reconstruction quality by using our newly developed feature refinement-based transfer learning is significantly better than these reconstructed with conventional Variational Feedback Network (VFN) with limited datasets.

#### CLINICAL RELEVANCE/APPLICATION

This study established and tested a new DL model of feature refinement-based transfer learning with strong ability to handle data heterogeneity and variability at speeding up MRI scans up to 4~8 times faster. This method will be able to shorten clinical MRI scan time for improved patient experience and reduced cost while maintaining the quality for diagnosis.

### Viability of an AI-enabled 0.5T Scanner to Improve MR Access

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Arjun Narula, MBBS, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Access to MRI is known to have improved clinical outcomes. However, it is limited to high economic regions due to high cost, lack of infrastructure and unavailability of skilled labor. Lower field strength MRI along with lower gradient and RF specifications will reduce cost and infrastructure requirements. However, image quality from these derated systems have historically not been sufficient for clinical use. Recent developments in image acquisition and reconstruction with artificial intelligence (AI) could enable improvement of quality of images obtained from such systems to make it clinically viable. This abstract tests the hypothesis that an AI-enabled 0.5T system with low gradient and RF power would provide clinically sufficient information compared to a conventional 1.5T clinical scanner.

#### METHODS AND MATERIALS

Routine brain and cervical spine exams were collected from 197 patients (1188 series in total) on 0.5T, low gradient and low RF AI-enabled scanner with custom made 14-channel HNU coil. The same patients were also scanned on a commercial 1.5T scanner. The scan duration of the 0.5T AI-enabled scanner was comparable to the clinical scanner and at the most less than 2 times the clinical scanner's scan duration. Comparisons were made to study the clinical sufficiency for diagnosis of the AI-enabled 0.5T scanner images to those obtained from 1.5T scanner by at least 4 radiologists from a pool of 10 global radiologists. The radiologists rated the images on a Likert scale between 1 and 9 (1: clinically useless, 5: diagnostic quality, 9: better than reference).

#### RESULTS

The 0.5T scans were rated on an average as  $6.11 \pm 1.2$ ; significantly above diagnostic quality 5 ( $p < 1e-4$ ). On a subset of the data, conventional (non-AI) reconstructed images were compared with AI-reconstructed images. AI reconstruction significantly improved ( $p < 1e-14$ ) the rating average by  $2 \pm 0.96$  points on the Likert scale. Only a total of 81 series out of 1188 obtained an average rating below 5 (diagnostic) and were mostly due to motion artefacts. The rest were due to poor acquisition parameter choices in the early phase of the study.

#### CONCLUSION

This study has shown that AI-based image quality improvement can enable head and c-spine images from a 0.5T system to be diagnostically sufficient. Further assessment on other anatomies and additional AI methods for acceleration is required.

#### CLINICAL RELEVANCE/APPLICATION

AI-enabled low-field systems can provide diagnostic image quality similar to clinically accepted 1.5T scanners and has good potential to help improve access of MRI to underprivileged regions.

### Improving Juxta-vascular Pulmonary Nodule Detection Capability Using a Deep Learning-based AI Detection System in Low-dose Computed Tomography (LDCT)

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Fang Wang, PhD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the performance of a deep learning computer aided diagnostic (CAD) system to improve detection rate for juxta-vascular pulmonary nodules in LDCT.

#### METHODS AND MATERIALS

104 healthy patients who underwent low-dose chest CT screening using a 256slice wide-detector CT (Revolution, GE Healthcare) were enrolled. Protocols were adjusted so that effective dose was set to approximately 1.5 mSv. All DICOM images were sent to a deep learning (DL) computer aided diagnostic system (InferRead CT Lung Research, Infervision) for automatic pulmonary nodule detection. Three methods were used to read the images. Method A: Independent reading of axial images by two radiologists to detect juxta-vascular pulmonary nodule (JVPN) reaching consensus. Method B: DL assisted reading result was analyzed by radiologists to judge whether they were JVPN. Method C: Based on method B results, radiologists read the films by combining the axial images. The total number and locations of nodules for each patient detected in each method were recorded. Two senior chief radiologists' consensus readings were used as the gold standard nodules. The detection rate and false positive rate of each method were calculated respectively.

#### RESULTS

216 JVPNs were confirmed as gold standard. In method A, 158 nodules were detected, among which 156 were true positive JVPNs; in method B, 215 nodules were detected, among which 190 were true positive JVPNs; In method C, 212 nodules were detected, among which 208 were true JVPNs. In method C, the detection rate of all JVPNs was 96.29% which was higher than that in method A and B (72.22% and 87.96). The false positive rate for juxta-vascular pulmonary nodules detected by method C (4%) was significantly lower than that by method A (12%) and B (24%).

#### CONCLUSION

The screening method of image reading combined with DL-CAD results interpreted by radiologists significantly improves the detection rate and reduce false positive rate of juxta-vascular pulmonary nodules in LDCT screening.

#### CLINICAL RELEVANCE/APPLICATION

Reading combined with DL-CAD results interpreted by radiologists can improve the detection efficiency of juxta-vascular pulmonary nodules which could be used as a preferred method for LDCT screening of pulmonary nodules in high risk patients.

### **Towards a Fully Autonomous Artificial Intelligence Volume-rendered Segmentation Workflow for CT Angiography of the Thoracic Aorta**

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Ahmed S. Negm, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Three-dimensional (3D) surface rendering enables global qualitative assessment of aortic anatomy. Generating a surface model for 3D visualization requires time-consuming manual or semi-automated segmentation, taking an average of 32 minutes per case at our institution. This amounts to 2.74 FTE of 3D lab technologist time. To decrease manual effort, we developed a deep learning model to automate aortic segmentation and 3D surface model creation from CTA images, integrating an artificial intelligence (AI)-assisted workflow into the clinical practice. We then compared the visual quality of AI-assisted and fully automated surface renderings of the thoracic aorta.

#### **METHODS AND MATERIALS**

An AI model was trained on 304 manually created segmentation maps created for clinical purposes at our institution. Processing time for the AI model was 6 minutes with GPU acceleration. In this IRB-approved study, we retrospectively analyzed the visual quality of 25 3D surface renderings for CTAs acquired at a single center. Twenty-five sets of renderings were then blindly assessed by two experienced cardiovascular radiologists, comparing deep learning segmentations to those that had been manually adjusted by an experienced 3D lab technologist. Comparisons were made using a 5-point Likert scale and covered multiple anatomic features as well as overall quality.

#### **RESULTS**

The renderings based on the AI-only segmentations were assessed to be equivalent to the AI-corrected renderings ( $p \geq 0.19$ ) across all anatomic regions except for the coronary arteries ( $p = 0.06$ ), which favored the AI-corrected results. The coronary arteries are not consistently segmented across all exams, which may have caused the model to underperform in these features. The overall reader agreement was very good (Gwet AC1 = 0.68).

#### **CONCLUSION**

Fully automated AI-based segmentation of the thoracic aorta produces 3D renderings of equal quality compared to the existing manual process, which may allow for significant time savings by fully automating 3D postprocessing.

#### **CLINICAL RELEVANCE/APPLICATION**

An AI-only workflow yielded similar image quality for thoracic aorta segmentation indicating the potential to fully automate thoracic aortic CTA post-processing.

### Validation of the QuCAD Evaluation Tool to Quantify Wait-Time-Savings from a Computer-Aided Triage and Notification (CADt) Device

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Berkman Sahiner, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

This work validates our queueing theory-based QuCAD evaluation tool designed to quantify the wait-time savings that a computer-aided triage and notification (CADt) device may bring to chest CT and chest CT angiography (CTA) pulmonary embolism (PE) STAT cases from a tertiary academic medical center.

#### METHODS AND MATERIALS

To validate the QuCAD evaluation tool, we retrospectively retrieved clinical reader timestamp data to characterize radiologists' work queue via the number of readers, image inter-arrival time to the PACS, and radiologists' effective reading time. The effective reading time of each radiologist was defined as the time between the opening of two consecutive readings. An exponential curve is fit to the distributions of inter-arrival times and effective reading times. We compared the wait-time savings predicted by QuCAD with the mean difference in clinical turnaround time from data before and after CADt adoption. Turnaround time is defined as the time from when an image entered the PACS to when the first review is completed by a radiologist. We stratified this comparison by cases arriving between 8am and 5pm (day shift) and those between 5pm and 8am (night shift).

#### RESULTS

Between 2019 and 2022, 9,864 chest CT/CTA PE STAT cases were reviewed by 70+ radiologists. On average, 2 to 3 readers reviewed images at a given timepoint. The overall case arrival rate was 0.327/min, and the mean effective reading times were 20.1 min for positive PE studies and 14.9 min for negative PE cases. When having 2, 3, and 4 radiologists reviewing images, QuCAD predicts wait-time-savings for positive PE cases to be 14.9 min [95% CI: 13.3, 16.8], 1.27 min [1.00, 1.54], and 0.25 min [0.16, 0.33] respectively. From positive clinical PE cases, the mean difference in turnaround time before and after the use of CADt is 22.9 min during day shift hours. During night shift hours, the mean turnaround time difference drops to 8.26 min.

#### CONCLUSION

Using 4 years of workflow data from a tertiary academic medical center, this study successfully validated the QuCAD tool designed to quantify potential wait-time-savings a CADt can bring to positive findings. Despite a large variability in clinical workflow, wait-time saving predictions from QuCAD estimates align with the turnaround time reduction from the clinical data.

#### CLINICAL RELEVANCE/APPLICATION

CADt devices use artificial intelligence (AI) to process patient images and prioritize cases with suspected findings. Previous work developed an evaluation tool (QuCAD) that quantifies the time-saving benefits via queueing theory. This study validated QuCAD using timestamp data from a real clinic. QuCAD is now publicly available for evaluating the time-saving benefits of CADt devices.

### Improving Image Quality of Blood Vessels through Deep Learning-Based Denoising and Enhancement Method Based on Low-Energy DSA

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Ruizhi Hou (*Presenter*) Nothing to Disclose

#### PURPOSE

This work investigates the feasibility and efficacy of a novel approach that combines low-energy digital subtraction angiography (DSA) images with a new denoising and enhancement framework for improving the image quality of blood vessels while reducing ionizing radiation during surgical procedures.

#### METHODS AND MATERIALS

Between December 2021 and December 2022, 140 patients participated in a retrospective study on DSA intervention therapy for cerebral arteries, renal arteries, coronary arteries, and lower limb arteries. The study had IRB approval and waived written consent. These patients were randomly divided into training, validation, and test sets, with 98, 14, and 28 patients, respectively. The denoising and enhancement network framework consisted of a noise estimator, a denoising network, and a refinement network. The network was trained using only the noisy DSA image for joint denoising and enhancement. An ROI measuring 256 x 256 was placed over the arterial angiography region, with the non-angiographic region serving as the background. Measurements of pixel values and standard deviation were taken for the artery, and the signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated for the ROI region. The image quality was assessed using the Peak Signal to Noise Ratio (PSNR) and Structural Similarity Index Measure (SSIM). Images obtained through low-energy transmission with deep learning-based denoising and enhancement were assigned to the prediction group, while images obtained through normal-energy X-ray fluoroscopy were assigned to the ground truth group for objective evaluations.

#### RESULTS

Effective use of deep learning techniques can reduce image noise and increase CNR and SNR. Low-energy DSA, when combined with denoising and enhancement network (PSNR:  $40.72 \pm 2.85$ dB; SSIM:  $0.9370 \pm 0.0440$ ; SNR:  $34.86 \pm 3.46$ ; CNR:  $5.10 \pm 4.48$ ), proves to be superior to low-energy DSA (PSNR:  $26.05 \pm 0.03$ dB; SSIM:  $0.3770 \pm 0.0436$ ; SNR:  $20.71 \pm 1.19$ ; CNR:  $2.37 \pm 2.56$ ); A single image of 1024 x 1024 with a processing speed can be achieved in 0.051 seconds.

#### CONCLUSION

Low-energy DSA combined with deep learning denoising and enhancement techniques can enhance the contrast between arteries and surrounding tissues, optimize the quality of arterial images, reduce noise, and maintain real-time efficiency.

#### CLINICAL RELEVANCE/APPLICATION

Combining low-energy DSA with deep learning denoising and enhancement techniques can effectively reduce noise and enhance the shape of displayed arteries in real time, providing valuable assistance for various interventional procedures in clinical practice.

### Quantitative Analysis of Lower Extremity Muscle Features Measured from Computed Tomography Angiography for Diagnosis of Peripheral Arterial Disease

Sunday, Nov. 26 12:15PM - 12:45PM Room: Learning Center

Ge Hu (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore whether lower extremity muscle features can be used for the diagnosis of peripheral arterial disease (PAD).

#### METHODS AND MATERIALS

Data of patients with PAD who visited our hospital between July 2016 and September 2020 were retrospectively collected. Two radiologists evaluated PAD severity on digital subtraction angiography (DSA) and computed tomography angiography (CTA) images using the runoff score. With the DSA score as reference standard, the patients were divided into two groups: mild PAD (DSA score = 7) vs. severe PAD (DSA score > 7). After segmenting lower extremity muscles from CTA images, 95 features were extracted for: univariable analysis, logistic regression model (LRM) analysis, and sub-dataset analysis (to verify whether PAD diagnosis can be realized through only part of the lower leg images).

#### RESULTS

A total of 56 patients ( $69 \pm 11$  years; 38 men) with 56 lower legs were enrolled in this study. The lower leg muscles of the mild PAD group (36 patients) showed higher CT values (44.6 vs. 39.5,  $P < 0.001$ ) with smaller dispersion (35.6 vs. 41.0,  $P < 0.001$ ) than those in the severe PAD group (20 patients). The area under the curve (AUC) of the CTA score, LRM-I (model constructed with muscle features), and LRM-II (model constructed with muscle features and CTA score) for PAD diagnosis were 0.81, 0.84, and 0.89, respectively. The highest diagnostic performance was observed in the image subset of the middle and inferior segments of the lower extremity (LRM-I, 0.83; LRM-II, 0.90).

#### CONCLUSION

Lower extremity muscle features can be used for PAD diagnosis.

#### CLINICAL RELEVANCE/APPLICATION

Quantitative analysis of lower extremity muscle features can be a useful supplement to the current clinical imaging diagnosis methods of PAD and compensate for the limitations of vascular stenosis diagnosis from the perspective of muscle ischemia evaluation.

### S3-STCE1-1 The Feasibility of Endovascular Management of Acute Stroke with a Large Ischemic Territory: A Meta-Analysis and Markov Cost-Effectiveness Analysis

Assala Aslan, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Mechanical thrombectomy (MT) for acute ischemic stroke is generally avoided when the expected infarction is large (defined as ASPECT score of  $< 5$ ). However, three recent trials including RESCUE-Japan, SELECT2, and ANGEL-ASPECT, showed that patients with large cerebral infarctions had better functional outcomes, measured as modified Rankin Scale (mRS) score of 0-3 at 90 days, with MT as compared to best medical management (BMM) alone. In this study we performed a meta-analysis of these trials comparing MT vs. BMM for treatment of acute ischemic stroke with large infarction territory, and then analyzed the cost-effectiveness associated with those treatments.

#### METHODS AND MATERIALS

A meta-analysis of the RESCUE-Japan, SELECT2, and ANGEL-ASPECT trials was conducted using R Studio. Statistical analysis employed the Weighted Average Normal (WAN) method for calculating mean differences from medians in continuous variables and the Risk Ratio (RR) for categorical variables. TreeAge software was used to construct a cost-effectiveness analysis model comparing MT vs. BMM in the treatment of ischemic stroke with large infarction territory.

#### RESULTS

In the meta-analysis, MT was associated with a significant reduction in mRS with a mean difference (MD) across all studies of  $-0.55$  ( $P < 0.0001$ , 95% CI:  $-0.78 - -0.33$ ) indicating better functional outcomes compared to BMM (Figure 1). In the base-case analysis using a timeline of 10 years, MT and BMM alone were found to have a total gain of 2.54 QALY and 1.82 QALY, respectively. MT was also associated with a lower total cost of \$248,525, compared to \$265,456 with BMM alone (Figure 2). MT had a total incremental effectiveness of 0.72 QALY when compared with BMM alone, with an incremental cost-effectiveness ratio of \$-23,535.

#### CONCLUSION

This study shows that, besides having a better functional outcome at 90-day follow-up, MT was more cost-effective compared to BMM, when accounting for healthcare cost associated with treatment outcome.

#### CLINICAL RELEVANCE/APPLICATION

In this meta-analysis, we found that mechanical thrombectomy (MT) had superior functional outcomes measure as mRS of 0-3 at 90-days, compared to best medical management (BMM) for treatment of AIS with low ASPECT score ( $< 6$ ). Additionally, using Markov model and projection over 10 years period, MT was also found to be more cost effective than BMM, and was associated with lower better healthcare costs on the long term.

### S3-STCE1-2 Design and Creation of a 3D Printed Realistic Anthropomorphic Kidney Phantom for Theranostics (Lutetium-177) Dosimetry

Sara Belko, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

Lutetium-177 prostate-specific membrane antigen-617 ( $^{177}\text{Lu}$ -PSMA-617) is a radioligand theranostic that delivers beta-particle radiation to PSMA-expressing cells in metastatic castration-resistant prostate cancer. [1]  $^{177}\text{Lu}$ -PSMA-617 has been shown to accumulate in the kidneys which can lead to possible injury thus is an organ of interest to monitor during treatment. [1] To ensure proper dosimetry, phantoms of a known activity can be used to assess imaging partial-volume

errors. [2] Previous studies have used multipart spherical and ellipsoidal models to represent a kidney. These models can be time consuming to make and do not account for artifacts from organic curvature of the kidney and quantifying two kidneys adjacently. The purpose of this project was to design and three dimensional (3D) print a realistic anthropomorphic model with right and left kidneys with two compartments (medulla and cortex).

#### **METHODS AND MATERIALS**

Left and right kidneys without pathology were segmented from a deidentified CT scan using Materialize MIMICs (version 25.0). Kidney segmentation allowed for more organic realistic shapes and curvatures. The parts were pulled into Materialize 3-Matic (version 17.0) for computer aided design (CAD). CAD modifications included: Hollowing and creating an inner chamber resulting in a 67% volume cortical (outer) chamber and 31% volume medulla (inner) chamber, [3] Creation of luer ports to be used with one way valves to inject water and <sup>177</sup>Lu-PSMA-617 into the chambers, A peg and base system to allow the kidneys to be positioned in their natural anatomic positions when being scanned and immersed in water. The kidneys were printed using stereolithography (SLA) on a FormLabs 3B printer ([www.formlabs.com](http://www.formlabs.com)). Each multi-chambered kidney was printed individually as one piece in FormLabs clear resin ([www.formlabs.com](http://www.formlabs.com)). The models were post-processed in isopropyl alcohol, cured, and finished according to the instructions for use published by the material manufacturer. The positioning base was printed in white polylactic acid using fused deposition modeling (FDM) on a Ultimaker S5 printer (<https://ultimaker.com/>). It was printed at 100% infill to ensure it would not float when submerged.

#### **RESULTS**

A water tight anthropomorphic phantom with 2-chamber left and right kidneys was developed and tested with <sup>177</sup>Lu-PSMA-617. The material cost of the model was 82 dollars.

#### **CONCLUSION**

A low-cost, easily printable, realistic kidney model was developed to be used for theranostic dosimetry or calibration. Dosimetry studies will be published in the future.

#### **CLINICAL RELEVANCE/APPLICATION**

3D printing allows for the creation of low-cost, anthropomorphic phantoms that can be used to calculate radiation dosimetry in theranostics.

### **S3-STCE1-3 A radiomics approach to noninvasively predict PD-1 expression and prognosis in patients with HCC treated with sorafenib after surgery**

Feng Che, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To investigate the impact of preoperative contrast-enhanced CT-based radiomics model on PD-1 status prediction in hepatocellular carcinoma (HCC) patients.

#### **METHODS AND MATERIALS**

The study included 105 HCC patients (training cohort: 72; validation cohort: 33) who underwent preoperative contrast-enhanced CT and received systemic sorafenib treatment after surgery. Radiomics score was built for each patient and was integrated with independent clinicoradiologic predictors into the radiomics model using multivariable logistic regression analysis.

#### **RESULTS**

Seventeen radiomics features were finally selected to construct the radiomics score. In multivariate analysis, serum creatine and peritumoral enhancement were significant independent factors for PD-1 expression prediction. The radiomics model integrated radiomics signature with serum creatine and peritumoral enhancement showed good discriminative performance (AUC of 0.897 and 0.794 in the training and validation cohort). Overall survival (OS) was significantly different between the radiomics-predicted PD-1-positive and PD-1-negative groups (OS: 29.66 months, CI:16.03-44.40 vs. 31.04 months, CI: 17.10-44.07, P<0.001). Radiomics-predicted PD-1 was an independent predictor of OS of patients treated with sorafenib after surgery. (Hazard ratio [HR]: 1.61 [1.23-2.1], P<0.001).

#### **CONCLUSION**

The proposed model based on radiomic signature helps to evaluate PD-1 status of HCC patients and may be used for evaluating patients most likely to benefit from sorafenib as a potentially combination therapy regimen with immune checkpoint therapies.

#### **CLINICAL RELEVANCE/APPLICATION**

PD-1 was an independent predictor of overall survival of patients treated with sorafenib after surgery. A contrast-enhanced CT radiomics model was built and showed satisfactory value for preoperative prediction of PD-1 in HCC patients. The radiomics features may provide a promising opportunity to improve clinical decision support for patients with immunotherapeutic approaches.

#### Sub-Events

### S3-STCE2-1 Evaluation of ChatGPT-Generated Pamphlets for Common Interventional Radiology Procedures

Soheil Kooraki, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aimed to evaluate the accuracy and reliability of educational patient pamphlets created by ChatGPT, a large AI language model, for common interventional radiology (IR) procedures.

#### METHODS AND MATERIALS

Twenty frequently performed IR procedures were selected, and five users were tasked to independently request ChatGPT to generate educational patient pamphlets for each procedure using identical commands. Subsequently, two independent radiologists assessed the quality and accuracy of the pamphlets. The review focused on identifying potential errors, inaccuracies, the consistency of pamphlets.

#### RESULTS

The review of the pamphlets revealed that 25% (25/100) of generated pamphlets contained errors, with a total number of 31 identified errors. The most common errors were related to the omission of information regarding sedation for the procedure (9/31), pre-procedural preparation details (5/31), procedural steps for Y-90 radioembolization (3/31), and precautionary measures for the procedure (3/31). There were inter-user structural variations in the pamphlets created for each IR procedure.

#### CONCLUSION

Although the study showed promising results for ChatGPT-generated educational patient pamphlets, the pamphlets were not entirely accurate and were prone to errors and inter-user structural variabilities.

#### CLINICAL RELEVANCE/APPLICATION

Future advancements and refinements in AI language models could potentially improve their utility in creating reliable educational medical content, but human supervision and expert validation are still necessary to ensure accuracy and patient safety.

### S3-STCE2-2 ChatGPT vs. Hybrid NLP/Rule Based Algorithm for Determination of Referral Specialty from Right Upper Quadrant Ultrasound Reports

Jacob L. Kraus, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Artificial intelligence (AI) tools can be used to identify clinically significant findings in radiology reports and help providers by suggesting referral services based on them. The aim of this study is to evaluate and compare the abilities Chat GPT and a hybrid Natural Language Processing (NLP)/rule-based algorithm in the determination of appropriate specialty referral for patients based on right upper quadrant (RUQ) ultrasound reports.

#### METHODS AND MATERIALS

300 RUQ reports were randomly collected from March 23 to April 4, 2023 from an academic tertiary level 1000+ bedded hospital. Reports were manually de-identified of any PHI, labeled for clinically significant findings (CSF) and interpreted in order to determine need for follow-up and, if necessary, specialty referral. Labeling and interpretation were done under the

guidance of a board-certified radiology attending. Both Chat GPT and a hybrid NLP/rule-based algorithm were then prompted with the reports and asked to determine whether patients required follow up based on findings, the reason for that determination, and what specialty the patient should be referred to. As the hybrid algorithm can only determine the need for specialty referral to one of 4 services (hepatobiliary, urology, primary care and gynecology), Chat GPT was prompted with that same constraint. Responses were then analyzed for their ability to determine what specialty a patient would need referral to if any at all. The set of true referrals used as the ground truth only included correct referrals for combinations of CSFs that were used to create the rule set of the hybrid algorithm.

## RESULTS

ChatGPT's recall achieved a precision of 54.37%, a recall of 76.54%, an F1 Score of 63.58%, and an accuracy of 74.69%. The hybrid algorithm achieved a precision of 96.31%, a recall of 70.66%, an F1 Score of 81.51%, and an accuracy of 90.78%.

## CONCLUSION

: When prompted with rule-based constraints ChatGPT's precision, accuracy and F1 score were limited when compared to our hybrid algorithm. This is in part could be due to an affirmative bias which resulted in a significantly higher number of false positives from ChatGPT (167 vs. 7). Our hybrid model's low false positive was likely due to its integrated rule set which constrained referral generation to a smaller set of CSF combinations. ChatGPT's recall was slightly higher than that of our hybrid algorithm which may be due to its zero shot learning capabilities which allow it to classify samples from classes not trained on.

## CLINICAL RELEVANCE/APPLICATION

Comparing the ability of an internally constructed hybrid NLP/rule-based model to Chat GPT in the determination of appropriate follow up specialty from right upper quadrant ultrasound radiology reports.

### S3-STCE2-3 ChatGPT for Determination of Need for Follow Up from Right Upper Quadrant Ultrasound Reports

Jacob L. Kraus, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Patient follow-up is a key component of patient care. In radiology, coordinating patient follow-up from imaging report findings is challenging because of the multiple communication systems and steps between the imaging report findings and patient follow-up. The increase in volume of imaging that has occurred in the past decade also contributes to the challenge of coordinating patient follow-up. This study aimed to determine the viability of using Chat GPT, a generative AI, to binarily determine whether or not a patient requires follow-up based on findings in their right upper quadrant ultrasound reports.

## METHODS AND MATERIALS

300 RUQ reports were randomly collected from March 23 to April 4, 2023, from an academic tertiary level 1000+ bedded hospital. Reports were manually de-identified of any PHI. Reports were then labeled as clinically significant findings and interpreted in order to determine the need for follow-up and, if necessary, specialty referral. A total of 23 groups of clinically significant findings were identified. Labeling and interpretation were done under the guidance of a board-certified radiology attending. Chat GPT was then prompted with the reports and asked to determine whether or not patients required follow up based on findings, the reason for that determination, and what specialty the patient should be referred to. Chat GPT responses were then labeled in the context of the previous questions. Chat GPT's determination of need for follow up was then compared to the true need for follow up.

## RESULTS

234 out 300 reports necessitated follow up after manual interpretation. ChatGPT determined that 223 of the 300 reports necessitated follow up. Recall was 90.6%, precision was 95.07%, accuracy was 89%, and F1 Score was 92.78 %.

## CONCLUSION

ChatGPT achieved a recall of 90.6%, precision of 95.07%, accuracy was 89%, and an F1 Score of 92.78%. ChatGPT could provide a method of automatically labelling reports that would alert providers when their patients imaging requires follow up and could be expanded to take into urgency of specific findings. The limits of this study include a lack of specificity in prompting, interpreter bias, site specific practice patterns lending importance to certain findings, as well site-specific reporting norms. Additionally, limitations of generative AI technologies such as a lack of training data in specific areas, mislabeled training data, non-structured responses, and bias may also play a role.

## CLINICAL RELEVANCE/APPLICATION

Evaluation of ChatGPT's ability to determine need for follow up from right upper quadrant ultrasound radiology reports.

Printed on: 08/22/24

This is in part could be due to an affirmative bias which resulted in a significantly higher number of false positives from ChatGPT (167 vs. 7). Our hybrid model's low false positive was likely due to its integrated rule set which constrained referral generation to a smaller set of CSF combinations. ChatGPT's recall was slightly higher than that of our hybrid algorithm which may be due to its zero shot learning capabilities which allow it to classify samples from classes not trained on.

#### CLINICAL RELEVANCE/APPLICATION

Comparing the ability of an internally constructed hybrid NLP/rule-based model to Chat GPT in the determination of appropriate follow up specialty from right upper quadrant ultrasound radiology reports.

Printed on: 08/22/24

### ChatGPT for Determination of Need for Follow Up from Right Upper Quadrant Ultrasound Reports

Sunday, Nov. 26 12:00PM - 12:30PM Room: Learning Center Theater 2

Jacob L. Kraus, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Patient follow-up is a key component of patient care. In radiology, coordinating patient follow-up from imaging report findings is challenging because of the multiple communication systems and steps between the imaging report findings and patient follow-up. The increase in volume of imaging that has occurred in the past decade also contributes to the challenge of coordinating patient follow-up. This study aimed to determine the viability of using Chat GPT, a generative AI, to binarily determine whether or not a patient requires follow-up based on findings in their right upper quadrant ultrasound reports.

#### METHODS AND MATERIALS

300 RUQ reports were randomly collected from March 23 to April 4, 2023, from an academic tertiary level 1000+ bedded hospital. Reports were manually de-identified of any PHI. Reports were then labeled as clinically significant findings and interpreted in order to determine the need for follow-up and, if necessary, specialty referral. A total of 23 groups of clinically significant findings were identified. Labeling and interpretation were done under the guidance of a board-certified radiology attending. Chat GPT was then prompted with the reports and asked to determine whether or not patients required follow up based on findings, the reason for that determination, and what specialty the patient should be referred to. Chat GPT responses were then labeled in the context of the previous questions. Chat GPT's determination of need for follow up was then compared to the true need for follow up.

#### RESULTS

234 out 300 reports necessitated follow up after manual interpretation. ChatGPT determined that 223 of the 300 reports necessitated follow up. Recall was 90.6%, precision was 95.07%, accuracy was 89%, and F1 Score was 92.78 %.

#### CONCLUSION

ChatGPT achieved a recall of 90.6%, precision of 95.07%, accuracy was 89%, and an F1 Score of 92.78%. ChatGPT could provide a method of automatically labelling reports that would alert providers when their patients imaging requires follow up and could be expanded to take into urgency of specific findings. The limits of this study include a lack of specificity in prompting, interpreter bias, site specific practice patterns lending importance to certain findings, as well site-specific reporting norms. Additionally, limitations of generative AI technologies such as a lack of training data in specific areas, mislabeled training data, non-structured responses, and bias may also play a role.

#### CLINICAL RELEVANCE/APPLICATION

Evaluation of ChatGPT's ability to determine need for follow up from right upper quadrant ultrasound radiology reports.

Printed on: 08/22/24

#### Sub-Events

### **S4-SSCH02-Successful Improvement in Lung Screening Enrollment for Women Undergoing Breast 1 Screening: The CALM Study (Coordinate A Lung Screening with Mammography)**

Kim L. Sandler, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Lung cancer has been the leading cause of cancer-related mortality in women for decades. Lung cancer screening saves lives through the early detection of lung cancer, yet uptake remains low. Mammography is well utilized with 70% of eligible women reporting having a mammogram in the past two years. We devised a study to investigate if screening mammography can be used as an opportunity to increase lung screening among women.

#### METHODS AND MATERIALS

Women undergoing screening mammography from November 2019 to December 2022 were included from two geographically unique academic hospitals (Sites A and B). Site A is a centralized lung screening program in the Southeast and Site B is a hybrid program in the Northeast. Electronic health records were reviewed to determine lung screening eligibility based on USPSTF recommendations. Researchers then notified patients directly or through their healthcare providers of their lung screening eligibility. Women previously enrolled in lung screening were excluded. The overall number of individuals screened at each site was recorded and compared to site-specific pre-intervention enrollment rates utilizing an interrupted time series with a flexible model specified for the historical data. Two months (March and April 2020) were excluded due to COVID-19 clinical shutdown.

#### RESULTS

The records of 32,165 mammography participants during the study period were reviewed, identifying 1,569 individuals eligible for LCS of whom 1,089 (69%) had not previously enrolled. At Site A, the total number of screenings significantly increased at 12 months compared to the number predicted from pre-intervention data ( $p = 0.011$ ). At Site B, a non-significant increase in screenings was found ( $p = 0.278$ ). Site B intervention effect may have been attenuated due to prolonged operational effects of the pandemic which did not occur at Site A.

#### CONCLUSION

Targeted outreach to patients and providers in the CALM study resulted in improved enrollment in lung screening. These outreach strategies can be customized to different program structures, as represented by the centralized and hybrid programs included in this initiative. Radiology practices are uniquely positioned to use this intervention to improve enrollment as all patients were seen for both mammography and low-dose CT.

#### CLINICAL RELEVANCE/APPLICATION

The intervention strategies utilized in the CALM study improved screening enrollment for women. Radiologists can apply this approach to combat historically poor lung screening rates and save lives through the early detection of lung cancer.

### **S4-SSCH02-Lung Cancer Screening Trends after Introducing the New 2021 US Preventive Services 2 Taskforce (USPSTF)**

Valeria Pena-Trujillo, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To describe the impact of the 2021-USPSTF lung cancer screening guidelines eligibility-criteria expansion on the clinical and sociodemographic characteristics of the targeted population

## METHODS AND MATERIALS

In this retrospective study, the imaging database of a large academic multisite center was assessed to identify all patients who underwent a clinically-indicated baseline lung CT from 4/2021-12/2022 as part of our lung cancer screening program. Collected data included sociodemographic (sex, race, ethnic group, language, zip code) and clinical characteristics (smoking status, LungRads Score [LRS], other interstitial lung diseases, etc.). Patients' zip codes were used to estimate median household income by pairing them with IRS data. Distances between the patient's residence and exam site were calculated as a straight line between zip codes. The collected cohort included individuals eligible under the 2013-USPSTF guidelines and newly eligible patients under the expanded recommendations. As a nonoverlapping group to the 2013-USPSTF, the characteristics of the 2021-USPSTF cohort were assessed and compared. Sociodemographic and clinical variables between both cohorts were compared using nonparametric tests for continuous variables and X<sup>2</sup>-tests for categorical variables

## RESULTS

From 7720 patients, 2301 baseline screening CTs were included for further analysis (1539 old recommendations; 727 expanded recommendations) after excluding follow-ups and non-eligible patients under USPSTF. Female patients represented 45.87% and 48% of the old vs. new guidelines cohorts, respectively. Mean age at screening was 64 vs. 57 years old ( $p=0.001$ ). No other statistically significant differences in sociodemographic variables were found. As expected, the number of packs-year was significantly lower (42.3 vs. 29.4;  $p<0.001$ ) in the revised recommendations. In addition, both cohorts had several significant differences ( $p=0.0172$ ) in terms of LRS; we found that patients screened under new guidelines had a lower proportion of LRS 3 (9.4 vs. 8%) and 4 (8 vs. 5.2%), and a higher proportion of LRS 1 (11.1 vs. 12.5%) and 2 (71.3 vs. 74.3%). For LRS 4, there was a higher proportion of 4B/X in the 2013-USPSTF (26.02 vs. 23.68%; 18.7 vs. 5.26%). We also found fewer Smodifiers in the new guideline's cohort (51.7 vs. 38%;  $p<0.01$ )

## CONCLUSION

The expansion of current guidelines may promote earlier detection of smoking-related lung malignancies. Future studies may reveal differences in gender or sociodemographic variables

## CLINICAL RELEVANCE/APPLICATION

Our results suggest that the eligibility-criteria expansion of the new USPSTF lung cancer screening guidelines may promote earlier detection of smoking-related lung malignancies

## S4-SSCH02-Association between Altered Subcutaneous Adipose Tissue and Survival in a High-Risk Population of Heavy Smokers Participating in Lung Cancer Screening

Fabian Bernhard Pallasch, MD (*Presenter*) Nothing to Disclose

## PURPOSE

There is increasing evidence that body composition portraits prognostic relevance in cancer and cardiometabolic disease. While most studies focus on changes in muscle status, little is known about the role of adipose tissue, especially in a screening setting. Here, we used a deep learning model for fully automatic 3D quantification of subcutaneous adipose tissue (SAT) on chest CTs and investigated its association with mortality in a high-risk population of heavy smokers participating in lung cancer screening.

## METHODS AND MATERIALS

We used a 3D deep learning model to segment SAT on lung screening non-contrast enhanced chest CTs of 26,144 individuals participating in the National Lung Screening Trial at baseline and after one year follow-up ( $n=52,228$  scans). For analysis, SAT volume (SATvol) and SAT density (SATHU) as a measure of SAT quality were quantified. The primary outcome was all-cause mortality. Additional outcomes were lung cancer and cardiovascular mortality. Multivariable Cox proportional hazards regression was used to assess the association between SATvol as well as SATHU and mortality at baseline and a decrease in SATvol and SATHU ( $=10\%$ ) within one year and mortality.

## RESULTS

Among 26,144 individuals (age  $61.4 \pm 5.0$  years; 40.9% female) a total of 1,839 (7%) deaths occurred over a median follow-up of 6.5 years. At baseline, only SATHU was independently associated with all-cause mortality after multivariable adjustment for clinical risk factors (age, sex, race, smoking status, pack years, prevalent hypertension, diabetes, and past stroke or myocardial infarction; HR: 1.07, 95% CI [1.02-1.12];  $p = 0.003$ ). Individuals with a decline in SATvol or SATHU  $=10\%$  over a period of one year, had a significantly worse outcome compared to those with stable SATvol or SATHU (hazard ratios adjusted for the same risk factors SATvol: HR 1.94, 95% CI [1.77-2.13],  $p<0.001$ ; SATHU: HR 3.1, 95% CI [2.79-3.44],  $p<0.001$ ). Similar associations were found for lung cancer and cardiovascular mortality as outcome of interest.

## CONCLUSION

A deep learning model can automatically quantify altered SAT on chest CT in an opportunistic fashion.  $SAT_{HU}$  at baseline and a decrease in  $SAT_{vol}$  or  $SAT_{HU}$  within one year are independently associated with mortality in lung cancer screening eligible heavy smokers beyond clinical risk factors, which may help to improve personalized risk assessment and prevention.

## CLINICAL RELEVANCE/APPLICATION

Our results show that automated methods can provide a fast and low-cost solution to identify high-risk individuals participating in lung cancer screening. This can accelerate clinical implementation to guide management and improve population health.

### S4-SSCH02-Large Language Models and Lung Cancer: A Comparative Study on the Appropriateness of Artificial Intelligence Statements

Amir A. Rahsepar, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The recent release of large language models (LLMs) for public use, such as ChatGPT and Google Bard, has opened up a multitude of potential benefits as well as challenges. To evaluate and compare the accuracy and relevance of responses generated by ChatGPT and Google Bard to non-expert questions related to lung cancer prevention, screening, and terminology commonly used in radiology reports based on the recommendation of Lung Imaging Reporting and Data System (Lung-RADS) v2022 from American College of Radiology and Fleischner society.

#### METHODS AND MATERIALS

Forty exactly the same questions were created and presented to ChatGPT and Google Bard by three different authors of this paper. Each answer was reviewed by two radiologists for accuracy. Responses were scored as correct, partially correct, incorrect, or unanswered. Consistency was also evaluated among the answers provided by ChatGPT and Google Bard. Here, consistency was defined as the agreement between the three answers provided by either ChatGPT or Google Bard, regardless of whether the concept conveyed was correct or incorrect.

#### RESULTS

ChatGPT answered all questions. Out of 120 answers, 85 (70.8%) were correct, 14 (11.7%) were partially correct, and 21 (17.5%) were incorrect. Google Bard did not answer 23 (19.1%) questions. Among the 97 questions answered by Google Bard, 62 (51.7%) were correct, 11 (9.2%) were partially correct, and 24 (20%) were incorrect. We found that ChatGPT's answers were consistent 36 out of 40 times (90%), while Google Bard's answers were consistent 23 out of 40 times (57.5%).

## CONCLUSION

Although the use of artificial intelligence offers new possibilities in fields like medicine, it also presents challenges that must be carefully reviewed by experts to prevent undue burden on patients and healthcare workers.

## CLINICAL RELEVANCE/APPLICATION

It is essential that LLM developers be aware of the complexity of healthcare decision-making and implement serious guardrails for all healthcare-related interactions.

### S4-SSCH02-Rate of Benign Surgeries in an Academic CT Lung Cancer Screening Program

Raquelle H. El Alam, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Screening with low dose computed tomography (CT) can reduce lung cancer related death at the expense of unavoidable false positive results. The purpose of this study is to measure the rate of surgery for benign nodules and evaluate characteristics of those nodules.

#### METHODS AND MATERIALS

In this study, we evaluated patients in the Lung Cancer Screening (LCS) program across a large tertiary healthcare network from 5/2015 through 10/2021 who underwent surgical resection for a lung nodule. We reviewed the pathology reports and subsequent follow-up to establish whether the nodule was benign or malignant, and only benign nodules were included for this study. Imaging characteristics of the nodules were evaluated by a radiology fellow, and we recorded Lung-RADS category, nodule status (baseline, stable, new, growing), FDG uptake on PET/CT, and calculated the risk from the Brock model.

## RESULTS

During the study period, a total of 21366 LCS CT was performed in 9050 patients, and 260 patients underwent surgical resection. Review of the pathology results revealed: 220 lung cancer (85%), 2 other malignancies (1%), and 38 benign findings (15%). Pathology of the benign nodules was as follows: 12 with scarring/fibrosis, 5 with benign neoplasms, 14 with infection/inflammation, and 7 with other diagnoses. Lung-RADS category was as follows: 4 (11%) Lung-RADS 2, 2 (5%) Lung-Rad 3, 11 (29%) Lung-RADS 4A, 13 (34%) Lung-RADS 4B, and 8 (21%) Lung-RADS 4X. The size of the nodules ranged from 4 to 41 mm with a median of 13 mm. 2 (5%) were ground glass, 10 (26%) were part-solid, and 26 (68%) were solid. FDG-PET/CT was performed in 19 out of 38 cases, of which: 2 (11%) had no uptake, 10 (53%) had mild uptake, 3 (16%) had moderate uptake, and 4 (21%) had intense uptake. Risk assessment by Brock calculator revealed that 9 (24) had <5% (very low) risk; 27 (71%) had 5-65% (low-intermediate) risk, and 2 (5%) had >65% (high) risk.

## CONCLUSION

Surgical resection of benign nodules is unavoidable despite application of Lung-RADS guidelines in a modern screening program, with approximately 15% of surgeries being performed for benign lesions.

## CLINICAL RELEVANCE/APPLICATION

Surgeries for benign pulmonary nodules are an inevitable part of a lung cancer screening program due to overlap between the appearance of benign and malignant pulmonary nodules.

## S4-SSCH02-Improving the Readability of Patient-Facing Information about Lung Cancer using Large Language Models: ChatGPT, GPT-4 and Bard

Hana L. Haver, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Access to information remains a modifiable contributor to disparities in lung cancer screening. With the increasing attention towards using large language models in generating health information has shown early promise, little has been reported about the capability of these models to improve readability of health information and its accessibility to the general public. Here, we assessed how 3 large language models (LLM): ChatGPT, GPT-4 and Bard, perform in summarizing and simplifying health information about lung cancer prevention and screening.

## METHODS AND MATERIALS

We evaluated the readability of answers to common questions about lung cancer prevention and screening that were generated by ChatGPT. We then asked ChatGPT, GPT-4 and Bard to simplify this answer set, and assessed the simplified answers for language complexity (Flesch Reading Ease) and readability on 5 established scales: Flesch-Kincaid Grade Level, Gunning-Fog Index, Coleman-Liau Index, Automated Readability Index, and Simple Measure of Gobbledygook. Complexity score of 60 and greater and readability score of grade 8 and below was considered adequate for an average audience. Statistical analysis utilized paired t-testing between readability scores from the original and simplified answers for each model. Simplified answers were blindly rated for clinical appropriateness by 3 fellowship-trained cardiothoracic radiologists.

## RESULTS

The baseline answers to questions generated by ChatGPT in response to questions related to lung cancer had an overall mean language complexity of 49.7 and an overall mean readability of grade 12.6. Following simplification of these answers by ChatGPT, GPT-4 and Bard, the overall mean language complexity and readability were found to be improved when each was compared to the score of the original text (Figure 1). Upon blinded assessment of clinical appropriateness of the simplified answers, our board-certified cardiothoracic radiologists determined that they were clinically appropriate 84% (ChatGPT), 79% (GPT-4) and 95% (Bard) of the time.

## CONCLUSION

Lung cancer information provided by ChatGPT is complex and difficult to read. LLM's including ChatGPT, GPT-4 and Bard demonstrate the capability to simplify the language of lung cancer information to a level more accessible for the general public, though the non-trivial number of inappropriate or inconsistent answers of the simplified content imply that further study is required.

## CLINICAL RELEVANCE/APPLICATION

ChatGPT generates responses to questions about lung cancer that are difficult to read. ChatGPT, GPT-4 and Bard can be used to simplify this texts with varying degrees of clinical appropriateness, indicating early potential to improve access to health information for the average audience.

### Rate of Benign Surgeries in an Academic CT Lung Cancer Screening Program

Sunday, Nov. 26 1:00PM - 2:00PM Room: N228

Raquelle H. El Alam, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Screening with low dose computed tomography (CT) can reduce lung cancer related death at the expense of unavoidable false positive results. The purpose of this study is to measure the rate of surgery for benign nodules and evaluate characteristics of those nodules.

#### METHODS AND MATERIALS

In this study, we evaluated patients in the Lung Cancer Screening (LCS) program across a large tertiary healthcare network from 5/2015 through 10/2021 who underwent surgical resection for a lung nodule. We reviewed the pathology reports and subsequent follow-up to establish whether the nodule was benign or malignant, and only benign nodules were included for this study. Imaging characteristics of the nodules were evaluated by a radiology fellow, and we recorded Lung-RADS category, nodule status (baseline, stable, new, growing), FDG uptake on PET/CT, and calculated the risk from the Brock model.

#### RESULTS

During the study period, a total of 21366 LCS CT was performed in 9050 patients, and 260 patients underwent surgical resection. Review of the pathology results revealed: 220 lung cancer (85%), 2 other malignancies (1%), and 38 benign findings (15%). Pathology of the benign nodules was as follows: 12 with scarring/fibrosis, 5 with benign neoplasms, 14 with infection/inflammation, and 7 with other diagnoses. Lung-RADS category was as follows: 4 (11%) Lung-RADS 2, 2 (5%) Lung-Rad 3, 11 (29%) Lung-RADS 4A, 13 (34%) Lung-RADS 4B, and 8 (21%) Lung-RADS 4X. The size of the nodules ranged from 4 to 41 mm with a median of 13 mm. 2 (5%) were ground glass, 10 (26%) were part-solid, and 26 (68%) were solid. FDG-PET/CT was performed in 19 out of 38 cases, of which: 2 (11%) had no uptake, 10 (53%) had mild uptake, 3 (16%) had moderate uptake, and 4 (21%) had intense uptake. Risk assessment by Brock calculator revealed that 9 (24) had <5% (very low) risk; 27 (71%) had 5-65% (low-intermediate) risk, and 2 (5%) had >65% (high) risk.

#### CONCLUSION

Surgical resection of benign nodules is unavoidable despite application of Lung-RADS guidelines in a modern screening program, with approximately 15% of surgeries being performed for benign lesions.

#### CLINICAL RELEVANCE/APPLICATION

Surgeries for benign pulmonary nodules are an inevitable part of a lung cancer screening program due to overlap between the appearance of benign and malignant pulmonary nodules.

### Improving the Readability of Patient-Facing Information about Lung Cancer using Large Language Models: ChatGPT, GPT-4 and Bard

Sunday, Nov. 26 1:00PM - 2:00PM Room: N228

Hana L. Haver, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Access to information remains a modifiable contributor to disparities in lung cancer screening. With the increasing attention towards using large language models in generating health information has shown early promise, little has been reported about the capability of these models to improve readability of health information and its accessibility to the general public. Here, we assessed how 3 large language models (LLM): ChatGPT, GPT-4 and Bard, perform in summarizing and simplifying health information about lung cancer prevention and screening.

#### METHODS AND MATERIALS

We evaluated the readability of answers to common questions about lung cancer prevention and screening that were generated by ChatGPT. We then asked ChatGPT, GPT-4 and Bard to simplify this answer set, and assessed the simplified answers for language complexity (Flesch Reading Ease) and readability on 5 established scales: Flesch-Kincaid Grade Level, Gunning-Fog Index, Coleman-Liau Index, Automated Readability Index, and Simple Measure of Gobbledygook. Complexity score of 60 and greater and readability score of grade 8 and below was considered adequate for an average audience. Statistical analysis utilized paired t-testing between readability scores from the original and simplified answers for each model. Simplified answers were blindly rated for clinical appropriateness by 3 fellowship-trained cardiothoracic radiologists.

#### RESULTS

The baseline answers to questions generated by ChatGPT in response to questions related to lung cancer had an overall mean language complexity of 49.7 and an overall mean readability of grade 12.6. Following simplification of these answers by ChatGPT, GPT-4 and Bard, the overall mean language complexity and readability were found to be improved when each was compared to the score of the original text (Figure 1). Upon blinded assessment of clinical appropriateness of the simplified answers, our board-certified cardiothoracic radiologists determined that they were clinically appropriate 84% (ChatGPT), 79% (GPT-4) and 95% (Bard) of the time.

#### CONCLUSION

Lung cancer information provided by ChatGPT is complex and difficult to read. LLM's including ChatGPT, GPT-4 and Bard demonstrate the capability to simplify the language of lung cancer information to a level more accessible for the general public, though the non-trivial number of inappropriate or inconsistent answers of the simplified content imply that further study is required.

#### CLINICAL RELEVANCE/APPLICATION

ChatGPT generates responses to questions about lung cancer that are difficult to read. ChatGPT, GPT-4 and Bard can be used to simplify this texts with varying degrees of clinical appropriateness, indicating early potential to improve access to health information for the average audience.

#### S4-SSIN01- TotalSegmentator: Robust Segmentation of 104 Anatomical Structures on CT Data

1

Martin Segeroth (*Presenter*) Nothing to Disclose

#### PURPOSE

To present a deep-learning segmentation model that can automatically segment all major anatomical structures in body CT images. An easy-to-use model that shows robust performance on any clinical data would enable radiological studies using large sample sizes and increase the impact of radiologic examinations.

#### METHODS AND MATERIALS

In 1204 CT examinations, we segmented 104 anatomical structures (27 organs, 59 bones, 10 muscles, 8 vessels) covering many relevant structures for use cases such as organ volumetry, disease characterization, and surgical or radiotherapy planning. The CT images were randomly sampled from the University Hospital Basel PACS consisting of routine clinical studies and thus represent a real-world dataset (different ages, pathologies, scanners, body parts, sequences, and sites). 57 subjects were used for validation and 65 as test datasets. We trained a nnU-Net segmentation algorithm on this dataset and calculated Dice similarity coefficients (Dice) to evaluate the model's performance. The trained algorithm was applied to a second dataset of an aging study with 4004 whole-body polytrauma CTs acquired between 2011 and 2020 to investigate volume and density age dependent changes.

#### RESULTS

The test set was randomly sampled thus the data demonstrates variability caused by different scanners and protocols. Since the test set includes a wide range of clinical data, it also exhibits some pathologies. Nevertheless, our model demonstrated a high Dice (0.943, CI: 0.938 - 0.947) on the test set. Our model significantly outperformed other publicly available segmentation models (Dice 0.932 versus 0.871,  $p < 0.001$ ). On patients with major pathologies (e.g. large hernia or kidney transplant) the model generated robust results. In our aging study, we found significant correlations between age and volume/mean attenuation for a variety of organ groups (e.g. aorta volume [ $r = 0.62$ ;  $p < 0.001$ ], mean attenuation of the hips [ $r = -0.60$ ;  $p < 0.001$ ], mean attenuation of the autochthonous dorsal musculature [ $r = -0.72$ ;  $p < 0.001$ ]) and volume of iliopsoas or kidneys).

#### CONCLUSION

Our segmentation model is (1) publicly available (<https://github.com/wasserth/TotalSegmentator>) including training data (<https://doi.org/10.5281/zenodo.6802613>); (2) easy to use ([www.totalsegmentator.com](http://www.totalsegmentator.com)); (3) segments most anatomically relevant structures in the entire body; and (4) works robustly in any clinical setting.

#### CLINICAL RELEVANCE/APPLICATION

The model enables any researcher / clinician to perform robust and accurate segmentation of 104 anatomical structures. This may accelerate radiological research and finally improve radiological reports.

#### S4-SSIN01- AbdomenAtlas-8K: Human-in-the-Loop Annotating Eight Anatomical Structures for 8,448 Three-Dimensional Computed Tomography Volumes in Three Weeks

2

Zongwei Zhou, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Segmenting anatomical structures can facilitate precise robotic surgery, personalized treatment planning, and improved patient outcomes, but it is a highly cumbersome and time-intensive process. We seek to expedite this process using an efficient human-in-the-loop approach.

## METHODS AND MATERIALS

We first pre-trained an AI model on 14 publicly available datasets using the partial labels provided by each dataset. The model was then used to generate pseudo labels of 8,448 three-dimensional CT volumes for segmenting eight critical structures in the abdominal region, including the spleen, liver, kidneys, stomach, gallbladder, pancreas, aorta, and IVC. The quality of the pseudo labels was assessed by inconsistency, uncertainty, and overlapping measurements. The integration of these three measurements resulted in a list that prioritized the CT volumes and regions in the volume that required medical professionals to review and revise the pseudo labels. The revised labels were used to fine-tune the model. This process was repeated until the professionals confirmed that the highest-priority CT volumes on the list did not require further revision. From the human-in-the-loop approach, we summarized a taxonomy of common errors made by AI and medical professionals, which minimized the duplication in human revision and improved the efficiency of continuous refinement of AI models and organ annotations. A commercial software called Pair was used by the medical professional for revising the annotations. Finally, the professional confirmed the annotation of all the CT volumes by visual inspection.

## RESULTS

AbdomenAtlas-8K is a high-quality dataset consisting of 8,448 CT volumes with eight anatomical structures annotated in detail. 99% of the annotations were generated by AI algorithms and the remaining 1% by a medical professional. We demonstrated high sensitivity and precision (0.78 and 0.83, respectively) in detecting AI errors, highlighting the efficiency of human revisions.

## CONCLUSION

Our human-in-the-loop approach can significantly reduce annotation effort while maintaining high-quality annotations. With this approach, we have annotated 8,448 CT scans within three weeks. The annotations were of superior quality, ensuring precision and dependability in segmenting critical abdominal structures.

## CLINICAL RELEVANCE/APPLICATION

AbdomenAtlas-8K will be made publicly available to advance medical research, providing doctors, researchers, patients, and students with a comprehensive understanding of human anatomy and facilitating early cancer detection. It will enable researchers to identify abnormalities associated with various diseases and provide insights into imaging characteristics of cancer, diabetes, and heart disease.

## S4-SSIN01- Efficient Segmentation using Diffusion Model Support

3

Veit Sandfort, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Segmentation is a cornerstone of cardiovascular image analysis. Manual labeling of CT angiographic (CTA) images is prohibitively tedious, time-consuming, and expensive for 3D/4D data. Diffusion models (DMs) for image generation have recently made tremendous progress. DMs are based on multi-step addition of noise and learned denoising to generate synthetic samples. This can be used to extract semantically meaningful features from medical images. We aimed to evaluate the performance of a diffusion model supported Unet (DM-Unet) for CT segmentation compared to a standard U-net in the task of completing partial manual segmentations of cardiovascular structures.

## METHODS AND MATERIALS

A DM was trained in an unsupervised fashion on 2D slices from 1,800 chest CTAs. 44 CTAs were fully segmented with the labels ascending aorta (AA), left atrium (LA), left ventricle (LV), left atrial appendage (LAA), right atrium (RA), right ventricle (RV), papillary muscle, and LV myocardium (Myo). As baseline, a standard-Unet was trained on a small number ( $n=50$  and  $n=100$ ) of randomly selected slices of the 44 CTs to predict the remainder of the segmentations. Strong data augmentation (rotation, flip, crop, noise) was used. For the DM-Unet, we used the pretrained DM to extract internal network activations, automatically selected the 64 most meaningful features with a gradient boosting method, and trained a Unet on the extracted feature maps of randomly selected slices ( $n=50$  and  $n=100$ ) to predict the remainder of the segmentations. Performance was evaluated using dice coefficient. Statistical significance was tested using paired Wilcoxon test.

## RESULTS

The DM-Unet showed significantly higher performance compared to the standard U-net ( $p < 0.0001$  for all tested features). The difference in performance was higher when fewer training samples were used (train slices  $n=50$  compare to  $n=100$ , see figure). Subjectively, the DM-Unet also resulted in visually more consistent segmentations. The inability of the standard Unet to delineate the boundary between RA and RV with very sparse training data is striking.

## CONCLUSION

Standard Unets are unable to achieve acceptable performance in the setting of very few manual annotations. Diffusion models trained in unsupervised fashion can successfully support standard-Unets leading to significantly improved segmentation efficiency and enabling significant labor and cost reductions for segmentation tasks.

## CLINICAL RELEVANCE/APPLICATION

Manual segmentations are required for a variety of image quantification tasks in clinical radiology and research. Decreasing the manual effort for segmentation would be highly desirable.

### S4-SSIN01- Optimization of STL Generation for Patient-Specific 3D Printed Models

4

Maxwell B. Lohss, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

3D printing at the point-of-care requires accurate recreation of a patient's anatomy. Despite the development of advanced software platforms, conversion of a segmented image into a surface mesh (STL) can be a complex, poorly-optimized process that often requires manual correction. To improve the efficiency and accuracy of the mesh creation process, we evaluated and optimized settings for 3D printing computed tomography (CT) imaging of cam-type femoroacetabular impingement (FAI) using Mimics Medical 25.0.

#### METHODS AND MATERIALS

CT images of 5 femurs with cam-type FAI were segmented by an experienced engineer and validated by a board-certified radiologist to create anatomical reference meshes. STL mesh contours were manually adjusted across the model to maximize accuracy and mesh quality. The image mask was converted to meshes using the Low, Medium, High, and Optimal presets settings in Mimics. 3D deviation analyses comparing each mesh to the reference were performed with Geomagic Control 2014. Models were evaluated for mesh irregularities including non-manifold edges, self-intersections, highly creased edges, spikes, and holes. Starting with the Optimal preset, 40 different meshes were created by modifying the smooth factor (SF) and smoothing iteration (SI) settings from 0.3-1 and 1-20 respectively. Meshes were identified that showed an average root mean square deviation (RMSD) below 0.20 mm and a mesh that had a similar surface quality to the reference. These meshes were further evaluated using planar deviation analyses formatted around the femoral neck axis to assess error at the most clinically relevant portion of the model around the cam deformity.

#### RESULTS

The Low, Medium, High, and Optimal settings showed an average RMSD of 1.63 mm, 0.72 mm, 0.44 mm, and 0.26 mm, respectively. The number of mesh irregularities normalized to the number of mesh triangles were 0.138, 0.159, 0.132, and 0.365, respectively, and 0.021 for the reference. Custom meshes with SF > 0.9 and SI = 20 had an average RMSD of 0.20 mm with a similar number of mesh irregularities normalized to mesh triangles compared to the reference (Cohen's d < 0.80). The planar deviation analyses performed in the region of the cam deformity showed an RMSD of 0.07 mm.

## CONCLUSION

Predefined settings in Mimics can create meshes that are error-prone and of poor quality. Optimizing the pre-defined smoothing parameters in mesh conversion with SF > 0.9 and SI = 20 produces a mesh that retains the anatomical detail and surface quality of a mesh that was manually corrected and smoothed.

## CLINICAL RELEVANCE/APPLICATION

Our analysis identified optimal parameters for converting femur image segmentation to surface meshes with high mesh quality while maintaining accuracy.

### S4-SSIN01- What is the Optimal Number of Readers needed to Establish a Reference Standard for AI Segmentation Algorithms? Insights from a Prostate MRI Segmentation Study Involving Multiple Readers

5

Sebastien Moliere, MD,BMedSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Developing reliable and accurate automatic segmentation algorithms for organs requires a reference standard established by multiple readers. This study aims to determine the ideal number of readers necessary to establish a reference standard by quantifying the inter-observer variability of manual prostate contour segmentation.

#### METHODS AND MATERIALS

Seven radiologists with various experience independently performed a manual segmentation of the prostate contour (whole-gland (WG) and transition zone (TZ)) on 40 MRI. To quantify inter-observer variability, a comparative analysis of the delineations was performed using standard metrics (Dice, Hausdorff and volume-based metrics), and impact of the number of

raters (from 2 to 7) on variability using two measurement strategies - pairwise metrics and metrics with respect to a reference segmentation - was evaluated.

## RESULTS

The average segmentation Dice score (DSC) for pairwise comparison of 2 readers was 0.919 (WG) / 0.876 (TZ). The interquartile range of the DSC decreased rapidly with the number of readers, with the smallest range (0.002 (WG) / 0.0037 (TZ)) observed for 6 raters. The minimum variability was often found for three readers using consensus methods, with STAPLE resulting in a DSC of 0.96 (WG) and 0.94 (TZ), and interquartile range being minimal for 3 raters.

## CONCLUSION

The number of readers has a significant impact on inter-reader variability. Variability has often been found to be minimal for 3 raters, or 3 raters represent a tipping point in the variability evolution, with both pairwise-based metrics or metrics with respect to a reference.

## CLINICAL RELEVANCE/APPLICATION

Three readers may be an ideal number to consider for consensual references in developing automatic segmentation algorithms for prostate contour segmentation, as it minimizes inter-observer variability.

## S4-SSIN01- Large Language-Image Model for Multi-Organ Segmentation and Cancer Detection from 6 Computed Tomography

Zongwei Zhou, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the feasibility of using language-image models for the automated segmentation of 25 abdominal organs and the detection of six types of tumors in CT scans originating from various hospitals, institutes, and countries.

## METHODS AND MATERIALS

We proposed the CLIP-Driven Universal Model, which incorporates text embedding learned from Contrastive Language-Image Pre-training (CLIP) into segmentation models. This CLIP label encoding captures anatomical relationships, enabling the model to learn structured feature embedding and segment 25 organs and six types of tumors. As illustrated in the figure, our Universal Model consists of a text branch and a vision branch. The Universal Model was developed using an assembly of 14 public datasets, encompassing a total of 3,410 CT scans for training. We then evaluated its generalizability and transferability on 117 external CT scans from two external datasets, i.e., 3D-IRCADb and TotalSegmentator. In addition to public datasets, the Universal Model was independently evaluated on a large-scale dataset from Johns Hopkins Hospital, comprising 5,038 CT scans with 21 annotated organs, to investigate extensibility to novel classes. Dice Similarity Coefficient (DSC) and Normalized Surface Distance (NSD) were evaluated for organ/tumor segmentation; Sensitivity and Specificity were evaluated for tumor detection.

## RESULTS

We rank first on the Medical Segmentation Decathlon (MSD) public leaderboard and achieve state-of-the-art results on Beyond The Cranial Vault (BTCV). Six critical anatomical structures can be segmented by AI with a similar variance to two human experts. Furthermore, the Universal Model is computationally more efficient (6x faster) than previous dataset-specific models, generalizes better to CT scans from three different hospitals, and exhibits superior transfer learning performance on novel classes and image analysis tasks.

## CONCLUSION

The proposed CLIP-Driven Universal Model, integrating image representation with language, possessed remarkable efficiency, generalizability, transferability, and extensibility in organ segmentation and tumor detection.

## CLINICAL RELEVANCE/APPLICATION

The ability to segment organs and detect tumors in CT scans through our AI algorithms will provide direct assistance to radiologists in a cooperative manner by combining the best of human and AI expertise. The high-performing AI can facilitate the creation of large datasets that are significantly larger than current medical datasets, thus promoting larger-scale studies for early cancer detection in real-world settings.

#### **METHODS AND MATERIALS**

Seven radiologists with various experience independently performed a manual segmentation of the prostate contour (whole-gland (WG) and transition zone (TZ)) on 40 MRI. To quantify inter-observer variability, a comparative analysis of the delineations was performed using standard metrics (Dice, Hausdorff and volume-based metrics), and impact of the number of raters (from 2 to 7) on variability using two measurement strategies - pairwise metrics and metrics with respect to a reference segmentation - was evaluated.

#### **RESULTS**

The average segmentation Dice score (DSC) for pairwise comparison of 2 readers was 0.919 (WG) / 0.876 (TZ). The interquartile range of the DSC decreased rapidly with the number of readers, with the smallest range (0.002 (WG) / 0.0037 (TZ)) observed for 6 raters. The minimum variability was often found for three readers using consensus methods, with STAPLE resulting in a DSC of 0.96 (WG) and 0.94 (TZ), and interquartile range being minimal for 3 raters.

#### **CONCLUSION**

The number of readers has a significant impact on inter-reader variability. Variability has often been found to be minimal for 3 raters, or 3 raters represent a tipping point in the variability evolution, with both pairwise-based metrics or metrics with respect to a reference.

#### **CLINICAL RELEVANCE/APPLICATION**

Three readers may be an ideal number to consider for consensual references in developing automatic segmentation algorithms for prostate contour segmentation, as it minimizes inter-observer variability.

### Large Language-Image Model for Multi-Organ Segmentation and Cancer Detection from Computed Tomography

Sunday, Nov. 26 1:00PM - 2:00PM Room: S401

Zongwei Zhou, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the feasibility of using language-image models for the automated segmentation of 25 abdominal organs and the detection of six types of tumors in CT scans originating from various hospitals, institutes, and countries.

#### METHODS AND MATERIALS

We proposed the CLIP-Driven Universal Model, which incorporates text embedding learned from Contrastive Language-Image Pre-training (CLIP) into segmentation models. This CLIP label encoding captures anatomical relationships, enabling the model to learn structured feature embedding and segment 25 organs and six types of tumors. As illustrated in the figure, our Universal Model consists of a text branch and a vision branch. The Universal Model was developed using an assembly of 14 public datasets, encompassing a total of 3,410 CT scans for training. We then evaluated its generalizability and transferability on 117 external CT scans from two external datasets, i.e., 3D-IRCADb and TotalSegmentator. In addition to public datasets, the Universal Model was independently evaluated on a large-scale dataset from Johns Hopkins Hospital, comprising 5,038 CT scans with 21 annotated organs, to investigate extensibility to novel classes. Dice Similarity Coefficient (DSC) and Normalized Surface Distance (NSD) were evaluated for organ/tumor segmentation; Sensitivity and Specificity were evaluated for tumor detection.

#### RESULTS

We rank first on the Medical Segmentation Decathlon (MSD) public leaderboard and achieve state-of-the-art results on Beyond The Cranial Vault (BTCV). Six critical anatomical structures can be segmented by AI with a similar variance to two human experts. Furthermore, the Universal Model is computationally more efficient (6x faster) than previous dataset-specific models, generalizes better to CT scans from three different hospitals, and exhibits superior transfer learning performance on novel classes and image analysis tasks.

#### CONCLUSION

The proposed CLIP-Driven Universal Model, integrating image representation with language, possessed remarkable efficiency, generalizability, transferability, and extensibility in organ segmentation and tumor detection.

#### CLINICAL RELEVANCE/APPLICATION

The ability to segment organs and detect tumors in CT scans through our AI algorithms will provide direct assistance to radiologists in a cooperative manner by combining the best of human and AI expertise. The high-performing AI can facilitate the creation of large datasets that are significantly larger than current medical datasets, thus promoting larger-scale studies for early cancer detection in real-world settings.

#### S4-SSMK01-1 **Fat Fractions of the Rotator Cuff Muscles Acquired with Two-point Dixon MRI: Predicting Outcome after Arthroscopic Rotator Cuff Repair**

Georg C. Feuerriegel, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to quantify and compare intramuscular fat fraction (FF) and muscle volume between patients with failed and intact rotator cuff (RC) repair as well as a control group with conservative treatment to define reliable FF cut-off values for predicting the outcome of RC repair.

#### METHODS AND MATERIALS

In this retrospective study patients with full-thickness RC tears who received MRI before and after arthroscopic RC repair including a two-point Dixon sequence between July 2016 and December 2022 were screened for eligibility. Patients with re-tear of one or more RC tendons diagnosed on MRI (Sugaya IV and V) were enrolled into the study and matched for age, gender, BMI, and MRI time interval to patients with intact RC repair (Sugaya I and II). A third group with conservatively treated RC tears was included as reference and also matched to the failed RC repair group. Two radiologists analyzed morphological features including the size and location of RC tears (Cofield) as well as the integrity of the RC after repair (Sugaya). Furthermore, the tendon retraction (Patte) and fatty infiltration (Goutallier) were assessed. Quantitative FFs were calculated from the two-point Dixon sequence and the RC muscles were segmented semi-automatically to calculate the FF and volume for each muscle. ROC curves were used to determine the FF cut-off values which best predict RC re-tears. Mann-Whitney U and Wilcoxon Signed-Rank tests were used to assess the differences between groups.

#### RESULTS

In total 136 patients were enrolled, consisting of three groups: 41 (22%) patients had a failed RC repair (mean age  $58 \pm 7$  years, 16 women), 50 (27%) patients matched into the intact RC repair group and 45 patients were matched into the conservative treatment group. The mean time interval between baseline and follow-up MRI was  $17.0 \pm 2.7$  months. Preoperative FF was significantly higher in the failed repair group for all RC muscles compared to the intact repair group and the conservative treatment group ( $p < 0.05$ ). ROC curves showed reliable preoperative FF cut-off values for predicting re-tears at 6.0% for the SSP muscle (0.83 AUC), 7.4% for the ISP muscle (AUC 0.82) and 8.3% for the SSC muscle (0.94 AUC). Compared to the intact repair group a significant decrease in muscle volume was seen in the failed repair group for all muscles (SSP:  $P = 0.035$ , ISP:  $P = 0.023$ , SSC:  $P = 0.018$ ).

#### CONCLUSION

Preoperative quantitative FF calculated from two-point Dixon MRI can be used to predict the risk of re-tear after arthroscopic RC repair with reliable cut-off values between 6% and 8.3%.

#### CLINICAL RELEVANCE/APPLICATION

Muscle fatty infiltration is a predictor of successful RC repair and reliable cut-off values for FF might improve preoperative screening and risk assessment in patients with full-thickness RC tears.

#### S4-SSMK01-2 **US-guided Percutaneous Irrigation of Extra-shoulder Calcific Tendinopathy**

Domenico Albano (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the efficacy and safety of ultrasound-guided percutaneous irrigation of calcific tendinopathy (US-PICT) applied out of the shoulder comparing its effectiveness to US-PICT of the rotator cuff.

## METHODS AND MATERIALS

Patients subjected to US-PICT for extra-shoulder calcific tendinitis (Case Group) were compared to those subjected to US-PICT of the rotator cuff (Control Group). We had pre-procedure VAS pain score, 1-month and 3-month VAS of patients of the Case Group, pre-procedure and 3-month VAS of patients of the Control Group.

## RESULTS

The Case Group consisted of 41 patients (27 women; mean age: 45±9 years): 26 gluteus medius, 5 patellar tendon, 3 rectus femoris, 2 gluteus maximus, 2 extensor digitorum, 1 extensor carpi radialis longus, 1 ilio-tibial band, 1 peroneus longus. The Control Group included 41 patients (27 women; mean age: 47±11 years). No complications were observed in both Groups. We used 9-cm needles in 31/41 patients of the Case Group (76%) with deeply located calcifications within the gluteus medius, rectus femoris and gluteus maximus tendons, while 3-cm needles have been used in the remaining 10 patients. The mean pre-procedure VAS of the Case Group was 8.8±0.7 with a significant ( $P<0.001$ ) drop at 1 month (4.5±0.6) and 3 months (3.6±0.6). The mean pre-procedure VAS of the Control Group was 8±1.4 and dropped to 3.1±1.6 after 3 months ( $P<0.001$ ). Post-treatment VAS at 3 months was not significantly different between two Groups ( $p=0.134$ ). Similarly, the decrease of VAS from baseline to three months was not significantly different between the two Groups ( $p=0.264$ ).

## CONCLUSION

US-PICT is a safe and effective procedure that can be used out of the shoulder.

## CLINICAL RELEVANCE/APPLICATION

This study demonstrated the safety and effectiveness of US-PICT as a valuable therapeutic option for extra-shoulder calcific tendinitis, with similar clinical outcome to the same procedure performed in the rotator cuff. The technique must be adapted in some deeply located calcifications by means of the use of different needles and by thoroughly planning the access point for the procedure.

## S4- SSMK01-3 Shoulder Pain in Breast Cancer Patients: How Much Do We Need to Worry about Metastases

Rosa E. Ochoa Albiztegui, MD, MS (*Presenter*) Nothing to Disclose

## PURPOSE

To determine the frequency of metastatic disease as the cause for shoulder pain in patients with breast cancer.

## METHODS AND MATERIALS

This is a single-center IRB approved retrospective study. Patients with breast cancer who were referred for MRI of the shoulder [subsequently: "MRI"] due to pain from January 2012 to December 2021 were reviewed. Additionally, 420 FDG PET-CT and 857 CT examinations within 1 year prior to MRI were reviewed to ascertain whether patients had known metastases. Descriptive statistics are presented as counts and % of the total n.

## RESULTS

We included  $n = 639$  patients. Mean patient age was 60 years old (range 29-96 years). On average the first patient MRI was 3 years after breast cancer diagnosis. Fifty-seven patients (9%) had osseous metastases; of these, 47 (7%) patients had only osseous metastases and 10 (2%) patients additionally had other metastases. In their first MRI, there were 54 patients (8.5%) with osseous metastases. Out of 77 patients with multiple MRIs, only 3 developed osseous metastases on subsequent MRIs (3.8%). In patients with bone metastasis on MRI, 40 patients (70%) had already known bone metastasis from prior imaging. On the other hand, 155 patients with prior imaging and no bone metastases, none had metastases on MRI. Only in 14 patients (2.2%), the initial diagnosis of a bone metastasis was made in MRI, and none of these patients had prior imaging. There were 23 patients with soft-tissue metastasis on MRI, but only in 6 cases (0.9%) metastasis were not known from prior imaging.

## CONCLUSION

Shoulder pain is not associated with bone or soft tissue metastasis in most patients with breast cancer. None of the patients in our cohort without bone metastasis on prior CT or PET/CT had a shoulder metastasis on MRI.

## CLINICAL RELEVANCE/APPLICATION

Patients with shoulder pain and recent CT or PET-CT negative for bone metastasis are unlikely to present metastatic disease on shoulder MRI. IV contrast may not be necessary due to low probability of metastatic disease. Breast cancer patients with shoulder pain may benefit from an optimized assessment of anatomical structures to investigate other causes of pain.

#### **S4-SSMK01-4 T2 Quantification and Synthetic T2-weighted Images Derived from GRAPPATINI for Evaluation of Shoulder Joint: Comparison to Conventional T2-weighted MRI**

Seung Yun Lee, MD (*Presenter*) Nothing to Disclose

##### **PURPOSE**

GRAPPATINI can provide accelerated acquisition of T2 map and subsequent generation of synthetic T2-weighted image (T2WI). We evaluated the diagnostic equivalence of synthetic T2WI derived from GRAPPATINI compared with conventional T2WI in the shoulder joint, and the correlation of T2 value from GRAPPATINI for glenoid cartilage evaluation.

##### **METHODS AND MATERIALS**

Consecutive patients with shoulder pain were recruited retrospectively from November 2022 to January 2023. We acquired conventional fat-saturated (fs) T2WI, and T2 map and subsequent synthetic fs-T2WI derived from the GRAPPATINI of the shoulder joint. The diagnostic equivalence was evaluated in terms of image quality and lesion detectability by comparing conventional and synthetic fs-T2WI. The image quality was assessed by the relative signal-to-noise ratio (rSNR) and relative contrast-to-noise ratio (rCNR) measurements using fluid, muscle, cartilage, and tendon. The lesion detectability was evaluated by four radiologists, by measuring 5-point ordinal scores for the likelihood of pathologic change in the supraspinatus tendon (SST) and superior labrum. Also, the T2 values were measured from the T2 map of GRAPPATINI by selecting four regions of interest at each quadrant of glenoid fossa cartilage. Statistical analysis was performed with Wilcoxon signed rank test for image quality analysis and interchangeability test for lesion detectability analysis, respectively. Also, the difference of estimated T2 value depending on cartilage degeneration was evaluated by Student t-test, with the reference of cartilage finding on conventional fs-T2WI.

##### **RESULTS**

23 patients were included (20 females, median age = 62). In the image quality assessment, the rSNR showed statistically significant difference in cartilage ( $p=0.037$ ) and tendon ( $p=0.007$ ), and rCNR showed no significant difference between conventional and synthetic fs-T2WI. Regarding the lesion detectability, conventional and synthetic fs-T2WI were clinically interchangeable for evaluating pathologic change in SST and superior labrum (upper limits of 95% confidence intervals of differences between rates of agreement = 3.7% in SST and = 2.7% in labrum). Estimated T2 values of GRAPPATINI showed statistical differences between the groups of normal and degenerative cartilage findings ( $p=0.006$ ).

##### **CONCLUSION**

T2 map and synthetic T2WI acquired from GRAPPATINI were determined to be of diagnostic equivalence with the conventional T2WI and can be used for clinical assessment of shoulder joint pathology.

##### **CLINICAL RELEVANCE/APPLICATION**

T2 quantification and subsequent synthetic T2WI derived by GRAPPATINI can be acquired simultaneously with reduced scan time and applied for the detection of degenerative change and cartilage evaluation.

#### **S4-SSMK01-5 Accelerated 2-3-Minute Multi-echo Ultra-short Echo Time (mecho UTE) using Conjugate Gradient SENSE (CG-SENSE) Reconstruction**

Hung P. Do, PhD, MSc (*Presenter*) Employee, Canon Medical Systems Corporation

##### **PURPOSE**

Multi-echo Ultra-short Echo-Time (mecho UTE) allows visualizations and quantitative assessment of short T2\* tissues (tendon, ligament, meniscus, bone, etc.), which are invisible (i.e., signal void) in routine clinical images (Figure 0). Currently, mecho UTE with gridding, a traditional reconstruction method for non-Cartesian, often takes ~5-6 min scan time. This study aimed to accelerate the current mecho UTE using Conjugate Gradient SENSE (CG-SENSE) reconstruction (Pruessmann et. al.).

##### **METHODS AND MATERIALS**

Data Collection: Experiments were performed on healthy volunteers under an approved IRB using a 3T MRI scanner. Mecho UTE sequence parameters are shown in Table 1. Reference 5min UTE as well as prospectively accelerated 3min and 2min UTE scans were acquired. Three datasets were reconstructed with both Gridding and CG-SENSE. Data Analysis: Subtraction (2nd echo was subtracted from 1st echo) images were generated for visualization of short T2\* tissues. Logarithmic inversion (Wiesinger et. al.) of the first echo ( $TE1 = 0.096ms$ ) yields CT-like images. Mono-exponential fitting of mecho UTE data was used to generate T2\* map. Full-Width at Half-Maximum (FWHM) was calculated to assess the sharpness of CG-SENSE and Gridding.

##### **RESULTS**

Figure 1 shows the first echo ( $TE1 = 96$  micro-seconds) images of three datasets with CG-SENSE and Gridding. Figures 2 3 show subtraction images ( $TE1 - TE2$ ), which allow visualization of short T2\* tissues and CT-like images generated via

logarithmic inversion, respectively. Shoulder tendons (arrow) and bone, which are invisible in conventional imaging, are better delineated. CG-SENSE enables sharper images compared to Gridding. Additionally, 2min CG-SENSE image shows higher image quality than the current standard 5min mecho UTE with Gridding. Figure 4 shows T2\* maps generated from mono-exponential fitting. T2\* values measured from a small region of interest (ROI) on the shoulder tendon (arrow) are similar in all reconstructions and approximately ~7ms, which is in the range reported in the literature for tendons (Juras et. al. Qiao et. al.). Figures 5 6 show feature profiles and FWHM. CG-SENSE shows smaller FWHMs, which means sharper images compared to Gridding.

#### **CONCLUSION**

The feasibility of accelerated 2-3 min mecho UTE using CG-SENSE was demonstrated. Compared to the current standard (5min UTE with Gridding), the accelerated mecho UTE provides sharper images with similar quantitative T2\*.

#### **CLINICAL RELEVANCE/APPLICATION**

CG-SENSE allows 2-3 min mecho UTE, which provides visualization and quantification of short T2\* tissues, which are invisible in routine clinical MRI. This may enable the widespread adoption of mecho UTE into the clinical settings.

#### **S4-SSMK01-6 Accelerated MRI-Acquisition using Deep-Learning Image Reconstruction and Edge Sharpening, and Standard Acquisition Protocol in Evaluating Patients after Rotator Cuff Repair: A Comparison**

Roy P. Marcus, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To assess the diagnostic performance of accelerated MRI acquisition with deep-learning reconstruction and edge sharpening in patients after rotator cuff repair.

#### **METHODS AND MATERIALS**

This prospective study was approved by the local IRB. Unenhanced MRI scans of the operated shoulder were performed on 116 patients using a 3 Tesla (T) scanner (MAGNETOM Prisma, Siemens Healthineers). Standard and accelerated protocols were used during the same scanning session acquiring three sequences in coronal plane (TIRM, PD TSE and PD FS), two sequences in sagittal plane (TIRM and T1 TSE) and one sequence in axial plane (PD FS) with a slice thickness of 3 mm each. The acquisition times and artifacts of the standard and the accelerated protocols were recorded. Two experienced radiologists, blinded to the acquisition protocol, evaluated postsurgical changes of the tendons as per Sugaya classification (1: sufficient thickness, 2: sufficient thickness with partial high intensity, 3: insufficient thickness, 4: minor discontinuity, 5: major discontinuity).

#### **RESULTS**

Inter-rater and intra-rater reliabilities of the evaluated 207 operated tendons were almost perfect ( $\kappa = 0.824 - 0.863$ ). The accelerated protocol reduced the acquisition time by 80% (3.7 minutes [2.5 - 6.3] vs. 18.4 minutes [17 - 33.7] for accelerated vs. standard protocol,  $p < 0.001$ ). A total of four intra-rater disagreements were observed (2%) due to motion artifact in the standard acquisition or slightly different acquisition planes. No motion artifact was recorded during the accelerated protocol.

#### **CONCLUSION**

Accelerated MRI acquisition with -deep-learning reconstruction and edge sharpening significantly shortens the acquisition time while allowing a reliable evaluation of the shoulder after rotator cuff repair.

#### **CLINICAL RELEVANCE/APPLICATION**

Accelerated MRI protocols significantly reduced scanning time. Metal artifacts after rotator cuff repair do not impair the image quality or the dependability of the examination.

### **Fat Fractions of the Rotator Cuff Muscles Acquired with Two-point Dixon MRI: Predicting Outcome after Arthroscopic Rotator Cuff Repair**

Sunday, Nov. 26 1:00PM - 2:00PM Room: E353B

Georg C. Feuerriegel, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The purpose of this study was to quantify and compare intramuscular fat fraction (FF) and muscle volume between patients with failed and intact rotator cuff (RC) repair as well as a control group with conservative treatment to define reliable FF cut-off values for predicting the outcome of RC repair.

#### **METHODS AND MATERIALS**

In this retrospective study patients with full-thickness RC tears who received MRI before and after arthroscopic RC repair including a two-point Dixon sequence between July 2016 and December 2022 were screened for eligibility. Patients with re-tear of one or more RC tendons diagnosed on MRI (Sugaya IV and V) were enrolled into the study and matched for age, gender, BMI, and MRI time interval to patients with intact RC repair (Sugaya I and II). A third group with conservatively treated RC tears was included as reference and also matched to the failed RC repair group. Two radiologists analyzed morphological features including the size and location of RC tears (Cofield) as well as the integrity of the RC after repair (Sugaya). Furthermore, the tendon retraction (Patte) and fatty infiltration (Goutallier) were assessed. Quantitative FFs were calculated from the two-point Dixon sequence and the RC muscles were segmented semi-automatically to calculate the FF and volume for each muscle. ROC curves were used to determine the FF cut-off values which best predict RC re-tears. Mann-Whitney U and Wilcoxon Signed-Rank tests were used to assess the differences between groups.

#### **RESULTS**

In total 136 patients were enrolled, consisting of three groups: 41 (22%) patients had a failed RC repair (mean age  $58 \pm 7$  years, 16 women), 50 (27%) patients matched into the intact RC repair group and 45 patients were matched into the conservative treatment group. The mean time interval between baseline and follow-up MRI was  $17.0 \pm 2.7$  months. Preoperative FF was significantly higher in the failed repair group for all RC muscles compared to the intact repair group and the conservative treatment group ( $p < 0.05$ ). ROC curves showed reliable preoperative FF cut-off values for predicting re-tears at 6.0% for the SSP muscle (0.83 AUC), 7.4% for the ISP muscle (AUC 0.82) and 8.3% for the SSC muscle (0.94 AUC). Compared to the intact repair group a significant decrease in muscle volume was seen in the failed repair group for all muscles (SSP:  $P = 0.035$ , ISP:  $P = 0.023$ , SSC:  $P = 0.018$ ).

#### **CONCLUSION**

Preoperative quantitative FF calculated from two-point Dixon MRI can be used to predict the risk of re-tear after arthroscopic RC repair with reliable cut-off values between 6% and 8.3%.

#### **CLINICAL RELEVANCE/APPLICATION**

Muscle fatty infiltration is a predictor of successful RC repair and reliable cut-off values for FF might improve preoperative screening and risk assessment in patients with full-thickness RC tears.

### Accelerated 2-3-Minute Multi-echo Ultra-short Echo Time (mecho UTE) using Conjugate Gradient SENSE (CG-SENSE) Reconstruction

Sunday, Nov. 26 1:00PM - 2:00PM Room: E353B

Hung P. Do, PhD, MSc (*Presenter*) Employee, Canon Medical Systems Corporation

#### PURPOSE

Multi-echo Ultra-short Echo-Time (mecho UTE) allows visualizations and quantitative assessment of short T2\* tissues (tendon, ligament, meniscus, bone, etc.), which are invisible (i.e., signal void) in routine clinical images (Figure 0). Currently, mecho UTE with gridding, a traditional reconstruction method for non-Cartesian, often takes ~5-6 min scan time. This study aimed to accelerate the current mecho UTE using Conjugate Gradient SENSE (CG-SENSE) reconstruction (Pruessmann et. al.).

#### METHODS AND MATERIALS

Data Collection: Experiments were performed on healthy volunteers under an approved IRB using a 3T MRI scanner. Mecho UTE sequence parameters are shown in Table 1. Reference 5min UTE as well as prospectively accelerated 3min and 2min UTE scans were acquired. Three datasets were reconstructed with both Gridding and CG-SENSE. Data Analysis: Subtraction (2nd echo was subtracted from 1st echo) images were generated for visualization of short T2\* tissues. Logarithmic inversion (Wiesinger et. al.) of the first echo (TE1 = 0.096ms) yields CT-like images. Mono-exponential fitting of mecho UTE data was used to generate T2\* map. Full-Width at Half-Maximum (FWHM) was calculated to assess the sharpness of CG-SENSE and Gridding.

#### RESULTS

Figure 1 shows the first echo (TE1 = 96 micro-seconds) images of three datasets with CG-SENSE and Gridding. Figures 2 3 show subtraction images (TE1 - TE2), which allow visualization of short T2\* tissues and CT-like images generated via logarithmic inversion, respectively. Shoulder tendons (arrow) and bone, which are invisible in conventional imaging, are better delineated. CG-SENSE enables sharper images compared to Gridding. Additionally, 2min CG-SENSE image shows higher image quality than the current standard 5min mecho UTE with Gridding. Figure 4 shows T2\* maps generated from mono-exponential fitting. T2\* values measured from a small region of interest (ROI) on the shoulder tendon (arrow) are similar in all reconstructions and approximately ~7ms, which is in the range reported in the literature for tendons (Juras et. al. Qiao et. al.). Figures 5 6 show feature profiles and FWHM. CG-SENSE shows smaller FWHMs, which means sharper images compared to Gridding.

#### CONCLUSION

The feasibility of accelerated 2-3 min mecho UTE using CG-SENSE was demonstrated. Compared to the current standard (5min UTE with Gridding), the accelerated mecho UTE provides sharper images with similar quantitative T2\*.

#### CLINICAL RELEVANCE/APPLICATION

CG-SENSE allows 2-3 min mecho UTE, which provides visualization and quantification of short T2\* tissues, which are invisible in routine clinical MRI. This may enable the widespread adoption of mecho UTE into the clinical settings.

### Accelerated MRI-Acquisition using Deep-Learning Image Reconstruction and Edge Sharpening, and Standard Acquisition Protocol in Evaluating Patients after Rotator Cuff Repair: A Comparison

Sunday, Nov. 26 1:00PM - 2:00PM Room: E353B

Roy P. Marcus, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the diagnostic performance of accelerated MRI acquisition with deep-learning reconstruction and edge sharpening in patients after rotator cuff repair.

#### METHODS AND MATERIALS

This prospective study was approved by the local IRB. Unenhanced MRI scans of the operated shoulder were performed on 116 patients using a 3 Tesla (T) scanner (MAGNETOM Prisma, Siemens Healthineers). Standard and accelerated protocols were used during the same scanning session acquiring three sequences in coronal plane (TIRM, PD TSE and PD FS), two sequences in sagittal plane (TIRM and T1 TSE) and one sequence in axial plane (PD FS) with a slice thickness of 3 mm each. The acquisition times and artifacts of the standard and the accelerated protocols were recorded. Two experienced radiologists, blinded to the acquisition protocol, evaluated postsurgical changes of the tendons as per Sugaya classification (1: sufficient thickness, 2: sufficient thickness with partial high intensity, 3: insufficient thickness, 4: minor discontinuity, 5: major discontinuity).

#### RESULTS

Inter-rater and intra-rater reliabilities of the evaluated 207 operated tendons were almost perfect ( $\kappa = 0.824 - 0.863$ ). The accelerated protocol reduced the acquisition time by 80% (3.7 minutes [2.5 - 6.3] vs. 18.4 minutes [17 - 33.7] for accelerated vs. standard protocol,  $p < 0.001$ ). A total of four intra-rater disagreements were observed (2%) due to motion artifact in the standard acquisition or slightly different acquisition planes. No motion artifact was recorded during the accelerated protocol.

#### CONCLUSION

Accelerated MRI acquisition with deep-learning reconstruction and edge sharpening significantly shortens the acquisition time while allowing a reliable evaluation of the shoulder after rotator cuff repair.

#### CLINICAL RELEVANCE/APPLICATION

Accelerated MRI protocols significantly reduced scanning time. Metal artifacts after rotator cuff repair do not impair the image quality or the dependability of the examination.

#### Sub-Events

#### **S4-SSMK02-2 Employing Generative AI to Visualize Ideal Total Hip Arthroplasty and Conduct Patient-Specific Surgical Templating on Plain Radiographs**

Pouria Rouzrokh, MD, MPH (*Presenter*) Nothing to Disclose

#### PURPOSE

Total hip arthroplasty (THA) templating involves manual measurements and 2D implant renderings on preoperative radiographs. While a tedious process, optimal templating improves surgical efficiency and reduces complications by visualizing desirable surgical outcomes and anticipating challenges. This study introduces THA-Net, a deep learning (DL) algorithm that simulates postoperative THA radiographs with a single preoperative pelvis input, generating predictions unconditionally (algorithm selects implants) or conditionally (surgeon selects implants). We hypothesized that THA-Net would produce images as valid and realistic as actual radiographs while needing no or minimal surgeon inputs.

#### METHODS AND MATERIALS

THA-Net utilizes a pretrained YOLO-v5 model to crop the hip joint from an input preoperative pelvis radiograph and then employs a classifier-free conditional diffusion model for inpainting THA implants and generating realistic postoperative radiographs. The diffusion model offers two modes: 1) automated, requiring only the input radiograph, and 2) hardware-aware, allowing user-specified components. Trained on 356,305 radiographs from 14,357 patients (2000-2022), the model was conditioned on the 2-year complication outcomes and acetabular inclination angles available for the training data to ensure optimal implant selection/positioning and consider complication risk minimization during inference. Two orthopedic surgeons blindly assessed the surgical validity and realism of 100 real and 100 synthetic postoperative radiographs. Synthetic radiographs were also assessed against software-based criteria.

#### RESULTS

The surgical validity of synthetic postoperative radiographs (THA-Net output) was significantly higher than real ones (mean difference: 0.8 and 1.1 points on a 10-point Likert scale for automated and hardware-aware generations, respectively;  $p < 0.001$ ). Blinded expert reviews couldn't differentiate real and synthetic radiographs regarding realism. Synthetic radiographs were rated as realistic as their real counterparts in 95% of hardware-aware and 98% of automated generations. They exhibited excellent validity and realism when analyzed using validated software.

#### CONCLUSION

We developed a DL-based next-generation THA templating tool to generate synthetic postoperative radiographs with highly valid and realistic surgical execution.

#### CLINICAL RELEVANCE/APPLICATION

As a standalone technology, this tool enables patient-specific surgical planning and identifies the optimal postoperative target. Further refinement of this tool may allow it to interface with robotics, navigation, and AR/VR technologies to achieve desirable surgical execution while reducing dependence on 3D imaging data.

#### **S4-SSMK02-3 Hip MRI: Patients with Hip Dysplasia can Present with Femoral Version Deformities and with Combined Acetabular and Femoral Version Deformities**

Till D. Lerch, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Frequency of abnormal femoral torsion (FT) is unclear for patients with hip dysplasia. Increased FT was associated with hip dysplasia but only few studies investigated the true FT. The purpose of this study was to investigate frequency of increased or decreased FT or acetabular version (AV) and combined version on preoperative MRI of patients with hip dysplasia.

## METHODS AND MATERIALS

A retrospective comparative study that involved 419 hips of symptomatic patients with hip dysplasia undergoing periacetabular osteotomy was performed. Mean age was 28 years, 88% were female patients and mean preoperative LCE angle was 11°. All patients had FT > 25°. Preoperative MRI was performed for all patients in clinical routine for evaluation of cartilage and labrum lesions and for dGEMRIC. Preoperative hip MRI was evaluated for assessment of FT, AV and combined version on axial T1-weighted images. Combined version equals the sum of FT and AV. FT was measured by one radiology resident with 5 years of experience in musculoskeletal imaging according to the Reikeras method. Field of view of the CT scan and MRI included pelvis and knee.

## RESULTS

Mean FT of 419 hips was 16° (-20-57°), and mean central AV was 19° (3-35°) and mean combined version was 35° (-8-78°). 44% of hips had FT between 10-25°, 24% had FT > 25° and 32% had FT < 10°. FT > 35° was found in 6% and FT < 0° was found in 8%. The combination of normal FV and AV was present in 36%, while 19% have increased FT > 25° and normal AV and 27% have decreased FT < 10° and normal AV. Decreased combined version < 20° was present in 12%, increased combined version > 50° was present in 14%.

## CONCLUSION

One third of patients with hip dysplasia have normal FT combined with normal AV. Almost a third of patients have decreased FV < 10°, while 23% have increased FT > 25°. Patients with hip dysplasia can exhibit combined deformities. This is important for preoperative planning of hip preservation surgery (periacetabular osteotomy or femoral derotation osteotomy).

## CLINICAL RELEVANCE/APPLICATION

Preoperative hip MRI allows assessment of FT and detection of deformities of FT such as increased or decreased FT for patients with hip dysplasia and hip pain.

## S4-SSMK02-4 Low Dose Photon Counting Computed Tomography of the Pelvis with Tin Filter and Denoising: How Low Can We Go

Roy P. Marcus, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the quality of images of the pelvis using a Photon Counting Computed Tomography (PCCT) at ultra-low dose.

## METHODS AND MATERIALS

Images were acquired on a standard pelvis phantom using a clinical PCCT (NAEOTOM Alpha, Siemens Healthineers) and an energy integrating Computed Tomography (EID) (SOMATOM Edge Plus, Siemens Healthineers) at 100 kV with tin filter and at varying radiation doses (CTDI 1.5, 1, 0.75, 0.5, 0.25, 0.1, 0.05 mGy). Two-millimeter axial images were reconstructed using a smooth soft tissue (B40) and a bone kernel. In addition, the PCCT bone reconstructions were denoised using a clinical DICOM-based denoising tool (ClariCT.AI, ClariPi). Two radiologists, blinded of either the modality or dose, evaluated the images; settings and radiation exposure were equivalent to the ones used in clinical practice. In addition to SNR measurements, delineation of the cortical and cancellous bone, as well as artifacts and overall image quality were assessed using a 5 point Likert-scale (1 = extremely bad, 5 = excellent). An average of a Likert Score > 3 was considered clinically satisfactory.

## RESULTS

SNR measured in PCCT images was significantly higher than in EID images ( $p < 0.001$ ). Denoising contributed to an additional SNR increase in PCCT images ( $p < 0.001$ ). Inter-rater reliability was excellent to almost perfect ( $\kappa = 0.87 - 1$ ). Photon starvation artifacts were observed only in EID at 0.05 mGy. Acquisitions = 0.25 mGy on the PCCT and = 0.5 mGy on the EID were diagnostically valid. With additional denoising, the PCCT can produce pelvic scans with a good image quality at already 0.1 mGy.

## CONCLUSION

CT of the pelvic structures can be obtained on PCCT combined with a denoising software at significantly lower radiation exposure, while preserving image quality.

## CLINICAL RELEVANCE/APPLICATION

The use of ultra-low dose PCCT and denoising software generate CT scans of the pelvis at a radiation exposure lower than conventional radiographs.

### S4-SSMK02-5 **Disparities in DEXA Scan Utilization Varies Across Racial/Ethnic Groups Prior to and After Hip Fractures**

Katelyn E. Rudisill, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Geriatric hip fractures are common and important sentinel events regarding bone health. While dual X-ray absorptiometry (DEXA) scans are a standard method for determining bone density, differences in use among various race/ethnic groups around the time of hip fracture may reveal disparities within the healthcare system. The current study aimed to evaluate for racial/ethnic variations in DEXA scan utilization among a cohort of geriatric hip fracture patients.

#### METHODS AND MATERIALS

The 2014 to 2016 Medicare Standard Analytic Files (SAF) PearlDiver dataset was used to identify geriatric patients sustaining hip fractures. From that cohort, those who had a DEXA scan prior to or following their fracture were defined, and patient age, sex, Elixhauser Comorbidity Index (ECI), race/ethnicity, and income (based on zip code) were characterized. Demographic factors of patients who did and did not receive a DEXA scan before or after hip fracture were compared with univariate and multivariate analyses. Predictive factors for receiving a DEXA scan were determined.

#### RESULTS

Of 58,099 hip fracture patients, 19.8% had a DEXA scan before fracture, and 3.9% of those who did not receive a pre-fracture DEXA scan had a scan following their fracture. Of the study cohort, 91.0% identified as white and 9.0% as non-white (Native American, Black, Hispanic, Asian, or Other). Prior to hip fracture, 20.3% of White patients had a DEXA scan, compared to 14.7% of Asians, 14.4% of Hispanics, 14.0% of Blacks, 10.7% of Native Americans, and 16.4% of "Other" patients. Controlling for patient age, sex, ECI, and income, compared to white patients, all non-white patients were at lesser odds of having a DEXA scan performed before hip fracture (Native American odds ratio [OR] 0.39, Black OR 0.59, Hispanic OR 0.64, Asian OR 0.69, and other OR 0.77,  $p < 0.0001$  for all except other,  $p = 0.0262$ ). Following hip fracture, Black OR 0.66 ( $p$ -value = 0.0021), Hispanic OR 0.57 ( $p$ -value = 0.0251), and other OR 0.75 ( $p$ -value = 0.024) patients were also at lesser odds of having a DEXA scan.

#### CONCLUSION

Using a large Medicare dataset, controlling for patient age, sex, ECI, and income marker, the current study revealed disparities in DEXA scan utilization across race/ethnic groups before and after presenting with a fragility hip fracture. Identifying such disparities highlights the need for improved medical access and care in this at-risk hip fracture population.

## CLINICAL RELEVANCE/APPLICATION

DEXA scan utilization identifies patients with low bone densities, and early detection can prevent individuals from developing a hip fragility fracture. Varying use of DEXA scans for different racial/ethnic groups highlights disparities in the healthcare system - which may negatively impact care outcomes among disadvantaged groups.

### S4-SSMK02-6 **Radiographic Assessment of the Pubic Symphysis in Elite Male Adolescent Football Players: Development and Reliability of the Maturing Adolescent Pubic Symphysis (MAPS) Classification**

David Hanff, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The pubic symphysis is susceptible to growth related injuries long after the adolescent growth spurt. The late age of ossification of the pubic symphysis was recently demonstrated using advanced imaging. Our study describes the radiographic maturation of the pubic symphysis on pelvic radiographs in adolescent football players and introduces the Maturing Adolescent Pubic Symphysis classification (MAPS classification).

#### METHODS AND MATERIALS

Anteroposterior pelvic radiographs of 105 healthy adolescent male football players between 12 and 24 years old were used to develop the classification system. The radiological scoring of the symphyseal joint was developed over five rounds. The final MAPS classification items were scored in random order by two experienced raters, blinded to the age of the participant and to each other's scoring. The inter- and intra-rater reliability were examined using weighted kappa (?).

## RESULTS

We developed a classification system with descriptive definitions and an accompanying pictorial atlas. The symphyseal joint was divided into three regions: the superior corners, and the upper and lower regions of the joint line. The superior corners are classified as rounded, squared or beaked. The upper region of the joint line: round or straight. The lower region of the joint line: straight, diagonal, or "in between". Inter-rater reliability was substantial to almost perfect: superior region:  $\kappa = 0.70$  (95% CI 0.60 - 0.79), upper region of the joint line:  $\kappa = 0.89$  (95% CI 0.86 - 0.92), lower region of the joint line:  $\kappa = 0.65$  (95% CI 0.55 - 0.75). The intra-observe reliability showed similar results.

## CONCLUSION

The Maturing Adolescent Pubic Symphysis classification (MAPS-classification) is a reliable descriptive classification of the radiographic maturation of the pubic symphysis joint in athletic males. Maturation starts at the superior corner, creating a squared edge. The joint line then gradually ossifies - from superior to inferior. The stages can provide a basis for understanding in clinical practice and will allow future research in this field.

## CLINICAL RELEVANCE/APPLICATION

This study raises awareness to all health professionals that many radiographic findings at the pubic symphysis represent non-complete ossification rather than pathology. The maturation process can still be ongoing at 23 years old in males. This also suggests that pubic-related groin pain could be linked to maturation until a relatively high age.

### Low Dose Photon Counting Computed Tomography of the Pelvis with Tin Filter and Denoising: How Low Can We Go

Sunday, Nov. 26 1:00PM - 2:00PM Room: E353C

Roy P. Marcus, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the quality of images of the pelvis using a Photon Counting Computed Tomography (PCCT) at ultra-low dose.

#### METHODS AND MATERIALS

Images were acquired on a standard pelvis phantom using a clinical PCCT (NAEOTOM Alpha, Siemens Healthineers) and an energy integrating Computed Tomography (EID) (SOMATOM Edge Plus, Siemens Healthineers) at 100 kV with tin filter and at varying radiation doses (CTDI 1.5, 1, 0.75, 0.5, 0.25, 0.1, 0.05 mGy). Two-millimeter axial images were reconstructed using a smooth soft tissue (B40) and a bone kernel. In addition, the PCCT bone reconstructions were denoised using a clinical DICOM-based denoising tool (ClariCT.AI, ClariPi). Two radiologists, blinded of either the modality or dose, evaluated the images; settings and radiation exposure were equivalent to the ones used in clinical practice. In addition to SNR measurements, delineation of the cortical and cancellous bone, as well as artifacts and overall image quality were assessed using a 5 point Likert-scale (1 = extremely bad, 5 = excellent). An average of a Likert Score >3 was considered clinically satisfactory.

#### RESULTS

SNR measured in PCCT images was significantly higher than in EID images ( $p < 0.001$ ). Denoising contributed to an additional SNR increase in PCCT images ( $p < 0.001$ ). Inter-rater reliability was excellent to almost perfect ( $\kappa = 0.87 - 1$ ). Photon starvation artifacts were observed only in EID at 0.05 mGy. Acquisitions =0.25 mGy on the PCCT and =0.5 mGy on the EID were diagnostically valid. With additional denoising, the PCCT can produce pelvic scans with a good image quality at already 0.1 mGy.

#### CONCLUSION

CT of the pelvic structures can be obtained on PCCT combined with a denoising software at significantly lower radiation exposure, while preserving image quality.

#### CLINICAL RELEVANCE/APPLICATION

The use of ultra-low dose PCCT and denoising software generate CT scans of the pelvis at a radiation exposure lower than conventional radiographs.

### Disparities in DEXA Scan Utilization Varies Across Racial/Ethnic Groups Prior to and After Hip Fractures

Sunday, Nov. 26 1:00PM - 2:00PM Room: E353C

Katelyn E. Rudisill, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Geriatric hip fractures are common and important sentinel events regarding bone health. While dual X-ray absorptiometry (DEXA) scans are a standard method for determining bone density, differences in use among various race/ethnic groups around the time of hip fracture may reveal disparities within the healthcare system. The current study aimed to evaluate for racial/ethnic variations in DEXA scan utilization among a cohort of geriatric hip fracture patients.

#### METHODS AND MATERIALS

The 2014 to 2016 Medicare Standard Analytic Files (SAF) PearlDiver dataset was used to identify geriatric patients sustaining hip fractures. From that cohort, those who had a DEXA scan prior to or following their fracture were defined, and patient age, sex, Elixhauser Comorbidity Index (ECI), race/ethnicity, and income (based on zip code) were characterized. Demographic factors of patients who did and did not receive a DEXA scan before or after hip fracture were compared with univariate and multivariate analyses. Predictive factors for receiving a DEXA scan were determined.

#### RESULTS

Of 58,099 hip fracture patients, 19.8% had a DEXA scan before fracture, and 3.9% of those who did not receive a pre-fracture DEXA scan had a scan following their fracture. Of the study cohort, 91.0% identified as white and 9.0% as non-white (Native American, Black, Hispanic, Asian, or Other). Prior to hip fracture, 20.3% of White patients had a DEXA scan, compared to 14.7% of Asians, 14.4% of Hispanics, 14.0% of Blacks, 10.7% of Native Americans, and 16.4% of "Other" patients. Controlling for patient age, sex, ECI, and income, compared to white patients, all non-white patients were at lesser odds of having a DEXA scan performed before hip fracture (Native American odds ratio [OR] 0.39, Black OR 0.59, Hispanic OR 0.64, Asian OR 0.69, and other OR 0.77,  $p < 0.0001$  for all except other,  $p = 0.0262$ ). Following hip fracture, Black OR 0.66 ( $p$ -value = 0.0021), Hispanic OR 0.57 ( $p$ -value = 0.0251), and other OR 0.75 ( $p$ -value = 0.024) patients were also at lesser odds of having a DEXA scan.

#### CONCLUSION

Using a large Medicare dataset, controlling for patient age, sex, ECI, and income marker, the current study revealed disparities in DEXA scan utilization across race/ethnic groups before and after presenting with a fragility hip fracture. Identifying such disparities highlights the need for improved medical access and care in this at-risk hip fracture population.

#### CLINICAL RELEVANCE/APPLICATION

DEXA scan utilization identifies patients with low bone densities, and early detection can prevent individuals from developing a hip fragility fracture. Varying use of DEXA scans for different racial/ethnic groups highlights disparities in the healthcare system - which may negatively impact care outcomes among disadvantaged groups.

The intra-observe reliability showed similar results.

#### **CONCLUSION**

The Maturing Adolescent Pubic Symphysis classification (MAPS-classification) is a reliable descriptive classification of the radiographic maturation of the pubic symphysis joint in athletic males. Maturation starts at the superior corner, creating a squared edge. The joint line then gradually ossifies - from superior to inferior. The stages can provide a basis for understanding in clinical practice and will allow future research in this field.

#### **CLINICAL RELEVANCE/APPLICATION**

This study raises awareness to all health professionals that many radiographic findings at the pubic symphysis represent non-complete ossification rather than pathology. The maturation process can still be ongoing at 23 years old in males. This also suggests that pubic-related groin pain could be linked to maturation until a relatively high age.

#### **S4-SSNR01-1 Progressive Reduction in Basal Ganglia Explains and Predicts Cerebral Structural Alteration in Type 2 Diabetes Mellitus**

Minchul Kim, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Type 2 diabetes is consistently reported to be associated with reduced gray matter, mainly in the cortical-striatal-limbic networks. However, little is known about how the progression of diabetes affects cerebral gray matter. We investigate gray matter alterations according to diabetes progression and the causal relationship to the whole brain.

#### **METHODS AND MATERIALS**

Among 1121 participants who attended health screenings, 543 age- and sex-matched participants were enrolled and divided among the nondiabetes, prediabetes, and diabetes groups according to their glycosylated hemoglobin (HbA1c) levels. Voxel-based morphometry using a linear trend model was performed to reveal brain regions associated with disease progression. The Granger causal network of structural covariance was used to assess the causal relationships of brain structural alterations according to disease progression. Multivariable pattern analysis was applied for the stage-specific predictions of hyperglycemia.

#### **RESULTS**

With diabetes progression, a linear trend of gray matter volume reduction in the basal ganglia ( $P < 0.05$ , FWER corrected) was detected, which caused a reduction in bilateral temporal gyri, frontal pole, parahippocampus, and bilateral posterior cingulate/precuneus volumes. In addition, the gray matter pattern of the basal ganglia could predict patients with diabetes (accuracy 60.12%,  $p = 0.002$ ).

#### **CONCLUSION**

The basal ganglia is the area of the brain with progressive gray matter reduction that is associated with diabetes progression. The reduced volume in the basal ganglia causes widespread, networkwise gray matter volume reductions throughout diabetes progression. These findings indicate that the basal ganglia play a key role in diabetes by affecting the cortical-striatal-limbic network.

#### **CLINICAL RELEVANCE/APPLICATION**

We demonstrated that the basal ganglia is the area of stepwise gray matter reduction according to diabetes progression. The reduced volume in the basal ganglia causes widespread, networkwise gray matter reduction over diabetes progression. To interpret the result, we propose a basal ganglia initiation and networkwise propagation model of hyperglycemia affecting the brain. These findings indicate that the basal ganglia play a key role in type 2 diabetes by affecting the cortical-striatal-limbic network.

#### **S4-SSNR01-3 Network Connectivity Anomalies in Limbic-predominant Age-related TDP-43 Encephalopathy Neuropathological Change (LATE-NC)**

Mahir Tazwar, BS (*Presenter*) Nothing to Disclose

## PURPOSE

Limbic-predominant age-related TDP-43 encephalopathy neuropathological change (LATE-NC) is a common neurodegenerative pathology in the brain of older adults and is associated with accelerated cognitive impairment. The anatomical distribution of LATE-NC typically involves the amygdala, hippocampus, and other subcortical, temporal, and frontal lobe regions. But its impact on the structural integrity of this network of regions remains unknown. In this study, we tested the hypothesis that LATE-NC is associated with abnormalities in graph theoretic measures of structural connectivity in the network of regions known to be involved in LATE-NC.

## METHODS AND MATERIALS

This study included 148 deceased older adults participating in Rush Memory and Aging Project and Religious Orders Study. Ex-vivo diffusion tensor imaging (DTI) scans were acquired on 3T scanners, followed by detailed neuropathologic examination by a board-certified neuropathologist. Fractional anisotropy (FA) maps derived from DTI scans were used to define region-to-region structural connectivity in a network of 19 regions known to be involved in LATE-NC using graph theory-based network measures. General linear models were used to investigate the association of global and local graph measures with LATE-NC stages, controlling for other neuropathologies (Alzheimer's disease, Lewy bodies, arteriolosclerosis, atherosclerosis, cerebral amyloid angiopathy, gross and microscopic infarcts), demographics (age at death, sex, education), total white matter hyperintensity volume, postmortem intervals, and scanner variables. Statistical significance was set at  $p < 0.05$ .

## RESULTS

Linear regression revealed that greater LATE-NC stage was associated with increased characteristic path length and with lower values of the remaining global network measures ( $p < 0.05$ ). LATE-NC was also associated with lower local efficiency, increased nodal path length, lower nodal strength, and lower clustering coefficient in 74%, 79%, 32%, and 63% of the nodes, respectively ( $p < 0.05$ ). Finally, LATE-NC was associated with both greater (in 21% of nodes) and lower (in 16% of nodes) eigenvector centrality, and with both greater and lower betweenness centrality in 21% of nodes, respectively ( $p < 0.05$ ).

## CONCLUSION

Using graph theory and a hypothesis-driven approach, we found significant degradation of structural integrity in white matter of the network of regions affected by LATE-NC.

## CLINICAL RELEVANCE/APPLICATION

These findings may shed light on the effects of LATE-NC on brain connectivity, and in combination with other imaging and clinical information, may aid towards the development of tools for in-vivo detection of this devastating neuropathology.

## S4-SSNR01-4 Cerebral Microstructural Alterations in Post-Covid-Condition are Related to Cognitive Impairment, Olfactory Dysfunction and Fatigue

Alexander Rau, MD (*Presenter*) Nothing to Disclose

## PURPOSE

In the aftermath of the Corona Virus Disease 2019 (COVID-19), approximately 10-25% of patients developed a "Post-COVID-condition" (PCC) which is characterized, among other symptoms, by neurocognitive deficits, disturbed olfaction and fatigue. However, the pathophysiological basis of this condition is poorly understood. Diffusion microstructure imaging (DMI) is a promising approach to fill this gap, as it detects even small volume shifts between microstructural compartments of a neural tissue model.

## METHODS AND MATERIALS

Prospective cross-sectional study of  $n=89$  patients with PCC who received DMI. DMI parameters were read for the whole gray matter and tested for association with clinical data. To reveal the spatial distribution of microstructural alterations, we carried out voxel-wise group comparisons with threshold-free cluster enhancement and FWE-correction after adjustment for age and sex.

## RESULTS

Due to PCC-symptoms, 53% of patients could not return to the previous level of independence/employment. The cognitive performance measured by the MoCA-test was impaired in 41% (26, IQR [4] points,  $< 26/30$  is cut-off value). The olfactory performance was impaired in 73% (9, IQR [4] items identified,  $< 11/12$  is cut-off value). The WEIMuS questionnaire indicated fatigue in 78% (43, IQR [17] points,  $> 33/68$  is cut-off value). PCC patients were compared to matched healthy controls (healthy non-COVID, HNC;  $n = 47$ ) and controls that passed COVID-19 without developing a PCC (unimpaired post-COVID, UPC;  $n = 38$ ). Analysis of whole-brain DMI-data revealed a volume-shift from the extraneurite compartment (V-extra) into the free water fraction (V-CSF) for the gray matter that was positively associated with the severity of initial COVID-19 infection ( $P = 0.004$ ). To further determine microstructural correlates of PCC-associated symptoms after COVID-19, voxel-based associations of V-extra with clinical scores were performed. Here, symptom-specific networks emerged that were significantly correlated with impaired MoCA- or olfactory-performance and fatigue.

## CONCLUSION

In summary, DMI revealed long-lasting microstructural changes after COVID-19 infection with different patterns in patients with and without PCC. Expression of PCC-symptoms was associated with affection of specific cerebral networks, suggesting a pathophysiological basis of this syndrome.

## CLINICAL RELEVANCE/APPLICATION

Due to the high prevalence of PCC, our findings are of high relevance as they allow for an insight into the pathophysiology of neurological symptoms.

### **S4-SSNR01-5 Enlarged Choroid Plexus Related to Iron Rim Lesions and Deep Gray Matter Atrophy in Relapsing-Remitting Multiple Sclerosis**

Li Yongmei, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

To investigate the association between choroid plexus (CP) volume and brain lesions load, especially iron rim lesions (IRLs) load and atrophy in multiple sclerosis (MS), and its relationship with clinical characteristics.

## METHODS AND MATERIALS

3.0 T brain MRI images were acquired from 99 relapsing-remitting MS (RRMS) and 60 healthy controls (HCs) to obtain the volumes of CP, whole brain and lesions. Volumes were expressed as a ratio of intracranial volume. Expanded Disability Status Scale (EDSS), Montreal Cognitive Assessment (MoCA) and Symbol Digit Modalities Test (SDMT) were used to assess the severity of disability and cognitive function. Student's t-test and Multivariable regression analyses were performed to evaluate the difference of CP volumes between RRMS and HC and the association between CP volume and lesions load, brain volumes and clinical scale scores in RRMS.

## RESULTS

CP volume was 30% larger in patients with RRMS than HCs ( $p < 0.001$ ) and was 20% larger in patients with IRLs than those without IRLs ( $p = 0.007$ ). Moreover, the larger CP volume was related to greater white matter lesions (WMLs) volume in the whole RRMS ( $r = 0.46$ ,  $p < 0.001$ ). Further analysis in patients with IRLs showed a positive correlation between CP volume and WMLs volume ( $r = 0.45$ ,  $p = 0.003$ ), and IRLs volume ( $r = 0.51$ ,  $p < 0.001$ ). Meanwhile, enlarged CP was related to lower volumes in the whole brain ( $r = -0.30$ ,  $p = 0.006$ ), deep gray matter ( $r = -0.51$ ,  $p < 0.001$ ) and most regional deep gray matter nuclei (except amygdala), but no correlation with cortical lesions or cortex volume (both  $p > 0.05$ ). In addition, CP volume was significantly higher in patients with cognitive impairment than those with cognitive preservation by MoCA scores ( $p = 0.011$ ); the larger CP volume was associated with higher EDSS scores ( $r = 0.25$ ;  $p = 0.014$ ) and lower SDMT Z scores in RRMS ( $r = -0.26$ ;  $p = 0.014$ ).

## CONCLUSION

The enlargement of CP in RRMS had close correlations with inflammatory lesions, especially IRLs and deep gray matter atrophy, but not the cortex. Meanwhile, the larger CP volume was associated with higher disability and lower cognitive scores. CP volume may be a surrogate imaging marker for MS disease activity.

## CLINICAL RELEVANCE/APPLICATION

CP is considered to be linked to inflammation of MS, but its connection with markers of inflammation in vivo in MS is unclear, the markers such as lesions load and brain atrophy, particularly the WMLs edge surrounded by an iron rim, termed as IRLs. Our study provides an essential imaging basis for exploring the pathophysiological mechanism of CP involved in the brain inflammatory and neurodegeneration.

### **S4-SSNR01-6 A Folate Receptor-Targeted Nanoparticle Contrast Agent Enables Molecular MRI of Neuroinflammation in Mouse Models of Amyloid and Tau Pathology**

Andrew A. Badachhape, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Neuroinflammation frequently accompanies worsening pathogenesis and cognitive decline in neurodegenerative conditions such as Alzheimer's disease (AD). An MRI contrast agent capable of visualizing neuroinflammation would be highly desirable due to widespread use of MRI in the context of neurological disorders. Folate receptor  $\beta$ , a marker of the pro-inflammatory phenotype, is expressed on microglia and may serve as a potential imaging target. In this work, we investigated a liposomal, folate-targeted nanoparticle contrast agent coupled with gadolinium for molecular MRI of neuroinflammation in mouse models of AD that develop amyloid and tau pathology.

## **METHODS AND MATERIALS**

In vivo studies were performed in P301S mice, a model of tau pathology and APP/PSEN1 mice, a model of amyloid pathology. Transgenic mice and wild-type (WT), control littermates (n=6/genotype, 24 total) underwent baseline, pre-contrast MRI using T1-weighted spin echo sequences with 160 um in-plane resolution and 1.2 mm slice thickness. Delayed MRI was performed 4 days after systemic administration of a high T1 relaxivity folate-targeted liposomal-Gd contrast agent (0.15 mmol Gd/kg). Animals were euthanized after the final imaging session for microscopic analysis of the brain. Signal changes between pre-contrast and post-contrast MRI were determined in target regions of the brain.

## **RESULTS**

Transgenic mice demonstrated signal enhancement in post-contrast T1w-MRI compared to baseline scans. In comparison, WT control mice did not show signal enhancement. APP/PSEN1 transgenic mice exhibited greater relative enhancement (+5.9%,  $p < 0.005$ ) than P301S mice (3.9%,  $p < 0.05$ ). Immunofluorescence analysis demonstrated higher levels of activated microglia in brains of transgenic mice compared to WT control mice.

## **CONCLUSION**

A folate receptor  $\beta$ -targeted liposomal-Gd contrast agent enables *in vivo* MRI of neuroinflammation in mouse models of Alzheimer's disease.

## **CLINICAL RELEVANCE/APPLICATION**

Targeted imaging agents could play an important role in monitoring of Alzheimer's disease progression leading to cognitive decline and evaluation of therapies that target neuroinflammation.

### **Cerebral Microstructural Alterations in Post-Covid-Condition are Related to Cognitive Impairment, Olfactory Dysfunction and Fatigue**

Sunday, Nov. 26 1:00PM - 2:00PM Room: E351

Alexander Rau, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

In the aftermath of the Corona Virus Disease 2019 (COVID-19), approximately 10-25% of patients developed a "Post-COVID-condition" (PCC) which is characterized, among other symptoms, by neurocognitive deficits, disturbed olfaction and fatigue. However, the pathophysiological basis of this condition is poorly understood. Diffusion microstructure imaging (DMI) is a promising approach to fill this gap, as it detects even small volume shifts between microstructural compartments of a neural tissue model.

#### **METHODS AND MATERIALS**

Prospective cross-sectional study of n=89 patients with PCC who received DMI. DMI parameters were read for the whole gray matter and tested for association with clinical data. To reveal the spatial distribution of microstructural alterations, we carried out voxel-wise group comparisons with threshold-free cluster enhancement and FWE-correction after adjustment for age and sex.

#### **RESULTS**

Due to PCC-symptoms, 53% of patients could not return to the previous level of independence/employment. The cognitive performance measured by the MoCA-test was impaired in 41% (26, IQR [4] points, < 26/30 is cut-off value). The olfactory performance was impaired in 73% (9, IQR [4] items identified, < 11/12 is cut-off value). The WEIMuS questionnaire indicated fatigue in 78% (43, IQR [17] points, > 33/68 is cut-off value). PCC patients were compared to matched healthy controls (healthy non-COVID, HNC; n = 47) and controls that passed COVID-19 without developing a PCC (unimpaired post-COVID, UPC; n = 38). Analysis of whole-brain DMI-data revealed a volume-shift from the extraneurite compartment (V-extra) into the free water fraction (V-CSF) for the gray matter that was positively associated with the severity of initial COVID-19 infection (P = 0.004). To further determine microstructural correlates of PCC-associated symptoms after COVID-19, voxel-based associations of V-extra with clinical scores were performed. Here, symptom-specific networks emerged that were significantly correlated with impaired MoCA- or olfactory-performance and fatigue.

#### **CONCLUSION**

In summary, DMI revealed long-lasting microstructural changes after COVID-19 infection with different patterns in patients with and without PCC. Expression of PCC-symptoms was associated with affection of specific cerebral networks, suggesting a pathophysiological basis of this syndrome.

#### **CLINICAL RELEVANCE/APPLICATION**

Due to the high prevalence of PCC, our findings are of high relevance as they allow for an insight into the pathophysiology of neurological symptoms.

### Enlarged Choroid Plexus Related to Iron Rim Lesions and Deep Gray Matter Atrophy in Relapsing-Remitting Multiple Sclerosis

Sunday, Nov. 26 1:00PM - 2:00PM Room: E351

Li Yongmei, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the association between choroid plexus (CP) volume and brain lesions load, especially iron rim lesions (IRLs) load and atrophy in multiple sclerosis (MS), and its relationship with clinical characteristics.

#### METHODS AND MATERIALS

3.0 T brain MRI images were acquired from 99 relapsing-remitting MS (RRMS) and 60 healthy controls (HCs) to obtain the volumes of CP, whole brain and lesions. Volumes were expressed as a ratio of intracranial volume. Expanded Disability Status Scale (EDSS), Montreal Cognitive Assessment (MoCA) and Symbol Digit Modalities Test (SDMT) were used to assess the severity of disability and cognitive function. Student's t-test and Multivariable regression analyses were performed to evaluate the difference of CP volumes between RRMS and HC and the association between CP volume and lesions load, brain volumes and clinical scale scores in RRMS.

#### RESULTS

CP volume was 30% larger in patients with RRMS than HCs ( $p < 0.001$ ) and was 20% larger in patients with IRLs than those without IRLs ( $p = 0.007$ ). Moreover, the larger CP volume was related to greater white matter lesions (WMLs) volume in the whole RRMS ( $r = 0.46$ ,  $p < 0.001$ ), Further analysis in patients with IRLs showed a positive correlation between CP volume and WMLs volume ( $r = 0.45$ ,  $p = 0.003$ ), and IRLs volume ( $r = 0.51$ ,  $p < 0.001$ ). Meanwhile, enlarged CP was related to lower volumes in the whole brain ( $r = -0.30$ ,  $p = 0.006$ ), deep gray matter ( $r = -0.51$ ,  $p < 0.001$ ) and most regional deep gray matter nuclei (except amygdala), but no correlation with cortical lesions or cortex volume (both  $p > 0.05$ ). In addition, CP volume was significantly higher in patients with cognitive impairment than those with cognitive preservation by MoCA scores ( $p = 0.011$ ); the larger CP volume was associated with higher EDSS scores ( $r = 0.25$ ;  $p = 0.014$ ) and lower SDMT Z scores in RRMS ( $r = -0.26$ ;  $p = 0.014$ ).

#### CONCLUSION

The enlargement of CP in RRMS had close correlations with inflammatory lesions, especially IRLs and deep gray matter atrophy, but not the cortex. Meanwhile, the larger CP volume was associated with higher disability and lower cognitive scores. CP volume may be a surrogate imaging marker for MS disease activity.

#### CLINICAL RELEVANCE/APPLICATION

CP is considered to be linked to inflammation of MS, but its connection with markers of inflammation in vivo in MS is unclear, the markers such as lesions load and brain atrophy, particularly the WMLs edge surrounded by an iron rim, termed as IRLs. Our study provides an essential imaging basis for exploring the pathophysiological mechanism of CP involved in the brain inflammatory and neurodegeneration.

Sara G. Tedla, MD (*Moderator*) Nothing to Disclose

#### Sub-Events

#### **S4-SSNR02-1 Higher Intracranial Volumes but Lower White Matter Volumes in Parkinson Patients Compared to Controls: An MRI-Based Volumetric Analysis With Deep-Learning Segmentation**

Nikhil Gupta (*Presenter*) Nothing to Disclose

#### PURPOSE

Parkinson's disease (PD) has been associated with morphological changes in subcortical volumes. These volumes are highly dependent on covariates such as age, gender and intracranial volume (ICV). This study evaluates the ability of MRI volumetric analysis based on a deep learning segmentation to characterize volumetric abnormalities in patients with PD compared to controls, considering potential effects of covariates.

#### METHODS AND MATERIALS

100 patients with PD and 100 controls with 3DT1-weighted MR images were randomly selected from the available PPMI database. NeuroShield (InMed Prognostics), a deep learning-based brain MRI segmentation algorithm, was used for automated segmentation and computation of several brain volumes: ICV, white matter (WM) volume, gray matter (GM) volume along with volumes of deep gray matter (dGM) structures. Comparison of computed volumes between PD and control subjects was done using univariate and multivariate linear regression analysis adjusting by covariates.

#### RESULTS

There were no significant between-group differences in GM or dGM volumes, adjusting or not by covariates. Interestingly, ICV was significantly higher in PD patients compared to controls (univariate p-value = 0.01). Gender-specific analysis revealed this difference was significant in males only (univariate p-value = 0.002, Fig. 1A). WM volume, on the contrary, was found to be significantly lower in PD patients compared to controls (multivariate p-value adjusting for covariates = 0.03). This was significant in males only (multivariate p-value adjusting for covariates = 0.02, Fig. 1B).

#### CONCLUSION

PD male patients were shown to have larger ICV compared to controls, a finding little reported in the literature possibly related to genetic factors or compensatory mechanisms to early brain damage. These results also suggest WM atrophy in those patients. Further studies are needed to better understand underlying mechanisms of these gender-specific volumetric abnormalities.

#### CLINICAL RELEVANCE/APPLICATION

As ICV can be significantly higher in PD patients compared to controls it is key to accurately measure and consider ICV in volumetric analysis of PD patients.

#### **S4-SSNR02-4 Choroid Plexus Volume, Dopaminergic Degeneration, and Motor Prognosis in Parkinson's Disease**

Chae Jung Park, MD (*Presenter*) Nothing to Disclose

## PURPOSE

There is increasing evidence that the choroid plexus (CP) is involved in the clearance of harmful metabolites from the brain, as a part of the glymphatic system. This study aimed to investigate the association between CP volume (CPV) and longitudinal motor outcomes in patients with Parkinson's disease (PD).

## METHODS AND MATERIALS

This retrospective study evaluated patients with drug-naïve, early stage PD who underwent dopamine transporter (DAT) scanning and high-resolution 3-tesla T1-weighted structural magnetic resonance imaging. All patients showed a decrease in DAT availability in the posterior putamen. The CP volume of each patient was automatically segmented, and the ratio to intracranial volume was used in subsequent analyses. The relationship between CP volume and baseline Unified Parkinson's Disease Rating Scale Part III (UPDRS-III) scores was assessed using multivariate linear regression. We performed Cox regression and linear mixed model analyses to assess longitudinal motor outcomes (i.e., development of levodopa-induced dyskinesia [LID], wearing-off, or freezing-of-gait [FOG] and longitudinal increases in the dose of dopaminergic medications) according to CP volume.

## RESULTS

A total of 322 drug-naïve, early stage PD patients (mean age,  $64.14 \pm 9.72$  [SD] years; 170 females) were included. CP volume was positively associated with the UPDRS-III score after adjusting for age at symptom onset, sex, disease duration, body mass index, and white matter high signal intensity volumes. The Cox regression model showed that baseline CP volume did not significantly affect the development of LID (hazard ratio [HR] = 1.202,  $P = 0.402$ ) and wearing-off (HR = 1.278,  $P = 0.218$ ), however, a larger CP volume was associated with the future development of FOG (HR = 1.539,  $P = 0.027$ ) after adjusting for covariates. Further, a more rapid increase in dopaminergic medication in the linear mixed model (CP volume  $\times$  time,  $P = 0.037$ ).

## CONCLUSION

These findings suggest that CP volume has the potential to serve as a biomarker for baseline and longitudinal motor disabilities in patients with PD.

## CLINICAL RELEVANCE/APPLICATION

Choroid plexus volume was associated with higher baseline UPDRS-III, a higher risk of developing freezing-of-gait, and more rapid increases in dopaminergic medications over time in patients with Parkinson's disease. These findings suggest that a choroid plexus volume is associated with parkinsonian motor deficits at initial assessment, as well as poor outcomes with respect to the progression of motor disabilities during the follow-up. The choroid plexus volume, which can be easily and automatically obtained from MRI, has the potential to serve as a biomarker for baseline and longitudinal motor disabilities in Parkinson's disease patients.

## S4-SSNR02-6 Detection and Classification of Parkinson's Disease From Dat Scans Using Machine Learning: A Systematic Review of 8,364 Patients

Faranak Ebrahimian Sadabad, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Parkinson's disease (PD) is the second most common neurodegenerative disorder that affects daily quality of life, and early diagnosis is crucial for proper treatment. Dopamine Transporter Single-photon Emission Computed Tomography (DaTscan) is widely used for clinical diagnosis. To improve PD diagnosis accuracy, Machine Learning (ML) and Deep learning (DL) methods, such as convolutional neural networks (CNNs) and support vector machines (SVMs), Artificial neural network (ANN) and Dense Convolutional Network (Dense NET), are being applied to improve PD diagnosis accuracy. The purpose of this study is to review the current state of using ML methods for PD diagnosis with DaTscans

## METHODS AND MATERIALS

Systematic searches were done through PubMed, Scopus, Web of Science, PPMI, and IEEE. Overall, we found 271 articles that were screened, and data were abstracted by 6 observers. The sensitivity, specificity, and accuracy of different algorithms and methods were reported.

## RESULTS

8364 PD subjects and 3524 healthy controls (HCs) across 27 studies were included. DL was used in 10 studies and classical ML was used in 15 studies. The remaining 2 studies applied transfer learning approaches combined with deep learning. The most commonly used algorithms of deep and machine learning were convolutional neural networks (CNNs) and support vector machines (SVMs), respectively. 7 studies employed DaTscan as the imaging modality, 13 utilized other SPECT tracers, and 7 applied a combination of the two. Ultimately, a total of 25, 24, 25, and 13 studies among the included records reported sensitivity, specificity, accuracy, and AUC, respectively, which led to a median sensitivity of 96.42% (range: 78.13% - 100%), a median specificity of 95.01% (range: 38.89% - 100%), a median accuracy of 95.20% (range: 64% - 99.20%), and a median AUC of 0.98 (range: 0.76 - 0.99).

## **CONCLUSION**

To the best of our knowledge, this is the first systematic review that compares different methods for the diagnosis of PD. Detailed analyses like correlation to disease stages and progression are currently being explored.

## **CLINICAL RELEVANCE/APPLICATION**

Overall, ML and DL have high sensitivity and specificity in the detection of Parkinson's disease by DaT scans.

### Higher Intracranial Volumes but Lower White Matter Volumes in Parkinson Patients Compared to Controls: An MRI-Based Volumetric Analysis With Deep-Learning Segmentation

Sunday, Nov. 26 1:00PM - 2:00PM Room: E352

Nikhil Gupta (*Presenter*) Nothing to Disclose

#### PURPOSE

Parkinson's disease (PD) has been associated with morphological changes in subcortical volumes. These volumes are highly dependent on covariates such as age, gender and intracranial volume (ICV). This study evaluates the ability of MRI volumetric analysis based on a deep learning segmentation to characterize volumetric abnormalities in patients with PD compared to controls, considering potential effects of covariates.

#### METHODS AND MATERIALS

100 patients with PD and 100 controls with 3DT1-weighted MR images were randomly selected from the available PPMI database. NeuroShield (InMed Prognostics), a deep learning-based brain MRI segmentation algorithm, was used for automated segmentation and computation of several brain volumes: ICV, white matter (WM) volume, gray matter (GM) volume along with volumes of deep gray matter (dGM) structures. Comparison of computed volumes between PD and control subjects was done using univariate and multivariate linear regression analysis adjusting by covariates.

#### RESULTS

There were no significant between-group differences in GM or dGM volumes, adjusting or not by covariates. Interestingly, ICV was significantly higher in PD patients compared to controls (univariate p-value = 0.01). Gender-specific analysis revealed this difference was significant in males only (univariate p-value = 0.002, Fig. 1A). WM volume, on the contrary, was found to be significantly lower in PD patients compared to controls (multivariate p-value adjusting for covariates = 0.03). This was significant in males only (multivariate p-value adjusting for covariates = 0.02, Fig. 1B).

#### CONCLUSION

PD male patients were shown to have larger ICV compared to controls, a finding little reported in the literature possibly related to genetic factors or compensatory mechanisms to early brain damage. These results also suggest WM atrophy in those patients. Further studies are needed to better understand underlying mechanisms of these gender-specific volumetric abnormalities.

#### CLINICAL RELEVANCE/APPLICATION

As ICV can be significantly higher in PD patients compared to controls it is key to accurately measure and consider ICV in volumetric analysis of PD patients.

### Choroid Plexus Volume, Dopaminergic Degeneration, and Motor Prognosis in Parkinson's Disease

Sunday, Nov. 26 1:00PM - 2:00PM Room: E352

Chae Jung Park, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

There is increasing evidence that the choroid plexus (CP) is involved in the clearance of harmful metabolites from the brain, as a part of the lymphatic system. This study aimed to investigate the association between CP volume (CPV) and longitudinal motor outcomes in patients with Parkinson's disease (PD).

#### METHODS AND MATERIALS

This retrospective study evaluated patients with drug-naïve, early stage PD who underwent dopamine transporter (DAT) scanning and high-resolution 3-tesla T1-weighted structural magnetic resonance imaging. All patients showed a decrease in DAT availability in the posterior putamen. The CP volume of each patient was automatically segmented, and the ratio to intracranial volume was used in subsequent analyses. The relationship between CP volume and baseline Unified Parkinson's Disease Rating Scale Part III (UPDRS-III) scores was assessed using multivariate linear regression. We performed Cox regression and linear mixed model analyses to assess longitudinal motor outcomes (i.e., development of levodopa-induced dyskinesia [LID], wearing-off, or freezing-of-gait [FOG] and longitudinal increases in the dose of dopaminergic medications) according to CP volume.

#### RESULTS

A total of 322 drug-naïve, early stage PD patients (mean age,  $64.14 \pm 9.72$  [SD] years; 170 females) were included. CP volume was positively associated with the UPDRS-III score after adjusting for age at symptom onset, sex, disease duration, body mass index, and white matter high signal intensity volumes. The Cox regression model showed that baseline CP volume did not significantly affect the development of LID (hazard ratio [HR] = 1.202,  $P = 0.402$ ) and wearing-off (HR = 1.278,  $P = 0.218$ ), however, a larger CP volume was associated with the future development of FOG (HR = 1.539,  $P = 0.027$ ) after adjusting for covariates. Further, a more rapid increase in dopaminergic medication in the linear mixed model (CP volume  $\times$  time,  $P = 0.037$ ).

#### CONCLUSION

These findings suggest that CP volume has the potential to serve as a biomarker for baseline and longitudinal motor disabilities in patients with PD.

#### CLINICAL RELEVANCE/APPLICATION

Choroid plexus volume was associated with higher baseline UPDRS-III, a higher risk of developing freezing-of-gait, and more rapid increases in dopaminergic medications over time in patients with Parkinson's disease. These findings suggest that a choroid plexus volume is associated with parkinsonian motor deficits at initial assessment, as well as poor outcomes with respect to the progression of motor disabilities during the follow-up. The choroid plexus volume, which can be easily and automatically obtained from MRI, has the potential to serve as a biomarker for baseline and longitudinal motor disabilities in Parkinson's disease patients.

### S4-SSPH02-1 Ex-Vivo Assessment of Multi-Contrast X-ray Imaging for the Diagnosis of Lung Cancer

Dan Bushe, PhD, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

Lung cancer remains the leading cause of cancer-related mortality worldwide. Early detection and accurate diagnosis of lung cancers are crucial for improving patient outcomes. Chest X-ray radiography has the potential to provide a powerful low-dose screening tool to enable the early detection of lung cancers. However, the X-ray absorption contrast mechanism is poorly suited for the detection of small, low-density lung nodules during the early stages of lung cancer. Recently, grating-based multi-contrast X-ray imaging has emerged as a promising approach to overcome the limitations of conventional X-ray radiography by offering the dark-field imaging capacity to probe the microstructures of the lungs and generate contrast when the tissue-to-air ratio of the alveolar-air interfaces is changed. The purpose of this study is to evaluate the potential for multi-contrast imaging using a human-compatible prototype system to detect lung cancers.

#### METHODS AND MATERIALS

An ex-vivo swine lung was injected with 0.5 mL to 1 mL of a 3% agar gel solution at depths of 1 to 3 cm to simulate five pulmonary nodules. Following confirmation of the location and formation of each nodule with CT (Fig. 1A), the lung specimen was imaged on a novel multi-contrast chest X-ray imaging system. Multi-contrast images (simultaneous absorption and dark-field contrast) were acquired in a single scanning acquisition at 70 kVp with an estimated effective dose of 0.23 mSv. Contrast and contrast-to-noise ratio (CNR) measurements were made for each of the five nodules by placing regions of interest over the five nodules and in a homogenous background region of the upper right lung.

#### RESULTS

The mean HU of the injected nodules was  $-9 \pm 18$  HU,  $24 \pm 48$  HU,  $-19 \pm 23$  HU,  $-18 \pm 49$ , and  $-14 \pm 8$  HU. Absorption, dark-field, differential phase, and three novel absorption-dark field fusion images of the healthy and diseased lung specimens are presented in Fig. 1B. The absorption-normalized dark-field signal provided the highest contrast level across all five lesions. The dark field CNR was improved when compared to the absorption CNR for four out of the five nodules, with the greatest improvement being a 3.73 factor increase in CNR.

#### CONCLUSION

The incorporation of the additional information generated from a single multi-contrast acquisition can be leveraged to improve the detection and confirmation of lesions when compared to conventional chest radiography. The dark field provided an increase in CNR in four out of the five lesions when compared to the absorption CNR.

#### CLINICAL RELEVANCE/APPLICATION

The integration of the additional information provided by X-ray dark-field imaging in clinical practice has the potential to improve the detection of lung cancers and ultimately improve patient outcomes.

### S4-SSPH02-2 Breast Density and Radiation Exposure in Screening with Digital Breast Tomosynthesis: A Subanalysis of the Randomized TOSYMA Trial

Walter Heindel, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

The randomized TOSYMA trial showed that digital breast tomosynthesis plus synthesized mammography (DBT+SM) detects significantly higher rates of invasive breast cancers than digital mammography (DM); this was particularly pronounced in women with dense breasts. On the other hand, DBT is known to operate with higher average glandular doses (AGD) of radiation than DM. In the present subanalysis of TOSYMA, we evaluated how the average glandular doses (AGD) applied with DBT+SM or DM, respectively, related to the density of examined breast.

## METHODS AND MATERIALS

From 2018 to 2020, TOSYMA, a multicentric, multivendor randomised controlled screening trial, recruited 99,689 women aged 50 to 69 years. The trial was embedded in the routine German Mammography-Screening Program. In this study, the median AGD, and the women's age and breast thickness were compared per study arm and across the breast density categories A (fatty), B (scattered), C (heterogeneously dense), or D (extremely dense). Mean AGD levels were modeled in multivariable regression models using breast density and study arm as predictor variables and breast thickness and age group as confounder variables.

## RESULTS

The analyses included 196,622 (DBT+SM) and 197,037 (DM) exposures. Women's age and breast thickness decreased markedly and similarly in both trial arms from category A to D ( $p < .001$ ). Overall, the AGD was higher in the DBT+SM than in the DM group (+ 0.94 mGy,  $p < .001$ ). However, while the median AGD applied in the DM screening arm changed only slightly with rising breast density (from 1.36 mGy (A) to 1.33 mGy (D), i.e., by -2.9%), the median AGD applied in DBT+SM decreased from 2.22 mGy in density group A to 1.73 mGy in category D, a difference of -22.0%. Multivariable regression analyses revealed that the decline of the applied radiation dose in women with higher breast density was specific to the DBT+SM screening arm (interaction term  $p < .001$ ) and not explained by women's age or breast thickness.

## CONCLUSION

This study confirms that the median AGD is generally higher in DBT+SM than in DM screening. Remarkably, however, the median AGD decreased significantly with increasing breast density only in the DBT+SM, but not in the DM arm.

## CLINICAL RELEVANCE/APPLICATION

This finding should be appraised against the previous evidence from TOSYMA that DBT+SM screening detects substantially more invasive cancers in dense breasts than DM. The presented data seem to indicate that this asset of DBT+SM is achieved with a relatively low radiation dose.

## S4-SSPH02-3 ACR Dose Index Registry for Digital Radiography: Developing Adult Dose Index Benchmarks

Xiang Li, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

In 2021, the American College of Radiology (ACR) dose index registry (DIR) launched a new pilot project in digital radiography (DR). An important goal was to develop national benchmarks for the dose indices used in DR. The purpose of this abstract was to report the first set of benchmarks for adult patients based on two years of pilot project data.

## METHODS AND MATERIALS

The pilot project included 7 institutions, which configured some of their DR devices to submit Radiation Dose Structured Reports to the ACR. A comprehensive exam mapping system was developed to map different local exam descriptions to the same ACR Common IDs. Each Common ID represented one type of radiographic procedure (e.g., 4002472 XRAY, abdomen). All event-level dose-index values from the participating institutions over a two-year period (2021 and 2022) were recorded. The recorded dose indices included the exposure index (EI), exposure index target (EIT), and deviation index (DI) defined by the IEC 62-494 standard as well as the kerma-area product (KAP). First, facility-level statistics were calculated using the event-level data from each facility. For example, "EI median" and "DI standard deviation" were used to describe the central tendency and the dispersion of the EI data from a given facility. Registry statistics (quartiles) were then calculated from the facility-level results.

## RESULTS

41 ACR Common ID procedures had sufficient event counts to allow registry statistics to be generated for adult patients, among which 15 procedures had more than 20,000 events each. For these high-volume procedures, the "registry EI median" ranged from 190 for chest to 1281 for unilateral hand. In general, central body work (chest, abdomen, and spine) had lower median EI values than extremity exams (elbow, hand, wrist, tibia/fibula and foot). The "registry DI standard deviation" ranged from 1.3 for unilateral hand to 3.1 for cervical spine. The "registry KAP median" ranged range 0.15 for unilateral wrist to 24.6 for lumbar spine (unit: dGy-cm<sup>2</sup>). Finally, the "registry KAP Interquartile Range" ranged from 0.09 for unilateral wrist to 31.5 for lumbar spine.

## CONCLUSION

Using two years of pilot project data, we established the first set of national benchmarks for DR dose indices. Individual facilities can benchmark their local performance against these national values and make data-driven decisions for quality improvement. Increased participation in DIR DR across the US will improve generalizability of future benchmarks.

## CLINICAL RELEVANCE/APPLICATION

The ACR Dose Index Registry for Digital Radiography will enable participants to benchmark their dose indices performance data against national values.

### S4-SSPH02-4 **Dependence of Reported Exposure Index Values on Vendor Algorithm: An Anthropomorphic Phantom Study**

Kathleen A. Scilla, MS (*Presenter*) Nothing to Disclose

## PURPOSE

IEC 62494-1 defined a standardized Exposure Index (EI) for radiography but left methods for determining the relevant image region and value of interest (VOI) when computing EI to vendor discretion. The aim of this study was to investigate the impact of vendor algorithm for VOI on EI.

## METHODS AND MATERIALS

Four anthropomorphic phantoms (hand, foot, head, and thorax) were imaged on ten radiographic units (one fixed and one mobile from five different manufacturers). Manual techniques for each setup were set to achieve a specified half value layer and unattenuated detector air kerma ( $K_{ref}$ ) at a specified source-to-image distance. Exam tags investigated were PA Hand and Wrist (setup 1); LAT Foot and Ankle (setup 2); LAT Skull (setup 3); AP Chest (setup 4); and AP T-Spine, Upper Ribs, and Lower Ribs (setup 5). For each exam tag (e), three images of the phantom were taken for each of three field sizes (f) - 8"x10", 10"x12", and 14"x17"- and EI was recorded. EI values were corrected for detector EI accuracy and differences in measured air kerma and  $K_{ref}$  for each setup, and the mean corrected EI value for each unit (k) at a given e and f was calculated ( $E_{Ie,f,k}$ ). Then the median  $E_{Ie,f,k}$  across f was determined ( $E_{Ie,med,k}$ ) and compared to the median across all k ( $E_{Ie,med,all}$ ).

## RESULTS

Three units failed to correctly detect the radiation field for AP Chest exams for 8"x10", and  $E_{Ie,f,k}$  nearly doubled when electronic collimation was manually adjusted on the images to the correct area. Use of 14"x17" increased  $E_{Ie,f,k}$  by 111% (hand/wrist) relative to 8"x10" for one unit, while others maintained  $E_{Ie,f,k}$  to within 16%. Field size had a moderate impact on  $E_{Ie,f,k}$  for head, foot and thorax phantoms, resulting in variations of -21% to 57% for the same e and k. Variations of -40% to 276% were observed in  $E_{Ie,f,k}$  for the thorax phantom for the same f and k for vendors A and D. Differences in  $E_{Ie,f,k}$  were negligible between exam tags with hand and foot phantoms. Vendor algorithm resulted in differences up to 70% between  $E_{Ie,med,k}$  and  $E_{Ie,med,all}$  ( $\%E_{Ie,med,all}$ ).  $E_{Ie,med,k}$  for vendor A was 2-58% lower than  $E_{Ie,med,all}$ , whereas vendor E was 1-25% higher.  $\%E_{Ie,med,k}$  for vendor D ranged from -66% to 70%.

## CONCLUSION

Proper collimation reduces variability in EI. Results indicate fundamental differences in vendor determination of VOI, making it difficult to compare EI between vendors despite a standardized EI definition.

## CLINICAL RELEVANCE/APPLICATION

Vendor-specific algorithms for identifying VOI impact displayed EI. Care should be taken when comparing dose statistics between different systems and target EI likely need to be vendor specific.

### S4-SSPH02-5 **A Monte Carlo Framework to Explore Novel X-ray Spectrum Optimization Strategies using Alternative Patient and Operator Dose Metrics in Interventional Radiology**

Rodrigo T. Massera, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Increased energies can be used to limit skin dose in interventional radiology (IR), however this can adversely affect patient and operator organ doses. This work implements a Monte Carlo (MC) framework for x-ray spectrum optimization of (IR) systems using alternative dose metrics, such as an averaged patient dose from phantom model ( $D_p$ ), dose at the patient center using the same model ( $D_c$ ) and operator effective dose ( $D_{eff}$ ).

## METHODS AND MATERIALS

The PENELOPE /penEasy(2020) MC code was used to simulate IR procedures with a C-arm system in an IR suite. System components included the x-ray tube, spectral filter, patient table, x-ray detector and antiscatter grid. The operator was modelled using an ORNL anthropomorphic phantom modified to include some missing organs of interest for dosimetry. A

cylinder composed of a homogenous body-tissue mixture with varying diameter and length was used to represent patients. Personal protective equipment (PPE) (lead aprons, eyeglasses, ceiling and table shields) was modelled to quantify its impact on staff doses. The dose metrics were calculated for x-ray spectra covering 40 kVp to 120 kVp, with Cu additional filtration between 0 and 0.9 mm. Image quality was quantified using signal difference-to-noise difference (SDNR) between a 1 x 1 cm<sup>2</sup> region at the center of the detector, with and without a 0.2 mm thick iron object placed inside the phantom. The FOM was defined as  $SDNR^2/D$ , where D is one of the dose metrics.

## RESULTS

At patient thicknesses of 10 cm and 40 cm, optimal tube potential increased from 50 kVp to 77 kVp using an FOM based on D<sub>p</sub>, and from 44 kVp to 55 kVp for an FOM utilizing D<sub>c</sub>. Switching to an FOM calculated using operator dose D<sub>eff</sub> gave slightly lower optimal potentials, namely 46 kVp and 65 kVp, for 10 cm and 40 cm, respectively. These low x-ray energies result from assuming an ideal x-ray tube, while in practice x-ray tube power limits these settings. The optimal tube potential for D<sub>p</sub> is within the 90% maximum FOM for the D<sub>eff</sub>. When all PPE is used, a reduction in D<sub>eff</sub> of 95% could be achieved compared to no PPE, when averaged over a large selection of scenarios. Adding 0.2 mm Cu filtration, and using the optimal kVp at each thickness can reduce D<sub>p</sub> or D<sub>eff</sub> by approximately 30%.

## CONCLUSION

In general, lower energies should be selected when optimizing to average patient dose, center dose and operator dose, compared to patient entrance dose. Optimal dose scenarios for a chosen metrics will depend on available x-ray tube power. Personal protective equipment remains the most effective means of limiting operator dose.

## CLINICAL RELEVANCE/APPLICATION

The flexibility afforded by the MC framework allows optimization of IR systems for alternative dose metrics such as averaged patient dose, dose at the patient center and effective dose of the operator.

### S4-SSPH02-6 **Opportunistic Bone Mineral Density Quantification from Single-shot Dual-energy Radiography using a Triple-layer Flat Panel Detector**

Stephen Z. Liu, BS (*Presenter*) Nothing to Disclose

## PURPOSE

The recently introduced triple-layer flat panel detector (FPD) enables single-shot dual-energy (DE) radiography. We investigate its application in opportunistic bone mineral density (BMD) screening from lumbar spine radiographs using kernel-based scatter correction and optimization-based material decomposition.

## METHODS AND MATERIALS

The triple-layer FPD was deployed as a retrofit on an Ysio Max (Siemens Healthineers) digital radiography system. Posterior-anterior single-shot DE radiographs of an anthropomorphic lumbar spine phantom were obtained in a contact scan configuration using 180.6 cm source-detector distance, a 13:1 vertical Pb/Al anti-scatter grid, and x-ray tube settings of 121 kV (+1.5 mm Al) and 6.2 mAs. Full (43 cm) and half (21 cm) axial collimation settings were compared. Scatter in each detector layer was estimated by a kernel-based approach; kernel parameters were calibrated from a Monte Carlo simulation of a digital cadaver phantom different from the phantom used in the experiments. Projection-domain decomposition with a beam-hardening model was applied to scatter-subtracted three-layer data to obtain water and CaHA pathlengths. Areal BMD (aBMD) of L1, L3 and L4 vertebrae were calculated from the CaHA imaging and compared to reference derived from a CT scan of the phantom.

## RESULTS

Despite the anti-scatter grid, the kernel-estimated scatter-to-primary ratios (SPRs) behind the vertebrae were high in all three FPD layers, e.g., ~120% for L4 in the top layer radiograph at 21 cm collimation and ~156% at 43 cm collimation. Due to relatively poor spectral separation between layers, uncorrected scatter leads to substantial underestimation of BMD at both collimations (>110% error for L1, L3 and L4). With scatter correction, errors are reduced to ~100%-43% and ~2%-45% for narrow and wide collimated scans, respectively, depending on the vertebra.

## CONCLUSION

Opportunistic BMD screening by single-shot DE radiography with the emerging triple-layer FPDs may be feasible using the proposed algorithmic scatter correction and model-based projection-domain decomposition. Ongoing work investigated the reproducibility of this approach to change imaging conditions.

## CLINICAL RELEVANCE/APPLICATION

The study investigates the feasibility of applying a novel, single-exposure dual-energy radiographic detector technology in opportunistic screening for bone mineral density loss.

### Ex-Vivo Assessment of Multi-Contrast X-ray Imaging for the Diagnosis of Lung Cancer

Sunday, Nov. 26 1:00PM - 2:00PM Room: N227B

Dan Bushe, PhD, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

Lung cancer remains the leading cause of cancer-related mortality worldwide. Early detection and accurate diagnosis of lung cancers are crucial for improving patient outcomes. Chest X-ray radiography has the potential to provide a powerful low-dose screening tool to enable the early detection of lung cancers. However, the X-ray absorption contrast mechanism is poorly suited for the detection of small, low-density lung nodules during the early stages of lung cancer. Recently, grating-based multi-contrast X-ray imaging has emerged as a promising approach to overcome the limitations of conventional X-ray radiography by offering the dark-field imaging capacity to probe the microstructures of the lungs and generate contrast when the tissue-to-air ratio of the alveolar-air interfaces is changed. The purpose of this study is to evaluate the potential for multi-contrast imaging using a human-compatible prototype system to detect lung cancers.

#### METHODS AND MATERIALS

An ex-vivo swine lung was injected with 0.5 mL to 1 mL of a 3% agar gel solution at depths of 1 to 3 cm to simulate five pulmonary nodules. Following confirmation of the location and formation of each nodule with CT (Fig. 1A), the lung specimen was imaged on a novel multi-contrast chest X-ray imaging system. Multi-contrast images (simultaneous absorption and dark-field contrast) were acquired in a single scanning acquisition at 70 kVp with an estimated effective dose of 0.23 mSv. Contrast and contrast-to-noise ratio (CNR) measurements were made for each of the five nodules by placing regions of interest over the five nodules and in a homogenous background region of the upper right lung.

#### RESULTS

The mean HU of the injected nodules was  $-9 \pm 18$  HU,  $24 \pm 48$  HU,  $-19 \pm 23$  HU,  $-18 \pm 49$ , and  $-14 \pm 8$  HU. Absorption, dark-field, differential phase, and three novel absorption-dark field fusion images of the healthy and diseased lung specimens are presented in Fig. 1B. The absorption-normalized dark-field signal provided the highest contrast level across all five lesions. The dark field CNR was improved when compared to the absorption CNR for four out of the five nodules, with the greatest improvement being a 3.73 factor increase in CNR.

#### CONCLUSION

The incorporation of the additional information generated from a single multi-contrast acquisition can be leveraged to improve the detection and confirmation of lesions when compared to conventional chest radiography. The dark field provided an increase in CNR in four out of the five lesions when compared to the absorption CNR.

#### CLINICAL RELEVANCE/APPLICATION

The integration of the additional information provided by X-ray dark-field imaging in clinical practice has the potential to improve the detection of lung cancers and ultimately improve patient outcomes.

### Breast Density and Radiation Exposure in Screening with Digital Breast Tomosynthesis: A Subanalysis of the Randomized TOSYMA Trial

Sunday, Nov. 26 1:00PM - 2:00PM Room: N227B

Walter Heindel, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

The randomized TOSYMA trial showed that digital breast tomosynthesis plus synthesized mammography (DBT+SM) detects significantly higher rates of invasive breast cancers than digital mammography (DM); this was particularly pronounced in women with dense breasts. On the other hand, DBT is known to operate with higher average glandular doses (AGD) of radiation than DM. In the present subanalysis of TOSYMA, we evaluated how the average glandular doses (AGD) applied with DBT+SM or DM, respectively, related to the density of examined breast.

#### METHODS AND MATERIALS

From 2018 to 2020, TOSYMA, a multicentric, multivendor randomised controlled screening trial, recruited 99,689 women aged 50 to 69 years. The trial was embedded in the routine German Mammography-Screening Program. In this study, the median AGD, and the women's age and breast thickness were compared per study arm and across the breast density categories A (fatty), B (scattered), C (heterogeneously dense), or D (extremely dense). Mean AGD levels were modeled in multivariable regression models using breast density and study arm as predictor variables and breast thickness and age group as confounder variables.

#### RESULTS

The analyses included 196,622 (DBT+SM) and 197,037 (DM) exposures. Women's age and breast thickness decreased markedly and similarly in both trial arms from category A to D ( $p < .001$ ). Overall, the AGD was higher in the DBT+SM than in the DM group (+ 0.94 mGy,  $p < .001$ ). However, while the median AGD applied in the DM screening arm changed only slightly with rising breast density (from 1.36 mGy (A) to 1.33 mGy (D), i.e., by -2.9%), the median AGD applied in DBT+SM decreased from 2.22 mGy in density group A to 1.73 mGy in category D, a difference of -22.0%. Multivariable regression analyses revealed that the decline of the applied radiation dose in women with higher breast density was specific to the DBT+SM screening arm (interaction term  $p < .001$ ) and not explained by women's age or breast thickness.

#### CONCLUSION

This study confirms that the median AGD is generally higher in DBT+SM than in DM screening. Remarkably, however, the median AGD decreased significantly with increasing breast density only in the DBT+SM, but not in the DM arm.

#### CLINICAL RELEVANCE/APPLICATION

This finding should be appraised against the previous evidence from TOSYMA that DBT+SM screening detects substantially more invasive cancers in dense breasts than DM. The presented data seem to indicate that this asset of DBT+SM is achieved with a relatively low radiation dose.

### ACR Dose Index Registry for Digital Radiography: Developing Adult Dose Index Benchmarks

Sunday, Nov. 26 1:00PM - 2:00PM Room: N227B

Xiang Li, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

In 2021, the American College of Radiology (ACR) dose index registry (DIR) launched a new pilot project in digital radiography (DR). An important goal was to develop national benchmarks for the dose indices used in DR. The purpose of this abstract was to report the first set of benchmarks for adult patients based on two years of pilot project data.

#### METHODS AND MATERIALS

The pilot project included 7 institutions, which configured some of their DR devices to submit Radiation Dose Structured Reports to the ACR. A comprehensive exam mapping system was developed to map different local exam descriptions to the same ACR Common IDs. Each Common ID represented one type of radiographic procedure (e.g., 4002472 XRAY, abdomen). All event-level dose-index values from the participating institutions over a two-year period (2021 and 2022) were recorded. The recorded dose indices included the exposure index (EI), exposure index target (EIT), and deviation index (DI) defined by the IEC 62-494 standard as well as the kerma-area product (KAP). First, facility-level statistics were calculated using the event-level data from each facility. For example, "EI median" and "DI standard deviation" were used to describe the central tendency and the dispersion of the EI data from a given facility. Registry statistics (quartiles) were then calculated from the facility-level results.

#### RESULTS

41 ACR Common ID procedures had sufficient event counts to allow registry statistics to be generated for adult patients, among which 15 procedures had more than 20,000 events each. For these high-volume procedures, the "registry EI median" ranged from 190 for chest to 1281 for unilateral hand. In general, central body work (chest, abdomen, and spine) had lower median EI values than extremity exams (elbow, hand, wrist, tibia/fibula and foot). The "registry DI standard deviation" ranged from 1.3 for unilateral hand to 3.1 for cervical spine. The "registry KAP median" ranged from 0.15 for unilateral wrist to 24.6 for lumbar spine (unit: dGy-cm<sup>2</sup>). Finally, the "registry KAP Interquartile Range" ranged from 0.09 for unilateral wrist to 31.5 for lumbar spine.

#### CONCLUSION

Using two years of pilot project data, we established the first set of national benchmarks for DR dose indices. Individual facilities can benchmark their local performance against these national values and make data-driven decisions for quality improvement. Increased participation in DIR DR across the US will improve generalizability of future benchmarks.

#### CLINICAL RELEVANCE/APPLICATION

The ACR Dose Index Registry for Digital Radiography will enable participants to benchmark their dose indices performance data against national values.

### Dependence of Reported Exposure Index Values on Vendor Algorithm: An Anthropomorphic Phantom Study

Sunday, Nov. 26 1:00PM - 2:00PM Room: N227B

Kathleen A. Scilla, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

IEC 62494-1 defined a standardized Exposure Index (EI) for radiography but left methods for determining the relevant image region and value of interest (VOI) when computing EI to vendor discretion. The aim of this study was to investigate the impact of vendor algorithm for VOI on EI.

#### METHODS AND MATERIALS

Four anthropomorphic phantoms (hand, foot, head, and thorax) were imaged on ten radiographic units (one fixed and one mobile from five different manufacturers). Manual techniques for each setup were set to achieve a specified half value layer and unattenuated detector air kerma ( $K_{ref}$ ) at a specified source-to-image distance. Exam tags investigated were PA Hand and Wrist (setup 1); LAT Foot and Ankle (setup 2); LAT Skull (setup 3); AP Chest (setup 4); and AP T-Spine, Upper Ribs, and Lower Ribs (setup 5). For each exam tag (e), three images of the phantom were taken for each of three field sizes (f) - 8"x10", 10"x12", and 14"x17"- and EI was recorded. EI values were corrected for detector EI accuracy and differences in measured air kerma and  $K_{ref}$  for each setup, and the mean corrected EI value for each unit (k) at a given e and f was calculated ( $E_{Ie,f,k}$ ). Then the median  $E_{Ie,f,k}$  across f was determined ( $E_{Ie,med,k}$ ) and compared to the median across all k ( $E_{Ie,med,all}$ ).

#### RESULTS

Three units failed to correctly detect the radiation field for AP Chest exams for 8"x10", and  $E_{Ie,f,k}$  nearly doubled when electronic collimation was manually adjusted on the images to the correct area. Use of 14"x17" increased  $E_{Ie,f,k}$  by 111% (hand/wrist) relative to 8"x10" for one unit, while others maintained  $E_{Ie,f,k}$  to within 16%. Field size had a moderate impact on  $E_{Ie,f,k}$  for head, foot and thorax phantoms, resulting in variations of -21% to 57% for the same e and k. Variations of -40% to 276% were observed in  $E_{Ie,f,k}$  for the thorax phantom for the same f and k for vendors A and D. Differences in  $E_{Ie,f,k}$  were negligible between exam tags with hand and foot phantoms. Vendor algorithm resulted in differences up to 70% between  $E_{Ie,med,k}$  and  $E_{Ie,med,all}$  ( $\%E_{Ie,med,all}$ ).  $E_{Ie,med,k}$  for vendor A was 2-58% lower than  $E_{Ie,med,all}$ , whereas vendor E was 1-25% higher.  $\%E_{Ie,med,k}$  for vendor D ranged from -66% to 70%.

#### CONCLUSION

Proper collimation reduces variability in EI. Results indicate fundamental differences in vendor determination of VOI, making it difficult to compare EI between vendors despite a standardized EI definition.

#### CLINICAL RELEVANCE/APPLICATION

Vendor-specific algorithms for identifying VOI impact displayed EI. Care should be taken when comparing dose statistics between different systems and target EI likely need to be vendor specific.

### A Monte Carlo Framework to Explore Novel X-ray Spectrum Optimization Strategies using Alternative Patient and Operator Dose Metrics in Interventional Radiology

Sunday, Nov. 26 1:00PM - 2:00PM Room: N227B

Rodrigo T. Massera, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Increased energies can be used to limit skin dose in interventional radiology (IR), however this can adversely affect patient and operator organ doses. This work implements a Monte Carlo (MC) framework for x-ray spectrum optimization of (IR) systems using alternative dose metrics, such as an averaged patient dose from phantom model ( $D_p$ ), dose at the patient center using the same model ( $D_c$ ) and operator effective dose ( $D_{eff}$ ).

#### METHODS AND MATERIALS

The PENELOPE /penEasy(2020) MC code was used to simulate IR procedures with a C-arm system in an IR suite. System components included the x-ray tube, spectral filter, patient table, x-ray detector and antiscatter grid. The operator was modelled using an ORNL anthropomorphic phantom modified to include some missing organs of interest for dosimetry. A cylinder composed of a homogenous body-tissue mixture with varying diameter and length was used to represent patients. Personal protective equipment (PPE) (lead aprons, eyeglasses, ceiling and table shields) was modelled to quantify its impact on staff doses. The dose metrics were calculated for x-ray spectra covering 40 kVp to 120 kVp, with Cu additional filtration between 0 and 0.9 mm. Image quality was quantified using signal difference-to-noise difference (SDNR) between a  $1 \times 1 \text{ cm}^2$  region at the center of the detector, with and without a 0.2 mm thick iron object placed inside the phantom. The FOM was defined as  $SDNR^2/D$ , where D is one of the dose metrics.

#### RESULTS

At patient thicknesses of 10 cm and 40 cm, optimal tube potential increased from 50 kVp to 77 kVp using an FOM based on  $D_p$ , and from 44 kVp to 55 kVp for an FOM utilizing  $D_c$ . Switching to an FOM calculated using operator dose  $D_{eff}$  gave slightly lower optimal potentials, namely 46 kVp and 65 kVp, for 10 cm and 40 cm, respectively. These low x-ray energies result from assuming an ideal x-ray tube, while in practice x-ray tube power limits these settings. The optimal tube potential for  $D_p$  is within the 90% maximum FOM for the  $D_{eff}$ . When all PPE is used, a reduction in  $D_{eff}$  of 95% could be achieved compared to no PPE, when averaged over a large selection of scenarios. Adding 0.2 mm Cu filtration, and using the optimal kVp at each thickness can reduce  $D_p$  or  $D_{eff}$  by approximately 30%.

#### CONCLUSION

In general, lower energies should be selected when optimizing to average patient dose, center dose and operator dose, compared to patient entrance dose. Optimal dose scenarios for a chosen metrics will depend on available x-ray tube power. Personal protective equipment remains the most effective means of limiting operator dose.

#### CLINICAL RELEVANCE/APPLICATION

The flexibility afforded by the MC framework allows optimization of IR systems for alternative dose metrics such as averaged patient dose, dose at the patient center and effective dose of the operator.

### Opportunistic Bone Mineral Density Quantification from Single-shot Dual-energy Radiography using a Triple-layer Flat Panel Detector

Sunday, Nov. 26 1:00PM - 2:00PM Room: N227B

Stephen Z. Liu, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

The recently introduced triple-layer flat panel detector (FPD) enables single-shot dual-energy (DE) radiography. We investigate its application in opportunistic bone mineral density (BMD) screening from lumbar spine radiographs using kernel-based scatter correction and optimization-based material decomposition.

#### METHODS AND MATERIALS

The triple-layer FPD was deployed as a retrofit on an Ysio Max (Siemens Healthineers) digital radiography system. Posterior-anterior single-shot DE radiographs of an anthropomorphic lumbar spine phantom were obtained in a contact scan configuration using 180.6 cm source-detector distance, a 13:1 vertical Pb/Al anti-scatter grid, and x-ray tube settings of 121 kV (+1.5 mm Al) and 6.2 mAs. Full (43 cm) and half (21 cm) axial collimation settings were compared. Scatter in each detector layer was estimated by a kernel-based approach; kernel parameters were calibrated from a Monte Carlo simulation of a digital cadaver phantom different from the phantom used in the experiments. Projection-domain decomposition with a beam-hardening model was applied to scatter-subtracted three-layer data to obtain water and CaHA pathlengths. Areal BMD (aBMD) of L1, L3 and L4 vertebrae were calculated from the CaHA imaging and compared to reference derived from a CT scan of the phantom.

#### RESULTS

Despite the anti-scatter grid, the kernel-estimated scatter-to-primary ratios (SPRs) behind the vertebrae were high in all three FPD layers, e.g., ~120% for L4 in the top layer radiograph at 21 cm collimation and ~156% at 43 cm collimation. Due to relatively poor spectral separation between layers, uncorrected scatter leads to substantial underestimation of BMD at both collimations (>110% error for L1, L3 and L4). With scatter correction, errors are reduced to ~100%-43% and ~2%-45% for narrow and wide collimated scans, respectively, depending on the vertebra.

#### CONCLUSION

Opportunistic BMD screening by single-shot DE radiography with the emerging triple-layer FPDs may be feasible using the proposed algorithmic scatter correction and model-based projection-domain decomposition. Ongoing work investigated the reproducibility of this approach to change imaging conditions.

#### CLINICAL RELEVANCE/APPLICATION

The study investigates the feasibility of applying a novel, single-exposure dual-energy radiographic detector technology in opportunistic screening for bone mineral density loss.

### S4-SSVA01-Deep Learning-Based Radiomics of CTA to Predict Adverse Events After Initial Endovascular Repair for Acute Uncomplicated Stanford Type B Aortic Dissection<sup>1</sup>

Xuefang Lu, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Patients undergoing thoracic endovascular aortic repair (TEVAR) with acute uncomplicated Stanford type B aortic dissection (uTBAD) are associated with a high rate of postoperative adverse events (AE). To develop a prediction model using deep learning-based radiomics features of computed tomography angiography (CTA) and clinical features to predict AE of acute uTBAD after initial TEVAR.

#### METHODS AND MATERIALS

A retrospective study of 232 patients between January 2015 and January 2022 undergoing TEVAR with acute uTBAD was conducted. The three-dimensional (3D) deep convolutional neural network (CNN) was used to automatically recognize and segment CTA images and obtain the required general radiomic features. Analysis of Variance and the Least Absolute Shrinkage and Selection Operation algorithms were implemented for feature selection and radiomics score building. The radiomics score (Rad-Score) and clinical factors were incorporated in a nomogram using the multivariable logistic regression analysis. The Hosmer-Lemeshow test was used to check the calibration of models. The Kaplan-Meier curve was used to stratify the risk of patients.

#### RESULTS

The Rad-Score incorporation with platelet and C-reactive protein showed moderate improvement in the efficiency with an AUC of 0.82 (95% CI, 0.74-0.89) in the training cohort and AUC of 0.72 (95% CI, 0.57-0.86) in inter-validation cohort. The specific performance of the combined model was shown AUC of 0.77(95%CI,0.66-0.88) in the independent validation cohort collected in 2020 and 2021, the accuracy of 0.72, precision of 0.65, sensitivity of 0.85, specificity of 0.62. The Hosmer-Lemeshow test was statistically significant in the combined model ( $t_{\text{training}}=0.15$ ,  $t_{\text{inter-validation}}=0.19$ ,  $t_{\text{independent validation}}=0.18$ ,  $p>0.05$ ). The Kaplan-Meier curve confirmed that patients with low-risk Rad-scores tended to have better survival.

#### CONCLUSION

The combination of deep learning-based radiomics of CTA and clinical indicators can predict AE after initial TEVAR in acute uTBAD patients. The nomogram was verified to be clinically useful. It is expected to provide early warning of patients' prognosis during follow-up examinations.

#### CLINICAL RELEVANCE/APPLICATION

The combination of image morphological and clinical indicators can predict acute uTBAD patients with high risk of AE after initial TEVAR. The Rad-Score incorporation with clinical factors with an AUC of 0.82 (95% CI, 0.74-0.89) in the training cohort, AUC of 0.72 (95% CI, 0.57-0.86) in the inter-validation cohort, and AUC of 0.77(95%CI,0.66-0.88) in the independent validation cohort. The nomogram was verified to be clinically useful. It is expected to provide early warning of patients' prognosis during follow-up examinations.

### S4-SSVA01-Possible Impact of the Revised 2022 ACC Aha Aortic Disease Guideline on the Management of "High-Risk Uncomplicated" Type B Aortic Dissection<sup>2</sup>

Malgorzata Polacin, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

The role of preventive thoracic endovascular aortic repair (TEVAR) in patients with uncomplicated type B aortic dissection (uTBAD) is a matter of debate. The updated 2022 ACC/AHA aortic disease guideline acknowledges the existence of a "high-risk (HR)" subcategory of uTBAD, with the assignment of a class 2B consideration for TEVAR. We explore the frequency of HR imaging features in a retrospective cohort of patients with uTBAD and compare the actual frequency of interventions with the rate of interventions that could have been considered according to the updated 2022 guideline.

## **METHODS AND MATERIALS**

We retrospectively analyzed 86 consecutive patients (mean age  $49 \pm 17$  years) with acute TBAD between 2013 and 2017. Out of 86 patients 26 were classified as complicated TBAD at the time of the event, based on organ/limb ischemia (n=20) or impending aortic rupture (n=4). 60 patients were classified as initially uTBAD at the time of the event. Baseline and follow-up CTs were reviewed by two cardiovascular radiologists (8 and 25 years of experience). Patients were reclassified according to the 2022 guideline into uTBAD and the new HR-uTBAD category, if at least one high-risk imaging feature was present. The rate of patients who could have been considered for intervention was compared to the actual intervention rate.

## **RESULTS**

Out of 60 patients originally classified as uTBAD, 48 demonstrated at least one HR imaging feature enumerated in the 2022 guideline at baseline (initial aortic diameter of  $>40$  mm, false lumen diameter  $>22$  mm, entry tear diameter  $>10$  mm, entry tear at the lesser aortic curvature, radiographic-only malperfusion, hemorrhagic pleural effusion), and additional 7 patients demonstrated a high-risk feature within 2 years (aortic growth  $>5$  mm in sequential imaging), resulting in a total of 55 HR-uTBAD out of the original 60 uTBAD. Within 2 years, only 15 of 60 uTBADs required intervention for late complications (12 with aortic growth, 2 with branch vessel occlusion, 1 with impending rupture). From 60 patients classified as HR uTBAD 40 had no late complications. If the presence of HR imaging features had been used to guide preemptive TEVAR in acute TBAD, the rate of interventions would have increased from 30% (cTBAD only) to 94% (cTBAD and HR-uTBAD).

## **CONCLUSION**

Applying the recently introduced "high-risk" subcategory of uTBAD in the updated 2022 guideline, more than 90% of all uTBADs would have qualified as HR-uTBAD and would be eligible for preemptive TEVAR, although secondary complications occurred in only 25% of patients.

## **CLINICAL RELEVANCE/APPLICATION**

This updated guideline will significantly influence cardiovascular radiologists and their reports with the potential need for structured reporting of HR features when diagnosing patients with acute TBAD.

## **S4-SSVA01-Quantification of Abdominal Aortic Aneurysm Strain Using MR Feature Tracking: Accuracy and Association with Progression Rate**

Huiming Dong, PhD (*Presenter*) Nothing to Disclose

## **PURPOSE**

Abdominal Aortic Aneurysm (AAA) management, primarily determined by maximum aneurysm diameter and growth rate, fails to preempt many catastrophic ruptures. Aortic wall strain may provide additional insight into risk of progression. MR feature tracking (FT) measures myocardial tissue strain from standard cine steady-state free precession (SSFP) MR images. This study aimed to (1) assess the accuracy of AAA wall circumferential strain by MR FT (MR Strain) using an in silico approach, and (2) investigate its relationship with recent AAA progression in patients under surveillance.

## **METHODS AND MATERIALS**

MR strain was measured using a work-in-progress FT software package. Accuracy of MR strain was assessed against the ground-truth strain in 54 synthetic cine MRIs created from finite element model (FEM) simulation of a patient's abdomen using a range of aortic pulse pressures, tissue motions, luminal signal intensity variations and image noise. Association of in vivo MR strain with progression was assessed in 25 consecutive AAA patients that had a prior MRI or CT study within  $>6$  months and  $\leq 2$  years from which maximum diameter (Dmax) growth rate was quantified. Pulse-gated cine bSSFP imaging was acquired at the level of the AAA and the normal caliber aorta, proximal to the aneurysm. Univariate and multivariate regression were used to associate growth rate with clinical variables, Dmax and peak circumferential MR strain across the cardiac cycle. Two independent readers measured MR strain to assess interoperator variability.

## **RESULTS**

In silico, bias and limits of agreement (LoA) of MR strain were  $0.48 \pm 0.42\%$ , with a correlation slope of 0.963 to ground-truth. In vivo, MR strain was significantly lower in AAA ( $1.2 \pm 0.6\%$ ) than the non-aneurysmal aorta ( $2.4 \pm 1.7\%$ ; Wilcoxon sign-rank test  $P < .001$ ). In univariate analyses Dmax (regression coefficient = 0.087,  $P < .001$ ) and peak strain (regression coefficient = -1.563,  $P < .001$ ) significantly associated with growth rate while diabetes, hypertension and current smoking nearly reached significance. MR strain remained an independent predictor of growth rate (regression coefficient = -0.904,

P=.014) after controlling for Dmax. MR strain was highly reproducible (bias±LoA: 0.03±0.31%, intraclass correlation coefficient: 97.8%, coefficient of variation: 7.14%).

#### **CONCLUSION**

MR feature tracking can reliably measure AAA wall circumferential strain and is associated with recent growth rate independent of aneurysm diameter.

#### **CLINICAL RELEVANCE/APPLICATION**

MR strain of AAA may reflect the underlying dynamic degenerative remodeling of elastin fibers and shifting of the mechanical load to the much stiffer collagen, offering improved AAA risk stratification.

### **S4-SSVA01-Predictors of Late Adverse Events in Patients with Surgically Managed Type I Aortic Dissection**

Hyejin Park (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate and find predictors of adverse events in patients with AD type I using early postoperative CT after ascending aorta replacement.

#### **METHODS AND MATERIALS**

From January 2011 to December 2017, 103 consecutive patients (55.43±13.94 years, men 49.5%) who underwent ascending aorta replacement due to AD type I and have available early postoperative CT within 3 months were included. Primary outcome was AD-related adverse events that defined as AD-related death and 2<sup>nd</sup> aorta operation due to AD associated aortic aneurysm or impending rupture. Secondary outcome was annual growth rate of the aorta. Postoperative CT exams were evaluated to determine the location and size of primary intimal tear, multi-level maximum diameter of the aorta, and false lumen status. Univariate and multivariable cox regression analyses were performed to find predictors that associated with AD-related adverse events.

#### **RESULTS**

Of all, 24 (23.3%) patients presented AD-related adverse events. Marfan syndrome, initial maximum diameter at multi-level of the aorta, and primary intimal tear size (=10 mm) were independently associated with adverse events in univariate cox regression analysis. In multivariable cox regression analysis, Marfan syndrome (HR [hazard ratio], 15.33; 95% confidence interval [CI], 5.37-43.74; P<0.001), maximal aorta diameter =40 mm (HR, 4.90; 95% CI, 1.93-12.40; P<0.001), and multiple intimal tears =3 (HR, 7.12; 95% CI, 2.68-18.92; P<0.001) were significant factors associated with AD-related adverse events.

#### **CONCLUSION**

Maximal aortic diameter ≥40 mm and multiple intimal tears on early postoperative CT will help to identify patients with high risk of adverse events in whom more aggressive management would be necessary.

#### **CLINICAL RELEVANCE/APPLICATION**

Early postoperative CT findings can identify patients with high risk of adverse events, and careful follow-up with preventive intervention can be considered in those with high risk findings.

### **S4-SSVA01-Recurrent Aortic Dissection: Imaging and Clinical Outcomes**

5

Apichaya Sriprachyakul, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To describe the frequency, risk factors, radiologic findings and clinical outcome of recurrent aortic dissection (AD) compared with initial aortic dissection.

#### **METHODS AND MATERIALS**

The initial CT angiograms and all follow-up imaging studies of 445 consecutive patients with acute aortic syndrome (AAS) were retrospectively reviewed by 2 cardiovascular radiologists, and patients with acute aortic dissection were identified. Follow-up CT angiograms were assessed to determine recurrent AD. The demographics and risk factors were collected. CT scans at initial and recurrent ADs were evaluated for involved aortic segment (same, different, or overlapping segments), involved lumen (true, false or both lumens), and aneurysm formation. Associations between radiologic findings and mortality were evaluated using chi-squared or Fisher exact tests. Mortality rate was calculated. Prognostic factors were analyzed by log-rank test and Cox proportional hazards modelling.

## RESULTS

We identified 276 initial ADs (196 men, mean age 60 years, range 23-95 years) and 24 recurrent ADs (20 men, mean age 55 years, range 23-81 years). Patients with recurrent AD were younger than patients experiencing a first AD (52±15 versus 60±15 years; P=0.008). The Marfan syndrome was significantly more common in recurrent AD (21% versus 7%; P=0.004). The recurrent AD involved the same (previously dissected) or a different (previously non-dissected) aortic segments in 43% and 39%, respectively. If a recurrent AD affected the same segment (n=10), the new dissection delaminated the already thinned, previously dissected outer wall of the false lumen in 6, and dissected the former true-lumen wall in 4. The involved aortic segment, involved lumen, and aneurysm formation in recurrent AD were not associated with mortality (P=0.679, 0.470, and 0.539 respectively). Patients with recurrent AD had a higher mortality rate at 1 year than in patients with initial AD (25.2% and 13.6%). Recurrent AD (HR =1.87; 95% CI 0.79-4.46; P=0.155) was positively associated with 1-year mortality but was not a statically significant predictor.

## CONCLUSION

Among patients with aortic dissection, 8 % present with recurrent AD. Recurrent AD is strongly associated with Marfan syndrome and younger age. Although a recurrent AD in the same segment can further delaminate an already thinned aortic wall, radiologic features were not significantly associated with mortality in this study. Recurrent AD was not significantly associated with early mortality.

## CLINICAL RELEVANCE/APPLICATION

Recurrent AD is considered a rare but grave late complication of AD, particularly if it affects a previously dissected aortic segment; early mortality is similar, however, most patients survive into their next chronic phase of the disease.

## S4-SSVA01-Clinical Evaluation of Non-contrast-Enhanced QISS Magnetic Resonance Angiography as Follow-up Examination Modality for the Evaluation of Aneurysms and Their Endoleaks After Abdominal Endovascular Aneurysm Repair

Karim Mostafa, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Clinical evaluation of non-contrast-enhanced QISS magnetic resonance angiography in its ability to diagnose and monitor endoleaks and aneurysm diameters after abdominal endovascular aneurysm repair (EVAR) in direct comparison to contrast-enhanced computed tomography angiography (CE-CTA).

## METHODS AND MATERIALS

Our study included 20 patients (17 male, median age 79.8 years) who underwent radial QISS-MRA and CE-CTA after non-fenestrated infrarenal EVAR at their first follow-up examination. Two radiologists evaluated datasets from both techniques for each patient concerning presence of endoleaks, types of endoleaks, aneurysm diameters and image quality.

## RESULTS

Compared to CE-CTA, all endoleaks after abdominal EVAR were detected and classified correctly on QISS-MRA. The interobserver agreement between CE-CTA and QISS-MRA was almost perfect, except for type 2 endoleaks, where agreement was substantial. Intermodal aneurysm diameter measurements correlate "very strongly" for both observers. All results were statistically significant. Hyperdense imaging artefacts in CE-CTA cause aneurysm diameter measurements to be inaccurate by up to 1 cm. These artifacts were not present in QISS-MRA. Also, QISS-MRA seems to be more sensitive in detecting type II endoleaks. Some type II endoleaks could only be detected in QISS-MRA but not in CE-CTA, which was most likely due to low-flow endoleak-characteristics.

## CONCLUSION

QISS-MRA is a contrast agent free technique for diagnosing and monitoring all types of endoleaks and aneurysms in patients after abdominal EVAR. It provides information about specific clinical questions concerning aneurysm size as well as presence and types of endoleaks without exposure to radiation and contrast agents.

## CLINICAL RELEVANCE/APPLICATION

After implantation of an aortic prosthesis, patients will undergo a contrast-enhanced CT examination to then be stratified to risk groups. For low- and intermediate risk patients, aneurysm monitoring is recommended with ultrasound. In cases where ultrasound is not feasible due to its known limitations, CT diagnostics will be necessary with the side effect of radiation and contrast media exposure. In this scenario, QISS magnetic resonance angiography constitutes a radiation- and contrast free imaging modality that can answer specific clinical questions concerning aneurysm diameter and presence of endoleaks. In all patients after EVAR, a follow-up CT examination is recommended five years after prosthesis implantation. Here, QISS magnetic resonance angiography can be implemented as well, as it can provide necessary information about the aneurysm and its endoleaks with the advantage of avoidance radiation and contrast media exposure.

### Deep Learning-Based Radiomics of CTA to Predict Adverse Events After Initial Endovascular Repair for Acute Uncomplicated Stanford Type B Aortic Dissection

Sunday, Nov. 26 1:00PM - 2:00PM Room: N226

Xuefang Lu, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Patients undergoing thoracic endovascular aortic repair (TEVAR) with acute uncomplicated Stanford type B aortic dissection (uTBAD) are associated with a high rate of postoperative adverse events (AE). To develop a prediction model using deep learning-based radiomics features of computed tomography angiography (CTA) and clinical features to predict AE of acute uTBAD after initial TEVAR.

#### METHODS AND MATERIALS

A retrospective study of 232 patients between January 2015 and January 2022 undergoing TEVAR with acute uTBAD was conducted. The three-dimensional (3D) deep convolutional neural network (CNN) was used to automatically recognize and segment CTA images and obtain the required general radiomic features. Analysis of Variance and the Least Absolute Shrinkage and Section Operation algorithms were implemented for feature selection and radiomics score building. The radiomics score (Rad-Score) and clinical factors were incorporated in a nomogram using the multivariable logistic regression analysis. The Hosmer-Lemeshow test was used to check the calibration of models. The Kaplan-Meier curve was used to stratify the risk of patients.

#### RESULTS

The Rad-Score incorporation with platelet and C-reactive protein showed moderate improvement in the efficiency with an AUC of 0.82 (95% CI, 0.74-0.89) in the training cohort and AUC of 0.72 (95% CI, 0.57-0.86) in inter-validation cohort. The specific performance of the combined model was shown AUC of 0.77(95%CI,0.66-0.88) in the independent validation cohort collected in 2020 and 2021, the accuracy of 0.72, precision of 0.65, sensitivity of 0.85, specificity of 0.62. The Hosmer-Lemeshow test was statistically significant in the combined model ( $t_{\text{training}}=0.15$ ,  $t_{\text{inter-validation}}=0.19$ ,  $t_{\text{independent validation}}=0.18$ ,  $p>0.05$ ). The Kaplan-Meier curve confirmed that patients with low-risk Rad-scores tended to have better survival.

#### CONCLUSION

The combination of deep learning-based radiomics of CTA and clinical indicators can predict AE after initial TEVAR in acute uTBAD patients. The nomogram was verified to be clinically useful. It is expected to provide early warning of patients' prognosis during follow-up examinations.

#### CLINICAL RELEVANCE/APPLICATION

The combination of image morphological and clinical indicators can predict acute uTBAD patients with high risk of AE after initial TEVAR. The Rad-Score incorporation with clinical factors with an AUC of 0.82 (95% CI, 0.74-0.89) in the training cohort, AUC of 0.72 (95% CI, 0.57-0.86) in the inter-validation cohort, and AUC of 0.77(95%CI,0.66-0.88) in the independent validation cohort. The nomogram was verified to be clinically useful. It is expected to provide early warning of patients' prognosis during follow-up examinations.

### Possible Impact of the Revised 2022 ACC Aha Aortic Disease Guideline on the Management of "High-Risk Uncomplicated" Type B Aortic Dissection

Sunday, Nov. 26 1:00PM - 2:00PM Room: N226

Malgorzata Polacin, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The role of preventive thoracic endovascular aortic repair (TEVAR) in patients with uncomplicated type B aortic dissection (uTBAD) is a matter of debate. The updated 2022 ACC/AHA aortic disease guideline acknowledges the existence of a "high-risk (HR)" subcategory of uTBAD, with the assignment of a class 2B consideration for TEVAR. We explore the frequency of HR imaging features in a retrospective cohort of patients with uTBAD and compare the actual frequency of interventions with the rate of interventions that could have been considered according to the updated 2022 guideline.

#### METHODS AND MATERIALS

We retrospectively analyzed 86 consecutive patients (mean age 49 ±17 years) with acute TBAD between 2013 and 2017. Out of 86 patients 26 were classified as complicated TBAD at the time of the event, based on organ/limb ischemia (n=20) or impending aortic rupture (n=4). 60 patients were classified as initially uTBAD at the time of the event. Baseline and follow-up CTs were reviewed by two cardiovascular radiologists (8 and 25 years of experience). Patients were reclassified according to the 2022 guideline into uTBAD and the new HR-uTBAD category, if at least one high-risk imaging feature was present. The rate of patients who could have been considered for intervention was compared to the actual intervention rate.

#### RESULTS

Out of 60 patients originally classified as uTBAD, 48 demonstrated at least one HR imaging feature enumerated in the 2022 guideline at baseline (initial aortic diameter of >40 mm, false lumen diameter >22 mm, entry tear diameter >10 mm, entry tear at the lesser aortic curvature, radiographic-only malperfusion, hemorrhagic pleural effusion), and additional 7 patients demonstrated a high-risk feature within 2 years (aortic growth >5 mm in sequential imaging), resulting in a total of 55 HR-uTBAD out of the original 60 uTBAD. Within 2 years, only 15 of 60 uTBADs required intervention for late complications (12 with aortic growth, 2 with branch vessel occlusion, 1 with impending rupture). From 60 patients classified as HR uTBAD 40 had no late complications. If the presence of HR imaging features had been used to guide preemptive TEVAR in acute TBAD, the rate of interventions would have increased from 30% (cTBAD only) to 94% (cTBAD and HR-uTBAD).

#### CONCLUSION

Applying the recently introduced "high-risk" subcategory of uTBAD in the updated 2022 guideline, more than 90% of all uTBADs would have qualified as HR-uTBAD and would be eligible for preemptive TEVAR, although secondary complications occurred in only 25% of patients.

#### CLINICAL RELEVANCE/APPLICATION

This updated guideline will significantly influence cardiovascular radiologists and their reports with the potential need for structured reporting of HR features when diagnosing patients with acute TBAD.

### Quantification of Abdominal Aortic Aneurysm Strain Using MR Feature Tracking: Accuracy and Association with Progression Rate

Sunday, Nov. 26 1:00PM - 2:00PM Room: N226

Huiming Dong, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Abdominal Aortic Aneurysm (AAA) management, primarily determined by maximum aneurysm diameter and growth rate, fails to preempt many catastrophic ruptures. Aortic wall strain may provide additional insight into risk of progression. MR feature tracking (FT) measures myocardial tissue strain from standard cine steady-state free precession (SSFP) MR images. This study aimed to (1) assess the accuracy of AAA wall circumferential strain by MR FT (MR Strain) using an in silico approach, and (2) investigate its relationship with recent AAA progression in patients under surveillance.

#### METHODS AND MATERIALS

MR strain was measured using a work-in-progress FT software package. Accuracy of MR strain was assessed against the ground-truth strain in 54 synthetic cine MRIs created from finite element model (FEM) simulation of a patient's abdomen using a range of aortic pulse pressures, tissue motions, luminal signal intensity variations and image noise. Association of in vivo MR strain with progression was assessed in 25 consecutive AAA patients that had a prior MRI or CT study within >6 months and ≤2 years from which maximum diameter (Dmax) growth rate was quantified. Pulse-gated cine bSSFP imaging was acquired at the level of the AAA and the normal caliber aorta, proximal to the aneurysm. Univariate and multivariate regression were used to associate growth rate with clinical variables, Dmax and peak circumferential MR strain across the cardiac cycle. Two independent readers measured MR strain to assess interoperator variability.

#### RESULTS

In silico, bias and limits of agreement (LoA) of MR strain were  $0.48 \pm 0.42\%$ , with a correlation slope of 0.963 to ground-truth. In vivo, MR strain was significantly lower in AAA ( $1.2 \pm 0.6\%$ ) than the non-aneurysmal aorta ( $2.4 \pm 1.7\%$ ; Wilcoxon sign-rank test  $P < .001$ ). In univariate analyses Dmax (regression coefficient = 0.087,  $P < .001$ ) and peak strain (regression coefficient = -1.563,  $P < .001$ ) significantly associated with growth rate while diabetes, hypertension and current smoking nearly reached significance. MR strain remained an independent predictor of growth rate (regression coefficient = -0.904,  $P = .014$ ) after controlling for Dmax. MR strain was highly reproducible (bias ± LoA:  $0.03 \pm 0.31\%$ , intraclass correlation coefficient: 97.8%, coefficient of variation: 7.14%).

#### CONCLUSION

MR feature tracking can reliably measure AAA wall circumferential strain and is associated with recent growth rate independent of aneurysm diameter.

#### CLINICAL RELEVANCE/APPLICATION

MR strain of AAA may reflect the underlying dynamic degenerative remodeling of elastin fibers and shifting of the mechanical load to the much stiffer collagen, offering improved AAA risk stratification.

### Predictors of Late Adverse Events in Patients with Surgically Managed Type I Aortic Dissection

Sunday, Nov. 26 1:00PM - 2:00PM Room: N226

Hyejin Park (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate and find predictors of adverse events in patients with AD type I using early postoperative CT after ascending aorta replacement.

#### **METHODS AND MATERIALS**

From January 2011 to December 2017, 103 consecutive patients ( $55.43 \pm 13.94$  years, men 49.5%) who underwent ascending aorta replacement due to AD type I and have available early postoperative CT within 3 months were included. Primary outcome was AD-related adverse events that defined as AD-related death and 2<sup>nd</sup> aorta operation due to AD associated aortic aneurysm or impending rupture. Secondary outcome was annual growth rate of the aorta. Postoperative CT exams were evaluated to determine the location and size of primary intimal tear, multi-level maximum diameter of the aorta, and false lumen status. Univariate and multivariable cox regression analyses were performed to find predictors that associated with AD-related adverse events.

#### **RESULTS**

Of all, 24 (23.3%) patients presented AD-related adverse events. Marfan syndrome, initial maximum diameter at multi-level of the aorta, and primary intimal tear size ( $=10$  mm) were independently associated with adverse events in univariate cox regression analysis. In multivariable cox regression analysis, Marfan syndrome (HR [hazard ratio], 15.33; 95% confidence interval [CI], 5.37-43.74;  $P < 0.001$ ), maximal aorta diameter  $\geq 40$  mm (HR, 4.90; 95% CI, 1.93-12.40;  $P < 0.001$ ), and multiple intimal tears  $\geq 3$  (HR, 7.12; 95% CI, 2.68-18.92;  $P < 0.001$ ) were significant factors associated with AD-related adverse events.

#### **CONCLUSION**

Maximal aortic diameter  $\geq 40$  mm and multiple intimal tears on early postoperative CT will help to identify patients with high risk of adverse events in whom more aggressive management would be necessary.

#### **CLINICAL RELEVANCE/APPLICATION**

Early postoperative CT findings can identify patients with high risk of adverse events, and careful follow-up with preventive intervention can be considered in those with high risk findings.

### Recurrent Aortic Dissection: Imaging and Clinical Outcomes

Sunday, Nov. 26 1:00PM - 2:00PM Room: N226

Apichaya Sriprachyakul, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To describe the frequency, risk factors, radiologic findings and clinical outcome of recurrent aortic dissection (AD) compared with initial aortic dissection.

#### METHODS AND MATERIALS

The initial CT angiograms and all follow-up imaging studies of 445 consecutive patients with acute aortic syndrome (AAS) were retrospectively reviewed by 2 cardiovascular radiologists, and patients with acute aortic dissection were identified. Follow-up CT angiograms were assessed to determine recurrent AD. The demographics and risk factors were collected. CT scans at initial and recurrent ADs were evaluated for involved aortic segment (same, different, or overlapping segments), involved lumen (true, false or both lumens), and aneurysm formation. Associations between radiologic findings and mortality were evaluated using chi-squared or Fisher exact tests. Mortality rate was calculated. Prognostic factors were analyzed by log-rank test and Cox proportional hazards modelling.

#### RESULTS

We identified 276 initial ADs (196 men, mean age 60 years, range 23-95 years) and 24 recurrent ADs (20 men, mean age 55 years, range 23-81 years). Patients with recurrent AD were younger than patients experiencing a first AD ( $52 \pm 15$  versus  $60 \pm 15$  years;  $P=0.008$ ). The Marfan syndrome was significantly more common in recurrent AD (21% versus 7%;  $P=0.004$ ). The recurrent AD involved the same (previously dissected) or a different (previously non-dissected) aortic segments in 43% and 39%, respectively. If a recurrent AD affected the same segment ( $n=10$ ), the new dissection delaminated the already thinned, previously dissected outer wall of the false lumen in 6, and dissected the former true-lumen wall in 4. The involved aortic segment, involved lumen, and aneurysm formation in recurrent AD were not associated with mortality ( $P=0.679$ , 0.470, and 0.539 respectively). Patients with recurrent AD had a higher mortality rate at 1 year than in patients with initial AD (25.2% and 13.6%). Recurrent AD (HR =1.87; 95% CI 0.79-4.46;  $P=0.155$ ) was positively associated with 1-year mortality but was not a statically significant predictor.

#### CONCLUSION

Among patients with aortic dissection, 8 % present with recurrent AD. Recurrent AD is strongly associated with Marfan syndrome and younger age. Although a recurrent AD in the same segment can further delaminate an already thinned aortic wall, radiologic features were not significantly associated with mortality in this study. Recurrent AD was not significantly associated with early mortality.

#### CLINICAL RELEVANCE/APPLICATION

Recurrent AD is considered a rare but grave late complication of AD, particularly if it affects a previously dissected aortic segment; early mortality is similar, however, most patients survive into their next chronic phase of the disease.

### **Clinical Evaluation of Non-contrast-Enhanced QISS Magnetic Resonance Angiography as Follow-up Examination Modality for the Evaluation of Aneurysms and Their Endoleaks After Abdominal Endovascular Aneurysm Repair**

Sunday, Nov. 26 1:00PM - 2:00PM Room: N226

Karim Mostafa, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Clinical evaluation of non-contrast-enhanced QISS magnetic resonance angiography in its ability to diagnose and monitor endoleaks and aneurysm diameters after abdominal endovascular aneurysm repair (EVAR) in direct comparison to contrast-enhanced computed tomography angiography (CE-CTA).

#### **METHODS AND MATERIALS**

Our study included 20 patients (17 male, median age 79.8 years) who underwent radial QISS-MRA and CE-CTA after non-fenestrated infrarenal EVAR at their first follow-up examination. Two radiologists evaluated datasets from both techniques for each patient concerning presence of endoleaks, types of endoleaks, aneurysm diameters and image quality.

#### **RESULTS**

Compared to CE-CTA, all endoleaks after abdominal EVAR were detected and classified correctly on QISS-MRA. The interobserver agreement between CE-CTA and QISS-MRA was almost perfect, except for type 2 endoleaks, where agreement was substantial. Intermodal aneurysm diameter measurements correlate "very strongly" for both observers. All results were statistically significant. Hyperdense imaging artefacts in CE-CTA cause aneurysm diameter measurements to be inaccurate by up to 1 cm. These artifacts were not present in QISS-MRA. Also, QISS-MRA seems to be more sensitive in detecting type II endoleaks. Some type II endoleaks could only be detected in QISS-MRA but not in CE-CTA, which was most likely due to low-flow endoleak-characteristics.

#### **CONCLUSION**

QISS-MRA is a contrast agent free technique for diagnosing and monitoring all types of endoleaks and aneurysms in patients after abdominal EVAR. It provides information about specific clinical questions concerning aneurysm size as well as presence and types of endoleaks without exposure to radiation and contrast agents.

#### **CLINICAL RELEVANCE/APPLICATION**

After implantation of an aortic prosthesis, patients will undergo a contrast-enhanced CT examination to then be stratified to risk groups. For low- and intermediate risk patients, aneurysm monitoring is recommended with ultrasound. In cases where ultrasound is not feasible due to its known limitations, CT diagnostics will be necessary with the side effect of radiation and contrast media exposure. In this scenario, QISS magnetic resonance angiography constitutes a radiation- and contrast free imaging modality that can answer specific clinical questions concerning aneurysm diameter and presence of endoleaks. In all patients after EVAR, a follow-up CT examination is recommended five years after prosthesis implantation. Here, QISS magnetic resonance angiography can be implemented as well, as it can provide necessary information about the aneurysm and its endoleaks with the advantage of avoidance radiation and contrast media exposure.

Sunday, Nov. 26 1:00PM - 1:30PM Room: Learning Center Theater 1

#### Sub-Events

### S4-STCE1-1 A Variety Driven Generative Model for Binary Classifications in Radiological Imaging

Dong Ni, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Despite the potential benefits of using data augmentation for alleviating data insufficiency, traditional augmentation methods make decision boundary ambiguous. On the other hand, the quality of generated images remains uncertain, particularly in small-scale datasets. We developed a novel generative model effectively controlling the changes of generated images in cross-domain and inner-domain. If further validated, this generative model could have great clinical utility in limited annotated radiological datasets.

#### METHODS AND MATERIALS

A generative model enabling parameterized data projection is developed to online augment the training data. We use vertical and horizontal projection to generate cross-domain and inner-domain images respectively. The target images' projection distances are measured so that the parameterized generators learn to control the degree of variation while translating the source images in the forward pass. An auxiliary pre-trained classifier using hinge loss constructs a hyperplane to guide the projections. The source images' projection distance is also considered as the specified controllable parameter in the backward reconstruction pass. We mix two public ultrasound datasets for benign and malignant breast lesion classification and use a public CT dataset for non-COVID-19 and COVID-19 classification. The data split for breast ultrasound is set as 598(train), 106 (validation) and 106 (test), and for covid-19 detection is as 425(train), 118 (validation) and 203 (test). All training data is pre-augmented by horizontal flip.

#### RESULTS

The proposed generative model improved the generalization ability of the downstream classifiers. For the breast lesion classification, the AUC score increased by 0.026(AlexNet), 0.035(VGG13), 0.028(VGG16), 0.040(GoogleNet), 0.017(ResNet18), 0.009(ResNet34), 0.045(DenseNet121), 0.052(MobileNet V3), 0.023(Convnext) and decreased by -0.04(EfficientNet B5). For the covid-19 detection, the AUC score increased by 0.038 (AlexNet), 0.027(VGG16), 0.028(GoogleNet), 0.088(ResNet18), 0.094(ResNet34), 0.039(DenseNet121), 0.012(MobileNet V3), 0.006(EfficientNet B5), 0.019(Convnext) and decreased by -0.003(VGG13).

#### CONCLUSION

We showcase the effectiveness of parameterized data projection embedded in generators for generating images to improve the various downstream binary classifiers. We observe that enabling the control of the variety of generated data has more impact than blindly increasing the number of training data.

#### CLINICAL RELEVANCE/APPLICATION

The proposed generative model has the potential to alleviate training data insufficiency in clinical application. This is especially true in the medical field because of the data privacy issue and labeling cost.

### S4-STCE1-2 GPT language models for automated synoptic reporting and determination of resectability in pancreatic cancer

Rajesh Bhayana, MD, FRCPC (*Presenter*) Nothing to Disclose

#### PURPOSE

Structured radiology reports for pancreatic ductal adenocarcinoma (PDAC) staging are superior to free-text reports for surgical planning, but radiologist adoption is variable. The purpose of this study is to assess the accuracy of foundational GPT

language models in extracting key information from PDAC staging free-text reports to create synoptic reports, and to explore their ability to apply National Comprehensive Cancer Network (NCCN) criteria to determine tumor resectability.

## **METHODS AND MATERIALS**

In this IRB-approved retrospective study in progress, 100 consecutive initial PDAC staging CT free-text reports of patients referred to a quaternary care pancreatic cancer centre in 2018 were included. With few-shot prompting, GPT language models (GPT-3.5-turbo, GPT-4) were given free-text reports to create synoptic reports with 14 key parameters, including: tumor location, size, duct dilatation, status of major vessels, arterial variant anatomy, lymph nodes and metastases. Using the synoptic report, separately tuned models were prompted with a few-shot approach to classify the tumor as resectable, borderline resectable, locally advanced (unresectable), or metastatic (unresectable) using NCCN criteria. Synoptic reports were assessed for accuracy in data extraction overall and for each of the 14 parameters, along with classification of resectability.

## **RESULTS**

100 free-text PDAC staging CT reports were included. GPT-3.5 was 96.5% accurate in extracting key parameters into synoptic reports (1351 of 1400). It demonstrated near perfect or perfect accuracy in extracting tumor location (98%), size (98%), pancreatic duct dilatation (99%), biliary dilatation (97%), lymph nodes (99%), and metastases (98%); along with celiac artery (98%), common hepatic artery (100%), and aortic (100%) status. GPT-3.5 was less accurate at extracting superior mesenteric artery (92%) and venous (92%) status. GPT-3.5 correctly classified tumor resectability in 71% of cases (71 of 100). GPT-4 results and assessment of surgeon report preference are pending.

## **CONCLUSION**

With few-shot prompting, foundational GPT language models demonstrate impressive accuracy in extracting key parameters from free-text pancreatic cancer staging reports into synoptic reports. On the more advanced task of resectability determination, GPT-3.5 was less accurate.

## **CLINICAL RELEVANCE/APPLICATION**

Accurate automated synoptic reports derived from free-text pancreatic cancer staging reports would improve surgical planning by improving accessibility of key information. They could also save radiologists time and benefit researchers. More advanced and task-specific fine-tuned models may further improve classification of resectability, which could aid clinical decision making.

## **S4-STCE1-3 RoentGen: Vision-Language Model for text-guided Chest X-Ray Generation**

Christian A. Bluethgen, MD, MSc (*Presenter*) Nothing to Disclose

## **PURPOSE**

1) To generate synthetic chest x-rays (CXR) based on radiological text reports by adapting a generative latent denoising diffusion probabilistic model and a transformer-based text encoder to the radiology domain. 2) To establish an evaluation framework for text-conditioned synthesis of CXR. 3) To evaluate the added value of synthetic CXR for training deep learning (DL) models for radiological downstream tasks.

## **METHODS AND MATERIALS**

A large public dataset of 337k real CXR and corresponding radiology text reports (MIMIC-CXR) was used to fine-tune a denoising diffusion probabilistic model (Stable Diffusion, SD). The model's U-Net component and the model's transformer-based text-encoder (CLIP/ViT-L14) were fine-tuned alone or jointly. The evaluation framework consisted of multiple steps: 1) human evaluation by two board-certified radiologists for image quality and text-image alignment; 2) quantitative image assessment in the form of Frechet inception distance (FID) and MS-SSIM as measures of fidelity and generative diversity, respectively; 3) multi-label classification performance of classifiers trained on real CXR. Finally, synthetic CXR were used to train multilabel classification models.

## **RESULTS**

As confirmed by radiologists and quantitative metrics, the adapted model can synthesize high-quality artificial CXR whose appearance follows radiological text prompts (e.g., "large left-sided pleural effusion"). Quantitatively, synthetic CXR improved over a previous baseline in a few-shot setting in terms of fidelity (FID of 3.6 vs. 19.5 baseline), diversity (MS-SSIM of  $0.14 \pm 0.06$  vs.  $0.28 \pm 0.07$  baseline), classification performance (avg. AUC 0.81 vs. 0.61 baseline). Using synthetic CXR to train classification models slightly decreased in-distribution performance compared to training on real CXR (up to -3%) but improved performance in two out-of-distribution datasets (Chexpert, VinDr-CXR) by up to 5%.

## **CONCLUSION**

Domain adaptation of a large-scale pretrained text-to-image generative models for the creation of synthetic CXR is possible. The resulting CXR convey radiological concepts with high fidelity as established by the proposed evaluation framework, and may improve generalization performance of deep learning models.

## **CLINICAL RELEVANCE/APPLICATION**

Text-conditioned synthesis of CXR allows the creation of tailored training data, which could help in the context of data sharing (to mitigate privacy concerns) and could help to mitigate class imbalances (e.g., when training models for diseases with low prevalences or in the context of heavily biased data). An immediate clinical application is the education of medical students and residents, as synthetic CXR capture radiological concepts with high fidelity.

For the covid-19 detection, the AUC score increased by 0.038 (AlexNet), 0.027(VGG16), 0.028(GoogleNet), 0.088(ResNet18), 0.094(ResNet34), 0.039(DenseNet121), 0.012(MobileNet V3), 0.006(EfficientNet B5), 0.019(Convnext) and decreased by -0.003(VGG13).

#### CONCLUSION

We showcase the effectiveness of parameterized data projection embedded in generators for generating images to improve the various downstream binary classifiers. We observe that enabling the control of the variety of generated data has more impact than blindly increasing the number of training data.

#### CLINICAL RELEVANCE/APPLICATION

The proposed generative model has the potential to alleviate training data insufficiency in clinical application. This is especially true in the medical field because of the data privacy issue and labeling cost.

### **GPT language models for automated synoptic reporting and determination of resectability in pancreatic cancer**

Sunday, Nov. 26 1:00PM - 1:30PM Room: Learning Center Theater 1

Rajesh Bhayana, MD, FRCPC (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Structured radiology reports for pancreatic ductal adenocarcinoma (PDAC) staging are superior to free-text reports for surgical planning, but radiologist adoption is variable. The purpose of this study is to assess the accuracy of foundational GPT language models in extracting key information from PDAC staging free-text reports to create synoptic reports, and to explore their ability to apply National Comprehensive Cancer Network (NCCN) criteria to determine tumor resectability.

#### **METHODS AND MATERIALS**

In this IRB-approved retrospective study in progress, 100 consecutive initial PDAC staging CT free-text reports of patients referred to a quaternary care pancreatic cancer centre in 2018 were included. With few-shot prompting, GPT language models (GPT-3.5-turbo, GPT-4) were given free-text reports to create synoptic reports with 14 key parameters, including: tumor location, size, duct dilatation, status of major vessels, arterial variant anatomy, lymph nodes and metastases. Using the synoptic report, separately tuned models were prompted with a few-shot approach to classify the tumor as resectable, borderline resectable, locally advanced (unresectable), or metastatic (unresectable) using NCCN criteria. Synoptic reports were assessed for accuracy in data extraction overall and for each of the 14 parameters, along with classification of resectability.

#### **RESULTS**

100 free-text PDAC staging CT reports were included. GPT-3.5 was 96.5% accurate in extracting key parameters into synoptic reports (1351 of 1400). It demonstrated near perfect or perfect accuracy in extracting tumor location (98%), size (98%), pancreatic duct dilatation (99%), biliary dilatation (97%), lymph nodes (99%), and metastases (98%); along with celiac artery (98%), common hepatic artery (100%), and aortic (100%) status. GPT-3.5 was less accurate at extracting superior mesenteric artery (92%) and venous (92%) status. GPT-3.5 correctly classified tumor resectability in 71% of cases (71 of 100). GPT-4 results and assessment of surgeon report preference are pending.

#### **CONCLUSION**

With few-shot prompting, foundational GPT language models demonstrate impressive accuracy in extracting key parameters from free-text pancreatic cancer staging reports into synoptic reports. On the more advanced task of resectability determination, GPT-3.5 was less accurate.

#### **CLINICAL RELEVANCE/APPLICATION**

Accurate automated synoptic reports derived from free-text pancreatic cancer staging reports would improve surgical planning by improving accessibility of key information. They could also save radiologists time and benefit researchers. More advanced and task-specific fine-tuned models may further improve classification of resectability, which could aid clinical decision making.

### RoentGen: Vision-Language Model for text-guided Chest X-Ray Generation

Sunday, Nov. 26 1:00PM - 1:30PM Room: Learning Center Theater 1

Christian A. Bluethgen, MD, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

1) To generate synthetic chest x-rays (CXR) based on radiological text reports by adapting a generative latent denoising diffusion probabilistic model and a transformer-based text encoder to the radiology domain. 2) To establish an evaluation framework for text-conditioned synthesis of CXR. 3) To evaluate the added value of synthetic CXR for training deep learning (DL) models for radiological downstream tasks.

#### METHODS AND MATERIALS

A large public dataset of 337k real CXR and corresponding radiology text reports (MIMIC-CXR) was used to fine-tune a denoising diffusion probabilistic model (Stable Diffusion, SD). The model's U-Net component and the model's transformer-based text-encoder (CLIP/ViT-L14) were fine-tuned alone or jointly. The evaluation framework consisted of multiple steps: 1) human evaluation by two board-certified radiologists for image quality and text-image alignment; 2) quantitative image assessment in the form of Frechet inception distance (FID) and MS-SSIM as measures of fidelity and generative diversity, respectively; 3) multi-label classification performance of classifiers trained on real CXR. Finally, synthetic CXR were used to train multilabel classification models.

#### RESULTS

As confirmed by radiologists and quantitative metrics, the adapted model can synthesize high-quality artificial CXR whose appearance follows radiological text prompts (e.g., "large left-sided pleural effusion"). Quantitatively, synthetic CXR improved over a previous baseline in a few-shot setting in terms of fidelity (FID of 3.6 vs. 19.5 baseline), diversity (MS-SSIM of  $0.14 \pm 0.06$  vs.  $0.28 \pm 0.07$  baseline), classification performance (avg. AUC 0.81 vs. 0.61 baseline). Using synthetic CXR to train classification models slightly decreased in-distribution performance compared to training on real CXR (up to -3%) but improved performance in two out-of-distribution datasets (Chexpert, VinDr-CXR) by up to 5%.

#### CONCLUSION

Domain adaptation of a large-scale pretrained text-to-image generative models for the creation of synthetic CXR is possible. The resulting CXR convey radiological concepts with high fidelity as established by the proposed evaluation framework, and may improve generalization performance of deep learning models.

#### CLINICAL RELEVANCE/APPLICATION

Text-conditioned synthesis of CXR allows the creation of tailored training data, which could help in the context of data sharing (to mitigate privacy concerns) and could help to mitigate class imbalances (e.g., when training models for diseases with low prevalences or in the context of heavily biased data). An immediate clinical application is the education of medical students and residents, as synthetic CXR capture radiological concepts with high fidelity.

S4-STCE2

### Science Session (Theranostics)

Sunday, Nov. 26 1:00PM - 1:30PM Room: Learning Center Theater 2

#### Sub-Events

#### **S4-STCE2-1 Impact of pre- and post-contrast-enhanced MR-based attenuation correction on tracer quantification in malignant lesions in 68Ga-DOTATOC PET/MRI**

Aleksandar Milosevic, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Peptide Receptor Radionuclide Therapy (PRRT) is an established treatment concept in patients with neuroendocrine tumors (NET). Therefore, PETCT and PET/MRI imaging with 68Ga-DOTATOC is an important tool for initial receptor status assessment and treatment monitoring. As MR-based attenuation correction (MRAC) can be influenced by gadolinium-based contrast agents (CA), the purpose of the present study was to quantify the effects of CA administration on MRAC in the evaluation of target lesions in 68Ga-DOTATOC PET/MRI.

#### **METHODS AND MATERIALS**

Twenty-four NET patients with tumor lesions underwent whole-body 68Ga DOTATOC PET/MRI for staging purposes. According to a consensus reading, 72 target lesions (primaries and metastases) were selected for measurement of standardized uptake values (SUVmax, SUVpeak, SUVmean). High-resolution CAIPI-accelerated Dixon 3D VIBE sequences with bone atlas and truncation correction using HUGE method (B0 homogenization with gradient enhancement) were acquired before and after CA administration. PET data were subsequently reconstructed using both resulting  $\mu$ maps (MRACnative and MRACpostCA). Each target lesion was measured in both versions of MRAC-PET utilizing a volume of interest (VOI). Measured values were compared using the Pearson Correlation Coefficient. In addition, a Bland-Altman-analysis was performed to determine the limits of agreement (LOA).

#### **RESULTS**

A strong correlation was achieved for the SUV values before and after contrast medium administration (SUVmax. 0.99; SUVpeak. 0.997; SUVmean. 0.993;  $p < 0,001$ ). While Bland-Altman-analysis showed acceptable LOAs for SUVpeak (1.7 and -2.1), and SUVmean (1.8 and -2.2), wide LOAs for SUVmax (4.5 and -4.7) could be observed.

#### **CONCLUSION**

Certain deviations between the measured values in pre- and post-contrast attenuation-corrected corrected PET-images may occur due to the application of a gadolinium-based CAs.

#### **CLINICAL RELEVANCE/APPLICATION**

As the administration of CA can influence MRAC, special attention should be paid to the timepoint of CA administration in patients requiring 68Ga DOTATOC PET/MRI for treatment monitoring of PRRT.

#### **S4-STCE2-2 Assessment of Myocardial Viability in the Subacute Phase of Myocardial Infarction: A Comparative Study of Native T1, T2 Mapping, and Strain Analysis with Late Gadolinium Enhancement**

Ali Mohammadzadeh Koupareh, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study aims to evaluate the potential of myocardial strain, T1, and T2 mapping as non-contrast-based methods for assessing myocardial damage extent and distinguishing viable from non-viable myocardium in the subacute phase of myocardial infarction.

## **METHODS AND MATERIALS**

Forty-three patients (mean age  $56.05 \pm 10$  years, 86% male) and eight sex and age-matched healthy volunteers underwent 1.5 T CMR with a viability protocol. Global myocardial strain parameters, including global longitudinal strain (GLS), global radial strain (GRS), and global circumferential strain (GCS), were measured and compared between the patient and control groups. Additionally, global T1 and T2 values were compared between the two groups. The segmental strain values and T1/T2 mapping were assessed in viable and non-viable myocardium, with late gadolinium enhancement (LGE) serving as the gold standard for viability assessment.

## **RESULTS**

GCS demonstrated the highest diagnostic accuracy (AUC 0.827,  $p < 0.001$ , 95%CI 0.792-0.861) in differentiating viable from non-viable myocardium among segmental parameters. A GCS cut-off of -8.809 enabled the differentiation of viable and non-viable segments with 81% sensitivity and 71% specificity.

## **CONCLUSION**

This findings suggest that strain, T1, and T2 mapping can be an effective non-contrast-based methods for assessing myocardial viability, with significant differences observed in parametric values between viable and non-viable segments. Moreover, the significant correlations between global values and enhanced/grey zone size support their potential use for viability assessment without the need for gadolinium contrast agents.

## **CLINICAL RELEVANCE/APPLICATION**

Determining viable from non viable myocardium is important in clinical decision making, if we can assess it through non invasive imaging it can help in patient management and treatment planning.

## **S4-STCE2-3 Machine Learning-based Prediction of Ventricular Function, Myocardial T2 star, and Liver Parameters in Thalassemia Patients using MRI Images**

Ali Mohammadzadeh Koupareh, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

In this study we introduce a method that could predict iron cardiomyopathy in thalassemia major patients. This situation is preventable, but delayed diagnosis may lead to grim prognosis. We want to predict left ventricular function, myocardial and liver T2 star in thalassemia major patients using machine learning methods based on MRI images. This can enhance our capability in diagnosis, treatment and preventing iron overload cardiomyopathy. This research has implications for early intervention and better management of thalassemia-associated cardiac complications.

## **METHODS AND MATERIALS**

We studied 300 thalassemia major patients who underwent cardiac MR imaging to assess cardiac status. The inclusion criteria were; patients with a left ventricular ejection fraction (LVEF) greater than 55%, cardiac iron deposition (T2 star) less than 20 ms, and liver deposition (T2 star) less than 11.4 ms based on CMR. valvular heart problems, congenital heart diseases, infectious diseases, hypertension, liver failure, diabetes, kidney diseases, and those using medications affecting myocardial function were excluded. after 18-month, CMR was repeated, and individuals with LVEF<55%, heart T2 star<20 ms, and liver T2 star<11.4 ms were selected for comparative analysis. three feature selection methods (LASSO, MRMR, and NCA) and also seven different classifiers were used for predictive modeling.

## **RESULTS**

495 radiomics features were extracted separately for end systole and end diastole from the images. Additionally, a set of features for the liver, as well as a combined set of features for end systole, diastole, and liver, along with clinical features such as age and gender, were utilized for feature selection and modeling. Among these, features based on GLCM (Gray level co matrix), as haaralick and tamura features, showed significant difference among groups who had decline in cardiac function and those who had not.

## **CONCLUSION**

This study showcases the capabilities of machine learning methods in risk stratifying of iron overload in thalassemia major patients by MRI images.

## **CLINICAL RELEVANCE/APPLICATION**

By predicting those patients who are at greater risk of developing iron overload cardiomyopathy, more aggressive treatment can delay cardiomyopathy and improve patient survival.

Janice S. Sung, MD (*Moderator*) Research Grant, General Electric Company

#### Sub-Events

### S5-SSBR02-Role of Contrast-Enhanced Mammography (CEM) In the Assessment of the Outcome of Cryoablation Following One Year of Treatment<sup>1</sup>

Federica Di Naro, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the efficacy of ultrasound-guided cryoablation (UGC) of low-risk early-stage breast cancer, combining CEM and re-evaluation with biopsy.

#### METHODS AND MATERIALS

UGC was performed at our center on 28 biopsy-proven malignant lesions of 28 patients (mean age 73.4 years old) held inoperable by a multidisciplinary group, under hormone therapy. All the lesions were ultrasound-visible invasive ductal carcinoma (<30 mm), low to intermediate grade, HR-positive, HER2-negative. Each patient underwent Contrast Enhanced Mammography (CEM) staging to confirm the unifocality. Patients were subdivided according to molecular subtype, Ki67% and 1 cm dimensional cut-off. The outcome of UGC was analyzed assessing the size reduction rate (RR) with US, at 1, 3 and 6 months and with CEM and biopsy at 12 months. Samples were collected in the outer and core zones of the site. Our gold standard was the histology result. Fisher test and chi-square test were applied.

#### RESULTS

28 lesions had a mean RR of 20.1%, 66.4% and 94% at 1, 3 and 6 months respectively. Hyperechoic procedural scarrings were visible without any US recognizable trace of the index lesion in 13/28 after 3 months, and in 25/28 after 6 months. 14 were Luminal-A (Lum-A) and 14 Luminal B Her-2 negative (Lum-B): after 1 month, mean (RR) was similar for both subtypes (21.6% Lum-A, 19.8% Lum-B), after 3 months RR was higher for Lum-A (70.2%) versus 60.7% of Lum-B and after 6 months it was 96.8% for Lum-A and 93.4% for Lum-B. 24/28 were BC>1 cm and 4/28 we BC<1 cm: after 1 month RR was 19.7% for BC>1 cm and 23% for BC<1 cm, after 3 months RR was higher for BC<1 cm (84.4%) versus BC>1 cm (63.4%); after 6 months it was 100% for BC<1 cm and 93% for BC>1 cm. Furthermore, after 1 month RR for BC with Ki67<20% was 24.6% and 18.8% for BC with Ki67>20%. After 3 months it was 62.8% for BC with Ki67>20% and 65.3% for Ki67<20%. At 6 months, RR was 96.5% for BC with Ki67>20% and 93.4% for Ki67<20%. Any statistical significant difference emerged. At 12 months, all 28 patients underwent CEM. In 26 cases, no enhancement was detectable, in 2/28 enhancement was found (mainly as mass). In these cases, biopsy confirmed residual traces of B5 lesions only in the core zone of the scarring site, corresponding perfectly to CEM results. In all the negative CEM cases, biopsy reported only benign lesions (flogosis).

#### CONCLUSION

CEM findings perfectly matched the histology results, indeed enhancing masses were detected only where histology reported traces of B5 lesions. UGC is a safe, feasible and effective and CEM is a necessary useful and reliable exam in the follow up.

#### CLINICAL RELEVANCE/APPLICATION

Combining CEM and re-evaluation with biopsy, in selected histology of breast cancer, proved the efficacy of the UGC and the reliability of CEM as an essential useful annual follow-up exam

### S5-SSBR02-Factors Influencing False Positive Recall Rates on Contrast-Enhanced Mammography (CEM)<sup>2</sup>

Wendie A. Berg, MD, PhD (*Presenter*) Institutional Research Grant, Koios Medical, Inc

## PURPOSE

Breast density increases recalls on mammography as does background parenchymal enhancement (BPE) on MRI. We sought to evaluate impact of breast density, BPE, menopausal status, prior radiation therapy (XRT), and use of tamoxifen or aromatase inhibitors, on false-positive recall (FPR) rates on contrast-enhanced mammography (CEM).

## METHODS AND MATERIALS

From two ongoing IRB-approved studies of screening CEM, we evaluated false-positive recall rates by breast for prevalence screening CEM for exams completed through 12/31/2022. We prospectively recorded menopausal status [more than 1 year since last menstrual period (LMP) or bilateral oophorectomy; or date of LMP]; prior XRT; current endocrine therapy; visual BI-RADS density; and BPE (minimal, mild, moderate, marked). We considered each of two prospective specialist radiologist interpretations. We examined FPR rates as a function of each of these factors in bivariate analysis and then in a logistic regression model, and we report odds ratios [OR, (95%CI)] for FPR.

## RESULTS

Women ranged in age from 31 to 85 years and, overall, there were 7070 interpretations of 3535 breasts, including 555/7070 (7.9%) false-positives. Of the 7070 breast interpretations, 55 (0.8%) were in fatty breasts; 2630 (37.2%) scattered fibroglandular tissue; 4172 (59.0%) heterogeneously dense; and 213 (3.0%) extremely dense. Binarized as dense or not dense, in bivariate analysis the OR for FPR was 1.56 (1.29,1.89) for women with dense compared to non-dense breasts. Of the 7070 breast interpretations, BPE was minimal in 3804 (53.8%), mild in 2416 (34.2%), moderate in 731 (10.3%), and marked in 119 (1.7%); 1116 (15.8%) were in premenopausal women and 5954 (84.2%) postmenopausal; 1010 (14.3%) were in women taking endocrine therapy and 2166 (30.6%) were in breasts with prior XRT. Spearman's correlation of BPE with density was 0.36. With minimal BPE as referent, for mild BPE, OR was 1.74 (1.41,2.13); for moderate BPE, OR was 2.48 (1.85,3.33); for marked BPE, OR was 2.16 (1.18,3.75); and density was not independently significant, with OR 1.17 (0.95,1.44). Premenopausal status increased risk of FPR with OR 1.30 (1.03,1.65) and endocrine therapy tended to reduce FPR, OR 0.77 (0.58,1.02). Prior XRT did not affect FPR [OR1.14 (0.92,1.39)].

## CONCLUSION

The lowest FPR rates were seen in postmenopausal women with minimal BPE at 5.1% (180/3564) and highest at 16.7% (62/371) in premenopausal women with moderate-marked BPE.

## CLINICAL RELEVANCE/APPLICATION

Understanding the greater potential for false-positive recalls in premenopausal women with elevated BPE may help reduce such recalls and increase the net benefit of screening CEM.

## S5-SSBR02-Diagnostic Performance of Contrast-Enhanced Mammography for Varying Levels of Background Parenchymal Enhancement

Sarah Eskreis-Winkler, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Contrast-enhanced mammography (CEM) is increasingly used for breast cancer screening in the intermediate risk population but its diagnostic performance for varying levels of background parenchymal enhancement (BPE) has not yet been characterized. Herein, we compare CEM performance across the four BPE assessment categories.

## METHODS AND MATERIALS

In this IRB-approved HIPAA-compliant study, screening CEMs performed at our institution from 2013-2022 were retrospectively reviewed. Exams were excluded if they lacked standardized BPE assessments or lacked 12 month follow up. CEM was performed with dual-energy mammography, with imaging initiated 2-2.5 min after contrast injection. Standard performance metrics, including cancer detection rate (CDR), interval cancer rate (IC) and positive predictive value of biopsy (PPV3) were calculated for all patients, and for each BPE category. Metrics for high BPE (marked or moderate) were compared to low BPE (mild or minimal). For all comparisons, a two-tailed two-proportion Z-test was calculated.

## RESULTS

A total of 2938 screening CEDMs were included in the analysis. There were 1,005 (34%) minimal BPE, 1285 (44%) mild BPE, 491 (17%) moderate BPE, and 61 (2%) marked BPE exams. CDR was not statistically significantly different between high and low BPE (7.1 per 1000 v. 3.5 per 1000;  $p = 0.24$ ). PPV3 (33.3% v. 21.2%;  $p = 0.4$ ) and IC (5.3 per 1,000 v. 2.2 per 1,000;  $p=0.4$ ) were also not significantly different. However, both CDR and PPV showed an increasing trend from minimal to mild to moderate BPE. The pattern dropped off for marked BPE, possibly due to the small number of cases ( $n=61$ ).

## CONCLUSION

There is no statistically significant difference in the performance of CEM with increasing BPE. In fact, a trend of increasing CDR and PPV were observed from minimal to moderate BPE, possibly related to an intrinsic increase in risk, and further evaluation is warranted with a larger dataset.

## CLINICAL RELEVANCE/APPLICATION

CEM is increasingly used as a breast cancer screening tool in intermediate risk women, but its performance across BPE subtypes has not yet been evaluated. Despite concerns that high levels of BPE may mask cancer, this evaluation finds no statistically significant differences in performance across BPE categories, although further evaluation is warranted with a larger dataset.

### S5-SSBR02-Quantitative Analysis of Background Parenchymal Enhancement in Contrast Enhanced Mammography

Chang Liu, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Contrast Enhanced Mammography (CEM) has shown clinical benefits, in a similar role as breast DCE-MRI. DCE-MRI background parenchymal enhancement (BPE), known as the contrast enhancement of fibroglandular tissue, is an important measure to characterize breast tumor. Recently, ACR released the BI-RADS criteria for qualitatively assessing BPE in CEM, but quantitative analytics of BPE in CEM is unexplored. We aim to establish an automated pipeline for quantifying CEM BPE and assess its characteristics on cancer and benign patients.

#### METHODS AND MATERIALS

Under an IRB-approved protocol, 292 consenting patients with 332 BI-RADS 4A/4B/4C or 5 breast lesions underwent pre-biopsy CEM (Biopsy outcome: 78 cancer and 254 benign), generating dual low (LE), high energy, and digital energy subtraction (DES) images. An experienced radiologists produced qualitative BPE using the BI-RADS descriptors (i.e., minimal, mild, moderate, marked). Following a similar concept to breast DCE-MRI, we developed an automatic pipeline to calculate three quantitative BPE measures: |BPE| (absolute area of enhanced pixels in fibroglandular tissue); BPE\_b% (|BPE| over the entire breast region), and BPE\_f% (|BPE| over the fibroglandular tissue region). We computed BPE measures with respect to a range of thresholds for two types of cutoffs: (A) the absolute pixel intensity (range: 2000- 2160) of DES image or (B) the intensity ratio (0%-200%) of DES over LE image. A pixel with an equal or greater value than a threshold is considered enhanced. We conducted t-test to compare BPE between patients with biopsy-proven cancer or benign lesions. We built a logistic regression model using quantitative vs. qualitative BPE and 5-fold cross-validation to compare AUCs of classifying cancer vs. benign cases.

#### RESULTS

A range of cutoff thresholds had a significant difference ( $p < 0.05$ ) between cancer and benign cases. The differences were significant for |BPE| and | BPE\_b% when the threshold fell into the intensity range of 2000-2064. A similar trend was seen when the ratio threshold was in 0%-80%. BPE\_f% showed distinguishing ability only in the range of 2080-2012. BPE under the two different cutoffs showed overall similar patterns. The AUC of radiologist's qualitative BPE is 0.59 (std=0.09) while it is 0.63 (std=0.11;  $p=0.39$ ) for the quantitative BPE.

#### CONCLUSION

We build an automated pipeline to quantify BPE in CEM. Similar to breast DCE-MRI, there is a range of thresholds where the derived BPE measures show significant differences between cancer and benign cases.

## CLINICAL RELEVANCE/APPLICATION

Characterizing BPE in CEM is important in evaluating CEM with respect to breast DCE-MRI. Automated quantification of BPE provides reproducible measures to increase clinical utilities of CEM.

### S5-SSBR02-Background Parenchymal Enhancement in CEM and MRI: Is There Always a High Agreement

Francesca Ferrara, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Background parenchymal enhancement (BPE) refers to the physiological contrast enhancement of breast fibroglandular tissue on magnetic resonance imaging (MRI). BPE is increasingly recognized as a potential imaging biomarker. It remains unclear, whether insights on BPE in MRI can be translated to contrast-enhanced mammography (CEM), a novel technology based on the same physiological principles. The aim of this study was to determine the agreement between BPE on CEM and MRI and to investigate potential confounders.

#### METHODS AND MATERIALS

Eligible for this retrospective, IRB-approved, single-center study were women recalled from screening or with inconclusive findings on conventional imaging who were imaged by both CEM and MRI between 2018 and 2022 at our institution. Both MRI and CEM protocols followed international guidelines and recommendations. Exclusion criteria were more than one month between the two examinations and incomplete examinations. Two blinded breast fellows assessed breast density and BPE levels on CEM and MRI, according to BI-RADS. BPE on MRI was also graded in the late post-contrast acquisition. Data on

menopausal status and technical parameters (breast thickness, compression force) were retrieved. Univariate and multivariate tests were used to investigate the BPE agreement between CEM and MRI and the influence of confounders including menopausal status, mammographic density, and breast compression force on CEM.

## **RESULTS**

A total of 343 patients (mean age 55.6; SD 11.1; range 30-87) were consecutively enrolled in this study. In both modalities, post-menopausal patients showed significantly lower BPE levels ( $p < 0.001$ ). Agreement on BPE levels between CEM and MRI in the early phase was fair in both readers ( $R1 ? 0.342$ ,  $R2 ? 0.383$ ). Agreement between CEM and MRI in the late phase was moderate for R1 and fair for R2 ( $R1 ? 0.432$ ,  $R2 ? 0.368$ ). There was a significant correlation between BPE and density in CEM ( $R1 ? 0.399$ ,  $R2 ? 0.441$ ;  $p < 0.001$ ). A negative correlation was found between BPE on CEM and compression force in each projection ( $r = -0.100$ ,  $p = 0.001$ ). Inter-reader agreement for grading BPE on CEM and MRI in both phases was substantial (CEM  $? 0.678$ , BPE MRI early  $? 0.690$ , BPE MRI late  $? 0.692$ ).

## **CONCLUSION**

The agreement of BPE assessment between MRI and CEM was fair to moderate and reproducibility among readers in both modalities was high. While these results indicate that CEM and MRI measure a comparable physiological phenomenon, compression force, and mammographic breast density had an impact on BPE in CEM.

## **CLINICAL RELEVANCE/APPLICATION**

Mechanisms behind BPE on CEM are still under-investigated and might differ from those affecting MRI. Technical factors and breast density could play a major role in determining BPE levels on CEM.

### Role of Contrast-Enhanced Mammography (CEM) In the Assessment of the Outcome of Cryoablation Following One Year of Treatment

Sunday, Nov. 26 2:30PM - 3:30PM Room: E450B

Federica Di Naro, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the efficacy of ultrasound-guided cryoablation (UGC) of low-risk early-stage breast cancer, combining CEM and re-evaluation with biopsy.

#### METHODS AND MATERIALS

UGC was performed at our center on 28 biopsy-proven malignant lesions of 28 patients (mean age 73.4 years old) held inoperable by a multidisciplinary group, under hormone therapy. All the lesions were ultrasound-visible invasive ductal carcinoma (<30 mm), low to intermediate grade, HR-positive, HER2-negative. Each patient underwent Contrast Enhanced Mammography (CEM) staging to confirm the unifocality. Patients were subdivided according to molecular subtype, Ki67% and 1 cm dimensional cut-off. The outcome of UGC was analyzed assessing the size reduction rate (RR) with US, at 1, 3 and 6 months and with CEM and biopsy at 12 months. Samples were collected in the outer and core zones of the site. Our gold standard was the histology result. Fisher test and chi-square test were applied.

#### RESULTS

28 lesions had a mean RR of 20.1%, 66.4% and 94% at 1, 3 and 6 months respectively. Hyperechoic procedural scarrings were visible without any US recognizable trace of the index lesion in 13/28 after 3 months, and in 25/28 after 6 months. 14 were Luminal-A (Lum-A) and 14 Luminal B Her-2 negative (Lum-B): after 1 month, mean (RR) was similar for both subtypes (21.6% Lum-A, 19.8% Lum-B), after 3 months RR was higher for Lum-A (70.2%) versus 60.7% of Lum-B and after 6 months it was 96.8% for Lum-A and 93.4% for Lum-B. 24/28 were BC>1 cm and 4/28 we BC<1 cm: after 1 month RR was 19.7% for BC>1 cm and 23% for BC<1 cm, after 3 months RR was higher for BC<1 cm (84.4%) versus BC>1 cm (63.4%); after 6 months it was 100% for BC<1 cm and 93% for BC>1 cm. Furthermore, after 1 month RR for BC with Ki67<20% was 24.6% and 18.8% for BC with Ki67>20%. After 3 months it was 62.8% for BC with Ki67>20% and 65.3% for Ki67<20%. At 6 months, RR was 96.5% for BC with Ki67>20% and 93.4% for Ki67<20%. Any statistical significant difference emerged. At 12 months, all 28 patients underwent CEM. In 26 cases, no enhancement was detectable, in 2/28 enhancement was found (mainly as mass). In these cases, biopsy confirmed residual traces of B5 lesions only in the core zone of the scarring site, corresponding perfectly to CEM results. In all the negative CEM cases, biopsy reported only benign lesions (flogosis).

#### CONCLUSION

CEM findings perfectly matched the histology results, indeed enhancing masses were detected only where histology reported traces of B5 lesions. UGC is a safe, feasible and effective and CEM is a necessary useful and reliable exam in the follow up.

#### CLINICAL RELEVANCE/APPLICATION

Combining CEM and re-evaluation with biopsy, in selected histology of breast cancer, proved the efficacy of the UGC and the reliability of CEM as an essential useful annual follow-up exam

### Factors Influencing False Positive Recall Rates on Contrast-Enhanced Mammography (CEM)

Sunday, Nov. 26 2:30PM - 3:30PM Room: E450B

Wendie A. Berg, MD, PhD (*Presenter*) Institutional Research Grant, Koios Medical, Inc

#### PURPOSE

Breast density increases recalls on mammography as does background parenchymal enhancement (BPE) on MRI. We sought to evaluate impact of breast density, BPE, menopausal status, prior radiation therapy (XRT), and use of tamoxifen or aromatase inhibitors, on false-positive recall (FPR) rates on contrast-enhanced mammography (CEM).

#### METHODS AND MATERIALS

From two ongoing IRB-approved studies of screening CEM, we evaluated false-positive recall rates by breast for prevalence screening CEM for exams completed through 12/31/2022. We prospectively recorded menopausal status [more than 1 year since last menstrual period (LMP) or bilateral oophorectomy; or date of LMP]; prior XRT; current endocrine therapy; visual BI-RADS density; and BPE (minimal, mild, moderate, marked). We considered each of two prospective specialist radiologist interpretations. We examined FPR rates as a function of each of these factors in bivariate analysis and then in a logistic regression model, and we report odds ratios [OR, (95%CI)] for FPR.

#### RESULTS

Women ranged in age from 31 to 85 years and, overall, there were 7070 interpretations of 3535 breasts, including 555/7070 (7.9%) false-positives. Of the 7070 breast interpretations, 55 (0.8%) were in fatty breasts; 2630 (37.2%) scattered fibroglandular tissue; 4172 (59.0%) heterogeneously dense; and 213 (3.0%) extremely dense. Binarized as dense or not dense, in bivariate analysis the OR for FPR was 1.56 (1.29,1.89) for women with dense compared to non-dense breasts. Of the 7070 breast interpretations, BPE was minimal in 3804 (53.8%), mild in 2416 (34.2%), moderate in 731 (10.3%), and marked in 119 (1.7%); 1116 (15.8%) were in premenopausal women and 5954 (84.2%) postmenopausal; 1010 (14.3%) were in women taking endocrine therapy and 2166 (30.6%) were in breasts with prior XRT. Spearman's correlation of BPE with density was 0.36. With minimal BPE as referent, for mild BPE, OR was 1.74 (1.41,2.13); for moderate BPE, OR was 2.48 (1.85,3.33); for marked BPE, OR was 2.16 (1.18,3.75); and density was not independently significant, with OR 1.17 (0.95,1.44). Premenopausal status increased risk of FPR with OR 1.30 (1.03,1.65) and endocrine therapy tended to reduce FPR, OR 0.77 (0.58,1.02). Prior XRT did not affect FPR [OR1.14 (0.92,1.39)].

#### CONCLUSION

The lowest FPR rates were seen in postmenopausal women with minimal BPE at 5.1% (180/3564) and highest at 16.7% (62/371) in premenopausal women with moderate-marked BPE.

#### CLINICAL RELEVANCE/APPLICATION

Understanding the greater potential for false-positive recalls in premenopausal women with elevated BPE may help reduce such recalls and increase the net benefit of screening CEM.

### Diagnostic Performance of Contrast-Enhanced Mammography for Varying Levels of Background Parenchymal Enhancement

Sunday, Nov. 26 2:30PM - 3:30PM Room: E450B

Sarah Eskreis-Winkler, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Contrast-enhanced mammography (CEM) is increasingly used for breast cancer screening in the intermediate risk population but its diagnostic performance for varying levels of background parenchymal enhancement (BPE) has not yet been characterized. Herein, we compare CEM performance across the four BPE assessment categories.

#### METHODS AND MATERIALS

In this IRB-approved HIPAA-compliant study, screening CEMs performed at our institution from 2013-2022 were retrospectively reviewed. Exams were excluded if they lacked standardized BPE assessments or lacked 12 month follow up. CEM was performed with dual-energy mammography, with imaging initiated 2-2.5 min after contrast injection. Standard performance metrics, including cancer detection rate (CDR), interval cancer rate (IC) and positive predictive value of biopsy (PPV3) were calculated for all patients, and for each BPE category. Metrics for high BPE (marked or moderate) were compared to low BPE (mild or minimal). For all comparisons, a two-tailed two-proportion Z-test was calculated.

#### RESULTS

A total of 2938 screening CEDMs were included in the analysis. There were 1,005 (34%) minimal BPE, 1285 (44%) mild BPE, 491 (17%) moderate BPE, and 61 (2%) marked BPE exams. CDR was not statistically significantly different between high and low BPE (7.1 per 1000 v. 3.5 per 1000;  $p = 0.24$ ). PPV3 (33.3% v. 21.2%;  $p = 0.4$ ) and IC (5.3 per 1,000 v. 2.2 per 1,000;  $p=0.4$ ) were also not significantly different. However, both CDR and PPV showed an increasing trend from minimal to mild to moderate BPE. The pattern dropped off for marked BPE, possibly due to the small number of cases ( $n=61$ ).

#### CONCLUSION

There is no statistically significant difference in the performance of CEM with increasing BPE. In fact, a trend of increasing CDR and PPV were observed from minimal to moderate BPE, possibly related to an intrinsic increase in risk, and further evaluation is warranted with a larger dataset.

#### CLINICAL RELEVANCE/APPLICATION

CEM is increasingly used as a breast cancer screening tool in intermediate risk women, but its performance across BPE subtypes has not yet been evaluated. Despite concerns that high levels of BPE may mask cancer, this evaluation finds no statistically significant differences in performance across BPE categories, although further evaluation is warranted with a larger dataset.

### Quantitative Analysis of Background Parenchymal Enhancement in Contrast Enhanced Mammography

Sunday, Nov. 26 2:30PM - 3:30PM Room: E450B

Chang Liu, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

Contrast Enhanced Mammography (CEM) has shown clinical benefits, in a similar role as breast DCE-MRI. DCE-MRI background parenchymal enhancement (BPE), known as the contrast enhancement of fibroglandular tissue, is an important measure to characterize breast tumor. Recently, ACR released the BI-RADS criteria for qualitatively assessing BPE in CEM, but quantitative analytics of BPE in CEM is unexplored. We aim to establish an automated pipeline for quantifying CEM BPE and assess its characteristics on cancer and benign patients.

#### METHODS AND MATERIALS

Under an IRB-approved protocol, 292 consenting patients with 332 BI-RADS 4A/4B/4C or 5 breast lesions underwent pre-biopsy CEM (Biopsy outcome: 78 cancer and 254 benign), generating dual low (LE), high energy, and digital energy subtraction (DES) images. An experienced radiologist produced qualitative BPE using the BI-RADS descriptors (i.e., minimal, mild, moderate, marked). Following a similar concept to breast DCE-MRI, we developed an automatic pipeline to calculate three quantitative BPE measures: |BPE| (absolute area of enhanced pixels in fibroglandular tissue); BPE\_b% (|BPE| over the entire breast region), and BPE\_f% (|BPE| over the fibroglandular tissue region). We computed BPE measures with respect to a range of thresholds for two types of cutoffs: (A) the absolute pixel intensity (range: 2000- 2160) of DES image or (B) the intensity ratio (0%-200%) of DES over LE image. A pixel with an equal or greater value than a threshold is considered enhanced. We conducted t-test to compare BPE between patients with biopsy-proven cancer or benign lesions. We built a logistic regression model using quantitative vs. qualitative BPE and 5-fold cross-validation to compare AUCs of classifying cancer vs. benign cases.

#### RESULTS

A range of cutoff thresholds had a significant difference ( $p < 0.05$ ) between cancer and benign cases. The differences were significant for |BPE| and |BPE\_b% when the threshold fell into the intensity range of 2000-2064. A similar trend was seen when the ratio threshold was in 0%-80%. BPE\_f% showed distinguishing ability only in the range of 2080-2012. BPE under the two different cutoffs showed overall similar patterns. The AUC of radiologist's qualitative BPE is 0.59 (std=0.09) while it is 0.63 (std=0.11;  $p=0.39$ ) for the quantitative BPE.

#### CONCLUSION

We build an automated pipeline to quantify BPE in CEM. Similar to breast DCE-MRI, there is a range of thresholds where the derived BPE measures show significant differences between cancer and benign cases.

#### CLINICAL RELEVANCE/APPLICATION

Characterizing BPE in CEM is important in evaluating CEM with respect to breast DCE-MRI. Automated quantification of BPE provides reproducible measures to increase clinical utilities of CEM.

### Background Parenchymal Enhancement in CEM and MRI: Is There Always a High Agreement

Sunday, Nov. 26 2:30PM - 3:30PM Room: E450B

Francesca Ferrara, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Background parenchymal enhancement (BPE) refers to the physiological contrast enhancement of breast fibroglandular tissue on magnetic resonance imaging (MRI). BPE is increasingly recognized as a potential imaging biomarker. It remains unclear, whether insights on BPE in MRI can be translated to contrast-enhanced mammography (CEM), a novel technology based on the same physiological principles. The aim of this study was to determine the agreement between BPE on CEM and MRI and to investigate potential confounders.

#### METHODS AND MATERIALS

Eligible for this retrospective, IRB-approved, single-center study were women recalled from screening or with inconclusive findings on conventional imaging who were imaged by both CEM and MRI between 2018 and 2022 at our institution. Both MRI and CEM protocols followed international guidelines and recommendations. Exclusion criteria were more than one month between the two examinations and incomplete examinations. Two blinded breast fellows assessed breast density and BPE levels on CEM and MRI, according to BI-RADS. BPE on MRI was also graded in the late post-contrast acquisition. Data on menopausal status and technical parameters (breast thickness, compression force) were retrieved. Univariate and multivariate tests were used to investigate the BPE agreement between CEM and MRI and the influence of confounders including menopausal status, mammographic density, and breast compression force on CEM.

#### RESULTS

A total of 343 patients (mean age 55.6; SD 11.1; range 30-87) were consecutively enrolled in this study. In both modalities, post-menopausal patients showed significantly lower BPE levels ( $p < 0.001$ ). Agreement on BPE levels between CEM and MRI in the early phase was fair in both readers (R1 ? 0.342, R2 ? 0.383). Agreement between CEM and MRI in the late phase was moderate for R1 and fair for R2 (R1 ? 0.432, R2 ? 0.368). There was a significant correlation between BPE and density in CEM (R1 ? 0.399, R2 ? 0.441;  $p < 0.001$ ). A negative correlation was found between BPE on CEM and compression force in each projection (? -0.100,  $p = 0.001$ ). Inter-reader agreement for grading BPE on CEM and MRI in both phases was substantial (CEM ? 0.678, BPE MRI early ? 0.690, BPE MRI late ? 0.692).

#### CONCLUSION

The agreement of BPE assessment between MRI and CEM was fair to moderate and reproducibility among readers in both modalities was high. While these results indicate that CEM and MRI measure a comparable physiological phenomenon, compression force, and mammographic breast density had an impact on BPE in CEM.

#### CLINICAL RELEVANCE/APPLICATION

Mechanisms behind BPE on CEM are still under-investigated and might differ from those affecting MRI. Technical factors and breast density could play a major role in determining BPE levels on CEM.

### S5-SSCA02-Compressed SENSE Accelerated Single-breath-hold 3D Isotropic Late Gadolinium Enhancement: Clinical Evaluation<sup>2</sup>

Lenhard Pennig, MD (*Presenter*) Speakers Bureau, Koninklijke Philips NV; Institutional Grant, Koninklijke Philips NV

#### PURPOSE

The purpose of this study was to investigate the clinical application of Compressed SENSE accelerated single-breath-hold late gadolinium enhancement (LGE) with 3D isotropic resolution (3D isotropic LGE) compared to conventional LGE imaging acquired in multiple breath-holds.

#### METHODS AND MATERIALS

This was a retrospective, single-center study including 105 examinations of 101 patients ( $48.2 \pm 16.8$  years, 47 females) referred for evaluation of ischemic or non-ischemic cardiomyopathies who received conventional breath-hold and 3D isotropic LGE ( $0.96 \times 0.96 \times 1.1$  mm<sup>3</sup> reconstructed voxel size, Compressed SENSE factor 6.5) sequences at 1.5T in clinical routine. Independently, two radiologists each evaluated 3,570 segments of the left ventricle (LV) for the presence of hyperenhanced lesions (including localization and transmural extent) and their scar edge sharpness (SES) based on a 5-point scale (1 poor - 5 excellent). Confidence of LGE assessment, image quality (IQ), and artifacts were rated using 5-point scales (1 poor - 5 excellent/none). Effects of LV ejection fraction (LVEF), heart rate, body mass index (BMI), and gender as possible confounders on IQ, artifacts, and confidence of LGE assessment were evaluated employing ordinal logistic regression analysis.

#### RESULTS

Using 3D isotropic LGE (average breath hold duration:  $16.0 \pm 3.0$  seconds), readers detected more hyperenhanced lesions ( $n=246$ , 13.8% of analyzed segments) compared to standard breath-hold LGE ( $n=216$ , 12.1% of analyzed segments;  $P < .0001$ ), pronounced at subendocardial, midmyocardial, and subepicardial localizations and for 1-50% of transmural extent. SES was rated superior in 3D isotropic LGE ( $4.1 \pm 0.8$  vs.  $3.3 \pm 0.8$ ;  $P < .001$ ). While 3D isotropic LGE yielded more artifacts ( $3.8 \pm 1.0$  vs.  $4.0 \pm 3.8$ ,  $P = .002$ ), IQ ( $4.1 \pm 1.0$  vs.  $4.2 \pm 0.9$ ;  $P = .122$ ) and confidence of LGE assessment ( $4.3 \pm 0.9$  vs.  $4.3 \pm 0.8$ ;  $P = .374$ ) were comparable between both techniques. Female gender negatively influenced artifacts in 3D isotropic LGE ( $P = .0028$ ) while increased heart rate led to decreased IQ in standard breath-hold LGE ( $P = .0029$ ). LVEF and BMI did not yield a significant influence.

#### CONCLUSION

In clinical routine, Compressed SENSE accelerated single-breath-hold 3D isotropic LGE yields image quality and confidence of LGE assessment comparable to standard breath-hold LGE while providing improved delineation of smaller LGE lesions with superior SES.

#### CLINICAL RELEVANCE/APPLICATION

Given the acquisition of 3D isotropic datasets in one breath hold with subsequent reformation in any arbitrary orientation, Compressed SENSE accelerated single-breath-hold 3D isotropic LGE can drastically reduce the acquisition time of LGE imaging.

### S5-SSCA02-Applying of 7 T Cardiac Magnetic Resonance Imaging to Investigate the Effect of Sodium Selenite on Right Ventricular Structure and Function Secondary to Pulmonary Arterial Hypertension<sup>3</sup>

MD (*Presenter*) Nothing to Disclose

## PURPOSE

Selenium is a trace element with antioxidant stress and anti-inflammatory pro-apoptotic properties. After the onset of pulmonary arterial hypertension (PAH), right ventricular (RV) status are the most crucial factors affecting the patient's prognosis. However, the specific effects of Sodium selenite (SS) on structure and function of the right ventricle secondary to PAH and the related mechanisms are yet to be proven. In this study, we aimed to investigate the effects of SS on RV structure and function subsequent to PAH by cardiac magnetic resonance (CMR) and to elucidate its properties mentioned above.

## METHODS AND MATERIALS

Sixty-two male SD rats were housed for 7 months at the Qinghai-Tibet Plateau with hypobaric hypoxic environment and divided into four groups: CON, MCT, MCT+SE and MCT+SI. The model of MCT/Hypoxia PAH was established by intraperitoneal injection 60 mg/kg of monocrotaline (MCT). One week later, 0.7 mg/kg of SS and 5 mg/kg of sildenafil were given to the MCT+SE group and MCT+SI, respectively. Then, all groups of rats underwent CMR imaging, including FLASH-cine and T2 mapping sequences, to evaluate RV function, strain and edema. Eventually, the sample of blood, heart and lung were obtained for relevant tests.

## RESULTS

Compared with the MCT group, SS intervention significantly elevated RV ejection fraction ( $51.98 \pm 7.88$  vs  $61.30 \pm 6.09$ ), global longitudinal ( $-12.90 \pm 3.53$  vs  $-18.05 \pm 3.43$ ) and circumferential ( $-20.46 \pm 2.47$  vs  $-22.67 \pm 1.32$ ) strain. However, there was no significant difference in T2 relaxation time between groups. Additionally, the blood biochemical results showed that superoxide dismutase ( $216.50 \pm 19.15$  vs  $292.60 \pm 44.38$ ) and glutathione peroxidase ( $9974.00 \pm 900.80$  vs  $17843.00 \pm 3585.00$ ) were significantly higher, while malondialdehyde ( $9.01 \pm 5.59$  vs  $5.53 \pm 1.15$ ), creatine kinase-MB ( $353.00 \pm 61.11$  vs  $210.80 \pm 59.57$ ) and lactic dehydrogenase ( $747.30 \pm 278.80$  vs  $357.90 \pm 135.70$ ) were significantly lower. These findings may be related to upregulate the expression of NRF2 and HO-1, as verified by PCR, immunohistochemical and WB assay. Cardiac-related staining demonstrated that SS treatment impeded the pathological inflammation and promoted RV apoptosis.

## CONCLUSION

Our study shows that SE treatment was found to significantly increase RVEF, GLS, and GCS by CMR imaging. In this regard, we have explored the corresponding mechanisms with the help of some assays.

## CLINICAL RELEVANCE/APPLICATION

Our work is expected to lay a foundation for the clinical evaluation and management of right ventricular dysfunction secondary to PAH.

## S5-SSCA02-Non-Inferiority of Low-Field Cine Cardiovascular Magnetic Resonance Imaging Parameters using a Novel Commercially Available 0.55 T Scanner: A Pilot Study Including Healthy Volunteers and Patients

Martin Segeroth (*Presenter*) Nothing to Disclose

## PURPOSE

To assess time-resolved (cine) cardiovascular magnetic resonance (CMR) imaging at 0.55T by comparing volume and function parameters as well as measures of subjective and objective image quality to a standard 1.5T scanner and thereby testing for non-inferiority.

## METHODS AND MATERIALS

11 healthy participants and 20 patients underwent same-day cine imaging on a 0.55T scanner (Siemens Free.Max) using an ECG-gated prototype cine sequence and on a standard 1.5T scanner (Siemens Avanto fit) system using a product sequence. Based on the results of a blinded, crossover reading study of the healthy participants regarding left- and right ventricular (LV/RV) volume and function parameters including two expert readers (R1/R2) we calculated the needed sample size of the patient cohort regarding non-inferiority with a power of 80% and 10% deviation for LV parameters (15% for RV parameters). Regarding the patient cohort, written reports from clinical routine of cine images acquired on a 1.5T scanner, assessed in a joined fashion by experts from cardiology/radiology, were compared with a blinded reading of two separate experts in cardiac imaging (R1/R2) of the same-patient, same-day 0.55T dataset. Bonferroni-correction was performed, yielding a significance level of 0.00113. Participant and patients evaluated comfort between the two scanners using a Likert-Score of 1 to 5.

## RESULTS

The image quality at both 0.55T and 1.5T was diagnostic for all datasets. Regarding the healthy participants, a high intrareader correlation (R1: 0.86; R2: 0.94) was observed. The average percentual deviation of 0.55T LV parameters from 1.5T was -2% (CI -7% - 3%), for RV -1% (CI -9% - 6%) for both readers. Regarding the patient cohort, a very strong

correlation was observed between 0.55T and 1.5T (R1:  $r = 0.97$ ; R2:  $r = 0.92$ ). LV parameters demonstrated an average percentual deviation of 0.55T from 1.5T of -1% (CI -5% - 3%), respectively RV -1% (CI -6% - 4%). All parameters except end-systolic volume of the LV and RV and SV of the LV demonstrated significantly non-inferiority. In a direct comparison, the participants and patients preferred the 0.55T scanner set-up (mean Likert-Score: 4.2 and 4.4).

#### **CONCLUSION**

Cardiovascular cine imaging at 0.55T yields no general inferior results for quantitative volume and function parameters compared to established imaging at 1.5T. Comfort was reported to be higher at the 0.55T system with the larger bore.

#### **CLINICAL RELEVANCE/APPLICATION**

Due to the larger bore, the lower total costs of ownership and the capability to deal with blackouts of the 0.55T, cine CMR imaging may expand to a larger patient population both in developed and emerging countries.

### **S5-SSCA02-Assessment of Left Ventricular Strain in Children: Comparison Between Free-Breathing 5 Compressed Sensing and Conventional Cine Cardiovascular Magnetic Resonance**

Ke Xu, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Cardiac magnetic resonance (CMR) feature-tracking (FT) (CMR-FT) has emerged as an established tool for quantitative analysis of myocardial strain which is typically performed on segmented balanced steady-state free precession (bSSFP) with breath holds (BHs). Recently, the compressed sensing (CS) technique has been applied to cine CMR, which has drastically reduced its acquisition time. However, it is unclear whether FT-strain measurements can be reliably derived from free breathing (FB) CS cine imaging, allowing for evaluation of pediatric population with impaired BH capacity. Thus, the aim of this study was to determine the feasibility, reproducibility and agreement of FB CS cine with conventional BH cine CMR for LV strain parameters measurement in children.

#### **METHODS AND MATERIALS**

Forty-one participants (28 patients: mean age  $12.3 \pm 2.4$  years; 13 volunteers:  $11.8 \pm 1.5$  years) were prospective enrolled and underwent both retrospective conventional cine CMR and adaptive CS cine CMR at 3 T. LV short-axis cine images covering the entire LV and vertical 2-chamber long axis and horizontal 4-chamber cine series were obtained and used for FT strain analysis. LV myocardial deformation parameters, including global longitudinal strain (GLS) and strain rate (GLSR), global circumferential strain (GCS) and strain rate (GCSR), as well as global radial strain (GRS) and strain rate (GRSR) were calculated from both cine CMR sequences. Interobserver and intra-observer variabilities of the LV strain values for the two cines method were determined using intraclass correlation coefficient (ICC).

#### **RESULTS**

The total examination time was  $122.4 \pm 7.6$  s for standard cine CMR and  $15.6 \pm 2.2$  s for CS cine CMR ( $p < 0.0001$ ). There was a small but significant ( $p < 0.05$ ) underestimation of GCS (2.2%) and GLS (3.3%) using the CS technique. Nevertheless, the limits of agreement between CS and conventional cine for all strains were narrow. We also observed a small but significant underestimation of GRSR (0.5 s<sup>-1</sup>). However, no significant differences were found in GCSR and GLSR between conventional and CS cine CMR. No difference in inter-observer or intra-observer variability were observed between the BH conventional cine and FB CS cine derived strain and strain rate metrics

#### **CONCLUSION**

FB CS cine CMR showed good agreement and reproducibility for the quantitative assessment of global strain and strain rate assessment by CMR-FT in children compared with conventional BH cine CMR.

#### **CLINICAL RELEVANCE/APPLICATION**

Free-breathing CS cine may have potential as a valid and reliable method for quantification of LV strain parameters with significantly shorter scan times in pediatric population with impaired BH capacity.

### **S5-SSCA02-Left Ventricular Flow Analysis: Changes in Flow Components and Kinetic Energy Profiles in 6 Heart Failure Patients with 4D Flow**

Hau Wai Wong, MBBS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study aims to assess correlation between LV functions and flow components volume and kinetic energy using 4D Flow in asymptomatic controls and heart failure patients.

#### **METHODS AND MATERIALS**

32 heart-failure with preserved ejection fraction (HFpEF) patients, 7 heart failure with mid-range ejection fraction (HFmrEF) patients, 11 heart failure with reduced ejection fraction (HFrEF) patients, and 54 controls were included. Their cardiac MRI

images from Oct 2020 to Apr 2023 were retrospectively analysed with Circle Cardiovascular Imaging. Left intraventricular flow is divided into 4 components: direct flow (DF), delayed ejection (DE), retained inflow (RI) and residual volume(ReV) with 4D flow. Volume and kinetic energy (KE) of each component are expressed in its relative proportion and correlated with left ventricular ejection fraction (LVEF) and left ventricular end-diastolic volume index (LV-EDVi).

## **RESULTS**

Direct flow (DF) and residual volume (ReV) components correlate with LVEF and LV-EDVi. When LVEF increases, volume proportion (%) of DF increases ( $p < .001$ ) but that of ReV decreases ( $p < .001$ ). When LV-EDVi increases, volume proportion of DF decreases ( $p < .001$ ) but that of ReV increases ( $p < .001$ ). For KE, when LVEF increases, proportion of KE contributed by DF at peak-systolic and peak-diastolic phases of total KE increases ( $p < .001$ ), while that of ReV decreases ( $p < .001$ ). When LV-EDVi increases, proportion of KE contributed by DF decreases ( $p < .001$ ), while that by ReV increases ( $p < .001$ ). Comparing component's volume in controls and heart failure groups, controls have the highest DF portion, followed by HFpEF, HFmrEF and HFrEF (controls  $35.0 \pm 9.44$  vs. HFpEF  $23.6 \pm 10.6$  vs. HFmrEF  $15.8 \pm 8.06$  vs. HFrEF  $6.73 \pm 4.03$ ,  $p < .001$ ). Conversely, controls have the lowest ReV portion, followed by HFpEF, HFmrEF, and HFrEF (controls  $26.1 \pm 9.39$  vs. HFpEF  $33.2 \pm 13.7$  vs. HFmrEF  $38.4 \pm 12.6$  vs. HFrEF  $51.9 \pm 11.0$ ,  $p < .001$ ). Volume portions of DE and RI are similar. Comparing KE profiles, controls show the highest KE contribution (%) from DF and lowest from ReV, followed by HFpEF, HFmrEF and HFrEF patients (DF KE at peak-systole: controls  $65.0 \pm 10.2$  vs. HFpEF  $47.5 \pm 17.6$  vs. HFmrEF  $33.7 \pm 17.3$  vs. HFrEF  $15.7 \pm 13.1$ ) (ReV KE at peak-systole: controls  $3.46 \pm 1.77$  vs. HFpEF  $7.51 \pm 10.7$  vs. HFmrEF  $15.4 \pm 6.82$  vs. HFrEF  $25.9 \pm 18.6$ ).

## **CONCLUSION**

DF's volume and KE portion increases with LVEF but decreases with LV-EDVi. ReV's volume and KE portion decreases with LVEF but increases with LV-EDVi. CMR 4D flow derived LV DF and ReV parameters allows evaluation of HF patient's severity and delineates them from asymptomatic control.

## **CLINICAL RELEVANCE/APPLICATION**

4D Flow visualizes intraventricular flow and provides novel biomarkers in clinical assessment and management in heart failure patients.

### Compressed SENSE Accelerated Single-breath-hold 3D Isotropic Late Gadolinium Enhancement: Clinical Evaluation

Sunday, Nov. 26 2:30PM - 3:30PM Room: E451A

Lenhard Pennig, MD (*Presenter*) Speakers Bureau, Koninklijke Philips NV; Institutional Grant, Koninklijke Philips NV

#### PURPOSE

The purpose of this study was to investigate the clinical application of Compressed SENSE accelerated single-breath-hold late gadolinium enhancement (LGE) with 3D isotropic resolution (3D isotropic LGE) compared to conventional LGE imaging acquired in multiple breath-holds.

#### METHODS AND MATERIALS

This was a retrospective, single-center study including 105 examinations of 101 patients ( $48.2 \pm 16.8$  years, 47 females) referred for evaluation of ischemic or non-ischemic cardiomyopathies who received conventional breath-hold and 3D isotropic LGE ( $0.96 \times 0.96 \times 1.1$  mm<sup>3</sup> reconstructed voxel size, Compressed SENSE factor 6.5) sequences at 1.5T in clinical routine. Independently, two radiologists each evaluated 3,570 segments of the left ventricle (LV) for the presence of hyperenhanced lesions (including localization and transmural extent) and their scar edge sharpness (SES) based on a 5-point scale (1 poor - 5 excellent). Confidence of LGE assessment, image quality (IQ), and artifacts were rated using 5-point scales (1 poor - 5 excellent/none). Effects of LV ejection fraction (LVEF), heart rate, body mass index (BMI), and gender as possible confounders on IQ, artifacts, and confidence of LGE assessment were evaluated employing ordinal logistic regression analysis.

#### RESULTS

Using 3D isotropic LGE (average breath hold duration:  $16.0 \pm 3.0$  seconds), readers detected more hyperenhanced lesions ( $n=246$ , 13.8% of analyzed segments) compared to standard breath-hold LGE ( $n=216$ , 12.1% of analyzed segments;  $P < .0001$ ), pronounced at subendocardial, midmyocardial, and subepicardial localizations and for 1-50% of transmural extent. SES was rated superior in 3D isotropic LGE ( $4.1 \pm 0.8$  vs.  $3.3 \pm 0.8$ ;  $P < .001$ ). While 3D isotropic LGE yielded more artifacts ( $3.8 \pm 1.0$  vs.  $4.0 \pm 3.8$ ,  $P = .002$ ), IQ ( $4.1 \pm 1.0$  vs.  $4.2 \pm 0.9$ ;  $P = .122$ ) and confidence of LGE assessment ( $4.3 \pm 0.9$  vs.  $4.3 \pm 0.8$ ;  $P = .374$ ) were comparable between both techniques. Female gender negatively influenced artifacts in 3D isotropic LGE ( $P = .0028$ ) while increased heart rate led to decreased IQ in standard breath-hold LGE ( $P = .0029$ ). LVEF and BMI did not yield a significant influence.

#### CONCLUSION

In clinical routine, Compressed SENSE accelerated single-breath-hold 3D isotropic LGE yields image quality and confidence of LGE assessment comparable to standard breath-hold LGE while providing improved delineation of smaller LGE lesions with superior SES.

#### CLINICAL RELEVANCE/APPLICATION

Given the acquisition of 3D isotropic datasets in one breath hold with subsequent reformation in any arbitrary orientation, Compressed SENSE accelerated single-breath-hold 3D isotropic LGE can drastically reduce the acquisition time of LGE imaging.

### Applying of 7 T Cardiac Magnetic Resonance Imaging to Investigate the Effect of Sodium Selenite on Right Ventricular Structure and Function Secondary to Pulmonary Arterial Hypertension

Sunday, Nov. 26 2:30PM - 3:30PM Room: E451A

Hongke Yin, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Selenium is a trace element with antioxidant stress and anti-inflammatory pro-apoptotic properties. After the onset of pulmonary arterial hypertension (PAH), right ventricular (RV) status are the most crucial factors affecting the patient's prognosis. However, the specific effects of Sodium selenite (SS) on structure and function of the right ventricle secondary to PAH and the related mechanisms are yet to be proven. In this study, we aimed to investigate the effects of SS on RV structure and function subsequent to PAH by cardiac magnetic resonance (CMR) and to elucidate its properties mentioned above.

#### METHODS AND MATERIALS

Sixty-two male SD rats were housed for 7 months at the Qinghai-Tibet Plateau with hypobaric hypoxic environment and divided into four groups: CON, MCT, MCT+SE and MCT+SI. The model of MCT/Hypoxia PAH was established by intraperitoneal injection 60 mg/kg of monocrotaline (MCT). One week later, 0.7 mg/kg of SS and 5 mg/kg of sildenafil were given to the MCT+SE group and MCT+SI, respectively. Then, all groups of rats underwent CMR imaging, including FLASH-cine and T2 mapping sequences, to evaluate RV function, strain and edema. Eventually, the sample of blood, heart and lung were obtained for relevant tests.

#### RESULTS

Compared with the MCT group, SS intervention significantly elevated RV ejection fraction ( $51.98 \pm 7.88$  vs  $61.30 \pm 6.09$ ), global longitudinal ( $-12.90 \pm 3.53$  vs  $-18.05 \pm 3.43$ ) and circumferential ( $-20.46 \pm 2.47$  vs  $-22.67 \pm 1.32$ ) strain. However, there was no significant difference in T2 relaxation time between groups. Additionally, the blood biochemical results showed that superoxide dismutase ( $216.50 \pm 19.15$  vs  $292.60 \pm 44.38$ ) and glutathione peroxidase ( $9974.00 \pm 900.80$  vs  $17843.00 \pm 3585.00$ ) were significantly higher, while malondialdehyde ( $9.01 \pm 5.59$  vs  $5.53 \pm 1.15$ ), creatine kinase-MB ( $353.00 \pm 61.11$  vs  $210.80 \pm 59.57$ ) and lactic dehydrogenase ( $747.30 \pm 278.80$  vs  $357.90 \pm 135.70$ ) were significantly lower. These findings may be related to upregulate the expression of NRF2 and HO-1, as verified by PCR, immunohistochemical and WB assay. Cardiac-related staining demonstrated that SS treatment impeded the pathological inflammation and promoted RV apoptosis.

#### CONCLUSION

Our study shows that SE treatment was found to significantly increase RVEF, GLS, and GCS by CMR imaging. In this regard, we have explored the corresponding mechanisms with the help of some assays.

#### CLINICAL RELEVANCE/APPLICATION

Our work is expected to lay a foundation for the clinical evaluation and management of right ventricular dysfunction secondary to PAH.

### **Non-Inferiority of Low-Field Cine Cardiovascular Magnetic Resonance Imaging Parameters using a Novel Commercially Available 0.55 T Scanner: A Pilot Study Including Healthy Volunteers and Patients**

Sunday, Nov. 26 2:30PM - 3:30PM Room: E451A

Martin Segeroth (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To assess time-resolved (cine) cardiovascular magnetic resonance (CMR) imaging at 0.55T by comparing volume and function parameters as well as measures of subjective and objective image quality to a standard 1.5T scanner and thereby testing for non-inferiority.

#### **METHODS AND MATERIALS**

11 healthy participants and 20 patients underwent same-day cine imaging on a 0.55T scanner (Siemens Free.Max) using an ECG-gated prototype cine sequence and on a standard 1.5T scanner (Siemens Avanto fit) system using a product sequence. Based on the results of a blinded, crossover reading study of the healthy participants regarding left- and right ventricular (LV/RV) volume and function parameters including two expert readers (R1/R2) we calculated the needed sample size of the patient cohort regarding non-inferiority with a power of 80% and 10% deviation for LV parameters (15% for RV parameters). Regarding the patient cohort, written reports from clinical routine of cine images acquired on a 1.5T scanner, assessed in a joined fashion by experts from cardiology/radiology, were compared with a blinded reading of two separate experts in cardiac imaging (R1/R2) of the same-patient, same-day 0.55T dataset. Bonferroni-correction was performed, yielding a significance level of 0.00113. Participant and patients evaluated comfort between the two scanners using a Likert-Score of 1 to 5.

#### **RESULTS**

The image quality at both 0.55T and 1.5T was diagnostic for all datasets. Regarding the healthy participants, a high intrareader correlation (R1: 0.86; R2: 0.94) was observed. The average percentual deviation of 0.55T LV parameters from 1.5T was -2% (CI -7% - 3%), for RV -1% (CI -9% - 6%) for both readers. Regarding the patient cohort, a very strong correlation was observed between 0.55T and 1.5T (R1:  $r = 0.97$ ; R2:  $r = 0.92$ ). LV parameters demonstrated an average percentual deviation of 0.55T from 1.5T of -1% (CI -5% - 3%), respectively RV -1% (CI -6% - 4%). All parameters except end-systolic volume of the LV and RV and SV of the LV demonstrated significantly non-inferiority. In a direct comparison, the participants and patients preferred the 0.55T scanner set-up (mean Likert-Score: 4.2 and 4.4).

#### **CONCLUSION**

Cardiovascular cine imaging at 0.55T yields no general inferior results for quantitative volume and function parameters compared to established imaging at 1.5T. Comfort was reported to be higher at the 0.55T system with the larger bore.

#### **CLINICAL RELEVANCE/APPLICATION**

Due to the larger bore, the lower total costs of ownership and the capability to deal with blackouts of the 0.55T, cine CMR imaging may expand to a larger patient population both in developed and emerging countries.

### Assessment of Left Ventricular Strain in Children: Comparison Between Free-Breathing Compressed Sensing and Conventional Cine Cardiovascular Magnetic Resonance

Sunday, Nov. 26 2:30PM - 3:30PM Room: E451A

Ke Xu, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Cardiac magnetic resonance (CMR) feature-tracking (FT) (CMR-FT) has emerged as an established tool for quantitative analysis of myocardial strain which is typically performed on segmented balanced steady-state free precession (bSSFP) with breath holds (BHs). Recently, the compressed sensing (CS) technique has been applied to cine CMR, which has drastically reduced its acquisition time. However, it is unclear whether FT-strain measurements can be reliably derived from free breathing (FB) CS cine imaging, allowing for evaluation of pediatric population with impaired BH capacity. Thus, the aim of this study was to determine the feasibility, reproducibility and agreement of FB CS cine with conventional BH cine CMR for LV strain parameters measurement in children.

#### METHODS AND MATERIALS

Forty-one participants (28 patients: mean age  $12.3 \pm 2.4$  years; 13 volunteers:  $11.8 \pm 1.5$  years) were prospectively enrolled and underwent both retrospective conventional cine CMR and adaptive CS cine CMR at 3 T. LV short-axis cine images covering the entire LV and vertical 2-chamber long axis and horizontal 4-chamber cine series were obtained and used for FT strain analysis. LV myocardial deformation parameters, including global longitudinal strain (GLS) and strain rate (GLSR), global circumferential strain (GCS) and strain rate (GCSR), as well as global radial strain (GRS) and strain rate (GRSR) were calculated from both cine CMR sequences. Interobserver and intra-observer variabilities of the LV strain values for the two cine methods were determined using intraclass correlation coefficient (ICC).

#### RESULTS

The total examination time was  $122.4 \pm 7.6$  s for standard cine CMR and  $15.6 \pm 2.2$  s for CS cine CMR ( $p < 0.0001$ ). There was a small but significant ( $p < 0.05$ ) underestimation of GCS (2.2%) and GLS (3.3%) using the CS technique. Nevertheless, the limits of agreement between CS and conventional cine for all strains were narrow. We also observed a small but significant underestimation of GRSR (0.5 s<sup>-1</sup>). However, no significant differences were found in GCSR and GLSR between conventional and CS cine CMR. No difference in inter-observer or intra-observer variability were observed between the BH conventional cine and FB CS cine derived strain and strain rate metrics.

#### CONCLUSION

FB CS cine CMR showed good agreement and reproducibility for the quantitative assessment of global strain and strain rate assessment by CMR-FT in children compared with conventional BH cine CMR.

#### CLINICAL RELEVANCE/APPLICATION

Free-breathing CS cine may have potential as a valid and reliable method for quantification of LV strain parameters with significantly shorter scan times in pediatric population with impaired BH capacity.

### Left Ventricular Flow Analysis: Changes in Flow Components and Kinetic Energy Profiles in Heart Failure Patients with 4D Flow

Sunday, Nov. 26 2:30PM - 3:30PM Room: E451A

Hau Wai Wong, MBBS (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aims to assess correlation between LV functions and flow components volume and kinetic energy using 4D Flow in asymptomatic controls and heart failure patients.

#### METHODS AND MATERIALS

32 heart-failure with preserved ejection fraction (HFpEF) patients, 7 heart failure with mid-range ejection fraction (HFmrEF) patients, 11 heart failure with reduced ejection fraction (HFrEF) patients, and 54 controls were included. Their cardiac MRI images from Oct 2020 to Apr 2023 were retrospectively analysed with Circle Cardiovascular Imaging. Left intraventricular flow is divided into 4 components: direct flow (DF), delayed ejection (DE), retained inflow (RI) and residual volume(ReV) with 4D flow. Volume and kinetic energy (KE) of each component are expressed in its relative proportion and correlated with left ventricular ejection fraction (LVEF) and left ventricular end-diastolic volume index (LV-EDVi).

#### RESULTS

Direct flow (DF) and residual volume (ReV) components correlate with LVEF and LV-EDVi. When LVEF increases, volume proportion (%) of DF increases ( $p < .001$ ) but that of ReV decreases ( $p < .001$ ). When LV-EDVi increases, volume proportion of DF decreases ( $p < .001$ ) but that of ReV increases ( $p < .001$ ). For KE, when LVEF increases, proportion of KE contributed by DF at peak-systolic and peak-diastolic phases of total KE increases ( $p < .001$ ), while that of ReV decreases ( $p < .001$ ). When LV-EDVi increases, proportion of KE contributed by DF decreases ( $p < .001$ ), while that by ReV increases ( $p < .001$ ). Comparing component's volume in controls and heart failure groups, controls have the highest DF portion, followed by HFpEF, HFmrEF and HFrEF (controls  $35.0 \pm 9.44$  vs. HFpEF  $23.6 \pm 10.6$  vs. HFmrEF  $15.8 \pm 8.06$  vs. HFrEF  $6.73 \pm 4.03$ ,  $p < .001$ ). Conversely, controls have the lowest ReV portion, followed by HFpEF, HFmrEF, and HFrEF (controls  $26.1 \pm 9.39$  vs. HFpEF  $33.2 \pm 13.7$  vs. HFmrEF  $38.4 \pm 12.6$  vs. HFrEF  $51.9 \pm 11.0$ ,  $p < .001$ ). Volume portions of DE and RI are similar. Comparing KE profiles, controls show the highest KE contribution (%) from DF and lowest from ReV, followed by HFpEF, HFmrEF and HFrEF patients (DF KE at peak-systole: controls  $65.0 \pm 10.2$  vs. HFpEF  $47.5 \pm 17.6$  vs. HFmrEF  $33.7 \pm 17.3$  vs. HFrEF  $15.7 \pm 13.1$ ) (ReV KE at peak-systole: controls  $3.46 \pm 1.77$  vs. HFpEF  $7.51 \pm 10.7$  vs. HFmrEF  $15.4 \pm 6.82$  vs. HFrEF  $25.9 \pm 18.6$ ).

#### CONCLUSION

DF's volume and KE portion increases with LVEF but decreases with LV-EDVi. ReV's volume and KE portion decreases with LVEF but increases with LV-EDVi. CMR 4D flow derived LV DF and ReV parameters allows evaluation of HF patient's severity and delineates them from asymptomatic control.

#### CLINICAL RELEVANCE/APPLICATION

4D Flow visualizes intraventricular flow and provides novel biomarkers in clinical assessment and management in heart failure patients.

### S5-SSGI03- Association between Body Composition and Survival in Patients with Gastroesophageal Adenocarcinoma: An Automated Deep Learning Approach<sup>1</sup>

Matthias Jung, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Body composition (BC) measures may play an important role for risk assessment and outcome prognostication in cancer patients. With advances in artificial intelligence, new possibilities to automatically quantify BC are available. We developed a deep learning (DL) model for fully automatic BC quantification on routine staging CTs and determined its prognostic role in a clinical cohort of patients with gastroesophageal adenocarcinoma (GEAC).

#### METHODS AND MATERIALS

We trained a DL model to quantify subcutaneous (SAT) and visceral adipose tissue (VAT), and skeletal muscle (SM) on manually annotated CTs at L3 level (n=100) and tested the model on an independent test set (n=40) using standard performance measures. Subsequently, the deep learning model estimated BC from a retrospective cohort of GEAC patients on baseline and 3-, 6-, and 12-month postoperative follow-up CTs (964 CT scans). The primary outcome was all-cause mortality. Multivariable Cox proportional hazards regression assessed the association between (I) body composition measures at baseline and mortality, and (II) the decrease in VAT and SAT (= 10%) and SM (= 20%) between baseline and postoperative follow ups and mortality.

#### RESULTS

Model performance was high in the independent test set: Dice coefficients were  $0.97 \pm 0.01$  for SAT,  $0.94 \pm 0.06$  for VAT, and  $0.97 \pm 0.02$  for SM. Among 356 patients with GEAC (age  $62.8 \pm 10.8$  years-old; 20.2% female), 172 (48.3%) deaths over a median follow-up of 28.3 months occurred. Baseline BC measures were associated with all-cause mortality after multivariable adjustment (age, sex, height, weight, neoadjuvant therapy. SAT: HR 1.33, 95% CI [1.03-1.73],  $p = 0.032$ ; VAT: HR: 1.24, 95% CI [1.01-1.54],  $p=0.049$ ; Muscle: HR: 0.37, 95% CI [0.15-0.92];  $p = 0.032$ ). Patients with a decrease in SAT and VAT >10% in the 6- to 12-month follow up had a significantly worse outcome than patients with stable adipose tissue measures (hazard ratios adjusted for age, sex, height, weight, neoadjuvant therapy, resection status, tumor grading. SAT: HR 1.82, 95% CI [1.13-2.92],  $p = 0.014$ ; VAT: HR 2.77, 95% CI [1.29-5.94],  $p = 0.009$ ). No association was detected for a decrease in SM measures.

#### CONCLUSION

DL can automatically quantify BC measures from routine staging CTs and provide prognostic information. Baseline BC and a decline in VAT and SAT in the 6- to 12-month follow up were associated with mortality in GEAC patients and may serve as an imaging biomarker to improve clinical decision making beyond traditional risk factors.

#### CLINICAL RELEVANCE/APPLICATION

DL-based opportunistic screening of BC can identify GEAC patients with worse outcome beyond traditional risk factors. Implementation of such methods may provide a fast and low-cost solution to inform risk assessment and improve patient management.

### S5-SSGI03- Trajectories of Body Composition in Hepatocellular Carcinoma Treated with Transarterial Chemoembolization plus Immunotherapy: A Longitudinal, Multicenter, Cohort Study<sup>2</sup>

Zhicheng Jin, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

This study aims to characterize longitudinal trajectories of body composition (BC) and evaluate its impact on clinical outcomes in hepatocellular carcinoma (HCC) patients treated with transarterial chemoembolization (TACE) plus immunotherapy.

## **METHODS AND MATERIALS**

Patients who underwent TACE plus immunotherapy with available abdominal computed tomography between April 2018 and May 2021 were included. The measurements of BC including skeletal muscle mass (SMM), subcutaneous adipose tissue (SAT), and visceral adipose tissue (VAT) were carried out with computed tomography at the L3 vertebra at baseline and follow-up imaging. Overall survival (OS) as primary study endpoint was analyzed by Kaplan-Meier and Cox regression. The overall trend of BC change and its impact on prognosis was identified by a joint model. A latent class trajectory model was applied to distinguish potential BC dynamic changing trajectories.

## **RESULTS**

A total of 392 consecutive HCC patients with 2054 time-point measurements were included. The median follow-up time point was 5 times (range: 3-17). The BC SMM, SAT, and VAT shows significant association with survival (for SMM, hazard ratio [HR]: 0.964, 95% confidence interval [CI]: 0.955-0.973,  $P < 0.001$ ; for SAT, HR: 0.982, 95%CI: 0.978-0.986,  $P < 0.001$ ; for VAT, HR: 0.992, 95%CI: 0.989-0.995,  $P < 0.001$ ), and all measurements exhibits an overall declining trend ( $P < 0.001$ ) along time. Thereafter, two distinct trajectories of SMM were identified, labeled as progressive decline (14.8%,  $n = 58$ ) and stable (85.2%,  $n = 334$ ). There was a significant difference in median overall survival between the two classes (17.0 months vs. 24.6 months;  $P < 0.001$ ). Treatment-emergent adverse events occurred in 10.7% and 31.0% of patients in stable and progressive decline groups ( $P < 0.001$ ), respectively.

## **CONCLUSION**

Longitudinal BC changes are significantly associated with survival for HCC treated with immunotherapy plus TACE. Progressive skeletal muscle decline occurs in a subset of patients, even those who have baseline high SMM, with poor prognosis and tolerance to treatment.

## **CLINICAL RELEVANCE/APPLICATION**

Longitudinal BC changes affect the prognosis of HCC patients. Our study first identified patients who are more likely to experience a progressive decline in skeletal muscle, and highlights the heterogeneity in these population.

## **S5-SSGI03- Spectral CT-based Iodine Quantification in Assessment of Response Following Locoregional Therapy in Liver Tumors**

Jinjin Cao, MD, MS (*Presenter*) Nothing to Disclose

## **PURPOSE**

To investigate the role of spectral CT-based iodine quantification in the assessment of treatment response in liver tumors receiving locoregional therapy.

## **METHODS AND MATERIALS**

In this study, we included 45 patients (20 F;  $63.4 \pm 11.8$  years) who received locoregional therapy for primary and metastatic liver malignancies and underwent DECT scans before and after treatment. Treatment response determination was performed using tumor dimension (RECIST 1.1 and mRECIST), tumor attenuation, and iodine concentration. ? Attenuation value and ? Iodine concentration were obtained by subtracting baseline value from post-treatment value. Baseline and post treatment tumor parameters were compared using non-parametric Wilcoxon signed-rank test. Linear regression and Pearson correlation were used to correlate treatment response with survival metrics (survival time= deceased date- treatment finished date). A  $p$  value of  $< 0.05$  was considered statistically significant.

## **RESULTS**

A total of 45 target lesions were included for assessment (mean size:  $63.4 \pm 11.8$  mm before treatment) out of which  $n = 18$  patients with HCC, 19 with liver metastasis, 7 with cholangiocarcinoma, 1 with liver hemangiopericytoma. No significant difference was demonstrated before and after TACE or SIRT treatment while using RECIST 1.1 ( $p = 0.246$ ). There was significant difference before and after TACE/SIRT when using mRECIST, ? Attenuation value, and ? Iodine concentration ( $p = 0.003$ ,  $p < 0.001$ ,  $p < 0.001$  separately). Linear regression analysis was performed on the 27 deceased patients which indicated a significant positive correlation between survival time and ? Attenuation value ( $\beta = 0.382$ ,  $p = 0.025$ ). However, there was no statistically significant correlation between survival time and ? Iodine concentration, mRECIST, and RECIST 1.1 (Pearson correlation coefficients 0.102, 0.085, -0.005 separately) probably owing to the small sample size.

## **CONCLUSION**

Spectral CT-based iodine quantification enables assessment of response to locoregional therapy in hepatic malignancies.

## CLINICAL RELEVANCE/APPLICATION

Iodine quantification has the potential to be a surrogate imaging biomarker for assessment of response to locoregional therapies.

### **S5-SSGI03- What is the Optimal Strategy for Initial Staging of Esophageal Cancer: Comparison of Standard Staging Procedures (EUS, CT and FDG-PET/CT) and MRI**

Vincent Levy, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To compare the diagnostic performance of MRI, CT, EUS and PET/CT and different combinations for the initial staging of esophageal cancer.

#### **METHODS AND MATERIALS**

In this prospective study we included 60 patients (M/F 50/10, mean age  $66 \pm 9$  yrs) with newly diagnosed esophageal cancer (34 adenocarcinomas, 25 squamous cell carcinomas and 2 neuroendocrine carcinomas). Each patient underwent a 3T MRI in addition to the standard staging procedures (EUS, contrast-enhanced CT and FDG-PET/CT) for initial tumor staging. Two independent readers (except for EUS) were asked to determine TNM-stage based on each procedure (T-stage using MRI, CT and EUS, N-stage using MRI, CT, PET/CT and EUS, M-stage using MRI, CT and PET/CT). Consensus was obtained in case of discordant cases using a third reader. The reference standard was the histopathology of the surgical specimen or TNM-staging established during the tumor board meeting considering all available imaging and endoscopic data. Interreader agreement was assessed. The diagnostic performance of each procedure was analyzed.

#### **RESULTS**

For T-stage, sensitivities and specificities for classifying non-advanced tumors (T1-T2) versus advanced tumors (T3-T4) were 98% and 80% for MRI, 92.5% and 100% for CT and 91.3% and 90% for EUS, respectively. Interreader agreement was strong for MRI and moderate for CT ( $\kappa=0.877$  and  $\kappa=0.788$ ). For N-stage, sensitivities and specificities for classifying N0 versus N+ were 87.5% and 69.2% for MRI, 94.4% and 55.6% for CT, 67.4% and 100% for PET/CT and 89.1% and 66.7% for EUS, respectively. Interreader agreement was moderate for MRI and PET/CT and strong for CT ( $\kappa=0.712$ ,  $\kappa=0.703$  and  $\kappa=0.901$ ). For M-stage, sensitivities and specificities for classifying M0 versus M+ were 100% and 100% for MRI and PET/CT and 40% and 100% for CT, respectively. Interreader agreement was moderate for PET/CT and strong to almost perfect for MRI and CT ( $\kappa=0.781$ ,  $\kappa=0.816$  and  $\kappa=1$ ). The combination of MRI+PET/CT showed optimal performance in differentiating T1-T2N0M0 from T3-T4N1-3M0.

#### **CONCLUSION**

MRI is highly accurate for initial TNM staging and allows optimal differentiation of early stage from advanced or metastatic esophageal cancer.

## CLINICAL RELEVANCE/APPLICATION

Non-invasive MRI allows an accurate staging of esophageal cancer as it reliably differentiates early-stage tumors from advanced tumors, and facilitates correct stage-dependent treatment decisions.

### **S5-SSGI03- Can Hepatobiliary Contrast Uptake Patterns on Gadoteric Acid-Enhanced MRI Predict Prognosis in Breast Cancer Liver Metastases?**

Bingjie Zheng, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study aimed to investigate whether the patterns of hepatobiliary phase (HBP) contrast uptake in liver metastases on gadoteric acid-enhanced magnetic resonance imaging (MRI) can predict overall survival (OS) in patients with breast cancer (BC).

#### **METHODS AND MATERIALS**

This retrospective study included 102 female patients (age range, 30-75 years) with BC and liver metastases who underwent gadoteric acid-enhanced MRI. The HBP signal characteristics were analyzed and liver metastases were classified as target-like or non-target-like groups. Kaplan-Meier analysis and Cox proportional hazards regression were used to evaluate prognostic factors for OS in BC and liver metastasis patients.

#### **RESULTS**

The target-like group (n=62), which included patients with target sign or reversed target sign, had a median OS of 26.5 months, while the non-target-like group (n=40), which included patients with inhomogeneous or homogeneous low signal, had a median OS of 38.2 months (P=0.009). The target-like group exhibited lower OS rates than the non-target-like group.

## **CONCLUSION**

The patterns of HBP contrast uptake in liver metastases on gadoxetic acid-enhanced MRI could be a useful imaging biomarker for predicting OS in patients with BC and liver metastases.

## **CLINICAL RELEVANCE/APPLICATION**

The identification of reliable biomarkers for predicting OS in BC patients with liver metastases is crucial for optimal clinical management. Based on the findings of this study, the patterns of HBP contrast uptake in liver metastases on gadoxetic acid-enhanced MRI could potentially serve as a non-invasive and useful imaging biomarker for predicting OS in female BC patients with liver metastases. This information could aid clinicians in making more informed treatment decisions and tailoring therapeutic strategies to individual patients.

### Association between Body Composition and Survival in Patients with Gastroesophageal Adenocarcinoma: An Automated Deep Learning Approach

Sunday, Nov. 26 2:30PM - 3:30PM Room: S404

Matthias Jung, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Body composition (BC) measures may play an important role for risk assessment and outcome prognostication in cancer patients. With advances in artificial intelligence, new possibilities to automatically quantify BC are available. We developed a deep learning (DL) model for fully automatic BC quantification on routine staging CTs and determined its prognostic role in a clinical cohort of patients with gastroesophageal adenocarcinoma (GEAC).

#### METHODS AND MATERIALS

We trained a DL model to quantify subcutaneous (SAT) and visceral adipose tissue (VAT), and skeletal muscle (SM) on manually annotated CTs at L3 level (n=100) and tested the model on an independent test set (n=40) using standard performance measures. Subsequently, the deep learning model estimated BC from a retrospective cohort of GEAC patients on baseline and 3-, 6-, and 12-month postoperative follow-up CTs (964 CT scans). The primary outcome was all-cause mortality. Multivariable Cox proportional hazards regression assessed the association between (I) body composition measures at baseline and mortality, and (II) the decrease in VAT and SAT (= 10%) and SM (= 20%) between baseline and postoperative follow ups and mortality.

#### RESULTS

Model performance was high in the independent test set: Dice coefficients were  $0.97 \pm 0.01$  for SAT,  $0.94 \pm 0.06$  for VAT, and  $0.97 \pm 0.02$  for SM. Among 356 patients with GEAC (age  $62.8 \pm 10.8$  years-old; 20.2% female), 172 (48.3%) deaths over a median follow-up of 28.3 months occurred. Baseline BC measures were associated with all-cause mortality after multivariable adjustment (age, sex, height, weight, neoadjuvant therapy. SAT: HR 1.33, 95% CI [1.03-1.73],  $p = 0.032$ ; VAT: HR: 1.24, 95% CI [1.01-1.54],  $p=0.049$ ; Muscle: HR: 0.37, 95% CI [0.15-0.92];  $p = 0.032$ ). Patients with a decrease in SAT and VAT >10% in the 6- to 12-month follow up had a significantly worse outcome than patients with stable adipose tissue measures (hazard ratios adjusted for age, sex, height, weight, neoadjuvant therapy, resection status, tumor grading. SAT: HR 1.82, 95% CI [1.13-2.92],  $p = 0.014$ ; VAT: HR 2.77, 95% CI [1.29-5.94],  $p = 0.009$ ). No association was detected for a decrease in SM measures.

#### CONCLUSION

DL can automatically quantify BC measures from routine staging CTs and provide prognostic information. Baseline BC and a decline in VAT and SAT in the 6- to 12-month follow up were associated with mortality in GEAC patients and may serve as an imaging biomarker to improve clinical decision making beyond traditional risk factors.

#### CLINICAL RELEVANCE/APPLICATION

DL-based opportunistic screening of BC can identify GEAC patients with worse outcome beyond traditional risk factors. Implementation of such methods may provide a fast and low-cost solution to inform risk assessment and improve patient management.

### Trajectories of Body Composition in Hepatocellular Carcinoma Treated with Transarterial Chemoembolization plus Immunotherapy: A Longitudinal, Multicenter, Cohort Study

Sunday, Nov. 26 2:30PM - 3:30PM Room: S404

Zhicheng Jin, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

This study aims to characterize longitudinal trajectories of body composition (BC) and evaluate its impact on clinical outcomes in hepatocellular carcinoma (HCC) patients treated with transarterial chemoembolization (TACE) plus immunotherapy.

#### METHODS AND MATERIALS

Patients who underwent TACE plus immunotherapy with available abdominal computed tomography between April 2018 and May 2021 were included. The measurements of BC including skeletal muscle mass (SMM), subcutaneous adipose tissue (SAT), and visceral adipose tissue (VAT) were carried out with computed tomography at the L3 vertebra at baseline and follow-up imaging. Overall survival (OS) as primary study endpoint was analyzed by Kaplan-Meier and Cox regression. The overall trend of BC change and its impact on prognosis was identified by a joint model. A latent class trajectory model was applied to distinguish potential BC dynamic changing trajectories.

#### RESULTS

A total of 392 consecutive HCC patients with 2054 time-point measurements were included. The median follow-up time point was 5 times (range: 3-17). The BC SMM, SAT, and VAT shows significant association with survival (for SMM, hazard ratio [HR]: 0.964, 95% confidence interval [CI]: 0.955-0.973,  $P < 0.001$ ; for SAT, HR: 0.982, 95%CI: 0.978-0.986,  $P < 0.001$ ; for VAT, HR: 0.992, 95%CI: 0.989-0.995,  $P < 0.001$ ), and all measurements exhibits an overall declining trend ( $P < 0.001$ ) along time. Thereafter, two distinct trajectories of SMM were identified, labeled as progressive decline (14.8%,  $n = 58$ ) and stable (85.2%,  $n = 334$ ). There was a significant difference in median overall survival between the two classes (17.0 months vs. 24.6 months;  $P < 0.001$ ). Treatment-emergent adverse events occurred in 10.7% and 31.0% of patients in stable and progressive decline groups ( $P < 0.001$ ), respectively.

#### CONCLUSION

Longitudinal BC changes are significantly associated with survival for HCC treated with immunotherapy plus TACE. Progressive skeletal muscle decline occurs in a subset of patients, even those who have baseline high SMM, with poor prognosis and tolerance to treatment.

#### CLINICAL RELEVANCE/APPLICATION

Longitudinal BC changes affect the prognosis of HCC patients. Our study first identified patients who are more likely to experience a progressive decline in skeletal muscle, and highlights the heterogeneity in these population.

### Spectral CT-based Iodine Quantification in Assessment of Response Following Locoregional Therapy in Liver Tumors

Sunday, Nov. 26 2:30PM - 3:30PM Room: S404

Jinjin Cao, MD, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the role of spectral CT-based iodine quantification in the assessment of treatment response in liver tumors receiving locoregional therapy.

#### METHODS AND MATERIALS

In this study, we included 45 patients (20 F; 63.4±11.8 years) who received locoregional therapy for primary and metastatic liver malignancies and underwent DECT scans before and after treatment. Treatment response determination was performed using tumor dimension (RECIST 1.1 and mRECIST), tumor attenuation, and iodine concentration. ? Attenuation value and ? Iodine concentration were obtained by subtracting baseline value from post-treatment value. Baseline and post treatment tumor parameters were compared using non-parametric Wilcoxon signed-rank test. Linear regression and Pearson correlation were used to correlate treatment response with survival metrics (survival time= deceased date- treatment finished date). A p value of < 0.05 was considered statistically significant.

#### RESULTS

A total of 45 target lesions were included for assessment (mean size: 63.4 ± 11.8 mm before treatment) out of which n= 18 patients with HCC, 19 with liver metastasis, 7 with cholangiocarcinoma, 1 with liver hemangiopericytoma. No significant difference was demonstrated before and after TACE or SIRT treatment while using RECIST 1.1 (p=0.246). There was significant difference before and after TACE/SIRT when using mRECIST, ? Attenuation value, and ? Iodine concentration (p=0.003, p<0.001, p<0.001 separately). Linear regression analysis was performed on the 27 deceased patients which indicated a significant positive correlation between survival time and ? Attenuation value ( $\beta=0.382$ , p=0.025). However, there was no statistically significant correlation between survival time and ? Iodine concentration, mRECIST, and RECIST 1.1 (Pearson correlation coefficients 0.102, 0.085, -0.005 separately) probably owing to the small sample size.

#### CONCLUSION

Spectral CT-based iodine quantification enables assessment of response to locoregional therapy in hepatic malignancies.

#### CLINICAL RELEVANCE/APPLICATION

Iodine quantification has the potential to be a surrogate imaging biomarker for assessment of response to locoregional therapies.

### What is the Optimal Strategy for Initial Staging of Esophageal Cancer: Comparison of Standard Staging Procedures (EUS, CT and FDG-PET/CT) and MRI

Sunday, Nov. 26 2:30PM - 3:30PM Room: S404

Vincent Levy, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare the diagnostic performance of MRI, CT, EUS and PET/CT and different combinations for the initial staging of esophageal cancer.

#### METHODS AND MATERIALS

In this prospective study we included 60 patients (M/F 50/10, mean age  $66 \pm 9$  yrs) with newly diagnosed esophageal cancer (34 adenocarcinomas, 25 squamous cell carcinomas and 2 neuroendocrine carcinomas). Each patient underwent a 3T MRI in addition to the standard staging procedures (EUS, contrast-enhanced CT and FDG-PET/CT) for initial tumor staging. Two independent readers (except for EUS) were asked to determine TNM-stage based on each procedure (T-stage using MRI, CT and EUS, N-stage using MRI, CT, PET/CT and EUS, M-stage using MRI, CT and PET/CT). Consensus was obtained in case of discordant cases using a third reader. The reference standard was the histopathology of the surgical specimen or TNM-staging established during the tumor board meeting considering all available imaging and endoscopic data. Interreader agreement was assessed. The diagnostic performance of each procedure was analyzed.

#### RESULTS

For T-stage, sensitivities and specificities for classifying non-advanced tumors (T1-T2) versus advanced tumors (T3-T4) were 98% and 80% for MRI, 92.5% and 100% for CT and 91.3% and 90% for EUS, respectively. Interreader agreement was strong for MRI and moderate for CT ( $\kappa=0.877$  and  $\kappa=0.788$ ). For N-stage, sensitivities and specificities for classifying N0 versus N+ were 87.5% and 69.2% for MRI, 94.4% and 55.6% for CT, 67.4% and 100% for PET/CT and 89.1% and 66.7% for EUS, respectively. Interreader agreement was moderate for MRI and PET/CT and strong for CT ( $\kappa=0.712$ ,  $\kappa=0.703$  and  $\kappa=0.901$ ). For M-stage, sensitivities and specificities for classifying M0 versus M+ were 100% and 100% for MRI and PET/CT and 40% and 100% for CT, respectively. Interreader agreement was moderate for PET/CT and strong to almost perfect for MRI and CT ( $\kappa=0.781$ ,  $\kappa=0.816$  and  $\kappa=1$ ). The combination of MRI+PET/CT showed optimal performance in differentiating T1-T2N0M0 from T3-T4N1-3M0.

#### CONCLUSION

MRI is highly accurate for initial TNM staging and allows optimal differentiation of early stage from advanced or metastatic esophageal cancer.

#### CLINICAL RELEVANCE/APPLICATION

Non-invasive MRI allows an accurate staging of esophageal cancer as it reliably differentiates early-stage tumors from advanced tumors, and facilitates correct stage-dependent treatment decisions.

### **S5-SSGI04- Feasibility of Deep Learning-Accelerated Nonenhanced Abbreviated Liver MRI for Solid Focal Lesion Detection**

Yoonhee Lee, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

For abbreviated liver MRI, deep learning reconstruction (DL) is expected to be highly advantageous by reducing scan time without compromising sensitivity for focal liver lesion (FLL) detection. This study evaluated the feasibility of nonenhanced abbreviated liver MRI by assessing image quality, per-lesion sensitivity for solid FLL, and scan time in sets of combinations of DL HASTE, free-breathing (FB) DL-DWI and breath-hold (BH) DL-DWI against conventional HASTE and FB-DWI (C-DWI).

#### METHODS AND MATERIALS

Consecutive 51 patients (30 males; mean age  $\pm$  SD, 60.6  $\pm$  13 years) with 40 FLLs who underwent routine liver MRI with additional DL HASTE, FB DL-DWI, and BH DL-DWI were included. Twenty-eight (54.9%) patients had chronic liver disease or liver cirrhosis. FLLs assessed were 12 (30%) HCCs, 16 (40%) metastases, and 12 (30%) hemangiomas. The DL scan parameters were matched to conventional sequences, except for the parallel imaging factor and number of averages in DWI. Two abdominal radiologists independently rated structural sharpness, artifacts, image noise, and overall image quality on a 5-point scale. Three sets of nonenhanced MRI sequences were reviewed for FLL detection: (1) HASTE/FB C-DWI, (2) DL-HASTE/FB DL-DWI, and (3) DL-HASTE/BH DL-DWI. Per-lesion sensitivity, lesion conspicuity, and margin sharpness were assessed and compared across image sets. Student's t-test and Mann-Whitney test with Bonferroni correction compared qualitative features.

#### RESULTS

The scan times for sets (1), (2), and (3) were 4 min 11 sec, 2 min 29 sec, and 1 min 37 sec, respectively. DL-HASTE and FB DL-DWI showed significantly better sharpness, fewer artifacts, less noise, and better overall image quality than their conventional counterparts ( $p$ s = 0.001). BH DL-DWI showed significantly less noise ( $p$  = 0.002) compared to FB C-DWI, while other qualitative scores were comparable. On FLL assessment, both DL sets showed a significantly sharper margin than set (1). The pooled per-lesion sensitivity for sets (1), (2), and (3) was 95.1%, 95.1%, and 85.1%, with no significant difference ( $p$  = 0.131). The overall sensitivities for detecting malignancies were 98.1%, 98.1%, and 93.7% in sets 1, 2, and 3, respectively. For detecting malignancies in patients at risk for HCC, the sensitivities were comparable across sets: (1) 96.8%, (2) 96.8%, and (3) 89.8% ( $p$  = 0.175).

#### CONCLUSION

DL-accelerated HASTE and FB DWI showed significantly better image quality and comparable sensitivity for solid FLL detection in 83% of the scan time compared to conventional sequences. BH DL-DWI markedly reduced scan time but showed lower sensitivity, which requires further refinement.

#### CLINICAL RELEVANCE/APPLICATION

DL-accelerated HASTE and FB DWI are feasible options for abbreviated nonenhanced liver MRI.

### **S5-SSGI04- Fully Automated Pancreatic Adenocarcinoma Localization: Validation of a Convolutional Neural Network (CNN) Model Using Standard-of-Care CTs**

Sovanlal Mukherjee, PhD (*Presenter*) Nothing to Disclose

## **PURPOSE**

To develop a CNN model for a fully-automated localization of PDA on standard-of-care CT exams.

## **METHODS AND MATERIALS**

Manual volumetric reference tumor segmentation was performed by radiologists on a highly curated CT dataset (portal phase; slice thickness=5-mm) from 1151 patients with treatment-naïve PDA [mean (range) tumor diameter: 4.34 (1.1-12.6)-cm]. Dataset was randomly divided into training/validation (n=921) and test subsets (n=230). A 3D CNN Detection model was trained using 5-fold cross-validation. Final model was obtained as an ensemble of the five models from the 5-fold training process. The model's output was a predicted bounding box that aimed to circumscribe the reference PDA segmentation. Model's performance was evaluated on the test subset using volumetric true positive fraction (TPF), which describes the proportion of the reference segmentation in the automated model-predicted bounding box. Model's generalizability was evaluated on The Cancer Imaging Archive (TCIA) (n=41) and Medical Segmentation Decathlon (MSD) (n=152) public datasets. Furthermore, model's performance in the test subset was sub-stratified for different image acquisition parameters (vendor, slice thickness) as well as tumoral features (location, density, and AJCC tumor-stage).

## **RESULTS**

On the test subset, the model had a TPF [mean (SD)] of 0.87(0.22). Model's performance was generalizable to MSD and TCIA datasets [TPF: 0.90(0.21), 0.89(0.24) respectively;  $p>0.05$ ]. There was no significant difference in the model's performance for different CT vendors and slice thicknesses ( $p>0.05$ ). Model's TPF was resilient to tumor density [hypodense: 0.88 (0.21) versus isodense: 0.81(0.27);  $p=0.06$ ] and tumor location [head: 0.87 (0.21), body: 0.91(0.13), tail: 0.83(0.31), extra-pancreatic extension: 0.96(0.05);  $p=0.22$ ]. Additionally, model's performance was comparable for tumor stages II-IV [TPF: 0.87(0.23)-0.90(0.17);  $p=0.36$ ] with lower performance for stage I [TPF: 0.59(0.42);  $p<0.05$ , n=5].

## **CONCLUSION**

A CNN model developed on a large CT dataset shows high accuracy and generalizability for a fully-automated PDA localization on standard-of-care CT exams.

## **CLINICAL RELEVANCE/APPLICATION**

Fully-automated PDA localization provides a critical tool for quantitative imaging biomarker-driven multi-omics models for PDA risk stratification, treatment response assessment, and prognostication.

## **S5-SSGI04- Comparison of Image Quality and Focal Lesions Between Free-Breathing deep Learning Diffusion-Weighted Imaging and Conventional Images in Liver MRI**

Jiyoung Yoon, MD (*Presenter*) Nothing to Disclose

## **PURPOSE**

To compare image quality and diagnostic performance of focal liver lesions for malignancy between free-breathing diffusion weighted image using deep learning reconstruction (DWI-DL) and conventional DWI (c-DWI) in patients undergoing clinically indicated liver MRI.

## **METHODS AND MATERIALS**

A total of 199 consecutive patients who underwent 3 T liver MRI with DWI-DL and c-DWI were retrospectively included. DWI was performed with single-shot spin-echo echo-planar technique and fat-suppression in free breathing with matching parameters. Three radiologists evaluated two sequences for subjective image quality, independently. The apparent diffusion coefficient (ADC) was measured in 15 regions of the liver. A total of 64 patients with 160 focal liver lesions (FLLs) showing high signal intensity on DWI were analyzed by four radiologists regarding per-lesion diagnostic performance for malignancy.

## **RESULTS**

DWI-DL was 43.0% faster than c-DWI (119 vs. 209 sec). Compared with c-DWI, DWI-DL scored higher for all subjective image quality parameters (all,  $P < 0.001$ ). ADC values showed slightly more homogeneous on DWI-DL than those on c-DWI. And ADC values in the right lower section and the left upper, middle, and lower section revealed different between DWI-DL and c-DWI ( $P = 0.010$ ,  $<0.001$ ,  $<0.001$ , and  $0.003$ , respectively). Of 160 lesions, 116 malignancies (61 hepatocellular carcinoma, 3 cholangiocarcinoma, 52 metastasis) and 44 benignities were included. The diagnostic performance of DWI-DL showed comparable sensitivity (75.0-90.5% vs 75.9-82.8%), specificity (87.0-93.3% vs 82.6-97.7%), and accuracy (80.1-90.6% vs 80.5-84.4%), compared with c-DWI.

## **CONCLUSION**

Free-breathing DWI-DL is a clinically feasible technique achieving high image quality and diagnostic performance for malignancy with shorter acquisition time compared to c-DWI.

## CLINICAL RELEVANCE/APPLICATION

Free-breathing DWI using deep learning reduced scan time while improving image quality, compared with conventional DWI. The diagnostic performance of DWI-DL was comparable sensitivity (75.0-90.5% vs 75.9-82.8%), specificity (87.0-93.3% vs 82.6-97.7%), and accuracy (80.1-90.6% vs 80.5-84.4%), compared with c-DWI. Free-breathing DWI using deep learning may minimize motion-induced measurement error in ADC map while showing small differences of ADC values, compared with conventional DWI.

## S5-SSGI04- A Transformer-based deep Learning Model for Liver Stiffness Classification using Multiparametric Abdominal MRI in Children and Adults

Redha Ali, PhD (*Presenter*) Nothing to Disclose

### PURPOSE

To develop a deep learning model that stratifies the degree of liver stiffening based on multiparametric MRI images from pediatric and adult patients with known or suspected chronic liver disease.

### METHODS AND MATERIALS

In this HIPAA-compliant, IRB-approved, multi-site retrospective study, patients with known or suspected chronic liver disease who underwent clinical abdominal MRI examinations with MR elastography (MRE) assessment of liver stiffness between 2011 and 2022 were identified from four institutions, including <BLINDED INSTITUTIONS>. Three conventional MRI sequences, including axial T1-weighted (T1w), T2-weighted (T2w), and diffusion-weighted (DWI) MR images were retrieved. Patients were categorized into two groups using multiple liver stiffness thresholds ( $=2.5$  kPa,  $=3$  kPa,  $=3.5$  kPa,  $=4$  kPa, and  $=5$  kPa) to formulate a series of binary classification tasks, reflecting various degrees of liver stiffening. Our multi-sequence DeepLiverNet 2.0 uses pre-trained Swin Transformer model to extract latent features for classification (Fig. 1A). We constructed three branches of multi-channel transfer learning feature extractors from 11 mid-liver slices of T1w, T2w, and DWI (highest b-value) images. We evaluated model performance using accuracy, sensitivity, specificity, and area under the receiver operating characteristic curve (AuROC) in both internal multi-site 10-fold cross-validation (CV) and external validation experiments.

### RESULTS

A total of 3,365 patients (mean  $\pm$  SD age,  $49.9 \pm 16.6$  years; BMI  $28.8 \pm 6.5$  kg/m<sup>2</sup>; 1737 (51.6%) Females) were selected in two batches. Batch 1 (2,150 patients) was selected from 4 sites between 2011 and 2020 for internal CV, and later Batch 2 (1,215 patients) was selected from three sites <BLINDED INSTITUTIONS> between 2021 to 2022 for external temporal holdout validation. The model achieved mean [95% CI] AuROCs of 0.82 [0.80, 0.84], and 0.81 [0.78, 0.84] for internal and external validation, respectively, when using the  $= 3.0$  kPa threshold. Additional validation results are listed in Figs. 1B and 1C.

### CONCLUSION

The proposed DeepLiverNet 2.0 AI model demonstrated moderate diagnostic performance on a large, multi-site combined pediatric and adult dataset for categorically classifying the degree of liver stiffening using anatomic T1w, T2w, and DWI MRI data.

## CLINICAL RELEVANCE/APPLICATION

Our DeepLiverNet 2.0 AI model can categorically classify the severity of liver stiffening using multiparametric T1w, T2w, and DWI MRI data in children and adult. Model refinements and incorporation of clinical features may further improve performance and soon decrease the need for MRE elastography.

## S5-SSGI04- Effective Opportunistic Gastric Cancer Screening on Noncontrast CT Scans

6

Ling Zhang (*Presenter*) Nothing to Disclose

### PURPOSE

We devised an AI model for the detection of gastric cancer (GC) tumors using noncontrast CT scans, which shows potential to serve as an effective tool for opportunistic cancer screening.

### METHODS AND MATERIALS

We trained the AI model using 1,891 3D noncontrast CT volumes from a single hospital, comprising 687 patients with pathology-confirmed gastric cancer and 1,204 patients for normal control. The masks of tumors were annotated on the venous phase by an experienced radiologist specializing in gastric cancer with reference to clinical and endoscopy records as needed, and then registered to the noncontrast phase. Our model is a novel Mask Transformer-based framework that jointly segments the stomach and potential gastric cancer and outputs the probability of abnormality, using noncontrast CT only. The performance of the model was evaluated on a hold-out test set comprising 100 gastric cancer cases and 148 normal cases, as

well as an external test set of 903 normal cases. The performance of the model was also compared to a reader study of two experienced radiologists on the hold-out test set.

## **RESULTS**

The model's ROC curve in the task of gastric cancer detection (cancer vs. normal) on the held-out test set was above both two readers, with an area under the curve (AUC) of 0.939. Furthermore, the model's sensitivity (Sens 85.0%) and specificity (Spec 92.6%) exceeded the mean performance of the radiologists (Sens 73.5%, Spec 84.2%). The model outperformed the best-performing radiologist in detecting early-stage gastric cancer (T1 60.0% vs. 50.0%, T2 77.8% vs. 55.6%). The model achieved a specificity of 97.7% on the external test set with 903 normal cases. For relative performance comparison to established gastric cancer screening tests, i.e., blood test and endoscopy, we adjust the threshold of our model to achieve the same level of specificity and compare the sensitivity. The model achieved a comparable sensitivity (69.4% vs. 66.7%) at a specificity of 99.5% compared to the blood test, and obtained a higher sensitivity (85.0% vs. 69.0%) at a specificity of 96.0% compared to endoscopy.

## **CONCLUSION**

The proposed model detected gastric cancer tumors on noncontrast CT scans with a high degree of sensitivity and specificity, exceeding the performance of average radiologists by a large margin.

## **CLINICAL RELEVANCE/APPLICATION**

Our study aims to explore the viability of noncontrast CT plus AI as a novel, non-invasive opportunistic screening method for gastric cancer. Compared to traditional screening tools, such as blood tests and endoscopy, our findings suggest that noncontrast CT scans demonstrate favorable accuracy as a new clinical tool for the detection of gastric cancer. This approach may be particularly promising due to its simplicity, accessibility, and no additional costs.

### Feasibility of Deep Learning-Accelerated Nonenhanced Abbreviated Liver MRI for Solid Focal Lesion Detection

Sunday, Nov. 26 2:30PM - 3:30PM Room: S405

Yoonhee Lee, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

For abbreviated liver MRI, deep learning reconstruction (DL) is expected to be highly advantageous by reducing scan time without compromising sensitivity for focal liver lesion (FLL) detection. This study evaluated the feasibility of nonenhanced abbreviated liver MRI by assessing image quality, per-lesion sensitivity for solid FLL, and scan time in sets of combinations of DL HASTE, free-breathing (FB) DL-DWI and breath-hold (BH) DL-DWI against conventional HASTE and FB-DWI (C-DWI).

#### METHODS AND MATERIALS

Consecutive 51 patients (30 males; mean age  $\pm$  SD,  $60.6 \pm 13$  years) with 40 FLLs who underwent routine liver MRI with additional DL HASTE, FB DL-DWI, and BH DL-DWI were included. Twenty-eight (54.9%) patients had chronic liver disease or liver cirrhosis. FLLs assessed were 12 (30%) HCCs, 16 (40%) metastases, and 12 (30%) hemangiomas. The DL scan parameters were matched to conventional sequences, except for the parallel imaging factor and number of averages in DWI. Two abdominal radiologists independently rated structural sharpness, artifacts, image noise, and overall image quality on a 5-point scale. Three sets of nonenhanced MRI sequences were reviewed for FLL detection: (1) HASTE/FB C-DWI, (2) DL-HASTE/FB DL-DWI, and (3) DL-HASTE/BH DL-DWI. Per-lesion sensitivity, lesion conspicuity, and margin sharpness were assessed and compared across image sets. Student's t-test and Mann-Whitney test with Bonferroni correction compared qualitative features.

#### RESULTS

The scan times for sets (1), (2), and (3) were 4 min 11 sec, 2 min 29 sec, and 1 min 37 sec, respectively. DL-HASTE and FB DL-DWI showed significantly better sharpness, fewer artifacts, less noise, and better overall image quality than their conventional counterparts ( $p = 0.001$ ). BH DL-DWI showed significantly less noise ( $p = 0.002$ ) compared to FB C-DWI, while other qualitative scores were comparable. On FLL assessment, both DL sets showed a significantly sharper margin than set (1). The pooled per-lesion sensitivity for sets (1), (2), and (3) was 95.1%, 95.1%, and 85.1%, with no significant difference ( $p = 0.131$ ). The overall sensitivities for detecting malignancies were 98.1%, 98.1%, and 93.7% in sets 1, 2, and 3, respectively. For detecting malignancies in patients at risk for HCC, the sensitivities were comparable across sets: (1) 96.8%, (2) 96.8%, and (3) 89.8% ( $p = 0.175$ ).

#### CONCLUSION

DL-accelerated HASTE and FB DWI showed significantly better image quality and comparable sensitivity for solid FLL detection in 83% of the scan time compared to conventional sequences. BH DL-DWI markedly reduced scan time but showed lower sensitivity, which requires further refinement.

#### CLINICAL RELEVANCE/APPLICATION

DL-accelerated HASTE and FB DWI are feasible options for abbreviated nonenhanced liver MRI.

### Fully Automated Pancreatic Adenocarcinoma Localization: Validation of a Convolutional Neural Network (CNN) Model Using Standard-of-Care CTs

Sunday, Nov. 26 2:30PM - 3:30PM Room: S405

Sovanlal Mukherjee, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop a CNN model for a fully-automated localization of PDA on standard-of-care CT exams.

#### METHODS AND MATERIALS

Manual volumetric reference tumor segmentation was performed by radiologists on a highly curated CT dataset (portal phase; slice thickness=5-mm) from 1151 patients with treatment-naïve PDA [mean (range) tumor diameter: 4.34 (1.1-12.6)-cm]. Dataset was randomly divided into training/validation (n=921) and test subsets (n=230). A 3D CNN Detection model was trained using 5-fold cross-validation. Final model was obtained as an ensemble of the five models from the 5-fold training process. The model's output was a predicted bounding box that aimed to circumscribe the reference PDA segmentation. Model's performance was evaluated on the test subset using volumetric true positive fraction (TPF), which describes the proportion of the reference segmentation in the automated model-predicted bounding box. Model's generalizability was evaluated on The Cancer Imaging Archive (TCIA) (n=41) and Medical Segmentation Decathlon (MSD) (n=152) public datasets. Furthermore, model's performance in the test subset was sub-stratified for different image acquisition parameters (vendor, slice thickness) as well as tumoral features (location, density, and AJCC tumor-stage).

#### RESULTS

On the test subset, the model had a TPF [mean (SD)] of 0.87(0.22). Model's performance was generalizable to MSD and TCIA datasets [TPF: 0.90(0.21), 0.89(0.24) respectively;  $p>0.05$ ]. There was no significant difference in the model's performance for different CT vendors and slice thicknesses ( $p>0.05$ ). Model's TPF was resilient to tumor density [hypodense: 0.88 (0.21) versus isodense: 0.81(0.27);  $p=0.06$ ] and tumor location [head: 0.87 (0.21), body: 0.91(0.13), tail: 0.83(0.31), extra-pancreatic extension: 0.96(0.05);  $p=0.22$ ]. Additionally, model's performance was comparable for tumor stages II-IV [TPF: 0.87(0.23)-0.90(0.17);  $p=0.36$ ] with lower performance for stage I [TPF: 0.59(0.42);  $p<0.05$ , n=5].

#### CONCLUSION

A CNN model developed on a large CT dataset shows high accuracy and generalizability for a fully-automated PDA localization on standard-of-care CT exams.

#### CLINICAL RELEVANCE/APPLICATION

Fully-automated PDA localization provides a critical tool for quantitative imaging biomarker-driven multi-omics models for PDA risk stratification, treatment response assessment, and prognostication.

### Comparison of Image Quality and Focal Lesions Between Free-Breathing deep Learning Diffusion-Weighted Imaging and Conventional Images in Liver MRI

Sunday, Nov. 26 2:30PM - 3:30PM Room: S405

Jiyoung Yoon, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare image quality and diagnostic performance of focal liver lesions for malignancy between free-breathing diffusion weighted image using deep learning reconstruction (DWI-DL) and conventional DWI (c-DWI) in patients undergoing clinically indicated liver MRI.

#### METHODS AND MATERIALS

A total of 199 consecutive patients who underwent 3 T liver MRI with DWI-DL and c-DWI were retrospectively included. DWI was performed with single-shot spin-echo echo-planar technique and fat-suppression in free breathing with matching parameters. Three radiologists evaluated two sequences for subjective image quality, independently. The apparent diffusion coefficient (ADC) was measured in 15 regions of the liver. A total of 64 patients with 160 focal liver lesions (FLLs) showing high signal intensity on DWI were analyzed by four radiologists regarding per-lesion diagnostic performance for malignancy.

#### RESULTS

DWI-DL was 43.0% faster than c-DWI (119 vs. 209 sec). Compared with c-DWI, DWI-DL scored higher for all subjective image quality parameters (all,  $P < 0.001$ ). ADC values showed slightly more homogeneous on DWI-DL than those on c-DWI. And ADC values in the right lower section and the left upper, middle, and lower section revealed different between DWI-DL and c-DWI ( $P = 0.010, < 0.001, < 0.001, \text{ and } 0.003$ , respectively). Of 160 lesions, 116 malignancies (61 hepatocellular carcinoma, 3 cholangiocarcinoma, 52 metastasis) and 44 benignities were included. The diagnostic performance of DWI-DL showed comparable sensitivity (75.0-90.5% vs 75.9-82.8%), specificity (87.0-93.3% vs 82.6-97.7%), and accuracy (80.1-90.6% vs 80.5-84.4%), compared with c-DWI.

#### CONCLUSION

Free-breathing DWI-DL is a clinically feasible technique achieving high image quality and diagnostic performance for malignancy with shorter acquisition time compared to c-DWI.

#### CLINICAL RELEVANCE/APPLICATION

Free-breathing DWI using deep learning reduced scan time while improving image quality, compared with conventional DWI. The diagnostic performance of DWI-DL was comparable sensitivity (75.0-90.5% vs 75.9-82.8%), specificity (87.0-93.3% vs 82.6-97.7%), and accuracy (80.1-90.6% vs 80.5-84.4%), compared with c-DWI. Free-breathing DWI using deep learning may minimize motion-induced measurement error in ADC map while showing small differences of ADC values, compared with conventional DWI.

### Genitourinary Imaging (Advances in Diagnosis and Staging of Renal Cell Carcinoma)

Sunday, Nov. 26 2:30PM - 3:30PM Room: N227B

Luciana Costa, PhD (*Moderator*) Nothing to Disclose  
Martin H. Goodenberger, MD (*Moderator*) Nothing to Disclose

#### Sub-Events

#### S5-SSGU02-1 **CT-based Clear Cell Likelihood Scores for Small Renal Masses: External Validation of Three Contemporary Independent Systems and Their Comparative Performance**

Satheesh Krishna, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Small renal masses (SRMs) defined as being  $\leq 4$ cm are benign up to 20% of the time. In addition, different subtypes have different behaviour with clear cell RCC (ccRCC) having the highest risk of aggressiveness and risk of metastasis. Surgical resection may be considered for ccRCC, while biopsy or active surveillance may be appropriate strategies for non clear cell RCC. MRI based Clear Cell Likelihood scores have been established and validated. Multiple CT based clear cell likelihood scoring algorithms have been proposed (Al Nasibi et al - Multiparametric CT-score algorithm; Eldehimi et al - Modified CT score; Tubtawee et al - UCLA CT-score) but require validation.

#### METHODS AND MATERIALS

This IRB-approved retrospective, cross-sectional study included 194 consecutive solid SRMs (97 ccRCC (50%), 44 papillary RCC (23%), 27 chromophobe RCC (14%), 16 angiomyolipomas (8%), 9 oncocytomas (5%) and 1 collecting duct carcinoma) with a dedicated renal mass protocol CT and surgical histopathology reference standard. Cystic masses and those with macroscopic fat were excluded. Two readers assessed the individual variables which were part of the 3 scoring algorithms described above. The diagnostic accuracy was calculated for each scoring system.

#### RESULTS

Using a threshold of  $\geq 4$  for ccRCC, Al Nasibi et al - Multiparametric CT-score algorithm had a sensitivity of 63% and specificity of 90%. Using a similar threshold of  $\geq 4$  for ccRCC, Eldehimi et al Modified CT score had a sensitivity of 66% and specificity of 89%. When using a threshold of  $\geq 4$ , the Tubtawee et al - UCLA CT-score had a lower sensitivity but higher specificity of 15% and 97%; but when a threshold of  $\geq 3$  was used, sensitivity of 67%, specificity of 82% was identified (Table 1). While multiparametric CT-score algorithm and Modified CT score performed better than UCLA CT-score for a threshold of  $\geq 4$  ( $p < 0.001$ ), when the UCLA CT-score threshold of  $\geq 3$  was used, they were not statistically different ( $p = 0.34$ ).

#### CONCLUSION

Clear cell likelihood CT based scoring systems have a high specificity and moderate sensitivity. Multiparametric CT-score algorithm ( $\geq 4$ ), Modified CT score ( $\geq 4$ ) and UCLA CT-score ( $\geq 3$ ) have similar performance.

#### CLINICAL RELEVANCE/APPLICATION

There is potential for the use of CT based scoring systems as an alternative to MRI based ccLS in the triaging of SRMs. This can assist in the management of SRMs, particularly regarding active surveillance vs surgical resection.

#### S5-SSGU02-3 **Utility of Qualitative and Quantitative Imaging Features to Identify Perinephric Fat Invasion in Renal Cell Carcinoma**

Madhu Gowda, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the utility of quantifying kidney surface nodularity (SN) and perinephric fat attenuation in identifying perinephric fat invasion (PFI) and other high-grade features in RCC.

## METHODS AND MATERIALS

124 patients with RCC >7cm underwent pre-procedural CT imaging. A single rater used a repurposed surface nodularity tool to measure an average surface nodularity score by painting regions of interest along the lateral kidney surface with contralateral normal kidney as a control. A total distance of 50-80 cm along the tumor surface was measured. Attenuation of perinephric fat using five 100mm<sup>2</sup> regions of interest (ROIs) at representative levels along the tumor and five ROIs at similar levels on the non-tumor side was measured. A fellowship-trained abdominal radiologist provided subjective interpretation of PFI for comparison. Quantitative assessment was correlated with presence of perinephric fat invasion, nuclear grade, sarcomatoid features, metastasis and pathologic stage.

## RESULTS

A total of 124 tumors were assessed (82m/42F, mean age 60.5 yrs). Average tumor size was 10 cm, 102 clear cell, 65 high nuclear grade (grade 3-4), 40 with PFI, 9 sarcomatoid, 30 with necrosis, 32 with metastatic disease, 67 advanced stage (T3a or higher). Mean and median SN score in patients without PFI were 5.7±1.2, 5.5 compared to 6.4±1.2, 6.2 in those with PFI (p=0.01). SN demonstrated an AUC of 0.64 in identifying PFI and performed better than SN ratio. It also showed a weak association with presence of metastatic disease and higher pathologic stage (AUC 0.62, 0.62 respectively). Mean and median perinephric fat attenuation in patients without PFI was -72HU±22 and -76HU, compared to -65HU±12.9 and -63HU in patients with PFI (p=0.01). Fat attenuation and fat attenuation ratio showed similar performance in identifying PFI, with AUCs of 0.64 and 0.65 respectively; and also showed weak association with presence of metastatic disease and pathologic stage (AUC 0.65, 0.66 respectively). In multivariate analysis combining SN score and attenuation ratio, there is improvement in identification of PFI (AUC: 0.69). We found the performance of subjective assessment of PFI comparable to the objective measures, with slightly improved performance when all 3 (SN+fat attenuation+subjective assessment) are combined with an AUC of 0.74 in identifying PFI.

## CONCLUSION

SN and perinephric fat attenuation showed some association with presence of PFI, metastatic disease and advanced pathologic stage. When objective measures were combined with subjective assessment in a multivariate model, improved moderate association was seen.

## CLINICAL RELEVANCE/APPLICATION

Perinephric fat invasion (PFI) of renal cell carcinoma (RCC) is associated with a worse survival outcomes.

## S5-SSGU02-4 Contrast-enhanced CT Radiomic Analysis for the Preoperative Prediction of Pathological T3a Upstaging in Renal Cell Carcinoma

Enyu Yuan, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

To develop and validate of contrast-enhanced CT-based radiomic model for predicting pathological T3a upstaging in patients with renal cell carcinoma.

## METHODS AND MATERIALS

A total of 743 patients with renal cell carcinoma in our hospital were retrospectively enrolled. The pathological T3a status of each patient was pathologically confirmed. Radiomic features of the lesion and the 5mm peritumoral area were extracted from the manually labeled portal venous phase CT images. The least absolute shrinkage and selection operator method was used for feature selection. Different predictive models based on selected radiomics features from the tumor, the peritumoral area, and their combination were constructed using logistic regression classifier. To minimize sampling bias, the Monte Carlo cross-validation were used to evaluate the models. The data were split into training and validation dataset in a 7:3 manner, and the splitting was repeated for 1000 times with different random state number. The model in each experiment was evaluated by using metrics of discrimination, calibration, and clinical utility, and the mean performance of 1000 experiments was reported. The frequencies of features being selected were also analyzed.

## RESULTS

For the tumor area, shape features were the most frequently selected features. For the peritumoral area, the gray level size zone matrix features were the most frequently selected features. In the training dataset, the combine model showed the best predictive capability with mean area under receiver operating characteristics curve (AUC) achieving 0.841, which was significantly higher than the tumor model (AUC, 0.839; p < 0.001) or the peritumoral model (AUC, 0.806; p < 0.001). Similar performance was observed in the validation dataset, and the mean AUCs of the tumor model, the peritumoral model and the combine model were 0.832, 0.796 and 0.834. The calibration curve showed good calibration of the tumor model and the combine model in both training and validation datasets. DCA demonstrated similarly good clinical usefulness in both training and validation datasets.

## CONCLUSION

The radiomic model that incorporated radiomics features from the tumor and peritumoral area showed favorable performance in predicting pathological T3a upstaging preoperatively in renal cell carcinoma patients, which could benefit clinical decision making.

## CLINICAL RELEVANCE/APPLICATION

The contrast-enhanced CT-based radiomic model showed good discrimination, calibration and clinical utility for preoperatively prediction of pathological T3a upstaging in renal cell carcinoma.

### S5-SSGU02-5 **Multiphase CT Radiomics Correlation with Clear Cell Renal Cell Carcinoma Tumor Immune Microenvironment: A Study on Tumor-Infiltrating Lymphocytes and Tumor-Associated Macrophages**

Alexander Shieh, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Clear cell renal cell carcinoma (ccRCC) is the most common type of kidney cancer. The tumor immune microenvironment (TIME) signatures of ccRCC have been studied as biomarkers for overall prognosis or response to future immunotherapy. However, TIME assessment is currently tissue-based, which can be expensive and time inefficient. In this study, we investigated radiomics correlation to histopathology-grounded TIME using standard multiphase CT. Two markers that correlated to poor clinical outcomes in ccRCC in prior studies: (1) elevated PD1+CD8+ to CD8+ ratio (2) elevated CD68+ to PanCK+ ratio were explored in depth. We demonstrated the feasibility of predicting these markers with an established CT radiomics panel and report the performance of both tasks.

## METHODS AND MATERIALS

Volumes of 78 primary ccRCC tumors from contrast-enhanced multiphase CT were manually segmented and analyzed using our radiomics pipeline validated on several RCC studies. The tumor specimens obtained via nephrectomy were stained with PanCK, CD8, PD1 and CD68 using the Opal multiplex immunohistochemistry (mIHC) kit. Areas of viable tumor epithelium were selected by expert pathologist for subsequent automated tissue and cell segmentation using the inForm software to delineate tumor and stroma as well as identifying specific cell phenotypes. Statistical machine learning methods including Random Forest, AdaBoost and Elastic Net were used to predict intratumoral PD1+CD8+ to CD8+ ratio and CD68+ to PanCK+ ratio. Sequential experiments with elevated ratio threshold defined at 0.2, 0.3 and 0.4 were performed.

## RESULTS

A total of 1,076 regions of interest were selected from the mIHC samples. After cell segmentation, 3,229,582 cells were identified. For radiomic correlation to PD1+CD8+ to CD8+ ratio, the AdaBoost model achieved the best AUROC of 0.77 (95% CI: [0.63, 0.91]) at threshold 0.3. The excretory phase discrete cosine transform features are most dominant in this experiment. As for CD68+ to PanCK+ ratio, the Random Forest model achieved the best AUROC of 0.73 (95% CI: [0.6, 0.87]) at threshold 0.4. The gray level size zone matrix features of the secretory phase had the highest importance in this model.

## CONCLUSION

We demonstrated the feasibility of using radiomics to correlate tumor-infiltrating lymphocyte (TIL) distribution (PD1+CD8+ to CD8+ ratio) and tumor-associated macrophage (TAM) quantification (CD68+ to PanCK+ ratio). Validation of the results with a larger sample size and external data is warranted.

## CLINICAL RELEVANCE/APPLICATION

We reported the first use of multiphase CT radiomics as a non-invasive method to assess TIL and TAM in ccRCC. These are TIME features that are associated with ccRCC prognosis and can possibly aid immunotherapy patient selection in the future.

### S5-SSGU02-6 **Identification of CT Imaging Features of High-grade Renal Cell Carcinoma using Precise Radiologic Pathologic Correlation**

Madhu Gowda, BS (*Presenter*) Nothing to Disclose

## PURPOSE

To assess the CT imaging features of high nuclear grade in renal cell carcinoma (RCC) using precise radiologic-pathologic correlation in ex vivo specimens

## METHODS AND MATERIALS

20 patients with large (>7 cm) renal cell carcinoma were prospectively recruited for this HIPAA compliant, IRB approved study and written informed consent was obtained. Using preprocedure imaging, a formlabs kidney/ tumor mold was 3D printed prior to surgical resection. After kidney resection, it was placed in the mold for orientation and 3 tissue localization

clips were inserted into the tumor. The specimen was imaged with non-contrast CT then taken to surgical pathology. Three 1 cm pathology samples were taken around each tissue localization clip and a pathologic map was generated showing the nuclear grade for that site within the tumor. This was precisely correlated with unenhanced CT using the clips as landmarks, corresponding 2D ROIs were drawn, and radiomics features were extracted from each site. Nuclear grade 1-2 was categorized as low grade, 3-4 high. Ten machine learning algorithms were trained using radiomics data from CT images in order to identify high versus low grade tumors.

## **RESULTS**

20 tumors (14M/6F, ave age 63.1 yrs, 15 clear cell) were scanned with CT, 137 ROIs were evaluated (51 high grade, 86 low grade). The k-nearest neighbor algorithm demonstrated the best performance, with AUC 0.86, sensitivity 0.88, specificity 0.85 in identifying areas of high grade tumor. The next best performing algorithm was bagged decision tree (AUC 0.76, sens/spec 0.56/0.96). Logistic regression (LR) performed best in identification of areas of tumor necrosis, AUC 0.86, sensitivity/specificity 0.86/0.86 respectively.

## **CONCLUSION**

High grade areas of heterogeneous RCC may be identifiable with unenhanced CT radiomics features when precise radiologic-pathologic correlation is used.

## **CLINICAL RELEVANCE/APPLICATION**

Identification of high grade features in renal cell carcinoma impacts prognosis, outcomes and management.

### CT-based Clear Cell Likelihood Scores for Small Renal Masses: External Validation of Three Contemporary Independent Systems and Their Comparative Performance

Sunday, Nov. 26 2:30PM - 3:30PM Room: N227B

Satheesh Krishna, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Small renal masses (SRMs) defined as being  $\leq 4$ cm are benign up to 20% of the time. In addition, different subtypes have different behaviour with clear cell RCC (ccRCC) having the highest risk of aggressiveness and risk of metastasis. Surgical resection may be considered for ccRCC, while biopsy or active surveillance may be appropriate strategies for non clear cell RCC. MRI based Clear Cell Likelihood scores have been established and validated. Multiple CT based clear cell likelihood scoring algorithms have been proposed (Al Nasibi et al - Multiparametric CT-score algorithm; Eldehimi et al - Modified CT score; Tubtawee et al - UCLA CT-score) but require validation.

#### METHODS AND MATERIALS

This IRB-approved retrospective, cross-sectional study included 194 consecutive solid SRMs (97 ccRCC (50%), 44 papillary RCC (23%), 27 chromophobe RCC (14%), 16 angiomyolipomas (8%), 9 oncocytomas (5%) and 1 collecting duct carcinoma) with a dedicated renal mass protocol CT and surgical histopathology reference standard. Cystic masses and those with macroscopic fat were excluded. Two readers assessed the individual variables which were part of the 3 scoring algorithms described above. The diagnostic accuracy was calculated for each scoring system.

#### RESULTS

Using a threshold of  $\geq 4$  for ccRCC, Al Nasibi et al - Multiparametric CT-score algorithm had a sensitivity of 63% and specificity of 90%. Using a similar threshold of  $\geq 4$  for ccRCC, Eldehimi et al Modified CT score had a sensitivity of 66% and specificity of 89%. When using a threshold of  $\geq 4$ , the Tubtawee et al - UCLA CT-score had a lower sensitivity but higher specificity of 15% and 97%; but when a threshold of  $\geq 3$  was used, sensitivity of 67%, specificity of 82% was identified (Table 1). While multiparametric CT-score algorithm and Modified CT score performed better than UCLA CT-score for a threshold of  $\geq 4$  ( $p < 0.001$ ), when the UCLA CT-score threshold of  $\geq 3$  was used, they were not statistically different ( $p = 0.34$ ).

#### CONCLUSION

Clear cell likelihood CT based scoring systems have a high specificity and moderate sensitivity. Multiparametric CT-score algorithm ( $\geq 4$ ), Modified CT score ( $\geq 4$ ) and UCLA CT-score ( $\geq 3$ ) have similar performance.

#### CLINICAL RELEVANCE/APPLICATION

There is potential for the use of CT based scoring systems as an alternative to MRI based cCLS in the triaging of SRMs. This can assist in the management of SRMs, particularly regarding active surveillance vs surgical resection.

### Utility of Qualitative and Quantitative Imaging Features to Identify Perinephric Fat Invasion in Renal Cell Carcinoma

Sunday, Nov. 26 2:30PM - 3:30PM Room: N227B

Madhu Gowda, BS (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate the utility of quantifying kidney surface nodularity (SN) and perinephric fat attenuation in identifying perinephric fat invasion (PFI) and other high-grade features in RCC.

#### METHODS AND MATERIALS

124 patients with RCC >7cm underwent pre-procedural CT imaging. A single rater used a repurposed surface nodularity tool to measure an average surface nodularity score by painting regions of interest along the lateral kidney surface with contralateral normal kidney as a control. A total distance of 50-80 cm along the tumor surface was measured. Attenuation of perinephric fat using five 100mm<sup>2</sup> regions of interest (ROIs) at representative levels along the tumor and five ROIs at similar levels on the non-tumor side was measured. A fellowship-trained abdominal radiologist provided subjective interpretation of PFI for comparison. Quantitative assessment was correlated with presence of perinephric fat invasion, nuclear grade, sarcomatoid features, metastasis and pathologic stage.

#### RESULTS

A total of 124 tumors were assessed (82m/42F, mean age 60.5 yrs). Average tumor size was 10 cm, 102 clear cell, 65 high nuclear grade (grade 3-4), 40 with PFI, 9 sarcomatoid, 30 with necrosis, 32 with metastatic disease, 67 advanced stage (T3a or higher). Mean and median SN score in patients without PFI were 5.7±1.2, 5.5 compared to 6.4±1.2, 6.2 in those with PFI (p=0.01). SN demonstrated an AUC of 0.64 in identifying PFI and performed better than SN ratio. It also showed a weak association with presence of metastatic disease and higher pathologic stage (AUC 0.62, 0.62 respectively). Mean and median perinephric fat attenuation in patients without PFI was -72HU±22 and -76HU, compared to -65HU±12.9 and -63HU in patients with PFI (p=0.01). Fat attenuation and fat attenuation ratio showed similar performance in identifying PFI, with AUCs of 0.64 and 0.65 respectively; and also showed weak association with presence of metastatic disease and pathologic stage (AUC 0.65, 0.66 respectively). In multivariate analysis combining SN score and attenuation ratio, there is improvement in identification of PFI (AUC: 0.69). We found the performance of subjective assessment of PFI comparable to the objective measures, with slightly improved performance when all 3 (SN+fat attenuation+subjective assessment) are combined with an AUC of 0.74 in identifying PFI.

#### CONCLUSION

SN and perinephric fat attenuation showed some association with presence of PFI, metastatic disease and advanced pathologic stage. When objective measures were combined with subjective assessment in a multivariate model, improved moderate association was seen.

#### CLINICAL RELEVANCE/APPLICATION

Perinephric fat invasion (PFI) of renal cell carcinoma (RCC) is associated with a worse survival outcomes.

### Contrast-enhanced CT Radiomic Analysis for the Preoperative Prediction of Pathological T3a Upstaging in Renal Cell Carcinoma

Sunday, Nov. 26 2:30PM - 3:30PM Room: N227B

Enyu Yuan, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop and validate of contrast-enhanced CT-based radiomic model for predicting pathological T3a upstaging in patients with renal cell carcinoma.

#### METHODS AND MATERIALS

A total of 743 patients with renal cell carcinoma in our hospital were retrospectively enrolled. The pathological T3a status of each patient was pathologically confirmed. Radiomic features of the lesion and the 5mm peritumoral area were extracted from the manually labeled portal venous phase CT images. The least absolute shrinkage and selection operator method was used for feature selection. Different predictive models based on selected radiomics features from the tumor, the peritumoral area, and their combination were constructed using logistic regression classifier. To minimize sampling bias, the Monte Carlo cross-validation were used to evaluate the models. The data were split into training and validation dataset in a 7:3 manner, and the splitting was repeated for 1000 times with different random state number. The model in each experiment was evaluated by using metrics of discrimination, calibration, and clinical utility, and the mean performance of 1000 experiments was reported. The frequencies of features being selected were also analyzed.

#### RESULTS

For the tumor area, shape features were the most frequently selected features. For the peritumoral area, the gray level size zone matrix features were the most frequently selected features. In the training dataset, the combine model showed the best predictive capability with mean area under receiver operating characteristics curve (AUC) achieving 0.841, which was significantly higher than the tumor model (AUC, 0.839;  $p < 0.001$ ) or the peritumoral model (AUC, 0.806;  $p < 0.001$ ). Similar performance was observed in the validation dataset, and the mean AUCs of the tumor model, the peritumoral model and the combine model were 0.832, 0.796 and 0.834. The calibration curve showed good calibration of the tumor model and the combine model in both training and validation datasets. DCA demonstrated similarly good clinical usefulness in both training and validation datasets.

#### CONCLUSION

The radiomic model that incorporated radiomics features from the tumor and peritumoral area showed favorable performance in predicting pathological T3a upstaging preoperatively in renal cell carcinoma patients, which could benefit clinical decision making.

#### CLINICAL RELEVANCE/APPLICATION

The contrast-enhanced CT-based radiomic model showed good discrimination, calibration and clinical utility for preoperatively prediction of pathological T3a upstaging in renal cell carcinoma.

### **Multiphase CT Radiomics Correlation with Clear Cell Renal Cell Carcinoma Tumor Immune Microenvironment: A Study on Tumor-Infiltrating Lymphocytes and Tumor-Associated Macrophages**

Sunday, Nov. 26 2:30PM - 3:30PM Room: N227B

Alexander Shieh, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Clear cell renal cell carcinoma (ccRCC) is the most common type of kidney cancer. The tumor immune microenvironment (TIME) signatures of ccRCC have been studied as biomarkers for overall prognosis or response to future immunotherapy. However, TIME assessment is currently tissue-based, which can be expensive and time inefficient. In this study, we investigated radiomics correlation to histopathology-grounded TIME using standard multiphase CT. Two markers that correlated to poor clinical outcomes in ccRCC in prior studies: (1) elevated PD1+CD8+ to CD8+ ratio (2) elevated CD68+ to PanCK+ ratio were explored in depth. We demonstrated the feasibility of predicting these markers with an established CT radiomics panel and report the performance of both tasks.

#### **METHODS AND MATERIALS**

Volumes of 78 primary ccRCC tumors from contrast-enhanced multiphase CT were manually segmented and analyzed using our radiomics pipeline validated on several RCC studies. The tumor specimens obtained via nephrectomy were stained with PanCK, CD8, PD1 and CD68 using the Opal multiplex immunohistochemistry (mIHC) kit. Areas of viable tumor epithelium were selected by expert pathologist for subsequent automated tissue and cell segmentation using the inForm software to delineate tumor and stroma as well as identifying specific cell phenotypes. Statistical machine learning methods including Random Forest, AdaBoost and Elastic Net were used to predict intratumoral PD1+CD8+ to CD8+ ratio and CD68+ to PanCK+ ratio. Sequential experiments with elevated ratio threshold defined at 0.2, 0.3 and 0.4 were performed.

#### **RESULTS**

A total of 1,076 regions of interest were selected from the mIHC samples. After cell segmentation, 3,229,582 cells were identified. For radiomic correlation to PD1+CD8+ to CD8+ ratio, the AdaBoost model achieved the best AUROC of 0.77 (95% CI: [0.63, 0.91]) at threshold 0.3. The excretory phase discrete cosine transform features are most dominant in this experiment. As for CD68+ to PanCK+ ratio, the Random Forest model achieved the best AUROC of 0.73 (95% CI: [0.6, 0.87]) at threshold 0.4. The gray level size zone matrix features of the secretory phase had the highest importance in this model.

#### **CONCLUSION**

We demonstrated the feasibility of using radiomics to correlate tumor-infiltrating lymphocyte (TIL) distribution (PD1+CD8+ to CD8+ ratio) and tumor-associated macrophage (TAM) quantification (CD60+ to PanCK+ ratio). Validation of the results with a larger sample size and external data is warranted.

#### **CLINICAL RELEVANCE/APPLICATION**

We reported the first use of multiphase CT radiomics as a non-invasive method to assess TIL and TAM in ccRCC. These are TIME features that are associated with ccRCC prognosis and can possibly aid immunotherapy patient selection in the future.

### S5-SSOB01-2 **Placenta Accreta Spectrum Disorders: MRI-Based Scoring of Placental Invasion using Qualitative Imaging Parameters**

Benjamin D. Parnes, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To determine the predictive performance of qualitative MRI features with and without clinical information for the diagnosis of placenta accreta spectrum (PAS) in pregnant women, and to develop a scoring system based on these features.

#### METHODS AND MATERIALS

131 pregnant women (mean age 36 years, age range 21-54; mean gestational age 28 weeks, (GA range 12-37 weeks) undergoing MRI for placental (n=122) or fetal/maternal indication (n=9, normal controls) were included in this 5 year retrospective study from (2016-2021). Demographic and clinical data were recorded. Three independent radiologists (Obs. 1, 1 year; Obs. 2, 3 years, Obs. 3, 19 years) analyzed the MRIs for the presence of MRI features: intraplacental T2-dark bands, uterine/placental bulge, loss of low T2 retroplacental line, myometrial thinning/disruption, bladder wall interruption, focal exophytic placental mass, abnormal vasculature of the placental bed, serosal vessel sign, bladder vessel sign, parametrial vessel sign, and placenta previa. Inter-reader disagreements for the 2 experienced radiologists were adjudicated by a consensus review by 2 separate radiologists (Obs. 4, 13 years; Obs. 5; 12 years), which was then used for initial analysis. The reference standard for PAS was established by pathology and/or inter-operative findings at delivery. Data were evaluated for PAS using univariable and multivariable logistic regression, which was used to create a scoring system. Area under the curve (AUC) and 95% confidence intervals (95%CI) were estimated. Inter-reader agreement for the qualitative MRI findings was assessed using Kappa statistics. Analyses were conducted using SPSS.

#### RESULTS

53 women had >1 prior C-section and 61 had >1 prior delivery. PAS was found in 54/113 at the reference standard. All 11 MRI features and prior delivery history were significant at univariable analysis (all p-values =0.05). Multivariable analysis found 3 MRI features yielded the strongest AUC for PAS: uterine/placental bulge (p=0.0016), focal exophytic placental mass (p=0.0084), and bladder vessel sign (p=0.0080). The AUC of the 3-predictor model was 0.83 (95%CI 0.76-0.90). Placenta previa showed high inter-reader agreement (kappa range 0.81-0.87), while the remaining MRI variables demonstrated moderate/low agreement (kappas <0.53).

#### CONCLUSION

A 3-predictor model based on MRI findings of uterine/placental bulge, exophytic placental mass and bladder vessel sign demonstrates an excellent AUC for predicting PAS.

#### CLINICAL RELEVANCE/APPLICATION

Placenta accreta spectrum (PAS) can cause severe maternal complications. MRI is used to guide management in challenging cases, although no validated MRI-based scoring system for prediction exists.

### S5-SSOB01-3 **Comparison of the Ultrasound Placenta Accreta Index in Severe Placenta Accreta Spectrum at Different Gestational Ages**

Quyen N. Do, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

The placenta accreta index (PAI) is a standardized evaluation of ultrasound (US) parameters for the prediction of placenta accreta spectrum (PAS). The purpose of this study was to determine if the PAI value assigned in sonograms obtained between 17-27 weeks differ from PAI value of sonograms after 27 weeks within the same patient identified to have US and clinical risk factors for PAS.

## METHODS AND MATERIALS

This is a single-center retrospective study of pregnancies with concern for PAS between Sep 2019-Feb 2023 evaluated by serial US (17-27 weeks and after 27 weeks) with at least 5 weeks between sonograms. The Society of Maternal-Fetal Medicine recommends the use of a standardized approach for PAS US markers. At our center this is achieved by the application of the PAI. Medical records were reviewed for US-PAI parameters (Table 1) and surgical outcomes; patients were grouped according to outcome of cesarean hysterectomy, based on clinical FIGO classification of severe PAS at the time of cesarean delivery. Demographics were compared between groups (Wilcoxon and Fisher Exact test). Intraclass correlation coefficient (ICC) was used to assess the agreement between US-PAI before and after 27 weeks. Univariate logistic regression models and receiver operating areas under the curve (AUC) for the US-PAIs and number of prior cesarean deliveries were generated.

## RESULTS

Surgical outcomes were available on 44 pregnant patients with serial US-PAI; 24 (54.5%) required cesarean hysterectomy for PAS; 20 (45.5%) had a routine cesarean delivery. There were no differences in age, race, or gestational age at sonograms (Table 2). The number of prior cesarean deliveries was significantly associated with risk for cesarean hysterectomy ( $p=0.048$ ). US-PAIs obtained from 17-27 weeks sonograms and after 27 weeks sonograms had excellent agreement (ICC 0.88, 95% CI (0.79, 0.93), figure 1). AUC's of US-PAI were significantly predictive of the need for cesarean hysterectomy regardless of the gestational groups (Figure 2). When compared with number of prior cesarean deliveries alone, PAI was significantly more predictive of the need for cesarean hysterectomy (Prior cesarean deliveries' AUC of 0.67 versus 0.86 with  $p < 0.001$  for US-PAI before 27 weeks, and versus 0.91 with  $p < 0.001$  for US-PAI after 27 weeks).

## CONCLUSION

US-PAI AUCs obtained from sonograms between 17-27 weeks and after 27 weeks correlate to severe PAS requiring cesarean hysterectomy. There was no statistical difference between US-PAI obtained at earlier or later sonograms.

## CLINICAL RELEVANCE/APPLICATION

US-PAI is superior to prior cesarean number in predicting the need for cesarean hysterectomy for severe PAS, at both 17-27 weeks and after 27 weeks epochs, highlighting the consistency of this technique in prediction of PAS.

## S5-SSOB01-4 Comparison of Best Landmarks for Calculating Fetal Jaw Index by Ultrasound and MRI to Predict Postnatal Outcomes in Micrognathia

Bailey Lyttle, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Micrognathia is associated with significant perinatal mortality due to airway compromise at birth. Prenatal ultrasound is routinely used to diagnose micrognathia but is technically challenging and imperfect in its ability to predict postnatal outcomes. Fetal MRI has been utilized for measuring the jaw index (JI) using the posterior border of the masseter muscle, but its indistinct margins can lead to inaccuracy. The mandibular teeth buds are more clearly depicted by MRI. We hypothesize that the MRI JI measured using the posterior teeth buds, rather than the masseter muscles, more closely correlates with the ultrasound JI and postnatal outcomes.

## METHODS AND MATERIALS

We performed a retrospective review of pregnancies complicated by micrognathia who underwent fetal ultrasound and MRI between September 2013 and June 2022. MRI JI was calculated using both masseter muscles and posterior teeth buds as the posterior mandibular landmark. Each MRI measurement was performed independently by two radiologists. Pearson's correlations were used to assess inter-reader variability as well as correlation between MRI and ultrasound. Logistic regression was used to evaluate the predictability of postnatal outcomes including intubation or tracheostomy at delivery, need for jaw distraction, and postnatal mortality.

## RESULTS

Forty-three fetuses were included in the analysis. JI could not be obtained by ultrasound in 16 (37%) cases and by MRI in 3 (7.0%) cases. The correlation between MRI JI readers was stronger when using teeth buds ( $R=0.83$ ,  $p < 0.0001$ ) compared to masseter muscles ( $R=0.45$ ,  $p=0.003$ ). When comparing MRI JI to ultrasound JI, there was a stronger correlation when teeth buds were used ( $R=0.4$ ,  $p=0.03$ ) versus masseter muscles ( $R=0.32$ ,  $p=0.10$ ). MRI JI predicted need for jaw distraction when measured by tooth buds ( $p=0.01$ ) and masseter muscles ( $p=0.04$ ); but ultrasound did not. No measurement was predictive of other postnatal outcomes (Table).

## CONCLUSION

MRI JI correlated with ultrasound JI in fetuses with micrognathia. There was a stronger correlation and less inter-reader variability when using posterior teeth buds compared to masseter muscles on MRI. Ultrasound images were more frequently nondiagnostic for jaw measurements when compared to MRI and MRI JI was more predictive for need of postnatal jaw distraction, suggesting it is a useful tool for prenatal counseling and post-delivery planning.

## CLINICAL RELEVANCE/APPLICATION

Appropriate and accurate prenatal imaging is instrumental in adequately counseling families during the pregnancy and planning for potential interventions following delivery. Our findings highlight the utility of fetal MRI and its potential benefits for diagnosis and counseling.

## S5-SSOB01-6 Assessing the Corelation of Ultrasonography of Maternal Ophthalmic Artery Doppler as a Predictor of Pre-eclampsia

Khushboo Juneja, MD (*Presenter*) Nothing to Disclose

## PURPOSE

The purpose of this study is to report the methodology for ophthalmic artery Doppler and summarize findings from the implementation of such assessment in the prediction of Preclampsia in later stage of pregnancy and correlate doppler indices value with maternal and fetal outcome.

## METHODS AND MATERIALS

Study was conducted on pregnant female between 14 to 22 weeks coming for routine antenatal scan at Radiology department. The study comprised 252 patients between time period of March 2021 to December 2022. Ophthalmic artery doppler were performed at 14 to 22 week and the same patients were followed up at 30 to 36 weeks. The data was analyzed using standard sensitivity and specificity formulas.

## RESULTS

In our study on comparing the foetal outcome with hypertensive status, most patients with low birth weight, IUFD and foetal distress were among preeclamptic patients, indicating a significant association between adverse fetal outcome and preeclampsia. On comparing the adverse maternal outcome with the hypertensive status, there was a significant ( $p < 0.001$ ) association between preeclampsia and adverse maternal complication. • Ophthalmic artery parameters such as PSV1, PSV2, PSV ratio, PI, RI, and uterine artery PI were used to predict preeclampsia. It was found there was a significant association observed among PSV2, PSV ratio, PI, and uterine artery PI, but there were no significant associations observed in measuring PSV1 and RI. Our study found that the PSV ratio is a better predictor of adverse maternal outcomes, and uterine artery PI is a better predictor of adverse foetal outcomes. On analysing the efficacy of the PSV ratio for predicting preeclampsia, the AUC was 0.845, which indicates a good predictor for PE, with 83.1% sensitivity and 42.9% specificity.

## CONCLUSION

Based on study, it was found there was a significant association observed among PSV2, PSV ratio, ophthalmic artery PI and uterine artery PI but there were no significant associations observed in measuring PSV1 and RI. Our study found that the PSV ratio is a better predictor of adverse maternal outcomes, and uterine artery PI is a better predictor of adverse foetal outcomes. On analysing the efficacy of the PSV ratio for predicting preeclampsia, the AUC was 0.845, which indicates a good predictor for PE, with 83.1% sensitivity and 42.9% specificity.

## CLINICAL RELEVANCE/APPLICATION

In the present study, there was an association between the abnormal ophthalmic artery indices and preeclampsia, among which the PSV ratio was an excellent predictor. The identification of the high-risk group be beneficial, so the clinician could provide timely interventions to prevent the development of PE and potentially reduce maternal and perinatal death and morbidity.

### Placenta Accreta Spectrum Disorders: MRI-Based Scoring of Placental Invasion using Qualitative Imaging Parameters

Sunday, Nov. 26 2:30PM - 3:30PM Room: N229

Benjamin D. Parnes, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To determine the predictive performance of qualitative MRI features with and without clinical information for the diagnosis of placenta accreta spectrum (PAS) in pregnant women, and to develop a scoring system based on these features.

#### METHODS AND MATERIALS

131 pregnant women (mean age 36 years, age range 21-54; mean gestational age 28 weeks, (GA range 12-37 weeks) undergoing MRI for placental (n=122) or fetal/maternal indication (n=9, normal controls) were included in this 5 year retrospective study from (2016-2021). Demographic and clinical data were recorded. Three independent radiologists (Obs. 1, 1 year; Obs. 2, 3 years, Obs. 3, 19 years) analyzed the MRIs for the presence of MRI features: intraplacental T2-dark bands, uterine/placental bulge, loss of low T2 retroplacental line, myometrial thinning/disruption, bladder wall interruption, focal exophytic placental mass, abnormal vasculature of the placental bed, serosal vessel sign, bladder vessel sign, parametrial vessel sign, and placenta previa. Inter-reader disagreements for the 2 experienced radiologists were adjudicated by a consensus review by 2 separate radiologists (Obs. 4, 13 years; Obs. 5; 12 years), which was then used for initial analysis. The reference standard for PAS was established by pathology and/or inter-operative findings at delivery. Data were evaluated for PAS using univariable and multivariable logistic regression, which was used to create a scoring system. Area under the curve (AUC) and 95% confidence intervals (95%CI) were estimated. Inter-reader agreement for the qualitative MRI findings was assessed using Kappa statistics. Analyses were conducted using SPSS.

#### RESULTS

53 women had >1 prior C-section and 61 had >1 prior delivery. PAS was found in 54/113 at the reference standard. All 11 MRI features and prior delivery history were significant at univariable analysis (all p-values =0.05). Multivariable analysis found 3 MRI features yielded the strongest AUC for PAS: uterine/placental bulge (p=0.0016), focal exophytic placental mass (p=0.0084), and bladder vessel sign (p=0.0080). The AUC of the 3-predictor model was 0.83 (95%CI 0.76-0.90). Placenta previa showed high inter-reader agreement (kappa range 0.81-0.87), while the remaining MRI variables demonstrated moderate/low agreement (kappas <0.53).

#### CONCLUSION

A 3-predictor model based on MRI findings of uterine/placental bulge, exophytic placental mass and bladder vessel sign demonstrates an excellent AUC for predicting PAS.

#### CLINICAL RELEVANCE/APPLICATION

Placenta accreta spectrum (PAS) can cause severe maternal complications. MRI is used to guide management in challenging cases, although no validated MRI-based scoring system for prediction exists.

### Comparison of the Ultrasound Placenta Accreta Index in Severe Placenta Accreta Spectrum at Different Gestational Ages

Sunday, Nov. 26 2:30PM - 3:30PM Room: N229

Quyên N. Do, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

The placenta accreta index (PAI) is a standardized evaluation of ultrasound (US) parameters for the prediction of placenta accreta spectrum (PAS). The purpose of this study was to determine if the PAI value assigned in sonograms obtained between 17-27 weeks differ from PAI value of sonograms after 27 weeks within the same patient identified to have US and clinical risk factors for PAS.

#### METHODS AND MATERIALS

This is a single-center retrospective study of pregnancies with concern for PAS between Sep 2019-Feb 2023 evaluated by serial US (17-27 weeks and after 27 weeks) with at least 5 weeks between sonograms. The Society of Maternal-Fetal Medicine recommends the use of a standardized approach for PAS US markers. At our center this is achieved by the application of the PAI. Medical records were reviewed for US-PAI parameters (Table 1) and surgical outcomes; patients were grouped according to outcome of cesarean hysterectomy, based on clinical FIGO classification of severe PAS at the time of cesarean delivery. Demographics were compared between groups (Wilcoxon and Fisher Exact test). Intraclass correlation coefficient (ICC) was used to assess the agreement between US-PAI before and after 27 weeks. Univariate logistic regression models and receiver operating areas under the curve (AUC) for the US-PAIs and number of prior cesarean deliveries were generated.

#### RESULTS

Surgical outcomes were available on 44 pregnant patients with serial US-PAI; 24 (54.5%) required cesarean hysterectomy for PAS; 20 (45.5%) had a routine cesarean delivery. There were no differences in age, race, or gestational age at sonograms (Table 2). The number of prior cesarean deliveries was significantly associated with risk for cesarean hysterectomy ( $p=0.048$ ). US-PAIs obtained from 17-27 weeks sonograms and after 27 weeks sonograms had excellent agreement (ICC 0.88, 95% CI (0.79, 0.93), figure 1). AUC's of US-PAI were significantly predictive of the need for cesarean hysterectomy regardless of the gestational groups (Figure 2). When compared with number of prior cesarean deliveries alone, PAI was significantly more predictive of the need for cesarean hysterectomy (Prior cesarean deliveries' AUC of 0.67 versus 0.86 with  $p < 0.001$  for US-PAI before 27 weeks, and versus 0.91 with  $p < 0.001$  for US-PAI after 27 weeks).

#### CONCLUSION

US-PAI AUCs obtained from sonograms between 17-27 weeks and after 27 weeks correlate to severe PAS requiring cesarean hysterectomy. There was no statistical difference between US-PAI obtained at earlier or later sonograms.

#### CLINICAL RELEVANCE/APPLICATION

US-PAI is superior to prior cesarean number in predicting the need for cesarean hysterectomy for severe PAS, at both 17-27 weeks and after 27 weeks epochs, highlighting the consistency of this technique in prediction of PAS.

### Comparison of Best Landmarks for Calculating Fetal Jaw Index by Ultrasound and MRI to Predict Postnatal Outcomes in Micrognathia

Sunday, Nov. 26 2:30PM - 3:30PM Room: N229

Bailey Lyttle, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Micrognathia is associated with significant perinatal mortality due to airway compromise at birth. Prenatal ultrasound is routinely used to diagnose micrognathia but is technically challenging and imperfect in its ability to predict postnatal outcomes. Fetal MRI has been utilized for measuring the jaw index (JI) using the posterior border of the masseter muscle, but its indistinct margins can lead to inaccuracy. The mandibular teeth buds are more clearly depicted by MRI. We hypothesize that the MRI JI measured using the posterior teeth buds, rather than the masseter muscles, more closely correlates with the ultrasound JI and postnatal outcomes.

#### METHODS AND MATERIALS

We performed a retrospective review of pregnancies complicated by micrognathia who underwent fetal ultrasound and MRI between September 2013 and June 2022. MRI JI was calculated using both masseter muscles and posterior teeth buds as the posterior mandibular landmark. Each MRI measurement was performed independently by two radiologists. Pearson's correlations were used to assess inter-reader variability as well as correlation between MRI and ultrasound. Logistic regression was used to evaluate the predictability of postnatal outcomes including intubation or tracheostomy at delivery, need for jaw distraction, and postnatal mortality.

#### RESULTS

Forty-three fetuses were included in the analysis. JI could not be obtained by ultrasound in 16 (37%) cases and by MRI in 3 (7.0%) cases. The correlation between MRI JI readers was stronger when using teeth buds ( $R=0.83$ ,  $p<0.0001$ ) compared to masseter muscles ( $R=0.45$ ,  $p=0.003$ ). When comparing MRI JI to ultrasound JI, there was a stronger correlation when teeth buds were used ( $R=0.4$ ,  $p=0.03$ ) versus masseter muscles ( $R=0.32$ ,  $p=0.10$ ). MRI JI predicted need for jaw distraction when measured by tooth buds ( $p=0.01$ ) and masseter muscles ( $p=0.04$ ); but ultrasound did not. No measurement was predictive of other postnatal outcomes (Table).

#### CONCLUSION

MRI JI correlated with ultrasound JI in fetuses with micrognathia. There was a stronger correlation and less inter-reader variability when using posterior teeth buds compared to masseter muscles on MRI. Ultrasound images were more frequently nondiagnostic for jaw measurements when compared to MRI and MRI JI was more predictive for need of postnatal jaw distraction, suggesting it is a useful tool for prenatal counseling and post-delivery planning.

#### CLINICAL RELEVANCE/APPLICATION

Appropriate and accurate prenatal imaging is instrumental in adequately counseling families during the pregnancy and planning for potential interventions following delivery. Our findings highlight the utility of fetal MRI and its potential benefits for diagnosis and counseling.

### Assesing the Corelation of Ultrasonography of Maternal Ophthalmic Artery Doppler as a Predictor of Pre-eclampsia

Sunday, Nov. 26 2:30PM - 3:30PM Room: N229

Khushboo Juneja, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study is to report the methodology for ophthalmic artery Doppler and summarize findings from the implementation of such assessment in the prediction of Preclampsia in later stage of pregnancy and correlate doppler indices value with maternal and fetal outcome.

#### METHODS AND MATERIALS

Study was conducted on pregnant female between 14 to 22 weeks coming for routine antenatal scan at Radiology department. The study comprised 252 patients between time period of March 2021 to December 2022. Ophthalmic artery doppler were performed at 14 to 22 week and the same patients were followed up at 30 to 36 weeks. The data was analyzed using standard sensitivity and specificity formulas.

#### RESULTS

In our study on comparing the foetal outcome with hypertensive status, most patients with low birth weight, IUFD and foetal distress were among preeclamptic patients, indicating a significant association between adverse fetal outcome and preeclampsia. On comparing the adverse maternal outcome with the hypertensive status, there was a significant ( $p < 0.001$ ) association between preeclampsia and adverse maternal complication. • Ophthalmic artery parameters such as PSV1, PSV2, PSV ratio, PI, RI, and uterine artery PI were used to predict preeclampsia. It was found there was a significant association observed among PSV2, PSV ratio, PI, and uterine artery PI, but there were no significant associations observed in measuring PSV1 and RI. Our study found that the PSV ratio is a better predictor of adverse maternal outcomes, and uterine artery PI is a better predictor of adverse foetal outcomes. On analysing the efficacy of the PSV ratio for predicting preeclampsia, the AUC was 0.845, which indicates a good predictor for PE, with 83.1% sensitivity and 42.9% specificity.

#### CONCLUSION

Based on study, it was found there was a significant association observed among PSV2, PSV ratio, ophthalmic artery PI and uterine artery PI but there were no significant associations observed in measuring PSV1 and RI. Our study found that the PSV ratio is a better predictor of adverse maternal outcomes, and uterine artery PI is a better predictor of adverse foetal outcomes. On analysing the efficacy of the PSV ratio for predicting preeclampsia, the AUC was 0.845, which indicates a good predictor for PE, with 83.1% sensitivity and 42.9% specificity.

#### CLINICAL RELEVANCE/APPLICATION

In the present study, there was an association between the abnormal ophthalmic artery indices and preeclampsia, among which the PSV ratio was an excellent predictor. The identification of the high-risk group be beneficial, so the clinician could provide timely interventions to prevent the development of PE and potentially reduce maternal and perinatal death and morbidity.

### Science Session (Sustainability in Imaging)

Sunday, Nov. 26 2:30PM - 3:00PM Room: Learning Center Theater 1

#### Sub-Events

#### S5-STCE1-1 Energy Stewardship in MRI

Anurag Dalai, BSc, MD (*Presenter*) Nothing to Disclose

##### PURPOSE

MRI scanning is energy intensive. We aimed to understand our department's MRI energy consumption and evaluate potential methods of improving energy efficiency during clinical operation.

##### METHODS AND MATERIALS

Operational approval was obtained from our hospital, including Departments of Medical Imaging and Facilities Management. Both MRI scanners (1.5T and 3T) were equipped with energy data loggers for 1 week in August 2021. Energy use was calculated (per time unit) for inactive downtime (department closed), active downtime (between cases) and individual cases (including subspecialty) using PACS time stamps. Cases scanned were also coded by subspecialty (musculoskeletal, neuroradiology including spine, body imaging and cardiac imaging). Carbon emissions were calculated using local emission conversion factor of 0.51 CO<sub>2</sub>/kWh. Kilowatt-hour cost was calculated by the price of electricity during the recorded billing cycle (0.1104 \$/kWh) at our institution.

##### RESULTS

The total week's MRI energy consumption was 7,612.1 kWh. The cost of electricity was \$840.40 CAD and the estimated emissions were 3,882.3 kg CO<sub>2</sub>. Collectively, the average energy use per MRI case was 19.8 kWh/case. The 3T and 1.5T scanners actively scanned for 51 and 47 hours respectively, but the 3T scanner used 70.4 % of total energy consumption. Subspecialty exam energy use across musculoskeletal, neuroradiology including spine, body and cardiac cases were similar. Energy use per minute was higher in active downtime (in-between cases) than inactive downtime (overnight) and highest while actively scanning. Average emissions per minute active scanning was 0.16 kg CO<sub>2</sub>/min and 0.43 kg CO<sub>2</sub>/min for the 1.5T and 3T scanners respectively.

##### CONCLUSION

Our weekly MRI emissions were 3,882.3 kg CO<sub>2</sub>, similar to an annual Canadian passenger vehicle emissions of 3,830 kg CO<sub>2</sub>. Since energy use was higher in active scanning, we implemented shorter protocols where possible such as FAST knee MRI protocols to improve clinical energy efficiency. Reduced case specific carbon emissions would require further work to confirm. This comes with the added benefits of shorter exams and therefore hopefully an improved patient experience.

##### CLINICAL RELEVANCE/APPLICATION

There is increasing awareness of the impact that radiology departments have on carbon emissions. Radiology departments present unique challenges when analyzing energy use while also present an opportunity to place radiologists amongst key stakeholders in healthcare's transition to energy sustainable model of care. This study may allow support for other radiology departments to improve MRI energy efficiency.

#### S5-STCE1-2 Unveiling a Paradigm in Sustainable Radiography: The World's Smallest and Lightest Carbon Nanotube-Based Pocket X-ray System for Soft X-ray Imaging and Irradiation, Featuring Low Energy Consumption and Powered by AAA Batteries

Amar P. Gupta, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

To develop and characterize the carbon nanotube (CNTs)-based X-ray source that is smaller than the size of the human palm, powered by AAA battery, requiring half the energy to operate compared to filament-based X-ray source, and applicable for soft X-ray imaging, cell irradiation, and radiation survey meters calibration purposes. The study highlights its efficiency, portability, and potential contribution to sustainable and energy efficient X-ray source.

## METHODS AND MATERIALS

The diode ceramic X-ray tube was fabricated using vacuum brazing process, with CVD grown CNTs as the electron emitter (cathode) and Beryllium as the anode target. The X-ray tube dimensions were 10 mm in diameter, 14 mm in height, and 4.4 gm in weight. Subsequently, an X-ray system weighing 82.7 gm and measuring (75 X 33 X 28) mm was assembled. The system comprised X-ray tube, 3D printed envelope, two switches, two AAA batteries, and a compact, customized high-voltage pulsed power source capable of generating 16 kHz, 7 kV and 0.3 mA. The X-ray spectrum was obtained using an XR-100-CdTe X-ray detector. X-ray dosage measurement was done with a Fluke 451B Ion Chamber Survey meter positioned at 10 cm away from the X-ray window. Lastly, feasibility X-ray imaging tests were carried out using a highly sensitive mammo X-ray detector, evaluating various soft and hard objects.

## RESULTS

The current-voltage graph showed that at 4950 V, a tube current of 50 uA was obtained, resulting in a radiation dosage rate of 60 mGy/hr at 10 cm from the X-ray window. Interestingly, when the survey meter was placed adjacent to the X-ray window, the X-ray dose rate increased significantly to 950 mGy/hr. In the X-ray imaging tests using 7 kV and 1.8 mAs for 6 seconds, clear imaging of soft materials like leaves and banana chips was achieved, while harder materials like teeth or metal phantoms showed shadows like less distinct imaging results.

## CONCLUSION

CNT-based X-ray technology is paradigm shifting the medical X-ray field. Researches regarding the size reduction potential of CNT-based X-ray sources lacked substantiation. Our study, however, resulted in the creation of the world's foremost compact X-ray system, capable of soft X-ray imaging at 7 kV, yielding approximately 1 Gy/hr of radiation dose. This innovation positions it as a promising contender for Brachytherapy applications, operating proficiently with low-energy AAA batteries. Future endeavors will focus on enhancing X-ray energy and doses without substantial alterations to the system's dimensions.

## CLINICAL RELEVANCE/APPLICATION

This highly portable X-ray device is well-suited for on-site x-ray imaging of soft materials in every set up and convenient radiotherapy in skin cancer treatments at home for patients.

## S5-STCE1-3 Evaluating Maximum Echo Time Sufficient for Quantitative Susceptibility Mapping MRI in Brain

Salil Soman, MD, MS (*Presenter*) Nothing to Disclose

## PURPOSE

The selection of an appropriate Time to Echo (TE) plays a crucial role in Quantitative Susceptibility Mapping (QSM) image generation and impacts scan time. Shortening scan times in medical imaging has the potential to make imaging more sustainable. Embracing energy-efficient and sustainable practices in healthcare contributes to both environmental conservation and improved patient care. In this study, we aimed to evaluate the application of statistical methods to identify the optimal TE sampling strategy for generating high-quality QSM images using the Multi-echo Complex Total Field Inversion (mcTFI) method that can balance shortening scan times with the necessary image quality for accurate diagnosis.

## METHODS AND MATERIALS

A cohort of 53 subjects (47 of them with known intracranial hemorrhage) who had undergone imaging an 11 echo multi-echo GRE imaging acquisition were included. For each subject, subsets of 3 or more echoes were selected from the original 11, and the corresponding mcTFI QSM image volume was created for each subset group. These subset-based mcTFI QSM images were then compared against the 11 echo mcTFI image using multiple 14 statistical metrics, including Mean Absolute Error (MAE), Root Mean Square Error (RMSE) Normalized Mutual Information (NMI) and etc.

## RESULTS

An inspection is conducted to explore the relationship between maximum echo time and statistical values. LMMD, GMMD, PMMD, DICE, NMI, and SSIM recommend the smallest maximum echo time due to unchanged imaging similarity compared to the largest. MAE shows periodic waves, with the 10th echo time having the maximum value. As the maximum TE value increases, imaging similarity generally decreases due to higher MAE or RMSE. RMSE reaches its minimum at the 10th echo time. LPIPS scores worsen when using all echo times but drop at the 10th or 9th echo time. C-FID trends reach a trough at the 10th echo time, possibly reducing further to 7-8th echo times. SAM values increase with larger maximum TE values, minimum at the 10th echo time. MS-SSIM score worsens at smaller maximum TE values, peaking at the 8th echo time. PSNR

has drops indicating worsened imaging similarity. ISSM generally increases with decreasing max TE values, peaking at the 10th echo time.

### **CONCLUSION**

The maximum echo time can be reduced to the 10th echo time to generate similar mCTFI QSM images from all 11 echoes. Six metrics suggest using the shortest echo time as the maximum instead of the largest, while the rest have their own thresholds. This makes it highly possible to reduce scan time using a shorter maximum echo time for desired QSM images.

### **CLINICAL RELEVANCE/APPLICATION**

Shortening imaging time for susceptibility neuroimaging.

#### **S5-STCE2-1 Potential of Large Language Models for Chest X-ray Labeling from Their Radiology Reports**

Soyeon Kim (*Presenter*) Nothing to Disclose

#### **PURPOSE**

The extraction of clinical observations from chest X-rays (CXRs) reports has attracted significant interest as it enables large-scale training of medical imaging models. In this study, we developed an automatic labeling model using the Large Language Model (LLM) for 14 radiologic findings from CXR and aimed to whether utilizing LLM could achieve higher performance in this task.

#### **METHODS AND MATERIALS**

Among MIMIC-CXR dataset, we extracted 1,500 radiology reports with 1,000 reports for fine-tuning and 500 reports for internal test. For external test, another 500 CXR reports were randomly selected from the Open-I dataset. Reference standards for labels from CXR reports were made by a board-certified radiologist for the 14 radiologic findings following CheXpert labels: No Finding, mediastinal widening, cardiomegaly, lung lesion, lung opacity, edema, consolidation, pneumonia, atelectasis, pneumothorax, pleural effusion, pleural other, fracture, and support devices. The labels for each observation are either positive, negative, or uncertain. We generated a dataset for fine-tuning, which consisted of an instruction (prompt for the task), input (report), and output (14 labels) triplet, and developed out model using Meta's publicly-available LLM, LLaMA-13B. Following the Alpaca training methodology, we fine-tuned it using an instruction-tuning technique to enhance its task processing and understanding capabilities. To evaluate the model's performance, we computed Macro-F1 scores for each of the 14 radiologic findings and compared our model with two existing models: CheXpert and CheXbert, both of which were pretrained on a large-scale dataset with over 200,000 reports.

#### **RESULTS**

Our model showed Macro-F1 scores of 0.794 and 0.758 on internal and external tests respectively, surpassing CheXpert's scores of 0.685 and 0.671 and CheXbert's scores of 0.720 and 0.741. Compared to the existing two models, our model achieved higher F1 scores on 12 out of 14 observations in the internal test and 8 out of 14 observations in external test. Specifically, the largest improvements are observed for pneumothorax (0.271), lung lesion (0.172) in internal test, and No Finding (0.249) and pleural effusion (0.222) in external test compared to CheXbert.

#### **CONCLUSION**

Using LLM, we effectively extracted radiologic findings from CXR reports, achieving better performance with just 0.5% of the training data compared with previous models.

#### **CLINICAL RELEVANCE/APPLICATION**

The extracted observations from CXR reports can be used for large-scale training for medical AI model and standardization radiology reports for structured form.

#### **S5-STCE2-2 Comparison of diagnostic accuracy of commonly-encountered general surgery diagnoses using a novel radiology-pathology correlation tool.**

Michael C. Larson, MD, PhD (*Presenter*) Stockholder, D3Sciences; Stockholder, Emagine Solutions Technology

#### **PURPOSE**

Radiologists are often encountered with unclear indications when interpreting abdomen and/or pelvis scans. The goal of this was to evaluate radiology studies' diagnostic accuracy of commonly-encountered general surgery diagnoses regardless of clinical indication using a novel machine learning platform linking radiology to pathology reports.

## **METHODS AND MATERIALS**

PATHFINDER matches radiology and pathology reports with specific anatomic and pathologic annotations based on a medical lexicon (SNOMED CT from the UMLS 2022AA release), using large language and transformer models to train transformer-based text classifiers. PATHFINDER was used to evaluate the diagnostic accuracy, sensitivity and specificity of appendicitis and cholecystitis comparing various radiology modalities at different time points in any hospitalized or emergency department patient of a tertiary academic medical center over the past 3 years. The number of studies included in evaluation of appendicitis were 74 at week 1 up to 94 at week 3 for non-contrast CT evaluation of the abdomen and pelvis (CT A/P), 1007 to 1139 for contrast-enhanced CT A/P, and 603 to 626 for ultrasound of the pelvis. There were 86 to 121 nuclear scans, 867 to 1568 CT scans, 268 to 410 MRIs and 4312 to 5725 ultrasounds of the abdomen in evaluating cholecystitis across different follow-up time points after the radiology exam.

## **RESULTS**

Various diagnostic statistics at different follow-up time points can be seen in figure 1. Diagnostic accuracy for acute cholecystitis and appendicitis was above 0.83 for all modalities across all timepoints. Interestingly, accuracy of diagnosing acute appendicitis was not substantially different between contrast or non-contrast CT of the abdomen and pelvis. Sensitivity for cholecystitis for all modalities was lower than many published values (ranging from 0.38 to 0.74), while specificity was 0.89 or higher for all modalities. The timing of follow-up resulted in variable sensitivity values; for example, a 1 week follow-up time point after nuclear medicine evaluation for cholecystitis yielded only sensitivity of only 0.40, but this increased to 0.60 at 3 weeks.

## **CONCLUSION**

This shows the utility of a novel language-processing tool linking radiology reports to pathology in broadly evaluating diagnostic performance of various medical imaging modalities at different time points.

## **CLINICAL RELEVANCE/APPLICATION**

Diagnostic statistics should be interpreted with caution, as this novel rad-path tool highlights how such can vary depending on details such as the use of contrast or not and the timing of follow-up.

### Potential of Large Language Models for Chest X-ray Labeling from Their Radiology Reports

Sunday, Nov. 26 2:30PM - 3:00PM Room: Learning Center Theater 2

Soyeon Kim (*Presenter*) Nothing to Disclose

#### PURPOSE

The extraction of clinical observations from chest X-rays (CXRs) reports has attracted significant interest as it enables large-scale training of medical imaging models. In this study, we developed an automatic labeling model using the Large Language Model (LLM) for 14 radiologic findings from CXR and aimed to whether utilizing LLM could achieve higher performance in this task.

#### METHODS AND MATERIALS

Among MIMIC-CXR dataset, we extracted 1,500 radiology reports with 1,000 reports for fine-tuning and 500 reports for internal test. For external test, another 500 CXR reports were randomly selected from the Open-I dataset. Reference standards for labels from CXR reports were made by a board-certified radiologist for the 14 radiologic findings following CheXpert labels: No Finding, mediastinal widening, cardiomegaly, lung lesion, lung opacity, edema, consolidation, pneumonia, atelectasis, pneumothorax, pleural effusion, pleural other, fracture, and support devices. The labels for each observation are either positive, negative, or uncertain. We generated a dataset for fine-tuning, which consisted of an instruction (prompt for the task), input (report), and output (14 labels) triplet, and developed out model using Meta's publicly-available LLM, LLaMA-13B. Following the Alpaca training methodology, we fine-tuned it using an instruction-tuning technique to enhance its task processing and understanding capabilities. To evaluate the model's performance, we computed Macro-F1 scores for each of the 14 radiologic findings and compared our model with two existing models: CheXpert and CheXbert, both of which were pretrained on a large-scale dataset with over 200,000 reports.

#### RESULTS

Our model showed Macro-F1 scores of 0.794 and 0.758 on internal and external tests respectively, surpassing CheXpert's scores of 0.685 and 0.671 and CheXbert's scores of 0.720 and 0.741. Compared to the existing two models, our model achieved higher F1 scores on 12 out of 14 observations in the internal test and 8 out of 14 observations in external test. Specifically, the largest improvements are observed for pneumothorax (0.271), lung lesion (0.172) in internal test, and No Finding (0.249) and pleural effusion (0.222) in external test compared to CheXbert.

#### CONCLUSION

Using LLM, we effectively extracted radiologic findings from CXR reports, achieving better performance with just 0.5% of the training data compared with previous models.

#### CLINICAL RELEVANCE/APPLICATION

The extracted observations from CXR reports can be used for large-scale training for medical AI model and standardization radiology reports for structured form.

##### T1-SSCH05-Evaluating the Robustness of 2D and 3D Deep Learning-based Models for Idiopathic Pulmonary Fibrosis (IPF) Diagnosis within an Interstitial Lung Disease (ILD) Population Under Different CT Imaging Protocols

2

Wenxi Yu (*Presenter*) Nothing to Disclose

#### PURPOSE

Deep learning-based systems have not yet been broadly implemented in clinical practice, in part due to unknown robustness across multiple imaging protocols. We aim to evaluate the robust AI model using various CT imaging protocols, to access the model performance in diagnosis.

#### METHODS AND MATERIALS

Three deep learning-based models, including one 2D and two 3D models, have been previously developed to classify interstitial lung disease (ILD) patients into idiopathic pulmonary fibrosis (IPF) or non-IPF based on chest CT scans. Three models were trained on CT image data from 389 IPF and 700 non-IPF ILD patients, retrospectively obtained from multi-center studies (model construction stage, these CT series are referred to as reference conditions). In one non-IPF ILD study, due to its specific study protocol, many patients had multiple CT image data sets that were acquired under both prone and supine positions and/or reconstructed under different imaging parameters from their clinical visit. To assess the robustness of the model, we used available CT data from this study (343 subjects) that had paired sets of CT images on the same patient between model construction stage and model evaluation stage (evaluation conditions). Generalized linear mixed effects model (GLMM) was utilized to identify the significant CT technical and clinical parameters that were associated with getting conflicting diagnostic results between reference and evaluation conditions. Selected parameters include effective tube current-time product (known as "effective mAs"), reconstruction kernels, slice thickness, patient orientation, manufacture model name, and clinical diagnosis.

#### RESULTS

For all three models, the overall specificity of the non-IPF ILD diagnosis model decreased when that model was applied to the evaluation conditions ( $P < 0.001$  for 2D and 3D-2 models, not for 3D-1 model). GLMM further suggests that for two out of three models, mean effective mAs across the scan is the key factor that leads to the decrease in model predictive performance ( $P < 0.001$ ); the difference of mean effective mAs between the reference and evaluation conditions, patient position, and slice thickness (3mm) are flagged as significant factors for one out of three models ( $p < 0.01$ ,  $p = 0.03$ , and  $p = 0.08$  at least in one model).

#### CONCLUSION

Preliminary findings demonstrated the lack of robustness of IPF diagnosis model when applying to CT series collected under different imaging protocols, which indicated that care should be taken when developing and deploying deep learning models into clinical practice.

## CLINICAL RELEVANCE/APPLICATION

Improving the explainability, assessing and enhancing the generalizability of DL models are indispensable steps towards building reliable AI models in clinical practice.

### T1-SSCH05-The Lung and Short of It: The Impact of Telomere Shortening on Progression of Interstitial Lung Disease

John A. Knopf (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to compare radiologic progression of interstitial lung disease (ILD) between patients with abnormal and normal telomere length.

#### METHODS AND MATERIALS

We conducted a retrospective analysis of medical records and imaging studies of patients who had undergone telomere length testing and at least 2 chest high-resolution computed tomography (HRCT) scans. The most common indications for telomere length measurement were personal or family history of ILD, pre-operative evaluation for lung transplant, and bone marrow failure. The patients were divided into two groups based on their telomere length: abnormal (less than the 10th percentile for age) and normal (above the 10th percentile for age).

#### RESULTS

Telomere length was abnormally decreased in 20 patients and normal in 50 patients. Fibrotic HRCT findings were identified in 70% of the abnormal group compared to 62% in the normal group. The rate of radiographic progression was significantly higher (70% vs. 42%) in the short telomere group. Multivariable logistic regression analysis showed that telomere length and fibrotic findings on HRCT were significantly associated with radiographic progression. The ORs were 0.32 (95% CI: 0.07 to 0.57) for telomere length at 1-10th percentile, 0.46 (95% CI: 0.02 to 0.51) for telomere length at =1st percentile, and 0.27 (0.03 to 0.52) for fibrotic HRCT findings.

#### CONCLUSION

Patients with abnormally short telomere length had a higher rate of ILD progression, particularly in patients with fibrotic HRCT findings at baseline and those with telomere length below the 1<sup>st</sup> percentile. These findings highlight the importance of identifying those with abnormal telomere length and monitoring them for radiographic abnormalities.

## CLINICAL RELEVANCE/APPLICATION

The findings of this study can potentially affect the management of ILD patients by identifying the subset who are at higher risk of radiographic deterioration. These high risk patients may benefit from close observation or early intervention.

### T1-SSCH05-Association Between Fat Depletion During the Disease Course and Prognosis of Idiopathic Pulmonary Fibrosis: CT-based Body Composition Analysis

Ji Young Lee, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the association between the changes in body composition derived from chest CT, using deep learning-based technique, during the first-year disease course and outcomes in patients with idiopathic pulmonary fibrosis (IPF).

#### METHODS AND MATERIALS

This retrospective study included consecutive patients diagnosed with IPF between January 2010 and December 2020 who had undergone chest CT and pulmonary function tests (PFTs) at diagnosis and a 1-year follow-up. Averaged fat area (cm<sup>2</sup>, sum of visceral and subcutaneous fat) and muscle area (cm<sup>2</sup>) at the T12-L1 level were calculated for baseline and first-year follow-up CT images using a commercially available deep learning-based body composition analysis software. The changes in averaged fat and muscle areas were dichotomized using the thresholds for the lowest quartiles, respectively. The composite outcome was the occurrence of lung transplantation or death. Multivariable Cox regression analyses and Kaplan-Meier plots with log-rank tests were performed to assess the prognostic implications of body composition changes during the disease courses.

#### RESULTS

A total of 307 IPF patients (mean age, 69.3±8.1; 238 men) were included. During the first year, averaged muscle and fat areas decreased by 1cm<sup>2</sup> and 15.4cm<sup>2</sup>, respectively. Body mass index (BMI) decreased by 0.4kg/m<sup>2</sup>. Regarding PFT, 93 (30.3%) and 59 (19.2%) patients had a decline of forced vital capacity of 5% and carbon monoxide diffusing capacity of 10%, respectively. During the median follow-up of 47 months, 146 patients had composite outcomes (47.6%; lung transplantation, n=15; death, n=139). After adjusting for baseline clinical variables, including age, sex, baseline PFT results, and IPF extent and pulmonary artery diameter on baseline CT, a significant decrease in the fat area during the first year

disease course was a poor prognostic factor (hazard ratio [HR], 1.617; 95% confidence interval [CI]: 1.1, 2.376, P=.014). In another model with variables including changes in BMI and PFT results, a significant decrease in the fat area was also a poor prognostic factor (HR, 1.495; 95% CI: 1.039, 2.151; P=.03), but BMI change was not (P=.905). Patients with a significant decrease in the fat area had more unfavorable outcomes than those without a significant decrease in the fat area (58.4% versus 43.9%, P=.007).

#### **CONCLUSION**

A significant decrease in body fat in the first-year disease course, derived from chest CT images by deep learning-based technique, was a poor prognostic factor in patients with IPF.

#### **CLINICAL RELEVANCE/APPLICATION**

During the disease courses, nutritional support based on the CT-derived body composition analysis can improve outcomes in patients with IPF.

### **T1-SSCH05-Automated and Semi-automated Quantitative CT Biomarkers for Predicting Transplant Free Survival in Idiopathic Pulmonary Fibrosis**

Steven A. Rothenberg, MD (*Presenter*) Founder, Empower Therapeutics Inc ;Member, Translation Holdings LLC;Consultant, Radiostics LLC

#### **PURPOSE**

To compare the accuracy of fully-automated and semi-automated quantitative CT (QCT) biomarkers for predicting transplant-free survival (TFS) in participants with idiopathic pulmonary fibrosis (IPF).

#### **METHODS AND MATERIALS**

For this retrospective multi-institutional study, high resolution chest CT (HRCT) images and survival outcomes were gathered from 63 centers and 546 participants with IPF who were prospectively enrolled in the Pulmonary Fibrosis Foundation patient registry. A fully automated artificial intelligence (AI) algorithm that was trained on external data was applied to the baseline axial HRCT images and used to quantify interstitial lung abnormalities including whole lung percentage and rind percentage (ILA-WL and ILA-R, respectively). The pulmonary surface irregularity (PSI) score was measured in a semi-automated manner using the same baseline axial HRCT images. The Gender-Age-Physiology (GAP) score, comprised of gender, age, pulmonary function test results, was also available at baseline. Each of the biomarkers were categorized into three groups. Cut points for the QCT biomarkers were derived from exploratory data analysis and Youden J statistics. Kaplan-meier plots with log rank test, cox hazards models, and concordance index were used to assess the accuracy of each biomarker for predicting TFS.

#### **RESULTS**

The cohort included 72% males and was 93% white. Mean age was 70 years. Mean BMI was 28. When comparing the highest to lowest stages for each biomarker, the risk of death was 5.7x for ILA-WL (HR:5.7, p<.001), 3.8x for ILA-R (HR:3.8, p<.001), 7.0x for the combination of ILA-WL/ILA-R (HR:7.0, p<.001), 3.4x for PSI score (HR:3.4, p<.001), 8.6x for the combination of ILA-WL/ILA-R/PSI score (HR:8.6, p<.001), 2.4x for GAP score (HR:2.4, p<.001), and 10.7x for the combination of ILA-WL/ILA-R/PSI score/GAP score (HR:10.7, p<.001). Concordance statistics for predicting TFS were 0.67 for ILA-WL, 0.65 for ILA-R, 0.65 for the combination of ILA-WL/ILA-R, 0.63 for PSI score, 0.67 for the combination of ILA-W/ILA-R/PSI score, 0.58 for GAP score, and 0.67 for the combination of ILA-W/ILA-R/PSI score/GAP score.

#### **CONCLUSION**

A fully-automated AI algorithm designed to quantify ILA findings on HRCT had higher accuracy for predicting TFS than the semi-automated PSI score and the GAP score in a multi-institutional cohort with IPF.

#### **CLINICAL RELEVANCE/APPLICATION**

IPF is the most common progressive and fatal fibrotic lung disease, and patients are universally evaluated by HRCT. A quantitative CT biomarker could be applied to existing HRCT images and would add no additional patient cost or radiation. In this study, we compare fully-automated and semi-automated quantitative CT biomarkers to the GAP score, a prognostic clinical marker.

### **T1-SSCH05-Utility of Automated CT Lung Texture Imaging Analysis for Surveillance in Lung Transplantation**

Grace K. Grafham, BSc, MSc (*Presenter*) Nothing to Disclose

#### **PURPOSE**

CT is indicated at chronic lung allograft dysfunction (CLAD) onset in lung transplant recipients. Recent evidence indicates that automated CT lung texture analysis and calculated pulmonary vessel volume (PVV) could accurately phenotype and prognosticate CLAD. However, there is limited data on CT imaging of the lung allograft at baseline despite the updated International Society of Heart and Lung Transplantation (ISHLT) CLAD consensus recommending that baseline CT be

performed at 6-months. The purpose of this study was to characterize the 6-month baseline CT in a cohort of lung transplant recipients and identify how lung texture and PVV change at CLAD onset.

## **METHODS AND MATERIALS**

This was a prospective double-lung transplant cohort (11/2017-11/2019) with CT at 6-month baseline. An automated CT analysis tool quantified normal, ground-glass opacity, reticulation, hyperlucent lung and pulmonary vessel volume (PVV) as a percent of CT total lung capacity. Values were correlated with pulmonary function at 6-months. In patients who developed CLAD (censor 04/2023), the CT closest to CLAD diagnosis was analyzed and compared to baseline. CLAD was phenotyped according to ISHLT consensus and grouped as bronchiolitis obliterans syndrome (BOS) or non-BOS.

## **RESULTS**

Of the 128 included patients, 44 developed CLAD (28 BOS, 7 restrictive allograft syndrome (RAS) or mixed, 9 unclassified or undefined). CT texture at baseline was predominately normal (median [IQR], 94.2% [85-97%]) with a PVV of 2.4% (2-3%). PVV outperformed lung texture in correlation with total lung capacity ( $r=-0.59$ ,  $p<0.01$ ) and forced expiratory volume in the first second ( $r=-0.55$ ,  $p<0.01$ ). CT variables were similar at 6-months between patients who develop CLAD and those who remained CLAD-free. From baseline to non-BOS CLAD onset, hyperlucent texture decreased (-1.3%,  $p=0.04$ ) and ground-glass (+4.2%,  $p=0.04$ ), reticulation (+2.8%,  $p<0.01$ ), and PVV increased (+1.8%,  $p=0.02$ ). Likewise, ground-glass (+4.9%,  $p=0.01$ ), reticulation (+2.7%,  $p<0.001$ ), and PVV (+2.2%,  $p=0.005$ ) were greater at onset of non-BOS versus BOS CLAD. PVV and lung texture were not different from baseline to BOS onset.

## **CONCLUSION**

PVV increased from baseline to CLAD onset for non-BOS phenotypes, in line with its previously described accuracy in phenotyping and strong association with poor prognosis. By identifying normal ranges at the 6-month baseline, we found that PVV in BOS was unchanged at CLAD onset consistent with its bronchocentric pathology and in contrast to the microvascular damage observed in non-BOS CLAD.

## **CLINICAL RELEVANCE/APPLICATION**

Increases in pulmonary vessel volume from the 6-month baseline CT were associated with chronic lung allograft dysfunction of a non-bronchiolitis obliterans syndrome phenotype.

During the median follow-up of 47 months, 146 patients had composite outcomes (47.6%; lung transplantation, n=15; death, n=139). After adjusting for baseline clinical variables, including age, sex, baseline PFT results, and IPF extent and pulmonary artery diameter on baseline CT, a significant decrease in the fat area during the first year disease course was a poor prognostic factor (hazard ratio [HR], 1.617; 95% confidence interval [CI]: 1.1, 2.376, P=.014). In another model with variables including changes in BMI and PFT results, a significant decrease in the fat area was also a poor prognostic factor (HR, 1.495; 95% CI: 1.039, 2.151; P=.03), but BMI change was not (P=.905). Patients with a significant decrease in the fat area had more unfavorable outcomes than those without a significant decrease in the fat area (58.4% versus 43.9%, P=.007).

#### CONCLUSION

A significant decrease in body fat in the first-year disease course, derived from chest CT images by deep learning-based technique, was a poor prognostic factor in patients with IPF.

#### CLINICAL RELEVANCE/APPLICATION

During the disease courses, nutritional support based on the CT-derived body composition analysis can improve outcomes in patients with IPF.

### Automated and Semi-automated Quantitative CT Biomarkers for Predicting Transplant Free Survival in Idiopathic Pulmonary Fibrosis

Tuesday, Nov. 28 8:00AM - 9:00AM Room: S404

Steven A. Rothenberg, MD (*Presenter*) Founder, Empower Therapeutics Inc ;Member, Translation Holdings LLC;Consultant, Radiostics LLC

#### PURPOSE

To compare the accuracy of fully-automated and semi-automated quantitative CT (QCT) biomarkers for predicting transplant-free survival (TFS) in participants with idiopathic pulmonary fibrosis (IPF).

#### METHODS AND MATERIALS

For this retrospective multi-institutional study, high resolution chest CT (HRCT) images and survival outcomes were gathered from 63 centers and 546 participants with IPF who were prospectively enrolled in the Pulmonary Fibrosis Foundation patient registry. A fully automated artificial intelligence (AI) algorithm that was trained on external data was applied to the baseline axial HRCT images and used to quantify interstitial lung abnormalities including whole lung percentage and rind percentage (ILA-WL and ILA-R, respectively). The pulmonary surface irregularity (PSI) score was measured in a semi-automated manner using the same baseline axial HRCT images. The Gender-Age-Physiology (GAP) score, comprised of gender, age, pulmonary function test results, was also available at baseline. Each of the biomarkers were categorized into three groups. Cut points for the QCT biomarkers were derived from exploratory data analysis and Youden J statistics. Kaplan-meier plots with log rank test, cox hazards models, and concordance index were used to assess the accuracy of each biomarker for predicting TFS.

#### RESULTS

The cohort included 72% males and was 93% white. Mean age was 70 years. Mean BMI was 28. When comparing the highest to lowest stages for each biomarker, the risk of death was 5.7x for ILA-WL (HR:5.7,  $p<.001$ ), 3.8x for ILA-R (HR:3.8,  $p<.001$ ), 7.0x for the combination of ILA-WL/ILA-R (HR:7.0,  $p<.001$ ), 3.4x for PSI score (HR:3.4,  $p<.001$ ), 8.6x for the combination of ILA-WL/ILA-R/PSI score (HR:8.6,  $p<.001$ ), 2.4x for GAP score (HR:2.4,  $p<.001$ ), and 10.7x for the combination of ILA-WL/ILA-R/PSI score/GAP score (HR:10.7,  $p<.001$ ). Concordance statistics for predicting TFS were 0.67 for ILA-WL, 0.65 for ILA-R, 0.65 for the combination of ILA-WL/ILA-R, 0.63 for PSI score, 0.67 for the combination of ILA-W/ILA-R/PSI score, 0.58 for GAP score, and 0.67 for the combination of ILA-W/ILA-R/PSI score/GAP score.

#### CONCLUSION

A fully-automated AI algorithm designed to quantify ILA findings on HRCT had higher accuracy for predicting TFS than the semi-automated PSI score and the GAP score in a multi-institutional cohort with IPF.

#### CLINICAL RELEVANCE/APPLICATION

IPF is the most common progressive and fatal fibrotic lung disease, and patients are universally evaluated by HRCT. A quantitative CT biomarker could be applied to existing HRCT images and would add no additional patient cost or radiation. In this study, we compare fully-automated and semi-automated quantitative CT biomarkers to the GAP score, a prognostic clinical marker.

### Utility of Automated CT Lung Texture Imaging Analysis for Surveillance in Lung Transplantation

Tuesday, Nov. 28 8:00AM - 9:00AM Room: S404

Grace K. Grafham, BSc, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

CT is indicated at chronic lung allograft dysfunction (CLAD) onset in lung transplant recipients. Recent evidence indicates that automated CT lung texture analysis and calculated pulmonary vessel volume (PVV) could accurately phenotype and prognosticate CLAD. However, there is limited data on CT imaging of the lung allograft at baseline despite the updated International Society of Heart and Lung Transplantation (ISHLT) CLAD consensus recommending that baseline CT be performed at 6-months. The purpose of this study was to characterize the 6-month baseline CT in a cohort of lung transplant recipients and identify how lung texture and PVV change at CLAD onset.

#### METHODS AND MATERIALS

This was a prospective double-lung transplant cohort (11/2017-11/2019) with CT at 6-month baseline. An automated CT analysis tool quantified normal, ground-glass opacity, reticulation, hyperlucent lung and pulmonary vessel volume (PVV) as a percent of CT total lung capacity. Values were correlated with pulmonary function at 6-months. In patients who developed CLAD (censor 04/2023), the CT closest to CLAD diagnosis was analyzed and compared to baseline. CLAD was phenotyped according to ISHLT consensus and grouped as bronchiolitis obliterans syndrome (BOS) or non-BOS.

#### RESULTS

Of the 128 included patients, 44 developed CLAD (28 BOS, 7 restrictive allograft syndrome (RAS) or mixed, 9 unclassified or undefined). CT texture at baseline was predominately normal (median [IQR], 94.2% [85-97%]) with a PVV of 2.4% (2-3%). PVV outperformed lung texture in correlation with total lung capacity ( $r=-0.59$ ,  $p<0.01$ ) and forced expiratory volume in the first second ( $r=-0.55$ ,  $p<0.01$ ). CT variables were similar at 6-months between patients who develop CLAD and those who remained CLAD-free. From baseline to non-BOS CLAD onset, hyperlucent texture decreased (-1.3%,  $p=0.04$ ) and ground-glass (+4.2%,  $p=0.04$ ), reticulation (+2.8%,  $p<0.01$ ), and PVV increased (+1.8%,  $p=0.02$ ). Likewise, ground-glass (+4.9%,  $p=0.01$ ), reticulation (+2.7%,  $p<0.001$ ), and PVV (+2.2%,  $p=0.005$ ) were greater at onset of non-BOS versus BOS CLAD. PVV and lung texture were not different from baseline to BOS onset.

#### CONCLUSION

PVV increased from baseline to CLAD onset for non-BOS phenotypes, in line with its previously described accuracy in phenotyping and strong association with poor prognosis. By identifying normal ranges at the 6-month baseline, we found that PVV in BOS was unchanged at CLAD onset consistent with its bronchocentric pathology and in contrast to the microvascular damage observed in non-BOS CLAD.

#### CLINICAL RELEVANCE/APPLICATION

Increases in pulmonary vessel volume from the 6-month baseline CT were associated with chronic lung allograft dysfunction of a non-bronchiolitis obliterans syndrome phenotype.

### T1-SSGI08- The Association of Pancreatic Cystic Lesions on MRI with a Future Diagnosis of Pancreatic Carcinoma: Systematic Review<sup>1</sup>

Nika Elmi, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

To conduct a systematic review and meta-analysis of proportions to determine the percentage of pancreatic cystic lesions (PCLs) on MRI that are associated with a future diagnosis of pancreatic carcinoma.

#### METHODS AND MATERIALS

MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials and Scopus were searched by an experienced hospital librarian up to April 1, 2022 (PROSPERO: CRD42022320502). All studies documenting PCLs and a future diagnosis of pancreatic carcinoma in adults were eligible. MRI was required to be >1.5 T with at least one T2-weighted sequence. Studies limited to PCLs that are not normally surveilled (e.g. serous cystadenomas), pancreatitis-related collections, patients with a history of pancreatic carcinoma, syndromes, and studies with <100 cases were excluded. Patients were confirmed positive for pancreatic carcinoma based on pathology-proof or a composite clinical reference standard. Patients were confirmed negative if there was no evidence of pancreatic carcinoma on histopathology, bloodwork or future imaging. Risk of bias was assessed using the QUADAS-2 tool. A meta-analysis of proportions was performed at the patient-level with 95% confidence intervals (95%CI) and meta-regression to explore the impact of risk of bias and the presence of Fukuoka criteria worrisome features or high-risk stigmata.  $P < 0.05$  = significance.

#### RESULTS

Ten studies with 3,560 patients were included. All studies included patients followed on imaging, and none consisted exclusively of patients who underwent surgical resection. Follow-up duration varied, with 9/10 studies having a median follow-up period =3 years, and the three largest studies having a median =4 years. 3.44% (95%CI 1.68%, 5.74%) of patients with a PCL on MRI developed pancreatic carcinoma on follow-up. Within-study heterogeneity  $I^2$  was high (88%) however between-study variance  $t^2$  was low (0.03). Study risk of bias had no impact ( $p=0.51$ ). The percentage of patients who developed pancreatic carcinoma did not differ in studies that included exclusively patients without worrisome features or high-risk stigmata ( $p=0.60$ ). Flow and timing was the main source of potential bias due to patients not undergoing a consistent follow-up protocol.

#### CONCLUSION

A low percentage of patients with PCLs on MRI develop pancreatic carcinoma at follow-up. Multiple societal guidelines recommending many years to lifelong surveillance of these patients may need to be revisited.

#### CLINICAL RELEVANCE/APPLICATION

The association of pancreatic cystic lesions on MRI with future pancreatic cancer is likely weaker than implied in older studies that were limited to patients imaged using less-sensitive techniques and who underwent surgical resection.

### T1-SSGI08- Inter-reader Agreement and Diagnostic Performance of Pancreatic Adenocarcinoma Resectability Assessment with Photon Counting CT Compared with Conventional Energy Integrating Detector CT<sup>2</sup>

Jesi Kim, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Improved spatial resolution and iodine contrast to noise is achievable with photon counting CT (PCCT) compared with conventional energy-integrating CT (EIDCT). The purpose of this study is to determine the diagnostic performance and interreader agreement of pancreatic ductal adenocarcinoma (PDAC) resectability assessment with PCCT compared with EIDCT.

## METHODS AND MATERIALS

A HIPAA-compliant, IRB-approved retrospective database search identified all contrast-enhanced pancreatic protocol abdominal PCCT and EIDCT with PDAC between 4/11/2022 and 10/30/2022. Two abdominal radiologists assessed the degree of tumor involvement of the celiac artery, common hepatic artery, SMA, SMV, and main portal vein (MPV) [not involved, abuts (<180 degree), encases (>180 degree)] and classified tumor resectability (resectable, borderline resectable, locally advanced unresectable, unresectable metastatic). Reader confidence was assessed using a 5-point Likert scale. For immediately preoperative CT scans, diagnostic performance of PCCT and EIDCT for PDAC adenocarcinoma vascular involvement were determined using the operative note as the reference. CTDIVol was recorded. Fisher's exact and Mann-Whitney U tests were used for statistical comparisons. A  $p < .05$  indicated statistical significance.

## RESULTS

67 patients (36 men, mean[SD] age: 67[10]years) with PCCT and 66 patients (36 men, mean[SD] age: 64[9]years) with EIDCT were included. 38 (29%) patients had surgery immediately following the index CT scan. Interreader agreement (PCCT/EIDCT) was 83%/82%, ( $p = .96$ ) for celiac artery, 91%/88% ( $p = .76$ ) for common hepatic artery, 82%/87% ( $p = .60$ ) for SMA, 79%/73% ( $p = .53$ ) for SMV, 76%/81% ( $p = .62$ ) for MPV, and 66%/61% ( $p = .60$ ) for tumor classification. Overall interreader agreement between PCCT and EIDCT was similar (82.1% (312/380), 82.2% (304/370),  $p = .99$ , respectively). Diagnostic confidence (PCCT/EIDCT) was 4.64/4.62 ( $p = .42$ ) for reader 1 and 4.78/4.58 ( $p = .008$ ) for reader 2. There was significant improvement in diagnostic accuracy of MPV involvement for both readers (90% (18/20) for PCCT, 44% (8/18) EIDCT,  $p = .005$ ) and SMA involvement for reader 1 (100% (20/20) for PCCT, 78% (14/18) for EIDCT,  $p = .04$ ). Diagnostic performance for celiac artery, common hepatic artery, and SMV were similar ( $p > .05$ ). CTDIVol for PCCT and EIDCT were 17[7] and 30[27] mGy, respectively ( $p = .006$ ).

## CONCLUSION

In PDAC preoperative imaging, PCCT afforded significantly improved diagnostic accuracy of MPV and SMA involvement at lower patient radiation exposure. Radiologists also had greater diagnostic confidence with PCCT.

## CLINICAL RELEVANCE/APPLICATION

With its improved accuracy of vascular involvement assessment, PCCT could be preferentially utilized for surgical planning.

## T1-SSGI08- Correlation Between MRI-Based Radiomics and Tissue Metabolomics in Patients with Pancreatic Cancer: A Preliminary Study

Ying Zhao JR (*Presenter*) Nothing to Disclose

## PURPOSE

To explore the associations between radiomics scores (radscores) based on magnetic resonance imaging (MRI) and tissue metabolomics biomarkers in pancreatic cancer (PC) patients and to determine the potential metabolic pathways.

## METHODS AND MATERIALS

We performed an untargeted metabolomics study based on the tissue samples of pancreatic cancer tissue (PCT) and their corresponding non-tumorous tissue adjacent to the tumors (NTT) from 18 PC patients between July 2018 and August 2021. The paired-samples t test, fold change (FC) analysis, and orthogonal partial least squares discrimination analysis (OPLS-DA) were used to select the differential metabolites between PCT and NTT groups. Radiomics features based on T2WI, DWI, ADC, and arterial phase (AP) images were extracted. The spearman's correlation test, univariate logistic analysis, and least absolute shrinkage and selection operator (LASSO) were used for radiomics feature selection, and radscores were also constructed with four MRI sequences respectively. The publicly available multiomics network algorithm xMWAS that automated existing network algorithms was applied to identify and graph clusters of correlated data between radscores and differential metabolites. We further conducted metabolic pathway enrichment analyses among the metabolites in each imaging-metabolite cluster to determine the potential metabolic pathways associated with PC patients in our cohort.

## RESULTS

In total, 126 differentially expressed metabolites were found in PC samples compared with controls, which were mainly related to ceramide, fatty acyl carnitine, glycerophosphocholine, glycerophosphoethanolamine, glycerophosphoglycerol, glycerophosphoinositol, glycosphingolipid, lysoglycerophosphocholine, lysoglycerophosphoethanolamine, sphingomyelin, and ubiquinone (Figure 1, Figure 2). The radscores of PCT group were significantly higher than NTT group. The integration of the radscores in PC patients with the 126 metabolic features generated two unique imaging-metabolite clusters (Figure 3).

Metabolic pathway analysis indicated dysregulated pathways in the glycerophospholipid metabolism was associated with PC (Figure 4).

#### **CONCLUSION**

Our study demonstrated that tissue metabolomics were associated with MRI-based radiomics in PC patients and preliminarily found the potential dysregulated metabolic pathway involving glycerophospholipid metabolism.

#### **CLINICAL RELEVANCE/APPLICATION**

These findings may provide potential metabolomics biomarkers associated with MRI-based radiomics for pancreatic cancer patients and potential targets for novel metabolic therapeutics.

### **T1-SGGI08- A Clinical-radiomics Nomogram Based on Dual-layer Spectral Detector CT to Predict Cancer Stage in Pancreatic Ductal Adenocarcinoma**

Linxia Wu (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the performance of radiomics signatures based on polyenergetic images (PEI) and virtual monoenergetic images (VMI) obtained from dual-layer spectral detector CT (DLCT) and to build a clinical-radiomics nomogram based on DLCT for predicting cancer stage (early stage: stage I-II, advanced stage: stage III-IV) in pancreatic ductal adenocarcinoma (PDAC).

#### **METHODS AND MATERIALS**

From June 2020 to October 2022, 173 patients with pathologically confirmed PDAC who underwent contrast-enhanced DLCT were collected. Radiomics features were extracted from PEI and 40 keV VMI which were reconstructed at arterial phase as well as portal venous phase. Clinical information were collected and CT parameters were measured. PEI-based and 40keV VMI-based radiomics signatures were constructed respectively using the least absolute shrinkage and selection operator with tenfold cross-validation. Multivariate logistic regression analysis was performed to identify key clinical factors related to PDAC stage and develop a clinical-radiomics nomogram which integrated radiomics signature and relevant clinical factors. Receiver operating characteristics (ROC) curves, calibration curves and decision curves analysis (DCA) were utilized to assess the performance of the nomogram on discrimination, calibration and clinical utility, respectively.

#### **RESULTS**

Among 173 patients (mean age, 61 years  $\pm$  9 [SD]; 106 male), 49 were early PDAC and 124 were advanced PDAC. All patients were randomly divided into training (n=122) and test (n=51) cohorts at a 7:3 ratio. The PEI-based radiomics signature showed satisfactory diagnostic efficacy with the areas under ROC curves (AUCs) in the training and test cohorts of 0.92 and 0.92, respectively. The optimal radiomics signature based on 40keV VMI with the AUCs in the training and test cohorts of 0.96 and 0.94, respectively. The nomogram combined 40keV VMI-based radiomics signature with two clinical parameters (tumor diameter and normalized iodine density at portal venous phase) showed promising calibration and discrimination in the training and test cohorts (0.97 and 0.91, respectively). DCA exhibited the best clinical benefit of the clinical-radiomics nomogram.

#### **CONCLUSION**

The radiomics signature derived from 40keV VMI and the clinical-radiomics nomogram based on DLCT both showed outstanding performance for stratifying early from advanced stage in PDAC which helped clinical decision-making for PDAC patients.

#### **CLINICAL RELEVANCE/APPLICATION**

Early diagnosis and suitable treatment are very critical and important for survival and prognosis of patients with PDAC. Clinical-radiomics nomogram based on DLCT is a reliable method for accurately differentiating stage for PDAC.

### **T1-SGGI08- Extracellular Volume Fraction Determined by Equilibrium Contrast-enhanced CT to Predict the Survival Outcomes in Patients with Resectable Pancreatic Ductal Adenocarcinoma**

Hongwei Liang SR, MS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate whether extracellular volume (ECV) fraction with equilibrium contrast-enhanced computed tomography (CT) can predict survival outcomes in patients with resectable pancreatic ductal adenocarcinoma (PDAC).

#### **METHODS AND MATERIALS**

Eighty-three PDAC patients who underwent radical resection and preoperative pancreatic CT from January 2014 to January 2019 were retrospectively included. ECV fraction was calculated using ROI measurement within the primary tumor and aorta on unenhanced and equilibrium-phase CT images, followed by the correction of hematocrit value. The CT variables (tumor margins, parenchymal atrophy, main pancreatic duct dilation, peripancreatic tumor infiltration, venous contact, adjacent

organ invasion) were assessed. Multivariable Cox proportional-hazards models were conducted to evaluate the effects of clinical factors, CT variables and ECV fraction on the recurrence-free survival (RFS) and overall survival (OS). Survival rates were derived by Kaplan-Meier method. We also evaluated the association between ECV fraction and recurrence pattern in PDAC.

## RESULTS

Median OS and RFS were 17.1 and 10.7 months, respectively. On multivariate analysis, tumor ECV fraction and adjacent organ invasion were found to be associated with RFS ( $P=0.017$ ;  $P=0.006$ ), and only tumor ECV fraction showed an independent prognostic factor for OS ( $P=0.022$ ). Increasing ECV fraction was associated with a positive effect on RFS (HR, 0.968; 95% CI: 0.942, 0.994), and OS (HR, 0.968; 95% CI: 0.942, 0.995). When stratified patients into low and high ECV groups, based on the median ECV fraction (35.4%, [IQR, 29.0-43.2%]). The median RFS and OS of patients with high ECV group were significantly longer than that of those with low ECV group (RFS, 14.7 months vs 8.3 months,  $P=0.047$ ; OS, 27.9 months vs 12.2 months,  $P=0.021$ ). In recurrence pattern analysis, the ECV fraction did not exhibit association between local recurrence and non-local recurrence groups ( $P=0.455$ ), while patients in low-ECV group were more inclined to experience distant recurrence ( $P=0.037$ ).

## CONCLUSION

ECV fraction determined by equilibrium contrast-enhanced CT was a useful imaging biomarker for predicting survival outcomes in resectable PDAC patients, which may facilitate further risk stratification and personalized care.

## CLINICAL RELEVANCE/APPLICATION

As equilibrium phase CT images can be easily integrated into routine examinations, the CT-derived ECV is expected to become a potential prognostic biomarker for risk stratification and treatment guidance in patients with PDAC.

## T1-SSGI08- Rim Enhancement and Peripancreatic Fat Stranding in Preoperative MDCT as Predictors for Occult Metastasis in PDAC Patients

Qing Xu, MD (*Presenter*) Nothing to Disclose

## PURPOSE

To identify the radiological features and clinical biomarkers that could predict the occult metastasis (OM) of pancreatic ductal adenocarcinoma (PDAC).

## METHODS AND MATERIALS

This retrospective study included PDAC patients who were radiologically diagnosed resectable (R) or borderline resectable (BR) and underwent surgical exploration from January 2018 to December 2021. Depending on whether distant metastasis was found during the exploration, patients were divided into OM and non-OM groups. Tumor imaging features were retrospectively evaluated, and clinical data were collected. Rim enhancement was defined as the ring-like enhancement around a relatively hypodense central area. Peripancreatic fat stranding was defined as the presence of haziness or strand structures derived from the tumor. Univariate and multivariable logistic regression analyses were performed to determine the radiological and clinical predictors for occult metastases. Model performance was determined by discrimination and calibration.

## RESULTS

A total of 502 patients were enrolled, among which 68 (13.5%) patients were found with distant metastases, with 45 liver-only, 19 peritoneal-only, four patients had both liver and peritoneal metastases. Rim enhancement and peripancreatic fat stranding were more frequent in the OM group than in the non-OM group. Tumor size ( $P=0.028$ ), tumor resectability ( $P=0.031$ ), rim enhancement ( $P<0.001$ ), peripancreatic fat stranding ( $P<0.001$ ) and level of CA125 ( $P=0.021$ ) were independent predictors of OM according to the multivariable analyses, and AUCs of predictors were 0.703, 0.594, 0.638, 0.655, 0.631, respectively. The combined model, with sensitivity of 83.82% and specificity of 68.89%, showed the highest AUC of 0.823 and was superior to the clinical model excluded two radiological features.

## CONCLUSION

Rim enhancement, peripancreatic fat stranding, tumor size, tumor resectability and level of CA125 are risk factors for OM of PDAC. The combined model of radiological and clinical features may help the preoperative prediction of OM in PDAC.

## CLINICAL RELEVANCE/APPLICATION

For PDAC patients, the only curative option is surgical resection, while some patients were detected with OM, defined as metastatic diseases invisible in preoperative imaging and encountered during the surgery. Our study introduced two newly discovered and simple radiological features of PDAC into model establishment, including rim enhancement and peripancreatic fat stranding. It is believed that the combination of radiological and clinical features might help identify patients with a higher risk of OM before surgery. Further examination will be recommended for these patients, to achieve accurate staging and assist in the final decision of curative operation.

### Inter-reader Agreement and Diagnostic Performance of Pancreatic Adenocarcinoma Resectability Assessment with Photon Counting CT Compared with Conventional Energy Integrating Detector CT

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E352

Jesi Kim, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Improved spatial resolution and iodine contrast to noise is achievable with photon counting CT (PCCT) compared with conventional energy-integrating CT (EIDCT). The purpose of this study is to determine the diagnostic performance and interreader agreement of pancreatic ductal adenocarcinoma (PDAC) resectability assessment with PCCT compared with EIDCT.

#### METHODS AND MATERIALS

A HIPAA-compliant, IRB-approved retrospective database search identified all contrast-enhanced pancreatic protocol abdominal PCCT and EIDCT with PDAC between 4/11/2022 and 10/30/2022. Two abdominal radiologists assessed the degree of tumor involvement of the celiac artery, common hepatic artery, SMA, SMV, and main portal vein (MPV) [not involved, abuts (<180 degree), encases (>180 degree)] and classified tumor resectability (resectable, borderline resectable, locally advanced unresectable, unresectable metastatic). Reader confidence was assessed using a 5-point Likert scale. For immediately preoperative CT scans, diagnostic performance of PCCT and EIDCT for PDAC adenocarcinoma vascular involvement were determined using the operative note as the reference. CTDI<sub>vol</sub> was recorded. Fisher's exact and Mann-Whitney U tests were used for statistical comparisons. A  $p < .05$  indicated statistical significance.

#### RESULTS

67 patients (36 men, mean[SD] age: 67[10]years) with PCCT and 66 patients (36 men, mean[SD] age: 64[9]years) with EIDCT were included. 38 (29%) patients had surgery immediately following the index CT scan. Interreader agreement (PCCT/EIDCT) was 83%/82%, ( $p = .96$ ) for celiac artery, 91%/88% ( $p = .76$ ) for common hepatic artery, 82%/87% ( $p = .60$ ) for SMA, 79%/73% ( $p = .53$ ) for SMV, 76%/81% ( $p = .62$ ) for MPV, and 66%/61% ( $p = .60$ ) for tumor classification. Overall interreader agreement between PCCT and EIDCT was similar (82.1% (312/380), 82.2% (304/370),  $p = .99$ , respectively). Diagnostic confidence (PCCT/EIDCT) was 4.64/4.62 ( $p = .42$ ) for reader 1 and 4.78/4.58 ( $p = .008$ ) for reader 2. There was significant improvement in diagnostic accuracy of MPV involvement for both readers (90% (18/20) for PCCT, 44% (8/18) EIDCT,  $p = .005$ ) and SMA involvement for reader 1 (100% (20/20) for PCCT, 78% (14/18) for EIDCT,  $p = .04$ ). Diagnostic performance for celiac artery, common hepatic artery, and SMV were similar ( $p > .05$ ). CTDI<sub>vol</sub> for PCCT and EIDCT were 17[7] and 30[27] mGy, respectively ( $p = .006$ ).

#### CONCLUSION

In PDAC preoperative imaging, PCCT afforded significantly improved diagnostic accuracy of MPV and SMA involvement at lower patient radiation exposure. Radiologists also had greater diagnostic confidence with PCCT.

#### CLINICAL RELEVANCE/APPLICATION

With its improved accuracy of vascular involvement assessment, PCCT could be preferentially utilized for surgical planning.

### Correlation Between MRI-Based Radiomics and Tissue Metabolomics in Patients with Pancreatic Cancer: A Preliminary Study

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E352

Ying Zhao JR (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the associations between radiomics scores (radscores) based on magnetic resonance imaging (MRI) and tissue metabolomics biomarkers in pancreatic cancer (PC) patients and to determine the potential metabolic pathways.

#### METHODS AND MATERIALS

We performed an untargeted metabolomics study based on the tissue samples of pancreatic cancer tissue (PCT) and their corresponding non-tumorous tissue adjacent to the tumors (NTT) from 18 PC patients between July 2018 and August 2021. The paired-samples t test, fold change (FC) analysis, and orthogonal partial least squares discrimination analysis (OPLS-DA) were used to select the differential metabolites between PCT and NTT groups. Radiomics features based on T2WI, DWI, ADC, and arterial phase (AP) images were extracted. The spearman's correlation test, univariate logistic analysis, and least absolute shrinkage and selection operator (LASSO) were used for radiomics feature selection, and radscores were also constructed with four MRI sequences respectively. The publicly available multiomics network algorithm xMWAS that automated existing network algorithms was applied to identify and graph clusters of correlated data between radscores and differential metabolites. We further conducted metabolic pathway enrichment analyses among the metabolites in each imaging-metabolite cluster to determine the potential metabolic pathways associated with PC patients in our cohort.

#### RESULTS

In total, 126 differentially expressed metabolites were found in PC samples compared with controls, which were mainly related to ceramide, fatty acyl carnitine, glycerophosphocholine, glycerophosphoethanolamine, glycerophosphoglycerol, glycerophosphoinositol, glycosphingolipid, lysoglycerophosphocholine, lysoglycerophosphoethanolamine, sphingomyelin, and ubiquinone (Figure 1, Figure 2). The radscores of PCT group were significantly higher than NTT group. The integration of the radscores in PC patients with the 126 metabolic features generated two unique imaging-metabolite clusters (Figure 3). Metabolic pathway analysis indicated dysregulated pathways in the glycerophospholipid metabolism was associated with PC (Figure 4).

#### CONCLUSION

Our study demonstrated that tissue metabolomics were associated with MRI-based radiomics in PC patients and preliminarily found the potential dysregulated metabolic pathway involving glycerophospholipid metabolism.

#### CLINICAL RELEVANCE/APPLICATION

These findings may provide potential metabolomics biomarkers associated with MRI-based radiomics for pancreatic cancer patients and potential targets for novel metabolic therapeutics.

### **A Clinical-radiomics Nomogram Based on Dual-layer Spectral Detector CT to Predict Cancer Stage in Pancreatic Ductal Adenocarcinoma**

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E352

Linxia Wu (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To evaluate the performance of radiomics signatures based on polyenergetic images (PEI) and virtual monoenergetic images (VMI) obtained from dual-layer spectral detector CT (DLCT) and to build a clinical-radiomics nomogram based on DLCT for predicting cancer stage (early stage: stage I-II, advanced stage: stage III-IV) in pancreatic ductal adenocarcinoma (PDAC).

#### **METHODS AND MATERIALS**

From June 2020 to October 2022, 173 patients with pathologically confirmed PDAC who underwent contrast-enhanced DLCT were collected. Radiomics features were extracted from PEI and 40 keV VMI which were reconstructed at arterial phase as well as portal venous phase. Clinical information were collected and CT parameters were measured. PEI-based and 40keV VMI-based radiomics signatures were constructed respectively using the least absolute shrinkage and selection operator with tenfold cross-validation. Multivariate logistic regression analysis was performed to identify key clinical factors related to PDAC stage and develop a clinical-radiomics nomogram which integrated radiomics signature and relevant clinical factors. Receiver operating characteristics (ROC) curves, calibration curves and decision curves analysis (DCA) were utilized to assess the performance of the nomogram on discrimination, calibration and clinical utility, respectively.

#### **RESULTS**

Among 173 patients (mean age, 61 years  $\pm$  9 [SD];106 male), 49 were early PDAC and 124 were advanced PDAC. All patients were randomly divided into training (n=122) and test (n=51) cohorts at a 7:3 ratio. The PEI-based radiomics signature showed satisfactory diagnostic efficacy with the areas under ROC curves (AUCs) in the training and test cohorts of 0.92 and 0.92, respectively. The optimal radiomics signature based on 40keV VMI with the AUCs in the training and test cohorts of 0.96 and 0.94, respectively. The nomogram combined 40keV VMI-based radiomics signature with two clinical parameters (tumor diameter and normalized iodine density at portal venous phase) showed promising calibration and discrimination in the training and test cohorts (0.97 and 0.91, respectively). DCA exhibited the best clinical benefit of the clinical-radiomics nomogram.

#### **CONCLUSION**

The radiomics signature derived from 40keV VMI and the clinical-radiomics nomogram based on DLCT both showed outstanding performance for stratifying early from advanced stage in PDAC which helped clinical decision-making for PDAC patients.

#### **CLINICAL RELEVANCE/APPLICATION**

Early diagnosis and suitable treatment are very critical and important for survival and prognosis of patients with PDAC. Clinical-radiomics nomogram based on DLCT is a reliable method for accurately differentiating stage for PDAC.

### Extracellular Volume Fraction Determined by Equilibrium Contrast-enhanced CT to Predict the Survival Outcomes in Patients with Resectable Pancreatic Ductal Adenocarcinoma

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E352

Hongwei Liang SR, MS (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate whether extracellular volume (ECV) fraction with equilibrium contrast-enhanced computed tomography (CT) can predict survival outcomes in patients with resectable pancreatic ductal adenocarcinoma (PDAC).

#### METHODS AND MATERIALS

Eighty-three PDAC patients who underwent radical resection and preoperative pancreatic CT from January 2014 to January 2019 were retrospectively included. ECV fraction was calculated using ROI measurement within the primary tumor and aorta on unenhanced and equilibrium-phase CT images, followed by the correction of hematocrit value. The CT variables (tumor margins, parenchymal atrophy, main pancreatic duct dilation, peripancreatic tumor infiltration, venous contact, adjacent organ invasion) were assessed. Multivariable Cox proportional-hazards models were conducted to evaluate the effects of clinical factors, CT variables and ECV fraction on the recurrence-free survival (RFS) and overall survival (OS). Survival rates were derived by Kaplan-Meier method. We also evaluated the association between ECV fraction and recurrence pattern in PDAC.

#### RESULTS

Median OS and RFS were 17.1 and 10.7 months, respectively. On multivariate analysis, tumor ECV fraction and adjacent organ invasion were found to be associated with RFS ( $P=0.017$ ;  $P=0.006$ ), and only tumor ECV fraction showed an independent prognostic factor for OS ( $P=0.022$ ). Increasing ECV fraction was associated with a positive effect on RFS (HR, 0.968; 95% CI: 0.942, 0.994), and OS (HR, 0.968; 95% CI: 0.942, 0.995). When stratified patients into low and high ECV groups, based on the median ECV fraction (35.4%, [IQR, 29.0-43.2%]). The median RFS and OS of patients with high ECV group were significantly longer than that of those with low ECV group (RFS, 14.7 months vs 8.3 months,  $P=0.047$ ; OS, 27.9 months vs 12.2 months,  $P=0.021$ ). In recurrence pattern analysis, the ECV fraction did not exhibit association between local recurrence and non-local recurrence groups ( $P=0.455$ ), while patients in low-ECV group were more inclined to experience distant recurrence ( $P=0.037$ ).

#### CONCLUSION

ECV fraction determined by equilibrium contrast-enhanced CT was a useful imaging biomarker for predicting survival outcomes in resectable PDAC patients, which may facilitate further risk stratification and personalized care.

#### CLINICAL RELEVANCE/APPLICATION

As equilibrium phase CT images can be easily integrated into routine examinations, the CT-derived ECV is expected to become a potential prognostic biomarker for risk stratification and treatment guidance in patients with PDAC.

### **Rim Enhancement and Peripancreatic Fat Stranding in Preoperative MDCT as Predictors for Occult Metastasis in PDAC Patients**

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E352

Qing Xu, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To identify the radiological features and clinical biomarkers that could predict the occult metastasis (OM) of pancreatic ductal adenocarcinoma (PDAC).

#### **METHODS AND MATERIALS**

This retrospective study included PDAC patients who were radiologically diagnosed resectable (R) or borderline resectable (BR) and underwent surgical exploration from January 2018 to December 2021. Depending on whether distant metastasis was found during the exploration, patients were divided into OM and non-OM groups. Tumor imaging features were retrospectively evaluated, and clinical data were collected. Rim enhancement was defined as the ring-like enhancement around a relatively hypodense central area. Peripancreatic fat stranding was defined as the presence of haziness or strand structures derived from the tumor. Univariate and multivariable logistic regression analyses were performed to determine the radiological and clinical predictors for occult metastases. Model performance was determined by discrimination and calibration.

#### **RESULTS**

A total of 502 patients were enrolled, among which 68 (13.5%) patients were found with distant metastases, with 45 liver-only, 19 peritoneal-only, four patients had both liver and peritoneal metastases. Rim enhancement and peripancreatic fat stranding were more frequent in the OM group than in the non-OM group. Tumor size ( $P=0.028$ ), tumor resectability ( $P=0.031$ ), rim enhancement ( $P<0.001$ ), peripancreatic fat stranding ( $P<0.001$ ) and level of CA125 ( $P=0.021$ ) were independent predictors of OM according to the multivariable analyses, and AUCs of predictors were 0.703, 0.594, 0.638, 0.655, 0.631, respectively. The combined model, with sensitivity of 83.82% and specificity of 68.89%, showed the highest AUC of 0.823 and was superior to the clinical model excluded two radiological features.

#### **CONCLUSION**

Rim enhancement, peripancreatic fat stranding, tumor size, tumor resectability and level of CA125 are risk factors for OM of PDAC. The combined model of radiological and clinical features may help the preoperative prediction of OM in PDAC.

#### **CLINICAL RELEVANCE/APPLICATION**

For PDAC patients, the only curative option is surgical resection, while some patients were detected with OM, defined as metastatic diseases invisible in preoperative imaging and encountered during the surgery. Our study introduced two newly discovered and simple radiological features of PDAC into model establishment, including rim enhancement and peripancreatic fat stranding. It is believed that the combination of radiological and clinical features might help identify patients with a higher risk of OM before surgery. Further examination will be recommended for these patients, to achieve accurate staging and assist in the final decision of curative operation.

### **T1-SSGI09- CT-Radiomics Derived Early Chemotherapy Response Prediction in Advanced Pancreatic Ductal Adenocarcinoma** 1

Felix N. Harder, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the value of radiomics-derived early chemotherapy response prediction in advanced pancreatic ductal adenocarcinoma (PDAC) based on features from the primary tumor site and hepatic metastases. Although the presence of liver metastases significantly impacts clinical outcome in PDAC the prognostic value of radiomics features derived from hepatic metastases has yet not been scrutinized. Moreover, current studies on radiomics in advanced PDAC lack prospectively collected datasets.

#### METHODS AND MATERIALS

164 patients with locally advanced and metastatic PDAC were retrospectively enrolled from a closely monitored large-scale prospective clinical study (COMPASS trial). Of these, 115 patients (70%) presented with liver metastases at first diagnosis. All patients underwent first-line chemotherapy treatment with modified FOLFIRINOX or gemcitabine/nab-paclitaxel. 3D radiomics features were obtained from the primary tumor site and the largest liver metastases at pre-therapeutic baseline CT. Radiomics-only and clinical-radiomics (+Moffitt signature) models were built to predict early progressive disease at first follow-up CT according to RECIST 1.1 in the overall cohort and liver metastases only cohort.

#### RESULTS

The clinical-radiomics model outperformed the radiomics-only model in the overall cohort for prediction of early progression at first follow-up CT (AUC: 0.788 vs. 0.731;  $p < 0.001$ ). In the liver metastases cohort, the clinical-radiomics model, combining features from the primary tumor site, largest liver metastasis (L1) and Moffitt-signature (AUC: 0.842) outperformed the radiomics-only models incorporating features from the primary site only (AUC = 0.721), L1 only (AUC = 0.702) and a combined primary and L1 model (AUC = 0.777) (all  $p < 0.001$ ). Based on the radiomics score, patients were stratified into high-risk and low-risk patients demonstrating significantly ( $p=0.011$ ) prolonged overall survival in low-risk patients in the full cohort.

#### CONCLUSION

Clinical-radiomics models enabled superior benefit to radiomics-only models for early response prediction in advanced PDAC. In patients with liver metastases, incorporating metastases-derived features provided additive value compared to primary tumor models alone. This finding in synopsis with the known clinical impact of hepatic metastases underlines the need to take metastasis-derived features into account when building prediction models in metastatic PDAC.

#### CLINICAL RELEVANCE/APPLICATION

Clinical-radiomics models may improve early chemotherapy response prediction in patients with advanced PDAC. Moreover, we propose that future studies take metastasis-derived features into account when building prediction models in metastatic PDAC.

### **T1-SSGI09- Monitor PDAC Tumor Response to Stroma-Targeting Therapy using CEST MRI** 2

Guanshu Liu, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

We sought to develop dextran-enhanced CEST MRI to accurately assess the therapeutic effects of stroma-targeting treatment in pancreatic ductal adenocarcinoma (PDAC). Thanks to their naturally carried, abundant exchangeable hydroxyl (OH) protons, dextrans have been explored as a new type of Chemical Exchange Saturation Transfer (CEST) contrast agent for a 'label-free' molecular imaging. The wide size range of dextrans makes them suitable for characterizing the tumor vascular permeability in the macro- to nano-size range, a feature especially useful for monoclonal antibodies and nanoparticulate therapeutics.

## METHODS AND MATERIALS

Animal model: The murine PDAC KPC cells were derived from Kras<sup>LSL.G12D/+</sup>; p53<sup>R172H/+</sup>; Pdx<sup>Cretg/+</sup> (or KPC) mice. To form syngeneic allograft PDAC tumors subcutaneously, 1 million cells (in 200  $\mu$ L) were subcutaneously injected into both flanks of C57BL/6J mice to form two tumors. PEGPH20 treatment. Randomly selected mice (n=4) will be treated with PEGylated human hyaluronidase (PEGPH20)<sup>2</sup> at 4.5 mg/kg, i.v. twice weekly for 3 weeks<sup>3</sup>. MRI: Mice were imaged using an 11.7 T Bruker Biospec scanner, with CEST MRI performed before and after the i.v. injection of 200  $\mu$ L dex10 (500 mg/kg b.w), using parameters: B<sub>1</sub>= 1.8  $\mu$ T, T<sub>sat</sub>= 3 s,  $\omega_1$  = -3 to +3 ppm, step= 0.2 ppm. MTR<sub>asym</sub>=(S<sub>- $\omega_1$</sub>  - S<sub>+ $\omega_1$</sub> )/S<sub>0</sub> was computed after the B<sub>0</sub> correction using the WASSR method.  $\Delta$ MTR<sub>asym</sub> (1 ppm) at each time point was calculated by MTR<sub>asym</sub> (t)- MTR<sub>asym</sub> (pre). Area-under-curve (AUC) was calculated by  $\Delta$ MTR<sub>asym</sub> between 0 and 22.5 min post-injection.

## RESULTS

The representative CEST maps and plots are shown in Figures 1a-c: without PEGPH20 treatment, KPC tumors had negligible Dex10 contrast enhancement, attributed to tumor desmoplasia, whereas PEGPH20 treatment led to substantial Dex10 contrast enhancement in the tumor. The quantitative analyses (Figures 1d-e) showed that the PEGPH20 treatment resulted in a 3-fold increased area under curve (AUC) within the first 22.5 min, and a 5-fold increased enhancing fraction (V<sub>f</sub>), the fraction of the tumor volume with non-zero enhancement voxels in the parametric maps.

## CONCLUSION

We have evaluated dextran-enhanced CEST MRI's ability to assess tumor responses to stroma-targeting therapy. Our data indicates that 10 kD dextran is suitable for monitoring the tumor responses to PEGPH20. Reference: 1. Dubick, M. A., et al., *J Trauma* 1994, 36 (3), 323-330. 2. Provenzano, P. P., et al., *Cancer cell* 2012, 21(3), 418-29. 3. Thompson, C. B., et al., *Mol Cancer Ther* 2010, 9 (11), 3052-3064.

## CLINICAL RELEVANCE/APPLICATION

Dextran-enhanced CEST MRI provides a safe while effective imaging approach to guide and monitor stroma-targeting therapies to achieve optimized outcomes in hypo-permeable PDAC.

## T1-SSGI09- Initial SHAPE Evaluation of Pancreatic Cancers Undergoing Chemotherapy with Sonoporation Treatment

Priscilla Machado, MD (*Presenter*) Nothing to Disclose

## PURPOSE

Sonoporation is a novel method that can enhance therapeutic efficacy of co-administered chemotherapy by localized CEUS imaging, which temporarily changes tumor vascular microenvironment. An ongoing Phase II clinical trial aims to improve standard of care (SoC) chemotherapy treatment by adding sonoporation (i.e., augmenting treatment with CEUS and microbubbles). As part of this study, a noninvasive ultrasound technique, subharmonic-aided pressure estimation (SHAPE), was used to acquire intra-tumoral pressure measurements. The objective of this study was to use SHAPE during the chemotherapy with sonoporation treatment to evaluate changes in treatment response.

## METHODS AND MATERIALS

Subjects recently diagnosed with pancreatic cancer stages II, III or IV undergoing chemotherapy are eligible to be enrolled in this ongoing, IRB-approved study. Enrolled subjects underwent their SoC chemotherapy treatment (FOLFIRINOX or Gemcitabine/ Nab-Paclitaxel regimen) with 20 minutes of sonoporation treatment for each chemotherapy visit. A Logiq E10 scanner (GE Healthcare, Waukesha, WI) with C1-6 probe was used to image, target and induce sonoporation. This system also acquired SHAPE pressure measurements values (in dB) with mean difference between the values acquired with and without microbubbles used in the final analysis. Subjects were divided into responders and non-responders and their SHAPE values compared at three time points: first, third and last cycles of chemotherapy using t-tests.

## RESULTS

To date, 5 of the subjects enrolled in this ongoing study completed their first line chemotherapy treatment and had their SHAPE pressure data analyzed. The mean age of the subjects was 56 years (range: 43-67 years). Subjects were divided into responders (n = 1) and non-responders (n = 4) to the treatment regimen. First cycle values were  $-2.79 \pm 1.05$  dB for responders and  $-3.72 \pm 1.10$  dB for non-responders (p = 0.21). Third cycle values were  $3.25 \pm 4.08$  dB for responders and

-3.95 ± 1.02 dB for non-responders (p = 0.005). Last cycle values were -5.50 ± 1.37 dB for responders and -1.92 ± 1.03 dB for non-responders (p = 0.002).

#### **CONCLUSION**

This initial comparison of SHAPE intra-tumoral pressure measurements between responders and non-responders showed significant statistical differences for the third and for the last cycle (p < 0.006) suggesting SHAPE may be used to indicate chemotherapy response; albeit based on a small sample size.

#### **CLINICAL RELEVANCE/APPLICATION**

The use of non-invasive methods to determine intra-tumoral pressure measurements that evaluate chemotherapy response could help with patient care by providing a more precise indication of the tumor response to treatment.

#### **T1-SSGI09- Mucin Content in Rectal Adenocarcinoma: Quantity and Association with Clinical Outcomes after Total Neoadjuvant Therapy**

Sidra Javed-Tayyab, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Evaluate relationship between mucin pool and patient outcomes on baseline and restaging rectal magnetic resonance imaging (MRI) after total neoadjuvant therapy (TNT).

#### **METHODS AND MATERIALS**

This retrospective study analyzed the data of 199 patients (mean age, 58 years; range, 49-68; 81 women) diagnosed with rectal adenocarcinoma and treated with TNT between January 2018 and December 2018. The patients' baseline and restaging MRI scans, along with their treatment information, were carefully reviewed by two expert abdominal radiologists. The mucin content of the tumors was classified into five categories: no mucin, < 25%, 25-50%, 50-75%, or >75% mucin. Logistic regression was performed to compare patient outcomes for non-mucinous (< 50% mucin) versus mucinous (> 50% mucin) tumors, as well as for no mucin versus any mucin content tumors.

#### **RESULTS**

On baseline MRI, most had mid-rectal tumor (43%), majority were T3 (71%), positive nodes (79%), no extramural vascular invasion (EMVI) (82%), and positive circumferential resection margin (CRM) (55%). The majority had no mucin (85%), followed by 7% who had < 25% mucin; 2.5% who had 25-50% mucin, 2.5% who had 50-75% mucin, and 3% who had >75% mucin. In addition, 52% patients underwent total mesorectal excision and 14% had pathological complete response (pCR), whereas 41% underwent nonoperative management and 40% had sustained clinical complete response (scCR) after 3 years of follow up. Overall, no statistically significant associations were found for local recurrence/ regrowth, distant recurrence, or recurrence free survival. Mucin pool was not associated with complete response [49.1% vs 40%, p value= 0.35].

#### **CONCLUSION**

Although patients with mucinous rectal tumors have been shown to have worse prognoses in the literature, mucin content was not associated with patient outcomes in our patient population who underwent total neoadjuvant therapy. Therefore, mucin status may not be a good predictor of prognosis in this specific population. Further research is needed to explore significance of mucin content on MRI.

#### **CLINICAL RELEVANCE/APPLICATION**

The prognostic implications of mucin content on MRI in rectal adenocarcinoma patients who are undergoing total neoadjuvant therapy is currently not established in the literature. Our study suggests that mucin content may not be predictive of worse outcomes when rectal adenocarcinoma patients are treated with the modern paradigm of total neoadjuvant therapy.

#### **T1-SSGI09- Noninvasive Prediction of Insufficient Biochemical Response after Ursodeoxycholic Acid Treatment in Patients with Primary Biliary Cholangitis based on Pretreatment Nonenhanced MRI**

Yun Zhang, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To explore the feasibility of pretreatment nonenhanced magnetic resonance imaging (MRI) in predicting insufficient biochemical response to ursodeoxycholic acid (UDCA) in patients with primary biliary cholangitis (PBC).

#### **METHODS AND MATERIALS**

From January 2009 to April 2022, consecutive PBC patients treated with UDCA who underwent non-enhanced MRI within 30 days before treatment were retrospectively enrolled. All MR images were independently evaluated by two blinded radiologists. Uni- and multivariable logistic regression analyses were performed to develop a predictive model for 12-month insufficient

biochemical response. Model performances were evaluated by computing the area under the receiver operating characteristic curve (AUC), sensitivity and specificity.

## **RESULTS**

A total of 74 patients ( $50.6 \pm 11.9$  years; 62 female) were included. Three pretreatment MRI features, including hepatomegaly (odds ratio [OR]: 4.580;  $p = 0.011$ ), periportal hyperintensity on T2-weighted imaging (T2WI) (OR: 4.795,  $p = 0.008$ ), and narrowing of the bile ducts (OR: 3.491;  $p = 0.027$ ) were associated with 12-month insufficient biochemical response at the multivariable analysis. A predictive model based on the above indicators showed an AUC of 0.781, sensitivity of 85.4%, and specificity of 61.5% for predicting insufficient biochemical response.

## **CONCLUSION**

A noninvasive model based on three pretreatment MRI features could accurately predict 12-month insufficient biochemical response to UDCA in patients with PBC. Early identification of PBC patients at increased risk for insufficient response can facilitate in time initiation of additional treatment.

## **CLINICAL RELEVANCE/APPLICATION**

There is an urgent need for identifying the characteristics or risk factors of PBC patients with insufficient response to UDCA, in order to achieve early screening of high-risk PBC patients prior to UDCA treatment and to assist in decision making. Our study developed a noninvasive model based on three pretreatment nonenhanced MRI features that can help in the early identification of high-risk PBC patients with an insufficient biochemical response to UDCA.

### Monitor PDAC Tumor Response to Stroma-Targeting Therapy using CEST MRI

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E351

Guanshu Liu, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

We sought to develop dextran-enhanced CEST MRI to accurately assess the therapeutic effects of stroma-targeting treatment in pancreatic ductal adenocarcinoma (PDAC). Thanks to their naturally carried, abundant exchangeable hydroxyl (OH) protons, dextrans have been explored as a new type of Chemical Exchange Saturation Transfer (CEST) contrast agent for a 'label-free' molecular imaging. The wide size range of dextrans makes them suitable for characterizing the tumor vascular permeability in the macro- to nano-size range, a feature especially useful for monoclonal antibodies and nanoparticulate therapeutics.

#### METHODS AND MATERIALS

Animal model: The murine PDAC KPC cells were derived from *Kras<sup>LSL.G12D/+</sup>; p53<sup>R172H/+</sup>; Pdx<sup>Cretg/+</sup>* (or KPC) mice. To form syngeneic allograft PDAC tumors subcutaneously, 1 million cells (in 200  $\mu$ L) were subcutaneously injected into both flanks of C57BL/6J mice to form two tumors. PEGPH20 treatment. Randomly selected mice (n=4) will be treated with PEGylated human hyaluronidase (PEGPH20)<sub>2</sub> at 4.5 mg/kg, i.v. twice weekly for 3 weeks<sup>3</sup>. MRI: Mice were imaged using an 11.7 T Bruker Biospec scanner, with CEST MRI performed before and after the i.v. injection of 200  $\mu$ L dex10 (500 mg/kg b.w), using parameters:  $B_1 = 1.8 \mu$ T,  $T_{sat} = 3$  s,  $\omega = -3$  to  $+3$  ppm, step = 0.2 ppm.  $MTR_{asym} = (S_{-} - S_{+}) / S_0$  was computed after the B0 correction using the WASSR method.  $MTR_{asym}$  (1 ppm) at each time point was calculated by  $MTR_{asym}(t) - MTR_{asym}(pre)$ . Area-under-curve (AUC) was calculated by  $MTR_{asym}$  between 0 and 22.5 min post-injection.

#### RESULTS

The representative CEST maps and plots are shown in Figures 1a-c: without PEGPH20 treatment, KPC tumors had negligible Dex10 contrast enhancement, attributed to tumor desmoplasia, whereas PEGPH20 treatment led to substantial Dex10 contrast enhancement in the tumor. The quantitative analyses (Figures 1d-e) showed that the PEGPH20 treatment resulted in a 3-fold increased area under curve (AUC) within the first 22.5 min, and a 5-fold increased enhancing fraction ( $V_f$ ), the fraction of the tumor volume with non-zero enhancement voxels in the parametric maps.

#### CONCLUSION

We have evaluated dextran-enhanced CEST MRI's ability to assess tumor responses to stroma-targeting therapy. Our data indicates that 10 kD dextran is suitable for monitoring the tumor responses to PEGPH20. Reference: 1. Dubick, M. A., et al., *J Trauma* 1994, 36 (3), 323-330. 2. Provenzano, P. P., et al., *Cancer cell* 2012, 21(3), 418-29. 3. Thompson, C. B., et al., *Mol Cancer Ther* 2010, 9 (11), 3052-3064.

#### CLINICAL RELEVANCE/APPLICATION

Dextran-enhanced CEST MRI provides a safe while effective imaging approach to guide and monitor stroma-targeting therapies to achieve optimized outcomes in hypo-permeable PDAC.

### Initial SHAPE Evaluation of Pancreatic Cancers Undergoing Chemotherapy with Sonoporation Treatment

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E351

Priscilla Machado, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Sonoporation is a novel method that can enhance therapeutic efficacy of co-administered chemotherapy by localized CEUS imaging, which temporarily changes tumor vascular microenvironment. An ongoing Phase II clinical trial aims to improve standard of care (SoC) chemotherapy treatment by adding sonoporation (i.e., augmenting treatment with CEUS and microbubbles). As part of this study, a noninvasive ultrasound technique, subharmonic-aided pressure estimation (SHAPE), was used to acquire intra-tumoral pressure measurements. The objective of this study was to use SHAPE during the chemotherapy with sonoporation treatment to evaluate changes in treatment response.

#### METHODS AND MATERIALS

Subjects recently diagnosed with pancreatic cancer stages II, III or IV undergoing chemotherapy are eligible to be enrolled in this ongoing, IRB-approved study. Enrolled subjects underwent their SoC chemotherapy treatment (FOLFIRINOX or Gemcitabine/ Nab-Paclitaxel regimen) with 20 minutes of sonoporation treatment for each chemotherapy visit. A Logiq E10 scanner (GE HealthCare, Waukesha, WI) with C1-6 probe was used to image, target and induce sonoporation. This system also acquired SHAPE pressure measurements values (in dB) with mean difference between the values acquired with and without microbubbles used in the final analysis. Subjects were divided into responders and non-responders and their SHAPE values compared at three time points: first, third and last cycles of chemotherapy using t-tests.

#### RESULTS

To date, 5 of the subjects enrolled in this ongoing study completed their first line chemotherapy treatment and had their SHAPE pressure data analyzed. The mean age of the subjects was 56 years (range: 43-67 years). Subjects were divided into responders ( $n = 1$ ) and non-responders ( $n = 4$ ) to the treatment regimen. First cycle values were  $-2.79 \pm 1.05$  dB for responders and  $-3.72 \pm 1.10$  dB for non-responders ( $p = 0.21$ ). Third cycle values were  $3.25 \pm 4.08$  dB for responders and  $-3.95 \pm 1.02$  dB for non-responders ( $p = 0.005$ ). Last cycle values were  $-5.50 \pm 1.37$  dB for responders and  $-1.92 \pm 1.03$  dB for non-responders ( $p = 0.002$ ).

#### CONCLUSION

This initial comparison of SHAPE intra-tumoral pressure measurements between responders and non-responders showed significant statistical differences for the third and for the last cycle ( $p < 0.006$ ) suggesting SHAPE may be used to indicate chemotherapy response; albeit based on a small sample size.

#### CLINICAL RELEVANCE/APPLICATION

The use of non-invasive methods to determine intra-tumoral pressure measurements that evaluate chemotherapy response could help with patient care by providing a more precise indication of the tumor response to treatment.

### **Mucin Content in Rectal Adenocarcinoma: Quantity and Association with Clinical Outcomes after Total Neoadjuvant Therapy**

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E351

Sidra Javed-Tayyab, MD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Evaluate relationship between mucin pool and patient outcomes on baseline and restaging rectal magnetic resonance imaging (MRI) after total neoadjuvant therapy (TNT).

#### **METHODS AND MATERIALS**

This retrospective study analyzed the data of 199 patients (mean age, 58 years; range, 49-68; 81 women) diagnosed with rectal adenocarcinoma and treated with TNT between January 2018 and December 2018. The patients' baseline and restaging MRI scans, along with their treatment information, were carefully reviewed by two expert abdominal radiologists. The mucin content of the tumors was classified into five categories: no mucin, < 25%, 25-50%, 50-75%, or >75% mucin. Logistic regression was performed to compare patient outcomes for non-mucinous (< 50% mucin) versus mucinous (> 50% mucin) tumors, as well as for no mucin versus any mucin content tumors.

#### **RESULTS**

On baseline MRI, most had mid-rectal tumor (43%), majority were T3 (71%), positive nodes (79%), no extramural vascular invasion (EMVI) (82%), and positive circumferential resection margin (CRM) (55%). The majority had no mucin (85%), followed by 7% who had < 25% mucin; 2.5% who had 25-50% mucin, 2.5% who had 50-75% mucin, and 3% who had >75% mucin. In addition, 52% patients underwent total mesorectal excision and 14% had pathological complete response (pCR), whereas 41% underwent nonoperative management and 40% had sustained clinical complete response (scCR) after 3 years of follow up. Overall, no statistically significant associations were found for local recurrence/ regrowth, distant recurrence, or recurrence free survival. Mucin pool was not associated with complete response [49.1% vs 40%, p value= 0.35].

#### **CONCLUSION**

Although patients with mucinous rectal tumors have been shown to have worse prognoses in the literature, mucin content was not associated with patient outcomes in our patient population who underwent total neoadjuvant therapy. Therefore, mucin status may not be a good predictor of prognosis in this specific population. Further research is needed to explore significance of mucin content on MRI.

#### **CLINICAL RELEVANCE/APPLICATION**

The prognostic implications of mucin content on MRI in rectal adenocarcinoma patients who are undergoing total neoadjuvant therapy is currently not established in the literature. Our study suggests that mucin content may not be predictive of worse outcomes when rectal adenocarcinoma patients are treated with the modern paradigm of total neoadjuvant therapy.

### Noninvasive Prediction of Insufficient Biochemical Response after Ursodeoxycholic Acid Treatment in Patients with Primary Biliary Cholangitis based on Pretreatment Nonenhanced MRI

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E351

Yun Zhang, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To explore the feasibility of pretreatment nonenhanced magnetic resonance imaging (MRI) in predicting insufficient biochemical response to ursodeoxycholic acid (UDCA) in patients with primary biliary cholangitis (PBC).

#### METHODS AND MATERIALS

From January 2009 to April 2022, consecutive PBC patients treated with UDCA who underwent non-enhanced MRI within 30 days before treatment were retrospectively enrolled. All MR images were independently evaluated by two blinded radiologists. Uni- and multivariable logistic regression analyses were performed to develop a predictive model for 12-month insufficient biochemical response. Model performances were evaluated by computing the area under the receiver operating characteristic curve (AUC), sensitivity and specificity.

#### RESULTS

A total of 74 patients ( $50.6 \pm 11.9$  years; 62 female) were included. Three pretreatment MRI features, including hepatomegaly (odds ratio [OR]: 4.580;  $p = 0.011$ ), periportal hyperintensity on T2-weighted imaging (T2WI) (OR: 4.795,  $p = 0.008$ ), and narrowing of the bile ducts (OR: 3.491;  $p = 0.027$ ) were associated with 12-month insufficient biochemical response at the multivariable analysis. A predictive model based on the above indicators showed an AUC of 0.781, sensitivity of 85.4%, and specificity of 61.5% for predicting insufficient biochemical response.

#### CONCLUSION

A noninvasive model based on three pretreatment MRI features could accurately predict 12-month insufficient biochemical response to UDCA in patients with PBC. Early identification of PBC patients at increased risk for insufficient response can facilitate in time initiation of additional treatment.

#### CLINICAL RELEVANCE/APPLICATION

There is an urgent need for identifying the characteristics or risk factors of PBC patients with insufficient response to UDCA, in order to achieve early screening of high-risk PBC patients prior to UDCA treatment and to assist in decision making. Our study developed a noninvasive model based on three pretreatment nonenhanced MRI features that can help in the early identification of high-risk PBC patients with an insufficient biochemical response to UDCA.

### **T1-SSPD03-Normative Model of Cranial Bone Development Unveils Abnormal Local Bone Density in Pediatric CT Associated With Intra-Cranial Hypertension and Non-syndromic Sagittal Craniosynostosis**

Antonio Porras Perez, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

After surgical treatment of children with non-syndromic sagittal craniosynostosis (NSSC), signs of intra-cranial hypertension (ICH) may trigger reoperation to prevent neurological damage. However, noninvasive evaluation of pediatric ICH is subjective and based on variable clinical symptoms, since precise measurement of intracranial pressure requires invasive monitoring. Although local bone anomalies associated with ICH have been qualitatively described in CT images, the absence of curated datasets and quantitative normative references have prevented their systematic study to identify ICH. We used a normative cranial bone development model to explore local mineral density anomalies in both patients with ICH and with NSSC.

#### METHODS AND MATERIALS

We used deep-learning methods to automatically segment the calvarium from preoperative CT images of 55 patients with ICH (26 male, 29 female, age  $4.21 \pm 3.11$  years) and 122 patients with NSSC (92 male, 30 female, age  $4.20 \pm 3.96$  months). The etiology of ICH included hydrocephalus, idiopathic intracranial hypertension, arachnoid cysts, or intracranial neoplasms. Patients with any form of craniosynostosis were excluded from the ICH group. For each patient, we used our age- and sex-specific normative model built from CT images of 2,068 control subjects (age 0-10 years) to quantify local bone mineral density anomalies (in Hounsfield Units, HU) at every location on the calvarium.

#### RESULTS

Patients with ICH showed a global decrease in average calvarial bone mineral density ( $-40.44 \pm 77.18$  HU,  $p < 0.001$ ) compared to the normative reference, which was significant in all calvarial bones ( $p < 0.05$ ). Patients with NSSC showed a global decrease compared to normative in average calvarial bone mineral density ( $-7.96 \pm 20.01$  HU,  $p < 0.001$ ), which was greater in the parietal ( $-10.85 \pm 22.36$  HU,  $p < 0.001$ ) and occipital ( $-11.11 \pm 29.28$  HU,  $p < 0.001$ ) than in the frontal bones ( $-2.24 \pm 25.89$  HU,  $p = 0.01$ ). Patients with NSSC presented increased mineral density in the frontal ( $p < 0.001$ ) and occipital bones ( $p < 0.001$ ) compared to patients with ICH, but not in the parietal bones ( $p = 0.43$ ).

#### CONCLUSION

We present the first systematic quantitative study of local cranial bone density anomalies associated with ICH. Our results demonstrate significant bone density loss in patients with ICH, and similar local density patterns in the fused parietal bones of patients with NSSC that may be produced by the increased pressure from the constrained brain.

#### CLINICAL RELEVANCE/APPLICATION

Our new quantitative findings show the potential of quantitative CT to support the clinical evaluation of pediatric ICH to achieve earlier interventions and avoid invasive monitoring.

### **T1-SSPD03-Hip MRI-Based Synthetic CT Versus Conventional CT: A Morphometric and Clinical Comparison in Young Patients**

Jade Iwasaka-Neder, MD (*Presenter*) Nothing to Disclose

## PURPOSE

MRI-based synthetic CT (sCT) generates CT-like images from MRI data that can easily undergo 2D and 3D reformatting, a process that would otherwise require complex segmentation programs for MRI sequences. This study aims to evaluate the equivalence and reliability of sCT versus conventional CT (cCT) for assessing hip morphology and maturity in pediatric and young patients.

## METHODS AND MATERIALS

This IRB-approved prospective study included patients = 25 years old referred for both cCT and MRI of the hip and pelvis within a 6 month interval for hip pathology evaluation. Patients were scanned on a 3 Tesla MRI scanner according to standard department protocol, including a high-resolution dual-echo GRE sequence used to generate sCT images via a commercially available deep-learning enabled post-processing software. cCT scans were performed according to standard protocols on state-of-the-art multidetector scanners with submillimeter resolution. De-identified images were reviewed by two pediatric musculoskeletal radiologists who measured the following on each hip: lateral center edge angle, anterior center edge angle, acetabular version, acetabular index, acetabular quotient, Sharp angle, and joint space width. Reliability and agreement of measurements were assessed via intraclass correlations (ICCs), Bland-Altman plots, and two one-sided tests for equivalence. 3D surface distances between cCT and sCT were computed. The status of physeal maturity (open versus closed) at sCT and cCT was established by consensus review at 7 locations and sCT's accuracy to correctly determine physeal maturity calculated. Images were scored on a 5 point Likert scale for overall diagnostic quality, SNR, bony margins definition, corticomedullary differentiation and artifacts and compared to cCT via Wilcoxon signed rank test.

## RESULTS

The study cohort consisted of 50 hips from 25 patients ( $18 \pm 3.8$  years, range 9-25; male=6). The mean surface distance between cCT- and sCT-based bone models was  $0.23 \pm 0.18$  mm. cCT- and sCT-based measurements demonstrated good to excellent inter- and intra-observer correlation ( $0.77 < \text{ICC} < 0.98$ ). All measurements were statistically equivalent ( $p < 0.001$ ), with average intermodal differences within intra-observer limits of agreement. The accuracy to determine physeal patency by sCT was 96.3%. Overall diagnostic quality, SNR and artifacts were higher on sCT ( $p < 0.05$ ); clarity of bony margin and corticomedullary difference were not significantly different ( $p > 0.05$ ).

## CONCLUSION

sCT is equivalent to cCT for the assessment of hip morphology and maturity in young patients.

## CLINICAL RELEVANCE/APPLICATION

MRI-based synthetic CT offers an accurate radiation-free alternative for hip structural evaluation in young adult and pediatric patients.

## T1-SSPD03-Olecranon Bone Age Assessment in Puberty Using a Lateral Elbow Radiograph and a Deep-Learning Model

Gayoung Choi, MD, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Accurate bone age evaluation is crucial for assessing skeletal maturation, especially during puberty. Hand bone age has limitations during this period, and elbow bone age evaluation can be a valuable alternative. This study aims to propose a more precise and feasible elbow bone age classification using characteristic morphological changes of the olecranon during puberty, and develop a deep-learning-based artificial intelligence (AI) model for olecranon bone age evaluation.

## METHODS AND MATERIALS

In this retrospective study, a total of 3508 lateral elbow radiographs were reviewed and classified based on the morphological changes of the olecranon ossification process. This novel classification of olecranon ossification process (novel olecranon method) was compared with previously established elbow bone age methods (Sauvegrain and Dimeglio) and hand and wrist bone age (Greulich Pyle and Korean standard bone age chart). Then, a deep-learning-based model for olecranon bone age classification was trained, validated, tested, and further improved through external validation.

## RESULTS

The novel olecranon method for puberty was established and the reference bone age was determined in correlation with Sauvegrain method. The interobserver agreement between two pediatric radiologists were 0.92 for the novel olecranon method, 0.90 for Dimeglio method, and 0.88 for Sauvegrain method. The novel olecranon method showed excellent reliability with both Sauvegrain and Dimeglio methods (ICC 0.97 and 0.98 in girls, 0.96 and 0.98 in boys each), and good reliability with hand and wrist bone age by both GP method (0.78 in girls, 0.84 in boys) and KS chart (0.87 in girls, 0.89 in boys). The deep-learning based model for olecranon bone age showed accuracy of 0.96 and specificity of 0.98 with Efficient-Det b4. In external validation, the accuracy was 0.86.

## CONCLUSION

The novel olecranon method for elbow bone age evaluation in puberty has several advantages, including the need for only a single lateral elbow radiograph, ease of use with greater detail compared to previous elbow bone age evaluation methods, almost perfect interobserver agreement, and excellent reliability with previous methods. Furthermore, the deep-learning-based AI model developed for the novel olecranon method exhibited high accuracy and specificity. The novel olecranon method and the developed AI model have the potential to enhance elbow bone age evaluation during puberty.

## CLINICAL RELEVANCE/APPLICATION

The novel olecranon method can be a simple and practical choice for bone age evaluation in puberty, a possible alternative for complicated Sauvegrain method and limited Dimeglio method. Deep-learning-based AI model for the novel olecranon method can further assist clinical practice.

## T1-SSPD03-Prospective Comparison of Low Dose Chest CT and Skeletal Survey for Detecting Fractures from Child Abuse

Kelly K. Horst, MD (*Presenter*) Nothing to Disclose

### PURPOSE

The purpose of this study is to prospectively compare skeletal survey (SS) to ultra-low dose non-contrast (ULD CCT) chest CT performed for suspected child abuse.

### METHODS AND MATERIALS

Consecutive pediatric patients suspected to be victims of child abuse underwent non-contrast ultra-low dose chest CT (ULD CCT) and radiographic SS as both an initial and follow-up exam to identify imaging findings of abuse. Three CAQ-certified pediatric radiologists reviewed randomized, deidentified images. Rib fractures were categorized by rib number, laterality, and according to the location on the rib (costochondral junction, lateral, or posterior). If the majority of the pediatric radiologists rated a fracture as being definitely present across any imaging modality and time point at a specific location, a fracture was considered present. Fracture-level sensitivity was evaluated across modality and time points based on whether the majority of readers definitely identified fractures, and testing for differences in sensitivity was performed using generalized estimating equations. We report reader-averaged patient-level specificity across modalities and time points based on the lack of false positive detected fractures.

### RESULTS

Twenty-nine children [mean age 181 days, range: 22-453, 9 female] underwent concurrent skeletal survey and ULD CCT. Estimated radiation dose for ULD CCT [CTDIvol 0.13±0.05 mGy; DLP 0.22±0.08 mSv] was lower than for SS [0.43±0.16 mSv]. There were 52 definite rib fractures identified in 11 patients. Initial exam fracture-level sensitivity was 40% for ULD CCT vs 33% for SS (P=0.68), while follow-up exam sensitivity was 83% for ULD CCT vs. 29% for SS (P=0.001). Follow-up ULD CCT sensitivity was also significantly higher than baseline (P=0.049). Patient level specificity was comparable at both initial (ULD CCT=96%; SS=98%) and follow-up exams (ULD CCT=98%; SS=94%). SS had one false positive, where a lesion was characterized as an osteochondroma on CT and one false negative, where a fracture was identified on CT. One patient had a liver laceration on CT, despite no initial concern (i.e., no bruising) on physical examination.

## CONCLUSION

ULD CCT identified nearly twice as many fractures compared to SS when used as a screening tool in the work-up for abuse, identifies rib fractures in patients with negative skeletal survey, identifies soft tissue lesions that are occult on physical exam, and better characterizes bony lesions that mimic fractures on x-ray. CT identifies additional fractures at follow-up that are occult on initial SS and CT.

## CLINICAL RELEVANCE/APPLICATION

ULD CCT identified nearly twice as many fractures compared to SS when used as a screening tool in the work-up for child abuse, with comparable specificity at lower radiation doses.

## T1-SSPD03-A Preliminary Study of Evaluating the Active Lesions of Juvenile Localized Scleroderma With Superb Microvascular Imaging

Na Xu (*Presenter*) Nothing to Disclose

### PURPOSE

Scleroderma is a chronic connective tissue disease, including systemic scleroderma (SSc) and localized scleroderma (LS). Skin sclerosis is primary clinical symptom of LS, which primarily affects children and has a worse prognosis than adult patients. The aim of this study is to examine the correlation between the changes of microvessel of lesion skin tissue in juvenile localized scleroderma (JLS) and normal skin using ultrasound superb microvascular imaging (SMI) technique, and the evaluation value of ultrasound SMI technique on the activity of JLS lesion.

## **METHODS AND MATERIALS**

A prospective analysis was conducted on 11 children with JLS, diagnosed clinically and pathologically in the Department of Dermatology or Rheumatic Immunology Department of X Hospital from March 2021 to April 2023. The localized scleroderma assessment tool (LoSCAT), including modified local scleroderma skin severity index (MLoSSI) and localized scleroderma damage index (LoSDI), was used to evaluate the activity of lesions. Lesions received a score higher than 0 were deemed to be active. The lesion and its symmetrical normal skin were scanned using the SMI technique (Canon Aplio i800), and the vascular index (VI) was employed to objectively quantify the microvessel of them. The differences of VI between skin of active lesions and normal, inactive lesions and normal were compared.

## **RESULTS**

There were 12 active lesions and 12 inactive lesions in 11 children with JLS. The VI of skin of active lesions and normal were  $8.58 \pm 5.29\%$  and  $2.60 \pm 3.83\%$ , respectively. All active lesions' VI were higher than normal sides', and the difference was statistically significant ( $P < 0.05$ ). The VI of skin of inactive lesions and normal were  $0.21 \pm 0.69\%$  and  $0.06 \pm 0.18\%$ , respectively, and there was no significant difference between them ( $P > 0.05$ ).

## **CONCLUSION**

SMI technology could sensitively detect microvessel in the skin layer and indicate active lesions of children with JLS earlier than clinical evaluation. Moreover, ultrasound is practical and non-invasive, making it appropriate for tracking the development of JLS and determining the best course of action.

## **CLINICAL RELEVANCE/APPLICATION**

Skin sclerosis is primary clinical symptom of localized scleroderma (LS), which primarily affects children and has a worse prognosis than adult patients. This study examined the correlation between the changes of microvessel of lesion skin tissue in JLS and normal skin using ultrasound SMI technique. SMI technology could sensitively detect microvessel in the skin layer and indicate active lesions of children with JLS earlier than clinical evaluation. Ultrasound is practical and non-invasive, making it appropriate for tracking the development of lesions in children with JLS and determining the best course of action.

## **T1-SSPD03-The ACR Dose Index Registry for Digital Radiography: Developing Pediatric Registry Benchmarks**

Steven Don, MD (*Presenter*) Research Grant, Carestream Health, Inc.;

### **PURPOSE**

To develop pediatric dose-index benchmarks using data collected in the American College of Radiology (ACR) Dose Index Registry (DIR) for Digital Radiography (DR).

### **METHODS AND MATERIALS**

Dose-index values for exposure events from sites participating in the ACR DIR DR Working Group over a two-year period (2021 and 2022) were recorded. To be included, the data must have a local exam descriptor that is mapped to the ACR Common ID for that body part and the patient's age in years. The ACR TRIAD server automatically anonymized the data. The events were separated by age (<1, 1 to <5, 5 to <10, 10 to <15, 15 to 18, and adults >18 years old) and Common ID. For a Common ID to be included in the registry statistics there must be at least five facilities, each with =20 events per Common ID. The dose indices recorded are based on the IEC 62-494 standard and included the exposure index (EI), exposure index target (EIT), and deviation index (DI). Any EI <25 was excluded from the database. Kerma area-product (KAP) was also recorded. Each facility median values were tabulated and then the registry quartiles were compiled. The EIT mode was also reported.

### **RESULTS**

One children's hospital, five academic centers, and one community center submitted data. Some centers consisted of more than one facility. 219,039 pediatric exposure events were recorded over two years from 18 Common IDs for pediatrics, compared with 1,042,627 events from 41 Common IDs for adults. The pediatric Common IDs include chest, abdomen, clavicle, scoliosis, spine (cervical, thoracic, and lumbar), upper extremity (shoulder, elbow, radius/ulna, wrist, hand, and finger) and lower extremity (femur, knee, tibia/fibula, ankle, and foot). The EIT mode ranged from 160 (abdomen 1 to <5) to 400 (chest 2 age ranges). The most common EIT mode was 250, representing 78% of Common IDs. The adult EIT mode range was 242-800; the most common EIT mode was 250 (51%). As a general rule, central body work (chest, abdomen, and spine) had lower median EI values than extremity exams (elbow, hand, wrist, tibia/fibula and foot). Extremity exams (elbow, hand, wrist, tibia/fibula and foot) had a lower KAP than scoliosis, lumbar spine, and abdomen. Similar trends with adult examinations were noted for EI and KAP.

### **CONCLUSION**

Individual facilities can benchmark their results with this registry database. EI tended to be lower for central body work than for extremity exams while KAP was highest for scoliosis, lumbar spine and abdomen examinations. Pediatric exam registry

benchmarks were similar to the adult registry benchmarks. Increased participation will improve generalizability of future benchmarks.

**CLINICAL RELEVANCE/APPLICATION**

The ACR DIR for DR will enable participants to benchmark their dose indices' performance data against national values.

### Normative Model of Cranial Bone Development Unveils Abnormal Local Bone Density in Pediatric CT Associated With Intra-Cranial Hypertension and Non-syndromic Sagittal Craniosynostosis

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E353B

Antonio Porras Perez, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

After surgical treatment of children with non-syndromic sagittal craniosynostosis (NSSC), signs of intra-cranial hypertension (ICH) may trigger reoperation to prevent neurological damage. However, noninvasive evaluation of pediatric ICH is subjective and based on variable clinical symptoms, since precise measurement of intracranial pressure requires invasive monitoring. Although local bone anomalies associated with ICH have been qualitatively described in CT images, the absence of curated datasets and quantitative normative references have prevented their systematic study to identify ICH. We used a normative cranial bone development model to explore local mineral density anomalies in both patients with ICH and with NSSC.

#### METHODS AND MATERIALS

We used deep-learning methods to automatically segment the calvarium from preoperative CT images of 55 patients with ICH (26 male, 29 female, age  $4.21 \pm 3.11$  years) and 122 patients with NSSC (92 male, 30 female, age  $4.20 \pm 3.96$  months). The etiology of ICH included hydrocephalus, idiopathic intracranial hypertension, arachnoid cysts, or intracranial neoplasms. Patients with any form of craniosynostosis were excluded from the ICH group. For each patient, we used our age- and sex-specific normative model built from CT images of 2,068 control subjects (age 0-10 years) to quantify local bone mineral density anomalies (in Hounsfield Units, HU) at every location on the calvarium.

#### RESULTS

Patients with ICH showed a global decrease in average calvarial bone mineral density ( $-40.44 \pm 77.18$  HU,  $p < 0.001$ ) compared to the normative reference, which was significant in all calvarial bones ( $p < 0.05$ ). Patients with NSSC showed a global decrease compared to normative in average calvarial bone mineral density ( $-7.96 \pm 20.01$  HU,  $p < 0.001$ ), which was greater in the parietal ( $-10.85 \pm 22.36$  HU,  $p < 0.001$ ) and occipital ( $-11.11 \pm 29.28$  HU,  $p < 0.001$ ) than in the frontal bones ( $-2.24 \pm 25.89$  HU,  $p = 0.01$ ). Patients with NSSC presented increased mineral density in the frontal ( $p < 0.001$ ) and occipital bones ( $p < 0.001$ ) compared to patients with ICH, but not in the parietal bones ( $p = 0.43$ ).

#### CONCLUSION

We present the first systematic quantitative study of local cranial bone density anomalies associated with ICH. Our results demonstrate significant bone density loss in patients with ICH, and similar local density patterns in the fused parietal bones of patients with NSSC that may be produced by the increased pressure from the constrained brain.

#### CLINICAL RELEVANCE/APPLICATION

Our new quantitative findings show the potential of quantitative CT to support the clinical evaluation of pediatric ICH to achieve earlier interventions and avoid invasive monitoring.

### Hip MRI-Based Synthetic CT Versus Conventional CT: A Morphometric and Clinical Comparison in Young Patients

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E353B

Jade Iwasaka-Neder, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

MRI-based synthetic CT (sCT) generates CT-like images from MRI data that can easily undergo 2D and 3D reformatting, a process that would otherwise require complex segmentation programs for MRI sequences. This study aims to evaluate the equivalence and reliability of sCT versus conventional CT (cCT) for assessing hip morphology and maturity in pediatric and young patients.

#### METHODS AND MATERIALS

This IRB-approved prospective study included patients = 25 years old referred for both cCT and MRI of the hip and pelvis within a 6 month interval for hip pathology evaluation. Patients were scanned on a 3 Tesla MRI scanner according to standard department protocol, including a high-resolution dual-echo GRE sequence used to generate sCT images via a commercially available deep-learning enabled post-processing software. cCT scans were performed according to standard protocols on state-of-the art multidetector scanners with submillimeter resolution. De-identified images were reviewed by two pediatric musculoskeletal radiologists who measured the following on each hip: lateral center edge angle, anterior center edge angle, acetabular version, acetabular index, acetabular quotient, Sharp angle, and joint space width. Reliability and agreement of measurements were assessed via intraclass correlations (ICCs), Bland-Altman plots, and two one-sided tests for equivalence. 3D surface distances between cCT and sCT were computed. The status of physeal maturity (open versus closed) at sCT and cCT was established by consensus review at 7 locations and sCT's accuracy to correctly determine physeal maturity calculated. Images were scored on a 5 point Likert scale for overall diagnostic quality, SNR, bony margins definition, corticomedullary differentiation and artifacts and compared to cCT via Wilcoxon signed rank test.

#### RESULTS

The study cohort consisted of 50 hips from 25 patients ( $18 \pm 3.8$  years, range 9-25; male=6). The mean surface distance between cCT- and sCT-based bone models was  $0.23 \pm 0.18$  mm. cCT- and sCT-based measurements demonstrated good to excellent inter- and intra-observer correlation ( $0.77 < ICC < 0.98$ ). All measurements were statistically equivalent ( $p < 0.001$ ), with average intermodal differences within intra-observer limits of agreement. The accuracy to determine physeal patency by sCT was 96.3%. Overall diagnostic quality, SNR and artifacts were higher on sCT ( $p < 0.05$ ); clarity of bony margin and corticomedullary difference were not significantly different ( $p > 0.05$ ).

#### CONCLUSION

sCT is equivalent to cCT for the assessment of hip morphology and maturity in young patients.

#### CLINICAL RELEVANCE/APPLICATION

MRI-based synthetic CT offers an accurate radiation-free alternative for hip structural evaluation in young adult and pediatric patients.

### **Olecranon Bone Age Assessment in Puberty Using a Lateral Elbow Radiograph and a Deep-Learning Model**

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E353B

Gayoung Choi, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Accurate bone age evaluation is crucial for assessing skeletal maturation, especially during puberty. Hand bone age has limitations during this period, and elbow bone age evaluation can be a valuable alternative. This study aims to propose a more precise and feasible elbow bone age classification using characteristic morphological changes of the olecranon during puberty, and develop a deep-learning-based artificial intelligence (AI) model for olecranon bone age evaluation.

#### **METHODS AND MATERIALS**

In this retrospective study, a total of 3508 lateral elbow radiographs were reviewed and classified based on the morphological changes of the olecranon ossification process. This novel classification of olecranon ossification process (novel olecranon method) was compared with previously established elbow bone age methods (Sauvegrain and Dimeglio) and hand and wrist bone age (Greulich Pyle and Korean standard bone age chart). Then, a deep-learning-based model for olecranon bone age classification was trained, validated, tested, and further improved through external validation.

#### **RESULTS**

The novel olecranon method for puberty was established and the reference bone age was determined in correlation with Sauvegrain method. The interobserver agreement between two pediatric radiologists were 0.92 for the novel olecranon method, 0.90 for Dimeglio method, and 0.88 for Sauvegrain method. The novel olecranon method showed excellent reliability with both Sauvegrain and Dimeglio methods (ICC 0.97 and 0.98 in girls, 0.96 and 0.98 in boys each), and good reliability with hand and wrist bone age by both GP method (0.78 in girls, 0.84 in boys) and KS chart (0.87 in girls, 0.89 in boys). The deep-learning based model for olecranon bone age showed accuracy of 0.96 and specificity of 0.98 with Efficient-Det b4. In external validation, the accuracy was 0.86.

#### **CONCLUSION**

The novel olecranon method for elbow bone age evaluation in puberty has several advantages, including the need for only a single lateral elbow radiograph, ease of use with greater detail compared to previous elbow bone age evaluation methods, almost perfect interobserver agreement, and excellent reliability with previous methods. Furthermore, the deep-learning-based AI model developed for the novel olecranon method exhibited high accuracy and specificity. The novel olecranon method and the developed AI model have the potential to enhance elbow bone age evaluation during puberty.

#### **CLINICAL RELEVANCE/APPLICATION**

The novel olecranon method can be a simple and practical choice for bone age evaluation in puberty, a possible alternative for complicated Sauvegrain method and limited Dimeglio method. Deep-learning-based AI model for the novel olecranon method can further assist clinical practice.

### Prospective Comparison of Low Dose Chest CT and Skeletal Survey for Detecting Fractures from Child Abuse

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E353B

Kelly K. Horst, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study is to prospectively compare skeletal survey (SS) to ultra-low dose non-contrast (ULD CCT) chest CT performed for suspected child abuse.

#### METHODS AND MATERIALS

Consecutive pediatric patients suspected to be victims of child abuse underwent non-contrast ultra-low dose chest CT (ULD CCT) and radiographic SS as both an initial and follow-up exam to identify imaging findings of abuse. Three CAQ-certified pediatric radiologists reviewed randomized, deidentified images. Rib fractures were categorized by rib number, laterality, and according to the location on the rib (costochondral junction, lateral, or posterior). If the majority of the pediatric radiologists rated a fracture as being definitely present across any imaging modality and time point at a specific location, a fracture was considered present. Fracture-level sensitivity was evaluated across modality and time points based on whether the majority of readers definitely identified fractures, and testing for differences in sensitivity was performed using generalized estimating equations. We report reader-averaged patient-level specificity across modalities and time points based on the lack of false positive detected fractures.

#### RESULTS

Twenty-nine children [mean age 181 days, range: 22-453, 9 female] underwent concurrent skeletal survey and ULD CCT. Estimated radiation dose for ULD CCT [CTDIvol 0.13±0.05 mGy; DLP 0.22±0.08 mSv] was lower than for SS [0.43±0.16 mSv]. There were 52 definite rib fractures identified in 11 patients. Initial exam fracture-level sensitivity was 40% for ULD CCT vs 33% for SS (P=0.68), while follow-up exam sensitivity was 83% for ULD CCT vs. 29% for SS (P=0.001). Follow-up ULD CCT sensitivity was also significantly higher than baseline (P=0.049). Patient level specificity was comparable at both initial (ULD CCT=96%; SS=98%) and follow-up exams (ULD CCT=98%; SS=94%). SS had one false positive, where a lesion was characterized as an osteochondroma on CT and one false negative, where a fracture was identified on CT. One patient had a liver laceration on CT, despite no initial concern (i.e., no bruising) on physical examination.

#### CONCLUSION

ULD CCT identified nearly twice as many fractures compared to SS when used as a screening tool in the work-up for abuse, identifies rib fractures in patients with negative skeletal survey, identifies soft tissue lesions that are occult on physical exam, and better characterizes bony lesions that mimic fractures on x-ray. CT identifies additional fractures at follow-up that are occult on initial SS and CT.

#### CLINICAL RELEVANCE/APPLICATION

ULD CCT identified nearly twice as many fractures compared to SS when used as a screening tool in the work-up for child abuse, with comparable specificity at lower radiation doses.

### **A Preliminary Study of Evaluating the Active Lesions of Juvenile Localized Scleroderma With Superb Microvascular Imaging**

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E353B

Na Xu (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Scleroderma is a chronic connective tissue disease, including systemic scleroderma (SSc) and localized scleroderma (LS). Skin sclerosis is primary clinical symptom of LS, which primarily affects children and has a worse prognosis than adult patients. The aim of this study is to examine the correlation between the changes of microvessel of lesion skin tissue in juvenile localized scleroderma (JLS) and normal skin using ultrasound superb microvascular imaging (SMI) technique, and the evaluation value of ultrasound SMI technique on the activity of JLS lesion.

#### **METHODS AND MATERIALS**

A prospective analysis was conducted on 11 children with JLS, diagnosed clinically and pathologically in the Department of Dermatology or Rheumatic Immunology Department of X Hospital from March 2021 to April 2023. The localized scleroderma assessment tool (LoSCAT), including modified local scleroderma skin severity index (MLoSSI) and localized scleroderma damage index (LoSDI), was used to evaluate the activity of lesions. Lesions received a score higher than 0 were deemed to be active. The lesion and its symmetrical normal skin were scanned using the SMI technique (Canon Aplio i800), and the vascular index (VI) was employed to objectively quantify the microvessel of them. The differences of VI between skin of active lesions and normal, inactive lesions and normal were compared.

#### **RESULTS**

There were 12 active lesions and 12 inactive lesions in 11 children with JLS. The VI of skin of active lesions and normal were  $8.58 \pm 5.29\%$  and  $2.60 \pm 3.83\%$ , respectively. All active lesions' VI were higher than normal sides', and the difference was statistically significant ( $P < 0.05$ ). The VI of skin of inactive lesions and normal were  $0.21 \pm 0.69\%$  and  $0.06 \pm 0.18\%$ , respectively, and there was no significant difference between them ( $P > 0.05$ ).

#### **CONCLUSION**

SMI technology could sensitively detect microvessel in the skin layer and indicate active lesions of children with JLS earlier than clinical evaluation. Moreover, ultrasound is practical and non-invasive, making it appropriate for tracking the development of JLS and determining the best course of action.

#### **CLINICAL RELEVANCE/APPLICATION**

Skin sclerosis is primary clinical symptom of localized scleroderma (LS), which primarily affects children and has a worse prognosis than adult patients. This study examined the correlation between the changes of microvessel of lesion skin tissue in JLS and normal skin using ultrasound SMI technique. SMI technology could sensitively detect microvessel in the skin layer and indicate active lesions of children with JLS earlier than clinical evaluation. Ultrasound is practical and non-invasive, making it appropriate for tracking the development of lesions in children with JLS and determining the best course of action.

### The ACR Dose Index Registry for Digital Radiography: Developing Pediatric Registry Benchmarks

Tuesday, Nov. 28 8:00AM - 9:00AM Room: E353B

Steven Don, MD (*Presenter*) Research Grant, Carestream Health, Inc.;

#### PURPOSE

To develop pediatric dose-index benchmarks using data collected in the American College of Radiology (ACR) Dose Index Registry (DIR) for Digital Radiography (DR).

#### METHODS AND MATERIALS

Dose-index values for exposure events from sites participating in the ACR DIR DR Working Group over a two-year period (2021 and 2022) were recorded. To be included, the data must have a local exam descriptor that is mapped to the ACR Common ID for that body part and the patient's age in years. The ACR TRIAD server automatically anonymized the data. The events were separated by age (<1, 1 to <5, 5 to <10, 10 to <15, 15 to 18, and adults >18 years old) and Common ID. For a Common ID to be included in the registry statistics there must be at least five facilities, each with =20 events per Common ID. The dose indices recorded are based on the IEC 62-494 standard and included the exposure index (EI), exposure index target (EIT), and deviation index (DI). Any EI <25 was excluded from the database. Kerma area-product (KAP) was also recorded. Each facility median values were tabulated and then the registry quartiles were compiled. The EIT mode was also reported.

#### RESULTS

One children's hospital, five academic centers, and one community center submitted data. Some centers consisted of more than one facility. 219,039 pediatric exposure events were recorded over two years from 18 Common IDs for pediatrics, compared with 1,042,627 events from 41 Common IDs for adults. The pediatric Common IDs include chest, abdomen, clavicle, scoliosis, spine (cervical, thoracic, and lumbar), upper extremity (shoulder, elbow, radius/ulna, wrist, hand, and finger) and lower extremity (femur, knee, tibia/fibula, ankle, and foot). The EIT mode ranged from 160 (abdomen 1 to <5) to 400 (chest 2 age ranges). The most common EIT mode was 250, representing 78% of Common IDs. The adult EIT mode range was 242-800; the most common EIT mode was 250 (51%). As a general rule, central body work (chest, abdomen, and spine) had lower median EI values than extremity exams (elbow, hand, wrist, tibia/fibula and foot). Extremity exams (elbow, hand, wrist, tibia/fibula and foot) had a lower KAP than scoliosis, lumbar spine, and abdomen. Similar trends with adult examinations were noted for EI and KAP.

#### CONCLUSION

Individual facilities can benchmark their results with this registry database. EI tended to be lower for central body work than for extremity exams while KAP was highest for scoliosis, lumbar spine and abdomen examinations. Pediatric exam registry benchmarks were similar to the adult registry benchmarks. Increased participation will improve generalizability of future benchmarks.

#### CLINICAL RELEVANCE/APPLICATION

The ACR DIR for DR will enable participants to benchmark their dose indices' performance data against national values.

### **T1-SSPH06-Fast and Adaptive Parameter Mapping for Dynamic MRI using Active Learning and Autoregressive Flow**

Dongmyung Shin, PhD (*Presenter*) Researcher, RadiSen Co, Ltd

#### PURPOSE

A fast and adaptive parameter mapping using AI-guided dictionary learning is proposed for dynamic MRI. This method aims efficient computation to reduce computational cost and adapt to out-of-range parameters while maintaining accuracy (Fig. 1a b).

#### METHODS AND MATERIALS

Our method, which is referred to as Active dictionary learning, trains a neural network for parameter estimation via active dataset generation, reducing unnecessary simulation. The active learning approach begins with rough problem space learning, then adaptively generates additional data. An autoregressive flow model was used for exploring potential parameters. Our network was trained through iterative data recommendation and training. Initially, a small random dataset is used, followed by target signal inference. The inference was performed for a target signal, producing putative parameters as output. These outputs were applied to the simulator to generate signals which were utilized for the next network training. This process refines estimation results. Experiments demonstrated the quantification process with a FISP MRF sequence estimating  $M_0$ , T1, T2, B1, and  $\rho B_0$ . Target MR signals were simulated using tissue properties from in-vivo data, Gaussian-shaped B1, and horizontal-striped  $\rho B_0$ . Comparison included dictionary matching results and computational time. Experiment 1 validated the method in varying B1 and  $\rho B_0$  ranges. Experiment 2 evaluated a computationally expensive signal model with a 64-point slice profile. Experiment 3 showed adaptive estimation with out-of-range parameters.

#### RESULTS

In Experiment 1 (Fig. 1c), active dictionary learning estimated parameters using 60,000 simulations, with performance comparable to full dictionary matching, taking only 30 min for the entire process (Full dictionary matching: 6 hours generation and 36 hours matching). Experiment 2 (Fig. 1c) also demonstrate successful estimations, while taking only 3 hours despite the need for simulating the slice profile. In Experiment 3, our method demonstrated successful adaptation to the out-of-initial parameters range (Fig. 1d).

#### CONCLUSION

Our AI-guided Active dictionary learning for parameter quantification demonstrated efficient computation and adaptability to out-of-range parameters while maintaining accuracy. This approach significantly reduced the computational time compared to dictionary matching while achieving comparable or higher estimation accuracy.

#### CLINICAL RELEVANCE/APPLICATION

Our method may be valuable for dynamic imaging such as cardiac MRF, which changes the scan parameters for each subject, requiring dictionary generation for each case and, therefore, taking substantial computation and time when the conventional method is used.

### **T1-SSPH06-Development of Realistic Reference Phantoms for MR Sequence Design and AI Validation**

2

Paul Jahnke, MD (*Presenter*) Patent holder, DE202015104282U1; Patent holder, EP3135199A1; Patent holder, US9924919B2; Patent holder, US20180192986A1; Research funded, Berlin Institute of Health; Shareholder, PhantomX GmbH

## PURPOSE

To develop highly realistic phantoms reflecting human anatomy and pathology for objective assessment of MR imaging and AI performance.

## METHODS AND MATERIALS

We used inkjet printing with gadolinium-doped inks and hydrogel print substrates to create realistic phantoms for T1-weighted MR imaging. Our development encompassed agarose and polyacrylamide hydrogels, which we modified by coupling diethylenetriaminepentaacetic acid (DTPA) anchor molecules to bind printed gadolinium ions. We evaluated T1 mapping values and the modulation transfer function (MTF) in line pair phantoms to evaluate phantom stability over time. We produced anthropomorphic phantoms from scan data of patients with neck and liver masses and assessed the phantoms using similarity metrics and reader experiments.

## RESULTS

Inkjet printing of gadolinium-doped ink to DTPA-coupled hydrogel print substrates enabled production of highly realistic phantoms for T1-weighted MR imaging. Phantom stability was demonstrated by reproducible T1 mapping values and MTF results over a period of eighteen months. Highly accurate reproduction of anatomical and tumor detail was demonstrated by structural similarity index measure results =0.87 in neck and liver phantoms and confirmed by the results of the reader experiments.

## CONCLUSION

Gadolinium-doped inks and DTPA-coupled hydrogels enable inkjet printing of highly realistic MR phantoms. The method we present provides novel reference tools for the development, improvement and validation of sequence designs and artificial intelligence in MR imaging.

## CLINICAL RELEVANCE/APPLICATION

Patient scans are the only real-world data source, but have severe limitations in terms of accessibility and standardization for testing and validation purposes.

## T1-SSPH06-Retrospective Comparison of the Routine Brain MRI Protocol in Patients at 0.55T and 1.5/3T

Anna Lavrova, MD (*Presenter*) Research support, Siemens AG

## PURPOSE

To compare MRI images collected at 0.55T in patients as part of the clinical brain protocol with those collected at 1.5/3T, and to explore changes in radiologists' ratings of 0.55T images over time.

## METHODS AND MATERIALS

In this IRB-approved study, brain MRI images were collected on a 0.55T MRI system (MAGNETOM Free.Max, Siemens Healthineers, Erlangen, Germany) from 10/2021 to 04/2022 (30 patients) and from 09/2022 to 10/2022 (30 patients) using the same protocol and sequence settings. Images collected previously from the same patients at 1.5/3T were also identified; the average time between scans was 7.2 months. In total, 510 compatible image series were acquired using T1w SPACE ± CE, DWI/ADC, FLAIR, SWI, T1w TSE and T2w TSE sequences. All images were rated by two neuroradiologists for image quality (IQ) and anatomical features using a 3-point Likert scale (1: non-diagnostic, 2: acceptable, 3: good); the ability to answer the clinical question using only 0.55T images was also assessed. For each sequence, the mean ± SD of scores were calculated. Paired Wilcoxon test ( $p=0.05$ ) was used to compare the IQ between field strengths and between 0.55T ratings from both datasets. To determine inter-reader agreement the linear-weighted Cohen's Kappa coefficient was calculated.

## RESULTS

Brain image ratings at 0.55T show that it is possible to perform diagnostic quality exams on this MRI system, allowing radiologists to answer the clinical question. Overall, 98.8% of features in all sequences at 0.55T were rated as acceptable (=2). The one exception was T1w SPACE + CE in one patient, which Reader 1 identified as unacceptable (<2) due to motion artifacts. Upon comparison of 0.55T and 1.5/3T systems in the 1st dataset, all scores from Reader 1 for high-field (HF) images were significantly higher than those at 0.55T. For Reader 2, only HF DWI/ADC and SWI images were superior to those collected at 0.55T. Upon analyzing the 2nd dataset, a significant improvement in ratings for 0.55T images was seen in Reader 1 for FLAIR, T2w TSE, T1w SPACE + CE sequences; however, Reader 2 rated T1w SPACE significantly lower. The inter-rated agreement between two datasets improved from moderate ( $\kappa=0.439$ ) to substantial ( $\kappa=0.7537$ ).

## CONCLUSION

Diagnostic quality clinical brain images can be collected at 0.55T, despite lower ratings for sequences. Significant improvements in IQ scores for images collected at 0.55T were seen from one reader over time, indicating that experience reading 0.55T images may improve reader confidence.

## CLINICAL RELEVANCE/APPLICATION

Diagnostic quality brain images can be collected in patients at 0.55T, although some sequences had lower scores than at 1.5 or 3T. Ratings for 0.55T images improved over time, indicating that experience may increase reader confidence.

### **T1-SSPH06-Accuracy and Test-retest Repeatability of Stiffness Measurement with Magnetic Resonance Elastography: A Multicenter Phantom Study**

Efe Ozkaya, PhD, MSc (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Liver diseases due to various causes are a significant health concern. Liver biopsy is invasive, and there is a need for noninvasive methods, such as MRE, to stage liver fibrosis. The study aims to determine the accuracy and repeatability of MRE stiffness measurements in vitro in a multicenter study.

#### **METHODS AND MATERIALS**

Three cylindrical phantoms made of polyvinyl chloride gel with known stiffness (phantoms 1-3: low, medium and high stiffness) were circulated between 1 reference center and 4 testing centers and scanned on 10 MRE-equipped commercial systems (1.5T or 3T) from the 3 major vendors, using 2D gradient recalled echo (GRE) and/or 2D spin echo echoplanar imaging (SE-EPI) with similar acquisition parameters (Figure 1) and hardware. Mean phantom stiffness was measured by a single observer for each phantom/acquisition. Test-retest repeatability was measured during the same session at all centers. The reference standard measurements were obtained in the reference center. Accuracy error (based on the reference standard) and test-retest repeatability (based on Bland-Altman coefficient of repeatability) of stiffness measurement were calculated.

#### **RESULTS**

The reference stiffness measurements for phantoms 1-3 were (in kPa): 2.45, 4.41 and 7.52. The mean accuracy error [95% confidence intervals] for all 3 phantoms and both sequences combined was 10.2% [8.1%-12.3%]. Mean accuracy error was 8.3% [3.8%-12.9%] for the soft phantom, 8.8% [5.2%-12.4%] for the medium stiffness phantom and 13.2% [10.3%-16.1%] for the stiff phantom with both sequences combined (Figure 1). For 2D GRE and 2D SE-EPI sequences, mean accuracy error (all phantoms combined) was 8.5% [6.5%-10.6%] and 13.0% [8.5%-17.6%], respectively. The mean Bland-Altman coefficients of test-retest repeatability were 2.9% [1.9%-4.0%] for all phantoms and sequences combined. Test-retest repeatability for each individual phantom was 3.0% [0.3%-5.8%] for phantom 1, 1.9% [0.7%-3.0%] for phantom 2, and 3.7% [2.1%-5.5%] for phantom 3 with both sequences combined (Figure 1). Per sequence repeatability was 3.6% [1.5%-5.7%] for 2D SE-EPI and 2.5% [1.3%-3.6%] for 2D GRE (including all phantoms).

#### **CONCLUSION**

Our multicenter phantom study shows that MRE has excellent measurement accuracy and test-retest repeatability in vitro, when using the same protocol and hardware. These results may help design future multicenter MRE studies.

## CLINICAL RELEVANCE/APPLICATION

Liver stiffness measured with MRE can non-invasively stage liver fibrosis with high diagnostic performance, but there is limited knowledge on measurement accuracy, especially in the multicenter setting through an in vitro study.

### **T1-SSPH06-IAC Imaging at 7T using the Decoupled 8x2 Transceiver Head Coil**

Jullie W. Pan, MD, PhD (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Ultra-high field 7T MRI is known to be demanding for RF coil performance, as the shortened electromagnetic wavelength can generate artifacts with structural imaging using conventional coils. Furthermore, the increased susceptibility at 7T is excellent for T2\* studies but makes imaging through regions with brain/bone/ air interfaces difficult. In the basal aspects of the head, these problems are simultaneously present. We apply previously described methods with the 8x2 volume transceiver coil and a very high order shim insert at 7T to image the internal auditory canals IAC. This is compared with the Nova 8/32 volume coil in n=5 control subjects and assessed by two board certified clinical neuroradiologists.

#### **METHODS AND MATERIALS**

A Siemens 7T Terra operating with 8 channels in pTx mode was used with the Nova 8/32 volume head coil and decoupled 8x2 transceiver. The shim insert did not fit the Nova 8/32 head coil and was applied only with the transceiver. None of the acquisitions used dielectric pads, and n=5 (3F, 2M) control subjects were studied in random order with both coils. Table 1 shows the applied imaging parameters. First level SAR monitoring was used throughout. A 5 point scale in image quality was used for evaluation: IAC (left, right); trigeminal nerve (left, right), cerebellum, temporal lobes (combined L,R) and brainstem. The 5 level evaluation was: 1- Not visible, 2-Visible but with complete loss of detail, 3- visualization of some anatomical detail, 4- visualization of most anatomical detail, 5-perfect visualization of anatomical detail.

## RESULTS

Fig. 1 compares the achieved B1+ between the two coils. Over a group of n=3 subjects, the achieved mean B1+ of the Nova coil was 76% that of the transceiver with a 31.1% larger covariance. T2 SPC images from the two coils from two different subjects are shown in Fig. 2. Images are reformatted to show the IAC with a cross section showing the nerve roots of the facial and auditory nerves. Table 2 summarizes the radiological image quality evaluation between the various structures from the 0.63mm<sup>3</sup> T2 SPC; unpaired t-tests showed significantly better visibility for all structures with the transceiver with p values ranging from <0.001 to 0.05.

## CONCLUSION

At 7T, the skull base is difficult to image due to insufficient B1 and inhomogeneous B0. The decoupled 8x2 transceiver improved the B1 achieved in the inferior brain region without use of dielectric pads or adiabatic sequences and permitted improved visibility of the structures including the temporal lobe, cerebellum, IAC and trigeminal nerves.

## CLINICAL RELEVANCE/APPLICATION

We have presented methods that improve basilar brain imaging at 7T. Applications include high resolution 7T neuroimaging for lesions in the cerebellopontine angle, brainstem and vascular imaging.

## T1-SSPH06-Feasibility of Prostate MR Fingerprinting and ADC Mapping in the Quantitative Characterization of Malignant Transition Zone Lesions

Anna Lavrova, MD (*Presenter*) Research support, Siemens AG

## PURPOSE

To determine if MR Fingerprinting (MRF) combined with Apparent Diffusion Coefficient (ADC) mapping can be used to distinguish cancer from Normal Appearing Transition Zone (NATZ) and low from intermediate/high-grade TZ tumors, and to determine if MRF based TZ lesion characterization in a general screening population undergoing TRUS or modality agnostic targeted biopsy yields similar results to published literature for patients pre-selected for MR guided targeted biopsy.

## METHODS AND MATERIALS

In this IRB-approved, HIPAA-compliant, single institution study, prostate MRI studies from 34 patients (mean age 64, range 46-76 years) were acquired on 3T scanners between 12/2016 and 10/2020. All patients had biopsy-proven (from 17 systematic and 17 targeted biopsies - 9 fusion, 7 in-gantry and 1 cognitive) malignant TZ lesions corresponding to PIRADS v2 lesions identified on MRI. MRF (T1 and T2 maps) and ADC maps were analyzed retrospectively by a research fellow with 5 years of non-US radiology training. Regions of interest (ROIs) were drawn encompassing the entire TZ lesion as guided by the clinical radiology reports and on the contralateral NATZ on T1, T2 and ADC maps with 3D Slicer software. Paired t-test was used to assess for differences between tumors and NATZ, and between low-grade and clinically significant TZ tumors on MRF and ADC. Logistic regression was used to test the association of tumor grade (low vs high) with the measurements from T1, T2 and ADC maps ( $p=0.05$ ).

## RESULTS

Of 34 TZ tumors, 15 were low-grade (Gleason 6) and 19 clinically significant (Gleason score = 3+4=7). T1, T2 and ADC were lower in all tumors as compared to NATZ despite the marked heterogeneity of the TZ ( $p<0.0001$  for all,  $\Delta T1=289$  ms,  $\Delta T2=23$  ms,  $\Delta ADC=482 \times 10^{-6}$  mm<sup>2</sup>/s). There were no statistically significant differences between the T2 and ADC measurements of the various tumor grades ( $p>>0.05$ ). T1 measurements yielded a strong trend towards differentiating tumor grade ( $p=0.06$ ), though this did not reach statistical significance (mean  $\pm$  SD of T1 maps: 1526 msec  $\pm$  98 in low grade, and 1437 msec  $\pm$  125 in clinically significant tumors).

## CONCLUSION

MRF combined with ADC maps show significantly lower values in tumors compared to NATZ. Measurements of T1 values show a promising trend for differentiating low from intermediate/high grade tumor, which is similar to published literature. However, further work with more patients and carefully targeted biopsies or post-surgical radiological-pathological correlation is needed to see if there is a true difference in T1 in low and high grade TZ tumors.

## CLINICAL RELEVANCE/APPLICATION

MRF combined with ADC mapping are additional quantitative measures that can be used to distinguish tumor from and non-cancerous TZ tissue and predict the grade of TZ tumors.

### Fast and Adaptive Parameter Mapping for Dynamic MRI using Active Learning and Autoregressive Flow

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N227B

Dongmyung Shin, PhD (*Presenter*) Researcher, RadiSen Co, Ltd

#### PURPOSE

A fast and adaptive parameter mapping using AI-guided dictionary learning is proposed for dynamic MRI. This method aims efficient computation to reduce computational cost and adapt to out-of-range parameters while maintaining accuracy (Fig. 1a b).

#### METHODS AND MATERIALS

Our method, which is referred to as Active dictionary learning, trains a neural network for parameter estimation via active dataset generation, reducing unnecessary simulation. The active learning approach begins with rough problem space learning, then adaptively generates additional data. An autoregressive flow model was used for exploring potential parameters. Our network was trained through iterative data recommendation and training. Initially, a small random dataset is used, followed by target signal inference. The inference was performed for a target signal, producing putative parameters as output. These outputs were applied to the simulator to generate signals which were utilized for the next network training. This process refines estimation results. Experiments demonstrated the quantification process with a FISP MRF sequence estimating  $M_0$ , T1, T2, B1, and  $\rho B_0$ . Target MR signals were simulated using tissue properties from in-vivo data, Gaussian-shaped B1, and horizontal-striped  $\rho B_0$ . Comparison included dictionary matching results and computational time. Experiment 1 validated the method in varying B1 and  $\rho B_0$  ranges. Experiment 2 evaluated a computationally expensive signal model with a 64-point slice profile. Experiment 3 showed adaptive estimation with out-of-range parameters.

#### RESULTS

In Experiment 1 (Fig. 1c), active dictionary learning estimated parameters using 60,000 simulations, with performance comparable to full dictionary matching, taking only 30 min for the entire process (Full dictionary matching: 6 hours generation and 36 hours matching). Experiment 2 (Fig. 1c) also demonstrate successful estimations, while taking only 3 hours despite the need for simulating the slice profile. In Experiment 3, our method demonstrated successful adaptation to the out-of-initial parameters range (Fig. 1d).

#### CONCLUSION

Our AI-guided Active dictionary learning for parameter quantification demonstrated efficient computation and adaptability to out-of-range parameters while maintaining accuracy. This approach significantly reduced the computational time compared to dictionary matching while achieving comparable or higher estimation accuracy.

#### CLINICAL RELEVANCE/APPLICATION

Our method may be valuable for dynamic imaging such as cardiac MRF, which changes the scan parameters for each subject, requiring dictionary generation for each case and, therefore, taking substantial computation and time when the conventional method is used.

### Development of Realistic Reference Phantoms for MR Sequence Design and AI Validation

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N227B

Paul Jahnke, MD (*Presenter*) Patent holder, DE202015104282U1; Patent holder, EP3135199A1; Patent holder, US9924919B2; Patent holder, US20180192986A1; Research funded, Berlin Institute of Health; Shareholder, PhantomX GmbH

#### PURPOSE

To develop highly realistic phantoms reflecting human anatomy and pathology for objective assessment of MR imaging and AI performance.

#### METHODS AND MATERIALS

We used inkjet printing with gadolinium-doped inks and hydrogel print substrates to create realistic phantoms for T1-weighted MR imaging. Our development encompassed agarose and polyacrylamide hydrogels, which we modified by coupling diethylenetriaminepentaacetic acid (DTPA) anchor molecules to bind printed gadolinium ions. We evaluated T1 mapping values and the modulation transfer function (MTF) in line pair phantoms to evaluate phantom stability over time. We produced anthropomorphic phantoms from scan data of patients with neck and liver masses and assessed the phantoms using similarity metrics and reader experiments.

#### RESULTS

Inkjet printing of gadolinium-doped ink to DTPA-coupled hydrogel print substrates enabled production of highly realistic phantoms for T1-weighted MR imaging. Phantom stability was demonstrated by reproducible T1 mapping values and MTF results over a period of eighteen months. Highly accurate reproduction of anatomical and tumor detail was demonstrated by structural similarity index measure results  $\approx 0.87$  in neck and liver phantoms and confirmed by the results of the reader experiments.

#### CONCLUSION

Gadolinium-doped inks and DTPA-coupled hydrogels enable inkjet printing of highly realistic MR phantoms. The method we present provides novel reference tools for the development, improvement and validation of sequence designs and artificial intelligence in MR imaging.

#### CLINICAL RELEVANCE/APPLICATION

Patient scans are the only real-world data source, but have severe limitations in terms of accessibility and standardization for testing and validation purposes.

### Retrospective Comparison of the Routine Brain MRI Protocol in Patients at 0.55T and 1.5/3T

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N227B

Anna Lavrova, MD (*Presenter*) Research support, Siemens AG

#### PURPOSE

To compare MRI images collected at 0.55T in patients as part of the clinical brain protocol with those collected at 1.5/3T, and to explore changes in radiologists' ratings of 0.55T images over time.

#### METHODS AND MATERIALS

In this IRB-approved study, brain MRI images were collected on a 0.55T MRI system (MAGNETOM Free.Max, Siemens Healthineers, Erlangen, Germany) from 10/2021 to 04/2022 (30 patients) and from 09/2022 to 10/2022 (30 patients) using the same protocol and sequence settings. Images collected previously from the same patients at 1.5/3T were also identified; the average time between scans was 7.2 months. In total, 510 compatible image series were acquired using T1w SPACE ± CE, DWI/ADC, FLAIR, SWI, T1w TSE and T2w TSE sequences. All images were rated by two neuroradiologists for image quality (IQ) and anatomical features using a 3-point Likert scale (1: non-diagnostic, 2: acceptable, 3: good); the ability to answer the clinical question using only 0.55T images was also assessed. For each sequence, the mean ± SD of scores were calculated. Paired Wilcoxon test ( $p=0.05$ ) was used to compare the IQ between field strengths and between 0.55T ratings from both datasets. To determine inter-reader agreement the linear-weighted Cohen's Kappa coefficient was calculated.

#### RESULTS

Brain image ratings at 0.55T show that it is possible to perform diagnostic quality exams on this MRI system, allowing radiologists to answer the clinical question. Overall, 98.8% of features in all sequences at 0.55T were rated as acceptable (=2). The one exception was T1w SPACE + CE in one patient, which Reader 1 identified as unacceptable (<2) due to motion artifacts. Upon comparison of 0.55T and 1.5/3T systems in the 1st dataset, all scores from Reader 1 for high-field (HF) images were significantly higher than those at 0.55T. For Reader 2, only HF DWI/ADC and SWI images were superior to those collected at 0.55T. Upon analyzing the 2nd dataset, a significant improvement in ratings for 0.55T images was seen in Reader 1 for FLAIR, T2w TSE, T1w SPACE + CE sequences; however, Reader 2 rated T1w SPACE significantly lower. The inter-rated agreement between two datasets improved from moderate ( $\kappa=0.439$ ) to substantial ( $\kappa=0.7537$ ).

#### CONCLUSION

Diagnostic quality clinical brain images can be collected at 0.55T, despite lower ratings for sequences. Significant improvements in IQ scores for images collected at 0.55T were seen from one reader over time, indicating that experience reading 0.55T images may improve reader confidence.

#### CLINICAL RELEVANCE/APPLICATION

Diagnostic quality brain images can be collected in patients at 0.55T, although some sequences had lower scores than at 1.5 or 3T. Ratings for 0.55T images improved over time, indicating that experience may increase reader confidence.

### Accuracy and Test-retest Repeatability of Stiffness Measurement with Magnetic Resonance Elastography: A Multicenter Phantom Study

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N227B

Efe Ozkaya, PhD, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

Liver diseases due to various causes are a significant health concern. Liver biopsy is invasive, and there is a need for noninvasive methods, such as MRE, to stage liver fibrosis. The study aims to determine the accuracy and repeatability of MRE stiffness measurements in vitro in a multicenter study.

#### METHODS AND MATERIALS

Three cylindrical phantoms made of polyvinyl chloride gel with known stiffness (phantoms 1-3: low, medium and high stiffness) were circulated between 1 reference center and 4 testing centers and scanned on 10 MRE-equipped commercial systems (1.5T or 3T) from the 3 major vendors, using 2D gradient recalled echo (GRE) and/or 2D spin echo echoplanar imaging (SE-EPI) with similar acquisition parameters (Figure 1) and hardware. Mean phantom stiffness was measured by a single observer for each phantom/acquisition. Test-retest repeatability was measured during the same session at all centers. The reference standard measurements were obtained in the reference center. Accuracy error (based on the reference standard) and test-retest repeatability (based on Bland-Altman coefficient of repeatability) of stiffness measurement were calculated.

#### RESULTS

The reference stiffness measurements for phantoms 1-3 were (in kPa): 2.45, 4.41 and 7.52. The mean accuracy error [95% confidence intervals] for all 3 phantoms and both sequences combined was 10.2% [8.1%-12.3%]. Mean accuracy error was 8.3% [3.8%-12.9%] for the soft phantom, 8.8% [5.2%-12.4%] for the medium stiffness phantom and 13.2% [10.3%-16.1%] for the stiff phantom with both sequences combined (Figure 1). For 2D GRE and 2D SE-EPI sequences, mean accuracy error (all phantoms combined) was 8.5% [6.5%-10.6%] and 13.0% [8.5%-17.6%], respectively. The mean Bland-Altman coefficients of test-retest repeatability were 2.9% [1.9%-4.0%] for all phantoms and sequences combined. Test-retest repeatability for each individual phantom was 3.0% [0.3%-5.8%] for phantom 1, 1.9% [0.7%-3.0%] for phantom 2, and 3.7% [2.1%-5.5%] for phantom 3 with both sequences combined (Figure 1). Per sequence repeatability was 3.6% [1.5%-5.7%] for 2D SE-EPI and 2.5% [1.3%-3.6%] for 2D GRE (including all phantoms).

#### CONCLUSION

Our multicenter phantom study shows that MRE has excellent measurement accuracy and test-retest repeatability in vitro, when using the same protocol and hardware. These results may help design future multicenter MRE studies.

#### CLINICAL RELEVANCE/APPLICATION

Liver stiffness measured with MRE can non-invasively stage liver fibrosis with high diagnostic performance, but there is limited knowledge on measurement accuracy, especially in the multicenter setting through an in vitro study.

### IAC Imaging at 7T using the Decoupled 8x2 Transceiver Head Coil

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N227B

Jullie W. Pan, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Ultra-high field 7T MRI is known to be demanding for RF coil performance, as the shortened electromagnetic wavelength can generate artifacts with structural imaging using conventional coils. Furthermore, the increased susceptibility at 7T is excellent for T2\* studies but makes imaging through regions with brain/bone/ air interfaces difficult. In the basal aspects of the head, these problems are simultaneously present. We apply previously described methods with the 8x2 volume transceiver coil and a very high order shim insert at 7T to image the internal auditory canals IAC. This is compared with the Nova 8/32 volume coil in n=5 control subjects and assessed by two board certified clinical neuroradiologists.

#### METHODS AND MATERIALS

A Siemens 7T Terra operating with 8 channels in pTx mode was used with the Nova 8/32 volume head coil and decoupled 8x2 transceiver. The shim insert did not fit the Nova 8/32 head coil and was applied only with the transceiver. None of the acquisitions used dielectric pads, and n=5 (3F, 2M) control subjects were studied in random order with both coils. Table 1 shows the applied imaging parameters. First level SAR monitoring was used throughout. A 5 point scale in image quality was used for evaluation: IAC (left, right); trigeminal nerve (left, right), cerebellum, temporal lobes (combined L,R) and brainstem. The 5 level evaluation was: 1- Not visible, 2-Visible but with complete loss of detail, 3- visualization of some anatomical detail, 4- visualization of most anatomical detail, 5-perfect visualization of anatomical detail.

#### RESULTS

Fig. 1 compares the achieved B1+ between the two coils. Over a group of n=3 subjects, the achieved mean B1+ of the Nova coil was 76% that of the transceiver with a 31.1% larger covariance. T2 SPC images from the two coils from two different subjects are shown in Fig. 2. Images are reformatted to show the IAC with a cross section showing the nerve roots of the facial and auditory nerves. Table 2 summarizes the radiological image quality evaluation between the various structures from the 0.63mm<sup>3</sup> T2 SPC; unpaired t-tests showed significantly better visibility for all structures with the transceiver with p values ranging from <0.001 to 0.05.

#### CONCLUSION

At 7T, the skull base is difficult to image due to insufficient B1 and inhomogeneous B0. The decoupled 8x2 transceiver improved the B1 achieved in the inferior brain region without use of dielectric pads or adiabatic sequences and permitted improved visibility of the structures including the temporal lobe, cerebellum, IAC and trigeminal nerves.

#### CLINICAL RELEVANCE/APPLICATION

We have presented methods that improve basilar brain imaging at 7T. Applications include high resolution 7T neuroimaging for lesions in the cerebellopontine angle, brainstem and vascular imaging.

### Feasibility of Prostate MR Fingerprinting and ADC Mapping in the Quantitative Characterization of Malignant Transition Zone Lesions

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N227B

Anna Lavrova, MD (*Presenter*) Research support, Siemens AG

#### PURPOSE

To determine if MR Fingerprinting (MRF) combined with Apparent Diffusion Coefficient (ADC) mapping can be used to distinguish cancer from Normal Appearing Transition Zone (NATZ) and low from intermediate/high-grade TZ tumors, and to determine if MRF based TZ lesion characterization in a general screening population undergoing TRUS or modality agnostic targeted biopsy yields similar results to published literature for patients pre-selected for MR guided targeted biopsy.

#### METHODS AND MATERIALS

In this IRB-approved, HIPAA-compliant, single institution study, prostate MRI studies from 34 patients (mean age 64, range 46-76 years) were acquired on 3T scanners between 12/2016 and 10/2020. All patients had biopsy-proven (from 17 systematic and 17 targeted biopsies - 9 fusion, 7 in-gantry and 1 cognitive) malignant TZ lesions corresponding to PIRADS v2 lesions identified on MRI. MRF (T1 and T2 maps) and ADC maps were analyzed retrospectively by a research fellow with 5 years of non-US radiology training. Regions of interest (ROIs) were drawn encompassing the entire TZ lesion as guided by the clinical radiology reports and on the contralateral NATZ on T1, T2 and ADC maps with 3D Slicer software. Paired t-test was used to assess for differences between tumors and NATZ, and between low-grade and clinically significant TZ tumors on MRF and ADC. Logistic regression was used to test the association of tumor grade (low vs high) with the measurements from T1, T2 and ADC maps ( $p=0.05$ ).

#### RESULTS

Of 34 TZ tumors, 15 were low-grade (Gleason 6) and 19 clinically significant (Gleason score = 3+4=7). T1, T2 and ADC were lower in all tumors as compared to NATZ despite the marked heterogeneity of the TZ ( $p<0.0001$  for all,  $?T1=289$  ms,  $?T2=23$  ms,  $?ADC=482 \times 10^{-6}$  mm<sup>2</sup>/s). There were no statistically significant differences between the T2 and ADC measurements of the various tumor grades ( $p>>0.05$ ). T1 measurements yielded a strong trend towards differentiating tumor grade ( $p=0.06$ ), though this did not reach statistical significance (mean  $\pm$  SD of T1 maps: 1526 msec  $\pm$  98 in low grade, and 1437 msec  $\pm$  125 in clinically significant tumors).

#### CONCLUSION

MRF combined with ADC maps show significantly lower values in tumors compared to NATZ. Measurements of T1 values show a promising trend for differentiating low from intermediate/high grade tumor, which is similar to published literature. However, further work with more patients and carefully targeted biopsies or post-surgical radiological-pathological correlation is needed to see if there is a true difference in T1 in low and high grade TZ tumors.

#### CLINICAL RELEVANCE/APPLICATION

MRF combined with ADC mapping are additional quantitative measures that can be used to distinguish tumor from and non-cancerous TZ tissue and predict the grade of TZ tumors.

Printed on: 08/22/24

### T1-SSPH07-Simultaneous Photon Counting and Energy Integrating to Correct Pulse Pile-up Effects in Photon Counting Detectors 1

Kevin Treb, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

In photon counting detectors (PCDs), electric pulses from multiple x-ray photons can pile-up when their temporal separation is shorter than the detector deadtime, resulting in increased image noise for a given radiation dose, reduced quantitative accuracy of radiological path lengths, and worsened spectral resolution. The correction of pulse-pile-up-induced count loss is particularly difficult for paralyzable PCDs since a given value of recorded counts can correspond to two different true photon numbers. In comparison, energy integrating detectors (EIDs) integrate x-ray induced electric charge pulses rather than counting them, and do not suffer from pile-up losses. This work introduces an inexpensive and novel added readout circuit element to simultaneously collect integrated charge with photon counts to correct for pile-up-induced count losses.

#### METHODS AND MATERIALS

Prototype electronics with a digital counter and a charge integrator in parallel were connected to a CdTe-based PCD element so that the electric signal from the same x-ray interactions could be processed by both chains simultaneously. After recording PCD counts and the integrated charges for each imaging frame, a lookup table was generated to map raw counts in the total- and high-energy PCD bins and total charge to an estimate of pile-up-free counts in both energy bins. Proof-of-concept imaging experiments were also performed with a CdTe-based PCD array and a diagnostic x-ray tube with clinically relevant flux levels.

#### RESULTS

The proposed electronics successfully recorded photon counts and total charge simultaneously. With the proposed correction, PCD counts became linear with input flux for both energy bins, even under conditions where the PCD exhibits paralyzable behavior. Without the correction, log-normalized measurements of PMMA objects severely overestimated radiological path lengths for both energy bins; after correction, the measurements accurately represented the true path lengths. Image noise under severe pile-up conditions was reduced with the correction and remained unchanged under negligible pile-up. No impact on spatial resolution was observed after the correction in images of line-pair patterns.

#### CONCLUSION

Total charge can be collected simultaneously with photon counts using inexpensive electronics and used to correct for pulse pile-up in photon counting detectors. PCD counts in two energy bins were corrected in experimental studies, and image noise was reduced under severe pile-up conditions.

#### CLINICAL RELEVANCE/APPLICATION

Pulse pile-up may reduce dose efficiency, quantitative accuracy, and spectral resolution in PCD x-ray and CT. The proposed correction is inexpensive to implement and can correct the PCD counts data for all three of these effects.

### T1-SSPH07-Evaluation of a Prototype Photon-counting CT for Pulmonary Imaging using Patient-based Lung Phantoms 2

Kai Mei, PhD (*Presenter*) Nothing to Disclose

## PURPOSE

Characterization of a prototype photon-counting CT (PCCT) for pulmonary imaging using a realistic 3D-printed patient-based lung phantom.

## METHODS AND MATERIALS

In this study, a PixelPrint lung phantom containing four distinct lung nodules (two solid and two subsolid) was inserted into the outer ring of a multi-energy CT (MECT) phantom (Gammex, Sun Nuclear), to assess low-dose pulmonary imaging using both a conventional energy-integrating CT (EIDCT) and a prototype photon-counting CT (PCCT) system (Canon Medical Systems Corporation). Scans were performed at a tube voltage of 120 kVp with various exposure settings (200, 100, 50, 25, 20, and 17.5 mAs). All scans were reconstructed using a lung-specific reconstruction kernel. Seven circular regions of interest (ROIs) with a radius of 4 mm were placed in areas of different densities, including one ROI in the MECT phantom, and their locations were registered pairwise for each acquisition. Mean and standard deviation of HU values were measured in the ROIs, and noise levels were compared across all dose levels. Contrast-to-noise ratios (CNR) was evaluated from reconstructions obtained using the ROIs measured in EID and PCCT scans.

## RESULTS

The PixelPrint phantom yielded highly realistic and high-quality images in both EIDCT and PCCT scans. Lung nodules and other important CT image features were clearly visible at varying dose levels. In terms of accuracy, mean values in all regions showed minimal differences of less than 20 Hounsfield Units (HU) between EIDCT and PCCT scans. As expected, standard deviation in all regions increased with decreasing radiation exposure. Notably, PCCT images exhibited lower noise compared to EIDCT images, particularly at exposure levels below 50 mAs. In terms of CNR, PCCT outperformed EIDCT with a significant improvement of nearly 50% at all dose levels.

## CONCLUSION

PCCT consistently exhibited accurate Hounsfield Unit measurements, stability, and low noise levels across a broad range of dose values. Furthermore, the PCCT system demonstrated the capability to effectively visualize textures and small structures within the lung even at low dose levels.

## CLINICAL RELEVANCE/APPLICATION

As PCCT imaging becomes more prevalent in clinical routine, its low dose capabilities (particularly from the reduced influence of electronic noise) will enable further advancements in pulmonary imaging, including low-dose lung cancer screening.

## T1-SSPH07-Photon Counting Detector Cardiac CT: Impact of Patient Size, Scan Mode, Tube Potential (kV), and X-ray Tube Power

Michael R. Bruesewitz, RT (*Presenter*) Nothing to Disclose

## PURPOSE

Photon-counting-detector (PCD) CT has shown substantial benefits in cardiac imaging using an ultra-high-resolution (UHR) scan mode. However, image noise is a major limiting factor, especially for large patients, sharp reconstruction (recon) kernels, thin slices, and when at tube power limits (TPL) due to small UHR focal spot. This study aims to systematically optimize scan and recon parameters in coronary CT angiography (CTA) (scan mode, tube potential (kV), recon kernel, and slice thickness) as a function of patient size and TPL.

## METHODS AND MATERIALS

Anthropomorphic thorax phantoms and coronary artery stenosis rods (QRM GmbH) were used to emulate cardiac CT patients of multiple sizes (lateral width 30 to 50 cm). Phantoms were scanned on a clinical dual-source PCD-CT (NAEOTOM Alpha, Siemens) using both UHR (60 kW tube power) and standard resolution (SR) (120 kW tube power) cardiac imaging protocols. UHR scans used 120 x 0.2 mm collimation and tube potentials of 90 and 120 kV. SR scans used 144 x 0.4 mm collimation, tube potentials of 120 and 140 kV, and CARE-keV optimized for vascular (Vas) and non-contrast (NC) exams. Low-energy threshold (T3D) images were obtained using an iterative recon algorithm (QIR, strength=4), vascular kernels (Bv60 and Bv64), and slice thicknesses of [0.2 mm (UHR only) and 0.4 mm]. Qualitative and quantitative image quality (IQ) assessments performed included basic visual comparison, image contrast, noise, and iodine contrast-to-noise ratio (CNR).

## RESULTS

At 30 and 35 cm, the 90kV-UHR images at 0.2 mm and Bv64 kernel had the best IQ and highest CNR. At 40 cm, the 90kV-UHR mode reached TPL, increasing the noise and requiring images at 0.4 mm and Bv60. The 120kV-UHR scan had the best overall IQ, while 90kV-UHR had higher CNR. At 45 cm, 120kV-UHR reached TPLs but still provided reasonable image quality with the highest CNR (3.6). The 120kV-SR-Vas mode had similar dose as that of 120kV-UHR but worse image quality (CNR = 2.4). The 120kV-SR-NC had overall best IQ, however, dose was 1.7x greater than that of 120kV-UHR. At 50 cm, the 120kV-UHR was significantly past TPLs; 120kV-SR-NC had the best IQ and higher CNR (3.6), however, dose was 1.85x greater.

## CONCLUSION

Cardiac UHR PCD-CT provides high-quality images up to 40 cm width but encounters TPLs beyond 40 cm due to small focal spot. For large patients (e.g., 50 cm width), SR mode with larger focal spot and high tube power should be used. Scan mode, kV, recon kernel, and slice thickness need to be adapted to accommodate large patients, with radiation dose carefully considered.

## CLINICAL RELEVANCE/APPLICATION

A systematic approach to optimize coronary CTA imaging protocol in terms of scan and recon techniques based on patient size, scan mode, and TPL is critical to ensure optimal IQ and radiation dose.

### T1-SSPH07-Empirical Energy Weighting Optimization for Fast Grayscale Image Generation with Photon Counting CT

Yirong Yang, MEng (*Presenter*) Research support, General Electric Company

#### PURPOSE

To develop a novel algorithm to generate real-time, artifact-free, quantitative grayscale images from photon counting CT (PCCT) scans without additional noise, for fast CT image reconstruction.

#### METHODS AND MATERIALS

Photon counting CT leverages multiple energy bins to enable material decomposition (MD) and virtual monoenergetic images (VMI) for quantitative imaging. However, the MD process is computationally intensive, leading to longer reconstruction times and increased hardware cost. In practice, real-time, high-quality grayscale images are needed for the operator to verify image quality (IQ). We propose a method to combine the energy bins using energy weighting optimization based on a specified bias-variance trade-off (BVT), followed by a spectral correction (SC) to generate a VMI at a target energy (e.g., 60 keV). To obtain the optimal weights and SC parameters, we design an objective function that optimizes the BVT of the VMI projections. We utilize measurement-based MD calibration to map energy bin counts to known material thickness pairs, then calculate the corresponding variance and bias of the VMI projection estimation as well as the ground truth values. The algorithm is evaluated using an edge-on-irradiated silicon PCCT prototype with 8 energy bins and scans of a Gammex Multienergy phantom ("head" configuration) with 0, 2.5, 5, and 10 mg/ml iodine inserts. The results for optimal weights, as well as total counts (equal weighting of energy bins), are compared with reference MD-derived VMIs.

#### RESULTS

Grayscale images generated using optimal weights and total counts are reconstructed offline. The variance, absolute bias, and RMSE compared to the reference VMI for 4 ROIs are computed. With our optimal weighting method, we observe less than 5% noise increase, less than 4 HU absolute bias, and few beam hardening or ring artifacts, while total counts produce higher bias and more artifacts. The lower noise level of the total counts image is due to the induced bias, as the RMSE of our optimal weights image is lower or comparable to that of total counts.

## CONCLUSION

An IQ-based heuristic-driven weight optimization algorithm for near real-time, reduced artifact, accurate quantitative grayscale image generation is proposed. No additional calibration data are required to compute the weights. Subjective IQ exceeds that for conventional total counts. The algorithm is substantially faster than reconstruction via the MD-to-VMI process.

## CLINICAL RELEVANCE/APPLICATION

We present a novel algorithm for near real-time, high-quality, quantitative grayscale image generation from PCCT scans, which can be applied to photon counting image processing pipelines for fast CT image generation.

### T1-SSPH07-Plaque and Stent Appearance in a Novel Silicon-based Photon-counting CT Prototype: An ex Vivo Phantom Study

Emma Verelst, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare plaque and stent appearance between a prototype silicon-based photon-counting CT (Si-PCCT) and a conventional energy-integrating detector CT (EIDCT) system.

#### METHODS AND MATERIALS

A human-resected and stented (Atrium Advanta V12, Atrium Medical Corporation,  $d = 6$  mm) femoral artery was centrally embedded in a 2% agar-water cylindrical phantom ( $d = 20$  cm). Helical scans were acquired using a prototype Si-PCCT and a conventional EIDCT system (Revolution CT, GE Healthcare) at similar scan parameters (120 kV, 40 mm collimation, 0.9 pitch, 0.5 s rotation, 9 mGy CTDIvol). Images were reconstructed with a bone kernel and ASIRO, a 15 cm and 5 cm field-of-view

(FOV) and a slice thickness of 0.42 mm (Si-PCCT) and 0.63 mm (EIDCT). Quantitatively, plaque and stent appearance were evaluated by 1) a plaque-stent contrast ratio, i.e. a signal ratio relative to the plaque signal, 2) comparison of the true diameter and measured diameter obtained from a Hounsfield Unit (HU) profile through the stent wall, and 3) blooming as a ratio between inner and outer stent diameter. Qualitatively, two vascular radiologists in consensus evaluated plaque and stent appearance, plaque distinction and blooming using a 5-point Likert scale. Interreader agreement was assessed by using an intra-class correlation (ICC) coefficient. Quantitative and qualitative differences between Si-PCCT and EIDCT were tested by using a paired sample t-test and a Wilcoxon signed-rank test.

## RESULTS

Quantitatively, Si-PCCT images resulted in an increased plaque-stent contrast ratio (Si-PCCT:  $85.5\% \pm 37.4\%$ ; EIDCT:  $14\% \pm 11.5\%$ ,  $p = 0.005$ ), and reduced blooming artefacts (Si-PCCT:  $33\% \pm 2.5\%$ ; EIDCT:  $58.9\% \pm 4.5\%$ ,  $p < 0.001$ ). At a 5 cm FOV, Si-PCCT images resulted in improved diameter accuracy (Si-PCCT:  $6\text{ mm} \pm 0.2\text{ mm}$ ; EIDCT:  $6.3\text{ mm} \pm 0.1$ ;  $p = 0.017$ ). Qualitatively, Si-PCCT images were rated higher than EIDCT images based on: plaque appearance (Si-PCCT:  $4.3 \pm 0.5$ ; EIDCT:  $1.3 \pm 0.5$ ,  $p < 0.001$ ), stent appearance (Si-PCCT:  $4.3 \pm 0.5$ ; EIDCT:  $1.6 \pm 0.5$ ;  $p = 0.002$ ), plaque distinction (Si-PCCT:  $3.9 \pm 0.5$ ; EIDCT:  $1.7 \pm 0.7$ ;  $p = 0.002$ ), and blooming (Si-PCCT:  $3.8 \pm 0.4$ ; EIDCT:  $1.6 \pm 0.5$ ;  $p = 0.002$ ) with excellent interreader (ICC = 0.93) agreement.

## CONCLUSION

This study demonstrated an improved spatial resolution of a novel Si-PCCT prototype, leading to better plaque and stent appearance with respect to plaque-stent contrast, a more accurate stent diameter and reduced blooming, when compared to EIDCT.

## CLINICAL RELEVANCE/APPLICATION

Plaque and stent imaging remains challenging with EIDCT systems as these are prone to blooming and beam hardening artefacts. This study evaluated the ability of Si-PCCT to overcome those limitations by using an ex vivo vascular phantom.

## T1-SSPH07-Evaluation of Eigenbin Compression for Reducing Photon-counting CT Data Size

6

Taly Gilat Schmidt, PhD (*Presenter*) Research Grant, General Electric Company; Research collaboration, Varian Medical Systems, Inc

## PURPOSE

Photon-counting CT (PCCT) systems can acquire multiple spectral measurements at high spatial resolution, generating a large amount of data to transfer across the gantry slip ring. This experimental study on a silicon PCCT clinical prototype evaluates a data compression method based on principal component analysis (PCA).

## METHODS AND MATERIALS

The PCCT prototype acquires 8 energy bins; each projection measurement thus represents a point in an eight-dimensional (8-D) space. The proposed method performs PCA on a set of PCCT calibration measurements. PCA finds the orthogonal axes, or eigenvectors, that capture the maximum variance in the 8-D photon-count vector space. To reduce the dimensionality of the PCCT data, the data are linearly transformed into the N-D ( $N < 8$ ) space spanned by the N eigenvectors with highest eigenvalues (i.e., the vectors that account for most of the information in the data). Only N coefficients are then transferred per measurement, which we term eigenbin values. After transmission, the 8 energy-bin measurements are estimated as a linear combination of the N eigenvectors. We acquired PCCT data by scanning a 20 cm-diameter Gammex Multienergy phantom with different material inserts. The method is evaluated with the number of eigenbins varied between two and five. In each case, the eigenbins are used to estimate the 8-bin data, after which material decomposition is performed. The mean and standard deviation of values in the reconstructed basis and virtual monoenergetic images are compared for the original 8-bin data and the eigenbin data.

## RESULTS

Material decomposition basis images reconstructed from four eigenbins (50% data reduction) demonstrate accurate mean values with a 4-6% increase in noise standard deviation. Further reduction in dimensionality increases noise and error in the basis images. The 65 keV virtual monoenergetic image demonstrates less than 3% change in the mean values as well as noise standard deviation, when two or more eigenbins are used for compression.

## CONCLUSION

For the material decomposition basis images, the proposed eigenbin compression method reduces PCCT data volume by 50% while maintaining quantitative material decomposition accuracy and with a noise standard deviation penalty of approximately 5%. For VMI grayscale images, eigenbin compression provides 75% data reduction without affecting mean values or noise in this example.

## CLINICAL RELEVANCE/APPLICATION

The proposed eigenbin method demonstrates potential for reducing PCCT data volume, which may improve efficiency and reduce data transfer times for applications that require fast image generation. PCCT could thus benefit a wider range clinical

applications. Decreased hardware requirements can increase PCCT availability by reducing system cost.

### Simultaneous Photon Counting and Energy Integrating to Correct Pulse Pile-up Effects in Photon Counting Detectors

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N226

Kevin Treb, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

In photon counting detectors (PCDs), electric pulses from multiple x-ray photons can pile-up when their temporal separation is shorter than the detector deadtime, resulting in increased image noise for a given radiation dose, reduced quantitative accuracy of radiological path lengths, and worsened spectral resolution. The correction of pulse-pile-up-induced count loss is particularly difficult for paralyzable PCDs since a given value of recorded counts can correspond to two different true photon numbers. In comparison, energy integrating detectors (EIDs) integrate x-ray induced electric charge pulses rather than counting them, and do not suffer from pile-up losses. This work introduces an inexpensive and novel added readout circuit element to simultaneously collect integrated charge with photon counts to correct for pile-up-induced count losses.

#### METHODS AND MATERIALS

Prototype electronics with a digital counter and a charge integrator in parallel were connected to a CdTe-based PCD element so that the electric signal from the same x-ray interactions could be processed by both chains simultaneously. After recording PCD counts and the integrated charges for each imaging frame, a lookup table was generated to map raw counts in the total- and high-energy PCD bins and total charge to an estimate of pile-up-free counts in both energy bins. Proof-of-concept imaging experiments were also performed with a CdTe-based PCD array and a diagnostic x-ray tube with clinically relevant flux levels.

#### RESULTS

The proposed electronics successfully recorded photon counts and total charge simultaneously. With the proposed correction, PCD counts became linear with input flux for both energy bins, even under conditions where the PCD exhibits paralyzable behavior. Without the correction, log-normalized measurements of PMMA objects severely overestimated radiological path lengths for both energy bins; after correction, the measurements accurately represented the true path lengths. Image noise under severe pile-up conditions was reduced with the correction and remained unchanged under negligible pile-up. No impact on spatial resolution was observed after the correction in images of line-pair patterns.

#### CONCLUSION

Total charge can be collected simultaneously with photon counts using inexpensive electronics and used to correct for pulse pile-up in photon counting detectors. PCD counts in two energy bins were corrected in experimental studies, and image noise was reduced under severe pile-up conditions.

#### CLINICAL RELEVANCE/APPLICATION

Pulse pile-up may reduce dose efficiency, quantitative accuracy, and spectral resolution in PCD x-ray and CT. The proposed correction is inexpensive to implement and can correct the PCD counts data for all three of these effects.

### Evaluation of a Prototype Photon-counting CT for Pulmonary Imaging using Patient-based Lung Phantoms

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N226

Kai Mei, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Characterization of a prototype photon-counting CT (PCCT) for pulmonary imaging using a realistic 3D-printed patient-based lung phantom.

#### METHODS AND MATERIALS

In this study, a PixelPrint lung phantom containing four distinct lung nodules (two solid and two subsolid) was inserted into the outer ring of a multi-energy CT (MECT) phantom (Gammex, Sun Nuclear), to assess low-dose pulmonary imaging using both a conventional energy-integrating CT (EIDCT) and a prototype photon-counting CT (PCCT) system (Canon Medical Systems Corporation). Scans were performed at a tube voltage of 120 kVp with various exposure settings (200, 100, 50, 25, 20, and 17.5 mAs). All scans were reconstructed using a lung-specific reconstruction kernel. Seven circular regions of interest (ROIs) with a radius of 4 mm were placed in areas of different densities, including one ROI in the MECT phantom, and their locations were registered pairwise for each acquisition. Mean and standard deviation of HU values were measured in the ROIs, and noise levels were compared across all dose levels. Contrast-to-noise ratios (CNR) was evaluated from reconstructions obtained using the ROIs measured in EID and PCCT scans.

#### RESULTS

The PixelPrint phantom yielded highly realistic and high-quality images in both EIDCT and PCCT scans. Lung nodules and other important CT image features were clearly visible at varying dose levels. In terms of accuracy, mean values in all regions showed minimal differences of less than 20 Hounsfield Units (HU) between EIDCT and PCCT scans. As expected, standard deviation in all regions increased with decreasing radiation exposure. Notably, PCCT images exhibited lower noise compared to EIDCT images, particularly at exposure levels below 50 mAs. In terms of CNR, PCCT outperformed EIDCT with a significant improvement of nearly 50% at all dose levels.

#### CONCLUSION

PCCT consistently exhibited accurate Hounsfield Unit measurements, stability, and low noise levels across a broad range of dose values. Furthermore, the PCCT system demonstrated the capability to effectively visualize textures and small structures within the lung even at low dose levels.

#### CLINICAL RELEVANCE/APPLICATION

As PCCT imaging becomes more prevalent in clinical routine, its low dose capabilities (particularly from the reduced influence of electronic noise) will enable further advancements in pulmonary imaging, including low-dose lung cancer screening.

### Photon Counting Detector Cardiac CT: Impact of Patient Size, Scan Mode, Tube Potential (kV), and X-ray Tube Power

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N226

Michael R. Bruesewitz, RT (*Presenter*) Nothing to Disclose

#### PURPOSE

Photon-counting-detector (PCD) CT has shown substantial benefits in cardiac imaging using an ultra-high-resolution (UHR) scan mode. However, image noise is a major limiting factor, especially for large patients, sharp reconstruction (recon) kernels, thin slices, and when at tube power limits (TPL) due to small UHR focal spot. This study aims to systematically optimize scan and recon parameters in coronary CT angiography (CTA) (scan mode, tube potential (kV), recon kernel, and slice thickness) as a function of patient size and TPL.

#### METHODS AND MATERIALS

Anthropomorphic thorax phantoms and coronary artery stenosis rods (QRM GmbH) were used to emulate cardiac CT patients of multiple sizes (lateral width 30 to 50 cm). Phantoms were scanned on a clinical dual-source PCD-CT (NAEOTOM Alpha, Siemens) using both UHR (60 kW tube power) and standard resolution (SR) (120 kW tube power) cardiac imaging protocols. UHR scans used 120 x 0.2 mm collimation and tube potentials of 90 and 120 kV. SR scans used 144 x 0.4 mm collimation, tube potentials of 120 and 140 kV, and CARE-keV optimized for vascular (Vas) and non-contrast (NC) exams. Low-energy threshold (T3D) images were obtained using an iterative recon algorithm (QIR, strength=4), vascular kernels (Bv60 and Bv64), and slice thicknesses of [0.2 mm (UHR only) and 0.4 mm]. Qualitative and quantitative image quality (IQ) assessments performed included basic visual comparison, image contrast, noise, and iodine contrast-to-noise ratio (CNR).

#### RESULTS

At 30 and 35 cm, the 90kV-UHR images at 0.2 mm and Bv64 kernel had the best IQ and highest CNR. At 40 cm, the 90kV-UHR mode reached TPL, increasing the noise and requiring images at 0.4 mm and Bv60. The 120kV-UHR scan had the best overall IQ, while 90kV-UHR had higher CNR. At 45 cm, 120kV-UHR reached TPLs but still provided reasonable image quality with the highest CNR (3.6). The 120kV-SR-Vas mode had similar dose as that of 120kV-UHR but worse image quality (CNR = 2.4). The 120kV-SR-NC had overall best IQ, however, dose was 1.7x greater than that of 120kV-UHR. At 50 cm, the 120kV-UHR was significantly past TPLs; 120kV-SR-NC had the best IQ and higher CNR (3.6), however, dose was 1.85x greater.

#### CONCLUSION

Cardiac UHR PCD-CT provides high-quality images up to 40 cm width but encounters TPLs beyond 40 cm due to small focal spot. For large patients (e.g., 50 cm width), SR mode with larger focal spot and high tube power should be used. Scan mode, kV, recon kernel, and slice thickness need to be adapted to accommodate large patients, with radiation dose carefully considered.

#### CLINICAL RELEVANCE/APPLICATION

A systematic approach to optimize coronary CTA imaging protocol in terms of scan and recon techniques based on patient size, scan mode, and TPL is critical to ensure optimal IQ and radiation dose.

### Empirical Energy Weighting Optimization for Fast Grayscale Image Generation with Photon Counting CT

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N226

Yirong Yang, MEng (*Presenter*) Research support, General Electric Company

#### PURPOSE

To develop a novel algorithm to generate real-time, artifact-free, quantitative grayscale images from photon counting CT (PCCT) scans without additional noise, for fast CT image reconstruction.

#### METHODS AND MATERIALS

Photon counting CT leverages multiple energy bins to enable material decomposition (MD) and virtual monoenergetic images (VMI) for quantitative imaging. However, the MD process is computationally intensive, leading to longer reconstruction times and increased hardware cost. In practice, real-time, high-quality grayscale images are needed for the operator to verify image quality (IQ). We propose a method to combine the energy bins using energy weighting optimization based on a specified bias-variance trade-off (BVT), followed by a spectral correction (SC) to generate a VMI at a target energy (e.g., 60 keV). To obtain the optimal weights and SC parameters, we design an objective function that optimizes the BVT of the VMI projections. We utilize measurement-based MD calibration to map energy bin counts to known material thickness pairs, then calculate the corresponding variance and bias of the VMI projection estimation as well as the ground truth values. The algorithm is evaluated using an edge-on-irradiated silicon PCCT prototype with 8 energy bins and scans of a Gammex Multienergy phantom ("head" configuration) with 0, 2.5, 5, and 10 mg/ml iodine inserts. The results for optimal weights, as well as total counts (equal weighting of energy bins), are compared with reference MD-derived VMIs.

#### RESULTS

Grayscale images generated using optimal weights and total counts are reconstructed offline. The variance, absolute bias, and RMSE compared to the reference VMI for 4 ROIs are computed. With our optimal weighting method, we observe less than 5% noise increase, less than 4 HU absolute bias, and few beam hardening or ring artifacts, while total counts produce higher bias and more artifacts. The lower noise level of the total counts image is due to the induced bias, as the RMSE of our optimal weights image is lower or comparable to that of total counts.

#### CONCLUSION

An IQ-based heuristic-driven weight optimization algorithm for near real-time, reduced artifact, accurate quantitative grayscale image generation is proposed. No additional calibration data are required to compute the weights. Subjective IQ exceeds that for conventional total counts. The algorithm is substantially faster than reconstruction via the MD-to-VMI process.

#### CLINICAL RELEVANCE/APPLICATION

We present a novel algorithm for near real-time, high-quality, quantitative grayscale image generation from PCCT scans, which can be applied to photon counting image processing pipelines for fast CT image generation.

### Plaque and Stent Appearance in a Novel Silicon-based Photon-counting CT Prototype: An ex Vivo Phantom Study

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N226

Emma Verelst, MSc (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare plaque and stent appearance between a prototype silicon-based photon-counting CT (Si-PCCT) and a conventional energy-integrating detector CT (EIDCT) system.

#### METHODS AND MATERIALS

A human-resected and stented (Atrium Advanta V12, Atrium Medical Corporation,  $d = 6$  mm) femoral artery was centrally embedded in a 2% agar-water cylindrical phantom ( $d = 20$  cm). Helical scans were acquired using a prototype Si-PCCT and a conventional EIDCT system (Revolution CT, GE Healthcare) at similar scan parameters (120 kV, 40 mm collimation, 0.9 pitch, 0.5 s rotation, 9 mGy CTDIvol). Images were reconstructed with a bone kernel and ASIRO, a 15 cm and 5 cm field-of-view (FOV) and a slice thickness of 0.42 mm (Si-PCCT) and 0.63 mm (EIDCT). Quantitatively, plaque and stent appearance were evaluated by 1) a plaque-stent contrast ratio, i.e. a signal ratio relative to the plaque signal, 2) comparison of the true diameter and measured diameter obtained from a Hounsfield Unit (HU) profile through the stent wall, and 3) blooming as a ratio between inner and outer stent diameter. Qualitatively, two vascular radiologists in consensus evaluated plaque and stent appearance, plaque distinction and blooming using a 5-point Likert scale. Interreader agreement was assessed by using an intra-class correlation (ICC) coefficient. Quantitative and qualitative differences between Si-PCCT and EIDCT were tested by using a paired sample t-test and a Wilcoxon signed-rank test.

#### RESULTS

Quantitatively, Si-PCCT images resulted in an increased plaque-stent contrast ratio (Si-PCCT:  $85.5\% \pm 37.4\%$ ; EIDCT:  $14\% \pm 11.5\%$ ,  $p = 0.005$ ), and reduced blooming artefacts (Si-PCCT:  $33\% \pm 2.5\%$ ; EIDCT:  $58.9\% \pm 4.5\%$ ,  $p < 0.001$ ). At a 5 cm FOV, Si-PCCT images resulted in improved diameter accuracy (Si-PCCT:  $6 \text{ mm} \pm 0.2 \text{ mm}$ ; EIDCT:  $6.3 \text{ mm} \pm 0.1$ ;  $p = 0.017$ ). Qualitatively, Si-PCCT images were rated higher than EIDCT images based on: plaque appearance (Si-PCCT:  $4.3 \pm 0.5$ ; EIDCT:  $1.3 \pm 0.5$ ,  $p < 0.001$ ), stent appearance (Si-PCCT:  $4.3 \pm 0.5$ ; EIDCT:  $1.6 \pm 0.5$ ;  $p = 0.002$ ), plaque distinction (Si-PCCT:  $3.9 \pm 0.5$ ; EIDCT:  $1.7 \pm 0.7$ ;  $p = 0.002$ ), and blooming (Si-PCCT:  $3.8 \pm 0.4$ ; EIDCT:  $1.6 \pm 0.5$ ;  $p = 0.002$ ) with excellent interreader (ICC = 0.93) agreement.

#### CONCLUSION

This study demonstrated an improved spatial resolution of a novel Si-PCCT prototype, leading to better plaque and stent appearance with respect to plaque-stent contrast, a more accurate stent diameter and reduced blooming, when compared to EIDCT.

#### CLINICAL RELEVANCE/APPLICATION

Plaque and stent imaging remains challenging with EIDCT systems as these are prone to blooming and beam hardening artefacts. This study evaluated the ability of Si-PCCT to overcome those limitations by using an ex vivo vascular phantom.

### Evaluation of Eigenbin Compression for Reducing Photon-counting CT Data Size

Tuesday, Nov. 28 8:00AM - 9:00AM Room: N226

Taly Gilat Schmidt, PhD (*Presenter*) Research Grant, General Electric Company; Research collaboration, Varian Medical Systems, Inc

#### PURPOSE

Photon-counting CT (PCCT) systems can acquire multiple spectral measurements at high spatial resolution, generating a large amount of data to transfer across the gantry slip ring. This experimental study on a silicon PCCT clinical prototype evaluates a data compression method based on principal component analysis (PCA).

#### METHODS AND MATERIALS

The PCCT prototype acquires 8 energy bins; each projection measurement thus represents a point in an eight-dimensional (8-D) space. The proposed method performs PCA on a set of PCCT calibration measurements. PCA finds the orthogonal axes, or eigenvectors, that capture the maximum variance in the 8-D photon-count vector space. To reduce the dimensionality of the PCCT data, the data are linearly transformed into the N-D ( $N < 8$ ) space spanned by the N eigenvectors with highest eigenvalues (i.e., the vectors that account for most of the information in the data). Only N coefficients are then transferred per measurement, which we term eigenbin values. After transmission, the 8 energy-bin measurements are estimated as a linear combination of the N eigenvectors. We acquired PCCT data by scanning a 20 cm-diameter Gammex Multienergy phantom with different material inserts. The method is evaluated with the number of eigenbins varied between two and five. In each case, the eigenbins are used to estimate the 8-bin data, after which material decomposition is performed. The mean and standard deviation of values in the reconstructed basis and virtual monoenergetic images are compared for the original 8-bin data and the eigenbin data.

#### RESULTS

Material decomposition basis images reconstructed from four eigenbins (50% data reduction) demonstrate accurate mean values with a 4-6% increase in noise standard deviation. Further reduction in dimensionality increases noise and error in the basis images. The 65 keV virtual monoenergetic image demonstrates less than 3% change in the mean values as well as noise standard deviation, when two or more eigenbins are used for compression.

#### CONCLUSION

For the material decomposition basis images, the proposed eigenbin compression method reduces PCCT data volume by 50% while maintaining quantitative material decomposition accuracy and with a noise standard deviation penalty of approximately 5%. For VMI grayscale images, eigenbin compression provides 75% data reduction without affecting mean values or noise in this example.

#### CLINICAL RELEVANCE/APPLICATION

The proposed eigenbin method demonstrates potential for reducing PCCT data volume, which may improve efficiency and reduce data transfer times for applications that require fast image generation. PCCT could thus benefit a wider range clinical applications. Decreased hardware requirements can increase PCCT availability by reducing system cost.

### Federated Deep Learning Model Predicts Breast Cancer Risk from Mammography Images

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Daly B. Avendano, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To externally validate Mirai, a DL breast cancer risk model based on mammography studies, applied in the Hispanic population with two distinct mammography vendors, utilizing a federated learning approach.

#### METHODS AND MATERIALS

This study retrospectively reviewed a database of 58,321 consecutive screening mammograms obtained from 24,060 women who received care at the TecSalud health system between January 1, 2014, and December 31, 2021. The Mirai model was utilized without the need for data sharing, using a federated learning approach. Cancer outcomes were obtained through the institutional tumor registry or imaging follow-up. The primary objective of this study was to evaluate the performance of the Mirai model in predicting the risk of breast cancer at 1-5 years from the time of the mammogram. We assessed the C-index as a measure of predictive accuracy.

#### RESULTS

Among the 23,340 patients with breast cancer-negative mammograms, 23,170 had no evidence of cancer in the following 5 years, while 170 were diagnosed with cancer during this timeframe. Mirai's performance was evaluated using a concordance index, which was found to be 0.74 (95% CI 0.71 to 0.77).

#### CONCLUSION

Our evaluation of MIRAI risk predictions indicates that the model is well calibrated, with an accurate accumulation of risk and estimations of risk over time. Our findings demonstrate that MIRAI's predictions align well with the observed number of events among both the full patient cohort and the case-matched control group.

#### CLINICAL RELEVANCE/APPLICATION

Breast cancer risk assessment is the angular stone for personalized screening. Artificial intelligence models have demonstrated promising results. The use of fair algorithms is essential for accurately assessing the overall population and avoiding the underrepresentation of minority groups. To enhance the effectiveness of these algorithms and ultimately lead to better outcomes. By adopting these practices, we can establish more equitable and inclusive systems that benefit everyone.

### Comparison of Quantitative Volumetric and Subjective BI-RADS Density Classification in Women with Dense Breasts

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Stuart S. Kaplan, MD (*Presenter*) Advisory Panel, Hologic, Inc; Advisory Panel, Delphinus Medical Technologies, Inc

#### PURPOSE

Increased breast density is an independent risk factor for breast cancer. A radiation-free tool for breast density assessment would be advantageous, especially for younger women. The purpose of this study was to determine the level of agreement between automated breast density based on whole breast ultrasound tomography volumetric data and commercially available volumetric breast density from 3D mammography in dense breasts. We examined agreement of quantitatively derived BI-RADS density from these two modalities with subjective mammography density assessment by breast radiologists and technologists.

#### METHODS AND MATERIALS

448 women with heterogeneously or extremely dense breasts were enrolled in a prospective case collection registry between December 2016 and October 2019. Participants underwent their annual screening digital breast tomosynthesis (DBT) (Hologic) and same day SoftVue™ automated whole breast ultrasound tomography (SV). Technologists assessed breast density using the BI-RADS density composition scale. Radiologists interpreted the mammogram and SV simultaneously and included a final BI-RADS density assessment. Quantitative volumetric density data was gathered for each case from mammography with Volpara and from SV. The Volpara overall score was used. The SV density index, a number from 0 to 100 derived from the volume-averaged sound speed, was recorded for each breast and categorized as a through d. The densest rating from the two breasts was selected. Four- way and pairwise agreement was tested using Kendall's coefficient of concordance (W). Additional analysis was completed for the disagreement cohorts.

#### RESULTS

In women with dense breasts, there was statistically significant good agreement between SV, Volpara, the radiologists' and technologists' BI-RADS density assessments. When SV was analyzed with each of the 3 other methods, there was statistically significant agreement with slightly higher concordance values. The SV BI-RADS was at a lower density level than Volpara in 12.1% of cases and at a higher density level in 13.3%.

#### CONCLUSION

SV density index, algorithmically calculated from whole breast ultrasound transmission data, has good agreement with automated breast density assessments using 3D mammography. SV breast density index is comparable with both radiologist and technologist subjective BI-RADS assessments from mammography.

#### CLINICAL RELEVANCE/APPLICATION

SV's ultrasound breast density offers accuracy comparable with DBT-based tools or rating by radiologists and technologists. Clinical risk assessment using breast density may be applied, especially to women under age 40, without unnecessary radiation.

### Association of Breast Density Measured on Low-dose Chest Computed Tomography with Subsequent Breast Cancer Risk in Screened Population

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Hyo-Jae Lee (*Presenter*) Nothing to Disclose

#### PURPOSE

Few studies identified the relationship between CT breast density and breast cancer risk, often with limited numbers of study cohorts and based on computer-aided quantitative methods which require laborious inputs by a trained user. This study aimed to determine the association between CT breast density grading by radiologists and breast cancer risk in a large screened population, furthermore the results were compared with mammographic density.

#### METHODS AND MATERIALS

In a retrospective cohort study using screened population in a tertiary hospital, women aged at least 40 years without a history of cancer who underwent both mammographic screening and low-dose chest CT in 2007-2016 were followed up through December 2022. Two board-certified radiologists with each special expertise in mammography and CT independently reviewed the breast density on mammography and CT images and classified each case into one of the four BI-RADS grades. The primary outcome focused on the occurrence of new cases of breast cancer, including both invasive breast cancer and ductal carcinoma in situ. The hazard ratio (HR) was calculated using Cox proportional hazard regression and adjusted for other covariates. To compare the relationship between breast densities on mammography and CT, the Spearman's correlation coefficient was adopted. Interreader agreements for the mammographic density and CT density grades were determined by using the Cohen weighted kappa statistic.

#### RESULTS

Among 1576 women (mean age, 65 years  $\pm$  9), the ascertainment of 17 incident breast cancers was obtained. CT density grade 4 showed a higher risk of breast cancer compared with those with grade 1 and 2 (HR, 10.502 [95% CI:1.227, 89.918],  $p = 0.032$  for reader 1; 6.368 [1.227, 33.049],  $p = 0.028$  for reader 2). There was a significant correlation on breast density between mammography and CT ( $r = 0.770$  and  $0.941$ , for reader 1 and 2, respectively) and the interreader agreement was good ( $\kappa = 0.613$  and  $0.701$ , for mammography and CT, respectively).

#### CONCLUSION

In this preliminary result, CT density provided future breast cancer risk information and correlated well with that from mammography.

#### CLINICAL RELEVANCE/APPLICATION

Low-dose chest CT scans for lung cancer screening can estimate breast density without sacrificing interreader agreement, and have an association with breast cancer risk, promising for future research on dedicated breast CT scans.

### Early Adulthood Adiposity, Attained Adiposity and Breast Parenchymal Complexity in Premenopausal Women

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Sneha Das Gupta, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Adiposity measures such as weight, body-mass index (BMI) and body fat% are associated with breast cancer risk. We assessed the relationship of breast parenchymal complexity with early adulthood adiposity, changes in adiposity over the life course, and attained adiposity among premenopausal women, while also accounting for breast density.

#### METHODS AND MATERIALS

We analyzed routine screening digital mammograms (Selenia Dimensions; Hologic) from 325 premenopausal women without breast cancer, recruited at the Joanne Knight Breast Health Center, Washington University in St. Louis, MO from December 2015 to October 2016. Trained research personnel assessed attained adiposity measures, while weight at ages 18 and 30 were self-reported. A wide array of radiomic features were automatically extracted from each mammogram using a validated computational imaging pipeline, standardized, and fused into a breast parenchymal complexity signature (BPCS). Volumetric percent density (VPD) was calculated using the Volpara software. Spearman correlations ( $r$ ) and multivariable linear regression models were used to evaluate the associations of adiposity measures with BPCS, adjusting for potential confounders (age, race, family history of breast cancer and parity) and VPD.

#### RESULTS

BPCS was moderately correlated ( $r = 0.61$ ) with VPD. Higher BPCS was significantly ( $p < 0.05$ ) associated with lower weight and BMI at age 18 and at age 30, independently of age, race, family history of breast cancer and parity; inverse associations with BPCS were also found for absolute and annual weight changes between age 18 and attained age as well as between age 30 and attained age ( $-0.60 < r < -0.15$ ; linear regression coefficients ( $b$ ) for adiposity measures ranging from  $-0.672$  to  $-0.008$ ). Attained weight, BMI and body fat were also significantly inversely associated with BPCS. When further adjusting for VPD, statistical significance was preserved, yet slightly attenuated, for most adiposity measures ( $-0.60 < r < -0.25$ ;  $-0.498 < b < -0.012$ ). Among all adiposity measures, strongest associations with BPCS were preserved for annual weight change from age 18 to attained age and annual weight change from age 30 to attained age.

#### CONCLUSION

Our preliminary data suggest that adiposity in early adulthood, as well as weight gain from early adulthood to attained age are inversely associated with breast parenchymal complexity among premenopausal women, and may have a lifelong impact on breast parenchymal tissue patterns, beyond breast density.

#### CLINICAL RELEVANCE/APPLICATION

Deeper understanding of the pathways through which early-adulthood adiposity modifies breast parenchymal tissue, and possibly breast cancer risk, can open new avenues for preventive interventions in premenopausal women.

### Predictive Performance of a Deep Learning Image-Based Five-Year Breast Cancer Risk Model Across Race/Ethnicity, Age, Breast Density and Family History of Breast Cancer

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Hari Trivedi, MD (*Presenter*) Founder, Lightbox AI ; Consultant, Sirona Medical, Inc ; Consultant, Flatiron Health ; Consultant, PMX Inc ; Research support, Kheiron Medical Technologies ; Research support, Clairity, Inc ; Research support, Nightingale Open Science ;

#### PURPOSE

Traditional breast cancer risk models demonstrate modest predictive accuracy and are limited by worse performance in races/ethnicities outside of European Caucasian ancestry. We measured the performance of a deep learning (DL) image-based five-year breast cancer risk model across race/ethnicity, age, breast density, and family history of breast cancer.

#### METHODS AND MATERIALS

This retrospective study included 31,047 consecutive bilateral 2D full field digital screening mammograms from 11,536 patients from January 2011 through December 2016 from six screening facilities. These exams were not part of model training. Self-reported race and ethnicity were categorized as Black, Asian, Hispanic, White, or as all other races and ethnicities. To account for the large number of White, non-Hispanic patients, race and ethnicity were further classified as White/non-Hispanic (W/NH) or as patients of color and/or Hispanic ethnicity (POC/H). Age (<50 vs >50), breast density (dense vs not dense), and first-degree family history of breast cancer were extracted from electronic medical records. Cancer outcomes were obtained from local tumor registries and included DCIS and any invasive breast cancer. Model prediction was estimated across subgroups using areas under the receiver operating characteristic curve (AUCs).

#### RESULTS

We found point estimate AUCs consistently at or above 0.73 across all subgroups. AUC by subgroup: W/NH 0.75 [95% CI 0.73, 0.77] (n = 27,323), POC/H 0.75 [95% CI 0.68, 0.82] (n = 2,529); age < 50 0.73 [95% CI 0.70, 0.76] (n = 13,742), age >= 50 0.74 [95% CI 0.72, 0.77] (n = 16,110); dense 0.75 [95% CI 0.75, 0.76] (n = 17,146), not dense 0.79 [95% CI 0.78, 0.80] (n = 13,052); 1st degree relative with breast cancer 0.77 [95% CI 0.73, 0.80] (n=6,713), 1st degree relative without breast cancer 0.79 [95% CI 0.76, 0.83] (n=10,618), 1st degree relative with breast cancer (unknown) 0.76 [95% CI 0.74, 0.78] (n=13,172).

#### CONCLUSION

The DL model performed consistently at or above 0.73 AUC in all subgroups of race/ethnicity, age, breast density and first-degree family history of breast cancer. No differences in performance were identified in patients identifying as POC/H compared to those identifying as W/NH. Performance was significantly higher in not dense vs dense exams. No significant differences were found between other subgroups. This DL image-based model appears to reduce differences in performance associated with traditional risk models.

#### CLINICAL RELEVANCE/APPLICATION

A DL based breast cancer risk prediction model can perform consistently across key patient subgroups and appears to reduce limitations of traditional risk assessment, such as differences in performance across race/ethnic groups.

### Artificial Intelligence for Mammography to Predict Future Breast Cancer Risk : Incorporating Longitudinal Changes to Enhance a Feasibility

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Sanghyup S. Lee, MD (*Presenter*) Employee, Lunit Inc

#### PURPOSE

To investigate mammographic parenchymal patterns and longitudinal changes that are related to breast cancer beyond the mammographic breast density and develop an artificial intelligence (AI) model to predict future breast cancer risk.

#### METHODS AND MATERIALS

We developed a mammography-based deep learning algorithm for an AI predictive model to show the risk score for future breast cancer. risk model using a total of 16,113 full-field digital mammograms (Hologic, 72.3%; Siemens, 27.7%) from 9,113 women in the United States, who underwent at least mammogram and have information of pathology-confirmed breast cancer outcomes within 5 years. To discover the feasibility of incorporating prior images to train longitudinal changes of mammographic parenchymal patterns, the baseline model (AI-1) trained prior mammograms of non-cancer women and women with breast cancer, respectively, and the other model (AI-2) additionally trained with paired current and prior examinations per woman. Discriminatory performance was assessed using C-indices and receiver operating characteristic (ROC) curves for 1- to 3-year outcomes. Mammographic breast density was evaluated for each mammogram according to the BI-RADS composition category.

#### RESULTS

A total of 2,000 examinations, of which 500 cases were followed by a cancer diagnosis were evaluated with two AI predictive models. C-indices increased from 0.68 (95% CI: 0.65, 0.71) of AI-1 to 0.73 (95% CI: 0.70, 0.76) of AI-2 ( $P=0.004$ ). The AI-2 model demonstrated the risk of breast cancer with AUC of 0.75 (95% CI: 0.70, 0.79) at 1-year, 0.76 (95% CI: 0.68, 0.83) at 2-year, and 0.73 (95% CI: 0.68, 0.78) at 3-year. The performance was comparable in fatty (C-index, 0.74; 95% CI, 0.70, 0.78) and dense (0.71; 0.65, 0.76) breasts. 1076 of 2000 examinations showed no longitudinal changes of mammographic density, and the performance of AI-2 for this subgroup was similar (C-index, 0.72, 95% CI, 0.70, 0.76) to the overall performance.

#### CONCLUSION

This preliminary study demonstrated the feasibility of the AI predictive model to identify mammographic parenchymal features of future breast cancer. Incorporation of longitudinal changes might be feasible to enhance risk stratification of breast cancer.

#### CLINICAL RELEVANCE/APPLICATION

The image-based risk model has a potential to be used to improve personalized screening of breast cancer.

T2-SPBR-7

### Performance of Traditional Breast Cancer Risk Models Compared to a Deep Learning Model Overall and by Race/Ethnicity

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Hari Trivedi, MD (*Presenter*) Founder, Lightbox AI ; Consultant, Sirona Medical, Inc ; Consultant, Flatiron Health ; Consultant, PMX Inc ; Research support, Kheiron Medical Technologies ; Research support, Clairity, Inc ; Research support, Nightingale Open Science ;

#### PURPOSE

To compare the performance of traditional breast cancer risk models to a new deep learning (DL) image-based five-year breast cancer risk model overall and by race/ethnicity.

#### METHODS AND MATERIALS

This retrospective study included 10,101 consecutive bilateral 2D full field digital screening mammograms from 8,688 patients from February 2015 through December 2016 from a U.S.-based center that operates six screening facilities. Patient race/ethnicity and traditional risk model scores (Breast Cancer Risk Assessment Tool [BCRAT] and Tyrer-Cuzick v6 [TC6]) were extracted from electronic medical records. Patient self-reported race/ethnicity was used to create two groups: White, non-Hispanic (W/NH) and patients of color and/or Hispanic (POC/H). Cancer outcomes were obtained from local tumor registries. Cancer rates were defined as total cancers (DCIS and any invasive cancer) diagnosed within five years after the index mammogram/total exams. Model predictions were estimated using areas under the receiver operating characteristic curve (AUCs) and compared across risk models overall and by race/ethnicity using Chi-squared tests. NCCN thresholds were used to categorize predicted five-year risk scores as follows: average risk < 1.7%, intermediate risk > 1.7% and < 3.0%, and high risk > 3.0%.

#### RESULTS

DL model five-year predictions significantly outperformed BCRAT and TC6 five-year predictions. Overall AUC [95% confidence interval] and number of exams (n) by risk model: DL 0.75 [0.72, 0.77] (n = 10,101), BCRAT 0.62 [0.59, 0.65] (n = 10,101), and TC6 0.59 [0.56, 0.62] (n = 10,101). Observed five-year cancer rates by race/ethnicity: W/NH 4.4% and POC/H 4.2%. Predictions by BCRAT and TC6 models, but not DL model, exhibited statistically significant differences across race/ethnicity groups. Comparing risk group distributions for W/NH to POC/H generated chi-squared statistic and p-values of: BCRAT 162.36 (p<.00001), TC6 84.49 (p<.00001), DL 0.954 (p=.621). Compared to POC/H, W/NH patients were 3.8 times more likely to be labeled high risk by BCRAT and 2.3 times more likely by TC6. The DL model assessed a nearly identical percentage of W/NH and POC/H as high risk.

#### CONCLUSION

An image-based DL model outperformed traditional risk models in predicting five-year breast cancer risk. Traditional risk models exhibited meaningful differences in performance across race/ethnicity that was not observed in the DL model.

#### CLINICAL RELEVANCE/APPLICATION

A deep-learning based approach to breast cancer risk prediction outperforms traditional risk models and appears to remove differences in performance observed across racial/ethnic groups associated with traditional risk models

T2-SPBR-8

### Cryoablation, Ultraconservative Treatment for Low-risk Early Breast Cancer $\leq 2$ cm: Analysis of its Efficacy

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Maria Jose Roca Navarro, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

To evaluate if in patients with Her2- luminal tumors  $\leq 2$ cm and ultrasound negative axilla, after cryoablation guided by ultrasound, there is absence of infiltrating carcinoma in the lumpectomy specimen. To demonstrate that the placement of pre-surgical seed at the moment prior to cryoablation does not interfere subsequently in the disappearance of tumor cells by freezing.

#### METHODS AND MATERIALS

Between April 2021 and March 2023 we performed preoperative cryoablation in 49 patients (aged 53-79 years) with 50 unifocal infiltrating ductal carcinomas (IDC) (between 4mm and 20mm). All IDCs were visible on ultrasound, were luminals low grade and ultrasound negative axilla. All patients were studied with mammography and tomosynthesis, staged and biopsied by ultrasound. MRI was performed to rule out extensive intraductal component in 16 of the 19 patients with associated intraductal carcinoma (DCIs) in the core needle biopsy (CNB). All of them underwent pre-surgical marking with ferromagnetic seed and cryoablation with 17G or 14G needle on the same procedure, taking advantage of the same anesthesia and cutaneous access. We used the ICEfx Galil Boston Scientific cryoablation system, applying the usual triple-phase protocol: freezing-passive thawing-freezing and duration of approximately 40 minutes. Subsequently we checked the correct placement of the seed with mammographic projection

#### RESULTS

Out of 50 low-risk unifocal IDC: -31 were pure IDC (without associated intraductal component in the diagnostic CNB): in none there was residual IDC in the lumpectomy specimen after performing pre-surgical cryoablation. -19 were IDC mixed (with associated DCIs in the diagnostic CNB): In 4 cases residual IDC was found in the surgical specimen, with some IDC focus remaining in the periphery of the post-cryoablation necrosis. In 8 patients, DCIs foci were detected far from the cryoablation area. All the specimens were considered by the pathologist to have tumor-free margins. There was no relevant complication.

#### CONCLUSION

Cryoablation is effective in 100% of cases for pure infiltrating tumors  $\leq 2$ cm. The presence of nests of DCIs away from the cryoablation area or millimeter foci of IDC at the margin of steatonecrosis in mixed IDC does not indicate failure of the technique, *as all surgical specimens were considered by the pathologist to have tumor-free margins*. Subsequent standard adjuvant treatment will equalize the risk of relapse to conventional lumpectomy, so it may be an alternative therapy in selected patients.

#### CLINICAL RELEVANCE/APPLICATION

In the near future, after evaluating studies with a larger number of cases and follow-up, in selected patients with luminal tumors = 2cm, cryoablation could be an alternative therapy thus avoiding surgery.

### Upgrade of MRI Detected Papillomas in Asymptomatic High Risk Patients, Patients with a History of Cancer, and Patients with Known Malignancy

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Kathryn W. Zamora, MD, MPH (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose is to evaluate the upgrade of papilloma identified on MRI biopsy in patients with breast cancer and high-risk patients with or without a history of breast cancer.

#### METHODS AND MATERIALS

In this HIPAA-compliant IRB-approved retrospective study, all MRI-guided biopsies from 1/1/2011 to 1/31/2020 yielding papilloma were reviewed. Only patients with an imaging indication of high-risk screening, known breast malignancy, or history of breast malignancy were included. Other indications, including breast symptoms such as palpable masses or nipple discharge, were excluded. All included patients had a surgical excision with clear pathology or, at minimum, a 2-year follow-up MRI after biopsy. All cases without surgical excision or imaging follow-up were excluded. All MRI biopsy procedures were performed on a GE 1.5 T magnet using a Suros Atec 9-gauge vacuum-assisted biopsy device.

#### RESULTS

Of the initial 258 MRI-guided biopsies demonstrating papilloma, 45.3% (117/263) met inclusion criteria. Of the 141 patients excluded, 90 biopsies were excluded because of breast symptoms. Most examinations, 57% (67/117), were performed for high-risk screening, including a personal history of breast cancer. The other 43% (50/117) of examinations were performed for extent of disease. Of the 117 biopsies, 4.3% (5/117) were upgraded to malignancy. One biopsy (1/117, 0.9%) was upgraded to invasive malignancy and four (4/117, 3.4%) were upgraded to DCIS. Of the 117 biopsies, 31.6% (37/117) demonstrated atypia or additional high-risk pathology at time of percutaneous biopsy while 68.4% (80/117) demonstrated benign papilloma. The upgrade rate of benign papilloma at biopsy was 3.8% (3/80) with all cases non-invasive. The upgrade rate of papilloma with atypia or additional high-risk lesion at biopsy was 5.4% (2/37) with one non-invasive and one invasive malignancy. Age, race, ipsilateral malignancy, lesion type, or additional high-risk lesion at biopsy were not associated with upgrade rate.

#### CONCLUSION

Surgical excision of biopsy-proven papilloma identified by MRI biopsy in asymptomatic high-risk patients and patients with known malignancy may not be necessary.

#### CLINICAL RELEVANCE/APPLICATION

Excision is often recommended for papillomas in high-risk patients. In these patients with papillomas found on MRI, a low upgrade rate suggests surgical excision may not be necessary.

### Cardiac Magnetic Resonance Imaging Features of Myocardial Involvement in Psoriasis

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Lorenzo Dominici, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Psoriasis is a systemic chronic inflammatory condition, primarily affecting skin and joints, associated with increased risk of developing major cardiovascular events (MACEs). Inflammatory myocardial involvement in psoriasis (P-IMI) has been reported but not thoroughly investigated. The aim of our study was to describe the findings at cardiac magnetic resonance (CMR) imaging in a series of patients with psoriasis related myocarditis.

#### METHODS AND MATERIALS

One hundred consecutive patients (62M, mean age  $55 \pm 13.7$  years) with psoriasis were screened by 2D echocardiography for cardiac abnormalities. Among them, five male patients showed hypokinetic dilated cardiomyopathy (HDCM). All patients with HDCM underwent invasive coronary angiography (ICA), CMR and endomyocardial biopsies (EMB) with real time PCR for cardiotropic viruses and western blot analysis for myocardial expression of Toll-Like Receptor 4 (TLR-4) and Interleukin-17A (IL-17A). CMR exams were performed on a 1.5 T scanner. Protocol included cine-bSSFP, T2-weighted STIR, T2-prep sequences for T2 mapping, MOLLI sequences for T1 mapping, acquired before and after gadolinium administration and CE T1w IR for late gadolinium enhancement images.

#### RESULTS

All patients presented with heart failure with reduced ejection fraction (HFrEF, EF  $19 \pm 2.8\%$ ), NYHA Class III-IV and various ECG abnormalities. ICA showed normal coronary arteries in all patients. All five patients were diagnosed with acute/subacute myocarditis on CMR imaging according to the updated 2018 Lake Louise Criteria. Among them, two patients showed myocardial edema on T2WI, three patients had positive LGE, while all of them had increased T1 and T2 mapping relaxation times. EMB confirmed imaging findings as an active virus-negative lymphocytic myocarditis was revealed in all patients with positive anti-heart autoantibodies, overexpression of TLR-4 and enhancement of IL-17A at western blot analysis.

#### CONCLUSION

P-IMI is an underrecognized condition in patients with psoriasis, presenting with severe ventricular dysfunction at echocardiography, lymphocytic myocarditis at EMB and with variable myocardial signal abnormalities at CMR.

#### CLINICAL RELEVANCE/APPLICATION

Timely detection of P-IMI is crucial due to its prognostic and therapeutic implications. CMR may play a pivotal role, as a reliable and accurate non-invasive tool to identify myocardial inflammation and ventricular dysfunction.

### Left and Right Ventricle Feature Tracking CMR Strain in Patients with Thoracic Sarcoidosis

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Juan J. Urbina, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Patients with sarcoidosis may have clinically silent disease in 20-25%. Early detection of disease is essential for adequate therapy and prevent negative outcomes. This study aims to assess cardiac magnetic resonance (CMR) feature tracking (FT) strain for detection of subclinical cardiac dysfunction in patients with biopsy-proven extracardiac sarcoidosis.

#### METHODS AND MATERIALS

This retrospective study included patients who underwent chest CT and CMR examinations for biopsy-proven extracardiac sarcoidosis. For comparison age-matched controls with normal CMR were included. All CMR studies were performed with 1.5T or 3T scanners (Siemens). Chest CT examinations were conducted with 64-256 slice scanners (Siemens, General Electric). CMR used a standard protocol with b-SSFP cine sequences in long (2,3,4chamber) and short axis views for volumes/function analysis. Late gadolinium enhancement (LGE) sequences in the same orientation were performed >10 min after administration of Gadovist (0.1 mmol/Kg). CMR image analysis including strain (Global longitudinal, circumferential, or radial strain) was performed with dedicated software (CVI 42). Chest CT was analyzed by based on established criteria for the diagnosis of sarcoidosis.

#### RESULTS

The cohort included 49 patients (58.2±9.5y, 26m). Subgroups were defined by extracardiac sarcoidosis with/without lymph adenopathy and parenchymal disease (+chest) or cardiac involvement (+CMR). Group 1 13/49 (56.7±8.6y, 8m) with +chest/+CMR, group 2 33/49 (57.7±9.4y,16m) with +chest/-CMR and group 3 3/49 patients (70.3±9.0y, 2m) with -chest/-CMR for sarcoidosis. 10 studies (57.5±12.3y, 6m) served as controls. LVGLS was impaired in all three groups compared to controls. LVGLS was significantly different between Group 1 and controls (-13.0±5.1 vs. 17.9±1, p-value=0.0112) and Group 2 and controls (-13.8±3.3 vs. 17.9±1.7; p-value=0.0124). LVGRS LAX was significantly different between Group 1 and controls (20.6%±9.6 vs. 31%±3.6; p-value=0.0086) and Group 2 and controls (23%±7.2 vs. 31%±3.6p-value=0.022). Positive LGE was detected in 13 patients: subendocardial 3/13, midmyocardial 6/13, midmyocardial/subepicardial 1/13, subepicardial/transmural 1/13 and subendocardial/midmyocardial/subepicardial in 2/13.

#### CONCLUSION

In patients with biopsy-proven extracardiac sarcoidosis independent of cardiac involvement LV GLS and LV GRS are abnormal, even when LVEF is within normal range.

#### CLINICAL RELEVANCE/APPLICATION

Therefore, LV strain can be used to detect subclinical LV dysfunction in patients with extracardiac sarcoidosis.

### Primary Chylopericardium: A Study Based on CT Lymphangiography

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Yimeng Zhang (*Presenter*) Nothing to Disclose

#### **PURPOSE**

To investigate the diagnostic value of CT lymphangiography (CTL) in primary chylopericardium.

#### **METHODS AND MATERIALS**

The clinical and imaging data of 39 patients with primary chylopericardium were retrospectively analyzed. All patients underwent CTL scan. CTL evaluated abnormal contrast distribution and reflux in the neck, chest, abdomen, pelvis and abnormalities in the pericardium, mediastinum, and lungs. The composition ratio of qualitative data was used for statistical description.

#### **RESULTS**

All 39 patients with CTL showed abnormal iodine oil deposition and reflux at different sites: (1) neck: 11 cases of the end of thoracic duct, 3 cases of the end of right lymphatic duct, 24 cases of cervical trunk reflux, 25 cases of subclavian trunk reflux; (2) chest: 23 cases of bronchial mediastinal trunk reflux, 22 cases of anterior mediastinum, 12 cases of main pulmonary artery window, 29 cases of peritracheal and bronchial, 30 cases of subcarina, 24 cases of posterior mediastinum, 7 cases of thoracic duct trunk reflux, 15 cases of pericardial reflux, 11 of which were transbronchial mediastinal trunk reflux, and 10 cases of abnormal distribution of intercostal, pleural, and Supra-diaphragm. (3) Abnormalities in the abdomen and pelvic region: 4 cases in the subdiaphragm, 18 cases of dilated and condensed iliac lymphatics on the contrast side, 21 cases of contralateral iliac reflux, 16 cases of abnormal distribution of contrast in the ipsilateral lumbar trunk, and 23 cases of contralateral lumbar trunk reflux. Extra-lymphatic manifestations of abnormalities: 39 cases showed fluid density in the pericardial cavity, 2 cases showed cloudy and swollen mediastinal soft tissues, 24 cases showed abnormalities in both lungs, 10 cases showed thickened lobular septa, 11 cases showed ground glass density, 10 cases showed thickened bronchovascular bundles, 5 cases showed thickened bronchial walls, 16 cases showed pleural effusion, and 11 cases showed pulmonary atelectasis or insufficiency. 16 patients were treated surgically and 7 cases were relieved after surgery.

#### **CONCLUSION**

CT lymphangiography can show the abnormalities of thoracic duct and accessory branches in primary chylopericardium, and abnormal lesions of mediastinum, pericardium and lungs in this disease, which can help to explore the pathogenesis, diagnosis and differential diagnosis of this disease.

#### **CLINICAL RELEVANCE/APPLICATION**

Exploring the CTL presentation features of primary chylopericardium will help the pathogenesis study, diagnosis and differential diagnosis of this disease.

### **Detection of Monosodium Urate Depositions & Atherosclerotic Plaques in the Cardiovascular System by Dual-energy Computed Tomography**

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Haolin Ren (*Presenter*) Nothing to Disclose

#### **PURPOSE**

This study employed Dual-energy CT (DECT) material separation technology to quantitatively assess the urate accumulated in coronary plaques, and to compare this to the Coronary CTA (CCTA) Calcium score scan for distinguishing urate deposition from atherosclerosis. Additionally, this study aimed to explore the relationship between urate deposition and surrounding atherosclerotic plaques, and to confirm the contribution of urate deposition to the development of coronary atherosclerosis.

#### **METHODS AND MATERIALS**

We investigated the role of dual-energy computed tomography (DECT) in diagnosis of coronary atherosclerotic plaques and urate depositions in the patients with clinically suspected coronary artery disease. The patients were examined with DECT imaging system, and their clinical data were collected.

#### **RESULTS**

DECT showed among 872 patients, 441 patients had plaques in coronary arteries, the incidence of plaque was 50.6%. Among the patients with coronary plaques, there were 348 patients (78.9%) with simple atherosclerotic plaque (AP), 8 patients (1.8%) with simple urate depositions (UD), 85 patients (19.3%) with urate depositions and atherosclerotic plaques (UDAP). Compared with AP group, total plaque area and calcification score around the plaque in UDAP group were significantly increased, and urate deposition areas were correlated with surrounding atherosclerotic area ( $r=0.325$ ,  $p<0.001$ ). Compared with AP patients, cardiac ejection fraction in UDAP patients was slightly decreased ( $p<0.05$ ). There was no statistical difference in blood uric acid concentration and other clinical parameters between two groups.

#### **CONCLUSION**

Notably, patients with gout or a history of hyperuricemia were more likely to exhibit urate deposition in their atherosclerotic plaques. Furthermore, we observed a strong correlation between urate deposition and atherosclerotic plaques with larger volumes and higher calcification. Cardiac ejection fraction in UDAP patients was slightly decreased compared with AP patients.

#### **CLINICAL RELEVANCE/APPLICATION**

DECT may provide a relatively simple method for detection and identification of coronary urate deposition at risk for cardiovascular diseases.

### Periaortic Adipose Radiomics Texture Features Associated with Increased Coronary Calcium Score: First Results on a Photon-Counting CT

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Isabelle Ayx, MD (*Presenter*) Research Consultant, AstraZeneca PLC

#### PURPOSE

Cardiovascular diseases remain the world's primary cause of death. Identifying and treating patients at risk of cardiovascular events is as important as ever. Adipose tissue counts as a classic risk factor for cardiovascular diseases. It has been linked to systemic inflammation and is suspected to contribute to vascular calcification. To further investigate this issue, the use of texture analysis of adipose tissue using radiomics features could prove a feasible option.

#### METHODS AND MATERIALS

In this retrospective IRB-approved single-center study, 55 patients (mean age 55, 34 male, 21 female) were scanned on a first-generation photon-counting CT. On axial unenhanced images, periaortic adipose tissue surrounding the thoracic descending aorta was segmented manually. Patients were divided into three groups for feature extraction, depending on coronary artery calcification (Agatston Score 0, Agatston Score 1-99, Agatston Score =100). 106 features were extracted using pyradiomics. R statistics was used for statistical analysis, calculating mean and standard deviation with Pearson correlation coefficient for feature correlation. Feature selection was performed using Random Forest classification and visualized using Boxplots and heatmaps. Additionally, monovariate logistic regression predicting an Agatston Score > 0 was performed, selected features were tested for multicollinearity and a 10-fold cross-validation investigated the stability of the leading feature.

#### RESULTS

Two higher-order radiomics features, namely "glcm\_ClusterProminence" and "glcm\_ClusterTendency" were found to differentiate between patients without coronary artery calcification and those with coronary artery calcification with respective mean values (Agatston Score 0/1-99/=100) of 92.77/79.23/77.05 for "original\_glcm\_ClusterProminence" ( $p = 0.019$ ) and 5.72/5.33/5.24 for "original\_glcm\_ClusterTendency" ( $p = 0.078$ ). As the leading differentiating feature "glcm\_ClusterProminence" was identified after assessing multicollinearity.

#### CONCLUSION

Changes in periaortic adipose tissue texture seem to correlate with coronary artery calcium score, supporting a possible influence of inflammatory or fibrotic activity in perivascular adipose tissue. Radiomic texture features may potentially aid as corresponding biomarkers in the future.

#### CLINICAL RELEVANCE/APPLICATION

The possible correlation between PAAT texture and coronary artery sclerosis may allow the hypothesis of possible texture changes through inflammatory or fibrotic processes in perivascular adipose tissue influencing the process of arteriosclerosis. A radiomics signature could serve as an imaging biomarker for cardiovascular prevention in the future.

### Baseline Whole-lung CT Features Deriving from Deep Learning and Dadiomics: Prediction of Benign and Malignant Pulmonary Ground-glass Nodules

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Wenjun Huang (*Presenter*) Nothing to Disclose

#### PURPOSE

To develop and validate the model for predicting benign and malignant ground-glass nodules (GGN) based on the whole-lung baseline CT features deriving from deep learning and radiomics.

#### METHODS AND MATERIALS

This retrospective study included 385 GGN from 3 hospitals, confirmed by pathology. 239 GGN from Hospital 1 were used as the training and internal validation set. 115 and 31 GGN from Hospital 2 and Hospital 3 were used as the external test sets 1 and 2, respectively. Clinical and morphological features of GGN at baseline chest CT were evaluated, and the whole-lung radiomics features were extracted simultaneously. Besides, baseline whole-lung CT image features are further assisted and extracted using the convolutional neural network. Back propagation neural network was used to construct five prediction models based on different collocations of the features used for training. The area under the receiver operator characteristic curve (AUC) was used to compare the prediction performance among the five models. The Delong test was used to compare the differences in AUC between models pairwise.

#### RESULTS

The model integrated clinical-morphological features, whole-lung radiomic features, and whole-lung image features (CMRI) performed best among the five models, achieved the highest AUC in the internal validation set (Hospital 1), external test set 1 (Hospital 2), and external test set 2 (Hospital 3), which were 0.886 [95% confidence interval (CI): 0.841-0.921], 0.830 (95%CI: 0.749-0.893) and 0.879 (95%CI: 0.712-0.968), respectively. In all three sets, the differences in AUC between the CMRI model and other models were significant (all  $P < 0.05$ ).

#### CONCLUSION

The whole-lung baseline CT features were feasible to predict the benign and malignant GGN. The model combining clinical-morphological features, whole-lung radiomics, and whole-lung image features showed the best performance.

#### CLINICAL RELEVANCE/APPLICATION

The deep learning model based on whole-lung features can provide non-invasive and low-cost prediction and save the time of nodule segmentation.

### Deep Learning Models for Malignancy Estimation of Pulmonary Solid Nodules After Novel Classification

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Zichang Ma (*Presenter*) Nothing to Disclose

#### PURPOSE

Identifying the malignancy of pulmonary solid nodules larger than 8mm remains a challenging task. Our study is to make a novel classification of pulmonary solid nodules based on the adjacent relationship between the pulmonary pleura and nodules and use deep learning models to diagnose the pathology-confirmed nodules divided by this classification on CT scans of the chest.

#### METHODS AND MATERIALS

A total of 453 patients with pathology-confirmed solid nodules were enrolled from 2014 to 2022 and were randomly separated into training, validation, and test cohorts. Then we made a classification of solid nodules. Nodules that were adjacent to the pleura in the largest cross-sectional area were included in the pulmonary pleura solid nodules (PPSN) group. Nodules that were adjacent to only the lung tissues were included in the isolated solid nodules (ISN) group. Two groups were also divided into three cohorts. The Swin Transformer as a deep learning model, was used to identify the malignancy.

#### RESULTS

Before classification, the area under the receiver operating characteristic curve (AUC), specificity, and sensitivity in the validation and independent test cohorts were 0.892 [95% CI: 0.864, 0.920], 0.765, and 0.858; 0.878 [95% CI: 0.831, 0.924], 0.741, and 0.871. After classification, AUC, specificity, and sensitivity in validation and independent test cohorts in the ISN group were 0.921 [95% CI: 0.884, 0.958], 0.809, and 0.868; 0.905 [95% CI: 0.873, 0.938], 0.809, and 0.868. In the PPSN group, AUC, specificity, and sensitivity in the validation and test cohorts were 0.875 [95% CI: 0.776, 0.974], 0.632, 0.934; 0.806 [95% CI: 0.735, 0.876], 0.425, 0.871. The AUC of two divided groups in the independent test cohort was significantly different as determined by the DeLong test ( $p = 0.012$ ). The AUC in the ISN group is greater than that in the whole group.

#### CONCLUSION

When using deep learning models to predict pulmonary nodules, it is necessary to consider the surrounding tissues of the tumor, and detailed classification may help improve the prediction effect.

#### CLINICAL RELEVANCE/APPLICATION

After specific classification, the accuracy of using deep learning models to predict lung nodules surrounded by lung tissue would be improved.

### Prediction of Lung Malignancy Progression and Survival with Deep Learning Based on Pre-treatment FDG-PET/CT

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Yongheng Luo, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Artificial intelligence (AI) demonstrated potential for improved accuracy in the characterization of lung malignancies with fluorodeoxyglucose positron-emission tomography and computed tomography (FDG-PET/CT), but studies mostly relied on handcrafted features rather than deep learning, and focused on the prognostic utilities of CT and PET individually without investigating their additive value. The purpose of this study was to use deep learning with pre-treatment FDG-PET/CT to predict progression of lung malignancies and overall survival (OS).

#### METHODS AND MATERIALS

A retrospective review across three institutions identified patients with a pre-procedure FDG-PET/CT and an associated malignancy diagnosis. Lesions were manually and automatically segmented, and convolutional neural networks (CNNs) were trained using FDG-PET/CT inputs to predict malignancy progression. Performance was evaluated using area under the receiver operating characteristic curve (AUC), accuracy, sensitivity, and specificity. Image features were extracted from CNNs and by radiomics feature extraction, and random survival forests (RSF) were constructed to predict OS. Concordance index (C-index) and integrated brier score (IBS) were used to evaluate OS prediction.

#### RESULTS

1168 nodules (n=965 patients) were identified. 792 nodules had progression and 376 were progression-free. The most common malignancies were adenocarcinoma (n=740) and squamous cell carcinoma (n=179). For progression risk, the PET+CT ensemble model with manual segmentation (accuracy=0.790, AUC=0.876) performed similarly to the CT only (accuracy=0.723, AUC=0.888) and better compared to the PET only (accuracy=0.664, AUC=0.669) models. For OS prediction with deep learning features, the PET+CT+clinical RSF ensemble model (C-index=0.737) performed similarly to the CT only (C-index=0.730) and better than the PET only (C-index=0.595), and clinical only (C-index=0.595) models. RSF models constructed with radiomics features had comparable performance to those with CNN features.

#### CONCLUSION

CNNs trained using pre-treatment FDG-PET/CT and extracted performed well in predicting lung malignancy progression and OS. OS prediction performance with CNN features was comparable to a radiomics approach. The prognostic models could inform treatment options and improve patient care.

#### CLINICAL RELEVANCE/APPLICATION

Features extracted from the deep learning models predict overall survival well. After prospective validation, this model based on FDG-PET/CT could predict lung malignancy progression and overall survival with high accuracy, and therefore help inform treatment options and improve patient care.

### Effect of Emphysema on Lung Nodule Detection Performance of AI Software

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Nikolaos Sourlos (*Presenter*) Nothing to Disclose

#### PURPOSE

Emphysema influences the appearance of the lungs in chest CT scans. It is unclear how well artificial intelligence (AI) based software performs in emphysema presence. The goal of this study is to check if there is a difference in lung nodule detection performance between an AI software and the human reader when emphysema is present.

#### METHODS AND MATERIALS

We selected 121 participants with (n=39) and without (n=82) emphysema (mean age 61±8, 48% men) from the Imaging in Lifelines cohort. Detection of nodules sized 30-300mm<sup>3</sup> by a commercial AI software was compared to human reading, and findings only detected by the reader or AI (discrepancies) were reviewed by an expert panel of two radiologists (gold standard). Using the gold standard, the detection performance was compared between AI and human reader for emphysema and non-emphysema groups, based on sensitivity, F1 score, and FP/scan. McNemar's test was utilized to check if there are differences between findings detected by AI and human reader.

#### RESULTS

The human reader detected 206 nodular findings and AI 223. The expert panel reviewed 211 discrepancies. Of these, 30 were actual lung nodules, 68 non-nodules, and 113 lymph nodes. In the emphysema group, AI sensitivity was 0.95 [95%CI 0.83-0.99] vs 0.87 [95%CI 0.73-0.94] for the human reader, with 0.51 FP/scan for AI vs 0.15 FP/scan for the human reader (for nodules p=0.45, for FPs p=0.01). In the non-emphysema group, AI's sensitivity was 0.87 [95%CI 0.77-0.93] vs 0.80 [95%CI 0.69-0.88] for the human reader, with 0.23 FP/scan for AI vs 0.28 FP/scan for the human reader (for nodules p=0.40, for FPs p=0.64). AI performance based on the F1 score was slightly lower than that of the human reader in participants with emphysema (0.77 [95%CI 0.68-0.84] vs 0.86 [95%CI 0.77-0.92] respectively), whereas performance of AI was slightly better than the human reader in non-emphysema participants (F1 score 0.81 [95%CI 0.74-0.87] vs 0.75 [95%CI 0.68-0.81] respectively).

#### CONCLUSION

Overall, sensitivity of AI for lung nodules was higher than for the human reader but at the cost of higher false positive rate in emphysema presence. This resulted in slightly worse performance of AI (based on F1 score) in emphysema but slightly better than the human reader in non-emphysema.

#### CLINICAL RELEVANCE/APPLICATION

AI software can sensitively detect lung nodules in individuals with and without emphysema at least as well as the human reader, but with a higher number of FPs in emphysema cases.

### CT-derived Radiomics Signatures as a Prognostic Factor in Osteosarcoma Patients with Pulmonary Metastasis Treated with Tyrosine Kinase Inhibitors

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Shan Shui Zhou (*Presenter*) Nothing to Disclose

#### PURPOSE

The tyrosine kinase inhibitors (TKIs) have become the main therapy in relapsed or advanced unresectable patients with osteosarcoma (OS). However, no accurate predictive biomarkers for response to TKIs have been found or reported. This study aims to explore the prognosis value of CT-based radiomics signatures and develop a multidimensional nomogram for predicting the progression-free (PFS) in OS patients with pulmonary metastasis treated with TKIs.

#### METHODS AND MATERIALS

A total of 90 OS patients with pulmonary metastasis were retrospectively enrolled in this study and were randomly divided into a training cohort (60) and a testing cohort (30). A total of 854 radiomics features were extracted from the segmentation of regions of interest based on baseline chest CT images. The intra-class correlation coefficient (ICC) was implemented to evaluate the feature reproducibility and stability. Only features with ICC greater than 0.8 were retained. The random survival forest (RSF) was performed to select features and generate radiomics signatures. Kaplan-Meier survival analysis with log-rank test was implemented for univariate selection. Two multivariate cox proportional hazards regression models were established with radiomics signatures and clinical factors (R-model and C-model) respectively. A multidimensional nomogram was then built based on all predictive parameters (RC-model). The discrimination abilities, goodness of fit and clinical benefits of models were validated and compared on both training and testing sets.

#### RESULTS

The R-model and radiomics signatures which was constructed with these 37 features showed good predictive ability and prognostic value in both training and testing cohorts (Training: C-index, 0.798, log-rank test,  $p < 0.0001$ ; Testing: C-index, 0.775, log-rank test,  $p = 0.04$ ). There are significant differences in C-index between the C-model from the R-model and RC-model in both training and testing cohorts (C-model: C-index, 0.567 and 0.556; RC-model: C-index, 0.798 and 0.773; all  $p < 0.05$ ). The calibration curves based on 12 and 24-month survival prediction showed better agreement between the predicted and actual probability of PFS in the R-model and RC-model than the C-model. The decision curve analysis curves showed that the R-model was similar to the RC-model, and gained much more net benefits than the C-model.

#### CONCLUSION

Radiomics signature derived by chest CT images is a potential predictor for the response to TKIs in OS patients with pulmonary metastasis.

#### CLINICAL RELEVANCE/APPLICATION

Radiomics could be promising for identifying whether OS patients with relapsed or advanced unresectable disease have a good prognosis after treatment with TKIs and personalize risk stratification and treatment decisions.

### Radiogenomics For EGFR Mutation Status Prediction in CT Images: Impact Of Model Design on Performance and Prospective Generalizability

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Jacob Gordon, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

We hypothesized that design choices could affect predictive performance and generalizability of radiogenomic models. We investigated the impact of feature extraction and selection approaches on models developed to predict EGFR mutation status (EGFRm+/-) in NSCLC, assessing robustness on two different input CT image types.

#### METHODS AND MATERIALS

We analyzed CT images from CT and PET/CT studies of US patients with NSCLC from TCIA (25% EGFRm+). Two feature extraction techniques were compared: hand-crafted features from segmented lesions and deep features from a pre-trained ResNet applied to a bounding box around the largest tumor. Principal component analysis (PCA) or Least Absolute Shrinkage and Selection Operator (LASSO) was used to select 5 features prior to classification by a support vector machine, with model performances evaluated via 5-fold cross validation AUC. Splits were stratified by EGFRm and disease stage. Prospective generalizability was evaluated using a temporal split (80:20 based on shifted dates). AUCs were reported as median and interquartile range.

#### RESULTS

When predicting EGFR status from diagnostic CT images (n=171), hand-crafted features selected either with PCA or LASSO resulted in effective stratification: AUC of 0.80 (0.73 - 0.80) and 0.80 (0.69 - 0.82), respectively, and encouraging prospective generalizability (0.86 for PCA and 0.76 for LASSO). By contrast, deep features showed poor performance using either PCA (0.60 [0.60 - 0.67]) or LASSO (0.46 [0.44 - 0.66]) as well as poor prospective generalizability (0.68 and 0.38, respectively). When utilizing low-fidelity CT from PET/CT studies (n=134), hand-crafted features selected with PCA resulted in an AUC of 0.75 (0.73 - 0.77) vs. 0.66 (0.64 - 0.76) for LASSO. However, LASSO showed better prospective generalizability (0.79 vs 0.76). In this dataset, deep features combined with PCA showed improved predictive power compared with LASSO: AUCs of 0.72 (0.69 - 0.8) and 0.47 (0.46 - 0.67), respectively. With regard to prospective generalizability AUCs were 0.73 and 0.44 for PCA and LASSO, respectively.

#### CONCLUSION

Performance and prospective generalizability for predicting EGFR mutation status varied widely across design settings. Tumor-based hand-crafted features filtered by PCA performed better than deep feature-based approaches regardless of image type. The effectiveness of the hand-crafted feature models supports the potential of radiogenomics in early identification of patients likely to harbor EGFR mutations.

#### CLINICAL RELEVANCE/APPLICATION

Treatment planning in NSCLC depends on EGFRm. Radiogenomic models may help to rapidly identify patients who may harbor EGFRm. However, rigorous analysis of model design is key to successful model development.

### Impact of Body Composition on Lung Tumor Growth

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Jiantao Pu, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

Lung nodules, a sign of lung cancer, are common abnormal findings on low-dose computed tomography (LDCT). After a lung nodule is detected, the next step is to assess its likelihood of being cancerous, usually by monitoring its growth rate through follow-up CT scans. A nodule's growth rate can suggest its chance of being malignant and indicate the need for further tests such as biopsy or positron emission tomography (PET). This study aims to investigate the potential impact of body composition tissues as depicted on LDCT on tumor growth over time.

#### METHODS AND MATERIALS

We conducted a study involving 109 subjects (55 male and 54 female) who had undergone multiple LDCT lung cancer screenings and were found to have lung nodules on their baseline CT scans. The nodules identified on both baseline and follow-up scans were segmented, and their doubling time (DT) in days was calculated. These subjects were grouped based on a DT threshold of 365 days. We also segmented five different body composition tissues depicted on the baseline LDCT scans were segmented, including skeleton muscle (SM), subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT), intramuscular adipose tissue (IMAT), and bone, and computed their volumes and densities in Hounsfield unit (HU). The backward stepwise multivariable logistic regression analysis was used to identify the body composition features associated with DT while adjusting for potential confounding factors, such as age, gender, pack/year, and presence of emphysema. The multicollinearity was checked by the variance inflation factor (VIF), where  $VIF > 3.0$  indicates high collinearity. The area under the receiver operating characteristics (ROC) curve (AUC) was used to evaluate the performance of the prediction models using a 5-fold cross-validation method.

#### RESULTS

The identified CT-derived body composition features significantly associated with DT include VAT volume ( $p=0.043$ ) and SAT volume ( $p<0.001$ ), while SM density is marginally significant ( $p=0.067$ ). Their combination achieved an AUC of 0.717 (95% CI: 0.619-0.814).

#### CONCLUSION

Body composition characteristics are significantly associated with the growth rate of a lung nodule over time and may be considered as novel image biomarkers to facilitate the assessment of indeterminate lung nodules detected in the screening setting.

#### CLINICAL RELEVANCE/APPLICATION

Approximately 50% of individuals who undergo LDCT lung cancer screening are found to have pulmonary nodules. Although the majority of lung nodules identified on CT scans (>95%) are not malignant, their presence can be worrisome for healthcare providers and anxiety-provoking for patients. Therefore, it is imperative to identify new biomarkers that can aid in the evaluation of indeterminate nodules.

### Preoperative CT-based Radiomics Model to Predict Tumor Status of Spread through Air Space in Non-small Cell Lung Cancer

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Kaihua Lou (*Presenter*) Nothing to Disclose

#### PURPOSE

This study is to establish radiomics model that can predict the spread through air space (STAS) of non-small cell lung cancer before surgery, and to explore whether the model efficiency can be improved by peritumoral information.

#### METHODS AND MATERIALS

A total of 373 patients were retrospectively collected from the two centers between January 2015 to June 2022. Patients in Center 1 were randomly divided into the training group and the internal test group in a 7:3 ratio, with Center 2 serving as the external test group. Classical tumor region of interest (ROI) and expanded tumor ROI were delineated for each lesion on Shenrui scientific research platform. Correlation analysis and logistic regression are used for feature screening, and support vector machine classifier is used for the establishment of prediction model, which is verified in both internal and external test groups. Receiver operating characteristic curve and area under the curve (AUC) are used to evaluate the effectiveness of the prediction model.

#### RESULTS

In this study, five models were established to predict the STAS status of patients with non-small cell lung cancer, including one clinical model, two radiomics models (classic tumor radiomics model and expanded tumor radiomics model) and two combined models (classic tumor combined model and expanded tumor combined model). In the external test group, the seven screened radiomics features show relatively good performance in predicting the STAS state alone, and most of the features had AUC values greater than 0.80. Among the prediction models, the clinical model shows relatively poor prediction efficiency, with AUC value of 0.63; The classic tumor combined model showed a relatively good prediction efficiency, with the AUC value of 0.84, which was higher than that of the single radiomics model (AUC was 0.82 and 0.71, respectively) and the expanded combined tumor model (AUC was 0.76).

#### CONCLUSION

The results of this study showed that the seven selected radiomics features showed good efficiency in the identification of STAS status alone. The classical tumor radiomics model and the classical tumor combined model can predict the STAS status of patients well, but the expanded tumor ROI does not significantly improve the efficacy of the model.

#### CLINICAL RELEVANCE/APPLICATION

STAS status affects the choice of surgical methods and prognosis of patients. The model established in this study can predict STAS status before surgery, which is conducive to guiding the selection of clinical surgical methods.

## Abstract Archives of the RSNA, 2023

T2-SPER-1

### The Impact of Dermoid Size on the Chance of Torsion and the Diagnostic Performance of CT Observations in Emergency Department Patients

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Maitray D. Patel, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Evaluate performance of CT observations for diagnosing twisted dermoids based on dermoid size..

#### METHODS AND MATERIALS

Text search of consecutive CT reports and pathology records between 1/1/2010 and 5/31/2022 identified ED patients with an ovarian dermoid, symptoms relevant to possible ovarian torsion, and absence of CT observations indicating alternative diagnosis. Operative and clinical notes established outcome...Three abdominal radiologists blinded to history, outcome, and cohort creation independently evaluated a maximum-size-matched review cohort containing all twisted dermoids with approximately twice as many non-twisted dermoids, scoring 6 adnexal torsion CT observations using a Likert scale:●●● tubal thickening●●● whirlpool sign●●● concentric or asymmetric wall thickening●●● adnexal deviation●●● uterine deviation●●● pelvic fat infiltration..Observation diagnostic metrics (sensitivity/specificity/accuracy/PPV/NPV) were based on presence of the observation indicated by at least two of the reviewers..

#### RESULTS

325 patients had 350 studies (19 patients with 2 studies, 3 patients with 3 studies, 10 patients with bilateral dermoids), showing 39 twisted dermoids and 321 non-twisted dermoids. The 10.8% overall torsion prevalence varied by dermoid size:●●● <40 mm = 0/180 (0%)●●● 40-69 mm = 6/96 (6.3%)●●● 70-99 mm = 16/43 (37.2%)●●● 100-159 mm = 15/30 (50.0%)●●● =160 mm = 2/11 (18.2%)..Tubal thickening and whirlpool sign had highest diagnostic performance in the review cohort (39 twisted averaging 97 mm and 70 non-twisted averaging 99 mm; 35.8% torsion prevalence).●●● For 84 dermoids =70 mm: the review cohort had all 51 of 51 non-twisted and 33 of 33 twisted dermoids of this size-----Tubal thickening: 84.8%/70.6%/76.2%/65.1%/87.8%-----Whirlpool sign: 63.6%/84.3%/76.2%/72.4%/78.2%●●● For 25 dermoids 40-69 mm: to achieve size match, the review cohort had 19 of the 90 non-twisted and 6 of the 6 twisted dermoids of this size-----Tubal thickening: 50.0%/89.5%/80.0%/60.0%/85.0%-----Whirlpool sign: 33.3%/94.7%/80.0%/66.7%/81.8%..Applying 40-69 mm diagnostic metrics to all 96 dermoids that size reduced tubal thickening PPV to 24.1% and reduced whirlpool sign PPV to 29.5%, reflecting more false positives due to low torsion prevalence..

#### CONCLUSION

10.8% of ovarian dermoids in ED patients with relevant symptoms and no other CT-identified cause for symptoms were twisted, involving no dermoids <40 mm, 6.3% of dermoids 40-69 mm, and 39.3% of dermoids ≥70 mm. Tubal thickening and whirlpool sign showed highest accuracy (80%), but with substantially lower PPV for dermoids <70 mm.

#### CLINICAL RELEVANCE/APPLICATION

Consider US confirmation of suspected dermoid torsion on CT when <70 mm due to low torsion prevalence.

### Determination of the Most Suitable Monoenergetic Level of Virtual Monochromatic Images in Dual-source CT for the Diagnosis of Bowel Obstruction and Colitis

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Djamel Dabli (*Presenter*) Nothing to Disclose

#### PURPOSE

To determine the monoenergetic level with the best image quality for the diagnosis of colitis and bowel obstruction in an emergency context.

#### METHODS AND MATERIALS

The images of 64 patients who benefited from an enhanced abdominal-pelvis scan in dual-energy CT (DECT) mode for the diagnosis of colitis or bowel obstruction were retrospectively analyzed. Acquisitions were performed on a third-generation dual-source CT (DSCT) scanner at portal phase. Acquisitions were performed at 100/Sn150kVp. Mixed images (simulating images at 120kVp) were generated as well as virtual monochromatic images (VMI) at 40/50/60/70keV. An objective image quality assessment was performed by measuring contrast, noise and contrast-to-noise ratio (CNR). Subjective analysis was performed by anonymous scoring of the images by two radiologists evaluating the noise, smoothing, overall quality and diagnostic quality on a Likert scale. The results were compared between the different images using the Mann-Whitney U test for paired samples.

#### RESULTS

Of all the patients, 33 had intestinal obstruction, and 31 had colitis. The mean age was  $65\pm 20$  and  $49\pm 22$  years, respectively. The maximum CNR was measured in VMI at 60keV for both examination types, but the difference was significant only compared to 70keV for bowel obstruction and to 40keV, 70keV and mixed images for colitis. A good inter-observer agreement for all subjective criteria was found with a kappa index higher than 0.86. The VMI at 60keV presented higher scores for all criteria for bowel obstruction and colitis with no significant difference in smoothing score compared to mixed images ( $p=0.119$  and  $p=0.888$ , respectively).

#### CONCLUSION

VMI at 60keV could provide better image quality compared with other low monoenergetic levels and mixed images for the diagnosis of bowel obstruction and colitis.

#### CLINICAL RELEVANCE/APPLICATION

Improved diagnosis of colitis and digestive tract obstructions. Reduction of examination interpretation time in the emergency context by optimizing the DECT image workflow

### Improving Preoperative Prediction of High-risk Esophageal Varices in Cirrhotic Patients: A Logistic Regression Model Based on Dual Energy CT Combined with Platelets

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Jiewen Chen (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the significance of preoperative prediction of high-risk esophageal varices (EV) in cirrhotic patients using ultrafast synchronized KV/mA switching dual energy CT (DECT), and to investigate the effectiveness of regression models that incorporate quantitative DECT parameters in conjunction with platelet for preoperative prediction.

#### METHODS AND MATERIALS

59 cirrhotic patients who underwent upper abdominal enhanced DECT scanning (Revolution Apex CT, GE) and gastroscopy were retrospectively enrolled. The risk of EV bleeding was divided into a low-risk group (LRV, n=38) and a high-risk group (HRV, n=21) based on gastroscopic findings. Basic clinical characteristics, hepatic transient elastography parameters derived by ultrasound (US), and DECT parameters in EV including portal phase esophageal venous iodine concentration (IC<sub>EV</sub>) was recorded for all patients. Non-parametric test was used to identify independent risk factors. Logistic regression models were constructed based on mixed models of DECT combined, and US combined with clinical factors, respectively. The receiver operating characteristic (ROC) curves, area under the ROC curve (AUC) and confusion matrix were calculated for assessing performance of two models.

#### RESULTS

A total of 59 patients were included, 38 with low-risk esophageal varices and 21 with high-risk esophageal varices. Non-parametric tests revealed significant differences between the high- and low-risk groups in terms of clinical characteristics including platelets (PLT), US factors including Liver stiffness, and DECT parameters including IC<sub>EV</sub>. The mixed model of US and PLT showed a 78% precision and sensitivity of 61.9%, specificity of 86.8%, positive prediction rate of 39% and negative prediction rate of 86.8%, and an AUC of 0.817. The mixed model of DECT and PLT demonstrated a precision of 83.1%, sensitivity of 76.2%, specificity of 86.8%, positive prediction rate of 48.5% and negative prediction rate of 86.8%, and an AUC of 0.916.

#### CONCLUSION

IC<sub>EV</sub> based on DECT combined with platelets can effectively exclude high-risk EV and has higher diagnostic efficacy than liver stiffness combined with platelets.

#### CLINICAL RELEVANCE/APPLICATION

According to Baveno VI guidelines, patients with cACLD at liver stiffness <20 Kpa and platelet count >150,000/ul may not require gastroscopy. The predictive model constructed for combined IC<sub>EV</sub> and PLT had better performance than the model combined liver stiffness and PLT, and was a potential model for non-invasive screening of high-risk EV in cirrhotic patients and avoiding gastroscopy.

### Feasibility Study of Quantitative Parameters of Single-source Dual Energy CT Spectrum Analysis Parameters to Predict Ki-67 Expression in Gastrointestinal Stromal Tumor

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Hongyu Zhang (*Presenter*) Nothing to Disclose

#### PURPOSE

To investigate the feasibility of preoperative prediction of Ki-6 expression in gastrointestinal stromal tumors(GIST)by multi-quantitative parameters of single-source dual-energy CT.

#### METHODS AND MATERIALS

The imaging data of 64 patients with GIST confirmed by single-source dual-energy CT three-phase energy spectrum enhanced scan and surgical pathology immunohistochemical index including Ki-67 were retrospectively analyzed. According to the Ki-67 expression index(>6 for high expression, <6 for low expression )the patients were divided into high expression group (n=28 )and low expression group(n=36 )The single energy CT value and iodine concentration IC value of the parenchymal area of the two groups were measured at 40-70 kV,and the normalized iodine concentration NIC)value and the slope of the energy spectrum curve were calculated.Univariate and multivariate Logistic regression analysis was performed on the two groups of patients to establish independent risk factors for predicting Ki-67 expression.

#### RESULTS

The CT values of 40-70 keV and NIC value in the arterial phase of the Ki-67 high expression group were higher than those in the low expression group, and the differences were statistically significant ( $P<0.05$ ), while the differences in the slope of the energy spectrum were not statistically significant ( $P>0.05$ ); The differences in the venous 40-70 keV CT values, slope of the energy spectrum and NIC values between the two groups were not statistically significant ( $P>0.05$ ). The CT values of 40~70 keV and slope of the energy spectrum value in the delayed phase of the Ki-67 high expression group were lower than those in the low expression group, and the differences were statistically significant ( $P<0.05$ ), while the differences in NIC values were not statistically significant ( $P>0.05$ ).Univariate and multivariate logistic regression showed that arterial phase,delayed phase 40KeV,70KeV CT values,and standardized iodine concentration values were independent risk factors for predicting Ki67 high expression.

#### CONCLUSION

Preoperative single-source dual-energy CT spectral parameters are helpful in predicting the expression of Ki-67 in gastrointestinal stromal tumors before surgery.

### Equilibrium Phase Imaging of the Abdomen on Photon-counting CT: Assessment of the Value of 50-keV vs 70-keV Imaging

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Toru Honda, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Equilibrium phase (EP) imaging of the abdominal CT has several diagnostic values but suffers from low contrast. The aim of this study was to perform the quantitative and qualitative assessments of virtual monochromatic images (VMIs) generated by photon counting CT (PCCT) during abdominal EP.

#### METHODS AND MATERIALS

This study included 20 patients who underwent abdominal dynamic contrast-enhanced CT using PCCT for the assessment of liver and pancreatic diseases including four patients with hepatocellular carcinoma and seven patients with pancreatic solid tumor. Portal venous phase (PVP) imaging was reconstructed to VMIs at 70 keV and EP imaging was reconstructed at 50 keV and 70 keV. One radiologist placed regions of interest on the three images and signal-to-noise ratio (SNR) were measured for the liver parenchyma, portal vein, hepatic vein, pancreas, and adrenal glands, as well as calculating the contrast-to-noise ratio (CNR) of the hepatic vessels and lesions. Two radiologists assessed the image quality using a 5-point scale regarding image noise, sharpness, organ and lesion conspicuity, and overall image quality. Friedman's test was used for the comparison among the three imaging.

#### RESULTS

The SNRs at 50 keV-EP imaging were significantly higher for the hepatic vessels ( $p < 0.05$ ), equivalent for the pancreas and adrenal glands, and significantly lower for the liver parenchyma compared with 70 keV-EP imaging ( $p < 0.05$ ). SNRs at the 50 keV- and 70keV-EP imaging were significantly lower than those at the 70 keV PVP imaging for all structures ( $p < 0.05$ ) except for the equivalent SNR for the portal vein at 50 keV-EP. CNRs of the hepatic vessels at 50 keV-EP were significantly higher than those at 70 keV-EP, but significantly lower than those at 70 keV-PVP ( $p < 0.05$ ). There were no significant differences among the three images in the CNR of the lesions. In the qualitative analyses, 70 keV-EP and -PVP imaging showed significantly better noise, sharpness, and overall image quality than 50 keV-EP imaging for both readers ( $p < 0.05$ ). The conspicuity of the hepatic vessels at 50 keV-EP were significantly higher than that at 70-keV EP for both readers ( $p < 0.05$ ), and equivalent to that at 70 keV-PVP for one reader. Conspicuity of the lesions and adrenal veins were significantly the highest at 50 keV-EP.

#### CONCLUSION

Although 50 keV-EP imaging had worse image quality, it provided the best conspicuity of hepatic or pancreatic lesions and adrenal veins compared with 70 keV-EP and 70 keV-PVP imaging.

#### CLINICAL RELEVANCE/APPLICATION

Virtual monoenergetic imaging at 50 keV during the equilibrium phase of abdominal CT may be helpful for the assessment of hepatocellular carcinoma, pancreatic cancer, and adrenal veins.

### The Extracellular Volume Fraction with Iodine (water) Image of Dual-energy Computed Tomography in Predicting P53 Expression of Rectal Cancer

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Chen Anliang (*Presenter*) Nothing to Disclose

#### PURPOSE

To assess the feasibility of extracellular volume (ECV) fraction determined with iodine(water) image of dual-energy computed tomography (DECT) for prediction of P53 expression of rectal cancer.

#### METHODS AND MATERIALS

A retrospective analysis was performed on 41 rectal cancer patients confirmed with P53 expression according to their postoperative pathology results who received abdominal enhanced DECT in our hospital. They were divided into group 1 (high-group; 21 patients; 14 male, 7 female, mean age: 67.95 years, range: 52-91 years) and group 2 (low-group; 20 patients, 15 male, 5 female, mean age: 64.60 years, range: 44-89 years) according to their P53 expression. Three ROIs were placed in the largest layer of rectal cancer in iodine(water) images created from equilibrium-phase contrast-enhanced DECT images. The iodine values of the left external iliac artery or femoral artery at the same layer with lesions were also measured. The ECV fraction were calculated and were analyzed with independent sample t-test. The ROC curve was generated using the ECV fraction, and the area under curve (AUC) was calculated to analyze the diagnostic performance of using the ECV fraction in predicting P53 expression of rectal cancer.

#### RESULTS

There was a statistically significant difference in the ECV fraction between high-group ( $45.83 \pm 9.76\%$ ) and low-group ( $55.81 \pm 12.83\%$ ) ( $p < 0.05$ ). The AUC, maximum Youden index and diagnostic threshold of using the ECV fraction for prediction of P53 expression of rectal cancer was 0.717, 0.407 and 56.73%, and the sensitivity and specificity were 55.0% and 85.7%, respectively.

#### CONCLUSION

ECV fraction determined with equilibrium contrast-enhanced iodine(water) image of DECT images was useful for predicting P53 expression of rectal cancer.

#### CLINICAL RELEVANCE/APPLICATION

ECV fraction created from gemstone spectral imaging (GSI) has a prospective clinical application in predicting the P53 expression of rectal cancer for the treatment decision-making.

### Assessment of the Liver Low-density Lesions with a Spectral CT

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Ying Xu (*Presenter*) Nothing to Disclose

#### PURPOSE

This study was aimed to compare and evaluate the image quality of intra-hepatic low-density lesions in spectrum computed tomography (CT) with different monochromatic energy images in the arterial phase, the portal vein phase, and the delayed phase, respectively, and to explore the exact monochromatic value of optimum image quality.

#### METHODS AND MATERIALS

Patients with intra-hepatic low-density lesions were prospectively enrolled in our institution. GE Revolution CT was used to perform enhanced upper abdominal scan. Adaptive statistical iterative reconstruction (ASIR-V) was set with 40%, 50%, 40%, and 30% for true non-enhanced abdominal scanning, enhanced abdominal scanning in the arterial phase, the portal vein phase, and the delayed phase, respectively. The arterial phase and the portal vein phase applied a spectral mode with fast switch 80/140 kV, and tube current was automatic (range from 100 to 600 mA). The average CT value and standard deviation (SD) of the lesions were measured and recorded at 50, 60, 70 and 80 keV in the arterial phase, the portal vein phase respectively, and the signal-to-noise ratio value was calculated and compared pair-to-pair. Paired-samples t-test was used to compare the mean value of SNR and SD in the arterial phase, the portal vein phase, and the delayed phase, respectively.  $P < 0.05$  was considered statistically significant.

#### RESULTS

A total of twenty patients were prospectively included finally (male: 5, female: 15; mean age: 65.4 years old), with a total of 35 lesions. For the arterial phase, the signal-to-noise ratio values of the lesion in the imaging with 80KeV was higher than those of 50, 60 and 70 keV ( $12.75 \pm 1.16$ ,  $0.49 \pm 1.18$ ,  $0.71 \pm 1.30$ ,  $0.94 \pm 1.41$ , respectively;  $P < 0.001$ ), and there was no statistically significant difference among the 50, 60, and 70 keV groups. For the portal vein phase, the signal-to-noise ratio values of 50, 60, 70, and 80 keV groups were  $1.32 \pm 1.08$ ,  $1.41 \pm 1.26$ ,  $1.49 \pm 1.44$ ,  $1.58 \pm 1.61$ , respectively; and there was no statistical difference among the different keV groups ( $P > 0.05$ ).

#### CONCLUSION

The image quality with 80keV of single-energy imaging of spectrum CT was significantly better than that of other monochromatic energy (50, 60, 70 keV) imaging in the arterial phase. But for the portal vein phase imaging, there was no statistical difference in the imaging quality of the liver lesions in scans with different keV. As a result, it is supposed to reduce the radiation dose of scans by decreasing the keV in the portal vein phase without compromising the image quality prospectively, but not in the arterial phase.

#### CLINICAL RELEVANCE/APPLICATION

It is supposed to reduce the radiation dose of scans by decreasing the keV in the portal vein phase without compromising the image quality prospectively, but not in the arterial phase.

### The Difference Between Virtual Non-enhanced Imaging and True Non-enhanced Imaging: A Comparison Study

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Ying Xu (*Presenter*) Nothing to Disclose

#### PURPOSE

To compare the difference in image quality and radiation dose between virtual non-enhanced (VNE) images and true non-enhanced (TNE) images in the arterial and the portal phase.

#### METHODS AND MATERIALS

Sixty-four patients were enrolled in this prospective study. GE Revolution CT was used for enhanced upper abdominal scanning. Adaptive statistical iterative reconstruction (ASIR-V) were set with 40%, 50%, 40%, and 30% for true non-enhanced abdominal scanning, enhanced abdominal scanning in arterial phase, portal vein phase, and delayed phase, respectively. The effective radiation dose (ED) and the size-specific dose estimation (SSDE) of virtual non-enhanced images and true non-enhanced images were calculated respectively. The mean CT values and standard deviation (SD) of liver parenchyma, spleen parenchyma and renal cortex in VNE images and TNE images were measured, and the signal-to-noise ratio (SNR) was calculated.

#### RESULTS

For radiation dose, the ED of VNE images gained from portal vein phase was the highest, followed by VNE from arterial phase reconstruction, and the lowest ED belonged to TNE images ( $4.59 \pm 1.98$ ,  $3.81 \pm 1.44$ ,  $3.67 \pm 1.71$ , respectively). The differences of ED between the latter two were significant compared with the portal phase. The significant difference was detected only between VNE images from the arterial (SSDEa) and the portal phase (SSDEp) ( $1.47 \pm 2.27$  vs  $10.50 \pm 2.03$ ,  $p=0.036$ ). For image quality: Liver There was no significant difference between the SNR of VNE images (SNRVNE) obtained from arterial phase and TNE (SNRTNE) ( $p=0.083$ ). The SNRVNE obtained from portal phase was better than that obtained from arterial phase and the SNRTNE. (SNRTNE vs portal SNRVNE:  $7.26 \pm 1.32$  vs  $12.85 \pm 2.21$ ,  $p < 0.001$ ; arterial SNRVNE vs portal SNRVNE:  $6.53 \pm 1.98$  vs  $12.85 \pm 2.21$ ,  $p < 0.001$ ). Spleen: The SNRVNE obtained from arterial phase and portal phase were better than that of SNRTNE and the difference was statistically significant (all  $p < 0.001$ ). Kidney The SNRVNE obtained from arterial phase and portal phase were better than that of SNRTNE and the difference was statistically significant (all  $p < 0.05$ ).

#### CONCLUSION

In terms of the radiation dose, the dose of VNE from portal vein was still the highest for ED, but its SSDE was the lowest instead. In terms of image quality, the VNE images of some organs at certain phases (such as hepatic portal phase, splenic artery phase and portal vein phase, renal artery phase and portal vein phase) were better than that of TNE images.

#### CLINICAL RELEVANCE/APPLICATION

Spectral CT was comparable to conventional CT in image quality, and even superior than it in the imaging of some organs, while radiation dose needed to be further verified.

### From Biopsy to Resection: Using CT to Predict Histologic Upgrading of Renal Masses

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Sandra Fiset, MD, BEng (*Presenter*) Nothing to Disclose

#### PURPOSE

Despite the popularity of renal mass biopsy, discordance can occur between the biopsy nuclear grade and the surgical specimen grade. Nuclear grade affects recurrence and mortality rates, and any discordance can lead to suboptimal management. The rate of tumor growth has been used to predict upgrade despite limited literature evidence. This study aims to create a risk prediction model for upgrading of clear cell renal cell carcinoma (ccRCC) based on CT imaging features and compare its performance against tumor growth rate.

#### METHODS AND MATERIALS

This IRB-approved single-center retrospective case-control study included 114 patients (76 male, median age=62 years) who underwent renal mass biopsy followed by surgical resection. The upgrade group (n=57) was defined as low grade ccRCC (ISUP 1 or 2) on biopsy and high grade (ISUP 3 or 4) on subsequent nephrectomy, while the control group (n=57) had no upgrade. The average growth in largest dimension per month and tumor volume doubling time were calculated using available cross-sectional imaging prior to resection. Twenty-two imaging features were assigned utilizing pre-biopsy renal triphasic CT. Features that had inadequate differentiation following univariable logistic regression were excluded. Remaining features were included in a multivariable logistic regression model using a stepwise model selection. The predictive performance of the final risk prediction model was evaluated using repeated 10-fold cross-validation and compared with measures of tumor growth.

#### RESULTS

Arterial enhancement, delayed enhancement, relative arterial enhancement, relative delayed enhancement, arterial wash-in and imaging necrosis were significantly different between the groups ( $p<0.05$ ). Importantly, tumor growth rate and doubling time were not statistically different. Four features (1 qualitative, 3 quantitative) were included in the final risk prediction model: mass heterogeneity ("heterogeneous" or "homogeneous"; OR=0.53), arterial enhancement (OR=0.46), relative delayed enhancement (OR=0.64), and enhancement ratio (OR=4.01). Using this model, a nomogram was constructed to predict probability of upgrade. The final risk prediction model resulted in a mean AUC of 0.69 (SD=0.17). This model performed better than measures of tumor growth ( $p<0.001$ ).

#### CONCLUSION

A model using CT imaging features performed better than measures of tumor growth and can be used to stratify the risk of renal mass upgrade at the time of surgical resection.

#### CLINICAL RELEVANCE/APPLICATION

This model identifies patients appropriate for active surveillance (low likelihood of upgrade) or immediate surgery (high likelihood of upgrade), avoiding the need for follow up imaging to assess tumor growth rates.

### **Beyond the Knife: A Retrospective Study on Surveillance-Based Management of Bilateral Multifocal Renal Oncocytomas**

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Shiva Singh, MBBS (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Bilateral multifocal renal oncocytomas account for approximately 4-6% of renal oncocytomas, and their optimal management strategy is still not well-defined due to a lack of consensus guidelines. This study aims to compare clinical, functional, and oncological outcomes of active surveillance (AS) versus surgical management in patients with bilateral multifocal renal oncocytomas, and to determine the appropriate management strategy for this group of patients.

#### **METHODS AND MATERIALS**

We conducted an IRB-approved retrospective cohort study on 62 patients with histopathologically confirmed bilateral multifocal renal oncocytomas. Patients with genetic alterations as seen in Birt-Hogg-Dubé syndrome or inadequate follow-up were excluded. The cohort was divided into three subgroups based on management received: active surveillance (AS) only, single unilateral surgery followed by AS, and multiple/bilateral surgeries. Clinical and imaging data were analyzed for longitudinal monitoring of tumor growth, new tumor/recurrence, and renal function changes. Statistical analysis was conducted to compare outcomes between the three management strategies.

#### **RESULTS**

The median age of the patients (n=62) was 64 years (IQR 57.5-69), and 49 (79%) were males. Patients were followed for an average of 5.5 years (2.8-7.2 years), and the median number of tumors per patient was 7, with no metastasis observed in any group. The overall median tumor growth rate was 0.3 cm/year (IQR 0.1-0.5), with no significant difference among the three management groups (p=0.73). The median age at death was 78.5 years (IQR 74.5-81.3, p=0.37), and no significant differences were found in serum creatinine levels between the three groups at the initial time point (p=0.67), final time point (p=0.5), or change in serum creatinine levels over the period of treatment (p=0.7).

#### **CONCLUSION**

Management strategies for bilateral multifocal renal oncocytomas are challenging, and clinicians face difficulties in choosing between surgical management and active surveillance. Findings of our study suggest that active surveillance is a safe and viable alternative to surgical management in patients with bilateral multifocal renal oncocytomas, with no detrimental impact on clinical, oncological, or functional outcomes as compared to surgical management.

#### **CLINICAL RELEVANCE/APPLICATION**

Active surveillance may be a safe alternative to surgical management of bilateral multifocal renal oncocytomas, especially for elderly patients or patients with comorbidities who are at a heightened risk of developing surgery-related adverse events.

### Predicting Growth Rate of Clear Cell Renal Cell Carcinoma: A Comprehensive Analysis using Machine-Learning

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Pouria Yazdian, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Von Hippel-Lindau (VHL) syndrome is associated with multiple benign and malignant neoplasms, including renal cell carcinomas (RCC), resections of which overtime can lead to end-stage renal disease (ESRD). Active surveillance is recommended for small renal masses to avoid unnecessary surgeries while preserving renal function. However, there is currently no reliable method to predict the growth rate of renal lesions.

#### METHODS AND MATERIALS

A single-center retrospective study of 55 patients with VHL was conducted from 2015 to 2021. Prior to partial or radical nephrectomy, patients underwent two MRI scans, and tumors were pathologically confirmed. Two abdominal radiologists assessed lesions based on 12 unique anatomical and sequence-specific imaging parameters using preoperative MRI scans. Lesions were divided into slow-growing (SG) and rapid-growing (RG) groups based on a 0.5 cm/year growth rate threshold. A stacked ensemble technique was employed to combine XGBoost and Random Forest algorithms, creating models that associate radiomic signatures with tumor grades. Optimal algorithm parameters were determined using 5-fold cross-validation, and performance was assessed on 100 different random test and train set combinations (85% train, 15% test) to identify the best model. Results were reported using positive predictive value (PPV), sensitivity, F1 score, and area under the Receiver Operating Characteristic curve (AUC-ROC). by using inter class correlation between two readers, they had moderate agreement.

#### RESULTS

The stacked ensemble machine-learning model demonstrated promising performance in predicting the growth rate of clear cell renal cell carcinoma in VHL patients. The model demonstrated high accuracy (90%) and promising performance metrics, including a precision of 0.97 for SG tumors, recall of 0.98 for RG tumors, and an F1 score of 0.92 and 0.88 for SG and RG, respectively. The macro average for precision and recall was 0.89 and 0.92, respectively, with an overall F1 score of 0.90. The Matthews Correlation Coefficient (MCC) was 0.52, indicating a moderate correlation between the model's predictions and the true growth rates.

#### CONCLUSION

This study demonstrates the potential utility of using a stacked ensemble machine-learning model for predicting the growth rate of clear cell renal cell carcinomas in VHL patients. The model's high performance suggests it could be a valuable tool for guiding patient management and improving clinical decision-making in the active surveillance of small renal masses.

#### CLINICAL RELEVANCE/APPLICATION

This machine-learning model could help optimize patient care by reducing the need for unnecessary surgeries, preserving renal function, and enabling timely interventions for patients with renal neoplasms.

### Artificial Intelligence Model to Predict Bethesda Score in Thyroid Nodule CT Imaging

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Isabel Gomez Alonso, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this work is to predict the Bethesda score of thyroid nodules by performing radiomic analysis of these nodules on CT images.

#### METHODS AND MATERIALS

This retrospective cohort study was performed by selecting 57 adult patients with thyroid nodules who underwent a CT scan of the neck and a fine needle aspiration biopsy between 2013 and 2021. Segmentation of the thyroid nodules was performed by three PGY4 radiology residents using CT images. Subsequently, 3D Slicer was used to extract the radiomic data of every segmented section in each patient. Data were processed with Python, using logistic regression and Machine Learning algorithms to predict the different Bethesda scores (score II-V) based on the radiomic features obtained. Visual assessment of the nodules was also performed by the three PGY4 radiology residents. Results were processed using IBM SPSS Statistics software. The whole process was supervised by a 5 year experienced head and neck radiologist and a 30 year experienced neuroradiologist.

#### RESULTS

In differentiating Bethesda II and V nodules, both logistic regression and K means showed a low performance (45% precision, 33% sensitivity and 57% specificity for logistic regression and 51% precision for K means). Random Forest classifier displayed 69% precision, 100% sensitivity and 100% negative predictive value, being able to detect all Bethesda V nodules. Finally, Support Vector Machine classifier showed 77% precision (75% sensitivity, 77% specificity, 87% negative predictive value).

#### CONCLUSION

Texture analysis-based artificial intelligence algorithms have demonstrated a 77% precision in differentiating Bethesda II and V nodules on CT imaging.

#### CLINICAL RELEVANCE/APPLICATION

Thyroid nodule management is complex and often requires to perform invasive diagnostic procedures. Radiologists using artificial intelligence models may help predicting nodule malignancy and, consequently, reducing limitations of current diagnostic algorithms.

### **Pioneering a Multi-Modal Deep Learning Approach for Hypopharyngeal Cancer Segmentation: Comprehensive Evaluation and Performance Analysis using Diverse MRI Data Across Multiple Institutions**

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

HE LIN KU, MA (*Presenter*) Nothing to Disclose

#### **PURPOSE**

Accurately annotating tumors is a time-consuming process, thus it is crucial to design an approach that can automate this process while maintaining accuracy. The study aims to develop and evaluate a multi-modality deep learning-based segmentation model for accurate and efficient delineation of hypopharyngeal cancer from T1-weighted image, contrast-enhanced T1-weighted image (T1c), and T2-weighted MRI scans. We utilized the nnU-Net architecture, ensembling techniques, and multi-institution datasets to improve the performance of our model.

#### **METHODS AND MATERIALS**

In this study, we used a dataset of 209 patients with hypopharyngeal cancer from National Taiwan University Hospital (NTUH) to train and ensemble three separate nnU-Net models on T1-weighted image, contrast-enhanced T1 (T1c), and T2-weighted MRI scans. To determine the best combination of models, we utilized nested five-fold cross-validation and ensembled the cross-validation results. The tumor annotations were performed by experienced oncologists on the patients treated between February 2011 and January 2015. We evaluated our model using various metrics on a testing dataset from Chang Gung Memorial Hospital (CGMH), which includes 91 patients treated between 2003 and 2013. The nnU-Net architecture was selected for this study due to its remarkable performance in various medical image segmentation challenges, which is expected to improve the segmentation results of hypopharyngeal cancer from multi-modality MRI scans. It consists of a 3D U-Net with an end-to-end pipeline that includes pre-processing, data augmentation, and post-processing.

#### **RESULTS**

The average tumor size in our training dataset from NTUH was 27.5 cm<sup>3</sup>. Our ensemble model achieved a mean Dice similarity coefficient (DSC) of 0.92 during training. On the independent testing dataset from CGMH our model achieved an overall DSC of 0.75 and a Hausdorff distance of 19 mm, demonstrating its robustness and generalizability.

#### **CONCLUSION**

The developed deep learning-based segmentation model can accurately and efficiently delineate hypopharyngeal cancer from multi-modalities and multi-institutional MRI scans, which has the potential to enhance clinical diagnosis and treatment planning for patients with hypopharyngeal cancer. The nnU-Net architecture and ensembling approach improve the segmentation performance and increase the robustness of the model, and have the potential to be applied to other cancer types and imaging modalities.

#### **CLINICAL RELEVANCE/APPLICATION**

Our metric analysis showed that the model has the potential to efficiently optimize hypopharyngeal cancer segmentation workflows and to be implemented in clinical decision support.

### AI for Automatic Localization and 3D Segmentation of Lymph Node Metastasis in Head and Neck Cancer

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Miriam Rinneburger, MD (*Presenter*) Nothing to Disclose

#### PURPOSE

Evaluation of an AI algorithm for localization and segmentation of lymph nodes (LNs) in contrast-enhanced computed tomography scans (CECTs) of the head and neck region on patients with head and neck cancer with confirmed LN metastasis.

#### METHODS AND MATERIALS

We searched our local database for patients sent from the otorhinolaryngological department from January 2000 to January 2021 for staging of a head and neck cancer who had at least one untreated LN metastasis confirmed through central necrosis, PET/CT-positivity, positive histology and/or progression/regression in a follow up scan. All 125 CECTs had a slice thickness of 1-2.5 mm, were conducted supine with venous contrast enhancement and reconstructed with a soft kernel. Patient age was 61,96 +/- 10,7 years, 25 patients were female and 100 male. On this cohort, we applied our existing 3D LN segmentation model. Independently, all LNs with a short axis diameter of  $\geq 5$  mm were manually segmented by an experienced radiologist and double-checked by a second radiologist as a reference. Additionally, LN metastases were labelled to evaluate the AI model's performance specifically on LN metastases.

#### RESULTS

In 125 CECT scans of the head and neck, the AI model marked 4271 LNs whilst 3656 LNs were segmented manually. Out of 544 LNs manually labelled as a clinical metastasis, the model detected 486. Overall, an average localization rate (LR) of 83.56% with 12.8 false positives (FPs) per CT scan was achieved. On average, only one of these FPs had an SAD of  $\leq 5$ mm. The model showed a statistically significant ( $p = 0.0029$ ) higher localization performance for metastatic LNs with an LR of 89.0% whilst for non-metastatic LNs, it reached an LR of 82.8%. The average global Dice accounts to 0.58 per CT scan. Segmentation accuracy was higher for non-metastatic LNs with a global Dice of 0.65 while it accounts to 0.42 for LN metastases. Sensitivity was higher in metastatic (0.69) than in non-metastatic LNs (0.58).

#### CONCLUSION

Our existing AI model for 3D segmentation of cervical LNs generalizes well to metastatic LNs. Overall, LR and segmentation sensitivity are higher in metastatic than in non-metastatic LNs whilst Dice is slightly worse. Clinical applicability of this model for metastatic LNs appears feasible.

#### CLINICAL RELEVANCE/APPLICATION

Automatic LN localization for N staging can speed up clinical practice. LN metastasis of head and neck cancer can differ from other malignancies in shape and texture. Thus, localization might need explicit training.

### TransUNet for Fully Automated Abdominal Multi-Organ Segmentation

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Khoschy Schawkat, MD, PhD (*Presenter*) Nothing to Disclose

#### PURPOSE

The purpose of this study was to validate the efficacy of CNN-Transformer hybrid architectures for multi-organ segmentation when applied to an independent, in-house dataset consisting of abdominal CT scans. The goal is to achieve a fully automated and highly accurate abdominal multi-organ segmentation computational framework that can be applied to the routine clinical workflow.

#### METHODS AND MATERIALS

The dataset consisted of 200 abdominal CT scans with 59 axial non-contrast and 131 contrast-enhanced abdominal (20 arterial phase, 90 portal venous phase, 19 late venous phase, and 12 elimination phase) clinical CT image series. Each CT volume consists of 44-392 slices of 512 x 512 pixels. The organ segmentations were performed manually and semiautomatically with manual verification on the liver, pancreas, left and right kidney, and spleen using free software for medical image processing (3D Slicer, version 4.11.0). We use the TransUNet architecture for our network, and train it using 5-fold cross validation with splits of 160/20 scans. TransUNet is trained on 4 organs of interest; liver, pancreas, kidneys and spleen. The 4 highest individual performing models are then ensembled. We report the average dice scores on a test set of 20 scans.

#### RESULTS

DICE scores for the labelmaps generated by the network, when compared against our ground truth images, for the liver, pancreas, kidneys, and spleen were 96.51, 83.02, 94.08, and 95.42, respectively. All organs of interest outperform the original scores reported in the authors' paper.

#### CONCLUSION

TransUNet, a U-Net structure in combination with transformers, achieves excellent performance in CT based multi-organ segmentation as shown in our independent in-house dataset.

#### CLINICAL RELEVANCE/APPLICATION

Large scale application of this fully-automated CT based multi-organ segmentation model allows for efficient assessment of volumetric and radiomics data.

### **Semi-Automated Longitudinal Performance Monitoring for Deployed Large Vessel Occlusion Detection Algorithm**

Tuesday, Nov. 28 9:00AM - 9:30AM Room: Learning Center

Chintan Shah, MD, MS (*Presenter*) Spouse, Employee, Merck & Co, Inc

#### **PURPOSE**

Real-world performance of artificial intelligence (AI) models can vary and degrade over time. However, local performance and monitoring are often overlooked and are resource-intensive. We built a semi-automated method in order to reduce the manual effort required for local performance monitoring of an AI algorithm, using intracranial large vessel occlusion (LVO) as a use case. We utilize a framework consisting of a combination of structured reporting (SR), language processing (LP), and manual review of reports to assess performance.

#### **METHODS AND MATERIALS**

Between January and May 2022, 1702 CTAs of the head and neck for stroke alert were processed with a commercial LVO detection algorithm (Viz LVO, Viz.ai). Scans were done at 17 different sites, including 12 hospitals, and 5 standalone ERs. Exams were interpreted by a neuroradiologist, asked to indicate concordance via an SR template. An analytical pipeline was developed for processing the reports utilizing KNIME analytics software (KNIME AG, Switzerland). Radiologist concordance was determined using SR when available. Language processing (LP) was then applied utilizing regular expression searches to identify positive or negative reports. LP results were reviewed to determine accuracy. Indeterminate reports were manually reviewed and categorized, as were those marked as discordant by either SR or LP. Summary performance statistics were calculated.

#### **RESULTS**

Radiologist compliance with the SR concordance statement was 57% (966/1702). Among the remainder, 74.3% (547/736) could be categorized as positive or negative reports utilizing LP, leaving 11% of original volume (189/1702) requiring manual review. Of exams marked as discordant in the SR template by the interpreting radiologist, 63% (42/67) were correctly categorized. The performance of LP in categorizing reports showed a sensitivity, specificity, negative- (NPV), and positive-predictive value (PPV) of 85, 95, 99, and 47%, respectively. After SR, LP and manual review, the sensitivity, specificity, NPV, and PPV of the commercial LVO detection algorithm were 77, 96, 98, and 59%, respectively.

#### **CONCLUSION**

SR alone was insufficient due to incomplete compliance and errors in categorization. The combined pipeline substantially reduced the workload of manual review better than structured reporting alone. The benefits persist after accounting for LP errors, which occurred more often with discordant than concordant results. We were able to corroborate local performance in this large multi-hospital dataset similar to that previously published.

#### **CLINICAL RELEVANCE/APPLICATION**
