SSCA04-1 Cardiac MRI In Patients With Prolonged Cardiorespiratory Symptoms After Uncomplicated COVID-19 Infection

Participants
Dmitrij Kravchenko, MD, Bonn, Germany (*Presenter*) Stockholder, Pfizer Inc;Stockholder, Viatris;Stockholder, AbbVie Inc;Stockholder, Johnson and Johnson

PURPOSE

Myocardial injury and inflammation on cardiac MRI in patients suffering from coronavirus disease 19 (COVID-19) have been described in recent publications. Concurrently, more and more cases of chronic COVID-19 syndrome (CCS) after COVID-19 infection have been observed manifesting with symptoms like fatigue and exertional dyspnea. The purpose of this study was to explore the relationship between CCS and myocardial injury and inflammation as an underlying cause of the persistent complaints in previously healthy individuals.*Methods and Materials In this prospective study from January 2021 to April 2021, participants without known cardiac or pulmonary diseases prior to COVID-19 infection with persisting CCS symptoms like fatigue or exertional dyspnea after convalescence and healthy control participants underwent cardiac MRI. Cardiac MRI protocol included parameters such as T1 and T2 relaxation times, extracellular volume (ECV), T2 signal intensity ratio, and late gadolinium enhancement (LGE). Student t test, Mann-Whitney U test, and ?2 test were used for statistical analysis.*Results A total of 41 participants with CCS (39 ± 13 years; 18 men) and 42 control participants (39 ± 16 years; 26 men) were evaluated. Parameters indicating myocardial inflammation and edema were comparable between participants with CCS and control participants: T1 relaxation time (977.8 ± 22.6 ms vs 970.5 ± 25.2 ms; P = .17), T2 relaxation time (52.7 ± 2.1 ms vs 52.4 ± 2.4 ms; P = .47), T2 signal intensity ratio (1.64 ± 0.24 vs 1.55 ± 0.28; P = .10). Visible myocardial edema was present in none of the participants. Only 3 of 41 (7%) participants with CCS demonstrated non-ischemic LGE compared to none in the control group (0 of 42 [0%], P = .07). None of the participants fulfilled the 2018 Lake Louise criteria for the diagnosis of myocarditis.*Conclusions Participants with CCS did not demonstrate signs of active myocardial injury or inflammation with only a fraction of symptomatic participants demonstrating LGE findings (3 of 41, 7%).*Clinical Relevance/Application No signs of active myocardial inflammation were present on cardiac MRI in previously healthy participants with prolonged cardiorespiratory symptoms after COVID-19 infection. There is no indication that cardiac MRI should be used a screening tool for CCS.

RESULTS

A total of 41 participants with CCS (39 ± 13 years; 18 men) and 42 control participants (39 ± 16 years; 26 men) were evaluated. Parameters indicating myocardial inflammation and edema were comparable between participants with CCS and control participants: T1 relaxation time (977.8 ± 22.6 ms vs 970.5 ± 25.2 ms; P = .17), T2 relaxation time (52.7 ± 2.1 ms vs 52.4 ± 2.4 ms; P = .47), T2 signal intensity ratio (1.64 ± 0.24 vs 1.55 ± 0.28; P = .10). Visible myocardial edema was present in none of the participants. Only 3 of 41 (7%) participants with CCS demonstrated non-ischemic LGE compared to none in the control group (0 of 42 [0%], P = .07). None of the participants fulfilled the 2018 Lake Louise criteria for the diagnosis of myocarditis.

CLINICAL RELEVANCE/APPLICATION

No signs of active myocardial inflammation were present on cardiac MRI in previously healthy participants with prolonged cardiorespiratory symptoms after COVID-19 infection. There is no indication that cardiac MRI should be used a screening tool for CCS.

SSCA04-2 Cardiac MRI And Imaging Markers Of Myocarditis In Competitive Athletes With Recent SARS-CoV-2 Infection: Results From The Big Ten COVID-19 Cardiac Registry

Participants
Jean Jeudy JR, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

To understand the frequency of myocarditis in student athletes recovering from SARS-Cov-2 infection.*Methods and Materials A central IRB for the Big Ten COVID-19 Cardiac Registry (coordinated by Ohio State University) approved this study. A survey of participating Big Ten University principal investigators reported the total number of athletes screened for SARS-CoV-2, the number with positive PCR, the number completing cardiac screening with and without CMR, and the number with findings that were consistent with myocarditis by the assessment of the local clinical team. CMR findings were classified based on updated 2018 Lake Louise criteria (LLC). The diagnosis of myocarditis by LLC requires presence of both a T2 based criterion (T2 mapping or T2 weighted abnormality) and T1 based criteria, (T1 mapping abnormality or late gadolinium enhancement (LGE)). Isolated right ventricular insertion point fibrosis was not used to diagnose myocarditis.*Results Comprehensive cardiovascular testing was performed in 1597 athletes comprised from 13 institutions. Thirty-seven were diagnosed with COVID-19 myocarditis (overall 2.3%,

range per program 0-7.6%). Nine (24%) had clinical myocarditis and 28 (76%) had subclinical myocarditis. Twenty (54%) had neither cardiac symptoms nor cardiac testing abnormalities, except for CMR. If cardiac testing was based upon cardiac symptoms, only 5 cases would have been detected (detected prevalence 0.31%), and 32 (86%) may have been missed. CMR for all athletes yielded a 7.4-fold increase in detection. Follow up CMR performed in 27 (73%) demonstrated resolution of T2 elevation in all (100%) and late gadolinium enhancement in 11 (40.7%).*Conclusions Among 1597 COVID-19 positive athletes with CMR screening, 37 cases of myocarditis were identified (2.3%). Subclinical myocarditis was more common than clinical myocarditis. The role of CMR as a screening tool in this population needs to be explored.*Clinical Relevance/Application The implications of post-COVID myocardial injury detected by CMR are still unknown. This registry looks to study these questions in both the convalescent window and post-acute sequela of COVID-19.

RESULTS

Comprehensive cardiovascular testing was performed in 1597 athletes comprised from 13 institutions. Thirty-seven were diagnosed with COVID-19 myocarditis (overall 2.3%, range per program 0-7.6%). Nine (24%) had clinical myocarditis and 28 (76%) had subclinical myocarditis. Twenty (54%) had neither cardiac symptoms nor cardiac testing abnormalities, except for CMR. If cardiac testing was based upon cardiac symptoms, only 5 cases would have been detected (detected prevalence 0.31%), and 32 (86%) may have been missed. CMR for all athletes yielded a 7.4-fold increase in detection. Follow up CMR performed in 27 (73%) demonstrated resolution of T2 elevation in all (100%) and late gadolinium enhancement in 11 (40.7%).

CLINICAL RELEVANCE/APPLICATION

The implications of post-COVID myocardial injury detected by CMR are still unknown. This registry looks to study these questions in both the convalescent window and post-acute sequela of COVID-19.

SSCA04-3   Quantifying Incidence And Outcomes In COVID-19 Associated Takotsubo Cardiomyopathy

Participants
Brandon Metra, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Takotsubo cardiomyopathy (TCM) is a potential cardiovascular complication of COVID-19. However, the incidence and clinical outcomes of TCM are not known in the context of the COVID-19 pandemic.*Methods and Materials This retrospective cohort study examined adults diagnosed with COVID-19 and or TCM with TriNetX, a global research network that aggregates real-time electronic health records from over 78 million patients. ICD-10, CPT, and SNOMED codes were used to define variables of interest. The diagnosis of TCM was defined by the diagnosis of TCM within one year of cardiac catheterization or coronary CT angiography, excluding all cases with subsequent coronary angioplasty, stenting, or bypass graft. In one analysis, we analyzed mortality in adults diagnosed with COVID-19 from 01/01/2020 - 01/31/2021 to adults diagnosed with TCM after COVID-19 infection. In another analysis, we compared adults with COVID-19 to adults with influenza to compare the TCM incidence. A third analysis examined mortality in adults with COVID and TCM to patients with TCM before the COVID-19 pandemic (TCM up to 01/01/2020). Balanced cohorts were created using propensity matching for age and gender.*Results Out of 4,171,131 patients with COVID-19, 339 patients had TCM (mean age 65.1 ± 13.6 years, 82.6% female). Compared to a cohort of 4,170,975 patients with COVID-19 alone, patients with COVID-19 and TCM had a higher risk of 1-year mortality (risk ratio 5.488 [95% confidence interval 3.849-7.826], p < 0.0001 before propensity matching; RR 2.800 [1.382-5.673], p=0.0027 in balanced cohorts of n=339 after matching). The incidence of TCM was not significantly different between cohorts of 4,171,131 COVID-19 and 768,997 influenza patients (RR 1.27 [0.968,1.668], p=0.0837 before matching; RR 1.349 [0.975-1.867], p=0.0697 in balanced cohorts of 428,038 after matching). Finally, in comparing the 339 patients with COVID-19 and TCM to a cohort of 4,123 patients with TCM alone before the pandemic, COVID-19 and TCM patients did not have a significantly higher risk of 1-year mortality (RR 1.280 [0.881,1.860]; p=0.1971 with matching not utilized to preserve cohort size).*Conclusions Myocarditis is a recognized potential component of COVID-19 infection; combined with the physical and psychological stresses of COVID-19, this may result in Takotsubo cardiomyopathy. We found increased mortality in patients with COVID-19 and TCM compared to COVID-19 alone. Due to a higher risk of significant morbidity and mortality in TCM, this disorder is an important screening and diagnostic consideration in COVID-19 patients.*Clinical Relevance/Application Clinicians should screen and recognize Takotsubo cardiomyopathy as a potential cardiac complication of COVID-19 infection.

RESULTS

Out of 4,171,131 patients with COVID-19, 339 patients had TCM (mean age 65.1 ± 13.6 years, 82.6% female). Compared to a cohort of 4,170,975 patients with COVID-19 alone, patients with COVID-19 and TCM had a higher risk of 1-year mortality (risk ratio 5.488 [95% confidence interval 3.849-7.826], p < 0.0001 before propensity matching; RR 2.800 [1.382-5.673], p=0.0027 in balanced cohorts of n=339 after matching). The incidence of TCM was not significantly different between cohorts of 4,171,131 COVID-19 and 768,997 influenza patients (RR 1.27 [0.968,1.668], p=0.0837 before matching; RR 1.349 [0.975-1.867], p=0.0697 in balanced cohorts of 428,038 after matching). Finally, in comparing the 339 patients with COVID-19 and TCM to a cohort of 4,123 patients with TCM alone before the pandemic, COVID-19 and TCM patients did not have a significantly higher risk of 1-year mortality (RR 1.280 [0.881,1.860]; p=0.1971 with matching not utilized to preserve cohort size).

CLINICAL RELEVANCE/APPLICATION

Clinicians should screen and recognize Takotsubo cardiomyopathy as a potential cardiac complication of COVID-19 infection.

SSCA04-4   Evaluation For Potential Cardiac Involvement In Athletes Recovering From COVID-19 Infection With Cardiac Magnetic Resonance Imaging- Should Cardiac Magnetic Resonance Imaging Be Used As A Screening Tool?

Participants
Tugce Agirlar Trabzonlu, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

Myocarditis is a known cause of sudden cardiac death in athletes. Prior studies demonstrated college athletes who have recovered from COVID-19 infection may have cardiovascular involvement detectable by cardiac magnetic resonance imaging (CMR). However, there is no consensus for the utility of CMR screening prior to the return to athletic participation in otherwise healthy athletes after their recovery from COVID-19. Our aim is to describe the prevalence of CMR findings of cardiac involvement in a population of Division 1 college athletes recovered from COVID-19 infection.*Methods and Materials The study was IRB approved. We retrospectively identified athletes who underwent CMR following documented COVID-19 infection before their return to strenuous

exercise between March 1, 2020 and April 30, 2021. The standardized CMR protocol included cine, T1 and T2 mapping, dark blood T2 imaging, extracellular volume (ECV) fraction, and late gadolinium enhancement (LGE) on a 1.5 T scanner. The MRI findings were reviewed by experienced cardiovascular radiologists in the course of normal clinical work. Diagnosis of acute myocarditis was based on the modified Lake Louise criteria. The presence of pericarditis was determined by reviewing abnormal pericardial enhancement, pericardial fluid and/or thickening.*Results A total number of 112 student athletes (75 male and 37 female athletes; mean age 20 years; range 18-23 years) recovered from COVID-19 were included. Two athletes [1.8%, (95%CI, 0.6 - 4.2%)] had MRI findings compatible with acute myocarditis. Of these, one had focal non-ischemic subepicardial LGE with associated abnormal T2 signal (56-64 msec, normal value range in our institution is 52.18 ± 3.4 ms). The second athlete had globally elevated ECV value of 33%, and abnormal native T2 signal (60-65 msec). Pericardial effusion was present in the second athlete in addition to CMR evidence of myocarditis. One athlete [0.9%; (95%CI, -0.8 - 2.6%)] had findings of pericarditis. 5 athletes [4.5%; (95%CI, 0.6 - 8.3%)] had focal LGE in the inferior right ventricle insertion point without abnormal T2 signal, suggestive of prior myocardial injury and/or athletic remodeling.*Conclusions The prevalences of acute myocarditis (1.8%) and acute pericarditis (0.9%) were low in student athletes recovered from COVID-19 infection.*Clinical Relevance/Application The routine use of cardiac MRI as a screening tool in student athletes recovered from COVID-19 infection is controversial as the prevalence among this population is low.

RESULTS

A total number of 112 student athletes (75 male and 37 female athletes; mean age 20 years; range 18-23 years) recovered from COVID-19 were included. Two athletes [1.8%, (95%CI, 0.6 - 4.2%)] had MRI findings compatible with acute myocarditis. Of these, one had focal non-ischemic subepicardial LGE with associated abnormal T2 signal (56-64 msec, normal value range in our institution is 52.18 ± 3.4 ms). The second athlete had globally elevated ECV value of 33%, and abnormal native T2 signal (60-65 msec). Pericardial effusion was present in the second athlete in addition to CMR evidence of myocarditis. One athlete [0.9%; (95%CI, -0.8 - 2.6%)] had findings of pericarditis. 5 athletes [4.5%; (95%CI, 0.6 - 8.3%)] had focal LGE in the inferior right ventricle insertion point without abnormal T2 signal, suggestive of prior myocardial injury and/or athletic remodeling.

CLINICAL RELEVANCE/APPLICATION

The routine use of cardiac MRI as a screening tool in student athletes recovered from COVID-19 infection is controversial as the prevalence among this population is low.

SSCA04-5 Quantification Of Lumen Diameter Within Coronary Artery Stents Using A High Resolution Photon Counting Detector CT And A Deep Convolutional Neural Network Denoising Algorithm

Participants
Emily Koons, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To quantify the effective lumen diameter within coronary stents using an energy-integrating-detector (EID) CT system and compare to results achieved using an investigational photon-counting-detector (PCD) CT and convolutional neural network (CNN) denoising algorithm.*Methods and Materials Seven different types of coronary stents with inner diameters between 3.12-4.47mm were inflated and deployed in plastic tubes containing 20mg/mL of iodine solution, mimicking stented contrast-enhanced coronary arteries. Tubes were placed in an anthropomorphic phantom (QRM) simulating an average-sized patient and scanned on EID and PCD. EID scans were performed using our standard CTA protocol (120kV, 180 quality reference mAs). PCD scans were performed in high resolution (HR) mode (120x0.2mm collimation) at 120kV with tube current adjusted so CTDIvol was matched to EID scans. EID images were reconstructed per our routine clinical protocol (Br40, 0.6mm thickness). PCD images were reconstructed at a thickness of 0.6mm using a sharp kernel (Br89) that is only possible with the PCD HR mode. To address increased noise introduced by the Br89 kernel, an image-based CNN denoising algorithm was applied to PCD images. Stent inner diameters were segmented based on full width half maximum thresholding and morphological operations. Lumen area and effective diameter were calculated and compared to reference sizes measured with a caliper.*Results Substantial blooming artifacts were observed on EID, resulting in larger stent struts and reduced lumen sizes (effective diameter underestimated by 40%). Overall image quality was substantially improved on PCD, with higher spatial resolution and reduced blooming artifacts, resulting in clearer delineation of stent struts. Effective lumen diameters were very accurate relative to reference (2% underestimation). CNN reduced image noise by 44% on PCD images without impacting lumen quantification (< 0.6% difference).*Conclusions The PCD HR mode improved in-stent lumen quantification for all seven stents as compared to EID images due to decreased blooming artifact. Implementation of CNN denoising algorithms to PCD data substantially improved image quality.*Clinical Relevance/Application Improved lumen visibility in stented coronary arteries will allow more accurate non-invasive assessment of in-stent restenosis, potentially avoiding unnecessary interventions.

RESULTS

Substantial blooming artifacts were observed on EID, resulting in larger stent struts and reduced lumen sizes (effective diameter underestimated by 40%). Overall image quality was substantially improved on PCD, with higher spatial resolution and reduced blooming artifacts, resulting in clearer delineation of stent struts. Effective lumen diameters were very accurate relative to reference (2% underestimation). CNN reduced image noise by 44% on PCD images without impacting lumen quantification (< 0.6% difference).

CLINICAL RELEVANCE/APPLICATION

Improved lumen visibility in stented coronary arteries will allow more accurate non-invasive assessment of in-stent restenosis, potentially avoiding unnecessary interventions.

SSCA04-6 Myocardial T2 Value Is The Imaging Biomarker Of Myocardial Involvement In Active COVID-19

Participants
Livia Marchitelli, MD, Rome, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Subclinical myocardial injury is not uncommon in COVID-19 and recognizes a complex multifactorial pathogenesis. We hypothesized that CMR with myocardial mapping techniques would allow non-invasive detection of myocardial structural damage in patients with active infection.*Methods and Materials In this retrospective observational cohort study, we enrolled 27 patients with active COVID-19. Clinical and laboratory characteristics, including high sensitivity troponin T (hs-cTnT), were collected within 48 hours prior to scan. Cooperative patients underwent a combined cardiothoracic-MRI protocol for the comprehensive assessment of cardiovascular structures, lung parenchyma and pulmonary arterial tree; unstable patients underwent a 25-minutes fast protocol to

rule out myocardial and to assess pulmonary involvement.Relationships between CMR parameters, clinical and laboratory findings were explored.Both uni and multivariate analyses (Chi-squared, t-test, Pearson correlation coefficient and regression model) were performed to evaluate most significant predictors of myocardial injury.*Results CMR T1 and T2 values were increased in 11/27 and 14/27 patients, respectively, ranging from 987 to 1210 ms for T1 values and 47 and 63 ms for T2.Left ventricle ejection fraction was impaired in 10/27 patients, ranging from 41% to 65%.Almost all patients were classified as "mild" according to Chinese CDC clinical scoring for SARS-CoV-2 infection.Pulmonary parenchyma consolidation was detected in 11/27, ground-glass opacity in 23/27, interlobular septal thickening in 9/27 and pleural effusion in 4/27 patients. DWI revealed active lung inflammation in 17/27 patients. No pulmonary embolism was identified at MRA sequence, avoiding the CT angiography.A significant correlation was found between T1 map, T2map and ECVmap alterations and increase HsTn (p<0,05). The regression model analysis also showed a significant relationship between T2 value and CRP, WBC and lymphocytes count and Hs-cTnT.*Conclusions CMR mapping predicts subclinical myocardial damage in COVID-19 active disease and correlates with WBC and lymphocytes count, CRP and HscTnT levels.Myocardial T2 appears to be the prevalent imaging biomarker in active COVID-19 patients and the best predictor of myocardial injury.Underlying pathological substrate likely includes a combination of tissue edema and myocarditis-like fibrosis/necrosis changes.*Clinical Relevance/Application Myocardial damage in active COVID-19 patients consists in heterogeneous patterns of injury ranging from acute myocarditis, to MINOCA, pericarditis, and CMR evidence of isolated edematous changes. The prompt recognition of pattern disease is pivotal to drive therapy and patient's management.

RESULTS

CMR T1 and T2 values were increased in 11/27 and 14/27 patients, respectively, ranging from 987 to 1210 ms for T1 values and 47 and 63 ms for T2.Left ventricle ejection fraction was impaired in 10/27 patients, ranging from 41% to 65%.Almost all patients were classified as "mild" according to Chinese CDC clinical scoring for SARS-CoV-2 infection.Pulmonary parenchyma consolidation was detected in 11/27, ground-glass opacity in 23/27, interlobular septal thickening in 9/27 and pleural effusion in 4/27 patients. DWI revealed active lung inflammation in 17/27 patients. No pulmonary embolism was identified at MRA sequence, avoiding the CT angiography.A significant correlation was found between T1 map, T2map and ECVmap alterations and increase HsTn (p<0,05). The regression model analysis also showed a significant relationship between T2 value and CRP, WBC and lymphocytes count and Hs-cTnT.

CLINICAL RELEVANCE/APPLICATION

Myocardial damage in active COVID-19 patients consists in heterogeneous patterns of injury ranging from acute myocarditis, to MINOCA, pericarditis, and CMR evidence of isolated edematous changes. The prompt recognition of pattern disease is pivotal to drive therapy and patient's management.

SSIN05-1   Computed Tomography-based Radiomic Feature Analysis In Non-Small Cell Lung Cancer For Patient Prognostic Stratification

Participants
Mitchell Chen, MD, London, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a radiomic prognostic vector using a comprehensive feature analysis of computed tomography (CT) scans from patients diagnosed with non-small cell lung cancer (NSCLC) for predicting patient prognosis.*Methods and Materials In this retrospective study, 292 patients (age: 68.6 ± 10.4, M:F = 172:120) with NSCLC diagnosed at our multicentre institution between 2014 - 2017 were included, all of whom had contrast-enhanced chest CTs demonstrating primary cancer at the time of diagnosis. Two radiologists double reviewed the scans, and performed semi-automated segmentation of the tumour, peritumoral penumbra, and a spherical parenchymal patch in the surrounding pulmonary lobe. The imaging data were pre-processed to ensure uniform voxel size and comprehensively analysed for radiomic features using in-house software. Unsupervised hierarchical clustering was performed for each histological subtype on the normalised radiomic profile. The dataset was 2:1 split into training and validation sets, balanced for patient's age, sex, and tumour histology. Least absolute shrinkage and selection operator (LASSO)-Cox regression feature selection was performed for deriving a composite radiomic prognostic vector (RPV), which was tested on the validation set following k-means clustering. A statistical significance level of 5% was used.*Results Unsupervised hierarchical clustering achieved significant difference in survival between the groups for each histology subtype (squamous cell: p = 0.0013, adenocarcinoma: p = 0.0080). RPV-based patient stratification showed significant difference in survival between the risk groups (p < 0.001). Univariate Cox regression showed significant predictive value of RPV for a more favourable survival in the higher risk group (Hazard ratio: 2.10, 95% confidence interval (CI): [1.51-3.04], p < 0.001). Significant Pearson's correlation was found between RPV and tumour T stage (0.29, 95% CI [0.088, 0.46], p = 0.005), pleural attachment (0.40, 95% CI [0.21, 0.55], p < 0.0001] and the presence of effusion (0.26, 95% CI [0.064, 0.44], p = 0.012). All quoted figures are those from the validation set.*Conclusions Radiomic feature analysis can be a useful tool for stratifying patient prognostic risk in NSCLC.*Clinical Relevance/Application Recent advances in image pattern recognition and data science have promoted a growing interest in using quantitative features in oncological imaging for predicting patient prognosis and tumour phenotype, thereby facilitating personalised cancer care. In this work, we present clear evidence supporting the clinical utility of CT-based radiomic analysis in NSCLC.

RESULTS

Unsupervised hierarchical clustering achieved significant difference in survival between the groups for each histology subtype (squamous cell: p = 0.0013, adenocarcinoma: p = 0.0080). RPV-based patient stratification showed significant difference in survival between the risk groups (p < 0.001). Univariate Cox regression showed significant predictive value of RPV for a more favourable survival in the higher risk group (Hazard ratio: 2.10, 95% confidence interval (CI): [1.51-3.04], p < 0.001). Significant Pearson's correlation was found between RPV and tumour T stage (0.29, 95% CI [0.088, 0.46], p = 0.005), pleural attachment (0.40, 95% CI [0.21, 0.55], p < 0.0001] and the presence of effusion (0.26, 95% CI [0.064, 0.44], p = 0.012). All quoted figures are those from the validation set.

CLINICAL RELEVANCE/APPLICATION

Recent advances in image pattern recognition and data science have promoted a growing interest in using quantitative features in oncological imaging for predicting patient prognosis and tumour phenotype, thereby facilitating personalised cancer care. In this work, we present clear evidence supporting the clinical utility of CT-based radiomic analysis in NSCLC.

SSIN05-2   Results Of The COVID-19 Lung CT Lesion Segmentation Challenge 2020

Participants
Marius Linguraru, DPhil, Washington, Dist. of Columbia (*Presenter*) Co-founder, PediaMetrix LLC

PURPOSE

Artificial intelligence (AI) for automatic detection and quantification of COVID-19 lesions in chest CT might play a role in the asymptomatic detection, monitoring, or management of the disease. We organized a public challenge to directly compare different AI algorithms and to establish a state-of-the-art benchmark for the detection task. We provide an overview and present the major outcomes of this challenge.*Methods and Materials The challenge was hosted on grand-challenge.org to control data access. Public images (n=295) from The Cancer Imaging Archive were expert annotated to include all CT lesions. In Phase 1, participants were provided access to the "seen" data source for training (n=199) and validation (n=50). Twenty-three cases from this "seen" data source were used for Phase 2 (testing) together with 23 cases from an "unseen" similar data source. The challenge started on Nov. 2, 2020. Phase 1 data were released and 1,096 teams registered. The 225 teams that completed Phase 1 were given access

to Phase 2 data on Dec. 8, 2020, which 98 teams from 29 countries on 6 continents completed. Teams disclosed the use of external training data or networks pre-trained on other lung pathology. The challengeR toolkit for statistical ranking was used to form a consensus of algorithmic performance on different metrics, i.e., Dice coefficient, normalized surfaced, and normalized absolute volume error.*Results The top performing AI algorithm achieved a mean Dice of 0.74±0.20 on the "seen" test data, and 0.60±0.26 on the "unseen" test data, utilizing external data in a semi-supervised fashion. All top 10 teams used a variation of the 2D/3D UNet. Participants took advantage of the open source packages like nnUNet and MONAI, which were adopted by 5 and 1 out of 10 teams, respectively.*Conclusions The AI teams were able to rapidly train well-performing AI algorithms towards automatic detection and quantification of COVID-19 lung lesions. However, robustness to unseen data decreased in the testing phase. This gap may indicate that larger and more diverse data may be beneficial for training, as well as generalizability, and inherent goal/task for any clinically-relevant AI tool.*Clinical Relevance/Application AI models may be rapidly trained by multiple teams for visualization and measurement of COVID-19 specific lesions, potentially providing data at key clinical time points in the disease process towards timely and patient-specific medical countermeasures, such as isolation of asymptomatic or pre-symptomatic patients undergoing CT, or response to therapy. As more and more AI applications arise in the biomedical space, it is essential to be able to validate and compare the functionality of these applications, of which a Grand-Challenge-like competition can prove useful.

RESULTS

The top performing AI algorithm achieved a mean Dice of 0.74±0.20 on the "seen" test data, and 0.60±0.26 on the "unseen" test data, utilizing external data in a semi-supervised fashion. All top 10 teams used a variation of the 2D/3D UNet. Participants took advantage of the open source packages like nnUNet and MONAI, which were adopted by 5 and 1 out of 10 teams, respectively.

CLINICAL RELEVANCE/APPLICATION

AI models may be rapidly trained by multiple teams for visualization and measurement of COVID-19 specific lesions, potentially providing data at key clinical time points in the disease process towards timely and patient-specific medical countermeasures, such as isolation of asymptomatic or pre-symptomatic patients undergoing CT, or response to therapy. As more and more AI applications arise in the biomedical space, it is essential to be able to validate and compare the functionality of these applications, of which a Grand-Challenge-like competition can prove useful.

SSIN05-3   Automated And Comprehensive Quantification Of Airway Wall Thickness In A Large Patient Collective As CT Imaging Biomarker Of Chronic Obstructive Pulmonary Disease

Participants
Thomas Weikert, MD, Basel, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

Airway wall thickening is a consequence of inflammatory disease of the airways that is usually only qualitatively described in radiology reports. The purpose of this study is to automatically quantify airway wall thickness throughout the lungs with the help of Artificial Intelligence and assess its diagnostic potential by the example of Chronic Obstructive Pulmonary Disease (COPD).*Methods and Materials This retrospective, single-center study included a consecutive series of unenhanced, high-resolution chest CTs. Inclusion criteria were the mentioning of an explicit COPD GOLD stage in the written radiology report (time period: March, 2013 - April, 2021). A control group of HRCTs with completely unremarkable lungs (identified using the written radiology report and visually confirmed by a radiology resident; PGY-5). The DICOM images of all cases (slice thickness: 1mm) were processed by a validated AI algorithm pipeline consisting of (1) a 3D UNet for segmentation of the bronchial tree (B) extraction of image patches perpendicular to the centerlines of the bronchi (every 1 mm), and (C) a 2D UNet for segmentation of the bronchial walls. Wall thickness was calculated locally across the full bronchial tree and then aggregated per bronchial generation. For evaluation, the average of generations 4 to 9 was calculated per patient. Differences between control vs. COPD and between GOLD stages were analyzed using two-sample t-tests, hypothesizing higher values in the COPD group.*Results A total of 756 chest CTs were identified and processed. Of those, 708 patients had been diagnosed with COPD (GOLD Stage 4: 185). The control group comprised 48 cases. Mean wall thickness differed statistically significantly between the control group and COPD patients. [1.67 mm (SD: 0.13) vs. 1.83 mm (SD: 0.13); $p < 0.001$]. Of note, the mean wall thickness in GOLD group 4 was statistically significantly higher compared to groups GOLD 1-3 ($p < 0.001$).*Conclusions Whereas increased wall thickness as sign of chronic inflammation in COPD is known, the approach presented in this study allows to provide evidence from a large patient collective due to its automated nature. Bronchial walls were slightly, but statistically significantly thicker in patients with COPD and in higher GOLD stages.*Clinical Relevance/Application Quantitative measurements considering the full bronchial tree instead of qualitative description could enhance radiology reports and allow for precise monitoring of disease progression. Running in the background, the algorithm could also point radiologist to cases with imaging biomarker values suspicious for inflammatory disease.

RESULTS

A total of 756 chest CTs were identified and processed. Of those, 708 patients had been diagnosed with COPD (GOLD Stage 4: 185). The control group comprised 48 cases. Mean wall thickness differed statistically significantly between the control group and COPD patients. [1.67 mm (SD: 0.13) vs. 1.83 mm (SD: 0.13); $p < 0.001$]. Of note, the mean wall thickness in GOLD group 4 was statistically significantly higher compared to groups GOLD 1-3 ($p < 0.001$).

CLINICAL RELEVANCE/APPLICATION

Quantitative measurements considering the full bronchial tree instead of qualitative description could enhance radiology reports and allow for precise monitoring of disease progression. Running in the background, the algorithm could also point radiologist to cases with imaging biomarker values suspicious for inflammatory disease.

SSIN05-4   Racoon: Building A Nationwide Radiological Infrastructure For Collaborative Imaging Research On COVID-19

Participants
Tobias Penzkofer, MD, Berlin, Germany (*Presenter*) Researcher, Aprea Therapeutics AB;Researcher, Astellas Group;Researcher, AstraZeneca PLC;Researcher, Celgene Corporation ;Researcher, Genmab A/S;Researcher, Incyte Corporation;Researcher, Lion Biotechnologies, Inc;Researcher, Takeda Pharmaceutical Company Limited;Researcher, Eisai Co, Ltd;Researcher, Merck & Co, Inc;Researcher, GlaxoSmithKline plc;Researcher, F. Hoffmann-La Roche Ltd;

PURPOSE

To build a nationwide infrastructure as an end-to-end solution for radiological research, AI training and biomarker development during the COVID-19 pandemic.*Methods and Materials A collaborative initiative was created following a public funding initiative by

the Federal Ministry of Education and Research to fight the current COVID-19 pandemic and build pandemic preparedness measures. The imaging platform RACOON (Radiology COOperative Network) was proposed to provide image based diagnosis, management and follow-up research on a nation-wide scale.*Results All 36 university hospitals in Germany participate in this network project. Primary goals were (a) to build a unique hybrid network infrastructure with both, distributed hardware nodes at each university hospital for federated analysis and a cloud based central environment (b) to develop dedicated toolsets for structured reporting and annotation of image datasets and AI training (c) to define a common data-model of CT reporting and aggregated clinical data (d) to enable research use cases from the entire academic radiological community concerning the analysis of COVID-19. A cohort of 14,400 chest imaging datasets are collected and reported according to the RACOON data model. Additionally, segmentations of 2880 of the datasets are performed for AI research. Over 30 individual research topics ranging from screening to prognostic models were defined and are being collaboratively executed within the project.*Conclusions Sparked by the extraordinary challenge of a global pandemic we were able to create a unique collaborative infrastructure which, to our knowledge, has never been available with this functionality or on this scale. RACOON allows oligo- and multicentric imaging research across the entire academic radiological community nationwide while largely reducing the organizational overhead for federated AI training.*Clinical Relevance/Application - A radiological network was built that enables science ready data acquisition on a nation-wide level- Dedicated toolsets ensure data quality and foster image analysis research and AI development

RESULTS

SSIN05-6   Predicting Patient Demographic Information From Chest Radiographs With Deep Learning

Participants
Jason Adleberg, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning models are increasingly playing a role in making important medical decisions within radiology in the United States. Some decisions are especially high-stakes, such as whether a patient is experiencing an acute hemorrhagic stroke. However, many deep learning models are trained on medical image datasets that poorly represent the diversity of the American population. In turn, models may not perform well when making medical decisions for underrepresented populations. In this study, we create and evaluate deep learning models to classify the biological sex, age decade, ethnicity, and insurance status of an individual patient from a given chest radiograph. This technology can be used to ensure the creation of equitable medical imaging datasets and deep learning models. Furthermore, it can illuminate certain anatomical regions that may differ in different groups of patients.*Methods and Materials Deep Learning models were trained and tested on subsets from a pool of 63,663 posteroanterior (PA) radiographs in the MIMIC-CXR dataset. When possible, a separate dataset, CheXpert, containing 29,452 PA radiographs was used as a validation dataset. Four classification models were created: biological sex, age decade, ethnicity, and insurance status. EfficientNet-B4 architecture was used, along with extra layers for Gradient-weighted Class Activation Mapping (Grad-CAM) analysis. The EfficientNet-B4 was initialized with ImageNet pretrained weights. Training was done on the Google Colab Pro platform. GPU hardware varied per training session but typically was either an Nvidia K80 or an Nvidia P100.*Results On held-out test data from the MIMIC-CXR dataset, macro-averaged ROC scores were as follows: 0.999 for biological sex (2 labels), 0.917 for age decade (7 labels), 0.907 for ethnicity (4 labels), and 0.709 for insurance status (3 labels). On the CheXpert validation dataset, ROC scores were 0.994 for biological sex and 0.871 for age decade.*Conclusions Deep learning models can predict the biological sex, age, ethnicity, and insurance status of a patient from their chest radiograph. Visualization techniques are useful to ensure models function as intended, and to demonstrate anatomical regions of interest. The Google Colab notebooks used in their creation are open-source and will be made available at the time of publication.*Clinical Relevance/Application Deep learning models can predict the biological sex, age, ethnicity, and insurance status of a patient from their chest radiograph.

RESULTS

On held-out test data from the MIMIC-CXR dataset, macro-averaged ROC scores were as follows: 0.999 for biological sex (2 labels), 0.917 for age decade (7 labels), 0.907 for ethnicity (4 labels), and 0.709 for insurance status (3 labels). On the CheXpert validation dataset, ROC scores were 0.994 for biological sex and 0.871 for age decade.

CLINICAL RELEVANCE/APPLICATION

Deep learning models can predict the biological sex, age, ethnicity, and insurance status of a patient from their chest radiograph.

SSPH08-1 Noise And Streak Artifacts Reduction In Cone-beam Computed Tomography Using Wavelet Decomposition

Participants
Mohamed Eldib, Aurora, Colorado (*Presenter*) Nothing to Disclose

PURPOSE

We have been developing a 2D anti-scatter grid (2D ASG) to improve the quality of cone-beam computed tomography (CBCT) in image-guided radiation therapy. While 2D ASG significantly improves CT number accuracy, it also introduces fixed-pattern noise in projections and artifacts in CBCT images. In this work, we introduce a method to reduce both stochastic noise and streak artifacts, and artifacts induced by 2D ASG.*Methods and Materials A noise reduction filter was developed using wavelet decomposition, which uses a bank of wavelet filters that sequentially removes high-frequency signal in projections and preserves low-frequency signal containing the object information. Daubechies wavelets dB8 at level 4 were used with Bayes denoising. To preserve spatial resolution after wavelet filtering, wavelet denoised CBCT image was subtracted from the original CBCT image. Subsequently, the difference image was smoothed using a Gaussian filter, and smoothed difference image was added to the wavelet denoised CT image. To test the method, imaging experiments were performed using a clinical linac-mounted CBCT system. CBCT projections of phantoms were acquired using a 2D ASG with a grid ratio of 12 and a grid pitch of 1.2 mm. Images were reconstructed offline, using a modified FDK method.*Results With the proposed method, both stochastic noise and 2D ASG induced artifacts in CBCT images were significantly reduced. More than a factor of two improvements in signal-to-noise ratio and contrast-to-noise ratio were observed, while the spatial resolution was preserved.*Conclusions The proposed method successfully reduced noise and noise-induced streak artifacts without compromising spatial resolution. Since our method is frequency domain-based and does not involve forward/backward projection, it is computationally fast. Finally, our work shows that wavelet-based denoising may be a viable choice to reduce 2D-ASG induced image artifacts.*Clinical Relevance/Application We are developing 2D ASGs to improve the quality of CBCT images used in image-guided radiation therapy. This work proposes a novel noise reduction method when 2D ASGs are used during CBCT scans.

RESULTS

With the proposed method, both stochastic noise and 2D ASG induced artifacts in CBCT images were significantly reduced. More than a factor of two improvements in signal-to-noise ratio and contrast-to-noise ratio were observed, while the spatial resolution was preserved.

CLINICAL RELEVANCE/APPLICATION

We are developing 2D ASGs to improve the quality of CBCT images used in image-guided radiation therapy. This work proposes a novel noise reduction method when 2D ASGs are used during CBCT scans.

SSPH08-2 Improving Intraoperative Visualization Of Arterial Branching Pattern Using A High Spatial Resolution C-arm Photon Counting Detector CT System

Participants
Ke Li, PhD, Madison, Wisconsin (*Presenter*) Research Consultant, Pulmera Inc.

PURPOSE

During transarterial embolization procedures, it is crucial to provide treating physicians a clear visualization of complex arterial branching patterns. The purpose of this work was to investigate the potential application of a C-arm photon counting detector CT (PCD-CT) system for improving the visualization of arterial branching patterns during interventional procedures.*Methods and Materials The developed C-arm PCD-CT system has a switchable add-on CdTe PCD to the conventional flat panel detector (FPD)-based imaging platform. Cone beam CT acquisitions are performed in a binned mode to achieve the required readout frame rate. In comparison, the PCD has a pixel size of 100 um and no binning is required to achieve up to 100 frames/s data acquisitions and thus can potentially image small vessels with improved visualization. To demonstrate this potential, an anthropomorphic phantom containing models of iodinated cerebral arteries, with its smallest branches down to 0.5 mm, was scanned by both the PCD-CT and FPD-CBCT with matched narrow beam collimation (2.5 cm). A low dose protocol (7.1 mGy) with a short data acquisition time (7 s) was used. Reconstruction pixel size (0.47 mm) and slice thickness (0.85 mm) were matched between PCD and FPD scans. MIP images of vascular tree were generated over a range of 10 mm for performance evaluations.*Results 1) Distal vessels completely or partial missed on FPD-CBCT images were clearly visualized on C-arm PCD-CT images. 2) When all distal and smaller artery branches

(0.5 mm) are considered, the CNR was 6.9 [95% CI: 5.8, 8.0] in PCD-CT and 2.9 [95% CI: 2.1, 3.7] in FPD-CBCT. 3) The limiting spatial resolution of PCD-CT was measured to be 21 lp/cm compared with 12 lp/cm for FPD-CBCT.*Conclusions C-arm PCD-CT offers potential advantages in improving the visualization of arterial branching pattern during interventional procedures.*Clinical Relevance/Application Improved visualization of small arterial branching patterns in the interventional suite will significantly facilitate the treatment planning in endovascular interventions.

RESULTS

1) Distal vessels completely or partial missed on FPD-CBCT images were clearly visualized on C-arm PCD-CT images. 2) When all distal and smaller artery branches (0.5 mm) are considered, the CNR was 6.9 [95% CI: 5.8, 8.0] in PCD-CT and 2.9 [95% CI: 2.1, 3.7] in FPD-CBCT. 3) The limiting spatial resolution of PCD-CT was measured to be 21 lp/cm compared with 12 lp/cm for FPD-CBCT.

CLINICAL RELEVANCE/APPLICATION

Improved visualization of small arterial branching patterns in the interventional suite will significantly facilitate the treatment planning in endovascular interventions.

SSPH08-3 Correction Of Spectral Inconsistency-induced Image Artifacts In C-arm Photon Counting CT

Participants
Kevin J. Treb, Madison, Wisconsin (*Presenter*) Nothing to Disclose

PURPOSE

Recently, a photon counting detector CT (PCD-CT) prototype system was developed using a C-arm gantry. Since the PCD used in this system consists of 20 individual CdTe panels, variations in the detector responses across these panels lead to low-frequency concentric artifacts in PCD-CT images. The purpose of this study was to develop a method to correct these artifacts.*Methods and Materials The underlying principle of the method is to decompose the measured data into a combination of two parts: a part that is intrinsic to the image object and the other part that is extrinsic, dependent on factors such as the panel response function and x-ray spectrum. To achieve this objective, materials with known compositions and thicknesses (i.e., acrylic and Al plates) were imaged by the PCD. The measured data were used to fit a target function that aims to perform the aforementioned decomposition. After the decomposition function is determined, the method was then used to correct data by isolating the image object dependent component, and the final image is reconstructed using the corrected data. The method was validated using an anthropomorphic head phantom with iodinated vessels and a Gammex dual-energy CT characterization phantom with both iodine and calcium inserts. The method was compared with a conventional Fourier-based ring artifact correction method in terms of image nonuniformity index (NUI), CNR, and spatial resolution.*Results Compared with the conventional ring correction method, the proposed method successfully removed both beam hardening and concentric artifacts in the individual energy bin images and material basis images. The NUI reduced from 30 to 8 HU (low-energy bin) or from 37 to 3 HU (high-energy bin) following correction. The CNR of the material inserts was improved by at least a factor of 2 by the proposed method without any loss in spatial resolution. The quantification bias of the inserts was reduced by at least 35% to be within 0.7 mg/ml.*Conclusions With the proposed correction method, high-quality and artifact-free C-arm PCD-CT images can be generated to provide improved imaging guidance for interventional procedures.*Clinical Relevance/Application This work provides a new pathway to generate high-quality spectral CT images in the interventional room to help physicians perform immediate post-treatment assessments and monitor for hemorrhages.

RESULTS

Compared with the conventional ring correction method, the proposed method successfully removed both beam hardening and concentric artifacts in the individual energy bin images and material basis images. The NUI reduced from 30 to 8 HU (low-energy bin) or from 37 to 3 HU (high-energy bin) following correction. The CNR of the material inserts was improved by at least a factor of 2 by the proposed method without any loss in spatial resolution. The quantification bias of the inserts was reduced by at least 35% to be within 0.7 mg/ml.

CLINICAL RELEVANCE/APPLICATION

This work provides a new pathway to generate high-quality spectral CT images in the interventional room to help physicians perform immediate post-treatment assessments and monitor for hemorrhages.

SSPH08-4 Performance Evaluation Of An IGZO-Based Flat-Panel Detector In 2D Fluoroscopy And 3D Cone-Beam CT

Participants
Niral Sheth, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Emerging flat-panel detectors (FPDs) based on high electron mobility oxide TFTs offer improvements in electronic noise, frame rate, and fill factor compared to conventional FPDs with readout based on a-Si:H TFTs. We report the imaging performance for both 2D fluoroscopy and 3D cone-beam CT (CBCT) of a new indium gallium zinc oxide (IGZO) TFT detector (3131Z, Varex, Salt Lake City UT).*Methods and Materials The IGZO FPD features oxide TFTs combined with a-Si:H photodiodes and a high-resolution CsI scintillator. The detector was implemented on an x-ray imaging bench in comparison to a conventional a-Si:H FPD (4030CB, Varex, Salt Lake City UT) with system geometry emulating intraoperative CBCT (O-armTM imaging system, Medtronic, Littleton MA). 2D imaging performance was characterized in terms of electronic readout noise, gain, linearity, lag, spatial resolution (MTF), image noise (NPS), and detective quantum efficiency (DQE). CBCT performance for the IGZO system was evaluated for the first time in terms of 3D MTF and NEQ, soft-tissue contrast-to-noise ratio (CNR), and visual image quality in anthropomorphic head and body phantoms across a range of imaging protocols and dose levels.*Results The IGZO detector demonstrated ~2.5x lower electronic noise than the a-Si:H system and ~27% increase in 2D DQE (at 1 mm-1) at matched pixel size and dose (EAK / frame < 1 μGy). Tenth-frame image lag was reduced by ~26%, indicative of improved electron mobility. In CBCT imaging, the IGZO FPD exhibited better uniformity (reduced ring artifacts) attributable to improved electronic noise characteristics and 3D MTF consistent with high-resolution bone imaging applications. The improved 3D NEQ and CNR for the IGZO system (e.g., CNR = 6.1 for a 50 HU contrast brain lesion at 4.7 mGy) benefit soft-tissue CBCT imaging.*Conclusions The FPD based on oxide TFTs demonstrated enhancements in electronic noise, readout rate, and uniformity that improve 2D and 3D imaging performance compared to conventional FPD based on a-Si:H TFTs. This technology appears to maintain the advantages of maturity and cost of a-Si:H sensors while advancing the performance of the underlying active matrix TFT readout.*Clinical Relevance/Application Flat Panel Detectors with oxide TFTs could form a new base technology with higher performance for digital x-ray detectors in fluoroscopy, radiography, and CBCT.

RESULTS

The IGZO detector demonstrated ~2.5x lower electronic noise than the a-Si:H system and ~27% increase in 2D DQE (at 1 mm-1) at matched pixel size and dose (EAK / frame < 1 µGy). Tenth-frame image lag was reduced by ~26%, indicative of improved electron mobility. In CBCT imaging, the IGZO FPD exhibited better uniformity (reduced ring artifacts) attributable to improved electronic noise characteristics and 3D MTF consistent with high-resolution bone imaging applications. The improved 3D NEQ and CNR for the IGZO system (e.g., CNR = 6.1 for a 50 HU contrast brain lesion at 4.7 mGy) benefit soft-tissue CBCT imaging.

CLINICAL RELEVANCE/APPLICATION

Flat Panel Detectors with oxide TFTs could form a new base technology with higher performance for digital x-ray detectors in fluoroscopy, radiography, and CBCT.

SSPH08-5   Feasibility Of Dual Energy Cone Beam Computed Tomography In Human Torso Sized Objects

Participants
Cem Altunbas, PhD, Aurora, Colorado (*Presenter*) Founder, M2 Technologies LLC

PURPOSE

While application of dual energy (DE) imaging principles in CBCT is an active area of research, utility of DE is currently limited to small objects, such as extremities or small test phantoms. In this work, we explored the feasibility of DE material decomposition for human torso sized objects, via implementing robust scatter mitigation methods in CBCT.*Methods and Materials High intensity of scatter is the primary cause of degraded CT number accuracy in CBCT. To achieve sufficient quantitative accuracy for DE processing, a novel 3D-printed antiscatter grid and a novel projection-domain based scatter correction algorithm were implemented in a flat panel detector based CBCT. Iodine vials (concentrations: 2 - 40 mg/ml) were placed in small (head equivalent), and large (pelvis equivalent) phantoms. CBCT and 16-slice multidetector CT (MDCT) scans of phantoms were obtained using sequential scans at 90 and 140 kVp. Small phantom images were used for calibration, whereas large phantom images were used for evaluating iodine mapping accuracy. CBCT and MDCT images were decomposed into iodine and water basis materials using an image-domain based material decomposition method.*Results At 90 and 140 kVp, CT numbers of iodine vials showed a high degree of linear correlation both in CBCT and MDCT images. Qualitatively, DE CBCT material decomposition in small and large phantoms yielded similar results, implying that DE material decomposition is viable in pelvis sized phantoms. Quantitative evaluations supported our observations; when compared to iodine concentration measurements in the small phantom, iodine concentration errors were 0.86±0.39 mg/ml and 0.32±0.31 mg/ml for CBCT and MDCT images, respectively, in the large phantom.*Conclusions We demonstrated that iodine mapping in DE CBCT can be achieved in human torso sized phantoms when robust scatter correction strategies are implemented. In our experiments, MDCT provided slightly better performance than CBCT. We attribute this discrepancy to other sources of image quality degradation in the CBCT system, such as effects of image lag, nonlinear response at low exposure levels, and relatively higher image noise.*Clinical Relevance/Application This work demonstrates the efficacy of iodine mapping in human torso sized phantoms using dual energy CBCT imaging.

RESULTS

At 90 and 140 kVp, CT numbers of iodine vials showed a high degree of linear correlation both in CBCT and MDCT images. Qualitatively, DE CBCT material decomposition in small and large phantoms yielded similar results, implying that DE material decomposition is viable in pelvis sized phantoms. Quantitative evaluations supported our observations; when compared to iodine concentration measurements in the small phantom, iodine concentration errors were 0.86±0.39 mg/ml and 0.32±0.31 mg/ml for CBCT and MDCT images, respectively, in the large phantom.

CLINICAL RELEVANCE/APPLICATION

This work demonstrates the efficacy of iodine mapping in human torso sized phantoms using dual energy CBCT imaging.

SSPH08-6   Performance Characterization Of A Prototype Dual-layer Cone Beam Computed Tomography System

Participants
Fredrik Stahl, MD, Stockholm, Sweden (*Presenter*) Nothing to Disclose

PURPOSE

Conventional cone-beam CT (CBCT) provides limited discrimination between low-contrast tissues. Furthermore it is limited to single-energy acquisitions. A dual-energy CBCT system could be used to separate photon energy with the potential to increase visibility of clinically relevant features and acquire additional information relevant in a multitude of clinical imaging settings. In this work, the performance of a novel dual-layer dual-energy CBCT c-arm system is characterized for the first time.*Methods and Materials A prototype dual-layer detector was fitted into a commercial interventional c-arm CBCT system. The modulation transfer function (MTF) of the prototype CBCT was compared to that of a commercial CBCT. Noise and uniformity characteristics were evaluated using a cylindrical water phantom. Effective atomic numbers and electron densities were estimated in clinically relevant tissue substitutes. Iodine quantification was performed and virtual non-contrast (VNC) images were evaluated. Lastly, contrast-to-noise ratios (CNR) and CT number accuracy were estimated.*Results The prototype and commercial CBCT showed similar spatial resolution, with a mean 10% MTF of 5.98 and 6.28 cycles/cm, respectively. The lowest noise was seen in the 80 keV virtual monoenergetic (VM) images (7.4 HU) and the most uniform images were seen at VM 60 keV (4.7 HU) or VM 80 keV (2.0 HU), depending on the uniformity measure used. The mean accuracy in effective atomic number and electron density were 98.2% and 100.3%, respectively. Iodine quantification images showed a mean difference of -0.1 mg/ml compared to the true iodine concentration. For VNC images, all water-containing iodine substitutes measured a mean CT number of 2.6 HU, blood substitutes containing iodine averaged 43.2 HU, whereas the blood-only substitute measured 44.8 HU. A noise-suppressed dataset showed a CNR peak at VM 40 keV and low at VM 120 keV. In the same dataset without noise suppression applied, a peak in CNR was obtained at VM 70 keV. The estimated CT numbers of clinically relevant objects were very close to the calculated CT number.*Conclusions Spatial resolution and noise were comparable with a commercially available c-arm CBCT system, while offering dual-energy capability. Iodine quantifications, effective atomic numbers and electron densities were in good agreement with expected values, indicating that the system can be used to reliably evaluate the material composition of clinically relevant tissues. The virtual non-contrast and monoenergetic images indicate a consistent ability to separate clinically relevant tissues.*Clinical Relevance/Application The results presented indicate that the system could find utility in diagnostic, interventional and radiotherapy planning settings.

RESULTS

The prototype and commercial CBCT showed similar spatial resolution, with a mean 10% MTF of 5.98 and 6.28 cycles/cm

The prototype and commercial CBCT showed similar spatial resolution, with a mean 10% MTF of 5.98 and 6.28 cycles/cm, respectively. The lowest noise was seen in the 80 keV virtual monoenergetic (VM) images (7.4 HU) and the most uniform images were seen at VM 60 keV (4.7 HU) or VM 80 keV (2.0 HU), depending on the uniformity measure used. The mean accuracy in effective atomic number and electron density were 98.2% and 100.3%, respectively. Iodine quantification images showed a mean difference of -0.1 mg/ml compared to the true iodine concentration. For VNC images, all water-containing iodine substitutes measured a mean CT number of 2.6 HU, blood substitutes containing iodine averaged 43.2 HU, whereas the blood-only substitute measured 44.8 HU. A noise-suppressed dataset showed a CNR peak at VM 40 keV and low at VM 120 keV. In the same dataset without noise suppression applied, a peak in CNR was obtained at VM 70 keV. The estimated CT numbers of clinically relevant objects were very close to the calculated CT number.

CLINICAL RELEVANCE/APPLICATION

The results presented indicate that the system could find utility in diagnostic, interventional and radiotherapy planning settings.

SSBR04-1   Sentinel Lymph Node Identification In Breast Cancer Patients Using Lymphosonography

Participants

Priscilla Machado, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the efficacy of contrast-enhanced ultrasound (CEUS) lymphosonography in the identification of sentinel lymph nodes (SLNs) in patients with breast cancer undergoing surgical excision.*Methods and Materials To date 66 women scheduled for breast cancer surgery with SLN excision were enrolled in this ongoing, IRB-approved study. Subjects underwent percutaneous Sonazoid (GE Healthcare, Oslo, Norway) injections around the tumor area at the 12,-3,-6,-and 9 o'clock positions for a total of 1.0 ml. Lymphosonography was done using Cadence Pulse Sequencing on an S3000 HELX scanner (Siemens Healthineers, Mountain View, CA) with a 9L4 linear probe. Subjects received blue dye and radioactive tracer as part of their standard of care. After surgical excision, the ex-vivo SLNs specimen were scanned using color Doppler to confirm the uptake of Sonazoid and sent for pathology. The excised SLNs were classified as positive or negative for presence of blue dye, radioactive tracer and Sonazoid. The results were compared between methods and pathology findings.*Results One-hundred and ninety-five SLNs were surgically excised from 66 subjects, 125 were positive for blue dye, 175 were positive for the radioactive tracer and 166 were positive for Sonazoid. Comparison with the reference standard (blue dye) showed that the radioactive tracer had an accuracy of 67%, while lymphosonography achieved an accuracy of 73% (p=0.56). When the comparison was done with radioactive tracer as the reference standard, the blue dye injections had an accuracy of 66%, while lymphosonography achieved an accuracy of 80% (p<0.001). Of the 195 SLNs excised, 26 were determined to be malignant by pathology; amongst them 13 were positive for blue dye, 19 were positive for radioactive tracer and 26 were positive for Sonazoid, which translated into an accuracy of 50% for blue dye, 73% for radioactive tracer and 100% for lymphosonography (p<0.008).*Conclusions Lymphosonography achieved better accuracy compared with radioactive tracer and blue dye for identifying SLNs in breast cancer patients. All the 26 SLNs positive for malignancy were identified by lymphosonography.*Clinical Relevance/Application Lymphosonography is an ultrasound modality that uses ultrasound contrast agents to identify SLNs, which is an important aspect of predicting outcomes for patients with breast cancer.

RESULTS

One-hundred and ninety-five SLNs were surgically excised from 66 subjects, 125 were positive for blue dye, 175 were positive for the radioactive tracer and 166 were positive for Sonazoid. Comparison with the reference standard (blue dye) showed that the radioactive tracer had an accuracy of 67%, while lymphosonography achieved an accuracy of 73% (p=0.56). When the comparison was done with radioactive tracer as the reference standard, the blue dye injections had an accuracy of 66%, while lymphosonography achieved an accuracy of 80% (p<0.001). Of the 195 SLNs excised, 26 were determined to be malignant by pathology; amongst them 13 were positive for blue dye, 19 were positive for radioactive tracer and 26 were positive for Sonazoid, which translated into an accuracy of 50% for blue dye, 73% for radioactive tracer and 100% for lymphosonography (p<0.008).

CLINICAL RELEVANCE/APPLICATION

Lymphosonography is an ultrasound modality that uses ultrasound contrast agents to identify SLNs, which is an important aspect of predicting outcomes for patients with breast cancer.

SSBR04-2   Percutaneous Sonazoid Enhanced Ultrasonography Combined With In Vitro Verification For Detection And Characterization Of Sentinel Lymph Nodes In Early Breast Cancer

Participants

Yan Sun, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

To assess the efficacy of percutaneous Sonazoid-enhanced ultrasound and in vitro verification for identification sentinel lymph nodes (SLNs) and diagnosis of metastatic SLNs in patients with early breast cancer(BC).*Methods and Materials 115 patients with early BC were enrolled finally. After the induction of general anesthesia, 0.4 ml of Sonazoid (SNZ), a new second-generation tissue specific ultrasound contrast agent (UCA), mixed with 0.6ml of methylene blue, was injected intradermally. The lymphatic vessels and connected SLNs were immediately observed and marked. After being resected, these SLNs were soaked in saline water and examined still in the mode of contrast enhanced ultrasound (CEUS) in vitro, This procedure could ensure that all the enhanced nodes had been removed as much as possible. The numbers of SLNs detected by UCA and blue dye were recorded. The enhancement patterns of SLNs were compared with the final pathological results.*Results SLNs detection rate by SNZ-CEUS was 94.78%. CEUS identified a median of 1.5 nodes, while blue dye identified a median of 1.84 nodes per case(P<0.001). When homogeneous high perfusion, complete annular high perfusion and low perfusion were considered negative, the diagnostic sensitivity and specificity of CEUS for SLN were 90.91% and 84.50%, and the negative predictive value was 97.32%. The FNR was 9.09%. The

diagnostic performance of CEUS for SLN is better than that of gray scale ultrasonography.*Conclusions Percutaneous SNZ-enhanced ultrasonography combined with in vitro verification is a feasible and reliable method for SLNs identification intraoperatively. Enhancement patterns can be helpful in determining the status of SLNs.*Clinical Relevance/Application (1)CEUS with percutaneous injection of Sonazoid can successfully and accurately identify and character SLNs in early breast cancer patients. (2) Sonazoid, with high affinity with reticuloendothelial cells, increases the imaging time of SLNs and facilitates biopsy intraoperatively better than Sonovue as a lymphatic tracer.

RESULTS

SLNs detection rate by SNZ-CEUS was 94.78%. CEUS identified a median of 1.5 nodes, while blue dye identified a median of 1.84 nodes per case(P<0.001). When homogeneous high perfusion, complete annular high perfusion and low perfusion were considered negative, the diagnostic sensitivity and specificity of CEUS for SLN were 90.91% and 84.50%, and the negative predictive value was 97.32%. The FNR was 9.09%. The diagnostic performance of CEUS for SLN is better than that of gray scale ultrasonography.

CLINICAL RELEVANCE/APPLICATION

(1)CEUS with percutaneous injection of Sonazoid can successfully and accurately identify and character SLNs in early breast cancer patients. (2) Sonazoid, with high affinity with reticuloendothelial cells, increases the imaging time of SLNs and facilitates biopsy intraoperatively better than Sonovue as a lymphatic tracer.

SSBR04-4   3D Harmonic And Subharmonic US For Characterizing Breast Lesions: A Multi-center Clinical Trial

Participants
Flemming Forsberg, PhD, Philadelphia, Pennsylvania (*Presenter*) Research Grant, Canon Medical Systems Corporation;Research support, Canon Medical Systems Corporation;Research support, General Electric Company;Speaker, General Electric Company;Research support, Siemens AG;Research Grant, Butterfly Network, Inc;Research support, Lantheus Medical Imaging, Inc;Research support, Bracco Group

PURPOSE

Breast cancer is the second most common cancer in the world and the most frequent type of cancer among women (30% of all cancers). This multi-center study assessed the ability of contrast-enhanced, nonlinear 3D US imaging to characterize previously indeterminate breast lesions using quantitative parameters and clinical assessments.*Methods and Materials In total 236 women with biopsy-proven breast lesions were enrolled in this prospective, FDA approved study (IND: 112,241). Following conventional US and power Doppler imaging (PDI), an US contrast agent (Definity, Lantheus Medical Imaging, N Billerica, MA) was administrated IV. Contrast-enhanced 3D harmonic imaging (HI; transmitting/receiving at 5.0/10.0 MHz) as well as 3D subharmonic imaging (SHI; transmitting/receiving at 5.8/2.9 MHz) were performed using a modified Logiq 9 scanner (GE Healthcare, Waukesha, WI) with a 4D10L probe. Five radiologists blinded to other results independently scored the 4 randomized US modes using a 7-point BIRADS scale from negative to highly suggestive of malignancy as well as lesion vascularity and diagnostic confidence. Quantitative parametric volumes were constructed from time-intensity curves for vascular heterogeneity, perfusion and area under the curve. Diagnostic accuracy for US and mammography were determined relative to pathology using ROC and reverse, step-wise logistical regression analyses. The ? statistic was calculated for inter-reader agreement.*Results Of the 236 cases, 219 were successfully scanned and biopsies indicated 164 (75%) benign and 55 (25%) malignant lesions. 3D HI showed flow in 8 lesions, whereas 3D SHI visualized flow in 83 lesions. SHI depicted more anastomoses and vascularity than HI (p<0.021), but there were no differences by pathology (p>0.27). US modes achieved accuracies from 79-85%, which was significantly better than mammography (72%; p<0.03). SHI increased diagnostic confidence by 3-6% (p<0.01), but inter-reader agreements were medium to low (?<0.52). The best logistical regression model achieved a 96% accuracy by combining clinical reads and quantitative 3D SHI parameters.*Conclusions 3D SHI is better at detecting contrast flow in vascular breast masses than 3D HI. Characterization of indeterminate breast lesions with quantitative 3D SHI parameters and clinical assessments improves diagnostic accuracy.*Clinical Relevance/Application Combining quantitative 3D SHI parameters and radiologists' assessments increase the accuracy and confidence for characterizing indeterminate breast lesions.

RESULTS

Of the 236 cases, 219 were successfully scanned and biopsies indicated 164 (75%) benign and 55 (25%) malignant lesions. 3D HI showed flow in 8 lesions, whereas 3D SHI visualized flow in 83 lesions. SHI depicted more anastomoses and vascularity than HI (p<0.021), but there were no differences by pathology (p>0.27). US modes achieved accuracies from 79-85%, which was significantly better than mammography (72%; p<0.03). SHI increased diagnostic confidence by 3-6% (p<0.01), but inter-reader agreements were medium to low (?<0.52). The best logistical regression model achieved a 96% accuracy by combining clinical reads and quantitative 3D SHI parameters.

CLINICAL RELEVANCE/APPLICATION

Combining quantitative 3D SHI parameters and radiologists' assessments increase the accuracy and confidence for characterizing indeterminate breast lesions.

SSBR04-5   Artificial Intelligence (AI) System For Automated Triage Of Breast Ultrasound (US) Exams

Participants
Linda Moy, MD, New York, New York (*Presenter*) Grant, Siemens AG ;Advisory Board, Lunit Inc;Advisory Board, iCad, Inc

PURPOSE

To train an AI system to triage breast US exams into an enhanced assessment workflow and a no radiologist workflow (standalone AI interpretation of US exams with very low probability for malignancy), with the goal of reallocating radiologist time towards exams with high suspicion of malignancy.*Methods and Materials Our AI model was based on a neural network inspired by the Globally-Aware Multiple Instance Classifier. To develop and validate this system, we curated a dataset consisting of 288,767 breast US exams with 5,442,907 total images acquired from 143,203 patients examined between 2012 and 2019 at a large academic medical center. 28,914 of these exams were associated with at least one biopsy procedure, 5,593 of which had biopsies yielding malignant findings. Pathology was used as the reference standard. This dataset was split on into training (60%), validation (10%), and test datasets (30%). The AI system was initially trained to automatically detect and classify breast lesions on US imaging with imaging-level data and did not require region of interest input from radiologists. Predictions from this system were then used to channel women to the two new workflows: a no radiologist workflow and an enhanced assessment workflow.*Results On a test set of 44,755 exams, the AI system achieved an AUC of 0.976 for identifying exams with malignant lesions. When triaging 60%, 70%, or 80% of women with the lowest AI scores from the test set into the no radiologist workflow, the false negative rate of the AI

system was 1 out every 11905 exams (0.008%), 4608 exams (0.02%), and 2532 exams (0.04%) respectively. When this triage system was used to evaluate 3553 exams from the test set which were given a BI-RADS 3 assessment at the time of original read, it reclassified 60%, 70%, and 80% of exams with the lowest AI scores as benign without missing any malignant lesions. When the AI system utilized a high specificity threshold to triage exams it considered to be at high risk for malignancy, it placed 978 (2.2% of total) exams into an enhanced assessment workflow, with high positive predictive value (69.6%) that significantly exceeded that of the breast radiologists who initially evaluated the test set exams (15.7%). Despite representing only 2.2% of the test dataset, this enhanced assessment workflow contained 56.5% of all malignant cases in the dataset.*Conclusions Our AI system could potentially eliminate up to 60-80% of breast US exams from the radiologist worklist, with a false-negative rate of 0.008-0.04%.*Clinical Relevance/Application Using a high sensitivity threshold, AI based software may function as a standalone interpreter and eliminate low probability of malignancy cases from the radiologist worklist.

RESULTS

On a test set of 44,755 exams, the AI system achieved an AUC of 0.976 for identifying exams with malignant lesions. When triaging 60%, 70%, or 80% of women with the lowest AI scores from the test set into the no radiologist workflow, the false negative rate of the AI system was 1 out every 11905 exams (0.008%), 4608 exams (0.02%), and 2532 exams (0.04%) respectively. When this triage system was used to evaluate 3553 exams from the test set which were given a BI-RADS 3 assessment at the time of original read, it reclassified 60%, 70%, and 80% of exams with the lowest AI scores as benign without missing any malignant lesions. When the AI system utilized a high specificity threshold to triage exams it considered to be at high risk for malignancy, it placed 978 (2.2% of total) exams into an enhanced assessment workflow, with high positive predictive value (69.6%) that significantly exceeded that of the breast radiologists who initially evaluated the test set exams (15.7%). Despite representing only 2.2% of the test dataset, this enhanced assessment workflow contained 56.5% of all malignant cases in the dataset.

CLINICAL RELEVANCE/APPLICATION

Using a high sensitivity threshold, AI based software may function as a standalone interpreter and eliminate low probability of malignancy cases from the radiologist worklist.

SSBR04-6 Artificial Intelligence (AI) System Reduces False-Positive Findings In The Interpretation Of Breast Ultrasound (US) Exams

Participants
Linda Moy, MD, New York, New York (*Presenter*) Grant, Siemens AG ;Advisory Board, Lunit Inc;Advisory Board, iCad, Inc

PURPOSE

To evaluate an AI system to assist radiologists in interpreting breast US exams.*Methods and Materials We developed and evaluated an AI system using a DCNN inspired by the Globally-Aware Multiple Instance Classifier. The model automatically identified malignant and benign lesions without requiring manual annotations from radiologists. The AI system was trained using our internal dataset of 288,767 US exams with 5,442,907 total images acquired from 143,203 patients between 2012-2019, including screening and diagnostic exams. 28,914 of these exams were associated with at least one biopsy procedure, 5,593 of which had biopsies yielding malignant findings. Pathology was used as the reference standard. This dataset was split on a patient level into training (60%), validation (10%), and test datasets (30%). We validated our AI system with a reader study with 10 board-certified breast radiologists (average 14.5 years of experience). Each reader reviewed 663 exams that were sampled from the test set. A hybrid decision-making model was created for each reader which made predictions by evenly weighting the predictions of the reader and AI system. Diagnostic accuracy of the AI system, readers, and hybrid models were evaluated using ROC curves.*Results On a test set of 44,755 exams, the AI system achieved an AUC of 0.976 for identifying exams with malignancies. Among the 663 reader study exams, the AI system had an AUC of 0.962, which was significantly higher than the average radiologist (0.929 ± 0.018, p < 0.001). At the average radiologist's sensitivity (90.1%), the AI system had a higher specificity (85.6% vs 80.7%, p < 0.001) and recommended fewer biopsies (19.8% vs 24.3%, p < 0.001). On average, the hybrid models improved radiologists' AUC from 0.929 to 0.960. At the radiologists' sensitivity levels, the hybrid models increased their average specificity from 80.7% to 88.4% (p < 0.001), increased their PPV from 27.1% to 39.2% (p < 0.001), and decreased their average biopsy rate from 24.3% to 17.2% (p < 0.001). The reduction in biopsies using the hybrid models represented 29.4% of all recommended biopsies.*Conclusions Our AI system detected and diagnosed cancer on breast US with accuracy that exceeds that of board-certified radiologists. Our hybrid decision-making models may potentially enhance the performance of breast imagers without the added cost of a second human reader.*Clinical Relevance/Application Breast US detects additional cancers when used as a supplemental screening exam, but has high false-positive rates. AI decision support improves diagnostic accuracy by decreasing unnecessary biopsies.

RESULTS

On a test set of 44,755 exams, the AI system achieved an AUC of 0.976 for identifying exams with malignancies. Among the 663 reader study exams, the AI system had an AUC of 0.962, which was significantly higher than the average radiologist (0.929 ± 0.018, p < 0.001). At the average radiologist's sensitivity (90.1%), the AI system had a higher specificity (85.6% vs 80.7%, p < 0.001) and recommended fewer biopsies (19.8% vs 24.3%, p < 0.001). On average, the hybrid models improved radiologists' AUC from 0.929 to 0.960. At the radiologists' sensitivity levels, the hybrid models increased their average specificity from 80.7% to 88.4% (p < 0.001), increased their PPV from 27.1% to 39.2% (p < 0.001), and decreased their average biopsy rate from 24.3% to 17.2% (p < 0.001). The reduction in biopsies using the hybrid models represented 29.4% of all recommended biopsies.

CLINICAL RELEVANCE/APPLICATION

Breast US detects additional cancers when used as a supplemental screening exam, but has high false-positive rates. AI decision support improves diagnostic accuracy by decreasing unnecessary biopsies.

SSGI16-1   Deep Learning-enabled Single-kV Deluxe Abdominal CT Imaging With Spectral CT Functionalities

Participants
Meghan G. Lubner, MD, Madison, Wisconsin (*Presenter*) Grant, Koninklijke Philips NV;Grant, Johnson & Johnson

PURPOSE

Dual-energy or spectral CT has been implemented using advanced tube or detector technologies to provide virtual non-contrast (VNC) and quantitative material basis images. Due to higher hardware costs, clinical workflow challenges, and other limitations, the dissemination and employment of spectral CT in clinical abdominal CT practice have been restricted. The purpose of this work was to develop and evaluate a novel deep learning network to harvest the hidden spectral information encoded in routine single-kV contrast-enhanced abdominal CT projection data to generate an additional deluxe series of images with the desired spectral CT functionalities.*Methods and Materials A deep learning architecture including a material basis generator and a VNC generator was developed. The deep learning model was trained using a curated data set of 4,034 pairs of a high kV image and the corresponding material basis images from hardware-based DECT acquisitions (Gemstone Spectral Imaging). The trained network was evaluated using an independent test cohort of 90 subjects acquired at a different institution using different CT platforms and scan protocols: among them, 74 subjects received GSI-based DECT but only the 140 kV-component of the acquired data were processed by the network; the GSI images provide the needed reference standard for quantifying the network-based spectral CT accuracy. The other 16 subjects received single-kV contrast-enhanced CT and true non-contrast CT and/or MRI to establish the gold standard diagnosis.*Results Across the 74 test subjects, Bland-Altman analysis showed that the mean relative difference in spectral CT image signal values between the GSI and the proposed method is 3.8% and the 95% limits of agreement are [-0.6%, 8.2%]. Two One-Sided Test (TOST) for equivalence with an alpha of 0.05 showed that single-kV VNC images and true non-contrast images have equivalent means within a bound of [-5HU, +5HU] (p<0.05) for all tissue types evaluated. As confirmed by MRI and other clinical gold standards, the single-kV VNC images, iodine images, and atomic number maps provide the needed baseline HU and quantitative contrast-uptake information for characterizing adrenal and renal masses and confidently prescribing diagnosis.*Conclusions The deep learning-based method in this work enables conventional CT scanners and single-kV scan protocols to generate spectral abdominal CT images with added quantitative imaging capability to improve diagnostic accuracy and confidence.*Clinical Relevance/Application This method enables an integrated clinical abdominal CT workflow to improve diagnostic accuracy and confidence while reducing radiation dose to patients and overall healthcare costs.

RESULTS

Across the 74 test subjects, Bland-Altman analysis showed that the mean relative difference in spectral CT image signal values between the GSI and the proposed method is 3.8% and the 95% limits of agreement are [-0.6%, 8.2%]. Two One-Sided Test (TOST) for equivalence with an alpha of 0.05 showed that single-kV VNC images and true non-contrast images have equivalent means within a bound of [-5HU, +5HU] (p<0.05) for all tissue types evaluated. As confirmed by MRI and other clinical gold standards, the single-kV VNC images, iodine images, and atomic number maps provide the needed baseline HU and quantitative contrast-uptake information for characterizing adrenal and renal masses and confidently prescribing diagnosis.

CLINICAL RELEVANCE/APPLICATION

This method enables an integrated clinical abdominal CT workflow to improve diagnostic accuracy and confidence while reducing radiation dose to patients and overall healthcare costs.

SSGI16-2   Multireader Assessment Of A Hybrid Dataset Of Real And Simulated Hypoenhancing Liver Lesions In Dual-Energy CT Examinations

Participants
Fides Schwartz, MD, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To assess whether virtual monoenergetic image reconstructions of dual-energy (DE) CT scans at 70 keV can improve detectability of hypoenhancing liver lesions in comparison with the current standard mixed reconstructions, similar to the improvement seen in hyperenhancing liver lesions.*Methods and Materials This retrospective study included DECT scans from 50 patients scanned with second and third generation dual-source CT. A hybrid dataset was built including 11 patients with hypoenhancing liver lesions on portal venous phase, and 39 patients without lesions, including several with hepatic steatosis. In 33 of the datasets without lesions, small low-contrast lesions were artificially inserted into the parenchyma peripherally or near vessels following a previously validated technique adapted to DECT that enables the design of challenging-to-detect lesions with diameters of 10, 15 or 20 mm

and -10, -15 or -20 HU of contrast relative to the liver parenchyma. Six lesion free datasets functioned as negative controls. Two reconstructions were made: standard mixed images, and 70 keV. Three readers (6, 7 and 12 years of experience in diagnostic radiology) evaluated the resulting 100 images in blinded, randomized order, marking low density liver lesions on the images and giving their level of confidence with the lesion identification on a scale of 0 (not confident at all) to 100 (fully confident) as well as an overall image quality score (0=image quality completely non-diagnostic, 100=perfect image quality). Accuracy, sensitivity and specificity of lesion identification was evaluated per reconstruction. Detection confidence and image quality scores were compared using t-tests.*Results Accuracy of lesion detection was 87% and 83% for 70 keV and mixed images respectively. Sensitivity was 89% and 80%, respectively and specificity was 78% and 96%, respectively. Reader confidence in lesion detection was not significantly different between mixed images (82%) and 70 keV images (80%; P=0.26). Image quality was not rated statistically significantly different between mixed images (79%) and 70 keV images (77%; P=0.67).*Conclusions Hypoenhancing liver lesion detection accuracy and sensitivity was higher using 70 keV image reconstruction though specificity was lower than the standard mixed images. Image quality and confidence were rated similar between 70 keV reconstructions and standard reconstructions.*Clinical Relevance/Application Hypoenhancing liver lesions can be detected with higher accuracy and sensitivity on 70 keV reconstructions compared to standard mixed images and could be the new standard for clinical practice.

RESULTS

Accuracy of lesion detection was 87% and 83% for 70 keV and mixed images respectively. Sensitivity was 89% and 80%, respectively and specificity was 78% and 96%, respectively. Reader confidence in lesion detection was not significantly different between mixed images (82%) and 70 keV images (80%; P=0.26). Image quality was not rated statistically significantly different between mixed images (79%) and 70 keV images (77%; P=0.67).

CLINICAL RELEVANCE/APPLICATION

Hypoenhancing liver lesions can be detected with higher accuracy and sensitivity on 70 keV reconstructions compared to standard mixed images and could be the new standard for clinical practice.

SSGI16-3 Contrast-enhanced Abdominal CT With Clinical Photon-counting CT: Assessment Of Image Quality And Comparison With Energy-integrating Detector CT

Participants
Kai Higashigaito, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To determine the image quality of contrast-enhanced abdomen with clinical photon counting CT (PCCT) compared to energy integrating detector CT (EID-CT) at the same radiation dose.*Methods and Materials Twenty-four consecutive patients (mean age 63.7 ± 10.5 years, 4 females, mean body mass index 26.9 ± 6.2 kg/m2) were included in this prospective study. Inclusion criteria were clinically indicated, contrast-enhanced abdominal CT in the portal-venous phase and previously obtained abdominal CT with EID-CT in the same patients and using the same contrast media protocol. PCCT was performed using the QuantumPlus mode (obtaining complete spectral data) at 120kVp. EID-CT was performed using automated tube voltage selection (reference 100 kVp). For PCCT, virtual monoenergetic images (VMI) were reconstructed in 10 keV intervals from 40-90 keV using the same soft tissue reconstruction kernel (Br36) and slice thickness as with EID-CT. Tube current-time product was modified in PCCT for each patient to obtain the same CTDIvol values as with previous EID-CT. Attenuation of parenchymatous organs (liver, pancreas, spleen, kidney) and vascular structures (abdominal aorta, portal vein, inferior caval vein) were measured, noise was quantified using the standard deviation of attenuation in the psoas muscle, and contrast-to-noise ratio (CNR) was calculated. Two independent, blinded radiologists assessed subjective image quality (overall image quality, image noise, image contrast).*Results Median time interval between EID-CT and PCCT was 11 months. Inter-reader agreement for subjective image quality was good (Krippendorff's alpha = 0.774-0.902). CTDIvol (6.08 mGy, p=0.990) and body mass index (p=0.930) were similar between scans. Average CNRorgans and CNRvascular for EID-CT was 3.7 ± 1.4 and 4.9 ± 2.2 respectively, CNRorgans and CNRvascular for 40-90 keV ranged from 6.8 ± 2.2 to 1.9 ± 0.9 and 9.0 ± 2.8 to 2.6 ± 2.5 respectively. CNRorgans and CNRvascular of VMI at 40 and 50 keV were significantly higher compared to EID-CT (all, p<0.05). Compared to EID-CT, overall image quality of VMI was rated higher at 60 keV, image contrast was rated higher at 40, 50 and 60 keV, and subjective image noise higher at 40 keV (all, p<0.05).*Conclusions Our intra-individual analysis indicates that at identical radiation dose, clinical PCCT with reconstruction of VMI at 50 and 60 keV shows significantly better image quality compared to EID-CT.*Clinical Relevance/Application Initial experience of clinical PCCT of contrast-enhanced abdominal CT. Results indicate significant improvements of image quality of the PCCT system compared to conventional EID-CT.

RESULTS

Median time interval between EID-CT and PCCT was 11 months. Inter-reader agreement for subjective image quality was good (Krippendorff's alpha = 0.774-0.902). CTDIvol (6.08 mGy, p=0.990) and body mass index (p=0.930) were similar between scans. Average CNRorgans and CNRvascular for EID-CT was 3.7 ± 1.4 and 4.9 ± 2.2 respectively, CNRorgans and CNRvascular for 40-90 keV ranged from 6.8 ± 2.2 to 1.9 ± 0.9 and 9.0 ± 2.8 to 2.6 ± 2.5 respectively. CNRorgans and CNRvascular of VMI at 40 and 50 keV were significantly higher compared to EID-CT (all, p<0.05). Compared to EID-CT, overall image quality of VMI was rated higher at 60 keV, image contrast was rated higher at 40, 50 and 60 keV, and subjective image noise higher at 40 keV (all, p<0.05).

CLINICAL RELEVANCE/APPLICATION

Initial experience of clinical PCCT of contrast-enhanced abdominal CT. Results indicate significant improvements of image quality of the PCCT system compared to conventional EID-CT.

SSGI16-4 Comparison Of Conventional And Spectral-based Tagged Stool Cleansing Algorithms At CT Colonography

Participants
Sergio Grosu, MD, Munich, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To compare the performance of conventional versus spectral-based electronic stool cleansing for iodine-tagged CT colonography (CTC) using a dual-layer (DL) spectral detector scanner.*Methods and Materials We retrospectively evaluated iodine contrast stool-tagged CTC scans of 30 consecutive asymptomatic patients (mean age: 69±8 years) undergoing colorectal cancer screening obtained on a spectral DL detector CT scanner. One reader identified locations of electronic cleansing artifacts (n=229) on conventional and spectral cleansed images. Three additional independent readers then evaluated these locations using a conventional cleansing algorithm (Intellispace Portal, Philips, Best, Netherlands) and two experimental spectral cleansing algorithms

(i.e. fully transparent and translucent tagged stool). For each cleansed image set, readers recorded the severity of over- and under-cleansing artifact on a five-point Likert scale (0=none to 4=severe) and readability compared to uncleansed images. Wilcoxon signed-rank tests were used to assess artifact severity, type and readability (worse, unchanged, better).*Results Compared with conventional electronic stool cleansing (mean score 3.02), the severity of overall cleansing artifacts was lower in translucent spectral cleansing (mean score 2.32, p<0.001). Under-cleansing artifact severity was lower in transparent (mean score 2.28, p<0.001) and translucent (mean score 1.81, p<0.001) spectral cleansing compared with conventional cleansing (mean score 2.66). Over-cleansing artifact severity was worse in transparent (mean score 0.62, p<0.001) and translucent (mean score 0.51, p<0.05) spectral cleansing compared with conventional cleansing (mean score 0.36). Overall readability was significantly improved in transparent (p<0.001) and translucent spectral cleansing (p<0.001) compared with conventional cleansing.*Conclusions Spectral cleansing provides more robust electronic stool cleansing of iodine tagged stool than conventional cleansing. Translucent spectral stool cleansing is preferred over full transparent stool subtraction.*Clinical Relevance/Application Spectral-based electronic cleansing of tagged stool at CTC provides superior images with less perceived anatomic distortion than does conventional cleansing. Further clinical trials are warranted.

RESULTS

Compared with conventional electronic stool cleansing (mean score 3.02), the severity of overall cleansing artifacts was lower in translucent spectral cleansing (mean score 2.32, p<0.001). Under-cleansing artifact severity was lower in transparent (mean score 2.28, p<0.001) and translucent (mean score 1.81, p<0.001) spectral cleansing compared with conventional cleansing (mean score 2.66). Over-cleansing artifact severity was worse in transparent (mean score 0.62, p<0.001) and translucent (mean score 0.51, p<0.05) spectral cleansing compared with conventional cleansing (mean score 0.36). Overall readability was significantly improved in transparent (p<0.001) and translucent spectral cleansing (p<0.001) compared with conventional cleansing.

CLINICAL RELEVANCE/APPLICATION

Spectral-based electronic cleansing of tagged stool at CTC provides superior images with less perceived anatomic distortion than does conventional cleansing. Further clinical trials are warranted.

SSGI16-5 Dynamic Liver MRI During Free Breathing - A Feasibility Study With A Motion Compensated Variable Density Radial Acquisition And A Viewsharing High Pass Filtering Reconstruction

Participants
Christoph Endler, MD, Bonn, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Robust dynamic liver MRI sequences are essential for accurate detection and characterization of focal liver lesions. As optimal dynamic imaging usually requires multiple breath-holds, its inherent susceptibility to motion artifacts frequently results in degraded image quality in incompliant patients. Since free breathing imaging may overcome this drawback, the aim of this study was to evaluate a MRI sequence acquired during free breathing using the VDGA SOS radial sampling scheme, that so far has not been implemented in 4D applications.*Methods and Materials In a prospective pilot study, 27 patients received a routine abdominal MRI protocol including the prototype free-breathing sequence (4DFreeBreathing) for dynamic imaging. This enables more convenient and faster reconstruction through VDGA-SOS without the use of additional reconstruction hardware, and hypothetically higher robustness regarding motion artefacts through soft-gating. A standard breath-hold sequence performed hereafter served as reference standard. Out of the continuous dynamic data sets each dynamic phase was analyzed regarding image quality, motion artifacts and vessel conspicuity using 5-point Likert scales. Furthermore, correct timing of the late arterial phase was compared to the pre-examinations.*Results 4DFreeBreathing delivered motion-free dynamic images with high temporal resolution in each subject. Overall image quality scores were rated good or excellent for 4DFreeBreathing and the gold standard without significant differences (P=0.34). There were significantly less motion artifacts in the 4DFreeBreathing sequence (P<0.0001), while vessel conspicuity in each dynamic phase was comparable for both groups (P=0.45, P>0.99, P=0.22, respectively). Correct timing of the late arterial phase could be achieved in 27/27 (100%) examinations using 4DFreeBreathing vs. 35/53 (66%) pre-examinations using gold standard (P<0.001).*Conclusions 4DFreeBreathing is a valuable technique that should be considered in special patient groups with foreseeable non-compliance or with preceding non-diagnostic dynamic liver MRI as a beneficial alternative to standard breath-hold sequences.*Clinical Relevance/Application 4DFreeBreathing allows for more convenient and faster reconstruction than current free breathing techniques with even higher motion robustness due to the VDGA SOS radial sampling scheme. This is beneficial in incompliant patients groups.

RESULTS

4DFreeBreathing delivered motion-free dynamic images with high temporal resolution in each subject. Overall image quality scores were rated good or excellent for 4DFreeBreathing and the gold standard without significant differences (P=0.34). There were significantly less motion artifacts in the 4DFreeBreathing sequence (P<0.0001), while vessel conspicuity in each dynamic phase was comparable for both groups (P=0.45, P>0.99, P=0.22, respectively). Correct timing of the late arterial phase could be achieved in 27/27 (100%) examinations using 4DFreeBreathing vs. 35/53 (66%) pre-examinations using gold standard (P<0.001).

CLINICAL RELEVANCE/APPLICATION

4DFreeBreathing allows for more convenient and faster reconstruction than current free breathing techniques with even higher motion robustness due to the VDGA SOS radial sampling scheme. This is beneficial in incompliant patients groups.

SSGI16-6 Respiratory Triggered Diffusion-weighted Imaging With A Single Diffusion Sensitising Gradient To Reduce Image Acquisition Time -a Feasibility Study In The Workup Of Hepatocellular Carcinoma.

Participants
Adarsh Ghosh, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

We evaluated respiratory triggered unidirectional single-shot echo-planar imaging (u-SSEPI) as a time-saving measure in diffusion imaging of the upper abdomen. Specifically, we compared the ADC values obtained from unidirectional DWI(u-SSEPI) and routine DWI (4t-SSEPI) and also the diagnostic accuracies of unidirectional and routine DWI sequences in the identification of focal liver lesions in the setting of chronic liver disease (CLD).*Methods and Materials This prospective, IRB approved study, included 48 patients of CLD who underwent-DCE-MRI on a 1.5 T scanner for hepatocellular carcinoma (HCC) workup. In addition to 4t-SSEPI, u-SSEPI was acquired with the diffusion sensitising gradient being applied in only one direction; keeping all other parameters same as 4t-SSEPI. Two blinded radiologists evaluated the DWI studies for image quality and detection of liver lesions. A composite gold

standard was established using DCE-MRI, follow-up imaging and patient clinical details. The apparent diffusion coefficients (ADCs) of the liver, spleen and the lesions were compared between the two sequences. ROC analysis evaluated the diagnostic accuracy of ADC from both the sequences in identifying HCC.*Results Eighty-eight lesions were identified using the composite gold standard. u-SSEPI resulted in 3 times faster image acquisition. No statistically significant differences were demonstrated between the unidirectional and routine DWI sequences for image quality parameters and lesion detection rates. Lesion wise comparison of the ADC values from both the sequences was not statistically different (p = 0.8) with a coefficient of variation = 12-14%. The Bland-Altman plots and the Passing-Bablock regression analysis demonstrated a systematic and proportional bias between the ADC values obtained. The AUC of the ROC curve, however, was 0.63-o1; 0.62-o2 for routine DWI and 0.65; 0.62 for unidirectional DWI when ADC was used to identify HCC (the AUCs were not statistically different (p = 0.6-0.8)).*Conclusions No significant differences were demonstrated in the diagnostic accuracies of unidirectional and routine DWI in the diagnosis of HCC. Unidirectional diffusion may be further evaluated in other organs where diffusion is isotropic, especially in respiratory triggered sequences where the imaging time dividend is significant.*Clinical Relevance/Application Utilising diffusion sensitising gradient in a single direction with respiratory triggering can reduce image acquisition times with no significant differences in image quality or diagnostic accuracies

RESULTS

Eighty-eight lesions were identified using the composite gold standard. u-SSEPI resulted in 3 times faster image acquisition. No statistically significant differences were demonstrated between the unidirectional and routine DWI sequences for image quality parameters and lesion detection rates. Lesion wise comparison of the ADC values from both the sequences was not statistically different (p = 0.8) with a coefficient of variation = 12-14%. The Bland- Altman plots and the Passing-Bablock regression analysis demonstrated a systematic and proportional bias between the ADC values obtained. The AUC of the ROC curve, however, was 0.63-o1; 0.62-o2 for routine DWI and 0.65; 0.62 for unidirectional DWI when ADC was used to identify HCC (the AUCs were not statistically different (p = 0.6-0.8)).

CLINICAL RELEVANCE/APPLICATION

Utilising diffusion sensitising gradient in a single direction with respiratory triggering can reduce image acquisition times with no significant differences in image quality or diagnostic accuracies

SSNMMI06-1 The Relation Of The Gleason Score, Prostate Health Index, Immunochemistry Staining Specific For PSMA, 68Ga-PSMA-11 Accumulation, Apparent Diffusion Coefficient And Pharmacokinetic Analysis During PET/MRI

Participants
Jiri Ferda, MD, PhD, Pilsen, Czech Republic (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the relationship between the level of the accumulation of the prostate specific membrane antigen (PSMA) ligand 68Ga-PSMA-11 (HBED), apparent diffusion coefficient, the pharmacokinetic parameters of the tissue enhancement, the level of the expression of the PSMA and Gleason score, and the prostate health index (PHI)*Methods and Materials Prospective study evaluated 40 whole mount prostate gross sections of 40 male patients with prostate cancer, they underwent the staging PET/MRI with the application of 68Ga-PSMA-11, the biopsy confirmed the prostate carcinoma within three weeks. The evaluation of the prostate carcinoma accumulation used the measurement of the standardized uptake value of 68Ga-PSMA-11s. The pathological staining was made using immunochemistry targeted the molecule of PSMA. The samples to be stained were removed from whole mount section according to the findings of PET/MRI. Gleason score was set in all patients. The following qualities were compared using Spearman correlation coefficient: Gleason score, four step scale of the immunochemistry confirmation of expression of PSMA, PHI (including proPSA level), than MRI derived values ADC (minimum value), Ktrans, iAUC, Ve , Kep .*Results The correlation of the expression of PSMA assessed using histochemistry with the accumulation of 68Ga-PSMA-11 was found by the Spearmann correlation coefficient (p=0.0011), the better correlation was found in patients where Gleason score pattern was 3 or 4 (p= 0.006). ADC correlated with PSA level (p=0.0074), with Gleason score pattern when it was 4 and 5 or, and with the overall accumulation of 68Ga-PSMA-11 (p=0.0157). Only Kep pharmacokinetic parameter correlates with the 68Ga-PSMA-11 (p=0.0052). ProPSA correlates with size of the tumor and extraprostatic extension (both p<0.0001), PHI correlates with ADC weekly (p=0.0391)*Conclusions The level of the PSMA ligand accumulation correlates with the PSMA expression assesed by the PSMA targeting immunochemistry staining; 68Ga-PSMA-11 accumulation correlates surprisingly weakly to the Gleason score, when the pattern is 5, then accumulation tends to be less expressed. The important finding is that the 68Ga-PSMA-11 accumulation relates to the real expression of PSMA molecule within the prostatic gland cell membrane.*Clinical Relevance/Application The relevances of the presented finding is important to the interpretationof the PET images using 68Ga-PSMA-11, when the accumulation is limited, the real presence of the PSMA protein within prostatic glandular cells is limited

RESULTS

The correlation of the expression of PSMA assessed using histochemistry with the accumulation of 68Ga-PSMA-11 was found by the Spearmann correlation coefficient (p=0.0011), the better correlation was found in patients where Gleason score pattern was 3 or 4 (p= 0.006). ADC correlated with PSA level (p=0.0074), with Gleason score pattern when it was 4 and 5 or, and with the overall accumulation of 68Ga-PSMA-11 (p=0.0157). Only Kep pharmacokinetic parameter correlates with the 68Ga-PSMA-11 (p=0.0052). ProPSA correlates with size of the tumor and extraprostatic extension (both p<0.0001), PHI correlates with ADC weekly (p=0.0391)

CLINICAL RELEVANCE/APPLICATION

The relevances of the presented finding is important to the interpretationof the PET images using 68Ga-PSMA-11, when the accumulation is limited, the real presence of the PSMA protein within prostatic glandular cells is limited

SSNMMI06-2 Comparative Efficacy Of PSMA-targeted 18F-DCFPyL PET-CT Scan And Multi-parametric MRI For Detection And Staging Of Prostate Cancer: A Prospective Study

Participants
Soheil Kooraki, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

PURPOSE

To compare the efficacy of 18F-DCFPyL PET/CT scan for detection of intra-prostatic and extra-prostatic lesions in individuals with prostate cancer (PCa), compared to multiparametric MRI (mpMRI) of prostate.*Methods and Materials This IRB-approved, HIPAA-compliant, open label, single-center, prospective study was nested in a clinical trial study which assesses clinical applications of 18F-DCFPyL PET/CT in individuals with PCa. Data of 110 patients who had undergone 18F-DCFPyL PET/CT were reviewed and 34 patients (mean age 70, ranged 59-92 years, mean PSA 20.7 ng/mL at the time of performing scan) who had completed a diagnostic mpMRI no more than three months before acquisition of 18F-DCFPyL PET/CT were included. Whole body PET/CT scan was acquired

either for initial staging or restaging of PCa, approximately 60 minutes after injection of 9 ± 1 mCi 18F-DCFPyL. PET/CT scans were interpreted by an experienced nuclear medicine specialist, blinded to the results of mpMRI. Findings were later compared to those of mpMRI. The pre- and post- scan questionnaires were completed by the referring physician within two weeks before and four weeks after 18F-DCFPyL PET/CT study, respectively.*Results 18F-DCFPyL PET/CT scan and mpMRI were concordant for detection of intraprostatic lesions in 73.5% (25/34) of the study cohort. The intraprostatic findings were discordant in 9 patients, of whom two had negative, and one had non-diagnostic mpMRI. Also, mpMRI found extra-capsular extension in 32.3% (11/34) of patients, for which PET/CT study was limited. Positive regional and non-regional lymph nodes were found in 32.3% (11/34) and 5.9% (2/34) of individuals by 18F-DCFPyL PET/CT, respectively, vs. regional lymph nodes in 2.9% (1/34) on mpMRI. Skeletal metastasis was detected in 17.6% (6/34) by 18F-DCFPyL PET/CT compared to 2.9% (1/34) by mpMRI. Overall, based on the results of 18F-DCFPyL PET/CT scan, staging was altered in 44.1% (15/34) of patients.*Conclusions 18F-DCFPyL PET/CT scan and mpMRI were concordant for detection of intraprostatic lesions in 73.5% of the study cohort. 18F-DCFPyL PET/CT is more sensitive to detect regional and non-regional lymph nodes and skeletal metastasis.*Clinical Relevance/Application In addition to localization of intraprostatic lesions, 18F-DCFPyL PET/CT has the advantage of depicting nodal and skeletal metastasis; therefore, acquiring 18F-DCFPyL PET/CT and mpMRI together can be beneficial for patient care in the diagnostic path of PCa.

RESULTS

18F-DCFPyL PET/CT scan and mpMRI were concordant for detection of intraprostatic lesions in 73.5% (25/34) of the study cohort. The intraprostatic findings were discordant in 9 patients, of whom two had negative, and one had non-diagnostic mpMRI. Also, mpMRI found extra-capsular extension in 32.3% (11/34) of patients, for which PET/CT study was limited. Positive regional and non-regional lymph nodes were found in 32.3% (11/34) and 5.9% (2/34) of individuals by 18F-DCFPyL PET/CT, respectively, vs. regional lymph nodes in 2.9% (1/34) on mpMRI. Skeletal metastasis was detected in 17.6% (6/34) by 18F-DCFPyL PET/CT compared to 2.9% (1/34) by mpMRI. Overall, based on the results of 18F-DCFPyL PET/CT scan, staging was altered in 44.1% (15/34) of patients.

CLINICAL RELEVANCE/APPLICATION

In addition to localization of intraprostatic lesions, 18F-DCFPyL PET/CT has the advantage of depicting nodal and skeletal metastasis; therefore, acquiring 18F-DCFPyL PET/CT and mpMRI together can be beneficial for patient care in the diagnostic path of PCa.

SSNMMI06-3   Whole Prostate SUVmax On 18f-fluciclovine PET Correlates With Gleason Grade (Grade Group) Change After Radical Prostatectomy In High Risk Patients With Primary Prostate Cancer

Participants
Olayinka Abiodun-Ojo, MD,MPH, Atlanta, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

Preoperative Gleason score (GS)/Grade group (GG) are important parameters for prostate cancer (PCa) staging and treatment planning. The role of 18F-fluciclovine in primary PCa staging is currently being explored. The aim of this study was to determine whether fluciclovine uptake in the prostate gland correlates with GS/GG change after radical prostatectomy (RP).*Methods and Materials Fifty-six patients (mean age 61.8 [±7.1] years) with unfavorable intermediate to high risk PCa considered eligible for surgery underwent 18F-fluciclovine PET/CT prior to robotic RP with extended pelvic lymph node dissection. Patients were diagnosed with PCa and risk category was determined based on 12-core trans-rectal prostate biopsy findings and prostate-specific antigen (PSA). On PET, regions of interest were highlighted around the prostate gland to determine the maximum standardized uptake values (SUVmax). Following surgery, histopathologic assessment was performed and GS/GG were reported. GS/GG at prostate biopsy and RP were compared and grade changes documented. Grade change was defined as any upward or downward change in GG. PET prostate findings were correlated with GS/GG and grade change.*Results Median preoperative PSA was 15.50 ng/mL (2.49-147.03 ng/mL). All patients had abnormal fluciclovine uptake in the prostate. There was no significant difference in whole prostate SUVmax across GG at biopsy (p = 0.188) and RP (p = 0.708). Of the 56 prostate specimens analyzed, significant GG change was found in 9/56 (16.1%) patients. GG downgrade and upgrade rates were 7/56 (12.5%) and 2/56 (3.6%), respectively. Patients that were downgraded at RP had significantly lower whole prostate SUVmax than patients with no grade change (8.5 ± 2.6 vs 6.4 ± 0.6; p<0.01).Additionally, fluciclovine uptake (SUVmax) was significantly higher in upgraded than downgraded cases (8.9 ± 2.2 vs. 6.8 ± 1.7; p <0.01). ROC analysis showed SUVmax (area under curve = 0.78; 95% CI: 0.59-0.97) with cutoff of 7.3 yielded a sensitivity of 80% and specificity of 79% for fluciclovine PET to predict upgrade. SUVmax was significantly associated with upgrading only when downgraded cases were used as the reference group (p = 0.02). After adjusting for PSA, there was a non-significant association between SUVmax and upgrading (p = 0.062).*Conclusions Fluciclovine PET uptake parameters may indicate upgrading of patients with primary prostate cancer postoperatively, which is critical for accurate staging, treatment planning, and outcome.*Clinical Relevance/Application Fluciclovine PET appears to be a valuable tool for pre-treatment staging and treatment planning of primary prostate cancer patients.

RESULTS

Median preoperative PSA was 15.50 ng/mL (2.49-147.03 ng/mL). All patients had abnormal fluciclovine uptake in the prostate. There was no significant difference in whole prostate SUVmax across GG at biopsy (p = 0.188) and RP (p = 0.708). Of the 56 prostate specimens analyzed, significant GG change was found in 9/56 (16.1%) patients. GG downgrade and upgrade rates were 7/56 (12.5%) and 2/56 (3.6%), respectively. Patients that were downgraded at RP had significantly lower whole prostate SUVmax than patients with no grade change (8.5 ± 2.6 vs 6.4 ± 0.6; p<0.01).Additionally, fluciclovine uptake (SUVmax) was significantly higher in upgraded than downgraded cases (8.9 ± 2.2 vs. 6.8 ± 1.7; p <0.01). ROC analysis showed SUVmax (area under curve = 0.78; 95% CI: 0.59-0.97) with cutoff of 7.3 yielded a sensitivity of 80% and specificity of 79% for fluciclovine PET to predict upgrade. SUVmax was significantly associated with upgrading only when downgraded cases were used as the reference group (p = 0.02). After adjusting for PSA, there was a non-significant association between SUVmax and upgrading (p = 0.062).

CLINICAL RELEVANCE/APPLICATION

Fluciclovine PET appears to be a valuable tool for pre-treatment staging and treatment planning of primary prostate cancer patients.

SSNMMI06-4   18F-fluciclovine PET/CT And 68GA-PSMA PET/CT Guidance Of Salvage Radiotherapy In Patients With Biochemical Recurrence Postprostatectomy: Interim Analysis Of A Secondary Endpoint From A Randomized Trial

Participants

Olayinka Abiodun-Ojo, MD,MPH, Atlanta, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

We examined the potential influence of 18F-fluciclovine and 68Ga-PSMA PET/CT on salvage radiotherapy (RT) management decisions (planned secondary endpoint) in patients with biochemical recurrence postprostatectomy.*Methods and Materials 68 patients (accrual goal: 140) with detectable prostate-specific antigen (PSA) postprostatectomy were randomized to treatment planning guided by fluciclovine (mean dose: 9.96 ± 0.80 mCi) [arm A] or Ga-PSMA (mean dose: 5.07 ± 0.21 mCi) with 20 mg Lasix given unless contraindicated [arm B] in an ongoing prospective intention-to-treat clinical trial. Pre-PET RT plans were based on clinical history, histopathology findings at prostatectomy, PSA trajectory and conventional imaging findings. Post-PET RT plans were based on PET findings: no uptake or prostate bed (PB) only uptake - RT to PB only; pelvic nodal uptake - RT to PB+pelvis; extrapelvic nodal uptake - no RT. For each arm, pre- and post-PET management decisions were compared and significance of decision changes were determined using the Clopper-Pearson (exact) binomial method.*Results 3/68 patients dropped out before PET scanning. Of the remaining 65 patients analyzed, 32 (median PSA 0.29 ng/mL) underwent fluciclovine PET and 33 (median PSA 0.31 ng/mL) Ga-PSMA PET. No significant difference in PSA at PET (p = 0.48), Gleason score (p = 0.73) and surgery-PET interval (p = 0.94) between arms. On whole body analysis, positivity rate of fluciclovine was significantly higher than Ga-PSMA (96.9% vs 60.6%; p < 0.01). Overall RT decision change was 9/32 (28.1%) in arm A; in 4/32 (12.5%) patients, RT decision was withdrawn because of systemic disease detected on PET. 5/28 (17.9%) patients with sustained plans to undergo RT had treatment fields changed from RT to PB and pelvis to PB only. RT decision change was 12/33 (36.4%) in arm B; 5/33 (15.2%) patients had RT decision withdrawn because of extrapelvic uptake on PET. 7/28 (25.0%) patients with final decision to undergo RT had fields changed; 6/28 (21.4%) had fields reduced from RT to PB and pelvis to PB only, while 1/28 (3.6%) had fields increased from RT to PB only to PB and pelvis. Changes in overall RT decisions and fields were statistically significant (P < 0.01) for both arms.*Conclusions In this interim analysis, whole body positivity rate for fluciclovine was significantly higher than Ga-PSMA. Both fluciclovine and Ga-PSMA had a significant influence on salvage RT management decisions.*Clinical Relevance/Application For PCa patients with biochemical recurrence fluciclovine PET had higher positivity rate primarily due to superior ability to detect local recurrence compared with Ga-PSMA. Both fluciclovine and Ga-PSMA had a significant influence on salvage radiotherapy management decisions.

RESULTS

3/68 patients dropped out before PET scanning. Of the remaining 65 patients analyzed, 32 (median PSA 0.29 ng/mL) underwent fluciclovine PET and 33 (median PSA 0.31 ng/mL) Ga-PSMA PET. No significant difference in PSA at PET (p = 0.48), Gleason score (p = 0.73) and surgery-PET interval (p = 0.94) between arms. On whole body analysis, positivity rate of fluciclovine was significantly higher than Ga-PSMA (96.9% vs 60.6%; p < 0.01). Overall RT decision change was 9/32 (28.1%) in arm A; in 4/32 (12.5%) patients, RT decision was withdrawn because of systemic disease detected on PET. 5/28 (17.9%) patients with sustained plans to undergo RT had treatment fields changed from RT to PB and pelvis to PB only. RT decision change was 12/33 (36.4%) in arm B; 5/33 (15.2%) patients had RT decision withdrawn because of extrapelvic uptake on PET. 7/28 (25.0%) patients with final decision to undergo RT had fields changed; 6/28 (21.4%) had fields reduced from RT to PB and pelvis to PB only, while 1/28 (3.6%) had fields increased from RT to PB only to PB and pelvis. Changes in overall RT decisions and fields were statistically significant (P < 0.01) for both arms.

CLINICAL RELEVANCE/APPLICATION

For PCa patients with biochemical recurrence fluciclovine PET had higher positivity rate primarily due to superior ability to detect local recurrence compared with Ga-PSMA. Both fluciclovine and Ga-PSMA had a significant influence on salvage radiotherapy management decisions.

SSNMMI06-5 The Impact Of 18F-DCFPyL (PSMA)PET On The Primary Staging And Management Of Men With Unfavorable Intermediate Or High-risk Prostate Cancer

Participants
Adriano Basso Dias, MD, Toronto, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

To determine whether 18F-DCFPyL (PSMA) PET (PET/CT or PET/MRI) performed at initial staging of men with unfavorable intermediate or high-risk prostate cancer detects pelvic nodal and distant metastases more frequently than conventional imaging (=CI; bone scan and CT± MR) and to assess the impact of PSMA PET on patient management.*Methods and Materials There were 108 men with biopsy-proven unfavorable intermediate or high-risk prostate cancer with no metastases (n=84), oligometastatic disease (=4 metastases) (n=22) or equivocal for extensive disease (>4 metastases) on CI (n=2) referred for primary staging with PSMA PET. The diagnostic performance of PET for detection of pelvic nodal and distant metastatic disease was compared to staging with CI. Metastatic sites and disease stage were recorded for each modality and compared with a composite reference standard including histopathologic examination (when available), correlative imaging and clinical/biochemical follow-up. Pre-PET intended treatment was recorded and compared to treatment after PET.*Results The performance (95% CI) of CI and PSMA PET for the detection of pelvic nodal metastases was 0.79 (0.49, 0.95) vs 0.97 (0.84, 1.00) for sensitivity and 0.74 (0.63, 0.83) vs. 0.97 (0.90, 1.00) for specificity, respectively; and for distant metastases was 0.75 (0.43, 0.95) vs 1.00 (0.86, 1.00) for sensitivity and 0.82 (0.72, 0.89) vs. 0.98 (0.91, 1.00) for specificity, respectively. PSMA PET altered stage in 42/108 (39%) and management in 24/108 (23%) men. The most frequent change in management was from systemic to locoregional therapy in 10/108 (9.3%) and from locoregional to systemic therapy in 9/108 (8.3%). Equivocal findings were encountered less frequently with PET (1/108, 0.9%) than conventional imaging (27/108, 25%).*Conclusions In patients with unfavorable intermediate or high-risk biopsy prostate cancer, initial staging with PSMA PET detects more nodal and distant metastases than CI and results in a change in management in >20% of men. Long term follow-up is needed to determine whether this translates to better clinical outcomes.*Clinical Relevance/Application PSMA PET is more sensitive in identifying nodal and distant metastases at initial staging of men with unfavorable intermediate or high-risk prostate cancer, resulting in a frequent change in management.

RESULTS

The performance (95% CI) of CI and PSMA PET for the detection of pelvic nodal metastases was 0.79 (0.49, 0.95) vs 0.97 (0.84, 1.00) for sensitivity and 0.74 (0.63, 0.83) vs. 0.97 (0.90, 1.00) for specificity, respectively; and for distant metastases was 0.75 (0.43, 0.95) vs 1.00 (0.86, 1.00) for sensitivity and 0.82 (0.72, 0.89) vs. 0.98 (0.91, 1.00) for specificity, respectively. PSMA PET altered stage in 42/108 (39%) and management in 24/108 (23%) men. The most frequent change in management was from systemic to locoregional therapy in 10/108 (9.3%) and from locoregional to systemic therapy in 9/108 (8.3%). Equivocal findings were encountered less frequently with PET (1/108, 0.9%) than conventional imaging (27/108, 25%).

CLINICAL RELEVANCE/APPLICATION

PSMA PET is more sensitive in identifying nodal and distant metastases at initial staging of men with unfavorable intermediate or high-risk prostate cancer, resulting in a frequent change in management.

SSNR14-1 Clinical Evaluation Of An AI-accelerated Two-minute Multi-shot EPI Protocol For Comprehensive High-quality Brain MRI In An Emergency And Inpatient Setting

Participants
Augusto Goncalves Filho, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Rapid, multi-contrast MRI of the brain can improve the evaluation of acutely ill patients who may not be able to tolerate prolonged exams. In this work, we performed an initial clinical evaluation of an artificial-intelligence-accelerated multi-shot echo-planar imaging (msEPI)-based method that provides multi-contrast images with high signal-to-noise ratio, high tissue contrast, and minimal distortions within two minutes.*Methods and Materials With IRB approval, 26 patients from emergency and inpatient care settings were prospectively scanned on two 3T systems (MAGNETOM Prisma and Skyra, Siemens) with prototype 2-min fast msEPI-based sequences including the following contrasts: T2, T2*, inversion recovery-based T1, T2-FLAIR, and diffusion-weighted imaging (Fig. 1). Corresponding clinical reference scans lasting 10-min using turbo spin echo (TSE) scans were also acquired for comparison. Two neuroradiologists blinded to sequence type independently reviewed the imaging data sets for the presence of 6 major imaging findings (intracranial masses, hemorrhage, WM hyperintensities, subarachnoid FLAIR, diffusion restriction, and hydrocephalus). The raters used a 3-point score to evaluate image degradation by noise and artifacts.*Results Data from 19 study participants were included (7 subjects excluded due to incomplete datasets). ICCs showed almost perfect interobserver agreement for the evaluation of intracranial masses (ICC = 1), WM hyperintensities (ICC = 0.83), diffusion restriction (ICC = 0.83), and hydrocephalus (ICC = 1); and substantial agreement for intracranial hemorrhage (ICC = 0.76) and subarachnoid FLAIR hyperintensities (ICC = 0.65). Comparisons of image quality (Fig. 2) showed increased noise on the msEPI exams for the T1, FLAIR and DWI (p<0.05) and increased artifacts on T2, T2* and FLAIR (p<0.05), without compromising detection of the imaging findings.*Conclusions The AI-accelerated 2-minute multi-shot EPI protocol provides rapid, comprehensive brain MRI evaluation of emergency and hospitalized patients with a high degree of interobserver agreement for major brain imaging findings, similar to that of a 10-minute conventional TSE-based protocol.*Clinical Relevance/Application A 2-min AI-accelerated multi-contrast brain MRI exam was evaluated in acutely ill patients and shown to detect most imaging findings, in agreement with those on a conventional 10-min brain MRI exam.

RESULTS

Data from 19 study participants were included (7 subjects excluded due to incomplete datasets). ICCs showed almost perfect interobserver agreement for the evaluation of intracranial masses (ICC = 1), WM hyperintensities (ICC = 0.83), diffusion restriction (ICC = 0.83), and hydrocephalus (ICC = 1); and substantial agreement for intracranial hemorrhage (ICC = 0.76) and subarachnoid FLAIR hyperintensities (ICC = 0.65). Comparisons of image quality (Fig. 2) showed increased noise on the msEPI exams for the T1, FLAIR and DWI (p<0.05) and increased artifacts on T2, T2* and FLAIR (p<0.05), without compromising detection of the imaging findings.

CLINICAL RELEVANCE/APPLICATION

A 2-min AI-accelerated multi-contrast brain MRI exam was evaluated in acutely ill patients and shown to detect most imaging findings, in agreement with those on a conventional 10-min brain MRI exam.

SSNR14-2 Multi-center Multi-reader Clinical Evaluation Of Deep Learning Model For 10x Dose Reduction In Contrast-enhanced Brain MRI With A Focus On Tumor Categorization

Participants
Srivathsa Venkata, MSc, Menlo Park, California (*Presenter*) Employee, Subtle Medical, Inc;Stockholder, Subtle Medical, Inc

PURPOSE

To evaluate the diagnostic performance of a deep learning (DL) algorithm for reduced gadolinium dosage through qualitative assessment and quantitative study.*Methods and Materials 3D T1-weighted scans for pre-contrast injection, low dose (10%), and full dose (100%) were acquired from 119 patients (59 females, 60 males;54+/-16 years) from 3 institutions and 3 scanners using different protocols. The dataset (56 train/13 validation/50 test) was used to train a DL model using the zero-dose and low-dose images to predict the full-dose image thus reducing the dosage by 90%. 50 test cases were randomized and presented to 3 board-certified neuroradiologists(10,15 & 23 years experience) who performed blinded evaluation of 100 image volumes (50 full-dose & 50 DL-synthesized). The evaluation criteria were tumor category (no tumor, enhancing, and non-enhancing tumors), overall image quality (IQ) and image artifacts(IA). IQ & IA were scored using a 5 point Likert scale. Confusion matrices for the individual readers were plotted for the 3 scoring criteria. Cohen's kappa scores were computed for pairwise agreement between readers on the tumor category for the DL-synthesized images. Enhancing tumor cases as identified by the readers were used to generate tumor masks using a DL-based tumor segmentation algorithm. Dice scores were computed between the masks of ground truth and DL

synthesized images.*Results Using a majority voting scheme among readers to determine outcome, 98% (49/50) agreement was observed for the tumor category. The 3 readers had substantial pairwise agreement of tumor category on the DL synthesized images (Cohen's kappa=0.61, 0.67 & 0.66 respectively). High values in the confusion matrix diagonals demonstrate good agreement in the tumor category. High values in the right bottom elements in the confusion matrices of IQ and IA show that the DL synthesized images are similar or better than the ground truth in terms of image quality and artifacts. Average Dice score was 0.88+/-0.06 (median = 0.91) for 17 enhancing tumor cases.*Conclusions DL algorithm reduced the gadolinium dosage by 90% with diagnostic equivalence and non-inferior image quality.*Clinical Relevance/Application Given the growing concerns over the use of gadolinium-based contrast agents, DL can reduce contrast dosage in diverse clinical settings.

RESULTS

Using a majority voting scheme among readers to determine outcome, 98% (49/50) agreement was observed for the tumor category. The 3 readers had substantial pairwise agreement of tumor category on the DL synthesized images (Cohen's kappa=0.61, 0.67 & 0.66 respectively). High values in the confusion matrix diagonals demonstrate good agreement in the tumor category. High values in the right bottom elements in the confusion matrices of IQ and IA show that the DL synthesized images are similar or better than the ground truth in terms of image quality and artifacts. Average Dice score was 0.88+/-0.06 (median = 0.91) for 17 enhancing tumor cases.

CLINICAL RELEVANCE/APPLICATION

Given the growing concerns over the use of gadolinium-based contrast agents, DL can reduce contrast dosage in diverse clinical settings.

SSNR14-3 It'S Not Magic - Image Quality Improvement Of High Resolution 3d Brain Images Using Deep Learning

Participants
Woojin Jung, Seoul, Korea, Republic Of (*Presenter*) Employee, AIRS Medical Inc

PURPOSE

Thanks to recent advances, modern clinical 3T MR system enables sub-millimeter resolution brain images. To achieve this, long scan time for sufficient signal-to-noise ratio (SNR) is required. However, it is not always possible, depending on clinical situation. Also, it might aggravate motion artifacts. While acquisition of high-resolution image with sufficient SNR in reasonable scan time is desirable, it is a challenging goal. In this study, we developed and applied a deep-learning-based approach to enhance image quality of high-resolution 3D T1-weighted images of the brain without an increase in scan time, and explore their clinical values.*Methods and Materials From 80 sets of 3D MPRAGE data (60 for training, 6 for validation, and 14 for test) with 0.7 x 0.7 x 0.7 mm3 resolution (TR/TE/TI = 2300/3.2/1040 ms, GRAPPA factor 2, scan time 320 s) at 3T clinical scanner, we trained and tested a deep-learning model adopted Noise2Noise framework as a fundamental architecture. For the assessment of image quality, visual appropriateness and identification of several clinically relevant anatomical structures were assessed by two experienced neuroradiologists. PSNR was calculated for quantitative image quality evaluation, using retrospective noise simulation from the two full-sampled data.*Results In all test set data, denoising was successfully applied in under-sampled data. In visual assessment, there was definite image quality improvement as compared to conventional reconstruction results, and to fully sampled data (n=2). Proposed images enabled clear depiction of putamina tail, cerebellar folia and hippocampus, as compared to conventional reconstruction images. Fine structures such as mammillothalamic tract, claustrum, periaqueductal gray, and substantia nigra were consistently and clearly identified. Some of them were not clearly seen in conventional reconstruction images, or even in fully sampled data. There was significant improvement of PSNR, demonstrating the performance of the proposed method for the image quality improvement.*Conclusions Our approach enables effective suppression of noise from undersampled MR images. As a result, we obtained 7T-like high resolution 3D T1 weighted images in about 5 minutes at 3T scanner. It would be helpful to detect abnormalities in fine structures and for deep brain stimulation targeting.*Clinical Relevance/Application From this approach, high-quality 3D T1-weigted images can be obtained in reasonable scan time at clinical 3T MR. It would be helpful to detect abnormalities in fine structures, such as hippocampus, and for deep brain stimulation targeting.

RESULTS

In all test set data, denoising was successfully applied in under-sampled data. In visual assessment, there was definite image quality improvement as compared to conventional reconstruction results, and to fully sampled data (n=2). Proposed images enabled clear depiction of putamina tail, cerebellar folia and hippocampus, as compared to conventional reconstruction images. Fine structures such as mammillothalamic tract, claustrum, periaqueductal gray, and substantia nigra were consistently and clearly identified. Some of them were not clearly seen in conventional reconstruction images, or even in fully sampled data. There was significant improvement of PSNR, demonstrating the performance of the proposed method for the image quality improvement.

CLINICAL RELEVANCE/APPLICATION

From this approach, high-quality 3D T1-weigted images can be obtained in reasonable scan time at clinical 3T MR. It would be helpful to detect abnormalities in fine structures, such as hippocampus, and for deep brain stimulation targeting.

SSNR14-5 K-space Based Deep Learning Reconstruction Empowers 60-70% Acceleration Of MR Imaging Of The Spine

Participants
Lawrence N. Tanenbaum, MD, Riverside, Connecticut (*Presenter*) Speaker, General Electric Company;Speaker, Siemens AG;Speaker, Guerbet SA;Speaker, Koninklijke Philips NV;Consultant, Enlitic, Inc;Consultant, icoMetrix NV;Consultant, Subtle Medical, Inc;Consultant, Columbo;Consultant, Canon Medical Systems Corporation;Consultant, FUJIFILM Holdings Corporation

PURPOSE

This prospective, multireader study evaluates the impact on perceived image quality of highly scan-time reduced cervical (72%) and lumbar (64%) spine MRI reconstructed with deep learning (DL).*Methods and Materials With IRB approval and patient consent, 26 consecutive patients underwent standard-of-care (SOC) and accelerated (FAST) spine MRI exams acquired on a GE 3T Architect scanner. DL processing of the FAST scan data set (FAST-DL) was performed using an FDA-cleared CNN based, DL image enhancement product - Air Recon DLTM. The k-space based tool offers powerful denoising, sharpness enhancement and elimination of some artifacts such as truncation ringing. Two neuroradiologists were presented with the image sets in a paired side-by-side fashion. Datasets were blinded and randomized in sequence and left-right display order. Image features were preference rated on a 5-point Likert scale for overall quality, structural conspicuity, cord/CSF contrast, sharpness, SNR and artifacts. Readers were

advised to search for image aberrations that could be attributable to DL processing.*Results FAST-DL was qualitatively better than SOC and FAST for perceived signal-to-noise ratio (SNR) sharpness and artifacts. No image aberrations were noted.*Conclusions DL enables 64-72% spine MRI scan time reduction as well as what radiologists perceive as enhanced image quality with benefits in SNR, image sharpness and artifact reduction over SOC and FAST images without DL processing, providing gains in efficiency and portending practice utility for routine use.*Clinical Relevance/Application Deep learning based MR image reconstruction techniques can reduce scan times and improve quality and are now commercially available from multiple vendors suggesting the potential for widespread use in practice.

RESULTS

FAST-DL was qualitatively better than SOC and FAST for perceived signal-to-noise ratio (SNR) sharpness and artifacts. No image aberrations were noted.

CLINICAL RELEVANCE/APPLICATION

Deep learning based MR image reconstruction techniques can reduce scan times and improve quality and are now commercially available from multiple vendors suggesting the potential for widespread use in practice.

SSNR14-6   Pilot Study To Evaluate The Feasibility Of Replacing Conventional Head CT Images With A Single Series Of Thin-slice, Low-noise Images Created Using A Multi-kernel Synthesis Method

Participants
Akitoshi Inoue, MD,PhD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

Multi-kernel synthesis (MKS) is a CNN method to create CT images with high spatial resolution in bone regions (as with bone reconstruction kernels) and low noise in brain regions (as with head reconstruction kernels). MKS creates a single, thin-slice image series that can display bone and brain pathology. Our purpose was to determine if MKS images are non-inferior to routine clinical images in diagnosing acute bone and brain lesions in head CT.*Methods and Materials 50 patients underwent head CT due to trauma or acute-onset symptoms. Axial MKS (0.75mm) and routine (bone [0.75mm] and brain [5mm and 0.75mm]) images were reconstructed. A non-reader neuroradiologist defined the reference standard for brain and bone pathology using routine CT, prior and follow-up CT/MRI, and medical records. Three neuroradiologists, blinded to clinical information, reviewed either MKS or routine images in two sessions, marking brain and bone pathologies and rating image quality. Subsequently, a side-by-side comparison was performed (-4=MKS is worse, 0=MKS is equal to routine, +4=MKS is better).*Results The reference standard included 20 fractures in 11 patients and 71 intracranial pathologies in 31 patients. Overall patient-level sensitivity and specificity were 0.89 (93/105; 95% CI: 0.70—0.95) and 0.84 (38/45; 95% CI: 0.68—1.00) for routine CT and 0.87 (91/105; 95% CI: 0.63—0.92) and 0.89 (40/45; 95% CI: 0.68—1.00) for MKS. For intracranial pathologies, sensitivity and specificity were 0.69 (95% CI: 0.62—0.75) and 0.81 (95% CI: 0.75—0.87) for routine CT and 0.69 (95% CI: 0.62—0.75) and 0.76 (95% CI: 0.69—0.82) for MKS. For fractures, lesion-level sensitivity and positive predictive value were 0.48 (95% CI: 0.35—0.62) and 0.81 (95% CI: 0.64—0.92) for routine CT and 0.40 (95% CI: 0.28—0.53) and 0.73 (95% CI: 0.54—0.87) for MKS. The comparison scores of brain and bone images were -0.17±1.30 (range: -2—3) and -0.31±0.57 (range: -2—1), respectively, indicating only subtle differences.*Conclusions Reader performance for identification of fractures and intracranial pathology in head CT was similar using a single series of thin-slice MKS images compared to routine clinical CT with different slice thicknesses and kernels.*Clinical Relevance/Application MKS creates a single series of low-noise, thin-slice images that can potentially replace multiple image series for head CT in the emergency setting.

RESULTS

The reference standard included 20 fractures in 11 patients and 71 intracranial pathologies in 31 patients. Overall patient-level sensitivity and specificity were 0.89 (93/105; 95% CI: 0.70—0.95) and 0.84 (38/45; 95% CI: 0.68—1.00) for routine CT and 0.87 (91/105; 95% CI: 0.63—0.92) and 0.89 (40/45; 95% CI: 0.68—1.00) for MKS. For intracranial pathologies, sensitivity and specificity were 0.69 (95% CI: 0.62—0.75) and 0.81 (95% CI: 0.75—0.87) for routine CT and 0.69 (95% CI: 0.62—0.75) and 0.76 (95% CI: 0.69—0.82) for MKS. For fractures, lesion-level sensitivity and positive predictive value were 0.48 (95% CI: 0.35—0.62) and 0.81 (95% CI: 0.64—0.92) for routine CT and 0.40 (95% CI: 0.28—0.53) and 0.73 (95% CI: 0.54—0.87) for MKS. The comparison scores of brain and bone images were -0.17±1.30 (range: -2—3) and -0.31±0.57 (range: -2—1), respectively, indicating only subtle differences.

CLINICAL RELEVANCE/APPLICATION

MKS creates a single series of low-noise, thin-slice images that can potentially replace multiple image series for head CT in the emergency setting.

SSNR09-1 Admission NIHSS As A Clinical Marker Of Penumbra Underestimates The Size Of Tissue-at-Risk In Right Versus Left-Sided Large Vessel Occlusion Stroke

Participants
Adrian Mak, New Haven, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

Admission NIHSS is used as clinical surrogate for penumbra when determining eligibility for endovascular therapy (ET) in the 6-24 hours extended time window after acute large vessel occlusion (LVO) stroke. However, it is known that the admission NIHSS for an infarct of a given volume is higher in left compared to right hemispheric stroke. We aimed to determine the effects of LVO side on final infarct volume and clinical outcome after ET with regards to admission NIHSS score.*Methods and Materials We analyzed the post-thrombectomy infarct volume and distribution as well as discharge outcome in patients with anterior LVO that received ET and follow-up MRI. We applied a multivariate voxel-wise general linear model to assess infarct distribution in relation to admission NIHSS, post-thrombectomy reperfusion (mTICI), and discharge modified Rankin Scale (mRS) score. We performed multivariate regression analyses to identify independent predictors of clinical and tissue outcomes, and ANOVA to investigate their interactions.*Results A total of 469 patients were included (254 left; 215 right). Admission NIHSS was higher among those with left (median 16: IQR 10-22) versus right-sided LVO (11: 8-16, p>0.001). In voxel-wise analysis, worse reperfusion (lower mTICI), lower admission NIHSS, and poor discharge outcome (mRS >2) were associated with right-hemispheric infarct lesions. In multivariate analysis, right-sided LVO was an independent predictor of larger final infarct volume (ß=18.3, p=0.003). There was a significant three-way interaction between admission stroke severity (based on NIHSS), LVO side, and mTICI regarding infarct volume (F(7,440)=2.11, p=0.041). Specifically, in patients with moderate stroke (NIHSS 6-15), incomplete reperfusion (mTICI 0-2b) was associated with larger infarct volume (55.5±76.6ml vs. 30.0±47.2ml, p<0.001) and worse discharge mRS (4: 2-4 vs. 3: 1-4, p=0.022) in right compared to left-sided LVO. More tissue is saved for each degree of mTICI in patients with moderate stroke and right-sided LVO (F(4,440)=3.19, p=0.013).*Conclusions Incomplete reperfusion leads to larger infarction of eloquent brain tissue and worse clinical outcome in patients with right-sided LVO compared to left-sided LVO. These results likely represent larger tissue-at-risk in patients with right-sided LVO for a given admission NIHSS score.*Clinical Relevance/Application Using admission NIHSS as "clinical penumbra" for ET eligibility may lead to underestimation of tissue-at-risk and consequently to undertreatment among patients with right-sided LVO, highlighting the advantage of objective imaging biomarkers for penumbra.

RESULTS

A total of 469 patients were included (254 left; 215 right). Admission NIHSS was higher among those with left (median 16: IQR 10-22) versus right-sided LVO (11: 8-16, p>0.001). In voxel-wise analysis, worse reperfusion (lower mTICI), lower admission NIHSS, and poor discharge outcome (mRS >2) were associated with right-hemispheric infarct lesions. In multivariate analysis, right-sided LVO was an independent predictor of larger final infarct volume (ß=18.3, p=0.003). There was a significant three-way interaction between admission stroke severity (based on NIHSS), LVO side, and mTICI regarding infarct volume (F(7,440)=2.11, p=0.041). Specifically, in patients with moderate stroke (NIHSS 6-15), incomplete reperfusion (mTICI 0-2b) was associated with larger infarct volume (55.5±76.6ml vs. 30.0±47.2ml, p<0.001) and worse discharge mRS (4: 2-4 vs. 3: 1-4, p=0.022) in right compared to left-sided LVO. More tissue is saved for each degree of mTICI in patients with moderate stroke and right-sided LVO (F(4,440)=3.19, p=0.013).

CLINICAL RELEVANCE/APPLICATION

Using admission NIHSS as "clinical penumbra" for ET eligibility may lead to underestimation of tissue-at-risk and consequently to undertreatment among patients with right-sided LVO, highlighting the advantage of objective imaging biomarkers for penumbra.

SSNR09-3 High-Speed Angiography At 1000 Fps Used To Assess Blood Flow Changes Induced By A Flow Diverting Stent In-Vitro

Participants
Allison Shields, Buffalo, New York (*Presenter*) Research Grant, Canon Medical Systems Corporation

PURPOSE

Flow diversion is a well-established endovascular treatment option for intracranial aneurysms (IA's). Current evaluation of treatment success is generally restricted to qualitative evaluation of low-frame rate angiographic sequences. High-speed angiography (HSA) was utilized to perform a quantitative assessment of hemodynamic changes induced by a flow diverting (FD) stent.*Methods and Materials Blood flow changes were evaluated in a 3D-printed, patient-specific middle cerebral artery (MCA) saccular aneurysm model. Baseline images of the flow into the aneurysm were acquired using 1000 fps HSA, enabled by a 5x7.5 cm FOV photon-counting detector. Iodinated contrast injections were performed with an automated syringe injector, operated at a constant rate and volume for all acquisitions. Flow was evaluated before treatment and after partial and full deployment of a Flow-Redirecting

Endoluminal Device (FRED) stent. Individual 1-ms images were evaluated sequentially to determine the flow velocity in the aneurysm sac using an optical flow method.*Results Flow patterns in the high-speed sequences showed reduction of vortex flow in the aneurysm after full FRED deployment. This phenomenon was further illustrated through the change in streamlines between each deployment stage, which were calculated from the 1-ms velocity distributions obtained via optical flow. Partial FD deployment, which is comparable to suboptimal device deployment or sizing, in this case resulted in more contrast entering the aneurysm and thus had little flow diversion effect. Post-FD analysis showed a drastic improvement in both the magnitude and spatial distribution of velocities in the aneurysm sac, at a resolution of one vector per 100 μm.*Conclusions This study illustrated the ability of HSA to provide high-temporal resolution, quantitative hemodynamic information before and after deployment of a FD stent. These results demonstrate the feasibility of using such a method in an interventional setting to evaluate detailed velocity distribution changes following IA treatment, which could be used as an additional predictive measure of treatment outcome at the time of the procedure.*Clinical Relevance/Application High-temporal resolution, quantitative-flow data obtained during the endovascular intervention may provide additional key information to assess the efficacy of the intervention.

RESULTS

Flow patterns in the high-speed sequences showed reduction of vortex flow in the aneurysm after full FRED deployment. This phenomenon was further illustrated through the change in streamlines between each deployment stage, which were calculated from the 1-ms velocity distributions obtained via optical flow. Partial FD deployment, which is comparable to suboptimal device deployment or sizing, in this case resulted in more contrast entering the aneurysm and thus had little flow diversion effect. Post-FD analysis showed a drastic improvement in both the magnitude and spatial distribution of velocities in the aneurysm sac, at a resolution of one vector per 100 μm.

CLINICAL RELEVANCE/APPLICATION

High-temporal resolution, quantitative-flow data obtained during the endovascular intervention may provide additional key information to assess the efficacy of the intervention.

SSGI12-1   Iodine Quantification In Patients With Clinical Scans On Different Dual-energy CT Scanners: Impact Of Normalization On Inter-scanner Variability

Participants
Simon Lennartz, MD, Boston, Massachusetts (*Presenter*) Institutional research support, Koninklijke Philips NV

PURPOSE

To compare intra-patient iodine quantification between different dual-energy CT (DECT) scanner types and investigate normalization to mitigate clinical inter-scanner variability.*Methods and Materials 44 patients who underwent regular abdominal CT for cancer follow-up on a dual-source (dsDECT), a rapid kVp switching (rsDECT) and a dual-layer detector scanner (dlDECT) between 01/2016 and 09/2020 were included. Iodine concentrations were obtained ROI-based in the liver, pancreas, kidney, aorta, portal vein, muscle, gallbladder and retroperitoneal fat. Absolute (IC) and three different normalized iodine concentrations (NICAA: normalized to aorta; NICPV: normalized to portal vein; NICALL: normalized to overall iodine load of the liver, kidneys, pancreas, aorta, portal vein) were compared between scanner types and median inter-scanner variability was calculated.*Results The time between CT exams on different scanners as well as the amount of iodinated contrast media that was applied were comparable for all inter-scanner comparisons (p-range: 0.9-0.99). IC was significantly different between DECT scanner types for all tissues included except for the kidney and the aorta; largest differences in IC between scanner types were found in the liver and in the retroperitoneal fat. The median inter-scanner variability of IC was highest in the liver for all inter-scanner comparisons (dsDECT vs dlDECT: 24.97% (13.73-47.55%); dsDECT vs rsDECT: 27.51% (14.61-57.85%); rsDECT vs dlDECT: 22.59% (8.24-35.02%)), lowest for the kidneys (dsDECT vs dlDECT: 14.89% (7.41-26.12%); dsDECT vs rsDECT: 14.79%(8.86-23.91%); rsDECT vs dlDECT: 11.19% (4.16-23.02%)) and intermediate for the pancreas (dsDECT vs dlDECT 21.23% (6.96-37.37%); dsDECT vs rsDECT 19.86 % (10.9-27.14%); rsDECT vs dlDECT: 12.81% (7.63-27.16%)). NICALL was the only normalization approach that decreased inter-scanner variability of the pancreas and kidneys for all inter-scanner comparisons, whereas for the liver, it only reduced variability between rsDECT and dlDECT (NICALL: 18.21% (8.52-27.94) vs IC: 22.59% (8.24-35.02)).*Conclusions Inter-scanner variability of iodine quantification in DECT can in part be mitigated by normalization, yet variability in the liver remains on a high level. *Clinical Relevance/Application Inter-scanner variability of iodine quantification in DECT should be acknowledged if the latter is used longitudinally in patients examined on different DECT scanner types.

RESULTS

The time between CT exams on different scanners as well as the amount of iodinated contrast media that was applied were comparable for all inter-scanner comparisons (p-range: 0.9-0.99). IC was significantly different between DECT scanner types for all tissues included except for the kidney and the aorta; largest differences in IC between scanner types were found in the liver and in the retroperitoneal fat. The median inter-scanner variability of IC was highest in the liver for all inter-scanner comparisons (dsDECT vs dlDECT: 24.97% (13.73-47.55%); dsDECT vs rsDECT: 27.51% (14.61-57.85%); rsDECT vs dlDECT: 22.59% (8.24-35.02%)), lowest for the kidneys (dsDECT vs dlDECT: 14.89% (7.41-26.12%); dsDECT vs rsDECT: 14.79%(8.86-23.91%); rsDECT vs dlDECT: 11.19%(4.16-23.02%)) and intermediate for the pancreas (dsDECT vs dlDECT 21.23% (6.96-37.37%); dsDECT vs rsDECT 19.86 % (10.9-27.14%); rsDECT vs dlDECT: 12.81% (7.63-27.16%)). NICALL was the only normalization approach that decreased inter-scanner variability of the pancreas and kidneys for all inter-scanner comparisons, whereas for the liver, it only reduced variability between rsDECT and dlDECT (NICALL: 18.21% (8.52-27.94) vs IC: 22.59% (8.24-35.02)).

CLINICAL RELEVANCE/APPLICATION

Inter-scanner variability of iodine quantification in DECT should be acknowledged if the latter is used longitudinally in patients examined on different DECT scanner types.

SSGI12-2   Orally Administered Mangoral (Manganese Chloride Tetrahydrate) And Intravenously Administered Gadobenate Dimeglumine For MRI Of Colorectal Liver Metastases - An Intraindividual Comparison

Participants
Kohkan Shamsi, MD, PhD, Conshohocken, Pennsylvania (*Presenter*) Consultant, Ascelia Pharma

PURPOSE

The purpose of the study was to compare the diagnostic efficacy of orally administered mangoral-enhanced MRI (MMRI) with intravenously administered gadobenate-enhanced MRI (GMRI).*Methods and Materials This is an independent re-read of a previously reported phase II, single center study in which 20 patients with colorectal liver metastases underwent both MMRI and

GMRI within 1 week interval. Three independent radiologists (R1, R2, R3) evaluated unenhanced and enhanced T1 and T2-weighted images describing number and size of the detected lesions and also assessed lesion border delineation and lesion contrast compared to liver using a 4-point scale. A fourth radiologist tracked and matched the lesions identified by each of the three readers and performed additional quantitative assessments on T1-weighted images. Descriptive statistics and CI were used to assess the differences.*Results A higher number of liver lesions were detected by MMRI compared to GMRI by all 3 readers with overlapping 95%-confidence intervals (CI) (mean lesion number: R1: 2.15 vs 1.60; R2: 2.40 vs 2.15; 3.00 vs 2.65 for MMRI and GMRI respectively). For border delineation, the scores for MMRI ranged from 6.40-9.37 compared to 4.41-7.79 for GMRI. Two out of 3 readers showed higher scores for lesion delineation for MMRI compared to GMRI with overlapping CIs. Two out of 3 readers had higher scores for MMRI for lesion contrast compared to the liver with overlapping CIs (MMRI score: 6.80-10.84; GMRI score: 5.18-8.74). Signal-to-noise ratio was 95 for MMRI and 96 for GMRI, lesion-to-liver contrast was 1.97 for MMRI and 1.65 for GMRI. The liver enhancement ratio was 1.60 for MMRI and 1.31 for GMRI with overlapping CIs. Compared to unenhanced MRI, both MMRI and GMRI enabled detection of smaller lesions.*Conclusions Orally administered manganese enhanced MRI showed similar efficacy in terms of lesion detection, lesion visualization, lesion to liver contrast and lesion delineation of liver metastases as compared to intravenous gadolinium enhanced MRI.*Clinical Relevance/Application Orally administered Mangoral, a manganese based liver specific contrast agent, could be a valuable alternative for MRI of the liver in patients in whom use of gadolinium agents is restricted or contra-indicated.

RESULTS

A higher number of liver lesions were detected by MMRI compared to GMRI by all 3 readers with overlapping 95%-confidence intervals (CI) (mean lesion number: R1: 2.15 vs 1.60; R2: 2.40 vs 2.15; 3.00 vs 2.65 for MMRI and GMRI respectively). For border delineation, the scores for MMRI ranged from 6.40-9.37 compared to 4.41-7.79 for GMRI. Two out of 3 readers showed higher scores for lesion delineation for MMRI compared to GMRI with overlapping CIs. Two out of 3 readers had higher scores for MMRI for lesion contrast compared to the liver with overlapping CIs (MMRI score: 6.80-10.84; GMRI score: 5.18-8.74). Signal-to-noise ratio was 95 for MMRI and 96 for GMRI, lesion-to-liver contrast was 1.97 for MMRI and 1.65 for GMRI. The liver enhancement ratio was 1.60 for MMRI and 1.31 for GMRI with overlapping CIs. Compared to unenhanced MRI, both MMRI and GMRI enabled detection of smaller lesions.

CLINICAL RELEVANCE/APPLICATION

Orally administered Mangoral, a manganese based liver specific contrast agent, could be a valuable alternative for MRI of the liver in patients in whom use of gadolinium agents is restricted or contra-indicated.

SSGI12-3   Gallstones Detection On Dual Energy Computerized Tomography (DECT)- Is It Ready For Real-world Use? A Retrospective Observational Study

Participants
Shambo Guha Roy, MBBS, Darby, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Historically, CT was not seen as a reliable imaging modality for detection of gallstones (GS), as most of them are non-calcified. However, with growing use of DECT it is time to reevaluate this notion. The advanced reconstruction algorithm of DECT in the form of virtual non contrast (VNC) and virtual monochromatic (VMC) images improve the ability to detect non-calcified GS which was shown in a few preliminary studies. However, none of them included a control group, thus the real-world sensitivity and specificity of DECT for GS detection is yet to be addressed.*Methods and Materials This IRB approved retrospective study included all the patients between January 2018 through December 2020 who underwent both DECT of the abdomen and right upper quadrant ultrasound (US) within 6 months of each other. The presence or absence of GS on US was used as standard. All the DECT were acquired in the portal phase and all of them includes polychromatic, VNC, VMC at 50Kev and Iodine map images in axial plane. The CTs were reviewed by 4 attending radiologists, who were blinded to the US results. The CT results were taken as either positive or negative for GS when at least 3 readers were in agreement. In case of a 2:2 results, a 5th reader was used.*Results A total of 209 DECT were reviewed. Among them 106 (48 males) had GS on US and 103 (43 males) were negative for GS. Patients with GS were significantly older with mean age 61.5+16.3 years compared patients without GS (mean age 53.3+15.7 years). In 197 of 209 DECTs there was 3:1 agreement between the readers. The rest of the 12 DECTs were reviewed by a 5th radiologist. The agreement between 4 readers was assessed using Fleiss' Kappa which was 0.76 suggesting a substantial agreement. The DECT was reported as positive in 95 out of 106 patients with US proven GS. Furthermore, 98 out of 103 patient without gallstone on US were reported as negative on DECT. The overall sensitivity, specificity, positive predictive value, negative predictive value and accuracy were 89.6%, 95.1%, 95%, 89.9% and 92.3%. Of note, in the actual DECT report only 74 out of 106 patients were reported as positive for GS, corresponding to a sensitivity of only 69.8%, suggesting an education opportunity.*Conclusions DECT has excellent sensitivity and specificity for detection of GS. VNC and low energy VMC images increase the detectability of GS over the standard polychromatic images. Further research is needed to evaluate results of training and establishment of formal diagnostic criteria on improving interobserver agreement.*Clinical Relevance/Application To our knowledge this is the first paper to address the real-world accuracy of DECT for detection of GS and demonstrating strong clinical value of VNC and VMC images for increasing GS detection rate when DECT is utilized for abdominal imaging.

RESULTS

A total of 209 DECT were reviewed. Among them 106 (48 males) had GS on US and 103 (43 males) were negative for GS. Patients with GS were significantly older with mean age 61.5+16.3 years compared patients without GS (mean age 53.3+15.7 years). In 197 of 209 DECTs there was 3:1 agreement between the readers. The rest of the 12 DECTs were reviewed by a 5th radiologist. The agreement between 4 readers was assessed using Fleiss' Kappa which was 0.76 suggesting a substantial agreement. The DECT was reported as positive in 95 out of 106 patients with US proven GS. Furthermore, 98 out of 103 patient without gallstone on US were reported as negative on DECT. The overall sensitivity, specificity, positive predictive value, negative predictive value and accuracy were 89.6%, 95.1%, 95%, 89.9% and 92.3%. Of note, in the actual DECT report only 74 out of 106 patients were reported as positive for GS, corresponding to a sensitivity of only 69.8%, suggesting an education opportunity.

CLINICAL RELEVANCE/APPLICATION

To our knowledge this is the first paper to address the real-world accuracy of DECT for detection of GS and demonstrating strong clinical value of VNC and VMC images for increasing GS detection rate when DECT is utilized for abdominal imaging.

SSGI12-5   Computer-aided Liver Metastases Follow-up Changes Analysis In Cect By Volumetric Deep Learning: A Comparative Study To Linear Recist 1.1

Participants
Leo Joskowicz, Jerusalem, Israel (*Presenter*) Officer, HighRAD Ltd

PURPOSE

To compare disease status classification of abdominal contrast enhanced CT (CECT) of liver metastases by radiologists to computer-aided reading with a novel deep learning classification method that simultaneously analyzes liver metastasis changes between the current and the prior CECT scans.*Methods and Materials Forty-three pairs of current and prior CECT scan studies of patients with metastatic liver disease were retrospectively analyzed. The pairs of scans were acquired 4.9 (std=4.3, range=1.4-21.0) months apart. The total number of liver metastases in all scans was 1,041 (mean=12.1, std=11.9, range=1-21). Two radiologists performed a total of 172 readings to assess disease status classification using linear measurements with RECIST 1.1 (43 pairs each) and after two weeks with computer-aided evaluation (43 pairs each). The primary outcome measure was the disease status and the tumor burden difference (TBD). The reference standard was defined by a third radiologist who manually delineated all lesions and graded the disease status.Computer aided evaluation was performed with our novel method. It inputs the prior and current CECT scans and automatically detects and segments the liver metastases in each scan with a simultaneous 3D U-Net classifier. It identifies the changes in the number of metastases and computes the total metastases' volume and the metastases' burden changes. The 3D U-Net was trained on 68 additional pairs of CECT scans of patients with metastatic disease with a total of 2,042 liver metastases.*Results There was agreement between the conventional and computer-aided readings by the two radiologists in 62 (72%) readings of cases (PR=12, SD=26,PD=24) and discrepancy between them in 24 (28%) of cases (PR vs. SD =1, PR vs. PD = 1, SD vs. PR = 11, SD vs. PD = 8, PD vs. SD = 3). Of the 24 reading discrepancies, 19 (73%) were between SD vs. PR or SD vs. PD. The difference between the RECIST 1.1 and the computer aided readings was statistically significant (p=0.02). The main reason for the difference between the conventional and the computer-aided readings was the TBD (p=0.01). In comparison to the third reader reference standard, both readers using the computerized tools had no statistically significant categorization differences (p= 0.07-0.57).*Conclusions Automatic liver metastases change analysis by deep learning can accurately and reliably compute the changes in the number of metastases, the total metastases volume, and the metastases burden between prior and current CECT scans.*Clinical Relevance/Application AI-based computer-aided automatic liver metastases detection and volume change may improve the estimation of changes of neoplastic involvement of the liver and the accuracy of disease status evaluation.

RESULTS

There was agreement between the conventional and computer-aided readings by the two radiologists in 62 (72%) readings of cases (PR=12, SD=26,PD=24) and discrepancy between them in 24 (28%) of cases (PR vs. SD =1, PR vs. PD = 1, SD vs. PR = 11, SD vs. PD = 8, PD vs. SD = 3). Of the 24 reading discrepancies, 19 (73%) were between SD vs. PR or SD vs. PD. The difference between the RECIST 1.1 and the computer aided readings was statistically significant (p=0.02). The main reason for the difference between the conventional and the computer-aided readings was the TBD (p=0.01). In comparison to the third reader reference standard, both readers using the computerized tools had no statistically significant categorization differences (p= 0.07-0.57).

CLINICAL RELEVANCE/APPLICATION

AI-based computer-aided automatic liver metastases detection and volume change may improve the estimation of changes of neoplastic involvement of the liver and the accuracy of disease status evaluation.

SSGI12-6   Clinical And Gd-EOB-DTPA-enhanced MR Imaging Features Associated With High Risk Hepatic Adenomas

Participants
Justin Tse, MD, Cerritos, California (*Presenter*) Research Grant, General Electric Company ;Research Grant, Bayer AG

PURPOSE

To identify clinical and quantitative Gd-EOB-DTPA-enhanced MR imaging features associated with high-risk hepatic adenomas (defined as beta-catenin-activated exon 3 genotype (BCAex3) or hemorrhage on surgical pathology).*Methods and Materials In this retrospective, IRB-approved, and HIPAA compliant study, 64 hepatic adenomas (HCAs) from 53 adult patients (46 female, 7 male) from 2009-2020 with Gd-EOB-DTPA-enhanced MRI and tissue pathology were reviewed. HCAs were classified as inflammatory (I-HCA), hepatocyte nuclear factor-1 alpha mutated (H-HCA), beta-catenin-activated exon 3 (B-HCA), mixed beta-catenin-activated exon 3 inflammatory (BI-HCA), or unclassified (U-HCA) with immunohistochemistry. Signal intensity ratios (SIR) were calculated by comparing regions of interests of HCA to adjacent liver.*Results 64 HCAs were classified into 31 I-HCA, 16 H-HCA, 6 B-HCA, 4 BI-HCA, and 7 U-HCA. BCAex3 genotype was associated with male sex (p=0.004; logistic regression) but not symptoms, AFP, age, BMI, or number of HCAs. Increased HCA size was associated with both hemorrhage (p=0.004) and BCAex3 genotype (p=0.001). On Gd-EOB-DTPA-enhanced MRI, only the hepatobiliary phase could distinguish among subtypes. Hepatobiliary phase SIR ± standard deviation were: I-HCA=0.70±0.08; H-HCA =0.46±0.12; B-HCA or BI-HCA=1.04±0.21; U-HCA=0.75±0.12; p=0.004, one-way ANOVA). Post hoc Tukey test for multiple comparisons showed that SI ratios for I-HCA, H-HCA, and B-HCA or BI-HCA were statistically different from each other (p<0.0001). Sensitivity and specificity of hepatobiliary phase SIR>0.8 for identifying BCAex3 genotype was 90% and 93%, respectively.*Conclusions BCAex3 genotype was associated with higher hepatobiliary phase SIR, larger HCA size, and male sex. Histopathologic hemorrhage was associated with larger size.*Clinical Relevance/Application Current guidelines (European Association for the Study of the Liver) recommend HCA management based on patient sex and lesion size, but not subtype. Noninvasive identification of BCAex3 genotype (most likely to undergo malignant transformation) or those more likely to bleed may improve risk stratification.

RESULTS

64 HCAs were classified into 31 I-HCA, 16 H-HCA, 6 B-HCA, 4 BI-HCA, and 7 U-HCA. BCAex3 genotype was associated with male sex (p=0.004; logistic regression) but not symptoms, AFP, age, BMI, or number of HCAs. Increased HCA size was associated with both hemorrhage (p=0.004) and BCAex3 genotype (p=0.001). On Gd-EOB-DTPA-enhanced MRI, only the hepatobiliary phase could distinguish among subtypes. Hepatobiliary phase SIR ± standard deviation were: I-HCA=0.70±0.08; H-HCA =0.46±0.12; B-HCA or BI-HCA=1.04±0.21; U-HCA=0.75±0.12; p=0.004, one-way ANOVA). Post hoc Tukey test for multiple comparisons showed that SI ratios for I-HCA, H-HCA, and B-HCA or BI-HCA were statistically different from each other (p<0.0001). Sensitivity and specificity of hepatobiliary phase SIR>0.8 for identifying BCAex3 genotype was 90% and 93%, respectively.

CLINICAL RELEVANCE/APPLICATION

Current guidelines (European Association for the Study of the Liver) recommend HCA management based on patient sex and lesion size, but not subtype. Noninvasive identification of BCAex3 genotype (most likely to undergo malignant transformation) or those more likely to bleed may improve risk stratification.

SSMK05-2   Deep Learning Based Fully Automated 3D Models Of Hip Labrum Based On MR Arthrography Are Feasible And Allow Detection Of Differences In Labrum Volume Among Different Hip Deformities: A Pilot Study

Participants

Malin Meier, MD, Bern, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

Evaluation of hip labrum is mainly based on morphologic 2D MRI. 3D reconstruction is possible via manual segmentation, but is time consuming and therefore not part of clinical practice. We aimed to (1) develop and validate a deep learning approach for fully automatic labrum segmentation based on MR hip arthrography against manual segmentation; (2) compare labrum volume among different hip deformities.*Methods and Materials IRB-approved retrospective study of 48 patients (mean age 31 ± 9 years, 52% women) with femoroacetabular impingement and hip dysplasia (DDH) undergoing 3T MR arthrography including a 3D T1 MP2RAGE sequence (0.5 x 0.5 x 1 mm voxel size). Patients were assigned to three subgroups based on acetabular coverage assessed on AP pelvic radiographs: DDH with a lateral center edge angle (LCE<23°; n=20), normal acetabular coverage (LCE 23-38°; n=13), and deep/ retroverted hips (LCE>38°; n=15). Manual segmentations of labrum served as training data for the neural network (3D U-Net) to obtain an automated 3D labrum model. A 5-fold cross validation was performed and dice-, spearman correlation coefficient and mean bias were calculated to assess the accuracy between manual and automatic segmented labrum models. Kruskal-Wallis test was performed to compare labrum volume among different hip pathologies followed by pairwise comparisons using Mann-Whitney test.*Results Spatial overlap (dice coefficient) of 3D manual and automatic labrum models was 76 ± 5 % corresponding to a mean bias of 90 mm3 (95%CI: -24.4 to 203.5, p = 0.12) and almost perfect correlation (rs = 0.90, p <0.0001). Mean labrum volume differed (p = 0.025) among the hip deformities with 2840 ±1332 mm3 for DDH, 1825 ± 488 mm3 for normal coverage and 2341 ± 670 mm3 for deep / retroverted hips: Pairwise comparison showed significant differences in labrum volume between normal coverage and DDH (p = 0.010) and between normal coverage and deep / retroverted hips (p = 0.0367). Labrum volume between DDH and deep / retroverted hips did not differ significantly (p = 0.587).*Conclusions This pilot study shows the feasibility of automatic segmentation of 3D labrum models using deep learning methods, allowing detection of differences in labrum volume across different hip deformities.*Clinical Relevance/Application This validation highlights the potential for 3D assessment of labrum in large data sets and paves way to routine use of these 3D MRI labrum models to potentially improve surgical decision making.

RESULTS

Spatial overlap (dice coefficient) of 3D manual and automatic labrum models was 76 ± 5 % corresponding to a mean bias of 90 mm3 (95%CI: -24.4 to 203.5, p = 0.12) and almost perfect correlation (rs = 0.90, p <0.0001). Mean labrum volume differed (p = 0.025) among the hip deformities with 2840 ±1332 mm3 for DDH, 1825 ± 488 mm3 for normal coverage and 2341 ± 670 mm3 for deep / retroverted hips: Pairwise comparison showed significant differences in labrum volume between normal coverage and DDH (p = 0.010) and between normal coverage and deep / retroverted hips (p = 0.0367). Labrum volume between DDH and deep / retroverted hips did not differ significantly (p = 0.587).

CLINICAL RELEVANCE/APPLICATION

This validation highlights the potential for 3D assessment of labrum in large data sets and paves way to routine use of these 3D MRI labrum models to potentially improve surgical decision making.

SSMK05-3   Deep Learning Tool For Accurate And Precise Automatic Measurement Of Femoral Component Subsidence Following Total Hip Arthroplasty From Plain Radiographs

Participants

Pouria Rouzrokh, MD,MPH, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

Femoral component subsidence is a worrisome radiographic finding following total hip arthroplasty (THA) that may be a sign of loosening and prosthesis failure. Subsidence is usually assessed on two consecutive anteroposterior (AP) hip radiographs, a manual process that is tedious and prone to measurement errors. This study introduces a deep learning tool to automatically measure the femoral component subsidence between two serial AP radiographs.*Methods and Materials We first trained a dynamic UNet to automatically segment femur, implant, and magnification markers on a dataset of 700 (500 training, 100 validation, and 100 test) AP hip radiographs. Input images were zero-padded, resized to 2048×2048-pixel resolution, normalized, and finally augmented using a variation of random rotation (range: -20 to +20°), random zooming (max: 10%), and the addition of Gaussian noise. The UNet had an an ImageNet-pretrained EfficientNetB0 architecture as its encoder and used Squeeze and Excitation attention layers in its decoder. We trained the model with an Adam optimizer, while changing the learning rate following a one-cycle learning rate policy. After training the UNet model, an image processing algorithm was developed to calculate subsidence by: (1) measuring the femur-

stem distance on segmented masks for two AP radiographs, (2) correcting the measured distances based on radiographs' magnification, and (3) subtracting the two standardized femur-stem distances. We finally compared the algorithm's performance with manual subsidence measurements by two independent orthopedic surgeon reviewers on 135 unseen patients.*Results The deep learning algorithm achieved the Dice Similarity Coefficients of 0.97, 0.98, and 0.94 for segmenting the femur, implant, and the magnification markers respectively. Among the 135 test cases, 96 had documented subsidence of > 0.04 mm (range: 0.04-14.01). The mean, median, and the standard deviation of measurement discrepancy between the automatic and manual measurements were 0.57, 0.35, and 0.74 mm, respectively. Our tool quantified subsidence as small as 0.1 mm. An app version of the tool was also developed to showcase its automatic usability (Figure).*Conclusions We developed a fully automatic deep learning tool to measure subtle femoral component subsidence without human annotation. Performance metrics indicate highly accurate and precise measurements compared to human annotation, with very infrequent clinically relevant discrepancies.*Clinical Relevance/Application The automatic deep learning tool may improve THA surveillance and earlier detection of impending component failure. Also, the automatic nature of our tool can help for quick and easy annotation of big imaging datasets for research purposes.

RESULTS

The deep learning algorithm achieved the Dice Similarity Coefficients of 0.97, 0.98, and 0.94 for segmenting the femur, implant, and the magnification markers respectively. Among the 135 test cases, 96 had documented subsidence of > 0.04 mm (range: 0.04-14.01). The mean, median, and the standard deviation of measurement discrepancy between the automatic and manual measurements were 0.57, 0.35, and 0.74 mm, respectively. Our tool quantified subsidence as small as 0.1 mm. An app version of the tool was also developed to showcase its automatic usability (Figure).

CLINICAL RELEVANCE/APPLICATION

The automatic deep learning tool may improve THA surveillance and earlier detection of impending component failure. Also, the automatic nature of our tool can help for quick and easy annotation of big imaging datasets for research purposes.

SSMK05-4   Random Forest-based Radiomics Models For Preoperative Prediction Of Multiple Classifications Of Pelvic And Sacral Tumors

Participants
Ping Yin, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Pelvic and sacral tumors vary in type, but they are treated differently. Accurate preoperative identification of these tumors is essential for the development of individualized treatment. This study aimed to assess the performance of random forest (RF)-based radiomics approaches based on 3D computed tomography (CT) and clinical features to predict the types of pelvic and sacral tumors.*Methods and Materials A total of 795 patients with pathologically confirmed pelvic and sacral tumors were analyzed, including metastatic tumors (n = 181), chordomas (n = 85), giant cell tumors (n =120), chondrosarcoma (n = 127), osteosarcoma (n = 106), neurogenic tumors (n = 95), and Ewing's sarcoma (n = 81). After semi-automatic segmentation, 1316 hand-crafted radiomics features of each patient were extracted. First, we divided the patients into the benign tumors group and malignant tumors group, and built the first radiomics model (RM1) by using RF. RM2, a two-class RF-based radiomics model, was built to identify GCTs and neurogenic tumors. After that, we constructed two triple-classification models, namely, RM3 and RM4. RM3 was used to identify metastatic tumors, chordomas, and sarcomas. RM4 was used to identify osteosarcomas, chondrosarcomas, and Ewing's sarcomas. In addition, we also constructed a seven-classification model, namely, clinica-RM5, to identify these seven types of tumors. The area under the receiver operating characteristic curve (AUC) and accuracy (ACC) were used to evaluate different models.*Results In total, 795 patients (432 males, 363 females; mean age of 42.1 ± 17.8 years) were consisted of 215 benign tumors and 580 malignant tumors. The sex, age, history of malignancy and tumor location had significant differences between benign and malignant tumors (P < 0.05). For the two-class models, clinical-RM2 (AUC = 0.928, ACC = 0.877) performed better than clinical-RM1 (AUC = 0.899, ACC = 0.854). For the three-class models, the proposed clinical-RM3 achieved AUCs between 0.923 (for chordoma) and 0.964 (for sarcoma), while the AUCs of the clinical-RM4 ranged from 0.799 (for osteosarcoma) to 0.869 (for chondrosarcoma) in the validation set. In addition, the AUC and ACC of clinical-RM5 in the training set were 0.771 and 0.580, and those in the validation set were 0.722 and 0.533, respectively.*Conclusions The RF-based clinical-radiomics models provided high discriminatory performance in predicting pelvic and sacral tumor types, which could be used for clinical decision-making.*Clinical Relevance/Application Our models can provide a simple, non-invasive and accurate auxiliary diagnostic tool for the differentiation of pelvic and sacral tumors, improving the diagnostic efficiency of clinicians.

RESULTS

In total, 795 patients (432 males, 363 females; mean age of 42.1 ± 17.8 years) were consisted of 215 benign tumors and 580 malignant tumors. The sex, age, history of malignancy and tumor location had significant differences between benign and malignant tumors (P < 0.05). For the two-class models, clinical-RM2 (AUC = 0.928, ACC = 0.877) performed better than clinical-RM1 (AUC = 0.899, ACC = 0.854). For the three-class models, the proposed clinical-RM3 achieved AUCs between 0.923 (for chordoma) and 0.964 (for sarcoma), while the AUCs of the clinical-RM4 ranged from 0.799 (for osteosarcoma) to 0.869 (for chondrosarcoma) in the validation set. In addition, the AUC and ACC of clinical-RM5 in the training set were 0.771 and 0.580, and those in the validation set were 0.722 and 0.533, respectively.

CLINICAL RELEVANCE/APPLICATION

Our models can provide a simple, non-invasive and accurate auxiliary diagnostic tool for the differentiation of pelvic and sacral tumors, improving the diagnostic efficiency of clinicians.

SSMK05-5   MRI Findings In The Hip Pointer

Participants
Alessandra Sax, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

A "hip pointer" is term used in the sports medicine community to describe an injury to the iliac crest, involving the oblique musculature. It is common in high performance athletes. Based on its relative paucity in the literature, we aimed to describe the imaging findings commonly seen in hip pointer injuries, with the hope of guiding treatment, and potentially predict return to play.*Methods and Materials We retrospectively mined our PACS database for the words "internal oblique" and "external oblique". We then documented which muscle(s) were involved, the strain grade, and the tendon gap for high grade tears. We documented patients' age, gender, and athletic preferences. We then conducted a chart review and determined treatment regimens, as well as

the return to play time for the professional athletes.*Results 44 MRI exams were reviewed (average age 30.6 years, 9 female, 35 male). 48% were grade 1 strains, 39% were grade 2, and 14% were grade 3. 36% had measurable tendon gaps, with an average gap of 19mm. Treatment regimens were available for 26 patients. Of the grade 1 strains, 57% had concurrent injuries to the rectus abdominis-adductor aponeurosis requiring repair, and 22% had surgery to repair the oblique and/or iliac crest. 33% of the surgically managed patients sustained season or career ending injuries. Isolated grade 1 strains managed conservatively missed no significant game time. Of the grade 2 strains, 22% had concurrent injuries to the rectus abdominis-adductor aponeurosis requiring repair which ended the patients' season or professional career, and 22% had surgery to repair the oblique and/or iliac crest. Of the grade 3 strains, 100% were treated with repair of the oblique tear, but only 25% recovered. The remainder had career or season ending injuries. An additional 10 patients had obliques tears at their origin from the inferior ribs, 7 had apophysitis, and 9 patients had other injuries such as heterotopic ossification, hernia, or denervation.*Conclusions "Hip pointers" are injuries to the oblique musculature at their attachment on the iliac crest. We were able to document/categorize imaging findings, as well as common mimickers. We documented treatment regimens, showing that lower grade injuries are commonly associated with tears at the rectus abdominis-adductor aponeurosis, while higher grade tears were more likely isolated and required direct tendon repair. Associated rectus abdominis-adductor aponeurosis injuries portended a worse prognosis, even after surgical repair.*Clinical Relevance/Application By documenting and categorizing the MR findings in a "hip pointer", as well as treatment regimens and return to play, we hope to provide clarity in a relatively sparse realm of musculoskeletal imaging.

RESULTS

44 MRI exams were reviewed (average age 30.6 years, 9 female, 35 male). 48% were grade 1 strains, 39% were grade 2, and 14% were grade 3. 36% had measurable tendon gaps, with an average gap of 19mm. Treatment regimens were available for 26 patients. Of the grade 1 strains, 57% had concurrent injuries to the rectus abdominis-adductor aponeurosis requiring repair, and 22% had surgery to repair the oblique and/or iliac crest. 33% of the surgically managed patients sustained season or career ending injuries. Isolated grade 1 strains managed conservatively missed no significant game time. Of the grade 2 strains, 22% had concurrent injuries to the rectus abdominis-adductor aponeurosis requiring repair which ended the patients' season or professional career, and 22% had surgery to repair the oblique and/or iliac crest. Of the grade 3 strains, 100% were treated with repair of the oblique tear, but only 25% recovered. The remainder had career or season ending injuries. An additional 10 patients had obliques tears at their origin from the inferior ribs, 7 had apophysitis, and 9 patients had other injuries such as heterotopic ossification, hernia, or denervation.

CLINICAL RELEVANCE/APPLICATION

By documenting and categorizing the MR findings in a "hip pointer", as well as treatment regimens and return to play, we hope to provide clarity in a relatively sparse realm of musculoskeletal imaging.

SSMK05-6 Identification Of Acetabular Labral Tears: Diagnostic Accuracy Of Dual Energy CT Versus MR Arthrography Of The Hip

Participants
Giovanni Foti, MD, Negrar, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To compare the diagnostic accuracy of dual-energy Computed Tomography arthrography (DECTA) and MR arthrography (MRA) of the hip in depicting acetabular labral tears (ALT) and chondral defects (CD).*Methods and Materials This prospective IRB study included 24 consecutive patients (13 males and 11 females; mean age 38.3, range 18-62 years) studied between January 2018 and January 2021. Articular cavity was distended by using a mixture of saline and iodinate contrast material before DECTA (80 kV and tin filter 150 kV) and MRA. DECTA data were postprocessed (SyngoVia®); mono-energetic application was employed to choose the best kV values in order to enhance contrast material and to reduce artifacts. Two radiologists (26 and 16 years of experience), blinded to clinical data, evaluated the presence of ALT and CD on DECTA and MRA. Surgical findings served as standard of reference. Sensitivity and specificity values were calculated. Inter-observer and intra-observer agreement were calculated with k-statistics.*Results At surgery, ALT and CD were depicted respectively in 18/24 (75.0%) and 16/24 (66.6%) patients. Reader 1 achieved 83.3% sensitivity (20/24) and 100% specificity (6/6) for ALT and 93.7% sensitivity (15/16) and 87.5% specificity (7/8) for CD by reading DECTA, and 91.7% sensitivity (22/24) and 83.3% specificity (5/6) for ALT and 87.5% sensitivity (14/16) and 87.5% specificity (7/8) for CD by reading MRA. Reader 2 achieved 79.2% sensitivity (19/24) and 100% specificity (6/6) for ALT and 87.5% sensitivity (14/16) and 100% specificity (8/8) for CD by reading DECTA, and 87.5% sensitivity (21/24) and 83.3% specificity (5/6) for ALT and 81.3% sensitivity (13/16) and 87.5% specificity (7/8) for CD by reading MRA. By using McNemar test, the difference of accuracy between DECTA and MRA was not significant (p=0.21). The inter-observer (k=0.86) and intra-obsever agreement (k=0.88) were near perfect.*Conclusions DECTA can identify ALT and CD with similar performance with respect to MRA.*Clinical Relevance/Application DECTA is a reliable imaging tool for demonstration of ALT and CD in the hip arthrography and could be used as an alternative imaging tool to MRA.

RESULTS

At surgery, ALT and CD were depicted respectively in 18/24 (75.0%) and 16/24 (66.6%) patients. Reader 1 achieved 83.3% sensitivity (20/24) and 100% specificity (6/6) for ALT and 93.7% sensitivity (15/16) and 87.5% specificity (7/8) for CD by reading DECTA, and 91.7% sensitivity (22/24) and 83.3% specificity (5/6) for ALT and 87.5% sensitivity (14/16) and 87.5% specificity (7/8) for CD by reading MRA. Reader 2 achieved 79.2% sensitivity (19/24) and 100% specificity (6/6) for ALT and 87.5% sensitivity (14/16) and 100% specificity (8/8) for CD by reading DECTA, and 87.5% sensitivity (21/24) and 83.3% specificity (5/6) for ALT and 81.3% sensitivity (13/16) and 87.5% specificity (7/8) for CD by reading MRA. By using McNemar test, the difference of accuracy between DECTA and MRA was not significant (p=0.21). The inter-observer (k=0.86) and intra-observer agreement (k=0.88) were near perfect.

CLINICAL RELEVANCE/APPLICATION

DECTA is a reliable imaging tool for demonstration of ALT and CD in the hip arthrography and could be used as an alternative imaging tool to MRA.

SSNMMI04-2   Concordance Of PET Tau Visual Reads With PET Tau Quantification And CSF PTau

Participants

Charles Chen, St. Louis, Missouri (*Presenter*) Nothing to Disclose

PURPOSE

Tau status is central to Amyloid(Aß)/Tau/Neurodegeneration (ATN) diagnoses of Alzheimer disease (AD), evaluated using positron emission tomography (PET) or cerebrospinal fluid (CSF). ATN has limited clinical validation, and tau status from PET or CSF may impact clinical interpretation differently. This study assessed the concordance of PET tau visual reads with PET tau quantification and CSF phosphorylated tau (pTau).*Methods and Materials Two radiologists followed manufacturer's guidelines for visual interpretation of Tauvid (18F-flortaucipir) PET images to classify 199 cases (baseline=161, three-year follow-up=38) as positive or negative. A mixture model quantified the same cases by defining a global PET tau standardized uptake value ratio (SUVR) as the mean of bilateral fusiform, middle temporal, inferior parietal, and isthmus cingulate SUVRs, with a positivity cutoff at 1.57. A majority of participants underwent lumbar puncture (n=119, follow-up=29). Mixture models were used to define a pTau181/Aß40 cutoff at 0.00419, and a Aß42/Aß40 cutoff at 0.0760.*Results At baseline, the agreement between visual readers was high (100%, ?=1) and moderate with SUVRs (95%, ?=0.761). Using visual reads as a standard, false negatives from SUVR analysis had asymmetric parietal or occipital uptake without temporal uptake as a defining characteristic, while false positives had anterolateral temporal, diffusely nonconfluent, or striatal/brainstem uptake. Agreement with pTau181/Aß40 was fair (79%, ?=0.419) and superior to unnormalized pTau181 (71%, ?=0.315). The 25 discordant cases were largely PET-/CSF+ (92%) and Aß42/Aß40 positive (76%); in contrast, PET-/CSF- cases were largely Aß42/Aß40 negative (81.25%). Cases did not change tau status at follow up, with two exceptions: a PET-/CSF- case converted to PET-/CSF+, remaining cognitively normal; a PET+ case changed to PET-, developing memory impairment.*Conclusions SUVR agreement with visual reads was moderate, and may improve by compensating for asymmetric uptake using finer-grained, unilateral parcellations. CSF agreement with visual reads was fair, with discordances from CSF pTau elevating before PET tau in preclinical AD, suggesting caution in ATN diagnoses.*Clinical Relevance/Application This study used manufacturer's guidelines for visual interpretation of Tauvid PET, finding agreement high between readers, moderate with PET tau quantification, and fair with CSF pTau.

RESULTS

At baseline, the agreement between visual readers was high (100%, ?=1) and moderate with SUVRs (95%, ?=0.761). Using visual reads as a standard, false negatives from SUVR analysis had asymmetric parietal or occipital uptake without temporal uptake as a defining characteristic, while false positives had anterolateral temporal, diffusely nonconfluent, or striatal/brainstem uptake. Agreement with pTau181/Aß40 was fair (79%, ?=0.419) and superior to unnormalized pTau181 (71%, ?=0.315). The 25 discordant cases were largely PET-/CSF+ (92%) and Aß42/Aß40 positive (76%); in contrast, PET-/CSF- cases were largely Aß42/Aß40 negative (81.25%). Cases did not change tau status at follow up, with two exceptions: a PET-/CSF- case converted to PET-/CSF+, remaining cognitively normal; a PET+ case changed to PET-, developing memory impairment.

CLINICAL RELEVANCE/APPLICATION

This study used manufacturer's guidelines for visual interpretation of Tauvid PET, finding agreement high between readers, moderate with PET tau quantification, and fair with CSF pTau.

SSNMMI04-4   Comprehensive Functional Evaluation Of The Spectrum Of Progressive Nuclear Palsy With 18F-FDG PET/CT And 99mTc TRODAT-1 SPECT

Participants

Harsh Mahajan, MD,MBBS, New Delhi, India (*Presenter*) Director, Mahajan Imaging Pvt Ltd;Research collaboration, General Electric Company;Research collaboration, Koninklijke Philips NV;Research collaboration, Qure.ai;Research collaboration, Predible Health

PURPOSE

To elucidate the patterns of characteristic hypometabolism on 18F-FDG PET/CT in various subtypes of PSP and correlation with the core clinical features.*Methods and Materials A retrospective analysis of 124 patients of clinically suspected PSP was done. All the subjects were clinically analyzed and rated using the Progressive supra nuclear palsy rating scale proposed by the Movement Disorder Society by the Neurologist and were further clinically segregated into five sub types- PSP with Richardson's syndrome, PSP with predominant parkinsonism, PSP with speech/language presentation, PSP with frontal presentation and PSP with predominant

ocular presentation. All the subjects underwent 99mTc TRODAT-1 SPECT study and 18F-FDG PET/CT scan on two separate days. The scans were analyzed qualitatively (visually) and semi-quantitatively and the FDG uptake patterns were recorded and areas of hypometabolism that were two standard deviations from the mean were considered as abnormal.*Results 99mTc TRODAT-1 scan was abnormal in all the subjects, establishing degenerative Parkinsonism. The subjects of PSP with Richardson's syndrome showed diffuse hypometabolism involving anterior cingulate and orbital frontal cortices with diffuse hypometabolism involving basal ganglia, thalami, mid brain and sensori-motor cortices. In subjects with PSP with speech/language and frontal presentation variable additional involvement of the anterior and medial frontal association, insular and anterior temporal cortices was seen.*Conclusions Dopamine transporter imaging agent 99mTc TRODAT-1 SPECT helps in confirmation of degenerative Parkinsonian disorders. Characteristic patterns of hypometabolism may help in differentiation of the subtypes of PSP in the presence of clinically overlapping symptoms.*Clinical Relevance/Application Characteristic hypometabolism is seen on 18F-FDG PET/CT in various subtypes of PSP

RESULTS

99mTc TRODAT-1 scan was abnormal in all the subjects, establishing degenerative Parkinsonism. The subjects of PSP with Richardson's syndrome showed diffuse hypometabolism involving anterior cingulate and orbital frontal cortices with diffuse hypometabolism involving basal ganglia, thalami, mid brain and sensori-motor cortices. In subjects with PSP with speech/language and frontal presentation variable additional involvement of the anterior and medial frontal association, insular and anterior temporal cortices was seen.

CLINICAL RELEVANCE/APPLICATION

Characteristic hypometabolism is seen on 18F-FDG PET/CT in various subtypes of PSP

SSNMMI04-5   Contrast-enhanced In Vivo MRI Molecular Imaging Of A-Synuclein In A Mouse Model Of Parkinson's Disease

Participants
Eric Tanifum, PhD, Houston, Texas (*Presenter*) Consultant, Alzeca Biosciences, LLC;Stockholder, Alzeca Biosciences, LLC;

PURPOSE

Parkinson's disease (PD) is characterized by progressive deposition of misfolded a-synuclein (a-syn) aggregates in the form of Lewy bodies and Lewy neurites in the brain. The pathology has been shown to originate from the olfactory bulb and brainstem, and progressively spread to other parts of the brain. Noninvasive imaging technologies are considered vital tools for early diagnosis, monitoring disease progression, and evaluation of therapeutic efficacy of PD drugs. We present the preparation and in vivo evaluation of a novel a-syn targeted MRI molecular imaging agent in the A53T a-synuclein transgenic line M83 mouse model.*Methods and Materials T-1 relaxive macrocyclic Gd(III) a-syn targeted liposomes (with a proprietary Lipid-PEG-a-syn-Ligand conjugate as the targeting component) and a non-targeted control formulation were prepared using standard hydration/extrusion protocols. MRI was performed on a 1T permanent magnet scanner. Images were acquired using a T1-weighted spin echo (T1w-SE) sequence with the following parameters: SE parameters: TR = 600 ms, TE = 11.5 ms, slice thickness = 1.2 mm, matrix = 192 × 192, FOV = 30 mm, slices = 16, NEX = 4. A53T a-synuclein transgenic line M83 mice (16-18 months old, n=6) were pre-scanned, followed by intravenous administration of the targeted agent (TgT) at a dose of 0.20 mmol Gd/kg of body weight. Delayed scans were performed 4 days post-contrast, after which animals were euthanized and brains harvested for histology analysis. Controls included age-matched wildtype mice (n=6) injected with the targeted agent (WtT) and transgenic mice (n=6) injected with the non-targeted formulation (TgNT). Brain tissues were histologically assessed with a-syn 4D6 antibody to confirm a-syn pathology.*Results Post-contrast in vivo MR images showed significant signal enhancement in the transgenic mice treated with the targeted agent compared to controls. This was attributed to an association between the targeted nanoparticle and a-synuclein pathology. Signal quantification demonstrated statistically significant differences between test animals versus controls, and histological analysis, suggested that the observed differences were consistent with the regional distribution and density of the pathology in this mouse model.*Conclusions Intravenous administration of a-syn targeted liposomes bearing an MRI contrast payload, results in increase in signal intensity consistent with regional distribution of a-syn pathology in the brains of A53T a-synuclein transgenic line M83 mice.*Clinical Relevance/Application A potential widely accessible tool for early detection of synucleinopathies, including Parkinson's disease, dementia with Lewy bodies, and multiple system atrophy.

RESULTS

Post-contrast in vivo MR images showed significant signal enhancement in the transgenic mice treated with the targeted agent compared to controls. This was attributed to an association between the targeted nanoparticle and a-synuclein pathology. Signal quantification demonstrated statistically significant differences between test animals versus controls, and histological analysis, suggested that the observed differences were consistent with the regional distribution and density of the pathology in this mouse model.

CLINICAL RELEVANCE/APPLICATION

A potential widely accessible tool for early detection of synucleinopathies, including Parkinson's disease, dementia with Lewy bodies, and multiple system atrophy.

SSMK11-1 Temporal Evolution Of Clinical Confidence With Dual Energy CT In The Diagnosis And Treatment Of Gout.

Participants
Gregory Aird, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the differences in clinical utilization of dual energy CT (DECT) for the evaluation and management of gout from 2013 and 2020.*Methods and Materials We performed a retrospective review using an institutional database to identify patients with a high clinical suspicion for gout from two time periods. There were 100 patients with a total of 100 DECT from 2013 and 102 patients with a total of 131 DECT from 2020. Three radiologists interpreted the imaging and reviewed the clinical charts and diagnostic radiology reports for each patient cohort. All statistical analyses were performed using R version 3.6.2.*Results The differences between the number of positive, negative, and equivocal cases in each cohort is statistically significant (p<0.001). In the 2013 cohort, 43 cases (43%) were classified as positive for monosodium urate (MSU) crystal deposits, 22 (22%) were negative, and 35 (35%) were equivocal. In the 2020 cohort, 48 cases (37%) were positive, 62 (47%) were negative, and 21 (16%) were equivocal. While there was a significant association between a history of gout and DECT results in the 2020 cohort (p<0.001), no such association was identified with the 2013 cohort (p=0.123). Fewer number of patients in the 2020 cohort underwent a joint aspiration to evaluate for the presence of MSU crystal depositions compared to the 2013 cohort (16/131 patients (12%) and 34/100 patients (34%), respectively (p<0.001). Following a DECT positive for MSU crystals, 43/48 (90%) patients in the 2020 cohort had a clinical diagnosis of gout, with 36/48 (75%) patients undergoing a treatment change (p<0.001). Similar findings were observed in the 2013 cohort with 43/43 (100%) were diagnosed with gout and 35/43 (81%) of these patients having a change in treatment (p<0.001).*Conclusions DECT remains a reliable non-invasive technique to diagnose and manage the treatment of gout. There were fewer equivocal DECT results and joint aspirations performed in the 2020 cohort, which is consistent with an apparent increase in the diagnostic confidence in DECT results.*Clinical Relevance/Application Following advances in technology and improved acquisition times, DECT has seen increased utilization in the clinical setting. Of the many clinical applications of DECT, one of the well-studied and widespread uses of the modality is in the diagnosis and management of gout. While various studies have demonstrated the increasing reliability and accuracy of of DECT in detecting the presence of MSU crystals, none have explored or measured its impact on the clinical management of the condition. The present study provides quantitative data on how clinician confidence in the diagnostic results of DECT results has evolved over time.

RESULTS

The differences between the number of positive, negative, and equivocal cases in each cohort is statistically significant (p<0.001). In the 2013 cohort, 43 cases (43%) were classified as positive for monosodium urate (MSU) crystal deposits, 22 (22%) were negative, and 35 (35%) were equivocal. In the 2020 cohort, 48 cases (37%) were positive, 62 (47%) were negative, and 21 (16%) were equivocal. While there was a significant association between a history of gout and DECT results in the 2020 cohort (p<0.001), no such association was identified with the 2013 cohort (p=0.123). Fewer number of patients in the 2020 cohort underwent a joint aspiration to evaluate for the presence of MSU crystal depositions compared to the 2013 cohort (16/131 patients (12%) and 34/100 patients (34%), respectively (p<0.001). Following a DECT positive for MSU crystals, 43/48 (90%) patients in the 2020 cohort had a clinical diagnosis of gout, with 36/48 (75%) patients undergoing a treatment change (p<0.001). Similar findings were observed in the 2013 cohort with 43/43 (100%) were diagnosed with gout and 35/43 (81%) of these patients having a change in treatment (p<0.001).

CLINICAL RELEVANCE/APPLICATION

Following advances in technology and improved acquisition times, DECT has seen increased utilization in the clinical setting. Of the many clinical applications of DECT, one of the well-studied and widespread uses of the modality is in the diagnosis and management of gout. While various studies have demonstrated the increasing reliability and accuracy of of DECT in detecting the presence of MSU crystals, none have explored or measured its impact on the clinical management of the condition. The present study provides quantitative data on how clinician confidence in the diagnostic results of DECT results has evolved over time.

SSMK11-2 Diffusion Weighted Imaging (DWI) In Diagnosis, Staging, And Treatment Response Assessment Of Multiple Myeloma: A Systematic Review And Meta-analysis

Participants
Pooya Torkian, MD, Minneapolis, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the role of Diffusion-Weighted Imaging (DWI) in the initial diagnosis, staging, and assessment of treatment response in patients with multiple myeloma (MM).*Methods and Materials A systematic literature review was conducted in PubMed, the Cochrane Library, EMBASE, Scopus, and Web of Science databases to identify studies related to the role of DWI in lesion detection, staging, and treatment response assessment in patients with MM. The Primary outcomes were defined as the diagnostic performance of DWI for disease detection, staging of MM, and assessing response to treatment in these patients.*Results Of 5881 initially reviewed publications, 33 articles were selected for in-depth review and eventually were included in the final qualitative and quantitative meta-analysis. The diagnostic performance of DWI in detection of patients with MM revealed pooled sensitivity and specificity of 86% (95% CI: 84-89) and 63% (95% CI: 56-70), respectively with the diagnostic Odds Ratio (OR) of 14.98 (95% CI: 4.24-52.91). The pooled risk difference of 0.19 (95% CI: 0.06-0.39) was reported in favor of upstaging with DWI compared to conventional MRI (P value=0.1). Treatment response evaluation and ADCmean values changes across different studies showed sensitivity and specificity of about 78% (95% CI: 72-83) and 73% (95% CI: 61-83), respectively with the diagnostic OR of 7.21 in distinguishing responders from non-responders. Pooled value of 25.97% (95% CI: 6.50-45.44) was achieved for percent of changes in ADCmean after therapy in responders in comparison with non-responders (P value=0.009).*Conclusions DWI is not only a promising tool for the diagnosis of MM, but also it is useful in initial staging and re-staging of the disease and treatment response assessment. This can help clinicians with earlier initiation or change in treatment strategy, which could have prognostic significance for patients.*Clinical Relevance/Application DWI has revolutionized imaging evaluation for MM from traditional anatomic imaging to functional quantitative imaging. DWI improves diagnosis, staging, and treatment response assessment in patients with MM.

RESULTS

Of 5881 initially reviewed publications, 33 articles were selected for in-depth review and eventually were included in the final qualitative and quantitative meta-analysis. The diagnostic performance of DWI in detection of patients with MM revealed pooled sensitivity and specificity of 86% (95% CI: 84-89) and 63% (95% CI: 56-70), respectively with the diagnostic Odds Ratio (OR) of 14.98 (95% CI: 4.24-52.91). The pooled risk difference of 0.19 (95% CI: 0.06-0.39) was reported in favor of upstaging with DWI compared to conventional MRI (P value=0.1). Treatment response evaluation and ADCmean values changes across different studies showed sensitivity and specificity of about 78% (95% CI: 72-83) and 73% (95% CI: 61-83), respectively with the diagnostic OR of 7.21 in distinguishing responders from non-responders. Pooled value of 25.97% (95% CI: 6.50-45.44) was achieved for percent of changes in ADCmean after therapy in responders in comparison with non-responders (P value=0.009).

CLINICAL RELEVANCE/APPLICATION

DWI has revolutionized imaging evaluation for MM from traditional anatomic imaging to functional quantitative imaging. DWI improves diagnosis, staging, and treatment response assessment in patients with MM.

SSMK11-4   MRI Long-term Follow-up Of Incidentally Detected Enchondromas Of The Long Bones

Participants
Moritz Dreier, BSC, Kempten, Germany (*Presenter*) Nothing to Disclose

PURPOSE

The incidental finding of an enchondroma (EC) within a long bone is a common reason for referral to a bone tumor unit, and the population prevalence of incidental cartilage tumors on MRI scans is increasing due to the higher number of MRI scans performed. The reported risk of malignant transformation varies between 0 and 6% and there is no valid data on the long-term growth behavior of EC. There is no consensus or recommendation on follow-up for EC. The aim of this study was to analyze the long-term changes of incidentally detected EC of the long tubular bones on MRI.*Methods and Materials This retrospective study included 110 patients with EC of the long bones suggestive of an EC diagnosed between 2006 and 2009. A follow-up period of at least 10 years after the initial diagnosis was the main inclusion criterion. To investigate the growth behavior, the change in size was analyzed. Malignant transformation was assessed using radiological criteria including cortical breach, endosteal scalloping, peritumoral edema, and soft tissue component. In addition, the rate of secondary surgeries was analyzed during the observation period.*Results 77/110 (70%) patients were reached by phone and 24/77 (31%) agreed to a follow-up MRI examination. The mean follow-up time for the MRI group (n=24) was 140 months (range 120-172 months). The localization of EC was: 17 femur (71%), 3 tibia (13%), 2 humerus (8%), 1 fibula (4%), 1 ulna (4%). The mean age of the patients at initial diagnosis was 49 years (range, 27-67). 11 EC (46%) increased in size, 10 EC (42%) remained stable, and 3 EC decreased in size. The mean increase in EC size was 3 mm (range -2 mm - +18 mm) between the initial and subsequent MRI. Two patients developed endosteal scalloping, one patient showed new peritumoral edema, in one patient cortical breach with periosteal reaction was found. Overall, 6/77 (8%) patients underwent secondary surgery, all lesions were histologically confirmed as EC.*Conclusions This study has shown that imaging follow-up is justified for all EC, irrespective of initial lesion size, as EC has shown unpredictable growth patterns. As progression is slow, it seems reasonable to extend follow-up intervals to several years. The presence of solitary features of biological aggressiveness, such as endosteal scalloping, without clinical symptoms, does not require surgery but follow-up.*Clinical Relevance/Application This study has shown that long-term imaging follow-up is justified for all EC, irrespective of initial lesion size, as suggested in the past.It seems reasonable to extend follow-up intervals of EC to several years instead of annual or biannual follow-up.

RESULTS

77/110 (70%) patients were reached by phone and 24/77 (31%) agreed to a follow-up MRI examination. The mean follow-up time for the MRI group (n=24) was 140 months (range 120-172 months). The localization of EC was: 17 femur (71%), 3 tibia (13%), 2 humerus (8%), 1 fibula (4%), 1 ulna (4%). The mean age of the patients at initial diagnosis was 49 years (range, 27-67). 11 EC (46%) increased in size, 10 EC (42%) remained stable, and 3 EC decreased in size. The mean increase in EC size was 3 mm (range -2 mm - +18 mm) between the initial and subsequent MRI. Two patients developed endosteal scalloping, one patient showed new peritumoral edema, in one patient cortical breach with periosteal reaction was found. Overall, 6/77 (8%) patients underwent secondary surgery, all lesions were histologically confirmed as EC.

CLINICAL RELEVANCE/APPLICATION

This study has shown that long-term imaging follow-up is justified for all EC, irrespective of initial lesion size, as suggested in the past.It seems reasonable to extend follow-up intervals of EC to several years instead of annual or biannual follow-up.

SSMK11-5   MRI Radiomics-based Machine Learning Classification Of Atypical Cartilaginous Tumor And G2 Chondrosarcoma Of Long Bones

Participants
Salvatore Gitto, MD, Milano, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Atypical cartilaginous tumors (ACT) and G2 chondrosarcomas (CS2) of long bones are respectively managed with curettage/watchful waiting and wide resection. Preoperatively, imaging diagnosis can be challenging due to interobserver variability and biopsy suffers from sampling errors. Our aim was to determine diagnostic performance of MRI radiomics-based machine learning for classification of ACT and CS2 of long bones.*Methods and Materials 158 patients (98 women; median age: 57 years) with surgically treated and histology-proven cartilaginous bone tumors were retrospectively included at two tertiary bone tumor centers. The training cohort consisted of 93 MRI scans from center 1 (74 ACT; 19 CS2). The external test cohort consisted of 65 MRI scans from center 2 (45 ACT; 20 CS2). Bidimensional segmentation was manually performed on preoperative T1-weighted MRI sequences. First-order, shape-based and texture features were extracted. Dimensionality reduction consisting of stability, variance and inter-correlation analyses and recursive feature elimination, after class balancing in center 1 (CS2 oversampled to n=74), was performed. Thus, a machine-learning classifier (Extra Trees Classifier) was automatically tuned on the training cohort using 10-fold cross-validation and tested on the external test cohort.*Results 919 radiomic features were extracted and then reduced to 17 through dimensionality reduction. After tuning on the training cohort (AUC=0.87), the machine-learning classifier had 91% accuracy (59/65, AUC=0.94) in identifying the lesions in the external test cohort. Specifically, its accuracy in classifying ACT and CS2 was 96% (43/45) and 80% (16/20), respectively.*Conclusions Machine learning showed high accuracy in classifying ACT and CS2 of long bones based on preoperative MRI radiomic features.*Clinical Relevance/Application Radiomics-based machine learning is an objective MRI method, using T1-weighted images only, that may be used in clinical decision making by accurately differentiating between ACT and CS2.

RESULTS

919 radiomic features were extracted and then reduced to 17 through dimensionality reduction. After tuning on the training cohort (AUC=0.87), the machine-learning classifier had 91% accuracy (59/65, AUC=0.94) in identifying the lesions in the external test cohort. Specifically, its accuracy in classifying ACT and CS2 was 96% (43/45) and 80% (16/20), respectively.

CLINICAL RELEVANCE/APPLICATION

Radiomics-based machine learning is an objective MRI method, using T1-weighted images only, that may be used in clinical decision making by accurately differentiating between ACT and CS2.

SSMK11-6 Deep Learning Radiomic Nomogram To Predict Recurrence In Soft Tissue Sarcoma: A Multi-institutional Study

Participants
Wang Hexiang, MD, Qing Dao, China (*Presenter*) Nothing to Disclose

PURPOSE

Resection of soft tissue sarcoma (STS) still has a high relapse rate, and the routinely applied prognostic method is not sufficiently accurate.*Methods and Materials In total, 282 patients who underwent MRI and resection for STS at three independent centers were retrospectively enrolled. We separated the participants into a development cohort and an external test cohort. Two MRI-based DLRNs for prediction of tumor relapse after resection of STS were established. We universally tested the DLRNs and compared them with competitive models that do not employ radiomics, but instead use widespread adopted predictors (i.e., staging systems and Ki67).*Results The DLRN1 model incorporated 282 plain MRI-based radiomics signatures into the clinical data, and the DLRN2 model integrated 113 plain and enhanced MRI-based radiomics signatures with the clinical predictors. Across both study sets, the two MRI-based DLRNs had relatively better prognostic capability (C index =0.721 and median AUC = 0.746; $p < 0.05$ compared with most other models and predictors) and less opportunity for prediction error (integrated Brier score = 0.159). The decision curve analysis indicates that the DLRNs have greater benefits than staging systems, Ki67, and other models. We selected appropriate cutoff values for the DLRNs to divide STS recurrence into three risk strata (low,medium, and high) and calculated those groups' cumulative risk rates.*Conclusions The DLRNs helped to predict STS relapse after resection.*Clinical Relevance/Application It is necessary to establish a model to predict the recurrence risk of STS before operation and stratify patients' risk levels so that patients can receive more effective and targeted treatment.

RESULTS

The DLRN1 model incorporated 282 plain MRI-based radiomics signatures into the clinical data, and the DLRN2 model integrated 113 plain and enhanced MRI-based radiomics signatures with the clinical predictors. Across both study sets, the two MRI-based DLRNs had relatively better prognostic capability (C index =0.721 and median AUC = 0.746; $p < 0.05$ compared with most other models and predictors) and less opportunity for prediction error (integrated Brier score = 0.159). The decision curve analysis indicates that the DLRNs have greater benefits than staging systems, Ki67, and other models. We selected appropriate cutoff values for the DLRNs to divide STS recurrence into three risk strata (low,medium, and high) and calculated those groups' cumulative risk rates.

CLINICAL RELEVANCE/APPLICATION

It is necessary to establish a model to predict the recurrence risk of STS before operation and stratify patients' risk levels so that patients can receive more effective and targeted treatment.

SPR-BR-1   Race And Ethnicity Based Variability In Breast Cancer Risk Assessment By Traditional Models

Participants
Leslie Lamb, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Decisions for and insurance payment of genetic testing, chemoprevention, and supplemental screening are driven by an individual's breast cancer risk score. There are limited data on model performance outside of White/Non-Hispanic (W/NH) populations on which these models were developed. Our purpose was to compare variability of traditional breast cancer risk assessment models across diverse races.*Methods and Materials This retrospective, multisite study included consecutive patients undergoing screening mammography from September 17, 2017 to April 1, 2021. NCI Breast Cancer Risk Assessment Tool (BRCAT) and Tyrer-Cuzick version 8 (TC8)/IBIS 5-year and lifetime models were used to assess risk based on patients' survey responses. Cancer outcomes were obtained through linkage to a regional tumor registry. Increased 5-year risk was defined as >1.67% and high lifetime risk as >20%. We compared the proportion of high-risk patients across models and racial groups using Pearson's Chi-squared test.*Results Of 155,218 patients who underwent bilateral screening mammography during the study period, 117,899 met inclusion criteria. Median patient age was 58.0 years (IQR: 50.0 to 67.0 years). 81.8% (96,460) were W/NH and 18.2% (21,439) were persons of color (POC) or Hispanic (H) [5.4% (6,341) Black, 6.1% (7,190) Asian, 1.6% (1,877) Hispanic, and 5.1% (6,031) Other]. Significantly more W/NH patients were classified as high-risk by all models, compared to POC/H patients (p<0.001). For 5-year risk, 67.0% of W/NH patients were classified as increased risk by either NCI or TC8, 53.1% by NCI, and 50.2% by TC8, compared to 37.2%, 27.9%, and 24.4% in POC/H patients (p<0.001). For lifetime risk, 13.8% of W/NH patients were classified as high-risk by either NCI or TC8, 12.1% by TC8, and 4.4% by NCI, compared to 7.8%, 6.6%, and 2.4% in POC/H patients (p<0.001).*Conclusions Commonly used risk models produce substantial race and ethnicity-based variability in categorizing patients as high-risk for developing breast cancer. Significantly more W/NH patients are classified as high-risk compared to POC/H patients across all methods, directly impacting access to additional services.*Clinical Relevance/Application Compared to W/NH patients, significantly fewer POC/H patients are assessed as high risk by common risk models, potentially contributing to inequitable access to supplemental services.

RESULTS

Of 155,218 patients who underwent bilateral screening mammography during the study period, 117,899 met inclusion criteria. Median patient age was 58.0 years (IQR: 50.0 to 67.0 years). 81.8% (96,460) were W/NH and 18.2% (21,439) were persons of color (POC) or Hispanic (H) [5.4% (6,341) Black, 6.1% (7,190) Asian, 1.6% (1,877) Hispanic, and 5.1% (6,031) Other]. Significantly more W/NH patients were classified as high-risk by all models, compared to POC/H patients (p<0.001). For 5-year risk, 67.0% of W/NH patients were classified as increased risk by either NCI or TC8, 53.1% by NCI, and 50.2% by TC8, compared to 37.2%, 27.9%, and 24.4% in POC/H patients (p<0.001). For lifetime risk, 13.8% of W/NH patients were classified as high-risk by either NCI or TC8, 12.1% by TC8, and 4.4% by NCI, compared to 7.8%, 6.6%, and 2.4% in POC/H patients (p<0.001).

CLINICAL RELEVANCE/APPLICATION

Compared to W/NH patients, significantly fewer POC/H patients are assessed as high risk by common risk models, potentially contributing to inequitable access to supplemental services.

SPR-BR-11   The Prognostic Value Of Enhancing Lesion Volume In Patients With Breast Cancer That Were Evaluated As Stable Disease By Recist1.1 Criterion After Early Neoadjuvant Chemotherapy

Participants
Jie Ding, Yinchuan, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the prognostic value of enhancing lesion volume (ELV) in patients with breast cancer that were evaluated as stable disease (SD) by RECIST1.1 criterion after early neoadjuvant chemotherapy (NAC).*Methods and Materials Seventy-three patients with 73 unilateral lesions which were evaluated as SD by RECIST1.1 criterion after early NAC were included in this study. The lesions with decreased maximum diameter were regarded as responders, otherwise were non-responders according RECIST1.1. All the lesions were then assessed by ELV method, and the lesions with complete or partial response, or SD but decreased ELV were considered as responders, others were classified as non-responders. According to the Miller-Payne (MP) grading system, the lesions with Grade1-2 were defined as non-responders, and Grade3-5 were responders. The diagnostic performance of the two methods were compared with pathological results. The change rate of maximum diameter based on RECIST1.1 and enhancing lesion volume based on ELV method before and after NAC were analyzed and compared for pathological predictive performances via receiver operating characteristic (ROC) curve.*Results Fifty-five lesions were diagnosed as responders and other 23 lesions were non-responders according to pathological MP grading results, and RECIST1.1 and TLV criteria identified 59 and 66 responders, 14 and 7 non-responders, respectively. The values of sensitivity (SE) specificity (SP), positive predictive value (PPV), negative predictive value (NPV), and accuracy based on ELV and RECIST1.1 criteria for predicting pathologic response were 94% vs. 87.3% (P>0.05), 22.2% vs. 38.9% (P>0.05), 78.8 vs. 81.4%, 57.1 vs. 50%, and 76.7% vs. 75.3%, respectively. For the quantitative diagnostic performance of change rate, the areas under the ROC curves (AUC) according to ELV and RECIST1.1 were 0.79 (95%CI: 0.68 to

0.88) and 0.64 (95%CI: 0.52 to 0.75), respectively (P<0.05). The SE and SP were 61.82% and 94.44% (Youden index: 0.563, cut-off: -37.87%), 87.27% and 44.44% (Youden index: 0.317, cut-off: -2.47%), respectively.*Conclusions Both ELV and RECIST1.1 have prognostic value for predicting pathological response in patients with breast cancer after early NAC, and ELV may be a more effective method with statistically higher AUC value.*Clinical Relevance/Application Considering the overall tumor burden, ELV has a high specificity in predicting the prognosis of patients with stable disease in the early evaluation of neoadjuvant chemotherapy for breast cancer, and has a good reference value for guiding clinical medication.

RESULTS

Fifty-five lesions were diagnosed as responders and other 23 lesions were non-responders according to pathological MP grading results, and RECIST1.1 and TLV criteria identified 59 and 66 responders, 14 and 7 non-responders, respectively. The values of sensitivity (SE) specificity (SP), positive predictive value (PPV), negative predictive value (NPV), and accuracy based on ELV and RECIST1.1 criteria for predicting pathologic response were 94% vs. 87.3% (P>0.05), 22.2% vs. 38.9% (P>0.05), 78.8 vs. 81.4%, 57.1 vs. 50%, and 76.7% vs. 75.3%, respectively. For the quantitative diagnostic performance of change rate, the areas under the ROC curves (AUC) according to ELV and RECIST1.1 were 0.79 (95%CI: 0.68 to 0.88) and 0.64 (95%CI: 0.52 to 0.75), respectively (P<0.05). The SE and SP were 61.82% and 94.44% (Youden index: 0.563, cut-off: -37.87%), 87.27% and 44.44% (Youden index: 0.317, cut-off: -2.47%), respectively.

CLINICAL RELEVANCE/APPLICATION

Considering the overall tumor burden, ELV has a high specificity in predicting the prognosis of patients with stable disease in the early evaluation of neoadjuvant chemotherapy for breast cancer, and has a good reference value for guiding clinical medication.

SPR-BR-12 Development And Validation Of Nomograms Integrating Ultrasound Features To Predict Disease-free Survival Of Patients With Triple-negative Breast Cancer

Participants
Liu Lixian, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the relationship between ultrasonographic characteristics and disease-free survival (DFS) of patients with triple-negative breast cancer (TNBC), and to establish a nomogram integrating ultrasound features to predict the prognosis of patients with TNBC.*Methods and Materials Patients with TNBC who underwent surgical treatment from 2013 to 2018 were retrospectively selected. All the data were randomly divided into training and validation groups in a 7:3 ratio. Univariate and multivariate analyses were carried out on the clinical, pathological and ultrasonic characteristics of the training group, and independent prognostic factors were chosen to build a Clinic model, an Image model, a Combined model (including the clinical and ultrasonic factors) and a TNM model, respectively. The concordance index (C-index) of the four models were calculated. The model with the highest prediction efficiency is visualized by a nomogram. The calibration curves were used to evaluate the predictive power of the nomogram.*Results A total of 515 patients were included for analysis. There is no significant difference between the training and validation groups. Three independent ultrasonic factors, including echo pattern, posterior features and status of the deep layer of superficial fascia, and four independent clinicopathological factors, including menopausal status, T, N stage and albumin level were identified. The C-index of the combined model was significantly higher than that of the other models both in the training and validation group. The C-index of the Combined, Image, Clinic and TNM models in the training group were 0.758, 0.725, 0.695 and 0.674, respectively and 0.680, 0.621, 0.625 and 0.673 in the validation group. In addition, the nomogram was built based on the combined model. The calibration curves of the presented nomogram for the probability of DFS at 3 or 5 years show an optimal agreement both in the training and validation group.*Conclusions Ultrasound features combined with clinicopathological factors are predictive for DFS in TNBC. We established and validated a novel nomogram that can provide individual prediction of DFS for TNBC.*Clinical Relevance/Application To our knowledge, this study was firstly estabalished and validated a novel nomogram intergrating ultrasonic features to predict disease-free survival in patients with triple-negative breast cancer (TNBC), which emphasizing the importance of ultrasound in daily clinic work. In addition, preoperative ultrasonic features may be predictive for the prognosis of TNBC, which may help for decision making in clinic work.

RESULTS

A total of 515 patients were included for analysis. There is no significant difference between the training and validation groups. Three independent ultrasonic factors, including echo pattern, posterior features and status of the deep layer of superficial fascia, and four independent clinicopathological factors, including menopausal status, T, N stage and albumin level were identified. The C-index of the combined model was significantly higher than that of the other models both in the training and validation group. The C-index of the Combined, Image, Clinic and TNM models in the training group were 0.758, 0.725, 0.695 and 0.674, respectively and 0.680, 0.621, 0.625 and 0.673 in the validation group. In addition, the nomogram was built based on the combined model. The calibration curves of the presented nomogram for the probability of DFS at 3 or 5 years show an optimal agreement both in the training and validation group.

CLINICAL RELEVANCE/APPLICATION

To our knowledge, this study was firstly estabalished and validated a novel nomogram intergrating ultrasonic features to predict disease-free survival in patients with triple-negative breast cancer (TNBC), which emphasizing the importance of ultrasound in daily clinic work. In addition, preoperative ultrasonic features may be predictive for the prognosis of TNBC, which may help for decision making in clinic work.

SPR-BR-13 Evaluation Of Breast Galactography By Using Digital Breast Tomosynthesis: A Clinical Exploratory Study

Participants
Juan Tao, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare the application value of Digital Breast Tomosynthesis (DBT) and full-field digital mammography (FFDM) in breast galactography.*Methods and Materials 128 patients with pathological nipple discharge (PND) were selected to undergo galactography. DBT and FFDM were performed for each patient after injecting the contrast agent; the radiation dose of DBT and FFDM was calculated, and the image quality was evaluated in consensus by two senior breast radiologists. Histopathologic data were found in 49 of the 128 patients. Sensitivity, specificity, PPV and NPV for both FFDM- and DBT-galactography were calculated having histopathologic results as a reference standard. Data were presented as percentages with their 95% confidence intervals

(CI).*Results The average age of the 128 patients was 46.53 years. The average glandular dose (AGD) of DBT-galactography was slightly higher than FFDM-galactograhpy (P<0.001). DBT- galactograhpy was 30.7% higher than FFDM- galactograhpy in CC view, while DBT increased by 21.7% compared with FFDM in ML view. In the catheter anatomic distortion, detail structure, and overall image quality groups, DBT scores were higher than FFDM scores, and there were significant differences in each group(P<0.05). In 49 patients with pathological nipple discharge, we found that the DBT - galactography has higher sensitivity, specificity, PPV and NPV (93.3%,75%,97.7% and 50%) than FFDM-galactography (91.1%,50%,95.3% and 33.3%, respectively).*Conclusions Compared to FFDM-galactography, within the acceptable radiation dose range, DBT-galactography not only improves the image quality but also increases the sensitivity and specificity of lesion detection, providing more confidence for the diagnosis of clinical ductal lesions.*Clinical Relevance/Application This study used tomosynthesis in galactography and compared DBT-with FFDM-galactography from three aspects of AGD, image quality and diagnostic efficiency. As a new technique of catheter imaging, DBT-Galactography increases the confidence of clinical diagnosis of intraductal lesions and better detection of intraductal lesions. It provides more possibilities for image examination.

RESULTS

The average age of the 128 patients was 46.53 years. The average glandular dose (AGD) of DBT-galactography was slightly higher than FFDM-galactograhpy (P<0.001). DBT- galactograhpy was 30.7% higher than FFDM- galactograhpy in CC view, while DBT increased by 21.7% compared with FFDM in ML view. In the catheter anatomic distortion, detail structure, and overall image quality groups, DBT scores were higher than FFDM scores, and there were significant differences in each group(P<0.05). In 49 patients with pathological nipple discharge, we found that the DBT - galactography has higher sensitivity, specificity, PPV and NPV (93.3%,75%,97.7% and 50%) than FFDM-galactography (91.1%,50%,95.3% and 33.3%, respectively).

CLINICAL RELEVANCE/APPLICATION

This study used tomosynthesis in galactography and compared DBT-with FFDM-galactography from three aspects of AGD, image quality and diagnostic efficiency. As a new technique of catheter imaging, DBT-Galactography increases the confidence of clinical diagnosis of intraductal lesions and better detection of intraductal lesions. It provides more possibilities for image examination.

SPR-BR-14　Diffusion-weighted Imaging Derived Parameters Of Breast Cancer As A Predictive Biomarker Of Distant Metastasis-free Survival

Participants
Maya Honda, Osaka, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To investigate whether intravoxel incoherent motion (IVIM) and non-gaussian diffusion parameters are associated with distant metastasis-free survival in breast cancer patients.*Methods and Materials This prospective study was approved by our institutional review board and included 101 patients (mean age 60.0, age range 28-88) with unilateral breast carcinoma who underwent breast MRI from June 2013 to March 2015. All images were acquired using a 3T MR scanner (Tim Trio; Siemens Healthcare, Erlangen, Germany) and a dedicated 16-channel dedicated breast coil. DW images were acquired with b values of 5, 10, 20, 30, 50, 70, 100, 200, 400, 600, 800, 1000, 1500, 2000 and 2500 s/mm2. Two independent radiologists manually drew regions of interest for each patient over the largest lesion to estimate the following parameters: IVIM-derived pseudodiffusion coefficient (D*) and flowing blood volume fraction (fIVIM), ADC0 and kurtosis (K) using kurtosis model, standard ADC calculated using b values of 0 and 800 s/mm2 (ADC0-800) and shifted ADC calculated using b values of 200 and 1500 s/mm2 (sADC200-1500). Distant metastasis-free survival was the primary end point and was defined as the time from the date of MR examination to the date of distant metastasis. Distant metastasis-free survival curves were generated according to the Kaplan-Meier method and were compared by using the log-rank test. Univariable Cox proportional hazards models were used to assess the effects of each parameter on distant metastasis-free survival. All statistical analyses were performed using R-4.0.4. The optimal cut-off values were calculated using the maxstat package.*Results Of the 101 patients, 12 (11.9%) developed distant metastasis, with a median time to metastasis of 79 months (range, 10-92 months). Kaplan-Meier survival analysis showed that the distant metastasis-free survival times were significantly shorter in patients with higher K (> 0.92, p = 0.04) and those with lower ADC0-800 values (< 0.76 x 10-3 mm2/s, p = 0.03). Cox regression analysis showed no statistically significant association between these parameters with distant metastasis-free survival.*Conclusions K and ADC0-800 values can be useful prognostic markers for predicting distant metastasis of breast cancer. The results suggest that non-Gaussian diffusion may be associated with prognosis in breast cancer.*Clinical Relevance/Application Pre-treatment MRI-derived K and ADC0-800 in breast cancer may be used to predict distant metastasis.

RESULTS

Of the 101 patients, 12 (11.9%) developed distant metastasis, with a median time to metastasis of 79 months (range, 10-92 months). Kaplan-Meier survival analysis showed that the distant metastasis-free survival times were significantly shorter in patients with higher K (> 0.92, p = 0.04) and those with lower ADC0-800 values (< 0.76 x 10-3 mm2/s, p = 0.03). Cox regression analysis showed no statistically significant association between these parameters with distant metastasis-free survival.

CLINICAL RELEVANCE/APPLICATION

Pre-treatment MRI-derived K and ADC0-800 in breast cancer may be used to predict distant metastasis.

SPR-BR-15　Change In The ADC Value On Diffusion-Weighted MRI As A Predictive Tool For Pathologic Complete Response In Patients With Breast Cancer Undergoing Neoadjuvant Chemotherapy

Participants
Ahreum Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the efficacy of the apparent diffusion coefficient (ADC) on diffusion-weighted imaging (DWI) for predicting pathological response to neoadjuvant chemotherapy (NAC) in patients with breast cancer.*Methods and Materials Following IRB approval, 434 women with breast cancer who underwent magnetic resonance imaging (MRI) before and after NAC before surgery between 2015 and 2018 were retrospectively identified. The mean ADC values of the tumor on pre- and post-NAC DW MRI (ADCpre and ADCpost, respectively) were measured. The change in the mean tumor ADC value (?ADC) was calculated as follows: ?ADC = ADCpost - ADCpre. The pathological response was classified into either a complete response (pCR) or an incomplete response (non-pCR) according to the Miller & Payne grading system. The predictive value of the ADC for pCR was assessed including the interaction of the tumor subtype, which was categorized as luminal A, luminal B, human epidermal growth factor receptor 2 (HER2)-enriched, and triple-negative tumors.*Results Among 434 women, 103 (23.7%) achieved pCR (pCR group) and 331 (76.3%) did not

(non-pCR group). The ADCpost and ?ADC values were significantly different between the pCR and non-pCR groups (1.5±0.5 vs. 1.2±0.4 and 0.5±0.6 vs. 0.2±0.4, respectively; P<0.001). In the analysis for the potential effect of the interaction, there was a significant interaction between the tumor subtype and ?ADC for predicting pCR (P for interaction=0.016) in the entire cohort. Among the tumor subtypes, ?ADC was significantly associated with pCR in only the HER2-enriched subtype (adjusted odds ratio= 5.70, 95% confidence interval: 1.25, 32.70, P=0.036) in the multivariate analysis including an interaction effect. In the receiver operating characteristic curve analysis, the area under the curve (AUC) was 0.650 in the entire cohort (52.4% sensitivity and 80.7% specificity), and the AUC was 0.766 in patients with the HER2-enriched subtype (81.8% sensitivity and 71.9% specificity).*Conclusions An increase in the mean tumor ADC value on DWI after NAC was useful for predicting pCR. The ?ADC value was an independent predictor for pCR in only patients with the HER2-enriched subtype.*Clinical Relevance/Application The change in the mean tumor ADC value on DWI after neoadjuvant chemotherapy was a useful predictor for pCR, but it depended on the tumor subtype.

RESULTS

Among 434 women, 103 (23.7%) achieved pCR (pCR group) and 331 (76.3%) did not (non-pCR group). The ADCpost and ?ADC values were significantly different between the pCR and non-pCR groups (1.5±0.5 vs. 1.2±0.4 and 0.5±0.6 vs. 0.2±0.4, respectively; P<0.001). In the analysis for the potential effect of the interaction, there was a significant interaction between the tumor subtype and ?ADC for predicting pCR (P for interaction=0.016) in the entire cohort. Among the tumor subtypes, ?ADC was significantly associated with pCR in only the HER2-enriched subtype (adjusted odds ratio= 5.70, 95% confidence interval: 1.25, 32.70, P=0.036) in the multivariate analysis including an interaction effect. In the receiver operating characteristic curve analysis, the area under the curve (AUC) was 0.650 in the entire cohort (52.4% sensitivity and 80.7% specificity), and the AUC was 0.766 in patients with the HER2-enriched subtype (81.8% sensitivity and 71.9% specificity).

CLINICAL RELEVANCE/APPLICATION

The change in the mean tumor ADC value on DWI after neoadjuvant chemotherapy was a useful predictor for pCR, but it depended on the tumor subtype.

SPR-BR-16   3D Amide Proton Transfer-weighted Imaging In Evaluation Of Breast Lesions: Comparison With Diffusion-weighted Imaging

Participants
Ruhua Wang, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the value of 3D amide proton transfer-weighted imaging (APTWI) and its combination with diffusion-weighted imaging (DWI) for discriminating breast benign from malignant lesions.*Methods and Materials Two hundred and twenty-six patients were enrolled in the study prospectively with suspected breast lesions clinically. 3.0T MRI scan was performed in all patients, including T1WI, T2WI, DWI, APTWI and dynamic contrast-enhanced magnetic resonance imaging. The ADC and MTRasym(3.5 ppm) values were obtained from DWI and APTWI. The pathology results were confirmed by surgery or biopsy (totally 226 lesions, with 102 benign lesions and 124 malignant lesions). Receiver operating characteristic (ROC) curve was used to evaluate the diagnostic efficacy of APTWI and DWI for distinguishing breast benign from malignant lesions.*Results The ADC and MTRasym(3.5 ppm) values were significantly lower in breast malignant than in benign lesions (P<0.05, respectively). The areas under ROC curves of ADC and MTRasym(3.5 ppm) values for differentiating breast benign from malignant lesions were 0.817 and 0.752, respectively. Taking the maximum Youden's index of ADC value as the ROC optimal cut-off, the diagnostic sensitivity, specificity and accuracy for distinguishing breast benign from malignant lesions were 94.4% (117/124), 62.7% (64/102) and 80.1% (181/226), respectively. Taking the maximum Youden's index of MTRasym(3.5 ppm) value as the ROC optimal cut-off, the diagnostic sensitivity, specificity and accuracy for distinguishing breast benign from malignant lesions were 73.4% (91/124),64.7% (66/102),69.5% (157/226), respectively. Combing the parameters of both DWI and APTWI, the diagnostic performance was superior to either single parameter (P<0.05, respectively), which the area under the ROC curve was 0.868, and the diagnostic sensitivity, specificity and accuracy for distinguishing breast benign from malignant lesions were 82.3% (102/124),79.4% (81/102) and 81.0% (183/226).*Conclusions APTWI can be used to distinguish breast benign from malignant lesions, and the combination of APTWI and DWI parameters could obtain a better diagnostic performance than the single method.*Clinical Relevance/Application APTWI is a novel technique, which can be used to differentiate breast benign from malignant lesions noninvasively.

RESULTS

The ADC and MTRasym(3.5 ppm) values were significantly lower in breast malignant than in benign lesions (P<0.05, respectively). The areas under ROC curves of ADC and MTRasym(3.5 ppm) values for differentiating breast benign from malignant lesions were 0.817 and 0.752, respectively. Taking the maximum Youden's index of ADC value as the ROC optimal cut-off, the diagnostic sensitivity, specificity and accuracy for distinguishing breast benign from malignant lesions were 94.4% (117/124), 62.7% (64/102) and 80.1% (181/226), respectively. Taking the maximum Youden's index of MTRasym(3.5 ppm) value as the ROC optimal cut-off, the diagnostic sensitivity, specificity and accuracy for distinguishing breast benign from malignant lesions were 73.4% (91/124),64.7% (66/102),69.5% (157/226), respectively. Combing the parameters of both DWI and APTWI, the diagnostic performance was superior to either single parameter (P<0.05, respectively), which the area under the ROC curve was 0.868, and the diagnostic sensitivity, specificity and accuracy for distinguishing breast benign from malignant lesions were 82.3% (102/124),79.4% (81/102) and 81.0% (183/226).

CLINICAL RELEVANCE/APPLICATION

APTWI is a novel technique, which can be used to differentiate breast benign from malignant lesions noninvasively.

SPR-BR-17   Measurement Of Perfusion Heterogeneity With Habitats On MRI And Its Association With Prognosis In Breast Cancer Patients

Participants
Eun Sook Ko, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop intratumoral subregions sharing similar perfusional characteristics (habitats) in DCE MR by unsupervised clustering, to analyze their association with patients' outcomes, and to investigate the reproducibility of these discovered subregions in an independent cohort.*Methods and Materials We identified 455 patients with invasive breast cancer who underwent preoperative MRI from two hospitals. Pre-contrast, early, and delayed phase of contrast-enhanced MR images were utilized to construct

perfusion feature vector (PFV) of delta enhancement of early phase and late phase, and washout ratio for each voxel in the tumor region. K-means clustering was applied to the PFV to identify habitats of the training cohort (n = 308). Properties of the identified habitat were applied to the external validation cohort (n = 147). To measure perfusion heterogeneity, texture features across the habitats were computed. The ratio of each habitat to the whole tumor was also computed. Perfusion heterogeneity score (PHS) was calculated from perfusion heterogeneity measurements. Cox-LASSO model was used to determine the association of the PHS or clinicopathological variables with disease-free survival (DFS). Patients were divided into high- and low-risk groups based on the median PHS of the training cohort.*Results There were five habitats with distinct perfusion patterns. The perfusion patterns of the habitats were correlated with established kinetic features based on early and delayed MR images. On the external validation cohort, adding PHS improved the prediction of a worse DFS (hazard ratio = 4.128, P-value = 0.003, C-index = 0.760) when combined with clinical variables-only model (hazard ratio = 3.232, P-value = 0.018, C-index = 0.748).*Conclusions Measurement of perfusional heterogeneity with habitats on MRI would be useful in predicting patients' outcomes and understanding tumor biology.*Clinical Relevance/Application Habitat analysis is known to more accurately reflect intratumoral heterogeneity than whole-tumor analysis. Perfusional heterogeneity using habitat analysis is a rarely explored option and could affect patients' outcomes.

RESULTS

There were five habitats with distinct perfusion patterns. The perfusion patterns of the habitats were correlated with established kinetic features based on early and delayed MR images. On the external validation cohort, adding PHS improved the prediction of a worse DFS (hazard ratio = 4.128, P-value = 0.003, C-index = 0.760) when combined with clinical variables-only model (hazard ratio = 3.232, P-value = 0.018, C-index = 0.748).

CLINICAL RELEVANCE/APPLICATION

Habitat analysis is known to more accurately reflect intratumoral heterogeneity than whole-tumor analysis. Perfusional heterogeneity using habitat analysis is a rarely explored option and could affect patients' outcomes.

SPR-BR-18　Multiparametric MRI-based Radiogenomics Of Breast Cancer Using BI-RADS Lexicon And Quantitative Image Analysis: Association With RNA Sequencing

Participants
Ah Young Park, MD, Seongnam, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Multiparametric MRI features of breast cancer could be attributed to various genetic alterations. We explored the association between RNA sequencing profiles and multiparametric MRI features of breast cancer regarding tumor morphology, heterogeneity, and angiogenesis, and identified imaging markers to predict prognosis and determine treatment.*Methods and Materials From June 2017 to August 2018, breast MRI of 95 women (mean age, 53 years ± 10 [standard deviation]) with invasive breast cancer was prospectively evaluated. Whole genomic RNA obtained from surgical specimens was analyzed using next-generation sequencing. MRI features were evaluated using the Breast Imaging Reporting and Data System (BI-RADS) lexicon to assess tumor morphology, texture analysis to assess tumor heterogeneity, and enhancement kinetics and perfusion analysis to assess tumor angiogenesis. MRI features were correlated with gene expression profiles. Gene networks, enriched functions, and canonical pathways according to MRI features were analyzed using ingenuity pathway. The P value for differential expression was extracted by using a parametric F test comparing nested linear models.*Results 189 genes were associated with 87 MRI features (more than fourfold upregulated or downregulated; P<.05). Irregular mass shape in the BI-RADS was associated with upregulation of HOXA5 (5.1-fold; P=.001) and STC2 (4.9-fold; P=.02), and these genes are associated with estrogen receptor positivity, apoptosis, and survival in breast cancer. Of the lesion types in the BI-RADS, mass was associated with upregulation of SNORD46 (23.4-fold; P=.022), SNORA38 (20.4-fold; P=.005), and SNORA71B (4.2-fold; P=.009). Various texture and perfusion parameters were associated with breast cancer-related small nucleolar RNAs. Top networks according to entropy at T2-weighted imaging and lesion type were associated with cancer, cell death and survival.*Conclusions Compared with RNA sequencing, multiparametric MRI features regarding morphology, lesion heterogeneity and angiogenesis were associated with gene expressions or enriched functions related to molecular subtype, drug response, and prognosis in breast cancers.*Clinical Relevance/Application Multiparametric MRI analysis of breast cancer morphology, heterogeneity and angiogenesis using BI-RADS and quantitative variables can reflect genetic changes related to treatment and prognosis.

RESULTS

189 genes were associated with 87 MRI features (more than fourfold upregulated or downregulated; P<.05). Irregular mass shape in the BI-RADS was associated with upregulation of HOXA5 (5.1-fold; P=.001) and STC2 (4.9-fold; P=.02), and these genes are associated with estrogen receptor positivity, apoptosis, and survival in breast cancer. Of the lesion types in the BI-RADS, mass was associated with upregulation of SNORD46 (23.4-fold; P=.022), SNORA38 (20.4-fold; P=.005), and SNORA71B (4.2-fold; P=.009). Various texture and perfusion parameters were associated with breast cancer-related small nucleolar RNAs. Top networks according to entropy at T2-weighted imaging and lesion type were associated with cancer, cell death and survival.

CLINICAL RELEVANCE/APPLICATION

Multiparametric MRI analysis of breast cancer morphology, heterogeneity and angiogenesis using BI-RADS and quantitative variables can reflect genetic changes related to treatment and prognosis.

SPR-BR-2　Role Of CEM In Assessing Residual Disease Is Comparable To MR Imaging In Various Breast Cancer Tumor Subtypes Receiving NST

Participants
Bhavika Patel, MD, Phoenix, Arizona (*Presenter*) Research support, GRAIL, Inc;Research Grant, Hologic, Inc;Speaker, Hologic, Inc;

PURPOSE

To compare the diagnostic accuracy of contrast enhanced mammography (CEM) to magnetic resonance imaging (MRI) for the evaluation of residual tumor after neoadjuvant systemic treatment (NST).*Methods and Materials All women with newly diagnosed breast cancer who underwent post NST imaging from September 2014 to June 2020 were retrospectively reviewed. For this study, pathological complete response (pCR) was defined as the absence of invasive cancer or DCIS within the breast at surgery. Radiological complete response (rCR) was defined as no residual tumor seen on post-contrast post-treatment imaging. Size of residual malignancy on post-NST CEM and MRI was compared with surgical pathology.Sensitivity, specificity, PPV and NPV values were calculated. Accuracy was further stratified by various breast cancer tumor subtypes.*Results 371 unique breast cancer patients underwent post-treatment contrast-enhanced imaging, of which 223/371 (60%) patients had both CEM and MRI, 67/371

(18%) CEM only and 54/371 (15%) MR only. Mean age 54 (25-84) yrs, 57% (213/371) post-menopausal, 81% (294/371) white, 64% (237/371) dense breasts. NST: chemotherapy in 74% (274/371) and endocrine therapy in 26% (97/371) patients. Tumor subtype analyses: 38% (141/372) ER+/Her2-, 34% (126/371) HER2+ and 28% (104/371) TNBC. 94% (348/371) tumors were T2, (241/371) 65% had no axillary disease. 60% (221/371) underwent mastectomy, 40% (150/371) underwent BCT.rCR was identified in 48% (140/290) on CEM, 38% (104/277) on MR and 35% (130/371) achieved pCR. Lin's concordance correlation coefficient for CEM and MRI vs surgical pathology was 0.57 and 0.54; concordance between CEM and MR was 0.85. Size differences between CEM and MR were within +/- 1 cm in 79% (293/371) of cases. Comparing CEM versus MRI for assessment of complete response, the sensitivity was 83% versus 69%, specificity 72% versus 80%, positive predictive value 64% versus 66%, and negative predictive value 88% versus 82% respectively.*Conclusions Diagnostic accuracy of assessing residual malignancy in the post treatment patient on CEM imaging is comparable to that of MRI in in all breast cancer tumor subtypes.*Clinical Relevance/Application Given that CEM is comparable to the accuracy of breast MRI for assessing residual disease after NST, use of post treatment contrast mammography should be considered when MRI is contraindicated or not available.

RESULTS

371 unique breast cancer patients underwent post-treatment contrast-enhanced imaging, of which 223/371 (60%) patients had both CEM and MRI, 67/371 (18%) CEM only and 54/371 (15%) MR only. Mean age 54 (25-84) yrs, 57% (213/371) post-menopausal, 81% (294/371) white, 64% (237/371) dense breasts. NST: chemotherapy in 74% (274/371) and endocrine therapy in 26% (97/371) patients. Tumor subtype analyses: 38% (141/372) ER+/Her2-, 34% (126/371) HER2+ and 28% (104/371) TNBC. 94% (348/371) tumors were T2, (241/371) 65% had no axillary disease. 60% (221/371) underwent mastectomy, 40% (150/371) underwent BCT.rCR was identified in 48% (140/290) on CEM, 38% (104/277) on MR and 35% (130/371) achieved pCR. Lin's concordance correlation coefficient for CEM and MRI vs surgical pathology was 0.57 and 0.54; concordance between CEM and MR was 0.85. Size differences between CEM and MR were within +/- 1 cm in 79% (293/371) of cases. Comparing CEM versus MRI for assessment of complete response, the sensitivity was 83% versus 69%, specificity 72% versus 80%, positive predictive value 64% versus 66%, and negative predictive value 88% versus 82% respectively.

CLINICAL RELEVANCE/APPLICATION

Given that CEM is comparable to the accuracy of breast MRI for assessing residual disease after NST, use of post treatment contrast mammography should be considered when MRI is contraindicated or not available.

SPR-BR-20 The Added Value Of Integrating 3D Feature Learning In Developing An Ai-based Imaging Biomarker For Breast Tomosynthesis

Participants
Weonsuk Lee, Seoul, Korea, Republic Of (*Presenter*) Employee, Lunit Inc

PURPOSE

Compared to 2D mammography, digital breast tomosynthesis (DBT) visualizes the 3D morphology of breast cancer, but studies on the advantages of AI that can analyze DBT as 3D volume data are insufficient. In this study, we assessed whether the use of an AI algorithm capable of analyzing DBT as 3D volume data provides an additional benefit for developing a data-driven imaging biomarker for DBT (DIB-DBT), as compared to the AI algorithm analyzing each DBT slice as a 2D image.*Methods and Materials A total of 6,174 four-view DBT exams (1,536 cancer, 3,090 benign, 1,548 normal) were retrospectively collected from eight institutions in the United States and then divided into two sets: 5,174 exams for training (1,286 cancer, 2,590 benign, 1,298 normal) and 1,000 exams for validation (250 cancer, 500 benign, 250 normal), and the training set was used to develop DIB-DBTs for detecting breast cancer in DBT. The additional benefit of analyzing DBT as 3D volume data was evaluated in the validation set by comparing two DIB-DBTs developed with (a) DBT slices and (b) 3D volume data of DBT. This comparison was also conducted in subgroup datasets including cancers that present only as microcalcifications (without associated mass or asymmetry) and those that do not. DeLong's test was used to evaluate two correlated receiver operating characteristic (ROC) curves.*Results The area under the ROC curves (AUROC) of DIB-DBT using DBT slices vs 3D volume data were significantly different (0.908 vs 0.926, P < .001). For cancer lesions presenting only as microcalcifications, a significant difference between DBT slices vs 3D volume data was also demonstrated (AUC of 0.813 vs 0.866, P = .002). On the other hand, the difference between the two methods was not significant for the detection of cancer presenting as mass or asymmetry (AUC of 0.886 vs 0.894, P = .267).*Conclusions This study demonstrated the additional benefit of analyzing DBT as 3D volume data for developing an AI algorithm for breast cancer detection. Particularly in the detection of cancer presenting only as microcalcification, detection performance can be significantly improved by incorporating the spatial characteristics of the 3D volume.*Clinical Relevance/Application Instead of analyzing each DBT slice, analyzing 3D DBT volume is helpful in improving the diagnostic performance of an AI algorithm for breast cancer detection, especially for breast cancers presenting only as microcalcifications.

RESULTS

The area under the ROC curves (AUROC) of DIB-DBT using DBT slices vs 3D volume data were significantly different (0.908 vs 0.926, P < .001). For cancer lesions presenting only as microcalcifications, a significant difference between DBT slices vs 3D volume data was also demonstrated (AUC of 0.813 vs 0.866, P = .002). On the other hand, the difference between the two methods was not significant for the detection of cancer presenting as mass or asymmetry (AUC of 0.886 vs 0.894, P = .267).

CLINICAL RELEVANCE/APPLICATION

Instead of analyzing each DBT slice, analyzing 3D DBT volume is helpful in improving the diagnostic performance of an AI algorithm for breast cancer detection, especially for breast cancers presenting only as microcalcifications.

SPR-BR-21 Data-driven Imaging Biomarker To Detect Breast Cancer On Digital Breast Tomosynthesis: Reducing Texture Variability Across Different Institutions

Participants
Hyun Jae Lee, Seoul, Korea, Republic Of (*Presenter*) Employee, Lunit Inc

PURPOSE

To assess the feasibility of reducing texture variability across different institutions for developing a data-driven imaging biomarker on digital breast tomosynthesis (DIB-DBT, an imaging biomarker for the detection of breast cancer based on deep learning technology).*Methods and Materials A total of 5,492 4-view digital breast tomosynthesis (DBT) exams were retrospectively collected for training and validation from seven institutions according to the following criteria: (a) biopsy-confirmed cancer, (b) suspicious but benign on biopsy, (c) non-suspicious benign, and (d) normal. We divided 5,492 DBT exams into 4,492 exams for

training ((a) 1,117, (b) 1,122, (c) 1,126, (d) 1,127) and 1,000 for validation ((a) 250, (b) 250, (c) 250, (d) 250). For external validation, we collected 655 4-view DBT exams from another institution ((a) 163, (b) 164, (c) 164, (d) 164). The Texture Recalibration Module (TRM) was utilized to alleviate the texture variations inherent in different institutions due to varying devices, scanning settings, etc., which could be irrelevant factors for cancer detection. On top of the residual network, we compare methods of training (i) without TRM and (ii) with TRM for two different tasks - Task 1: discriminating cancer in all exams (i.e. (a) vs (b-d)); Task 2: discriminating cancer given a suspicious exam (i.e. (a) vs (b)). DeLong's test was used to compare two correlated ROC curves.*Results For detecting breast cancer (Task 1), per-exam area under the receiver operating characteristic curve (AUROC) of DIB-DBT without vs with TRM were 0.863 vs 0.879 (P =0.027) and 0.838 vs 0.857 (P = 0.075) in the internal and external validation datasets, respectively. The effects of using TRM were more significant in the task of distinguishing between (a) cancer and (b) suspicious but benign on biopsy. For Task 2, per-exam AUROC of DIB-DBT without vs with TRM were 0.762 vs 0.797 (P=0.002) and 0.785 vs 0.816 (P=0.029) in the internal and external validation datasets, respectively.*Conclusions This study demonstrated the effectiveness of TRM for developing DIB-DBT. It not only improves performance in the internal validation dataset by reducing texture discrepancy across different facilities, but also makes the network more robust to the external validation dataset by restraining unimportant texture. In particular, it shows significant improvement of diagnostic performance in the suspicious group (that is, in discriminating cancer given a suspicious exam).*Clinical Relevance/Application DIB-DBT can detect breast cancer with a high level of accuracy across a variety of devices. With further clinical validation, it could be used in the clinical setting as an effective diagnostic support tool for breast cancer screening.

RESULTS

For detecting breast cancer (Task 1), per-exam area under the receiver operating characteristic curve (AUROC) of DIB-DBT without vs with TRM were 0.863 vs 0.879 (P =0.027) and 0.838 vs 0.857 (P = 0.075) in the internal and external validation datasets, respectively. The effects of using TRM were more significant in the task of distinguishing between (a) cancer and (b) suspicious but benign on biopsy. For Task 2, per-exam AUROC of DIB-DBT without vs with TRM were 0.762 vs 0.797 (P=0.002) and 0.785 vs 0.816 (P=0.029) in the internal and external validation datasets, respectively.

CLINICAL RELEVANCE/APPLICATION

DIB-DBT can detect breast cancer with a high level of accuracy across a variety of devices. With further clinical validation, it could be used in the clinical setting as an effective diagnostic support tool for breast cancer screening.

SPR-BR-22   Vacuum Assisted Excision (VAE): A Potentially Approach For Percutaneous Treatment Of Small Breast Tumors.

Participants
Henrique Couto, PhD, Belo Horizonte, Brazil (*Presenter*) Speakers Bureau, Becton, Dickinson and Company;Speakers Bureau, Hologic, Inc

PURPOSE

Evaluate vacuum assisted excision (VAE) for percutaneous treatment of breast cancers.*Methods and Materials A retrospective analysis of 1061 vacuum assisted biopsies (VAB) and VAE in a breast unit between 04/13/2017-11/28/2020. 133 breast cancers were identified (both invasive (IC) and in situ (DCIS)). In total, 116 cases with complete data from VAB/VAE and surgical excision were evaluated. Excision following VAB/VAE was defined as complete resection (CR) if there was no residual tumor, minimal residual disease (MRD) if residual tumor =3mm, gross residual disease (GRD) if residual tumor >3mm and upgrade from DCIS on VAB/VAE to invasive cancer. CR and MRD were combined as potentially resected and treated percutaneously (PRTP). GRD and those with upgrade to invasion were determined not suitable for percutaneous treatment. Factors predictive of PRTP were evaluated.*Results Median age was 55.8 years (20-91; SD 12.15). Median IC size 7.1mm (1-25mm; SD 5.08), median DCIS size 12.5mm (2-65; SD 11.69). Of the 116 tumours, 29 (25%) were CR, 18 (15.5%) MRD, 64 (55.2%) GRD and 5 (4.3%) upgraded from DCIS to invasion.For 29 tumours with no residual disease at surgery, 21(72.4%) were IC and 8 (27.6%) DCIS. The largest completely resected tumor was 11mm for IC and 6mm for DCIS. 47 (40.5%) tumours were PRTP: 11 (23.4%) DCIS and 36 (76.6%) IC. For 77 tumours =10mm, 45 (58.5%) were PRTP. In multivariate analysis VAE (p 0,017 OR 3.2 95% CI), low/intermediate nuclear grade (p 0,003 OR 5.2 95% C.I.) and absence of DCIS with comedo necrosis (p=0.007 OR 4.0 C.I. 95%) were associated with PRTP. When low/intermediate nuclear grade tumours not associated to DCIS with comedo necrosis undergo VAE the chance of PRTP was 75.6%. Taking 10 mm tumor size cut off the multivariate analysis reveals significance for VAE (p 0,008 OR 4.4 95% CI), low/intermediate nuclear grade (p 0,000 OR 12.5 95% C.I.) and final T (TNM) =10mm (p 0,000 OR 56.3 C.I. 95%). When low/intermediate grade tumors =10mm undergo VAE the chance of PRTP is 81.7%.*Conclusions This data suggests that low/intermediate grade pT1a/b breast tumours can be completely excised with percutaneous VAE. Based on this, small (=10mm) invasive breast tumours of low/intermediate grade could be considered for entry to prospective randomized trials of VAE for local treatment, with long term follow up to assess recurrence rates. Standardization of the procedure should also be recommended.*Clinical Relevance/Application Invasive breast cancers, smaller than 10mm, low/intermediate grade are potentially resected and treated percutaneously by VAE.

RESULTS

Median age was 55.8 years (20-91; SD 12.15). Median IC size 7.1mm (1-25mm; SD 5.08), median DCIS size 12.5mm (2-65; SD 11.69). Of the 116 tumours, 29 (25%) were CR, 18 (15.5%) MRD, 64 (55.2%) GRD and 5 (4.3%) upgraded from DCIS to invasion.For 29 tumours with no residual disease at surgery, 21(72.4%) were IC and 8 (27.6%) DCIS. The largest completely resected tumor was 11mm for IC and 6mm for DCIS. 47 (40.5%) tumours were PRTP: 11 (23.4%) DCIS and 36 (76.6%) IC. For 77 tumours =10mm, 45 (58.5%) were PRTP. In multivariate analysis VAE (p 0,017 OR 3.2 95% CI), low/intermediate nuclear grade (p 0,003 OR 5.2 95% C.I.) and absence of DCIS with comedo necrosis (p=0.007 OR 4.0 C.I. 95%) were associated with PRTP. When low/intermediate nuclear grade tumours not associated to DCIS with comedo necrosis undergo VAE the chance of PRTP was 75.6%. Taking 10 mm tumor size cut off the multivariate analysis reveals significance for VAE (p 0,008 OR 4.4 95% CI), low/intermediate nuclear grade (p 0,000 OR 12.5 95% C.I.) and final T (TNM) =10mm (p 0,000 OR 56.3 C.I. 95%). When low/intermediate grade tumors =10mm undergo VAE the chance of PRTP is 81.7%.

CLINICAL RELEVANCE/APPLICATION

Invasive breast cancers, smaller than 10mm, low/intermediate grade are potentially resected and treated percutaneously by VAE.

SPR-BR-23   Attitude Of Women Towards Screening For Breast Cancer: Readiness To Accept False Positive Vs. False Negative Diagnoses

Participants
Toni Vomweg, Koblenz, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Breast cancer screening is under attack. Opponents argue that mammographic screening is associated with overdiagnosis and false positive findings, leading to harm and additional costs. On the other hand, mammographic screening may not be enough for women with dense breasts, who are at increased risk of a late diagnosis of cancer. However, novel breast cancer screening methods that could improve cancer detection in women with dense breasts usually also increase numbers of false-positive diagnoses. Research on improved breast cancer screening methods is therefore received with increasing skepticism from the general medical community. Little scientific evidence exists on women's preferences in this regard.*Methods and Materials A questionnaire was developed and worded in close cooperation with expert psychologists and women's representatives that first explained, in simple language, the fact that screening methods can cause 'false alarm' (false-positive findings), but can also fail to identify existing cancer (be false-negative), and the interdependence of both errors in breast cancer screening. Women were then asked twice, in simple language and in inverted order, whether they (a) prefer a method that avoids false-negative diagnoses, even if it increased the rate of false-positive findings, or (b), whether they would prefer a method that avoids 'false alarm', even if this meant that cancer may not always be found. The questionnaire was validated in a test cohort and underwent several revisions until the wording was sufficiently comprehensible. Then, consecutive women aged 50-69 who presented for routine screening in an organized mammographic screening program were asked to complete the questionnaire.*Results So far, 1031 women participated in this ongoing study. Questionnaires were incomplete in 125/1031. Of the remaining 906 women, 851 (93.9%; Clopper-Pearson 95%-CI: 92.2%-95.4%) preferred a screening test that ensures detection of breast cancer. A total 55 women (6.1%; CI: 4.6%-7.8%) preferred a test that ensures a low risk of false alarm. This distribution of preferences was stable across all age ranges included, and across different levels of education as indicated by the respective highest school or university degree.*Conclusions Women prefer screening tests that ensure detection of cancer, and are ready to accept more false-positive diagnoses.*Clinical Relevance/Application Knowing about women's views and priorities is important when discussing the tolerability of screening methods.

RESULTS

So far, 1031 women participated in this ongoing study. Questionnaires were incomplete in 125/1031. Of the remaining 906 women, 851 (93.9%; Clopper-Pearson 95%-CI: 92.2%-95.4%) preferred a screening test that ensures detection of breast cancer. A total 55 women (6.1%; CI: 4.6%-7.8%) preferred a test that ensures a low risk of false alarm. This distribution of preferences was stable across all age ranges included, and across different levels of education as indicated by the respective highest school or university degree.

CLINICAL RELEVANCE/APPLICATION

Knowing about women's views and priorities is important when discussing the tolerability of screening methods.

SPR-BR-24 Radiomics Of Multiparametric MRI For Assessing The Tumor Microenvironment In Breast Cancer: Correlation With Quantitative 3D Histological Imaging

Participants
Eun Sil Kim, MD, Ansan, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Tumor microenvironment plays a critical role in tumor progression and treatment response and consists of extracellular matrix, immune cells, and microvessels. Three-dimensional (3D) histological imaging has a larger tissue volume (100-200 µm) compared to two-dimensional histological slides (5 µm) and provides more accurate tissue information. We explored whether radiomic analysis of multiparametric MRI can assess the state of the tumor microenvironment in breast cancer using quantitative 3D histological imaging.*Methods and Materials This prospective study enrolled 48 consecutive women with invasive cancers from June 2020 to January 2021. Dynamic contrast-enhanced T1, T2, and diffusion-weighted imaging were performed at 3T MRI. A total of 144 radiomic features were extracted after 3D tumor segmentation. The features consisted of 66 histogram-based, 14 shape-based, 46 texture-based, and 18 filter-based. Core-needle biopsy breast cancer specimens were processed with CLARITY technique for 3D histological imaging and six immunohistochemical staining was performed to evaluate the tumor microenvironment components (collagen, laminin, nidogen, Foxp3, CD8, and CD34). The degree of positive staining was quantified and histological imaging results were dichotomized based on mean or median values. Mann-Whitney U test was used to evaluate the association between radiomic features and histological findings.*Results 11, 83, 125, 5, 33, and 14 MRI radiomic features were associated with expression of collagen, laminin, nidogen, Foxp3, CD8, and CD34, respectively (P < .05). Expression of collagen, laminin and nidogen (components of extracellular matrix) were associated with histogram- and texture (gray-level co-occurrence matrix)-based radiomic features. Expression of CD34 (marker for microvessels) was associated with shape- and texture (gray-level co-occurrence matrix)-based radiomic features.*Conclusions Multiparametric MRI-derived radiomic features can reflect the state of the tumor microenvironment in breast cancer. The extracellular matrix is ??associated with histogram and texture features, and angiogenesis is associated with shape features of the tumor.*Clinical Relevance/Application MRI-derived radiomics has the potential to assess the tumor microenvironment for predicting prognosis and drug resistance, and could lead to better precision medicine for breast cancer treatment.

RESULTS

11, 83, 125, 5, 33, and 14 MRI radiomic features were associated with expression of collagen, laminin, nidogen, Foxp3, CD8, and CD34, respectively (P < .05). Expression of collagen, laminin and nidogen (components of extracellular matrix) were associated with histogram- and texture (gray-level co-occurrence matrix)-based radiomic features. Expression of CD34 (marker for microvessels) was associated with shape- and texture (gray-level co-occurrence matrix)-based radiomic features.

CLINICAL RELEVANCE/APPLICATION

MRI-derived radiomics has the potential to assess the tumor microenvironment for predicting prognosis and drug resistance, and could lead to better precision medicine for breast cancer treatment.

SPR-BR-25 Missed Breast Cancers On MRI In High Risk Patients

Participants
Julie Bilocq-Lacoste, MD, Chambly, Quebec (*Presenter*) Nothing to Disclose

PURPOSE

To determine if MRI features of breast lesions and histologic subtype influences the detectability of breast cancer on MRI screening

in a high-risk population.*Methods and Materials Screening MRIs carried out between 2006-2020 in patients aged 70 and over less, at high risk of breast cancer (lifetime risk of 25% and over), at Sunnybrook Health Sciences Center in Toronto, were reviewed. Breast cancers were diagnosed within 3 months of an MRI describing a suspicious (BI-RADS 4) or highly suspicious (BI-RADS 5) breast lesion. The lesions' characteristics on MRI at the time of diagnosis (MR B) were compared with the characteristics of the same lesions on previous screening MRI (MR A), where either normal (BI-RADS 1), benign (BI-RADS 2) or probably benign (BI-RADS 3) results had been issued. The missed lesions were either unnoticed (not described in the radiological report of IRMM A) or misinterpreted, described as BIRADS-2 or BI-RADS-3 on MR A and subsequently described as BI-RADS-4 or BI-RADS 5 on MR B. The different characteristics of missed cancers were compared using the exact test Fisher and Wilcoxon's rank sum test.*Results There was no association between MRI characteristics and between the type of receptors and the frequency of missed cancers. The proportion of overlooked versus misinterpreted lesions was also not significantly different. Main factors that increased the false negative rate for misinterpreted lesions were mostly related to a complex history (multiple known breast lesions, prior biopsy or surgery, long term stability). Lesions were mostly overlooked because of their small size and high background parenchymal enhancement (BPE). Among the missed lesions, the ones with type 3/washout and type 2/plateau kinetics on MR B, more often had less suspicious kinetics on MR A, either plateau (45%) or progressive (50%) , respectively (P = 0.001). The lesions with progressive enhancement on MR B all had progressive kinetics on MR A.The proportion of basal subtype cancers was higher in patients carrying the BRCA1 gene (50%), than in non-carriers (12%), p = 0.0001 and the proporton of missed cancers was lower in carriers (p < 0.05).*Conclusions The detectability of breast cancers is not influenced by MRI characteristics or type of receptors. Lesions in a post surgical breast or with high BPE should be assessed with caution and long term stability does not rule out malignancy. Lowering threshold for biopsy for lesions with interval change of kinetic curve for a type 2 or 3 curve should be considered. The lower rate of missed cancers in BRCA 1 patients is attributed to the higher proportion of basal-like cancers, more aggressive in nature.*Clinical Relevance/Application To document the features of missed breast cancers on MRI in the aim of decreasing the number of missed cancers.

RESULTS

There was no association between MRI characteristics and between the type of receptors and the frequency of missed cancers. The proportion of overlooked versus misinterpreted lesions was also not significantly different. Main factors that increased the false negative rate for misinterpreted lesions were mostly related to a complex history (multiple known breast lesions, prior biopsy or surgery, long term stability). Lesions were mostly overlooked because of their small size and high background parenchymal enhancement (BPE). Among the missed lesions, the ones with type 3/washout and type 2/plateau kinetics on MR B, more often had less suspicious kinetics on MR A, either plateau (45%) or progressive (50%) , respectively (P = 0.001). The lesions with progressive enhancement on MR B all had progressive kinetics on MR A.The proportion of basal subtype cancers was higher in patients carrying the BRCA1 gene (50%), than in non-carriers (12%), p = 0.0001 and the proporton of missed cancers was lower in carriers (p < 0.05).

CLINICAL RELEVANCE/APPLICATION

To document the features of missed breast cancers on MRI in the aim of decreasing the number of missed cancers.

SPR-BR-26 Background Parenchymal Enhancement Influences Sensitivity Of Contrast-enhanced Mammography

Participants
Paola Clauser, MD, Vienna, Austria (*Presenter*) Speaker, Siemens AG

PURPOSE

The aim of this study was to evaluate the influence of background parenchymal enhancement (BPE) on the sensitivity of contrast-enhanced mammography (CEM).*Methods and Materials In this retrospective, cross-sectional, IRB approved study 128 patients that underwent CEM due to unclear or suspicious findings on conventional mammography or ultrasound were retrospectively evaluated by two radiologists (R1, R2). The mean age was 58.5 (SD 10.85). Most of the patients were post- or perimenopausal, only 17 patients were premenopausal. CEM was performed after intravenous administration of a iodine-based contrast agent. Only examinations with enhancing lesions were included. A standard of reference (image-guided biopsy or at least one year follow up) was available for all the included cases. Reading of mammography and CEM was performed independently. For each breast, BPE and density were assessed, for each lesion, size and BI-RADS were assessed. BPE was evaluated in 4 groups (a: minimal, b: mild, c: moderate, d: marked) according to BI-RADS. For statistical analysis, cases were divided into two groups: minimal or mild BPE (BPE a-b) and moderate or marked BPE (BPE c-d). The sensitivity of both readers with respect to BPE was calculated and compared. Age and lesion size differences according to BPE were investigated by t-tests. A chi-square test was used to assess the association of breast density with dichotomized BPE. Finally, multivariable logistic regression was performed.*Results For R1 98 cases were classified as having BPE a-b and 30 BPE c-d. For R2 94 cases were classified as having BPE a-b and 34 BPE c-d. Mean age was significantly lower in the BPE c-d group (p=0.004). There were no significant differences in mean lesion size (p=0.1400) and breast density (p=0.250) between the two groups. Sensitivity of CEM was significantly higher in the cases with BPE a-b than with BPE c-d for both readers: sensitivity for R1 decreased from 100% (BPE a-b) to 85.7% (BPE c-d) (p=0.002). Sensitivity for R2 decreased from 100% (BPE a-b) to 89.5% (BPE c-d) (P=0.009). Logistic regression confirmed that age had no significant effect on sensitivity, but BPE did.*Conclusions Distinct BPE is present in a significant number of CEM exams and can significantly reduce sensitivity of CEM, regardless of age, lesion size, and parenchymal density. This should be taken in account to avoid misses if BPE is particular moderate or marked.*Clinical Relevance/Application The level of BPE in CEM should be taken in consideration, as it influences the sensitivity significantly. Lesions can be missed, particularly if BPE is moderate or marked.

RESULTS

For R1 98 cases were classified as having BPE a-b and 30 BPE c-d. For R2 94 cases were classified as having BPE a-b and 34 BPE c-d. Mean age was significantly lower in the BPE c-d group (p=0.004). There were no significant differences in mean lesion size (p=0.1400) and breast density (p=0.250) between the two groups. Sensitivity of CEM was significantly higher in the cases with BPE a-b than with BPE c-d for both readers: sensitivity for R1 decreased from 100% (BPE a-b) to 85.7% (BPE c-d) (p=0.002). Sensitivity for R2 decreased from 100% (BPE a-b) to 89.5% (BPE c-d) (P=0.009). Logistic regression confirmed that age had no significant effect on sensitivity, but BPE did.

CLINICAL RELEVANCE/APPLICATION

The level of BPE in CEM should be taken in consideration, as it influences the sensitivity significantly. Lesions can be missed, particularly if BPE is moderate or marked.

SPR-BR-27 Diagnostic Performance And Image Quality Of Contrast Enhanced Spectral Mammography With Low Dose Contrast Agents In Detecting Breast Lesions

Participants
Huizhi Cao, PhD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the clinical value of contrast enhanced spectral mammography with low dose contrast agents in assessing breast lesions.*Methods and Materials In this IRB-approved retrospective study, 223 patients undergoing CESM were randomly assigned into two protocols: 113 patients were carried out exam with conventional dose (Iohexol at 1.5ml/kg;350 mg/ml), and other 100 patients underwent exam with low dose (Iohecol at 1 ml/kg; 350 mg/ml). All the patients accepted MRI examination within one week. The image of CESM, MRI and the histopathological data were analyzed. The clinical value of CESM and MRI were evaluated according to the histopathological results, respectively. The ROC curve was to applied to analyzed clinical efficiency. The tumor size was measured from CESM, MRI modalities and pathological data. By using the Bland-Altman analysis, the consistency of the maximum tumor size was assessed.*Results Histopathologic result revealed 33 benign and 67 malignant lesions in low dose group, and 35 benign and 78 malignant lesions in conventional group. CESM obtained from conventional group had similar AUC area, sensitivity, specificity, PPV, NPV to MRI imaging (0,928, 0.962, 0.846,0.783,0.821 vs. 0.903,0.974,0.809,0.805,0.856). Importantly, CESM of low dose group showed a comparison of clinical performance to MRI as well. (AUC area: 0.944 vs. 0.925; sensitivity:0.990 vs.0.941; specificity:0.825vs.0.831; PPV:0.802 vs. 0.825; NPV:0.855 vs. 0.895). For tumor size measurement, mean tumor size was 3.51 cm for CESM (conventional group) and 3.61 cm for MRI, compared with 3.38 cm on histopathological results, the average difference of diameters between CESM (conventional group), MRI and Histopathologic size was -0.02, -0.10cm, respectively. Additionally, average sizes were measured as 4.02 cm, 3.76 cm, 3.96 cm for CESM (low dose group), MRI and Histopathologic result, and the difference diameters compared to Pathologic data were -0.05, -0.08. Bland-Altman analysis showed best consistency on tumor size between CESM (low dose group), MRI and pathological results.*Conclusions Low doses of contrast agents used for CESM show a comparison both in diagnostic performance and tumor size assessment, compared to CESM obtained with conventional dose.*Clinical Relevance/Application Contrast enhanced spectral mammography performed at low dose of contrast agents can meet the clinical and imaging requirements without sacrificing diagnostic performance.

RESULTS

Histopathologic result revealed 33 benign and 67 malignant lesions in low dose group, and 35 benign and 78 malignant lesions in conventional group. CESM obtained from conventional group had similar AUC area, sensitivity, specificity, PPV, NPV to MRI imaging (0,928, 0.962, 0.846,0.783,0.821 vs. 0.903,0.974,0.809,0.805,0.856). Importantly, CESM of low dose group showed a comparison of clinical performance to MRI as well. (AUC area: 0.944 vs. 0.925; sensitivity:0.990 vs.0.941; specificity:0.825vs.0.831; PPV:0.802 vs. 0.825; NPV:0.855 vs. 0.895). For tumor size measurement, mean tumor size was 3.51 cm for CESM (conventional group) and 3.61 cm for MRI, compared with 3.38 cm on histopathological results, the average difference of diameters between CESM (conventional group), MRI and Histopathologic size was -0.02, -0.10cm, respectively. Additionally, average sizes were measured as 4.02 cm, 3.76 cm, 3.96 cm for CESM (low dose group), MRI and Histopathologic result, and the difference diameters compared to Pathologic data were -0.05, -0.08. Bland-Altman analysis showed best consistency on tumor size between CESM (low dose group), MRI and pathological results.

CLINICAL RELEVANCE/APPLICATION

Contrast enhanced spectral mammography performed at low dose of contrast agents can meet the clinical and imaging requirements without sacrificing diagnostic performance.

SPR-BR-28 Acquisition Of A Delayed Phase Image In Contrast Enhanced Mammography To Improve Diagnostic Accuracy

Participants
Paola Clauser, MD, Vienna, Austria (*Presenter*) Speaker, Siemens AG

PURPOSE

The aim of the study was to evaluate the diagnostic value of an additional post-contrast view to characterize enhancing lesions on contrast-enhanced mammography (CEM).*Methods and Materials In this cross-sectional, IRB approved study 128 patients that underwent CEM due to unclear or suspicious findings on conventional mammography or ultrasound were retrospectively evaluated by two radiologists (R1, R2). Patients' mean age was 58.5 (SD 10.85). CEM was performed after intravenous administration of an iodine-based contrast agent. After the acquisition of the four standard views, a post-contrast, cranio-caudal (CC), fifth view was performed in the breast with unclear or suspicious findings. Only examinations with enhancing lesions were included in the analysis. A standard of reference (image-guided biopsy or at least one year follow up) was available for all the included cases. Readings of mammography alone, CEM and CEM with the additional CC view were performed independently. For each lesion, a BI-RADS classification was given for 1) mammography, 2) CEM and 3) CEM with additional CC view. Diagnostic accuracy was calculated using the area under the receiver operating characteristic curve (AUC), and AUC were compared. The increase in radiation dose due to the additional view was estimated.*Results A total of 128 lesions were included, 82 malignant and 46 benign. The AUC of mammography was 0.804 for R1 and 0.795 for R2. The evaluation of the early-phase CEM improved the diagnostic accuracy of both readers (R1: 0.810, 95% confidence interval (CI) 0.731-0.874; R2: 0.837 95%CI 0.762-0.897). The evaluation of the additional CC view allowed a further improvement in the diagnostic performance, with an AUC of 0.877 for R1 (95%CI 0.807-0.928, p=0.002 compared to CEM) and of 0.850 for R2 (95%CI 0.776-0.907, p=0.371). The acquisition of the additional view determined an increase in the radiation dose between 19.5% and 26.6%, dependent on breast thickness.*Conclusions The acquisition of an additional CC view in the presence of an enhancing lesion on CEM improved diagnostic accuracy with a minor increase in radiation dose.*Clinical Relevance/Application The evaluation of the enhancement curve with the acquisition of an additional cranio-caudal view could improve lesion characterization with CEM.

RESULTS

A total of 128 lesions were included, 82 malignant and 46 benign. The AUC of mammography was 0.804 for R1 and 0.795 for R2. The evaluation of the early-phase CEM improved the diagnostic accuracy of both readers (R1: 0.810, 95% confidence interval (CI) 0.731-0.874; R2: 0.837 95%CI 0.762-0.897). The evaluation of the additional CC view allowed a further improvement in the diagnostic performance, with an AUC of 0.877 for R1 (95%CI 0.807-0.928, p=0.002 compared to CEM) and of 0.850 for R2 (95%CI 0.776-0.907, p=0.371). The acquisition of the additional view determined an increase in the radiation dose between 19.5% and 26.6%, dependent on breast thickness.

CLINICAL RELEVANCE/APPLICATION

The evaluation of the enhancement curve with the acquisition of an additional cranio-caudal view could improve lesion

SPR-BR-29   Microwave Imaging In Breast Cancer - Results From The First-in-human Trial Of The Wavelia System

Participants
Brian Moloney, MBBCh, Galway, Ireland (*Presenter*) Nothing to Disclose

PURPOSE

Microwave Breast Imaging(MBI) is an emerging non-ionizing technology with the potential to detect and characterize breast pathology. The Wavelia MBI system is a low-power electromagnetic wave prototype that demonstrated the ability to detect dielectric contrast between tumor and fibroglandular tissue in preclinical studies with synthetic breast phantoms. Herein, we evaluate the Wavelia system in the clinical setting and establish the safety profile and patient experience. The ability of the system to estimate lesion size and probability of malignancy of breast lesions is investigated, and the clinical usefulness determined.*Methods and Materials The study was registered with the U.S. National Library of Medicine (ClinicalTrials.gov NCT03475992). Patients were recruited to one of 3 groups: Biopsy-proven breast cancers(Group-1), unaspirated cysts(Group-2) and biopsy-proven benign breast lesions(Group-3). MBI lesion size estimations were compared with conventional imaging and post-surgery histology. A Quadratic Discriminant Analysis(QDA) classifier was trained on shape and texture-based features. A hypersurface partitioning the employed 3D feature space in two disjoint continuous subspaces (malignant and benign lesions subspaces) was defined and the classification loss rate computed. An independent review of the results was performed by two breast radiologists. Subjects were surveyed to assess patient experience.*Results 24 patients were included in final analysis(11 Group-1, 8 Group-2 and 5 Group-3). The MBI system detected 12/13 benign lesions, and 9/11 cancers. This included 1 radiographically occult invasive lobular cancer. The MBI system accurately estimated the size of the majority of cancer lesions, with comparison to post-surgery histology. The QDA classifier discriminated benign from malignant breast lesions in 88.5% of cases. The addition of MBI and the generated probability of malignancy was deemed useful by both radiologists. No negative patient feedback was recorded.*Conclusions Wavelia MBI detected, correctly estimated the size and location, and determined the malignancy risk of the majority of breast lesions. This modality has exciting potential as a non-invasive and non-ionizing adjunct for breast cancer diagnosis. Larger studies will be conducted to validate these findings.*Clinical Relevance/Application In this study, the results of the First-in-Human clinical trial of the Wavelia MBI system is detailed. This imaging system demonstrated the capacity to detect, localize and characterize underlying breast pathology, including biopsy confirmed invasive carcinomas and benign breast diseases.

RESULTS

24 patients were included in final analysis(11 Group-1, 8 Group-2 and 5 Group-3). The MBI system detected 12/13 benign lesions, and 9/11 cancers. This included 1 radiographically occult invasive lobular cancer. The MBI system accurately estimated the size of the majority of cancer lesions, with comparison to post-surgery histology. The QDA classifier discriminated benign from malignant breast lesions in 88.5% of cases. The addition of MBI and the generated probability of malignancy was deemed useful by both radiologists. No negative patient feedback was recorded.

CLINICAL RELEVANCE/APPLICATION

In this study, the results of the First-in-Human clinical trial of the Wavelia MBI system is detailed. This imaging system demonstrated the capacity to detect, localize and characterize underlying breast pathology, including biopsy confirmed invasive carcinomas and benign breast diseases.

SPR-BR-4   Use Of Artificial Intelligence Software To Identify Clinically Aggressive Lesions On Prior Digital Breast Tomosynthesis Exams Based On Molecular Subtypes

Participants
Mary F. Ice, MD, Houston, Texas (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate use of a deep learning artificial intelligence (AI) system to identify and score lesions in prior digital breast tomosynthesis (DBT) screening exams of cancer cases, potentially assisting radiologists to detect clinically relevant breast cancer earlier.*Methods and Materials An IRB approved, HIPAA compliant retrospective study with AI (ProFound AI, iCAD, Nashua NH) was conducted with 505 biopsy-proven index cancers and 749 normal DBT cases with 12-18 month prior normal screening DBT exams from 14 community-based centers in the U.S. Three breast imaging radiologists determined if AI detected malignant lesions on index exams. The radiologists also evaluated if these lesions were visible and actionable on the prior exam and if detected by AI. Case-level sensitivity and specificity of AI, including molecular subtypes of invasive cancers of index exams and prior exams were evaluated with 95% confidence intervals (CIs).*Results AI sensitivity on index exams was 89.3% (451/505; 95% CI: 86.6-92.0%) and specificity was 49.0% (367/749; 95% CI: 45.4-52.6%). Radiologists determined that 40.6% (205/505) of cancers were visible and actionable on prior exams. Case-level AI sensitivity on prior exams based on these areas of interest was 80.5% (165/205; 95% CI: 75.1-89.5%) and for all prior exams was 32.7% (165/505; 95% CI 28.6%, 36.8%). AI specificity on priors was 34.7% (260/749; 95% CI: 31.2-38.1%). Invasive cancers were present in 71.9% (363/505) of cancer cases and visible and actionable on 46.3% (168/363) of prior exams. For index exams, sensitivity for luminal A cases was 90.8% (266/293; 95% CI: 87.5-94.1%), for luminal B cases 95.5% (21/22; 95% CI: 86.8-100%), for triple negative cases 96.7% (29/30; 95% CI: 90.2-100%), for HER2+ cases 75.0% (3/4; 95% CI: 32.6-100%) and for cases with unknown molecular subtype lesions 64.3% (9/14; 95% CI: 39.2-89.4%). Based on visible and actionable lesions on prior exams, sensitivity for luminal A cases was 80.8% (118/146; 95% CI: 74.4-87.2%), for luminal B cases 77.8% (7/9; 95% CI: 50.6-100%), for triple negative cases 62.5% (5/8; 95% CI: 29.0-96.0%), for HER2+ cases 100% (2/2; 95% CI: 100-100%) and for cases with unknown molecular subtype lesions 66.7% (2/3; 95% CI: 13.3-100%).*Conclusions In 32.7% of 505 cancer cases, AI identified visible and actionable lesions on the prior exams, indicating that breast cancer could have been detected 12 to 18 months earlier with the use of AI.*Clinical Relevance/Application An AI system is correctly able to identify 77.8% luminal B and 62.5% triple negative cancers 12-18 months prior to clinical diagnosis. This provides an opportunity to detect more aggressive cancers earlier, potentially leading to better outcomes.

RESULTS

AI sensitivity on index exams was 89.3% (451/505; 95% CI: 86.6-92.0%) and specificity was 49.0% (367/749; 95% CI: 45.4-52.6%). Radiologists determined that 40.6% (205/505) of cancers were visible and actionable on prior exams. Case-level AI sensitivity on prior exams based on these areas of interest was 80.5% (165/205; 95% CI: 75.1-89.5%) and for all prior exams was 32.7% (165/505; 95% CI 28.6%, 36.8%). AI specificity on priors was 34.7% (260/749; 95% CI: 31.2-38.1%). Invasive cancers were present in 71.9% (363/505) of cancer cases and visible and actionable on 46.3% (168/363) of prior exams. For index exams, sensitivity for luminal A cases was 90.8% (266/293; 95% CI: 87.5-94.1%), for luminal B cases 95.5% (21/22; 95% CI: 86.8-100%),

for triple negative cases 96.7% (29/30; 95% CI: 90.2-100%), for HER2+ cases 75.0% (3/4; 95% CI: 32.6-100%) and for cases with unknown molecular subtype lesions 64.3% (9/14; 95% CI: 39.2-89.4%). Based on visible and actionable lesions on prior exams, sensitivity for luminal A cases was 80.8% (118/146; 95% CI: 74.4-87.2%), for luminal B cases 77.8% (7/9; 95% CI: 50.6-100%), for triple negative cases 62.5% (5/8; 95% CI: 29.0-96.0%), for HER2+ cases 100% (2/2; 95% CI: 100-100%) and for cases with unknown molecular subtype lesions 66.7% (2/3; 95% CI: 13.3-100%).

CLINICAL RELEVANCE/APPLICATION

An AI system is correctly able to identify 77.8% luminal B and 62.5% triple negative cancers 12-18 months prior to clinical diagnosis. This provides an opportunity to detect more aggressive cancers earlier, potentially leading to better outcomes.

SPR-BR-5 Prediction Of Pathological Complete Response To Neoadjuvant Systemic Therapy Of Triple Negative Breast Cancers Via Deep Learning

Participants
Zijian Zhou, Houston, Texas (*Presenter*) Nothing to Disclose

PURPOSE

Triple-negative breast cancer (TNBC) accounts for approximately 15% of breast cancers and has a relatively poor prognosis. Neoadjuvant systemic therapy (NAST) and surgery are the standard of care treatment, although only approximately 40-50% of the patients achieve pathological complete response (pCR) after NAST. To predict pCR before surgery is currently not possible but would be helpful in guiding treatment and improving patient outcomes. We investigated using deep learning (DL) on sequential MRIs obtained during the early course of NAST for pCR prediction.*Methods and Materials In an ongoing prospective clinical trial (NCT02276443), the baseline and post 4 cycles (C4) of NAST MRIs of 112 TNBC patients were collected; 56 patients (50%) had pCR confirmed at surgery. Positive enhancement integral (PEI) maps derived from the early DCE phase and the b800 DWI were used in our study. Due to the currently limited number of patients, four-fold cross-validation was used for network training and evaluation. The patients were randomly split into four folds. Each fold consisted of 28 patients and had the same pCR:non-pCR ratio of 1. Three folds were grouped and split as the training and internal validation sets with the ratio of 66/18, and the remaining fold was reserved for independent testing. The training/validation/testing process was repeated four rounds and each fold served as the testing set once. Tumor patches from the images were cropped and normalized between [0, 1]. All patches were padded with zeros to the same pixel size of 192×192×64 for PEI, and 192×192×16 for DWI. The DL network was constructed with stacked 3D convolutional and MaxPooling layers, and consisted of four input channels. The extracted features from the four channels were concatenated and used for pCR prediction through three fully connected layers. Binary cross-entropy was used as the loss function, and the network was optimized using an Adam optimizer with the initial learning rate of 0.0001. For each round of testing, the receiver operating characteristic (ROC) curve was plotted and the area under the curve (AUC) was calculated. The final results were the averaged performances of all testing rounds.*Results The DL network achieved an average AUC of 0.81 ± 0.03. The average accuracy was 0.79 ± 0.03, the positive predictive value for pCRs was 0.75 ± 0.05, and the negative predictive value for non-pCRs was 0.88 ± 0.12.*Conclusions Using baseline and C4 PEI and DWI, a deep learning model can potentially predict pCR early during the course of NAST with relatively high AUC.*Clinical Relevance/Application A deep learning model with a high AUC in predicting response early during NAST can potentially help to triage non-responders to alternative treatments, including novel clinical trials for TNBC.

RESULTS

The DL network achieved an average AUC of 0.81 ± 0.03. The average accuracy was 0.79 ± 0.03, the positive predictive value for pCRs was 0.75 ± 0.05, and the negative predictive value for non-pCRs was 0.88 ± 0.12.

CLINICAL RELEVANCE/APPLICATION

A deep learning model with a high AUC in predicting response early during NAST can potentially help to triage non-responders to alternative treatments, including novel clinical trials for TNBC.

SPR-BR-6 The Role Of Magnetic Resonance Imaging (MRI) For Postoperative Surveillance After Mastectomy With Reconstruction Surgery In Breast Cancer Patients

Participants
Jeong Min Lee, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the role of magnetic resonance imaging (MRI) for postoperative surveillance in women who underwent nipple-sparing or skin-sparing mastectomy with immediate reconstruction surgery for breast cancer.*Methods and Materials The 270 consecutive women who underwent nipple-sparing or skin-sparing mastectomy with reconstruction surgery for breast cancer in our institution between August 2016 and March 2019 were included. The women who lacked a postoperative follow-up period less than 2 years, or who did not undergo postoperative MRI, were excluded. Local recurrence which was defined as newly developed breast cancer in the reconstructed breast, was investigated. We assessed the detection rate of MRI and ultrasound for recurrent lesions.*Results One hundred fifty-five patients were finally enrolled. Of 155 patients, 20 recurrent lesions were detected in 16 patients (10.3%). Of 20 recurrent lesions, 11 lesions were symptomatic and 9 were asymptomatic. The asymptomatic lesions were initially detected by MRI (n = 7, 78%) or ultrasound (n = 2, 22%) as routine surveillance, showing significantly higher detection rate of MRI (p = 0.005). Of these MR detected 7 cases, four cases were only detected in MRI. The recurrence interval of asymptomatic lesions was significantly longer (mean 23.9 +/- SD 15.4 months) than that of symptomatic lesions (mean 11.9 +/- SD 5.5 months, p = 0.05). There was no significant difference of size of recurrent lesions between symptomatic lesions (mean 0.74 +/- SD 0.38cm) and asymptomatic lesions (mean 0.72 +/- SD 0.44 cm, p = 0.91).*Conclusions The overall recurrence rate of our study was higher than those of previous studies using mammography only as postoperative surveillance after mastectomy. The detectability of MRI was significantly higher than that of ultrasound, especially in asymptomatic recurrence, which can imply the usefulness of postoperative MRI after nipple-sparing or skin-sparing mastectomy with immediate reconstruction surgery in cancer patients.*Clinical Relevance/Application This study is relevant that it suggests the need for postoperative MR surveillance to detect early disease recurrence in breast cancer patients who underwent nipple-sparing or skin sparing mastectomy with immediate reconstruction surgery.

RESULTS

One hundred fifty-five patients were finally enrolled. Of 155 patients, 20 recurrent lesions were detected in 16 patients (10.3%). Of 20 recurrent lesions, 11 lesions were symptomatic and 9 were asymptomatic. The asymptomatic lesions were initially detected by

MRI (n = 7, 78%) or ultrasound (n = 2, 22%) as routine surveillance, showing significantly higher detection rate of MRI (p = 0.005). Of these MR detected 7 cases, four cases were only detected in MRI. The recurrence interval of asymptomatic lesions was significantly longer (mean 23.9 +/- SD 15.4 months) than that of symptomatic lesions (mean 11.9 +/- SD 5.5 months, p = 0.05). There was no significant difference of size of recurrent lesions between symptomatic lesions (mean 0.74 +/- SD 0.38cm) and asymptomatic lesions (mean 0.72 +/- SD 0.44 cm, p = 0.91).

CLINICAL RELEVANCE/APPLICATION

This study is relevant that it suggests the need for postoperative MR surveillance to detect early disease recurrence in breast cancer patients who underwent nipple-sparing or skin sparing mastectomy with immediate reconstruction surgery.

SPR-BR-7   Abbreviated Screening Breast MRI For Women With A Personal History Of Breast Cancer: Comparison With Full-protocol MRI Using Propensity Score Matching

Participants
Sooyeon Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Screening abbreviated breast MRI (ABMR) has shown reduced scan times and comparable cancer detection rates to full-protocol MRI (FPMR). The application of ABMR has been extended to supplemental screening in women with a personal history of breast cancer (PHBC). However, in most of the prior studies, simulated ABMR protocols were retrospectively evaluated instead of being applied prospectively. Furthermore, few studies have compared the performances of ABMR and FPMR in women with PHBC. Therefore, we aimed to compare the screening performances of ABMR and FPMR in women with PHBC using a matched cohort.*Methods and Materials Women with PHBC underwent FPMR (January 2008-August 2017) or ABMR (September 2017-April 2019) screening. One MRI examination per each woman was randomly selected using stratified random sampling and then a cohort was matched using propensity score matching according to demographic, MRI, and first breast cancer characteristics. Diagnostic performances were compared with biopsy results and at least 1 year of follow-up data.*Results In total, 726 women were allocated to each group. ABMR showed comparable sensitivity (100.0% [15 of 15] vs 69.2% [9 of 13]; P =.086), cancer detection rate (20.7 [15 of 726] vs 12.4 [9 of 726] per 1000; P = .286), and interval cancer rate (0 [0 of 726] vs 5.5 [4 of 726] per 1000; P = .125) along with superior specificity (92.8% [660 of 711] vs 85.8% [612 of 713]; P <.001) compared to FPMR. The BI-RADS category 3 rate of ABMR was less than half that of FPMR (5% [39 of 726] vs 12% [87 of 726]; P <.001). Most (93%; 14 of 15) cancers detected on ABMR were node-negative T1-invasive cancers or ductal carcinoma in situ.*Conclusions ABMR screening showed comparable sensitivity, cancer detection rate, and interval cancer rate along with superior specificity compared to FPMR by reducing unnecessary short-term follow-ups. *Clinical Relevance/Application Abbreviated breast MRI with short scan time might replace full-protocol MRI when screening MRI is considered for women with a personal history of breast cancer.

RESULTS

In total, 726 women were allocated to each group. ABMR showed comparable sensitivity (100.0% [15 of 15] vs 69.2% [9 of 13]; P =.086), cancer detection rate (20.7 [15 of 726] vs 12.4 [9 of 726] per 1000; P = .286), and interval cancer rate (0 [0 of 726] vs 5.5 [4 of 726] per 1000; P = .125) along with superior specificity (92.8% [660 of 711] vs 85.8% [612 of 713]; P <.001) compared to FPMR. The BI-RADS category 3 rate of ABMR was less than half that of FPMR (5% [39 of 726] vs 12% [87 of 726]; P <.001). Most (93%; 14 of 15) cancers detected on ABMR were node-negative T1-invasive cancers or ductal carcinoma in situ.

CLINICAL RELEVANCE/APPLICATION

Abbreviated breast MRI with short scan time might replace full-protocol MRI when screening MRI is considered for women with a personal history of breast cancer.

SPR-BR-8   Survival Outcomes Of Preoperative Breast MRI In Women With Breast Cancer Aged <=35 Years: A Matched Cohort Study

Participants
Ahreum Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate and compare the effect of preoperative breast magnetic resonance imaging (MRI) on overall survival (OS) and recurrence-free survival (RFS) in women with newly diagnosed breast cancer aged 35 years or younger.*Methods and Materials Following IRB approval, 708 women diagnosed with breast cancer (=35 years) between January 2007 and December 2016 were retrospectively identified. Patients who had undergone preoperative MRI (MRI group) were matched to those who had not undergone preoperative MRI (No MRI group) according to 21 variables regarding to patient and tumor characteristics to create a balanced covariate distribution between the two groups. OS and RFS were compared between the MRI and the No MRI groups using the Kaplan-Meier method and the log-rank test. Cox proportional hazard regression analysis was performed to estimate hazard ratios (HR) with a 95% confidence interval (CI).*Results Of total 708 patients, 125 patient pairs from each group were matched. In the matched cohort, no significant association between MRI and No MRI group was observed in the total recurrence (HR, 1.00; p=0.99), locoregional recurrence (HR, 1.31; p=0.42), contralateral breast recurrence (HR, 0.66, p=0.39) and distant recurrence (HR, 0.89, p=0.79). However, improved overall survival was observed in the MRI group, with statistical significance (HR, 0.47; p=0.07). In Cox proportional hazard regression analysis of unmatched cohort, MRI was not a significant independent factor of RFS (HR, 0.99; p=0.95) or OS (HR, 0.65; p=0.14).*Conclusions Although preoperative breast MRI was not a significant prognostic factor for RFS, better overall survival with 53% reduction in the MRI group was observed in women with breast cancer aged 35 years or younger.*Clinical Relevance/Application Preoperative MRI was a significant prognostic factor for improved overall survival in women with breast cancer (=35 years).

RESULTS

Of total 708 patients, 125 patient pairs from each group were matched. In the matched cohort, no significant association between MRI and No MRI group was observed in the total recurrence (HR, 1.00; p=0.99), locoregional recurrence (HR, 1.31; p=0.42), contralateral breast recurrence (HR, 0.66, p=0.39) and distant recurrence (HR, 0.89, p=0.79). However, improved overall survival was observed in the MRI group, with statistical significance (HR, 0.47; p=0.07). In Cox proportional hazard regression analysis of unmatched cohort, MRI was not a significant independent factor of RFS (HR, 0.99; p=0.95) or OS (HR, 0.65; p=0.14).

CLINICAL RELEVANCE/APPLICATION

Preoperative MRI was a significant prognostic factor for improved overall survival in women with breast cancer (=35 years).

SPR-BR-9   **Residual Microcalcifications In Breast Cancer Patients With Complete Response On MRI After Neoadjuvant Chemotherapy: Factors Predicting Residual Malignancy**

Participants
Sohi Kang I, MD,MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate factors that can predict whether the residual microcalcifications are malignant in the patients with complete responseon MRI after neoadjuvant chemotherapy (NAC) for breast cancer.*Methods and Materials We retrospectively reviewed the data base of 2,144 breast cancer patients who underwent neoadjuvant chemotherapy before surgery between January 2017 and December 2019. Consecutive patients who showed radiologic complete response (rCR) on MRI and had surgery for residual mammographic microcalcifications were included. We analyzed patient characteristics, mammographic findings, histologic characteristics of tumors obtained from the percutaneous biopsy before NAC; molecular subtype (ER-positive and HER2-negative, HER2-positive, or triple negative), Ki-67 index, and changes of microcalcifications after NAC. Uni- and multivariate analysis was used to identify predictors of pathological residual malignant calcifications.*Results A total of 134 patients with a median age of 52 years (interquartile range, 42-62 years) showed rCR on breast MRI and residual microcalcifications after NAC. Surgery for residual microcalcifications revealed residual malignancy in 31.3% (42/134) and the other 94 patients had no residua. According to the logistic regression analysis, molecular subtype and Ki-67 were significant independent factors associated with residual malignancy (P < 0.001, P = 0.006). Residual microcalcifications in ER-positive, HER2-negative cancers showed significantly higher malignancy rate (80.0%, 12/15) than those in HER2-positive cancers (22.6%, 21/93) (P < 0.001). The malignancy rate of residual microcalcifications in the cancers with low Ki-76 was significantly higher than that of high Ki-76 (60.0% vs. 15.6%, p = 0.011).*Conclusions Residual microcalcifications in the patients with ER-positive, HER2-negative cancer were mostly malignant despite of rCR on breast MRI. HER2-positive cancer or high Ki-67 index cancer with rCR on breast MRI can achieve pathological CR even with residual microcalcifications on mammography after NAC.*Clinical Relevance/Application Residual microcalcifications in breast cancer patients with complete response on MRI after neoadjuvant chemotherapy (NAC) do not always mean residual malignancy. The results of our study could guide the surgical management of residual microcalcifications after NAC.

RESULTS

A total of 134 patients with a median age of 52 years (interquartile range, 42-62 years) showed rCR on breast MRI and residual microcalcifications after NAC. Surgery for residual microcalcifications revealed residual malignancy in 31.3% (42/134) and the other 94 patients had no residua. According to the logistic regression analysis, molecular subtype and Ki-67 were significant independent factors associated with residual malignancy (P < 0.001, P = 0.006). Residual microcalcifications in ER-positive, HER2-negative cancers showed significantly higher malignancy rate (80.0%, 12/15) than those in HER2-positive cancers (22.6%, 21/93) (P < 0.001). The malignancy rate of residual microcalcifications in the cancers with low Ki-76 was significantly higher than that of high Ki-76 (60.0% vs. 15.6%, p = 0.011).

CLINICAL RELEVANCE/APPLICATION

Residual microcalcifications in breast cancer patients with complete response on MRI after neoadjuvant chemotherapy (NAC) do not always mean residual malignancy. The results of our study could guide the surgical management of residual microcalcifications after NAC.

SSPD03-1   Temporal Progression Of Liver Stiffness In Children With Fontan Physiology: Findings From Serial Magnetic Resonance Elastography (MRE)

Participants
Adarsh Ghosh, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Temporal progression of liver and spleen stiffness measured using MRE has not been evaluated in children with Fontan physiology and may represent the progression of hepatic congestion to Fontan associated liver disease (FALD). We assessed the relationship of the temporal evolution of MRE (t-MRE) with biochemical markers of FALD, from which a model for end-stage liver disease (MELD) score was generated.*Methods and Materials In this IRB approved retrospective study, Fontan patients who had more than one liver MRE between 2010-2020 were identified. The annual rate of change in hepatic and splenic stiffness was determined using MRE as a marker of the temporal progression of stiffness.*Results 34 patients with Fontan physiology were identified with age [median (IQR)] at the 1st MRE 15.6 (14.8-17.9) years. The median time interval between completion of Fontan palliation and the 1st MRE was 13.2 (11.6-16.1) years. Twenty-five patients had two temporally separate MRE scans, while 3, 4, and 5 MRE scans were available in 6, 1 and 2 respectively, with a median time interval between the 1st and last scan being 1.9 (1.1-2.6) years. Baseline and subsequent liver stiffness values obtained by MRE were 3.8 (3.4-4.5) kPa and 4.7 (4.1-5.2) kPa with an annual rate of change in liver stiffness = 0.33 (0.11-0.58) kPa/year. Repeated spleen MRE was available for 29 of these 34 patients, with baseline and subsequent splenic stiffness values of 4.9 (3.9-5.8) kPa and 6.2 (5.4-7.7) kPa, respectively. The annual rate of change of splenic stiffness was 0.62 (-0.19 - 1.47) kPa/year. While the temporal change in liver MRE did not correlate with the temporal change in MELD score (r = -0.205, p = 0.372), the temporal change in spleen MRE showed a moderate negative correlation with the MELD score (r = -0.597 p=0.009). There was a strong positive correlation between the temporal changes of liver stiffness and serum Brain Natriuretic Peptide (BNP) (r= 0.602, p= 0.002).*Conclusions In a pediatric cohort, while there is a temporal progression of liver and splenic stiffness, the liver stiffness does not correlate with the changes in MELD score. This is contrary to the findings in adults and may reflect the natural course of FALD, with the congestion predominating in the early years of life. This is further reiterated by the strong correlation between the temporal changes of BNP (a marker of congestion/heart failure) and liver stiffness.*Clinical Relevance/Application In contrast to findings in adults, temporal increase in liver stiffness in a paediatric cohort does not correlate with increase in MELD scores, and may reflect early stages of the progressively increasing congestion from Fontan Physiology prior to the onset of frank FALD.

RESULTS

34 patients with Fontan physiology were identified with age [median (IQR)] at the 1st MRE 15.6 (14.8-17.9) years. The median time interval between completion of Fontan palliation and the 1st MRE was 13.2 (11.6-16.1) years. Twenty-five patients had two temporally separate MRE scans, while 3, 4, and 5 MRE scans were available in 6, 1 and 2 respectively, with a median time interval between the 1st and last scan being 1.9 (1.1-2.6) years. Baseline and subsequent liver stiffness values obtained by MRE were 3.8 (3.4-4.5) kPa and 4.7 (4.1-5.2) kPa with an annual rate of change in liver stiffness = 0.33 (0.11-0.58) kPa/year. Repeated spleen MRE was available for 29 of these 34 patients, with baseline and subsequent splenic stiffness values of 4.9 (3.9-5.8) kPa and 6.2 (5.4-7.7) kPa, respectively. The annual rate of change of splenic stiffness was 0.62 (-0.19 - 1.47) kPa/year. While the temporal change in liver MRE did not correlate with the temporal change in MELD score (r = -0.205, p = 0.372), the temporal change in spleen MRE showed a moderate negative correlation with the MELD score (r = -0.597 p=0.009). There was a strong positive correlation between the temporal changes of liver stiffness and serum Brain Natriuretic Peptide (BNP) (r= 0.602, p= 0.002).

CLINICAL RELEVANCE/APPLICATION

In contrast to findings in adults, temporal increase in liver stiffness in a paediatric cohort does not correlate with increase in MELD scores, and may reflect early stages of the progressively increasing congestion from Fontan Physiology prior to the onset of frank FALD.

SSPD03-2   Change Over Time In Quantitative MRI Metrics In Children And Young Adults With Sclerosing Cholangitis

Participants
Neeraja Mahalingam, MSc,BSC, Cincinnati, Ohio (*Presenter*) Research support, Perspectum Ltd

PURPOSE

Multiple quantitative magnetic resonance imaging (MRI) methods exist to monitor liver disease in patients with Primary Sclerosing Cholangitis (PSC) and Autoimmune Sclerosing Cholangitis (ASC). These include quantitative magnetic resonance cholangiopancreatography (MRCP), MR elastography (MRE), and iron (T2*)-corrected T1 mapping (cT1). The purpose of this study

is to investigate associations between longitudinal change in quantitative MRI metrics over a one-year period in children and young adults with PSC and ASC.*Methods and Materials This single-center, cross-sectional study, was Health Insurance Portability and Accountability Act (HIPAA)-compliant and institutional review board (IRB)-approved. Autoimmune liver disease registry participants underwent research MRI exams of the liver that included: 3D fast spin-echo MRCP, 2D gradient recalled echo MRE, and cT1 mapping (MOLLI sequence) at baseline and one year later. MRCP+ and LiverMultiscan (both Perspectum Ltd., Oxford, UK) and MREplus+ (Resoundant Inc., Rochester, MN) were used to post-process images. Spearman correlation coefficients were used to assess univariate associations.*Results Nineteen patients with PSC or ASC were included in this study. Mean patient age was 14.7 years (range: 8-20 years; 13 males). Change in liver stiffness significantly positively correlated with changes in several quantitative MRCP measurements, including biliary tree volume as well as total number and length of ducts, strictures, and dilations (r=0.44-0.59; p=0.004-0.03). Changes in whole liver mean cT1 and cT1 interquartile range (IQR) significantly positively correlated with changes in median diameter measurements of the right and left hepatic ducts (r=0.56, and 0.47, respectively; p=0.04).*Conclusions Changes in quantitative MRCP metrics over time correlate with changes in liver stiffness, cT1, and cT1 IQR. Worsening cholangiopathy defined by quantitative MRCP metrics is associated with increasing liver stiffness in children and young adults with PSC and ASC.*Clinical Relevance/Application There is need to explore how quantitative MRI metrics change over time in patients with chronic liver disease, thus helping inform which non-invasive imaging methods best characterize disease progression.

RESULTS

Nineteen patients with PSC or ASC were included in this study. Mean patient age was 14.7 years (range: 8-20 years; 13 males). Change in liver stiffness significantly positively correlated with changes in several quantitative MRCP measurements, including biliary tree volume as well as total number and length of ducts, strictures, and dilations (r=0.44-0.59; p=0.004-0.03). Changes in whole liver mean cT1 and cT1 interquartile range (IQR) significantly positively correlated with changes in median diameter measurements of the right and left hepatic ducts (r=0.56, and 0.47, respectively; p=0.04).

CLINICAL RELEVANCE/APPLICATION

There is need to explore how quantitative MRI metrics change over time in patients with chronic liver disease, thus helping inform which non-invasive imaging methods best characterize disease progression.

SSPD03-3 Pediatric Hepatocellular Carcinoma: Does An Underlying Predisposition Affect Clinical And Imaging Features At Presentation?

Participants
Mitchell Rees, MD, Columbus, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate clinical and imaging features of hepatocellular carcinoma (HCC) in children with and without predisposition to HCC.*Methods and Materials This HIPAA compliant, IRB approved, retrospective study included children (=18 years) with classic HCC who underwent multiphase CT or MRI at one of four institutions between July 2009 and April 2019. Clinical data included age, sex, alpha fetoprotein (AFP) levels, presence or absence of distant metastases, and presence (P+) or absence (P-) of underlying predisposition to HCC. Two radiologists, blinded to predisposing conditions, independently assessed each study for imaging features of classic HCC (non-rim arterial hyperenhancement, non-rim washout, capsule), tumor size, tumor-in-vein (TIV), Pre-Treatment Extent of Tumor (PRETEXT) stage, and PRETEXT annotation factors (extrahepatic extension, multifocality, tumor rupture). One-way ANOVA test or Kruskal-Wallis test were performed for numerical covariates. Chi-square test or Fisher's exact test were employed for categorical covariates.*Results 39 children comprised the study cohort: 22 P- (mean age 11 years +/- 5; 12 boys) and 17 P+ (mean age 11 years +/- 5; 9 boys). In 12/17 patients (70%), P+ factor was a cholestatic disorder or hepatic fibrosis. P- patients had a higher AFP level at presentation (mean 185,739 ng/dL) than P+ patients (mean 6,466 ng/dL) (p 0.028). P- patients had larger tumors (Reader1: P- mean 11.9 cm, P+ mean 6 cm, p 0.003; Reader2: P- mean 12.9 cm, P+ mean 6 cm; p <0.001) and more frequent TIV (Reader1: P- 9/22(41%), P+ 0/17(0%), p 0.002; Reader2: P- 8/22(36%); P+ 0/17(0%), p 0.006). No other imaging feature reached statistical significance for each reader. The most common PRETEXT stage was IV for P- (Reader1: 11/22(50%); Reader2: 12/22(55%)) and II for P+ (Reader1: 7/17(41%); Reader2: 8/17(42%)). Presence of classic imaging features ranged from 27% for capsule (Reader2: 6/22 P-) to 59% for arterial-phase hyperenhancement (Reader1: 13/22 P-).*Conclusions Patients with sporadic HCC (P-) presented with larger tumors, more frequent TIV, and higher PRETEXT stage. Classic HCC imaging features were inconsistently observed in the P- and P+ groups.*Clinical Relevance/Application Compared to HCC in children with underlying predisposition, sporadic pediatric HCC tends to present as a larger mass involving multiple hepatic sections with more frequent tumor thrombus.

RESULTS

39 children comprised the study cohort: 22 P- (mean age 11 years +/- 5; 12 boys) and 17 P+ (mean age 11 years +/- 5; 9 boys). In 12/17 patients (70%), P+ factor was a cholestatic disorder or hepatic fibrosis. P- patients had a higher AFP level at presentation (mean 185,739 ng/dL) than P+ patients (mean 6,466 ng/dL) (p 0.028). P- patients had larger tumors (Reader1: P- mean 11.9 cm, P+ mean 6 cm, p 0.003; Reader2: P- mean 12.9 cm, P+ mean 6 cm; p <0.001) and more frequent TIV (Reader1: P- 9/22(41%), P+ 0/17(0%), p 0.002; Reader2: P- 8/22(36%); P+ 0/17(0%), p 0.006). No other imaging feature reached statistical significance for each reader. The most common PRETEXT stage was IV for P- (Reader1: 11/22(50%); Reader2: 12/22(55%)) and II for P+ (Reader1: 7/17(41%); Reader2: 8/17(42%)). Presence of classic imaging features ranged from 27% for capsule (Reader2: 6/22 P-) to 59% for arterial-phase hyperenhancement (Reader1: 13/22 P-).

CLINICAL RELEVANCE/APPLICATION

Compared to HCC in children with underlying predisposition, sporadic pediatric HCC tends to present as a larger mass involving multiple hepatic sections with more frequent tumor thrombus.

SSPD03-5 The Performance Of Ultrasound In The Evaluation Of Midgut Malrotation And Midgut Volvulus: A Multicenter Study

Participants
Haithuy N. Nguyen, MD, Houston, Texas (*Presenter*) Research Grant, Siemens AG

PURPOSE

To determine the performance of abdominal ultrasound (US) in the evaluation of midgut malrotation and midgut volvulus.*Methods and Materials Multicenter retrospective study. Children evaluated by US for suspected midgut malrotation and volvulus from 01/2018 to 03/2021 were included. Children with known heterotaxy, ventral wall defect, and congenital diaphragmatic hernia, as

well as repeat exams, were excluded from the malrotation evaluation. Demographics, US reports, additional imaging studies, surgeries, alternative surgical diagnoses, and clinical follow-up information were recorded. Reference standards for malrotation included surgery, UGI, CT, and MR, and for volvulus included the above plus clinical follow-up. Sensitivity and specificity were determined for malrotation and volvulus separately.*Results Preliminary data from 420 patients (219 male; median age 40 days, range 0 days - 18 years) with 438 exams were examined. 408 US met inclusion criteria to evaluate for malrotation and 438 for volvulus. 103/408 (25.2%) malrotation cases and 90/438 (20.5%) volvulus cases were deemed inconclusive due to overlying bowel gas or did not report on presence or absence of malrotation and volvulus despite the indication. Of the 305/408 diagnostic exams for malrotation the sensitivity and specificity were respectively 92.9% and 96.5%. Of the 348/438 diagnostic exams for volvulus the sensitivity and specificity were respectively 95.5% and 99.4%. Alternate surgical diagnoses were identified in 56/420 (13.3%) patients.*Conclusions US performs well for the diagnosis of midgut malrotation and volvulus in real life with high sensitivity and specificity.*Clinical Relevance/Application Abdominal US is increasingly being clinically used to evaluate for midgut malrotation and volvulus. We provide data on its performance. Alternate diagnoses found on US are not infrequent.

RESULTS

Preliminary data from 420 patients (219 male; median age 40 days, range 0 days - 18 years) with 438 exams were examined. 408 US met inclusion criteria to evaluate for malrotation and 438 for volvulus. 103/408 (25.2%) malrotation cases and 90/438 (20.5%) volvulus cases were deemed inconclusive due to overlying bowel gas or did not report on presence or absence of malrotation and volvulus despite the indication. Of the 305/408 diagnostic exams for malrotation the sensitivity and specificity were respectively 92.9% and 96.5%. Of the 348/438 diagnostic exams for volvulus the sensitivity and specificity were respectively 95.5% and 99.4%. Alternate surgical diagnoses were identified in 56/420 (13.3%) patients.

CLINICAL RELEVANCE/APPLICATION

Abdominal US is increasingly being clinically used to evaluate for midgut malrotation and volvulus. We provide data on its performance. Alternate diagnoses found on US are not infrequent.

SSIN08-3   Using Natural Language Processing To Assign Fleischner Society Pulmonary Nodule Recommendations To Unstructured Chest CT Reports

Participants

Murray D. Becker, MD, PhD, East Brunswick, New Jersey (*Presenter*) Stockholder, Screen Point Medical;Stockholder, Coverahealth

PURPOSE

Use natural language processing to derive Fleischner Society-based recommendations for incidental pulmonary nodules for Chest CT reports. This pilot study employs a simplified 3 category set of guidelines.*Methods and Materials 2,258 Chest CT reports containing Fleischner Society recommendations were used to train an NLP model to derive nodule follow-up recommendations. To generalize to Chest CT reports that do not explicitly contain recommendations, the Fleischner recommendations were used as labels and stripped from the text before training. Three simplified, aggregated Fleischner-type follow-up categories were used: "Category 1" - no follow-up (65% of cases), "Category 2" - chest CT follow-up (15% of cases), and "Category 3" - urgent follow up (Biopsy, PET/CT, or CT at 3 months) (20% of cases). The data set was split in training, validation and test with a 70:15:15 ratio. The NLP model isolated the text from the report's "Impression" section using heuristics. The text was then encoded using a BERT encoder architecture followed by a linear classification layer. For training, the final (12th) layer of the transformer encoder and the linear layer's weights were fine-tuned. The softmax of the logit outputs from the linear layer were used to classify each impression section into the 3 follow-up categories. Two distinct formulations of the models were used: a binary classification of Category 1 versus Category 2 or 3; and a three-class model using all categories.*Results The binary classifier achieved an ROC-AUC of 0.93 with sensitivity of 0.83 and specificity of 0.85. The three class model had an average ROC-AUC of 0.90 with average sensitivity of 0.76 and average specificity of 0.88. For each of the individual classes within the 3-class model, the ROC-AUC, sensitivity and specificity were 0.91, 0.91, 0.74 for "Category 1", 0.87, 0.56, and 0.92 for "Category 2", and 0.93, 0.80, 0.99 for "Category 3".*Conclusions NLP is able to derive a simplified 2 or 3 class incidental pulmonary nodule follow-up recommendation based on Fleischner guidelines. As part of a QA program, this can help understand errors made using guidelines and may even allow automatic inclusion of recommendations into a study's report.*Clinical Relevance/Application NLP can enhance chest CT reporting by ensuring that all reports contain appropriate, standard nodule follow-up recommendations, and also be used as a measurement tool for chest CT QA programs. The information presented in this paper is based on research results that are not commercially available.

RESULTS

The binary classifier achieved an ROC-AUC of 0.93 with sensitivity of 0.83 and specificity of 0.85. The three class model had an average ROC-AUC of 0.90 with average sensitivity of 0.76 and average specificity of 0.88. For each of the individual classes within the 3-class model, the ROC-AUC, sensitivity and specificity were 0.91, 0.91, 0.74 for "Category 1", 0.87, 0.56, and 0.92 for "Category 2", and 0.93, 0.80, 0.99 for "Category 3".

CLINICAL RELEVANCE/APPLICATION

NLP can enhance chest CT reporting by ensuring that all reports contain appropriate, standard nodule follow-up recommendations, and also be used as a measurement tool for chest CT QA programs. The information presented in this paper is based on research results that are not commercially available.

SSIN08-5   Deep Reinforcement Learning For Aortic Branch Localization In CTA Scans Of Patients With Uncomplicated Type B Aortic Dissection: An International Multicenter Study

Participants

Marina Codari, PhD, Palo Alto, California (*Presenter*) Employee, Arterys Inc.;Spouse, Employee, Carl Zeiss AG

PURPOSE

False lumen outflow patterns are associated with late complications in patients with initially uncomplicated type B aortic dissection (uTBAD). Localization of aortic branches is essential for automated assessment of false lumen outflow patterns on computed tomography angiography (CTA). We sought to evaluate the performance of several deep reinforcement learning (DRL) agents in localizing major aortic branches on CTA scans of uTBAD patients.*Methods and Materials We developed six end-to-end trainable DRL algorithms using a dataset of 145 CTA scans from 7 aortic centers. All agents had the same convolutional neural network

architecture and navigated the image volume using a multiresolution approach. To harmonize data across centers, we resampled all scans to an isotropic voxel resolution of 0.5 mm and applied a [-80, 420] Hounsfield unit density window. Each agent localized the ostium of one of the following arteries: left subclavian, celiac trunk, superior and inferior mesenteric, and left and right renal arteries. We randomly split data from 6 centers into training (80%) and validation (20%) sets, while data from the 7th center served as an independent testing set. Manual annotations performed by aortic imaging experts were used as reference standards. Inter-expert variability in landmark annotation was assessed in the testing dataset and compared with the automatic localization error, defined as the Euclidean distance between paired landmarks. Finally, we recorded the processing time on testing data. Descriptive statistics are reported as median and interquartile range. Pairwise comparisons were performed using Wilcoxon tests.*Results The testing data showed no significant difference between automatic and inter-expert localization error for the left subclavian [3.8 (2.4-7.0) mm vs. 3.7 (2.4-5.1) mm; $P=0.424$]; celiac trunk [2.9 (2.1-5.1) mm vs. 3.7 (2.6-4.5) mm; $P=0.694$] and left renal arteries [(2.3 (1.6-4.4) mm vs. 2.6 (2.1-3.4) mm; $P=0.345$]. Significant differences were found for the right renal [(3.9 (2.4-6.3) mm vs. 2.6 (1.5-3.8) mm; $P=0.004$]; superior mesenteric [(3.3 (2.7-4.7) mm vs. 1.9 (1.4-3.6) mm; $P=0.045$] and inferior mesenteric [(3.0 (2.3-15.2) mm vs. 2.0 (1.4-2.6) mm; $P<0.001$] arteries. The median processing time was 0.7 (0.6-0.9) sec per branch.*Conclusions DRL represents a highly efficient approach to localize multiple branch ostia in uTBAD CTA scans. Nevertheless, the proposed method needs optimization to reach expert-level performance in all branches.*Clinical Relevance/Application Efficient localization of aortic branches allows to assess their involvement in the dissection and the determination of false lumen outflow patterns, potentially leading to better risk-stratification of uTBAD patients.

RESULTS

The testing data showed no significant difference between automatic and inter-expert localization error for the left subclavian [3.8 (2.4-7.0) mm vs. 3.7 (2.4-5.1) mm; $P=0.424$]; celiac trunk [2.9 (2.1-5.1) mm vs. 3.7 (2.6-4.5) mm; $P=0.694$] and left renal arteries [(2.3 (1.6-4.4) mm vs. 2.6 (2.1-3.4) mm; $P=0.345$]. Significant differences were found for the right renal [(3.9 (2.4-6.3) mm vs. 2.6 (1.5-3.8) mm; $P=0.004$]; superior mesenteric [(3.3 (2.7-4.7) mm vs. 1.9 (1.4-3.6) mm; $P=0.045$] and inferior mesenteric [(3.0 (2.3-15.2) mm vs. 2.0 (1.4-2.6) mm; $P<0.001$] arteries. The median processing time was 0.7 (0.6-0.9) sec per branch.

CLINICAL RELEVANCE/APPLICATION

Efficient localization of aortic branches allows to assess their involvement in the dissection and the determination of false lumen outflow patterns, potentially leading to better risk-stratification of uTBAD patients.

SSIN08-6   Uncertainty-based Fast Anomaly Detection With Generative Adversarial Networks On Chest Radiographs

Participants
Jaeyeong Ko, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop an uncertainty-based fast anomaly detection framework with generative adversarial networks (GANs) to detect various abnormalities on chest radiographs in an unsupervised manner.*Methods and Materials The training process of our framework is divided into two processes. First, we trained our GAN model with 72,958 normal chest radiographs. The network used in this work was StyleGAN2-ada, and the input images were resized into a resolution of 1024 by 1024. Second, we trained an encoder for latent space mapping with ResNet34 as a backbone. During the encoder training, the generator and discriminator of GAN were fixed. The loss function used for training the encoder were the sum of encoder loss (Lenc), residual loss (Lres), and feature loss (Lfea). In the anomaly detection process, we exploited Monte Carlo Dropout method to consider the uncertainties in residual map (i.e., differences between input and generated normal images). We also developed a novel visualization method for the residual map, so that abnormality area can be more emphasized. We obtained anomaly score for the input images, and the area under curve (AUC) were used for evaluating the performance of our anomaly detection framework.*Results Our GAN model achieved FID (Fréchet inception distance) score of 1.38 at generating normal chest radiographs. The anomaly detection process took about 1-2 seconds for a single input image. The test dataset contains 14 classes: nodule (n=9), pleural effusion (n=9), pneumothorax (n=10), rib fracture (n=10), pneumomediastinum (n=10), subcuemphysema (n=6), pneumoperitoneum (n=10), calcification (n=10), consolidation (n=7), interstitial opacity (n=10), atelectasis (n=10), mediastinal widening (n=7), cardiomegaly (n=10), and normal (n=100). The AUC of our anomaly detection framework was 0.874 for binary classification of normal and abnormal images.*Conclusions Our uncertainty-based fast anomaly detection model can detect various diseases on chest radiographs without training for each disease. Also, the model provides a fast inference speed comparable to that of supervised models. We propose that our framework can overcome the limitation of current CAD system.*Clinical Relevance/Application Our uncertainty-based fast anomaly detection framework provides anomalous areas through residual maps with uncertainties, which could be helpful for evaluation of chest radiographs.

RESULTS

Our GAN model achieved FID (Fréchet inception distance) score of 1.38 at generating normal chest radiographs. The anomaly detection process took about 1-2 seconds for a single input image. The test dataset contains 14 classes: nodule (n=9), pleural effusion (n=9), pneumothorax (n=10), rib fracture (n=10), pneumomediastinum (n=10), subcuemphysema (n=6), pneumoperitoneum (n=10), calcification (n=10), consolidation (n=7), interstitial opacity (n=10), atelectasis (n=10), mediastinal widening (n=7), cardiomegaly (n=10), and normal (n=100). The AUC of our anomaly detection framework was 0.874 for binary classification of normal and abnormal images.

CLINICAL RELEVANCE/APPLICATION

Our uncertainty-based fast anomaly detection framework provides anomalous areas through residual maps with uncertainties, which could be helpful for evaluation of chest radiographs.

SSGI08-1   Pilot Prospective Evaluation Of An Oral Dark Borosilicate Contrast Media Using Dual-energy CT In A Multi-institutional Study

Participants
Payam Mohammadinejad, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the ability of a new oral dark borosilicate contrast media (DBCM) to display the GI tract on contrast-enhanced abdomino-pelvic dual-energy CT (DECT).*Methods and Materials Patients with known or suspected bowel or peritoneal disease consented to participate in this IRB-approved study. Patients underwent clinically-indicated CT using commercially available oral contrast followed by DECT using 1200 mL of DBCM (Nextrast, Inc; Hillsborough CA). Two GI radiologists rated bowel wall visualization and distention (from the stomach to the ileum) using 5-point and 4-point Likert scales, respectively. Radiologists also rated preference between oral agents for visualization of each GI tract segment and three abnormal imaging findings (-2 to +2 scale, with ±2 indicating change in diagnostic confidence). The optimal virtual monoenergetic image keV setting for bowel wall visualization was also estimated.*Results 14 patients (5 female) underwent clinically-indicated CT (4 with 1000 mL positive oral agent, abdominal CT; 10 with 1350 mL neutral oral agent, CT enterography) followed by DBCM DECT. No patients had serious adverse effects after ingestion of DBCM. Radiologists identified 19 and 21 bowel/peritoneal findings in 13 pts, respectively. Mean bowel wall visualization score was significantly higher for DBCM for stomach (3.3±0.8 vs. 2.8±0.7; P<.05), duodenum (2.9±0.5 vs. 2.6±0.7; P=.02), jejunum (3.5±0.5 vs. 2.6±0.8; P=.005), and ileum (3.4±0.7 vs. 3.0±0.7; P=.02). Mean distention scores were significantly higher using DBCM for all GI tract segments (P=.042), except for the stomach. Radiologists' mean preferences were higher for DBCM across all GI tract segments and imaging abnormalities (mean preference 0.4-1.1). Use of DBCM yielded visualization of new imaging findings in 2 patients (14%), and improved diagnostic confidence (preference=2) in another 10-16%, depending on reader. Optimal keV for viewing was 40-50 keV, depending on patient size.*Conclusions Compared to commercially available oral contrast agents, the use of DBCM resulted in improved visualization and distention of the GI tract, with increased diagnostic confidence in a substantial number of abnormal imaging findings.*Clinical Relevance/Application Use of a new oral Dark Borosilicate Contrast Material with DECT may improve the evaluation of the gastrointestinal tract and peritoneal disease during contrast-enhanced abdomino-pelvic CT exams.

RESULTS

14 patients (5 female) underwent clinically-indicated CT (4 with 1000 mL positive oral agent, abdominal CT; 10 with 1350 mL neutral oral agent, CT enterography) followed by DBCM DECT. No patients had serious adverse effects after ingestion of DBCM. Radiologists identified 19 and 21 bowel/peritoneal findings in 13 pts, respectively. Mean bowel wall visualization score was significantly higher for DBCM for stomach (3.3±0.8 vs. 2.8±0.7; P<.05), duodenum (2.9±0.5 vs. 2.6±0.7; P=.02), jejunum (3.5±0.5 vs. 2.6±0.8; P=.005), and ileum (3.4±0.7 vs. 3.0±0.7; P=.02). Mean distention scores were significantly higher using DBCM for all GI tract segments (P=.042), except for the stomach. Radiologists' mean preferences were higher for DBCM across all GI tract segments and imaging abnormalities (mean preference 0.4-1.1). Use of DBCM yielded visualization of new imaging findings in 2 patients (14%), and improved diagnostic confidence (preference=2) in another 10-16%, depending on reader. Optimal keV for viewing was 40-50 keV, depending on patient size.

CLINICAL RELEVANCE/APPLICATION

Use of a new oral Dark Borosilicate Contrast Material with DECT may improve the evaluation of the gastrointestinal tract and peritoneal disease during contrast-enhanced abdomino-pelvic CT exams.

SSGI08-4   Detection Of Hepatic Steatosis On Contrast-enhanced Dual-energy CT: Role And Efficacy Of Virtual Non-contrast CT

Participants
Roberta Catania, MD, Chicago, Illinois (*Presenter*) Institutional Research Grant, Siemens AG

PURPOSE

To investigate performance and diagnostic accuracy of virtual non-contrast (VNC) images for detection of hepatic steatosis.*Methods and Materials In this IRB-approved retrospective study, imaging studies of adult patients who had multiphasic liver-protocol dual-energy CT (DECT) using the same scanner (SOMATOM Definition Drive, Siemens Healthcare) between January 2019 and October 2020 were included. VNC set of images were reconstructed based on hepatic arterial phase. Similar-sized region of interests (ROIs) were placed in the left lateral, left medial, right anterior, and right posterior segments of the liver on true non

contrast (TNC) and VNC images. Average liver density was calculated as the mean of the four measurements. Attenuation of the spleen and liver attenuations on portal-venous-phase were also recorded. Receiver operating curves (ROC) and area under the curve (AUC) were calculated to assess the accuracy of VNC for detection of hepatic steatosis (which was defined as liver attenuation <40 HU and less than splenic density on TNC). Paired t-test and Pearson's correlation coefficient (r) were used to compare the liver attenuation on VNC and TNC. Bland-Altman plots were used to depict the agreement between TNC and VNC. A p-value of <0.05 was set as a statistically significant difference.*Results 238 patients were included in the final analysis (125 female; mean age 60 ±15.4 years; mean BMI 27 ±5.7 kg/m²). Mean liver attenuation values were 51.3 ± 10.9 HU and 58.1 ±11.6 HU for TNC and VNC, respectively, which were statistically different (p<0.001) with a mean difference of 6.8 HU. The correlation between TNC and VNC was very strong (r=0.8, p<0.001). The AUCs of TNC for detection of hepatic steatosis were 0.92 (95% CI: 0.86-0.98), 0.92 (95% CI: 0.87-0.97), 0.93 (95% CI: 0.86-0.99), 0.91 (95% CI: 0.85-0.97), and 0.87 (95% CI: 0.80-0.95) for entire liver, left lateral, left medial, right anterior, and right posterior segments, respectively. Sensitivity and specificity of VNC for detection of hepatic steatosis were 70% and 95%, respectively, when a threshold level of 46HU was used. They were 41% and 100%, respectively, when a threshold of 40HU was used.*Conclusions Hepatic liver attenuation on TNC is significantly correlated with that of TNC and showed high accuracy to detect hepatic steatosis.*Clinical Relevance/Application The VNC images may be used for detection of hepatic steatosis with high specificity, when TNC images not available.

RESULTS

238 patients were included in the final analysis (125 female; mean age 60 ±15.4 years; mean BMI 27 ±5.7 kg/m²). Mean liver attenuation values were 51.3 ± 10.9 HU and 58.1 ±11.6 HU for TNC and VNC, respectively, which were statistically different (p<0.001) with a mean difference of 6.8 HU. The correlation between TNC and VNC was very strong (r=0.8, p<0.001). The AUCs of TNC for detection of hepatic steatosis were 0.92 (95% CI: 0.86-0.98), 0.92 (95% CI: 0.87-0.97), 0.93 (95% CI: 0.86-0.99), 0.91 (95% CI: 0.85-0.97), and 0.87 (95% CI: 0.80-0.95) for entire liver, left lateral, left medial, right anterior, and right posterior segments, respectively. Sensitivity and specificity of VNC for detection of hepatic steatosis were 70% and 95%, respectively, when a threshold level of 46HU was used. They were 41% and 100%, respectively, when a threshold of 40HU was used.

CLINICAL RELEVANCE/APPLICATION

The VNC images may be used for detection of hepatic steatosis with high specificity, when TNC images not available.

SSGI08-5　Synthetic Extracellular Volume Fraction Without Hematocrit Sampling For Hepatic Applications

Participants
Narine Mesropyan, Bonn, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Calculation of extracellular volume fraction (ECV) currently receives increasing interest as a potential biomarker for non-invasive assessment of liver fibrosis. ECV calculation requires hematocrit (Hct) sampling, which might be difficult to obtain in a high-throughput radiology department. The aim of this study was to generate synthetic ECV for hepatic applications without the need for Hct sampling.*Methods and Materials In this prospective study participants underwent liver MRI. T1 mapping was performed before and after contrast administration. Blood Hct was obtained prior to MRI. We hypothesized that the relationship between Hct and longitudinal relaxation rate of blood (R1=1/T1blood) could be calibrated and used to generate the equation for synthetic Hct and ECV calculation. Conventional and synthetic ECV were calculated. Pearson correlation, linear regression and Bland-Altman method were used for statistical analysis.*Results 180 consecutive patients were divided into derivation (n=90) and validation (n=90) cohorts. In the derivation cohort, native R1 blood and Hct showed a linear relationship (HctMOLLI = 98.04 x (1/T1blood) - 33.17, R2 =0.75, P<0.001), which was used to calculate synthetic ECV in the validation and whole study cohorts. Synthetic and conventional ECV showed significant correlations in the derivation, validation and in the whole study cohorts (r=0.99, 0.97 and 0.99, respectively, P<0.001 respectively) with minimal bias according to the Bland-Altman analysis.*Conclusions Synthetic ECV offers an alternative method for the non-invasive quantification of hepatic ECV.*Clinical Relevance/Application The application of synthetic ECV may potentially overcome an important barrier to clinical implementation of ECV and thus enables a broader use of hepatic ECV in routine clinical practice.

RESULTS

180 consecutive patients were divided into derivation (n=90) and validation (n=90) cohorts. In the derivation cohort, native R1 blood and Hct showed a linear relationship (HctMOLLI = 98.04 x (1/T1blood) - 33.17, R2 =0.75, P<0.001), which was used to calculate synthetic ECV in the validation and whole study cohorts. Synthetic and conventional ECV showed significant correlations in the derivation, validation and in the whole study cohorts (r=0.99, 0.97 and 0.99, respectively, P<0.001 respectively) with minimal bias according to the Bland-Altman analysis.

CLINICAL RELEVANCE/APPLICATION

The application of synthetic ECV may potentially overcome an important barrier to clinical implementation of ECV and thus enables a broader use of hepatic ECV in routine clinical practice.

SSGI08-6　Liver Fat Quantification With Ultrasound (UDFF): Validation With MRI (PDFF) And Analysis Of Confounding Factors

Participants
Reinhard I. Kubale, MD, Homburg/Saar, Germany (*Presenter*) Research Consultant, Siemens AG

PURPOSE

Aim of the study was to evaluate feasibility and confounding factors of a new quantitative sonographic method based on a combination of attenuation and backscatter coefficients (UDFF: Ultrasound derived fat fraction) in correlation with the fat fraction measured by MRI (PDFF: Proton density fat fraction). *Methods and Materials Examinations were done with 2 US-machines (Sequoia and S2000: Siemens) with 5C1, DAX and 6C1 transducers with an algorithm based on a phantom corrected combination of attenuation (AC) and backscatter coefficient (BSC). Measurements of a ROI of 9 cm2 were correlated with MRI PDFF values of segmented liver (segPDFF) and a ROI in the right liver lobe (RLL) in the same position (Vida, Siemens - LiverLab®). To test the reproducibility we examined in a pilot study 20 patients with two UDFF-measurements on different days. The effect of fasting state was tested by performing UDFF before, 1, 3 and 5 hours after a standard meal. The main study consists of 165 consecutive patients (98 male, 67 female), who received a liver MRI for clinical reasons.*Results In the pilot study PDFF of the segPDFF (10.3±9.4%), was significantly higher than in the corresponding ROI (8.65±9.6%). The correlation of PDFF-measurements with scan heads (5C1, DAX, 6C1) were r=0.94 /0.91 and 0.85. Repeated measurements showed values of r=0.99/0.97 and 0.89 with best

reproducibility of the DAX. Measurements before, 1, 3 and 5 hours after meal showed no significant differences between the time points (Friedmann-Test). The main study shows a significant difference in segPDFF (11.6±9.1%) and the ROI (8.9±9.5%). Although AC and BSC are not linear related to PDFF, the model with both parameters shows a significant correlation between UDFF and PDFF of the whole liver and the corresponding ROI and Voxel for all patients r=0.80/0.7 and 0.6 (6C1). Bland-Altmann shows, that main confounding factors are severe liver cirrhosis with a small RLL, patients after chemotherapy / lipiodol application, sarcoidosis and amyloidosis. Problems in MRI arose in severe Hemochromatosis, patients over 150 kg due to artifacts. *Conclusions UDFF shows a strong positive correlation with PDFF. Confounding factors could be identified hypothetically allowing for improvement in the future.*Clinical Relevance/Application UDFF could be a screening tool for early diagnosis of NAFLD and a biomarker for therapy control.

RESULTS

In the pilot study PDFF of the segPDFF (10.3±9.4%), was significantly higher than in the corresponding ROI (8.65±9.6%). The correlation of PDFF-measurements with scan heads (5C1, DAX, 6C1) were r=0.94 /0.91 and 0.85. Repeated measurements showed values of r=0.99/0.97 and 0.89 with best reproducibility of the DAX. Measurements before, 1, 3 and 5 hours after meal showed no significant differences between the time points (Friedmann-Test). The main study shows a significant difference in segPDFF (11.6±9.1%) and the ROI (8.9±9.5%). Although AC and BSC are not linear related to PDFF, the model with both parameters shows a significant correlation between UDFF and PDFF of the whole liver and the corresponding ROI and Voxel for all patients r=0.80/0.7 and 0.6 (6C1). Bland-Altmann shows, that main confounding factors are severe liver cirrhosis with a small RLL, patients after chemotherapy / lipiodol application, sarcoidosis and amyloidosis. Problems in MRI arose in severe Hemochromatosis, patients over 150 kg due to artifacts.

CLINICAL RELEVANCE/APPLICATION

UDFF could be a screening tool for early diagnosis of NAFLD and a biomarker for therapy control.

SSNR01-3   Longitudinal Changes In Brain Connectivity In Hypertensive Patients From The SPRINT Trial: Intensive Blood Pressure Management Is Associated With Less Decline In Connectivity

Participants

Chintan Shah, MD, MS, Cleveland, Ohio (*Presenter*) Spouse, Employee, Merck & Co, Inc

PURPOSE

The Systolic blood PRessure INTervention (SPRINT) trial randomized 9361 adults with hypertension (HTN) to intensive or standard blood pressure management. Intensive therapy resulted in improved cardiovascular outcomes and slower progression of white matter lesions (WML). Here, we assess longitudinal changes in brain functional connectivity (?FC) to determine (1) whether intensive treatment results in less decline in FC and (2) how ?FC relates to changes in brain structure.*Methods and Materials In this IRB-approved multicenter trial, 549 participants underwent brain MRI including 3D T1, 3D T2 FLAIR, and resting state fMRI (axial BOLD EPI; TR/TE 2000/25 ms, 3.5 mm voxels, 120 volumes). Intracranial tissues were segmented using multiatlas label fusion, and WML were identified using deep-learning based classification. Resting state brain networks were identified via group-level independent component analysis (ICA) using MELODIC, followed by group-information-guided ICA. Mean connectivity score (MCS) was calculated for each network as the average within-network FC. ?MCS was compared between groups for six networks of interest using a 2-sample t-test, followed by voxel-wise t-test for the significant network. Subgroup analysis was performed using age, baseline WML, ?WML, and change in ICV-normalized total brain volume (?TBVr). In the full cohort, adjusted linear regression analysis was performed between ?MCS and both ?WML and ?TBVr.*Results Analysis included 406 participants with two scans that passed quality control. SPRINT participants in the standard BP group demonstrated significantly greater decline in MCS of the Auditory-salience-language network (ASLN) relative to those in the intensive treatment group (p=0.014), but not in other networks. A voxel-wise t-test of the ASLN demonstrated regions of significant difference in the cingulate and right insular regions (Figure). In subgroup analyses, SPRINT participants in high baseline WML, older age, and lower ?TBVr subgroups had significantly greater decline in MCS of the ASLN (p<0.05). Agnostic of treatment group, ?MCS of the DMN demonstrated significant correlation with ?WML and ?TBVr (p<0.05).*Conclusions In HTN patients, longitudinal increase in WML burden or decrease in TBV is associated with declines in FC of the DMN. Intensive treatment is associated with less decline in FC of the ASLN, particularly in older patients or those with higher WML.*Clinical Relevance/Application Intensive management of hypertension demonstrates a protective effect on brain function in addition to previously seen impacts on brain structure and cardiovascular outcomes.

RESULTS

Analysis included 406 participants with two scans that passed quality control. SPRINT participants in the standard BP group demonstrated significantly greater decline in MCS of the Auditory-salience-language network (ASLN) relative to those in the intensive treatment group (p=0.014), but not in other networks. A voxel-wise t-test of the ASLN demonstrated regions of significant difference in the cingulate and right insular regions (Figure). In subgroup analyses, SPRINT participants in high baseline WML, older age, and lower ?TBVr subgroups had significantly greater decline in MCS of the ASLN (p<0.05). Agnostic of treatment group, ?MCS of the DMN demonstrated significant correlation with ?WML and ?TBVr (p<0.05).

CLINICAL RELEVANCE/APPLICATION

Intensive management of hypertension demonstrates a protective effect on brain function in addition to previously seen impacts on brain structure and cardiovascular outcomes.

SSNR01-6   Diagnostic Performance Of The Medial Temporal Lobe Atrophy Scale In Patients With Alzheimer's Disease: A Systematic Review And Meta-analysis

Participants

Sojeong Lee, MD, SEOUL, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic performance and reliability of the medial temporal lobe atrophy (MTA) scale in patients with Alzheimer's disease.*Methods and Materials A systematic literature search of MEDLINE and EMBASE databases was performed to select studies that evaluated the diagnostic performance or reliability of MTA scale, published up to January 21, 2021. Pooled estimates of

sensitivity and specificity were calculated using a bivariate random-effects model. Pooled correlation coefficients for intra- and interobserver agreement were calculated using the random effects model based on Fisher's Z transformation of correlations. Meta-regression was performed to explain the study heterogeneity. Subgroup analysis was performed to compare the diagnostic performance of the MTA scale and hippocampal volumetry.*Results Twenty-one original articles were included. The pooled sensitivity and specificity of the MTA scale in differentiating Alzheimer's disease from healthy control were 74% (95% CI, 68-79%) and 88% (95% CI, 83-91%), respectively. The area under the curve of the MTA scale was 0.88 (95% CI, 0.84-0.90). Meta-regression demonstrated that the difference in the method of rating the MTA scale was significantly associated with study heterogeneity (P = 0.04). No significant difference was observed in five studies regarding the diagnostic performance between MTA scale and hippocampal volumetry (P = 0.40). The pooled correlation coefficient for intra- and interobserver agreement were 0.85 (95% CI, 0.69-0.93) and 0.83 (95% CI, 0.66-0.92), respectively.*Conclusions Our meta-analysis demonstrated a good diagnostic performance and reliability of the MTA scale in Alzheimer's disease.*Clinical Relevance/Application Our study supports the use of the MTA scale in daily clinical practice for the evaluation of patients with cognitive impairment.

RESULTS

Twenty-one original articles were included. The pooled sensitivity and specificity of the MTA scale in differentiating Alzheimer's disease from healthy control were 74% (95% CI, 68-79%) and 88% (95% CI, 83-91%), respectively. The area under the curve of the MTA scale was 0.88 (95% CI, 0.84-0.90). Meta-regression demonstrated that the difference in the method of rating the MTA scale was significantly associated with study heterogeneity (P = 0.04). No significant difference was observed in five studies regarding the diagnostic performance between MTA scale and hippocampal volumetry (P = 0.40). The pooled correlation coefficient for intra- and interobserver agreement were 0.85 (95% CI, 0.69-0.93) and 0.83 (95% CI, 0.66-0.92), respectively.

CLINICAL RELEVANCE/APPLICATION

Our study supports the use of the MTA scale in daily clinical practice for the evaluation of patients with cognitive impairment.

SSMK08-1 Identification Of Bone Marrow Edema In Osteomyelitis Of The Lower Limb: Diagnostic Accuracy Of Dual-energy CT versus MRI

Participants
Giovanni Foti, MD, Negrar, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic accuracy values of dual-energy Computed Tomography (DECT) in identifying bone marrow edema (BME) around osteomyelitis foci of the lower limb.*Methods and Materials This prospective institutional review board-approved study included 20 consecutive patients (12 males and 8 females; mean age of 53.4, range 22-76 years) studied between January 2018 and January 2021. All patients underwent DECT (80 kV and tin filter 150 kV) and MRI within 7 days. DECT data were post-processed on a dedicated offline workstation (SyngoVia® VB20) by using a three-material decomposition algorithm for generating non-calcium images of the knee. Two radiologists (16 and 8 years of experience, respectively), blinded to clinical data, evaluated the presence of BME on dedicated color-coded maps. Also 2D high resolution images were evaluated. Diagnostic accuracy values of DECT were calculated by using MRI images as standard of reference. DECT numbers were assessed by using a region of interest (quantitative assessment). Receiver operator curves (ROC) and relative area under the curve (AUC) were calculated. Inter-observer and intra-observer agreement were calculated with k-statistics. Continuous and categorical variables were evaluated by using t test and x2 or Fisher exact test, as appropriate. A value of $p<0.05$ was considered statistically significant.*Results MRI revealed the presence of BME in 16/20 patients (80.0%), located at the level of femur (n=5), of tibia (n=10), of the foot (n=5). The sensitivity, specificity, and AUC of DECT were 87.5% (14/16), 75.0 % (3/4) with an AUC of 0.880 (95% CI: 0.757-0.912) for R1, and 75% (12/16) and 100% (4/4) with an AUC of 0.862 (95% CI: 0.744-0.906) for R2. DECT numbers were significantly different between positive (mean -15.2 ± 25.2 HU) and negative cases (mean -63.2 ± 41.2HU) with a p value <0.001. The interobserver and intraobsever agreements were near perfect (k=0.82 and k=0.84, respectively).*Conclusions DECT is an accurate imaging tool for the identification of BME around lower limb osteomyelitis foci.*Clinical Relevance/Application DECT represents a fast and accurate imaging tool for demonstration of BME in lower limb osteomyelitis, virtually free from motion artifacts and with the additional advantage to yield high resolution bone window images.

RESULTS

MRI revealed the presence of BME in 16/20 patients (80.0%), located at the level of femur (n=5), of tibia (n=10), of the foot (n=5). The sensitivity, specificity, and AUC of DECT were 87.5% (14/16), 75.0 % (3/4) with an AUC of 0.880 (95% CI: 0.757-0.912) for R1, and 75% (12/16) and 100% (4/4) with an AUC of 0.862 (95% CI: 0.744-0.906) for R2. DECT numbers were significantly different between positive (mean -15.2 ± 25.2 HU) and negative cases (mean -63.2 ± 41.2HU) with a p value <0.001. The interobserver and intraobsever agreements were near perfect (k=0.82 and k=0.84, respectively).

CLINICAL RELEVANCE/APPLICATION

DECT represents a fast and accurate imaging tool for demonstration of BME in lower limb osteomyelitis, virtually free from motion artifacts and with the additional advantage to yield high resolution bone window images.

SSMK08-3 Ultrasound Assessment Of Synovitis In Total Knee Replacements

Participants
Ji Lin, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

To determine if Ultrasound (US) can accurately depict the synovial appearances of infection and polymeric wear in total knee replacements.*Methods and Materials IRB approved study consisting of 2 cohorts of patients with painful total knee replacements (TKR). One cohort consisted of 70 patients undergoing MRI who also consented to a diagnostic US. The other cohort consisted of 149 patients with painful TKR undergoing US guided aspiration of the knee, who also had a diagnostic US prior to the aspiration. The diagnostic US in both cohorts consisted of grey scale cine clips and static images of the entire suprapatellar recess and parapatellar gutters in short and long axis planes. US studies were independently reviewed by 2 radiologists, grading the synovium as lamellated, polymeric, or normal/nonspecific, blinded to the MR appearance or the clinical outcome. Each MR exam was reviewed by a 3rd radiologist using the same grading system. Data was analyzed to determine (1) agreement between the MR grader and US graders, (2) agreement between US graders and results from joint fluid analysis and surgical/clinical follow-up, (3) sensitivity, specificity, PPV, and NPV of US.*Results Agreement between US and MRI was poor to fair (grader 1 kappa coefficient (?) 0.167; grader 2 ? 0.322) with moderate inter-rater agreement (? 0.505). Sensitivity and specificity of US for infection in the 2nd cohort was 0.267 and 0.832 for grader 1 and 0.429 and 0.835 for grader 2. PPV and NPV for grader 1 was 0.154 and 0.908. PPV and NPV for grader 2 was 0.115 and 0.967. Sensitivity and specificity of US for polymeric wear in the 2nd cohort was 0.056 and 0.960 for

grader 1 and 0.114 and 0.970 for grader 2. PPV and NPV for grader 1 was 0.375 and 0.889. PPV and NPV for grader 2 was 0.625 and 0.711.*Conclusions Compared to a validated modality (MRI) and aspiration/clinical results, US does not perform well in assessing for infection or polymeric synovitis. Sensitivity and PPV of US compared to aspirate and clinical follow-up was poor for both infection and polymeric synovitis but with good specificity and NPV.*Clinical Relevance/Application US cannot reliably differentiate the various synovial patterns to identify infection or polyethylene wear.

RESULTS

Agreement between US and MRI was poor to fair (grader 1 kappa coefficient (?) 0.167; grader 2 ? 0.322) with moderate inter-rater agreement (? 0.505). Sensitivity and specificity of US for infection in the 2nd cohort was 0.267 and 0.832 for grader 1 and 0.429 and 0.835 for grader 2. PPV and NPV for grader 1 was 0.154 and 0.908. PPV and NPV for grader 2 was 0.115 and 0.967. Sensitivity and specificity of US for polymeric wear in the 2nd cohort was 0.056 and 0.960 for grader 1 and 0.114 and 0.970 for grader 2. PPV and NPV for grader 1 was 0.375 and 0.889. PPV and NPV for grader 2 was 0.625 and 0.711.

CLINICAL RELEVANCE/APPLICATION

US cannot reliably differentiate the various synovial patterns to identify infection or polyethylene wear.

SSMK08-4   Metal Artifact Reduction In Photon-Counting CT Using Monoenergetic Reconstructions - Initial Experience

Participants
Daniel Popp, Augsburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

The objective of this study was to investigative to what extent the spectral information in CT acquisitions with a Photon-Counting Detector (PCD) can be utilized for metal artifact reduction in patients with metal implants.*Methods and Materials Here, we present initial data from 10 patients who are part of an ongoing study that will include 100 patients with metal implants. All patients underwent PCD-CT using a spectral acquisition mode on a novel photon counting dual-source CT scanner (NAEOTOM Alpha, Siemens Healthineers, Erlangen, Germany) as part of routine clinical workup. All datasets were evaluated for metal artifacts in monoenergetic reconstructions (50 keV, 70 keV, 100 keV and 160 keV) independently by two observers blinded to the keV value using a five point rating scale (1: no artifacts; 5: non-diagnostic image quality).*Results Across all measurements, readers showed high agreement in metal artifact score (kappa: 0.74). With increasing keV-levels, metal artifacts were rated substantially less pronounced with means of 3.9 ± 0.27, 3.4 ± 0.5, 2.5 ± 0.5 and 1.7 ± 0.6, for 50, 70, 100 and 160 keV, respectively. Differences of the score of the 160 keV reconstructions to all other keV levels were highly significant. While at 70 keV, 40% of datasets were rated as not fully diagnostic, 100% of datasets were rated as fully diagnostic at 160 keV.*Conclusions Monoenergetic reconstructions derived from photon counting CT scans substantially decrease metal artifacts and increase interpretability in patients with metal implants.*Clinical Relevance/Application Especially after spine surgery the presented PCD-based approach for metal artifact reduction greatly facilitates the evaluation of soft tissues in the surgical area.

RESULTS

Across all measurements, readers showed high agreement in metal artifact score (kappa: 0.74). With increasing keV-levels, metal artifacts were rated substantially less pronounced with means of 3.9 ± 0.27, 3.4 ± 0.5, 2.5 ± 0.5 and 1.7 ± 0.6, for 50, 70, 100 and 160 keV, respectively. Differences of the score of the 160 keV reconstructions to all other keV levels were highly significant. While at 70 keV, 40% of datasets were rated as not fully diagnostic, 100% of datasets were rated as fully diagnostic at 160 keV.

CLINICAL RELEVANCE/APPLICATION

Especially after spine surgery the presented PCD-based approach for metal artifact reduction greatly facilitates the evaluation of soft tissues in the surgical area.

SSMK08-6   Quantitative Dual-Energy CT Reveals Fluorine As A Noninvasive Biomarker For Osteomyelitis In A Tyrannosaurus Rex

Participants
Charlie Hamm, MD, Berlin, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To exploit dual-energy CT (DECT) imaging for the investigation of the diseased left dentary of a Tyrannosaurus rex (T. rex) using a clinical CT-scanner. *Methods and Materials This study investigated the left dentary of the T. rex MB.R. 91216 which is 79.5 cm long and has a max. thickness of 81 mm. CT imaging was performed on a medical 320-row CT scanner with an X-ray absorption measurement range from -32768 to +32767 HU. A dual-energy helical scan mode with 80 and 135 kVp was used that switches between the two energies once during each rotation. Two custom and validated DECT algorithms were applied for the detection of calcium and fluorine, based on a three-material decomposition approach. For quantitative analysis identical regions of interest were placed in different parts of the investigated bone in the calcium and fluorine DECT dataset, respectively, and ANOVA with the Bonferrroni´s multiple comparisons test was applied.*Results The left dentary shows two notable findings on visual inspection and CT imaging, a diffuse thickening of nearly the entire left dentary with a homogenous distribution of calcium and a focal exophytic mass on the ventral surface of the dentary with a significant accumulation of fluorine (p<0.0001). Furthermore, the focal exophytic mass showed diminutive diffuse lucencies extending from the surface to the tooth root of the 5th replacement tooth and demonstrated a tapering shape with a fistular-like center, which also demonstrated a significant fluorine accumulation respectively (p<0.0001). The perseverance of anatomical structures within the mass suggests the diagnosis of tumefactive osteomyelitis.*Conclusions While DECT imaging is a common clinical diagnostic tool, this study presents a novel DECT-based approach for the characterization of tumefactive osteomyelitis in a T. rex. Specifically, the noninvasive density- and element-based material decomposition of fossilized bone revealed that fluorine could serve as an imaging biomarker for areas with decreased bone density, helping paleontologists to investigate fossils without the need to harm their integrity.*Clinical Relevance/Application DECT-based quantification of fluorine revealed a novel noninvasive imaging biomarker for osteomyelitis in vertebrate paleontology, underlining the role of radiology in paleontological research.

RESULTS

The left dentary shows two notable findings on visual inspection and CT imaging, a diffuse thickening of nearly the entire left dentary with a homogenous distribution of calcium and a focal exophytic mass on the ventral surface of the dentary with a

significant accumulation of fluorine (p<0.0001). Furthermore, the focal exophytic mass showed diminutive diffuse lucencies extending from the surface to the tooth root of the 5th replacement tooth and demonstrated a tapering shape with a fistular-like center, which also demonstrated a significant fluorine accumulation respectively (p<0.0001). The perseverance of anatomical structures within the mass suggests the diagnosis of tumefactive osteomyelitis.

CLINICAL RELEVANCE/APPLICATION

DECT-based quantification of fluorine revealed a novel noninvasive imaging biomarker for osteomyelitis in vertebrate paleontology, underlining the role of radiology in paleontological research.

SSCH06-1 Free-breathing Radial 3D Fat-suppressed T1-weighted Gradient Echo (R-vibe) Sequence For Assessment Of Pulmonary Lesions: A Prospective Comparison Of CT and MRI

Participants

Xu Yang Zhang, Xianyang, China (*Presenter*) Nothing to Disclose

PURPOSE

To determine whether the pulmonary MR imaging with free-breathing radial 3D fat-suppressed T1-weighted gradient echo (r-VIBE) sequence can detect lung lesions and display lesion profiles with an accuracy comparable to that of computed tomography (CT), which is the reference standard in this study.*Methods and Materials Sixty-three consecutive patients were prospectively enrolled as their chest radiograph or CT raised suspicions of lung cancer between October, 2016 and March, 2017. All the patients received 3T MRI scanning with a free-breathing r-VIBE sequence within 48 hour after CT. Morphologic features of lesions were evaluated by two radiologists with a 5-point system. Chest standard CT were used as reference standard. Weighted kappa analysis and chi-squared test were used to determine both inter-observer agreement and inter-method agreement.*Results A total of 293 solid pulmonary nodules or masses and 1 ground-glass nodule were detected by CT. Compared to CT, r-VIBE correctly detected 94.8% of pulmonary nodules. The inter-method agreements were significant and either "substantial" or "excellent" in the evaluation of following features between r-VIBE and standard-dose CT: including lobulation, spiculation, convergence of vessels, bubble-like attenuation,cavitation and mediastinal lymph node enlargement (0.605=K=1.000; P<0.0001), with the sensitivity of 81.8%, 93.3%, 71.4%, 81.8%, 100% and 88.2%. However, K values for inter-method agreements were significant but "moderate" or "poor" for evaluating pleural tag, halo, and calcification (0.355=K=0.451;P<0.0001) with the sensitivity of 66.7%, 25%, 33.3%.*Conclusions The use of pulmonary MR imaging with r-VIBE showed high detection rate of pulmonary nodules and inter-method agreement with CT.*Clinical Relevance/Application It is also useful for nodule morphologic assessment.

RESULTS

A total of 293 solid pulmonary nodules or masses and 1 ground-glass nodule were detected by CT. Compared to CT, r-VIBE correctly detected 94.8% of pulmonary nodules. The inter-method agreements were significant and either "substantial" or "excellent" in the evaluation of following features between r-VIBE and standard-dose CT: including lobulation, spiculation, convergence of vessels, bubble-like attenuation,cavitation and mediastinal lymph node enlargement (0.605=K=1.000; P<0.0001), with the sensitivity of 81.8%, 93.3%, 71.4%, 81.8%, 100% and 88.2%. However, K values for inter-method agreements were significant but "moderate" or "poor" for evaluating pleural tag, halo, and calcification (0.355=K=0.451;P<0.0001) with the sensitivity of 66.7%, 25%, 33.3%.

CLINICAL RELEVANCE/APPLICATION

It is also useful for nodule morphologic assessment.

SSCH06-3 Impact Of Photon Counting CT In Reader Confidence In Diagnosis Of Interstitial Lung Disease

Participants

Akitoshi Inoue, MD,PhD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate impact of higher spatial resolution of investigational photon-counting detector (PCD)-CT on radiologist confidence in diagnosis of usual interstitial pneumonia (UIP) compared to conventional energy-integrating detector (EID)-CT.*Methods and Materials Patients suspected of interstitial lung disease were scanned on a prototype PCD-CT system after informed consent and clinically-indicated EID-CT. In two sessions, three thoracic radiologists blinded to clinical history and scanner type evaluated CT images of the right and left lungs separately on EID- or PCD-CT, reviewing each lung once/session, rating confidence in reticulations, traction bronchiectasis, honeycombing, ground-glass opacities (GGO), mosaic pattern, and lower lobe predominance (100-point scale: 0—33, likely absent, 34—66, indeterminate, 67—100, likely present). Radiologists rated confidence for the probability of UIP (0—20, normal; 21—40, inconsistent with UIP; 41—60, indeterminate UIP; 61—81; probable UIP; 81—100, definite UIP), and graded image quality (5-point Likert scale). Because a confidence scale of 50 represented completely equivocal findings, the absolute value of confidence scores from 50 was used for analysis (higher scores were more confident). Reader confidence was compared using linear mixed effects regression. The consistency of findings and diagnosis between two scanners were evaluated using McNemar's test and weighted kappa statistics, respectively.*Results 30 patients (mean age: 68.8 ± 11.0 years, M: F=18:12) underwent conventional EID and research PCD-CT. The confidence scales in PCD-CT were significantly higher than those in EID-CT for reticulation (40.7 v.s 38.3; P=0.023), GGO (34.4 v.s 31.7; P=0.019), and mosaic pattern (38.6 v.s 35.9 ; P=0.013), but not

traction bronchiectasis (41.7 v.s 41.4; P=0.749), honeycombing (42.8 v.s 42.0; P=0.370), or lower lung predominant (28.3 v.s 29.7; P=0.375). GGO and mosaic pattern demonstrated significant differences between interpretations of EID-CT and PCD-CT (P=0.028). Reader confidence in UIP changed significantly for 1/3 readers (p=0.009). PCD-CT had higher scores in overall image quality (4.84 ± 0.38) than those in EID-CT (4.02 ± 0.40; P<0.001).*Conclusions PCD-CT provided better image quality and improved reader's confidence for reticulation, GGO, and mosaic pattern with idiosyncratic effect on reader diagnosis of UIP.*Clinical Relevance/Application PCD-CT provides improved image quality that translates into increased diagnostic confidence in reticulations, mosaic pattern, and ground glass opacities, which may improve imaging diagnosis of UIP.

RESULTS

30 patients (mean age: 68.8 ± 11.0 years, M: F=18:12) underwent conventional EID and research PCD-CT. The confidence scales in PCD-CT were significantly higher than those in EID-CT for reticulation (40.7 v.s 38.3; P=0.023), GGO (34.4 v.s 31.7; P=0.019), and mosaic pattern (38.6 v.s 35.9 ; P=0.013), but not traction bronchiectasis (41.7 v.s 41.4; P=0.749), honeycombing (42.8 v.s 42.0; P=0.370), or lower lung predominant (28.3 v.s 29.7; P=0.375). GGO and mosaic pattern demonstrated significant differences between interpretations of EID-CT and PCD-CT (P=0.028). Reader confidence in UIP changed significantly for 1/3 readers (p=0.009). PCD-CT had higher scores in overall image quality (4.84 ± 0.38) than those in EID-CT (4.02 ± 0.40; P<0.001).

CLINICAL RELEVANCE/APPLICATION

PCD-CT provides improved image quality that translates into increased diagnostic confidence in reticulations, mosaic pattern, and ground glass opacities, which may improve imaging diagnosis of UIP.

SSCH06-4   Quantitative CT Analysis Of Ambient Particulate Matter Exposure-associated Multiscale Structure And Function Alteration In Healthy, Asthma, COPD, And IPF Lungs

Participants
Jiwoong Choi, PhD, Kansas City, Kansas (*Presenter*) Nothing to Disclose

PURPOSE

We explored to associate directly measured ambient particulate matter (PM) exposure with quantitative computed tomography (QCT)-based pulmonary structural and functional alteration in healthy adults and patients with asthma, chronic obstructive pulmonary disease (COPD) and idiopathic pulmonary fibrosis (IPF).*Methods and Materials Inspiratory and expiratory CTs, direct measurements of PM1, PM2.5, PM4, PM10, and total suspended particle (TSP), and pulmonary function test (PFT) results were prospectively collected from 128 participants (age=67.6±8.57, M:F=92:36) with healthy lungs (age=70.4±6.6, M:F=3:17), asthma (age=62.6±10.6, M:F=23:11), COPD (age=68.3±7.0, M:F=47:4), and IPF (age=71.2±6.9, M:F=19:4). 160 QCT features of multiscale structure and function, body composition, and vessel quantification were derived (Figure A). Machine learning analysis such as principal component analysis (PCA) and K-means clustering were used for dimension reduction and subgrouping. ANOVA and post-hoc Kruskal-Wallis test and Pearson's correlation were used for statistical analysis.*Results Four QCT-based clusters were obtained from PCA and K-means clustering. Cluster 1 through 4 (C1, C2, C3, and C4) showed significant differences in exposures to PM4 (C1>C2>C3>C4), PM10 (C1>C2=C3>C4) and TSP (C1>C2=C3>C4) (p<0.05). Highest exposure cluster C1 had significantly increased whole lung high attenuation area percent (HAA%) and significantly decreased mean local lung expansion (J) in all five lobes (p<0.05). Normalized airway diameters were significantly smaller in C1 than the minimally exposed cluster C4 (p<0.05). Airway cross-section circularity and normalized wall thickness in multiple regions were smaller in C1 than in C4 (p<0.05). In each disease type, significant correlations were also found between PM exposures with multiple QCT features (Figures B and C).*Conclusions QCT analysis showed impacts of ambient PM exposure on structural and functional characteristics of healthy, asthma, COPD, and IPF lungs.*Clinical Relevance/Application QCT analysis may provide more precise pathophysiological interpretation of association between ambient PM exposure with regional structural and functional alterations in healthy, asthma, COPD, and IPF lungs.

RESULTS

Four QCT-based clusters were obtained from PCA and K-means clustering. Cluster 1 through 4 (C1, C2, C3, and C4) showed significant differences in exposures to PM4 (C1>C2>C3>C4), PM10 (C1>C2=C3>C4) and TSP (C1>C2=C3>C4) (p<0.05). Highest exposure cluster C1 had significantly increased whole lung high attenuation area percent (HAA%) and significantly decreased mean local lung expansion (J) in all five lobes (p<0.05). Normalized airway diameters were significantly smaller in C1 than the minimally exposed cluster C4 (p<0.05). Airway cross-section circularity and normalized wall thickness in multiple regions were smaller in C1 than in C4 (p<0.05). In each disease type, significant correlations were also found between PM exposures with multiple QCT features (Figures B and C).

CLINICAL RELEVANCE/APPLICATION

QCT analysis may provide more precise pathophysiological interpretation of association between ambient PM exposure with regional structural and functional alterations in healthy, asthma, COPD, and IPF lungs.

SSCH06-5   Magnetic Resonance Imaging Sequences For Interstitial Lung Disease Assessment In Systemic Sclerosis

Participants
Giovanni Morana, MD, Treviso, Italy (*Presenter*) Speakers Bureau, Bracco Group

PURPOSE

Ultrashort Echo Time (UTE) Magnetic Resonance Imaging (MRI) sequences have been improved to counteract signal decay of lung parenchyma. Compressed Sensing (CS) sequences fast acquisitions should permit breath hold scans. We tested two MRI sequences, UTE Spiral VIBE and CS VIBE, in assessing Interstitial Lung Disease (ILD) related to Systemic Sclerosis (SSc), compared to computed tomography (CT). We aimed to tried out MRI for ILD detection and ILD, ground glass opacities (GGO), reticulation (RET), honeycombing (HC) and consolidation (CON) extent analysis.*Methods and Materials SSc patients in clinical need for chest CT were prospectively enrolled. CT, MRI free breathing UTE Spiral VIBE and inspiratory breath hold CS VIBE scans were performed. Two radiologists, independently and in consensus, computed a visual analysis of GGO, RET, HC and CON extents, on MRI and CT (vCT). The sum of the alterations was assumed as ILD extent. As regards ILD detection, patients were considered positive for ILD when ILD extent >5% total lung volume on visual scores. A quantitative texture analysis (qCT) was also performed on CT, providing ILD, GGO, RET and HC extents. Cohen's k was adopted for inter-reader concordance in visual ILD detection. Sensitivity and specificity of MRI for ILD detection were evaluated. Lin's concordance (CCC) was adopted to compute the agreement in extent analysis between readers and between CT and MRI.*Results 54 patients performed CT and MRI. 9 CT were discarded from qCT for inadequate segmentation. 3 UTE Spiral VIBE and 19 CS VIBE were excluded for low image quality. ILD was detected in 25/54 vCT.

Mean extents on vCT were: ILD 14.7%, GGO 7.7%, RET 6.8%. HC and CON extents were irrelevant and excluded. Inter-reader MRI k for ILD detection were 0.56 for UTE Spiral VIBE and 0.53 for CS VIBE, while ILD and GGO extent analysis CCC were 0.89 and 0.79 for UTE Spiral VIBE, 0.71 and 0.80 for CS VIBE, respectively. RET extent had lower inter-reader CCC for both MRI scans. UTE Spiral VIBE sensitivity and specificity in ILD detection were 95.8% and 77.8%, while ILD and GGO extent analysis obtained the following CCC with CT: 0.95 and 0.93 against vCT ILD and 0.89 and 0.88 against qCT, respectively. RET extent analysis obtained lower CCC. CS VIBE showed a sensitivity and specificity in ILD detection of 46.7% and 95.0%, but lower CCC in all extent analyses against CT.*Conclusions MRI UTE Spiral VIBE may suffer for different readers interpretations in ILD detection, presumably at low disease extents. However, UTE spiral VIBE could be a reliable tool in assessing ILD and GGO extent when the ILD is ascertained. CS VIBE are not a reliable tool.*Clinical Relevance/Application UTE Spiral VIBE could be considered for follow up of selected SSc-ILD patients, allowing a reduction of CT x-ray exposure.

RESULTS

54 patients performed CT and MRI. 9 CT were discarded from qCT for inadequate segmentation. 3 UTE Spiral VIBE and 19 CS VIBE were excluded for low image quality. ILD was detected in 25/54 vCT. Mean extents on vCT were: ILD 14.7%, GGO 7.7%, RET 6.8%. HC and CON extents were irrelevant and excluded. Inter-reader MRI k for ILD detection were 0.56 for UTE Spiral VIBE and 0.53 for CS VIBE, while ILD and GGO extent analysis CCC were 0.89 and 0.79 for UTE Spiral VIBE, 0.71 and 0.80 for CS VIBE, respectively. RET extent had lower inter-reader CCC for both MRI scans. UTE Spiral VIBE sensitivity and specificity in ILD detection were 95.8% and 77.8%, while ILD and GGO extent analysis obtained the following CCC with CT: 0.95 and 0.93 against vCT ILD and 0.89 and 0.88 against qCT, respectively. RET extent analysis obtained lower CCC. CS VIBE showed a sensitivity and specificity in ILD detection of 46.7% and 95.0%, but lower CCC in all extent analyses against CT.

CLINICAL RELEVANCE/APPLICATION

UTE Spiral VIBE could be considered for follow up of selected SSc-ILD patients, allowing a reduction of CT x-ray exposure.

SSCH06-6   Spectral Detector CT Derived Pulmonary Perfusion Maps And Pulmonary Parenchyma Characteristics For The Automated Diagnosis And Classification Of Pulmonary Hypertension

Participants
Roman Gertz, MD, Cologne, Germany (*Presenter*) Institutional research contract, Koninklijke Philips NV;

PURPOSE

To evaluate the usefulness of spectral detector CT (SDCT)-derived pulmonary perfusion maps and pulmonary parenchyma characteristics for the automated diagnosis and classification of pulmonary hypertension (PH) and to assess their association with hemodynamics.*Methods and Materials 162 consecutive patients with right heart catheter (RHC) proven PH of different etiologies as defined by the Nice classification who underwent CT pulmonary angiography (CTPA) on a SDCT and 20 patients with an invasive rule-out of PH were included in this retrospective study. Automatic lung segmentation into normal and malperfused areas based on iodine content as well as automatic, virtual non-contrast-based emphysema quantification were performed. Corresponding volumes, histogram features and the ID SkewnessPerfDef-Emphysema-Index (d-index) were computed and compared between groups. The relationship of volumetric parameters to hemodynamics was evaluated using Spearman's correlation, linear regression analysis and area under the receiver operating characteristic curve (AUC).*Results Patients with PH showed a significantly greater extent of malperfused lung areas (VPerfDef) as well as stronger and more homogenous perfusion defects. Perfusion deficits in Nice class 3 and 4 were significantly stronger and more homogenous compared to all other subgroups. The d-index allowed for further subclassification of subgroups 3 and 4 (AUC: 0.92, 95%-CI, 0.85 - 0.99). In pre-capillary PH the VPerfDef was not only in significant correlation with the pulmonary vascular resistance (PVR) but also a strong predictor of the PVR. In subgroup 4 the prognostic value of the VPerfDef remained even after the adjustment for established markers of an increased PVR. Moreover, the VPerfDef yielded a prognostic merit for an increased PVR above NT-pro BNP.*Conclusions The automated SDCT-based analysis of pulmonary perfusion maps and pulmonary parenchyma characteristics can aid the diagnosis of PH. It allows for an automated, reader-independent classification of PH subforms and yield additional value for a non-invasive severity prediction beyond established markers, particularly in the spectrum of pre-capillary PH.*Clinical Relevance/Application Our findings endorse the potential of SDCT to challenge current approaches in PH imaging. This is of urgent clinical need as the accurate diagnosis of PH remains challenging and no meaningful decrease in the time from symptom onset to diagnosis could be achieved throughout the last decades, also accounting for the high morbidity and mortality of PH.

RESULTS

Patients with PH showed a significantly greater extent of malperfused lung areas (VPerfDef) as well as stronger and more homogenous perfusion defects. Perfusion deficits in Nice class 3 and 4 were significantly stronger and more homogenous compared to all other subgroups. The d-index allowed for further subclassification of subgroups 3 and 4 (AUC: 0.92, 95%-CI, 0.85 - 0.99). In pre-capillary PH the VPerfDef was not only in significant correlation with the pulmonary vascular resistance (PVR) but also a strong predictor of the PVR. In subgroup 4 the prognostic value of the VPerfDef remained even after the adjustment for established markers of an increased PVR. Moreover, the VPerfDef yielded a prognostic merit for an increased PVR above NT-pro BNP.

CLINICAL RELEVANCE/APPLICATION

Our findings endorse the potential of SDCT to challenge current approaches in PH imaging. This is of urgent clinical need as the accurate diagnosis of PH remains challenging and no meaningful decrease in the time from symptom onset to diagnosis could be achieved throughout the last decades, also accounting for the high morbidity and mortality of PH.

SSPH01-2   Low-dose Dynamic Pulmonary CT Perfusion Using Only Two Volume Scans

Participants
Sabee Y. Molloi, PhD, Irvine, California (*Presenter*) Research Grant, Canon Medical Systems Corporation

PURPOSE

Existing dynamic CT perfusion (CTP) techniques are limited by the high radiation dose from multiple scans. The purpose of this study is to validate a low-dose, first-pass analysis (FPA) technique with only two volume scans.*Methods and Materials Seven Yorkshire swine (52.0±6.8 kg) were used in this validation study with 41 independent CTP acquisitions using a 320-slice CT scanner. Intravenous contrast material (370 mg/ml iodine, 0.5ml/kg) and saline chaser (0.5ml/kg) were injected at 5 ml/s for each CTP acquisition. For each swine, both retrospective and prospective dynamic CTP data were acquired. For the retrospective CTP acquisition, an average of twenty volume scans was acquired per acquisition for the CTP measurements and served as the reference standard. For the prospective CTP acquisition, only two volume scans were acquired, where the first low-dose (50 mA) volume scan was acquired before contrast injection and the second diagnostic (200 mA) volume scan was acquired following bolus-tracking in the main pulmonary artery with a time-to-peak delay calculated using the injection time interval. Two different scan modes were used in the prospective acquisition: a volume mode (16cm z-coverage, 0.35s rotation time) and a fast helical mode (25cm z-coverage, 2.5s scan time). All prospective CTP measurements were quantitatively compared to the reference standard CTP measurements using t-test and linear regression. The CT dose index for the retrospective, two-volume prospective, two-helical prospective CTP measurements were 307.3, 70.6 and 72.1mGy, respectively.*Results The prospective CTP measurements using the volume mode (PVOL) and helical mode (PHEL) were related to the reference CTP measurements by PVOL=1.30PRETRO-1.32 ml/min/g (r=0.75) and PHEL=0.97 PRETRO -0.82 ml/min/g (r=0.82), respectively.*Conclusions A low-dose CTP technique was validated in a swine model that can potentially be used for the assessment of pulmonary disease. This novel CTP technique using a helical mode enables dynamic whole-lung perfusion measurement with conventional CT scanners.*Clinical Relevance/Application The results indicate the potential for a significant reduction in radiation dose for accurate CTP measurement that can be used for physiological assessment of pulmonary disease.

RESULTS

The prospective CTP measurements using the volume mode (PVOL) and helical mode (PHEL) were related to the reference CTP measurements by PVOL=1.30PRETRO-1.32 ml/min/g (r=0.75) and PHEL=0.97 PRETRO -0.82 ml/min/g (r=0.82), respectively.

CLINICAL RELEVANCE/APPLICATION

The results indicate the potential for a significant reduction in radiation dose for accurate CTP measurement that can be used for physiological assessment of pulmonary disease.

SSPH01-3   Deep Learning Patient-specific Noise Reduction Framework For High Resolution Chest Photon Counting Detector CT

Participants
Nathan Huber, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this work was to develop a deep learning, patient-specific noise reduction framework and evaluate it for high-resolution chest CT on an investigational photon-counting-detector CT (PCD-CT; NAEOTOM Alpha, Siemens) scanner. Most deep learning noise reduction methods are difficult to implement because they require access to CT projection data and a large patient cohort for training. The framework described is widely accessible since it uses commercially available reconstructed images and can be trained with just one patient exam.*Methods and Materials A convolutional neural network (CNN) was trained and tested on a patient-specific basis. Each patient exam was reconstructed using filtered back projection (FBP) and iterative reconstruction (IR) with thin slice (0.2 mm) and sharp kernel (Qr76). The FBP and IR reconstructions were subtracted to generate a primarily noise-only difference image. A high-pass filter was applied to remove residual low-frequency anatomic structure from the difference image. To obtain a relatively low-noise signal reference image, adjacent IR images were averaged to simulate thick images (1.0 mm). CNN training inputs consisted of noise-only images superimposed on the IR signal reference. Training target consisted of the IR signal reference without added noise. Spatial decorrelation between the noise-only image and IR signal reference was used to avoid overfitting and reduce propagation of IR deficiencies into the CNN model. A U-Net architecture was trained with mean squared error and feature loss. The resulting CNN was applied to the original thin slice and sharp kernel FBP images. This framework was evaluated on three chest CT exams acquired from a PCD-CT scanner (kernel: Qr76, thickness: 0.2 mm).*Results When applied to

three chest FBP exams, the CNN framework reduced noise by 81 ± 2 %. The FBP/CNN difference images were uniform, which indicated that anatomic structures were not altered by the CNN. Line profile assessment showed that fine bronchi structures were preserved by the CNN.*Conclusions This CNN denoising framework provided extensive noise reduction while maintaining fine anatomic detail within high resolution PCD-CT images. Importantly, this method can be implemented on any CT scanner for which IR and FBP reconstruction are available.*Clinical Relevance/Application Recent advances in high resolution PCD-CT come at a cost of elevated noise. The developed technique can be used to mitigate this noise increase without sacrificing spatial resolution.

RESULTS

When applied to three chest FBP exams, the CNN framework reduced noise by 81 ± 2 %. The FBP/CNN difference images were uniform, which indicated that anatomic structures were not altered by the CNN. Line profile assessment showed that fine bronchi structures were preserved by the CNN.

CLINICAL RELEVANCE/APPLICATION

Recent advances in high resolution PCD-CT come at a cost of elevated noise. The developed technique can be used to mitigate this noise increase without sacrificing spatial resolution.

SSPH01-4   Increasing Volumetric Coverage Of A Prototype C-arm Photon Counting CT System Via Step-and-shoot Acquisitions

Participants
Kevin J. Treb, Madison, Wisconsin (*Presenter*) Nothing to Disclose

PURPOSE

An integrated C-arm interventional imaging system was developed by adding a switchable photon counting strip detector (PCD) to the current flat panel detector (FPD)-based imaging platform. This new platform offers quantitative imaging capability using the spectral PCD-CT method and provides much improved low contrast resolution for subtle lesion detection. However, the current cost-effective strip PCD only provides a longitudinal (z) coverage of 4 mm. The purpose of this work was to develop and test a method to increase the volume coverage using a step-and-shoot acquisition mode.*Methods and Materials After the CdTe-based strip PCD was switched into the field-of-view, a step-and-shoot data acquisition mode was triggered to increase the scan volume coverage: In this mode, the gantry is rotated in 10 sweeps (5 forward and 5 backward). During the transition period between the two rotation directions, the couch was translated by 4 mm along z to enable seamless scans of the patient. In each sweep, the C-arm gantry rotates 200 degrees in 7 s. To test the performance of this new step-and-shoot C-arm PCD-CT acquisition mode, image quality of the ramp pattern in the Catphan phantom was studied. The pattern has beads with 0.25 or 1 mm spacing along z. Also used was a head phantom with a realistic vascular tree and an ultra-low contrast lesion. Comparison was made to FPD-CBCT acquired with full beam collimation and matched narrow collimation at the same radiation dose level.*Results All finely and evenly spaced beads over a z-range of 4 cm were clearly distinguishable in the acquired PCD-CT without perceivable distortions or artifacts. PCD-CT images of the head phantom showed much improved visualization of the low-contrast lesion than the FPD-CBCT at matched narrow beam collimation and dose. The whole branching pattern of the anterior cerebral artery can be visualized in the sagittal PCD-CT images and the small vessel conspicuity is effectively improved by PCD-CT over FPD-CBCT.*Conclusions A step-and-shoot data acquisition mode can be used in the C-arm PCD-CT system with a strip detector to increase the volume coverage by a factor of 10 without introducing image artifacts.*Clinical Relevance/Application By increasing the scan volume coverage of the C-arm PCD-CT equipped with a cost-effective strip detector, the new imaging platform offers high quality image-guidance for interventional procedures.

RESULTS

All finely and evenly spaced beads over a z-range of 4 cm were clearly distinguishable in the acquired PCD-CT without perceivable distortions or artifacts. PCD-CT images of the head phantom showed much improved visualization of the low-contrast lesion than the FPD-CBCT at matched narrow beam collimation and dose. The whole branching pattern of the anterior cerebral artery can be visualized in the sagittal PCD-CT images and the small vessel conspicuity is effectively improved by PCD-CT over FPD-CBCT.

CLINICAL RELEVANCE/APPLICATION

By increasing the scan volume coverage of the C-arm PCD-CT equipped with a cost-effective strip detector, the new imaging platform offers high quality image-guidance for interventional procedures.

SSPH01-5   Determination Of In-vivo Kidney Stone Mixed Composition Using High-resolution Photon Counting CT With AI-based Denoising And Deconvolution

Participants
Scott Hsieh, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this work was to develop a convolutional neural network (CNN) to reduce image noise and improve spatial resolution for high-resolution (HR), photon-counting-detector CT (PCD-CT) imaging of urinary stones to assess internal stone morphology in vivo.*Methods and Materials 30 mixed composition human stones were secured in a custom holder that was placed in a 30 cm anthropomorphic water phantom and scanned using HR PCD-CT at a high dose (CTDIvol=30 mGy). Phantom-derived image noise was added to images using a validated technique to generate a noisy training set, with the high-dose low-noise images as the target. A CNN was trained with these data to simultaneously reduce image noise and improve spatial resolution. The resulting network was applied to routine dose (CTDIvol=7.5 mGy) images of the stone phantom. Histograms of stone CT numbers were used to determine stone composition, which was compared to the reference standard from microCT. Under IRB, patients undergoing a clinically indicated stone composition exam on a clinical energy-integrating-detector CT (EID-CT) dual-source scanner (Siemens Healthcare) were scanned with the same clinical dose on an investigational whole-body HR PCD-CT scanner (SOMATOM Count Plus, Siemens Healthcare). Phantom and patient data were evaluated using in-house quantitative stone analysis software.*Results CNN-processed images exhibited a factor of ten reduction in noise (CT number standard deviation) and markedly reduced blurring of internal structures. Stones of mixed composition could be clearly identified and delineated in HR-PCD data, and the relative contribution of the two major components could be determined from the CT number histograms. Two stones (3 and 5 mm maximum dimension) scanned in vivo were shown to have mixed composition using HR PCD-CT, which was indeterminate from the clinical exam.*Conclusions HR PCD-CT with AI-based noise reduction and deconvolution enabled more accurate in vivo characterization of mixed kidney stones at routine radiation doses.*Clinical Relevance/Application Improved assessment of stone size and composition will better inform treatment decisions and thereby may improve patient outcomes.

RESULTS

CNN-processed images exhibited a factor of ten reduction in noise (CT number standard deviation) and markedly reduced blurring of internal structures. Stones of mixed composition could be clearly identified and delineated in HR-PCD data, and the relative contribution of the two major components could be determined from the CT number histograms. Two stones (3 and 5 mm maximum dimension) scanned in vivo were shown to have mixed composition using HR PCD-CT, which was indeterminate from the clinical exam.

CLINICAL RELEVANCE/APPLICATION

Improved assessment of stone size and composition will better inform treatment decisions and thereby may improve patient outcomes.

SSGI06-2   Automatized Quantification Of Hepatic Tumor Load In Gd-EOB MRI - A Deep Learning Model To Support Therapy Response Assessment In Neuroendocrine Liver Metastases

Participants
Uli Fehrenbach, Berlin, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Rapid and precise full quantification of liver metastases is an unmet medical need. We therefore trained a deep learning model to fully quantify neuroendocrine liver metastases (NELM) using gadoxetic-acid (Gd-EOB)-enhanced MRI and evaluated its usefulness in therapy response assessment.*Methods and Materials Manual 3D-segmentations of liver parenchyma and NELM were performed in 149 patients (278 Gd-EOB MRI scans) and used to train a neural network based on U-Net architecture. The model's accuracy was validated in a two step approach (internal and external validation) using Matthew's correlation coefficient (f). Clinical usefulness in terms of therapy response assessment was evaluated in another 33 patients who were discussed in our multidisciplinary cancer conference (MCC) and received a Gd-EOB MRI at baseline and as follow-up examination (n = 66). The model's measurements (NELM volume; hepatic tumor load (HTL)) with corresponding absolute and relative changes (?absNELM; ?absHTL; ?relNELM; ?relHTL) were compared to MCC decisions of therapy success or failure.*Results Internal validation of the model's accuracy showed a high overlap for NELM and livers (f: 0.76/0.95, respectively) between manual and the model's segmentations. The model reached higher coefficients in larger NELM volume (0.80 vs. 0.71; p = 0.003). External validation confirmed the model's high accuracy for NELM (f=0.86) and livers (f=0.96). The model's response variables (?absNELM; ?absHTL; ?relNELM; ?relHTL) significantly differentiated between the MCC's decision of therapy success and failure (p < 0.001). The relative variables (?relNELM and ?relHTL) showed optimal discrimination between therapy success or failure (AUC:1.000; p < 0.001).*Conclusions The deep learning model reached high accuracy in 3D-quantification of NELM and HTL in Gd-EOB-MRI and paves the way for fully automated assessment of hepatic disease. The model's measurements correlated well with the decisions of an expert MCC in response evaluation.*Clinical Relevance/Application Complete quantification of liver metastases and their relationship to liver parenchyma is time consuming and not routinely performed. Instead, individual reference lesions are measured in one dimension and observed as they progress. Hepatic tumor burden and its predictive value is also neglected in common response criteria. The model presented here enables rapid and precise quantification of hepatic tumor burden and could aid in the assessment of therapy response comparable to the assessment by an expert MCC.

RESULTS

Internal validation of the model's accuracy showed a high overlap for NELM and livers (f: 0.76/0.95, respectively) between manual and the model's segmentations. The model reached higher coefficients in larger NELM volume (0.80 vs. 0.71; p = 0.003). External validation confirmed the model's high accuracy for NELM (f=0.86) and livers (f=0.96). The model's response variables (?absNELM; ?absHTL; ?relNELM; ?relHTL) significantly differentiated between the MCC's decision of therapy success and failure (p < 0.001). The relative variables (?relNELM and ?relHTL) showed optimal discrimination between therapy success or failure (AUC:1.000; p < 0.001).

CLINICAL RELEVANCE/APPLICATION

Complete quantification of liver metastases and their relationship to liver parenchyma is time consuming and not routinely performed. Instead, individual reference lesions are measured in one dimension and observed as they progress. Hepatic tumor burden and its predictive value is also neglected in common response criteria. The model presented here enables rapid and precise quantification of hepatic tumor burden and could aid in the assessment of therapy response comparable to the assessment by an expert MCC.

SSGI06-3   Machine-learning Based Radiomics To Predict Low-grade Intraductal Papillary Mucinous Neoplasm (IPMN) Of The Pancreas

Participants
Dania Daye, MD, PhD, Medford, Massachusetts (*Presenter*) Research Consultant, Sigilon Therapeutics;Research Consultant, Medtronic plc

PURPOSE

IPMNs exhibit a potential risk of invasive transformation, therefore, they comprise a clinically challenging entity. The aim of this study was to evaluate the role of preoperative machine-learning based radiomic features as predictors of low-grade IPMN.*Methods and Materials In this IRB-approved retrospective study, we identified 109 consecutive patients with 1) a histologically confirmed diagnosis of IPMN, 2) contrast-enhanced CT performed within 6 months of diagnosis, from 2009 to 2017. Patients were classified

into low-grade IPMN group (with low- or moderate-grade dysplasia, n=48) or high-grade IPMN group (high-grade or invasive, n=61), according to the Baltimore consensus classification. Clinicobiological variables were collected. All tumors were semi-automatically volumetrically segmented on pancreatic/delayed phase acquisitions. 112 radiomics features were extracted from each segmented tumor. Patients were divided into a training (n=88) and testing cohort (n=22). A random forest-based machine learning technique was applied to the extracted features. ROC was used to evaluate the performance of the constructed machine learning model.*Results The study enrolled 109 patients with 109 IPMNs (51% female, mean age 69±10 years). The mean lesion size was 2.7±1cm and 4.2±3cm in low- and high-grade groups, respectively (p=0.004). Mild, moderate and severe dilation of the main pancreatic duct was detected in 46%, 50% and 4% of low-grade and 69%, 23% and 8% of the high-grade IPMNs. An increased serum level of CA19-9 (>37 U/ml) was found in 11% of the low- and 30% of the high-grade groups. Univariate regression revealed 4 features (2 first order features and 2 shape features) to be independently associated with low- and moderate-grade dysplasia IPMN (p<0.04 on Wald test for all). A random forest-based machine learning model that included radiomic features resulted in good performance for low-grade IPMN prediction (AUC of 0.83). Specificity was 76% and sensitivity was 82%.*Conclusions Preoperative CT quantitative tumor radiomic features could effectively distinguish patients with low-grade IPMN.*Clinical Relevance/Application The clinical management goal to decrease the risk of invasive cancer is to observe low- and moderate-grade precursor lesions and to resect high-grade precursor lesions. Machine learning-based tumor radiomics may improve treatment methods and promote personalized therapy in patients with IPMNs.

RESULTS

The study enrolled 109 patients with 109 IPMNs (51% female, mean age 69±10 years). The mean lesion size was 2.7±1cm and 4.2±3cm in low- and high-grade groups, respectively (p=0.004). Mild, moderate and severe dilation of the main pancreatic duct was detected in 46%, 50% and 4% of low-grade and 69%, 23% and 8% of the high-grade IPMNs. An increased serum level of CA19-9 (>?37 U/ml) was found in 11% of the low- and 30% of the high-grade groups. Univariate regression revealed 4 features (2 first order features and 2 shape features) to be independently associated with low- and moderate-grade dysplasia IPMN (p<0.04 on Wald test for all). A random forest-based machine learning model that included radiomic features resulted in good performance for low-grade IPMN prediction (AUC of 0.83). Specificity was 76% and sensitivity was 82%.

CLINICAL RELEVANCE/APPLICATION

The clinical management goal to decrease the risk of invasive cancer is to observe low- and moderate-grade precursor lesions and to resect high-grade precursor lesions. Machine learning-based tumor radiomics may improve treatment methods and promote personalized therapy in patients with IPMNs.

SSGI06-4   AI-Powered Fully-automated Detection Of Pancreatic Ductal Adenocarcinoma (PDA) On Standard-of-care CT Scans

Participants
Garima Suman, MD,MBBS, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

Incidental PDA lesions tend to be missed on CT scans due to their subtle imaging features or inattentional bias. To address this challenge, our purpose was to develop a convolutional neural network (CNN) for fully automated detection of PDA on standard-of-care CT scans.*Methods and Materials Volumetric pancreas and tumor segmentation was performed by radiologists using 3D Slicer on a highly curated CT dataset (portal-venous phase CTs from 2008-2020, slice thickness = 3.75 mm) of 801 treatment-naïve patients with PDA and 1667 control subjects (median ages: 67 and 59 years, Male: Female=1.2:1 and 1:1, respectively). Training/validation set included randomly selected 522 CTs with PDA and 843 controls. Remaining 1103 CTs (279 CTs with PDA and 824 controls) comprised the test set. A classification CNN was trained utilizing a bounding box, which enveloped segmentations done by radiologists (Fig 1). However, on test cases, the CNN's performance for PDA detection was evaluated using two inputs: 1. Radiologists' segmentations, 2. Automated pancreatic segmentations using a previously described UNET architecture. Augmentations (random translation, artificial corruption of segmentation to simulate over- or under-segmentation errors, intensity shifting and rotations) were utilized to maximize model's performance potential and to compensate for the absence of radiologists' segmentations as input channels. Finally, an Atttention-ResNet classified each axial CT slice through the pancreas into cancer vs. normal.*Results Using the radiologists' segmentations as inputs, the CNN misclassified 9% (25/279) CTs with PDA as 'normal' and 10% (82/824) control CTs as 'cancer' [accuracy 0.90; area under the curve (AUC) 0.97]. In contrast, with automated segmentations as inputs, the CNN correctly classified 94% (1036/1103) of total CTs into 'cancer' versus 'normal' (accuracy 0.94; AUC 0.95). It incorrectly classified 16% (46/279) with PDA as 'normal' and 2.5% (21/824) of control CTs as 'cancer'. There was no difference in the CNN's performance with radiologists' segmentations vs. automated segmentations as inputs (p=0.112, DeLong test).*Conclusions Accurate AI-Powered detection of PDA on portal venous phase CTs is feasible. A fully automated approach shows performance metrics comparable to the approach that requires radiologists' segmentations as inputs.*Clinical Relevance/Application Integration of automated AI models for detection of PDA into clinical workflows can provide pre-screened images to radiologists to potentially reduce the incidence of missed pancreatic cancers.

RESULTS

Using the radiologists' segmentations as inputs, the CNN misclassified 9% (25/279) CTs with PDA as 'normal' and 10% (82/824) control CTs as 'cancer' [accuracy 0.90; area under the curve (AUC) 0.97]. In contrast, with automated segmentations as inputs, the CNN correctly classified 94% (1036/1103) of total CTs into 'cancer' versus 'normal' (accuracy 0.94; AUC 0.95). It incorrectly classified 16% (46/279) with PDA as 'normal' and 2.5% (21/824) of control CTs as 'cancer'. There was no difference in the CNN's performance with radiologists' segmentations vs. automated segmentations as inputs (p=0.112, DeLong test).

CLINICAL RELEVANCE/APPLICATION

Integration of automated AI models for detection of PDA into clinical workflows can provide pre-screened images to radiologists to potentially reduce the incidence of missed pancreatic cancers.

SSGI06-5   Deep-learning Based Software For Response Evaluation In Hepatocellular Carcinoma Treatment.

Participants
Matt Kelly, PhD, Oxford, United Kingdom (*Presenter*) Employee, Perspectum Diagnostics Ltd;Stockholder, Perspectum Diagnostics Ltd

PURPOSE

Clinical trials of novel treatment approaches for hepatocellular carcinoma work within the response evaluation criteria for solid

tumors (RECIST v1.1) which offers a standardized and widely applicable approach for categorizing treatment response. Modified RECIST extends this by focussing on contrast-enhancing tumor tissue.?Discordance between intra-and inter-reader observations has been regularly reported (Yoon E J Cancer 2016). This study describes the application of a new deep-learning based software tool to automatically perform lesion segmentation and diameter estimation of a large dataset from a completed HCC trial.*Methods and Materials Dual phase contrast-enhanced abdominal CT images and central (m)RECIST reads were curated from a database of 166 participants from a multi-center drug trial (TACE2) before and after treatment. A 3D convolutional neural network with two encoders was?trained with 133 samples to segment both liver and lesions, and was validated on the 33 remaining cases. Tumor diameter measurement of the largest lesion was generated for each patient and compared with the diameter reported by central radiologist read.*Results Automatic lesion segmentation masks (Figure 1) were generated and showed high agreement with manually drawn 3D masks (mean validation Dice Similarity Coefficient = 0.73).?The accuracy of automatic diameter measurement compared to central radiologist read was in close agreement (within range considered as stable disease per RECIST) for 76.7% for training and 81.8% for validation set.*Conclusions This?deep-learning based lesion detection and diameter measurement tool?can support radiologists by minimizing subjectivity in (m)RECIST measurements and reducing time per analysis. This has the potential to improve both routine care and clinical trial workflow.*Clinical Relevance/Application Deployment of this deep-learning based tool to support the radiologist may enhance objectivity of tumour response reporting, and improve the clinical trial radiology reporting pipeline.

RESULTS

Automatic lesion segmentation masks (Figure 1) were generated and showed high agreement with manually drawn 3D masks (mean validation Dice Similarity Coefficient = 0.73).?The accuracy of automatic diameter measurement compared to central radiologist read was in close agreement (within range considered as stable disease per RECIST) for 76.7% for training and 81.8% for validation set.

CLINICAL RELEVANCE/APPLICATION

Deployment of this deep-learning based tool to support the radiologist may enhance objectivity of tumour response reporting, and improve the clinical trial radiology reporting pipeline.

SSPD02-1 Semi Automated Measurement Of The Common Carotid Artery Intima Media Thickness In Children: Inter And Intra Observer Validation Study.

Participants
Emilie Alchourron, BSC, Montreal, Quebec (*Presenter*) Nothing to Disclose

PURPOSE

Although atherosclerotic plaques only appear in adulthood, atherogenesis starts during childhood. Common carotid artery Intima media thickness (cIMT) has been proven to be a subclinical radiological marker for early atherosclerosis in adults and children. Validation studies for the semi-automated IMT measurement technique on B-mode ultrasound lack in children. The objective is to validate this technique in children. Specific aim is to study the inter-observer and intra-observer correlation. The study will set the ground for the development of a robust subclinical radiological marker for atherosclerosis risk stratification in children.*Methods and Materials We calculated a sample size of 30 patients who were recruited in a prospective IRB approved study among healthy children presenting to the radiology department between November 2020 and March 2021. Semi-automated Math'SR B-mode ultrasound technique was used to measure cIMT according to the Mannheim recommendations by 2 ultrasonographers. Edge detection and quality index were verified. Measurements were done twice bilaterally. Four additional observers measured IMT later on for a total of 696 measurements. Anthropometric measures included Body mass index (BMI), waist circonference, blood pressure and artery diameter. Student t-test and intra-class correlation coefficient (ICC) were performed using SPSS.*Results The average age was 12.5 years (range 11-14.9), 46.4% were girls. Twenty-one patients had normal BMI and 7 increased BMI (>85th percentile). Two of the obese patients had elevated blood pressure (>95th percentile). Fifty percent of the patients had Tanner stage 4. Intra-observer ICCs for IMT were: 0.87, 0.90, 0.89, 0.90, 0.84 and 0.84 for each of the 6 operators. Intra-observer ICCs for the ratio IMT/carotid diameter were: 0.68, 0.583 0.81, 0.71, 0.52 and 0.65. Inter-observer ICC was 0.97. The mean IMT calculated for healthy children was 0.507 mm (+/-0.004).*Conclusions There is excellent inter and intra-observer agreement using the semi-automated cIMT B-mode technique in children provided operators pay attention to edge-detection. There is no gold standard technique in children. Further studies are needed to compare the reproductibility with the radiofrequency technique and generate normative charts for both techniques for the same cohort.*Clinical Relevance/Application Since early manifestations of atherosclerotic disease are reversible, developing a reliable, safe and quick radiological test assist in the clinical decision to guide treatment. A multidisciplinary team approach could eventually use IMT along other lab markers to better prevent disease progression/assess intervention efficacy in children with risk factors.

RESULTS

The average age was 12.5 years (range 11-14.9), 46.4% were girls. Twenty-one patients had normal BMI and 7 increased BMI (>85th percentile). Two of the obese patients had elevated blood pressure (>95th percentile). Fifty percent of the patients had Tanner stage 4. Intra-observer ICCs for IMT were: 0.87, 0.90, 0.89, 0.90, 0.84 and 0.84 for each of the 6 operators. Intra-observer ICCs for the ratio IMT/carotid diameter were: 0.68, 0.583 0.81, 0.71, 0.52 and 0.65. Inter-observer ICC was 0.97. The mean IMT calculated for healthy children was 0.507 mm (+/-0.004).

CLINICAL RELEVANCE/APPLICATION

Since early manifestations of atherosclerotic disease are reversible, developing a reliable, safe and quick radiological test assist in the clinical decision to guide treatment. A multidisciplinary team approach could eventually use IMT along other lab markers to better prevent disease progression/assess intervention efficacy in children with risk factors.

SSPD02-2 Validation Of Reduced Dose CT For Detection Of Lung Nodules In Children With Cancer

Participants
Samuel Brady, PHD, Cincinnati, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

Reduced dose chest CT is standard of care for lung cancer screening in high-risk adult patients. However, the use of reduced dose chest CT in pediatrics has not been extensively explored. The purpose of this study was to characterize the performance of a reduced dose CT technique for detection of lung nodules in children and young adults with cancer.*Methods and Materials In this Institutional Review Board approved prospective study, between November 2018 to August 2020, we enrolled patients 4-21 years-old with a history of malignancy who were undergoing clinically indicated chest CT with standard radiation dose to undergo a reduced dose CT of the chest in the same encounter. Reduced dose CT was performed with fixed technique. Deidentified CT examinations were reviewed in blinded fashion by three reviewers. A single reviewer performed a delayed review to match nodules between examinations. Agreement was calculated with Cohen's Kappa and intraclass correlation coefficients.*Results 78 patients (mean age=14.9±4.2 years, n=44 [56%] male) were enrolled. 45 (58%) patients had 162 total lung nodules (mean size=3.4±3.3 mm). Mean estimated effective dose was 1.8±1.1 mSv (clinical) and 0.3±0.1 mSv (reduced dose), an 82% reduction. Intra-

observer agreement on the presence of nodules was moderate to substantial (?=0.45-0.67), as assessed on standard radiation dose examination. Sensitivity and specificity of reduced dose CT for nodules ranged from 63-77% and 80-90% respectively per reviewer. Inter-observer agreement on the presence nodules was moderate (?=0.53) for reduced dose CT, similar to clinical CT (?=0.54). 92% of nodules were visible on reduced dose CT.*Conclusions Reduced dose CT depicts >90% of lung nodules in a pediatric cohort with cancer. Reviewers identified the presence of nodules with moderate sensitivity and high specificity. The observed diagnostic performance of reduced dose CT is within the expected range for CT for lung nodules in generally.*Clinical Relevance/Application Our results demonstrate that CT performed at a dose similar to a 2-view chest radiograph has acceptable diagnostic performance for nodule detection in children with cancer.

RESULTS

78 patients (mean age=14.9±4.2 years, n=44 [56%] male) were enrolled. 45 (58%) patients had 162 total lung nodules (mean size=3.4±3.3 mm). Mean estimated effective dose was 1.8±1.1 mSv (clinical) and 0.3±0.1 mSv (reduced dose), an 82% reduction. Intra-observer agreement on the presence of nodules was moderate to substantial (?=0.45-0.67), as assessed on standard radiation dose examination. Sensitivity and specificity of reduced dose CT for nodules ranged from 63-77% and 80-90% respectively per reviewer. Inter-observer agreement on the presence nodules was moderate (?=0.53) for reduced dose CT, similar to clinical CT (?=0.54). 92% of nodules were visible on reduced dose CT.

CLINICAL RELEVANCE/APPLICATION

Our results demonstrate that CT performed at a dose similar to a 2-view chest radiograph has acceptable diagnostic performance for nodule detection in children with cancer.

SSPD02-6 Hyperinflation Is More Clinically Relevant Than Hyperdensity In Neonatal Lung Disease Of Prematurity Via 3D MRI

Participants
Nara Higano, PhD, Cincinnati, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

Bronchopulmonary dysplasia (BPD) is a severe and multifaceted respiratory disease resulting from preterm birth, with both obstructive (air trapping, alveolar simplification) and restrictive (fibrosis, atelectasis, inflammation) components. While reader scores of these combined heterogeneous parenchymal abnormalities on structural chest imaging have demonstrated clinical relevance, it is unclear to what extent each type of pathology affects respiratory outcomes in extremely preterm infants. Here, we quantify the individual clinical relevance of hyperinflation and tissue hyperdensity as surrogates for obstructive and restrictive lung disease, respectively, in neonates with and without BPD using structural 3D ultrashort echo-time (UTE) MRI.*Methods and Materials 3D radial lung UTE MRI (0.7-mm isotropic resolution, proton-density weighting), was obtained in 79 quiet-breathing neonates (8 control, 8 mild BPD, 8 moderate, 55 severe) on a small-footprint, NICU-sited 1.5T scanner. Hyperinflation was quantified by normalizing volumes from whole-lung segmentations by body-surface area. Volume-percent of hyperdense lung tissue (defined as lung density exceeding +1s from mean control density) was quantified after normalizing lung intensity by muscle and noise. Hyperinflation and hyperdensity were compared with BPD severity in all patients and respiratory support at NICU discharge (DC) (4 none, 21 oxygen, 28 ventilator, 2 death prior to DC) in severe BPD (ANOVA, multi-group; unpaired t-test, 2-group).*Results Hyperinflation correlated with BPD severity in all patients (P=0.0011, Fig-A), and was higher in severe BPD than other severity grades (P<0.0001 for all). Likewise, hyperinflation correlated with DC support in severe BPD (P=0.0004, Fig-B). However, hyperdense volume-percent neither correlated with BPD severity in all patients (P=0.15, Fig-C), nor DC support in severe BPD (P=0.11, Fig-D). Hyperdensities did not significantly distinguish between mild, moderate, or severe BPD, nor between oxygen use, ventilator use, or death in severe BPD (P>0.05 for all).*Conclusions Hyperinflation primarily affects patients with severe BPD, while hyperdensity is present in all severity grades. Notably, hyperinflation is a stronger marker of poor clinical trajectories than hyperdensity in severe BPD patients, suggesting that imaging-based pulmonary scoring and quantification in neonatal BPD may be most clinically relevant with stronger emphasis on obstructive, rather than restrictive, components of lung disease.*Clinical Relevance/Application Obstructive lung disease is strongly correlated with respiratory outcomes, while restrictive lung disease is not, in preterm neonates using 3D structural ultrashort echo-time MRI.

RESULTS

Hyperinflation correlated with BPD severity in all patients (P=0.0011, Fig-A), and was higher in severe BPD than other severity grades (P<0.0001 for all). Likewise, hyperinflation correlated with DC support in severe BPD (P=0.0004, Fig-B). However, hyperdense volume-percent neither correlated with BPD severity in all patients (P=0.15, Fig-C), nor DC support in severe BPD (P=0.11, Fig-D). Hyperdensities did not significantly distinguish between mild, moderate, or severe BPD, nor between oxygen use, ventilator use, or death in severe BPD (P>0.05 for all).

CLINICAL RELEVANCE/APPLICATION

Obstructive lung disease is strongly correlated with respiratory outcomes, while restrictive lung disease is not, in preterm neonates using 3D structural ultrashort echo-time MRI.

SPR-NR-1   Multiparametric Radiogenomic Model To Predict Survival In Patients With Glioblastoma

Participants
Keon Mahmoudi, BS, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

Several clinical, histopathological, and imaging variables have been associated with prognosis in patients with glioblastoma (GBM). We aimed to develop a multiparametric radiogenomic model using a combination of MRI texture features, demographic data, and glioma biomarker status to predict prognosis in patients with GBM.*Methods and Materials In this retrospective study, patients were included if they had 1) confirmed diagnosis of GBM, 2) pre- and post-operative MRI including T1c+, FLAIR, and diffusion sequences, and 3) glioma biomarker data (IDH-1, EGFR, MGMT, ATRX). Survival data was obtained from patients' charts and dichotomized (< 18 months, = 18 months). Tumor segmentation was performed using volume-of-interest analysis, and a total of 92 texture features were obtained. From texture features, a predictive imaging model was developed using univariate analysis and Least Absolute Shrinkage and Selection Operator (LASSO) regularization to reduce the risk of overfitting. This imaging model was then inserted into a backward stepwise logistic regression model in conjunction with other variables including age, sex, initial tumor volume, resection volume (percentage), and 4 glioma biomarker (IDH-1, EGFR, MGMT, ATRX) status. Receiver-operating characteristic (ROC) and Kaplan-Meier curve analysis were performed.*Results A total of 116 patients (age: 59.6 ± 13.9, M/F 62/54) met our inclusion criteria. The median (IQR) survival was 12 (18) months. A total of 7 pre-operative texture features were used in generating our imaging model in determination of > 18-months survival with AUC (SE/95%CI) of 0.72 (0.05/0.63-0.80) (P=0.004). In logistic regression analysis, our imaging model remained as a significant (p<0.001) contributor to the final multiparametric model in conjunction with age (p=0.04) and MGMT status (p=0.02). The overall accuracy of this final radiogenomic model was AUC (SE/95%CI) of 0.79 (0.04/0.70-0.86) (p<0.001). Prediction of survival > 18 months yielded a sensitivity of 45.24%, specificity of 87.84%, and accuracy of 72.41%. Using this final radiogenomic model to predict survival, Kaplan-Meiyer analysis showed a significantly (p = 0.002, HR= 2.91) longer overall survival (Figure).*Conclusions Results show that our radiogenomic model generated from radiomic features at baseline (pre-operative) MRI in conjunction with age and MGMT status can predict survival > 18 months in patients with GBM.*Clinical Relevance/Application The model described above combines MRI tissue analysis, glioma biomarker, and demographic data to reliably predict survival in patients with preoperative gliomas. These findings provide valuable prognostic information that can help guide management in patients with treatment-naïve GBM.

RESULTS

A total of 116 patients (age: 59.6 ± 13.9, M/F 62/54) met our inclusion criteria. The median (IQR) survival was 12 (18) months. A total of 7 pre-operative texture features were used in generating our imaging model in determination of > 18-months survival with AUC (SE/95%CI) of 0.72 (0.05/0.63-0.80) (P=0.004). In logistic regression analysis, our imaging model remained as a significant (p<0.001) contributor to the final multiparametric model in conjunction with age (p=0.04) and MGMT status (p=0.02). The overall accuracy of this final radiogenomic model was AUC (SE/95%CI) of 0.79 (0.04/0.70-0.86) (p<0.001). Prediction of survival > 18 months yielded a sensitivity of 45.24%, specificity of 87.84%, and accuracy of 72.41%. Using this final radiogenomic model to predict survival, Kaplan-Meiyer analysis showed a significantly (p = 0.002, HR= 2.91) longer overall survival (Figure).

CLINICAL RELEVANCE/APPLICATION

The model described above combines MRI tissue analysis, glioma biomarker, and demographic data to reliably predict survival in patients with preoperative gliomas. These findings provide valuable prognostic information that can help guide management in patients with treatment-naïve GBM.

SPR-NR-10   7T High-resolution Metabolic Imaging Of Epilepsy: First Results

Participants
Gilbert Hangel, Vienna, Austria (*Presenter*) Nothing to Disclose

PURPOSE

We recently introduced high resolution 3D metabolic imaging at 7T based on CRT-FID-MRSI in healthy subjects (Hingerl 2020) and glioma patients (Hangel 2020). Previous MRS techniques lacked resolution and brain coverage for precise localisation of the epileptogenic zone but had identified changes like decreased N-acetylaspartate (NAA) and increased total choline and Creatine (tCho/tCr). We applied our technique to refractory epilepsy, investigating its potential to identify and determine the extent of the epileptogenic zone.*Methods and Materials Fourteen patients (28±7 y, 10f/4m) with refractory focal epilepsy were enrolled in the study after informed consent and with IRB approval. They were measured with a 3D-MRSI protocol at a Siemens Magnetom 7T imager: 15:30 min, 64×64×39 matrix, 220×220×133 mm³ FOV, 3.4 mm nominal resolution. Quantification used LCModel with a basis set including NAA, tCr, tCho, myo-inositol (Ins), glutamate (Glu), glutamine (Gln), and taurine (Tau) with a spectral range of 1.8-4.1 ppm. MRSI maps were compared to clinical neurological assessment based on MRI and EEG and, if available, histology.*Results Acceptable MRSI quality was achieved in 13/14 patients. Metabolic hotspots in the remaining thirteen patients corresponded at least partially to clinical preoperative assessment in 11/13. tCr and tCho were increased in all of these hotspots, while we found variable changes for Glu/Gln/Ins/NAA/Tau. An increase of NAA was found in most patients. In three verified FCD cases, metabolic

findings aligned well to later resection.*Conclusions We established an exploratory dataset of high-resolution metabolic images in thirteen refractory epilepsy patients, with tCr/tCho/Ins/NAA as promising metabolic markers. Our NAA findings contradict previous literature, but tCho to NAA increases corresponded to literature. This could be explained by previous studies missing moderate NAA increases or having difficulty to localise metabolic changes with single voxel spectroscopy or selection-box MRSI. Our study was limited by its small sample size so far and 7T B0- and B1-field inhomogeneities. Further research can overcome these challenges.*Clinical Relevance/Application Metabolic imaging of epilepsy with our new HR-7T-MRSI method could potentially identify epileptogenic zones in structurally normal MRI cases.

RESULTS

Acceptable MRSI quality was achieved in 13/14 patients. Metabolic hotspots in the remaining thirteen patients corresponded at least partially to clinical preoperative assessment in 11/13. tCr and tCho were increased in all of these hotspots, while we found variable changes for Glu/Gln/Ins/NAA/Tau. An increase of NAA was found in most patients. In three verified FCD cases, metabolic findings aligned well to later resection.

CLINICAL RELEVANCE/APPLICATION

Metabolic imaging of epilepsy with our new HR-7T-MRSI method could potentially identify epileptogenic zones in structurally normal MRI cases.

SPR-NR-11 Hypovascular Cellular Tumor In Primary Central Nervous System Lymphoma Is Associated With Treatment Resistance: Tumor Habitat Analysis With Physiologic MRI

Participants
Soyeong Jeong, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The microenvironment of lymphomas is known to be highly variable and closely related with treatment resistance and survival. We tried to develop physiologic MRI-based spatial habitat analysis to identify regions associated with treatment resistance to facilitate prediction of tumor response after initial chemotherapy in patients with primary central nervous system lymphoma (PCNSL).*Methods and Materials Eighty-one patients with pathologically confirmed PCNSL were enrolled. Pretreatment physiologic MRI was obtained, and k-means clustering was used to separate voxels into three spatial habitats according to apparent diffusion coefficient and cerebral blood volume values. Spatial habitats, clinical predictors, and conventional imaging predictors associated with time to progression (TTP) were analyzed using Cox proportional hazard modeling. The performance of significant predictors for TTP was assessed using C-index.*Results The three spatial habitats of hypervascular cellular tumor, hypovascular cellular tumor, and hypocellular tumor were identified. A large hypovascular cellular habitat was significantly associated with short TTP (HR, 2.83; P =.017). Presence of an atypical finding (HR, 4.41; P=.016), high performance score (HR, 5.82; P =.04), and high serum lactate dehydrogenase level (HR, 1.01; P=.013) were significantly associated with TTP. A predictive model constructed using habitat score and other imaging parameters showed a C-index for prediction of TTP of 0.70 (95% CI, 0.54-0.87).*Conclusions A hypovascular cellular tumor habitat is associated with treatment resistance in PCNSL, and its assessment may refine pre-chemotherapy imaging-based response prediction for patients with PCNSL before chemotherapy.*Clinical Relevance/Application The current results suggest that multiparametric physiologic MRI-based spatial habitat analysis provides meaningful results and may provide added value for predicting treatment response after initial chemotherapy in patients with PCNSL before chemotherapy.

RESULTS

The three spatial habitats of hypervascular cellular tumor, hypovascular cellular tumor, and hypocellular tumor were identified. A large hypovascular cellular habitat was significantly associated with short TTP (HR, 2.83; P =.017). Presence of an atypical finding (HR, 4.41; P=.016), high performance score (HR, 5.82; P =.04), and high serum lactate dehydrogenase level (HR, 1.01; P=.013) were significantly associated with TTP. A predictive model constructed using habitat score and other imaging parameters showed a C-index for prediction of TTP of 0.70 (95% CI, 0.54-0.87).

CLINICAL RELEVANCE/APPLICATION

The current results suggest that multiparametric physiologic MRI-based spatial habitat analysis provides meaningful results and may provide added value for predicting treatment response after initial chemotherapy in patients with PCNSL before chemotherapy.

SPR-NR-12 Morphologic And Functional Characteristics Of Intracranial Collateral Status Predict Outcomes Of Patients With Acute Anterior Large Artery Occlusion

Participants
Song Liu, Tianjin, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate differential characteristics of morphologic and functional collateral status in patients with acute anterior large artery occlusion, and to develop a predictive model for the outcomes of patients.*Methods and Materials Sixty-seven patients with middle cerebral artery or internal carotid artery occlusion (<24h) were collected and divided into good outcomes group (90 day mRS 0-2) and poor outcomes group (90 day mRS 3-6). Plain CT, multi-phase CT angiography (mCTA), and CT Perfusion (CTP) scans of all patients were obtained on 256-row Revolution CT. Iopamidol of intravenous contrast was used. Collateral Score of mCTA were assessed as Score 1-5. CBV, CBF, Tmax maps, and Hypoperfusion Intensity Ratio (HIR) with different threshold were assessed by RApid processing of PerfuIon and Diffusion (RAPID) software. Independent sample t test, Mann-Whitney U test, Chi-square test and Fisher's exact test were performed in the difference of variables. Multivariate logistic regression analysis and ROC curve were used to determine the relationship between significant variables and outcomes. P value <0.05 was considered significant for all tests.*Results HIR (rs = 0.669, P < 0.001), CS (rs = -0.359, P = 0.003), and NCCT-ASPECTS (rs = -0.406, P = 0.001) revealed as significant correlations with mRS, respectively. NIHSS of good outcomes group was significant lower than poor outcomes group (10.00 [6.00, 15.00] vs 15.00 [10.00, 20.50], Z=-2.703, P=0.006). Higher CS were seen in patients with good outcomes than that with poor outcomes (Score 5: 0% vs 0%; Score 4: 18.75% vs 11.43%; Score 3: 46.88% vs 37.14%; Score 2: 34.37% vs 34.29%; Score 1: 0% vs 17.14%; Score 0: 0% vs 0%; P=0.041). HIR (0.270 ± 0.180 vs 0.459 ± 0.190, t=-4.166, P=0.014), CBF<38% volume (0 [0, 13.25] vs 28.00 [5.75, 59.75], Z=-3.815, P<0.001) and CBV<42% volume (0 [0, 13.25] vs 33.00 [4.75, 59.25], Z=-3.906, P<0.001), and CBV<38% volume (0 [0, 11.50] vs 27.50 [3.75, 54.75], Z=-3.775, P<0.001) were the significant features in defining good outcomes of patients. Multiple logistic regression analysis showed that HIR (OR 5.290, 95%CI 8.057-48.781) was significantly associated with good outcomes of patients, and its AUC of receiver operating characteristic curves were 0.770.*Conclusions HIR and CS characterized by CTP and mCTA provided morphologic and functional characteristics of intracranial

collateral status of acute anterior circulation occlusion, and they were particularly effective predictive parameters for the outcomes of patients.*Clinical Relevance/Application HIR and CS, derived from CTP and mCTA, could provide complementary information in defined the morphologic and functional features of collateral status in acute anterior circulation occlusion patients.

RESULTS

HIR (rs = 0.669, P < 0.001), CS (rs = -0.359, P = 0.003), and NCCT-ASPECTS (rs = -0.406, P = 0.001) revealed as significant correlations with mRS, respectively. NIHSS of good outcomes group was significant lower than poor outcomes group (10.00 [6.00, 15.00] vs 15.00 [10.00, 20.50], Z=-2.703, P=0.006). Higher CS were seen in patients with good outcomes than that with poor outcomes (Score 5: 0% vs 0%; Score 4: 18.75% vs 11.43%; Score 3: 46.88% vs 37.14%; Score 2: 34.37% vs 34.29%; Score 1: 0% vs 17.14%; Score 0: 0% vs 0%; P=0.041). HIR (0.270 ± 0.180 vs 0.459 ± 0.190, t=-4.166, P=0.014), CBF<38% volume (0 [0, 13.25] vs 28.00 [5.75, 59.75], Z=-3.815, P<0.001) and CBV<42% volume (0 [0, 13.25] vs 33.00 [4.75, 59.25], Z=-3.906, P<0.001), and CBV<38% volume (0 [0, 11.50] vs 27.50 [3.75, 54.75], Z=-3.775, P<0.001) were the significant features in defining good outcomes of patients. Multiple logistic regression analysis showed that HIR (OR 5.290, 95%CI 8.057-48.781) was significantly associated with good outcomes of patients, and its AUC of receiver operating characteristic curves were 0.770.

CLINICAL RELEVANCE/APPLICATION

HIR and CS, derived from CTP and mCTA, could provide complementary information in defined the morphologic and functional features of collateral status in acute anterior circulation occlusion patients.

SPR-NR-13   Relationship Between Collateral Status And CT Perfusion Parameters In Patients With Chronic Cerebral Artery Occlusion

Participants
Ling Li, Bejing, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare collateral status on 4D CTA and single-phase CTA (sCTA) and evaluate the relationship between collateral status and CT perfusion parameters in patients with chronic cerebral artery occlusion.*Methods and Materials Fourteen cases with chronic cerebral artery occlusion who underwent one-stop CT angiography -CT perfusion reviewed retrospectively. Single-phase CTA and 4D CTA were reconstructed from CTP data and collateral status was evaluated by using Tan's scoring systems. CTP parameters such as rCBF, rCBV, and MTT were evaluated by two neuroradiologists independently. The independent sample t-test and Spearman correlation analysis were performed to assess the relationship of CT perfusion parameters and collateral status on sCTA and 4D CTA, separately.*Results Fourteen patients (14.3% of female, mean age 69.1plusminus10.3 years) were recruited. When compared with 4D CTA, sCTA obviously underestimated the status of collateral circulation (4D CTA, score 2.43plusminus0.51; sCTA, score 1.36plusminus0.93; p<0.01). For 4D CTA, rCBF values and MTT values were significantly different between the poor and good collateral status (p<0.05). While for sCTA, only rCBF values were different in the two groups (p<0.05). Both sCTA and 4D CTA collateral score had a positive correlation with rCBF values (r=0.57, p<0.05; r=0.68, p<0.01). 4D CTA had a negative correlation with MTT values (r=dash0.65, p<0.05).*Conclusions In comparison with sCTA, 4D CTA can better estimate the collateral status and correlate well with cerebral hemodynamic status.*Clinical Relevance/Application Collateral status on 4D CTA is recommended to be a relatively optimal technique for chronic cerebral artery occlusion patients.

RESULTS

Fourteen patients (14.3% of female, mean age 69.1plusminus10.3 years) were recruited. When compared with 4D CTA, sCTA obviously underestimated the status of collateral circulation (4D CTA, score 2.43plusminus0.51; sCTA, score 1.36plusminus0.93; p<0.01). For 4D CTA, rCBF values and MTT values were significantly different between the poor and good collateral status (p<0.05). While for sCTA, only rCBF values were different in the two groups (p<0.05). Both sCTA and 4D CTA collateral score had a positive correlation with rCBF values (r=0.57, p<0.05; r=0.68, p<0.01). 4D CTA had a negative correlation with MTT values (r=dash0.65, p<0.05).

CLINICAL RELEVANCE/APPLICATION

Collateral status on 4D CTA is recommended to be a relatively optimal technique for chronic cerebral artery occlusion patients.

SPR-NR-14   Angioarchitecture Analysis And Prognostication Of Intracranial Dural Arteriovenous Fistula - A Comparative Study Of Non-contrast Magnetic Resonance Angiographic Sequences.

Participants
Arun Balasubramanian, MD, APO, India (*Presenter*) Nothing to Disclose

PURPOSE

Intracranial dural arteriovenous fistulas (DAVF) are rare vascular malformations constituting 10 to 15 % of all intracranial vascular malformations with risk of hemorrhagic complications seen in higher grades of fistula. Conventional MR imaging has very limited role in detection and classification of DAVF. Advanced MRI sequences like 3D time of flight Angiography(3D TOF), arterial spin labelling and Susceptibility weighted imaging have shown promise in diagnosis and evaluation of these vascular malformations. The main purpose of this study is to compare the diagnostic performance of 3D time of flight Angiography, arterial spin labelling and Susceptibility weighted angiographic imaging with Digital subtraction angiography in accurate diagnosis and evaluation of DAVF.*Methods and Materials This combined retrospective and prospective study included 40 patients with dural arteriovenous fistula who had undergone both DSA and MR imaging comprising of 3D TOF MRA, 3D pseudocontinuous ASL(3D PCASL) and Susceptibility weighted angiography(SWAN). Two neuroradiologists assessed 3D PCASL, TOF MRA, SWAN with regards to location, number of fistulas, presence of cortical venous reflux, grading of the fistula as per Cognard grading, prominent arterial feeders in TOF MRA, immediate venous drainage in TOF MRA and presence of pseudophlebitic pattern in SWAN. Sensitivity, Positive predictive value, negative predictive value, accuracy, intermodality agreement and correlation analyses were performed to evaluate these sequences on comparison with the gold standard method Digital Subtraction angiography (DSA).*Results 3D ASL and SWAN showed high sensitivity (93% vs 94.5%), specificity (100%), accuracy (99%) and excellent agreement in localisation of fistula and grade the fistula as per Cognard grading. TOF MRA showed 94.4% sensitivity and 100 % specificity for localisation of the fistula as well as the grading of the fistula with good intermodality agreement and correlation. TOF MRA also showed 89% sensitivity in identifying the main arterial feeders and 85% sensitivity in identification of immediate venous drainage with 88 % accuracy. The findings of 3D ASL, SWAN, and TOF MRA showed excellent correlation with DSA(r - 0.99).*Conclusions Non contrast MR angiographic sequences are an excellent armamentarium in diagnosis of DAVF with excellent sensitivity and specificity for the site, grading and angioarchitectural evaluation of dural arteriovenous fistula.*Clinical Relevance/Application These non invasive sequences are very

useful in identification of the fistula and also may be an alternative to the invasive DSA for follow up of these cases post intervention for ruling out residual fistulas

RESULTS

3D ASL and SWAN showed high sensitivity (93% vs 94.5%), specificity (100%), accuracy (99%) and excellent agreement in localisation of fistula and grade the fistula as per Cognard grading. TOF MRA showed 94.4% sensitivity and 100 % specificity for localisation of the fistula as well as the grading of the fistula with good intermodality agreement and correlation. TOF MRA also showed 89% sensitivity in identifying the main arterial feeders and 85% sensitivity in identification of immediate venous drainage with 88 % accuracy. The findings of 3D ASL, SWAN, and TOF MRA showed excellent correlation with DSA(r - 0.99).

CLINICAL RELEVANCE/APPLICATION

These non invasive sequences are very useful in identification of the fistula and also may be an alternative to the invasive DSA for follow up of these cases post intervention for ruling out residual fistulas

SPR-NR-15   T1-weighted Structural Brain Network Assisted Dual-time-point 18F-FDG Uptake Consistency Evaluation Via Integrated PET-MRI Scans

Participants
Gang Feng, MD, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To verify the consistency of 18F-fluorodeoxyglucose (18F-FDG) uptake between two different delayed times after 18F-FDG injection in the frame of 3D high resolution T1 weighted (1mm*1mm*1mm) structural brain network.*Methods and Materials The local ethics committee has approved this study. Written, informed consent was obtained. A cohort of 60 cognitively normal subjects were included who underwent PET-MR scan during Jun. 2019 to Dec. 2020 in our center. Among them 30 subjects (14M/16F, age 51.40±7.70) from group A received a 45 min delayed PET-MR scan (referred as early) while the other 30 subjects(14M/16F, age 52.50±8.82) from group B received delayed scans at 90 min after tracer injection (referred as delayed). Each subject from group A has a counterpart in group B who is of the same age, gender and similar body weight. The whole brain was parcellated into 109 units with FSL and Freesurfer. The FDG uptake was expressed as maximal standard uptake value (SUVmax) in each parcellation unit of the structural brain network. Intraclass correlation coefficient, or ICC was used to test the reliability of brain measurements between the dual-time-point FDG uptake measurements. The quantification of the agreement between the measurements of parcellation units pair of two time points was evaluated with Bland-Altman plot (B-A plot). Limits of agreement between the two measurements are a 95% prediction interval of the difference.*Results There is a reduction of FDG uptake among all brain regions over time in this study, which shows that the values of delayed measurement are always lower than the early measurement. The intraclass correlation coefficients between two groups (values of 24 out of 30 are larger than 0.75) show a strong inter-group reliability for measuring FDG uptake in early as well as delayed scans. Moreover, from the perspective of parcellation-units-wise analysis, most data points of differences of mean FDG uptake values between early and delayed scan locate within 95% limits of agreements, which suggested the variability of FDG uptake of each parcellation units pair between two groups is minimal.*Conclusions The results of the present study demonstrate the consistency of 18F-FDG uptake variation in different delay times. FDG uptake decreases synchronously and proportionally in all parcellation units of brain as delayed time changes.*Clinical Relevance/Application To investigate the 18F-FDG metrics in a parcellation fashion, our study shows a proportional variation of FDG uptake in different delayed times. It promises the feasibility of neuroscience research based on data from multiple centers and different PET scan protocols.

RESULTS

There is a reduction of FDG uptake among all brain regions over time in this study, which shows that the values of delayed measurement are always lower than the early measurement. The intraclass correlation coefficients between two groups (values of 24 out of 30 are larger than 0.75) show a strong inter-group reliability for measuring FDG uptake in early as well as delayed scans. Moreover, from the perspective of parcellation-units-wise analysis, most data points of differences of mean FDG uptake values between early and delayed scan locate within 95% limits of agreements, which suggested the variability of FDG uptake of each parcellation units pair between two groups is minimal.

CLINICAL RELEVANCE/APPLICATION

To investigate the 18F-FDG metrics in a parcellation fashion, our study shows a proportional variation of FDG uptake in different delayed times. It promises the feasibility of neuroscience research based on data from multiple centers and different PET scan protocols.

SPR-NR-16   Arterial Transit Artifacts On Arterial Spin Labelling MRI As An Imaging Marker For The Prediction Of Cerebral Hyperperfusion After Carotid Endarterectomy

Participants
Xiaoyuan Fan, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Cerebral hyperperfusion syndrome is an important cause of hemorrhagic stroke after carotid revascularization. To date, a practical technique that can be regularly implemented in clinical practice for the prediction of postoperative cerebral hyperperfusion (CH) has not been reported. The purpose of this study was to investigate whether arterial transit artifacts (ATAs) on arterial spin labelling (ASL) MRI can be a practical imaging marker to identify patients at high risk of CH after carotid endarterectomy (CEA).*Methods and Materials Consecutive patients with carotid stenosis who underwent CEA between May 2015 and January 2021 were included. Pseudo-continuous ASL MRI was performed before and after CEA. CH was defined as an increase in cerebral blood flow > 100% compared with preoperative values on ASL images. Patients were divided into CH and non-CH groups. Two neuroradiologists scored ASL images based on the presence of ATAs in regions of interest corresponding to ASPECTS methodology: 0, no or minimal ASL signal; 1, low/moderate ASL signal with ATA; 2, high ASL signal with ATA; and 3, normal perfusion without ATA. The optimal cutoff value of ASL score for predicting CH after CEA was assessed by receiver operating characteristic analysis. Degree of stenosis and the status of primary and secondary collaterals were evaluated to correlate with ASL score.*Results Seventy-three patients were included (mean age: 66 ± 7 years, 74% were male). CH after CEA was presented in 18 (27.66%) patients. Preoperative ATA-based ASL score was independently associated with CH after CEA (p < 0.001, Table 1). The optimal cutoff value of preoperative ASL score for predicting CH was = 23 points (94.6% sensitivity, 88.9% specificity, Figure 1). Carotid near-occlusion (p = 0.002), opening of posterior communicating arteries (p = 0.003) and presence of leptomeningeal collaterals (p < 0.001) were associated

with lower ASL scores. A representative case was shown in Figure 2.*Conclusions ATA on ASL images is a comprehensive manifestation of the degree of stenosis and the status of primary and secondary collaterals. Based on the presence of ATAs, ASL can non-invasively predict CH after CEA in patients with carotid stenosis in routine clinical practice.*Clinical Relevance/Application ASL images can be non-invasively obtained using most clinical MRI scanners with the time consumption less than 5 minutes and ATAs were easy to collect from the original ASL images without post-processing steps. Therefore, ASL may be a useful tool that can be applied to routine clinical work for the prediction of CH after CEA.

RESULTS

Seventy-three patients were included (mean age: 66 ± 7 years, 74% were male). CH after CEA was presented in 18 (27.66%) patients. Preoperative ATA-based ASL score was independently associated with CH after CEA (p < 0.001, Table 1). The optimal cutoff value of preoperative ASL score for predicting CH was = 23 points (94.6% sensitivity, 88.9% specificity, Figure 1). Carotid near-occlusion (p = 0.002), opening of posterior communicating arteries (p = 0.003) and presence of leptomeningeal collaterals (p < 0.001) were associated with lower ASL scores. A representative case was shown in Figure 2.

CLINICAL RELEVANCE/APPLICATION

ASL images can be non-invasively obtained using most clinical MRI scanners with the time consumption less than 5 minutes and ATAs were easy to collect from the original ASL images without post-processing steps. Therefore, ASL may be a useful tool that can be applied to routine clinical work for the prediction of CH after CEA.

SPR-NR-18 Early Moderate Blood-brain Barrier Disruption Can Be Reversible While Severe Blood-brain Barrier Disruption Indicates The Risk Of Delayed Cerebral Ischemic Following Aneurysmal Subarachnoid Hemorrhage

Participants
Chao Zhang, MS, Wuhu, China (Presenter) Nothing to Disclose

PURPOSE

To evaluate the changes of blood brain barrier permeability (BBBP) after aneurysmal subarachnoid hemorrhage (aSAH) and find out whether BBBP within 24 h after onset can further improve the prediction of delayed cerebral ischemic (DCI).*Methods and Materials Whole-brain CTP was performed within 24 h after symptom onset and in the DCI time window (DCITW). Whole brain average values of the flow extraction product (mKtrans) derived from CTP, qualitative CTP patterns and quantitative CTP parameters, and clinical data were compared between DCI and non-DCI groups. The changes in mKtrans from admission to the DCITW were analysed using a Paired t test. Multivariate logistic regression analysis and receiver-operating characteristic (ROC) curve analysis were performed to identify predictors of DCI and assess the discriminative ability.*Results One hundred and twenty-eight of 167 patients were included in the study, 44 of whom underwent a follow-up CTP in the DCITW. Forty-one of 128 patients (32%) developed DCI. Patients in the DCI group had a high World Federation of Neurosurgery scale (WFNS), Hunt-Hess grade (H-H), and modified Fisher Score (mFS) (all P<0.05). The mKtrans in the DCI group was significantly higher than that in the non-DCI group both on admission (P<0.001) and in the DCITW (P=0.001). mKtrans decreased significantly in the non-DCI group (P<0.009), but not in DCI group (P=0.474). Stepwise multivariate logistic regression analysis showed that mKtrans (OR=1.07, 95%CI: 1.03-1.11, P<0.001), WFNS (OR=6.47, 95%CI: 1.04-40.12, P=0.045), H-H (OR=0.17, 95%CI: 0.02-1.30, P=0.087), mFS (OR=3.73, 95%CI: 1.23-11.30, P=0.020), and qualitative CTP patterns (OR=3.27, 95%CI: 1.11-9.67, P=0.032) were independent predictors of DCI. The mKtrans produced the largest area under the curve of 0.786 (95%CI: 0.70-0.88), and the threshold was 0.545 ml·100ml-1·min-1 with corresponding sensitivity and specificity of 68% and 82%, respectively.*Conclusions BBBP measurement within 24 h after onset can improve the prediction of DCI following aSAH. Early moderate BBB disruption can be reversible, whereas severe BBBP disruption indicates the risk of DCI.*Clinical Relevance/Application This study further proves the value of early BBBP changes in aSAH. BBBP measurement within 24 h after onset can improve the prediction of DCI following aSAH. Early moderate BBBP disruption can be reversible, whereas severe BBBP disruption indicates the risk of DCI. Therefore, quantitative evaluation of BBBP at the acute stage after aSAH may guide clinical management and improve the functional outcome.

RESULTS

One hundred and twenty-eight of 167 patients were included in the study, 44 of whom underwent a follow-up CTP in the DCITW. Forty-one of 128 patients (32%) developed DCI. Patients in the DCI group had a high World Federation of Neurosurgery scale (WFNS), Hunt-Hess grade (H-H), and modified Fisher Score (mFS) (all P<0.05). The mKtrans in the DCI group was significantly higher than that in the non-DCI group both on admission (P<0.001) and in the DCITW (P=0.001). mKtrans decreased significantly in the non-DCI group (P<0.009), but not in DCI group (P=0.474). Stepwise multivariate logistic regression analysis showed that mKtrans (OR=1.07, 95%CI: 1.03-1.11, P<0.001), WFNS (OR=6.47, 95%CI: 1.04-40.12, P=0.045), H-H (OR=0.17, 95%CI: 0.02-1.30, P=0.087), mFS (OR=3.73, 95%CI: 1.23-11.30, P=0.020), and qualitative CTP patterns (OR=3.27, 95%CI: 1.11-9.67, P=0.032) were independent predictors of DCI. The mKtrans produced the largest area under the curve of 0.786 (95%CI: 0.70-0.88), and the threshold was 0.545 ml·100ml-1·min-1 with corresponding sensitivity and specificity of 68% and 82%, respectively.

CLINICAL RELEVANCE/APPLICATION

This study further proves the value of early BBBP changes in aSAH. BBBP measurement within 24 h after onset can improve the prediction of DCI following aSAH. Early moderate BBBP disruption can be reversible, whereas severe BBBP disruption indicates the risk of DCI. Therefore, quantitative evaluation of BBBP at the acute stage after aSAH may guide clinical management and improve the functional outcome.

SPR-NR-19 Diffusion MRI Connectometry Of Pedunculopontine Nucleus Projections And Motor Disability In Parkinson's Disease

Participants
Pohchoo Seow, PhD,MSc, Singapore, Singapore (Presenter) Nothing to Disclose

PURPOSE

Diffusion spectrum imaging (DSI) is a high-order model-free MRI approach based on generalized q-sampling imaging. It is sensitive to intravoxel heterogeneities and allows for accurate mapping of axonal trajectories through decoupling of restricted and nonrestricted diffusion, and assessment of local inflammation. We investigated changes in local structural connectometry driven by cholinergic denervation in the pedunculopontine nucleus (PPN) in Parkinson's disease (PD) patients and their correlation to motor scores.*Methods and Materials 94 subjects underwent brain MRI with DSI and clinical motor assessments viz Unified Parkinson's

Disease Rating Scale subscore (UPDRS III) and Hoehn and Yahr scale (H&Y). Deterministic tractography was conducted to track axonal PPN projections after registration to the Human Connectome Project diffusion MRI template. DSI data were normalized to the standard template and pre-processed to generate restricted (RDI) and non-restricted (NRDI) diffusion indices which represent the density of intra- and extra-cellular diffusing spins. Connectometry analysis was performed for voxel-by-voxel correlation between RDI/NRDI in the PPN projections with motor scores.*Results There were 36 PD patients (9 women; mean age 64.6 years, H&Y 1.93, UPDRS III 31.9) and 58 healthy controls (32 women; mean age 64.9 years, H&Y 0.04, UPDRS III 5.24). Patients showed reduced RDI and NRDI in the PPN projections connected to the thalamic intralaminar and ventral posterolateral subnuclei, subthalamic nucleus, and substantia nigra compared to controls, and these demonstrated significant negative correlations (false-discovery-rate<0.05) with worse motor scores.*Conclusions Using diffusion MR connectometry, we found local changes in PPN projections to different deep grey nuclei in PD patients which correlated with the degree of motor disability. Our findings provide imaging evidence of dysregulation of PPN projections, in support of Braak's hypothesis, and congruent with literature proposing progressive neuroinflammation and neurodegeneration.*Clinical Relevance/Application DSI shows potential as an objective tool for monitoring of disease progression in Parkinson's disease and evaluation for deep brain stimulation surgery.

RESULTS

There were 36 PD patients (9 women; mean age 64.6 years, H&Y 1.93, UPDRS III 31.9) and 58 healthy controls (32 women; mean age 64.9 years, H&Y 0.04, UPDRS III 5.24). Patients showed reduced RDI and NRDI in the PPN projections connected to the thalamic intralaminar and ventral posterolateral subnuclei, subthalamic nucleus, and substantia nigra compared to controls, and these demonstrated significant negative correlations (false-discovery-rate<0.05) with worse motor scores.

CLINICAL RELEVANCE/APPLICATION

DSI shows potential as an objective tool for monitoring of disease progression in Parkinson's disease and evaluation for deep brain stimulation surgery.

SPR-NR-21 The Impact Of Brain Frailty On Collateral Status And Clinical Outcome In Acute Ischemic Stroke

Participants
Jia-Ying Zhou, Nanjing, China (*Presenter*) Nothing to Disclose

PURPOSE

We investigate the association of preexisting brain frailty markers with the collateral status and functional outcome in acute ischemic stroke.*Methods and Materials Consecutive stroke patients with proximal artery occlusion/severe stenosis presenting within 24 hours after symptom onset and who underwent baseline multiphase CTA and MRI within 5 days after onset from 2018 to 2020 were included. We graded the collateral status on multiphase CTA using Menon's six-point ordinal scale, and rated imaging markers of brain frailty on MRI (including atrophy [0-2 score], leukoaraiosis [0-2 score], evidence of old lacunes, and evidence of enlarged perivascular space). Total brain frailty burden scores were also quantified by adding the presence of atrophy, leukoaraiosis, and old lacunes (including severe burden score, slight burden score, and severe burden score without atrophy). Modified Rankin Scale (mRS) score at discharge was recorded as the clinical outcome. Multivariable ordinal logistic regression was performed to explore the associations between brain frailty markers with collaterals and mRS.*Results Of the 119 eligible patients (median age, 70 years; 61.3% men), 89.1% patients showed brain frailty imaging markers. Severe atrophy (P<0.001, P=0.002), severe leukoaraiosis (P<0.001, P=0.032) were always associated with the collateral score when using individual markers or combining all markers. Total burden scores were all significantly associated with collateral score (P<0.001), and severe burden score had the most marked effect (OR 4.38, 95% CI 2.67-7.19). Severe burden score (OR 1.74, 95% CI 1.07-2.81) was also an independent risk factor of worse mRS at discharge, and decreased the protective effect of collaterals on mRS (from OR 0.42 [95%CI 0.29-0.60], to OR 0.53 [95%CI 0.36-0.79]). Moreover, there was a significant interaction between severe burden score and collateral score (P=0.003, OR 1.27 [95%CI, 1.00-1.61]) in determining the excellent clinical outcome (mRS score 0-1).*Conclusions Preexisting brain frailty markers are significantly associated with poor collateral status and could mediate the prognostic value of collaterals on functional outcomes after stroke. These imply that therapies aimed at reducing the progression of brain frailty may protect against poor clinical outcomes via improving collateral status.*Clinical Relevance/Application Pre-stroke brain frailty markers are determinants of poor collateral status and functional outcomes after stroke, implying that therapies aimed at reducing the progression of brain frailty, especially atrophy and leukoaraiosis, may protect against poor clinical outcomes via improving collateral status.

RESULTS

Of the 119 eligible patients (median age, 70 years; 61.3% men), 89.1% patients showed brain frailty imaging markers. Severe atrophy (P<0.001, P=0.002), severe leukoaraiosis (P<0.001, P=0.032) were always associated with the collateral score when using individual markers or combining all markers. Total burden scores were all significantly associated with collateral score (P<0.001), and severe burden score had the most marked effect (OR 4.38, 95% CI 2.67-7.19). Severe burden score (OR 1.74, 95% CI 1.07-2.81) was also an independent risk factor of worse mRS at discharge, and decreased the protective effect of collaterals on mRS (from OR 0.42 [95%CI 0.29-0.60], to OR 0.53 [95%CI 0.36-0.79]). Moreover, there was a significant interaction between severe burden score and collateral score (P=0.003, OR 1.27 [95%CI, 1.00-1.61]) in determining the excellent clinical outcome (mRS score 0-1).

CLINICAL RELEVANCE/APPLICATION

Pre-stroke brain frailty markers are determinants of poor collateral status and functional outcomes after stroke, implying that therapies aimed at reducing the progression of brain frailty, especially atrophy and leukoaraiosis, may protect against poor clinical outcomes via improving collateral status.

SPR-NR-23 Diagnostic Yield Of Susceptibility-weighted Brain MR Imaging In Patients With Cognitive Impairment: Large Cohort Study With 6,977 Patients

Participants
Chong Hyun Suh, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

There is paucity of evidence for the need of susceptibility-weighted imaging (SWI) in patients attending outpatient clinic for cognitive impairment. We aimed to evaluate diagnostic yield of SWI in patients attending outpatient clinic for cognitive impairment.*Methods and Materials This retrospective, observational, single-institution study included 6,977 consecutive patients (mean age ± SD, 70 ± 11; 4,394 women) attending outpatient clinic for cognitive impairment who underwent brain MRI with SWI from January 2013 to February 2020. Patients with microbleeds were identified, and those meeting the criteria for cerebral amyloid

angiopathy (CAA) and hypertensive angiopathy were recognized. Diagnostic yield was defined as the proportion of patients with positive findings on SWI among all patients and exact 95% CIs were determined. Subgroup analyses were performed by age groups and sex, and Chi-square test was performed to compare the diagnostic yields between groups.*Results The overall diagnostic yield of SWI in patients with cognitive impairment was 23.1% (1,613/6,977; 95% CI, 22.1-24.1%). The diagnostic yield was 17.1% (1,193/6,977; 95% CI, 16.2-18.0%) for microbleeds. The diagnostic yield was 2.5% (175/6,977; 95% CI, 2.2-2.9%) for cerebral amyloid angiopathy, 1.1% (74/6,977; 95% CI, 0.83-1.3%) for hypertensive angiopathy, 0.95% (66/6,977; 95% CI, 0.73-1.2%) for mixed cerebral amyloid and hypertensive angiopathy and 0.69% (48/6,977; 95% CI, 0.51-0.91%) for superficial siderosis. The diagnostic yield was 0.54% (38/6,977; 95% CI, 0.39-0.75%) for cavernous malformation and 0.17% (12/6,977; 95% CI, 0.09-0.30%) for diffuse axonal injury or trauma. The diagnostic yield of SWI was higher in the older age group with = 70 years (41.4% vs 10.5%, P < .001). There was an incremental increase of the diagnostic yield from the age group 50-59 years (8.7%; 69/787) to 80-89 years (33.6%; 413/1,229).*Conclusions The diagnostic yield of SWI in patients with cognitive impairment was high with higher diagnostic yield in the older age group, and SWI identified microbleeds that meet the criteria for CAA, hypertensive angiopathy or both.*Clinical Relevance/Application This supports the need for SWI in evaluation of patients with cognitive impairment.

RESULTS

The overall diagnostic yield of SWI in patients with cognitive impairment was 23.1% (1,613/6,977; 95% CI, 22.1-24.1%). The diagnostic yield was 17.1% (1,193/6,977; 95% CI, 16.2-18.0%) for microbleeds. The diagnostic yield was 2.5% (175/6,977; 95% CI, 2.2-2.9%) for cerebral amyloid angiopathy, 1.1% (74/6,977; 95% CI, 0.83-1.3%) for hypertensive angiopathy, 0.95% (66/6,977; 95% CI, 0.73-1.2%) for mixed cerebral amyloid and hypertensive angiopathy and 0.69% (48/6,977; 95% CI, 0.51-0.91%) for superficial siderosis. The diagnostic yield was 0.54% (38/6,977; 95% CI, 0.39-0.75%) for cavernous malformation and 0.17% (12/6,977; 95% CI, 0.09-0.30%) for diffuse axonal injury or trauma. The diagnostic yield of SWI was higher in the older age group with = 70 years (41.4% vs 10.5%, P < .001). There was an incremental increase of the diagnostic yield from the age group 50-59 years (8.7%; 69/787) to 80-89 years (33.6%; 413/1,229).

CLINICAL RELEVANCE/APPLICATION

This supports the need for SWI in evaluation of patients with cognitive impairment.

SPR-NR-24 Progressive Microstructural Alterations In Gray Matter In Parkinson'S Disease

Participants
Xueqin Bai, Hangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the microstructural and macrostructural alterations in gray matter in Parkinson's disease (PD) at different stages using diffusion model of Neurite Orientation Dispersion and Density Imaging (NODDI) with gray matter-based spatial statistics (GBSS) and T1 imaging, respectively.*Methods and Materials 108 PD patients (64 patients in early-stage PD group (EPD) and 44 patients in moderate-late-stage PD group (MLPD)) and 64 healthy controls (HC) were included. Gray matter microstructural alterations were evaluated by neurite density (NDI), and orientation dispersion (ODI) and fraction of the isotropic compartment (fiso). Cortical thickness analyses were evaluated by T1 imaging with FreeSurfer. Randomize tool was used to examine the relationship between diffusion metrics and motor score of Unified Parkinson's Disease Rating Scale part-III (UPDRS-III).*Results For GBSS, compared with HC, EPD patients showed higher fiso and lower ODI in posterior cortical regions (occipital, temporal lobes), while MLPD patients showed diffuse higher fiso and lower ODI across bilateral frontal, parietal, temporal, occipital lobes and cingulate cortex (all Pfwe< 0.05). Compared with EPD, MLPD patients showed extensive higher fiso in bilateral frontal, occipital, cingulate cortex and right temporal lobes and lower ODI across bilateral frontal, parietal, temporal, occipital lobes and cingulate cortex (all Pfwe< 0.05). However, cortical thickness analyses failed to detect any GM differences in EPD and MLPD.*Conclusions PD has progressive microstructural alterations in the gary matter. NODDI is more sensitive than macrostructural imaging to detect cortical alterations during PD progression.*Clinical Relevance/Application Exploring the degenerative changes in gray matter in PD patients at different stages will improve the understanding of PD pathophysiology and will promote the identification of new markers to monitor disease progression in vivo. Our study also provides evidence supporting the notion that microstructural changes precede morphological changes in PD.

RESULTS

For GBSS, compared with HC, EPD patients showed higher fiso and lower ODI in posterior cortical regions (occipital, temporal lobes), while MLPD patients showed diffuse higher fiso and lower ODI across bilateral frontal, parietal, temporal, occipital lobes and cingulate cortex (all Pfwe< 0.05). Compared with EPD, MLPD patients showed extensive higher fiso in bilateral frontal, occipital, cingulate cortex and right temporal lobes and lower ODI across bilateral frontal, parietal, temporal, occipital lobes and cingulate cortex (all Pfwe< 0.05). However, cortical thickness analyses failed to detect any GM differences in EPD and MLPD.

CLINICAL RELEVANCE/APPLICATION

Exploring the degenerative changes in gray matter in PD patients at different stages will improve the understanding of PD pathophysiology and will promote the identification of new markers to monitor disease progression in vivo. Our study also provides evidence supporting the notion that microstructural changes precede morphological changes in PD.

SPR-NR-26 Perfusion And Atrophy Patterns Of Cerebral Deep Nucleus And Cerebellar Regions In Parkinson'S Disease And Parkinsonism-plus Syndrome

Participants
Zhaoxi Liu, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore discriminative patterns of deep nucleus arophy and cerebral blood flow (CBF) between patients with PD and PPS*Methods and Materials Two hundred and thirty-one subjects [81 patients with PD, 39 patients with progressive supranuclear palsy (PSP), 21 patients with Parkinson variant of multiple system atrophy (MSA-P), and 90 healthy controls (HCs)] underwent a morphometric and arterial spin labeling (ASL) MRI to measure volume and perfusion values within the deep nucleus and cerebellum. The PD 25 template was used for the deep nucleus (including 16 regions, figure 1). The SUIT template was used for segmenting cerebellar ROIs (including 34 regions). An ANOVA followed by post-hoc with Bonferroni correction was employed to identify significant differences among the groups*Results Patients with PD, PSP and MSA-P showed lower perfusion values than HCs in several regions (bilateral caudate nucleus, putamen, globuspallidus-externa, right V, bilateral VI, vermis VI, vermis VIIb, vermis VIIIa and right interposed nucleus) (all p <0.05). In particular, CBF in the bilateral caudate nucleus in the PSP group was significantly

lower than that in the PD, MSA-P and HC groups (p <0.05). The PSP group showed a higher degree of atrophy in left caudate nucleus (p <0.05) and bilateral thalami than those in HCs (p <0.001). Patients with MSA-P showed a higher atrophy in the left caudate, bilatral putamen and several cerebellar regions than that in the HCs. Additionally, the GM voluem of bilateral putmen and right V in the MSA-P group was significantly smaller than that of other groups (all p <0.05)*Conclusions Significant perfusion reduction in bilateral caudate nucleus could be a characteristic of PSP, while significant atrophy of bilateral putamen and right V may be a feature of MSA-P*Clinical Relevance/Application To aid the differential diagnosis among Parkinson disease (PD), progressive supranuclear palsy (PSP) and Parkinson variant of multiple system atrophy (MSA-P).

RESULTS

Patients with PD, PSP and MSA-P showed lower perfusion values than HCs in several regions (bilateral caudate nucleus, putamen, globuspallidus-externa, right V, bilateral VI, vermis VI, vermis VIIb, vermis VIIIa and right interposed nucleus) (all p <0.05). In particular, CBF in the bilateral caudate nucleus in the PSP group was significantly lower than that in the PD, MSA-P and HC groups (p <0.05). The PSP group showed a higher degree of atrophy in left caudate nucleus (p <0.05) and bilateral thalami than those in HCs (p <0.001). Patients with MSA-P showed a higher atrophy in the left caudate, bilatral putamen and several cerebellar regions than that in the HCs. Additionally, the GM voluem of bilateral putmen and right V in the MSA-P group was significantly smaller than that of other groups (all p <0.05)

CLINICAL RELEVANCE/APPLICATION

To aid the differential diagnosis among Parkinson disease (PD), progressive supranuclear palsy (PSP) and Parkinson variant of multiple system atrophy (MSA-P).

SPR-NR-27 Effects Of Aortic Arch Anatomy And Carotid Artery Tortuosity On Mechanical Thrombectomy Procedure Length And Complications

Participants
Elena Cora, MD, Halifax, Nova Scotia (*Presenter*) Nothing to Disclose

PURPOSE

Endovascular thrombectomy (EVT) is a procedure used to treat acute ischemic stroke. Given that the technical success of clot removal to achieve reperfusion has direct implications for patient outcomes, understanding the impact of anatomical variation on procedural success is important. Here we sought to characterize relevant anatomical characteristics and their impact on the success of EVT and related patient outcomes.*Methods and Materials We retrospectively reviewed all consecutive patients who underwent EVT for acute ischemic stroke due to large vessel occlusion in the anterior circulation at our institution from January 2019 to February 2021. Pre-procedure CT imaging was reviewed and scored independently by a board certified neuroradiologist. The type of aortic arch and tortuosity of the internal and common carotid arteries were scored. Using univariate analysis, the effect of these anatomical scores on patient outcomes, including time to final recanalization, mTICI, and mRS scores were analyzed.*Results A total of 128 patients were assessed, 55% females (70/128), mean age 71 (SD 12), median presenting NIHSS 15 and median ASPECTS score 9. Univariate analysis showed that more difficult arch anatomy corresponded to significantly increased fluoroscopic time throughout the procedures (p=0.035). Increasing common carotid arterial tortuosity was associated with a higher radiation dose (p=0.040) and there were more procedural complications (p=0.008), both of these being statistically significant. There was also a trend towards less successful recanalizations (p=0.076) with common carotid tortuosity. Internal carotid arterial tortuosity also showed a trend towards less successful recanalizations (p=0.079).*Conclusions Aortic arch, common and internal carotid tortuosity are important anatomical factors as they show association with multiple parameters that can lead to adverse clinical outcomes, including longer procedures with less successful recanalizations and more procedural complications in patients undergoing EVT.*Clinical Relevance/Application The vascular anatomy of the aortic arch and carotid arteries when routinely evaluated for tortuosity prior to undergoing EVT may be helpful in clinical decision making including deciding which tools to use, whether to perform the procedure under conscious sedation or a general anaesthetic and when discussing risks versus benefits during informed consent discussions.

RESULTS

A total of 128 patients were assessed, 55% females (70/128), mean age 71 (SD 12), median presenting NIHSS 15 and median ASPECTS score 9. Univariate analysis showed that more difficult arch anatomy corresponded to significantly increased fluoroscopic time throughout the procedures (p=0.035). Increasing common carotid arterial tortuosity was associated with a higher radiation dose (p=0.040) and there were more procedural complications (p=0.008), both of these being statistically significant. There was also a trend towards less successful recanalizations (p=0.076) with common carotid tortuosity. Internal carotid arterial tortuosity also showed a trend towards less successful recanalizations (p=0.079).

CLINICAL RELEVANCE/APPLICATION

The vascular anatomy of the aortic arch and carotid arteries when routinely evaluated for tortuosity prior to undergoing EVT may be helpful in clinical decision making including deciding which tools to use, whether to perform the procedure under conscious sedation or a general anaesthetic and when discussing risks versus benefits during informed consent discussions.

SPR-NR-29 Cerebral Small Vessel Disease In Patients With Carotid Stenosis: Relationship With Carotid Intraplaque Hemorrhage And Symptoms

Participants
Xiaoqian Zhang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the association between carotid intraplaque hemorrhage (IPH) and total burden of cerebral small vessel disease (CSVD) in patients with carotid stenosis, and to identify the imaging features that best help distinguish between symptomatic and asymptomatic patients with carotid stenosis.*Methods and Materials Consecutive 71 patients (mean age was 66 ± 7 years, and 84.3% were male) with unilateral carotid stenosis were included and brain magnetic resonance imaging (MRI) were performed. The total burden of CSVD was calculated by accumulating one point according to the presence of each of the four MRI markers: white matter hyperintensities, lacunes, perivascular spaces and cerebral microbleeds. Ordered logistic regression analysis was performed to evaluate the association between IPH and CSVD burdens. Age, sex, vascular risk factors, degree of stenosis and completeness of circle of Willis were also included as covariates. The symmetry of CSVD burdens between ipsilateral and contralateral hemispheres was tested. Clinical symptoms including absent/non-specific symptoms, transient ischemic attack, amaurosis and ischemic stroke were evaluated by a vascular surgeon. MRI features (CSVD score, degree of stenosis, IPH and complete circle of

Willis) were correlated with severity of clinical symptoms by using Kruskal-Wallis H tests and Fisher's exact tests.*Results IPH (OR = 4.12, 95% CI [1.48, 11.45], p = 0.007) was independently associated with a higher CSVD score, adjusted for other risk factors (Table 1). The presence of unilateral IPH was independently associated with the interhemispheric CSVD score difference (p = 0.046, Figure 1). The association between clinical symptoms and imaging characteristics are shown in Figure 2. CSVD score was the only imaging factor associated with more severe clinical symptoms (p < 0.001). The association between IPH and clinical symptoms was marginally significant (p = 0.064), while degree of stenosis (p = 0.115) and completeness of circle of Willis (p = 0.94) were not associated with symptomatic status.*Conclusions Carotid IPH is associated with a higher total burden of CSVD in patients with carotid stenosis. Compared with degree of stenosis or IPH, the total CSVD score is a more effective imaging marker linked with clinical symptoms.*Clinical Relevance/Application In patients with carotid stenosis, the total CSVD score as an imaging marker is worthy of attention. We found the total CSVD score was an effective imaging marker linked with clinical symptoms and in the future, the diagnostic and predictive value of the total CSVD burden needs to be further tested in patients with carotid stenosis.

RESULTS

IPH (OR = 4.12, 95% CI [1.48, 11.45], p = 0.007) was independently associated with a higher CSVD score, adjusted for other risk factors (Table 1). The presence of unilateral IPH was independently associated with the interhemispheric CSVD score difference (p = 0.046, Figure 1). The association between clinical symptoms and imaging characteristics are shown in Figure 2. CSVD score was the only imaging factor associated with more severe clinical symptoms (p < 0.001). The association between IPH and clinical symptoms was marginally significant (p = 0.064), while degree of stenosis (p = 0.115) and completeness of circle of Willis (p = 0.94) were not associated with symptomatic status.

CLINICAL RELEVANCE/APPLICATION

In patients with carotid stenosis, the total CSVD score as an imaging marker is worthy of attention. We found the total CSVD score was an effective imaging marker linked with clinical symptoms and in the future, the diagnostic and predictive value of the total CSVD burden needs to be further tested in patients with carotid stenosis.

SPR-NR-31 Comparison Of Flat Panel CT And Photon-counting Detector- Based Spectral CT To Evaluate Contrast Enhancement Of Chronic Subdural Hematomas After Embolization Of The Middle Meningeal Artery

Participants
Christoph Maurer, MD, Augsburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Middle meningeal artery (MMA) embolization targets the leaky dural vascular networks of chronic subdural hematoma (cSDH) to prevent hematoma re-accumulation. Post interventional flat panel CT imaging often shows enhancement of the dural membranes and the cSDH itself. Spectral CT can add additional information by differentiating between enhancement by iodine-based contrast agents and hemorrhage.*Methods and Materials All 105 patients who underwent MMA embolization in our institution between May 2018 and April 2021 were retrospectively reviewed. Post-procedural CT was either performed on a flat panel CT in the angio suit or on Photon-Counting Detector based CT(Quantum Technology, Siemens Healthineers, Germany) using a spectral acquisition technique. Flat panel CTs were evaluated for dural enhancement, enhancement of the hematoma and possible hemorrhage. Spectral CT acquisitions were post-processed to differentiate between iodine enhancement and blood. Available follow-up images were reviewed for hematoma re-accumulation.*Results Illustrative cases will be presented to compare the differences between postinterventional flat-panel CT and post procedural Spectral CT for patients undergoing MMA embolization. The potential of Spectral CT with a photon counting detector to discriminate between contrast enhancement and blood will be highlighted. Follow-up data on cSDH will be correlated with initial dural enhancement as well as enhancement of the hematoma.*Conclusions Preliminary results suggest that compared to post interventional flat panel CT Spectral CT facilitates differentiation between hematoma re-accumulation and contrast leakage and provides improved visualization of contrast enhancement of membranes within the cSDH and the dura itself. Postinterventional contrast enhancement of cSDHs might be a predictor of successful MMA embolization.*Clinical Relevance/Application Spectral CT provides additional prognostic and thereputic information after neuroradiological endovascular interventions.

RESULTS

Illustrative cases will be presented to compare the differences between postinterventional flat-panel CT and post procedural Spectral CT for patients undergoing MMA embolization. The potential of Spectral CT with a photon counting detector to discriminate between contrast enhancement and blood will be highlighted. Follow-up data on cSDH will be correlated with initial dural enhancement as well as enhancement of the hematoma.

CLINICAL RELEVANCE/APPLICATION

Spectral CT provides additional prognostic and thereputic information after neuroradiological endovascular interventions.

SPR-NR-32 Convergent And Divergent Intranetwork And Internetwork Connectivity Patterns In Drug-naïve Patients With Early Parkinson's Disease

Participants
Wenliang Fan, BMedSc,PhD, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the difference of intra- and internetwork architecture at three different level between individuals with Parkinson's disease (PD) and healthy controls (HC).*Methods and Materials A case-control study of 50 early-stage drug-naïve PD and 50 HC participants were collected. All participants were underwent resting-state functional MRI as well as a series of questionnaires to assess the severity of disease and the status of psychiatry. The intra- and internetwork architecture of resting state brain network of all participants were analysed at integrity level, network level and edge level. The scores of UPDRS-III, MMSE, MOCA, HAMA and HAMD reflecting the motor and non-motor symptoms of PD were collected for further regression analysis.*Results Compared to HC, reduced degree of functional connectivity were mainly observed in VSN, SMN, LBN and DGN (P<0.05, FDR corrected). Intra-network analysis indicates decreased functional connectivity of DGN, SMN, VAN and LBN. Inter-network analysis indicates reduced functional connectivity in nine pairs of RSNs. At edge level, LBN is the center of abnormal functional connectivity (P<0.05, FDR corrected). Regression analysis shows that the score of MOCA is associated with intra-network of DGN and inter-network of DGN-VAN.*Conclusions Our study demonstrated the variation of whole brain connection in drug-naïve patients with early PD compared with age-matched HC for the first time. It can be concluded that main changes focus on SMN, DGN, LBN and VSN, which may be relevant to the motor and non-motor symptoms in early PD. Meanwhile, our results reveal the changes of convergent and dvergent

intranetwork and internetwork connectivity patterns of drug-naïve patients with early Parkinson's disease.*Clinical Relevance/Application The present study provides neuroimaging evidence of the functional brain connectome alterations at three level in drug-naïve patients with early Parkinson's disease and corresponding potential biomarkers for clinical diagnosis and assessment of PD.

RESULTS

Compared to HC, reduced degree of functional connectivity were mainly observed in VSN, SMN, LBN and DGN (P<0.05, FDR corrected). Intra-network analysis indicates decreased functional connectivity of DGN, SMN, VAN and LBN. Inter-network analysis indicates reduced functional connectivity in nine pairs of RSNs. At edge level, LBN is the center of abnormal functional connectivity (P<0.05, FDR corrected). Regression analysis shows that the score of MOCA is associated with intra-network of DGN and inter-network of DGN-VAN.

CLINICAL RELEVANCE/APPLICATION

The present study provides neuroimaging evidence of the functional brain connectome alterations at three level in drug-naïve patients with early Parkinson's disease and corresponding potential biomarkers for clinical diagnosis and assessment of PD.

SPR-NR-33   Multiparametric MR-based Radiofusionomics Modeling For Differentiation Of Glioblastoma Multiforme From Solitary Brain Metastasis

Participants
Ruili Wei, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the diagnostic potential of a novel RadioFusionOmics (RFO) model in differentiating GBM and SBM through information fusion from multiple MR sequences and various classifiers based on the optimal volumetric lesion component.*Methods and Materials This retrospective study collected 183 patients diagnosed and treated in two institutions between September 2007 and September 2020, including 94 GBM patients and 89 SBM patients. Three volume of interests (VOIs) were delineated on the conventional axial MR images (T1WI, T2WI, T2_FLAIR and CE_T1WI), including the volumetric non-enhanced tumor (nET), enhanced tumor (ET), and peritumoral edema (pTE). Using the RFO model, radiomics features extracted from different combinations of multiparametric MRI sequence(s) and VOI(s) were fused by a novel feature fusion method and cross-validated by 15 classification models. The best sequence and VOI (or combinations) were determined. The top predictive models were ranked and screened out on the training/validation set. Model fusion, a procedure analogous to multidisciplinary consultation, was performed on the top-3 models to generate a final model, which was validated on an independent testing set. The top features were identified and the discrimination performance of RFO was compared with three board-certified radiologists.*Results Image features extracted from the volumetric ET (VOIET) showed dominant predictive performances over features from other VOIs combination. Fusion of VOIET features from the T1WI and T2_FLAIR sequences via the RFO model have achieved discrimination accuracy of AUC = 0.9249, accuracy = 0.8548, sensitivity = 0.8561, and specificity = 0.8529 on the independent testing set, which significantly outperformed three experienced radiologists (p=0.03, 0.01 and 0.02). The top-10 features included five first-order based features, four shape-based features, and one texture feature.*Conclusions Fusion of multiple MRI sequences and multiple classifiers can provide multifaceted information regarding tumor characteristics. The proposed RFO model may serve as a promising tool for computer-aided diagnosis of GBM vs. SBM in the clinical settings.*Clinical Relevance/Application A high-performing RadioFusionOmics model was built and could serve as a promising tool for computer-aided diagnosis of GBM vs. SBM.

RESULTS

Image features extracted from the volumetric ET (VOIET) showed dominant predictive performances over features from other VOIs combination. Fusion of VOIET features from the T1WI and T2_FLAIR sequences via the RFO model have achieved discrimination accuracy of AUC = 0.9249, accuracy = 0.8548, sensitivity = 0.8561, and specificity = 0.8529 on the independent testing set, which significantly outperformed three experienced radiologists (p=0.03, 0.01 and 0.02). The top-10 features included five first-order based features, four shape-based features, and one texture feature.

CLINICAL RELEVANCE/APPLICATION

A high-performing RadioFusionOmics model was built and could serve as a promising tool for computer-aided diagnosis of GBM vs. SBM.

SPR-NR-34   Cycle-consistent Adversarial Networks Increases Robustness Of Radiomics Model In Grading Meningiomas On External Validation

Participants
Yaewon Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The heterogeneity of MRI protocol is one of the major reason of decreased performance of the radiomics model in the external validation stage. We aimed to establish a robust model for predicting grade of meningiomas combining radiomics and Cycle-Consistent Adversarial Networks (CycleGAN) on external validation.*Methods and Materials A total of 257 patients with meningioma (162 low-grade, 95 high-grade) who underwent a brain magnetic resonance imaging protocol including contrast-enhanced T1 images were included in the institutional training set. After radiomics feature selection (n = 214), various combinations of classifiers were fine-tuned. The models were validated in the external validation set consisting of 61 patients with meningiomas (46 low-grade, 15 high-grade). To reduce the decrease of performance associated with the inter-institutional heterogeneity of MRI, we translated the style of the small image set of the external validation into the large image set style of the institutional training set using CycleGAN.*Results In the institutional training set, the area under the curve (AUC), accuracy, sensitivity, and specificity was 0.87 (95% confidence interval [CI 0.84-0.90], 77.1%, 82.2%, and 72.0%, respectively. In the original external validation dataset, the AUC, accuracy, sensitivity, and specificity were 0.62 (95% CI 0.46-0.78), 58.6%, 46.2%, and 62.2%, respectively. In the style-transferred external validation dataset, the AUC, accuracy, sensitivity, and specificity were 0.82 (95% CI 0.70-0.94), 70.7%, 76.9%, and 68.9%, respectively. The performance significantly increased in the external validation set after style-transfer was performed (P = 0.046).*Conclusions CycleGAN may be helpful to increase the robustness of a radiomics model in differentang meningioma grade on external validation.*Clinical Relevance/Application In our study, we focused on a practical and crucial problem encountered in implementing a machine learning model in medical imaging, which is increasing the robustness of an radiomics model on external validation. The inter-institutional heterogeneity of MRI protocol is one of the major reason of decreased performance. CycleGANs are a relatively newly type of Generative Adversarial Network (GAN), which has received much attention because of

their ability to capture characteristics of one image collection and figure generate synthetic images in the absence of any paired training examples. As there is no 'ground truth' dataset of paired training examples (consisting of internal and external MRI exams of identical patients at the same period) in real-world clinical practice, our method may serve as a useful approach to solve inter-institutional heterogeneity of image data.

RESULTS

In the institutional training set, the area under the curve (AUC), accuracy, sensitivity, and specificity was 0.87 (95% confidence interval [CI 0.84-0.90], 77.1%, 82.2%, and 72.0%, respectively. In the original external validation dataset, the AUC, accuracy, sensitivity, and specificity were 0.62 (95% CI 0.46-0.78), 58.6%, 46.2%, and 62.2%, respectively. In the style-transferred external validation dataset, the AUC, accuracy, sensitivity, and specificity were 0.82 (95% CI 0.70-0.94), 70.7%, 76.9%, and 68.9%, respectively. The performance significantly increased in the external validation set after style-transfer was performed (P = 0.046).

CLINICAL RELEVANCE/APPLICATION

In our study, we focused on a practical and crucial problem encountered in implementing a machine learning model in medical imaging, which is increasing the robustness of an radiomics model on external validation. The inter-institutional heterogeneity of MRI protocol is one of the major reason of decreased performance. CycleGANs are a relatively newly type of Generative Adversarial Network (GAN), which has received much attention because of their ability to capture characteristics of one image collection and figure generate synthetic images in the absence of any paired training examples. As there is no 'ground truth' dataset of paired training examples (consisting of internal and external MRI exams of identical patients at the same period) in real-world clinical practice, our method may serve as a useful approach to solve inter-institutional heterogeneity of image data.

SPR-NR-37   Chemical Exchange Saturation Transfer (CEST) Imaging In Various Brain Tumor Patients: Comparison Of Capability For Molecular-based Assessment Between 2D Spin Echo- And 3D Gradient Echo-based Sequences

Participants
Kazuhiro Murayama, MD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation

PURPOSE

To prospectively and directly compare the capability of chemical exchange saturation transfer (CEST) imaging for molecular-based assessment between 2D spin echo (SE) based and 3D gradient echo (GRE) based sequences in various brain tumor patients.*Methods and Materials 50 consecutive patients with 54 pathologically diagnosed brain tumors underwent CEST imaging by using 2D SE-based and 3D GRE-based sequences (i.e. 2D CEST and 3D CEST) at a 3T MR system. In each lesion, magnetization transfer ratio asymmetry (MTRasym) at 3.5ppm was calculated from z-spectra from each CEST data, and MTRasym map was computationally generated by pixel-by-pixel analysis. Then, MTRasym in each lesion was determined by ROI measurements on both MTRasym maps. To evaluate the relationship of MTRasym between two methods, Pearson's correlation was performed. Then, Bland-Altman analysis was performed to evaluate difference of MTRasym between 2D and 3D CEST data within same lesion. To compare MTRasyms from 2D and 3D CEST data between low-grade gliomas (Grade II) and high-grade glioma (Grade III or IV), Student t test was performed. Then, feasible threshold value of each MTRasym was determined by ROC-based positive test. Finally, when applied each feasible threshold value, diagnostic accuracy to differentiate high-grade gliomas from low-grade gliomas was compared between two methods by McNemar's test.*Results 3D CEST imaging had significant and excellent correlation with 2D CEST imaging (r=0.79, p<0.0001). The limits of agreement between 2D and 3D CEST imaging was -0.029±1.43% (mean±1.96standard deviation) and small enough for clinical purpose. MTRasym of high-grade gliomas of each method were significantly higher than those of low-grade gliomas (p<0.001). Accuracy for distinguishing from high-grade from low-grade gliomas had no significant difference between 2D CEST imaging (87.5 [21/24] %) and 3D CEST imaging (95.8 [23/24] %, p=0.480).*Conclusions 3D CEST imaging is considered at least as valuable as 2D CEST image in various brain tumor patients, although former has a superior potential to evaluate whole brain CEST assessment in routine clinical practice.*Clinical Relevance/Application 3D CEST imaging is considered at least as valuable as 2D CEST image in various brain tumor patients, although former has a superior potential to evaluate whole brain CEST assessment in routine clinical practice.

RESULTS

3D CEST imaging had significant and excellent correlation with 2D CEST imaging (r=0.79, p<0.0001). The limits of agreement between 2D and 3D CEST imaging was -0.029±1.43% (mean±1.96standard deviation) and small enough for clinical purpose. MTRasym of high-grade gliomas of each method were significantly higher than those of low-grade gliomas (p<0.001). Accuracy for distinguishing from high-grade from low-grade gliomas had no significant difference between 2D CEST imaging (87.5 [21/24] %) and 3D CEST imaging (95.8 [23/24] %, p=0.480).

CLINICAL RELEVANCE/APPLICATION

3D CEST imaging is considered at least as valuable as 2D CEST image in various brain tumor patients, although former has a superior potential to evaluate whole brain CEST assessment in routine clinical practice.

SPR-NR-38   Cost-effectiveness Of Emergency Short Protocol Brain MRI After Negative Head CT For Patients With Mild And Unspecific Neurologic Symptoms

Participants
Daniel Puhr-Westerheide, MD, Munich, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the cost-effectiveness of additional short-protocol brain MRI after negative non-contrast CT for the detection of minor strokes in patients with mild and unspecific neurological symptoms presenting to the emergency department.*Methods and Materials The economic evaluation was based on a prospective single-center diagnostic accuracy study validating the use of short-protocol brain MRI in the emergency setting. A decision-analytic Markov model distinguished the strategies "no additional imaging" and "additional short-protocol MRI" for evaluation. Minor stroke was assumed to be missed in 40% of patients without short-protocol MRI in the initial evaluation. Specialized post-stroke care with immediate secondary prophylaxis was assumed for patients with detected minor stroke. Utilities and quality of life measures were estimated as quality-adjusted life years (QALYs). Input parameters were obtained from the literature. The Markov model simulated a follow-up period of up to 30 years. Willingness-to-pay was set to $100,000 per QALY. Cost-effectiveness was calculated and deterministic and probabilistic sensitivity analysis was performed.*Results Additional short-protocol MRI turned out as the dominant strategy with overall costs of $26,304 (CT-only:

$27,109). Cumulative calculated effectiveness in the CT-only group was 14.25 QALYs (short-protocol MRI group: 14.31 QALYs). In the deterministic sensitivity analysis, additional short-protocol MRI remained the dominant strategy in all investigated ranges. Probabilistic sensitivity analysis results from the base case analysis were confirmed and additional short-protocol MRI resulted in lower costs and higher effectiveness.*Conclusions Additional short-protocol MRI in emergency patients with mild and unspecific neurological symptoms enables timely secondary prophylaxis through detection of minor strokes, resulting in lower costs and higher cumulative QALYs.*Clinical Relevance/Application Providing emergency short-protocol MRI is cost-effective as it helps to identify minor strokes for a timely initiation of secondary prophylaxis to prevent subsequent major strokes.

RESULTS

Additional short-protocol MRI turned out as the dominant strategy with overall costs of $26,304 (CT-only: $27,109). Cumulative calculated effectiveness in the CT-only group was 14.25 QALYs (short-protocol MRI group: 14.31 QALYs). In the deterministic sensitivity analysis, additional short-protocol MRI remained the dominant strategy in all investigated ranges. Probabilistic sensitivity analysis results from the base case analysis were confirmed and additional short-protocol MRI resulted in lower costs and higher effectiveness.

CLINICAL RELEVANCE/APPLICATION

Providing emergency short-protocol MRI is cost-effective as it helps to identify minor strokes for a timely initiation of secondary prophylaxis to prevent subsequent major strokes.

SPR-NR-39 Single-visit MRI-driven Stratification Of Multiple Sclerosis Patients Using Unsupervised Machine Learning

Participants
Giuseppe Pontillo, MD, Naples, Italy (*Presenter*) Nothing to Disclose

PURPOSE

We used a recently developed unsupervised machine learning algorithm (SuStaIn) to stratify Multiple Sclerosis (MS) patients based on volumetric features derived from brain MRI scans, aiming to demonstrate the biological reliability and clinical relevance of this approach.*Methods and Materials Baseline and longitudinal 3T brain MRIs of relapsing remitting MS patients including 3D-T1w and FLAIR-T2w sequences were collected, along with EDSS scores and long-term (10±2y) clinical outcomes (EDSS, cognition and transition to progressive course). From structural MRI, volumes of demyelinating lesions (TLV) and 116 atlas-defined GM regions were automatically segmented and expressed as z-scores referenced to an external population of healthy subjects. From baseline MRI scans, features that were mostly altered in MS patients were selected and fed into the SuStaIn algorithm, which estimates a set of subtypes characterized by distinct patterns of biomarker evolution, assigning each subject to a specific subtype and stage. The trained model was then applied to longitudinal MRIs.The stability of SuStaIn subtypes over time and the annualized change of SuStaIn stage were assessed via Krippendorf's a and multilevel linear regression models, respectively, while the clinical relevance of the SuStaIn classification was assessed with ordinal/logistic regression analyses.*Results A total of 425 MS patients were selected, corresponding to 1129 MRI visits. Based on 11 biomarkers surviving feature selection (TLV and volumes of 10 GM regions), two subtypes were identified, designated as "deep gray matter (DGM)-first" subtype (N=238) and "cortex-first" subtype (N=187) in view of the initial atrophy pattern. Disease subtypes were consistent over time (a=0.806), with significant annual increase in disease stage (b=0.20;p<0.001). Baseline EDSS correlated with SuStaIn stage (b=0.042;p<0.001) and the DGM-first subtype (b=-0.280;p=0.02), with baseline stage also predicting long-term disability (b=0.030; p=0.007) and transition to progressive course (b=0.079;p=0.03). Long-term cognitive impairment was associated with baseline stage (b=0.048;p<0.001) and the DGM-first subtype (b=-0.442;p=0.005).*Conclusions Unsupervised learning modelling of volumetric features derived from clinical brain MRI scans provides a biologically reliable and prognostically meaningful stratification of MS patients, with relevant implications for both clinical trials design and routine neurological practice.*Clinical Relevance/Application Using unsupervised machine learning, we obtained a single-visit MRI-driven stratification of MS patients which is both biologically reliable and prognostically relevant.

RESULTS

A total of 425 MS patients were selected, corresponding to 1129 MRI visits. Based on 11 biomarkers surviving feature selection (TLV and volumes of 10 GM regions), two subtypes were identified, designated as "deep gray matter (DGM)-first" subtype (N=238) and "cortex-first" subtype (N=187) in view of the initial atrophy pattern. Disease subtypes were consistent over time (a=0.806), with significant annual increase in disease stage (b=0.20;p<0.001). Baseline EDSS correlated with SuStaIn stage (b=0.042;p<0.001) and the DGM-first subtype (b=-0.280;p=0.02), with baseline stage also predicting long-term disability (b=0.030; p=0.007) and transition to progressive course (b=0.079;p=0.03). Long-term cognitive impairment was associated with baseline stage (b=0.048;p<0.001) and the DGM-first subtype (b=-0.442;p=0.005).

CLINICAL RELEVANCE/APPLICATION

Using unsupervised machine learning, we obtained a single-visit MRI-driven stratification of MS patients which is both biologically reliable and prognostically relevant.

SPR-NR-4 Basal Ganglia Manganese Deposition In Patients With HHT

Participants
Robert Weinstein, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

To describe the clinical characteristics of Manganese (Mn) accumulation in the brain in patients with hereditary hemorrhagic telangiectasia (HHT). Manganese deposits specifically in the Basal Ganglia, resulting in symptoms resembling that of Parkinson's disease. Mn also shares iron absorption mechanisms and may accumulate in the setting of iron deficiency anemia. The purpose of this study was to define the relationship between HHT, iron deficiency anemia, and the location of arteriovenous malformations.*Methods and Materials The institutional HHT database included 627 patients was searched for patients with brain MRI scans that were found to have Mn deposition in the basal ganglia. Of the 463 patients with a brain MRI available for review, 20 patients were found to have signal changes within the Basal Ganglia consistent with Mn deposition. These patients' electronic medical records were reviewed for clinical presentations and medical history.*Results Of the 20 patients identified, 95% (19/20) had bilateral Mn deposition in the Basal Ganglia, and 5% (1/20) had unilateral deposition. Of the same cohort, 80% (16/20) were diagnosed with Iron Deficiency Anemia. Five patients were genetically tested, and 80% (4/5) tested positive for pathogenic mutations in the ACVRL1 gene. It was discovered that 80% (16/20) of these patients had hepatic AVMs, compared to 45% (9/20) with pulmonary AVMs, and 5% (1/20) with cerebrospinal AVMs. On presenting labs, 45% (9/20) patients were found to have

elevated Liver Function Tests (LFTs). Clinically, 20% (4/20) of the patients suffered from motor symptoms such as tremors, rigidity, and/or restless leg syndrome. Additionally, 65% (13/20) of the patients experienced neuropsychiatric symptoms including depression, headaches, and/or memory loss.*Conclusions Neuropsychiatric symptoms were more common than Parkinsonian motor impairments in this series of patients with HHT related Mn basal ganglia deposition. Both hepatic AVM and iron deficiency anemia were found in 80% of the cohort, suggesting a possible connection with Mn-BG deposition in patients with HHT.*Clinical Relevance/Application This research underlines the importance of recognizing Mn deposition in HHT patients, especially for those with hepatic AVMs and iron deficiency anemia. Neuropsychological evaluation of patients with Mn Basal Ganglia deposition could be implemented in patients with HHT.

RESULTS

Of the 20 patients identified, 95% (19/20) had bilateral Mn deposition in the Basal Ganglia, and 5% (1/20) had unilateral deposition. Of the same cohort, 80% (16/20) were diagnosed with Iron Deficiency Anemia. Five patients were genetically tested, and 80% (4/5) tested positive for pathogenic mutations in the ACVRL1 gene. It was discovered that 80% (16/20) of these patients had hepatic AVMs, compared to 45% (9/20) with pulmonary AVMs, and 5% (1/20) with cerebrospinal AVMs. On presenting labs, 45% (9/20) patients were found to have elevated Liver Function Tests (LFTs). Clinically, 20% (4/20) of the patients suffered from motor symptoms such as tremors, rigidity, and/or restless leg syndrome. Additionally, 65% (13/20) of the patients experienced neuropsychiatric symptoms including depression, headaches, and/or memory loss.

CLINICAL RELEVANCE/APPLICATION

This research underlines the importance of recognizing Mn deposition in HHT patients, especially for those with hepatic AVMs and iron deficiency anemia. Neuropsychological evaluation of patients with Mn Basal Ganglia deposition could be implemented in patients with HHT.

SPR-NR-7   Weakly Supervised Segmentation Of Intracranial Hemorrhage In Head CT Using Class Activation Maps

Participants
Ian Pan, MD, Brookline, Massachusetts (*Presenter*) Consultant, MD.ai, Inc;Consultant, Centaur Labs;Consultant, Diagnósticos da América SA (Dasa);Consultant, CoRead AI

PURPOSE

To develop a deep learning model for segmentation of intracranial hemorrhage (ICH) using only classification labels.*Methods and Materials 739,336 images from 21,351 studies across 18,689 patients from the RSNA Intracranial Hemorrhage Detection challenge were used for this study. Data were split at the patient level. The training and validation sets comprised 19,258 studies (667,175 images) and 2,093 studies (72,161 images), respectively. The test set comprised 96 randomly sampled positive cases that were segmented by a radiologist (3-11 years of experience). All test cases were then reviewed and the segmentations adjusted as needed by a subspecialty-trained neuroradiologist. A ResNeSt-101 convolutional neural network (CNN) was trained to perform multi-label classification of the 6 ICH labels (epidural, subdural, intraparenchymal, intraventricular, subarachnoid, any hemorrhage). During inference, the final feature maps were extracted and averaged using the class-associated weights from the final linear layer to produce class activation maps (CAMs). For each slice, the CAM for the "any ICH" class was used as the segmentation prediction, only if the ICH class prediction was greater than 0.5. The prediction was post-processed such that only segmentation pixels in the range of 40 to 100 Hounsfield units were included. Binary closing and opening operations were applied for smoothing. The Dice score was used to evaluate performance.*Results Prior to post-processing, the naive CAM segmentation prediction achieved a mean Dice score of 0.374 (95% CI: 0.335, 0.413). After post-processing, the CAM segmentation achieved a mean Dice score of 0.471 (95% CI: 0.423, 0.517). Volumetric measurements from ground truth and predicted segmentations exhibited a correlation of 0.825.*Conclusions Using only classification labels, post-processed CAMs produced by a CNN were able to accurately segment ICH in head CT. Future work will focus on segmenting individual subtypes of ICH and improving overall performance.*Clinical Relevance/Application CAMs can be used to predict accurate segmentations of intracranial hemorrhage without the need for expensive segmentation labels, allowing for improved localization and quantitation of pathology and enhanced interpretability of model predictions.

RESULTS

Prior to post-processing, the naive CAM segmentation prediction achieved a mean Dice score of 0.374 (95% CI: 0.335, 0.413). After post-processing, the CAM segmentation achieved a mean Dice score of 0.471 (95% CI: 0.423, 0.517). Volumetric measurements from ground truth and predicted segmentations exhibited a correlation of 0.825.

CLINICAL RELEVANCE/APPLICATION

CAMs can be used to predict accurate segmentations of intracranial hemorrhage without the need for expensive segmentation labels, allowing for improved localization and quantitation of pathology and enhanced interpretability of model predictions.

SPR-NR-9   Visualization Of Cisternal Components By Deep Learning Reconstruction Of Twelve-fold Accelerated Submillimeter Whole Brain MR Cisternography

Participants
Yasutaka Fushimi, MD, PhD, Kyoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Two-dimensional parallel imaging has been applied for 3D MR imaging, and but image noise associated with high acceleration factor degrades the image quality of the image sequence. Recently developed deep learning reconstruction (DLR) is expected to reduce noise with keeping imaging quality. The denoising is performed in consideration of the g-factor distribution, therefore, adaptive removal of the spatially non-uniform noise caused by parallel imaging becomes possible. Effective denoising is expected even for high-speed imaging with a high g-factor. In this study, we applied twelve-fold accelerated submillimeter 3D MR cisternography with DLR.*Methods and Materials 61 patients (37 females, 65 [58-73] years) underwent 3D MR cisternography (Fast Advanced Spin Echo, FASE, an equivalent sequence of half Fourier single-shot turbo spine echo, HASTE) at MR unit (Vantage Galan 3T/ZGO, Canon Medical Systems Corporation, Otawara, Japan) with 32-channel head coil. 3D FASE was performed with slice thickness of 0.7 mm, resolution of 0.28 × 0.28 mm; acceleration factor of PE and SE, 3 × 4 and scan time of 2 min 6 sec. Interpeduncular cistern, pituitary stalk, abducens nerve, and Liliequist membrane were visually evaluated. ROI analysis was performed for the lateral ventricles and the genu of corpus callosum. Contrast noise ratio of each structure was evaluated. Sharpness of abducens nerves was calculated with the line profile function.*Results MR cisternography with DLR achieved clear visualization of the interpeduncular cistern in all patients, while that without DLR showed noisy visualization in 58 of 61 patients. Pituitary stalk was clearly visible in all

patients on both MR cisternography. Abducens nerves were clearly visualized in 55 of 61 patients on MR cisternography with DLR, and visible in 55 patients on that without DLR. Liliequist membrane was identified in 26 of 61 patients on MR cisternography with DLR, and in 12 of 61 patients on that without DLR. CNR of the lateral ventricles on MR cisternography was 5.39 ± 0.91 without DLR and 15.02 ± 4.42 with DLR (P<0.001). CNR of the genu was 1.30 ± 0.22 without DLR and 4.03 ± 1.13 with DLR (P<0.001). Sharpness of the abducens nerves was 9072.56 ±11804.44 without DLR and 7084.15 ± 2664.20 with DLR (P=0.07).*Conclusions Twelve-fold accelerated submillimeter whole brain 3D MR cisternography with DLR showed better image quality compared with that without DLR, and the delineation of fine structure such as the abducens nerves was preserved after DLR processing.*Clinical Relevance/Application We have demonstrated 12-fold accelerated submillimeter whole brain MR cisternography with DLR showed better contrast noise ratio compared with that without DLR. The delineation of cisternal structures is preserved after DLR processing.

RESULTS

MR cisternography with DLR achieved clear visualization of the interpeduncular cistern in all patients, while that without DLR showed noisy visualization in 58 of 61 patients. Pituitary stalk was clearly visible in all patients on both MR cisternography. Abducens nerves were clearly visualized in 55 of 61 patients on MR cisternography with DLR, and visible in 55 patients on that without DLR. Liliequist membrane was identified in 26 of 61 patients on MR cisternography with DLR, and in 12 of 61 patients on that without DLR. CNR of the lateral ventricles on MR cisternography was 5.39 ± 0.91 without DLR and 15.02 ± 4.42 with DLR (P<0.001). CNR of the genu was 1.30 ± 0.22 without DLR and 4.03 ± 1.13 with DLR (P<0.001). Sharpness of the abducens nerves was 9072.56 ±11804.44 without DLR and 7084.15 ± 2664.20 with DLR (P=0.07).

CLINICAL RELEVANCE/APPLICATION

We have demonstrated 12-fold accelerated submillimeter whole brain MR cisternography with DLR showed better contrast noise ratio compared with that without DLR. The delineation of cisternal structures is preserved after DLR processing.

SSIR02-1   Preliminary Results From A Prospective Study On The Immunological Effects Of Conventional Transarterial Chemoembolisation In Patients With Hepatocellular Carcinoma

Participants
Robin Schmidt, Berlin, Germany (*Presenter*) Travel support, Berliner Krebsgesellschaft e.V.;Traval Grant, German Roentgen Society;Traval Grant, Rolf W. Günter Foundation for Radiological Sciences

PURPOSE

To characterize the immune cell profiles of patients with hepatocellular carcinoma (HCC) and alterations induced by conventional transarterial chemoembolisation (TACE).*Methods and Materials This interim report of an ongoing single-site prospective clinical trial included 23 consecutive patients with unresectable HCC, who underwent TACE 08/2020-03/2021. Institutional review board approval and informed consent were obtained. Peripheral blood was sampled before and 24h and 8 weeks (wk) after TACE for spectral fluorescence-activated cell sorting (FACS, Cytek Aurora) analysis. A 24-color multiplex staining panel was applied to quantify lymphoid and myeloid cell populations and expression of checkpoint molecules. Absolute cell counts were obtained by adding precision count beads. FACS data was processed using a robust gating strategy including CD3, CD4, CD8, CD45, PD-1 and HLA-DR. Lipiodol distribution was assessed on non-contrast CT 24h post-TACE. Statistics included normality testing and paired mixed-effects with post-hoc testing.*Results FACS data at baseline, 24h, and 8wk post-TACE were available for n=23, n=22, and n=15 patients, respectively. Compared to baseline (CD4+ 65.3%, CD8+ 24.0%), a decrease in CD4+ T helper cells (59.3%, p=0.001) and an increase in CD8+ effector T cells (28.9%, p=0.006) were observed 24h post-TACE, respectively, while levels returned to baseline at 8wk. Multi-segmental Lipiodol distribution was associated with larger variations in both T cell subsets as compared to selective tumoral deposition. Specifically, activated HLA-DR+ CD8+ T cells were significantly elevated in patients with tumoral Lipiodol deposition (24h p=0.025; 8wk p=0.475) but decreased in those with less selective distribution (p=0.123; p=0.002). Similar trends were observed for PD1+ CD8+ T cell levels but without statistical significance.*Conclusions The preliminary results of this prospective trial show a consistent trend suggesting a possibly favorable TACE-induced boost in antitumoral T cell responses, thereby revealing Lipiodol as a potential indicator of the functional T cell status. While the most relevant changes are observed early after TACE, durable effects remain limited.*Clinical Relevance/Application If confirmed in a complete cohort, these results may help exploit TACE-induced immune-activation and guide personalized treatments using combinations of TACE with immuno-oncological therapies.

RESULTS

FACS data at baseline, 24h, and 8wk post-TACE were available for n=23, n=22, and n=15 patients, respectively. Compared to baseline (CD4+ 65.3%, CD8+ 24.0%), a decrease in CD4+ T helper cells (59.3%, p=0.001) and an increase in CD8+ effector T cells (28.9%, p=0.006) were observed 24h post-TACE, respectively, while levels returned to baseline at 8wk. Multi-segmental Lipiodol distribution was associated with larger variations in both T cell subsets as compared to selective tumoral deposition. Specifically, activated HLA-DR+ CD8+ T cells were significantly elevated in patients with tumoral Lipiodol deposition (24h p=0.025; 8wk p=0.475) but decreased in those with less selective distribution (p=0.123; p=0.002). Similar trends were observed for PD1+ CD8+ T cell levels but without statistical significance.

CLINICAL RELEVANCE/APPLICATION

If confirmed in a complete cohort, these results may help exploit TACE-induced immune-activation and guide personalized treatments using combinations of TACE with immuno-oncological therapies.

SSIR02-2   Transarterial Embolization With Lactate Dehydrogenase Inhibitor Provides Survival Benefit As Compared To Bland Embolization

Participants
Alexey Gurevich, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Hepatocellular carcinoma (HCC) is one of the most common causes of mortality worldwide. Locoregional therapy such as transarterial embolization (TAE) is the most commonly performed procedure for HCC. It takes advantage of the vascular biology of HCCs, which are primarily supplied by the hepatic artery, to embolize appropriate hepatic branches. Despite best practices, recurrences are still common as HCC cells undergo metabolic reprogramming to utilize anaerobic metabolic pathway via lactate dehydrogenase (LDH), enabling their survival. The goal of this study was to perform a translational study comparing response following administration of TAE along with an LDH inhibitor (LDHi) as compared to bland TAE and sham TAE.*Methods and Materials Wistar rats bearing DEN-induced autochthonous HCCs were tracked until the target tumor was in the 100mm^3 to 200mm^3 range. TAEs with LDHi (n=7) were performed using 100 uL of 50-100um Embosphere Microspheres (Merit Medical Systems) and 10ug/kg of

LDHi. Bland TAEs (n=6) were performed with 40-120um Embosphere Microspheres alone. Sham TAE controls (n=5) were performed using 100 uL of saline alone. After embolization, each rat underwent 3 MRI scans per week until a recurrence was noted. Recurrence was noted as tumor growth of 50% since previous scan. After recurrence, scans were performed once weekly until either natural expiration or until one of the criteria for euthanasia was met. Statistical analysis was performed with GraphPad Prism 8.0(GraphPad Software).*Results Statistical analysis demonstrated a significant difference in progression free survival (PFS, time to recurrence or death) between TAE with LDHi and Bland or Sham TAE (23.4±7 days vs 12.7±4.7 days P=0.0063, 23.4±7 days vs 4.2±1.6 days P<0.0001 respectively, Figure 1). In addition, the overall survival (OS) was also statistically different between the LDHi TAE and Bland or Sham TAE (23±6.8 days vs 11.6±4.3 days P=0.0058, 23±6.8 days vs 15±1.9 days P=0.0477 respectively, Figure 2).*Conclusions TAE with a metabolic inhibitor of LDH demonstrates significantly prolonged PFS and OS as compared to both Bland and Sham TAE. These findings emphasize the role of TAE in modulating the tumor microenvironment to generate targetable dependencies for improved outcomes.*Clinical Relevance/Application Hepatocellular carcinoma is a common disease that is difficult to target appropriately. Here we show how to leverage the innate tumor metabolism and locoregional therapy to improve outcomes in the animal model. These data provide motivation for an incipient clinical trial combining LDH inhibition with TAE.

RESULTS

Statistical analysis demonstrated a significant difference in progression free survival (PFS, time to recurrence or death) between TAE with LDHi and Bland or Sham TAE (23.4±7 days vs 12.7±4.7 days P=0.0063, 23.4±7 days vs 4.2±1.6 days P<0.0001 respectively, Figure 1). In addition, the overall survival (OS) was also statistically different between the LDHi TAE and Bland or Sham TAE (23±6.8 days vs 11.6±4.3 days P=0.0058, 23±6.8 days vs 15±1.9 days P=0.0477 respectively, Figure 2).

CLINICAL RELEVANCE/APPLICATION

Hepatocellular carcinoma is a common disease that is difficult to target appropriately. Here we show how to leverage the innate tumor metabolism and locoregional therapy to improve outcomes in the animal model. These data provide motivation for an incipient clinical trial combining LDH inhibition with TAE.

SSIR02-3   Biochemical Safety Of Ablative Yttrium-90 Transarterial Radioembolization For Hepatocellular Carcinoma As A Function Of Percent Liver Treated

Participants
Cynthia De la Garza Ramos, MD, Jacksonville, Florida (*Presenter*) Nothing to Disclose

PURPOSE

Transarterial radioembolization can serve as an ablative therapy for early-stage hepatocellular carcinoma (HCC) when targeting tumors with a Medical Internal Radiation Dose (MIRD) >190 Gy. This study aimed to establish percent liver treated (%LT) biochemical safety thresholds for segmental ablative radioembolization.*Methods and Materials A retrospective cohort of HCC patients treated at a tertiary care center with a single session of glass microsphere radioembolization and a MIRD =190 Gy from January 2017 through October 2020 was analyzed. %LT was calculated as treatment angiosome volume divided by whole liver volume. Biochemical toxicity events were defined as increases in Albumin-Bilirubin (ALBI) grade or Child-Pugh (CP) class compared to baseline, and the development of albumin or bilirubin adverse events (AE) per CTCAE v5.0 at 3- and 6 months. ROC curves were used to determine volumetric thresholds associated with these events. Multivariate logistic regression analysis assessed the impact of significant %LT thresholds on toxicities.*Results A total of 141 patients with a median age of 68 years were included. Baseline hepatic function distribution was 75 (53%) ALBI 1 vs 64 (45%) ALBI 2, and 111 (79%) CP-A vs 30 (21%) CP-B. At 3 months, increases were seen in 20 (27%) ALBI 1, 8 (12%) ALBI 2, 18 (16%) CP-A, and 6 (20%) CP-B. At 6 months, increases were reported in 17 (23%) ALBI 1, 6 (9%) ALBI 2, 12 (11%) CP-A, and 4 (13%) CP-B. A %LT =14.5% was significantly associated with increases in ALBI 2 patients at 3- (AUC: 0.84, sensitivity: 87%, specificity: 73%, p=0.002) and 6 months (AUC: 0.83, sensitivity: 83%, specificity: 79%, p=0.01), and CP-B at 6 months (AUC: 0.84, sensitivity: 100%, specificity: 85%, p=0.026). No significant threshold was found for ALBI 1 or CP-A patients. Logistic regression analysis showed a %LT =14.5% as an independent predictor of events in the ALBI 2 and CP-B groups (p<0.01). No grade 3/4 albumin or bilirubin AEs were observed. Grade 2 AEs occurred in 23 (16%) patients at 3 months and 15 (10%) at 6 months, with a whole liver volume <1.3 L associated to this toxicity (p=0.01).*Conclusions Primary HCC therapy with ablative radioembolization is generally well tolerated with a low frequency of AEs. ALBI 2 or CP-B patients receiving a MIRD =190 Gy to =14.5% of the liver are less likely to increase grade/class. No definitive %LT was associated to toxicities in ALBI 1 and CP-A within the parameters of this study. Grade 2 albumin or bilirubin AEs are more likely with a whole liver volume of <1.3 L.*Clinical Relevance/Application Segmental ablative transarterial radioembolization (>190 Gy) is emerging as a definitive therapy for early-stage HCC. Given the high volumetric variability of hepatic segments, %LT safety thresholds are necessary.

RESULTS

A total of 141 patients with a median age of 68 years were included. Baseline hepatic function distribution was 75 (53%) ALBI 1 vs 64 (45%) ALBI 2, and 111 (79%) CP-A vs 30 (21%) CP-B. At 3 months, increases were seen in 20 (27%) ALBI 1, 8 (12%) ALBI 2, 18 (16%) CP-A, and 6 (20%) CP-B. At 6 months, increases were reported in 17 (23%) ALBI 1, 6 (9%) ALBI 2, 12 (11%) CP-A, and 4 (13%) CP-B. A %LT =14.5% was significantly associated with increases in ALBI 2 patients at 3- (AUC: 0.84, sensitivity: 87%, specificity: 73%, p=0.002) and 6 months (AUC: 0.83, sensitivity: 83%, specificity: 79%, p=0.01), and CP-B at 6 months (AUC: 0.84, sensitivity: 100%, specificity: 85%, p=0.026). No significant threshold was found for ALBI 1 or CP-A patients. Logistic regression analysis showed a %LT =14.5% as an independent predictor of events in the ALBI 2 and CP-B groups (p<0.01). No grade 3/4 albumin or bilirubin AEs were observed. Grade 2 AEs occurred in 23 (16%) patients at 3 months and 15 (10%) at 6 months, with a whole liver volume <1.3 L associated to this toxicity (p=0.01).

CLINICAL RELEVANCE/APPLICATION

Segmental ablative transarterial radioembolization (>190 Gy) is emerging as a definitive therapy for early-stage HCC. Given the high volumetric variability of hepatic segments, %LT safety thresholds are necessary.

SSIR02-4   Utility Of CBCT And AVD For Intraprocedural Diagnosis And Treatment Of Gastrointestinal Bleeds

Participants
Leland Pung, MENG, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

Interventional Radiology (IR) management of gastrointestinal bleeding (GIB) is limited due to significant negative intraprocedural diagnostic rates. Empiric embolization of feeding vessels seen on CT angiography (CTA) has had limited adoption due to inability of

2D digital subtraction angiography (DSA) to conclusively identify feeding vessels. We assess whether intraprocedural Cone Beam CT (CBCT) improves diagnosis and embolization rates of acute GIB and if automatic vessel detection (AVD) software can identify feeding vessels(FV) for empiric embolization*Methods and Materials All patients who underwent procedures for GIB in IR between June 2020 and April 2021 were compiled for analysis. Patients with inconclusive DSA findings had CBCT performed at the discretion of the primary operator. Patients who had both CTA and subsequent CBCT underwent retrospective analysis with AVD software. Charts were analyzed for preprocedural imaging and clinical outcomes. Accuracy of CBCT was defined as the ability to detect a GIB site while clinical success was defined as successful embolization without evidence of rebleeding or death within 30 days. AVD success was defined by the ability to identify the FV on both CTA and CBCT upon independent review by 3 blinded IRs, who also assigned a degree of certainty on a 5-point Likert scale.*Results 70 patients had procedures for GIB in an IR suite capable of CBCT and AVD. Of these, 21 patients with GIB on pre-procedural CTA and inconclusive DSA underwent CBCT. In 18 patients (85.7%) the FV was not identified by DSA. In 3 cases, initial DSA identified a single FV but concern remained for additional FVs. Use of CBCT identified 8 bleeds not seen on DSA and an additional source artery in 1 case representing a 43% change in intraprocedural management as all findings were embolized. Clinical success was 85.7% for patients who underwent DSA and CBCT compared to 74.5% for patients who had DSA only. When a bleed could be identified on CBCT, the FV could be delineated on AVD 100% of the time, with an average certainty of 4.3. When a bleed could not be identified on CBCT, but the FV could be identified on CTA, the same suspected FV could be selected on AVD 62% of the time with an average certainty of 4.0.*Conclusions CBCT is useful in the intraprocedural detection of GIB when DSA is indeterminate, changing management in 43% of indeterminant cases. Furthermore, AVD software can be utilized to accurately identify FVs for empiric treatment when intraprocedural imaging is inconclusive, identifying 62% of vessels on CBCT.*Clinical Relevance/Application CBCT combined with AVD software can increase intraprocedural diagnostic sensitivity for GI bleeds and improve operator confidence for empiric embolization.

RESULTS

70 patients had procedures for GIB in an IR suite capable of CBCT and AVD. Of these, 21 patients with GIB on pre-procedural CTA and inconclusive DSA underwent CBCT. In 18 patients (85.7%) the FV was not identified by DSA. In 3 cases, initial DSA identified a single FV but concern remained for additional FVs. Use of CBCT identified 8 bleeds not seen on DSA and an additional source artery in 1 case representing a 43% change in intraprocedural management as all findings were embolized. Clinical success was 85.7% for patients who underwent DSA and CBCT compared to 74.5% for patients who had DSA only. When a bleed could be identified on CBCT, the FV could be delineated on AVD 100% of the time, with an average certainty of 4.3. When a bleed could not be identified on CBCT, but the FV could be identified on CTA, the same suspected FV could be selected on AVD 62% of the time with an average certainty of 4.0.

CLINICAL RELEVANCE/APPLICATION

CBCT combined with AVD software can increase intraprocedural diagnostic sensitivity for GI bleeds and improve operator confidence for empiric embolization.

SSIR02-5 **When Nothing Else Works Anymore: European Multicenter Study On Degradable Starch Microspheres Transarterial Chemoembolization (DSM-TACE) In HCC With High Tumor Burden Ineligible For Or Failing Other Palliative Therapies**

Participants
Johannes Ludwig, MD, Essen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the safety and efficacy of transarterial chemoembolization with degradable starch microspheres (DSM-TACE) for the treatment of patients with unresectable hepatocellular carcinoma (HCC) with high tumor burden ineligible for or failing other palliative therapies.*Methods and Materials One hundred twenty-one patients (median of 77 years old, 81% male) with high tumor burden (63.6% bilobar disease, 61.2%, and >3 HCC nodules in vascular invasion in 26.4%) from three European centers first treated between 03/2009 - 08/2018 were assessed retrospectively. Five hundred fifty-eight treatments with a median of four (range: 2-12) per patient were performed. mRECIST criteria were used for response assessment. Kaplan-Meier (KP) analysis for determining median overall survival and time to progression (OS/TTP in months) was performed. Cox proportional hazard model for uni- (UVA) & multivariate (MVA) analyses (hazard ratio; 95%CI, p-value) were assessed. Adverse events (AEs) were staged according to the CIRSE classification system (clinical AEs) and CTCAE v5 (laboratory AEs).*Results The median OS was 15.5 (13.3-18.7) months. UVA detected a survival benefit for patients with a lower Child-Pugh class (A/B/C: 17/15.2/8.95 months), lower BCLC-stage (A/B/C/D: 20.9/17.7/12.7/6.6 months), unilobar disease (19 vs. 13.6 months for bilobar), absence of vascular invasion (16.9 vs. 13.8 months for vascular invasion), lesions ? 10 cm (11.5 vs. 16.9 months for >10 cm), and absence of extrahepatic metastases (17.7 vs. 11.2 months with metastases). MVA identified tumors smaller than 10 cm (0.34; 0.17-0.68, p=0.002) and unilobar disease (0.63; 0.4-0.98, p=0.042) as independent prognostic factors for longer OS.Median TTP was 9.5 (7.6-10.3) months. The best response was achieved after a median of 3 (range: 1-6) treatments with CR/PR/SD/PD in 13.5%/44.5%/25.2%/16.8%, respectively. DSM-TACE was well tolerated with no major clinical AE and only limited major laboratory AEs. After repetitive DSM-TACE, preserved liver function was observed even when the liver was treated as a whole.*Conclusions DSM-TACE is an effective and safe alternative palliative treatment option for patients with a high tumor burden not suitable for or failing other therapies. Moreover, repetitive DSM-TACE preserves liver function over time, even in patients whose liver is treated as a whole.*Clinical Relevance/Application DSM-TACE is an effective treatment option for patients with high tumor burden HCC ineligible for or failing other palliative therapies (e.g., conventional TACE, radioembolization, or systemic therapy). Repetitive DSM-TACE can be performed safely with low adverse event rates and liver function preservation over time.

RESULTS

The median OS was 15.5 (13.3-18.7) months. UVA detected a survival benefit for patients with a lower Child-Pugh class (A/B/C: 17/15.2/8.95 months), lower BCLC-stage (A/B/C/D: 20.9/17.7/12.7/6.6 months), unilobar disease (19 vs. 13.6 months for bilobar), absence of vascular invasion (16.9 vs. 13.8 months for vascular invasion), lesions ? 10 cm (11.5 vs. 16.9 months for >10 cm), and absence of extrahepatic metastases (17.7 vs. 11.2 months with metastases). MVA identified tumors smaller than 10 cm (0.34; 0.17-0.68, p=0.002) and unilobar disease (0.63; 0.4-0.98, p=0.042) as independent prognostic factors for longer OS.Median TTP was 9.5 (7.6-10.3) months. The best response was achieved after a median of 3 (range: 1-6) treatments with CR/PR/SD/PD in 13.5%/44.5%/25.2%/16.8%, respectively. DSM-TACE was well tolerated with no major clinical AE and only limited major laboratory AEs. After repetitive DSM-TACE, preserved liver function was observed even when the liver was treated as a whole.

CLINICAL RELEVANCE/APPLICATION

DSM-TACE is an effective treatment option for patients with high tumor burden HCC ineligible for or failing other palliative therapies (e.g., conventional TACE, radioembolization, or systemic therapy). Repetitive DSM-TACE can be performed safely with low adverse

event rates and liver function preservation over time.

SSIR02-6 Magnetic Resonance Guided Focused Ultrasound Versus External Beam Radiation Therapy For The Treatment Of Pain In Bone Metastases: A Phase II Trial

Participants
Giulia Alfieri, MD, Rome, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To assess the efficacy of MR guided Focused Ultrasound (MRgFUS) for the palliative treatment of painful bone metastases in comparison to external beam radiation therapy (EBRT).*Methods and Materials This prospective double-arm phase II study was conducted between January 2019 and March 2019. Participants with painful bone metastases were included in the trial and underwent either MRgFUS or EBRT. The primary end point was improvement in self-reported pain score assessed by using Visual Analogue Scale (VAS) 1 month after treatment. Secondary end point was the improvement in VAS at 12-month and quality of life (QoL) assessed by QoL Questionnaire Cancer 15 Palliative Care (C15-PAL) and QoL Questionnaire Bone Metastases 22 (BM22). Statistical analysis was conducted using a per-protocol principle.*Results 198 study participants were included; 100 participants (mean age, 63.2 years ± 13.4) underwent MRgFUS and 98 (mean age, 65.3 years ± 14.5) underwent EBRT. Response rate for the primary endpoint was 55% in the MRgFUS arm and 30% in the EBRT (p= 0.001). No significant difference between groups was found for BM22 and C15-PAL. Subtests analysis of C15-PAL for areas of physical function (p=0.002), appetite (p<0.001), nausea and vomiting (p<0.001), dyspnea (p<0.001) and quality of life (p<0.001) showed significant differences in favor of MRgFUS.*Conclusions MRgFUS in comparison to EBRT showed promising response when used as a palliative treatment in patients with painful bone metastases.*Clinical Relevance/Application MRgFUS may represent a valid option for the palliative treatment of patients with metastatic bone disease, with promising results in terms of pain relief and quality of life when compared to EBRT

RESULTS

198 study participants were included; 100 participants (mean age, 63.2 years ± 13.4) underwent MRgFUS and 98 (mean age, 65.3 years ± 14.5) underwent EBRT. Response rate for the primary endpoint was 55% in the MRgFUS arm and 30% in the EBRT (p= 0.001). No significant difference between groups was found for BM22 and C15-PAL. Subtests analysis of C15-PAL for areas of physical function (p=0.002), appetite (p<0.001), nausea and vomiting (p<0.001), dyspnea (p<0.001) and quality of life (p<0.001) showed significant differences in favor of MRgFUS.

CLINICAL RELEVANCE/APPLICATION

MRgFUS may represent a valid option for the palliative treatment of patients with metastatic bone disease, with promising results in terms of pain relief and quality of life when compared to EBRT

SSMK06-4 The Relationship Between Bone Marrow Lesion Worsening And Statin Use In Knee Osteoarthritis Patients With Heberden's Nodes: Data From The Osteoarthritis Initiative

Participants
Bahram Mohajer, MD,MPH, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

There has been an interest for more than a decade in the potential disease-modifying osteoarthritis (OA) drug (DMOAD) properties of statins and result of previous studies are inconclusive. While no completed and published clinical trial is available, in a preliminary report from an ongoing trial authors reported statins reduced OA progression in OA patients with no baseline subchondral bone marrow lesions (BMLs). Other reports have suggested statins may be beneficial in generalized OA (GOA) phenotype. Here we aimed to explore potential responders to statin and assess the relationship between statin therapy and knee MRI-detected subchondral BML worsening in patients with Heberden's nodes (HNs) as the hallmark of GOA phenotype.*Methods and Materials We assessed worsening in BMLs volume and number of affected subregions in participants from the Osteoarthritis Initiative (OAI) cohort with HNs at baseline clinical examination (HN+), using the semi-quantitative MRI Osteoarthritis Knee Scores at baseline and 24 months. Participants were classified according to baseline BML involvement as "no/minimal" (=2 of 14 knee subregions affected and maximum BML score =1) or "moderate/severe." Potential confounders by indication were assessed using direct acyclic graph (age, sex, race, alcohol use, smoking, BMI, cardiovascular comorbidities, and physical activity). Missing data of covariates (<1.5% data) was imputed and statins users and non-users were selected using 1:1 propensity-score matching. Adjusted mixed-effect regression models were used to assess the association between statin use and increasing BML score and the number of affected subregions.*Results The propensity-score matched HN+ with no/minimal and moderate/severe BML cohorts consisted of 332 (166:166, statin user: non-users) and 380 (190:190) knees of participants respectively. In the HN+ participants with no/minimal BML, statin use was associated with lower odds of both BML score worsening (odds ratio, 95% confidence interval: 0.62, 0.39-0.98) and an increase in the number of affected subregions (0.54, 0.33-0.88). There was no such association in those HN+ patients with baseline moderate/severe BMLs or all HN- participants. Sensitivity analysis showed results were not sensitive to propensity-score matching.*Conclusions In subjects with GOA phenotype (HN+), statin use may be protective against the progression of OA-related subchondral bone changes only in subjects with no/minimal baseline BML.*Clinical Relevance/Application These findings insists on the role of subchondral bone and its lesions as the route of apparent statin DMOAD properties. Future mechanistic studies may enable the identification of potential statin responders for proper subject selection in clinical trials.

RESULTS

The propensity-score matched HN+ with no/minimal and moderate/severe BML cohorts consisted of 332 (166:166, statin user: non-users) and 380 (190:190) knees of participants respectively. In the HN+ participants with no/minimal BML, statin use was associated with lower odds of both BML score worsening (odds ratio, 95% confidence interval: 0.62, 0.39-0.98) and an increase in the number of affected subregions (0.54, 0.33-0.88). There was no such association in those HN+ patients with baseline moderate/severe BMLs or all HN- participants. Sensitivity analysis showed results were not sensitive to propensity-score matching.

CLINICAL RELEVANCE/APPLICATION

These findings insists on the role of subchondral bone and its lesions as the route of apparent statin DMOAD properties. Future mechanistic studies may enable the identification of potential statin responders for proper subject selection in clinical trials.

SSMK06-6 Color-coded Dual-energy CT Collagen Imaging For The Assessment Of The Crucial Ligaments After Acute Trauma: Initial Results Of A Multireader Diagnostic Accuracy Study

Participants
Christian Booz, MD, Frankfurt am Main, Germany (*Presenter*) Speaker, Siemens AG

PURPOSE

To evaluate the diagnostic accuracy of colored dual-energy CT collagen imaging for the assessment of the crucial ligaments after acute trauma.*Methods and Materials Data from 141 consecutive patients (70 male) with acute knee trauma who had undergone clinically indicated third-generation dual-source dual-energy CT and additional arthroscopy or MRI between January 2017 and February 2021 were retrospectively analyzed. Five blinded radiologists independently assessed the anterior crucial ligament (ACL) and posterior crucial ligament (PCL) using colored dual-energy CT collagen maps, which are based on collagen material decomposition. Arthroscopy (n = 77) or MRI (n = 64) served as reference standard (maximal time interval 7 days between dual-energy CT and the reference standard). Arthroscopy was performed by three board-certified surgeons (24, 13 and 10 years of experience in arthroscopy), MRI was evaluated by two board-certified radiologists (10 and 34 years of experience in knee MRI) in consensus reading sessions.*Results The reference standard revealed a total of 56 complete tears (ACL, 33; PCL, 23) and 93

partial tears (ACL, 52; PCL, 41) of the crucial ligaments. Color-coded collagen maps showed high overall sensitivity 92% (95%), specificity 90% (94%), and accuracy 91% (94%) for the assessment of complete ACL (PCL) tears. Regarding partial ACL (PCL) tears, sensitivity was 87% (91%), specificity was 92% (94%), and the accuracy was 90% (93%). Intact ACL (PCL) was detected with a sensitivity of 95% (96%), specificity of 96% (97%), and an accuracy of 95% (96%).*Conclusions Color-coded dual-energy CT collagen imaging yields excellent diagnostic accuracy for the assessment of the crucial ligaments by application of collagen material decomposition.*Clinical Relevance/Application Through application of dual-energy CT collagen imaging earlier detection of crucial ligament injuries may be achieved in case of limited MRI availability or contraindications, potentially improving patient management and clinical outcome.

RESULTS

The reference standard revealed a total of 56 complete tears (ACL, 33; PCL, 23) and 93 partial tears (ACL, 52; PCL, 41) of the crucial ligaments. Color-coded collagen maps showed high overall sensitivity 92% (95%), specificity 90% (94%), and accuracy 91% (94%) for the assessment of complete ACL (PCL) tears. Regarding partial ACL (PCL) tears, sensitivity was 87% (91%), specificity was 92% (94%), and the accuracy was 90% (93%). Intact ACL (PCL) was detected with a sensitivity of 95% (96%), specificity of 96% (97%), and an accuracy of 95% (96%).

CLINICAL RELEVANCE/APPLICATION

Through application of dual-energy CT collagen imaging earlier detection of crucial ligament injuries may be achieved in case of limited MRI availability or contraindications, potentially improving patient management and clinical outcome.

SSMK06-7 MRI Predictors Of Outcome After Arthroscopic Partial Meniscectomy

Participants
Naveen Subhas, MD, Cleveland, Ohio (*Presenter*) Research support, Siemens AG;

PURPOSE

Outcomes after arthroscopic partial meniscectomy (APM) in older patients is mixed and difficult to predict. The study objectives were to identify the preoperative baseline status, demographics factors and imaging findings predictive of outcome and test if preoperative knee MRI improves outcome prediction.*Methods and Materials Patients 45 years and older having undergone APM with Knee injury and Osteoarthritis Outcome Score for pain (KOOSpain) at the time of surgery and at least 1-year after surgery and knee MRI obtained within 6 months prior to surgery were included. Patients with any concomitant procedure performed with APM except for chondroplasty were excluded. Multi-variable regression model with only demographic and baseline status variables was constructed including all statistically significant predictors using a significance level of 0.10. MRI findings were then added and tested using a significance level of 0.05. The effect of MRI was quantified by the change in area under the ROC curve (AUC) between the model with and without MRI findings.*Results The 923 patient cohort had a mean age of 58.2 years (range 45 - 90) and were 49% female and 87% white with baseline KOOSpain = 47.1 (sd 17.1). The following factors were significant predictors (p < 0.05) of worse outcome in the model without MRI: higher baseline KOOSpain, lower mental component summary (MCS) score (a mental and emotional health metric), higher area deprivation index (ADI) scores (a socioeconomic status metric), female gender, BMI in the middle range, age between 50 - 70, and cigarette smoking as well as interactions between gender and age and BMI and baseline pain. After including MRI, these additional factors were significant predictors (p < 0.05) of worse outcome: more severe cartilage defects in the lateral femoral condyle and medial tibial plateau and lateral meniscal tears. The baseline model had an AUC of 0.657 and 95% confidence interval [0.614, 0.700] for a 10-point improvement in KOOSpain with an R2= 0.24 and the addition of MRI findings significantly increased the AUC to 0.710 (p=0.003) with an R2 = 0.28.*Conclusions MRI findings, specifically lateral meniscal tears and more severe cartilage defects, are independent predictors of worse outcome after APM and significantly improve the ability to predict which patients will not benefit from surgery when added to demographic factors and baseline status.*Clinical Relevance/Application The preoperative predictive factors of outcome identified in this study can be used to build prediction tools that can guide patients and surgeons when deciding on whether or not to proceed with APM.

RESULTS

The 923 patient cohort had a mean age of 58.2 years (range 45 - 90) and were 49% female and 87% white with baseline KOOSpain = 47.1 (sd 17.1). The following factors were significant predictors (p < 0.05) of worse outcome in the model without MRI: higher baseline KOOSpain, lower mental component summary (MCS) score (a mental and emotional health metric), higher area deprivation index (ADI) scores (a socioeconomic status metric), female gender, BMI in the middle range, age between 50 - 70, and cigarette smoking as well as interactions between gender and age and BMI and baseline pain. After including MRI, these additional factors were significant predictors (p < 0.05) of worse outcome: more severe cartilage defects in the lateral femoral condyle and medial tibial plateau and lateral meniscal tears. The baseline model had an AUC of 0.657 and 95% confidence interval [0.614, 0.700] for a 10-point improvement in KOOSpain with an R2= 0.24 and the addition of MRI findings significantly increased the AUC to 0.710 (p=0.003) with an R2 = 0.28.

CLINICAL RELEVANCE/APPLICATION

The preoperative predictive factors of outcome identified in this study can be used to build prediction tools that can guide patients and surgeons when deciding on whether or not to proceed with APM.

SSVA02-1   Deep Learning Automated Phase Error Correction For Abdominopelvic 4D Flow MRI

Participants
Sophie You, BA, San Diego, California (*Presenter*) Nothing to Disclose

PURPOSE

4D Flow MRI has the potential to provide hemodynamic insights in a variety of abdominopelvic vascular diseases, but it is currently impaired by eddy current-related background phase error. Image-based phase error correction can be challenging to perform and limits the clinical utility of this MRI technique. In this study, we assessed the feasibility of using convolutional neural networks (CNNs) to automatically perform image-based background phase error correction, and to evaluate their effectiveness for phase error correction relative to manual image-based correction.*Methods and Materials With HIPAA compliance, IRB approval, and waiver of informed consent, we retrospectively collected 140 abdominopelvic 4D Flow MRI acquisitions from 140 patients performed as part of routine clinical MRI examinations between January 2016 and July 2020. Manual phase error correction was performed using dedicated software (Arterys, San Francisco, CA). After reserving 40 examinations for testing, the remaining data was divided into two cohorts: 86% for training and 14% for validation. These were used to train a multichannel 3D U-Net. To evaluate performance, flow volume measurements were obtained for the infrarenal aorta, common iliac arteries, common iliac veins, and inferior vena cava. Statistical analyses of inflow-outflow consistency included Pearson correlation, Bland-Altman analysis, and F-tests with Holm correction.*Results After manually correcting phase error in test set MRI exams, mean infrarenal aortic flow was 1.63 L/min (range 0.67-3.21 L/min) and mean common iliac arterial flow was 0.69 L/min (range 0.28-1.43 L/min). Correlation of inflow and outflow improved following manual correction (?=0.95) compared to before (?=0.55). CNN-automated correction showed similar results (?=0.91) and demonstrated very strong correlation with manual correction (?=0.98). Both manual and CNN-automated correction methods reduced inflow-outflow variance of volumetric flow measurements (p<0.001, F-test) reducing limits of agreement from [-1.76, 1.46] L/min (uncorrected) to [-0.41, 0.54] L/min (manual) and [-0.46, 0.68] L/min (CNN-automated). Inflow-outflow variance was narrower for manual correction compared to automatic correction (p<0.001, F-test).*Conclusions CNN-based automated phase-error correction visually and quantitatively improved flow measurements from 4D Flow MRI, reducing inflow-outflow discrepancies with results comparable to manual image-based correction.*Clinical Relevance/Application CNNs can automatically recognize and correct phase error in 4D Flow MRI, a critical bottleneck in the clinical application of this technology for assessing abdominopelvic blood flow.

RESULTS

After manually correcting phase error in test set MRI exams, mean infrarenal aortic flow was 1.63 L/min (range 0.67-3.21 L/min) and mean common iliac arterial flow was 0.69 L/min (range 0.28-1.43 L/min). Correlation of inflow and outflow improved following manual correction (?=0.95) compared to before (?=0.55). CNN-automated correction showed similar results (?=0.91) and demonstrated very strong correlation with manual correction (?=0.98). Both manual and CNN-automated correction methods reduced inflow-outflow variance of volumetric flow measurements (p<0.001, F-test) reducing limits of agreement from [-1.76, 1.46] L/min (uncorrected) to [-0.41, 0.54] L/min (manual) and [-0.46, 0.68] L/min (CNN-automated). Inflow-outflow variance was narrower for manual correction compared to automatic correction (p<0.001, F-test).

CLINICAL RELEVANCE/APPLICATION

CNNs can automatically recognize and correct phase error in 4D Flow MRI, a critical bottleneck in the clinical application of this technology for assessing abdominopelvic blood flow.

SSVA02-2   Accuracy Subanalysis Of A Deep Learning Neural Network Specific For The Identification Of Infrarenal Abdominal Aortic Aneurysms

Participants
Justin Camara, MD, Loma Linda, California (*Presenter*) Nothing to Disclose

PURPOSE

To analyze the anatomic variables that influence the diagnostic accuracy of a trained convolutional neural network (CNN) that can identify infrarenal abdominal aortic aneurysms (AAA) on computed tomography angiogram (CTA) scans.*Methods and Materials From January 2015 to January 2020, a HIPAA-compliant, institutional review board-approved, retrospective clinical study was used to develop a AAA-specific trained CNN based on transfer learning of the VGG16 base model. Model accuracy and AUC were analyzed based on size of data sets (segmented, balanced or unbalanced), aneurysm size, extra-abdominal extension, dissections, and mural thrombus. Misjudgments were analyzed through a review of heatmaps generated via gradient weighted class activation mapping overlaid on original CT images.*Results The trained custom CNN model reported high test group accuracies of 94.1%, 99.1%, and

99.6% and AUC of 0.99, 0.9998, and 0.9993 in segmented (n = 120), balanced (n = 3,704), and unbalanced image sets (n = 31,899), respectively. Despite an eight fold difference between balanced and unbalanced image sets, the CNN model demonstrated high test group sensitivities (99.9% vs. 98.9%) and specificities (94.8% vs 99.3%) in unbalanced and balanced image sets, respectively. In regard to aneurysm size, the CNN model demonstrated improving accuracy based on larger aneurysm size: 47% (16/34) misjudgments for aneurysms less than 3.3 cm, 32% (11/34) misjudgments for aneurysms between 3.3 and 5 cm, and 20% (7/34) misjudgments for aneurysms greater than 5 cm. Aneurysms containing measurable mural thrombus were over-represented within type II (false negative) misjudgements compared to type I (false positive) misjudgements (71% versus 15%, p < 0.05). Other factors such as inclusion extra-abdominal aneurysm extension (thoracic or iliac artery) or dissection flaps in these imaging sets did not decrease the model's overall accuracy.*Conclusions Preliminary subanalysis of an AAA-specific CNN model can accurately screen and identify CTA findings of infrarenal abdominal aortic aneurysms despite varying aneurysm pathology and quantitative data sets. Pathologically, the highest anatomic misjudgments were seen in cases with small aneurysms (< 3.3 cm) or the presence of mural thrombus. Accuracy of the CNN model is maintained despite the inclusion of extra-abdominal pathology and imbalanced data sets.*Clinical Relevance/Application To analyze the anatomic variables that influence the diagnostic accuracy of a trained convolutional neural network (CNN) that can identify infrarenal abdominal aortic aneurysms (AAA) on computed tomography angiogram (CTA) scans.

RESULTS

The trained custom CNN model reported high test group accuracies of 94.1%, 99.1%, and 99.6% and AUC of 0.99, 0.9998, and 0.9993 in segmented (n = 120), balanced (n = 3,704), and unbalanced image sets (n = 31,899), respectively. Despite an eight fold difference between balanced and unbalanced image sets, the CNN model demonstrated high test group sensitivities (99.9% vs. 98.9%) and specificities (94.8% vs 99.3%) in unbalanced and balanced image sets, respectively. In regard to aneurysm size, the CNN model demonstrated improving accuracy based on larger aneurysm size: 47% (16/34) misjudgments for aneurysms less than 3.3 cm, 32% (11/34) misjudgments for aneurysms between 3.3 and 5 cm, and 20% (7/34) misjudgments for aneurysms greater than 5 cm. Aneurysms containing measurable mural thrombus were over-represented within type II (false negative) misjudgements compared to type I (false positive) misjudgements (71% versus 15%, p < 0.05). Other factors such as inclusion extra-abdominal aneurysm extension (thoracic or iliac artery) or dissection flaps in these imaging sets did not decrease the model's overall accuracy.

CLINICAL RELEVANCE/APPLICATION

To analyze the anatomic variables that influence the diagnostic accuracy of a trained convolutional neural network (CNN) that can identify infrarenal abdominal aortic aneurysms (AAA) on computed tomography angiogram (CTA) scans.

SSVA02-3 Multireader Evaluation Of The Impact Of High-Matrix Size Reconstructions In Image Quality And Diagnostic Confidence Of Peripheral Artery Disease In Arterial Runoff Studies Of The Lower Extremities

Participants
Fides Schwartz, MD, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To determine whether reconstruction with a higher than standard matrix size improves image quality and clinical decision making for lower extremity CTA studies.*Methods and Materials Raw data from 31 consecutive lower extremity CTA studies acquired on two MDCT scanners (SOMATOM Flash and Force) in patients with peripheral arterial disease (PAD) were identified. Data were reconstructed with standard (512x512) and higher resolution (768x768 and 1024x1024) matrix sizes using a prototype based on Precision Matrix technology (Siemens Healthineers). Three blinded readers (one diagnostic and one interventional radiologist, and one vascular surgeon with 7, 5, and 12 years experience, respectively) reviewed representative transverse images, containing soft or calcified vascular plaque, reconstructed with each matrix size in randomized order (3 images/patient). Using a scale of 0 (worst) - 100 (best), readers graded image quality for vascular wall definition, image noise, and ability to confidently determine the grade of stenosis. Scores were compared between reconstructions (overall and separately for tibial and femoropopliteal arteries) using mixed effects linear regression with matrix treated as a fixed effect and subject and reader as random effects. Inter-reader agreement was determined using Spearman's rank correlation test.*Results Reconstructions with a 1024x1024 matrix were ranked significantly better for wall definition (mean score 72, 95% CI=61-84), noise (74, CI=59-88), and confidence (70, CI=59-80) compared to 512x512 (wall definition=65, CI=53-77; noise=67, CI=52-81; confidence=62, CI=52-73; p=0.003, p=0.01, and p=0.004, respectively). There was no significant difference between 768x768 and 512x512 sizes. Compared to 512x512 the 1024x1204 matrix improved image quality in the tibial arteries (wall definition=50 vs 59, p=0.02; noise=55 vs 64, p=0.06; confidence=46 vs 56, p=0.007) to a greater degree than the femoral-popliteal arteries (wall definition=80 vs 85, p=0.05; noise=78 vs 83, p=0.06; confidence=78 vs 83, p=0.12). Inter-reader agreement was moderate at rho=0.5.*Conclusions Higher matrix reconstructions of 1024x1024 may improve image quality with higher resolution and enable more confident assessment of PAD.*Clinical Relevance/Application Higher matrix reconstructions of 1024x1024 instead of 512x512 should be the standard reconstructions for challenging examinations that need high resolution images such as arterial runoff studies.

RESULTS

Reconstructions with a 1024x1024 matrix were ranked significantly better for wall definition (mean score 72, 95% CI=61-84), noise (74, CI=59-88), and confidence (70, CI=59-80) compared to 512x512 (wall definition=65, CI=53-77; noise=67, CI=52-81; confidence=62, CI=52-73; p=0.003, p=0.01, and p=0.004, respectively). There was no significant difference between 768x768 and 512x512 sizes. Compared to 512x512 the 1024x1204 matrix improved image quality in the tibial arteries (wall definition=50 vs 59, p=0.02; noise=55 vs 64, p=0.06; confidence=46 vs 56, p=0.007) to a greater degree than the femoral-popliteal arteries (wall definition=80 vs 85, p=0.05; noise=78 vs 83, p=0.06; confidence=78 vs 83, p=0.12). Inter-reader agreement was moderate at rho=0.5.

CLINICAL RELEVANCE/APPLICATION

Higher matrix reconstructions of 1024x1024 instead of 512x512 should be the standard reconstructions for challenging examinations that need high resolution images such as arterial runoff studies.

SSVA02-5 Diagnostic Value Of Standardized Mr Angiography Protocol In The Evaluation Of Thoracic Outlet Syndrome

Participants
Cammillo Talei Franzesi, Milan, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic performance of a standardized MR angiography (MRA) protocol in the study of Thoracic Outlet Syndrome (TOS).*Methods and Materials From September 2016 to March 2020, a total of 20 patients who underwent MRA study to investigate vascular TOS were retrospectively enrolled. Protocol sequences includes Balanced Fast Field Echo M2D, Turbo Spin Echo T1 weighted, high-resolution TSE T1 weighted, HR TSE DIXON T2 weighted, contrast-enhanced MRA (CE- MRA), pre and post-contrast T1-weighted High Resolution Isotropic Volume Examination.Baseline sequences were performed with the arms in adduction, CE-MRA sequences were performed both with arms in adduction and abduction, with injection of contrast media repeated for each arms' position (Gadobutrol 1.0 mol/L; 5 + 5 ml). The overall total acquisition time is about 20 minutes.*Results Sixteen patients showed unilateral TOS (n=16, 80%), with the left side more frequently involved (n=10, 64.5%) than the right one (n=6, 45.5%). Thirteen patients showed venous compression (vTOS) (65%), 3 patients arterial TOS (aTOS) (15%), only in one case an overlap between vTOS-aTOS (5%) was reported.Eight patients showed compression with the arm in abduction (50%), 8 with the arm both in adduction and abduction (50%).In 5 cases TOS was caused by an osseus abnormalities both post-traumatic or post-surgical.In 6 patients (30%) vTOS was associated with thrombosis. Twenty percent of TOS were caused by muscle hypertrophy or wrong insertion.Five out of sixteen case involved the scalene triangle (31%), 8/16 the costo-clavicular space (50%) and 3/16 patients the subacromial-pectoralis space (19%). In 4/20 patients vascular TOS was not identified (20%).*Conclusions Angio-MRI protocol with CE-MRA sequence with arms in adduction and abduction allows to identify the presence of vascular TOS, along with the identification of the intrinsic and extrinsic abnormalities causing pathology.*Clinical Relevance/Application The proposed protocol is extremely effective in identifying vascular TOS, resulting in a valuable integration to clinical data for understanding the cause of symptoms and to guide the correct management.

RESULTS

Sixteen patients showed unilateral TOS (n=16, 80%), with the left side more frequently involved (n=10, 64.5%) than the right one (n=6, 45.5%). Thirteen patients showed venous compression (vTOS) (65%), 3 patients arterial TOS (aTOS) (15%), only in one case an overlap between vTOS-aTOS (5%) was reported.Eight patients showed compression with the arm in abduction (50%), 8 with the arm both in adduction and abduction (50%).In 5 cases TOS was caused by an osseus abnormalities both post-traumatic or post-surgical.In 6 patients (30%) vTOS was associated with thrombosis. Twenty percent of TOS were caused by muscle hypertrophy or wrong insertion.Five out of sixteen case involved the scalene triangle (31%), 8/16 the costo-clavicular space (50%) and 3/16 patients the subacromial-pectoralis space (19%). In 4/20 patients vascular TOS was not identified (20%).

CLINICAL RELEVANCE/APPLICATION

The proposed protocol is extremely effective in identifying vascular TOS, resulting in a valuable integration to clinical data for understanding the cause of symptoms and to guide the correct management.

SSCH05-2   A Pattern Based Approach To CT Of Interstitial Lung Disease Can Elevate The Differential Diagnosis Of Non-specialists To Equal That Of Specialist Thoracic Radiologists

Participants
Ali Dhanaliwala, MD,PhD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Interstitial lung diseases ((ILDs) can be difficult to diagnose for novices as well as non-thoracic trained radiologists. For new trainees, imaging findings can be non-specific making it difficult to create a useful differential diagnosis. While for general radiologists, the low incidence of ILD limits exposure to these studies and can result in missed diagnoses.*Methods and Materials A varied group of non-expert and expert readers were recruited including first year radiology residents, pulmonary medicine fellows, early career general radiologists, and cardio-thoracic fellowship radiologists. Readers were given a set of chest CTs and asked to identify the disease. The chest CTs were randomly assigned from a curated database of ILD cases identified through an imaging search of the radiology archives at our institution and verified through retrospective chart review. Following a washout period, the readers were given a short training module and flowsheet describing a pattern based approach for identifying key features in the CT and an "if this then that" algorithm for converting findings into a useful differential. Readers were then asked to re-read their cases and identify the most likely pattern and their top three differential in descending order of probability. Paired t-test analysis was used to compare the pre and post training module results.*Results Non-expert readers showed an overall 17% improvement in including the correct ILD within their top three differential diagnoses and an overall 11% improvement in correctly identifying as their top diagnosis, the four most common conditions within the database (connective tissue disease related ILD, idiopathic pulmonary fibrosis, sarcoid, and hypersensitivity pneumonitis). In addition, post training, non-experts correctly placed the correct diagnosis within their top three differential at a similar rate as experts.*Conclusions A pattern recognition approach and an "if this then that" flowsheet can improve the identification of ILDs by non-experts to levels approaching that of fellowship trained cardio-thoracic radiologists.*Clinical Relevance/Application Our training module for diagnosing diffuse parenchymal lung diseases from CT elevated non-expert radiologists to the level of cardiothoracic-trained radiologists in the creation of a differential diagnosis.

RESULTS

Non-expert readers showed an overall 17% improvement in including the correct ILD within their top three differential diagnoses and an overall 11% improvement in correctly identifying as their top diagnosis, the four most common conditions within the database (connective tissue disease related ILD, idiopathic pulmonary fibrosis, sarcoid, and hypersensitivity pneumonitis). In addition, post training, non-experts correctly placed the correct diagnosis within their top three differential at a similar rate as experts.

CLINICAL RELEVANCE/APPLICATION

Our training module for diagnosing diffuse parenchymal lung diseases from CT elevated non-expert radiologists to the level of cardiothoracic-trained radiologists in the creation of a differential diagnosis.

SSCH05-3   Antisynthetase Syndrome Related Interstitial Lung Disease: Longitudinal Imaging Findings

Participants
Wei Wu, MD, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

Interstitial lung disease (ILD) is a major determinant of morbidity and mortality in Antisynthetase syndrome (ASyS). However, initial and evolving patterns of ASyS-ILD on CT (computed tomography) chest are not well described. We sought to describe evolution of CT findings in ASyS-ILD and association with serological biomarkers and outcome.*Methods and Materials Serological biomarkers, longitudinal chest CT scans and clinical outcome data were retrospectively abstracted from medical records of 47 patients diagnosed with ASyS-ILD, followed at our center. Predominant imaging findings and radiographic patterns were analyzed for all CT scans. Fibrosis severity was qualitatively scored using an arbitrary visual scale of 10-30. Association between imaging features, serological biomarkers and outcomes were analyzed.*Results 31patients had Anti-Jo1 antibodies while 16 patients did not. 191 CT scans were analyzed with average of 4±2 CT scans per patient within median follow-up time of 46 (IQR:27-80) months. 7 patients died during follow-up. Initial radiographic patterns were consistent with non-specific interstitial pneumonia (NSIP) (38.3%), organizing pneumonia (OP) (29.8%), NSIP-OP overlap (14.9%), usual interstitial pneumonia (UIP) (8.5%) and unspecified (8.5%).

Patterns at last follow up were NSIP (59.6%), UIP (19.1%), OP (12.8%), NSIP-OP overlap (6.4%), and unspecified (6.4%). CT pattern evolved in 23 patients during follow-up; Evolution occurred more in OP and NSIP-OP overlap groups and less often in fibrotic NSIP and UIP groups (p=0.01). Median fibrosis score did not change over 40 months median follow up (0, range: -2, 18). Predominant ground-glass opacities (GGO) pattern on initial CT was associated with increased survival (p=0.03.) There were no significant associations between imaging pattern and type of antibody.*Conclusions Among patients with ASyS-ILD in this cohort, the most common initial imaging patterns were NSIP and OP. ILD pattern evolved in half of the patients during a median follow up of 4 years. The most frequent pattern change was from OP, NSIP-OP overlap or cNSIP to fNSIP. fNSIP or UIP patterns generally did not progress further or evolve. GGO predominance at initial CT was associated with increased survival.*Clinical Relevance/Application The study describes initial and subsequent imaging findings of ASyS-ILD that may have prognostic implications.

RESULTS

31patients had Anti-Jo1 antibodies while 16 patients did not. 191 CT scans were analyzed with average of 4±2 CT scans per patient within median follow-up time of 46 (IQR:27-80) months. 7 patients died during follow-up. Initial radiographic patterns were consistent with non-specific interstitial pneumonia (NSIP) (38.3%), organizing pneumonia (OP) (29.8%), NSIP-OP overlap (14.9%), usual interstitial pneumonia (UIP) (8.5%) and unspecified (8.5%). Patterns at last follow up were NSIP (59.6%), UIP (19.1%), OP (12.8%), NSIP-OP overlap (6.4%), and unspecified (6.4%). CT pattern evolved in 23 patients during follow-up; Evolution occurred more in OP and NSIP-OP overlap groups and less often in fibrotic NSIP and UIP groups (p=0.01). Median fibrosis score did not change over 40 months median follow up (0, range: -2, 18). Predominant ground-glass opacities (GGO) pattern on initial CT was associated with increased survival (p=0.03.) There were no significant associations between imaging pattern and type of antibody.

CLINICAL RELEVANCE/APPLICATION

The study describes initial and subsequent imaging findings of ASyS-ILD that may have prognostic implications.

SSCH05-6   Kurtosis Of Quantitative Evaluation Of Deep Learning-extracted Features To Classify IPF

Participants
Hyung Kim, PhD, Los Angeles, California (*Presenter*) Research Consultant, MedQIA Imaging Core Laboratory;Research Grant, Boehringer Ingelheim GmbH

PURPOSE

To be useful in medical imaging, artificial intelligence must be explainable. Attention mechanism, which is one attempt towards explainable artificial intelligence (XAI), can achieve accurate predictions and provide case-level "attention maps" (deep learning-extracted features) that highlight specific clinically meaningful outputs. However, the evaluation of attention maps is usually subjective. Distribution of Hounsfield units and measures of this distribution, including kurtosis, has been used to classify different forms of lung parenchyma disease processes, including idiopathic pulmonary fibrosis (IPF). Inspired by this, this study uses kurtosis to assess the attention maps as a quantitative explainability index to identify patients with IPF from other causes of pulmonary fibrosis.*Methods and Materials Using the previously developed explainable models with guided attentions, the model performance of the top three candidates was AUC of 0.98 using non-contrast HRCT images to distinguish IPF (N=279) from non-IPF with interstitial lung disease (ILD) (N=423). All three models were trained with different hyperparameters and each with five-fold cross-validation. To quantify the distribution of attention maps in two classes (IPF versus non-IPF), we use the estimated attention maps (dimension, X*Y*Z*# of channel, 64*64*32*8) for all IPF and non-IPF subjects, respectively. The attention maps resemble the classification of ILD patterns of pulmonary fibrosis (See Figure 1). We averaged whole lung and peripheral lung voxels, respectively, for each channel and model fold. A linear model was built to include both model fold, channel, interaction term, and a clinical diagnosis factor. One-sided hypothesis testing was conducted to test if IPF subjects have a lower kurtosis of attention maps than that of non-IPF population.*Results Means of kurtosis of the averaged attention maps among IPF subjects were 0.83, 1.23, and 1.99, which were significantly lower for two out of three constructed models with the means of 1.45, 2.13, and 1.54 among non-IPF subjects in the whole lung (whole lung: P < 0.001 and P=0.02; peripheral lung: P < 0.001 and P=0.05); not significant for one model (whole lung: P=0.82; peripheral: P=0.61).*Conclusions Kurtosis can be an effective measure for evaluating the explainability of deep learning-extracted features after building an IPF diagnosis model. Finding a quantitative explainable index for deep learning algorithms is feasible using prior domain knowledge and the output from attention maps.*Clinical Relevance/Application Evaluation of quantitative index for assessing deep learning-extracted features, such as using kurtosis to evaluate attention maps, is a necessary step of building XAI towards clinical utilization.

RESULTS

Means of kurtosis of the averaged attention maps among IPF subjects were 0.83, 1.23, and 1.99, which were significantly lower for two out of three constructed models with the means of 1.45, 2.13, and 1.54 among non-IPF subjects in the whole lung (whole lung: P < 0.001 and P=0.02; peripheral lung: P < 0.001 and P=0.05); not significant for one model (whole lung: P=0.82; peripheral: P=0.61).

CLINICAL RELEVANCE/APPLICATION

Evaluation of quantitative index for assessing deep learning-extracted features, such as using kurtosis to evaluate attention maps, is a necessary step of building XAI towards clinical utilization.

SSGI11-1 **Novel Point-of-care Perfusion Phantom Improves The Reproducibility Of Quantitative DCE-MRI Measurement Of Abdominal Tissues**

Participants
Martin Holland I, BEng,MENG, Homewood, Alabama (*Presenter*) Nothing to Disclose

PURPOSE

Purpose To develop a ready-to-use Point-of-care Portable Perfusion Phantom (P4) and demonstrate its ability to reduce the inter-scanner variability of quantitative Dynamic Contrast-Enhanced Magnetic Resonance Imaging (qDCE-MRI) measurement of human subjects.*Methods and Materials Methods: The P4 phantom was designed to fit beneath a patient in an MRI machine, acting as a reference to detect the scanner-driven errors in qDCE-MRI measurement. The contrast enhancement curve (CEC) of the P4 phantom was generated with the samples collected from the phantom using liquid chromatography-mass spectrometry (LC-MS), and its repeatability was determined with the measurements from five different P4 phantoms. Five healthy human volunteers (23-41 years of age; female) were recruited. Each subject was imaged together with the P4 phantom in three different 3T MRI scanners. The Ktrans of the liver, spleen, pancreas and prevertebral muscle were calculated based on Tofts model (TM), extended Tofts model (ETM), and shutter speed model (SSM). The reproducibility of Ktrans measurement was assessed with the intra-class correlation coefficients (ICC) before and after P4-based error correction.*Results Results The CEC of the P4 phantom was linear for 10 minutes after infusing an MR contrast agent (gadoteridol) (0.17 mM/min) with 96% of measurement accuracy. The repeatability of the CEC was 0.997 when assessed with ICC. The reproducibility of the Ktrans measurement based on TM, ETM, and SSM were 0.319, 0.384, and 0.730, respectively, before P4-based error correction, but those were improved to 0.904, 0.986, and 0.829, respectively, after correction.*Conclusions Conclusions The reproducibility of Ktrans measurement across three different scanners was markedly improved after P4-based error correction regardless of pharmacokinetic models.*Clinical Relevance/Application The proposed methodology shows significant potential to improve data consistency in a multi-institutional clinical trial employing qDCE-MRI for a new drug or therapeutic strategy development.

RESULTS

Results The CEC of the P4 phantom was linear for 10 minutes after infusing an MR contrast agent (gadoteridol) (0.17 mM/min) with 96% of measurement accuracy. The repeatability of the CEC was 0.997 when assessed with ICC. The reproducibility of the Ktrans measurement based on TM, ETM, and SSM were 0.319, 0.384, and 0.730, respectively, before P4-based error correction, but those were improved to 0.904, 0.986, and 0.829, respectively, after correction.

CLINICAL RELEVANCE/APPLICATION

The proposed methodology shows significant potential to improve data consistency in a multi-institutional clinical trial employing qDCE-MRI for a new drug or therapeutic strategy development.

SSGI11-2 **Quantitative Peritumoral MRI Fingerprinting Improves Machine Learning-based Prediction Of Overall Survival In Patients With Colon Cancer**

Participants
Dania Daye, MD, PhD, Medford, Massachusetts (*Presenter*) Research Consultant, Sigilon Therapeutics;Research Consultant, Medtronic plc

PURPOSE

This study investigates the role of MRI-based peritumoral heterogeneity as predictors of overall survival in patients with metastatic colorectal cancer.*Methods and Materials In this IRB-approved retrospective study, we identified 48 patients with colon cancer who underwent MRI from 2007-2015 for liver metastasis evaluation. Patient survival data was available for up to 95 months. Standard clinical and pathologic prognostic variables were extracted from the medical record. All metastatic hepatic lesions were identified on portal venous phase T1-weighted fat-suppressed post-contrast images and semi-automatically volumetrically segmented, for a total of 94 tumors. A vector consisting of 112 radiomic features (shape, first-order, texture) was extracted from a 1 cm region surrounding each segmented tumor. The dataset was divided into training and testing set at a ratio of 4:1. The random forest model was applied. Recursive feature elimination was used to select and test the effectiveness of different number of radiomic features. ROC analysis was used to assess the model performance. Survival curves were generated using Kaplan-Meier analysis.*Results A total of 48 patients were enrolled in the study (M:F 23:25; age 55.3 ± 18 years). 42% of tumors had high

microsatellite instability and KRAS mutation was detected in 68/94 (72%) tumors. Mean survival time was 35±21 months for the study population. 36% pf patients exhibited metastatic disease progression. Univariate regression revealed 21 textures features (9 first order and 12 GLCM features) to be independently associated with metastatic disease progression (all p<0.03). The trained random forest machine model resulted in an area under the ROC curve of 0.88.*Conclusions MRI-based peritumoral texture features may be used as predictive biomarkers for metastatic disease progression and patient survival in metastatic colorectal cancer.*Clinical Relevance/Application Peritumoral texture features may be used to help guide management decisions in patients with metastatic colorectal cancer.

RESULTS

A total of 48 patients were enrolled in the study (M:F 23:25; age 55.3 ± 18 years). 42% of tumors had high microsatellite instability and KRAS mutation was detected in 68/94 (72%) tumors. Mean survival time was 35±21 months for the study population. 36% pf patients exhibited metastatic disease progression. Univariate regression revealed 21 textures features (9 first order and 12 GLCM features) to be independently associated with metastatic disease progression (all p<0.03). The trained random forest machine model resulted in an area under the ROC curve of 0.88.

CLINICAL RELEVANCE/APPLICATION

Peritumoral texture features may be used to help guide management decisions in patients with metastatic colorectal cancer.

SSGI11-3   Fully-automated CT Biomarkers For Type 2 Diabetes Using Deep Learning

Participants
Hima Tallam, Wayne, New Jersey (*Presenter*) Nothing to Disclose

PURPOSE

To investigate CT biomarkers for type 2 diabetes in a large clinical dataset using fully-automated deep learning.*Methods and Materials The patient population consisted of 8,992 patients who underwent colorectal cancer screening with CT colonography, of whom?572 had type 2 diabetes (T2D) and 1,880 were dysglycemic.?The pancreas was segmented using a fully-automated deep learning method that outputs measurements of interest (biomarkers), including CT attenuation,?volume, fat content,?and?fractal dimension of the pancreas.?Additional biomarkers assessed from the scans included visceral fat and atherosclerotic plaque. Univariable and multivariable analyses were performed after separating patients into groups based on time between T2D diagnosis and CT scan date. Clinical factors (sex, age, BMI, BMI>30) were included. The best set of predictors for T2D were determined using multinomial logistic regressions.*Results The deep learning model had an average Dice similarity coefficient for the pancreas in the test set of 0.69 +/- 0.17, which is state-of-the-art for noncontrast CT. The univariable analysis showed that diabetics had on average lower pancreas CT attenuation (18.74 +/- 16.54 HU vs. 29.99 +/- 13.41 HU, P<0.0001) and higher visceral fat (235.0 +/- 108.6 mL vs. 130.9 +/- 96.3 mL, P<0.0001) than nondiabetics. Diabetics also showed a decrease in CT attenuation with greater duration of disease. The final multivariate model showed pairwise AUCs of 0.79 and 0.83 between nondiabetics and diabetics 0-2500 days pre and post diagnosis, respectively. Adding clinical data did not significantly improve upon CT-based AUC performance. The best predictors of T2D included standard deviation of pancreas CT attenuation, fractal dimension of the pancreas, visceral fat volume, severity of abdominal aortic plaque, BMI, and if patients had a BMI higher than 30 kg/m2.*Conclusions The diagnosis of diabetes is associated with CT biomarkers, especially measures of pancreas CT attenuation and visceral fat.*Clinical Relevance/Application Fully-automated CT biomarkers can be used for the opportunistic detection and prediction of type 2 diabetes on scans performed for other indications.

RESULTS

The deep learning model had an average Dice similarity coefficient for the pancreas in the test set of 0.69 +/- 0.17, which is state-of-the-art for noncontrast CT. The univariable analysis showed that diabetics had on average lower pancreas CT attenuation (18.74 +/- 16.54 HU vs. 29.99 +/- 13.41 HU, P<0.0001) and higher visceral fat (235.0 +/- 108.6 mL vs. 130.9 +/- 96.3 mL, P<0.0001) than nondiabetics. Diabetics also showed a decrease in CT attenuation with greater duration of disease. The final multivariate model showed pairwise AUCs of 0.79 and 0.83 between nondiabetics and diabetics 0-2500 days pre and post diagnosis, respectively. Adding clinical data did not significantly improve upon CT-based AUC performance. The best predictors of T2D included standard deviation of pancreas CT attenuation, fractal dimension of the pancreas, visceral fat volume, severity of abdominal aortic plaque, BMI, and if patients had a BMI higher than 30 kg/m2.

CLINICAL RELEVANCE/APPLICATION

Fully-automated CT biomarkers can be used for the opportunistic detection and prediction of type 2 diabetes on scans performed for other indications.

SSGI11-5   Pre-operative Radiomics Model For Prognostication In Resectable Pancreatic Adenocarcinoma: Multi-institutional Development And External Validation

Participants
Gerard Healy, BMBCh, Toronto, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

In patients with resectable pancreatic ductal adenocarcinoma (PDAC), there are few strictly pre-operative biomarkers available to guide therapy decisions. Radiomics has demonstrated potential value for prognostication, but lacks external validation. We aimed to develop and externally validate a pre-operative clinical-radiomic model.*Methods and Materials Retrospective international, multi-center study in patients with resectable PDAC who underwent pre-operative contrast-enhanced CT, without neoadjuvant therapy. 352 patients underwent CTs at five North-American hospitals and subsequently underwent resection at our center. Penalized Cox proportional hazard models were developed, incorporating (a) pre-operative clinical factors (clinical), (b) CT-based radiomics (Rad-score) and (c) pre-operative clinical plus radiomics features (clinical-radiomic). Outcomes were overall (OS) and disease-free survival (DFS). A post-operative model incorporating pathological findings (TNM) served as reference standard. The external test cohort consistent of 215 patients who underwent resection at a European center, following pre-operative CTs performed at 34 hospitals.*Results Four features (two attenuation and two heterogeneity) were selected for the Rad-score. In the external cohort, Rad-score was the dominant predictor of OS and DFS, with adjusted Hazard Ratios of 2.87 (95% CI 1.40-5.87, p<0.001) and 5.28 (95% CI 2.35-11.86, p<0.001) respectively, along with age (HR 1.02 for both, p<0.05). No other clinical features were significantly associated with OS and DFS. Median OS was 22.9 / 37 months (p=0.0092) and DFS 14.2 / 29.8 (p=0.0023) for the high / low risk groups in the external cohort. Calibration was moderate in the external cohort, with mean absolute error 0.074 and 0.132 for OS at 3 and 5 years. The clinical-radiomic model demonstrated significantly better discrimination performance than the clinical model

(p<0.001) and was similar to TNM (p=0.55). *Conclusions A pre-operative model containing clinical variables and radiomics significantly improved prognostication for patients with resectable PDAC compared to using clinical information alone and was similar to using pathological information, which are only available post-operatively. Our model may be useful for pre-operative therapy decisions.*Clinical Relevance/Application Incorporating radiomic data into a pre-operative prognostic model for PDAC improves performance. This clinical-radiomics model generalizes to a large external population and may help guide pre-operative therapy decisions.

RESULTS

Four features (two attenuation and two heterogeneity) were selected for the Rad-score. In the external cohort, Rad-score was the dominant predictor of OS and DFS, with adjusted Hazard Ratios of 2.87 (95% CI 1.40-5.87, p<0.001) and 5.28 (95% CI 2.35-11.86, p<0.001) respectively, along with age (HR 1.02 for both, p<0.05). No other clinical features were significantly associated with OS and DFS. Median OS was 22.9 / 37 months (p=0.0092) and DFS 14.2 / 29.8 (p=0.0023) for the high / low risk groups in the external cohort. Calibration was moderate in the external cohort, with mean absolute error 0.074 and 0.132 for OS at 3 and 5 years. The clinical-radiomic model demonstrated significantly better discrimination performance than the clinical model (p<0.001) and was similar to TNM (p=0.55).

CLINICAL RELEVANCE/APPLICATION

Incorporating radiomic data into a pre-operative prognostic model for PDAC improves performance. This clinical-radiomics model generalizes to a large external population and may help guide pre-operative therapy decisions.

SSGI11-6   Task-specific Shape Radiomic Features Of Mesenteric-portal Axis For Prediction Of Survival Of Patients With Pancreatic Ductal Adenocarcinoma.

Participants
Francesca Rigiroli, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To identify task-specific shape radiomic features of mesenteric-portal axis (MPA) tumor encasement that are associated with survival in patients with pancreatic ductal adenocarcinoma (PDAC).*Methods and Materials In an IRB-approved study, patients from 2 institutions who underwent neoadjuvant therapy and subsequent surgery for PDAC were included between January 2013 and December 2018. Two radiologists performed a volumetric segmentation of primary tumor and mesenteric-portal axis (MPA) from the intrahepatic segment to the first jejunal branch using a prototype segmentation software (Radiomics, Siemens Heathineers) on CT scans before (CTtp0) and after (CTtp1) neoadjuvant therapy. Segmentation masks and CT scans were exported into MATLAB and resampled into uniform 0.625 mm voxels to develop shape radiomic features (n=57). These features, derived from mathematical functions, aimed to assess MPA shape in CTtp0 and CTtp1 (original features), MPA narrowing by the tumor compared to its healthy segment (ratio features), changes in shape and diameter between CTtp0 and CTtp1 (difference features, D) and length of MPA segment affected by the tumor (tumor length features). A Kaplan-Meier curve was generated to estimate the survival function for the subjects. To identify reliable radiomic features that are associated with survival, a cox proportional hazards model was evaluated. The radiomic features were considered as candidate variables for the final cox proportional effects model using a variation of Collett's approach. Features that had an ICC = 0.80 and a statistically significant p-value < 0.05 were included in the univariable model. Relevant clinical features (sex, age, CA 19-9, and neoadjuvant therapy type) were included in the model a priori.*Results A total of 107 patients (60 men) who received chemoradiation, chemotherapy, or chemotherapy followed by chemoradiation, were included in this study. The median survival time was 895 days (95% CI: 717, 1061). Overall, 74 individuals died, and 33 individuals were lost to follow-up. The feature "ratio 1", calculated from the ratio between the narrowed segment and the healthy segment of the MPA on CTtp1, was selected for the model. For every unit increase in the z-score of ratio 1, there was a 33% reduced risk of death (Hazard Ratio=0.67; 95% CI: 0.50, 0.91; p=0.01), after accounting for sex, age, CA19-9, and neoadjuvant therapy type.*Conclusions Our preliminary results suggest that the developed shape radiomic features are correlated with survival in patients with PDAC.*Clinical Relevance/Application Task-specific shape radiomic features of MPA may provide critical information for the assessment of survival in patients with PDAC, therefore improving the clinical management of these patients.

RESULTS

A total of 107 patients (60 men) who received chemoradiation, chemotherapy, or chemotherapy followed by chemoradiation, were included in this study. The median survival time was 895 days (95% CI: 717, 1061). Overall, 74 individuals died, and 33 individuals were lost to follow-up. The feature "ratio 1", calculated from the ratio between the narrowed segment and the healthy segment of the MPA on CTtp1, was selected for the model. For every unit increase in the z-score of ratio 1, there was a 33% reduced risk of death (Hazard Ratio=0.67; 95% CI: 0.50, 0.91; p=0.01), after accounting for sex, age, CA19-9, and neoadjuvant therapy type.

CLINICAL RELEVANCE/APPLICATION

Task-specific shape radiomic features of MPA may provide critical information for the assessment of survival in patients with PDAC, therefore improving the clinical management of these patients.

SSRI02-2   Brain Myelination: Can It Be Visualized In Utero Using MRI?

Participants
Daniela Prayer, MD, Vienna, Austria (*Presenter*) Nothing to Disclose

PURPOSE

The image quality of the currently used T1-weighted sequences to assess fetal myelination in utero is limited due to insufficient contrast. An optimized T1-weighted sequence with improved contrast is the snapshot inversion recovery sequence (SNAPIR, Malamateniou C. et al, Radiology, 2011). We aimed to evaluate the advantage of SNAPIR and SNAPIR compressed sense (SNAPIR-CS) sequences over standard used T1 fast field echo (T1FFE) sequence for the qualitative and quantitative assessment of fetal brain myelination/ premyelination.*Methods and Materials Fetal brain MRI examinations containing all three SNAPIR, SNAPIR-CS and T1FFE sequences were reviewed. Two readers, blinded to gestational age (GA) of the fetuses, qualitatively scored fetal myelination on all three sequences at five brain regions (medulla oblongata, pons, mesencephalon, thalamus, central region) and findings were compared using the paired t test. Pearson's correlation analysis was used to detect correlations between GA and the fetal myelin total score (MTS) on each sequence. One rater performed region-of-interest analysis at the same five brain regions and the signal intensities were compared between the three sequences using regression analysis.*Results A total of 125 MRI examinations performed in the axial (n=48) and coronal (n=77) plane (GA between 20 and 39 weeks, mean 29.1 weeks) were included in the qualitative analysis. Sixty-nine MRI examinations performed in the axial plane (GA between 20 and 39 weeks, mean GA 28.5 weeks) were included in the quantitative analysis. On all three sequences the fetal MTS positively correlated with GA with r values ranging between 0.524 and 0.875. However, MTS measured on both axial and coronal plane was significantly higher on SNAPIR and SNAPIR-CS compared to T1FFE (p<0.001). Also, the signal intensities at the five brain regions on SNAPIR and SNAPIR-CS showed a steeper increase with GA in comparison to T1FFE.*Conclusions SNAPIR sequence is superior to T1FFE sequence in the visualization of fetal brain myelination/premyelination, as established by qualitative and quantitative methods.*Clinical Relevance/Application Snapshot inversion recovery sequence should be included into the fetal brain MRI protocol for assessment of brain myelination/premyelination.

RESULTS

A total of 125 MRI examinations performed in the axial (n=48) and coronal (n=77) plane (GA between 20 and 39 weeks, mean 29.1 weeks) were included in the qualitative analysis. Sixty-nine MRI examinations performed in the axial plane (GA between 20 and 39 weeks, mean GA 28.5 weeks) were included in the quantitative analysis. On all three sequences the fetal MTS positively correlated with GA with r values ranging between 0.524 and 0.875. However, MTS measured on both axial and coronal plane was significantly higher on SNAPIR and SNAPIR-CS compared to T1FFE (p<0.001). Also, the signal intensities at the five brain regions on SNAPIR and SNAPIR-CS showed a steeper increase with GA in comparison to T1FFE.

CLINICAL RELEVANCE/APPLICATION

Snapshot inversion recovery sequence should be included into the fetal brain MRI protocol for assessment of brain myelination/premyelination.

SSRI02-3   SARS-CoV-2 Infection During Pregnancy: Does Fetal MRI Show Signs Of Impaired Fetal Brain Development?

Participants
Sergio Grosu, MD, Munich, Germany (*Presenter*) Nothing to Disclose

PURPOSE

The world is kept in suspense by the ongoing pandemic of the novel coronavirus (SARS-CoV-2). While pregnant women seem to be more vulnerable to COVID-19 and therefore may show more severe courses of the disease, the likelihood and impact of a vertical transmission to the fetus remains unclear. The purpose of this study was to use fetal MRI to investigate whether fetal brain development is affected in cases of SARS-CoV-2 infection during pregnancy.*Methods and Materials 33 patients with SARS-CoV-2 infection during pregnancy were prospectively examined; fetal-MRI scans were acquired at 1.5 Tesla. T2-, T1-, and diffusion-weighted brain images were evaluated in consensus by two board-certified radiologists with 3 and 4 years of experience in fetal MRI. Structures of the brain stem and the posterior fossa were assessed quantitatively.*Results Mean gestational age (GA) was 28.4 weeks (min. 18 weeks; max. 39 weeks). Mean onset of symptoms was at 18.3 weeks GA, ranging from 4 to 34 weeks. Most common maternal symptoms were anosmia/hypoosmia (29/33; 87.9%), ageusia (26/33; 78.8%), dry cough (19/33; 57.6%), fever

(9/33; 27.3%) with a maximum temperature of 40.8°C (mean 38.6°C) and dyspnea (10/33; 30.3%). The assessed opercularisation of the Sylvian fissure, the cortical folding and the transverse cerebellar diameter were age-appropriate in all fetuses. Furthermore, a.p.-diameter and craniocaudal extent of pons, medulla oblongata, midbrain and cerebellar vermis were all within age-appropriate limits compared to an independent age-cohort (Dovjak et al., OUG 2021). No calcifications, edema or ventricular enlargement were detected. 7 fetuses showed mild asymmetry of the lateral ventricles with a maximum difference of 4 mm.*Conclusions In 33 cases of SARS-CoV-2 infection during various stages of pregnancy all fetuses showed normal brain development, including cortical folding and brain stem segmentation. There were no findings indicative of infection of the fetal brain.*Clinical Relevance/Application While evidence regarding vertical transmission of SARS-CoV-2 during pregnancy remains sparse our study did not reveal signs of infection or impaired development of the fetal brain on fetal MRI.

RESULTS

Mean gestational age (GA) was 28.4 weeks (min. 18 weeks; max. 39 weeks). Mean onset of symptoms was at 18.3 weeks GA, ranging from 4 to 34 weeks. Most common maternal symptoms were anosmia/hypoosmia (29/33; 87.9%), ageusia (26/33; 78.8%), dry cough (19/33; 57.6%), fever (9/33; 27.3%) with a maximum temperature of 40.8°C (mean 38.6°C) and dyspnea (10/33; 30.3%). The assessed opercularisation of the Sylvian fissure, the cortical folding and the transverse cerebellar diameter were age-appropriate in all fetuses. Furthermore, a.p.-diameter and craniocaudal extent of pons, medulla oblongata, midbrain and cerebellar vermis were all within age-appropriate limits compared to an independent age-cohort (Dovjak et al., OUG 2021). No calcifications, edema or ventricular enlargement were detected. 7 fetuses showed mild asymmetry of the lateral ventricles with a maximum difference of 4 mm.

CLINICAL RELEVANCE/APPLICATION

While evidence regarding vertical transmission of SARS-CoV-2 during pregnancy remains sparse our study did not reveal signs of infection or impaired development of the fetal brain on fetal MRI.

SSRI02-5   Accuracy Of Reported Adenomyosis On Pelvic Ultrasound And MRI Compared To Surgical Pathology

Participants
Nicole Zanolli, BA, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To demonstrate the accuracy of pelvic ultrasound and MRI adenomyosis reporting compared to histopathology in common clinical practice.*Methods and Materials An institutional database was searched for women 18 years of age or older who had undergone both a pelvic ultrasound and pelvic MRI with subsequent hysterectomy with documented pathology between 1/2014 and 12/2018. Imaging findings were abstracted from radiology and pathology reports, and the reported presence or absence of adenomyosis was documented for each modality.*Results 180 women met inclusion criteria. The mean age at the time of MRI was 49.1. Self-identified race was Asian (3.9%), Black (43.9%), Hispanic/Latino (8.3%), White (42.2%), and Other (5.1%). Adenomyosis was present in 64 (35.6%) cases on final pathology, however was only reported in 9 ultrasound and 36 MRI dictations. For the finding of adenomyosis, pelvic ultrasound had a sensitivity of 10.9%, specificity of 98.3%, positive predictive value (PPV) of 77.8%, negative predictive value (NPV) of 66.7% and accuracy of 67.2%. Pelvic MRI had a sensitivity of 29.7%, specificity of 85.3%, PPV of 52.8%, NPV of 68.8% and accuracy of 65.6%. 143 (79.4%) patients had concordant ultrasound and MRI findings, with an underlying adenomyosis prevalence of 30.8% on final pathology. With concordant imaging there was a sensitivity of 6.8%, specificity of 99.0%, PPV of 75.0% and NPV of 70.5%.*Conclusions Pelvic imaging reports were more specific than sensitive for adenomyosis. Compared to prior published data, the lower accuracies demonstrated in this study suggest that when not evaluated for in the setting of a clinical trial, adenomyosis may be under- and incorrectly reported. Even when ultrasound and MRI were concordant, sensitivity remained low, while specificity approached 99%. Given the infrequent reporting of adenomyosis on ultrasound, when reported, ultrasound may be more reliable than MRI at ruling in adenomyosis, while neither modality demonstrated a strong ability to rule out the presence of adenomyosis.*Clinical Relevance/Application Adenomyosis may be underreported on ultrasound and MRI. This is a consideration in the evaluation for procedures such as uterine artery embolization, when adenomyosis may change clinical management.

RESULTS

180 women met inclusion criteria. The mean age at the time of MRI was 49.1. Self-identified race was Asian (3.9%), Black (43.9%), Hispanic/Latino (8.3%), White (42.2%), and Other (5.1%). Adenomyosis was present in 64 (35.6%) cases on final pathology, however was only reported in 9 ultrasound and 36 MRI dictations. For the finding of adenomyosis, pelvic ultrasound had a sensitivity of 10.9%, specificity of 98.3%, positive predictive value (PPV) of 77.8%, negative predictive value (NPV) of 66.7% and accuracy of 67.2%. Pelvic MRI had a sensitivity of 29.7%, specificity of 85.3%, PPV of 52.8%, NPV of 68.8% and accuracy of 65.6%. 143 (79.4%) patients had concordant ultrasound and MRI findings, with an underlying adenomyosis prevalence of 30.8% on final pathology. With concordant imaging there was a sensitivity of 6.8%, specificity of 99.0%, PPV of 75.0% and NPV of 70.5%.

CLINICAL RELEVANCE/APPLICATION

Adenomyosis may be underreported on ultrasound and MRI. This is a consideration in the evaluation for procedures such as uterine artery embolization, when adenomyosis may change clinical management.

SSRI02-8   Classic Versus Non-classic Adnexal Lesions: Risk Of Ovarian Cancer In 878 Women

Participants
Elizabeth A. Sadowski, MD, Madison, Wisconsin (*Presenter*) Nothing to Disclose

PURPOSE

1. Categorize adnexal lesions (ALs) in the general patient population using a simple risk classification scheme of classic versus non-classic ultrasound (US) appearance, and determine rate of malignancy in each group. 2. Determine if age or any specific imaging features help predict risk of malignancy in an AL.*Methods and Materials This retrospective, IRB approved, HIPAA compliant multicentric study was performed in non-selected women presenting to radiology departments for pelvic US. Fellowship trained abdominal radiologists reviewed the US images. All ovarian cysts >3 cm in pre-menopausal women and >1 cm in post-menopausal women were included and classified as either classic (simple cysts, hemorrhagic cysts, endometriomas, and teratomas) or non-classic based on the US appearance. The lesions were then correlated with surgical histopathologic results or a minimum 2 years of clinical or imaging follow up. The sensitivity and specificity of this imaging classification scheme was evaluated. Frequency of malignancy was calculated based on patient's age, classification scheme and specific imaging features. Univariate and multivariate analyses were performed and lesion category comparisons were performed using Fisher's exact test.*Results Out of 970 ALs in 878

women who met inclusion criteria, 53 lesions (5.5%) were malignant. The frequency of malignancy was significantly higher in non-classic lesions (16.5%; 49/297) compared to classic lesions (0.6%; 4/673), (p<0.0001). The frequency of malignancy was also significantly higher in lesions with blood flow (32.0%; 33/103) compared to lesions without blood flow (8.3%; 16/194), (p<0.0001). Women older than 60 had a higher risk of malignancy (50%; 10/20) than women =60 years of age (27.7%; 23/83), however this difference did not reach statistical significance (p=.066). The sensitivity and specificity of this classification scheme (classic vs. non-classic) was 92.5% and 73.1%, respectively.*Conclusions Using a simple US classification scheme of identifying ALs as classic or non-classic results in high sensitivity and specificity for diagnosing malignancy similar to recently published risk categorization schemes. The highest risk of cancer was noted in non-classic lesions with vascular components, particularly in women over 60.*Clinical Relevance/Application Multiple US based classification systems can be clinically utilized for categorizing ALs as benign or potentially malignant. Due to their complexity and heterogeneity, there is a learning curve to implementing these in daily practice, particularly given the low prevalence of malignancy in the population undergoing the exam. A simple US classification scheme assessing risk of malignancy in an AL may be helpful in a busy clinical practice.

RESULTS

Out of 970 ALs in 878 women who met inclusion criteria, 53 lesions (5.5%) were malignant. The frequency of malignancy was significantly higher in non-classic lesions (16.5%; 49/297) compared to classic lesions (0.6%; 4/673), (p<0.0001). The frequency of malignancy was also significantly higher in lesions with blood flow (32.0%; 33/103) compared to lesions without blood flow (8.3%; 16/194), (p<0.0001). Women older than 60 had a higher risk of malignancy (50%; 10/20) than women =60 years of age (27.7%; 23/83), however this difference did not reach statistical significance (p=.066). The sensitivity and specificity of this classification scheme (classic vs. non-classic) was 92.5% and 73.1%, respectively.

CLINICAL RELEVANCE/APPLICATION

Multiple US based classification systems can be clinically utilized for categorizing ALs as benign or potentially malignant. Due to their complexity and heterogeneity, there is a learning curve to implementing these in daily practice, particularly given the low prevalence of malignancy in the population undergoing the exam. A simple US classification scheme assessing risk of malignancy in an AL may be helpful in a busy clinical practice.

SSRI02-9   Evaluation Of Placental Heterogeneity Using DWI In Placenta Accreta Spectrum

Participants
Mariana Meyers, MD, Aurora, Colorado (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the differences of placental apparent diffusion coefficient (ADC) assessed by low b-value diffusion-weighted imaging (DWI) in regions of normal placental development and abnormal placental adherence (placenta accreta spectrum disorder, PAS).*Methods and Materials A retrospective analysis was performed on thirty-one pregnant patients who were imaged between February 2019 and March 2021 for evaluation of PAS. Patients were grouped into no PAS (controls, n=13), accreta/increta (PAS Grade 1 and 2, n=8), and percreta (PAS Grades 3A, 3D, and 3E, n=10) based on operative and surgical pathology reports. Diffusion-weighted MRI data were collected at 1.5T with b-values = 10, 50, 100 s/mm2 and ADC was calculated. Regions of interest (ROIs) were defined throughout the placenta by a radiologist with 11 years of clinical experience in areas of normal placenta for all patients and areas of concern for patients with confirmed PAS. The average and standard deviation (serving as a measure of heterogeneity) of the ADC was computed across all ROIs.Controls were compared to all PAS cases for differences of mean ADC and ADC heterogeneity in both regions of normal placenta and areas of concern. Additionally, a repeated measures ANOVA was used to compare normal and invasive regions between accreta and percreta.*Results No differences were identified between the mean and standard deviation in controls compared to normal regions in PAS cases (mean ADC = 3.85×10^{-3} mm2/s, p=0.61). Areas of concern for abnormal placental adherence showed more heterogeneity compared to the normal placenta in controls (p=0.042), but no difference of the mean ADC (p=0.85). Repeated measures ANOVA tests showed differences of mean ADC (p=0.025) between accreta and percreta cases, and of ADC heterogeneity between normal and invasive regions (p=0.008).*Conclusions Low b-value DWI heterogeneity may be useful to differentiate normal implantation versus regions of suspected adherent or invasive placenta. Addition of advanced, quantitative imaging methods, including expansion of b-value range for IVIM processing could provide insight into microvascular blood flow changes that exist between normal and abnormally invaded regions of the uterine wall by the placenta.*Clinical Relevance/Application DW-MRI signal heterogeneity is increased in areas of suspected adherent or invading placenta and may help in the diagnosis and evaluation of placenta accreta spectrum disorder, ultimately guiding appropriate clinical management.

RESULTS

No differences were identified between the mean and standard deviation in controls compared to normal regions in PAS cases (mean ADC = 3.85×10^{-3} mm2/s, p=0.61). Areas of concern for abnormal placental adherence showed more heterogeneity compared to the normal placenta in controls (p=0.042), but no difference of the mean ADC (p=0.85). Repeated measures ANOVA tests showed differences of mean ADC (p=0.025) between accreta and percreta cases, and of ADC heterogeneity between normal and invasive regions (p=0.008).

CLINICAL RELEVANCE/APPLICATION

DW-MRI signal heterogeneity is increased in areas of suspected adherent or invading placenta and may help in the diagnosis and evaluation of placenta accreta spectrum disorder, ultimately guiding appropriate clinical management.

Vitali Koch, MD, Frankfurt am Main, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To determine the diagnostic accuracy of dual-energy CT (DECT) virtual noncalcium (VNCa) reconstructions for assessing thoracic disk herniation compared to standard grayscale CT.*Methods and Materials In this retrospective study, 87 patients (1131 intervertebral disks; mean age, 66 years; 47 women) who underwent third-generation dual-source DECT and 3.0-Tesla MRI within 3 weeks between November 2016 and April 2020 were included. Five blinded radiologists analyzed standard DECT and color-coded VNCa images after a time interval of 8 weeks for the presence and degree of thoracic disk herniation and spinal nerve root impingement. Consensus reading of independently evaluated MRI series served as the reference standard, assessed by two separate experienced readers. Additionally, image ratings were carried out by using five-point Likert scales.*Results MRI revealed a total of 133 herniated thoracic disks. Color-coded VNCa images yielded higher overall sensitivity (624/665 [94%; 95% CI, 0.89-0.96] vs 485/665 [73%; 95% CI, 0.67-0.80]), specificity (4775/4990 [96%; 95% CI, 0.90-0.98] vs 4066/4990 [82%; 95% CI, 0.79-0.84]) and accuracy (5399/5655 [96%; 95% CI, 0.93-0.98] vs 4551/5655 [81%; 95% CI, 0.74-0.86]) for the assessment of thoracic disk herniation compared to standard CT (all P < .001). Interrater agreement was excellent for VNCa and fair for standard CT (? = 0.82 vs 0.37; P < .001). In addition, VNCa imaging achieved higher scores regarding diagnostic confidence, image quality, and noise compared to standard CT (all P < .001).*Conclusions Color-coded VNCa imaging yielded substantially higher diagnostic accuracy and confidence for assessing thoracic disk herniation compared to standard CT.*Clinical Relevance/Application • Color-coded VNCa reconstructions derived from third-generation dual source dual-energy CT yielded significantly higher diagnostic accuracy for the assessment of thoracic disk herniation and spinal nerve root impingement compared to standard grayscale CT. • VNCa imaging provided higher diagnostic confidence and image quality at lower noise levels compared to standard grayscale CT. • Color-coded VNCa images may potentially serve as a viable imaging alternative to MRI under circumstances where MRI is unavailable or contraindicated.

RESULTS

MRI revealed a total of 133 herniated thoracic disks. Color-coded VNCa images yielded higher overall sensitivity (624/665 [94%; 95% CI, 0.89-0.96] vs 485/665 [73%; 95% CI, 0.67-0.80]), specificity (4775/4990 [96%; 95% CI, 0.90-0.98] vs 4066/4990 [82%; 95% CI, 0.79-0.84]) and accuracy (5399/5655 [96%; 95% CI, 0.93-0.98] vs 4551/5655 [81%; 95% CI, 0.74-0.86]) for the assessment of thoracic disk herniation compared to standard CT (all P < .001). Interrater agreement was excellent for VNCa and fair for standard CT (? = 0.82 vs 0.37; P < .001). In addition, VNCa imaging achieved higher scores regarding diagnostic confidence, image quality, and noise compared to standard CT (all P < .001).

CLINICAL RELEVANCE/APPLICATION

• Color-coded VNCa reconstructions derived from third-generation dual source dual-energy CT yielded significantly higher diagnostic accuracy for the assessment of thoracic disk herniation and spinal nerve root impingement compared to standard grayscale CT. • VNCa imaging provided higher diagnostic confidence and image quality at lower noise levels compared to standard grayscale CT. • Color-coded VNCa images may potentially serve as a viable imaging alternative to MRI under circumstances where MRI is unavailable or contraindicated.

SSMK01-3   Synthetic T2-weighted Contrasts Of The Lumbar Spine Derived From Highly-undersampled K-space Data At Arbitrary Chosen Echo Times - Offsetting Clinical Time Cost Of T2 Mapping

Participants
Marcus Raudner, MD, Vienna, Austria (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study was to investigate, whether synthetic T2w images derived by GRAPPATINI show contrast-to-noise ratios comparable to conventional T2w TSE images and sufficient interrater and intrarater agreements in the assessment of Pfirrmann classifications, annular tears and lumbar disk herniation. GRAPPATINI is a combination of a model-based approach for rapid T2 and M0 quantification (MARTINI) extended by generalized autocalibrating partial parallel acquistion (GRAPPA) and uses highly undersampled k-space data.*Methods and Materials In total, 58 individuals (26 female, 32 male, aged 23.3±8.1 years) were examined at 3 Tesla with sagittal and axial T2w turbo spin echo (TSE) sequences compared to synthetic T2-weighted contrasts derived at identical effective echo times and spatial resolutions. Two readers, blinded for clinical information, graded disk degeneration (Pfirrmann Classification) and evaluated the lumbar intervertebral disks for present herniation or annular tear. One

reader reassessed all studies after four weeks. Weighted kappa statistics were calculated to assess interrater and intrarater agreement. Also, all studies were segmented manually by one reader to compute contrast ratios (CR) and contrast-to-noise ratios (CNR) of the nucleus pulposus and the annulus fibrosus.*Results The interrater agreement was substantial to almost perfect (? = 0.808-0.925) with the intrarater agreement also substantial to almost perfect (? = 0.862-0.963). Overall, the CRT2w was 4.45±1.80 and CRT2synth was 4.71±2.14. Both correlated (rsp=0.768;p<0.001) and differed (0.26±1.38;p=0.002) significantly. The CNRT2w was 1.73±0.52 and CNRT2synth was 1.63±0.50. Both correlated (rsp=0.875;p<0.001) and differed (-0.10±0.25;p<0.001) significantly.*Conclusions This study concludes that synthetic T2w images derived by GRAPPATINI can be used for clinical routine assessment with inter-rater and intra-rater agreements comparable to conventional T2w TSE.*Clinical Relevance/Application This study shows that GRPAPATINI, a prototype multi-echo spin-echo sequence designed for accelerated T2 mapping using a combination of undersampling, model-based reconstruction and GRAPPA, can also deliver diagnostic T2-weighted images. This could potentially offset the additional time cost for T2 mapping in clinical routine.

RESULTS

The interrater agreement was substantial to almost perfect (? = 0.808-0.925) with the intrarater agreement also substantial to almost perfect (? = 0.862-0.963). Overall, the CRT2w was 4.45±1.80 and CRT2synth was 4.71±2.14. Both correlated (rsp=0.768;p<0.001) and differed (0.26±1.38;p=0.002) significantly. The CNRT2w was 1.73±0.52 and CNRT2synth was 1.63±0.50. Both correlated (rsp=0.875;p<0.001) and differed (-0.10±0.25;p<0.001) significantly.

CLINICAL RELEVANCE/APPLICATION

This study shows that GRPAPATINI, a prototype multi-echo spin-echo sequence designed for accelerated T2 mapping using a combination of undersampling, model-based reconstruction and GRAPPA, can also deliver diagnostic T2-weighted images. This could potentially offset the additional time cost for T2 mapping in clinical routine.

SSMK01-5   Intervertebral Disc Regeneration Techniques: Viable Allograft For Intervertebral Disc Supplementation - Viable Allograft Supplemented Disc Regeneration Trial (VAST)

Participants
Edward Yoon, MD, New York, New York (*Presenter*) Speaker, Vivex Biomedical, Inc;Research Consultant, Surgalign Holdings;

PURPOSE

To evaluate clinical and radiologic outcomes after intradiscal allograft augmentation for chronic discogenic back pain.*Methods and Materials 236 subjects with painful discogenic low back pain were screened at 15 U.S. sites with 224 entering the trial which was divided into a treatment group, a non-surgical management (NSM) group and a placebo control group with a 3.5:1:1 randomization ratio. The first 24 participants were assessed with a one month visit after enrollment. Two co-primary endpoints - back pain Visual Analog Scale (VAS) and Oswestry Disability Index (ODI) were evaluated along with safety data including reported adverse events (AEs) and changes in clinical laboratory evaluations. Data was collected at baseline, and at 3, 6 and 12 months. Structural outcomes were evaluated by x-rays and Magnetic Resonance Imaging (MRI) at 6 and at 12 months.*Results At 12 months, clinically meaningful improvements in mean VASPI and ODI scoreswere achieved in the investigational allograft and saline groups. Although mean clinical outcomes were not statistically significant between the treatment groups, a responder analysis demonstrated, a clinically meaningful reduction in ODI of =15 points at 12 months that was statistically significant; 76.5% of subjects randomized to allograft were responders (p = 0.03) as compared to 56.7% in the saline group. In the allograft group, 11 safety adverse events occurred in 141 subjects (3.5%) and there were no persistently symptomatic AEs.*Conclusions This large, prospective blinded RCT demonstrated safety and results indicating that viable disc tissue allograft may be a beneficial nonsurgical treatment for patients who have chronically painful lumbar degenerative discs.*Clinical Relevance/Application This is the largest randomized blinded prospective trial for treatment of single or two level degenerated disc disease with disc tissue allograft augmentation in patients with chronic discogenic back pain.

RESULTS

At 12 months, clinically meaningful improvements in mean VASPI and ODI scoreswere achieved in the investigational allograft and saline groups. Although mean clinical outcomes were not statistically significant between the treatment groups, a responder analysis demonstrated, a clinically meaningful reduction in ODI of =15 points at 12 months that was statistically significant; 76.5% of subjects randomized to allograft were responders (p = 0.03) as compared to 56.7% in the saline group. In the allograft group, 11 safety adverse events occurred in 141 subjects (3.5%) and there were no persistently symptomatic AEs.

CLINICAL RELEVANCE/APPLICATION

This is the largest randomized blinded prospective trial for treatment of single or two level degenerated disc disease with disc tissue allograft augmentation in patients with chronic discogenic back pain.

SSGU04-3 Contrast Free Prostate MRI Using Arterial Spin Labelling As Perfusion Imaging Alternative Can Visualize Prostate Cancer As Good As DCE

Participants
Matthias Boschheidgen, Dusseldorf, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To determine the capability of gadolinium-free arterial spin labelling (ASL) sequences as contrast-free, non-invasive alternative perfusion imaging method to differentiate prostate cancer (PCA) from benign prostate tissue compared to conventional DCE MRI.*Methods and Materials Thirty men with histologically confirmed PCA were included in this prospectively enrolled single center cohort study. All patients received multiparametric MRI (T2, DWI, DCE) at 3T with additional ASL of the PCA lesion. Primary endpoint was differentiability of PCA versus normal prostate tissue in ASL in comparison to DCE. Secondary objectives were differences in signal intensities (SI), contrast ratios (CR), and differences in the attenuation pattern of peripheral (PZ) and transition zone (TZ) PCA.*Results In both, ASL and DCE, average SI of PCA areas differed significantly from SI in reference areas in the TZ and PZ (p<0,01, respectively). ASL had significantly higher CR discerning PCA and benign tissue in PZ and TZ (PZ=5.2; TZ=6.5) compared to DCE (PZ=1.6; TZ=1.4) (p<0.01, respectively). In subjective evaluation, ASL could visualize PCA in 28 patients, compared to 29 in DCE.*Conclusions ASL had significantly higher contrast-ratios discerning PCA from benign tissue in PZ and TZ compared to DCE and visual discrimination of PCA does not differ significantly between the two sequences. As perfusion gadolinium-based contrast media is seen more critical in the last few years, ASL seems to be a promising alternative to DCE in PCA detection.*Clinical Relevance/Application Arterial spin labelling can visualize prostate cancer as good as conventional dynamic contrast-enhanced magnet resonance imaging of the prostate andmay be a promising, contrast free alternative.

RESULTS

In both, ASL and DCE, average SI of PCA areas differed significantly from SI in reference areas in the TZ and PZ (p<0,01, respectively). ASL had significantly higher CR discerning PCA and benign tissue in PZ and TZ (PZ=5.2; TZ=6.5) compared to DCE (PZ=1.6; TZ=1.4) (p<0.01, respectively). In subjective evaluation, ASL could visualize PCA in 28 patients, compared to 29 in DCE.

CLINICAL RELEVANCE/APPLICATION

Arterial spin labelling can visualize prostate cancer as good as conventional dynamic contrast-enhanced magnet resonance imaging of the prostate andmay be a promising, contrast free alternative.

SSGU04-4 The Impact Of 18F-DCFPyL PET/CT On The Management Of Patients With Recurrent Prostate Cancer: Results Of A Prospective, Multicenter Trial.

Participants
Ur Metser, MD, FRCPC, Toronto, Ontario (*Presenter*) Consultant, POINT Biopharma Inc

PURPOSE

To assess the disease detection rate of 18F-DCFPyL PET/CT (=PSMA PET) and the PET-directed change in the clinical management of men with suspected limited recurrent prostate cancer after primary therapy.*Methods and Materials This prospective, multicenter registry trial enrolled 1289 patients (Dec 2018-Sept 2020). Eligibility included biochemical failure after primary therapy, 0-4 sites of disease on conventional imaging (CT and bone scintigraphy) and one of the following predefined clinical cohorts: 1. Node positive or detectable serum PSA after radical prostatectomy (RP) 2. Post RP; 3. Post RP and pelvic radiotherapy; 4. Post RP or primary radiotherapy (RT) and androgen deprivation therapy; 5. Post lesion directed treatment for oligometastases (=4 sites); 6. Post primary RT.*Results 841/1289 men (65.2%) had disease detected with PSMA PET. PET detection rates among men with negative conventional imaging was 615/999 (61.6%). Detection rate of any lesion by serum PSA level (ng/ml) at enrollment were 160/424 (37.7%) for PSA <0.5; 107/171 (62.6%) 0.5-1.0 and 573/692 (82.8%) for PSA >1.0. On PSMA PET 399/1289 men (31.0%) had locoregional failure (limited to pelvis), 314/1289 men (24.4%) had oligometastatic disease and 128/1289 men (9.9%) had extensive metastatic disease (Table 1; results by cohort). Post PSMA PET, a change in planned management was recorded in 748/1289 men (58.0%) and in 371/1250 men (29.7%), there was a change in management intent, most commonly from palliative to potentially curative intent (255/1289; 19.8%); Figure 1. The most common change was conversion from observation or systemic therapy to salvage radiation or surgery for locoregional (236/1289;18.3%) or oligometastatic disease (132/1289; 10.2%). In 89 additional patients (6.9%) nodal-directed therapy was added to management plan after PET.*Conclusions PSMA-PET detects additional sites of disease compared with standard of care imaging in most men with biochemical failure and suspected low volume metastatic disease, resulting in frequent change in management including a change from palliative to curative/radical intent therapy in 20% of men. Long term follow-up is needed to determine whether this impacts disease control.*Clinical Relevance/Application The detection of additional disease sites on PSMA PET in men with biochemical failure after primary therapy and suspected low

volume metastatic disease results in a frequent change in management.

RESULTS

841/1289 men (65.2%) had disease detected with PSMA PET. PET detection rates among men with negative conventional imaging was 615/999 (61.6%). Detection rate of any lesion by serum PSA level (ng/ml) at enrollment were 160/424 (37.7%) for PSA <0.5; 107/171 (62.6%) 0.5-1.0 and 573/692 (82.8%) for PSA >1.0. On PSMA PET 399/1289 men (31.0%) had locoregional failure (limited to pelvis), 314/1289 men (24.4%) had oligometastatic disease and 128/1289 men (9.9%) had extensive metastatic disease (Table 1; results by cohort). Post PSMA PET, a change in planned management was recorded in 748/1289 men (58.0%) and in 371/1250 men (29.7%), there was a change in management intent, most commonly from palliative to potentially curative intent (255/1289; 19.8%); Figure 1. The most common change was conversion from observation or systemic therapy to salvage radiation or surgery for locoregional (236/1289;18.3%) or oligometastatic disease (132/1289; 10.2%). In 89 additional patients (6.9%) nodal-directed therapy was added to management plan after PET.

CLINICAL RELEVANCE/APPLICATION

The detection of additional disease sites on PSMA PET in men with biochemical failure after primary therapy and suspected low volume metastatic disease results in a frequent change in management.

SSGU04-5 Validation Of Prostate Tissue Composition Measurement Using Hybrid Multi-dimensional MRI: Agreement With Pathologists' Measures

Participants
Aritrick Chatterjee, PhD, Chicago, Illinois (*Presenter*) Stockholder, QMIS LLC

PURPOSE

To validate prostate tissue composition measured using Hybrid Multi-dimensional MRI (HM-MRI) by comparing with reference standard results from pathologists' interpretation of clinical histopathology slides following whole mount prostatectomy.*Methods and Materials 36 prospective participants with biopsy-confirmed prostate cancer underwent 3T MRI prior to radical prostatectomy. Axial HM-MRI was acquired with all combinations of echo times of 57, 70, 150, 200 ms and b-values of 0, 150, 750, 1500 s/mm2 and data was fitted using a 3-compartment signal model to generate volumes for each tissue component (stroma, epithelium, lumen). Three experienced genitourinary pathologists independently as well as in consensus reviewed each histology image and provide an estimate of percentage of epithelium and lumen for regions-of-interest corresponding to MRI (n = 165; 64 prostate cancers and 101 normal tissue). Agreement statistics using total deviation index (TDI0.9) was performed for tissue composition measured using HM-MRI and reference standard results from pathologists' consensus.*Results Based on the initial results showing typical variation among pathologists TDI0.9=25%, we determined we will declare acceptable agreement if the 95% one-sided upper confident limit of TDI0.9 is less than 30%. Tissue composition measured using HM-MRI and pathologists' consensus were similar for epithelium 28.3 ± 12.8 vs 27.7 ± 18.0% and lumen volume 26.3 ± 12.8 vs 36.6 ± 10.0%. The results of tissue composition measurement from HM-MRI compared to ground truth results from the consensus of 3 pathologists, reveal that ninety percent of absolute paired differences (TDI0.9) were within 18.8% and 22.4% in measuring epithelium and lumen, respectively. We are 95% confident that 90% of absolute paired differences were within 20.6% and 24.2% in measuring epithelium and lumen, respectively. These were less than our criterion of 30% and inter-pathologists' agreement (22.3% for epithelium and 24.2% for lumen) and therefore we accept the agreement performance of HM-MRI. The results revealed excellent area under the ROC curve for differentiating cancer from benign tissue based on epithelium (HM-MRI: 0.87, pathologists: 0.97) and lumen volume (HM-MRI: 0.85, pathologists: 0.77).*Conclusions The agreement in tissue composition measurement using hybrid-multidimensional MRI and consensus of pathologists is on par with the inter-raters (pathologists) agreement.*Clinical Relevance/Application HM-MRI can potentially be used for non-invasive prostate cancer diagnosis using tissue composition that are similar to measurements from pathologists' interpretation of clinical histopathology slides following whole mount prostatectomy.

RESULTS

Based on the initial results showing typical variation among pathologists TDI0.9=25%, we determined we will declare acceptable agreement if the 95% one-sided upper confident limit of TDI0.9 is less than 30%. Tissue composition measured using HM-MRI and pathologists' consensus were similar for epithelium 28.3 ± 12.8 vs 27.7 ± 18.0% and lumen volume 26.3 ± 12.8 vs 36.6 ± 10.0%. The results of tissue composition measurement from HM-MRI compared to ground truth results from the consensus of 3 pathologists, reveal that ninety percent of absolute paired differences (TDI0.9) were within 18.8% and 22.4% in measuring epithelium and lumen, respectively. We are 95% confident that 90% of absolute paired differences were within 20.6% and 24.2% in measuring epithelium and lumen, respectively. These were less than our criterion of 30% and inter-pathologists' agreement (22.3% for epithelium and 24.2% for lumen) and therefore we accept the agreement performance of HM-MRI. The results revealed excellent area under the ROC curve for differentiating cancer from benign tissue based on epithelium (HM-MRI: 0.87, pathologists: 0.97) and lumen volume (HM-MRI: 0.85, pathologists: 0.77).

CLINICAL RELEVANCE/APPLICATION

HM-MRI can potentially be used for non-invasive prostate cancer diagnosis using tissue composition that are similar to measurements from pathologists' interpretation of clinical histopathology slides following whole mount prostatectomy.

SSCH08-2   Progression Of Clinical Findings Of Smokers With Bronchiectasis On Baseline Low-dose CT Screening For Lung Cancer

Participants
Natthaya Triphuridet, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

To assess progression of clinical findings of smokers with bronchiectasis in a program of low-dose CT (LDCT) screening for lung cancer.*Methods and Materials Among 504 smokers with bronchiectasis on their initial LDCT, retrospective medical record review was performed of 131 participants with ELCAP-Bronchiectasis-Score (ELCAP-BrS) in the highest quartile to document respiratory symptoms, acute events, and investigations during two years before and after the LDCT.*Results Among the 131 participants, 128(97.7%) had right middle lobe and/or lingula bronchiectasis. Of the 73 participants with available records during the four-year review, 54(74.0%) participants had respiratory symptoms, 42(57.5%) had dyspnea, 36(49.3%) had chronic cough, and 29(39.7%) had acute event(s) before screening. The ELCAP-BrS was significantly higher among those with symptoms than those without symptoms (19.0 vs. 17.0, p=0.04). After screening, there was a significant increase in dyspnea with activity limitation (35.6% to 46.6%, p=0.01), exacerbations (35.6% to 50.7%, p=0.03), and positive cultures (20.0% to 77.8%, p=0.01). Among the positive cultures, NTM growth in the two years after screening was identified in 57.1% (4 of 7). A higher proportion of participants with chronic obstructive pulmonary disease (COPD) than those without COPD had symptoms (100% vs. 53.7%, p<0.001), acute events (56.3% vs. 26.8%, p=0.02) and hospitalization (15.6% vs. 0%, p=0.01).*Conclusions Most smokers with bronchiectasis in 4th quartile of ELCAP-BrS were symptomatic. Clinical deterioration was seen in participants with and without COPD, particularly dyspnea with activity limitation and exacerbation. For almost all, bronchiectasis involved the mid lung region and 57.1% (4 of 7) of the participants who had non-tuberculous mycobacteria diagnosed in respiratory cultures. Bronchiectasis should be reported in participants undergoing LDCT screening for lung cancer as they are older smokers, and recommend pulmonary consultation for appropriate investigation and treatment.*Clinical Relevance/Application • Most of smokers with bronchiectasis in 4th quartile of ELCAP-Bronchiectasis-Score had mid lung involvement, symptoms, and significant clinical deterioration, thus early detection of bronchiectasis and bronchiectasis-related diseases would be beneficial.

RESULTS

Among the 131 participants, 128(97.7%) had right middle lobe and/or lingula bronchiectasis. Of the 73 participants with available records during the four-year review, 54(74.0%) participants had respiratory symptoms, 42(57.5%) had dyspnea, 36(49.3%) had chronic cough, and 29(39.7%) had acute event(s) before screening. The ELCAP-BrS was significantly higher among those with symptoms than those without symptoms (19.0 vs. 17.0, p=0.04). After screening, there was a significant increase in dyspnea with activity limitation (35.6% to 46.6%, p=0.01), exacerbations (35.6% to 50.7%, p=0.03), and positive cultures (20.0% to 77.8%, p=0.01). Among the positive cultures, NTM growth in the two years after screening was identified in 57.1% (4 of 7). A higher proportion of participants with chronic obstructive pulmonary disease (COPD) than those without COPD had symptoms (100% vs. 53.7%, p<0.001), acute events (56.3% vs. 26.8%, p=0.02) and hospitalization (15.6% vs. 0%, p=0.01).

CLINICAL RELEVANCE/APPLICATION

• Most of smokers with bronchiectasis in 4th quartile of ELCAP-Bronchiectasis-Score had mid lung involvement, symptoms, and significant clinical deterioration, thus early detection of bronchiectasis and bronchiectasis-related diseases would be beneficial.

SSCH08-3   Lung Cancer Screening And Smoking Cessation: An Opportunity For Community Radiologists To Partner With Behavioral Health Specialists

Participants
Grayson Baird, PhD, Providence, Rhode Island (*Presenter*) Nothing to Disclose

PURPOSE

To examine smoking attitudes among current smokers undergoing lung cancer screening to better inform cessation intervention opportunities and efforts for this population.*Methods and Materials A voluntary assessment of smoking behaviors and attitudes was conducted among 1472 current smokers who presented for annual CT lung cancer screening from 04/19-05/20. Active smokers were eligible for a lung cancer screening if they were at least 30 pack year smokers and 55-77 years old. Data were modeled using

generalized linear modeling.*Results Nearly all participants (86.6%, 1175/1357) smoked cigarettes daily, while 30.1% smoked cigars daily; 98.2% of daily cigar smokers were also daily cigarette smokers. In total, 91.4% of participants were at least somewhat interested in quitting smoking, and 74.1% were seriously thinking about quitting within the next 6 months. Participants reported they would smoke less if told their screen was positive for cancer compared to negative (0.31, 95% CI [0.27, 0.34] vs. 0.77, 95% CI [0.72, 0.81]), p<.0001, although patients reported the desire to smoke less regardless of the result (see Figure 1). Only 8.4% of current smokers believe they do not have an inherent ability to stop smoking, while 22%, 37%, 19%, and 14% believe they have a little, somewhat, mostly, or completely inherent ability to quit if they wanted. For every one-unit increase in ability to quit, the odds of planning to quit increased 49% (OR: 1.492, 95% CI [1.4, 1.6], p<.0001.*Conclusions The number of smokers who undergo lung screening is expected to increase due to expanded guidelines adopted in 2021. Cessation interventions tailored to this population and setting should be developed as patients are interested in quitting and report planning to reduce how much they smoke regardless of their lung cancer screening result.*Clinical Relevance/Application Federal guidelines require that smoking cessation treatment is given during lung cancer screens. These data suggest the population will be receptive to well-designed treatment efforts. The community radiology setting provides an excellent opportunity to engage smokers about smoking cessation by directing them to behavioral medicine colleagues who can design and oversee tailored smoking cessation efforts.

RESULTS

Nearly all participants (86.6%, 1175/1357) smoked cigarettes daily, while 30.1% smoked cigars daily; 98.2% of daily cigar smokers were also daily cigarette smokers. In total, 91.4% of participants were at least somewhat interested in quitting smoking, and 74.1% were seriously thinking about quitting within the next 6 months. Participants reported they would smoke less if told their screen was positive for cancer compared to negative (0.31, 95% CI [0.27, 0.34] vs. 0.77, 95% CI [0.72, 0.81]), p<.0001, although patients reported the desire to smoke less regardless of the result (see Figure 1). Only 8.4% of current smokers believe they do not have an inherent ability to stop smoking, while 22%, 37%, 19%, and 14% believe they have a little, somewhat, mostly, or completely inherent ability to quit if they wanted. For every one-unit increase in ability to quit, the odds of planning to quit increased 49% (OR: 1.492, 95% CI [1.4, 1.6], p<.0001.

CLINICAL RELEVANCE/APPLICATION

Federal guidelines require that smoking cessation treatment is given during lung cancer screens. These data suggest the population will be receptive to well-designed treatment efforts. The community radiology setting provides an excellent opportunity to engage smokers about smoking cessation by directing them to behavioral medicine colleagues who can design and oversee tailored smoking cessation efforts.

SSCH08-4   The Potential Management Impact Of Interval Diagnostic Chest CTs In Lung Cancer Screening Patients

Participants
Pegah Khoshpouri, MD, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

PURPOSE

Lung cancer screening (LCS) participants may obtain diagnostic chest CT (DCT) outside of their recommended LCS schedule. At present, the American College of Radiology Lung- RADS guidelines recommend that LCS CT (LCSCT) be performed on an annual basis without consideration for intervening DCTs. We aimed to quantify the incidence of interval DCT, which has not been previously reported, and to assess the potential effect of these scans on LCSCT follow up.*Methods and Materials IRB approval was obtained for this HIPAA-compliant study. Among 8,073 LCSCTs obtained, 790 patients with at least two LCSCTs between 1/2016 and 8/2019 were identified. The medical record of these patients was reviewed to identify DCTs obtained between baseline and follow-up LCSCTs. Thirty-two patients had interval DCTs. Baseline and follow-up LCSCTs were reviewed and assigned Lung-RADS designations. Interval DCTs were reviewed and compared to both baseline and follow-up LCSCT to determine the potential impact on follow-up management recommendations.*Results Our cohort included 790 patients (404, 51.1% women; mean age 67+6 years). Thirty-two (4.1%) patients had interval DCTs. Median interval DCT was 163 (range 2-686) days from baseline LCSCT and 221 (range 30-454) days before the follow-up LCSCT. DCT images were unavailable in two cases, resulting in 30 scans available. Baseline nodules were obscured by new consolidation on one (3.3%) interval DCT which had resolved on the subsequent annual LCSCT. One (3.3%) interval DCT demonstrated an increase in nodule size which resolved on follow-up LCSCT. Pulmonary nodules were resolved on 2 (6.7%) interval DCTs which was confirmed on follow-up LCSCT. One (3.3%) case demonstrated development of a nodule flagged as "highly suspicious for lung cancer" on interval DCT and categorized as Lung-RADS 4X on follow-up LCSCT. In the majority of cases (28 patients, 93.3%) the findings on follow-up LCSCT did not add further clinical value to the interval DCT.*Conclusions DCTs performed between baseline and follow-up LCSCT were obtained in 4.1% of LCS participants. In a majority of patients (93.3%), nodule findings on interval DCT are similar to those on follow-up LCSCT. Therefore, follow-up and incidence LCSCT may potentially be timed using an interval DCT as a new baseline evaluation.*Clinical Relevance/Application In LCS participants, findings on interval DCTs can potentially be used to adjust the timing of subsequent LCSCT follow-up.

RESULTS

Our cohort included 790 patients (404, 51.1% women; mean age 67+6 years). Thirty-two (4.1%) patients had interval DCTs. Median interval DCT was 163 (range 2-686) days from baseline LCSCT and 221 (range 30-454) days before the follow-up LCSCT. DCT images were unavailable in two cases, resulting in 30 scans available. Baseline nodules were obscured by new consolidation on one (3.3%) interval DCT which had resolved on the subsequent annual LCSCT. One (3.3%) interval DCT demonstrated an increase in nodule size which resolved on follow-up LCSCT. Pulmonary nodules were resolved on 2 (6.7%) interval DCTs which was confirmed on follow-up LCSCT. One (3.3%) case demonstrated development of a nodule flagged as "highly suspicious for lung cancer" on interval DCT and categorized as Lung-RADS 4X on follow-up LCSCT. In the majority of cases (28 patients, 93.3%) the findings on follow-up LCSCT did not add further clinical value to the interval DCT.

CLINICAL RELEVANCE/APPLICATION

In LCS participants, findings on interval DCTs can potentially be used to adjust the timing of subsequent LCSCT follow-up.

SSCH08-5   Lung-rads 1.1: Evaluation Of Pleural Nodules Using The National Lung Screening Trial Dataset

Participants
Lydia Chelala, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

To determine the frequency of malignancy during lung cancer screening (LCS) associated with pleural nodules measuring 6mm to

10mm and assess the rate of reclassification of a benign subset of such nodules if managed like perifissural nodules in Lung-RADS 1.1.*Methods and Materials A secondary analysis of the NLST was performed. Non-calcified nodules measuring 6 to 10 mm found on incident scans were evaluated to identify the largest nodule. Nodules were categorized as pleural and non-pleural nodules. Pleural nodules were defined as directly abutting the costal or paramediastinal pleura. Relationship of the dominant nodule to the pleura, nodule location and nodule morphology (benign e.g. lentiform/nonbenign e.g. irregular) were determined by a reader blinded to benign vs malignant outcome. The impact of down-classification of pleural nodules was assessed.*Results 2,813 patients (62±5 years, 1717 men) with 4,408 non-calcified nodules (NCNs) were studied. 1073 nodules measuring 6-10 mm were included. Of these, 348 (32.4%) were pleural. The adoption of a classification scheme of pleural nodules equivalent to that for perifissural nodules per Lung-RADS 1.1 allowed down-classification of 310 nodules: 198 (89.2%) of category 3 nodules and 112 (88.9%) of category 4 pleural nodules to a category 2. None of the newly classified category 2 nodules were associated with malignancy. Only 2 out of total 348 pleural nodules (0.57%) were malignant (both non-benign morphology).*Conclusions This study demonstrates the low malignant potential of pleural nodules measuring 6mm to 10mm when benign in morphology. Extrapolating the current management of perifissural nodules to pleural nodules we estimate that 4.9% of patients would be down-classified to category 2 using Lung-RADS 1.1. This would lead to meaningful reduction of short-term follow-ups and false positive results.*Clinical Relevance/Application Pleural nodules constitute a significant proportion of nodules identified at LCS. Managing such nodules similar to perifissural nodules would help reduce false positive results.

RESULTS

2,813 patients (62±5 years, 1717 men) with 4,408 non-calcified nodules (NCNs) were studied. 1073 nodules measuring 6-10 mm were included. Of these, 348 (32.4%) were pleural. The adoption of a classification scheme of pleural nodules equivalent to that for perifissural nodules per Lung-RADS 1.1 allowed down-classification of 310 nodules: 198 (89.2%) of category 3 nodules and 112 (88.9%) of category 4 pleural nodules to a category 2. None of the newly classified category 2 nodules were associated with malignancy. Only 2 out of total 348 pleural nodules (0.57%) were malignant (both non-benign morphology).

CLINICAL RELEVANCE/APPLICATION

Pleural nodules constitute a significant proportion of nodules identified at LCS. Managing such nodules similar to perifissural nodules would help reduce false positive results.

SSCH08-6   **Might Lung Cancer Screening Mortality Benefits Be Even Greater Than Expected Once More African American/Black Smokers Are Included?**

Participants
Ashley Prosper, MD, Los Angeles, California (*Presenter*) Nothing to Disclose

PURPOSE

The National Lung Screening Trial demonstrated a 20% reduction in lung cancer mortality with annual lung cancer screening using low dose CT of the chest (LDCT) as compared to chest radiography. African American/Black (AA/Black) individuals comprised 4.4% of the NLST study population. Recognizing that AA/Black individuals are disproportionately affected by lung cancer, but experienced greater mortality reduction benefits with LDCT screening as compared to White individuals in the NLST, we sought to estimate mortality reduction benefits for synthetic populations with higher proportions of AA/Black individuals.*Methods and Materials Aiming to extrapolate results from the NLST to target populations with varying proportions of AA/Black individuals, a transportability formula was applied in secondary analysis of original NLST data. Transportability allows for extrapolation of treatment effects seen in randomized clinical trials to target populations in which the treatments or interventions are being considered. NLST results were transported to synthetic populations with 1) varying proportions of AA/Black individuals, 2) varying proportions AA/Black and female individuals, 3) varying proportions AA/Black and current smokers. The 95% confidence intervals (CIs) were calculated by repeating the analyses on 200 bootstrapped samples. All statistical analyses were performed with R version 4.0.2.*Results Increasing the proportions of AA/Black individuals in our synthetic populations resulted in greater relative reduction of lung cancer mortality with LDCT screening than seen in the NLST. For example, in a population with 40% AA/Black individuals, relative reduction in lung cancer mortality with LDCT screening increased to 26% (95% CI: 3-42) across the population as compared to 20% in the NLST.*Conclusions Extrapolating results from the NLST to populations with higher proportions of AA/Black individuals suggests that the mortality benefit achievable across a population with LDCT may be greater than that estimated by the NLST.*Clinical Relevance/Application These results emphasize the importance of building equitable and inclusive screening programs.

RESULTS

Increasing the proportions of AA/Black individuals in our synthetic populations resulted in greater relative reduction of lung cancer mortality with LDCT screening than seen in the NLST. For example, in a population with 40% AA/Black individuals, relative reduction in lung cancer mortality with LDCT screening increased to 26% (95% CI: 3-42) across the population as compared to 20% in the NLST.

CLINICAL RELEVANCE/APPLICATION

These results emphasize the importance of building equitable and inclusive screening programs.

SSPD05-3   Physeal Diffusion Tensor Tractography ROI Automation With A 3D Convolutional Neural Network

Participants
Simukayi Mutasa, MD, Newport Beach, California (*Presenter*) Nothing to Disclose

PURPOSE

There is growing research in diffusion tensor imaging (DTI) for providing metrics and images of physeal structure and function, particularly in evaluating children with possible growth disorders. There is a need for a faster automated process to segment the diffusion data, however. We utilized a deep learning algorithm to automatically generate a region of interest (ROI) for use in fully automatic diffusion tensor tractography of cartilage columns in the distal femoral physis.*Methods and Materials Following IRB approval, the authors retrospectively analyzed 80 knee DTI studies from 40 children including 20 neuroblastoma survivors with growth failure and 20 matched controls. Manual binary segmentation of the femoral physis on B0 images was performed on all 80 sequences. Saved volumes were automatically cropped to a 40x24x40 voxel 3-dimensional ROI including the distal femoral physis, femoral condyles, and proximal tibia. A novel, fully connected CNN based on a 3D modification of the U-Net architecture was trained on the output volumes (n=70) to generate segmentation masks of only the distal femoral physis. A holdout set of B0 sequences (n=10) was segregated prior to training to serve as the testing set. Training data augmentation mainly included random rigid affine rotation of the input volumes about the 3 axes and simulated Gaussian noise generation. The segmentation network was trained for 600 epochs. Software code was written in Python v3.6 using the TensorFlow v1.13 module on a Linux workstation with two NVidia Titan X GPUs.*Results The overall mean Dice correlation coefficient was 0.680 with a Matthews Correlation Coefficient of 0.672. Manual extraction and segmentation took 10 minutes per volume and had an interobserver correlation of 0.82, whereas DL segmentation took <1 second per volume and was deterministic, always producing the same result for a given input.*Conclusions Deep learning (DL) techniques can be applied to B0 sequences in DTI examinations in order to generate a deterministic ROI of the distal femoral physis. DL automates physeal mapping, increasing speed, and decreasing variability of tractography.*Clinical Relevance/Application Speeding up the process of tractography estimation can accelerate research in measuring physeal volume change which can illuminate disorders in children's growth and development. Along with guide surgical treatment for adolescence with injuries involving or near the physis.

RESULTS

The overall mean Dice correlation coefficient was 0.680 with a Matthews Correlation Coefficient of 0.672. Manual extraction and segmentation took 10 minutes per volume and had an interobserver correlation of 0.82, whereas DL segmentation took <1 second per volume and was deterministic, always producing the same result for a given input.

CLINICAL RELEVANCE/APPLICATION

Speeding up the process of tractography estimation can accelerate research in measuring physeal volume change which can illuminate disorders in children's growth and development. Along with guide surgical treatment for adolescence with injuries involving or near the physis.

SSPD05-4   Diagnosis Of Bone Marrow Metastases In Children And Young Adults With Solid Tumors:18F-FDG-PET Or DW-MRI?

Participants
Ali Rashidi, MD, Stanford, California (*Presenter*) Nothing to Disclose

PURPOSE

To compare the diagnostic performance of 18F-labeled fluorodeoxyglucose (18F-FDG) enhanced positron emission tomography (PET) and diffusion-weighted magnetic resonance imaging (DW-MRI) in the diagnosis of bone marrow metastases in children and young adults with solid malignancies.*Methods and Materials In a prospective clinical trial, we performed 64 simultaneous 18F-FDG-PET and DW-MRI scans (with a gadolinium chelate (gadobutrol, Gd) or an iron oxide nanoparticle compound (ferumoxytol)), including 21 baseline and 43 post-chemotherapy scans on twenty-three children and young adults (mean age 16.8 +/- 5.1 years, 16 males, 7 females) with bone marrow metastases. Four reviewers determined the presence or absence of 925 bone marrow metastases on 18F-FDG-PET and DW-MRI and measured the tumor-to-bone marrow contrast on 18F-FDG-PET and DW-MRI by calculating the difference between tumor and bone marrow standardized uptake values (SUV) and signal-to-noise ratios (SNR), respectively. The one-sample Wilcoxon test and Generalized Estimation Equation were used for statistical analysis.*Results At baseline, a high tumor-to-bone marrow contrast was detected in DW-MRI (SNR: 1069.57 +/- 815.45%) and 18F-FDG-PET (SUV: 1258.39 +/- 1325.95%, p=0.539). The sensitivities and specificities were 87.7% and 100%, respectively, for DW-MRI, as well as 95.4%, and 100% for 18F-FDG-PET, (p = 0.206). On post-treatment scans, the lesion-to-bone marrow contrast was higher on DW-MRI (SNR: 794.44 +/- 721.89%) compared to 18F-FDG-PET (SUV: 501.98 +/- 727.36 %; p=0.064). The sensitivities and specificities were 89.7% and

100% respectively, for DW-MRI and 89.1% and 100% for 18F-FDG-PET (p>0.999). Ferumoxytol-enhanced DW-MRI scans had higher diagnostic accuracy compared to Gd-enhanced DW-MRI scans (p=0.002). At both baseline and post-treatment scans, each modality missed lesions while the combination of DW-MRI and 18F-FDG-PET led to significantly higher sensitivities and specificities of 100% Compared to either technique alone (p<0.001).*Conclusions While either 18F-FDG-PET or DW-MRI can miss bone marrow metastases, the combined 18F-FDG-PET and DW-MRI is the most precise modality in the detection of bone marrow metastases in children and young adults.*Clinical Relevance/Application Both DW-MRI and 18F-FDG-PET can miss bone marrow metastases. The combined 18F-FDG-PET and DW-MRI can detect accurately the lesions missed on either modality alone.

RESULTS

At baseline, a high tumor-to-bone marrow contrast was detected in DW-MRI (SNR: 1069.57 +/- 815.45%) and 18F-FDG-PET (SUV: 1258.39 +/- 1325.95%, p=0.539). The sensitivities and specificities were 87.7% and 100%, respectively, for DW-MRI, as well as 95.4%, and 100% for 18F-FDG-PET, (p = 0.206). On post-treatment scans, the lesion-to-bone marrow contrast was higher on DW-MRI (SNR: 794.44 +/- 721.89%) compared to 18F-FDG-PET (SUV: 501.98 +/- 727.36 %; p=0.064). The sensitivities and specificities were 89.7% and 100% respectively, for DW-MRI and 89.1% and 100% for 18F-FDG-PET (p>0.999). Ferumoxytol-enhanced DW-MRI scans had higher diagnostic accuracy compared to Gd-enhanced DW-MRI scans (p=0.002). At both baseline and post-treatment scans, each modality missed lesions while the combination of DW-MRI and 18F-FDG-PET led to significantly higher sensitivities and specificities of 100% Compared to either technique alone (p<0.001).

CLINICAL RELEVANCE/APPLICATION

Both DW-MRI and 18F-FDG-PET can miss bone marrow metastases. The combined 18F-FDG-PET and DW-MRI can detect accurately the lesions missed on either modality alone.

SSPD05-5 Quantitative Magnetic Resonance Imaging Features Characterizing Pediatric Neuroblastic Tumours At Diagnosis

Participants
Andrea S. Doria, MD, Toronto, Ontario (*Presenter*) Research Grant, Shire plc;Research Grant, Novo Nordisk AS;

PURPOSE

Pediatric neuroblastoma is the most common solid tumour in childhood, comprising of malignant and benign types. These neoplasms derive from neural crest cells and arise from the dorsal root ganglion of the spinal cord or the medulla of the adrenal gland. Currently, there are no quantifiable non-invasive predictors of severity of disease, which relies on histopathological findings obtained through biopsy or at surgical diagnosis.The purpose of this study is To determine the relationship between magnetic resonance imaging (MRI) features and severity of neuroblastic tumours at the time of diagnosis. In particular, the study aims to establish the diagnostic accuracy of quantifiable MRI features to differentiate between malignant and benign types.Hypothesis: The hypothesis of this study is that quantifiable magnetic resonance imaging features can accurately predict the histopathology diagnosis.*Methods and Materials The study design is retrospective cross-sectional with the series of cases derived from a single study site (SickKids Hospital in Toronto, Canada) diagnosed between 2008 to 2020. Research Ethics Board approval was granted in accordance with ethical considerations. Inclusion criteria: diagnosis with one of the neuroblastic tumours by histopathology reference standard and diffusion-weighted imaging (DWI) MRI obtained within a month of pathology date. Exclusion criteria: no pathology or in-house DWI. The primary outcome measured was the diagnostic accuracy of two quantifiable MRI features, apparent diffusion coefficient (ADC) from DWI and total tumour volume.*Results Preliminary results indicate that the lower the ADC value, the more likely the neuroblastic tumour is a malignant type (neuroblastoma or ganglioneuroblastoma-nodular). The diagnostic accuracy of ADC, determined by the area under the curve (AUC) was 84%. An ADC cut-off value of 1.08 x 10^3 mm/s (to distinguish malignant from benign neuroblastic tumours) was determined by the peak of the ROC curve (86% sensitivity, 73% specificity).*Conclusions MRI is a non-invasive imaging procedure with no ionizing radiation exposure. Calculation of ADC from DWI does not require contrast and thus can avoid potential contrast issues. ADC derived from DWI-MRI can differentiate malignant from benign neuroblastic tumours with high accuracy. Given the low risks and high accuracy, we recommend that this quantifiable MRI feature be included in the diagnostic assessment of all neuroblastic tumours.*Clinical Relevance/Application This knowledge can help guide clinical decisions such as the need for further testing and treatment.

RESULTS

Preliminary results indicate that the lower the ADC value, the more likely the neuroblastic tumour is a malignant type (neuroblastoma or ganglioneuroblastoma-nodular). The diagnostic accuracy of ADC, determined by the area under the curve (AUC) was 84%. An ADC cut-off value of 1.08 x 10^3 mm/s (to distinguish malignant from benign neuroblastic tumours) was determined by the peak of the ROC curve (86% sensitivity, 73% specificity).

CLINICAL RELEVANCE/APPLICATION

This knowledge can help guide clinical decisions such as the need for further testing and treatment.

SSGI03-2   MRI Features Of HCC Histology Subtypes And Combined HCC-cholangiocarcinoma In American And French Cohort

Participants
Ali Serhal, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the prevalence of hepatocellular carcinoma (HCC) histology subtypes and combined hepatocellular-cholangiocarcinoma (cHCC-CCA) and to look for characteristics imaging features of the subtypes in a North American and European patient population recruited from tertiary centers.*Methods and Materials 120 HCCs and 19 cHCC-CCAs in 116 patients were included in the first subgroup (United States) and 190 HCCs and 44 cHCC-CCAs in 216 patients were included in the second subgroup (France). All patients had preoperative MRI and were classified into different histology subtypes based on surgical pathology. A radiologist scored all lesions on MRI for different parameters including LI-RADS features, type of enhancement, fat, diffusion signal, T2 signal and necrosis. Underlying liver disease and different parameters were compared between both groups.*Results 73 % were male. The most common causes of chronic liver disease were HCV infection (27%), alcohol abuse (18%), HBV (16%), NASH (14%), combined HCV and alcohol abuse (6%). Conventional HCC subtype was by far the most common subtype (56%), followed by combined hepatocellular-cholangiocarcinoma (cHCC-CCA, 14%), macrotrabecular massive (MTM) subtype (15%), steatohepatitic subtype (13%), and lymphoepithelioma like rich subtype (2.9%). Fat in mass was consistently seen more frequently in the steatohepatitic HCCs (70% versus 16%, p<0.01). Substantial necrosis was consistently seen in the MTM HCCs (61% versus 11%, p<0.01). The presence of rim-like enhancement (LR-M) and capsular retraction were more consistent with cHCC-CCAs (65% versus 8% and 31.5% versus 0% respectively, p<0.01). Sarcomatoid and neutrophil rich tumors although uncommon were more often large with necrosis.*Conclusions Our preliminary results suggest that imaging can play a role in differentiating HCC histologic subtypes and cHCC-CCAs with possible prognostic implications. imaging characteristics of the relevant subtypes were similar between the two subgroups, as well as those associated with cHCC-CCAs.*Clinical Relevance/Application Hepatocellular carcinoma can be divided into several distinct histologic subtypes of HCC which have distinct growth and morphological and prognostic implications. We aim to evaluate the imaging features of different subtype.

RESULTS

73 % were male. The most common causes of chronic liver disease were HCV infection (27%), alcohol abuse (18%), HBV (16%), NASH (14%), combined HCV and alcohol abuse (6%). Conventional HCC subtype was by far the most common subtype (56%), followed by combined hepatocellular-cholangiocarcinoma (cHCC-CCA, 14%), macrotrabecular massive (MTM) subtype (15%), steatohepatitic subtype (13%), and lymphoepithelioma like rich subtype (2.9%). Fat in mass was consistently seen more frequently in the steatohepatitic HCCs (70% versus 16%, p<0.01). Substantial necrosis was consistently seen in the MTM HCCs (61% versus 11%, p<0.01). The presence of rim-like enhancement (LR-M) and capsular retraction were more consistent with cHCC-CCAs (65% versus 8% and 31.5% versus 0% respectively, p<0.01). Sarcomatoid and neutrophil rich tumors although uncommon were more often large with necrosis.

CLINICAL RELEVANCE/APPLICATION

Hepatocellular carcinoma can be divided into several distinct histologic subtypes of HCC which have distinct growth and morphological and prognostic implications. We aim to evaluate the imaging features of different subtype.

SSGI03-4   Early Sonographic Features Of Gangrenous Cholecystitis: Mucosal Discontinuity And Echogenic Pericholecystic Fat

Participants
Justin Tse, MD, Cerritos, California (*Presenter*) Research Grant, General Electric Company ;Research Grant, Bayer AG

PURPOSE

To identify early sonographic features of gangrenous cholecystitis.*Methods and Materials 101 patients with acute cholecystitis

To identify early sonographic features of gangrenous cholecystitis.*Methods and Materials 101 patients with acute cholecystitis and a pre-operative sonogram were retrospectively reviewed by 3 radiologists in this IRB-approved and HIPAA-compliant study. Imaging data were correlated with histologic findings and compared using the Fisher's exact test or Student t test with p<0.05 to determine statistical significance.*Results 48 patients had gangrenous cholecystitis and 53 had non-gangrenous acute cholecystitis. Patients with gangrenous cholecystitis tended to be older (67±17 vs 48±18 years; p=0.0001), male (ratio of male:female 2:1 vs 0.6:1; p=0.005), tachycardic (60% vs 28%; p=0.001), and have a history of diabetes mellitus (25% vs 8%; p=0.001). Median time between pre-operative sonogram and surgery was 1 day. On imaging, patients with gangrenous cholecystitis were more likely to have echogenic pericholecystic fat (p=0.001), mucosal discontinuity (p=0.010), and frank perforation (p=0.004), while no statistically significant differences were seen in presence of sloughed mucosa (p=0.104), pericholecystic fluid (p=0.523) or wall striations (p=0.839). In patients with gangrenous cholecystitis and echogenic pericholecystic fat, a smaller subset had concurrent mucosal discontinuity (57%), and a smaller subset of those with mucosal discontinuity also had concurrent frank perforation (58%). The positive likelihood ratios for gangrenous cholecystitis with echogenic fat and mucosal discontinuity were 4.6 (95% confidence interval 1.9-11.3) and 14.4 (2.0-106), respectively. All patients with frank perforation had gangrenous cholecystitis.*Conclusions Among surgical patients presenting with acute cholecystitis, echogenic pericholecystic fat and mucosal discontinuity may be early precursors to frank perforation and were all associated with gangrenous cholecystitis.*Clinical Relevance/Application Echogenic pericholecystic fat and mucosal discontinuity are early sonographic findings that may suggest gangrenous cholecystitis prior to late findings of frank perforation.

RESULTS

48 patients had gangrenous cholecystitis and 53 had non-gangrenous acute cholecystitis. Patients with gangrenous cholecystitis tended to be older (67±17 vs 48±18 years; p=0.0001), male (ratio of male:female 2:1 vs 0.6:1; p=0.005), tachycardic (60% vs 28%; p=0.001), and have a history of diabetes mellitus (25% vs 8%; p=0.001). Median time between pre-operative sonogram and surgery was 1 day. On imaging, patients with gangrenous cholecystitis were more likely to have echogenic pericholecystic fat (p=0.001), mucosal discontinuity (p=0.010), and frank perforation (p=0.004), while no statistically significant differences were seen in presence of sloughed mucosa (p=0.104), pericholecystic fluid (p=0.523) or wall striations (p=0.839). In patients with gangrenous cholecystitis and echogenic pericholecystic fat, a smaller subset had concurrent mucosal discontinuity (57%), and a smaller subset of those with mucosal discontinuity also had concurrent frank perforation (58%). The positive likelihood ratios for gangrenous cholecystitis with echogenic fat and mucosal discontinuity were 4.6 (95% confidence interval 1.9-11.3) and 14.4 (2.0-106), respectively. All patients with frank perforation had gangrenous cholecystitis.

CLINICAL RELEVANCE/APPLICATION

Echogenic pericholecystic fat and mucosal discontinuity are early sonographic findings that may suggest gangrenous cholecystitis prior to late findings of frank perforation.

SSGI03-5 Using Nonparametric Bootstrap Method To Evaluate Normative (Reference) Ranges For Biliary System Measurements In Quantitative MRCP

Participants
Matt Kelly, PhD, Oxford, United Kingdom (*Presenter*) Employee, Perspectum Diagnostics Ltd;Stockholder, Perspectum Diagnostics Ltd

PURPOSE

Currently, ultrasound, endoscopic retrograde and magnetic resonance cholangiopancreatography (ERCP, MRCP) are the most commonly used imaging modalities to assess the biliary system and common bile duct (CBD), however, these qualitative assessments are subjective and lack robust quantitative characterisation. Quantitative MRCP (MRCP+) is a novel method which builds three-dimensional models of the biliary tree and enables measurement of bile duct widths and automatic detection of candidate strictures and dilatations. This study aimed to measure the normative ranges for individual duct-related metrics, tree-level summary metrics and bile duct abnormality related metrics generated from MRCP+ using the non-parametric bootstrap method.*Methods and Materials 20 healthy volunteers underwent 3D heavily T2-weighted MRCP imaging on a Siemens Prisma 3T. The acquired images were then post-processed with MRCP+ and 92 variables were generated, including 34 biliary anatomy related metrics (e.g. biliary tree volume, CBD diameter), and 58 bile duct abnormality related metrics (e.g., the total length of dilated/strictured ducts). The non-parametric bootstrap method [Coskun et al. 2013] was used to increase the sample size before the lower and upper limits of each variable were calculated.*Results Normative ranges for each individual duct metric can be seen in Table 1. A normative range for the median CBD diameter of 3.2 - 5.0 mm was found. This range is comparable to those reported in literature, where upper limits have been shown to range from 5-8 mm. Normative ranges of 2.7 - 6.9 ml and 4.4 - 20.2 ml were obtained for biliary tree volume and gallbladder volume, respectively. The normative range for the total length of the ducts affected by a candidate stricture/dilatation was calculated as 26.0 - 121.0 mm. Due to the common and uncommon anatomic variations present in 42% of the healthy population, the presence of candidate strictures/dilatations can be considered part of the "normal" biliary anatomy and is not representative of disease pathology in healthy volunteers, and the values are typically elevated in the diseased population.*Conclusions The ranges of biliary anatomy related metrics in this study agreed with those previously reported assessment., moreover, it is the first time to report the normative (reference) ranges for whole biliary tree and bile duct abnormality related metrics (e.g. the length of ducts affected by candidate strictures/dilatations) in quantitative MRCP using the non-parametric bootstrap method in a small cohort of healthy volunteers.*Clinical Relevance/Application Normative (reference) ranges for biliary-related variables obtained from MRCP+ have the potential to improve clinical management of patients with biliary diseases.

RESULTS

Normative ranges for each individual duct metric can be seen in Table 1. A normative range for the median CBD diameter of 3.2 - 5.0 mm was found. This range is comparable to those reported in literature, where upper limits have been shown to range from 5-8 mm. Normative ranges of 2.7 - 6.9 ml and 4.4 - 20.2 ml were obtained for biliary tree volume and gallbladder volume, respectively. The normative range for the total length of the ducts affected by a candidate stricture/dilatation was calculated as 26.0 - 121.0 mm. Due to the common and uncommon anatomic variations present in 42% of the healthy population, the presence of candidate strictures/dilatations can be considered part of the "normal" biliary anatomy and is not representative of disease pathology in healthy volunteers, and the values are typically elevated in the diseased population.

CLINICAL RELEVANCE/APPLICATION

Normative (reference) ranges for biliary-related variables obtained from MRCP+ have the potential to improve clinical management of patients with biliary diseases.

Preoperative CT-body Composition In Patients With Perihilar Cholangiocarcinoma - Specific Body Composition Types In Correlation To Perioperative Morbidity And Outcome

Laura Segger, MD, Berlin, Germany (*Presenter*) Nothing to Disclose

PURPOSE

As sarcopenic cancer patients appear to have a poor outcome during cancer treatments the aim of this study was to evaluate specific body composition types (sarcopenia, sarcopenic obesity and myosteatosis) in patients with perihilar cholangiocarcinoma (pCC) to evaluate the influence on peri- and postoperative morbidity and outcome.*Methods and Materials In this retrospective study, preoperative CT datasets of 197 patients with pCC, who underwent extended hemihepatectomy were evaluated. Single slice segmentations (lumbar vertebra 3 as landmark) of the psoas muscle, total abdominal muscle mass (TAMA), visceral and subcutaneous adipose tissue were performed. Lumbar skeletal muscle index (LSMI) was calculated by normalizing the TAMA by patients' height and was used to define sarcopenia, and sarcopenic obesity. Myosteatosis was based on the density (HU) of the segmented muscles. These body composition parameters were correlated to postoperative complications and outcome.*Results 61,4% (121/197) of the patients were sarcopenic, 3,6% (7/197) had sarcopenic obesity and 20,8% (41/197) had myosteatosis. Neither sarcopenia nor sarcopenic obesity were independent risk factors for the occurrence of peri- or postoperative complications. However, in patients with sarcopenic obesity the 90-day-survival was significantly decreased (p=0.009). Myosteatosis was associated with a prolonged ICU stay (p=0.014), poorer disease-free survival (p=0.003) and overall survival (p<0.001).*Conclusions Sarcopenia does not increase perioperative morbidity in patients with pCC undergoing extended hemihepatectomy, but sarcopenic obesity is associated with a poorer 90-day-survival. Myosteatosis is linked to prolonged ICU stays and decreased disease-free survival and overall survival.*Clinical Relevance/Application Preoperative staging CT scans are routinely performed in every patient, however body composition is usually neglected. Our study shows the value of identifying certain body composition types to optimize individual risk and outcome assessment, and should encourage their implementation into routine clinical practice.

RESULTS

61,4% (121/197) of the patients were sarcopenic, 3,6% (7/197) had sarcopenic obesity and 20,8% (41/197) had myosteatosis. Neither sarcopenia nor sarcopenic obesity were independent risk factors for the occurrence of peri- or postoperative complications. However, in patients with sarcopenic obesity the 90-day-survival was significantly decreased (p=0.009). Myosteatosis was associated with a prolonged ICU stay (p=0.014), poorer disease-free survival (p=0.003) and overall survival (p<0.001).

CLINICAL RELEVANCE/APPLICATION

Preoperative staging CT scans are routinely performed in every patient, however body composition is usually neglected. Our study shows the value of identifying certain body composition types to optimize individual risk and outcome assessment, and should encourage their implementation into routine clinical practice.

SSPH02-2   The Potential Benefits Of Pre-training In AI Algorithm Development For COVID-19 Classification Models Using Chest X-ray Images

Participants
Xin Tie, BS, Madison, Wisconsin (*Presenter*) Nothing to Disclose

PURPOSE

Development of artificially intelligent (AI) classification algorithms for COVID-19 patient stratification is of great clinical significance. Due to the fast-growing nature of the pandemic and the difficulty in sharing medical data, models are often trained from small datasets. The purpose of this work was to study the benefit of pre-training in this setting.*Methods and Materials A binary classification model was developed to differentiate high risk COVID-19 cases from non-COVID-19 patients using chest x-ray radiographs (CXR). Three datasets were used for model development: an NIH (CXR) dataset curated in the pre-COVID era, a COVID dataset from the Henry Ford Health System, and a COVID-19 dataset curated and made publicly available in Spain (BIMCV). To investigate the potential benefits of pre-training for AI model development, we studied its impact in the following two different scenarios: 1) Development of a site-specific model from scratch for the Henry Ford dataset and 2) transfer learning from the Henry Ford model from 1) to the Spain data set with varying amounts of training data sizes (from 200 patients to 4,938 patients). The performance of the model was quantified by the area under the receiver operating characteristics curve (AUC).*Results 1) Using the NIH dataset for pre-training, the AUC of the Henry Ford site-specific model on both the internal test sets and external test sets were significantly improved (>0.04), when compared to the model without pre-training. 2) In transfer learning from the Henry Ford model to the Spain model, with pre-training using the Henry Ford dataset, AUC improved by 0.01 to 0.03 for the varying training dataset from the Spain dataset. All the reported performance improvements were statistically significant.*Conclusions Pre-training using a publicly available NIH chest x-ray image dataset or a COVID data set from another site improves the performance of the classification model under the two different scenarios studied.*Clinical Relevance/Application The results reported in this study shed new light on AI model development and clinical deployment from one site to another by transfer learning.

RESULTS

1) Using the NIH dataset for pre-training, the AUC of the Henry Ford site-specific model on both the internal test sets and external test sets were significantly improved (>0.04), when compared to the model without pre-training. 2) In transfer learning from the Henry Ford model to the Spain model, with pre-training using the Henry Ford dataset, AUC improved by 0.01 to 0.03 for the varying training dataset from the Spain dataset. All the reported performance improvements were statistically significant.

CLINICAL RELEVANCE/APPLICATION

The results reported in this study shed new light on AI model development and clinical deployment from one site to another by transfer learning.

SSPH02-5   Fully Automated Artifact Reduction Method For Time-resolved Cone-beam CT Angiography

Participants
Chengzhu Zhang, BS, Madison, Wisconsin (*Presenter*) Nothing to Disclose

PURPOSE

Cone-beam CT angiography (CBCTA) acquired in the angiography suite often presents mis-registration artifacts due to patient motion and gantry instability. In this work, an automated machine learning method was developed to effectively eliminate artifacts in time-resolved CBCTA for image guidance in angiography suites.*Methods and Materials In the developed method, image voxels in initially acquired time-resolved CBCTA image volumes are classified into four clusters using a K-means clustering algorithm. For each cluster, a pre-trained deep learning model was used to score each cluster as artifacts or vessels. If the score is higher than 0.5, the cluster is considered to be a vessel, otherwise it is considered an artifact. This process of clustering-classifying is iteratively proceeded until the stopping criterion is satisfied. This fully automated algorithm was tested on a clinical cohort of 55 time-resolved CBCTA exams. Among them, 5 clinical cases were used for the training of the deep classifier. The remaining 50 clinical cases were used to test the performance. There are 14 cases with few artifacts, 15 cases with moderate artifacts, and 21 cases with severe artifacts. Time-to-arrival (TOA) color maps were used to visualize the result (warm color indicates earlier enhancement). To quantify artifact reduction level, a metric of image sparsity defined by the percentage of non-zero voxels was used.*Results 1) Significant artifact reduction has been achieved for all 50 clinical cases in the test cohort regardless of their initial artifact levels. 2) After artifact reduction, the visualization of TOA maps clearly shows different contrast enhancement phases of vessels with image sparsity of 5.1±3.4%, meaning >90% 'artifact' voxels are removed.*Conclusions The automated artifact reduction machine learning algorithm can effectively eliminate most of the mis-registration artifacts in time-resolved CBCTA.*Clinical Relevance/Application With artifact reduction using the developed fully automated method, time-resolved CBCTA image quality is

significantly improved for clinical uses in image-guided interventions.

RESULTS

1) Significant artifact reduction has been achieved for all 50 clinical cases in the test cohort regardless of their initial artifact levels. 2) After artifact reduction, the visualization of TOA maps clearly shows different contrast enhancement phases of vessels with image sparsity of 5.1±3.4%, meaning >90% 'artifact' voxels are removed.

CLINICAL RELEVANCE/APPLICATION

With artifact reduction using the developed fully automated method, time-resolved CBCTA image quality is significantly improved for clinical uses in image-guided interventions.

SSPH02-6   Accurate And Reliable Liver Steatosis Assessment From Conventional Ultrasound Images Trained With Subjective Ratings

Participants
Bowen Li, Bethesda, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Conventional ultrasound (US) is the frontline screening modality for liver steatosis. However, US-based diagnoses suffer from low intra- and inter-rater consistency. Other modalities, e.g., FibroScan, can provide quantitative measurements but their availability is limited. Computer-aided diagnosis (CAD) models applied directly to US could provide a quantitative assessment. But, training on subjective US diagnosis datasets, the only viable source of large-scale data, will expose them to contradictory label noise and biases. To address this challenge, we introduce auto-decoded deep latent embeddings (ADDLE).*Methods and Materials We retrospectively collected conventional US images from 3,405 patients, 32,188 studies, and 275,291 images. Images from 16 types of US scanners were used. Patients with hepatitis B (34.2%), hepatitis C (41.7%), nonalcoholic steatohepatitis (12.3%) and other diseases (11.8%) were all included. US diagnoses were produced by 65 different raters over the course of their clinical work. ADDLE explicitly models the tendencies of each rater, does not expect multiple raters per image in training, and does not increase in complexity as more raters are added. We use the ResNet18 deep learning model as the ADDLE backbone and train it to predict liver steatosis severity (as healthy, mild, moderate, or severe). Images from 4 liver viewpoints were used (left liver lobe, right liver lobe, liver-kidney contrast, and subcostal), and the final predictions correspond to the average across viewpoints. A dataset with 148 patients with gold standard histopathology fatty percentage served as the evaluation cohort.*Results High diagnostic performance was observed: area under the curve (AUC) of the ROC curve to classify greater or equal to mild steatosis, greater or equal to moderate steatosis, and equal to severe steatosis grades were 0.957, 0.931, and 0.899, respectively. The partial AUC (AUCp) for diagnosing severe steatosis was over 10% better than standard ResNet18, where we only consider the region with false positive rate<0.30. ADDLE also outperformed several competitor label-denoising methods and FibroScan.*Conclusions We proposed ADDLE to model the tendencies of subjective raters in a large-scale US steatosis dataset. Reported AUROCs were high and outperformed FibroScan.*Clinical Relevance/Application Our CAD system can provide an objective liver steatosis assessment to complement other important clinical biomarkers and factors. This can add additional support for accessible clinical decision making.

RESULTS

High diagnostic performance was observed: area under the curve (AUC) of the ROC curve to classify greater or equal to mild steatosis, greater or equal to moderate steatosis, and equal to severe steatosis grades were 0.957, 0.931, and 0.899, respectively. The partial AUC (AUCp) for diagnosing severe steatosis was over 10% better than standard ResNet18, where we only consider the region with false positive rate<0.30. ADDLE also outperformed several competitor label-denoising methods and FibroScan.

CLINICAL RELEVANCE/APPLICATION

Our CAD system can provide an objective liver steatosis assessment to complement other important clinical biomarkers and factors. This can add additional support for accessible clinical decision making.

SSHN01-1   Combined Machine Learning And Resting-state FMRI Reveals Aberrant Static And Dynamic Interhemispheric Functional Connectivity In Patients With Thyroid-associated Ophthalmopathy

Participants
Qian Wu, Nanjing, China (*Presenter*) Nothing to Disclose

PURPOSE

Thyroid-associated ophthalmopathy (TAO) is a debilitating and sight-threatening autoimmune orbital disease that severely impairs patients' quality of life. Besides the most common ophthalmic manifestations, the emotional and psychiatric disturbances are also usually observed in clinical settings. This study was to investigate the interhemispheric functional connectivity alterations in TAO patients using resting-state functional magnetic resonance imaging (rs-fMRI).*Methods and Materials Twenty-eight TAO patients and 22 healthy controls (HCs) underwent rs-fMRI scans. Static and dynamic voxel-mirrored homotopic connectivity (VMHC) values were calculated and compared between the two groups. A linear support vector machine (SVM) classifier was used to examine the performance of static and dynamic VMHC differences in distinguishing TAOs from HCs.*Results Compared with HCs, TAOs showed decreased static VMHC in lingual gyrus (LG)/calcarine (CAL), middle occipital gyrus, postcentral gyrus, superior parietal lobule, inferior parietal lobule and precuneus. Meanwhile, TAOs demonstrated increased dynamic VMHC in orbitofrontal cortex (OFC). In TAOs, static VMHC in LG/CAL was positively correlated with visual acuity ($r = 0.412$, $P = 0.036$), whilst dynamic VMHC in OFC was positively correlated with HARS score ($r = 0.397$, $P = 0.044$) and HDRS score ($r = 0.401$, $P = 0.042$). The SVM model showed good performance in distinguishing TAOs from HCs (area under the curve, 0.971; average accuracy, 94%).*Conclusions TAO patients had altered static and dynamic VMHC in the occipital, parietal and orbitofrontal areas, which could serve as personalized neuroimaging prediction markers of TAO.*Clinical Relevance/Application This study provided novel insights into brain function abnormalities in TAO patients, and indicated that neuropsychological aspect of the disease should be noticed in clinical diagnosis and treatment.

RESULTS

Compared with HCs, TAOs showed decreased static VMHC in lingual gyrus (LG)/calcarine (CAL), middle occipital gyrus, postcentral gyrus, superior parietal lobule, inferior parietal lobule and precuneus. Meanwhile, TAOs demonstrated increased dynamic VMHC in orbitofrontal cortex (OFC). In TAOs, static VMHC in LG/CAL was positively correlated with visual acuity ($r = 0.412$, $P = 0.036$), whilst dynamic VMHC in OFC was positively correlated with HARS score ($r = 0.397$, $P = 0.044$) and HDRS score ($r = 0.401$, $P = 0.042$). The SVM model showed good performance in distinguishing TAOs from HCs (area under the curve, 0.971; average accuracy, 94%).

CLINICAL RELEVANCE/APPLICATION

This study provided novel insights into brain function abnormalities in TAO patients, and indicated that neuropsychological aspect of the disease should be noticed in clinical diagnosis and treatment.

SSHN01-2   Papillary Thyroid Cancer At Dual-energy CT: Iodine Maps Based Radiomics To Predict Extrathyroidal Extension And Recurrence

Participants
Qian Wu, Nanjing, China (*Presenter*) Nothing to Disclose

PURPOSE

To conduct iodine maps based radiomics to predict extrathyroidal extension (ETE) and to explore its prognostic value for recurrence-free survival (RFS) in papillary thyroid cancer (PTC).*Methods and Materials Total 452 PTC patients between June 2017 and June 2020 were retrospectively recruited. Radiomics features were extracted from non-contrast images, dual-phase mixed images and iodine maps, respectively. Random forest (RF) and least absolute shrinkage and selection operator (LASSO) were applied to build six rad-scores (non-contrast rad-score_RF; non-contrast rad-score_Lasso; mixed rad-score_RF; mixed rad-score_Lasso; iodine rad-score_RF; iodine rad-score_Lasso) respectively. Logistic regression was used to construct six radiomics models incorporating six rad-scores with clinical risk factors, and compared with clinical model alone. A Radiomics model that achieved highest performance was presented as a nomogram. Nomogram performance was determined by discrimination, calibration, clinical usefulness and prognosis evaluation.*Results Iodine rad-scores performed significantly better than mixed rad-scores no matter RF or LASSO used. Both of them outperformed non-contrast rad-scores. Iodine maps based radiomics models significantly surpassed clinical model. A radiomics nomogram incorporating size, capsule contact and iodine rad-score_RF was built with highest performance (training set, AUC = 0.784; validation set, AUC = 0.835). Stratified analysis confirmed the nomogram stability, especially in CT-reported ETE negative group (AUC = 0.692). Nomogram-predicted ETE risk was an independent preoperative predictor for RFS. High risk for ETE portended significantly lower RFS than that for low risk ($p < 0.001$).*Conclusions Iodine maps based radiomics might be a supporting tool for predicting ETE and subsequent recurrence risk in PTC patients, thus facilitate clinical decision making.*Clinical Relevance/Application Although PTC has a favorable prognosis, it is prone to local-regional recurrence. ETE

has been considered as an adverse prognostic factor for recurrence for PTC. Conventional imaging (US and CT) and clinical risk factors are insufficient in diagnosing or predicting ETE. Our study conducted radiomics analysis of iodine maps and compared it with the performance of conventional CT (mixed images) and a clinical model. We found radiomics of iodine maps performed significantly better than that of conventional CT images. An iodine maps based radiomics nomogram significantly surpassed the clinical model in predicting ETE and subsequent recurrence risk. The nomogram can help accurate prediction of ETE and prognosis for PTC patients, thus determine individualized treatment plans and reduce recurrence.

RESULTS

Iodine rad-scores performed significantly better than mixed rad-scores no matter RF or LASSO used. Both of them outperformed non-contrast rad-scores. Iodine maps based radiomics models significantly surpassed clinical model. A radiomics nomogram incorporating size, capsule contact and iodine rad-score_RF was built with highest performance (training set, AUC = 0.784; validation set, AUC = 0.835). Stratified analysis confirmed the nomogram stability, especially in CT-reported ETE negative group (AUC = 0.692). Nomogram-predicted ETE risk was an independent preoperative predictor for RFS. High risk for ETE portended significantly lower RFS than that for low risk (p < 0.001).

CLINICAL RELEVANCE/APPLICATION

Although PTC has a favorable prognosis, it is prone to local-regional recurrence. ETE has been considered as an adverse prognostic factor for recurrence for PTC. Conventional imaging (US and CT) and clinical risk factors are insufficient in diagnosing or predicting ETE. Our study conducted radiomics analysis of iodine maps and compared it with the performance of conventional CT (mixed images) and a clinical model. We found radiomics of iodine maps performed significantly better than that of conventional CT images. An iodine maps based radiomics nomogram significantly surpassed the clinical model in predicting ETE and subsequent recurrence risk. The nomogram can help accurate prediction of ETE and prognosis for PTC patients, thus determine individualized treatment plans and reduce recurrence.

SSHN01-6   Could Parathyroid Gland Assessment On Routine CT Prevent Morbidity From Undiagnosed Primary Hyperparathyroidism?

Participants
Christopher Nguyen, Winston Salem, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

Primary hyperparathyroidism (PHPT) conveys substantial patient morbidity and healthcare costs. Diagnosis often lags years behind initial disease manifestations. Failure to recognize PHPT delays curative therapy, and disease duration correlates with end-organ damage.We hypothesize that assessment for enlarged parathyroids on routine imaging (e.g., neck CT, chest CT) could facilitate earlier diagnosis of unrecognized PHPT. Our purposes are to determine visibility of abnormal parathyroid glands on routine contrast-enhanced CT (CECT) acquired prior to PHPT diagnosis and assess associated, potentially preventable PHPT-related morbidity.*Methods and Materials This single institution, retrospective study included patients undergoing parathyroidectomy for PHPT from 10/2015 to 10/2020 with at least one CECT prior to PHPT diagnosis.A neuroradiologist reviewed prior CECTs for enlarged parathyroid glands (estimated weight >60 mg using 0.63 mg/mm3 x L (mm) x W (mm) x H (mm)), blinded to subsequent localization imaging and operative reports. Enlarged glands were marked in PACS. A parathyroid surgeon then reviewed operative notes and pathology reports to determine whether the marked glands corresponded to pathologically-proven parathyroid lesions.PHPT-related comorbidities, including renal (kidney stones and declining renal function), bone (fragility fractures and declining bone density), and neurocognitive (memory loss and depression) manifestations were abstracted from the electronic medical record.*Results The final cohort included 39 patients with PHPT and a prior CECT (8 male, 31 female, median age 66 years).Enlarged glands were identified on prior CECT in 29 (74%), and these CECTs predated screening for PHPT by an average of 3.25 years. Marked glands corresponded to proven parathyroid lesions in 26 (90%), but clinical evidence of residual parathyroid disease remained in the 3 for whom marked glands were not removed.Of the 29 with enlarged glands on prior CECT, 13 (45%) developed at least 1 new PHPT-related renal (21%), bone (17%) or neurocognitive (17%) comorbidity in the interval between the CECT and first screening for PHPT. Most also complained of the common PHPT symptoms fatigue (79%) and weakness (52%).*Conclusions Enlarged parathyroid glands are frequently visible on routine CECTs acquired years prior to PHPT diagnosis. Screening for PHPT on the basis of enlarged glands could potentially prevent associated complications in almost half of such patients.*Clinical Relevance/Application By routinely assessing for enlarged parathyroid glands, radiologists may identify patients who would benefit from PHPT screening, which may decrease PHPT-associated morbidity and costs through earlier curative intervention.

RESULTS

The final cohort included 39 patients with PHPT and a prior CECT (8 male, 31 female, median age 66 years).Enlarged glands were identified on prior CECT in 29 (74%), and these CECTs predated screening for PHPT by an average of 3.25 years. Marked glands corresponded to proven parathyroid lesions in 26 (90%), but clinical evidence of residual parathyroid disease remained in the 3 for whom marked glands were not removed.Of the 29 with enlarged glands on prior CECT, 13 (45%) developed at least 1 new PHPT-related renal (21%), bone (17%) or neurocognitive (17%) comorbidity in the interval between the CECT and first screening for PHPT. Most also complained of the common PHPT symptoms fatigue (79%) and weakness (52%).

CLINICAL RELEVANCE/APPLICATION

By routinely assessing for enlarged parathyroid glands, radiologists may identify patients who would benefit from PHPT screening, which may decrease PHPT-associated morbidity and costs through earlier curative intervention.

SSBR02-3   Radiomic Features On Breast MRI Predict Upgrade Of DCIS Lesions To Invasive Breast Cancer

Participants
Dana Ataya, MD, Tampa, Florida (*Presenter*) Nothing to Disclose

PURPOSE

Identification of the subset of ductal carcinoma in-situ (DCIS) lesions diagnosed on core biopsy which will be upgraded to invasive breast cancer on excision would impact clinical and surgical management of patients. Using dynamic contrast-enhanced (DCE) breast MRI in patients imaged prior to excision, DCIS lesion voxels with similar DCE characteristics may be segmented into sub-regions (habitats) to quantify lesion heterogeneity. In this study, we investigated whether intralesional and peri-lesional heterogeneity quantified on DCE-MRI predicted DCIS upgrade to invasive malignancy.*Methods and Materials 76 DCIS lesions in 74 women were divided into training (43) and validation (33) cohorts. DCIS lesions were segmented by two radiologists on pre-operative DCE-MRI. Four perfusion parameters were used to generate voxel multi-parametric maps: wash-in (WIS) and washout (WOS) slopes, percentage enhancement (PE), and signal enhancement ratio (SER). Consensus clustering and superpixel maps divided each tumor into low, moderate, and high perfusion habitats. A fourth habitat included the breast parenchyma in two 3-mm concentric rings bordering the DCIS lesion. For each DCIS lesion, a 4x4 multiregional spatial interaction matrix produced 22 features. A network-based strategy explored feature similarities. A spectral clustering algorithm stratified two groups of high and low DCIS risk. A machine learning model clustered multiparametric maps in the validation set into tumor habitats. A semi-supervised label propagation algorithm tested the ability of the model to predict upgrade of DCIS lesions to invasive malignancy. The Pearson correlation coefficient, Wilcoxon signed-rank test, and a least absolute shrinkage and selection operator (LASSO) multivariable logistic regression method were used to analyze the data.*Results Patient age, DCIS lesion size, ER positivity, and grade were similar between the cohorts. The frequency of upgrade was similar in both cohorts (16.3% training; 18.2% validation). Distributions of the four perfusion parameters in each subregion and within both cohorts were examined. When whole-tumor and surrounding rings (WT+Ring) were investigated, the model predicted upgrade to invasive malignancy with 86% accuracy in training and 79% in the validation cohort. Subregion 2 significantly predicted upgrade in training [AUC: 0.74] and validation [AUC: 0.72] (p=0.0317).*Conclusions Intratumoral perfusion heterogeneity on dynamic contrast enhanced breast MRI shows promise in stratifying DCIS lesions at low-risk and high-risk of upgrade to invasive malignancy.*Clinical Relevance/Application Radiomic features on DCE-MRI can assist in stratifying DCIS lesions, impacting clinical and surgical management of patients.

RESULTS

Patient age, DCIS lesion size, ER positivity, and grade were similar between the cohorts. The frequency of upgrade was similar in both cohorts (16.3% training; 18.2% validation). Distributions of the four perfusion parameters in each subregion and within both cohorts were examined. When whole-tumor and surrounding rings (WT+Ring) were investigated, the model predicted upgrade to invasive malignancy with 86% accuracy in training and 79% in the validation cohort. Subregion 2 significantly predicted upgrade in training [AUC: 0.74] and validation [AUC: 0.72] (p=0.0317).

CLINICAL RELEVANCE/APPLICATION

Radiomic features on DCE-MRI can assist in stratifying DCIS lesions, impacting clinical and surgical management of patients.

SSBR02-5   Abbreviation Of Breast MRI In A Real-world Scenario: How Relevant Is An Abbreviation Of The Imaging Protocol?

Participants
Philipp Stelzer, Vienna, Austria (*Presenter*) Nothing to Disclose

PURPOSE

Magnetic resonance mammography (MRM) is the most sensitive test for detection of breast cancer. As a way to increase patient throughput, MRM protocols are increasingly abbreviated, thereby saving table time (TT). Currently, there is no consensus on what "abbreviated" MRM is and approaches vary. However, the number of patients that can be examined per MRI unit in a given time also critically depends on the table switching time (TST) between patients. This institutional audit aimed to collect breast MRI measurement times in different clinical scenarios.*Methods and Materials The IRB waived the necessity for informed consent for this institutional audit. Data collection was performed without informing the operating personnel about the audit to avoid bias. Data collection included the TT and TST of consecutive examinations in a large tertiary care center (n=49) and an out-patient radiology

center (n=30). We also calculated virtual TT based on the data from our institution for two further abbreviated protocols (T2 + T1 native + early post-contrast and T1 native + early post-contrast only). TST, TT, switch-imaging-ratio (TST/TT) and relative switching time (TST/(TST+TT)) are presented as Median with IQR, statistic testing was done using Mann-Whitney-U-Test with an alpha of 0.05 to indicate significance.*Results TST ranged between 3,67-23,67 minutes in the out-patient center and 1,72-28,72 minutes in the tertiary care center. There was no significant difference in median TST between the tertiary care center (5,5 min; IQR 5,1-7,0) and out-patient exams (5,7 min., IQR 4,7-7,7) (p = 0,68). Median TT was significantly (p < 0,001) shorter in the out-patient setting (10,2 min, IQR 10,1-11,2) than at tertiary care center (13,3 min, IQR 12,3-13,3). Switching-imaging ratio and relative switching time were significantly lower in the tertiary care setting (0,43 vs. 0,58 min, p < 0,002 and 0,32 vs. 0,37, p < 0,002). The simulated switching-imaging ratio of the two abbreviated protocols was 0,63 (0,58-0,79) for T2 with T1 pre- and post-contrast and 0,83 (0,76-1,03) for T1 pre- and post-contrast only.*Conclusions TST significantly contribute to total examination time and challenge the use of protocol abbreviation. A reduction of this workflow-related parameter, e.g. by employing a dedicated radiotechnician for patient preparation, could provide a viable strategy to increase MRM capacity and cost-efficacy.*Clinical Relevance/Application We identified TST as an important parameter in the MRM workflow. To improve patient throughput in clinical practice, improvements should rather focus on this organizational problem rather than omitting diagnostically useful image acquisition.

RESULTS

TST ranged between 3,67-23,67 minutes in the out-patient center and 1,72-28,72 minutes in the tertiary care center. There was no significant difference in median TST between the tertiary care center (5,5 min; IQR 5,1-7,0) and out-patient exams (5,7 min., IQR 4,7-7,7) (p = 0,68). Median TT was significantly (p < 0,001) shorter in the out-patient setting (10,2 min, IQR 10,1-11,2) than at tertiary care center (13,3 min, IQR 12,3-13,3). Switching-imaging ratio and relative switching time were significantly lower in the tertiary care setting (0,43 vs. 0,58 min, p < 0,002 and 0,32 vs. 0,37, p < 0,002). The simulated switching-imaging ratio of the two abbreviated protocols was 0,63 (0,58-0,79) for T2 with T1 pre- and post-contrast and 0,83 (0,76-1,03) for T1 pre- and post-contrast only.

CLINICAL RELEVANCE/APPLICATION

We identified TST as an important parameter in the MRM workflow. To improve patient throughput in clinical practice, improvements should rather focus on this organizational problem rather than omitting diagnostically useful image acquisition.

SSIN04-2 Improving Automated Clinical Decision Making By Allowing Machine-learning Models To Say "I Don't Know": Balancing Performance Against Abstention

Participants
Philipp Wesp, Munich, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To transform a machine-learning classification task into a trade-off problem where the model has the ability to say "I don't know", by abstaining from predictions based on output scores and thereby increase classification performance for the remaining cases. We propose to extend the classification threshold to a window and to exclude cases with scores inside the window from classification ("abstention"). We hypothesize increased classification performance at the cost of abstention and explore this in a cancer screening setting.*Methods and Materials The trade-off between increased performance and abstention was explored by evaluating a machine-learning model from a previously reported radiomics study. In this study, a radiomics approach differentiated benign (hyperplastic polyp or regular mucosa) and premalignant (adenoma) colorectal polyps of all size categories and morphologies detected with CT colonography in an asymptomatic screening population. Two independent parameters, threshold position and window width, controlled the trade-off and different threshold-window combinations were explored. Performance was evaluated with Youden's index (=sensitivity+specificity-1), which combined sensitivity and specificity into a single metric.*Results Baseline Youden's index (threshold = 0.5, window = 0.0) for model predictions in 118 exemplifying cases without abstaining from decisions was 0.67 (sensitivity = 82%, specificity = 85%). For different threshold-window combinations (threshold range = 0.0 to 1.0, window range = 0.0 to 0.5), Youden's index was improved by 0.06 per 10% additional abstention on average. Youden's index reached a maximum of 0.96 (sensitivity = 96%, specificity = 100%) at the cost of abstaining from 57/118 (48%) decisions for a threshold of 0.46 and a window of 0.39.*Conclusions The demonstrated trade-off used machine-learning model output scores to abstain from making decisions in uncertain cases. Classification performance for the remaining samples increased with higher abstention rates. Abstention might highlight difficult cases which require particular investigation and could serve as a practical approach for radiologists to improve the quality of automated clinical decision making.*Clinical Relevance/Application Automated clinical decisions require high confidence, which is not guaranteed for all cases. Abstaining from decisions in uncertain cases may boost classification performance for the remaining cases.

RESULTS

Baseline Youden's index (threshold = 0.5, window = 0.0) for model predictions in 118 exemplifying cases without abstaining from decisions was 0.67 (sensitivity = 82%, specificity = 85%). For different threshold-window combinations (threshold range = 0.0 to 1.0, window range = 0.0 to 0.5), Youden's index was improved by 0.06 per 10% additional abstention on average. Youden's index reached a maximum of 0.96 (sensitivity = 96%, specificity = 100%) at the cost of abstaining from 57/118 (48%) decisions for a threshold of 0.46 and a window of 0.39.

CLINICAL RELEVANCE/APPLICATION

Automated clinical decisions require high confidence, which is not guaranteed for all cases. Abstaining from decisions in uncertain cases may boost classification performance for the remaining cases.

SSIN04-4 Decompose And Blend: Collaborative Utilization Of Gan-based Anomaly Detection And Supervised Learning In Chest Radiograph

Participants
Yisak Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Generative adversarial network (GAN)-based anomaly detection (AD) is considered to be a decent way to identify abnormal chest radiograph (CXR) classes that were not in the training data, since it only needs normal CXRs in training. However, it shows relatively lower performance than supervised learning since the final decision is commonly made by simply summing up the number of pixels of the anomaly area. Here, we propose an alternative way to collaboratively use robustness of AD and excellent performance of supervised learning; decomposing the anomaly region from CXR to distillate the knowledge of AD model and blending them again to train supervised learning model.*Methods and Materials A total of 56,596 and 40,533 CXRs with normal and abnormal findings (pulmonary nodules, tuberculosis, pneumonia, or pneumothorax) collected from single center were used to develop the algorithm, respectively. From here, 4,000 CXRs (2,000 normal, 2,000 abnormal) were randomly selected for internal validation. External validation was performed using two different datasets, 200 temporally independent CXRs (97 normal, 103 abnormal) reviewed by five radiologists and a public dataset that named CheXpert, consists of a total of 202 CXRs (26 normal, 176 abnormal) reviewed by

three radiologists. Fixed-Points-GAN, an AD model, was implemented to decompose anomaly by calculating residue map between original CXR and synthesized normal image, and then alpha-blending residue map and original CXR to generate blended image. We compared three different methods to classify abnormal CXRs; a) comparing the number of pixels in the residue maps as a traditional AD method, using supervised learning(Densenet121) trained with original CXRs and c) blended images, respectively.*Results The proposed method of using blended images showed significant improvements of areas under the receiver operating characteristics curve (AUROC) in all three validation sets: internal, temporally independent, and CheXpert (0.926 to 0.987, 0.907 to 0.965, 0.802 to 0.898; all p < .001). The performances of the proposed method and method using original CXRs showed no significant difference in internal validation (AUROC 0.987 for both). The proposed method showed significantly higher AUROC than the method using original CXRs in temporally independent CXRs and CheXpert (0.954 to 0.965, 0.881 to 0.898; all p < .05).*Conclusions Using blended image of original CXR and residue map in training supervised model may retain both the robustness of AD for the unseen abnormal classes and the excellent performance of the supervised learning.*Clinical Relevance/Application Using decomposed anomaly-related information may improve robustness of deep learning based automated system identifying abnormal findings in CXR.

RESULTS

The proposed method of using blended images showed significant improvements of areas under the receiver operating characteristics curve (AUROC) in all three validation sets: internal, temporally independent, and CheXpert (0.926 to 0.987, 0.907 to 0.965, 0.802 to 0.898; all p < .001). The performances of the proposed method and method using original CXRs showed no significant difference in internal validation (AUROC 0.987 for both). The proposed method showed significantly higher AUROC than the method using original CXRs in temporally independent CXRs and CheXpert (0.954 to 0.965, 0.881 to 0.898; all p < .05).

CLINICAL RELEVANCE/APPLICATION

Using decomposed anomaly-related information may improve robustness of deep learning based automated system identifying abnormal findings in CXR.

SSIN04-5   Improved Reader Design To Circumvent Bias In Artificial Intelligence Model Testing

Participants
Tara Retson, MD,PhD, San Diego, California (*Presenter*) Research writing, CureMetrix Inc

PURPOSE

Reader studies can be designed with biased test sets of "easy" rather than difficult cases, thereby falsely bolstering results with a given artificial intelligence (AI) algorithm. Also, many AI algorithms may be of greatest clinical benefit for difficult cases that are not obvious to all readers. Reader studies should include a measurable number of difficult exams to truly evaluate their potential impact in practice. We present an AI-based study design that yields greater statistical significance and a better proxy for clinical performance through creation of challenging test sets.*Methods and Materials A clinical reader study test set method was developed to incorporate difficult cases rather than only cases with high consensus or single reviewer validated. The aim was to include sufficient numbers of cases at varying levels of difficulty to ensure statistical significance. Image difficulty level is measured based on the number of readers in consensus, where the difficulty level increases as the reader consensus decreases. For example, a cancer case missed by the majority of readers is more difficult than a case where all readers identify the lesion. We illustrate this study design using the example of a mammography algorithm (cmDensity, CureMetrix, Inc, La Jolla, CA) using 7 readers and a set of 928 digital mammograms.*Results The test set was proven as high difficulty, as shown by the large number of cases that were not full reader consensus. As expected, the density algorithm showed higher agreement with the readers as reader consensus increased; from 4/7 to 7/ 7 reader consensus, with kappa = 0.65,0.82,0.94,0.97 respectively. Reader study results showed statistical significance in algorithm benefit across the spectrum of difficulty levels, especially for the high difficulty cases.*Conclusions The reported efficacy of an AI model is highly dependent on the choice of test data. AI models should include testing on difficult cases,which circumvents reporting of false high agreement results. Through this AI-based creation of measurable difficulty bins within a test set, a better sense of range in "real world" algorithm performance is provided.*Clinical Relevance/Application Through improved study design with more challenging cases, AI algorithm reader studies are better assessed and compared. The "shades of gray" of clinical reality can and should be incorporated and quantified in study design for AI reader studies.

RESULTS

The test set was proven as high difficulty, as shown by the large number of cases that were not full reader consensus. As expected, the density algorithm showed higher agreement with the readers as reader consensus increased; from 4/7 to 7/ 7 reader consensus, with kappa = 0.65,0.82,0.94,0.97 respectively. Reader study results showed statistical significance in algorithm benefit across the spectrum of difficulty levels, especially for the high difficulty cases.

CLINICAL RELEVANCE/APPLICATION

Through improved study design with more challenging cases, AI algorithm reader studies are better assessed and compared. The "shades of gray" of clinical reality can and should be incorporated and quantified in study design for AI reader studies.

SSIN04-6   Identifying Bias In Deep Learning Models For Edema Detection On Chest Radiographs: Is AUC Enough?

Participants
Paul Yi, MD, Baltimore, Maryland (*Presenter*) Consultant, FH Orthopedics SAS;Consultant, BunkerHill Health

PURPOSE

Deep convolutional neural networks (DCNNs) trained with unequal sex representation have shown bias against the underrepresented sex for disease identification on chest radiographs (CXRs) using differences in area under the receiver operating characteristic curve (AUC) as a proxy for fairness. However, it is unclear whether different definitions of fairness will result in different conclusions about the presence of bias in a model.The purpose of this study was to evaluate if sex imbalance produces biased DCNNs for detecting pulmonary edema and whether different definitions of fairness impact the identification of biased models.*Methods and Materials CXRs from the NIH ChestX-ray14 database were used to create 20 datasets, each consisting of 1196 images, curated through random undersampling to control for pathology labels and sex. Each dataset was divided into subsets of 100% male, 100% female, and equal male/female and split into 80%/10%/10% training/validation/test sets. Using DenseNet-121 DCNNs pre-trained on ImageNet, "male" and "female" models were developed using only male and female images, respectively, and "balanced" models using images with equal sex representation.Each model was evaluated on held-out test sets with equal sex representation. Fairness was evaluated by comparing mean AUCs between models and two definitions which have achieved consensus in the statistics

literature: 1) equality of opportunity (EOO) [defined as equal true positive rate (TPR)] and 2) equalized odds (EO) [defined as equal TPR and false positive rate (FPR)].*Results DCNNs developed using exclusively male/female and balanced images achieved mean AUCs of 0.82 to 0.85 (p>0.05) [Fig.1], suggesting no bias. However, more rigorous definitions of fairness revealed that most models were biased with fewer satisfying EO than EOO. For example, allowing for maximum 5% TPR/FPR disparity between subgroups, <30% of models would be fair under EOO and <10% under EO (Fig. 2).*Conclusions Conclusions about presence of bias in DCNNs trained for CXR pulmonary edema detection vary widely depending on the definition of fairness used. AUC comparison suggested unbiased/fair models, while more rigorous definitions of fairness uncovered high prevalence of bias against the underrepresented sex. We recommend caution in using AUC comparisons alone as a proxy for fairness in evaluation of deep learning models without consideration of other definitions of fairness, such as EOO and EO.*Clinical Relevance/Application More rigorous definitions of fairness reveal that CXR CNN models with similar AUCs are biased for pulmonary edema detection. This study showcases the limitations of evaluating fairness through performance metrics, such as AUC, which are commonly used in the literature.

RESULTS

DCNNs developed using exclusively male/female and balanced images achieved mean AUCs of 0.82 to 0.85 (p>0.05) [Fig.1], suggesting no bias. However, more rigorous definitions of fairness revealed that most models were biased with fewer satisfying EO than EOO. For example, allowing for maximum 5% TPR/FPR disparity between subgroups, <30% of models would be fair under EOO and <10% under EO (Fig. 2).

CLINICAL RELEVANCE/APPLICATION

More rigorous definitions of fairness reveal that CXR CNN models with similar AUCs are biased for pulmonary edema detection. This study showcases the limitations of evaluating fairness through performance metrics, such as AUC, which are commonly used in the literature.

SPR-GI-1 **Fully-automated Liver Couinaud Segmentation In Computed Tomography For Diagnosing Advanced Liver Fibrosis And Cirrhosis**

Participants
Sungwon Lee, MD,PhD, Bethesda, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

To develop and evaluate a fully-automated algorithm for segmenting the liver Couinaud segments from CT volume to detect left lateral and caudate hypertrophy in advanced liver fibrosis and cirrhosis.*Methods and Materials For this retrospective study, a convolutional neural network based on the 3D U-Net architecture was trained on 644 CT scans to perform Couinaud segmentation. Automated liver segmental volume ratio (LSVR) was defined by dividing the total volume of Couinaud segments I-III by that from segments IV-VIII. The algorithm was tested on two external datasets: "Dataset 1" consisted of 422 patients who received liver biopsy for hepatitis C evaluation from 2000 to 2016 (METAVIR F0-4, each 48, 65, 92, 65, 152). 184 asymptomatic renal donors were added to enrich the F0 class. "Dataset 2" consisted of 215 patients who received liver biopsy for hepatitis B, C, or D from 2001 to 2021 (Ishak stage 0-6, each 62, 33, 25, 29, 22, 10, 34). All biopsies were done within 1 year of a portal phase CT. AUCs for diagnosing advanced fibrosis (= F3/Ishak 4) and cirrhosis (F4/Ishak 6) with the automated LSVR were calculated for both dataset 1 and 2. Dataset 1 also had manual LSVR calculated from manual Couinaud segmentation done by six radiologists. Weighted kappa and linear regression were used to compare the manual and automated LSVR.*Results AUC values in distinguishing advanced fibrosis (= F3/Ishak 4) were 0.78 (95% CI 0.73-0.82) vs. 0.81 (95% CI 0.77-0.85) for the automated vs. manual LSVR in dataset 1, and 0.70 (95% CI 0.62-0.78) for the automated LSVR in dataset 2. In distinguishing cirrhosis (F4/Ishak 6), the AUCs were 0.82 (95% CI 0.78-0.86) vs. 0.84 (95% CI 0.80-0.89) for the automated vs. manual LSVR in dataset 1, and 0.73 (95% CI 0.63-0.83) for the automated LSVR in dataset 2. The weighted kappa between the automated and manual LSVR was 0.60 (95% CI 0.56-0.64, p<0.001) and the linear regression slope was 1.07 (R2=0.96).*Conclusions The fully-automated algorithm performed well in diagnosing histopathologic advanced fibrosis and cirrhosis with LSVR and was comparable to manual measurements.*Clinical Relevance/Application Anatomical liver segment (Couinaud segment) volumes can be obtained fully-automatically from an enhanced abdominal CT scan.

RESULTS

AUC values in distinguishing advanced fibrosis (= F3/Ishak 4) were 0.78 (95% CI 0.73-0.82) vs. 0.81 (95% CI 0.77-0.85) for the automated vs. manual LSVR in dataset 1, and 0.70 (95% CI 0.62-0.78) for the automated LSVR in dataset 2. In distinguishing cirrhosis (F4/Ishak 6), the AUCs were 0.82 (95% CI 0.78-0.86) vs. 0.84 (95% CI 0.80-0.89) for the automated vs. manual LSVR in dataset 1, and 0.73 (95% CI 0.63-0.83) for the automated LSVR in dataset 2. The weighted kappa between the automated and manual LSVR was 0.60 (95% CI 0.56-0.64, p<0.001) and the linear regression slope was 1.07 (R2=0.96).

CLINICAL RELEVANCE/APPLICATION

Anatomical liver segment (Couinaud segment) volumes can be obtained fully-automatically from an enhanced abdominal CT scan.

SPR-GI-10 **Predicting Microsatellite Instability Status In Colorectal Cancer Based On Triphasic Enhanced Computed Tomography Radiomics Signatures: A Multicenter Study**

Participants
Yuntai Cao, MS,MS, Xining, China (*Presenter*) Nothing to Disclose

PURPOSE

Microsatellite instability (MSI) status is a key clinical predictor for evaluating the treatment strategies and prognosis of colorectal cancer (CRC) patients. This study aimed to develop and validate a computed tomography (CT)-based radiomics model to predict microsatellite instability (MSI) status in colorectal cancer patients.*Methods and Materials In total, 502 colorectal cancer patients with preoperative contrast-enhanced CT images and available MSI status (441 in the training cohort and 61 in the external validation cohort) were enrolled from two centers in our retrospective study. Radiomic features of the entire primary tumor were extracted from arterial-, delayed-, and venous-phase CT images. The least absolute shrinkage and selection operator method was used to retain the features closely associated with MSI status. Radiomics, clinical, and combined clinicoradiomics models were built to predict MSI status. Model performance was evaluated by receiver operating characteristic curve analysis.*Results After removed irrelevant features by multiple steps, finally, 6 AP radiomics features, 10 VP radiomics features, and 16 DP radiomics features were retained as the final radiomics signatures for predicting MSI status. Delayed-phase models showed superior predictive performance compared to arterial- or venous-phase models. Additionally, age, location and carcinoembryonic antigen level were considered useful predictors of MSI status. The clinicoradiomics nomogram that incorporated both clinical risk factors and radiomics parameters showed excellent performance, with an AUC, accuracy, and sensitivity of 0.898, 0.837, and 0.821 in the training cohort and 0.964, 0.918, and 1.000 in the validation cohort, respectively.*Conclusions We proposed and validated a CT-based radiomics model, incorporating clinical risk factors and radiomics parameters, which showed a relatively high diagnostic performance for the risk prediction of MSI in patients with CRC.*Clinical Relevance/Application This model may be a potential tool for preoperatively identifying the MSI status and can be used in individualized therapeutic strategy planning and prognostic prediction.

RESULTS

After removed irrelevant features by multiple steps, finally, 6 AP radiomics features, 10 VP radiomics features, and 16 DP radiomics features were retained as the final radiomics signatures for predicting MSI status. Delayed-phase models showed superior predictive performance compared to arterial- or venous-phase models. Additionally, age, location and carcinoembryonic antigen level were considered useful predictors of MSI status. The clinicoradiomics nomogram that incorporated both clinical risk factors and radiomics parameters showed excellent performance, with an AUC, accuracy, and sensitivity of 0.898, 0.837, and 0.821 in the training cohort and 0.964, 0.918, and 1.000 in the validation cohort, respectively.

CLINICAL RELEVANCE/APPLICATION

This model may be a potential tool for preoperatively identifying the MSI status and can be used in individualized therapeutic strategy planning and prognostic prediction.

SPR-GI-11 Estimation Of Tumor Recurrence In Patients With Single Hepatocellular Carcinoma After Curative Resection: Development And Validation Of A Risk Score

Participants
So Hyun Park, MD, Incheon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a risk scoring system using gadoxetic acid-enhanced liver MRI features and clinical factors that predicts recurrence-free survival (RFS) after surgery for single hepatocellular carcinoma (HCC).*Methods and Materials In this retrospective study, consecutive patients with treatment-naïve single HCC who underwent curative surgery from January 2010 to December 2016 (development set) and from January 2013 to December 2016 (test set for external validation) were enrolled from two centers. In the development set, uni- and multivariable Cox proportional hazard models were used to select MRI features and clinical factors associated with RFS and to develop a risk scoring system that stratified the patients into high-, intermediate-, and low-risk groups. The discriminatory power of the risk scores was assessed and validated using Harrell C-index, AUC, and Kaplan-Meier analysis using log-rank test in the development and test sets.*Results A total of 295 patients were evaluated, including 205 patients (mean age, 57 years ± 10.2; 158 men) in the development set and 90 patients (mean age, 56.7 years ± 9.8; 69 men) in the test set. Five variables predicted risk of recurrence: nonresectable hypointense nodule on hepatobiliary phase (hazard ratio [HR], 4.31; 95% confidence interval [CI]: 2.83-6.59; P < 0.001), tumor size = 5 cm (HR, 2.01; 95% CI: 1.28-3.16; P = 0.002), tumor in vein or suspicious vessel invasion on MRI (HR, 1.86; 95% CI: 1.20-2.88; P = 0.006), targetoid appearance (HR, 1.53; 95% CI: 0.94-2.50; P = 0.09), and microvascular invasion (HR, 1.70; 95% CI: 1.08-2.66; P = 0.02). In the development set, the high-risk group showed shorter RFS than the intermediate- and low-risk groups (all log-rank Ps < 0.001). For each group, 2-year RFS was 88.6%, 73.8%, and 26.3%, respectively. In the test set, the risk score showed high discriminatory power (C-index, 0.81) with AUC for 2-year recurrence of 0.88 (95% CI: 0.80-0.95). The high-risk group likewise showed shorter RFS than the other lower-risk groups (all log-rank Ps < 0.001). Two-year RFS for each group was 86.5%, 71.1%, and 42.9%, respectively, in the test set.*Conclusions The developed and validated risk scoring system can estimate RFS after curative surgery for single HCC.*Clinical Relevance/Application Risk scores for predicting RFS after surgery for HCC have been developed and externally validated to yield high discriminatory ability across stratified groups.

RESULTS

A total of 295 patients were evaluated, including 205 patients (mean age, 57 years ± 10.2; 158 men) in the development set and 90 patients (mean age, 56.7 years ± 9.8; 69 men) in the test set. Five variables predicted risk of recurrence: nonresectable hypointense nodule on hepatobiliary phase (hazard ratio [HR], 4.31; 95% confidence interval [CI]: 2.83-6.59; P < 0.001), tumor size = 5 cm (HR, 2.01; 95% CI: 1.28-3.16; P = 0.002), tumor in vein or suspicious vessel invasion on MRI (HR, 1.86; 95% CI: 1.20-2.88; P = 0.006), targetoid appearance (HR, 1.53; 95% CI: 0.94-2.50; P = 0.09), and microvascular invasion (HR, 1.70; 95% CI: 1.08-2.66; P = 0.02). In the development set, the high-risk group showed shorter RFS than the intermediate- and low-risk groups (all log-rank Ps < 0.001). For each group, 2-year RFS was 88.6%, 73.8%, and 26.3%, respectively. In the test set, the risk score showed high discriminatory power (C-index, 0.81) with AUC for 2-year recurrence of 0.88 (95% CI: 0.80-0.95). The high-risk group likewise showed shorter RFS than the other lower-risk groups (all log-rank Ps < 0.001). Two-year RFS for each group was 86.5%, 71.1%, and 42.9%, respectively, in the test set.

CLINICAL RELEVANCE/APPLICATION

Risk scores for predicting RFS after surgery for HCC have been developed and externally validated to yield high discriminatory ability across stratified groups.

SPR-GI-12 Annual Non-contrast Liver MRI Vs. Biannual Liver Ultrasonography For Surveillance Of HCC In Patients With Liver Cirrhosis: Results Of A Prospective, Multicenter Trial NCT02551250 (MAGNUS-HCC)

Participants
Moon Hyung Choi, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Ultrasonography (US) is recommended as a standard surveillance tool for patients with high risk of hepatocellular carcinoma (HCC). However, the low sensitivity of US for small HCC may lead to surveillance failure. The purpose of this study is to evaluate the feasibility and performance of non-contrast liver MRI as a surveillance tool for HCC in patients with liver cirrhosis, compared with US.*Methods and Materials This study is a prospective, multicenter clinical trial with crossover design in a single arm of patients. We enrolled 218 patients with high-risk for HCC (annual risk > 5%) in six institutes. All patients underwent US every 6 months (6, 12, 18, 24, 30 and 36 months) and non-contrast MRI every 12 months (6, 18 and 30 months) for surveillance of HCC during the follow-up period of 3 years. Non-contrast MRI consists of T2 FSE, T2 SSFSE, in- and opposed-phased T1 GRE, and DWI (b-values of 0, 50 and 500 s/mm2). If a focal liver lesion suspected with HCC was detected, dynamic CT was performed for confirmation of HCC. After the last surveillance round, patients who were not diagnosed with HCC were evaluated with dynamic CT to exclude false negative. We compared the diagnostic performance, including sensitivity, positive predictive value (PPV) and false referral rate (FRR), of annual non-contrast MRI and biannual US.*Results 34 HCCs were developed in 31 patients. Per-patient and per-tumor sensitivity of MRI and US were 71.0% and 45.2% (p=0.0768), 73.5% and 47.1% (p=0.0490), respectively. PPV and FRR of MRI and US were 61.1% and 33.3% (p=0.0223), 2.71% and 2.85% (p=1.000), respectively. All four HCC patients diagnosed by US alone were found in follow-up rounds when US was performed without MRI. When simulating alternative examinations of non-contrast MRI

and US with 6-month interval, per-patient sensitivity was 83.9% and FRR was 2.85%.*Conclusions Annual non-contrast MRI surveillance was marginally superior in sensitivity to biannual US surveillance for HCC detection. PPV of annual non-contrast MRI was better than that of biannual US without significant difference of FRR. Alternating examinations of non-contrast MRI and US with 6-month interval could maximize the performance of HCC surveillance.*Clinical Relevance/Application Non-contrast MRI outperforms US as a HCC surveillance tool. Cheap, fast image acquisition time and no need for repetitive contrast injection are advantages of non-contrast MRI comparing to contrast-enhanced MRI.

RESULTS

34 HCCs were developed in 31 patients. Per-patient and per-tumor sensitivity of MRI and US were 71.0% and 45.2% (p=0.0768), 73.5% and 47.1% (p=0.0490), respectively. PPV and FRR of MRI and US were 61.1% and 33.3% (p=0.0223), 2.71% and 2.85% (p=1.000), respectively. All four HCC patients diagnosed by US alone were found in follow-up rounds when US was performed without MRI. When simulating alternative examinations of non-contrast MRI and US with 6-month interval, per-patient sensitivity was 83.9% and FRR was 2.85%.

CLINICAL RELEVANCE/APPLICATION

Non-contrast MRI outperforms US as a HCC surveillance tool. Cheap, fast image acquisition time and no need for repetitive contrast injection are advantages of non-contrast MRI comparing to contrast-enhanced MRI.

SPR-GI-13 Prognostic Value Of Gadoxetic Acid-enhanced MRI In Patients With Hepatocellular Carcinoma After Hepatectomy

Participants
Hong Wei, MMed, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the prognostic values of preoperative gadoxetic acid-enhanced MRI findings in patients with hepatocellular carcinoma (HCC) after surgical resection.*Methods and Materials This retrospective study included consecutive treatment-naïve patients with surgically proven HCC who underwent preoperative gadoxetic acid-enhanced MRI between August 2015 and September 2020. All MR images were reviewed by two independent radiologists who were blinded to all clinical, pathological and follow-up information with respect to all Liver Imaging Reporting and Data System (LI-RADS) version 2018 imaging features and several non-LI-RADS imaging features in consensus. Uni-variate and multi-variate Cox proportional hazards regression analyses were used to identify significant predictors for recurrence-free survival (RFS) and overall survival (OS) with five-fold cross-validation. Thereafter, regression-based predictive models were constructed for RFS and OS using backward stepwise approach with the Akaike information criterion. Model performances were estimated by the Harrell's concordance index (C index), calibration plots, and Kaplan-Meier curves.*Results Two hundred twenty-five patients (mean age: 52.6 ± 11.7 years, 186 men [82.7%]) were evaluated. The median follow-up period was 16.4 months (range: 3.1-65.8 months). There were 91 (40.4%) recurrences and 27 (12.0%) deaths. Factors significantly predictive of RFS included: age (Hazard Ratio [HR]: 0.978), multiplicity (HR: 1.533), tumor size > 5cm (HR: 1.733), tumor in vein (HR: 1.488), peritumoral hyperintense area on T2WI (HR: 1.712) and Eggel's growth classification (HR: 1.467). Factors significantly predictive of OS were: AFP level > 400 ng/mL (HR: 2.416), bilobar involvement (HR: 2.310), satellite nodule (HR: 2.204), corona enhancement (HR: 3.718), infiltrative appearance (HR: 2.614), non-smooth tumor margin (HR: 4.838) and peritumoral biliary dilatation (HR: 2.448). The C-index for RFS and OS was 0.717 (95% confidence interval [CI]: 0.656-0.778) and 0.878 (95%CI: 0.822-0.935), respectively.*Conclusions Nomograms incorporating preoperative gadoxetic acid-enhanced MRI findings and clinical factors can effectively predict risk of recurrence and survival of HCC patients after hepatectomy.*Clinical Relevance/Application MRI-based nomograms effectively predict postsurgical prognosis of HCC patients, which may contribute to the guidance of pretreatment clinical decision-making and optimization of patient management.

RESULTS

Two hundred twenty-five patients (mean age: 52.6 ± 11.7 years, 186 men [82.7%]) were evaluated. The median follow-up period was 16.4 months (range: 3.1-65.8 months). There were 91 (40.4%) recurrences and 27 (12.0%) deaths. Factors significantly predictive of RFS included: age (Hazard Ratio [HR]: 0.978), multiplicity (HR: 1.533), tumor size > 5cm (HR: 1.733), tumor in vein (HR: 1.488), peritumoral hyperintense area on T2WI (HR: 1.712) and Eggel's growth classification (HR: 1.467). Factors significantly predictive of OS were: AFP level > 400 ng/mL (HR: 2.416), bilobar involvement (HR: 2.310), satellite nodule (HR: 2.204), corona enhancement (HR: 3.718), infiltrative appearance (HR: 2.614), non-smooth tumor margin (HR: 4.838) and peritumoral biliary dilatation (HR: 2.448). The C-index for RFS and OS was 0.717 (95% confidence interval [CI]: 0.656-0.778) and 0.878 (95%CI: 0.822-0.935), respectively.

CLINICAL RELEVANCE/APPLICATION

MRI-based nomograms effectively predict postsurgical prognosis of HCC patients, which may contribute to the guidance of pretreatment clinical decision-making and optimization of patient management.

SPR-GI-14 2019 Korean Society Of Abdominal Radiology Consensus Recommendations For Extrahepatic Bile Duct Cancer: Diagnostic Accuracy And Interreader Agreement In Longitudinal Tumor Extent, Vascular Invasion, And Resectability Evaluation Using Multi-row Detector CT

Participants
Bohyun Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

In extrahepatic bile duct (EHD) cancer, accurate assessment of resectability is essential for curative surgery but pertinent guidelines in the perspectives of radiologists are pending. The Korean Society of Abdominal Radiology (KSAR) has recently announced consensus recommendations for a comprehensive evaluation of EHD cancer on imaging technique, tumor extent, major vessel involvement, and lymph node/distant metastasis outlined in a structured report form to facilitate radiologic prediction of resectability. The purpose of the study was to investigate the diagnostic performance of MDCT according to the recommendations and to evaluate interreader agreement.*Methods and Materials This retrospective study included EHD cancer patients who underwent multiphasic CT scans of = 3 mm slice thickness before surgery from Jan 2016 to Dec 2018. Three abdominal radiologists with 6-10 years of experience evaluated longitudinal extent of the tumor, presence of hepatic artery/portal vein invasion, and resectability per KSAR recommendations. The diagnostic performance was assessed by sensitivity, specificity, and AUC. Interreader agreement was determined using kappa statistics.*Results In total, 112 patients (mean age, 61.3 ± 11.3; 73 men) were evaluated.

Overall longitudinal tumor extent was correctly assessed in 72.3% (81/112) of the patients. In a biliary segment-wise analysis, the sensitivity for detecting 2° confluence involvement (n = 62) was lower than that for the 1° confluence or intrapancreatic duct (n = 115; 50.0-75.0% vs. 82.0-87.0%). For vascular invasion (n = 17), moderate sensitivity (70.0-71.4%) and high specificity (95.1-97.1%) were noted. For predicting R0 resection (n = 85), the sensitivity and specificity ranged 71.8-95.4% and 33.3-66.7%, respectively, with the AUC ranging 0.768 to 0.799. Interreader agreements for tumor extent, vascular invasion, and resectability were 0.649-0892, 0.273-0.643, and 0.465-0.525, respectively.*Conclusions The consensus recommendations provided moderate sensitivity and high specificity for assessing tumor extent and vascular invasion of EHD cancers using MDCT. For tumor resectability, high sensitivity and moderate specificity with moderate interreader agreement were noted.*Clinical Relevance/Application For preoperative evaluation of EHD cancer, the consensus recommendations enabled systemic assessment of the disease status and provided acceptable performance in predicting R0 resection.

RESULTS

In total, 112 patients (mean age, 61.3 ± 11.3; 73 men) were evaluated. Overall longitudinal tumor extent was correctly assessed in 72.3% (81/112) of the patients. In a biliary segment-wise analysis, the sensitivity for detecting 2° confluence involvement (n = 62) was lower than that for the 1° confluence or intrapancreatic duct (n = 115; 50.0-75.0% vs. 82.0-87.0%). For vascular invasion (n = 17), moderate sensitivity (70.0-71.4%) and high specificity (95.1-97.1%) were noted. For predicting R0 resection (n = 85), the sensitivity and specificity ranged 71.8-95.4% and 33.3-66.7%, respectively, with the AUC ranging 0.768 to 0.799. Interreader agreements for tumor extent, vascular invasion, and resectability were 0.649-0892, 0.273-0.643, and 0.465-0.525, respectively.

CLINICAL RELEVANCE/APPLICATION

For preoperative evaluation of EHD cancer, the consensus recommendations enabled systemic assessment of the disease status and provided acceptable performance in predicting R0 resection.

SPR-GI-15   Adrenal Nodules Detected On Staging CT In Patients With Potentially Resectable Gastric Cancer: Is Additional Imaging Necessary Before Surgery?

Participants
Hae Young Kim, MD,MS, Seongnam, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To measure the prevalence of adrenal nodule detected on staging CT in patients with potentially resectable gastric cancer, and the proportion of patients with malignant nodules among them.*Methods and Materials This retrospective study included 10250 consecutive patients who underwent staging CT and had potentially resectable gastric cancer in a high volume center. We measured the prevalence of adrenal nodule (= 10 mm) via retrospective CT image review (patients with CT-detected adrenal nodule out of 10250 patients with potentially resectable gastric cancer). Among the patients with CT-detected adrenal nodules, we measured the per-patient proportions of malignant nodules, adrenal metastasis from gastric cancer, and additional adrenal examination.*Results The prevalence of adrenal nodule was 4.5% (462/10250; 95% CI, 4.1%-4.9%). The proportions of malignant nodule, and the proportion of adrenal metastasis from gastric cancer were 0.4% (2/462; 0.1%-1.6%) and 0.0% (0/462; 0.0%-0.8%), respectively. 26.6% of the patients with CT-detected adrenal nodules (123/462; 22.7%-30.9%) underwent additional adrenal examination.*Conclusions Adrenal nodules detected on staging CTs in patients with otherwise resectable gastric cancer rarely turn out to be malignant. Only two of 10250 patients turned out to have malignant adrenal nodules, neither of whom had adrenal metastasis from gastric cancer.*Clinical Relevance/Application Guidelines recommending additional imaging for adrenal nodules detected on CT lack relevant epidemiology evidence. Our results suggest that current guidelines need a revision toward more selective use of additional imaging for adrenal nodules in patients with otherwise resectable gastric cancer.

RESULTS

The prevalence of adrenal nodule was 4.5% (462/10250; 95% CI, 4.1%-4.9%). The proportions of malignant nodule, and the proportion of adrenal metastasis from gastric cancer were 0.4% (2/462; 0.1%-1.6%) and 0.0% (0/462; 0.0%-0.8%), respectively. 26.6% of the patients with CT-detected adrenal nodules (123/462; 22.7%-30.9%) underwent additional adrenal examination.

CLINICAL RELEVANCE/APPLICATION

Guidelines recommending additional imaging for adrenal nodules detected on CT lack relevant epidemiology evidence. Our results suggest that current guidelines need a revision toward more selective use of additional imaging for adrenal nodules in patients with otherwise resectable gastric cancer.

SPR-GI-16   Deep Learning Image Reconstruction Algorithm For Pancreatic Protocol Dual-energy Computed Tomography: Image Quality And Quantification Of Iodine Concentration

Participants
Yoshihumi Noda, MD,PhD, Gifu, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the image quality and iodine concentration (IC) measurements in pancreatic protocol dual-energy CT (DECT) reconstructed using deep learning image reconstruction (DLIR) and compare them with those of images reconstructed using hybrid iterative reconstruction (IR).*Methods and Materials The local institutional review board approved this prospective study. Written informed consent was obtained from all participants. Thirty consecutive participants with pancreatic cancer (PC) underwent pancreatic protocol DECT for initial evaluation. DECT data were reconstructed at 70 keV using 40% adaptive statistical iterative reconstruction-Veo (hybrid-IR) and DLIR at medium and high levels (DLIR-M and DLIR-H, respectively). The diagnostic acceptability and conspicuity of PC were qualitatively assessed using a five-point scale. IC values of the abdominal aorta, pancreas, PC, liver, and portal vein; standard deviation (SD); and coefficient of variation (CV) were calculated. Qualitative and quantitative parameters were compared between the hybrid-IR, DLIR-M, and DLIR-H groups.*Results The diagnostic acceptability and conspicuity of PC were significantly better in the DLIR-M group compared with those in the other groups (P < .001-.001). The IC values of the anatomical structures were almost comparable between the three groups (P = .001-0.9). The SD of IC values was significantly lower in the DLIR-H group (P < .001) and resulted in the lowest CV (P < .001-.002) compared with those in the hybrid-IR and DLIR-M groups.*Conclusions DLIR could significantly improve image quality and reduce the variability of IC values than could hybrid-IR.*Clinical Relevance/Application DLIR algorithm can markedly reduce the background noise and demonstrate less iodine concentration variability values in pancreatic protocol dual-energy CT.

RESULTS

The diagnostic acceptability and conspicuity of PC were significantly better in the DLIR-M group compared with those in the other groups (P < .001-.001). The IC values of the anatomical structures were almost comparable between the three groups (P = .001-0.9). The SD of IC values was significantly lower in the DLIR-H group (P < .001) and resulted in the lowest CV (P < .001-.002) compared with those in the hybrid-IR and DLIR-M groups.

CLINICAL RELEVANCE/APPLICATION

DLIR algorithm can markedly reduce the background noise and demonstrate less iodine concentration variability values in pancreatic protocol dual-energy CT.

SPR-GI-17   Detection Of Incidental Esophageal Cancers On Chest CT By Deep Learning

Participants
Zhanhao Mo, Changchun, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop a deep learning-based model for improving detection of incidental esophageal cancer in unenhanced chest CT examination.*Methods and Materials We retrospectively collected 141 patients with esophageal cancers (mean age: 57.4, range: 34-87) and 273 non-esophageal cancer subjects (mean age: 41.7, range: 18-73) in unenhanced chest CT images from January 2017 to March 2019 in our hospital. These Data were used to establish a convolutional neural (CNN) network model for diagnosing esophageal cancer. The CNN model is a V-Net segmentation network that can segment the esophagus and localize the thickening positions of esophageal lesions. To validate this model, another 52 missed cases of patients with esophageal cancers (mean age: 58.8, range: 23-85) and 48 normal esophagi (mean age: 42.1, range: 19-62) were collected to evaluate the performance of the deep learning-based model and radiologists with or without assistance of the deep learning-based model respectively.*Results The sensitivity and specificity of the esophageal cancer detection model were 88.8% and 90.9%, respectively. Of the 52 missed esophageal cancer cases and 48 normal cases, the sensitivity, specificity and accuracy of the deep learning esophageal cancer detection model were 69% ,61%,65%, respectively, and the radiologists' independent reading results were sensitivity 25%,31%,27%, specificity 78%,75%,75%, and accuracy 53%,54%,53% in the absence of deep learning-based model assistance. With the aid of the deep learning-based model, the radiologists' reading results were improved to sensitivity 77%, 81%,75%, specificity 75%,74%,74% and accuracy 76%,77%,75% respectively.*Conclusions Deep learning-based model can effectively detect esophageal cancers in unenhanced chest CT scan to help improve incidental detection of esophageal cancer on CT.*Clinical Relevance/Application The Deep learning-based model is highly objective in detecting esophageal cancer and can provide more reliable abnormal reminders,and it also can improve the efficiency of image reading by quickly browsing images and judge abnormal images in a short time.

RESULTS

The sensitivity and specificity of the esophageal cancer detection model were 88.8% and 90.9%, respectively. Of the 52 missed esophageal cancer cases and 48 normal cases, the sensitivity, specificity and accuracy of the deep learning esophageal cancer detection model were 69% ,61%,65%, respectively, and the radiologists' independent reading results were sensitivity 25%,31%,27%, specificity 78%,75%,75%, and accuracy 53%,54%,53% in the absence of deep learning-based model assistance. With the aid of the deep learning-based model, the radiologists' reading results were improved to sensitivity 77%, 81%,75%, specificity 75%,74%,74% and accuracy 76%,77%,75% respectively.

CLINICAL RELEVANCE/APPLICATION

The Deep learning-based model is highly objective in detecting esophageal cancer and can provide more reliable abnormal reminders,and it also can improve the efficiency of image reading by quickly browsing images and judge abnormal images in a short time.

SPR-GI-18   Assessment Of Liver Steatosis By Ultrasound-guided Attenuation Parameter: Prospective Multi-center Study From 6 Japanese Sites

Participants
Katsutoshi Sugimoto, MD, PhD, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Ultrasound (US)-based attenuation marker called US-Guided Attenuation Parameter (UGAP) has proven to be efficient for the evaluation of liver steatosis in small-sized clinical trial. The purpose of this study was to investigate the diagnostic performance of UGAP in assessing liver steatosis in patients with chronic liver disease as findings form magnetic resonance imaging (MRI)-based proton density fat fraction (PDFF) were used for reference standard.*Methods and Materials This prospective multi-center study from 6 sites collected data from 1012 adult patients (mean age, 62 years ± 15 [standard deviation]; 561 men) with chronic liver disease who underwent MRI-PDFF and were enrolled February 2020 to February 2021. Most patients had nonalcoholic fatty liver disease (n=515) chronic hepatitis B (n=133), or hepatitis C (n=124). UGAP was measured using a US scanner (LOGIQ E10: GE healthcare). Diagnostic performance of UGAP was assessed using the area under the receiver operating characteristic curve (AUC) for the steatosis grade which was defined by MRI-PDFF. The correlation between UGAP and MRI-PDFF was determined.*Results The diagnostic performance of UGAP for steatosis grades =1, =2, and 3, as determined by MRI-PDFF were AUC of 0.91 (95% confidence interval [CI]: 0.89-0.93) with sensitivity of 87% and specificity of 82% at the threshold of 0.65 (dB/cm/MHz), 0.91 (95% CI: 0.89-0.93) with sensitivity of 78% and specificity of 91% at the threshold of 0.71 (dB/cm/MHz), and 0.89 (95% CI: 0.87-0.92) with sensitivity of 83% and specificity of 81% at the threshold of 0.71 (dB/cm/MHz), respectively. The correlation coefficient between PDFF values and UGAP values were 0.77 (95% CI: 0.74-0.79; P < .001).*Conclusions UGAP had high diagnostic performance for detecting hepatic steatosis in patients with chronic liver disease.*Clinical Relevance/Application US-Guided Attenuation Parameter can assess degree of liver steatosis accurately and easily in daily clinical practice.

RESULTS

The diagnostic performance of UGAP for steatosis grades =1, =2, and 3, as determined by MRI-PDFF were AUC of 0.91 (95% confidence interval [CI]: 0.89-0.93) with sensitivity of 87% and specificity of 82% at the threshold of 0.65 (dB/cm/MHz), 0.91 (95% CI: 0.89-0.93) with sensitivity of 78% and specificity of 91% at the threshold of 0.71 (dB/cm/MHz), and 0.89 (95% CI: 0.87-0.92) with sensitivity of 83% and specificity of 81% at the threshold of 0.71 (dB/cm/MHz), respectively. The correlation coefficient between PDFF values and UGAP values were 0.77 (95% CI: 0.74-0.79; P < .001).

CLINICAL RELEVANCE/APPLICATION

US-Guided Attenuation Parameter can assess degree of liver steatosis accurately and easily in daily clinical practice.

SPR-GI-2   Prediction Of Whole-body 3D Adipose Volume By A Single Axial Abdominal Cross-section 2D Adipose Area: Early Interim Analysis From The Dallas Heart Study Third Examination

Participants
Takeshi Yokoo, MD, PhD, Dallas, Texas (*Presenter*) Nothing to Disclose

PURPOSE

To assess the feasibility of predicting the whole-body visceral, subcutaneous, and total adipose tissue (VAT, SAT, TAT) compartment volumes from the cross-sectional segmented adipose areas on a single axial magnetic resonance imaging (MRI) section at the L2/L3 intervertebral level.*Methods and Materials This is an interim, cross-sectional analysis of participants from the third examination of the Dallas Heart Study, a longitudinal population-based cohort study in Dallas, TX. Forty-three (43) adult participants underwent whole-body (neck to knee) 3-D axial T1-weighted Dixon gradient echo MRI at 3T. The Dixon image data were analyzed for whole-body VAT, SAT, and TAT volumes (in cm3) using a validated technique by AMRA Medical (Linkoping University, Sweden). On the single cross section Dixon fat image at L2/L3 intervertebral level, the corresponding VAT, SAT, and TAT areas (cm2) were manually segmented. L2/L3 level was previously suggested as the most predictive and reproducible single abdominal axial section for total abdominal adiposity characterization. A linear prediction model was developed with age, sex, height, weight, and the L2/L3 adipose area as potential predictor variables of the whole-body adipose volume for each compartment.*Results For the whole-body VAT volume, only the association of L2/L3 VAT area (p<0.001) was significant. For the whole-body SAT volume, sex (p=0.021), weight (p<0.001), and L2/L3 SAT area (p<0.001) were significant. For the whole-body TAT volume, sex (p<0.001), weight (p=0.002), and L2/L3 TAT area (p<0.001) were significant. Using only these significant variables, the prediction models explained 85%, 88%, and 91% of the whole-body VAT, SAT, and TAT volume variations by regression R2, respectively. Representative subjects with segmented L2/L3 images and regression plots with 95% prediction interval in dotted red for VAT, SAT, and TAT are shown in Figure 1.*Conclusions Prediction of whole-body adipose compartment volumes may be feasible by single-slice abdominal cross-sectional adipose area segmentation.*Clinical Relevance/Application Whole-body adiposity assessment without whole-body imaging may enable large-scale retrospective and opportunistic studies of whole-body adiposity in whom only cross-sectional abdominal images are available.

RESULTS

For the whole-body VAT volume, only the association of L2/L3 VAT area (p<0.001) was significant. For the whole-body SAT volume, sex (p=0.021), weight (p<0.001), and L2/L3 SAT area (p<0.001) were significant. For the whole-body TAT volume, sex (p<0.001), weight (p=0.002), and L2/L3 TAT area (p<0.001) were significant. Using only these significant variables, the prediction models explained 85%, 88%, and 91% of the whole-body VAT, SAT, and TAT volume variations by regression R2, respectively. Representative subjects with segmented L2/L3 images and regression plots with 95% prediction interval in dotted red for VAT, SAT, and TAT are shown in Figure 1.

CLINICAL RELEVANCE/APPLICATION

Whole-body adiposity assessment without whole-body imaging may enable large-scale retrospective and opportunistic studies of whole-body adiposity in whom only cross-sectional abdominal images are available.

SPR-GI-20   Role Of FDG-PET In Re-staging Of Borderline Resectable Pancreatic Cancer After Neo-adjuvant Treatment

Participants
Seungchul Han, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To retrospectively evaluate the clinical significance of PET based systemic surveillance for distant metastasis in borderline resectable pancreatic cancer (BRPC) patients who are undergoing FOLFIRINOX based neoadjuvant chemotherapy (NAC).*Methods and Materials 78 patients who underwent FOLFIRINOX based NAC for BRPC from a single institute during January 2013 to December 2019 were retrospectively reviewed. All of the patients underwent an initial PET scan to confirm local disease. Image review including pre- and post-NAC (CT, MRI and PET) images was done by 2 radiologists in consensus based on the NCCN 2020 guideline. Clinical information including operative findings and pathologic findings were obtained from patients records. Risk factor analysis for disease progression and metastasis development was performed with binary logistic regression and Chi-square analysis.*Results Among the 78 patients who underwent NAC, 15.4% (12/78) of the patients converted to palliative setting due to local progression (7.7%, 6/78) or distant metastasis (7.7%, 6/78). The remaining 84.6% (66/78) of the patients proceeded to preoperative evaluation with (n=52) or without (n=14) PET evaluation. Among the patients with preoperative PET scan, distant metastasis was detected in 7.7% (4/52) of the patients. Among them, one liver metastasis (25%, 1/4) in one patient was only found on PET scan. Overall, 12.8% (10/78) patients developed metastasis during NAC. Among them, 2 cases of metastasis were only detected in the PET scan (2/10, 20%). Regarding the risk factors, the increment of CA 19-9 level during treatment was associated with development of metastasis during NAC (OR 13.1 [2.95-57.85], p=0.001).*Conclusions Considerable proportion of patients undergoing NAC for BRPC develop distant metastasis during treatment, especially for patients with increased CA 19-9 during the NAC, and systemic PET can aid in detection before undergoing curative resection.*Clinical Relevance/Application The results of this study suggests the clinical value of PET based systemic surveillance of de novo distant metastasis in patients with BRPC treated by NAC, and re-staging after NAC including PET may contribute in accurate patient allocation to surgical resection.

RESULTS

Among the 78 patients who underwent NAC, 15.4% (12/78) of the patients converted to palliative setting due to local progression (7.7%, 6/78) or distant metastasis (7.7%, 6/78). The remaining 84.6% (66/78) of the patients proceeded to preoperative evaluation with (n=52) or without (n=14) PET evaluation. Among the patients with preoperative PET scan, distant metastasis was detected in 7.7% (4/52) of the patients. Among them, one liver metastasis (25%, 1/4) in one patient was only found on PET scan. Overall, 12.8% (10/78) patients developed metastasis during NAC. Among them, 2 cases of metastasis were only detected in the PET scan (2/10, 20%). Regarding the risk factors, the increment of CA 19-9 level during treatment was associated with development of metastasis during NAC (OR 13.1 [2.95-57.85], p=0.001).

CLINICAL RELEVANCE/APPLICATION

The results of this study suggests the clinical value of PET based systemic surveillance of de novo distant metastasis in patients

with BRPC treated by NAC, and re-staging after NAC including PET may contribute in accurate patient allocation to surgical resection.

SPR-GI-21 Identification Of Intratumoral Cysts By Magnetic Resonance Imaging To Predict Prognosis In Patients With Pancreatic Ductal Adenocarcinoma After Curative Resection

Participants
Hokun Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Pancreatic ductal adenocarcinoma (PDAC) is often accompanied by intratumoralcysts such as necrosis or neoplastic mucin cysts on preoperative magnetic resonance imaging (MRI). We aimed to compare the prognosis of PDAC after curative resection according to the type of intratumoral cyst identified on MRI.*Methods and Materials This study included 112 consecutive patients who underwent upfront surgery with margin-negative resection between 2012 and 2019. All patients underwent MRI within 1 month before surgery. Three radiologists independently assessed the MRI findings, determined whether intratumoral cysts were present, and classified all intratumoral cysts by type (i.e., necrosis or neoplastic mucin cysts). Interobserver agreement was evaluated using the free-marginal multi-rater ? analysis. Recurrence-free survival (RFS) and overall survival (OS) were evaluated by the Kaplan-Meier method and the Cox proportional hazards model. Histopathological differences according to the type of intratumoral cyst were assessed.*Results Of the 112 patients with PDAC, intratumoral cysts were identified on MRI in 33(29.5%), among which 18 were classified as necrosis and 15 as neoplastic mucin cysts. Interobserver agreement for discriminating the intratumoral cysts was good (?=0.66). PDAC patients with necrosis demonstrated significantly shorter RFS (mean 6.1 months versus 47.3months; P<.001) and OS (18.4 months versus 55.0 months, P=.001) than those with neoplastic mucin cysts. Multivariable analysis showed that only the type of intratumoral cyst was significantly associated with RFS (hazard ratio [HR], 2.51 and 0.37; P=.003 and P=.038 for necrosis and neoplastic mucin cysts, respectively). Tumor size (HR, 1.19; P=.032) and lymph node metastasis (HR, 1.75; P=.032) showed independent associations with OS. PDAC with necrosis had more frequent histological necrosis, more aggressive tumor differentiation, and higher tumor cellularity than PDAC with neoplastic mucin cysts (P=.016).*Conclusions The detection and discrimination of intratumoral cysts on preoperative MRI may be useful in predicting the prognosis of PDAC patients after curative resection.*Clinical Relevance/Application PDAC patients with necrosis on preoperative MRI had a worse postsurgical prognosis than those with ordinary PDAC, while those with neoplastic mucin cysts had a better prognosis.

RESULTS

Of the 112 patients with PDAC, intratumoral cysts were identified on MRI in 33(29.5%), among which 18 were classified as necrosis and 15 as neoplastic mucin cysts. Interobserver agreement for discriminating the intratumoral cysts was good (?=0.66). PDAC patients with necrosis demonstrated significantly shorter RFS (mean 6.1 months versus 47.3months; P<.001) and OS (18.4 months versus 55.0 months, P=.001) than those with neoplastic mucin cysts. Multivariable analysis showed that only the type of intratumoral cyst was significantly associated with RFS (hazard ratio [HR], 2.51 and 0.37; P=.003 and P=.038 for necrosis and neoplastic mucin cysts, respectively). Tumor size (HR, 1.19; P=.032) and lymph node metastasis (HR, 1.75; P=.032) showed independent associations with OS. PDAC with necrosis had more frequent histological necrosis, more aggressive tumor differentiation, and higher tumor cellularity than PDAC with neoplastic mucin cysts (P=.016).

CLINICAL RELEVANCE/APPLICATION

PDAC patients with necrosis on preoperative MRI had a worse postsurgical prognosis than those with ordinary PDAC, while those with neoplastic mucin cysts had a better prognosis.

SPR-GI-22 Assessment Of Image Quality And Diagnostic Performance Of Deep Learning Image Reconstruction (DLIR) Algorithm In Abdominopelvic CT: A Perspective Of Radiation Dose Reduction

Participants
June Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate image quality and diagnostic performance of deep learning image reconstruction (DLIR) algorithm in lower-dose contrast-enhanced abdominopelvic CT (LDCT) images as compared with standard-dose CT (SDCT) images.*Methods and Materials Our retrospective study included 111 patients who undergone LDCT (100 kVp, noise index of 17) between May and November 2020 and also had prior SDCT (100 kVp, noise index of 14) by the same CT machine. LDCT images were reconstructed with ASiR-V 40% (AV-40), TrueFidelity moderate- and high-strength (TF-M and TF-H) while SDCT images were reconstructed with AV-40. A radiologist measured CT values and standard deviation values of ROIs on liver, muscle, aorta, and fat to assess image noise, SNR, and CNR. Overall image quality, image noise, image sharpness, artifactual texture, and lesion conspicuity were graded on the 5-point comparative scale by two radiologists: among LDCT images, the LDCT images which had the most similar quantitative values to SDCT images were compared with SDCT images. Diagnostic performance was also evaluated in 40 cases that had focal liver lesions.*Results In quantitative analysis, the LDCT TF-M was not significantly different from the SDCT with respect to image noise, SNR, and CNR. In qualitative analysis, the LDCT TF-M was equal to the SDCT for all parameters except image noise and overall image quality: the image noise was lesser (for one reader), and the overall image quality was better (for both readers) on the LDCT TF-M. Diagnostic performance was no significant difference between the two groups in per-lesion analysis (SN and PPV) and per-segment analysis (SN, SP, PPV, NPV, and accuracy). Reader-averaged AUC showed no performance difference between LDCT TF-M and SDCT (0.915 vs. 0.908, p = 0.72). An average 35.1% radiation dose reduction was achieved in the LDCT group compared to the SDCT group.*Conclusions With DLIR (TF-M), radiation dose could be reduced by 35.1% without deteriorating image quality and diagnostic performance for focal liver lesions.*Clinical Relevance/Application Implanting DLIR algorithms in abdominopelvic CT scans can reduce radiation exposure without sacrificing diagnostic accuracy.

RESULTS

In quantitative analysis, the LDCT TF-M was not significantly different from the SDCT with respect to image noise, SNR, and CNR. In qualitative analysis, the LDCT TF-M was equal to the SDCT for all parameters except image noise and overall image quality: the image noise was lesser (for one reader), and the overall image quality was better (for both readers) on the LDCT TF-M. Diagnostic performance was no significant difference between the two groups in per-lesion analysis (SN and PPV) and per-segment analysis (SN, SP, PPV, NPV, and accuracy). Reader-averaged AUC showed no performance difference between LDCT TF-M and SDCT (0.915 vs. 0.908, p = 0.72). An average 35.1% radiation dose reduction was achieved in the LDCT group compared to the SDCT group.

CLINICAL RELEVANCE/APPLICATION

Implanting DLIR algorithms in abdominopelvic CT scans can reduce radiation exposure without sacrificing diagnostic accuracy.

SPR-GI-23   Low-contrast Detectability And Radiation Dose Saving Potential Using Deep Learning Image Reconstruction: Phantom Experiment And Clinical Study With Hepatic Metastases

Participants
Peijie Lyu, MD, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the low-contrast detectability of deep learning imaging reconstruction (DLIR) on small hypoattenuating lesions under multiple radiation exposure levels in a contrast-detail phantom and to validate its performance for potential dose reduction in the detection of liver metastases.*Methods and Materials A proprietary low-contrast phantom consisting of low-contrast objects (two sizes [4 and 6 mm] and one contrast level selected) was scanned at five CT dose index levels (1, 2, 3, 6, and 10 mGy) with noise levels comparable to clinical images. A prospective, institutional review board-approved study was performed in 45 patients (mean age, 62 years ± 13; 23 men) who underwent multidetector CT of the hepatic metastasis at four dose levels (automatic exposure control settings: 60, 100, 140, and 200, quality reference mAs). All images were reconstructed using filtered back projection (FBP), hybrid model-based adaptive statistical IR (ASiR-V) 60%, and DLIR at medium strength level (DLIR-M). A generalized linear mixed-effects model was used to compare detection accuracy measured with a two-alternative forced-choice approach by eleven readers in the phantom. Noninferiority analysis was performed to evaluate the image quality, lesion conspicuity, and lesion detectability in the patient study.*Results The phantom data showed that detection accuracy of DLIR-M was not significantly different than ASiR-V 60% but improved by 3.0% compared to FBP on average across all variables (P < .001). In the patient study, 105 hepatic metastases were included (mean size, 1.8 cm; mean size-specific dose estimates for the four radiation dose levels, 4.1, 6.8, 9.5, and 13.6 mGy). For each radiation exposure level, readers' perception of image quality and lesion conspicuity was consistently ranked superior with DLIR-M compared to FBP and ASiR-V 60% (P <.05 for all comparisons) while the lesion detectability was similar among all the algorithms. Reduction of up to 70% in radiation exposure by using DLIR-M yielded similar reader rankings of image quality and lesion conspicuity, and comparable lesion detectability when compared with routine-dose FBP and ASiR-V 60%.*Conclusions For detection of hepatic metastases by using contrast-enhanced CT, DLIR allowed a substantial radiation dose reduction (70%) while preserving low-contrast detectability compared with FBP and ASiR-V 60%.*Clinical Relevance/Application Deep learning image reconstruction showed preferred abdominal CT imaging appearance for radiologists and allowed for substantial radiation dose reduction (70%) while maintaining image quality and preserving low-contrast lesion detectability.

RESULTS

The phantom data showed that detection accuracy of DLIR-M was not significantly different than ASiR-V 60% but improved by 3.0% compared to FBP on average across all variables (P < .001). In the patient study, 105 hepatic metastases were included (mean size, 1.8 cm; mean size-specific dose estimates for the four radiation dose levels, 4.1, 6.8, 9.5, and 13.6 mGy). For each radiation exposure level, readers' perception of image quality and lesion conspicuity was consistently ranked superior with DLIR-M compared to FBP and ASiR-V 60% (P <.05 for all comparisons) while the lesion detectability was similar among all the algorithms. Reduction of up to 70% in radiation exposure by using DLIR-M yielded similar reader rankings of image quality and lesion conspicuity, and comparable lesion detectability when compared with routine-dose FBP and ASiR-V 60%.

CLINICAL RELEVANCE/APPLICATION

Deep learning image reconstruction showed preferred abdominal CT imaging appearance for radiologists and allowed for substantial radiation dose reduction (70%) while maintaining image quality and preserving low-contrast lesion detectability.

SPR-GI-24   Comparison Of Diagnostic Performance Between HASTE T2WI Using Intermediate TE And Conventional T2WI In Liver MRI

Participants
Seungchul Han, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the image quality and the diagnostic performance of single-shot fast spin echo using intermediate TE (HASTE-iTE) using compressed sensing compared to conventional T2 weighted (T2W) sequence in patients with risk factors for developing HCC.*Methods and Materials The images of 231 patients (M: F=173:58) with viral hepatitis or cirrhosis and who underwent gadoxetic acid-enhanced liver MRI at 3T were included. The three sequences (HASTE-iTE with compressed sensing (CS) and deep learning (DL) reconstruction (HASTE-DL), HASTE-iTE with only CS reconstruction (HASTE-CS), and T2W image using BLADE) were provided to the reviewers in random order. Three radiologists independently reviewed the image quality, noise, vessel conspicuity on a four-point scale along with solid lesion detection. 280 solid lesions were designated as reference after reviewing the dynamic sequences and the follow-up images and LI-RADS score was assigned to the lesions. Image quality and lesion detection were compared between the sequences.*Results The acquisition time of HASTE-DL, HASTE-CS and T2W image was 70-, 84-, and 90-seconds, respectively. Both HASTE-DL and HASTE-CS images showed better overall image quality, less noise, and higher vessel conspicuity compared to those of T2W images (p < 0.001 for all). HASTE-DL additionally showed better overall image quality, less noise and higher vessel conspicuity than HASTE-CS images (p < 0.001 for all). In per-lesion analysis, HASTE-DL showed superior performance, calculated as figure of merit, compared to T2W image in all lesions (0.58 vs. 0.54, p=0.02), and LR-4, -5, -M lesions (0.59 vs. 0.53, p<0.001) and in lesions larger than 1cm in size (0.63 vs. 0.57, p=0.02). In per-patient analysis, HASTE-DL showed significantly higher sensitivity than conventional T2W image for lesions = 1cm (63.7% vs. 54.7%, p=0.015), and for LR-4, -5, -M lesions (58.1% vs. 47.6%, p=0.015). HASTE-CS also showed significantly higher sensitivity than T2W image for LR-4, -5, -M lesions (56.7% vs. 47.6%, p=0.01).*Conclusions HASTE-DL and HASTE-CS provided better diagnostic performance and image quality for detecting solid focal liver lesions compared to conventional T2W images.*Clinical Relevance/Application HASTE-iTE with DL and CS based reconstruction can provide images with better quality and superior diagnostic performance than conventional T2 weighted image with shorter acquisition time.

RESULTS

The acquisition time of HASTE-DL, HASTE-CS and T2W image was 70-, 84-, and 90-seconds, respectively. Both HASTE-DL and HASTE-CS images showed better overall image quality, less noise, and higher vessel conspicuity compared to those of T2W images (p < 0.001 for all). HASTE-DL additionally showed better overall image quality, less noise and higher vessel conspicuity than HASTE-CS images (p < 0.001 for all). In per-lesion analysis, HASTE-DL showed superior performance, calculated as figure of merit, compared to T2W image in all lesions (0.58 vs. 0.54, p=0.02), and LR-4, -5, -M lesions (0.59 vs. 0.53, p<0.001) and in lesions

larger than 1cm in size (0.63 vs. 0.57, p=0.02). In per-patient analysis, HASTE-DL showed significantly higher sensitivity than conventional T2W image for lesions = 1cm (63.7% vs. 54.7%, p=0.015), and for LR-4, -5, -M lesions (58.1% vs. 47.6%, p=0.015). HASTE-CS also showed significantly higher sensitivity than T2W image for LR-4, -5, -M lesions (56.7% vs. 47.6%, p=0.01).

CLINICAL RELEVANCE/APPLICATION

HASTE-iTE with DL and CS based reconstruction can provide images with better quality and superior diagnostic performance than conventional T2 weighted image with shorter acquisition time.

SPR-GI-25   Energy Spectral Parameters Of Mesenteric Adipose Tissue Assessed By Dual-energy CT Enterography: Potentially Novel Clinical Application For Quantitatively Evaluate Creeping Fat In Patients With Crohn's Disease

Participants
Xueying Long, MD, Changsha, China (*Presenter*) Nothing to Disclose

PURPOSE

To assess the energy spectral parameters of dual-energy CT enterography (CTE) between the normal mesenteric adipose tissue (MAT) in non-CD control group and the creeping fat in Crohn's disease (CD) group, and to evaluate the correlation of quantitative energy spectral parameters of creeping fat between inactive and active CD patients.*Methods and Materials This prospective study was approved by the Medical Ethics Committee of our hospital and written informed consents were obtained from all participants. In this study, the patients with known or suspected Crohn's disease who underwent the dual-energy CTE (with high-speed switching from 80 kVp to 140 kVp) at the enteric and the delayed phases on a 256-detector row CT scanner (Revolution CT, GE Healthcare) were enrolled. From March 1, 2019 to March 31, 2021, forty patients were selected as the creeping fat CD group according to the presence of creeping fat with surgical and pathologic correlations, and 40 non-CD patients were selected as control group. The quantitative parameters of the normal MAT or the creeping fat were obtained on the AW 4.7 workstation (GE Healthcare) with GSI software, including the slope of Hounsfield unit (HU) curve (?HU), normalized fat-water concentration (NFWC), normalized fat-iodine concentration (NFIC) and normalized fat volume fraction (NFVF) at the enteric and delayed phases. Mann-Whitney U test, Kruskal-Wallis H test and receiver operating characteristic (ROC) curve analysis were applied to compare quantitative parameters among various groups.*Results A significant difference was observed in ?HU, NFIC, NFWC and NFVF between normal MAT and creeping fat with CD both at the enteric and delayed phases (all P < 0.001). All quantitative parameters of creeping fat including ?HU, NFIC, NFWC and NFVF both at the enteric and delayed phases (all P < 0.01) had significant differences between inactive and active CD patients. ROC curve analysis showed that ?HU of creeping fat at the delayed phase had a better capability to distinguish inactive and active CD [AUC= 0.95, P < 0.001].*Conclusions Dual-energy CTE with quantitative parameters is a potentially novel noninvasive tool for evaluating creeping fat in CD.*Clinical Relevance/Application Recent studies have shown that the mesentery interacts closely with the affected bowel and plays a potential role in the development process of CD. Dual-energy CT can distinguish different tissues according to the behaviors of the material at different energy levels and spectral parameters may help quantitatively assessing mesenteric tissues in CD. However, the spectral parameters of creeping fat correlated with the surgical and pathologic findings of CD have not been reported so far.

RESULTS

A significant difference was observed in ?HU, NFIC, NFWC and NFVF between normal MAT and creeping fat with CD both at the enteric and delayed phases (all P < 0.001). All quantitative parameters of creeping fat including ?HU, NFIC, NFWC and NFVF both at the enteric and delayed phases (all P < 0.01) had significant differences between inactive and active CD patients. ROC curve analysis showed that ?HU of creeping fat at the delayed phase had a better capability to distinguish inactive and active CD [AUC= 0.95, P < 0.001].

CLINICAL RELEVANCE/APPLICATION

Recent studies have shown that the mesentery interacts closely with the affected bowel and plays a potential role in the development process of CD. Dual-energy CT can distinguish different tissues according to the behaviors of the material at different energy levels and spectral parameters may help quantitatively assessing mesenteric tissues in CD. However, the spectral parameters of creeping fat correlated with the surgical and pathologic findings of CD have not been reported so far.

SPR-GI-26   Effective Boolean Interpretation Model Using "T1wi Or Dwi Or Mrcp" In Discriminating Small Pancreatic Ductal Adenocarcinoma (pdac) From Control Group

Participants
Hainan Ren, BMedSc, Sendai, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic performance of findings on T1WI, T2WI, DWI, and MRCP separately and to identify an optimal Boolean interpretation model for discriminating patients with small PDAC from control groups in clinical practice.*Methods and Materials During April 2008 and September 2018, 30 patients with surgery confirmed small PDAC (=20 mm) and 302 patients without pancreatic abnormality were enrolled. The presence of masses was evaluated by T1WI, T2WI, and DWI. Abnormality of the main pancreatic duct (MPD) was evaluated by T2WI and MRCP. Multivariate logistic regression analysis was performed to select significant sequences for discriminating the small PDAC and control groups. Boolean operators "OR" or "AND" were used to construct sequence combinations. Diagnostic performances of these sequences and combinations were evaluated by X2 tests.*Results The sensitivity of T2WI was lowest (20%) for detecting masses. For evaluating MPD abnormality, sensitivity was higher for MRCP than for T2WI (86.7% vs. 53.3%). Multivariate logistic regression analysis showed that T1WI and DWI for detecting the presence of masses and MRCP for evaluating MPD abnormality were significantly associated with differentiation between the two groups (p = 0.0002, p = 0.0484 and p < 0.0001, respectively). Seven combinations were constructed with T1WI, DWI, and MRCP using "OR" or "AND". The combination of findings on "T1WI or DWI or MRCP" achieved the highest sensitivity of 96.7% and negative predictive value of 99.6%.*Conclusions The combination of findings on "T1WI or DWI or MRCP" might be an optimal Boolean interpretation model for discriminating small PDAC from control groups in clinical practice.*Clinical Relevance/Application When there is at least one positive finding from the three sequences including T1WI, DWI and MRCP, the presence of small PDAC is suggested, and further clinical examination should be considered.

RESULTS

The sensitivity of T2WI was lowest (20%) for detecting masses. For evaluating MPD abnormality, sensitivity was higher for MRCP

than for T2WI (86.7% vs. 53.3%). Multivariate logistic regression analysis showed that T1WI and DWI for detecting the presence of masses and MRCP for evaluating MPD abnormality were significantly associated with differentiation between the two groups (p = 0.0002, p = 0.0484 and p < 0.0001, respectively). Seven combinations were constructed with T1WI, DWI, and MRCP using "OR" or "AND". The combination of findings on "T1WI or DWI or MRCP" achieved the highest sensitivity of 96.7% and negative predictive value of 99.6%.

CLINICAL RELEVANCE/APPLICATION

When there is at least one positive finding from the three sequences including T1WI, DWI and MRCP, the presence of small PDAC is suggested, and further clinical examination should be considered.

SPR-GI-27   Prognostic Value Of Tumor-parenchymal Enhancement Ratio On Portal Venous Phase CT In Patients With Pancreatic Neuroendocrine Neoplasms: Comparison With Current Staging And Grading Systems

Participants
Hyo Jung Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Due to the diverse spectrum of the disease, the outcome of individual patients with pancreatic neuroendocrine neoplasm (PanNEN) varies after curative-intent resection. The major limitation of current prognostic tools such as AJCC staging system and WHO classification is that they are based on surgical pathology data. The tumor-to-parenchymal enhancement ratio on portal venous phase CT (CT portal enhancement ratio; CT-PER) has the potential for predicting the outcome of PanNENs. We aimed to evaluate its prognostic value in PanNEN, and to compare its prognostic performance to the current staging and grading systems.*Methods and Materials This retrospective study included 465 patients who underwent curative-intent resection for PanNEN with available dynamic CT performed within 30 days before surgery. CT was used to obtain CT-PER and tumor size (CT-Size). Optimal cutoffs of CT-PER and CT-Size were determined using a multi-way partitioning algorithm. Patients were classified according to CT-PER, CT-Size, 2019 WHO classification system (WHO), and the 8th American Joint Committee on Cancer staging system (AJCC). Harrell's C-index was used to assess the prognostic performance of each method.*Results CT-PER (cutoffs, 0.75, 0.95, and 1.25) showed a C-index of 0.78 (95% confidence interval [CI], 0.73-0.83) and 0.79 (95% CI, 0.71-0.87) for predicting recurrence-free survival (RFS) and overall survival (OS), respectively, which were equivalent to WHO (C-index, 0.80 [95% CI, 0.75-0.85] for RFS and 0.80 [95% CI, 0.72-0.88] for OS) and AJCC (C-index, 0.78 [95% CI, 0.74-0.83] for RFS and 0.74 [95% CI, 0.66-0.82] for OS). CT-Size (cutoffs, 2-cm and 4-cm) showed the lowest C-index for RFS (0.69 [95% CI, 0.64-0.74]) and OS (0.65 [95% CI, 0.57-0.72]).*Conclusions CT-PER showed similar ability to AJCC and WHO in predicting RFS and OS, indicating its possible use as a preoperatively available, non-invasive prognostic biomarker in PanNEN.*Clinical Relevance/Application CT-PER may serve as a preoperatively available, non-invasive prognostic tool for patients with resectable PanNEN.

RESULTS

CT-PER (cutoffs, 0.75, 0.95, and 1.25) showed a C-index of 0.78 (95% confidence interval [CI], 0.73-0.83) and 0.79 (95% CI, 0.71-0.87) for predicting recurrence-free survival (RFS) and overall survival (OS), respectively, which were equivalent to WHO (C-index, 0.80 [95% CI, 0.75-0.85] for RFS and 0.80 [95% CI, 0.72-0.88] for OS) and AJCC (C-index, 0.78 [95% CI, 0.74-0.83] for RFS and 0.74 [95% CI, 0.66-0.82] for OS). CT-Size (cutoffs, 2-cm and 4-cm) showed the lowest C-index for RFS (0.69 [95% CI, 0.64-0.74]) and OS (0.65 [95% CI, 0.57-0.72]).

CLINICAL RELEVANCE/APPLICATION

CT-PER may serve as a preoperatively available, non-invasive prognostic tool for patients with resectable PanNEN.

SPR-GI-28   Perfluorobutane-enhanced Ultrasound As A Diagnostic Tool For Hepatocellular Carcinoma In Individuals With High Risk: Intraindividual Comparison With Sulfur Hexafluoride-enhanced Ultrasound

Participants
Hyo-Jin Kang, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate which dynamic phase of perfluorobutane-enhanced ultrasound (PFB-US) is most appropriate to assess washout in the noninvasive diagnosis of HCC in participants with high risk by comparing to sulfur hexafluoride-enhanced ultrasound (SHF-US)*Methods and Materials We prospectively recruited participants at risk of HCC with treatment-naïve solid hepatic observations (=1 cm). They underwent same-day PFB-US and SHF-US with at least 30 min intervals. PFB-US imaging diagnosis of HCC was made using criteria of nonrim arterial phase hyperenhancement (APHE) and mild hypoechogenicity relative to the surrounding liver parenchyma, which refers to washout, between (1) 1-2 min and (2) 1-5 min after contrast injection, and (3) 1-min to the Kupffer phase. The Kupffer phase echogenicity for PFB-US was also evaluated. SHF-US imaging diagnosis of HCC was APHE and mild washout 1-min after contrast injection during a 5-min SHF-US examination. The diagnostic performance of SHF-US and PFB-US with different vascular phase were compared.*Results Eighty-nine participants with 89 observations (HCCs [n=61], non-HCC, malignancies [n=18], benign [n=10]) were evaluated. Among 61 HCCs, 54 (88.5%) in PFB-US and 56 (91.8%) in SHF-US showed nonrim APHE (p=0.73). Fifty-three HCCs (86.9%) in PFB-US and 51 (83.6%) in SHF-US showed mild washout (p=0.33). For the noninvasive diagnosis of HCC, PFB-US criterion 1 provided lower sensitivity (18.0%, 95%CI: 9.4-30.0%) than criterion 2 (52.5%, 95%CI: 39.3-65.4%), criterion 3 (52.5%, 95%CI: 39.3-65.4%), or SHF-US (47.5%, 95%CI: 34.6-90.7%). The specificity were 96.4% (95%CI: 81.7-99.9%) by criterion 1, 92.9% (95%CI: 76.5-99.1%) by criterion 2, 89.3% (95%CI: 71.8-97.7%) by criterion 3, and 96.4% (95%CI: 81.7-99.9%) by SHF-US. The Kupffer phase hypoechogenicity was more frequent in HCC (51/61, 83.6%; p=0.04) and non-HCC malignancies (17/18, 94.4%; p=0.02) than or benign lesions (5/10, 50.0%) but was not specific for HCC.*Conclusions To make a specific diagnosis of HCC using PFB-US, washout should be determined before 5-min after contrast injection.*Clinical Relevance/Application Perfluorobutane-enhanced ultrasound has different physiological characteristics from sulfur hexafluoride-enhanced ultrasound, but it is unclear whether HCC show similar wash-in and washout patterns. Our results would provide proper application of PFB-US to diagnose HCC.

RESULTS

Eighty-nine participants with 89 observations (HCCs [n=61], non-HCC, malignancies [n=18], benign [n=10]) were evaluated. Among 61 HCCs, 54 (88.5%) in PFB-US and 56 (91.8%) in SHF-US showed nonrim APHE (p=0.73). Fifty-three HCCs (86.9%) in PFB-US and 51 (83.6%) in SHF-US showed mild washout (p=0.33). For the noninvasive diagnosis of HCC, PFB-US criterion 1 provided lower

sensitivity (18.0%, 95%CI: 9.4-30.0%) than criterion 2 (52.5%, 95%CI: 39.3-65.4%), criterion 3 (52.5%, 95%CI: 39.3-65.4%), or SHF-US (47.5%, 95%CI: 34.6-90.7%). The specificity were 96.4% (95%CI: 81.7-99.9%) by criterion 1, 92.9% (95%CI: 76.5-99.1%) by criterion 2, 89.3% (95%CI: 71.8-97.7%) by criterion 3, and 96.4% (95%CI: 81.7-99.9%) by SHF-US. The Kupffer phase hypoechogenicity was more frequent in HCC (51/61, 83.6%; p=0.04) and non-HCC malignancies (17/18, 94.4%; p=0.02) than or benign lesions (5/10, 50.0%) but was not specific for HCC.

CLINICAL RELEVANCE/APPLICATION

Perfluorobutane-enhanced ultrasound has different physiological characteristics from sulfur hexafluoride-enhanced ultrasound, but it is unclear whether HCC show similar wash-in and washout patterns. Our results would provide proper application of PFB-US to diagnose HCC.

SPR-GI-29   Evaluation Of Intratumoral Vascular Structures Of Focal Liver Lesions Using Contrast-enhanced Ultrasonography And Post-processing Contrast Vector Imaging: A Prospective Study

Participants
Jeongin Yoo, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To demonstrate tumor-specific vascularization pattern of common focal liver lesions on post-processing contrast vector imaging (CVI), and to determine whether the combination of contrast-enhanced US and CVI can improve characterization of focal liver lesions.*Methods and Materials Between July 2019 and October 2020, 65 patients with focal lesions in the liver (HCC [n=18], non-HCC malignancy [n=13], and benign lesions [n=14]) were enrolled in this prospective study. Contrast-enhanced ultrasound (CEUS) using SonoVue® was performed with high frame rate contrast harmonic imaging technique by one of the two radiologists. Post-processing CVI including histogram of velocity was obtained and analyzed by the two radiologists independently and then in consensus.*Results Among 65 patients, post-processing CVI was technically successful in 53 patients (technical success rate, 81.5% [53/65]). There were significant differences in enhancement pattern (p=0.0023) and adjacent vascular structures (p=0.0009) on CVI among HCC (n=18), non-HCC malignancy (n=13), and benign groups (n=21); diffuse staining was frequent in HCC and benign groups, while peripheral rim was predominant in non-HCC malignancy. Regarding histogram pattern of velocity, there were no significant difference among three groups (p=0.315). However, significant difference was found between HCC and non-HCC groups (p=0.033); HCC group predominantly demonstrated variable distribution of velocity, whereas non-HCC group frequently showed low velocity.*Conclusions HCC, non-HCC, and benign groups demonstrated significantly different imaging features on CVI, including arterial enhancement pattern, adjacent vascular structures, and velocity histogram.*Clinical Relevance/Application Differences in imaging features on CVI could aid the diagnoses of focal liver lesions in addition to CEUS.

RESULTS

Among 65 patients, post-processing CVI was technically successful in 53 patients (technical success rate, 81.5% [53/65]). There were significant differences in enhancement pattern (p=0.0023) and adjacent vascular structures (p=0.0009) on CVI among HCC (n=18), non-HCC malignancy (n=13), and benign groups (n=21); diffuse staining was frequent in HCC and benign groups, while peripheral rim was predominant in non-HCC malignancy. Regarding histogram pattern of velocity, there were no significant difference among three groups (p=0.315). However, significant difference was found between HCC and non-HCC groups (p=0.033); HCC group predominantly demonstrated variable distribution of velocity, whereas non-HCC group frequently showed low velocity.

CLINICAL RELEVANCE/APPLICATION

Differences in imaging features on CVI could aid the diagnoses of focal liver lesions in addition to CEUS.

SPR-GI-30   Peritoneal Metastasis Score Based On CT Characteristics In The Prediction Of The Overall Survival Of Gastric Cancer Patients

Participants
Jia-Zheng Li, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop a peritoneal metastasis (PM) score based on CT characteristics (CT-PMS) to hierarchize gastric cancer (GC) patients with PM according to the life expectancy.*Methods and Materials This retrospective study enrolled 66 consecutive patients newly diagnosed as GC with synchronous PM. On CT, the manifestation of PM includes smudged appearance, multiple fibrosis strands, nodules, and omental cake. The following regions were assessed by radiologists: (1) gastrosplenic ligament(GSL); (2) gastrohepatic and hepatoduodenal ligament (GHL and HDL); (3) gastrocolic ligament (GCL); (4) peri-hepatic visceral peritoneum; (5) the mesenteries; (6) greater omentum; (7) superior parietal peritoneum; (8) posterior parietal peritoneum; (9) anterior parietal peritoneum; (10) pelvic parietal peritoneum. Based on the number of regions PM involved, the CT-PMS were acquired ranged from 0 to 10. We also recorded patients' age, gender, histology type of primary tumor, differentiation status of primary tumor, the location of primary tumor, the presence of linitis plastica, and the presence of extraperitoneal metastases.*Results The median OS was 315 days in all patients (range, 40-1440 days). We used X-tile plots to generate the optimal cutoff value of the CT-PMS as 2. CT-PMS >2 had great diagnostic accuracy for recognizing patients with OS < 100 days(sensitivity, 88.9%; specificity, 59.6%; accuracy, 63.6%; AUC, 0.743 [95% CI, 0.590-0.896]). Significant differences in OS were obtained between patients with CT-PMS >2 and patients with CT-PMS = 2 (P=0.006, log-rank test). Univariate analysis showed that CT-PMS >2 and the differentiation status were significant risk factors for reduced OS (P=0.007, P=0.045). Multivariate analysis showed that CT-PMS >2 was an independent risk factor for reduced OS (HR=1.965; 95% CI=1.168-3.306; P=0.011).*Conclusions The prognosis of PM patients depends on the extent of PM dissemination and patients with CT-PMS >2 had a dismal prognosis compared with those with CT-PMS = 2.*Clinical Relevance/Application CT-PMS provides a method for patient selection to identify the most optimal candidate and to avoid futile aggressive treatment including palliative gastrectomy, or treatment combining CRS and HIPEC.

RESULTS

The median OS was 315 days in all patients (range, 40-1440 days). We used X-tile plots to generate the optimal cutoff value of the CT-PMS as 2. CT-PMS >2 had great diagnostic accuracy for recognizing patients with OS < 100 days(sensitivity, 88.9%; specificity, 59.6%; accuracy, 63.6%; AUC, 0.743 [95% CI, 0.590-0.896]). Significant differences in OS were obtained between patients with CT-PMS >2 and patients with CT-PMS = 2 (P=0.006, log-rank test). Univariate analysis showed that CT-PMS >2 and the differentiation status were significant risk factors for reduced OS (P=0.007, P=0.045). Multivariate analysis showed that CT-PMS >2 was an independent risk factor for reduced OS (HR=1.965; 95% CI=1.168-3.306; P=0.011).

SPR-GI-31　A Nomogram Combining Radiomics Signature And Clinical Factors To Preoperatively Predict Histological Grade In Patients With Pancreatic Ductal Adenocarcinoma

Participants
Chunyuan Cen, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

In pancreatic ductal adenocarcinoma (PDAC), the histological grade is one of the most significant independent prognostic indicators of survival. In this study, we aimed to develop a nomogram integrating radiomics signature and clinical factors to preoperatively predict the histological grade of PDAC.*Methods and Materials A total of 182 patients with PDAC who underwent contrast-enhanced computed tomography (CECT) were enrolled, and were randomly divided into a training and validation cohort in an 8:2 ratio. 851 radiomics features were extracted from each arterial phase (AP) and portal venous phase (PVP) images. Maximum relevance minimum redundancy (mRMR) and least absolute shrinkage and selection operator regression (LASSO) were applied for feature selection, and then a radiomics signature was developed. Multivariable logistic regression analysis was used to develop the combined model, combining the radiomics signature and clinical factors. The Kaplan-Meier (KM) method was used for the overall survival (OS) analysis of tumor grades.*Results The radiomics signature showed favorable diagnostic efficacy, with the area under curves (AUCs) of the training and validation cohort of 0.870 and 0.812, respectively. The combined model, incorporating the radiomics signature, smoking status, CA12-5 level, maximum tumor diameter and cTNM, demonstrated better discrimination performance (training cohort: AUC = 0.896; validation cohort: AUC = 0.859) and calibration, outperforming the radiomics signature. The decision curve analysis (DCA) confirmed its clinical utility. KM analysis showed that the actual histological grade was significantly related to survival (P < 0.0001); that is, the higher grade the tumor was, the shorter the survival period. Moreover, the grade of histology predicted by our radiomics signature and combined nomogram were also related to survival (both P < 0.0001), which verified the accuracy of our models in predicting the histological grade.*Conclusions The radiomics signature was significantly associated with the histological grade of PDAC.The combined model integrating radiomics signature and clinical factors have the good diagnostic performance to preoperatively and non-invasively predict tumor grades in PDAC patients.The radiomics signature and the combined model were associated with OS may helpful for clinical decision-making and achieve a good survival outcome.*Clinical Relevance/Application The nomogram can serve as a preoperative, noninvasive, precise evaluation tool for histological grading of PDAC, which can help clinicians better tailor the treatment protocol for each patient and achieve better clinical outcomes.

RESULTS

The radiomics signature showed favorable diagnostic efficacy, with the area under curves (AUCs) of the training and validation cohort of 0.870 and 0.812, respectively. The combined model, incorporating the radiomics signature, smoking status, CA12-5 level, maximum tumor diameter and cTNM, demonstrated better discrimination performance (training cohort: AUC = 0.896; validation cohort: AUC = 0.859) and calibration, outperforming the radiomics signature. The decision curve analysis (DCA) confirmed its clinical utility. KM analysis showed that the actual histological grade was significantly related to survival (P < 0.0001); that is, the higher grade the tumor was, the shorter the survival period. Moreover, the grade of histology predicted by our radiomics signature and combined nomogram were also related to survival (both P < 0.0001), which verified the accuracy of our models in predicting the histological grade.

CLINICAL RELEVANCE/APPLICATION

The nomogram can serve as a preoperative, noninvasive, precise evaluation tool for histological grading of PDAC, which can help clinicians better tailor the treatment protocol for each patient and achieve better clinical outcomes.

SPR-GI-32　Impact Of LR-TR Category As A Predictor Of Recurrence After Curative Surgery For Hepatocellular Carcinoma Previously Treated With Locoregional Therapy: Risk Stratification Using Radiologic And Clinical Factors

Participants
Seo Yeon Youn, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

In HCC, locoregional therapy (LRT) is implemented as a bridging or downstaging treatment before curative surgery, but the impact of radiologic treatment response on the surgical outcome is little known. This study aimed to evaluate radiologic and clinical factors predicting recurrence-free survival (RFS) after curative surgery for LRT-treated HCC.*Methods and Materials This retrospective study included consecutive patients who underwent curative surgery for HCC after LRT from Dec 2010 to Nov 2016 and had baseline and post-LRT follow-up liver CT/MRI up to the point of surgery. Two radiologists assessed sequential treatment response with mRECIST and radiologic viable tumor by Liver Imaging Reporting and Data System treatment response (LR-TR) algorithm before surgery among other features. Clinical factors regarding LRT, laboratory data, and pathologic reports were collected. Uni- and multivariate Cox proportional hazard models determined factors predicting RFS and generated prognostic scores for risk stratification. RFS was analyzed by Kaplan-Meier method with log-rank test.*Results A total of 71 patients (mean age, 56 ± 10 years; 50 men) who received liver transplantation (53.5%; 38/71) or resection (46.5%; 33/71) were evaluated. During the median follow-up period of 64.0 months (range, 1-122 months), 28 (39.4%) recurrences were observed. Multivariate analysis revealed LR-TR viable category (Hazard ratio [HR] = 3.66; 95% confidence interval [CI], 1.02-13.2; P = 0.047) but not the pathologic viable tumor as a significant factor along with pre-operative AFP level > 200 ng/mL (HR = 4.14; 95% CI, 1.83-9.4; P = 0.001), greater number of LRT sessions (HR = 1.23; 95% CI, 1.1-1.39; P = 0.001), and resection compared to liver transplantation (HR = 3.46; 95% CI, 1.42-8.42; P = 0.006). Based on the multivariate analysis, risk scores were assigned as follows: high AFP level and LR-TR viable category, 2 points; resection, 1 point; number of LRT sessions, 1-2 points. The Kaplan-Meier curves for RFS showed significant risk stratification among three groups: = 4 points (high risk, 5-year RFS rate 19.0%), 2-3 points (intermediate risk, 63.6%%) and 0-1 points (low risk, 89.3%) (all log-rank Ps, < 0.025).*Conclusions Risk scoring system based on LR-TR viable category, high pre-operative AFP level, greater number of LRT, surgery type of resection effectively stratified risk of recurrence after curative surgery for LRT-treated HCC.*Clinical Relevance/Application LR-TR viable category on pre-operative image is a significant predictor of recurrence after curative surgery for LRT-treated HCC.

RESULTS

A total of 71 patients (mean age, 56 ± 10 years; 50 men) who received liver transplantation (53.5%; 38/71) or resection (46.5%; 33/71) were evaluated. During the median follow-up period of 64.0 months (range, 1-122 months), 28 (39.4%) recurrences were observed. Multivariate analysis revealed LR-TR viable category (Hazard ratio [HR] = 3.66; 95% confidence interval [CI], 1.02-13.2; P = 0.047) but not the pathologic viable tumor as a significant factor along with pre-operative AFP level > 200 ng/mL (HR = 4.14; 95% CI, 1.83-9.4; P = 0.001), greater number of LRT sessions (HR = 1.23; 95% CI, 1.1-1.39; P = 0.001), and resection compared to liver transplantation (HR = 3.46; 95% CI, 1.42-8.42; P = 0.006). Based on the multivariate analysis, risk scores were assigned as follows: high AFP level and LR-TR viable category, 2 points; resection, 1 point; number of LRT sessions, 1-2 points. The Kaplan-Meier curves for RFS showed significant risk stratification among three groups: = 4 points (high risk, 5-year RFS rate 19.0%), 2-3 points (intermediate risk, 63.6%%) and 0-1 points (low risk, 89.3%) (all log-rank Ps, < 0.025).

CLINICAL RELEVANCE/APPLICATION

LR-TR viable category on pre-operative image is a significant predictor of recurrence after curative surgery for LRT-treated HCC.

SPR-GI-33 Contrast-enhanced Ultrasound Liver Imaging Reporting And Data System V2017:patient Outcomes For Early-stage Hepatocellular Carcinoma Nodules With Category 3-5 And Category M

Participants
Yixin Hu, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate relationship between outcomes in patients with HCC at early-stage after initial therapy and retrospectively-assigned LI-RADS categories (LR 3-5 vs LR-M) at CEUS.*Methods and Materials In this retrospective study, 272 patients with high risks for HCC and solitary clinically or pathologically-confirmed HCC were identified between January 2010 and December 2015. Patients were initially treated by resection or radiofrequency ablation (RFA) according to the Barcelona Clinic Liver Cancer (BCLC) staging system and were follow-up until December 31, 2018. Recurrence-free survival (RFS) and overall survival (OS) were compared between nodules assigned as LR 3-5 or LR M according to CEUS LI-RADS v2017 by using the Kaplan-Meier curve, log-rank test, and Cox proportional hazard model. RFS and OS were also compared across each treatment and three treatments for each category.*Results There was no significantly difference in the liver background, clinically significant portal hypertension (CSPH), differentiation of hepatocytes, nodules sizes as well as treatment procedures and complete treatment reaction between LR-3-5 and LR-M patients (P>0.05). At both univariable and multivariable analysis, treatment procedures and LI-RADS category showed an independent correlation with OS and RFS (P <0.05). LR 3-5 category were more correlated with better OS compared with LR-M (88.6 months and 74.2 months, respectively; P =0.017). Surgical resection demonstrated longer OS and RFS than RFA in LR-M patients and longer OS in LR 3-5 patients (P <0.05). Besides, there was no significantly difference in OS and RFS between LR 3-5 and LR-M patients (P >0.05) in resection, while for patients treated with RFA, LR 3-5 patients showed significant longer OS and RFS than LR-M patients (P <0.05).*Conclusions Patients with HCC assigned as LR-M showed worse RFS and OS and surgical resection tended to be a more effective treatment for these patients.*Clinical Relevance/Application This study was aimed to investigate the feasibility of classification according to CEUS LI-RADS to predict the prognosis of early-stage hepatocellular carcinoma and guide the therapy decision

RESULTS

There was no significantly difference in the liver background, clinically significant portal hypertension (CSPH), differentiation of hepatocytes, nodules sizes as well as treatment procedures and complete treatment reaction between LR-3-5 and LR-M patients (P>0.05). At both univariable and multivariable analysis, treatment procedures and LI-RADS category showed an independent correlation with OS and RFS (P <0.05). LR 3-5 category were more correlated with better OS compared with LR-M (88.6 months and 74.2 months, respectively; P =0.017). Surgical resection demonstrated longer OS and RFS than RFA in LR-M patients and longer OS in LR 3-5 patients (P <0.05). Besides, there was no significantly difference in OS and RFS between LR 3-5 and LR-M patients (P >0.05) in resection, while for patients treated with RFA, LR 3-5 patients showed significant longer OS and RFS than LR-M patients (P <0.05).

CLINICAL RELEVANCE/APPLICATION

This study was aimed to investigate the feasibility of classification according to CEUS LI-RADS to predict the prognosis of early-stage hepatocellular carcinoma and guide the therapy decision

SPR-GI-35 Deep-learning Assisted Ultrasound Of The Gallbladder For Detection Of Malignancy

Participants
Pankaj Gupta, MD, Chandigarh, India (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the performance of deep learning (DL)-assisted ultrasound (US) for detection of gallbladder cancer.*Methods and Materials This IRB-approved prospective study comprised consecutive patients with gallbladder diseases who underwent US of the gallbladder. US evaluation was performed by two reviewers. The US images were anonymized and labeled using a single free-size axis-aligned rectangular box spanning the gallbladder. Another similar axis-aligned box was used for the pathological segments of the gallbladder. Multiple boxes were drawn in a single image if more than one finding was detected. A two-staged DL-model was utilized. In the first stage, gallbladder segmentation was performed using YOLOv4, Faster-RCNN, Reppoints, and CentripetalNet. In stage two, ResNet50 classification architecture was used to classify images into normal, benign, and malignant. Visual acuity (VA)-based curriculum learning was also used. For training in both the stages, data augmentation, and transfer learning techniques were utilized to improve the performance of the networks and prevent overfitting. The performance of the gallbladder detection algorithms was assessed using precision, recall, and mean intersection over union (mIoU). For classification of gallbladder abnormality, sensitivity, specificity, and area under the curve (AUC) were used.*Results Two hundred eighteen patients (1255 images) underwent US evaluation of the gallbladder during the study period. For algorithm training,1134 images were selected randomly. The normal, benign, and malignant classes included 402, 511, and 221 images respectively. For testing the algorithm, the rest of the 121 images were used (30 normal, 47 benign and 44malignant). The Faster-RCNN model had the best performance for the detection of gallbladder (mIoU 0.765, recall 0.994, and precision 0.937). The image classification model had sensitivity, specificity, and AUC of 89%, 86%, and 0.95, respectively. With the addition of VA-based curriculum learning, the performance improved (sensitivity 93%, specificity 97%, and AUC 0.98).*Conclusions The DL-based approach may improve the accuracy of detection of GBC on US. Larger studies with validation across different patient groups and specific gallbladder diseases may allow widespread application of this tool.*Clinical Relevance/Application DL-based US has the potential to improve the performance of radiologist for the characterization of gallbladder abnormalities.

RESULTS

Two hundred eighteen patients (1255 images) underwent US evaluation of the gallbladder during the study period. For algorithm training,1134 images were selected randomly. The normal, benign, and malignant classes included 402, 511, and 221 images respectively. For testing the algorithm, the rest of the 121 images were used (30 normal, 47 benign and 44malignant). The Faster-RCNN model had the best performance for the detection of gallbladder (mIoU 0.765, recall 0.994, and precision 0.937). The image classification model had sensitivity, specificity, and AUC of 89%, 86%, and 0.95, respectively. With the addition of VA-based curriculum learning, the performance improved (sensitivity 93%, specificity 97%, and AUC 0.98).

CLINICAL RELEVANCE/APPLICATION

DL-based US has the potential to improve the performance of radiologist for the characterization of gallbladder abnormalities.

SPR-GI-36 Semi-automated Classification Of Intestinal Fibrosis In Patients With Crohn'S Disease Using Computed Tomography Enterography Based Deep Learning

Participants
Jixin Meng, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Accurate evaluation of bowel fibrosis in Crohn's disease (CD) remains difficult. Computed tomography enterography (CTE) based radiomics reportedly enabled to assess bowel fibrosis, but it still existed deficiencies including significant time consumption. We aimed to develop and validate a CTE based deep learning model (DLM) for characterization of bowel fibrosis more efficiently and precisely.*Methods and Materials 235 patients with 312 resected bowel segments from three tertiary referral hospitals were enrolled in this retrospective and multicenter study. Data of training cohort and test cohort 1 were from center 1, data of test cohort 2 were from center 2 and 3. The transmural fibrosis severity was semi-quantitatively assessed. The interpretation of preoperative CTE was independently performed by two radiologists. Regions of interest (ROI) were annotated by the radiologists on venous phase CTE. A DLM was constructed in the training cohort using a 3D deep convolutional neural network based on ResNet, and an independent external validation was conducted on the multicenter test cohort. The radiomics model (RM) was developed as per the reported approach. The DeLong test and non-inferiority test were used to compare the ROC curves among the DLM, radiologists' interpretation and RM.*Results The DLM distinguished none-mild from moderate-severe bowel fibrosis with an AUC of 0.828 (P<0.001) in the training cohort and also exhibited robust performance in the total test cohort, test cohort 1 and 2 (AUC=0.811, 0.808 and 0.839, respectively; all P<0.001). In the total test cohort, DLM achieved better classification performance than that of two radiologists' interpretation (*1 AUC= 0.579, *2 AUC= 0.646, both P<0.05) and was not inferior to that of RM (AUC= 0.813, Z=3.869 > Z0.05=1.645). The time of feature extraction and selection for DLM (1.26 ± 0.55 s) was shorter than that of RM (811.21±1216.40 s, P<0.001).*Conclusions The performance of CTE based DLM in distinguishing moderate-severe and none-mild intestinal fibrosis in CD patients is better than radiologists' interpretation and not inferior to the RM in a more time-saving approach.*Clinical Relevance/Application In general, this study indicates the wide clinical application potential of a DLM for semi-automated identification and accurate binary classification of intestinal fibrosis in CD patients on CTE.

RESULTS

The DLM distinguished none-mild from moderate-severe bowel fibrosis with an AUC of 0.828 (P<0.001) in the training cohort and also exhibited robust performance in the total test cohort, test cohort 1 and 2 (AUC=0.811, 0.808 and 0.839, respectively; all P<0.001). In the total test cohort, DLM achieved better classification performance than that of two radiologists' interpretation (*1 AUC= 0.579, *2 AUC= 0.646, both P<0.05) and was not inferior to that of RM (AUC= 0.813, Z=3.869 > Z0.05=1.645). The time of feature extraction and selection for DLM (1.26 ± 0.55 s) was shorter than that of RM (811.21±1216.40 s, P<0.001).

CLINICAL RELEVANCE/APPLICATION

In general, this study indicates the wide clinical application potential of a DLM for semi-automated identification and accurate binary classification of intestinal fibrosis in CD patients on CTE.

SPR-GI-37 Spleen Stiffness - A Determinant Of Portal Hypertension With Esophageal Varices

Participants
Rajul Rastogi, MD, Greater Noida, India (*Presenter*) Nothing to Disclose

PURPOSE

Liver & spleen play a vital role in the splanchnic circulation. Variety of etiological agents can cause irreversible injury to hepatic cells leading to fibrosis & ultimately cirrhosis which is manifested in form of clinically significant portal hypertension and its complications including formation of varices at lower end of esophagus. Esophageal varices, an important cause of morbidity & mortality in cirrhotic patients can be diagnosed by upper gastrointestinal endoscopy and are managed according to various parameters. Recently, there is a growing interest in utilizing spleen stiffness by sonoelastography to predict portal hypertension & its complication viz. esophageal varices. Aims & Objectives: Our study aimed to determine the association of splenic stiffness with portal hypertension and esophageal varices.*Methods and Materials Sixty patients of portal hypertension, diagnosed clinically, radiologically & biochemically and those who were candidates for upper gastrointestinal endoscopy were evaluated by sonoelastography using Acoustic Radiation Forced Impulse technique to obtain mean value of spleen stiffness prior to endoscopy following IEC approval & written informed consent. The spleen stiffness measurements were then correlated with findings of endoscopy to calculate the cut-off values and various statistical parameters. In addition, spleen stiffness values were also measured in normal subjects who served as controls.*Results Spleen stiffness is significantly higher in patients of portal hypertension than in normal subjects (3.53+0.40m/s vs 2.24+0.29m/s). Furthermore, it is higher in patients of portal hypertension with esophageal varices than those without them (3.57m/s vs 3.18m/s). Mean SS value of >2.53m/s for predicting portal hypertension yielded the sensitivity, specificity and accuracy, 98.3%, 86.7%, and 92.5% respectively while mean SS value of >3.15m/s for predicting PHTN with EV, yielded the sensitivity, specificity, and accuracy, 87%, 66.7%, and 85% respectively.*Conclusions Mean spleen stiffness values are higher in patients with clinically significant portal hypertension than normal subjects with further higher values seen in patients of portal hypertension with esophageal varices. Hence, spleen stiffness measurement can be used as a non-invasive imaging tool for screening patients with portal hypertension as well as those with portal hypertension & esophageal varices.*Clinical Relevance/Application Utilizing noninvasive sonoelastography in predicting portal hypertension with esophageal varices can help time the invasive upper gastrointestinal endoscopy for appropriate management and not just for diagnosis of esophageal varices.

RESULTS

Spleen stiffness is significantly higher in patients of portal hypertension than in normal subjects (3.53+0.40m/s vs 2.24+0.29m/s). Furthermore, it is higher in patients of portal hypertension with esophageal varices than those without them (3.57m/s vs 3.18m/s). Mean SS value of >2.53m/s for predicting portal hypertension yielded the sensitivity, specificity and accuracy, 98.3%, 86.7%, and 92.5% respectively while mean SS value of >3.15m/s for predicting PHTN with EV, yielded the sensitivity, specificity, and accuracy, 87%, 66.7%, and 85% respectively.

CLINICAL RELEVANCE/APPLICATION

Utilizing noninvasive sonoelastography in predicting portal hypertension with esophageal varices can help time the invasive upper gastrointestinal endoscopy for appropriate management and not just for diagnosis of esophageal varices.

SPR-GI-38 Non-invasive Prediction Of KRAS Mutation In Rectal Cancer From T2-weighted MR Images And Clinical Risk Factors Using Deep Learning

Participants
Huanhuan Liu, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop diagnostic models using deep learning method based on T2-weighted MR images and clinical factors for preoperatively predicting the KRAS mutation of rectal cancer.*Methods and Materials A total of 360 consecutive patients with histopathologically confirmed rectal adenocarcinoma (development cohort, n = 288; independent testing cohort, n = 72) were retrospectively enrolled in this study. All patients underwent preoperative high-resolution MR examinations and the postoperative KRAS mutation status was pathologically diagnosed. Risk factors including clinical characteristics and MR features were extracted from medical reports. A clinical model was constructed on risk factors via multivariable logistic regression analysis, and two deep learning models based on modified MobileNetV2 architecture were proposed for predicting KRAS mutation based on MR images alone (Image model) or both MR images and clinical risk factors (Combined model). The performance of these predictive models was evaluated by receiver operating characteristics curve (ROC) analysis, calibration curve, and decision curve analysis (DCA).*Results Seven MR features and four clinical characteristics were selected as risk factors for model development. The AUCs of the clinical model, image model and combined model were 0.671 (95% CI, 0.614~0.725), 0.791 (95% CI, 0.739~0.836) and 0.850 (95% CI, 0.804~0.889) in the development cohort, respectively. The performance of these models was validated in the testing cohort with good calibration, with AUCs achieving 0.653 (95% CI, 0.532~0.761), 0.760 (95% CI, 0.645~0.853) and 0.815 (95% CI, 0.706~0.897). Delong's test indicated the combined model showed improved performance than the clinical model (p = 0.060) and image model (p = 0.483). DCA confirmed net benefit of the combined model was higher than other models across majority range of threshold probabilities.*Conclusions The proposed deep learning model incorporating T2-weighted MR images and clinical risk factors shows good predictive efficacy and can be served as a non-invasive method for predicting KRAS mutation in rectal cancer.*Clinical Relevance/Application The proposed deep learning model shows favorable performance in preoperatively predicting KRAS mutation via integrating T2-weighted MR images and clinical risk factor in patients with rectal cancer.

RESULTS

Seven MR features and four clinical characteristics were selected as risk factors for model development. The AUCs of the clinical model, image model and combined model were 0.671 (95% CI, 0.614~0.725), 0.791 (95% CI, 0.739~0.836) and 0.850 (95% CI, 0.804~0.889) in the development cohort, respectively. The performance of these models was validated in the testing cohort with good calibration, with AUCs achieving 0.653 (95% CI, 0.532~0.761), 0.760 (95% CI, 0.645~0.853) and 0.815 (95% CI, 0.706~0.897). Delong's test indicated the combined model showed improved performance than the clinical model (p = 0.060) and image model (p = 0.483). DCA confirmed net benefit of the combined model was higher than other models across majority range of threshold probabilities.

CLINICAL RELEVANCE/APPLICATION

The proposed deep learning model shows favorable performance in preoperatively predicting KRAS mutation via integrating T2-weighted MR images and clinical risk factor in patients with rectal cancer.

SPR-GI-39 Esophageal Squamous Cell Carcinoma: Correlation Of Tumor Size On Pre-treatment Mri With Recurrent Free Survival And Overall Survival

Participants
Wang Shaoyu, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To retrospectively investigate the prognostic value of MRI in patients with esophageal squamous cell carcinoma (ESCC).*Methods and Materials A total of 558 patients diagnosed with ESCC and had pre-treatment MRI between October 2014 and May 2017 were included in this retrospective study. Tumor length and thickness were measured on pre-treatment MRI by two readers. Kappa analysis was conducted to evaluate inter-reader agreement. The relationships between MR measurable features and overall survival (OS) as well as recurrent free survival (RFS) were evaluated by Cox regression model adjusting for clinical features. All analysis was conducted in SATA 13.0.*Results The final cohort included 506 ESCC patients (345 men, 68.2%); mean age ± standard deviation, 62.7 years ± 8.3). Mean RFS and OS was 44.0 months (95% CI, 41.6-46.5), and 45.6 months (95% CI, 43.2-48.0), respectively. Inter-reader agreements of MRI Tumor length and thickness were substantial or perfect (Kappa=0.953, 0.929, all P<0.001). At baseline, of the imaging parameters derived from MRI, tumor thickness and tumor length were predictors of RFS and OS. In multivariate analysis, only MRI tumor thickness predicted RFS and OS. MRI tumor thickness of > 12 mm was the only independent variable associated with RFS and OS.*Conclusions MRI tumor thickness > 12 mm was associated with great risk of recurrent free survival (RFS) and overall survival (OS) in patients with esophageal squamous cell carcinoma (ESCC).*Clinical Relevance/Application Tumor thickness > 12 mm at baseline MRI was associated with worse survival in patients with ESCC.

RESULTS

The final cohort included 506 ESCC patients (345 men, 68.2%); mean age ± standard deviation, 62.7 years ± 8.3). Mean RFS and OS was 44.0 months (95% CI, 41.6-46.5), and 45.6 months (95% CI, 43.2-48.0), respectively. Inter-reader agreements of MRI Tumor length and thickness were substantial or perfect (Kappa=0.953, 0.929, all P<0.001). At baseline, of the imaging parameters derived from MRI, tumor thickness and tumor length were predictors of RFS and OS. In multivariate analysis, only MRI tumor thickness predicted RFS and OS. MRI tumor thickness of > 12 mm was the only independent variable associated with RFS and OS.

CLINICAL RELEVANCE/APPLICATION

Tumor thickness > 12 mm at baseline MRI was associated with worse survival in patients with ESCC.

SPR-GI-4 Deep Network Segmentation Of The Normal Pancreas And Abnormal Pancreas With Pancreatic Ductal Adenocarcinoma On CT: Can Deep Network Segmentation Replace Manual Segmentation?

Participants
Satomi Kawamoto, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Accurate segmentation is necessary for AI based volumetric analyses of the pancreas. The purpose of the study is to quantitatively and qualitatively evaluate accuracy of deep network (DN) prediction of the normal and abnormal pancreas with pancreatic ductal adenocarcinoma (PDAC) on CT.*Methods and Materials Fifty-one potential renal donors without pancreatic abnormality (male=22, female=29, average age: 46±11 years) and 51 patients with PDAC (male=24, female=27, average age: 68±10 years) who had dedicated pancreas protocol CT between 2007 and 2018 were retrospectively evaluated. Venous phase CT data reconstructed at 0.75/0.5mm thickness/increment were used for analysis. Among variations of deep networks, the ResDSN (residual deep supervision network) developed for pancreatic tumor segmentation was used. For the training of the deep network, the entire pancreas (including PDAC) was segmented as 3D volumes in both groups by manual segmentation by experienced researchers supervised by radiologists and using the deep network. DICE similarity coefficients were calculated. Two experienced radiologists independently evaluated accuracy of DN prediction assigning score from 10 to 1 by estimated volume of correctly predicted pancreas (10:100%; 9:95-99%; 8:90-94%; 7:85-89%;...; 2:60-65%; 1:<60%), and recorded the areas of discrepancy.*Results DICE similarity coefficients was 87.7±3.2% [95% confidence interval: 78.6-92.4%] for normal pancreas, and 84.9±3.9% [72.8-93.0%] for abnormal pancreas with PDAC. Average score of DN prediction by each radiologist was 9.49±0.54 and 9.69±0.55 for normal pancreas, and 9.04±0.92 and 8.68±1.0 for abnormal pancreas with PDAC. The scores were agreed between the two radiologists in 35 cases (68.6%) and 23 cases (45.1%) for normal and abnormal pancreas, respectively. All normal pancreas were graded higher than score 7, and 61.8% of normal pancreas were graded as score 10 by average. All abnormal pancreas with PDAC were graded higher than score 5, and 30.4% were graded as score 10 by average. Minor discrepancy along the border of the pancreatic head and duodenum was the most common cause of incorrect prediction, with borders of the pancreas (tail, head or uncinate process) or peripancreatic vessels being less common causes in normal pancreas. A part of tumor and/or atrophic upstream pancreas were the additional causes for incorrect prediction in abnormal pancreas with PDAC.*Conclusions DN prediction of pancreas is highly accurate in normal pancreas and moderately accurate with abnormal pancreas with PDAC.*Clinical Relevance/Application DN prediction of pancreas is accurate and can be applied for AI based volumetric analyses in many cases. Minor manual editing may be necessary, more commonly in PDAC cases.

RESULTS

DICE similarity coefficients was 87.7±3.2% [95% confidence interval: 78.6-92.4%] for normal pancreas, and 84.9±3.9% [72.8-93.0%] for abnormal pancreas with PDAC. Average score of DN prediction by each radiologist was 9.49±0.54 and 9.69±0.55 for normal pancreas, and 9.04±0.92 and 8.68±1.0 for abnormal pancreas with PDAC. The scores were agreed between the two radiologists in 35 cases (68.6%) and 23 cases (45.1%) for normal and abnormal pancreas, respectively. All normal pancreas were graded higher than score 7, and 61.8% of normal pancreas were graded as score 10 by average. All abnormal pancreas with PDAC were graded higher than score 5, and 30.4% were graded as score 10 by average. Minor discrepancy along the border of the pancreatic head and duodenum was the most common cause of incorrect prediction, with borders of the pancreas (tail, head or uncinate process) or peripancreatic vessels being less common causes in normal pancreas. A part of tumor and/or atrophic upstream pancreas were the additional causes for incorrect prediction in abnormal pancreas with PDAC.

CLINICAL RELEVANCE/APPLICATION

DN prediction of pancreas is accurate and can be applied for AI based volumetric analyses in many cases. Minor manual editing may be necessary, more commonly in PDAC cases.

SPR-GI-40 Deep Learning Based Image Reconstruction Of 40-keV Virtual Monoenergetic Dual-energy CT For The Assessment Of Hypovascular Hepatic Metastasis: Comparison With Standard Linear Blended Images Regarding Image Quality And Lesion Detection

Participants
Taehee Lee, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To compared the image quality and the diagnostic performance in the detection of hypovascular hepatic metastasis of deep learning model (DLM) reconstructed, low virtual monoenergetic imaging (VMI) from dual energy CT (DECT), compared with standard linear blended images (simulated 100kVp) using advanced modeled iterative reconstruction (ADMIRE).*Methods and Materials The intuitional review board approved this retrospective study and waived informed consent. 131 patients (68 with metastases and 63 without) underwent contrast enhanced DECT (80-and 150-kVp with a tin filter) during the portal venous phase. DECT were reconstructed into a linearly blended image with a blending factor of 0.6 (60% 80kVp and 40% 150kVp), using ADMIRE, representing the standard 100-kVp acquisitions. DECT data were post-processed for 40-keV VMI using an advanced image-based reconstruction algorithm (Mono+), and these data were subsequently reconstructed using DLM (DLM 40keV VMIs). The CT attenuation and the image noise of various sites, including the metastatic lesion and the hepatic parenchyma were measured on three image sets: standard 40keV VMIs, linear blended images, and DLM 40keV VMIs. The contrast-to-noise ratios (CNRs) of the metastatic lesion to the liver were calculated. The edge rise gradient (ERG) was measured as an indicator of image sharpness at the hepatic artery and portal vein. Three abdominal radiologists independently assessed each of the three image sets with regard to image contrast, image noise, image sharpness, lesion conspicuity, diagnostic acceptability, and artificial sensation. They were asked to mark liver lesions and rate the probability of malignancy on a five-point confidence scale. Noninferiority analysis using jackknife alterative free-response ROC (JAFROC) was performed.*Results The DLM 40-keV VMIs showed a higher CNR, SNR, and better image contrast, image quality, lesion conspicuity, and diagnostic acceptability than 40-keV VMI and linear blended images using ADMIRE (p < 0.001). The average ESGs of DLM 40-keV VMIs were significantly higher than those of standard 40-keV VMI and linear blended images (p = 0.002, p < 0.001). In terms of lesion detection, reader-averaged JAFROC figure of merit (FOM) was significantly higher on the DLM 40-keV VMIs than on the 40-keV VMI (p < 0.05). The non-inferiority of the DLM 40-keV VMIs for metastases detection compared with simulated 100kVp using ADMIRE was confirmed.*Conclusions DLM based reconstruction of 40keV VMIs provides better image quality and non-inferior diagnostic performance for the detection of hepatic metastasis compared with standard linear blended images with ADMIRE.*Clinical Relevance/Application DLM based reconstruction of 40keV VMIs improves the depiction of hepatic metastasis.

RESULTS

The DLM 40-keV VMIs showed a higher CNR, SNR, and better image contrast, image quality, lesion conspicuity, and diagnostic acceptability than 40-keV VMI and linear blended images using ADMIRE (p < 0.001). The average ESGs of DLM 40-keV VMIs were significantly higher than those of standard 40-keV VMI and linear blended images (p = 0.002, p < 0.001). In terms of lesion detection, reader-averaged JAFROC figure of merit (FOM) was significantly higher on the DLM 40-keV VMIs than on the 40-keV VMI (p < 0.05). The non-inferiority of the DLM 40-keV VMIs for metastases detection compared with simulated 100kVp using ADMIRE was confirmed.

CLINICAL RELEVANCE/APPLICATION

DLM based reconstruction of 40keV VMIs improves the depiction of hepatic metastasis.

SPR-GI-41 Feasibility Of Contrast-enhanced T1-weighted Magnetic Resonance Enterography Using Compressed Sensing-sensitivity Encoding In Patients With Crohn's Disease

Participants
Jeongyun Kim, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the feasibility of using contrast enhanced magnetic resonance enterography (CE-MRE) with combined compressed sensing (CS) sensitivity encoding (SENSE) in Crohn's disease (CD).*Methods and Materials This retrospective study included patients with CD who underwent CE-MRE between June 2020 and September 2020. Both coronal T1-weighted enteric and portal phase images were obtained for all patients. Images for either the enteric or portal phase were randomly obtained using SENSE (acceleration factor 3), and images for the other phase were obtained using CS-SENSE (acceleration factor 5). Qualitative parameters evaluated by two radiologists were compared between SENSE and CS-SENSE using the Wilcoxon signed-rank test. The generalized estimating equation was used to compare diagnostic performances for the detection of active CD inflammation in 115 bowel segments.*Results A total of 41 patients (mean age ± standard deviation [SD], 34 ± 12 years; 31 men) were evaluated. The acquisition times of CE-MRE with CS-SENSE (mean ± SD, 11.5 ± 0.8 s) were shorter (33%) than SENSE (17.2 ± 1.1 s, P < .001). Image quality was better for CS-SENSE (4.2 ± 0.7) than SENSE (3.7 ± 1.1, P = .02). Fewer motion artifacts were observed with CS-SENSE than SENSE (4.0 ± 0.8 vs. 3.6 ± 1.2, P = .01). Regarding the diagnostic performance of CE-MRE, sensitivity (92% [67/73] vs. 80% [58/73], P = .01) and accuracy (91% [105/115] vs. 86% [99/115], P = .002) were higher with CS-SENSE compared to SENSE for reader 2. For reader 1, the two techniques were not significantly different (Ps = 0.08).*Conclusions CS-SENSE can improve the image quality of CE-MRE with shorter scan times compared to SENSE, and this may enhance the overall diagnostic performance of CE-MRE for CD.*Clinical Relevance/Application CS-SENSE can improve the image quality of CE-MRE while reducing scan times compared to SENSE, which may enhance the overall diagnostic performance of CE-MRE for CD.

RESULTS

A total of 41 patients (mean age ± standard deviation [SD], 34 ± 12 years; 31 men) were evaluated. The acquisition times of CE-MRE with CS-SENSE (mean ± SD, 11.5 ± 0.8 s) were shorter (33%) than SENSE (17.2 ± 1.1 s, P < .001). Image quality was better for CS-SENSE (4.2 ± 0.7) than SENSE (3.7 ± 1.1, P = .02). Fewer motion artifacts were observed with CS-SENSE than SENSE (4.0 ± 0.8 vs. 3.6 ± 1.2, P = .01). Regarding the diagnostic performance of CE-MRE, sensitivity (92% [67/73] vs. 80% [58/73], P = .01) and accuracy (91% [105/115] vs. 86% [99/115], P = .002) were higher with CS-SENSE compared to SENSE for reader 2. For reader 1, the two techniques were not significantly different (Ps = 0.08).

CLINICAL RELEVANCE/APPLICATION

CS-SENSE can improve the image quality of CE-MRE while reducing scan times compared to SENSE, which may enhance the overall diagnostic performance of CE-MRE for CD.

SPR-GI-42 Role Of Magnetic Resonance Elastography For Risk Stratification In Patients With Decompensated Cirrhosis

Participants
Jie Zhu, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

There is an established need for methods to predict risk of mortality in patients with decompensated cirrhosis. Magnetic resonance elastography (MRE) provides a quantitative biomarker in the form of liver stiffness that spans a large range (~5-10kPa) in patients who all have the same biopsy diagnosis of F4 fibrosis. The goal of this retrospective study was to assess the association between liver shear stiffness (LSS) measured by MRE and different states of decompensated cirrhosis, and to investigate the ability of LSS to predict the risk of transition from the first decompensation to further decompensation.*Methods and Materials In patients with decompensated cirrhosis who received MRE (2015-2019), a baseline cohort and follow-up cohort (patients with a first decompensated event) were established. Multivariate logistic regression analysis was used to analyze the relationship between LSS and the state of further decompensation in the baseline cohort. Cox proportional hazard analysis was used to determine the association between LSS and the development of further decompensation.*Results In the baseline cohort (n = 427), liver shear stiffness was significantly higher in 218 patients with further decompensation (6.77 kPa, IQR 5.25-8.86) than in 209 patients with the first decompensation (5.89, IQR 4.57-7.27). After adjustment for age, gender, etiology, Serum sodium, Model for End Stage Liver Disease score, white blood cell, and platelet count, LSS (odds, OR=1.106, 95%CI 1.005-1.217) was independently associated with further decompensation at baseline. In the follow-up cohort, 39 (23%) of 167 patients with the first decompensation developed further decompensation over a median follow-up of 30 months. The hazard of further decompensation was 1.281 (95% CI 1.111-1.478) per unit increase in LSS value over time. Among the first decompensated patients, the subgroup with LSS = 6.715 kPa has a hazard ratio of 4.030(95% CI 2.092-7.764, p<0.001) to develop further hepatic decompensation compared to subjects with LSS<6.715.*Conclusions Baseline LSS assessed by MRE is independently associated with further decompensated patients. LSS can predict the risk from a low-risk group transition to a high-risk group in patients with decompensated cirrhosis.*Clinical Relevance/Application The prognosis was significantly poor in cirrhotic patients with further decompensation than with the first decompensation. MRE is a non-invasive method reflecting distinct states of decompensated cirrhosis. LSS may be as an effective risk stratification tool in patients with decompensated cirrhosis, identifying a high-risk cohort for intensive management.

RESULTS

In the baseline cohort (n = 427), liver shear stiffness was significantly higher in 218 patients with further decompensation (6.77

kPa, IQR 5.25-8.86) than in 209 patients with the first decompensation (5.89, IQR 4.57-7.27). After adjustment for age, gender, etiology, Serum sodium, Model for End Stage Liver Disease score, white blood cell, and platelet count, LSS (odds, OR=1.106, 95%CI 1.005-1.217) was independently associated with further decompensation at baseline. In the follow-up cohort, 39 (23%) of 167 patients with the first decompensation developed further decompensation over a median follow-up of 30 months. The hazard of further decompensation was 1.281 (95% CI 1.111-1.478) per unit increase in LSS value over time. Among the first decompensated patients, the subgroup with LSS = 6.715 kPa has a hazard ratio of 4.030(95% CI 2.092-7.764, p<0.001) to develop further hepatic decompensation compared to subjects with LSS<6.715.

CLINICAL RELEVANCE/APPLICATION

The prognosis was significantly poor in cirrhotic patients with further decompensation than with the first decompensation. MRE is a non-invasive method reflecting distinct states of decompensated cirrhosis. LSS may be as an effective risk stratification tool in patients with decompensated cirrhosis, identifying a high-risk cohort for intensive management.

SPR-GI-44   Comparison Of Dual-layer Spectral CT And Contrast-enhanced MRI For The Diagnosis Of Focal Liver Lesions Using The Liver Imaging Reporting And Data System(lR-RADS) Version 2018

Participants
Wenqi Shi, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the Liver Imaging Reporting and Data System (LIRADS) version 2018 categorization of focal liver lesions (FLLs) on dual-layer spectral CT (DLSCT) in comparison with contrast-enhanced MRI (CE-MRI)*Methods and Materials 84 high-risk patients with 115 focal liver lesions (FLLs) who underwent both DLSCT and MRI within one month interval were retrospectively studied. The virtual monoenergetic images (VMIs) at 40keV derived from DLSCT in arterial and portal venous phases were reconstructed. The best available reference standard was applied for each FLL. Blinded to the reference standard, two radiologists scored LI-RADS major imaging features retrospectively and assigned each observation a category (LR 1-5, M and TIV) using LI-RADS v2018 on both VMIs at 40keV derived from DLSCT and MR images in consensus. Per-FLL sensitivity and specificity using DLSCT images and MRI images were assessed. Diagnostic performance and inter-modality agreement were calculated and compared among 40keV and MRI LI-RADS categories by McNemar test and Kappa test*Results The inter-modality agreement between VMIs at 40keV DLSCT and MR when categorizing LR-5 or LR-5 &TIV was 0.86 (P<0.05) . Using LI-RADS v2018, sensitivity of LR-5 &TIV category on VMIs at 40keV was higher than on MR, but without significant difference (89.61% vs. 84.42%, P=0.453), and specificity of two exams were the similar (89.74% vs. 89.74%, P= 0.500). When categorizing LR-5 alone, the sensitivity values of two modalities both decreased slightly (72.73% vs. 66.23%, DLSCT vs. MR, P=0.219) with significant difference (P<0.001) and specificity values remained similar (89.74% vs. 92.31%, DLSCT vs. MR, P=0.500) compared with LR-5 &TIV criteria*Conclusions The VMIs at 40keV derived from DLSCT showed comparable sensitivity and specificity for categorizing LR-5/TIV or LR-5 alone in LI-RADS v2018-based classification of liver lesions in comparison with CE-MRI*Clinical Relevance/Application VMIs at 40keV derived from DLSCT have comparable diagnostic performance for HCC by using LI-RADS Version 2018 versus MR. Further comparative studies between DLSCT and MR are needed to validate our preliminary results with a larger sample size in a prospective multi-center setting

RESULTS

The inter-modality agreement between VMIs at 40keV DLSCT and MR when categorizing LR-5 or LR-5 &TIV was 0.86 (P<0.05) . Using LI-RADS v2018, sensitivity of LR-5 &TIV category on VMIs at 40keV was higher than on MR, but without significant difference (89.61% vs. 84.42%, P=0.453), and specificity of two exams were the similar (89.74% vs. 89.74%, P= 0.500). When categorizing LR-5 alone, the sensitivity values of two modalities both decreased slightly (72.73% vs. 66.23%, DLSCT vs. MR, P=0.219) with significant difference (P<0.001) and specificity values remained similar (89.74% vs. 92.31%, DLSCT vs. MR, P=0.500) compared with LR-5 &TIV criteria

CLINICAL RELEVANCE/APPLICATION

VMIs at 40keV derived from DLSCT have comparable diagnostic performance for HCC by using LI-RADS Version 2018 versus MR. Further comparative studies between DLSCT and MR are needed to validate our preliminary results with a larger sample size in a prospective multi-center setting

SPR-GI-45   Subspecialist Radiological TNM Staging In Pancreatic Ductal Adenocarcinoma - Important Implications For Prognosis And Management

Participants
Sam Banks, BMedSc,MD, Melbourne, Australia (*Presenter*) Nothing to Disclose

PURPOSE

To identify the discrepancy in radiological staging between real-world radiological reporting practices and centralised staging according to AJCC guidelines by a blinded subspecialist radiologist.*Methods and Materials Cases were identified from the PURPLE Translational Registry; a prospective, multicentre electronic database which collates comprehensive, standardised data on demographics, diagnosis, clinic-pathological features, surgery, treatments received and disease outcome in consecutive pancreatic cancer patients. Data for patients treated between January 2016 - March 2020 at tertiary treatment centres across Australia were extracted. De-identified index CT staging scans were imported to a centralised database before being re-reported by a blinded subspecialist radiologist according to AJCC guidelines .*Results Findings from our study of 110 patients, revealed a high frequency of discordant T, N, & M scores between initial radiological staging and on centralised review. For T, N & M scores respectively such discrepancy occurred in 47/110 (43%), 40/110 (36%) and 10/110 (10%) of cases. In most instances these discrepancies were up upstaged on centralised review; for T, N & M scores this occurred in 43/47 (91%), 33/40 (83%) and 10/10 (100%) cases respectively. This resulted in an overall staging discrepancy of 63/110 (57%) with 43/63 (68%) of these resulting in overall upstaging. Survival outcomes between real-world CT staging vs. centralised review, were most noticeably different for stage 2 disease with a median overall survival of 17.3 months vs undefined at time of analysis (p=0.05).*Conclusions There is significant discrepancy between subspecialist and non-subspecialist radiological staging of PDAC in real-world CT practice. This likely results in patients with incurable disease undergoing futile interventions with associated morbidity and poorer outcomes.*Clinical Relevance/Application Pancreatic ductal adenocarcinoma (PDAC) is increasing in incidence. Surgical resection for localised PDAC offers the only hope of cure. Accurate CT-radiological staging is pivotal in determining resectability and prognosis.

RESULTS

Findings from our study of 110 patients, revealed a high frequency of discordant T, N, & M scores between initial radiological

staging and on centralised review. For T, N & M scores respectively such discrepancy occurred in 47/110 (43%), 40/110 (36%) and 10/110 (10%) of cases. In most instances these discrepancies were up upstaged on centralised review; for T, N & M scores this occurred in 43/47 (91%), 33/40 (83%) and 10/10 (100%) cases respectively. This resulted in an overall staging discrepancy of 63/110 (57%) with 43/63 (68%) of these resulting in overall upstaging. Survival outcomes between real-world CT staging vs. centralised review, were most noticeably different for stage 2 disease with a median overall survival of 17.3 months vs undefined at time of analysis (p=0.05).

CLINICAL RELEVANCE/APPLICATION

Pancreatic ductal adenocarcinoma (PDAC) is increasing in incidence. Surgical resection for localised PDAC offers the only hope of cure. Accurate CT-radiological staging is pivotal in determining resectability and prognosis.

SPR-GI-49   Clinical Phenotypic Clustering Of Patients With Intrahepatic Cholangiocarcinoma Highlights Important Prognostic Differences

Participants
Qian Li, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

To characterise patients with intrahepatic cholangiocarcinoma (ICC) into different clinical phenotypes using multiomics-based clustering analysis, and to further identify the clinical phenotypes associated with the prognostic outcomes.*Methods and Materials In this multiomics-based hierarchical clustering analysis, we included 308 consecutively recruited patients with ICC. Cox regression analysis was conducted to quantify the independent associations of the identified phenotypes with prognostic outcomes. Decision tree analysis was performed to predict cluster assignment.*Results Four clusters of patients with ICC, which had significantly different characteristics associated with prognostic outcomes, were identified. Cluster 1 (n=78, 25.32%) had a biliary dilation and low AFP value phenotype, cluster 2 (n=41, 13.31%) had a large tumour size and tumour in vein phenotype, cluster 3 (n=80, 25.97%) had a satellite nodule and multifocal phenotype, and cluster 4 (n=109, 35.39%) had a small tumour size and low radiomics phenotype. Of these phenotypes, cluster 2 was associated with the poorest median survival time of 12.1 months and lowest 1-year survival rate of 51.21%, while cluster 4 was associated with the longest median survival time of 27.0 months and longest 1-year, 3-year and 5-year survival rates of 91.51%, 39.45%, and 10.09%, respectively.*Conclusions Four clinical phenotypes with differential clinical and imaging features associated with prognostic outcomes were developed. Based on the results, we propose a novel clinical phenotypic classification of ICC that facilitates prognostic prediction and may support decision making with regard to the choice of therapy.*Clinical Relevance/Application Our study developed four clusters in patients with ICC in a real-world setting base on multiomics variables analysis before surgery. The prespecified clusters demonstrated significant prognostic differences after surgery.The developed clusters have important clinical implications for patient management and treatment decisions, which may help clinicians to consider systemic therapy more comprehensively than upfront surgery among high-risk patients with ICC, as well as inform the intensity of surveillance following resection.

RESULTS

Four clusters of patients with ICC, which had significantly different characteristics associated with prognostic outcomes, were identified. Cluster 1 (n=78, 25.32%) had a biliary dilation and low AFP value phenotype, cluster 2 (n=41, 13.31%) had a large tumour size and tumour in vein phenotype, cluster 3 (n=80, 25.97%) had a satellite nodule and multifocal phenotype, and cluster 4 (n=109, 35.39%) had a small tumour size and low radiomics phenotype. Of these phenotypes, cluster 2 was associated with the poorest median survival time of 12.1 months and lowest 1-year survival rate of 51.21%, while cluster 4 was associated with the longest median survival time of 27.0 months and longest 1-year, 3-year and 5-year survival rates of 91.51%, 39.45%, and 10.09%, respectively.

CLINICAL RELEVANCE/APPLICATION

Our study developed four clusters in patients with ICC in a real-world setting base on multiomics variables analysis before surgery. The prespecified clusters demonstrated significant prognostic differences after surgery.The developed clusters have important clinical implications for patient management and treatment decisions, which may help clinicians to consider systemic therapy more comprehensively than upfront surgery among high-risk patients with ICC, as well as inform the intensity of surveillance following resection.

SPR-GI-5   Comparison Of Diagnostic Performance Of Abbreviated Versus Comprehensive MRCP For Pancreatic Cyst Surveillance

Participants
Chenchan Huang, MD, Manhasset, New York (*Presenter*) Nothing to Disclose

PURPOSE

Pancreatic cysts are frequently detected on imaging studies and can progress to cancer or indicate increased risk of pancreatic cancer elsewhere. Multiple societal guidelines recommend long term surveillance with MRCP. We retrospectively compared the diagnostic performance of abbreviated MRCP (aMRCP) with comprehensive MRCP (cMRCP).*Methods and Materials 151 patients undergoing pancreatic cyst surveillance with a baseline contrast enhanced MRCP and follow-up index surveillance MRCP exam were included. Three sequences selected from index MRCP (axial and coronal HASTE, axial T1 fat-saturated pre-contrast, and 3D MRCP) comprised the aMRCP protocol and the entire index MRCP, including post-contrast sequences, was the cMRCP protocol. 3 blinded abdominal radiologists assessed for the presence of worrisome features, high risk stigmata, and signs of concurrent pancreatic adenocarcinoma with both aMRCP and cMRCP protocols, with a 2-week washout period between aMRCP and cMRCP review. Cyst multiplicity, location, morphology and duct communication were also assessed.*Results Overall high intra-reader (88-100%) and inter-reader (93-99%) agreement between aMRCP and cMRCP on key features of cyst characterization and secondary signs of solid pancreatic mass. 6/151 patients had surgically resected malignant IPMN. 2 (33%) were classified as benign on aMRCP by at least 1 reader. 7/151 had concurrent pancreatic adenocarcinomas, 2 of which were missed on aMRCP by at least one reader (29%).*Conclusions aMRCP showed high intra- and inter-reader agreement for pancreatic cyst characterization and secondary signs of solid pancreatic mass, but malignant IPMN and concurrent adenocarcinoma were occasionally missed with aMRCP.*Clinical Relevance/Application While aMRCP can save time, cost and anxiety associated with contrast administration, physicians and patients should understand the possibility of missing the more clinically significant pancreatic cancer.

RESULTS

Overall high intra-reader (88-100%) and inter-reader (93-99%) agreement between aMRCP and cMRCP on key features of cyst

characterization and secondary signs of solid pancreatic mass. 6/151 patients had surgically resected malignant IPMN. 2 (33%) were classified as benign on aMRCP by at least 1 reader. 7/151 had concurrent pancreatic adenocarcinomas, 2 of which were missed on aMRCP by at least one reader (29%).

CLINICAL RELEVANCE/APPLICATION

While aMRCP can save time, cost and anxiety associated with contrast administration, physicians and patients should understand the possibility of missing the more clinically significant pancreatic cancer.

SPR-GI-50   Selecting Candidates For Organ Preserving Strategy Of Rectal Cancer After Neoadjuvant Chemoradiotherapy: Model Development And Validation Integrating Radiomics And Pathomics

Participants
Lijuan Wan, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a multi-scale model incorporating radiomics and pathomics features for predicting patients with pathological good response (pGR) that down-staging to stage ypT0-1N0 after neoadjuvant chemoradiotherapy (nCRT) in locally advanced rectal cancer (LARC).*Methods and Materials This retrospective study included 153 patients (training group: n = 107; validation group: n = 46) with clinicopathologically confirmed LARC who received nCRT before surgery between January 2015 and March 2018. All patients underwent MRI examination before and after nCRT, as well as endoscopic biopsy before nCRT. Radiomics and pathomics features were extracted from MR images and digital histopathological slides, respectively. Two radiomics signatures, including pretreatment and posttreatment radiomics signature, and one pathomics signature were created by using a dimensionality reduction and feature selection process. Integrating three signatures and related clinicoradiological factors, a multi-scale pGR prediction model was established by multivariable logistic regression analysis. The diagnostic performance of the multi-scale model (calibration, discrimination, and clinical usefulness) was evaluated, and then compared with a model based on clinicoradiological factors alone.*Results A total of 19.6% patients achieved pGR. Pretreatment radiomics signature (odds ratio [OR] = 2.53; 95% CI: 1.58-4.66; p< 0.001), posttreatment radiomics signature (OR = 9.59; 95% CI: 3.04-41.46; p < 0.001), and pathomics signature (OR = 3.14; 95% CI: 1.40-8.31; p = 0.01) were retained in the multi-scale model as independent factors. The multi-scale model presented good calibration, and good discrimination with AUCs of 0.93 (95% CI: 0.88-0.98) and 0.90 (95% CI: 0.78-1.00) in the training and validation group. The diagnostic performance of the multi-scale model was improved than those of clinicoradiological model.*Conclusions The multi-scale model incorporating radiomics and pathomics features can effectively predict patients with pGR after nCRT in LARC.*Clinical Relevance/Application Our multi-scale model may be used for selecting suitable candidates for organ-preserving surgery in clinical practice.

RESULTS

A total of 19.6% patients achieved pGR. Pretreatment radiomics signature (odds ratio [OR] = 2.53; 95% CI: 1.58-4.66; p< 0.001), posttreatment radiomics signature (OR = 9.59; 95% CI: 3.04-41.46; p < 0.001), and pathomics signature (OR = 3.14; 95% CI: 1.40-8.31; p = 0.01) were retained in the multi-scale model as independent factors. The multi-scale model presented good calibration, and good discrimination with AUCs of 0.93 (95% CI: 0.88-0.98) and 0.90 (95% CI: 0.78-1.00) in the training and validation group. The diagnostic performance of the multi-scale model was improved than those of clinicoradiological model.

CLINICAL RELEVANCE/APPLICATION

Our multi-scale model may be used for selecting suitable candidates for organ-preserving surgery in clinical practice.

SPR-GI-51   Clinical-radiological Nomogram For Predicting Early Recurrence Of Early-stage Hepatocellular Carcinomas After Radiofrequency Ablation

Participants
Linqi Zhang, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Early recurrence rate of early-stage hepatocellular carcinoma (eHCC) patients after radiofrequency ablation (RFA) have been reported approximately 30-50%. It is very important to identify patients with eHCC at risk of early recurrence (ER) and then choose optimal treatment strategy. The aim of this study was to develop and validate the clinical-radiological nomogram estimating the probability of ER in patients with eHCC after RFA.*Methods and Materials 480 patients with eHCC who underwent preoperative dynamic contrast-enhanced MRI examinations within 1 month before RFA from 2008 to 2018 in our hospital were collected retrospectively and randomly divided into the derivation cohort (n = 320) and the internal validation cohort (n = 160). Multivariate Cox proportional hazards analysis was used to identify independent risk factors for ER after RFA by using clinical and imaging information of the derivation cohort, then established clinical nomogram and clinical-radiological nomogram, and their prediction values were compared by De-Long test. Performance of nomogram was assessed by concordance index (c-index) and a calibration curve.*Results Within the follow-up period (median 32 months), a total of 130 (40.63%,130/320) and 66 (41.25%, 66/160) patients experienced ER in derivation and validation cohort, respectively. Multiple tumor foci (P <0.001), tumor size=2 cm (P =0.001), AFP=40 ng/ml (P =0.001), irregular tumor margins (P<0.001), and peritumor enhancement (P=0.046) were identified as independent risk factors associated with 2-year recurrence-free survival (2 y-RFS).The clinical-radiological nomogram (AUC: 0.814, 95%CI: 0.767-0.861) outperformed only clinical nomogram (AUC: 0.646, 95%CI: 0.587-0.706) in predicting 2 y-RFS in derivation cohort, and the c-index for clinical-radiological nomogram in the internal validation cohort was 0.771 (95% CI, 0.734-0.843). Calibration curves showed good agreement between actual observation and nomogram prediction both in derivation (P=0.114) and validation (P=0.368)cohort.*Conclusions We developed one non-invasive combined clinical and MRI features-based data nomogram to estimate the probability of ER in patients with eHCC after RFA, with favorable discrimination and calibration values. And this clinical-radiological nomogram was superior to only clinical nomogram to predict ER.*Clinical Relevance/Application Our nomogram may be a useful clinical tool for identifying patients at high-risk for ER of eHCC after RAF, stratifying their treatment strategy and follow-up planning in clinical practice.

RESULTS

Within the follow-up period (median 32 months), a total of 130 (40.63%,130/320) and 66 (41.25%, 66/160) patients experienced ER in derivation and validation cohort, respectively. Multiple tumor foci (P <0.001), tumor size=2 cm (P =0.001), AFP=40 ng/ml (P =0.001), irregular tumor margins (P<0.001), and peritumor enhancement (P=0.046) were identified as independent risk factors associated with 2-year recurrence-free survival (2 y-RFS).The clinical-radiological nomogram (AUC: 0.814, 95%CI: 0.767-0.861) outperformed only clinical nomogram (AUC: 0.646, 95%CI: 0.587-0.706) in predicting 2 y-RFS in derivation cohort, and the c-index

for clinical-radiological nomogram in the internal validation cohort was 0.771 (95% CI, 0.734-0.843). Calibration curves showed good agreement between actual observation and nomogram prediction both in derivation (P=0.114) and validation (P=0.368)cohort.

CLINICAL RELEVANCE/APPLICATION

Our nomogram may be a useful clinical tool for identifying patients at high-risk for ER of eHCC after RAF, stratifying their treatment strategy and follow-up planning in clinical practice.

SPR-GI-52   CT-based Deep Learning Towards Early Detection Of Pancreatic Ductal Adenocarcinoma

Participants
Natália Alves, MSc, Nijmegen, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the performance of a 3D nnUnet based algorithm for pancreatic ductal adenocarcinoma (PDAC) detection and assess the potential of the model for early diagnosis by conducting a subgroup analysis on small (size < 2cm) tumors.*Methods and Materials Portal-venous phase contrast-enhanced computed tomography (CE-CT) scans from a cohort of 119 patients with pathology-proven PDAC and 122 consecutive patients with normal pancreas were included in this retrospective study. For the PDAC cohort, expert segmentations of the pancreas and tumor volumes were available, along with the tumor sizes measured on the CT scan. For the non-PDAC cohort, the pancreas segmentations were obtained using a pre-trained deep learning segmentation model. The pancreas segmentation determined a region of interest from the full CE-CT as input to the 3D nnUnet. The network was trained for 1000 epochs with 5-fold cross-validation to differentiate between tumor and normal voxels. The predicted heatmaps were thresholded at 0.1. An image was considered a positive case of PDAC if the predicted tumor volume was greater than 100 mm3.*Results The median tumor size on the PDAC cohort was 2.8 cm (range 1.2 cm - 9.3 cm). The detection task achieved an average sensitivity of 0.93 ± 0.04 (111/119), specificity of 0.98 ± 0.02 (119/122) and area under the receiver operating characteristic curve of 0.96 ± 0.04. The median DICE score between the expert and the network tumor segmentations was 0.68 ± 0.18. In 2 of the 3 false positive cases the network wrongly detected a hypodense region of the normal pancreas, which could be originated by fat accumulation or natural perfusion differences. The mean sensitivity in the sub-group of tumors with size smaller than 2 cm was 0.92 ± 0.1 (21/23), and the median DICE score in this sub-group was 0.56 ± 0.20.*Conclusions These preliminary results indicate that a 3D nnUnet based algorithm can accurately detect small tumors, suggesting that it could be useful at assisting in early PDAC diagnosis.*Clinical Relevance/Application Early diagnosis improves pancreatic cancer prognosis but requires significant expertise. An automatic tool for the detection of early-stage tumors would reduce expertise requirements.

RESULTS

The median tumor size on the PDAC cohort was 2.8 cm (range 1.2 cm - 9.3 cm). The detection task achieved an average sensitivity of 0.93 ± 0.04 (111/119), specificity of 0.98 ± 0.02 (119/122) and area under the receiver operating characteristic curve of 0.96 ± 0.04. The median DICE score between the expert and the network tumor segmentations was 0.68 ± 0.18. In 2 of the 3 false positive cases the network wrongly detected a hypodense region of the normal pancreas, which could be originated by fat accumulation or natural perfusion differences. The mean sensitivity in the sub-group of tumors with size smaller than 2 cm was 0.92 ± 0.1 (21/23), and the median DICE score in this sub-group was 0.56 ± 0.20.

CLINICAL RELEVANCE/APPLICATION

Early diagnosis improves pancreatic cancer prognosis but requires significant expertise. An automatic tool for the detection of early-stage tumors would reduce expertise requirements.

SPR-GI-54   Survival Prediction In Intrahepatic Cholangiocarcinoma: A Proof Of Concept Study Using Artificial Intelligence For Risk Assessment

Participants
Felix Hahn, MD,MSc, Mainz, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Several scoring systems have been devised to objectively predict survival for patients with intrahepatic cholangiocellular carcinoma (ICC) and support treatment stratification, but they have failed external validation. The aim of the present study was to improve prognostication using an artificial intelligence-based approach.*Methods and Materials We retrospectively identified 417 patients with ICC who were referred to our tertiary care center between 1997 and 2018. Of these, 293 met the inclusion criteria. Established risk factors served as input nodes for an artificial neural network (ANN) (Figure A). For an 80:20 split, all patients with an initial diagnosis before the 31st December 2013 (n = 233, 80%) were allocated to the training set. Patients with an initial diagnosis afterwards (n = 60, 20%) formed the holdout validation set. In the training set, a five-fold cross validation approach was used to maximize the training capabilities of the ANN (Figure B). We compared the performance of the trained model to the most widely used conventional scoring system, the Fudan score.*Results Predicting 1-year survival, the ANN reached an area under the ROC curve (AUC) of 0.89 for training and 0.80 for the validation set. The AUC of the Fudan score was significantly lower in the validation set (0.77, p < 0.001). In the training set, the Fudan score yielded a lower AUC (0.74) without reaching significance (p = 0.24).*Conclusions The ANN outperformed conventional risk scoring, leading to the conclusion that especially the inclusion of more risk factors offers a great potential for survival prediction. This study proved the feasibility of this approach for patients with ICC prior to treatment.*Clinical Relevance/Application Artificial intelligence-based approaches have the potential to improve treatment stratification when models trained on large multicenter data are openly available.

RESULTS

Predicting 1-year survival, the ANN reached an area under the ROC curve (AUC) of 0.89 for training and 0.80 for the validation set. The AUC of the Fudan score was significantly lower in the validation set (0.77, p < 0.001). In the training set, the Fudan score yielded a lower AUC (0.74) without reaching significance (p = 0.24).

CLINICAL RELEVANCE/APPLICATION

Artificial intelligence-based approaches have the potential to improve treatment stratification when models trained on large multicenter data are openly available.

SPR-GI-55 Ceus-based Classification Of Liver Tumors With Deep Learning

Participants
Hongyu Zhou, Tianjin, China (*Presenter*) Nothing to Disclose

PURPOSE

Contrast-enhanced ultrasound (CEUS) is considered the most convenient and efficient tool for checking focal liver lesions(FLLs) . However, to accurately diagnose a single case with CEUS, the radiologist should carry out a series of tasks with tedious details. All of the works are time-consuming and also highly experience-dependent. Therefore, the study aims to develop an effective computed-aided diagnosis (CADx) system for classifying the suspected liver lesions between benign and malignant by using a proposed deep learning algorithm for the CEUS sequence.*Methods and Materials A total of 420 focal liver lesions with 136 benign cases and 284 malignant cases were examined through CEUS by a 6-year experienced radiologist . For the data preprocessing, the recorded CEUS video for each case was cropped to a suitable size by bounding box to fit the lesion. A deep learning model based on two dimensional convolution neural network (2D CNN i.e. ResNet-18), a long short-term memory (LSTM) and a Linear classifier (with sigmoid) was developed to analysis the CEUS video from different contrast imaging phases. The 4-fold cross-validation was performed on the proposed algorithm to avoid sampling bias by stratified randomly partitioning the dataset. For comparison, a 3D CNN model and a machine-learning (ML)-based time-intensity curve (TIC) method were also used for the evaluation under the same dataset in the study*Results For evaluating the performance of the purposed algorithm for distinguishing benign and malignancy of liver lesions, the area under the receiver operation characteristic curve (AUC) was adopted as evaluation indices. Results of the 4-fold validation demonstrate the mean AUC is evaluated to 0.91, 0.88 and 0.78 for the purposed CNN-LSTM model, the 3D-CNN model and the ML-based TIC method, respectively. On the other hand, the results of sensitivity increased from 0.83 to 0.95 and the specificity decreased from 0.82 to 0.7 with the threshold of the predicted malignant probabilities by using the purposed CNN-LSTM model. The 3D CNN shows the highest sensitivity of 0.96, but with specificity of 0.55; the ML-based TIC method also shows the lowest specificity of 0.21 when the sensitivity is 0.96*Conclusions In summary, this study demonstrates a complete methodology from data preprocessing to model implementation for the diagnosis of focal liver lesions. The purposed CNN-LSTM model shows its ability to distinguish the benign and malignancy of the lesions with good performance compared to the relevant existing methods.*Clinical Relevance/Application the study aims to develop an effective computed-aided diagnosis (CADx) system for classifying the suspected liver lesions between benign and malignant by using a proposed deep learning algorithm for the CEUS sequence.

RESULTS

For evaluating the performance of the purposed algorithm for distinguishing benign and malignancy of liver lesions, the area under the receiver operation characteristic curve (AUC) was adopted as evaluation indices. Results of the 4-fold validation demonstrate the mean AUC is evaluated to 0.91, 0.88 and 0.78 for the purposed CNN-LSTM model, the 3D-CNN model and the ML-based TIC method, respectively. On the other hand, the results of sensitivity increased from 0.83 to 0.95 and the specificity decreased from 0.82 to 0.7 with the threshold of the predicted malignant probabilities by using the purposed CNN-LSTM model. The 3D CNN shows the highest sensitivity of 0.96, but with specificity of 0.55; the ML-based TIC method also shows the lowest specificity of 0.21 when the sensitivity is 0.96

CLINICAL RELEVANCE/APPLICATION

the study aims to develop an effective computed-aided diagnosis (CADx) system for classifying the suspected liver lesions between benign and malignant by using a proposed deep learning algorithm for the CEUS sequence.

SPR-GI-56 Dual-layer Spectral Detector CT For HCC Diagnosis Using LI-RADS Version 2018: Comparison Of Virtual Monoenergetic Images (VMIs) And Conventional Images (CIs)

Participants
Wu Zhang, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare the diagnostic value of virtual monoenergetic images (VMIs) at 40keV and conventional images(CIs) obtained from Dual-Layer Spectral Detector CT (DLSCT) for characterization of liver observations in patients at high risk for Hepatocellular carcinoma (HCC) by using Liver Imaging Reporting and Data System (LI-RADS) Version 2018.*Methods and Materials 116 liver observations in 84 patients at high risk for HCC who underwent multiphase contrast enhancement (370 mg/ml iodine) scanning by DLSCT were retrospectively enrolled in this study, including 77 HCCs, 8 non-HCCs malignancies, and 31 benign entities with biopsy-proven and/or follow-up confirmation. The CIs and VMIs at 40keV derived from DLCT in arterial and portal venous phases were reconstructed. Two blinded radiologists scored LI-RADS imaging features and assigned each observation a LI-RADS category based on main features using LI-RADS v2018 (including LR1-5, M and TIV) on both CIs and VMIs at 40keV in consensus. For the same patient with multiple liver observations, the LI-RADS category of each observation was adjusted based on spectral attenuation curve. Sensitivity and specificity were calculated and compared among CIs, VMIs at 40keV and adjusted 40keV LI-RADS categories by McNemar test.*Results Using LI-RADS v2018, LR-5&TIV at CIs provided 72.73% sensitivity and 97.44% specificity for HCC. LR-5&TIV criteria at VMIs at 40keV and adjusted 40keV significantly increased sensitivity (89.61%/93.51% vs. 72.73%, both P<0.001) without significantly reducing specificity (89.74%/87.18% vs 97.44%, both P>0.05). LR-5 criteria at CIs provided 54.55% sensitivity and 97.44% specificity for HCC. LR-5 criteria at VMIs at 40keV and adjusted 40keV significantly increased sensitivity (72.73%/76.62% vs. 54.55%, both P<0.001) without significantly reducing specificity (89.74%/87.18% vs 97.44%, both P>0.05). LR-5 criteria at VMIs at CIs, 40keV and adjusted 40keV has lower sensitivity (all P<0.001) while maintaining similar specificity compared with LR-5/TIV criteria (all P>0.05) in this study.*Conclusions VMIs at 40keV derived from DLSCT in combination with spectral attenuation curve significantly increases sensitivity without significantly reducing specificity for the diagnosis of HCC in patients at high risk for HCC. Confirmation is warranted in multi-center prospective studies.*Clinical Relevance/Application VMIs at 40keV obtained from DLSCT has better sensitivity for HCC than at CIs in patients at high risk for HCC by using LI-RADS Version 2018. Further studies with a larger sample size in a prospective multi-center setting are needed to validate our preliminary results.

RESULTS

Using LI-RADS v2018, LR-5&TIV at CIs provided 72.73% sensitivity and 97.44% specificity for HCC. LR-5&TIV criteria at VMIs at 40keV and adjusted 40keV significantly increased sensitivity (89.61%/93.51% vs. 72.73%, both P<0.001) without significantly reducing specificity (89.74%/87.18% vs 97.44%, both P>0.05). LR-5 criteria at CIs provided 54.55% sensitivity and 97.44% specificity for HCC. LR-5 criteria at VMIs at 40keV and adjusted 40keV significantly increased sensitivity (72.73%/76.62% vs. 54.55%, both P<0.001) without significantly reducing specificity (89.74%/87.18% vs 97.44%, both P>0.05). LR-5 criteria at VMIs at CIs, 40keV and adjusted 40keV has lower sensitivity (all P<0.001) while maintaining similar specificity compared with LR-5/TIV

criteria (all P>0.05) in this study.

CLINICAL RELEVANCE/APPLICATION

VMIs at 40keV obtained from DLSCT has better sensitivity for HCC than at CIs in patients at high risk for HCC by using LI-RADS Version 2018. Further studies with a larger sample size in a prospective multi-center setting are needed to validate our preliminary results.

SPR-GI-57   Influence Of Liver Iron Content And Fibrosis In Inter- And Intra-individual Quantification Of Hepatic Steatosis Using Fast-kilovolt-peak-switching Dual Energy Computed Tomography And Material Decomposition Technique: A Prospective Clinical Study.

Participants
Eriko Yoshizawa, Matsumoto, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To clarify the influence of iron content and fibrosis of the liver in clinical hepatic steatosis quantification using fast-kilovolt-peak-switching dual energy computed tomography (DECT) and material decomposition (MD) technique.*Methods and Materials This study included 88 sets of DECT and MR examinations (1.5T&3.0T) including MR elastography (MRE) performed prospectively on the same day before and after 6 months exercise therapy (interval walking training) in 38 patients with type 2 diabetes. Fat density (FD) derived from DECT, proton density fat fraction (PDFF1.5T, PDFF3.0T) and R2* (R2*1.5T, R2*3.0T) as an alternative indicator for hepatic fat and iron content derived from 6-point Dixon MR imaging by different magnetic field strength, liver stiffness (LS) as an alternative indicator for hepatic fibrosis derived from 1.5T MRE were measured. The difference of FD and PDFF (?FD, ?PDFF1.5T, ? PDFF3.0T), the mean of R2* and LS (mR2*1.5T, mLS) before and after exercise therapy were calculated, respectively. Univariate correlation analysis and multivariate stepwise linear regression analysis (MSLRA) were performed using PDFF and ?PDFF obtained from 1.5T MR imaging as a dependent variable, parameters obtained from DECT and 1.5T MR imaging as independent variables.*Results Correlation coefficient of FD and PDFF3.0T against PDFF1.5T were 0.83(95%CI:0.76,0.88) and 0.93(0.89,0.96), respectively. MSLRA revealed that FD and mR2*1.5T were significant independent variables for PDFF1.5T and there was not significant difference in correlation to PDFF1.5T between derived model (r=0.85;0.78,0.90) and PDFF3.0T. There was no significant difference in correlation coefficient against ?PDFF1.5T between ?FD (r=0.44;0.19,0.65) and ?PDFF3.0T(r=0.57;0.34,0.73). MSLRA revealed that only ?FD was a significant independent variables for ?PDFF1.5T. mLS was not significant independent variables for either PDFF1.5T or ?PDFF1.5T.*Conclusions Hepatic iron content corresponding to R2* significantly influences inter-individual quantification of hepatic steatosis using DECT and MD technique; however ?FD can be used as an alternative to ?PDFF in intra-individual quantification of hepatic steatosis.*Clinical Relevance/Application 1) The influence of hepatic iron content should be considered in inter-individual quantification of hepatic steatosis by current MD technique. 2) If it can be assumed that the interval change in hepatic iron content is small, current MD technique has a feasibility to quantify hepatic steatosis in intra-individual assessment. 3) Current MD technique can be applicable to patients with NAFLD in the early to late stages because liver fibrosis which corresponds to liver stiffness does not affect the quantification of hepatic steatosis.

RESULTS

Correlation coefficient of FD and PDFF3.0T against PDFF1.5T were 0.83(95%CI:0.76,0.88) and 0.93(0.89,0.96), respectively. MSLRA revealed that FD and mR2*1.5T were significant independent variables for PDFF1.5T and there was not significant difference in correlation to PDFF1.5T between derived model (r=0.85;0.78,0.90) and PDFF3.0T. There was no significant difference in correlation coefficient against ?PDFF1.5T between ?FD (r=0.44;0.19,0.65) and ?PDFF3.0T(r=0.57;0.34,0.73). MSLRA revealed that only ?FD was a significant independent variables for ?PDFF1.5T. mLS was not significant independent variables for either PDFF1.5T or ?PDFF1.5T.

CLINICAL RELEVANCE/APPLICATION

1) The influence of hepatic iron content should be considered in inter-individual quantification of hepatic steatosis by current MD technique. 2) If it can be assumed that the interval change in hepatic iron content is small, current MD technique has a feasibility to quantify hepatic steatosis in intra-individual assessment. 3) Current MD technique can be applicable to patients with NAFLD in the early to late stages because liver fibrosis which corresponds to liver stiffness does not affect the quantification of hepatic steatosis.

SPR-GI-59   Machine Learning (ML) Model Based On CT Radiomics Signature For Detection Of Pancreatic Ductal Adenocarcinoma (PDA) On Prediagnostic CT Scans

Participants
SOVANLAL MUKHERJEE, PhD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

Early detection of PDA is the key to improve outcomes. However, small PDAs are often missed on CT scans due to their subtle imaging features or inattentional bias. To address this challenge, our purpose was to evaluate a ML model based on CT radiomics features for detection of PDA on prediagnostic CT scans.*Methods and Materials Volumetric pancreas segmentation was performed by radiologists using 3D Slicer® on a highly curated prediagnostic CT dataset (portal-venous phase CTs from 2005-2016; slice thickness=5-mm; mean interval between CT and eventual histopathologic diagnosis of PDA:12 months) of 163 patients (median age:63 years; Male:Female=1.1:1) and an equal number of age- and sex-matched controls with normal pancreas. None of the prediagnostic CTs had focal imaging findings to suggest cancer. Total 78 radiomics features (first order and gray levels) were extracted using Pyradiomics to quantify the imaging phenotype and 24 features were selected through a F-score feature selection method to remove redundant features (figure). The dataset was divided into a training set (273 CTs: 136 prediagnostic plus 137 controls) and a test set (53 CTs: 27 prediagnostic and 26 controls). Four classifiers based on K-Nearest Neighbor (KNN), Support Vector Machine (SVM), Random Forest (RF) and XGBoost were evaluated for classification of CTs from the test set into PDA vs. normal. A leave-one-out cross-validation method was utilized to select the best hyperparameters for each classifier.*Results The respective sensitivity, specificity, accuracy and area under the curve (AUC) of the classifiers [mean (95% confidence intervals)] were as follows: KNN [0.55 (0.26, 0.88); 0.84 (0.56, 0.87); 0.69 (0.57, 0.82)]; 0.70 (0.57, 0.85)], SVM [0.74 (0.52, 0.91); 0.73 (0.58, 0.88); 0.74 (0.62, 0.85); 0.74 (0.58, 0.88)], RF [0.67 (0.43, 0.91); 0.73 (0.58, 0.88); 0.69 (0.58, 0.82); 0.70 (0.57, 0.85)] and XGBoost [0.67 (0.41, 0.92); 0.77 (0.58, 0.87); 0.72 (0.59, 0.84); 0.72 (0.58, 0.87)]. Thus, SVM yielded the highest performance metrics among different classifiers. It correctly classified 73% (19/26) normal CTs and 74% (20/27) pre-diagnostic CTs.*Conclusions A SVM ML classifier shows potential for detection of PDA by quantifying the radiomics-based imaging phenotype of cancer on prediagnostic CTs even in the absence of overt imaging findings.*Clinical Relevance/Application Once fine-tuned on

larger and heterogenous datasets, radiomics-based ML models may augment physician expertise for early PDA detection in high-risk cohorts (e.g. new onset diabetes with weight loss).

RESULTS

The respective sensitivity, specificity, accuracy and area under the curve (AUC) of the classifiers [mean (95% confidence intervals)] were as follows: KNN [0.55 (0.26, 0.88); 0.84 (0.56, 0.87); 0.69 (0.57, 0.82)]; 0.70 (0.57, 0.85)], SVM [0.74 (0.52, 0.91); 0.73 (0.58, 0.88); 0.74 (0.62, 0.85); 0.74 (0.58, 0.88)], RF [0.67 (0.43, 0.91); 0.73 (0.58, 0.88); 0.69 (0.58, 0.82); 0.70 (0.57, 0.85)] and XGBoost [0.67 (0.41, 0.92); 0.77 (0.58, 0.87); 0.72 (0.59, 0.84); 0.72 (0.58, 0.87)]. Thus, SVM yielded the highest performance metrics among different classifiers. It correctly classified 73% (19/26) normal CTs and 74% (20/27) pre-diagnostic CTs.

CLINICAL RELEVANCE/APPLICATION

Once fine-tuned on larger and heterogenous datasets, radiomics-based ML models may augment physician expertise for early PDA detection in high-risk cohorts (e.g. new onset diabetes with weight loss).

SPR-GI-6   VSI Teleultrasound Of The Right Upper Quadrant: A New Horizon In Imaging

Participants
Thomas Marini, MD, Rochester, New York (*Presenter*) Nothing to Disclose

PURPOSE

Although hepatic and biliary diseases are prevalent worldwide, the majority of people lack access to diagnostic medical imaging for their assessment. The liver and gallbladder are readily amenable to sonographic examination which may assist in diagnosis of pathology and alter patient management. However, ultrasound's deployment is limited by the lack of experienced sonographers. In this study, we tested an asynchronous telediagnostic system for right upper quadrant (RUQ) abdominal ultrasound examination operated by individuals without prior ultrasound experience to facilitate deployment of ultrasound to rural and underserved areas.*Methods and Materials The teleultrasound system utilized in this study employs volume sweep imaging (VSI) and a telemedicine app installed on a tablet which connects to an ultrasound machine. VSI is an ultrasound technique in which an individual scans the target region utilizing preset ultrasound sweeps demarcated by easily recognized external body landmarks. The sweeps are saved as video clips for later interpretation by an experienced radiologist. In our study, teleultrasound scans from a Peruvian clinic were sent to the United States for remote interpretation and quality assessment. Standard of care comparison was made to a same-day ultrasound examination performed by a radiologist.*Results 144 subjects were recruited to participate in the study. Among VSI exams of acceptable or excellent image quality (n=91), there was 95% agreement between standard of care and teleultrasound on whether an exam was normal or abnormal, with a Cohen's kappa of 0.84 (95% CI 0.7-0.98, p <0.0001). The liver and gallbladder showed greater than 80% visualization in a majority of the acceptable and excellent image quality cases. Among teleultrasound exams of acceptable or excellent image quality, the sensitivity for an abnormal gallbladder was 94% (95% CI 69.8%-99.8%) and the specificity was 97% (95% CI 89.5%-99.6%).*Conclusions This asynchronous telediagnostic system allows individuals without prior ultrasound experience to effectively scan the liver, gallbladder and right kidney with a high degree of agreement with standard of care ultrasound.*Clinical Relevance/Application VSI teleultrasound can be deployed to improve access to diagnostic imaging in low-resource areas.

RESULTS

144 subjects were recruited to participate in the study. Among VSI exams of acceptable or excellent image quality (n=91), there was 95% agreement between standard of care and teleultrasound on whether an exam was normal or abnormal, with a Cohen's kappa of 0.84 (95% CI 0.7-0.98, p <0.0001). The liver and gallbladder showed greater than 80% visualization in a majority of the acceptable and excellent image quality cases. Among teleultrasound exams of acceptable or excellent image quality, the sensitivity for an abnormal gallbladder was 94% (95% CI 69.8%-99.8%) and the specificity was 97% (95% CI 89.5%-99.6%).

CLINICAL RELEVANCE/APPLICATION

VSI teleultrasound can be deployed to improve access to diagnostic imaging in low-resource areas.

SPR-GI-60   Simultaneous Multislice Diffusion-weighted Imaging Versus Standard Diffusion-weighted Imaging In Whole-body PET/MRI

Participants
Felipe Furtado, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Diffusion-weighted imaging (DWI) is a magnetic resonance imaging (MRI) sequence useful for detecting primary tumors and metastases. However, DWI acquisition in abdominal and whole-body protocols is often lengthy and sensitive to artifacts. Simultaneous Multi-Slice (SMS) DWI is a parallel imaging technique that may address this issue. This study compared standard (STD) DWI and SMS-DWI during whole-body (WB) positron emission tomography (PET)/MRI in regard to acquisition duration and lesion detection sensitivity.*Methods and Materials Adult oncologic patients who underwent whole-body fluorodeoxyglucose positron emission tomography (PET)/MRI between 8/2018 and 3/2020 were prospectively enrolled. All data were acquired on a 3T Biograph mMR (Siemens Healthcare, Erlangen, Germany) using the spine coil and body coil arrays. MRI sequences included Axial T2 HASTE, a prototype Axial SMS-DWI, axial STD-DWI, coronal T2 HASTE, pre- and post-contrast axial T1 VIBE, and post-contrast coronal T1 VIBE. SMS-DWI and its computed ADC map were compared with their STD counterparts regarding acquisition time and lesion detection. The standard of reference for lesion detection included the anatomic MRI sequences and the PET data. Linear and ordinal logistic models were created to quantify the association between acquisition time and lesion detection to imaging modality. All model parameters were estimated using generalized estimating equations and odds ratios were computed.*Results 83 adults were enrolled, 57% (47/83) female, median age 64 years (IQR 52-71 years). The median STD-DWI acquisition time was 14.67 minutes (IQR 14.10-15.76 minutes), compared to 6.95 minutes (IQR 6.70-7.15) for SMS-DWI. Acquisition times using standard DWI were 2.21 (95%: 2.13 - 2.30) times longer than the SMS-DWI (p<0.001). STD-DWI detected 277 of the 356 (78%) lesions while SMS-DWI could locate 297 (83%) of them (odds ratio 1.44, p-value 0.036).*Conclusions SMS-DWI was able to significantly reduce acquisition time while improving the diagnostic yield.*Clinical Relevance/Application DWI is useful for whole-body oncologic imaging, but its acquisition time remains a challenge. SMS-DWI might enable faster acquisition while retaining or even improving diagnostic yield.

RESULTS

83 adults were enrolled, 57% (47/83) female, median age 64 years (IQR 52-71 years). The median STD-DWI acquisition time was 14.67 minutes (IQR 14.10-15.76 minutes), compared to 6.95 minutes (IQR 6.70-7.15) for SMS-DWI. Acquisition times using standard DWI were 2.21 (95%: 2.13 - 2.30) times longer than the SMS-DWI (p<0.001). STD-DWI detected 277 of the 356 (78%) lesions while SMS-DWI could locate 297 (83%) of them (odds ratio 1.44, p-value 0.036).

CLINICAL RELEVANCE/APPLICATION

DWI is useful for whole-body oncologic imaging, but its acquisition time remains a challenge. SMS-DWI might enable faster acquisition while retaining or even improving diagnostic yield.

SPR-GI-61   Meta-analysis And Systematic Review Of Contrast-enhanced Ultrasound In Evaluating The Treatment Response After Locoregional Therapy Of Hepatocellular Carcinoma

Participants
Esika Savsani, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Contrast-enhanced ultrasound (CEUS) is a useful tool to measure treatment response after ablation or transarterial chemoembolization (TACE) of hepatocellular carcinoma (HCC). Several single-site clinical validation studies have been conducted, and a summary of the studies in this field is needed. Here, we performed a systematic review and meta-analysis to evaluate the usefulness of CEUS in evaluation of tumor treatment response after locoregional therapy.*Methods and Materials PubMed, Scopus, and Cochrane library databases were searched from their inception until March 8, 2021, for diagnostic test accuracy studies comparing CEUS to a reference standard for identifying residual tumors after locoregional therapy for hepatocellular carcinoma (HCC). The pooled sensitivity, specificity, accuracy, and diagnostic odds ratio (DOR) were obtained using a bivariate random effects model. Subgroup analyses were performed by stratifying the studies based on study design, type of locoregional therapy, CEUS criteria for residual tumor, timing of CEUS, and type of standard reference to evaluate the influence of these factors on the overall effect.*Results Two reviewers independently evaluated 1479 publications. After full-text review, 142 studies were found to be relevant and 43 publications (50 cohorts) with sufficient study detail were included in the final meta-analysis. The overall sensitivity of CEUS in detection of residual disease estimated from the bivariate random effects model was 0.85 (95% CI 0.80-0.89). Similarly, the overall specificity was estimated to be 0.94 (95% CI 0.91-0.96). The accuracy (fraction of correct tests) was 93.5%. The DOR was 84.1 (95% CI 54.0-131.0), and the AUROC was 0.95. Initial subgroup analysis showed no apparent differences in the diagnostic performance between locoregional therapy (TACE vs. ablation) or criteria used to define residual enhancement (any intratumoral enhancement vs. arterial phase hyper-enhancement), timing for performing CEUS, study design, and type of reference standard.*Conclusions Evidence shows that CEUS is a highly effective method for identifying residual HCC after locoregional therapy.*Clinical Relevance/Application A meta-analysis of 43 studies including 2993 HCC nodules demonstrated that CEUS is an effective imaging modality for diagnosing residual tumor after locoregional therapy.

RESULTS

Two reviewers independently evaluated 1479 publications. After full-text review, 142 studies were found to be relevant and 43 publications (50 cohorts) with sufficient study detail were included in the final meta-analysis. The overall sensitivity of CEUS in detection of residual disease estimated from the bivariate random effects model was 0.85 (95% CI 0.80-0.89). Similarly, the overall specificity was estimated to be 0.94 (95% CI 0.91-0.96). The accuracy (fraction of correct tests) was 93.5%. The DOR was 84.1 (95% CI 54.0-131.0), and the AUROC was 0.95. Initial subgroup analysis showed no apparent differences in the diagnostic performance between locoregional therapy (TACE vs. ablation) or criteria used to define residual enhancement (any intratumoral enhancement vs. arterial phase hyper-enhancement), timing for performing CEUS, study design, and type of reference standard.

CLINICAL RELEVANCE/APPLICATION

A meta-analysis of 43 studies including 2993 HCC nodules demonstrated that CEUS is an effective imaging modality for diagnosing residual tumor after locoregional therapy.

SPR-GI-62   Comparison Between Conventional And Volumetric Response Criteria For Assessment Of Clinical Benefit From Systemic Immunotherapy In HCC

Participants
Azarakhsh Baghdadi, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

RECIST 1.1 is the most widely utilized imaging criteria for clinical trials of systemic therapies in HCC, but imaging assessments with RECIST may not reflect the full spectrum of clinical benefit. Here we compare the performance of RECIST, mRECIST, EASL, and viable tumor volume for imaging assessment with PD(L)1-based therapy in HCC.*Methods and Materials We conducted a retrospective review of patients receiving systemic immunotherapy for intermediate or advanced stage HCC at the Johns Hopkins Hospital from 2019-2020. Patients were eligible for inclusion if they had received immunotherapy as standard of care with at least 6 months of follow up, and paired imaging with contrast CT or MRI at treatment baseline and at the end of treatment. Anatomic (RECIST, mRECIST and EASL) and functional (total and viable tumor volume) imaging assessments were performed on the baseline and follow-up images. Patients who had more than 66% decrease in viable tumor volume and 50% decrease in total tumor volume were deemed responders.*Results Thirty-seven patients met our inclusion criteria and were included in our retrospective imaging review. A higher percentage of baseline and on-treatment lesions were evaluable by volumetric response criteria than by conventional response criteria (37 by viable tumor volume assessment, and 35 by RECIST 1.1). On imaging review, response rates for patients with evaluable lesions were higher with viable tumor volume assessment(35%) than by conventional imaging modalities (2.5% by RECIST, 19% by mRECIST and 19% by EASL).*Conclusions Viable tumor volume captures a higher number of responses with immunotherapy in HCC than conventional imaging modalities, especially in lesions that cannot be measured with conventional response criteria. Further prospective validation of viable tumor volume as a predictor of clinical outcomes is warranted in clinical trials of immunotherapy in HCC.*Clinical Relevance/Application Immunotherapy is a groundbreaking treatment and this study can be the foundation of future prospective studies and also clinical trials to assess response to immunotherapy in HCC.

RESULTS

Thirty-seven patients met our inclusion criteria and were included in our retrospective imaging review. A higher percentage of baseline and on-treatment lesions were evaluable by volumetric response criteria than by conventional response criteria (37 by viable tumor volume assessment, and 35 by RECIST 1.1). On imaging review, response rates for patients with evaluable lesions

were higher with viable tumor volume assessment(35%) than by conventional imaging modalities (2.5% by RECIST, 19% by mRECIST and 19% by EASL).

CLINICAL RELEVANCE/APPLICATION

Immunotherapy is a groundbreaking treatment and this study can be the foundation of future prospective studies and also clinical trials to assess response to immunotherapy in HCC.

SPR-GI-63 PET/MRI Versus PET/CT, MRI, And CT In The Diagnosis Of Peritoneal Carcinomatosis

Participants
Felipe Furtado, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To compare positron emission tomography (PET)/ Magnetic resonance imaging (MRI) to the standard of care imaging (SCI) regarding the diagnosis of peritoneal carcinomatosis (PC) in primary abdominal malignancies. PC has profound negative prognostic significance in several cancers including primary abdominopelvic malignancies. Its presence may preclude surgical cure or definitive cure. Thus, the detection of PC non-invasively by imaging is of compelling clinical interest in cancer staging and restaging.*Methods and Materials Adult patients were prospectively enrolled consecutively from 4/2019 to 3/2021. Inclusion criteria were: (a) acquisition of fluorodeoxyglucose PET/MRI, (b) confirmed primary abdominal neoplasm. Patients were excluded if: (a) the interval between SCI and PET/MRI exceeded 4 weeks, (b) if follow-up pathology, laparoscopy, or imaging results were not available. SCI consisted of whole-body contrast-enhanced (CE) PET/CT with diagnostic-quality (i.e. standard radiation dose) CT, abdominal CE-CT, or abdominal CE-MRI. If available, pathology, and laparoscopy/surgical description, served as the primary standard of reference, otherwise, imaging follow-up, which was acquired in every patient, served as the standard of reference.*Results One hundred sixty-four patients were studied, 85 (52%) were female. The median age was 60 years (IQR 50 - 69). Thirty-one cases ultimately had PC according to the reference standard, 18 females (58%), median age 56 years (IQR 52 - 66). The standard was pathology or laparoscopy for 51% (84/164) and imaging for 49% (80/164). PET/MRI had a sensitivity of 90% (95% CI 74% - 98%), a specificity of 92% (95% CI 86% - 96%), and accuracy of 91% (95% CI 86% - 95%), compared to 58% (95% CI 39% - 75%), 96% (95% CI 91% - 98%), and 89% (95% CI 83% - 93%), respectively, for SCI. When segmenting each individual modality, sensitivity, specificity, and accuracy were, respectively 59%, 96%, and 88% for PET/CT, 50%, 94%, and 88% for CT, and 67%, 100%, and 95% for MRI.*Conclusions PET/MRI provides a substantial increase in sensitivity for peritoneal involvement over SCI.*Clinical Relevance/Application Peritoneal carcinomatosis is not uncommon in gastrointestinal cancers, and its detection is paramount to establish adequate management. PET/MRI presents improved sensitivity for peritoneal carcinomatosis over the currently used modalities.

RESULTS

One hundred sixty-four patients were studied, 85 (52%) were female. The median age was 60 years (IQR 50 - 69). Thirty-one cases ultimately had PC according to the reference standard, 18 females (58%), median age 56 years (IQR 52 - 66). The standard was pathology or laparoscopy for 51% (84/164) and imaging for 49% (80/164). PET/MRI had a sensitivity of 90% (95% CI 74% - 98%), a specificity of 92% (95% CI 86% - 96%), and accuracy of 91% (95% CI 86% - 95%), compared to 58% (95% CI 39% - 75%), 96% (95% CI 91% - 98%), and 89% (95% CI 83% - 93%), respectively, for SCI. When segmenting each individual modality, sensitivity, specificity, and accuracy were, respectively 59%, 96%, and 88% for PET/CT, 50%, 94%, and 88% for CT, and 67%, 100%, and 95% for MRI.

CLINICAL RELEVANCE/APPLICATION

Peritoneal carcinomatosis is not uncommon in gastrointestinal cancers, and its detection is paramount to establish adequate management. PET/MRI presents improved sensitivity for peritoneal carcinomatosis over the currently used modalities.

SPR-GI-64 Sinogram-based Thin Slices Deep Learning Image Reconstruction Technique In Abdominal CT: Image Quantitative And Qualitative Analysis.

Participants
Jinjin Cao, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the image quality and perception of deep-learning image reconstruction (DLIR) for single-energy abdominal CT using 1.25 mm thin slices compared to 5 mm standard-of-care adaptive statistical iterative reconstruction (ASIR-V) images.*Methods and Materials This retrospective study included 52 patients (31 F; 56.9±16.9 years) undergoing portal venous phase abdominal CT. Four reconstructions [5-mm thickness ASIR-V at 40%, and 1.25-mm thickness DLIR at three strengths (low (DLIR-L), medium (DLIR-M) and high (DLIR-H)) were generated. Qualitative assessment was performed for image noise, contrast, visibility of small structures, sharpness and artifact by the two blinded radiologists on a 5-point-scale ranging from 1=excellent to 5=very poor. Radiologists also indicated image preference on a 3-point-scale (1=most preferred; 2=acceptable; 3=least preferred). Quantitative assessment was performed by measuring attenuation, image noise, and contrast-to-noise ratios (CNR).*Results DLIR-M and DLIR-H yielded better image quality scores compared to ASIR-V 40. Mean qualitative scores on DLIR-H for noise (1.77 ± 0.71), contrast (1.6 ± 0.68), small structure visibility (1.42 ± 0.66), sharpness (1.34 ± 0.55) and image preference (1.11 ± 0.34) were the best (p<0.05) followed by DLIR-M (2.66 ± 0.65, 2.12 ± 0.70, 1.97 ± 0.70, 1.78 ± 0.56, 1.30 ± 0.50), DLIR-L (3.22 ± 0.61, 2.41 ± 0.63, 2.32± 0.67, 2.02 ± 0.42, 1.56 ± 0.57) and ASIR-V (3.09 ± 0.64, 2.62 ± 0.60, 2.59 ± 0.73, 2.07 ± 0.42). There were no significant differences in image noise and sharpness scores between DLIR L and ASIR-V 40 (p=0.053 and p=0.275). There is significant difference image contrast and image preference scores between DLIR-L and ASIR-V 40 (p<0.05). Ratings for artifacts were similar for all reconstructions (p>0.05). There is no significant difference attenuation value among all the groups. For quantitative analysis, DLIR-H demonstrated the lowest image noise (9.17 ± 3.11) and the highest CNR (CNRliver = 26.88 ± 6.54 and CNRportal vein = 7.92 ± 3.85).*Conclusions DLIRs were preferred over iterative reconstruction subjectively and DLIR-H yielded better quantitative CNR due to improved image quality and lower noise.*Clinical Relevance/Application DLIR demonstrates potential benefit in clinical practice, allowing for potential radiation dose reduction while preserving good image quality and low image noise.

RESULTS

DLIR-M and DLIR-H yielded better image quality scores compared to ASIR-V 40. Mean qualitative scores on DLIR-H for noise (1.77 ± 0.71), contrast (1.6 ± 0.68), small structure visibility (1.42 ± 0.66), sharpness (1.34 ± 0.55) and image preference (1.11 ± 0.34) were the best (p<0.05) followed by DLIR-M (2.66 ± 0.65, 2.12 ± 0.70, 1.97 ± 0.70, 1.78 ± 0.56, 1.30 ± 0.50), DLIR-L (3.22 ± 0.61, 2.41 ± 0.63, 2.32± 0.67, 2.02 ± 0.42, 1.56 ± 0.57) and ASIR-V (3.09 ± 0.64, 2.62 ± 0.60, 2.59 ± 0.73, 2.07 ± 0.42). There were

no significant differences in image noise and sharpness scores between DLIR L and ASIR-V 40 (p=0.053 and p=0.275). There is significant difference image contrast and image preference scores between DLIR-L and ASIR-V 40 (p<0.05). Ratings for artifacts were similar for all reconstructions (p>0.05). There is no significant difference attenuation value among all the groups. For quantitative analysis, DLIR-H demonstrated the lowest image noise (9.17 ± 3.11) and the highest CNR (CNRliver = 26.88 ± 6.54 and CNRportal vein = 7.92 ± 3.85).

CLINICAL RELEVANCE/APPLICATION

DLIR demonstrates potential benefit in clinical practice, allowing for potential radiation dose reduction while preserving good image quality and low image noise.

SPR-GI-8   Converting Diffusion Weighted Rectal Tumor Imaging Data At Multiple B-values Into MNIST-like Pictures For The Pretreatment Prediction Of Pathological Complete Response To Neoadjuvant Chemoradiotherapy By Deep Learning

Participants
Haitao Zhu, PhD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Several non-Gaussian models have been proposed to predict the pathological results of locally advanced rectal cancers, including IVIM, stretched-exponential model, DKI, etc., but no model has been considered as the gold standard. In fact, all models aim to simplify diffusion physics into an equation with several parameters, but the true biological environment might be far more complicated than the models. It is desirable to skip the parameterizing step and directly utilize the decay curve of diffusion signal. In this study, we propose a method to convert DWI data acquired at multiple b-values into MNIST-like 2D pictures for deep learning. The method is used to predict the status of pathological complete response (pCR) after neoadjuvant chemoradiotherapy (NCRT) by using pretreatment DWI data.*Methods and Materials 472 subjects were enrolled and divided to a train group (n=200), a validation group (n=72) and a test group (n=200). All participants were scanned on a 3.0 Tesla MRI scanner (Discovery MR750) before the initiation of NCRT using an 8-channel phased array body coil in the supine position. DWI data were acquired with TR=2800 ms, TE=66 ms, FOV=340 mm, matrix=256×256, thickness=4 mm and gap=1 mm. The b-values were: 0, 20, 50, 100, 200, 400, 600, 800, 1000, 1200, 1400, and 1600 sec/mm2. ROI of rectal tumor was delineated by two experienced radiologists. DWI data were converted into a MNIST-like picture by: (1) A histogram was calculated from the logarithm format of signals in ROI at each b-value with 35 bins between 3 and 10; (2) the histograms of all b-values were piled to construct a 12×35 picture. It looks like a handwriting signature on a plate with gray level as x-axis, b-value as y-axis and pixel number as intensity. 3 repetitions of a convolutional layer, a pooling layer and a ReLU layer were used to classify the pictures into pCR and non-pCR. Pathological results were used as ground truth. Data augmentation was performed in the train and validation groups by randomly sampling half of the voxels in ROI by 100 times for pCR and 25 times for non-pCR to keep a balance in classes.*Results Validation group was used to optimize hyperparameters into batch=200, epochs=7.2e4 and learning rate=1e-5. Test group was evaluated by the final model determined above. Accuracy and AUC are 0.894 and 0.939 in the train group, 0.861 and 0.924 in the validation group, 0.915 and 0.924 in the test group.*Conclusions This study proposes a deep learning method of analyzing DWI data acquired at multiple b-values without parameterization and shows good prediction of pCR after NCRT by using pre-NCRT DWI data.*Clinical Relevance/Application Prediction of pathological result before NCRT for locally advanced rectal cancer makes it possible to change NCRT or surgery plan before the start of treatment.

RESULTS

Validation group was used to optimize hyperparameters into batch=200, epochs=7.2e4 and learning rate=1e-5. Test group was evaluated by the final model determined above. Accuracy and AUC are 0.894 and 0.939 in the train group, 0.861 and 0.924 in the validation group, 0.915 and 0.924 in the test group.

CLINICAL RELEVANCE/APPLICATION

Prediction of pathological result before NCRT for locally advanced rectal cancer makes it possible to change NCRT or surgery plan before the start of treatment.

SPR-GI-9   Low Volume Reduced Bowel Preparation Regimen For CT Colonography: A Randomized Noninferiority Trial

Participants
Simone Vicini, MD, Latina, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Bowel preparation is the most unpleasant step of CT colonography (CTC) due to high volume of cathartic solution to ingest and gastrointestinal discomfort. The aim of our study was to determine whether the quality of a low-volume reduced bowel preparation (LV-RBP) for CTC is noninferior to standard full-volume reduced bowel preparation (FV-RBP) regimen.*Methods and Materials In this randomized controlled trial, consecutive participants referred for CTC were randomly assigned (1:1 ratio, fixed blocks of 10) to receive LV-RBP (52.5 g of PMF104 in 500 mL of water) or FV-RBP (105 g of PMF104 in 1000 mL of water). Images were independently reviewed by five blinded readers who rated the quality of bowel preparation using a 4-point scale from 0 (best score) to 3 (worst score) on per-colonic segment basis.The primary outcome was the noninferiority of LV-RBP to FV-RBP in the proportion of segments scored 0 for colon cleansing quality, with a noninferiority margin of 10%. Noninferiority in residual fluids and colonic distension, and superiority in lesions and polyps detection rates and patient acceptability were secondary outcomes.*Results From March 2019 to January 2020, a total of 110 participants (mean age 65 years ± 14 [standard deviation]; 74 women) were allocated to LV-RBP (n=55) or FV-RBP (n=55) arms. There were 92% segment with score 0 in colon cleansing quality in LV-RBP and 94% in FV-RBP for prone scans, and 94% vs 92% as for supine scans. Risk difference was - 2.1 (95% CI: -5.9 to 1.7) and 1.5 (95% CI: - 2.4 to 5.4) for prone and supine positions, respectively. Residual fluids and colonic distension were also noninferior in LV-RBP. LV-RBP was associated with a lower number of evacuations during preparation (7±5 vs 10±6, p=0.002).There was almost perfect agreement for overall quality of colon cleansing and volume of residual fluids scoring among all readers (ICC = 0.90 [95% CI 0.88-0.91] and ICC = 0.88 [95% CI 0.87-0.90] in the LV-RBP and in the FV-RBP arm, respectively). Patients discomfort related to the bowel preparation was rated as mild by most participants for both regimens (median VAS score [range]: 2 (0 - 10) vs 2 (0 - 10); p=0.64). The LV-RBP regimen was associated with a lower number of evacuation during the bowel preparation compared.*Conclusions The low-volume bowel preparation for CT colonography demonstrated noninferior quality of colon cleansing with improved gastrointestinal tolerability compared to full-volume regimen.*Clinical Relevance/Application A low-volume reduced bowel preparation for CT colonography improves patients gastrointestinal tolerability while providing noninferior quality of colon

cleansing compared to a full volume regimen.

RESULTS

From March 2019 to January 2020, a total of 110 participants (mean age 65 years ± 14 [standard deviation]; 74 women) were allocated to LV-RBP (n=55) or FV-RBP (n=55) arms. There were 92% segment with score 0 in colon cleansing quality in LV-RBP and 94% in FV-RBP for prone scans, and 94% vs 92% as for supine scans. Risk difference was - 2.1 (95% CI: -5.9 to 1.7) and 1.5 (95% CI: -2.4 to 5.4) for prone and supine positions, respectively. Residual fluids and colonic distension were also noninferior in LV-RBP. LV-RBP was associated with a lower number of evacuations during preparation (7±5 vs 10±6, p=0.002).There was almost perfect agreement for overall quality of colon cleansing and volume of residual fluids scoring among all readers (ICC = 0.90 [95% CI 0.88-0.91] and ICC = 0.88 [95% CI 0.87-0.90] in the LV-RBP and in the FV-RBP arm, respectively). Patients discomfort related to the bowel preparation was rated as mild by most participants for both regimens (median VAS score [range]: 2 (0 - 10) vs 2 (0 - 10); p=0.64). The LV-RBP regimen was associated with a lower number of evacuation during the bowel preparation compared.

CLINICAL RELEVANCE/APPLICATION

A low-volume reduced bowel preparation for CT colonography improves patients gastrointestinal tolerability while providing noninferior quality of colon cleansing compared to a full volume regimen.

SSCH03-2   **Deep Learning Chest Age Estimation From Radiographs Improves Prediction Of Survival In Patients With Lung Cancer**

Participants
Jakob Weiss, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

One of the most important risk factors used for prognostication in cancer patients is chronological age. However, as people age at different rates, chronological age is an imperfect measure of aging, but medical imaging may provide quantitative data on biological aging. Here, we developed a deep learning model to estimate a biological chest age from a routine chest radiograph image (CXR Chest-Age), and evaluated its prognostic value in lung cancer screening eligible individuals and patients with confirmed lung cancer.*Methods and Materials The CXR Chest-Age model was developed using 147,497 chest radiographs of 40,643 asymptomatic participants in a prospective cancer screening trial. Subsequently, the model was applied to two independent test-sets without retraining, 1) 5,414 heavy smokers aged 55-74 having a screening chest radiograph in the National Lung Screening Trial (NLST), and 2) 604 patients with histologically confirmed lung cancer enrolled in the Boston Lung Cancer Study (BLCS). The prognostic power of CXR Chest-Age was compared to chronological age using the concordance index and Cox proportional hazards regression.*Results In NLST, 118 (5.0%) lung cancer deaths occurred over a median follow-up of 11.9±3.0 years and the C-index for CXR Chest-Age was 0.66 compared to chronological age 0.58 (p<0.001). A similar pattern was found for the BLCS patients (follow-up 3.3±3.2 years; 36.6% lung cancer deaths; C-index CXR Chest-Age vs. chronological age of 0.61 vs. 0.53; p<0.001). Adding CXR Chest-Age to a multivariate Cox model with demographic (age, race, smoking, BMI) and clinical risk factors (cancer stage, treatment) resulted in a significant improvement in the estimate of lung cancer-specific survival in the BLCS patients (C-index 0.77 vs. 0.76; p<0.001).*Conclusions Deep learning-based assessment of chest age from routine chest radiographs significantly improves prediction of survival in patients with lung cancer independent of baseline risk factors and beyond chronological age.*Clinical Relevance/Application Deep learning can automatically extract prognostic information from a routine chest radiograph and improve prognostication in screening and cancer populations, which may guide decision making, inform risk stratification and personalize patient management.

RESULTS

In NLST, 118 (5.0%) lung cancer deaths occurred over a median follow-up of 11.9±3.0 years and the C-index for CXR Chest-Age was 0.66 compared to chronological age 0.58 (p<0.001). A similar pattern was found for the BLCS patients (follow-up 3.3±3.2 years; 36.6% lung cancer deaths; C-index CXR Chest-Age vs. chronological age of 0.61 vs. 0.53; p<0.001). Adding CXR Chest-Age to a multivariate Cox model with demographic (age, race, smoking, BMI) and clinical risk factors (cancer stage, treatment) resulted in a significant improvement in the estimate of lung cancer-specific survival in the BLCS patients (C-index 0.77 vs. 0.76; p<0.001).

CLINICAL RELEVANCE/APPLICATION

Deep learning can automatically extract prognostic information from a routine chest radiograph and improve prognostication in screening and cancer populations, which may guide decision making, inform risk stratification and personalize patient management.

SSCH03-4   **Deep Learning Quantification Of Hepatic Steatosis And Mortality In The National Lung Screening Trial (NLST)**

Participants
Jakob Weiss, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Early detection of hepatic steatosis is important to initiate preventive measures. Although quantification is possible on non-contrast enhanced CT scans, it is not routinely performed, and its value in heavy smokers remains inconclusive. Here, we used an automatic deep learning algorithm to estimate hepatic steatosis from lung screening chest CTs and investigated its prognostic significance in 14,753 participants of the National Lung Screening Trial (NLST).*Methods and Materials We used a deep learning model to volumetrically segment the liver on chest CTs. Hepatic steatosis was defined as a mean hepatic attenuation <40 Hounsfield Units. Participants with hepatic steatosis were categorized as overweight (BMI=25) and lean (BMI<25). The association between hepatic steatosis and all-cause mortality as well as cardiovascular mortality was investigated in 14,753 NLST participants.*Results Over a

median follow-up of 6.5±1.0 years there were 7.2% (1,066/14,753) all-cause and 1.9% (282/14,753) cardiovascular deaths. The median liver density was not significantly different in lean and overweight participants (33.2 HU vs. 32.4 HU; p=0.63). There was a significant association between hepatic steatosis and all-cause mortality in lean (HR: 2.48 [95% CI 1.37-4.49]; p=0.003) but not in overweight participants (HR: 0.99 [95% CI 0.76-1.29]; p=0.93). This signal remained robust (HR: 2.56 [95% CI 1.41-4.66]; p=0.002) after adjustment for baseline demographic (age, race, gender, BMI) and cardiovascular risk factors (hypertension, diabetes, Agatston score, past MI and stroke). No significant association was found between hepatic steatosis and cardiovascular mortality for lean and overweight participants (HR: 0.84 [95% CI 0.12-5.96; p=0.86; and HR: 1.04 [95% CI 0.63-1.73; p=0.87].*Conclusions Hepatic steatosis shows a strong association with all-cause but not cardiovascular mortality in lean heavy smokers participating in a lung cancer screening trial.*Clinical Relevance/Application Deep learning-based approximation of the presence of hepatic steatosis helps to identify individuals at high risk and may guide preventive measures.

RESULTS

Over a median follow-up of 6.5±1.0 years there were 7.2% (1,066/14,753) all-cause and 1.9% (282/14,753) cardiovascular deaths. The median liver density was not significantly different in lean and overweight participants (33.2 HU vs. 32.4 HU; p=0.63). There was a significant association between hepatic steatosis and all-cause mortality in lean (HR: 2.48 [95% CI 1.37-4.49]; p=0.003) but not in overweight participants (HR: 0.99 [95% CI 0.76-1.29]; p=0.93). This signal remained robust (HR: 2.56 [95% CI 1.41-4.66]; p=0.002) after adjustment for baseline demographic (age, race, gender, BMI) and cardiovascular risk factors (hypertension, diabetes, Agatston score, past MI and stroke). No significant association was found between hepatic steatosis and cardiovascular mortality for lean and overweight participants (HR: 0.84 [95% CI 0.12-5.96; p=0.86; and HR: 1.04 [95% CI 0.63-1.73; p=0.87].

CLINICAL RELEVANCE/APPLICATION

Deep learning-based approximation of the presence of hepatic steatosis helps to identify individuals at high risk and may guide preventive measures.

SSNMMI02-2 Ultrafast, Low Dose FDG Oncologic Whole-body PET/CT: Phase III Findings

Participants

Michelle Knopp, Columbus, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

To validate the clinical equivalence of ultrafast (2 min), low dose (5 mCi) FDG oncologic whole body imaging using digital PET/CT and adaptive regularized reconstruction to conventional ~15-20 min acquisition in a prospective Phase III clinical trial.*Methods and Materials 275 whole-body FDG PET/CT in patients with an oncologic disease were prospectively enrolled and digital PET imaging performed 60 - 75 min p.i. using both a conventional 90s per bed position and investigational 9s per be position acquisition. The BMI averaged at 30 and glucose level 104. The target FDG dose was at the lowest FDA labeled at 5.0 mCi. An organ, BMI adaptive regularized reconstruction methodology was consistently used for the ultrafast acquisition while the 90s was performed using current system default settings. A blinded two reader, adjudicator visual and a quantitative assessment was performed.*Results Due to count sparsity, regularized adaptive reconstruction was essential and enabled all cases with a BMI <35 (213/213) to be assessed as diagnostic. In the 62 cases with BMI >=35, 7 were classified as non-diagnostic, 19 limited and 36 as diagnostic. An additional investigation of those cases that were rated limited or non-diagnostic with a simulated extended acquisition time that doubled the count density to 4 min table time demonstrated all to be diagnostic.*Conclusions Ultrafast (2 min) low dose (5 mCi) wholebody FDG PET/CT using regularized adaptive reconstruction was shown to be diagnostic equivalent to conventional PET/CT acquired using 10x longer acquisition times in all patients with BMI <35. In patients with BMI >=35, a 5x shorter acquisition time enabled full diagnostic equivalency.*Clinical Relevance/Application Shorter diagnostic wholebody PET/CT exam times are an important improvement for the patient experience and helpful for efficient patient throughput. This study confirmed diagnostic equivalency even at the lowest FDA allowable dose.

RESULTS

Due to count sparsity, regularized adaptive reconstruction was essential and enabled all cases with a BMI <35 (213/213) to be assessed as diagnostic. In the 62 cases with BMI >=35, 7 were classified as non-diagnostic, 19 limited and 36 as diagnostic. An additional investigation of those cases that were rated limited or non-diagnostic with a simulated extended acquisition time that doubled the count density to 4 min table time demonstrated all to be diagnostic.

CLINICAL RELEVANCE/APPLICATION

Shorter diagnostic wholebody PET/CT exam times are an important improvement for the patient experience and helpful for efficient patient throughput. This study confirmed diagnostic equivalency even at the lowest FDA allowable dose.

SSNMMI02-3 Multiparametric Integrated 18F-FDG PET/MRI Based Radiomics For Breast Cancer Phenotyping And Tumordecoding

Participants

Johannes Grueneisen, Essen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

This study investigated the performance of simultaneous 18F-FDG PET/MRI of the breast as a platform for comprehensive radiomics analysis for breast cancer subtype analysis, hormone receptor status, proliferation rate and lymphonodular and distant metastatic spread.*Methods and Materials 124 patients with 125 breast cancer tumors underwent simultaneous 18F-FDG PET/MRI. Breast tumors were segmented and radiomic features were extracted utilizing CERR software following the IBSI guidelines. LASSO regression was employed to select the most important radiomics features prior to model development. Five-fold cross validation was then utilzied alongside support vector machines, resulting in predictive models for various combinations of imaging data series.*Results Highest AUC and accuracy for differentiation between luminal A and B was achieved by all MR sequences (AUC 0.98; accuracy 97.3). Best results in AUC for prediction of hormone receptor status and proliferation rate were faciliated based on all MR and PET data (ER AUC 0.87, PR AUC 0.88, Ki-67 AUC 0.997). PET provided best determination of grading (AUC 0.71), while all MR and PET analysis yielded best results for lymphonodular and distant metastatic spread (0.81 and 0.99, respectively).*Conclusions 18F-FDG PET/MRI enables comprehensive high-quality radiomics analysis for breast cancer phenotyping and tumor decoding, utilizing the perks of simultaneously acquired morphologic, functional and metabolic data.*Clinical Relevance/Application 18F-FDG

PET/MRI serves as an excellent imaging platform for high quality non-invasive tissue characterization of breast cancer.

RESULTS

Highest AUC and accuracy for differentiation between luminal A and B was achieved by all MR sequences (AUC 0.98; accuracy 97.3). Best results in AUC for prediction of hormone receptor status and proliferation rate were faciliated based on all MR and PET data (ER AUC 0.87, PR AUC 0.88, Ki-67 AUC 0.997). PET provided best determination of grading (AUC 0.71), while all MR and PET analysis yielded best results for lymphonodular and distant metastatic spread (0.81 and 0.99, respectively).

CLINICAL RELEVANCE/APPLICATION

18F-FDG PET/MRI serves as an excellent imaging platform for high quality non-invasive tissue characterization of breast cancer.

SSNMMI02-4 Evaluation Of A High-sensitivity Organ-targeted PET Camera

Participants
Oleksandr Bubon, PhD, Thunder Bay, Ontario (*Presenter*) Shareholder, Radialis Medical;Officer, Radialis Medical

PURPOSE

The Radialis PET camera is an organ-targeted positron emission tomography (PET) system that uses seamless planar arrays of silicon photomultipliers. The aim of this work is to evaluate the image quality of the Radialis PET Camera to inform clinical applications.*Methods and Materials The image quality assessment was conducted according to the National Electrical Manufacturers Association (NEMA) NU-4 standards, with several modifications to accommodate the planar detector design, in terms of spatial resolution, sensitivity, count rate performance, scatter fraction and image quality. Furthermore, a side-by-side comparison of the clinical image quality acquired with the developed camera and a whole body (WB) PET is presented.*Results Micro hotspot phantom sources are visualized down to the 1.35 mm diameter rods. The sensitivity at the peak noise equivalent count rate is 5,400 cps/MBq. The system peak noise equivalent count rate is 17.8 kcps and the peak true count rate is 32.5 kcps. System scatter fraction is 24%. The maximum sensitivity achieved was 3.5%, with a system normalized sensitivity of 2.4%.*Conclusions Given the improved sensitivity compared to whole-body PET and organ-targeted PET systems, the Radialis PET Camera is suited to high-resolution imaging under significantly reduced activity levels.*Clinical Relevance/Application This is of a high significance for applications where the organ of interest is known before imaging and applications where current PET doses are prohibitive (including breast cancer imaging for patients for whom conventional x-ray mammography is suboptimal).

RESULTS

Micro hotspot phantom sources are visualized down to the 1.35 mm diameter rods. The sensitivity at the peak noise equivalent count rate is 5,400 cps/MBq. The system peak noise equivalent count rate is 17.8 kcps and the peak true count rate is 32.5 kcps. System scatter fraction is 24%. The maximum sensitivity achieved was 3.5%, with a system normalized sensitivity of 2.4%.

CLINICAL RELEVANCE/APPLICATION

This is of a high significance for applications where the organ of interest is known before imaging and applications where current PET doses are prohibitive (including breast cancer imaging for patients for whom conventional x-ray mammography is suboptimal).

SSNMMI02-5 Elastic Motion Correction With Deblurring: Quantitative Impacts In Oncologic PET/CT

Participants
Adeel Haq, MBBS, St. Louis, Missouri (*Presenter*) Nothing to Disclose

PURPOSE

Standard free-breathing PET images are often degraded by respiratory motion artifacts near the diaphragm. Conventional respiratory gating reduces motion artifacts but increases image noise, as many counts are discarded. This study assessed the quantitative impact of elastic motion correction with deblurring (EMCD), which generates motion-corrected PET images without discarding counts, in a general oncology population.*Methods and Materials To date, this IRB-approved, HIPAA-compliant prospective study has enrolled 10 patients with active malignancy in the lung bases (n = 7) or liver (n = 3). All subjects provided written informed consent. Imaging occurred on a Biograph Vision PET/CT (Siemens Healthineers). A weight-based FDG dose was given ~60 min before imaging. Using an Anzai system to track respiration, free-breathing PET data were acquired. Four PET reconstructions were performed: (1) without motion correction (uncorrected); (2) using only end-expiratory counts (EE-gate); (3) using EMCD to correct counts to a reference gate, as informed by the Anzai system (Anz-EMCD); and (4) using EMCD to correct counts to a reference gate via a purely data-driven approach (DD-EMCD). For each reconstruction, maximum SUV (SUV-max), metabolic tumor volume (MTV) based on an SUV-max 60% isocontour, and mean SUV (SUV-mean) of the MTV were extracted using MIM software. Statistical comparisons were based on the Wilcoxon signed-rank test (a = 0.05).*Results All data reported are medians [interquartile ranges] for the 10 subjects. SUV-max was significantly lower for uncorrected (5.6 [5.2]) images than for EE-gate (7.2 [6.4]; p = 0.02), Anz-EMCD (6.5 [6.7]; p = 0.01), or DD-EMCD (6.8 [5.8]; p = 0.01) images. MTV was significantly higher for uncorrected (1.3 ml [2.8]) images than for EE-gate (0.6 ml [0.6]; p = 0.01), Anz-EMCD (0.6 ml [0.7]; p = 0.01), or DD-EMCD (0.5 ml [1.0]; p = 0.01) images. SUV-mean of the MTV was significantly lower for uncorrected (4.2 [4.3]) images than for EE-gate (5.0 [4.7]; p = 0.02), Anz-EMCD (5.0 [5.2]; p = 0.01), or DD-EMCD (4.9 [4.5]; p = 0.01) images. There were no significant differences in these metrics among EE-gate, Anz-EMCD, and DD-EMCD images. However, for all subjects, image noise was visually lower for Anz-EMCD and DD-EMCD images relative to EE-gate images (data not shown).*Conclusions EMCD using either Anzai or data-driven respiratory signals results in higher SUV-max, smaller MTV, and higher SUV-mean of the MTV compared with uncorrected PET images, as well as lower image noise than conventional respiratory gating.*Clinical Relevance/Application Even without respiratory tracking, motion-corrected PET images with higher SUVs can be readily achieved in an oncology population, with potential for improved lesion detection and quantification.

RESULTS

All data reported are medians [interquartile ranges] for the 10 subjects. SUV-max was significantly lower for uncorrected (5.6 [5.2]) images than for EE-gate (7.2 [6.4]; p = 0.02), Anz-EMCD (6.5 [6.7]; p = 0.01), or DD-EMCD (6.8 [5.8]; p = 0.01) images. MTV was significantly higher for uncorrected (1.3 ml [2.8]) images than for EE-gate (0.6 ml [0.6]; p = 0.01), Anz-EMCD (0.6 ml [0.7]; p = 0.01), or DD-EMCD (0.5 ml [1.0]; p = 0.01) images. SUV-mean of the MTV was significantly lower for uncorrected (4.2 [4.3]) images than for EE-gate (5.0 [4.7]; p = 0.02), Anz-EMCD (5.0 [5.2]; p = 0.01), or DD-EMCD (4.9 [4.5]; p = 0.01) images. There were no significant differences in these metrics among EE-gate, Anz-EMCD, and DD-EMCD images. However, for all subjects, image noise was visually lower for Anz-EMCD and DD-EMCD images relative to EE-gate images (data not shown).

Even without respiratory tracking, motion-corrected PET images with higher SUVs can be readily achieved in an oncology population, with potential for improved lesion detection and quantification.

SSNMMI02-6 Harmonization Of Multi-centric 18F-FDG-PET/CT And PET/MRI Radiomic Data: Implications For Tissue Classification

Participants
Doris Leithner, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

To determine whether ComBat harmonization improves radiomics-based tissue discrimination in pooled clinical 18F-FDG-PET data obtained with different PET/CT and PET/MRI scanners; and to determine whether effects of ComBat harmonization differ between radiomic feature classes.*Methods and Materials 18F-FDG-PET datasets of 200 cancer patients who had undergone PET/CT (two scanners from different vendors; 50 patients each) or PET/MRI (two scanners from different vendors; 50 patients each) were retrospectively included. Fixed-size 2.5-cm spherical volumes of interest were placed in the disease-free liver, spleen, and bone marrow, and radiomic features of the following classes were calculated using PyRadiomics: first-order histogram, grey-level co-occurrence matrix (GLCM), run-length matrix (GLRLM), size-zone matrix (GLSZM), and neighborhood grey-tone difference matrix (NGTDM). ComBat harmonization was applied to radiomic features to correct for technical differences between scanners. For each feature class independently, a multi-layer perceptron neural network (MLP-NN) was used for separation of the three tissues (liver, spleen, bone marrow) in the pooled dataset, before and after Combat harmonization. Classification accuracies were the primary outcome measure.*Results ComBat-harmonized PET radiomic features were superior to unharmonized features in terms of separation of liver, spleen and bone marrow, with the following accuracies in training/validation sets: histogram, 70.4/69.7% (harmonized) vs. 60.8/57.9% (unharmonized); GLCM, 82.1/74.2% vs. 52.8/49.7%; GLRLM, 79.9/75.0% vs. 58.8/60.4%; GLSZM, 76.3/78.7% vs. 54.9/54.3%; and NGTDM, 68.5/67.4% vs. 51.2/53.6%.*Conclusions ComBat harmonization markedly improves 18F-FDG-PET radiomics-based tissue classification for all radiomic feature classes, and even when PET data from PET/CT and PET/MRI data are pooled.*Clinical Relevance/Application ComBat harmonization may be useful for multi-centric clinical PET radiomics studies that utilize a mix of different PET/CT and PET/MRI scanners.

RESULTS

ComBat-harmonized PET radiomic features were superior to unharmonized features in terms of separation of liver, spleen and bone marrow, with the following accuracies in training/validation sets: histogram, 70.4/69.7% (harmonized) vs. 60.8/57.9% (unharmonized); GLCM, 82.1/74.2% vs. 52.8/49.7%; GLRLM, 79.9/75.0% vs. 58.8/60.4%; GLSZM, 76.3/78.7% vs. 54.9/54.3%; and NGTDM, 68.5/67.4% vs. 51.2/53.6%.

CLINICAL RELEVANCE/APPLICATION

ComBat harmonization may be useful for multi-centric clinical PET radiomics studies that utilize a mix of different PET/CT and PET/MRI scanners.

SSBR06-1   A New Horizon For Breast Cancer Imaging: First Results Of Simultaneous FAPi-PET/MRI Targeting The Fibroblast Activation Protein

Participants
Matthias C. Burg, MD, Muenster, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Imaging plays a major role in the management of breast cancer. Different imaging modalities are used for assessing local tumor extent and whole-body staging.Integrated PET/MRI is a technically promising modality for breast assessment. The most frequently used tracer 18F-FDG is applied for whole-body staging in advanced breast cancer but has limited accuracy in evaluation of primary breast lesions. The fibroblast activation protein (FAP) is abundantly expressed in invasive breast cancer and FAP-directed PET tracers have recently become available.The aim of this study was to initially evaluate the potential of FAP-directed breast PET/MRI and consecutive whole-body scanning using the ligand 68Ga-FAPi-46 for staging of local disease extent and metastases in clinical use.*Methods and Materials In 19 female patients with breast cancer, we retrospectively analyzed 68Ga-FAPi-PET/MRI and PET/CT scans; 18 scans were performed to complement initial staging and 1 for re-staging after therapy for distant metastases. 30 min after injection of 149 ± 48 MBq (mean ± SD) 68Ga-FAPi-46 patients underwent a 25-min prone breast PET/MRI and subsequently either received supine whole-body PET/MRI or PET/CT.*Results Strong tracer accumulation was observed in every untreated primary breast malignancy (mean Standardized Uptake Values, SUVmax: 13.9, range: 7.9 - 29.9, median lesion diameter 26 mm, 9 - 155 mm) resulting in clear tumor delineation in every case independent of tumor grading, hormone receptor status and histological type. All preoperatively verified lymph node metastases in 13 patients demonstrated strong tracer accumulation (mean SUVmax 12.2, 3.3 - 22.4, mean diameter 21 mm, 14 - 35 mm). Tracer uptake established or supported extra-axillary lymph node involvement in 7 patients and impacted therapy decisions in 3 patients. In cases with distant metastases, FAPi-PET uncovered additional lesions.*Conclusions Combining 68Ga-FAPi-46 in simultaneous breast PET/MRI demonstrated highly favorable imaging characteristics. Subsequent whole-body scanning added incremental diagnostic information for detection of lymph node and distant metastases.*Clinical Relevance/Application Simultaneous FAPi-PET/MRI for imaging breast cancer is a promising imaging modality to assess the local tumor extent and for whole-body staging. Further prospective studies are needed to evaluate its additional benefit compared to the existing imaging modalities.

RESULTS

Strong tracer accumulation was observed in every untreated primary breast malignancy (mean Standardized Uptake Values, SUVmax: 13.9, range: 7.9 - 29.9, median lesion diameter 26 mm, 9 - 155 mm) resulting in clear tumor delineation in every case independent of tumor grading, hormone receptor status and histological type. All preoperatively verified lymph node metastases in 13 patients demonstrated strong tracer accumulation (mean SUVmax 12.2, 3.3 - 22.4, mean diameter 21 mm, 14 - 35 mm). Tracer uptake established or supported extra-axillary lymph node involvement in 7 patients and impacted therapy decisions in 3 patients. In cases with distant metastases, FAPi-PET uncovered additional lesions.

CLINICAL RELEVANCE/APPLICATION

Simultaneous FAPi-PET/MRI for imaging breast cancer is a promising imaging modality to assess the local tumor extent and for whole-body staging. Further prospective studies are needed to evaluate its additional benefit compared to the existing imaging modalities.

SSBR06-2   Simultaneous PET-MRI Using 18F-Fluoroethylcholine Can Provide Accurate Diagnosis And Characterization Of Breast Cancer

Participants
Paola Clauser, MD, Vienna, Austria (*Presenter*) Speaker, Siemens AG

PURPOSE

The aim of our study was to investigate the use of [18F] fluoroethylcholine (FEC) as a novel radiotracer to distinguish benign from malignant breast lesions and characterize breast cancer aggressiveness in simultaneous PET-MRI of the breast.*Methods and Materials This prospective, monocentric, diagnostic pharmaceutical phase II study was approved by the national authorities and local ethics committee and 101 patients gave their written informed consent. Patients with lesions classified as suspicious on mammography, tomosynthesis and/or ultrasound and no contraindications to contrast enhanced MRI and PET were included. PET-MRI of the breast were performed simultaneously in a prone position with a dedicated 16-channel MRI breast coil. A board certified nuclear medicine physician and an experienced breast radiologist evaluated the images together and measured the maximum standardized uptake value (SUVmax) of the MRI suspicious findings. PET imaging findings were correlated with MRI and with

histopathology. A reference standard by means of histopathology had to be present. Immunohistochemical (IHC) analysis was available for all malignant lesions. Differences in SUVmax between benign and malignant lesions and between malignant lesion IHC characteristics were evaluated with the Mann-Whitney-U-test. To calculate diagnostic performance metrics, the area under the curve (AUC) was used.*Results 101 patients (mean age 52.3 years, standard deviation 12.0) with 117 lesions were included (30 benign, 7 ductal carcinomas in situ (DCIS), 80 invasive carcinomas (IC)). FEC SUVmax was higher in malignant lesions compared to benign lesions (p<0.001), with an AUC for lesion characterization of 0.846. FEC SUVmax was higher in IC compared to DCIS (p<0.001). In the analysis of IC, FEC uptake was higher for lesions with a higher proliferation rate (p=0.011) and HER2 positive (p=0.041).*Conclusions The lesion uptake of FEC was significantly higher in malignant than in benign breast lesions. FEC SUVmax is a promising new PET imaging biomarker and seems to allow cancer subtyping.*Clinical Relevance/Application Our findings indicate the potential of [18F]FEC SUVmax to be used as an imaging biomarker for diagnosis of breast cancer and breast cancer aggressiveness.

RESULTS

101 patients (mean age 52.3 years, standard deviation 12.0) with 117 lesions were included (30 benign, 7 ductal carcinomas in situ (DCIS), 80 invasive carcinomas (IC)). FEC SUVmax was higher in malignant lesions compared to benign lesions (p<0.001), with an AUC for lesion characterization of 0.846. FEC SUVmax was higher in IC compared to DCIS (p<0.001). In the analysis of IC, FEC uptake was higher for lesions with a higher proliferation rate (p=0.011) and HER2 positive (p=0.041).

CLINICAL RELEVANCE/APPLICATION

Our findings indicate the potential of [18F]FEC SUVmax to be used as an imaging biomarker for diagnosis of breast cancer and breast cancer aggressiveness.

SSBR06-3   Prediction Of Pathologic Complete Response To Neoadjuvant Chemotherapy In Breast Cancer Using Bi-rads Mri Features

Participants
Caroline Malhaire, MD, Paris, France (*Presenter*) Research Consultant, AVATAR MEDICAL, LLC;Research Consultant, Therapixel SA

PURPOSE

To evaluate BI-RADS descriptors on pre-therapeutic MRI for the prediction of breast cancer (BC) pathological complete response (pCR) to neoadjuvant chemotherapy (NAC).*Methods and Materials In this retrospective study, we included patients treated for breast cancer by NAC. Estrogen and Progesterone receptor expression, Her2 status, histologic grade , Ki-67 and tumor infiltrating lymphocytes (TILs) levels from initial BC biopsy were collected. MR scans were acquired according to a protocol consisting of T1-WI, T2-WI, dynamic 3D contrast-enhanced sequences, diffusion weighted imaging. BC index lesion was described using descriptors from the Breast Imaging and Reporting Data System (BI-RADS). The presence of intratumoral high signal intensity, peritumoral, prepectoral and subcutaneous edema on T2W images, multifocality, index tumor size were evaluated. Tumor response was evaluated according to the Residual Cancer Burden on post-NAC surgical specimens. Two predictive models of pCR (RCB0) were built after feature selection by Boruta algorithm and evaluated with 5-fold cross-validation. A first model was designed on the total population of the study (Model 1) and a second on TN and Luminal BC subtypes (Model 2).*Results Out of 153 patients with a mean age of 47 years (range: 24-73), 72 achieved pCR (47%). The pCR was significantly different by BC subtype (<0.001, Chi-square test), achieved in 41 TN (59%) and 24 Her2+ (57%) versus 8 in luminal BC (19%). In univariate analysis, MR features associated with pCR were non spiculated margins (OR = 2.57 (1.33, 5.06), p = 0.005), oval or round shape (OR = 2.25 (1.06-4.89, p=0.037), no peripheral non-mass enhancement (OR = 2.98 (1.28, 7.61), p = 0.015), unifocality (OR = 2.36 (1.11-5.28, p=0.030). Multivariate logistic regression showed features independently associated with pCR were non spiculated margins (OR= 2.22 (1.03-4.91), p=0.044)), unifocality (OR = 2.53 (1.04-6.48, p=0.045)), Her2+ BC subtype (OR = 8.43 (2.94-26.92, p<0.001), TN BC subtype (OR = 4.43 (1.74-12.32, p=0.003) and TILs levels (OR = 1.02 (1.00-1.04, p=0.015)). Variables included in Model 1 were tumor margins, unifocality, BC subtype, Ki 67 and TILs. Model 1 achieved a mean AUC of 0.750 +/- 0.094. Variables included in Model 2 were tumor margins, BC subtype and TILs. Model 2 achieved a mean AUC of 0.782 +/- 0.054.*Conclusions Among the set of pre-therapeutic MRI descriptors, tumor margins and unifocality contribute to prediction of breast cancer pCR to NAC in association to histologic parameters such as TILs and molecular subtype.*Clinical Relevance/Application BI-RADS descriptors on pre-therapeutic MRI combined with histologic biomarkers may be valuable for pCR prediction modeling

RESULTS

Out of 153 patients with a mean age of 47 years (range: 24-73), 72 achieved pCR (47%). The pCR was significantly different by BC subtype (<0.001, Chi-square test), achieved in 41 TN (59%) and 24 Her2+ (57%) versus 8 in luminal BC (19%). In univariate analysis, MR features associated with pCR were non spiculated margins (OR = 2.57 (1.33, 5.06), p = 0.005), oval or round shape (OR = 2.25 (1.06-4.89, p=0.037), no peripheral non-mass enhancement (OR = 2.98 (1.28, 7.61), p = 0.015), unifocality (OR = 2.36 (1.11-5.28, p=0.030). Multivariate logistic regression showed features independently associated with pCR were non spiculated margins (OR= 2.22 (1.03-4.91), p=0.044)), unifocality (OR = 2.53 (1.04-6.48, p=0.045)), Her2+ BC subtype (OR = 8.43 (2.94-26.92, p<0.001), TN BC subtype (OR = 4.43 (1.74-12.32, p=0.003) and TILs levels (OR = 1.02 (1.00-1.04, p=0.015)). Variables included in Model 1 were tumor margins, unifocality, BC subtype, Ki 67 and TILs. Model 1 achieved a mean AUC of 0.750 +/- 0.094. Variables included in Model 2 were tumor margins, BC subtype and TILs. Model 2 achieved a mean AUC of 0.782 +/- 0.054.

CLINICAL RELEVANCE/APPLICATION

BI-RADS descriptors on pre-therapeutic MRI combined with histologic biomarkers may be valuable for pCR prediction modeling

SSBR06-4   Value Of 18F-Fluoroethylcholine PET-MRI For Axillary Lymph Node Staging In Breast Cancer Patients

Participants
Paola Clauser, MD, Vienna, Austria (*Presenter*) Speaker, Siemens AG

PURPOSE

The aim of our study was to investigate the usefulness of [18F] fluoroethylcholine (FEC) PET-MRI to diagnose lymph nodes metastases in patients with newly diagnosed breast cancer.*Methods and Materials This IRB-approved prospective, monocentric study investigated breast cancer patients. All were examined by FEC PET-MRI of the breast performed in prone position with a dedicated 16-channel MRI breast coil. The images were evaluated by two breast fellows (R1, R2) using standardized morphological criteria for MRI and a dichotomous evaluation for FEC PET (uptake/no uptake). A standard of reference for lymph node status (image-guided biopsy, sentinel node biopsy or axilla dissection before neoadjuvant treatment) had to be available. Sensitivity and specificity were calculated for MRI and PET alone and metastasis rates were calculated for patients both positive and both

negative in MRI and PET. Inter-reader agreement was calculated.*Results 74 patients (mean age 55.3 years, standard deviation 11.9) with 80 invasive carcinomas were included. A standard of reference was available in 55 cases (27 no lymph node involvement, 28 lymph node metastasis). MRI assessment had a low sensitivity (R1 46.4% and R2 50%) and a high specificity (both readers 96.3%). PET analysis revealed a higher sensitivity (R1 78.6% and R2 67.9%, P=.027 and P=.108, respectively) with a moderate decrease in specificity (R1 81.5% and R2 74.1%, P>.05). Except for one false positive, all cases that were suspicious on both MRI and PET presented with lymph node metastases (R1: 14/15; R2: 13/14). All the metastatic lymph node correctly classified with MRI alone, were also correctly classified with PET. Kappa agreement was substantial for MRI (0.622) and moderate for FEC PET (0.474).*Conclusions Combined simultaneous FEC PET-MRI of the breast can accurately stratify the risk of axillary lymph node metastasis in patients with newly diagnosed breast cancer.*Clinical Relevance/Application Combined simultaneous FEC PET-MRI of the breast is a promising tool for clinical decision making in breast cancer diagnosis and treatment.

RESULTS

74 patients (mean age 55.3 years, standard deviation 11.9) with 80 invasive carcinomas were included. A standard of reference was available in 55 cases (27 no lymph node involvement, 28 lymph node metastasis). MRI assessment had a low sensitivity (R1 46.4% and R2 50%) and a high specificity (both readers 96.3%). PET analysis revealed a higher sensitivity (R1 78.6% and R2 67.9%, P=.027 and P=.108, respectively) with a moderate decrease in specificity (R1 81.5% and R2 74.1%, P>.05). Except for one false positive, all cases that were suspicious on both MRI and PET presented with lymph node metastases (R1: 14/15; R2: 13/14). All the metastatic lymph node correctly classified with MRI alone, were also correctly classified with PET. Kappa agreement was substantial for MRI (0.622) and moderate for FEC PET (0.474).

CLINICAL RELEVANCE/APPLICATION

Combined simultaneous FEC PET-MRI of the breast is a promising tool for clinical decision making in breast cancer diagnosis and treatment.

SSBR06-5   Patients Presenting With Extensive Malignant Microcalcifications; Is Breast Conservation After Neoadjuvant Treatment Feasible?

Participants
Ali Sever, MD, Orpington, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

Patients with invasive breast cancer, associated with large area of malignant microcalcifications (MM) are often treated with mastectomy. Response to neoadjuvant chemotherapy (NAC) rarely alters the surgical plan. Whilst monitoring the invasive component during the treatment gives a good idea of response, the in situ component cannot be evaluated securely, as lack of enhancement on MRI would not necessarily indicate complete response. MM would remain on mammograms regardless of the response. Due to the risk of heterogeneous response, surgical approach is to remove the entire MM, and perform mastectomy when conservation is not possible. Also residual MM after lumpectomy may cause delay in the diagnosis of recurrence. This study aims to investigate the response to NAC in patients with biopsy-proven large segmental MM.*Methods and Materials Between 2017 and 2020, patients with invasive breast carcinoma and treated with NAC and subsequent surgery were retrospectively selected. A subgroup of patients who presented with large area of biopsy-proven MM were identified. HER2 status was recorded. Patients with abnormal axillary node(s) were biopsied before commencing chemotherapy. The initial size of MM, pre and post-treatment breast and axillary status were recorded.*Results 255 cases underwent NAC, 27 patients had associating biopsy-proven MM covering an area of 50 to 120 mm. 20/27 patients were node positive at presentation. 19 cases were HER2-positive. All 27 patients were treated with mastectomy. Of the 19 HER2-positive cases, 9 patients (47%) had complete pathological response. 6 of the 9 patients had involved node(s) at presentation, treated with axillary nodal clearance (ANC) (n=4) or with targeted axillary dissection (n=2). All 6 showed complete pathological axillary response. Remaining 3 patients were node negative at sentinel node biopsy. 10 patients had residual disease measuring between 2 - 110 mm. 5 of the 8 node positive cases at presentation revealed involved nodes at ANC. All 8 HER2-negative cases revealed residual disease in mastectomy specimen ranging up to 200 mm. 5 of the 6 node positive patients and 1 of the 2 node negative case showed residual axillary disease.*Conclusions HER2-positive breast tumors with in situ component respond very well to NAC, hence a mastectomy may be overtreatment. In carefully selected cases, patients with MM covering a large area may still be offered conservative surgery. A negative lumpectomy specimen alongside with complete pathological axillary response may be helpful in further planning.*Clinical Relevance/Application Patients with HER2-positive tumors with extensive malignant microcalcifications may respond very well to neoadjuvant chemotherapy. Breast conservation may be feasible in selected cases.

RESULTS

255 cases underwent NAC, 27 patients had associating biopsy-proven MM covering an area of 50 to 120 mm. 20/27 patients were node positive at presentation. 19 cases were HER2-positive. All 27 patients were treated with mastectomy. Of the 19 HER2-positive cases, 9 patients (47%) had complete pathological response. 6 of the 9 patients had involved node(s) at presentation, treated with axillary nodal clearance (ANC) (n=4) or with targeted axillary dissection (n=2). All 6 showed complete pathological axillary response. Remaining 3 patients were node negative at sentinel node biopsy. 10 patients had residual disease measuring between 2 - 110 mm. 5 of the 8 node positive cases at presentation revealed involved nodes at ANC. All 8 HER2-negative cases revealed residual disease in mastectomy specimen ranging up to 200 mm. 5 of the 6 node positive patients and 1 of the 2 node negative case showed residual axillary disease.

CLINICAL RELEVANCE/APPLICATION

Patients with HER2-positive tumors with extensive malignant microcalcifications may respond very well to neoadjuvant chemotherapy. Breast conservation may be feasible in selected cases.

SSBR06-6   Primary Treatment Of Low Risk Breast Cancers Using Image-Guided Cryoablation: A 6 Year Update Of The ICE3 Trial

Participants
Kenneth Tomkovich, MD, Freehold, New Jersey (*Presenter*) Speakers Bureau, IceCure Medical, Inc

PURPOSE

The ICE3 Trial was the first of its kind large scale multi-center trial in the world to evaluate cryoablation using ultrasound guidance as a primary treatment for breast cancer without surgical lumpectomy. We report 6 years follow up results and imaging findings.*Methods and Materials This HIPAA compliant and IRB approved trial enrolled patients for cryoablation of low risk infiltrating

ductal carcinoma of the breast. The study was limited to women ages 50 and over with biopsy proven ultrasound visible unifocal breast cancer measuring 1.5cm or less. Nottingham tumor scores of low grade I or intermediate grade II and tumor prognostic panels ER+/PR+ or ER+/PR- and HER 2- were accepted. Patients were clinically lymph node negative. All patients underwent ultrasound guided cryoablation using the liquid nitrogen based ProSenseTM system (IceCure Medical). Patients underwent a freeze, thaw, freeze cycle of approximately 8 minutes each using cryoablation with the goal of a visible ice ball producing an adequate lethal margin of ice around the tumor. All patients were followed with mammography at 6 and 12 months and then annually up to 60 months post ablation. Imaging with MRI or ultrasound was utilized as needed but was not a requirement. Patients did not undergo surgical lumpectomy. All patients had the option of post cryoablation chemotherapy, hormone therapy and or radiation therapy as clinically indicated. The primary outcome was ipsilateral breast cancer recurrence at the site of ablation at 5 years.*Results Enrollment began in October 2014 at 19 participating centers across the United States. A total of 194 patients ages 55-94 met inclusion criteria and were treated with ultrasound guided cryoablation. Tumor sizes ranged from 3 to 15mm. No major adverse events were reported. There has been 100% procedural success. 107 patients have had at least 36 months follow up. 80 patients have had at least 48 months follow up. 34 patients have completed 60 months follow up. No recurrence has been reported in 190/194 patients (98% success). These results are consistent with expected recurrence rates following surgical lumpectomy. Common mammographic findings following cryoablation include scarring and fat necrosis.*Conclusions Cryoablation of low-grade breast cancer is safe and is well tolerated with a 100% initial procedural success rate. Long term results are promising with an overall clinical success rate of 98% in patients with at least 36 months follow up.*Clinical Relevance/Application Results suggest that cryoablation is a safe and effective primary treatment for women with small low risk breast cancers as an alternative to surgical lumpectomy. This research is ongoing.

RESULTS

Enrollment began in October 2014 at 19 participating centers across the United States. A total of 194 patients ages 55-94 met inclusion criteria and were treated with ultrasound guided cryoablation. Tumor sizes ranged from 3 to 15mm. No major adverse events were reported. There has been 100% procedural success. 107 patients have had at least 36 months follow up. 80 patients have had at least 48 months follow up. 34 patients have completed 60 months follow up. No recurrence has been reported in 190/194 patients (98% success). These results are consistent with expected recurrence rates following surgical lumpectomy. Common mammographic findings following cryoablation include scarring and fat necrosis.

CLINICAL RELEVANCE/APPLICATION

Results suggest that cryoablation is a safe and effective primary treatment for women with small low risk breast cancers as an alternative to surgical lumpectomy. This research is ongoing.

SSNMMI05-2   Identification And Development Of Radioprotective Agents To Reduce DNA Damage Caused By Ionizing Radiation

Participants
Tyler Smith, MD, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

PURPOSE

Radioprotective agents (RPA) have been shown to reduce DNA damage caused by ionizing radiation and may therefore have a protective effect during medical imaging. Patients with Li-Fraumeni syndrome (LFS) have a mutation in p53, inhibiting normal DNA repair and have an increased susceptibility to radiation induced malignancy. Interventions to reduce the impact of radiation damage in these patients is critical. We aim to assess the potential role of RPAs in LFS cells in vitro to reduce DNA damage caused by ionizing radiation.*Methods and Materials Peripheral blood mononuclear cells (PBMCs) from healthy (WT) and LFS volunteers were cultured with or without an RPA (atorvastatin 0.016 mg/mL, resveratrol 0.2 mg/mL, or N-acetylcysteine (NAC) 3 mg/mL) for 24 hours. Cells were then irradiated with 0.1 Gy or 1 Gy of ionizing radiation. 1 hour after irradiation, cells were assessed for gamma-H2AX (?-H2AX), a marker for double stranded DNA breaks, by confocal microscopy acquired at 63x, and foci per cell were quantified using a semi-automated open source software (image J).*Results WT PMBCs demonstrated a background ?-H2AX foci per cell count of 2.4, which increased to 29.8 with 0.1 Gy of radiation and 30.2 with 1 Gy of radiation. PBMCs isolated from LFS donors had a background ?-H2AX foci count of 2.4 per cell, which increased to 10.4 with 0.1 Gy and 20.7 with 1 Gy. The only agent that consistently showed a reduction in ?-H2AX was NAC, which caused ?-H2AX foci per cell to decrease to near or below background levels following irradiation (WT PBMC 2.3 at 0.1 Gy (P=0.002) and 4.9 at 1 Gy (P<0.001); LFS PMBCs 1.2 at 0.1 Gy (P=0.02) and 1.5 at 1 Gy (P=0.002)).*Conclusions NAC reduces DNA damage caused by ionizing radiation in vitro in WT and LFS human PMBCs. In vivo and clinical studies are needed to assess the potential long-term benefit for patients (i.e. less cancer and improved survival).*Clinical Relevance/Application Reduction of damage due to ionizing radiation in LFS is critical and RPAs may be effective. WT and LFS PBMCs exposed to the RPA NAC in vitro significantly decreased DNA damage from ionizing radiation.

RESULTS

WT PMBCs demonstrated a background ?-H2AX foci per cell count of 2.4, which increased to 29.8 with 0.1 Gy of radiation and 30.2 with 1 Gy of radiation. PBMCs isolated from LFS donors had a background ?-H2AX foci count of 2.4 per cell, which increased to 10.4 with 0.1 Gy and 20.7 with 1 Gy. The only agent that consistently showed a reduction in ?-H2AX was NAC, which caused ?-H2AX foci per cell to decrease to near or below background levels following irradiation (WT PBMC 2.3 at 0.1 Gy (P=0.002) and 4.9 at 1 Gy (P<0.001); LFS PMBCs 1.2 at 0.1 Gy (P=0.02) and 1.5 at 1 Gy (P=0.002)).

CLINICAL RELEVANCE/APPLICATION

Reduction of damage due to ionizing radiation in LFS is critical and RPAs may be effective. WT and LFS PBMCs exposed to the RPA NAC in vitro significantly decreased DNA damage from ionizing radiation.

SSNMMI05-3   Combining Peptide Receptor Radiotherapy With Immune Check Point Inhibition Therapy To Improve The Management Of Neuroendocrine Tumors

Participants
Shadi Abdar Esfahani, MD,MPH, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Neuroendocrine tumors (NET) are known as immune deserts, due to paucity of immune cells in the tumor, which results in very low

response rate to immune check point inhibitors (ICI). Peptide receptor radiotherapy (PRRT) with somatostatin analogs (SSA) can hypothetically results in tumor inflammation and release of tumor antigens and thus increase the response rate to ICIs. Here we discuss the results of combining ICI and PRRT in a humanized mouse model of NET.*Methods and Materials IACUC approval was obtained. Humanized immunocompromised NSG-PBMC mice were implanted with QGP-1 cells in the flank. After the tumor reached 0.5 ml volume mice were treated with saline, pembrolizumab (anti-PD-1), high dose (HD) PRRT only, low-dose (LD), medium dose (MD) or HD PRRT + Pembro. At baseline and 6 days after pembrolizumab we performed 68Ga-NOTA-hGZP PET/MR in all the mice. We extracted the tumors and stained for granzyme B. Tumors were analyzed for immune cell populations using flowcytometry. Growth curves were drown for the tumors. Statistical analysis was performed using PRISM 9. Paired t-test and repeated measures ANOVA were used for comparison.*Results We observed a significant increase in the SUVmax of the tumors treated with pembro + HD PRRT (3.7±0.3) and pembro MD PRRT (3.4±0.3) compared to Pembro + LD PRRT (1.2±0.2), Pembro only (1.4±0.2) and Saline (1.3±0.2) (p<0.001). Also the there was a significant increase in the uptake value of Pembro+ MD PRRT and Pembro + HD PRRT compared to baseline (p<0.001), while there was no significant change in other groups (p > 0.05). We also observed as significant reduction in tumor volumes in the Pembro+ MD PRRT and Pembro + HD PRRT compared to other groups (p<0.001). The growth in the LD PRRT + Pembro and Pembro only groups were significantly less than the control, although tumors kept growing (p<0.01). The tumor volumes in the HD PRRT only group was significantly less than the LD PRRT + Pembro and Pembro only (p<0.01) but more than the HD and MD PRRT + Pembro (p<0.01). Staining of tissue in the Pembro+ MD PRRT and Pembro + HD PRRT showed extensive extracellular granzyme B expression. Flowcytometry data showed that the percentage of CD4+ and CD8+ / CD28-/CD45RA- (Teff) was significantly higher in MD and HD PRRT + Pembro compared other groups (p<0.01) while CD28+/CD45RA+ cells were higher in saline control.*Conclusions We demonstrated that combination pr PRRT and ICI therapy can markedly increase granzyme expression in the tumor and reduce tumor growth compared to other groups.*Clinical Relevance/Application Combination of PRRT and immune checkpoint inhibitors can improve immunotherapy in NETs.

RESULTS

We observed a significant increase in the SUVmax of the tumors treated with pembro + HD PRRT (3.7±0.3) and pembro MD PRRT (3.4±0.3) compared to Pembro + LD PRRT (1.2±0.2), Pembro only (1.4±0.2) and Saline (1.3±0.2) (p<0.001). Also the there was a significant increase in the uptake value of Pembro+ MD PRRT and Pembro + HD PRRT compared to baseline (p<0.001), while there was no significant change in other groups (p > 0.05). We also observed as significant reduction in tumor volumes in the Pembro+ MD PRRT and Pembro + HD PRRT compared to other groups (p<0.001). The growth in the LD PRRT + Pembro and Pembro only groups were significantly less than the control, although tumors kept growing (p<0.01). The tumor volumes in the HD PRRT only group was significantly less than the LD PRRT + Pembro and Pembro only (p<0.01) but more than the HD and MD PRRT + Pembro (p<0.01). Staining of tissue in the Pembro+ MD PRRT and Pembro + HD PRRT showed extensive extracellular granzyme B expression. Flowcytometry data showed that the percentage of CD4+ and CD8+ / CD28-/CD45RA- (Teff) was significantly higher in MD and HD PRRT + Pembro compared other groups (p<0.01) while CD28+/CD45RA+ cells were higher in saline control.

CLINICAL RELEVANCE/APPLICATION

Combination of PRRT and immune checkpoint inhibitors can improve immunotherapy in NETs.

SSNMMI05-4 Simulation Of Radiation Dosimetry Of Intraventricular Injection Of Commercially Available Radiopharmaceuticals For Intrathecal Radionuclide Therapy

Participants
Franklin C. Wong, MD, PhD, Houston, Texas (*Presenter*) Nothing to Disclose

PURPOSE

Leptomeningeal metastasis (LM) is a fatal cancer complication involving the arachnoids and the subarachnoid space and often treated by intrathecal therapy, either via intraventrical (IVent) route. This study is to simulate radiation dosimetry from IVent injection of 13 radiopharmaceuticals using a common CSF flow model. The effects of CSF ventricular stasis from pathologic obstruction are also simulated. The hypothesis is that simulation of radiation dosimetry on a common kinetic model allows rational choice of radionuclides and radiopharmaceuticals for treating LM.*Methods and Materials Established CSF bulk flow is simulated for the ventricle, C-spine, L-spine and Convexity and integrated with anthropomorphic models of major organs and red marrow. Ventricular stasis assume 90% retention of radionuclide. Monte Carlo simulations were performed with MNCP4b scheme, accounting for all photon emissions to <5% relative errors and betatron emissions to <10% relative errors. Depth doses are derived from concentric shells extending outwards from CSF space. Candidate commercially available radiopharmaceuticals are: Sm-153 EDTMP, Ga-67 citrate, Ga-68 citrate, In-111 DTPA, Tl-201 chloride, I-123 NaI, I-124 NaI, I-125 NaI, I-131 NaI, Y-90 Chloride, Y-90 DTPA, Y-90 Zevalin, and F-18 FDG.*Results Radiation dosimetry on the CSF compartments of ventricle, C-Spine, L-spine and convexity, major organs and red marrow are derived to allow comparison of the radiation absorbed dose in units of cGy/mCi to predict efficacy. The ratios of absorbed doses between the CSF compartment and bone marrow allow estimation of therapeutic windows to predict safety. Depth doses in the ventricle, convexity and spine also allow locoregional evaluation of efficacy and safety. Y-90 compounds provide the highest radiation absorbed dose to CSF space in the ventricle, C-spine, L-spine and the convexity (63, 200, 440 and 67 cGy/mCi, respectively) while the ratios of CSF to marrow predict that Y-90 DTPA has the largest therapeutic window (42, 133, 293 and 45 respectively), better than Y-90 Zevalin which in turn is better than Y-90 chloride (5, 17, 37 and 6, respectively). Stasis indeed delivers markedly higher radiation absorbed dose to the ventricle and also provides higher therapeutic window.*Conclusions Simulated radiation dosimetry using a common biokinetic /anthropomorphic model allows preliminary assessment of efficacy and safety of radiopharmaceuticals for LM therapy.*Clinical Relevance/Application Simulated radiation dosimetry models will enable rational design of radiopharmaceuticals for LM therapy. It also allows preliminary assessment of enhanced radiation delivery by ventricular stasis when obstruction is encountered and when intervention is contemplated.

RESULTS

Radiation dosimetry on the CSF compartments of ventricle, C-Spine, L-spine and convexity, major organs and red marrow are derived to allow comparison of the radiation absorbed dose in units of cGy/mCi to predict efficacy. The ratios of absorbed doses between the CSF compartment and bone marrow allow estimation of therapeutic windows to predict safety. Depth doses in the ventricle, convexity and spine also allow locoregional evaluation of efficacy and safety. Y-90 compounds provide the highest radiation absorbed dose to CSF space in the ventricle, C-spine, L-spine and the convexity (63, 200, 440 and 67 cGy/mCi, respectively) while the ratios of CSF to marrow predict that Y-90 DTPA has the largest therapeutic window (42, 133, 293 and 45 respectively), better than Y-90 Zevalin which in turn is better than Y-90 chloride (5, 17, 37 and 6, respectively). Stasis indeed delivers markedly higher radiation absorbed dose to the ventricle and also provides higher therapeutic window.

CLINICAL RELEVANCE/APPLICATION

Simulated radiation dosimetry models will enable rational design of radiopharmaceuticals for LM therapy. It also allows preliminary

assessment of enhanced radiation delivery by ventricular stasis when obstruction is encountered and when intervention is contemplated.

SSNR10-3   Anterior Pituitary Volume In Patients With Transfusion Dependent Anemias: Volumetric Approaches And Relation To Pituitary R2

Participants
Zhiyue Wang, PhD, Dallas, Texas (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this retrospective study was to determine both the accuracy of different approaches for assessment of anterior pituitary size and the relation between pituitary size and MRI-R2 relaxometry, also with respect to growth impairment and hypogonadism, in patients with transfusion dependent anemia (TDA).*Methods and Materials In 43 patients (21m / 22f; mean age 22 y) and 32 controls (19m / 13f; mean age 38 y) a sagittal T1 GRE 3D sequence at 1.5T was used to assess anterior pituitary gland size by 3D semi-automated threshold volumetry (V3D) (=reference standard), planimetric volumetry (V2D), approximate volumetry based on region of interest (VROI), ellipsoid (VEll), and area-length (VAL), and pituitary height. Pituitary R2 was assessed by fitting proton signal intensities to echo times using a multi-echo SE sequence. Serum ferritin levels, liver iron concentrations, cardiac and pancreatic MRI-R2* rates, and hypogonadic states referred to patient reports. BSA adjusted pituitary 3D volumes (V3Di) as functions of age were expressed as Z-values and growth percentiles were calculated.*Results Compared with reference V3D volumes, V2D volumes revealed the highest agreement (bias -4.8%; 95%CI: -8.8%|-0.7%) and good inter-operator agreement (bias 2.6%, 95%CI: -0.9%|6.1%). Pituitary volume Z-scores and pituitary R2 revealed threshold-derived sensitivity and specificities of 65% and 100% to discriminate patients from controls. In 71% and 75% of patients correctly classified by volume Z-scores and R2 rates, hypogonadism and growth impairment was present, respectively. Liver, cardiac and pancreatic iron accumulation was common in TDA patients, and pancreatic R2* was the strongest predictor for pituitary iron accumulation.*Conclusions Accurate assessment of pituitary size requires 3D or 2D volumetry. Pituitary volume Z-scores and R2 allow to identify TDA patients at risk of pituitary dysfunction.*Clinical Relevance/Application Pituitary R2 and volume assessed by MRI may serve as biomarkers of preclinical pituitary dysfunction.

RESULTS

Compared with reference V3D volumes, V2D volumes revealed the highest agreement (bias -4.8%; 95%CI: -8.8%|-0.7%) and good inter-operator agreement (bias 2.6%, 95%CI: -0.9%|6.1%). Pituitary volume Z-scores and pituitary R2 revealed threshold-derived sensitivity and specificities of 65% and 100% to discriminate patients from controls. In 71% and 75% of patients correctly classified by volume Z-scores and R2 rates, hypogonadism and growth impairment was present, respectively. Liver, cardiac and pancreatic iron accumulation was common in TDA patients, and pancreatic R2* was the strongest predictor for pituitary iron accumulation.

CLINICAL RELEVANCE/APPLICATION

Pituitary R2 and volume assessed by MRI may serve as biomarkers of preclinical pituitary dysfunction.

SSNR10-4   Clinical And MR Imaging Findings In A Large Population Of Autoimmune Encephalitis

Participants
Shivani Gillon, San Francisco, California (*Presenter*) Nothing to Disclose

PURPOSE

To describe the clinical and MRI findings of patients with antibody-proven autoimmune encephalitis (AE).*Methods and Materials We searched our institutional medical record for International Classification of Disease (ICD) code diagnosis of autoimmune encephalitis (2009-2019). Demographics, EEG, CSF, antibody testing and MRI at presentation were reviewed. Clinical features were compared across antibody groups using Chi2. Imaging features were described for each antibody and compared for significance using Fisher's exact test.*Results Of 104 cases of antibody-proven AE, 97 had MRI available for review. The median age at presentation was 35 years (IQR: 24-60, range: 2-75). 29% were male and 68% were female. EEG was abnormal in 71/97 (74%), normal in 8/97 (8%), not performed in 17/96 (18%). CSF showed pleocytosis in 65/97 (67%) and elevated protein in 40/97 (41%). 20 distinct types of AE antibodies were found (Table 1). The most common antibodies included anti-NMDA receptor encephalitis (N=40), anti-Gad antibody (N=8), and VGKC (N=6). 18/97 (19%) were Group 1 (Intracellular Antibodies), 69/97 (71%) were Group 2 (Extracellular Antibodies), and 10/97 (10%) were antibodies associated with demyelination. Thirty patients (30%) had a systemic malignancy that was pre-existing or discovered around time of AE diagnosis. The rates of malignancy did not differ significantly across antibody groups (p=0.27). The median time between diagnosis and MRI was 12 days (IQR: 0-25). MRI was abnormal in 65/97 (67%). The most common areas of signal abnormality in the overall cohort were limbic (30/97, 31%), periventricular white matter (24/97, 25%), and supratentorial cortex (20/97, 21%). Only 1/97 cases (1%, NMDA encephalitis) had susceptibility artifact. Notable imaging findings for each specific antibody are listed in Table 1.*Conclusions Patients with AE were often young and female. Two third of patients had an abnormal MRI at the time of symptom onset, most commonly involving the limbic system. Specific imaging features can help identify patients with suspected AE and direct further laboratory work-up.*Clinical Relevance/Application Diagnosing AE is

clinically and radiographically challenging. Early identification of features suggestive of AE will lead to earlier diagnosis, treatment and potential reversal of symptoms.

RESULTS

Of 104 cases of antibody-proven AE, 97 had MRI available for review. The median age at presentation was 35 years (IQR: 24-60, range: 2-75). 29% were male and 68% were female. EEG was abnormal in 71/97 (74%), normal in 8/97 (8%), not performed in 17/96 (18%). CSF showed pleocytosis in 65/97 (67%) and elevated protein in 40/97 (41%). 20 distinct types of AE antibodies were found (Table 1). The most common antibodies included anti-NMDA receptor encephalitis (N=40), anti-Gad antibody (N=8), and VGKC (N=6). 18/97 (19%) were Group 1 (Intracellular Antibodies), 69/97 (71%) were Group 2 (Extracellular Antibodies), and 10/97 (10%) were antibodies associated with demyelination. Thirty patients (30%) had a systemic malignancy that was pre-existing or discovered around time of AE diagnosis. The rates of malignancy did not differ significantly across antibody groups (p=0.27). The median time between diagnosis and MRI was 12 days (IQR: 0-25). MRI was abnormal in 65/97 (67%). The most common areas of signal abnormality in the overall cohort were limbic (30/97, 31%), periventricular white matter (24/97, 25%), and supratentorial cortex (20/97, 21%). Only 1/97 cases (1%, NMDA encephalitis) had susceptibility artifact. Notable imaging findings for each specific antibody are listed in Table 1.

CLINICAL RELEVANCE/APPLICATION

Diagnosing AE is clinically and radiographically challenging. Early identification of features suggestive of AE will lead to earlier diagnosis, treatment and potential reversal of symptoms.

SSNR10-6   Diagnostic Yield Of Brain Magnetic Resonance Imaging In Patients With Infective Endocarditis

Participants
Seongken Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the diagnostic yield of brain MRI in patients with IE.*Methods and Materials This retrospective, single-institution study included 138 patients who underwent brain MRI between March 2015 and October 2020. Consecutive patients who were diagnosed with definite IE or possible IE according to the modified Duke criteria were recruited. Brain MRI included diffusion-weighted imaging, gradient echo imaging or susceptibility-weighted imaging, contrast-enhanced T1-weighted imaging, time-of-flight and contrast-enhanced MR angiography. Diagnostic yield of brain MRI was defined as the number of patients with positive brain MRI findings divided by the number of patients with definite or possible IE. False referral rate of brain MRI was defined as the number of patients with negative brain MRI findings divided by the number of patients with definite or possible IE. Positive imaging findings included ischemic lesions, cerebral microbleeds, hemorrhagic lesions, mycotic aneurysms, abscesses, meningoencephalitis and ventriculitis.*Results A total 138 patients (mean age, 53 years±18 [standard deviation]; 78 men) were included. The diagnostic yield of brain MRI in patients with IE was 71% (98 of 138; 95% CI: 63%-78%). Ischemic lesion, cerebral microbleed, hemorrhagic lesion and abscess/meningoencephalitis/ventriculitis were detected on MRI in 51% (71 of 138), 51% (70 of 138), 17% (24 of 138), and 6% (8 of 138) of patients, respectively. Mycotic aneurysms were detected on MRI in 5% of patients (7 of 138), however, the mycotic aneurysms were not detected on MRI in 3 patients. Therefore, false referral rate of mycotic aneurysm was 2.2% (3 of 138). Among 10 patients with mycotic aneurysm, aneurysm rupture was occurred in 4 patients and median period of aneurysm rupture was 5 days (range: 4-78).*Conclusions The diagnostic yield of brain MRI in infective endocarditis was high and brain MRI may be considered in patients with infective endocarditis.*Clinical Relevance/Application Further evaluation including CT angiography and transfemoral cerebral angiography should be considered when mycotic aneurysm is suspected because of false referral rate.

RESULTS

A total 138 patients (mean age, 53 years±18 [standard deviation]; 78 men) were included. The diagnostic yield of brain MRI in patients with IE was 71% (98 of 138; 95% CI: 63%-78%). Ischemic lesion, cerebral microbleed, hemorrhagic lesion and abscess/meningoencephalitis/ventriculitis were detected on MRI in 51% (71 of 138), 51% (70 of 138), 17% (24 of 138), and 6% (8 of 138) of patients, respectively. Mycotic aneurysms were detected on MRI in 5% of patients (7 of 138), however, the mycotic aneurysms were not detected on MRI in 3 patients. Therefore, false referral rate of mycotic aneurysm was 2.2% (3 of 138). Among 10 patients with mycotic aneurysm, aneurysm rupture was occurred in 4 patients and median period of aneurysm rupture was 5 days (range: 4-78).

CLINICAL RELEVANCE/APPLICATION

Further evaluation including CT angiography and transfemoral cerebral angiography should be considered when mycotic aneurysm is suspected because of false referral rate.

SSMK02-1   Us-guided Fenestration And Surgery For The Treatment Of Chronic Lateral Epicondylosis: Time-dependent Changes In B-Mode US, Power Doppler And Elastography.

Participants
David Tobaly, MD, Montreal, Quebec (*Presenter*) Nothing to Disclose

PURPOSE

To assess and compare the time-dependent changes in B-mode US parameters, Power Doppler and shear wave elastography in the common extensor tendon and radial collateral ligament complex (CET-RCL) following fenestration or surgery in chronic lateral epicondylosis (CLE).*Methods and Materials Patients with clinically diagnosed CLE were prospectively randomized to open-release surgery (Group A) or to US-guided fenestration (Group B). Using an Acuson S3000 US scanner (Siemens Medical Systems, USA) with a standardized imaging protocol, a radiologist with 25-year experience in musculoskeletal US performed a grey-scale US scan and power Doppler evaluation with a 14L5SP MHz probe, and ARFI-mode elastography with a 9L4 MHz probe, at baseline, 6 and 12 months postintervention. The following parameters were assessed in the CET-RCL: maximal thickness, echogenicity, enthesophytes, calcifications, neovascularity, and long-axis mean shear wave velocity (SWV). Repeated-measures analysis of variance derived from linear-mixed or logistic-regression models were used to test the effect of the group, time and the interaction group*time on the parameters.*Results Following one exclusion in each group, 62 patients were equally randomized (Group A: age mean ± standard deviation of 50±7 years, 55% female; Group B: age 47±8 years, 36% female). According to a per-protocol analysis, 23 patients in Group A and 27 patients in Group B completed the 12-month evaluation. A group-by-time interaction effect was found in maximal thickness ($F2$, 100 = 13.43, P < 0.001) and in mean SWV ($F2$, 97 = 5.35, P = 0.006). Maximal tendon thickness was increased in Group A at 6 (P < 0.001) and 12 months (P < 0.035) postintervention, whereas there was no change from baseline to 12 months in Group B (P > 0.05). At 6 months, mean SWV increased in Group B (P = 0.035) and decreased in Group A (P = 0.132). Neovascularity decreased in both groups at 12 months (P < 0.001). Group A had 2.5 times the odds of having decreased echogenicity than Group B, at 6 and 12 months (P = 0.021). In either group, there was no change in the presence of enthesophytes nor calcifications.*Conclusions US-guided fenestration induces minor alterations in tendon structure and appears to promote faster improvement in mechanical properties than open-release surgery.*Clinical Relevance/Application US-guided fenestration is less invasive than open-release surgery and appears to promote more rapid healing of the tendon in chronic lateral epicondylosis.

RESULTS

Following one exclusion in each group, 62 patients were equally randomized (Group A: age mean ± standard deviation of 50±7 years, 55% female; Group B: age 47±8 years, 36% female). According to a per-protocol analysis, 23 patients in Group A and 27 patients in Group B completed the 12-month evaluation. A group-by-time interaction effect was found in maximal thickness ($F2$, 100 = 13.43, P < 0.001) and in mean SWV ($F2$, 97 = 5.35, P = 0.006). Maximal tendon thickness was increased in Group A at 6 (P < 0.001) and 12 months (P < 0.035) postintervention, whereas there was no change from baseline to 12 months in Group B (P > 0.05). At 6 months, mean SWV increased in Group B (P = 0.035) and decreased in Group A (P = 0.132). Neovascularity decreased in both groups at 12 months (P < 0.001). Group A had 2.5 times the odds of having decreased echogenicity than Group B, at 6 and 12 months (P = 0.021). In either group, there was no change in the presence of enthesophytes nor calcifications.

CLINICAL RELEVANCE/APPLICATION

US-guided fenestration is less invasive than open-release surgery and appears to promote more rapid healing of the tendon in chronic lateral epicondylosis.

SSMK02-2   Quantitative Musculoskeletal Imaging Via 3D Ultrasound Tomography

Participants
James Wiskin, PhD, Novato, California (*Presenter*) Employee, QT Imaging, Inc

PURPOSE

We validate here a non-invasive inexpensive and fast method of accurate imaging of the speed of sound (SOS) of muscle tissue, even in the presence of high-speed bone. We distinguish between muscle, cartilage, ligament, tendon and fat tissue based on SOS. This technique does not suffer from signal voids common for MRI, and it may be useful for monitoring of clinical treatment and cartilage/ligament/tendon damage.*Methods and Materials UT creates 3D images slice by slice using 2D algorithms (tomography) in ~20 seconds but has artifacts. 3D algorithms (volography) have required 32 hours using a 128-computer cluster. Our 3D volography algorithm emulates a convolutional neural network (CNN) on NVIDIA GPUs and is 64 times faster. than published results, using 2 NVIDIA cards. We first validated the knee cadaver tissue speed of sound (SOS) compared with SoS in unfixed tissue. We use ROI's (6- and 4-mm radius) in transverse sections and 3D volumetric segmentation of a cadaverous knee scanned in our adapted scanner (QT Imaging®) corresponding to muscle, fat, and cartilage and compare the average values (standard deviation) with the

literature. We validate clinically useful times. A refraction corrected reflection image is also created, using the SOS, in 2 minutes. All UT images were compared with simultaneous MR images*Results Our 3D volography images are available in ~25 minutes or less. We observed an average SoS of 1573 m/s for Vastus medialis muscle. For fat SoS (sd) was 1438.7 (20.5), and for cartilage SoS (sd) =1655.4 (15) - similar values to published literature. We compared ligaments and tendons as well, with good agreement. We show that Formalin fixation changes the SOS values by about 0.1%- 0.4% for fibroglandular tissue, fat and skin. We show regions that have no MR response yet are quantitatively imaged in 3D ultrasound volography. Sub-mm resolution is confirmed.*Conclusions The fast, quantitative high resolution (sub-mm) estimation of tissue characteristics is shown in the presence of bone. We image tissue types (lateral collateral ligaments, periosteum, Biceps Femoris and Patellar tendon where the MR signal is not present. These results indicate the utility of the QTUS images in monitoring DMD/BMD, exercise induced tissue damage, cartilage damage, etc. in the clinic.*Clinical Relevance/Application We have developed specific protocols that allow us to measure quantitatively, SOS in the presence of bone, which can be important clinically for monitoring musculoskeletal injury and muscular diseases such as Muscular Dystrophy (DMD & BMD). The scanner is mobile, self-contained and can be deployed to sports arenas, urban, rural and historically underserved regions. It requires only 2 NVIDIA cards (not 128 computers) and gives images in 10's of minutes not days.

RESULTS

Our 3D volography images are available in ~25 minutes or less. We observed an average SoS of 1573 m/s for Vastus medialis muscle. For fat SoS (sd) was 1438.7 (20.5), and for cartilage SoS (sd) =1655.4 (15) - similar values to published literature. We compared ligaments and tendons as well, with good agreement. We show that Formalin fixation changes the SOS values by about 0.1%- 0.4% for fibroglandular tissue, fat and skin. We show regions that have no MR response yet are quantitatively imaged in 3D ultrasound volography. Sub-mm resolution is confirmed.

CLINICAL RELEVANCE/APPLICATION

We have developed specific protocols that allow us to measure quantitatively, SOS in the presence of bone, which can be important clinically for monitoring musculoskeletal injury and muscular diseases such as Muscular Dystrophy (DMD & BMD). The scanner is mobile, self-contained and can be deployed to sports arenas, urban, rural and historically underserved regions. It requires only 2 NVIDIA cards (not 128 computers) and gives images in 10's of minutes not days.

SSMK02-3   Muscle Injuries And Recovery: Diffusion-tensor-imaging (DTI) And Physical Examination

Participants
Ibrahim Yel, MD, Frankfurt, Germany (*Presenter*) Nothing to Disclose

PURPOSE

MRI is limited to assess muscle morphology and the extent of structural damage. The recovery process and return-to-play decisions are individually determined by sports medicine specialists. We tried to enhance the informative value of MRI by correlating measurable diffusion-tensor parameters with physical/functional parameters.*Methods and Materials 25 male soccer players with a non-contact hamstring injury (10R,15L) were included and 3 consecutive 3-T-MRI- and physical examinations were performed at initial injury, three weeks and six weeks after injury. Freehand ROI-measurements were placed in the injured and contralateral healthy muscle to assess ADC-, fractional anisotropy, and sum of eigenvalues (trace).*Results Overall mean DTI-values for the injured muscle were as following (baseline, first follow-up, second follow-up): ADC (10-6mm2/s) -1882±218.4, 1800±135.5, 1732±82.9; Fractional anisotropy (FA) - 263.1±66.3, 305.1±73.2, 259.3±53.5; Trace - 40.7±10.2, 37.0±8.9, 36.9±9.2. Initial DTI values of the injured muscle were all significantly different compared to the healthy side(p<0.01), consistent with reduced ranges of motion in the functional examinations and the presence of pain(p<0.01). In the healing course, the FA-values (after 3 weeks) started to align with values of the healthy side(p=0.51) followed by the trace-values in the sixth week after injury(p=0.34). ADC showed significantly higher values throughout the recovery process(p<=0.023). Physical and functional parameters were comparable with the healthy side on the first follow-up examination(p=0.82).*Conclusions In the 6-week period after injury the DTI-parameters indicate significant changes for FA-, trace- and ADC-values. FA-values seem to be the fastest indicators of the healing process and show a similar trend to the clinical parameters, but without a statistical prove. All this indicates a complex physiologic healing mechanism (initial edema, fibrosis, development of new muscle tissue, etc) that in its entirety cannot be (linearly) correlated with DTI-values.*Clinical Relevance/Application Muscle injuries cause a significant dynamic in DTI-values, with time-specific assimiliations to the contralateral healthy side, however lagging behind the actual improvements in clinical and functional parameters. DTI could enhance muscle-imaging, if investigated further, leading to an improved informative value regarding recovery and integrity of muscle fibers.

RESULTS

Overall mean DTI-values for the injured muscle were as following (baseline, first follow-up, second follow-up): ADC (10-6mm2/s) - 1882±218.4, 1800±135.5, 1732±82.9; Fractional anisotropy (FA) - 263.1±66.3, 305.1±73.2, 259.3±53.5; Trace - 40.7±10.2, 37.0±8.9, 36.9±9.2. Initial DTI values of the injured muscle were all significantly different compared to the healthy side(p<0.01), consistent with reduced ranges of motion in the functional examinations and the presence of pain(p<0.01). In the healing course, the FA-values (after 3 weeks) started to align with values of the healthy side(p=0.51) followed by the trace-values in the sixth week after injury(p=0.34). ADC showed significantly higher values throughout the recovery process(p<=0.023). Physical and functional parameters were comparable with the healthy side on the first follow-up examination(p=0.82).

CLINICAL RELEVANCE/APPLICATION

Muscle injuries cause a significant dynamic in DTI-values, with time-specific assimiliations to the contralateral healthy side, however lagging behind the actual improvements in clinical and functional parameters. DTI could enhance muscle-imaging, if investigated further, leading to an improved informative value regarding recovery and integrity of muscle fibers.

SSMK02-5   Diagnostic Impact Of MR Neurography Of Lumbosacral Plexus For Failed Back Surgery Syndrome With Outcomes Analysis

Participants
Bayan Mogharrabi, BS, Dallas, Texas (*Presenter*) Nothing to Disclose

PURPOSE

To determine the value of MR neurography (MRN) of the lumbosacral plexus in clinical management of failed back surgery syndrome (FBSS) with outcomes analysis.*Methods and Materials A cross sectional study of 59 consecutive patients with MRN Lumbar plexus for FBSS and informed consent was waived. All MRN studies were formally read by fellowship trained MSK radiologists. Clinical data and results from other diagnostic tests were recorded from EMR by medical students on scholarly activity. MSK fellow and senior

MSK radiologist re-evaluated all cases and recorded the findings on a 3-point Likert scale for contribution to the final diagnosis as 1-non-contributory, 2- partially contributory, 3- definitely contributory. Impact of both sets of imaging were interpedently recorded- 'clinical data plus other imaging prior to MRN' and 'clinical data plus MRN' using the same scale. Patient charts were further reviewed for change in the clinical diagnosis and management on a 4-point Likert scale (0-no change, 1-minor: change in clinical diagnosis but no change in treatment, 2- moderate: change in clinical diagnosis and change in treatment, 3- major: change in clinical diagnosis, change in treatment, and improved patient outcome). Final patient outcomes were recorded.*Results There were 59 patients ranging from 28-81 years of age. 4/59 had spinal fusion, 10/59 had a decompression lamincectomy,1/59 had a laminotomy ,13/59 had a laminoforaminotomy,9/59 had a discectomy, 6/59 had a lumbar spine fusion, 2/59 had a non-specified back operation, 6/59 had a combination of the aforementioned operations,7/59 did not have surgery prior, and 1/59 could not access surgical history. MRN found nerve lesions in 9/59 cases in L5 nerve root, 5/59 in L4, 2/59 in S1, 2/59 in S2, 2/59 in sciatic, 2/59 in femoral, 26/59 cases had multiple nerve root and downstream femoral and/or sciatic neuropathies, and 11/59 were normal.7/59 MRN were non-contributory, 15/59 were partially contributory, and 37/59 were definitely contributory. Following MRN, 17/59 had surgery, 33/59 had injections or physical therapy, 2/59 had both surgery and injections, 3/59 had a spinal cord stimulator placed, and 4/59 had no treatment. In 9/59 cases, major change occurred due to MRN with improved patient outcomes, 5/59 had a moderate change with no significant change in outcomes, and 6/59 had a minor change with no change in treatment, and 39/59 had no change.*Conclusions MRN of the lumbar plexus was contributory in the clinical diagnosis in a majority of cases of FBSS above the conventional imaging modalities with improved outcomes in 15% of cases.*Clinical Relevance/Application FBSS is a difficult clinical scenario and MRN of lumbosacral plexus can provide diagnostically meaningful information for improved patient outcomes.

RESULTS

There were 59 patients ranging from 28-81 years of age. 4/59 had spinal fusion, 10/59 had a decompression lamincectomy,1/59 had a laminotomy ,13/59 had a laminoforaminotomy,9/59 had a discectomy, 6/59 had a lumbar spine fusion, 2/59 had a non-specified back operation, 6/59 had a combination of the aforementioned operations,7/59 did not have surgery prior, and 1/59 could not access surgical history. MRN found nerve lesions in 9/59 cases in L5 nerve root, 5/59 in L4, 2/59 in S1, 2/59 in S2, 2/59 in sciatic, 2/59 in femoral, 26/59 cases had multiple nerve root and downstream femoral and/or sciatic neuropathies, and 11/59 were normal.7/59 MRN were non-contributory, 15/59 were partially contributory, and 37/59 were definitely contributory. Following MRN, 17/59 had surgery, 33/59 had injections or physical therapy, 2/59 had both surgery and injections, 3/59 had a spinal cord stimulator placed, and 4/59 had no treatment. In 9/59 cases, major change occurred due to MRN with improved patient outcomes, 5/59 had a moderate change with no significant change in outcomes, and 6/59 had a minor change with no change in treatment, and 39/59 had no change.

CLINICAL RELEVANCE/APPLICATION

FBSS is a difficult clinical scenario and MRN of lumbosacral plexus can provide diagnostically meaningful information for improved patient outcomes.

SSNR15-1   **An Artificial Intelligence-based Algorithm Can Support Radiologists In Diagnosing Cervical Spine Fractures**

Participants
Sanders Chang, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

Artificial intelligence-based algorithms have been developed to assist radiologists in the diagnosis of critical neurologic findings. This project aims to assess the performance of a FDA-approved convolutional neural network model, Aidoc (Tel Aviv, Israel), in detecting cervical spinal fractures within a multi-institutional hospital system.*Methods and Materials Patients who received a cervical CT scan analyzed by Aidoc within a four-month period (August 2020 to November 2020) were included in this retrospective analysis. Scans flagged as positive were evaluated independently by two neuroradiologists with review of the original radiology reports to establish ground truth. Acute and chronic fractures (traumatic and pathologic) were considered true positives. False positives were documented according to their most likely etiology. Scans flagged as negative but had a corresponding radiology report indicating a fracture (i.e. "false negative") were further reviewed independently by two neuroradiologists to establish ground truth. Any discrepancies between the two readers were resolved by a third neuroradiologist.*Results 3165 patients were included in our analysis (mean, 60.6 ± 20.8 years of age; range, 16-103 years of age). 144 cases were flagged as positive by Aidoc, 54 of which were determined to be true positives (positive predictive value of 37.5%). Of note, 4 true positives (7.4%) were fractures not diagnosed in the original radiology report. 90 cases (63.2%) were determined to be false positives, the majority related to degenerative changes (67.8%), nutrient vessels (34.4%), and artifacts (16.7%). 4 false positives had additional fractures not detected by Aidoc and were simultaneously classified as false negatives. In total, 34 cases (1.1%) were determined to be false negatives, consisting of 19 chronic fractures (55.9%), 12 acute fractures (35.3%), and 3 age-indeterminate fractures (8.8%).*Conclusions Artificial intelligence-based algorithms can support radiologists in detecting cervical spine fractures that may be missed in practice. Further refinement of these algorithms will minimize the rate of false positives and false negatives.*Clinical Relevance/Application Artificial intelligence-based algorithms can support radiologists and potentially enhance their accuracy in diagnosing cervical spine fractures.

RESULTS

3165 patients were included in our analysis (mean, 60.6 ± 20.8 years of age; range, 16-103 years of age). 144 cases were flagged as positive by Aidoc, 54 of which were determined to be true positives (positive predictive value of 37.5%). Of note, 4 true positives (7.4%) were fractures not diagnosed in the original radiology report. 90 cases (63.2%) were determined to be false positives, the majority related to degenerative changes (67.8%), nutrient vessels (34.4%), and artifacts (16.7%). 4 false positives had additional fractures not detected by Aidoc and were simultaneously classified as false negatives. In total, 34 cases (1.1%) were determined to be false negatives, consisting of 19 chronic fractures (55.9%), 12 acute fractures (35.3%), and 3 age-indeterminate fractures (8.8%).

CLINICAL RELEVANCE/APPLICATION

Artificial intelligence-based algorithms can support radiologists and potentially enhance their accuracy in diagnosing cervical spine fractures.

SSNR15-2   **Arterial Spin Labeling MRI Can Detect Impaired Cerebrovascular Reactivity In Moyamoya Patients: A Cohort Study Using Simultaneous PET/MRI**

Participants
Yize Zhao, PhD, Palo Alto, California (*Presenter*) Nothing to Disclose

PURPOSE

Cerebrovascular reactivity (CVR) reflects the change in cerebral blood flow (CBF) in response to a vasoactive stimulus. Studies have demonstrated that impaired CVR was associated with a higher risk of stroke 1. PET imaging with 15O-water as the radiotracer has been the standard modality to measure CBF and CVR. However, it is impractical in most hospitals due to the requirement of an on-site cyclotron. Arterial spin labeling is a quantitative MRI technique that enables non-invasive CBF and CVR measurement. In this work, we compare the CVR of Moyamoya patients measured by ASL MRI with the reference-standard 15O-water PET.*Methods and Materials Imaging data were acquired from 26 Moyamoya patients (18-64 years, 16 females) using a simultaneous 3T PET/MRI system (GE SIGNA, Waukesha, WI, USA). All patients had unilateral or bilateral vessel occlusion at the anterior cerebral artery (ACA), middle cerebral artery (MCA), and/or posterior cerebral artery (PCA). The scanning parameters of the single post-labeling delay pseudo-continuous ASL (single-PLD PCASL), delay pseudo-continuous ASL (multi-PLD PCASL, 3 PLDs), and PET were

described in our previous work 2. PET and ASL data were acquired simultaneously at baseline and 15 minutes after the injection of the vasodilator acetazolamide (15 mg/kg with a maximum of 1 g). Each patient received 891±71.8 MBq of 15O-water. CBF of PET was computed using the single-compartment pharmacokinetic model; CBF of ASL was computed using the general kinetic model 3,4. CVR was computed as the percentage of CBF change compared with baseline CBF. Flow territories (right and left ACA, MCA, and PCA) were defined based on the Harvard-Oxford cortical and subcortical structural atlases 5. Mean CVR within the territories affected by occlusion and normal territories was computed for each subject. Paired t-tests were performed to compare the mean CVR between the affected and unaffected territories.*Results Figure 1 shows the mean CVR of the cohort in regions affected by occlusion and normal regions. Overall, the CVR of the affected regions was significantly lower than the normal regions (by 68%, 52%, and 56% for PET, single-PLD PCASL, and multi-PLD PCASL respectively).*Conclusions Both single and multi-delay ASL were effective in detecting impaired CVR in Moyamoya patients.*Clinical Relevance/Application Using 15O-water Pet as the reference, our data showed that the ASL MRI successfully detected impaired CVR in Moyamoya patients, allowing this technique to become a non-invasive modality to identify patients with a high risk of stroke.

RESULTS

Figure 1 shows the mean CVR of the cohort in regions affected by occlusion and normal regions. Overall, the CVR of the affected regions was significantly lower than the normal regions (by 68%, 52%, and 56% for PET, single-PLD PCASL, and multi-PLD PCASL respectively).

CLINICAL RELEVANCE/APPLICATION

Using 15O-water Pet as the reference, our data showed that the ASL MRI successfully detected impaired CVR in Moyamoya patients, allowing this technique to become a non-invasive modality to identify patients with a high risk of stroke.

SSNR15-3 Fully Automated Lumbar Spinal Stenosis (LSS) Grading System In MR Imaging Using 3D Deep Learning Pipeline

Participants
JinHyeong Park, PhD, New York, New York (*Presenter*) Employee, Covera Health

PURPOSE

Lumbar spinal stenosis (LSS) is commonly diagnosed on MR, but there is a high variation in grading severity. We propose a fully automated AI-powered 3D pipeline to detect, localize and grade LSS at each Functional Spinal Units (FSU) level (L1-2 through L5-S1) as grade 1 - none/mild, grade 2 - moderate or grade 3 - severe.*Methods and Materials Sag T1, Sag T2 and Ax T2 sequences from lumbar spine MR at 1.5T (67%) and 3.0T (33%) were collected from 5426 patients. 27,124 FSU were graded based on Stenotic Ratio, 0 - 0.25 (Mild), 0.25 - 0.75 (Moderate), 0.75 - 1, Schizas class C and D (severe). At least 1 of 8 experienced MSK- and neuro-radiologists assigned 22,957 FSU to grade 1 (85%), 1,745 to grade 2 (6%), and 2,422 to grade 3 (9%). The studies were randomly split into train-validation-test sets in a 7:1:2 ratio. A deep reinforcement model was trained to identify the L1-2 through L5-S1 discs. Associated FSUs were cropped (9 x 9 x 4 cm for axial and 8 x 8 x 5 cm for sagittal), then fed to a convolutional neural network. Three independent ResNet50-like encoders, one per each sequence, were trained to grade the stenosis. Derived embeddings were concatenated and normalized using an adaptive dropout to account for missing sequences. A final regression layer predicted a gaussian distribution representing LSS grades with continuous severity scores from 1 to 3. Final grade was set to the closest target grade.*Results Mean absolute error (MAE) between target, discrete grades 1, 2 or 3, and predicted grades, continuous values from 1 to 3, were computed. Overall MAE was 0.27 (std:0.32) and MAE for grades 1, 2, and 3 were 0.26 (std:0.32), 0.33 (std:0.34), and 0.33 (std:0.37). Micro and macro AUC were 0.95, and 0.91. AUC for grade 1, 2 and 3 were 0.94, 0.84, and 0.96. Inter-expert agreement was measured with sensitivity/specificity across 360 randomly selected FSUs. Sensitivity and specificity of grade 1 vs. grades 2 & 3 were 0.91 and 0.92 (0.88 and 0.98 from inter-expert), and grades 1 & 2 vs. grade 3 were 0.88 and 0.98 (0.94 and 0.82 from inter-expert).*Conclusions An AI pipeline is able to accurately detect the presence, location, and grade of lumbar spinal stenosis comparable to experienced, sub-specialized radiologists*Clinical Relevance/Application There is inter-observer variation when radiologists grade LSS, but this can be reduced by an AI pipeline. These research results are not commercially available.

RESULTS

Mean absolute error (MAE) between target, discrete grades 1, 2 or 3, and predicted grades, continuous values from 1 to 3, were computed. Overall MAE was 0.27 (std:0.32) and MAE for grades 1, 2, and 3 were 0.26 (std:0.32), 0.33 (std:0.34), and 0.33 (std:0.37). Micro and macro AUC were 0.95, and 0.91. AUC for grade 1, 2 and 3 were 0.94, 0.84, and 0.96. Inter-expert agreement was measured with sensitivity/specificity across 360 randomly selected FSUs. Sensitivity and specificity of grade 1 vs. grades 2 & 3 were 0.91 and 0.92 (0.88 and 0.98 from inter-expert), and grades 1 & 2 vs. grade 3 were 0.88 and 0.98 (0.94 and 0.82 from inter-expert).

CLINICAL RELEVANCE/APPLICATION

There is inter-observer variation when radiologists grade LSS, but this can be reduced by an AI pipeline. These research results are not commercially available.

SSNR15-4 A Pivotal Randomized Clinical Trial For Brain CT Interpretation Assisted By A Deep Learning-based Automatic Detection Algorithm For Detecting Acute Intracranial Hemorrhage

Participants
Jin Wook Choi, MD, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To validate the diagnostic performance of brain CT interpretation assisted by a deep learning-based automatic detection algorithm (DLAD) for detecting acute intracranial hemorrhage (AIH).*Methods and Materials A pivotal randomized clinical trial of DLAD (Medical Insight+ Brain Hemorrhage, SK Inc. C&C, Republic of Korea) was performed. AIH was evaluated by nine reviewers belonging to three subgroups (non-radiologist physicians, n=3; board-certified radiologists, n=3; and neuroradiologists, n=3) without or with assistance of the DLAD for a washout period of four weeks using 12,663 slices (2,508 AIH and 10,155 normal) of brain CTs from 296 patients (146 AIH and 150 normal). Our DLAD localized AIH with probability scores for both patients and slices wisely. Its diagnostic performance was evaluated using AUROC. Statistical significance was considered when Bonferroni-corrected P-value was less than 0.05.*Results Brain CT interpretation with the DLAD showed significantly higher AUROC than that without DLAD (0.970 [95% CI: 0.963, 0.976] vs. 0.947 [95% CI: 0.938, 0.955], P < 0.0009). Among three subgroups of reviewers, non-radiologist physicians showed the most improvement in diagnostic accuracy using brain CT interpretation with DLAD than that without DLAD (0.951 [95%

CI: 0.934, 0.964] vs. 0.919 [95% CI: 0.899, 0.936], P = 0.0009). For board-certified radiologists, brain CT interpretation with assistance by DLAD also showed significantly higher AUROC than that without DLAD (0.974 [95% CI: 0.961, 0.983] vs. 0.946 [95% CI: 0.929, 0.960], P = 0.0003). For neuroradiologists, although brain CT interpretation with assistance by DLAD also showed higher diagnostic accuracy than that without DLAD, the difference between the two was not statistically significant (0.987 [95% CI: 0.977, 0.993] vs. 0.976 [95% CI: 0.964, 0.985], P = 0.1776).*Conclusions Brain CT interpretation assisted by DLAD for detecting AIH showed better diagnostic performance than that without assistance by DLAD. The greatest improvement in diagnostic accuracy using brain CT interpretation assisted by DLAD was found for the subgroup of non-radiologist physicians among three subgroups of reviewers.*Clinical Relevance/Application 1. Brain CT interpretation assisted by our deep learning-based automatic detection algorithm showed improvement than that without assistance by deep learning-based automatic detection algorithm for detecting AIH on brain CT.2. When accompanied by our deep learning-based automatic detection algorithm, both non-radiologist physicians and board-certified radiologists improved their performances for detecting AIH, with non-radiologist physicians showing greater improvement in diagnostic accuracy.

RESULTS

Brain CT interpretation with the DLAD showed significantly higher AUROC than that without DLAD (0.970 [95% CI: 0.963, 0.976] vs. 0.947 [95% CI: 0.938, 0.955], P < 0.0009). Among three subgroups of reviewers, non-radiologist physicians showed the most improvement in diagnostic accuracy using brain CT interpretation with DLAD than that without DLAD (0.951 [95% CI: 0.934, 0.964] vs. 0.919 [95% CI: 0.899, 0.936], P = 0.0009). For board-certified radiologists, brain CT interpretation with assistance by DLAD also showed significantly higher AUROC than that without DLAD (0.974 [95% CI: 0.961, 0.983] vs. 0.946 [95% CI: 0.929, 0.960], P = 0.0003). For neuroradiologists, although brain CT interpretation with assistance by DLAD also showed higher diagnostic accuracy than that without DLAD, the difference between the two was not statistically significant (0.987 [95% CI: 0.977, 0.993] vs. 0.976 [95% CI: 0.964, 0.985], P = 0.1776).

CLINICAL RELEVANCE/APPLICATION

1. Brain CT interpretation assisted by our deep learning-based automatic detection algorithm showed improvement than that without assistance by deep learning-based automatic detection algorithm for detecting AIH on brain CT.2. When accompanied by our deep learning-based automatic detection algorithm, both non-radiologist physicians and board-certified radiologists improved their performances for detecting AIH, with non-radiologist physicians showing greater improvement in diagnostic accuracy.

SSNR15-5   Microstructural Alterations Of Major Thalamic Nuclei In The Chronic Pediatric Spinal Cord Injured Population

Participants
Mahdi Alizadeh, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Few studies have investigated microstructural alterations in the thalamus following spinal cord injury (SCI), especially in the pediatric population. In this study, we used diffusion tensor imaging (DTI) derived metrics to characterize microstructural changes in thalamic nuclei in pediatric SCI patients.*Methods and Materials We conducted a retrospective study of 18 subjects aged 8-20 years old with chronic SCIs. Subjects were assigned to three groups after assessing for SCI severity via the American Spinal Injury Association Impairment Scale (AIS). Five subjects were classified as AIS grade A, nine subjects were classified as AIS grade B, and four subjects were classified as AIS grade C and D. DTI scans were acquired in a 3T Siemens Verio MR scanner. Initial raw diffusion data was corrected for motion artifacts and eddy current distortions. Then, diffusion tensor estimates per voxel were fit to generate DTI scalars including FA, MD, AD, and RD, and registered in MNI space. Diffusion values were computed with the AAL3 thalamic atlas for 15 major thalamic nuclei, and a multiple Mann-Whitney U test was applied to identify group differences with significance threshold set at p < 0.05.*Results Significant differences in diffusion scalars were identified between AIS groups A vs CD and B vs CD. Between AIS A and CD, differences in FA in the left reuniens nucleus (p = 0.016) and RD in the parvocellular right mediodorsal lateral nucleus (p = 0.016) were significant. Between AIS B and CD, differences in AD (p = 0.020) and MD (p = 0.0056) in the right medial geniculate nucleus were significant.*Conclusions Our results suggest the presence of microstructural alterations in certain thalamic nuclei following SCI with respect to the severity based on AIS classification. The difference in diffusion metrics in certain nuclei of the thalamus between SCI patients of high grade and low grade severity may reflect neuroplastic changes that develop in chronic SCIs. These microstructural changes may indicate the response of thalamic neuronal cells to injury. While our results only show that differences in diffusion values between AIS groups were significant in just a few thalamic nuclei, these preliminary results are encouraging and warrant further studies with a larger population and with consideration of covariate factors such as age.*Clinical Relevance/Application DTI may provide imaging biomarkers that characterize adaptive neuroplastic changes in the brain after SCI and insight into how they affect the thalamus' role in sensorimotor and cognitive functions.

RESULTS

Significant differences in diffusion scalars were identified between AIS groups A vs CD and B vs CD. Between AIS A and CD, differences in FA in the left reuniens nucleus (p = 0.016) and RD in the parvocellular right mediodorsal lateral nucleus (p = 0.016) were significant. Between AIS B and CD, differences in AD (p = 0.020) and MD (p = 0.0056) in the right medial geniculate nucleus were significant.

CLINICAL RELEVANCE/APPLICATION

DTI may provide imaging biomarkers that characterize adaptive neuroplastic changes in the brain after SCI and insight into how they affect the thalamus' role in sensorimotor and cognitive functions.

SSNR15-6   A Deep Learning Model For Classifying Spontaneous Intracranial Hypotension On Brain MRI

Participants
Walter Wiggins, MD, PhD, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

Spontaneous intracranial hypotension (SIH) is an important, but underrecognized cause of positional headache. SIH is a debilitating but treatable condition. Characteristic brain MRI findings of smooth dural thickening/hyperenhancement, venous distention, and brain sag are key to this diagnosis. Thus, we sought to develop a deep learning model to assist radiologists in identifying potential cases of SIH on brain MRI examinations.*Methods and Materials In total 428 brain MRI examinations from unique subjects were included (155 positive for SIH and 273 normals). Positive cases were selected from an institutional database of confirmed SIH cases. Normal controls were identified by screening consecutive, contemporary brain MRI reports with a natural language

processing tool. Reports flagged as likely normal were manually reviewed and confirmed. Data were split at the subject level into training (45%), validation (30%), and test (25%) sets. Axial and coronal post-contrast, T1-weighted sequences were selected for further analysis. An empirically derived heuristic was applied to select 1 axial image and 2 coronal images from each study most likely to exemplify the characteristic findings of SIH. Transfer learning was employed with ResNet-50 architecture pre-trained on ImageNet, adapted to train 3 separate models for the axial and 2 coronal images. Models were fine-tuned for 50 epochs each. Predictions from the 3 models were ensembled with a logistic regression model to generate a final prediction. Performance was evaluated with receiver operating characteristic (ROC) and precision-recall (PR) curves, including area under the ROC (AUROC).*Results AUROC for axial and coronal models were 0.98, 0.98, and 0.97. Ensemble AUROC was 0.98. Given the surprisingly high accuracy of our results, subsequent testing and experiments were performed for validation. There was no evidence of data leakage. Running model inference on the test data set without fine-tuning the pre-trained model resulted in AUROC 0.55. Fine-tuning of the model on a small subset of the data - 10 positive and 20 negative cases from the training set, 5 positive and 10 negative from the validation set - resulted in a slight improvement with AUROC 0.61. Repeating training with the full dataset reproduced the result of AUROC 0.98.*Conclusions We successfully trained a highly accurate deep learning model capable of classifying SIH on brain MRI examinations from our institutional database.*Clinical Relevance/Application If shown to be generalizable to more challenging cases and/or cases from other institutions, this model could help radiologists identify possible cases of SIH on brain MRI examinations.

RESULTS

AUROC for axial and coronal models were 0.98, 0.98, and 0.97. Ensemble AUROC was 0.98. Given the surprisingly high accuracy of our results, subsequent testing and experiments were performed for validation. There was no evidence of data leakage. Running model inference on the test data set without fine-tuning the pre-trained model resulted in AUROC 0.55. Fine-tuning of the model on a small subset of the data - 10 positive and 20 negative cases from the training set, 5 positive and 10 negative from the validation set - resulted in a slight improvement with AUROC 0.61. Repeating training with the full dataset reproduced the result of AUROC 0.98.

CLINICAL RELEVANCE/APPLICATION

If shown to be generalizable to more challenging cases and/or cases from other institutions, this model could help radiologists identify possible cases of SIH on brain MRI examinations.

SPR-HN-1   VSI Teleultrasound Of The Thyroid: A New Horizon In Imaging

Participants
Thomas Marini, MD, Rochester, New York (*Presenter*) Nothing to Disclose

PURPOSE

Thyroid ultrasound is a key tool in the evaluation of the thyroid, but billions of people around the world lack access to ultrasound imaging. In this study, we tested an asynchronous telediagnostic ultrasound system operated by individuals without prior ultrasound training which may be used to effectively evaluate the thyroid and improve access to imaging worldwide.*Methods and Materials The telediagnostic system used in this study utilizes volume sweep imaging (VSI), an imaging technique in which the operator scans the target region with simple sweeps of the ultrasound probe based on external body landmarks. Sweeps are recorded and saved as video clips for later interpretation by an expert. Two operators without prior ultrasound experience underwent 8 hours of training on the thyroid VSI protocol and the operation of the telemedicine platform. After training, the operators scanned patients at a health center in Lima serving a low-income population. Telediagnostic examinations were sent to the United States for remote interpretation. Standard of care thyroid ultrasound was performed by an experienced radiologist at the time of VSI examination to serve as a reference standard.*Results Novice operators scanned 121 subjects with the thyroid VSI protocol. Of these exams, 88% were rated of excellent image quality showing complete or near complete thyroid visualization. There was 98.3% agreement on thyroid nodule presence between VSI and standard of care (Cohen's kappa 0.91, P <0.0001). VSI measured the thyroid size, on average, within 5 mm compared to standard of care. There was fair to moderate agreement on thyroid size measurements with intraclass correlation coefficients varying between 0.37 and 0.58. The Bland-Altman bias varied between 2.84 and 1.07, indicating that VSI tends to result in larger measurements compared to standard of care. The average nodule size in greatest dimension was 9.8 mm +/- 5.2 mm (standard deviation) on VSI and 10.1 mm +/- 8 mm on standard of care. There was no significant difference in measurement of thyroid nodule size (P = 0.74).*Conclusions Thyroid VSI telediagnostic ultrasound demonstrated both excellent visualization of the thyroid gland and agreement with standard of care thyroid ultrasound for nodules and thyroid size evaluation.*Clinical Relevance/Application This system could be deployed for evaluation of palpable thyroid abnormalities, nodule follow-up, and epidemiological studies to promote global health and improve the availability of diagnostic imaging in underserved communities.

RESULTS

Novice operators scanned 121 subjects with the thyroid VSI protocol. Of these exams, 88% were rated of excellent image quality showing complete or near complete thyroid visualization. There was 98.3% agreement on thyroid nodule presence between VSI and standard of care (Cohen's kappa 0.91, P <0.0001). VSI measured the thyroid size, on average, within 5 mm compared to standard of care. There was fair to moderate agreement on thyroid size measurements with intraclass correlation coefficients varying between 0.37 and 0.58. The Bland-Altman bias varied between 2.84 and 1.07, indicating that VSI tends to result in larger measurements compared to standard of care. The average nodule size in greatest dimension was 9.8 mm +/- 5.2 mm (standard deviation) on VSI and 10.1 mm +/- 8 mm on standard of care. There was no significant difference in measurement of thyroid nodule size (P = 0.74).

CLINICAL RELEVANCE/APPLICATION

This system could be deployed for evaluation of palpable thyroid abnormalities, nodule follow-up, and epidemiological studies to promote global health and improve the availability of diagnostic imaging in underserved communities.

SPR-HN-10   Post-COVID Fungal Rhinosinusitis Creating Havoc!!! From Radiologists' Perspective

Participants
Srijit Saha, MBBS, Nagpur, India (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the spectrum of radiological findings that involve orbits and paranasal sinuses using Computed Tomography scans in patients who have recovered from COVID-19 disease.To evaluate the demography, comorbidities and treatment modalities used in these patients which may attribute to development of Fungal Rhinosinusitis after recovery from COVID-19 infection.*Methods and Materials This is a retrospective cohort study of 67 patients who had recovered from COVID-19 pneumonia within 1 month and have been referred to the Radiodiagnosis Department for Contrast Enhanced Computed Tomography (CECT) of Orbit and Paranasal Sinuses with various complaints. Clinical, demographic, comorbidities and COVID-treatment historywere taken.The reports of nasal swabs were collected from Department of Microbiology. *Results Almost all- 66 (99%) had pansinusitis with some degree of nasal obstruction. 31 % patients had orbital cellulitis. 12% had orbital abscess formation. 67% patients had soft tissue density lesion within the paranasal sinuses. 9.5% patients had direct infraorbital extension of the soft tissue, while 17.9 % had direct intracranial extension. 4.5% cases had palatal perforation. Type II Diabetes Mellitus was the most common (79%) comorbid condition. 56% patients needed non-invasive ventilatory support during COVID treatment, 10% cases needed ventilatory support, 17.9% patients were given oxygen support while 14.9% patients did not need any oxygen support at all. 70% patients were treated with oral or injectable steroids during COVID infection, 79% were given broad-spectrum antibiotics while 18% were administered

immunomodulators. The swabs were positive for fungal growths in 62.7 % cases.*Conclusions COVID-19 is associated with a significant incidence of secondary infections, both bacterial and fungal probably due to immune dysregulation. Additionally, the widespread use of steroids/broad-spectrum antibiotics as part of the armamentarium against COVID-19 may lead to the development or exacerbation of preexisting fungal diseases. Patients on ventilatory support or with comorbidities like Diabetes Mellitus have a tendency for secondary fungal infections.*Clinical Relevance/Application Physicians should be aware of the possibility of invasive secondary fungal infections in patients with COVID-19 infection especially in patients with preexisting risk factors and should enable early diagnosis and treatment with the subsequent reduction of mortality and morbidity. The use of therapeutic agents should be monitored to achieve a therapeutic effect at the lowest dose and shortest durations. The use of broad-spectrum antibiotics, especially in the absence of infection, should be re-evaluated.

RESULTS

Almost all- 66 (99%) had pansinusitis with some degree of nasal obstruction. 31 % patients had orbital cellulitis. 12% had orbital abscess formation. 67% patients had soft tissue density lesion within the paranasal sinuses. 9.5% patients had direct infraorbital extension of the soft tissue, while 17.9 % had direct intracranial extension. 4.5% cases had palatal perforation. Type II Diabetes Mellitus was the most common (79%) comorbid condition. 56% patients needed non-invasive ventilatory support during COVID treatment, 10% cases needed ventilatory support, 17.9% patients were given oxygen support while 14.9% patients did not need any oxygen support at all. 70% patients were treated with oral or injectable steroids during COVID infection, 79% were given broad-spectrum antibiotics while 18% were administered immunomodulators. The swabs were positive for fungal growths in 62.7 % cases.

CLINICAL RELEVANCE/APPLICATION

Physicians should be aware of the possibility of invasive secondary fungal infections in patients with COVID-19 infection especially in patients with preexisting risk factors and should enable early diagnosis and treatment with the subsequent reduction of mortality and morbidity. The use of therapeutic agents should be monitored to achieve a therapeutic effect at the lowest dose and shortest durations. The use of broad-spectrum antibiotics, especially in the absence of infection, should be re-evaluated.

SPR-HN-3   Radiomics-based Predictive Analysis Of Lymph Node Metastasis Using Primary Head ; Neck Tumor CT And Fluorescence Lifetime Imaging

Participants
Nimu Yuan, PhD, Davis, California (*Presenter*) Nothing to Disclose

PURPOSE

This study investigates the potential of predicting lymph node metastasis (LNM) using radiomic features derived from pre-operative CT images of primary tumors, while additionally evaluating the benefit of combining the pre-operative CT images with an intra-operative label-free Fluorescence Lifetime Imaging (FLIm).*Methods and Materials Forty-eight patients undergoing oncologic surgical procedures of the oral cavity and oropharynx were investigated in this study following IRB approval. All patients had preoperative CT scans conducted prior to surgery as well as an intraoperative FLIm scan. Primary tumors in CT images were manually segmented by a radiologist to extract radiomic features. In total, 1218 CT features were obtained from each image and 42 FLIm features were extracted based on average lifetime and spectral intensity parameter values from three spectral channels for each point measurement. All 48 subjects were randomly divided into 8 equal subsets. For each subset of data, a classifier was trained using the 7 remaining subsets of data. A nested 7-fold cross-validation (CV) was performed using the 7 subsets to tune the hyper-parameters of the classifier. Before training, features were normalized by removing the mean and variance; dimension reduction was performed using principal component analysis based on the training data only. The Support Vector Machine with radial basis function kernel was selected for classification. Classifiers trained using only CT features were also evaluated for comparison.*Results The accuracies (ACC) of the trained classifiers are listed in Table 1. The classifiers using both features achieved an average testing ACC of 0.67, which outperformed the one using only CT features (testing ACC: 0.63).*Conclusions Herein, we developed a radiomic model that predicts Head & Neck cancer LNM using CT and FLIm-derived parameters of primary tumors. Our current study demonstrates that the combination of pre-operative CT and intra-operative FLIm features can improve the prediction accuracy when compared to using CT features alone. More methods to integrate CT and FLIm information will be investigated in the future.*Clinical Relevance/Application Lymph node metastasis is a significant prognostic factor in patients with Head & Neck cancer, and the ability to predict it accurately is essential to optimizing treatment.

RESULTS

The accuracies (ACC) of the trained classifiers are listed in Table 1. The classifiers using both features achieved an average testing ACC of 0.67, which outperformed the one using only CT features (testing ACC: 0.63).

CLINICAL RELEVANCE/APPLICATION

Lymph node metastasis is a significant prognostic factor in patients with Head & Neck cancer, and the ability to predict it accurately is essential to optimizing treatment.

SPR-HN-4   Comparison Of The Diagnostic Performance Of The Modified 2021 Korean Thyroid Imaging Reporting And Data System For Thyroid Malignancy With Three International Guidelines

Participants
Eun Ju Ha, MD, Suwon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

This study was performed to compare the diagnostic performance of the modified 2021 Korean Thyroid Imaging Reporting and Data System (K-TIRADS) for thyroid malignancy with three international guidelines using Thyroid Imaging Network of Korea registry.*Methods and Materials From June to September 2015, 5,708 thyroid nodules (= 1.0 cm) in 5,081 consecutive patients who underwent thyroid ultrasound (US) from 26 institutions were evaluated. US features of the thyroid nodules were retrospectively reviewed and classified according to the categories defined by each set of guidelines. In the modified 2021 K-TIRADS, the biopsy size threshold was changed to 2.0 cm for K-TIRADS 3 and 1.0 or 1.5 cm for K-TIRADS 4 (K-TIRADS1.0cm and K-TIRADS1.5cm, respectively). We compared diagnostic performance and unnecessary fine-needle aspiration biopsy (FNAB) rates for thyroid malignancy between the modified 2021 K-TIRADS and three international guidelines.*Results Of the 5,708 thyroid nodules, 4,597 (80.5%) were benign and 1,111 (19.5%) were malignant. The overall sensitivity was highest in the modified 2021 K-TIRADS1.0cm (91.0%), followed by the European (EU)-TIRADS (84.6%), American Association of Clinical Endocrinologists/American College of Endocrinology/Associazione Medici Endocrinologi (AACE/ACE/AME) (80.5%), American College of Radiology (ACR)-TIRADS (76.1%),

and modified 2021 K-TIRADS1.5cm (76.1%). For large nodules (> 2.0 cm), the sensitivity increased to 98.0% in both the modified 2021 K-TIRADS1.0cm and K-TIRADS1.5cm. For small nodules (= 2.0 cm), the unnecessary FNAB rate was lowest with the modified 2021 K-TIRADS1.5cm (17.6%), followed by the ACR-TIRADS (18.6%), AACE/ACE/AME (19.3%), EU-TIRADS (28.1%), and modified 2021 K-TIRADS1.0cm (31.2%).*Conclusions The modified 2021 K-TIRADS1.5cm can reduce the unnecessary FNAB rates for small nodules (1.0-2.0 cm), while maintaining high sensitivity for detecting malignancies > 2.0 cm.*Clinical Relevance/Application 1. This study compared the diagnostic performance of the new modified 2021 K-TIRADS with those of ACR-, AACE/ACE/AME-, and EU-TIRADS.2. The modified 2021 K-TIRADS can reduce the unnecessary FNAB rates for small nodules (1.0-2.0 cm), while maintaining high sensitivity for detecting malignancies > 2.0 cm.

RESULTS

Of the 5,708 thyroid nodules, 4,597 (80.5%) were benign and 1,111 (19.5%) were malignant. The overall sensitivity was highest in the modified 2021 K-TIRADS1.0cm (91.0%), followed by the European (EU)-TIRADS (84.6%), American Association of Clinical Endocrinologists/American College of Endocrinology/Associazione Medici Endocrinologi (AACE/ACE/AME) (80.5%), American College of Radiology (ACR)-TIRADS (76.1%), and modified 2021 K-TIRADS1.5cm (76.1%). For large nodules (> 2.0 cm), the sensitivity increased to 98.0% in both the modified 2021 K-TIRADS1.0cm and K-TIRADS1.5cm. For small nodules (= 2.0 cm), the unnecessary FNAB rate was lowest with the modified 2021 K-TIRADS1.5cm (17.6%), followed by the ACR-TIRADS (18.6%), AACE/ACE/AME (19.3%), EU-TIRADS (28.1%), and modified 2021 K-TIRADS1.0cm (31.2%).

CLINICAL RELEVANCE/APPLICATION

1. This study compared the diagnostic performance of the new modified 2021 K-TIRADS with those of ACR-, AACE/ACE/AME-, and EU-TIRADS.2. The modified 2021 K-TIRADS can reduce the unnecessary FNAB rates for small nodules (1.0-2.0 cm), while maintaining high sensitivity for detecting malignancies > 2.0 cm.

SPR-HN-5   A Multi-center Study Based On Artificial Intelligence To Revise ACR TI-RADS Risk Stratification Of Thyroid Nodules: Diagnostic Accuracy And Utility

Participants
Ying Liu, Guangzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To determine if artificial intelligence-based modification of Thyroid Imaging Reporting Data System (TI-RADS) would be better than the current American College of Radiology (ACR) TI-RADS for risk stratification of thyroid nodules.*Methods and Materials A total of 2061 thyroid nodules (in 1859 patients) sampled with fine-needle aspiration or operation between January 2017 and July 2020 were retrospectively analyzed. Two radiologists blinded to the pathologic diagnosis evaluated nodule features in five ultrasound categories and assigned TI-RADS scores by both ACR TI-RADS and AI TI-RADS. Inter-rater agreement was assessed by asking another two radiologists to independently score a set of 100 nodules. The reference standard was postoperative pathological or cytopathological diagnosis according to the Bethesda system. Inter-rater agreement was determined using intraclass correlation coefficient (ICC).*Results AI TI-RADS assigned lower TI-RADS risk levels than ACR TI-RADS (P<0.001), and had larger area under receiver operating characteristic curve (0.762 vs. 0.679, P <0.001). The sensitivities of ACR TI-RADS and AI TI-RADS were similar (86.7% vs. 82.2%, P = 0.052), but specificity was higher with AI TI-RADS (70.2% vs. 49.2%, P< 0.001). AI TI-RADS downgraded 743 (48.63%) benign nodules, indicating that 328 (42.3% of 776 biopsied nodules) unnecessary fine-needle aspirations could have been avoided. Inter-rater agreement was better with AI TI-RADS than with ACR TI-RADS (ICC, 0.808 vs. 0.861, P<0.001).*Conclusions AI TI-RADS can achieve meaningful reduction in the number of benign thyroid nodules recommended for biopsy and significantly improve diagnostic accuracy.*Clinical Relevance/Application This study retrospectively compared diagnostic performance between AI TI-RADS and ACR TI-RADS in a large sample and may help avoid unnecessary FNA in a significant proportion of benign thyroid nodules.

RESULTS

AI TI-RADS assigned lower TI-RADS risk levels than ACR TI-RADS (P<0.001), and had larger area under receiver operating characteristic curve (0.762 vs. 0.679, P <0.001). The sensitivities of ACR TI-RADS and AI TI-RADS were similar (86.7% vs. 82.2%, P = 0.052), but specificity was higher with AI TI-RADS (70.2% vs. 49.2%, P< 0.001). AI TI-RADS downgraded 743 (48.63%) benign nodules, indicating that 328 (42.3% of 776 biopsied nodules) unnecessary fine-needle aspirations could have been avoided. Inter-rater agreement was better with AI TI-RADS than with ACR TI-RADS (ICC, 0.808 vs. 0.861, P<0.001).

CLINICAL RELEVANCE/APPLICATION

This study retrospectively compared diagnostic performance between AI TI-RADS and ACR TI-RADS in a large sample and may help avoid unnecessary FNA in a significant proportion of benign thyroid nodules.

SPR-HN-6   Application Of Radiomic Model Based On CT For Distinguishing Adenolymphoma Of Parotid Gland From Pleomorphic Adenoma

Participants
Fei Ji, Dalian, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the diagnostic value of radiomic analysis in differentiating parotid adenolymphoma from pleomorphic adenoma based on CT plain images.*Methods and Materials A total of 235 patients with pathologically confirmed tumors of parotid gland were retrospectively collected, of whom 89 were adenolymphoma and 146 were pleomorphic adenoma. All cases were randomly divided into the training cohort (n=164) and the testing cohort (n=71) according to the proportion of 70% and 30%. We placed the region of interest (ROIs) at the slice with the maximun diameter of tumors on the CT images using the software of 3D Slicer to extract 145 quantitative parameters, and excluded duplicate features. We applied variance model,correlation coefficient algorithm,lasso model to screen optimal radiomics features and established the predictive model of adenolymphoma and pleomorphic adenoma through logistic regression (LR). The receiver operating characteristic (ROC) curve and area under the curve (AUC) were used to assess the diagnostic efficiency of the model.*Results The LR model combined 10 features: Maximum2DDiameterSlice,Mean,Variance,Idmn ,LargeDependenceLowGrayLevelEmphasis,GrayLevelNonUniformity,LongRunEmphasis,LowGrayLevelZoneEmphasis,ZonePercentage and Strength, among which Mean and LargeDependenceLowGrayLevelEmphasis were significantly different between the adenolymphoma group and the pleomorphic adenoma group(P<0.05). The model showed a desirable AUC of 0.868 , with a sensitivity of 82.3% and a specificity of 74.5% in the training cohort; while in the testing cohort, the AUC value was 0.842 , the sensitivity was 77.8%, and the specificity was 77.3%.*Conclusions It is helpful to distinguish parotid adenolymphoma from pleomorphic

adenoma using the prediction model based on radiomic features.*Clinical Relevance/Application Adenolymphoma and pleomorphic adenoma are the most common two types of parotid tumors, but they have different surgical procedures. It is more likely to recur if pleomorphic adenoma is incompletely removed, and its scope of surgery is required to be larger than that of adenolymphoma. Therefore, a clear preoperative diagnosis is important for the decision of surgical methods.

RESULTS

The LR model combined 10 features: Maximum2DDiameterSlice,Mean,Variance,Idmn ,LargeDependenceLowGrayLevelEmphasis,GrayLevelNonUniformity,LongRunEmphasis,LowGrayLevelZoneEmphasis,ZonePercentage and Strength, among which Mean and LargeDependenceLowGrayLevelEmphasis were significantly different between the adenolymphoma group and the pleomorphic adenoma group(P<0.05). The model showed a desirable AUC of 0.868 , with a sensitivity of 82.3% and a specificity of 74.5% in the training cohort; while in the testing cohort, the AUC value was 0.842 , the sensitivity was 77.8%, and the specificity was 77.3%.

CLINICAL RELEVANCE/APPLICATION

Adenolymphoma and pleomorphic adenoma are the most common two types of parotid tumors, but they have different surgical procedures. It is more likely to recur if pleomorphic adenoma is incompletely removed, and its scope of surgery is required to be larger than that of adenolymphoma. Therefore, a clear preoperative diagnosis is important for the decision of surgical methods.

SPR-HN-8 Application Study Of Pre-setted Adaptive Statistical Iterative Reconstruction VEO Children Low Doses in USCT

Participants
Hong Yin, MD, Qingdao, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the image quality and radiation dose with adaptive statistical iterative reconstruction-V (ASIR-V) technique of GE Revolution-CT at children sinus CT scan.*Methods and Materials 160 patients underwent sinus CT scan were prospectively collected and divided into the control group (group A, n=40) and the study group (group B, n=120) with random number table. According to pre-ASIR-V percentage, the control group 0 was used pre-ASIR-V scan. The study group was assigned into three groups (40 cases in each group). Group B1: 30% pre-ASIR-V scan; group B2: 60%pre-ASIR-V; group B3: 90%pre-ASIR-V. The tube voltage was 100kV, the tube current was automated mAs (Smart mA 10-720) technology, the noise index was six. The dose-length product of each sinus model group and patients group were record, the effective dose (ED) of each group was calculated and compared. Objective evaluation is based on CT axial image of sinus body mode. All the images were blind reading by three junior radiology doctors. The five points method is used to evaluate the image subjectively. Standard for evaluation: five (excellent): four points (good): 3 points (medium): 2 points (poor): the details are fuzzy, difficult to identify, and the noise is obvious, one points (range): Measurements were statistically compared.*Results The average ED value in group A was 0.90±0.19 mSv, and the mean ED value in group B1 was 0.69±0.35 mSv, the mean ED value in group B2 was 0.47±0.57 mSv, and the mean ED value in group B3 was 0.26±0.48 mSv. In the image quality evaluation, the 60%ASIR-V image has better image quality on the soft tissue window and bone window. The SD value of soft tissue in maxillary sinus, sinus muscle and fat (25.06±3.25, 25.06±3.25, 18.17±0.93) of the image was significantly lower than the SD values of 0%, 30%and 90%ASIR-V images (p<0 .05). The SNR (7.89±0.60, 8.40±0.56, 5.89±1.01) was significantly higher than the SNR value (p<0.05) of the 0%, 30%and 90%ASIR-V images. At the same time, the subjective score (3.89±0.55, 4.79±0.60) of the 60%ASIR-V image in the soft tissue window and the bone window was also better than the evaluation score of the 0%, 30%and 90%ASIR-V images (p<0.05).*Conclusions The ASIR-V technique of GE Revolution-CT with 60%pre-ASIR-V technique can reduce radiation dose while maintain good overall image quality.*Clinical Relevance/Application Adaptive statistical iterative reconstruction technology can significantly improve the children'ssinus radiation dose and CT image quality under low voltage scan conditions. The best new multi-model iterative reconstruction algorithm (ASIR-V) obtained in this study has certain guiding significance for low-tube voltage sinusCT scan in children.

RESULTS

The average ED value in group A was 0.90±0.19 mSv, and the mean ED value in group B1 was 0.69±0.35 mSv, the mean ED value in group B2 was 0.47±0.57 mSv, and the mean ED value in group B3 was 0.26±0.48 mSv. In the image quality evaluation, the 60%ASIR-V image has better image quality on the soft tissue window and bone window. The SD value of soft tissue in maxillary sinus, sinus muscle and fat (25.06±3.25, 25.06±3.25, 18.17±0.93) of the image was significantly lower than the SD values of 0%, 30%and 90%ASIR-V images (p<0 .05). The SNR (7.89±0.60, 8.40±0.56, 5.89±1.01) was significantly higher than the SNR value (p<0.05) of the 0%, 30%and 90%ASIR-V images. At the same time, the subjective score (3.89±0.55, 4.79±0.60) of the 60%ASIR-V image in the soft tissue window and the bone window was also better than the evaluation score of the 0%, 30%and 90%ASIR-V images (p<0.05).

CLINICAL RELEVANCE/APPLICATION

Adaptive statistical iterative reconstruction technology can significantly improve the children'ssinus radiation dose and CT image quality under low voltage scan conditions. The best new multi-model iterative reconstruction algorithm (ASIR-V) obtained in this study has certain guiding significance for low-tube voltage sinusCT scan in children.

SPR-HN-9 Establishment And Validation Of Cervical Vertebrae Muscle Wasting As A Marker Of Sarcopenia For Patients With Head And Neck Cancer

Participants
Brennan Olson, BA, Portland, Oregon (*Presenter*) Nothing to Disclose

PURPOSE

Sarcopenia, or excessive skeletal muscle wasting, is a significant predictor of survival and surgical complications for patients with cancers of the head and neck (HNC). However, current skeletal muscle index values for defining sarcopenia are specific to abdominal musculature. Since abdominal imaging is not regularly performed as part of the HNC workup, implementation of this important prognostic factor into clinical decision making remains challenging. Thus, we sought to establish and validate the use of cervical vertebrae skeletal muscle indexing in determining sarcopenia in HNC patients.*Methods and Materials Cross-sectional skeletal muscle area was measured at the third lumbar (L3) and third cervical (C3) vertebral levels in HNC patients with CT imaging. We performed independent correlative and thresholding analyses in these datasets to validate cervical vertebrae skeletal muscle area as a surrogate of lumbar skeletal muscle area for the detection of sarcopenia. We followed these datasets with a large cohort of HNC patients with only neck imaging available, applied our established cervical vertebrae thresholds, and analyzed survival

outcomes.*Results Correlation analyses demonstrated C3-defined sarcopenia thresholds of 14.0 cm2/m2 (men; p<0.001, r = 0.77) and 11.1 cm2/m2 (women; p<0.001, r = 0.80) as the most accurate predictors of L3-defined sarcopenia (defined by 52.4 cm2/m2 and 38.5 cm2/m2 in men and women, respectively). When applying these determined C3 sarcopenia thresholds in an independent HNC cohort with neck imaging alone (N = 536), we observed a significant survival effect of C3-based sarcopenia in both male (HR = 2.67, 95% CI = 1.72-4.15) and female (HR = 1.71, 95% CI = 1.06-2.78) HNC patients on multivariate analysis.*Conclusions Sarcopenia was recently identified as a strong prognostic factor in patients with HNC. However, identification of this high-risk disease feature is challenging in HNC patients due to the lack of standardized head and neck imaging assessments of skeletal muscle wasting. Herein, we identified sex-specific optimal C3 sarcopenia thresholds for predicting overall survival in this population and validated these results in a large cohort of HNC patients with neck imaging alone.*Clinical Relevance/Application This research establishes and validates the use of neck imaging as a useful tool for the identification of sarcopenia in HNC patients and will provide an additional clinical tool in guiding treatment for these high-risk patients.

RESULTS

Correlation analyses demonstrated C3-defined sarcopenia thresholds of 14.0 cm2/m2 (men; p<0.001, r = 0.77) and 11.1 cm2/m2 (women; p<0.001, r = 0.80) as the most accurate predictors of L3-defined sarcopenia (defined by 52.4 cm2/m2 and 38.5 cm2/m2 in men and women, respectively). When applying these determined C3 sarcopenia thresholds in an independent HNC cohort with neck imaging alone (N = 536), we observed a significant survival effect of C3-based sarcopenia in both male (HR = 2.67, 95% CI = 1.72-4.15) and female (HR = 1.71, 95% CI = 1.06-2.78) HNC patients on multivariate analysis.

CLINICAL RELEVANCE/APPLICATION

This research establishes and validates the use of neck imaging as a useful tool for the identification of sarcopenia in HNC patients and will provide an additional clinical tool in guiding treatment for these high-risk patients.

SSPH15-2   Use Of Exposure Indices For Gauging The Potential For Pulmonary Injury During Lung Ultrasound

Participants
Douglas L. Miller, PhD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

Lung ultrasound (LUS) has proven to be an exceptionally powerful and readily accessible tool in Covid19 disease, neonatal care and many other patient conditions. However, LUS safety research has identified a risk of lung injury that presents potential safety issues, and sonographers should consider the use of reduced ultrasound output for for some clinical examinations. This study evaluated the bioeffect of pulmonary capillary hemorrhage (PCH) in a rat model of LUS for different image scan rates and associated values of Mechanical Index (MI) and Thermal Index (TI) displayed on-screen to apprise the operator of ultrasound output.*Methods and Materials A Philips iE33 machine with L15-7io probe was used scan anesthetized rats in a warmed water bath with 9 MHz B mode, having ~160 ns pulse durations and ~16 kHz pulse repetition frequencies, for different frames-per-second (fps) settings of 34, 61 and 118 fps. Images were observed for causation of B lines (comet tail artifacts). After 2 min of exposure at a specific output, lung samples were obtained for assessment of any resulting PCH areas measured on the lung surface.*Results Initiation and growth of B line (comet tail) artifacts were observed in the LUS images as a result of ongoing PCH. PCH was zero for shams with only MI= 0.2 (TI=0) aiming exposure. Significant PCH occurred for MI=0.6 at 34 fps and MI=0.8 at 61 and 118 fps, or TI=0.3 at 34 and 61 fps and TI=0.4 at 118 fps. At similar MI, PCH (n=7) decreased with increasing fps, for example for 34 fps (MI=1.0, TI=0.8) 19.5 mm2 ± 9.9 mm2 sd, compared to 61 fps (MI=1.0, TI=0.5) 9.6 mm2 ± 4.3 mm2 sd (P<0.5) and 118 fps (MI=1.1, TI=0.4) 7.5 mm2 ± 2.4 mm2 sd (P<0.01). In contrast, the PCH for similar TI was not significantly different for 34 fps (TI= 0.5, MI=0.8) (10.7 mm2 ± 10.6 mm2 sd), compared to 61 fps and 118 fps, above.*Conclusions The results illustrate the counter-intuitive trends often seen in LUS PCH research: the PCH might have been anticipated to increase with increasing fps values, owing to the increasing number of images (considered as separate increments of exposure) within 2 min. Interestingly, even though the PCH bioeffect is known not to be thermal in origin, the TI was a more predictive indicator of the LUS impact in this study than the MI. The variation in impact may be associated with the slower scan rates for lower fps. The rarefactional pressure amplitudes followed a Gaussian trend at a point during an image scan with full-width-at-half-maxima of 1.46 ms, 0.87 ms, and 0.39 ms for the 34, 61 and 118 fps settings, for which the TIs were 0.8, 0.5 and 0.4, respectively.*Clinical Relevance/Application The TI may useful for LUS PCH exposure characterization and, in the future, the development of a new temporal average index of ultrasound energy exposure specifically for PCH should be of clinical value.

RESULTS

Initiation and growth of B line (comet tail) artifacts were observed in the LUS images as a result of ongoing PCH. PCH was zero for shams with only MI= 0.2 (TI=0) aiming exposure. Significant PCH occurred for MI=0.6 at 34 fps and MI=0.8 at 61 and 118 fps, or TI=0.3 at 34 and 61 fps and TI=0.4 at 118 fps. At similar MI, PCH (n=7) decreased with increasing fps, for example for 34 fps (MI=1.0, TI=0.8) 19.5 mm2 ± 9.9 mm2 sd, compared to 61 fps (MI=1.0, TI=0.5) 9.6 mm2 ± 4.3 mm2 sd (P<0.5) and 118 fps (MI=1.1, TI=0.4) 7.5 mm2 ± 2.4 mm2 sd (P<0.01). In contrast, the PCH for similar TI was not significantly different for 34 fps (TI= 0.5, MI=0.8) (10.7 mm2 ± 10.6 mm2 sd), compared to 61 fps and 118 fps, above.

CLINICAL RELEVANCE/APPLICATION

The TI may useful for LUS PCH exposure characterization and, in the future, the development of a new temporal average index of ultrasound energy exposure specifically for PCH should be of clinical value.

SSPH15-3   Ultrasound Guided Elastography: An Accurate And Reliable Technique For Liver Elasticity

Participants
Margo Gent, MSc, Groningen, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

Noninvasive assessment of liver fibrosis is important for determining the treatment and prognosis in patients with chronic liver disease. In a preliminary elastography study, we showed that ultrasound guided elastography (Philips Epic7, ElastPQ) showed equal or better clinical results compared to non-ultrasound guided elastography (Fibroscan) (Dam-Vervloet et al., 2018; Warringa et al., 2021). Now, our aim was to evaluate generalizability of this previous outcome to another ultrasound guided elastography system (Acuson Sequoia, Virtual Touch IQ).*Methods and Materials Phantom elasticity was measured to evaluate the performance of ElastPQ on an Epiq 7 (Philips) and Virtual Touch IQ on two Acuson Sequoia (Siemens) systems. Both applications use the point shear wave elastography technique (pSWE). A 5C1 transducer was used. Measurements were performed on a elastography CIRS-phantom (model 040 GSE (Cablon)) with different reference elasticities: 5.7±2, 13.6±3 and 28.3±5 kPa. All measurements were performed in tenfold and median and interquartile range (IQR) elasticity were computed. Accuracy was analyzed by comparing the

median elasticity ±IQR to the reference elasticity. A Wilcoxon test (alpha=0.01) was performed between the Philips system and both separate Siemens systems to test whether the outcomes were equivalent. Reproducibility of the Siemens systems was considered sufficient if IQR/median<0.30 (specifications Siemens).*Results Accuracy of the Siemens systems was high: all median elasticities ±IQR were within the uncertainty boundaries of the reference elasticity. Measured elasticities of neither Siemens system were significantly different from the Philips system (p=0.05 for Philips v.s. Siemens1 and p=0.83 for Philips v.s. Siemens2). Reproducibility of the systems was high with IQR/median ranging from 0.04 to 0.19 (Philips) and from 0.01 to 0.13 (Siemens, complies with specifications).*Conclusions This study shows similar elasticity measurements of three ultrasound systems that are highly reproducible and in accordance with the reference values, which suggests that ultrasound guided elastography systems is an accurate and reliable technique for liver elasticity measurements.*Clinical Relevance/Application pSWE elastography on Siemens ultrasound systems can be an alternative for existing elastography methods in liver fibrosis evaluation.

RESULTS

Accuracy of the Siemens systems was high: all median elasticities ±IQR were within the uncertainty boundaries of the reference elasticity. Measured elasticities of neither Siemens system were significantly different from the Philips system (p=0.05 for Philips v.s. Siemens1 and p=0.83 for Philips v.s. Siemens2). Reproducibility of the systems was high with IQR/median ranging from 0.04 to 0.19 (Philips) and from 0.01 to 0.13 (Siemens, complies with specifications).

CLINICAL RELEVANCE/APPLICATION

pSWE elastography on Siemens ultrasound systems can be an alternative for existing elastography methods in liver fibrosis evaluation.

SSPH15-5   High Resolution XACT Imaging For Radiotherapy

Participants
Kristina Bjegovic, BS, Irvine, California (*Presenter*) Nothing to Disclose

PURPOSE

X-ray induced Acoustic Computed Tomography (XACT) is a developing imaging modality with the capability to change the standard of care for cancer patients undergoing radiation therapy by introducing real time radiation dosimetry and allowing for image-guided dose and beam path adjustments during irradiation. Due to the energy and pulse width limitations of current clinical linear particle accelerators (LINACs), XACT results in images of low resolution (~5 mm) and low sensitivity. We propose to use a LINAC with higher energy and a pulse width as low as sub-microseconds, compared to a pulse width of 4-5us; XACT imaging can thus be performed at higher resolutions (sub-millimeter) and real time dosimetry for clinical translation can be realized.*Methods and Materials In MATLAB, the relationship between pulse width and signal generation efficiency was explored. Theoretical calculations determined ideal pulse width and target thickness for each transducer used. For the first step, a prototypical LINAC with a pulse width of 2us and a 500kHz transducer were used to acquire promising signals of a lead plate. Further experiments with a 0.2us pulse width and a 5MHz transducer will be used to demonstrate an increase in the resolution and sensitivity. Signal processing was done in MATLAB.*Results The MATLAB simulation depicted that a decrease in pulse width while maintaining delivered dose resulted in higher initial pressure X-ray acoustic waves and signal generation efficacy. This increase in acoustic signal generation efficacy will lead to an improvement in the imaging sensitivity for in vivo dosimetry during radiotherapy. Experimental testing with the sub-microsecond LINAC showed a proportional relationship between the energy of the LINAC and the SNR of the transducer output when imaging a lead plate target with a 500kHz transducer. Using averaging, background noise subtraction, and filtering (Savitsky-Golay, Butterworth), a good SNR was achieved; further tests with a shorter pulse width are expected to show better SNR, experimentally showing the increase in resolution seen in simulation.*Conclusions The resolution of XACT imaging can be increased by shortening the pulse duration of X-Ray delivery, generating higher frequency acoustic signal. Furthermore, the dose sensitivity of XACT for in vivo radiation dosimetry will be improved with the shorter pulsed X-ray beam. By increasing the resolution and sensitivity of XACT imaging, the need for real time dosimetry during radiotherapy can be addressed.*Clinical Relevance/Application Our ultimate goal is to apply X-ray induced Acoustic Computed Tomography (XACT) to in vivo dosimetry during clinical radiation therapy. This application will improve the resolution and sensitivity of XACT for precision radiotherapy.

RESULTS

The MATLAB simulation depicted that a decrease in pulse width while maintaining delivered dose resulted in higher initial pressure X-ray acoustic waves and signal generation efficacy. This increase in acoustic signal generation efficacy will lead to an improvement in the imaging sensitivity for in vivo dosimetry during radiotherapy. Experimental testing with the sub-microsecond LINAC showed a proportional relationship between the energy of the LINAC and the SNR of the transducer output when imaging a lead plate target with a 500kHz transducer. Using averaging, background noise subtraction, and filtering (Savitsky-Golay, Butterworth), a good SNR was achieved; further tests with a shorter pulse width are expected to show better SNR, experimentally showing the increase in resolution seen in simulation.

CLINICAL RELEVANCE/APPLICATION

Our ultimate goal is to apply X-ray induced Acoustic Computed Tomography (XACT) to in vivo dosimetry during clinical radiation therapy. This application will improve the resolution and sensitivity of XACT for precision radiotherapy.

SSPH15-6   Real-time Intrafraction Prostate Motion During Dose-escalated Linac-based SBRT

Participants
Denis Panizza, Monza, Italy (*Presenter*) Nothing to Disclose

PURPOSE

An electromagnetic (EM) transmitter-based tracking device for prostate and urethra localization and monitoring during prostate cancer SBRT was implemented. The aim of this study was to evaluate the intra-fraction prostate motion in the very first clinical use worldwide.*Methods and Materials Ten patients with organ-confined prostate cancer underwent dose-escalated SBRT in 4 or 5 fractions (BED1.5=279Gy and 253Gy, respectively), using Volumetric Modulated Arc Therapy (VMAT) techniques with flattening filter free (FFF) beams on VersaHD linac. The EM tracking device consisted in an integrated Foley catheter with a transmitter in a dedicated lumen. Signals sent by the transmitter were detected by antennas in a specific receiver placed on the linac couch. The system was calibrated to the treatment room isocenter and it allowed treatment localization in addition to motion tracking. Starting from the daily CBCT and during the delivery, the prostate motion was tracked with the EM system and SBRT was interrupted when a 2-mm threshold was trespassed and corrected by a new CBCT, unless the offset was transient. Real-time measurement of prostate displacement was recorded for each treatment fraction. These measurements were used to determine the duration and

magnitude of displacement along the three directional axes.*Results Total treatment time lasted on average 9.3 minutes [range 6-14], 5.8 minutes [range 3-9] for setup and 3.5 minutes [range 2-5] for beam delivery. In 41% of the monitored fractions, a new CBCT was mandated. The CBCT was repeated during the initial setup phase in 10 out of 44 fractions, while the beam delivery was interrupted only in 8. The transmitter shifts along x, y, and z axes for every treated patient during each phase of setup and beam delivery are reported in table 1. The majority of intra-fractional motion measured by the system occurred in the anteroposterior direction. The mean value of the target average deviation was -0.3 mm, -0.2 mm, and 0.0 mm in vertical, lateral, and longitudinal direction, respectively. The prostate was found within 1 mm from its initial position in 83.9% of the treatment time, between 1 and 2 mm in 13.0%, and exceeds 2 mm only in 3.1%.*Conclusions Our findings show that EM tracking is a reliable technique for real-time non-ionizing prostate monitoring during dose-escalated SBRT, allowing to keep the average target motion within 2 mm. Using FFF VMAT beams shortened the treatment time and significantly contributed to reduce intra-fractional motion.*Clinical Relevance/Application Linac-based SBRT by means of VMAT-FFF technique coupled with daily image guidance including real-time EM tracking allowed dose-escalated treatment with negligible early side effects.

RESULTS

Total treatment time lasted on average 9.3 minutes [range 6-14], 5.8 minutes [range 3-9] for setup and 3.5 minutes [range 2-5] for beam delivery. In 41% of the monitored fractions, a new CBCT was mandated. The CBCT was repeated during the initial setup phase in 10 out of 44 fractions, while the beam delivery was interrupted only in 8. The transmitter shifts along x, y, and z axes for every treated patient during each phase of setup and beam delivery are reported in table 1. The majority of intra-fractional motion measured by the system occurred in the anteroposterior direction. The mean value of the target average deviation was -0.3 mm, -0.2 mm, and 0.0 mm in vertical, lateral, and longitudinal direction, respectively. The prostate was found within 1 mm from its initial position in 83.9% of the treatment time, between 1 and 2 mm in 13.0%, and exceeds 2 mm only in 3.1%.

CLINICAL RELEVANCE/APPLICATION

Linac-based SBRT by means of VMAT-FFF technique coupled with daily image guidance including real-time EM tracking allowed dose-escalated treatment with negligible early side effects.

SSNR02-1   Profiles Of Resting State Functional Connectivity In Temporal Lobe Epilepsy Associated With Post-Laser Interstitial Thermal Therapy Seizure Outcomes

Participants
Mashaal Syed, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

This work seeks to evaluate whether patients with Temporal Lobe Epilepsy (TLE) with Mesial Temporal Sclerosis (MTS) who underwent Laser Interstitial Thermal Therapy (LiTT) display unique functional connectivity patterns; specifically in regards to those who experienced post-operative seizure freedom (SF) and those who did not experience post-operative seizure freedom (nSF) as determined by a 12 month follow up.*Methods and Materials The resting state functional MRIs of 17 controls (NC) (aged 21 - 35 years), 16 left-sided TLE-MTS SF (aged 31 - 66 years), and 16 left-sided TLE-MTS nSF (aged 23 - 69 years) were compared to determine the unique functional connectivity patterns with respect to seizure outcomes. This regions of interest (ROI)-to-ROI connectivity analysis encompassed a total of 171 ROIs, and accounted for age and duration of epileptic activity. Significant correlations were determined via two-sample t-tests and bonferroni correction with an alpha value of 0.05.*Results Comparing NC with the SF group depicted significant correlation between the contralateral (CL) superior frontal gyrus and the ipsilateral (IL) cerebellar hemisphere, lobule IX (p-value= 1.14e-4, mean z-score = -0.11 (SD 0.21), T = 4.46). Comparison of NC with the nSF group revealed significant correlation between the CL amgydala and the CL precuneus (p-value = 1.1e-5, mean z-score = -0.11 (SD 0.19), T= 5.29), as well as between the CL locus coreuleus and the CL anterior pulvinar (p-value = 5.7e-5, mean z-score = 0.09 (SD 0.17), T = -4.71). Between the SF and nSF groups, significant correlation was observed between the CL amgydala and the CL precuneus (p-value= 2.9e-5, mean z-score = -0.12 (SD 0.19), T = 4.98), as well as between the CL locus coreuleus and the IL intralaminar nucleus (p-value= 1.37e-4, mean z-score = 0.06 (SD 0.17), T = -4.41).*Conclusions Disruption in widespread network function - such as within the cerebellar, limbic, and thalamo-arousal networks - is more observed in nSF, as they exhibit bilateral alterations; in contrast, solely unilateral changes were observed in SF. Overall, with respect to post-surgical outcomes, we have demonstrated hyperactivity in the thalamo-arousal network of nSF in comparison to SF and NC.*Clinical Relevance/Application These very different activity patterns associated with post-operative outcomes may help explain why TLE often disrupts widespread network function, and thus, may provide insights to guide future treatment modalities.

RESULTS

Comparing NC with the SF group depicted significant correlation between the contralateral (CL) superior frontal gyrus and the ipsilateral (IL) cerebellar hemisphere, lobule IX (p-value= 1.14e-4, mean z-score = -0.11 (SD 0.21), T = 4.46). Comparison of NC with the nSF group revealed significant correlation between the CL amgydala and the CL precuneus (p-value = 1.1e-5, mean z-score = -0.11 (SD 0.19), T= 5.29), as well as between the CL locus coreuleus and the CL anterior pulvinar (p-value = 5.7e-5, mean z-score = 0.09 (SD 0.17), T = -4.71). Between the SF and nSF groups, significant correlation was observed between the CL amgydala and the CL precuneus (p-value= 2.9e-5, mean z-score = -0.12 (SD 0.19), T = 4.98), as well as between the CL locus coreuleus and the IL intralaminar nucleus (p-value= 1.37e-4, mean z-score = 0.06 (SD 0.17), T = -4.41).

CLINICAL RELEVANCE/APPLICATION

These very different activity patterns associated with post-operative outcomes may help explain why TLE often disrupts widespread network function, and thus, may provide insights to guide future treatment modalities.

SSNR02-2   Interaction Of The Salience Network, Ventral Attention Network, Dorsal Attention Network And Default Mode Network In Neonates And Early Development Of The Bottom-up Attention System

Participants
Valeria Onofri, Rome, Italy (*Presenter*) Nothing to Disclose

PURPOSE

The Salience Network (SN), Ventral Attention Network (VAN), Dorsal Attention Network (DAN) and Default Mode Network (DMN) have shown significant interactions and overlapping functions in bottom-up and top-down mechanisms of attention. In the present study we tested if the SN, VAN, DAN and DMN connectivity can infer the gestational age (GA) at birth. We also ascertained whether the connectivity of SN, VAN, DAN and DMN are able to infer the average functional connectivity of each other network.*Methods and Materials A total of 88 healthy neonates with a gestational age (GA) at birth from 28 weeks to 40 weeks were studied with resting state fMRI on a 3T scanner. The ability to infer GA at birth or another network's connectivity was evaluated using a multi-variate data-driven framework. A mediation analysis was also performed to determine whether the cross-validated inference on GA at birth using VAN acted as a mediator on the cross-validated inference on GA at birth using DMN and DAN.*Results The VAN, DAN and the DMN infer the GA at birth (p<0.05). The SN connectivity was found unable to infer the GA at birth (p>0.05). The SN, DMN and VAN were able to infer the average connectivity over the other networks (p<0.05). Mediation

analysis between VAN's and DAN's inference on GA found reciprocal transmittance of change of VAN's and DAN's connectivity (p<0.05).*Conclusions Our findings suggest that the VAN has a prominent role in the bottom-up salience detection in early infancy and that the VAN and the SN may overlap in their roles of bottom-up control of attention.The SN was the only network in our analysis unable to infer the gestational age at birth. This finding may indicate that the stage of maturation of the SN at birth might be too advanced to infer the GA.*Clinical Relevance/Application This is the first study performed with a on a cohort oh neonates with a multi-variate data-driven framework (i.e. Machine Learning framework) to suggest a prominent role of the VAN in the bottom-up salience detection in early infancy and that the VAN and the SN may overlap in their roles of bottom-up control of attention. We also found reciprocal influence of VAN and DAN on the development of each other network.

RESULTS

The VAN, DAN and the DMN infer the GA at birth (p<0.05). The SN connectivity was found unable to infer the GA at birth (p>0.05). The SN, DMN and VAN were able to infer the average connectivity over the other networks (p<0.05). Mediation analysis between VAN's and DAN's inference on GA found reciprocal transmittance of change of VAN's and DAN's connectivity (p<0.05).

CLINICAL RELEVANCE/APPLICATION

This is the first study performed with a on a cohort oh neonates with a multi-variate data-driven framework (i.e. Machine Learning framework) to suggest a prominent role of the VAN in the bottom-up salience detection in early infancy and that the VAN and the SN may overlap in their roles of bottom-up control of attention. We also found reciprocal influence of VAN and DAN on the development of each other network.

SSNR02-3 Diffusion Microstructure Imaging In Progressive Supranuclear Palsy: Reduced Axonal Volumes In The Superior Cerebellar Peduncles, Dentato-rubro-thalamic Tract, Ventromedial Thalami And Fronto-mesial White Matter

Participants
Alexander Rau, MD, Freiburg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

The differentiation between Parkinson´s disease (PD) and atypical Parkinson syndromes such as progressive supranuclear palsy (PSP), multiple system atrophy (MSA) and corticobasal degeneration is challenging in clinical practice. We evaluated whether diffusion microstructure imaging (DMI; calculation of diffusivities and volume fractions of intra- and extra-axonal and csf-compartments based on multishell-DWI) enables the identification of PSP patients within a cohort of suspected atypical parkinsonism.*Methods and Materials In a retrospective study, DMI parameters were analyzed in patients with clinically suspected atypical parkinsonism syndromes and healthy controls (HC). Between 2018 and 2020, an exploration cohort was used to identify Voxel- and Region-based differences and to calculate cut-off values in a receiver operating characteristic analysis. Afterwards, the accuracy was tested on a single subject level.*Results In the exploration cohort, 52 PSP patients were compared to 20 PD, 26 MSA, and 7 corticobasal syndrome patients, as well as 25 HC. PSP patients showed widespread intraaxonal volume loss in the superior cerebellar peduncles, the dentato-rubro-thalamic tracts, the ventromedial thalami and the frontal white matter (each p<0.001). Especially the ventromedial thalami showed a high area under the curve of 0.899 between PSP and others. The validation cohort (n=25) consisted of 12 PSP patients, eight with PD, four with MSA, while one patient had no final diagnosis of parkinsonism. The accuracy of the DMI approach in identifying PSP patients was confirmed in the thalamus and the frontal white matter (accuracy 0.96 each).*Conclusions DMI reveals a characteristic regional pattern of axonal degeneration in PSP patients. This fits well with published regions of specific changes in PSP in terms of atrophy and alterations in diffusion weighted imaging.*Clinical Relevance/Application DMI might be used to identify PSP patients on an individual level in a collective with suspected atypical Parkinson syndromes.

RESULTS

In the exploration cohort, 52 PSP patients were compared to 20 PD, 26 MSA, and 7 corticobasal syndrome patients, as well as 25 HC. PSP patients showed widespread intraaxonal volume loss in the superior cerebellar peduncles, the dentato-rubro-thalamic tracts, the ventromedial thalami and the frontal white matter (each p<0.001). Especially the ventromedial thalami showed a high area under the curve of 0.899 between PSP and others. The validation cohort (n=25) consisted of 12 PSP patients, eight with PD, four with MSA, while one patient had no final diagnosis of parkinsonism. The accuracy of the DMI approach in identifying PSP patients was confirmed in the thalamus and the frontal white matter (accuracy 0.96 each).

CLINICAL RELEVANCE/APPLICATION

DMI might be used to identify PSP patients on an individual level in a collective with suspected atypical Parkinson syndromes.

SSNR02-4 Role Of Shear Wave Elastography In Assessment Of Hypoxic Ischemic Injury (HII) In Preterm Neonates

Participants
Anjuna Reghunath, MD,MBBS, New Delhi, India (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the utility of ultrasound shear wave elastography (SWE) in determining the difference in brain stiffness in preterm neonates who had a history of asphyxia at birth as compared to preterm neonates who cried at birth (no history of asphyxia).*Methods and Materials A pilot study using shear wave elastography of the neonatal brain was performed in 40 preterm neonates (range of gestational age 28-37 weeks), of which 20 had clinically diagnosed hypoxic ischemic injury (HII), while the remaining 20 had no history of asphyxia. Stiffness was measured as Young's modulus (KPa) at 4 points: right and left ganglio-capsulo-thalamic region (deep gray nuclei) and the right and left periventricular parieto-occipital white matter (POWM). Mean and standard deviation was calculated at each of the 4 points for cases and controls respectively.*Results Mean (KPa) with standard deviation at each of the 4 points was as follows in the preliminary evaluation of data in the study: right deep gray nuclei (4.4295 ±2.36), left deep gray nuclei (4.65 ±2.42), right POWM (4.9865 ±3.3), and left POWM (5.272 ±2.7) for preterm neonates with asphyxia. Mean with standard deviation for preterm neonates without asphyxia was: right deep gray nuclei (4.7455±2.12), left deep gray nuclei (4.7305±2.26), right POWM (5.9045±2.23), and left POWM (6.0205±2.34).*Conclusions The stiffness in bilateral periventricular white matter as well as in deep gray nuclei was found to be slightly lower in preterm neonates with a clinical history of birth asphyxia as compared to preterm neonates without similar history, suggesting that the areas with brain injury are softer.*Clinical Relevance/Application Cranial ultrasound is commonly used to evaluate the neonatal brain in HII. However, it may be

limited by its lack of sensitivity and specificity. SWE might provide additional information to conventional gray-scale imaging and improve its specificity.

RESULTS

Mean (KPa) with standard deviation at each of the 4 points was as follows in the preliminary evaluation of data in the study: right deep gray nuclei (4.4295 ±2.36), left deep gray nuclei (4.65 ±2.42), right POWM (4.9865 ±3.3), and left POWM (5.272 ±2.7) for preterm neonates with asphyxia. Mean with standard deviation for preterm neonates without asphyxia was: right deep gray nuclei (4.7455±2.12), left deep gray nuclei (4.7305±2.26), right POWM (5.9045±2.23), and left POWM (6.0205±2.34).

CLINICAL RELEVANCE/APPLICATION

Cranial ultrasound is commonly used to evaluate the neonatal brain in HII. However, it may be limited by its lack of sensitivity and specificity. SWE might provide additional information to conventional gray-scale imaging and improve its specificity.

SSNR02-5 High-resolution MR Microscopy Of Hippocampus WITH SUBFIELD MAPPING In Patients With Mesial Temporal Sclerosis And Temporal Lobe Epilepsy For Prediction Of Post Operative Outcomes - A Multiparametric In-vivo And Histopathological Correlation Study

Participants
Rammohan Vadapalli, MD, Hyderabad, India (*Presenter*) Research Consultant, General Electric Company

PURPOSE

To correlate the Findings of in vivo MR microscopy of hippocampi and their subfields to Histopathology in patients with hippocampal sclerosis and its Surgical outcomes. *Methods and MaterialsStudy design: Prospective observational cohort study12 age and sex-matched normal controls and 125 patients with refractory temporal lobe epilepsy with definitive exclusion and inclusion criteria with IRB approval were Imaged on High field 3T MR system (Ingenia Philips Health care, Netherlands) using MR Microscopy sequences with a sub-mm resolution with 3D T1 .T2, FLAIR and Dual inversion recovery sequences. Hippocampal Subfield Mapping performed using ITK snap manual segmentation method and correlated with Histopathology and post-surgical outcomes*Results The present study results indicate a high correlation between MR microscopy and pathology to detect the abnormalities in the various segments of the Hippocampus and the temporal lobe. The sensitivities and specificities for HS detection, lateralization, and dual pathologies appear optimal with a strong correlation between MRI subfield mapping and Histopathology.*Conclusions The Pre surgical evaluation of HS using High-resolution Microscopy and subfield mapping of the Hippocampus enables the visualization of its internal architecture, region-specific epileptogenic substrates with the prediction of surgical outcomes.*Clinical Relevance/Application Clinical dilemmas and challenges exist in managing drug-resistant temporal lobe epilepsies due to the most common principal epileptogenic substrate, "Hippocampal sclerosis with sub-optimal long-term outcome of surgery despite the best surgical resection. This was the primary motivation for this study. histopathology.This study will impact the present TLE protocols for evidence-based Prognostic classification of patients with TLE and HS and has a future potential to bridge the gaps in the management of TLE -by offering preoperative intelligent predictive outcome analysis to improve patient selection for surgery by in Vivo Imaging -Increase the Sensitivity and specificity of HS detection and accurate lateralization even in the absence of atrophy or volume loss including MR negative occult coexisting dual pathologies in mesial temporal lobe structures (uncus, amygdala, parahippocampal gyrus)

RESULTS

The present study results indicate a high correlation between MR microscopy and pathology to detect the abnormalities in the various segments of the Hippocampus and the temporal lobe. The sensitivities and specificities for HS detection, lateralization, and dual pathologies appear optimal with a strong correlation between MRI subfield mapping and Histopathology.

CLINICAL RELEVANCE/APPLICATION

Clinical dilemmas and challenges exist in managing drug-resistant temporal lobe epilepsies due to the most common principal epileptogenic substrate, "Hippocampal sclerosis with sub-optimal long-term outcome of surgery despite the best surgical resection. This was the primary motivation for this study. histopathology.This study will impact the present TLE protocols for evidence-based Prognostic classification of patients with TLE and HS and has a future potential to bridge the gaps in the management of TLE -by offering preoperative intelligent predictive outcome analysis to improve patient selection for surgery by in Vivo Imaging -Increase the Sensitivity and specificity of HS detection and accurate lateralization even in the absence of atrophy or volume loss including MR negative occult coexisting dual pathologies in mesial temporal lobe structures (uncus, amygdala, parahippocampal gyrus)

SSNR02-6 Age-related Changes Of White Matter (WM) Microstructure In Autism Spectrum Disorder (ASD)

Participants
Clara Weber, New Haven, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

Previous studies of WM microstructure in children with ASD were limited by relatively small cohort size. We analyzed diffusion metrics of WM microstructure in 583 subjects from four different cohorts in the National Database of Autism Research.*Methods and Materials All imaging and clinical data of study cohorts with T1-weighted and diffusion tensor imaging (DTI) scans were retrieved. Using FSL, we generated Fractional Anisotropy (FA), Mean Diffusivity (MD), and Radial Diffusivity (RD) maps. Tract-based spatial statistics and a voxel-wise analysis were performed to compare ASD and typically developing individuals; using general linear models, we assessed the influences of age and ASD diagnosis. We also analyzed cortical thickness using voxel-based morphometry (VBM). Age is reported as median (interquartile) months.*Results Subjects from 4 study cohorts were included: (1) Infants ("A Longitudinal MRI Study of Infants at Risk for Autism"; age: 7(1) m, 34/121 ASD/control, 12% female); (2) toddlers ("Biomarkers of Autism at 12 months"; age: 33(12) m, 57/45 ASD/control, 16% female); (3) adolescents ("Multimodal Developmental Neurogenetics of Females with ASD" age: 158(51.5) m, 106/124 ASD/control, 48% female); and (4) young adults ("Atypical Late Neurodevelopment in Autism" age: 242(128.5) m, 67/29 ASD/control, 1.5% female). We find a pervasive age-related increase in FA across majority of WM tracts in all age-groups. In voxel-wise analysis, we find reduced FA among ASD subjects compared to controls within anterior/middle commissural tracts of corpus callosum only in adolescents (p=0.014) and young adults (p=0.007), but not infants (p=0.451) and toddlers (p=0.440). Corresponding increases in ASD-related MD and RD were found in young adults (p=0.003). Tract-based analysis also showed reduced ASD-related FA in the corpus callosum, after adjusting for age as covariate, among adolescents (p=0.026) and young adults (p=0.012), but not younger children (infants: p=0.316, toddlers: p= 0.861). In tract-based analysis, RD was increased in the corpus callosum of young adults after controlling for age (p=0.023). In VBM analysis, we found age-related decrease in cortical thickness of young adults, but without any significant differences related to ASD.*Conclusions In a large dataset with an age range of 1 to 50 years, we showed an age-related impairment of microstructural

integrity in anterior/middle corpus callosum commissural tracts among ASD patients compared to controls, starting in adolescence, and becoming more pronounced among young adults.*Clinical Relevance/Application Age-adjusted microstructural correlates of ASD can improve diagnostic algorithms and provide potential objective biomarkers to monitor treatment response.

RESULTS

Subjects from 4 study cohorts were included: (1) Infants ("A Longitudinal MRI Study of Infants at Risk for Autism"; age: 7(1) m, 34/121 ASD/control, 12% female); (2) toddlers ("Biomarkers of Autism at 12 months"; age: 33(12) m, 57/45 ASD/control, 16% female); (3) adolescents ("Multimodal Developmental Neurogenetics of Females with ASD" age: 158(51.5) m, 106/124 ASD/control, 48% female); and (4) young adults ("Atypical Late Neurodevelopment in Autism" age: 242(128.5) m, 67/29 ASD/control, 1.5% female). We find a pervasive age-related increase in FA across majority of WM tracts in all age-groups. In voxel-wise analysis, we find reduced FA among ASD subjects compared to controls within anterior/middle commissural tracts of corpus callosum only in adolescents (p=0.014) and young adults (p=0.007), but not infants (p=0.451) and toddlers (p=0.440). Corresponding increases in ASD-related MD and RD were found in young adults (p=0.003). Tract-based analysis also showed reduced ASD-related FA in the corpus callosum, after adjusting for age as covariate, among adolescents (p=0.026) and young adults (p=0.012), but not younger children (infants: p=0.316, toddlers: p= 0.861). In tract-based analysis, RD was increased in the corpus callosum of young adults after controlling for age (p=0.023). In VBM analysis, we found age-related decrease in cortical thickness of young adults, but without any significant differences related to ASD.

CLINICAL RELEVANCE/APPLICATION

Age-adjusted microstructural correlates of ASD can improve diagnostic algorithms and provide potential objective biomarkers to monitor treatment response.

SSIN06-1 Detection Of Racial/Ethnic Health Disparities In COVID-19 Patients Using A Deep Learning Chest Radiography Classifier

Participants

Ayis T. Pyrros, MD, Hinsdale, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

To detect health disparities among patients with coronavirus disease 2019 (COVID-19) by using a multitask neural network deep learning (DL) model, predicting comorbidities from frontal chest radiographs (CXRs) and associate them to self-reported race/ethnicity, relative to electronic health records (EHR).*Methods and Materials A multitask DL model was trained and tested on 14,121 ambulatory frontal CXRs from 2010 to 2019 at a single institution, modeling select comorbidities using the Medicare Advantage Hierarchical Condition Category (HCC) Risk Adjustment Model from electronic health records (EHRs) with PyTorch (version 1.7.1). Sex, age, and select HCC codes were then predicted on CXRs from ambulatory patients with COVID-19 (3/17/2020 to 10/24/2020) with CXRs dating back to 2018. The discriminatory ability of the DL model was assessed using area under receiver operating characteristic curve (AUC) compared to the HCC data from the EHR. Binominal logistical regression was then used to evaluate the relationship between the DL model predictions as independent variables and non-white/white as the dependent variable in R (version 4.0.3). CXR saliency maps and odds ratio plots were generated.*Results Among the 986 patients included, mean age was 50.3 years (median = 52, range = 15-97, IQR = 38); 656 were White (66%), 70 were Asian (7%), 130 were Hispanic (13%), 75 were African American (8%), and 55 were other or unknown (6%). AUC results with 95% confidence intervals for the DL model relative to EHR data were: diabetes with chronic complications 0.80 (0.76-0.85), morbid obesity 0.91 (0.88-0.94), congestive heart failure 0.88 (0.83-0.93), cardiac arrhythmias 0.81 (0.75-0.88), vascular disease 0.87 (0.84-0.90), chronic obstructive pulmonary disease 0.86 (0.80-0.91), and sex 0.99 (0.99-0.99). AUC for the DL comorbidity model in the prediction of self-reported race was 0.65 (0.62-0.69) versus the EHR 0.61 (0.55-0.62). DL predictions for COPD (OR = 0.01) and cardiac arrhythmias (OR= 0.004) were significant predictors for non-white race/ethnicity (P<.05), whereas for the EHR model only age (OR=0.01) was significantly associated.*Conclusions A multitask DL algorithm, using only frontal CXRs, was predictive of select comorbidities, and the comorbidity scores when modeled with logistic regression, were predictive of self-reported race/ethnicity with significant differences from the EHR.*Clinical Relevance/Application Unequal burden of comorbidities is a primary contributor to health disparities. Radiographic DL modeling can predict relevant comorbidities among COVID-19 patients, identifying those with health disparities who may benefit from mitigation.

RESULTS

Among the 986 patients included, mean age was 50.3 years (median = 52, range = 15-97, IQR = 38); 656 were White (66%), 70 were Asian (7%), 130 were Hispanic (13%), 75 were African American (8%), and 55 were other or unknown (6%). AUC results with 95% confidence intervals for the DL model relative to EHR data were: diabetes with chronic complications 0.80 (0.76-0.85), morbid obesity 0.91 (0.88-0.94), congestive heart failure 0.88 (0.83-0.93), cardiac arrhythmias 0.81 (0.75-0.88), vascular disease 0.87 (0.84-0.90), chronic obstructive pulmonary disease 0.86 (0.80-0.91), and sex 0.99 (0.99-0.99). AUC for the DL comorbidity model in the prediction of self-reported race was 0.65 (0.62-0.69) versus the EHR 0.61 (0.55-0.62). DL predictions for COPD (OR = 0.01) and cardiac arrhythmias (OR= 0.004) were significant predictors for non-white race/ethnicity (P<.05), whereas for the EHR model only age (OR=0.01) was significantly associated.

CLINICAL RELEVANCE/APPLICATION

Unequal burden of comorbidities is a primary contributor to health disparities. Radiographic DL modeling can predict relevant comorbidities among COVID-19 patients, identifying those with health disparities who may benefit from mitigation.

SSIN06-2 Deep Learning-based Natural Language Processing In Automating Imaging Protocol Selection

Participants

Jonathan Chung, MD, Chicago, Illinois (*Presenter*) Speaker, Veracyte, Inc;Consultant, Veracyte, Inc;Consultant, Boehringer Ingelheim GmbH;Speaker, Boehringer Ingelheim GmbH;Consultant, F. Hoffmann-La Roche Ltd;Speaker, F. Hoffmann-La Roche Ltd

PURPOSE

Mitigating the time-consuming protocol selection process by training state of the art deep learning-based natural language processing (NLP) systems. The proposed system is aimed to take as input free-form (unstructured) "Reason of Study" (RS) and/or "Study Description" (SD) texts posed by the examination orders and predict the protocol labels (PL) and/or body part labels (BL) as its output.*Methods and Materials The NLP-based protopcol selection models were developed using about 250,000 clinical orders along with corresponding protocol labels (PL) and body part labels (BL). Four state state of the art transformer-based deep learning systems, BERT-base, BioClinical BERT, DistilBERT, and RoBERTa, were fine-tuned with multi-label (linear/MLP) classifier at the

output. Each proposed system were trained and evaluated on a separate test set for the following cases of (input->output) pairs: Case1 (RS->PL), Case2 (RS->PL+BL), Case3 (RS+SD->PL), and Case4 (RS+SD->PL+BL). The number of unique protocol labels were 100 and the number of body parts were 12. Macro average F1 scores were calculated for each system and and each case scenario over the test of 50,000 reports.*Results Out of the four systems developed, the BERT-base yielded the best beformance. By fine-tuning and optimizing the hyperparameters of the learning the macro average F1 scores improved from 0.39, 0.27, 0.75, and 0.57 to of 0.45, 0.39, 0.79, and 0.66 for cases 1, 2, 3 and 4 respectively. And testing accuracy with inclusion of additional features went up from 0.75 to 0.93.*Conclusions The proposed system yields a protocol label prediction as well as a confidence score for this prediction, which in turn can be used by radiologists to amend their own or NLP-based system's protocol label proposals. Since significant increase in performance was seen when incorporating additional feature, we are in the process of adding lab values, allergies, renal function, and problem list data into our feature set and provide additional results.*Clinical Relevance/Application An NLP based automated protocoling algorithm could lead to substantial time savings for radiologist and cost savings to the hospital. This would allow centers to then allocate more resources to other tasks and clinical missions including direct patient care, education, and research.

RESULTS

Out of the four systems developed, the BERT-base yielded the best beformance. By fine-tuning and optimizing the hyperparameters of the learning the macro average F1 scores improved from 0.39, 0.27, 0.75, and 0.57 to of 0.45, 0.39, 0.79, and 0.66 for cases 1, 2, 3 and 4 respectively. And testing accuracy with inclusion of additional features went up from 0.75 to 0.93.

CLINICAL RELEVANCE/APPLICATION

An NLP based automated protocoling algorithm could lead to substantial time savings for radiologist and cost savings to the hospital. This would allow centers to then allocate more resources to other tasks and clinical missions including direct patient care, education, and research.

SSIN06-3   Visual Chest CT Score versus Artificial Intelligence For The Assessment Of COVID-19 Pneumonia Extension

Participants
Ignacio Soriano, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the feasibility and reliability of a visual semi-quantitative CT score for the assessment of disease burden in COVID-19 pneumonia compared to an automatic lung evaluation system.*Methods and Materials This retrospective study included 199 consecutive patients with COVID-19 pneumonia undergoing non-contrast chest CT, from 10th of March to 31st of July 2020. A chest radiologist with 16 years of experience calculated the CT extension score by visually estimating the degree of disease burden in each pulmonary lobe (from 0-4; 0=0%, 1 = 1-25%, 2 = 26-50%, 3 = 51-75% and 4>75%). The total CT score was obtained by summing the score of each lobe (from 0 to 20). Chest CT images were also analyzed by an automatic lung evaluation system (AI-Rad Companion Research CT Pneumonia Analysis v2.0; Siemens Healthineers), which automatically identifies the volume and percentage of the hyperdense pulmonary areas (both opacities and consolidations) corresponding to pneumonia. Degree of correlation between the visual score and the automatic detection system was assessed by the Spearman rank correlation coefficient.*Results A strong and statistically significant correlation was found between the total visual score given by the thoracic radiologist and the total percentage of lung opacities given by the AI (Rho = 0.817; p<0.001). Similar results were found for degree of involvement in each lobe (Rho RUL = 0.818; Rho RML = 0.774; Rho RLL = 0.796; Rho LUL = 0.803; Rho LLL = 0.804; p<0.001).*Conclusions The visual semi-quantitative score is an easy and widely available tool which provides a feasible and reliable assessment of the extension of COVID-19 pneumonia. The automatic lung evaluation system provides a more detailed analysis with accurate determination of the volume and percentage of lung involvement.*Clinical Relevance/Application Visual semi-quantitative chest CT score provides a prompt and objective degree of lung burden in patients with COVID-19 pneumonia, which could be of great value for its diagnosis and prognosis.

RESULTS

A strong and statistically significant correlation was found between the total visual score given by the thoracic radiologist and the total percentage of lung opacities given by the AI (Rho = 0.817; p<0.001). Similar results were found for degree of involvement in each lobe (Rho RUL = 0.818; Rho RML = 0.774; Rho RLL = 0.796; Rho LUL = 0.803; Rho LLL = 0.804; p<0.001).

CLINICAL RELEVANCE/APPLICATION

Visual semi-quantitative chest CT score provides a prompt and objective degree of lung burden in patients with COVID-19 pneumonia, which could be of great value for its diagnosis and prognosis.

SSIN06-6   Partially Automating The Workflow To Decrease Cherry Picking In An Academic Radiology Department

Participants
Andrew Sher, MD, Houston, Texas (*Presenter*) Nothing to Disclose

PURPOSE

An auto-assignment tool was deployed in our academic neuroradiology section to address their concern of uneven workloads which was primary attributed to cherry picking, but also decreased contribution by some. Using the partially automated workflow, non-stat MR and CT's were auto-assigned to individual radiologists 7a-5p weekdays, at 3 minute intervals. Stat studies remained unassigned, with the intent that higher capacity readers could preferentially interpret in a timely manner. Metrics to evaluate success were radiologists' compliance in interpreting assigned studies (a surrogate for improvement in cherry-picking) and change in workload variability using auto assignment. Error rates in peer learning and TATs for stat and non-stat were also compared before and following change to the new workflow.*Methods and Materials Study was HIPAA compliant and exempt from IRB approval. Data was retrieved from the radiology analytics platform, scheduling software, and peer learning database. Metrics (mean of assigned studies interpreted per radiologist, average wRVU/hr/radiologist, wRVU variability between radiologists, TAT's of stat and non-stat exams, and frequency of errors) were compared over 3 month time periods Jan-March 2020 and Jan-March 2021 (after changing to new workflow Dec 1, 2020), 7a-5p weekdays. Levene's and Fisher's exact tests were used for analysis.*Results Pre-intervention, there were 3430 exams, 650 stat (mean TAT 83 min) and 2780 non-stat (mean TAT 142 min) compared to 3536 in the post-intervention period (2021), 629 stat (mean TAT 59 min), and 2907 non-stat (mean TAT 144 min), with a significant decrease in stat TAT (p<0.0001), and no change in non-stat (p=0.61). Of assigned studies, 2535/2772 (91%) were read by the assigned

radiologist (range 48%-99%, mean 90%, median 96%). Using the new workflow, range of average hourly wRVU/radiologist decreased by 17.8% wRVU and standard deviation by 26.2%. There was no statistically significant difference in rates of errors submitted to the peer learning database with 9 errors/511 submissions (1.76%) before and 11/575 (1.91%) after (p=1).*Conclusions Using an auto-assignment workflow for non-stat daytime studies successfully addressed cherry picking and improved variability in productivity. Furthermore, TATs for stat studies was improved. Finally, the auto-assignment was not shown to effect error rates.*Clinical Relevance/Application By combining an auto-assignment managed workflow for non-stat studies and self-triage for stat exams, groups may be able to better meet demand by allowing the higher capacity readers to complete stat exams in a timely manner, while also decreasing cherry picking.

RESULTS

Pre-intervention, there were 3430 exams, 650 stat (mean TAT 83 min) and 2780 non-stat (mean TAT 142 min) compared to 3536 in the post-intervention period (2021), 629 stat (mean TAT 59 min), and 2907 non-stat (mean TAT 144 min), with a significant decrease in stat TAT (p<0.0001), and no change in non-stat (p=0.61). Of assigned studies, 2535/2772 (91%) were read by the assigned radiologist (range 48%-99%, mean 90%, median 96%). Using the new workflow, range of average hourly wRVU/radiologist decreased by 17.8% wRVU and standard deviation by 26.2%. There was no statistically significant difference in rates of errors submitted to the peer learning database with 9 errors/511 submissions (1.76%) before and 11/575 (1.91%) after (p=1).

CLINICAL RELEVANCE/APPLICATION

By combining an auto-assignment managed workflow for non-stat studies and self-triage for stat exams, groups may be able to better meet demand by allowing the higher capacity readers to complete stat exams in a timely manner, while also decreasing cherry picking.

SSMS01-2 Whole Body Low Dose Computed Tomography (WBLDCT) In Comparison With Whole Body Magnetic Resonance Imaging (WBMRI) In The Assessment Of Multiple Myeloma

Participants
Cammillo Talei Franzesi, Milan, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To compare the agreement between whole-body low-dose computed tomography (WBLDCT) and magnetic resonance imaging (WBMRI) in the evaluation of bone marrow involvement in patients with multiple myeloma (MM).*Methods and Materials Fifty-eight patients with biopsy-proven MM who underwent both WBLDCT (performed on a 256-slice scanner - iCT, Philips) and WBMRI (performed on a 1.5 T magnet -Ingenia, Philips, The Netherlands) were retrospectively enrolled. After identifying the infiltration pattern (focal, diffuse and combined), the whole skeleton was divided into five anatomic districts (skull, spine, sternum, and ribs, pelvis, limbs) and patients were grouped according to number and location of the lytic lesions (< 5, 5-20, and > 20), also according to Durie and Salmon PLUS system.*Results The agreement between CT and MRI regarding pattern, staging, lesion number and distribution was assessed using the Cohen Kappa statistics. According to both the diagnostic techniques, CT and MRI, the majority of patients showed a focal involvement, followed by diffuse and combined one. According to distribution and Durie Salmon staging, the agreement between CT and MRI was substantial or almost perfect for all patterns (all ? >0.60). The agreement increased proportionally with the number of lesions in the pelvis and spine (?=0.373 to ?=0.564, and ?=0.469 to ?=0.624), while for the skull the agreement proportionally decreased without reaching a statistically significant difference. WBLDCT showed an almost perfect agreement in the evaluation of pattern, staging, lesion number and distribution of bone involvement in comparison with WBMRI.*Conclusions WBLDCT is an effective imaging modality, useful to diagnose and stage MM patients, detecting even small osteolytic lesions. WBMRI should be considered to clarify inconclusive CT findings and those cases of MM-related osteopenia.*Clinical Relevance/Application WBLDCT should be considered a useful diagnostic tool in the evaluation of MM because it is cheaper, faster and less cumbersome if compared to WBMRI, maintaining a good overall diagnostic accuracy.

RESULTS

The agreement between CT and MRI regarding pattern, staging, lesion number and distribution was assessed using the Cohen Kappa statistics. According to both the diagnostic techniques, CT and MRI, the majority of patients showed a focal involvement, followed by diffuse and combined one. According to distribution and Durie Salmon staging, the agreement between CT and MRI was substantial or almost perfect for all patterns (all ? >0.60). The agreement increased proportionally with the number of lesions in the pelvis and spine (?=0.373 to ?=0.564, and ?=0.469 to ?=0.624), while for the skull the agreement proportionally decreased without reaching a statistically significant difference. WBLDCT showed an almost perfect agreement in the evaluation of pattern, staging, lesion number and distribution of bone involvement in comparison with WBMRI.

CLINICAL RELEVANCE/APPLICATION

WBLDCT should be considered a useful diagnostic tool in the evaluation of MM because it is cheaper, faster and less cumbersome if compared to WBMRI, maintaining a good overall diagnostic accuracy.

SSMS01-4 Trends In Cancer Imaging By Indication, Care Setting, And Hospital Type During The COVID-19 Pandemic And Recovery

Participants
Ottavia Zattra, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

The delivery of cancer care has been greatly affected by the COVID pandemic. We aim to investigate the effect of the pandemic on computed tomography (CT) imaging of cancer.*Methods and Materials Cancer-related CT exams were retrospectively analyzed during three periods of 2020: pre-COVID (1/5/20-3/14/20), COVID peak (3/15/20-5/2/20) and post-COVID peak (5/3/20-11/14/20). Volumes were assessed by 1) Imaging indication: cancer screening, initial workup, active cancer, surveillance; 2) Care setting: outpatient, inpatient, ED; 3) Hospital type: quaternary academic center (QAC), university-affiliated community hospital (UACH), sole community hospitals (SCHs).*Results During the COVID peak, a significant drop in CT volumes was observed (-42·2%, p<0·0001), with cancer screening, initial workup, active cancer and cancer surveillance experiencing declines by 81·7%, 54·8%, 30·7% and 44·7% respectively (p<0·0001). The emergency department (ED) was the only setting with stable cancer-related CT volumes. In the post-COVID peak period, CT volumes for cancer screening and for initial workup did not recover (-11·7%, p=0·037; -20·0%, p=0·031), with the outpatient setting particularly affected. CT volumes for active cancer recovered post-peak, but inconsistently across hospital types with the QAC experiencing a 9·4% decline (p=0·022) and the UACH a 41·5% increase (p<0·001). Outpatient CTs recovered during the post-peak period, but a shift in utilization away from the QAC (-8·7%, p=0·020)

toward the UACH (+13·3%, p=0·013) was observed. Inpatient and ED-based cancer-related CTs increased post-peak (+20·0%, p=0·004 and +33·2%, p=0·009, respectively).*Conclusions COVID severely impacted cancer imaging care. CTs for cancer screening and initial workup did not recover to pre-COVID levels well into 2020, a finding that suggests higher numbers of patients with advanced cancers may present in the future. A redistribution of imaging utilization away from the QAC and outpatient settings, toward the community hospitals and inpatient setting/ED was observed. The ED has remained a dependable healthcare delivery setting for patients with cancer throughout the pandemic.*Clinical Relevance/Application COVID has severely impacted cancer care, but few studies have explored its effects on cancer imaging in the late months of 2020. This study examines cancer imaging utilization during the COVID pandemic through November 2020.

RESULTS

During the COVID peak, a significant drop in CT volumes was observed (-42·2%, p<0·0001), with cancer screening, initial workup, active cancer and cancer surveillance experiencing declines by 81·7%, 54·8%, 30·7% and 44·7% respectively (p<0·0001). The emergency department (ED) was the only setting with stable cancer-related CT volumes. In the post-COVID peak period, CT volumes for cancer screening and for initial workup did not recover (-11·7%, p=0·037; -20·0%, p=0·031), with the outpatient setting particularly affected. CT volumes for active cancer recovered post-peak, but inconsistently across hospital types with the QAC experiencing a 9·4% decline (p=0·022) and the UACH a 41·5% increase (p<0·001). Outpatient CTs recovered during the post-peak period, but a shift in utilization away from the QAC (-8·7%, p=0·020) toward the UACH (+13·3%, p=0·013) was observed. Inpatient and ED-based cancer-related CTs increased post-peak (+20·0%, p=0·004 and +33·2%, p=0·009, respectively).

CLINICAL RELEVANCE/APPLICATION

COVID has severely impacted cancer care, but few studies have explored its effects on cancer imaging in the late months of 2020. This study examines cancer imaging utilization during the COVID pandemic through November 2020.

SSMS01-5 Improved Response Prediction Based On Dual Energy CT Radiomics In Patients With Stage IV Melanoma Before Immunotherapy

Participants
Andreas Brendlin, Tuebingen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To assess the additive value of dual energy CT (DECT) over single energy CT (SECT) to radiomics based response prediction in patients with metastatic melanoma undergoing immunotherapy.*Methods and Materials A total of 140 consecutive patients with melanoma (58 female, 63±16 years) for whom baseline DECT tumor load assessment revealed stage IV and who were subsequently treated with immunotherapy were included. Best response was determined using the clinical reports (81 responders: 27 complete response, 45 partial response, 9 stable disease). Individual lesion response was classified manually in the style of RECIST 1.1 through 1291 follow-up examinations on a total of 776 lesions (6.7±7.2 per patient). The patients were sorted chronologically into a study and a validation cohort (each n = 70). The baseline DECT was examined using specialized tumor segmentation software, and radiomic features were analyzed for response predictors. Significant features were selected using univariate statistics with Bonferroni correction and multiple logistic regression. The area under the curve of the best subset was computed (AUROC). A random forest classifier with 10-fold internal cross-validation was trained on the study cohort and tested on the validation cohort to confirm the predictive performance.*Results A total of 4074 timepoint evaluations were performed. Multivariate statistics selected significant features for patient response in SECT (min. brightness, AUROC = 0.67, MI = 0.077 R^2 = 0.112, padj. = 0.001) and DECT (textural coarseness, AUROC = 0.71, MI = 0.064, R^2 = 0.121, padj. = 0.001), as well as lesion response in SECT (mean absolute voxel intensity deviation, AUROC = 0.67, MI = 0.088 R^2 = 0.115, padj. = 0.001) and DECT (iodine uptake metrics, (AUROC = 0.88, MI = 0.1 R^2 = 0.12, padj. = 0.001) Machine-learning application validated the additive predictive power of DECT (patient response AUROC SECT = 0.5, DECT = 0.75; lesion response AUROC SECT = 0.61, DECT = 0.85; p < 0.001).*Conclusions The new method of DECT-specific radiomic analysis provides a significant additive value over SECT radiomics approaches for response prediction in patients with metastatic melanoma preceding immunotherapy, especially on a lesion-based level. As mixed tumor response is not uncommon in metastatic melanoma, this lends a powerful tool for clinical decision-making and may potentially be an essential step towards individualized medicine.*Clinical Relevance/Application Considering mixed responses under immunotherapy, this approach can be a powerful additional tool for oncological decision-making.

RESULTS

A total of 4074 timepoint evaluations were performed. Multivariate statistics selected significant features for patient response in SECT (min. brightness, AUROC = 0.67, MI = 0.077 R^2 = 0.112, padj. = 0.001) and DECT (textural coarseness, AUROC = 0.71, MI = 0.064, R^2 = 0.121, padj. = 0.001), as well as lesion response in SECT (mean absolute voxel intensity deviation, AUROC = 0.67, MI = 0.088 R^2 = 0.115, padj. = 0.001) and DECT (iodine uptake metrics, (AUROC = 0.88, MI = 0.1 R^2 = 0.12, padj. = 0.001) Machine-learning application validated the additive predictive power of DECT (patient response AUROC SECT = 0.5, DECT = 0.75; lesion response AUROC SECT = 0.61, DECT = 0.85; p < 0.001).

CLINICAL RELEVANCE/APPLICATION

Considering mixed responses under immunotherapy, this approach can be a powerful additional tool for oncological decision-making.

SSMS01-6 Prognostic Value Of Whole-body Low-dose CT (WBLDCT) In The Staging Of Patients With Multiple Myeloma (MM): A Long Term Follow-up

Participants
Davide Ippolito, MD, Monza, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the prognostic features of bone marrow involvement and behavior in patients with MM during a long period follow-up according to the dimensional parameter and infiltration pattern, using whole-body low-dose computed tomography (WBLDCT).*Methods and Materials 103 patients with a newly diagnosed MM who underwent WBLDCT (using a 256-slice scanner - iCT, Philips), every year during follow-up (minimum of three years) ,were retrospectively enrolled. The whole skeleton was divided into 5 anatomic districts and evaluated in terms of infiltration pattern. The evolution of osteolytic lesions over time was performed measuring the maximum axial diameter at the baseline (T0) and at the end of follow-up (Te). By using a cut-off value of 10 mm, we divided all lesions into "big lesions" (>10 mm) and "small lesions" (=10 mm). For each patient, location and dimension of up to 3 lesions were registered. Only a lytic lesion's dimensional increase or decrease of at least 2 mm was considered. The time-to-fracture (TTF), expressed in months, was recorded for each patient.*Results 63% of patients presented a focal pattern,22% a

diffuse pattern and 15% a combined one. The dimensional evolution of the small lesions demonstrated that 72% of patients presented stability, 1% showed a decrease and 27% an increase.Patients with big lesions showed a statistically significant difference regarding the mean difference of axial diameter between T0 and Te (p=0.015). During the whole follow-up period, 30 patients (29%) reported at least one bone fracture, most frequently in the pelvis (33%) and spine (66%), while patients with diffuse pattern didn't show any fracture (p<0.0001). Patients with big lesions showed an OR of 29.8 to develop at least one fracture during the follow-up period. Mean TTF was significantly lower in patients with big lesion in comparison with small ones (p=0.011).*Conclusions WBLDCT represents a reliable imaging-based tool for proper management of MM patients, useful to define the behavior of different bone involvement, showing that diffuse pattern or small lytic lesions may deserve a less frequent follow-up.*Clinical Relevance/Application WBLDCT represents a useful imaging based tool to correctly define management of MM patients along the course of follow-up.

RESULTS

63% of patients presented a focal pattern,22% a diffuse pattern and 15% a combined one. The dimensional evolution of the small lesions demonstrated that 72% of patients presented stability, 1% showed a decrease and 27% an increase.Patients with big lesions showed a statistically significant difference regarding the mean difference of axial diameter between T0 and Te (p=0.015). During the whole follow-up period, 30 patients (29%) reported at least one bone fracture, most frequently in the pelvis (33%) and spine (66%), while patients with diffuse pattern didn't show any fracture (p<0.0001). Patients with big lesions showed an OR of 29.8 to develop at least one fracture during the follow-up period. Mean TTF was significantly lower in patients with big lesion in comparison with small ones (p=0.011).

CLINICAL RELEVANCE/APPLICATION

WBLDCT represents a useful imaging based tool to correctly define management of MM patients along the course of follow-up.

SSIN02-2   Quantifying The Impact Of Structured Reporting On The Report Review Process And Turnaround Times Of Resident Reports In Neuroradiology

Participants
Jan Vosshenrich, MD, Basel, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To assess the effects of a change from free-text reporting to structured reporting on the report review process and turnaround times of resident reports over a 15-months period in the neuroradiology daily routine.*Methods and Materials Our neuroradiology section introduced in-house developed structured reporting templates for CT examinations in July 2019. Each report follows the same evolution in our RIS and passes through several states (i.e. draft, preliminary and final report). Residents predictate all studies without exception as "draft reports". Following joint read-out with an attending, residents sent corrected "preliminary reports" for final review and sign-off by the respective staff radiologist as "final reports". Reports dictated by residents during dayshifts from January 2019 to March 2020 were retrospectively assessed using quantitative parameters from report comparison. Through automatic analysis of text-string differences between report states, Jaccard similarities and edit distances between report states were calculated overall and for distinct reporting templates. Furthermore, turnaround times until preliminary and final report availability to clinicians were investigated. Parameters were visualized as trending line graphs and statistically compared between reporting standards using an independent Student's t-test or Mann-Whitney U test (significance level p<0.05).*Results 3,538 reports were included into analysis. Mean Jaccard similarity of resident drafts and staff-reviewed final reports increased from 0.53±0.37 to 0.79±0.22 after the introduction of structured reporting (p<.001). Both mean overall edits on draft reports by residents following read-out sessions (0.30±0.45 vs. 0.09±0.29; p<.001) and by staff radiologists during report sign-off (0.17±0.28 vs. 0.12±0.23, p=.001) decreased. Similar results were seen for most distinct reporting templates. With structured reporting, mean turnaround time until preliminary report availability to clinicians decreased by 20.7 minutes (246.9±207.0 vs. 226.2±224.9; p<.001). Similarly, final reports were available 35.0 minutes faster on average (558.0±515.1 vs. 523.0±497.3; p=.002).*Conclusions With structured reporting, resident draft reports require fewer edits during the report review process. This reduction in proofreading workload is likely responsible for substantially lower report turnaround times.*Clinical Relevance/Application Structured reporting is beneficial for residents and staff radiologists in the neuroradiology daily routine, as it facilitates and accelerates the report review process through higher overall report correctness / completeness compared to traditional free-text reports.

RESULTS

3,538 reports were included into analysis. Mean Jaccard similarity of resident drafts and staff-reviewed final reports increased from 0.53±0.37 to 0.79±0.22 after the introduction of structured reporting (p<.001). Both mean overall edits on draft reports by residents following read-out sessions (0.30±0.45 vs. 0.09±0.29; p<.001) and by staff radiologists during report sign-off (0.17±0.28 vs. 0.12±0.23, p=.001) decreased. Similar results were seen for most distinct reporting templates. With structured reporting, mean turnaround time until preliminary report availability to clinicians decreased by 20.7 minutes (246.9±207.0 vs. 226.2±224.9; p<.001). Similarly, final reports were available 35.0 minutes faster on average (558.0±515.1 vs. 523.0±497.3; p=.002).

CLINICAL RELEVANCE/APPLICATION

Structured reporting is beneficial for residents and staff radiologists in the neuroradiology daily routine, as it facilitates and accelerates the report review process through higher overall report correctness / completeness compared to traditional free-text reports.

SSIN02-3   Using Natural Language Processing To Derive A Structured Classification Of Lumbar Spine Pathologies From Unstructured MR Reports

Participants
JinHyeong Park, PhD, New York, New York (*Presenter*) Employee, Covera Health

PURPOSE

Create a robust automated pipeline that transforms freeform lumbar spine MR report text into a structured grid of pathologies with severity for each lumbar disc level.*Methods and Materials The dataset includes 1,223 expert-labeled lumbar MR reports with 5,431 distinct motion segment-specific findings (MS). This dataset was split into 531 studies for training (2,479 MS), 303 studies for validation (1,353 MS) and 389 studies for testing (1,599 MS). Additionally, weakly-supervised learning added an additional 7,032 MS

text segments to the training dataset to enhance generalizability. The NLP pipeline for structured report classification consists of three models for information extraction and segmentation. First, a custom named entity recognition model based on an Ordered Neuron LSTM was used to classify motion segment token spans. Next, we concatenated text and findings associated to motion segments, using a heuristic based on sentence boundaries and proximity to motion segment text spans. Finally, we trained a BERT-based architecture with our own radiology-specific language model on three relevant lumbar spine pathologies: central canal stenosis (CCS), disc herniation (DH) and nerve root impingement (NR). Pathologies were classified categorically, CCS into "None/Mild", "Moderate" or "Severe"; DH into "None", "Small", or "Moderate/Large"; and NR into "None" or "Present".*Results Across CCS, DH and NR, the unweighted average (macro) sensitivity was 0.93 and specificity was 0.96. CCS had an unweighted average (macro) sensitivity of 0.96 and specificity of 0.98. DH had an unweighted average (macro) sensitivity of 0.91 and specificity of 0.96. NR had an unweighted average (macro) sensitivity of 0.93 and specificity of 0.93.*Conclusions A deep learning pipeline is able to compress the diversity of language expressions present in lumbar spine MR reports into a predefined, structured format with a high accuracy and may be suitable for use in standardizing radiology study reporting and data mining.*Clinical Relevance/Application Transforming freeform MR reports into tabular lists of findings yields source data for quality and outcome metrics including accuracy, cohort selection, response to therapy, and correlation analysis. The information presented in this paper is based on research results that are not commercially available.

RESULTS

Across CCS, DH and NR, the unweighted average (macro) sensitivity was 0.93 and specificity was 0.96. CCS had an unweighted average (macro) sensitivity of 0.96 and specificity of 0.98. DH had an unweighted average (macro) sensitivity of 0.91 and specificity of 0.96. NR had an unweighted average (macro) sensitivity of 0.93 and specificity of 0.93.

CLINICAL RELEVANCE/APPLICATION

Transforming freeform MR reports into tabular lists of findings yields source data for quality and outcome metrics including accuracy, cohort selection, response to therapy, and correlation analysis. The information presented in this paper is based on research results that are not commercially available.

SSIN02-4 Automated De-identification Pipeline For Radiology Reports Combining Transformer And "Hide In Plain Sight" Rule-based Model

Participants
Pierre Chambon, BS, Stanford, California (*Presenter*) Nothing to Disclose

PURPOSE

Develop a de-identification pipeline to localize and classify personal health information (PHI) in radiology reports, replacing it with similar but fake information.*Methods and Materials The developed pipeline uses a transformer trained to classify radiology report tokens into PHI classes. The model was trained on a multi-institutional cohort (14 million unlabeled X-ray and CT reports containing PHI) and fine-tuned on 1000 labeled reports. We compared several pre-training approaches and fine-tuning methods, selected using Bayesian optimization with a tree-structured Parzen estimator. Then, a rule-based algorithm replaced annotated PHI with fake PHI (i.e., "hide in plain sight"). The replacement algorithm mimicked the format and content of the input data, and integrated a two-speed memory and document-level constraints to maintain the coherence of the fake PHI within and among reports. In addition, it could be used as a generator to perform data augmentation for the transformer. The algorithm was evaluated on a separate test set of 220 CT and X-ray reports.*Results Six classes of PHI were present in the training data: vendor, date, healthcare worker, hospital, and identifier. The optimal transformer model achieved a macro-averaged F1-score of 96.0 (95.6 recall, 96.5 precision). For the two most frequent PHI classes in the reports, date and healthcare worker, the model achieved F1 scores of 99.8 (99.9 recall, 99.5 precision) and 98.3 (99.3 recall, 97.3 precision) respectively. Lower performance was achieved for the remaining classes due to their scarcity in the training set. In a head-to-head comparison, our transformer had higher precision and similar recall to other publicly available de-identification algorithms. It enabled a large statistical study of PHI distribution in radiology reports.*Conclusions A transformer pipeline provides highly accurate de-identification of radiology reports. A "hide in plain sight" de-identification step helps prevent discovery of any remaining PHI.*Clinical Relevance/Application A de-identification model designed specifically for radiology reports ensured successful removal of almost all commonly occurring PHI classes, enabling wider distribution of radiology reports for research purposes.

RESULTS

Six classes of PHI were present in the training data: vendor, date, healthcare worker, hospital, and identifier. The optimal transformer model achieved a macro-averaged F1-score of 96.0 (95.6 recall, 96.5 precision). For the two most frequent PHI classes in the reports, date and healthcare worker, the model achieved F1 scores of 99.8 (99.9 recall, 99.5 precision) and 98.3 (99.3 recall, 97.3 precision) respectively. Lower performance was achieved for the remaining classes due to their scarcity in the training set. In a head-to-head comparison, our transformer had higher precision and similar recall to other publicly available de-identification algorithms. It enabled a large statistical study of PHI distribution in radiology reports.

CLINICAL RELEVANCE/APPLICATION

A de-identification model designed specifically for radiology reports ensured successful removal of almost all commonly occurring PHI classes, enabling wider distribution of radiology reports for research purposes.

SSIN02-5 Transformer Versus Traditional Natural Language Processing: How Much Data Is Enough For Automated Radiology Report Classification?

Participants
Eric Yang, BS, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Current state-of-the-art natural language processing (NLP) techniques use transformer deep learning architectures but depend on large datasets for training. We hypothesized that traditional NLP techniques may offer superior performance over transformers for smaller radiology report datasets.*Methods and Materials We compared the performance of different NLP models for the classification of medial (MM) or lateral (LM) meniscus tears on free-text knee MRI radiology reports from a single institution obtained from January 1, 2018 to December 31, 2018 (training set N=2861, test set N=726). The models trained included: (1) gradient boosted tree (XGBoost) model with features engineered using bag-of-words, (2) XGBoost model using medical entities extracted from the Clinspacy library, (3) XGBoost model using text embeddings from Clinspacy, and (4) BioBERT, a deep learning-based transformer model pre-trained on biomedical text. The NLP models were trained on the full training set and 2.5%, 10%, 25%, 50%

and 75% random subsets of the original training data. All models were evaluated on the test set.*Results Using all training data, BioBERT achieved the highest classification performance for MM and LM tear detection on knee MRI reports (MM F1 score 0.98, LM F1 score 0.96), followed by XGBoost with bag-of-words features (MM F1 score 0.94, LM F1 score 0.88), XGBoost with clinspacy medical entities features (MM F1 score 0.86, LM F1 score 0.75), and XGBoost with clinspacy embeddings (MM F1 score 0.84, LM F1 score 0.69). The performance for all models decreased as the training sample size decreased. This effect was most prominent for the BioBERT model, where at 2.5% of the training data, its performance (MM F1 score 0.44, LM F1 score 0.39) was lower than that of the XGBoost with bag-of-words features (MM F1 score 0.89, LM F1 score 0.74).*Conclusions With larger sample sizes, a deep learning-based transformer NLP model (BioBERT) achieved superior performance in radiology report classification; however, with smaller sample sizes (<1000), a traditional NLP technique (XGBoost with bag-of-words) may perform better.*Clinical Relevance/Application NLP is being increasingly used to automate analysis of radiology reports (e.g. clinical research, quality improvement). The best NLP method for a task may depend on the training dataset size.

RESULTS

Using all training data, BioBERT achieved the highest classification performance for MM and LM tear detection on knee MRI reports (MM F1 score 0.98, LM F1 score 0.96), followed by XGBoost with bag-of-words features (MM F1 score 0.94, LM F1 score 0.88), XGBoost with clinspacy medical entities features (MM F1 score 0.86, LM F1 score 0.75), and XGBoost with clinspacy embeddings (MM F1 score 0.84, LM F1 score 0.69). The performance for all models decreased as the training sample size decreased. This effect was most prominent for the BioBERT model, where at 2.5% of the training data, its performance (MM F1 score 0.44, LM F1 score 0.39) was lower than that of the XGBoost with bag-of-words features (MM F1 score 0.89, LM F1 score 0.74).

CLINICAL RELEVANCE/APPLICATION

NLP is being increasingly used to automate analysis of radiology reports (e.g. clinical research, quality improvement). The best NLP method for a task may depend on the training dataset size.

SSIN02-6 Automated Detection Of Adrenal Nodules In Radiology Reports: Proof Of Concept For Using Recurrent Neural Networks For Cohort Creating Using Radiology Reports.

Participants
Jayashree Kalpathy-Cramer, MS, PhD, Charlestown, Massachusetts (*Presenter*) Institutional Research Grant, General Electric Company;Institutional Research Grant, F. Hoffmann-La Roche Ltd

PURPOSE

Inferring the presence of distinct types of conditions from free-text reports is an important and common task in radiology, including the development of cohorts for machine learning (ML). We develop and test a two-step architecture - Long Short-Term Memory (LSTM) + Support Vector Machine, to automatically detect and classify the presence of adrenal nodules in radiology reports.*Methods and Materials The data cohort consists of 16,372 non-annotated reports and 1060 annotated reports (class balance: normal - 994 (93.77%), mass - 65 (6.23%). The annotated set is randomly partitioned at the report level with 70, 15, and 15% of reports used for algorithm training, validation, and testing, respectively. The text pertaining to the adrenal glands is filtered and embedded using the ClinicalBERT model. A bidirectional LSTM cell extracts features from these embeddings which are then processed by densely connected layers to produce logits; a binary cross-entropy loss function and an argmax function determine the final class predicted by the model. The model was further tested on the non-annotated data, and samples that were predicted as positive by this model (1015 in number) are subsequently labeled by a radiologist into six adrenal gland classes (surgically absent, mass, metastasis (>1cm and <1cm), normal, thickening, and unknown) on which a linear support vector classifier (SVC) is trained to perform multiclass classification.*Results The algorithm achieved an AUROC of 95%, an accuracy of 99%, and an F1 score of 95% with respect to the positive class when evaluated on the test set for binary classification. The false-positive rate was 10% while the false-negative rate was 0%. The accuracy of the subsequent SVC was 88% with the mass, surgically absent, and normal classes having F1 scores > 80%. The most frequently confused classes were found to be mass and thickening.*Conclusions By using context-specific embeddings from ClinicalBERT, an LSTM-based architecture, and an SVC, the presence of medical conditions in free-text medical reports can be inferred with high accuracy as demonstrated through the inference of the presence of adrenal nodules in radiology reports.*Clinical Relevance/Application The model is most useful for ML cohort creation using radiology reports and can be expanded to other use-cases, body parts, and modalities. Retrospective review for quality improvement purposes and epidemiological studies would also be greatly facilitated.

RESULTS

The algorithm achieved an AUROC of 95%, an accuracy of 99%, and an F1 score of 95% with respect to the positive class when evaluated on the test set for binary classification. The false-positive rate was 10% while the false-negative rate was 0%. The accuracy of the subsequent SVC was 88% with the mass, surgically absent, and normal classes having F1 scores > 80%. The most frequently confused classes were found to be mass and thickening.

CLINICAL RELEVANCE/APPLICATION

The model is most useful for ML cohort creation using radiology reports and can be expanded to other use-cases, body parts, and modalities. Retrospective review for quality improvement purposes and epidemiological studies would also be greatly facilitated.

SSGI05-2   Federated Versus Centralized Deep-learning Models For Liver And Tumor Segmentation In Multi-center Hepatic CT Datasets

Participants
Guibo Luo, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

This study was to develop and evaluate a reliable federated deep-learning for liver and tumor segmentation in multi-center hepatic CT datasets with different distributions.*Methods and Materials We retrospectively collected 667 contrast-enhanced venous phase abdominal CT scans, including 131 scans from LiTS (siteA), 405 scans from China (siteB), and 131 scans from US (siteC). These datasets were acquired by different scanners and protocols from different clinical sites, with a largely varying in-plane resolution from 0.55 mm to 1.0 mm and slice thickness from 0.45 mm to 6.0 mm. SiteA mainly contains small, metastatic tumors, siteB contains multiple types of tumors, and siteC mainly contains large, malignant tumors. All CT scans were randomly divided into 550 scans (82%) for training, and 117 scans (18%) for testing.For preprocessing, the 12-bit CT images were mapped to 8-bit images via a liver CT window-level setting, and each slice was concatenated with its two adjacent slices to utilize spatial and temporal information. Then, we trained five 2.5D UNet models for segmentation of liver and tumor, including three standard single-site models trained on each of local datasets, a single centralized model trained on a dataset consisting of the three local datasets, and a federated model with local batch normalization (BN). Specifically, the proposed federated learning model kept the BN layers updated locally without aggregating scheme. The Dice coefficient (Dice) was used as the evaluation metric.*Results For liver segmentation in testing data, the Dice of single model, centralized model, and federated model with localBN were 0.958, 0.959, 0.962 at siteA, and 0.979, 0.966, 0.969 at siteB, and 0.939, 0.937, 0.942 at siteC, respectively. Whereas for tumor segmentation in testing data, the Dice of single model, centralized model, and federated model with localBN were 0.509, 0.524, 0.524 at siteA, and 0.719, 0.707, 0.721 at siteB, and 0.563, 0.589, 0.581 at siteC, respectively.*Conclusions This study has demonstrated that our proposed federated deep-learning with local BN approach provided a comparable performance with centralized deep-learning for liver and tumor segmentation in multi-center datasets while has the potential of preserving data privacy. As a result, local BN can successfully solve the non-iid medical imaging data training in federal learning.*Clinical Relevance/Application Reliable federated learning may provide an effective solution for multi-center collaboratively training a deep learning model without data sharing.

RESULTS

For liver segmentation in testing data, the Dice of single model, centralized model, and federated model with localBN were 0.958, 0.959, 0.962 at siteA, and 0.979, 0.966, 0.969 at siteB, and 0.939, 0.937, 0.942 at siteC, respectively. Whereas for tumor segmentation in testing data, the Dice of single model, centralized model, and federated model with localBN were 0.509, 0.524, 0.524 at siteA, and 0.719, 0.707, 0.721 at siteB, and 0.563, 0.589, 0.581 at siteC, respectively.

CLINICAL RELEVANCE/APPLICATION

Reliable federated learning may provide an effective solution for multi-center collaboratively training a deep learning model without data sharing.

SSGI05-3   Accelerated T2-weighted MRI Of The Liver At 3T Using Single-Shot Technique With Deep Learning Based Image Reconstruction: Impact On The Image Quality And Lesion Detection

Participants
Luke Ginocchio, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

Fat-suppressed T2-weighted imaging (T2-FS) is a critical component of clinical liver MRI, but often requires a long scan time and can be wrought with motion artifacts, urging a need for the development of a shorter and more motion robust sequence. We aim to compare the image quality of a single-shot T2-weighted MRI prototype with deep learning based image reconstruction (DL HASTE-FS) with a standard T2-FS sequence for routine clinical liver MRI at 3T.*Methods and Materials 41 consecutive patients who underwent abdominal MRI examinations at 3T including standard T2-FS and DL HASTE-FS, between 5/6/2020 and 11/23/2020, comprised the study cohort. Images were reviewed independently by two radiologists who used a 5-point Likert scale for a number of measures regarding artifacts and image quality, in addition to assessing for the presence of liver lesions and, if present, assessing lesion contrast and lesion image quality.*Results Acquisition time for DL HASTE-FS was 54.93 +/- 16.69 seconds, significantly (p <0.001) shorter than that for standard T2-FS (114.00 +/- 32.98 seconds). DL HASTE-FS received significantly higher scores than standard T2-FS for sharpness of liver margin (mean 4.2 vs 3.3; p<0.001), hepatic vessel margin (4.0 vs 3.2; p<0.001), pancreatic duct margin (4.0 vs 1.6; p<0.001); in-plane (4.1 vs 3.1; p<0.001) and through plane (4.1 vs 3.0; p<0.001) motion artifacts; other ghosting artifacts (4.3 vs 2.9; p<0.001); and overall image quality (3.8 vs 2.8; p<0.001), in addition to

receiving a higher score for sharpness of lesion margin (4.4 vs 3.8; p<0.025), without receiving significant difference in scores for homogeneity/strength of fat suppression or liver-fat/lesion contrast (p>0.05).*Conclusions Single-shot T2-weighted MRI with deep learning based image reconstruction demonstrated superior image quality compared with the standard T2-FS sequence for routine clinical liver MRI at 3T, while being acquired in less than half the time.*Clinical Relevance/Application Novel single-shot T2-weighted MRI with deep learning based image reconstruction technique offers superior image quality and decreased acquisition time compared with standard T2-FS technique at 3T.

RESULTS

Acquisition time for DL HASTE-FS was 54.93 +/- 16.69 seconds, significantly (p <0.001) shorter than that for standard T2-FS (114.00 +/- 32.98 seconds). DL HASTE-FS received significantly higher scores than standard T2-FS for sharpness of liver margin (mean 4.2 vs 3.3; p<0.001), hepatic vessel margin (4.0 vs 3.2; p<0.001), pancreatic duct margin (4.0 vs 1.6; p<0.001); in-plane (4.1 vs 3.1; p<0.001) and through plane (4.1 vs 3.0; p<0.001) motion artifacts; other ghosting artifacts (4.3 vs 2.9; p<0.001); and overall image quality (3.8 vs 2.8; p<0.001), in addition to receiving a higher score for sharpness of lesion margin (4.4 vs 3.8; p<0.025), without receiving significant difference in scores for homogeneity/strength of fat suppression or liver-fat/lesion contrast (p>0.05).

CLINICAL RELEVANCE/APPLICATION

Novel single-shot T2-weighted MRI with deep learning based image reconstruction technique offers superior image quality and decreased acquisition time compared with standard T2-FS technique at 3T.

SSGI05-5   Deep-cleansing: Deep-learning Based Electronic Cleansing In Dual-energy CT Colonography

Participants
Guibo Luo, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

This study was to develop and evaluate a deep-learning based electronic cleansing (EC) method for subtraction of tagged fecal regions in the colon in dual-energy CTC (DE-CTC).*Methods and Materials We retrospectively collected 139 DE-CTC cases with an isotropic resolution of 0.6×0.6×0.6 mm. Each patient underwent a 24-hour low-fiber, low-residue dietary bowel preparation with oral administration of 150 ml of iodinated contrast agent Gastrografin (Bayer Schering Pharma). The regions of interest (ROIs) of the colon lumen and tagged regions were interactively segmented on the fused CT images on our in-house CTC platform by two image analysts. All DE-CTC scans (approximately 80K images) were randomly divided into 76 scans (55%) for training, 28 scans (20%) for validation, and 35 scans (25%) for testing. First, we calculated the "effective" anatomic number (EAN) by fractions of atomic mass number using the low- and high-energy images in DE-CTC. Then we trained and evaluated our Deep-Cleansing on the DE-CTC scans with two different backbone networks (VGG16 and EfficientNet) in U-Net architecture. Specifically, multiple types of combinations of input channels were investigated for the optimal performance of EC, including the combinations of the high-energy, low-energy, fused-energy CT images, and EAN maps. The Dice coefficient (Dice), cleansing ratio (Rec) and soft-tissue preservation ratio (Rst) were used as the evaluation metrics.*Results Our Deep-Cleansing U-Net scheme with EAN maps achieved the Dice, Rec, Rst of 0.953, 94.18%, 98.55% in validation datasets, and 0.956, 96.14%, 97.74% in testing datasets, respectively. Whereas that U-Net model without EAN maps had the Dice, Rec, Rst of 0.948, 93.65%, 98.48% in validation datasets, and 0.955, 95.74%, 97.86% in testing datasets, respectively. In comparison, the conventional method like mosaic decomposition for differentiation of tagged fecal residuals achieved Rec of 90.6% and Rst of 97.8%.*Conclusions This study demonstrated that EAN provides an effective solution to identify tagged fecal materials and U-Net can significantly improve the segmentation of tagged fecal regions in DE-CTC images.*Clinical Relevance/Application Electronic cleansing may "virtually cleanse" tagged fecal materials and preserve the soft-tissue structures in the colon for visualization of the entire colonic surface in CTC.

RESULTS

Our Deep-Cleansing U-Net scheme with EAN maps achieved the Dice, Rec, Rst of 0.953, 94.18%, 98.55% in validation datasets, and 0.956, 96.14%, 97.74% in testing datasets, respectively. Whereas that U-Net model without EAN maps had the Dice, Rec, Rst of 0.948, 93.65%, 98.48% in validation datasets, and 0.955, 95.74%, 97.86% in testing datasets, respectively. In comparison, the conventional method like mosaic decomposition for differentiation of tagged fecal residuals achieved Rec of 90.6% and Rst of 97.8%.

CLINICAL RELEVANCE/APPLICATION

Electronic cleansing may "virtually cleanse" tagged fecal materials and preserve the soft-tissue structures in the colon for visualization of the entire colonic surface in CTC.

SSRO01-1 Price Comparison For Stereotactic Brain Radiation Therapy Using Chargemaster Data From National Cancer Institute-Designated Centers

Participants
Rahul Prasad, MD, Columbus, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

Financial toxicity is a highly prevalent and damaging consequence of oncologic therapy potentially addressable through improved price transparency. Recently, the Centers for Medicare & Medicaid Services required all US hospitals to publish a "chargemaster" documenting non-negotiated list charges for all services. Patients often travel to tertiary centers for intracranial stereotactic radiotherapy (SRT), but cost comparison is complicated by multiple delivery systems and fractionation schemes. We hypothesized that listed prices for intracranial SRT vary by delivery system, fractionation scheme, and institution.*Methods and Materials We obtained online available chargemasters for the 63 US clinical National Cancer Institute (NCI)-designated centers. Listed technical charges for Gamma Knife (GK), single fraction linear-accelerator stereotactic radiosurgery (SRS), and 3-fraction fractionated stereotactic radiation therapy (FSRT) were obtained by searching for Current Procedural Terminology (CPT) billing codes first and then keywords. Institutional cost data was adjusted by the Medicare geographic cost price index (GPCI) to control for cost-of-living associated reimbursement differences. Pairwise comparisons were conducted to compare prices across modalities and geographic regions. Price association between modalities and relationships with cost index were examined using Spearman correlations.*Results 62 chargemasters were obtained, and 58 listed intracranial SRT prices. Median listed prices varied widely with large interquartile ranges (GK \$49,529; FSRT \$31,834; SRS \$22,915). After adjusting for GPCI, GK (p = .0003) and FSRT (p = .001) were significantly more expensive than SRS, and no difference in price was noted between regions. FSRT price was positively correlated with GPCI (p = .033) but other modalities were not. All modality prices were positively correlated (all p <.001).*Conclusions The listed price for intracranial stereotactic radiotherapy varies greatly by delivery system, fractionation scheme, and even between institutions. Price differences are not well explained by variability in cost of living. These inefficiencies expose patients already at high risk for financial toxicity to unnecessary costs.*Clinical Relevance/Application The listed price for brain stereotactic radiotherapy varies by delivery system, fractionation scheme, and even between institutions. These inefficiencies expose patients already at high risk for financial toxicity to unnecessary costs.

RESULTS

62 chargemasters were obtained, and 58 listed intracranial SRT prices. Median listed prices varied widely with large interquartile ranges (GK \$49,529; FSRT \$31,834; SRS \$22,915). After adjusting for GPCI, GK (p = .0003) and FSRT (p = .001) were significantly more expensive than SRS, and no difference in price was noted between regions. FSRT price was positively correlated with GPCI (p = .033) but other modalities were not. All modality prices were positively correlated (all p <.001).

CLINICAL RELEVANCE/APPLICATION

The listed price for brain stereotactic radiotherapy varies by delivery system, fractionation scheme, and even between institutions. These inefficiencies expose patients already at high risk for financial toxicity to unnecessary costs.

SSRO01-3 Availability Of Insurer-Negotiated Price Estimates For Radiotherapy And Systemic Therapy At National Cancer Institute-Designated Centers

Participants
Rahul Prasad, MD, Columbus, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

Financial toxicity is highly prevalent in oncology and linked to inferior health and quality of life outcomes. Starting January 2021, all US hospitals were required by the federal government to publish online, "shoppable," payer-negotiated prices for at least 300 services of which 70 (including specialty care such as joint and cataract surgery) were specified, but oncology price inclusion was optional. National Cancer Institute (NCI)-designated centers are referral sites for cancer care, but the rate at which they choose to report prices for radiation therapy (RT) or systemic therapy is unknown. We predicted that the proportion of NCI-designated cancer centers reporting RT and infusion prices would lag behind their general rate of compliance with publication of shoppable prices.*Methods and Materials In February 2021 (1 month after regulations took effect), through online query, shoppable price lists were identified for NCI-designated centers and queried for the charge per fraction for simple intensity modulated radiation therapy (IMRT) and the first hour of infusion of systemic therapy using the Current Procedural Terminology codes 77385 and 96413, respectively. Manual search terms such as "radiation," "radiotherapy," "IMRT", "chemotherapy," and "infusion" were also used. Primary endpoints were the rate of reporting of shoppable prices for IMRT and infusion. Secondary endpoints were the rate of publication of shoppable prices and the rate of reporting cost for any RT service. Descriptive statistics including proportions and

frequency counts were performed.*Results Although price transparency webpages for all 63 NCI-designated centers were identified, only 52 (83%) published shoppable prices in any format. 49 of these (78%) were user-friendly web-based tools and 3 were downloadable documents. Overall, 9 (17%) and 8 (15%) centers listed prices for IMRT and infusion, respectively, in their shoppable tools. 20 (38%) listed at least one RT price (such as cost of brachytherapy or CT simulation).*Conclusions Almost 1 in 5 NCI-designated centers are not fully complaint with federal mandates to publish shoppable price tools. Less than 20% report negotiated RT or systemic therapy prices in shoppable tools. Policy changes such as mandatory RT and infusion price reporting should be considered to mitigate financial burden by improving patient access to reliable cost estimates.*Clinical Relevance/Application Less than 20% of NCI-designated centers report insurer-negotiated prices for radiotherapy or systemic therapy complicating price comparison for patients at high risk of treatment-related financial toxicity. Policy changes such as mandatory price reporting might address financial burden by improving patient access to reliable cost estimates.

RESULTS

Although price transparency webpages for all 63 NCI-designated centers were identified, only 52 (83%) published shoppable prices in any format. 49 of these (78%) were user-friendly web-based tools and 3 were downloadable documents. Overall, 9 (17%) and 8 (15%) centers listed prices for IMRT and infusion, respectively, in their shoppable tools. 20 (38%) listed at least one RT price (such as cost of brachytherapy or CT simulation).

CLINICAL RELEVANCE/APPLICATION

Less than 20% of NCI-designated centers report insurer-negotiated prices for radiotherapy or systemic therapy complicating price comparison for patients at high risk of treatment-related financial toxicity. Policy changes such as mandatory price reporting might address financial burden by improving patient access to reliable cost estimates.

SSRO01-4 Time To Proton Therapy For Pediatric Ependymoma Patients: A Report Of The Pediatric Proton/Photon Consortium Registry (PPCR) Study

Participants
Molly Blau, MD,MS, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

For pediatric patients with localized grade II or grade III ependymoma, adjuvant radiation therapy (RT) reduces the risk of local recurrence of disease. Proton RT provides equivalent efficacy while reducing radiation exposure to critical organs at risk in the developing brain. However, children and their families often need to travel for this treatment because proton centers are not as common as photon centers in the US or internationally. On the most recent Children's Oncology Group trial, patients were to start RT within 56 days of diagnosis. Delays in starting radiation raise concerns about impacts on efficacy. In this study, we used a large multi-institution cohort to determine factors associated with increased time to proton RT.*Methods and Materials Using the Pediatric Proton Consortium Registry of US proton centers, we identified patients with localized grades II and III intracranial ependymoma who did not receive chemotherapy prior to RT, were referred for adjuvant radiation rather than observation, and started RT within 150 days of diagnosis. For all patients, we evaluated for association between time to starting proton RT with international vs domestic residency and age. For patients residing in the United States (US), time to start was assessed based on Medicaid vs. private/employer-provided insurance, age less than 5 years, patient living in the same state as the proton center, race and ethnicity.*Results 197 patients (age 1-21 yo) met the inclusion criteria, 143 (73%) of whom started radiation within 56 days of diagnosis. The median days from diagnosis to RT start was 45 days (range 12-135 days). Compared to international patients, US patients were more likely to start radiation within 56 days (82% vs 39%, p <0.01), and had fewer average days to start (46.5 days vs 68.6 days, p<0.01). US patients with private/employer insurance were also more likely to start radiation before day 57 (87% vs 68%, p=0.02) and had shorter average intervals to starting RT (45.1 vs 54.8 days, p<0.01). Other factors, including race and ethnicity among US patients, did not affect time to RT start.*Conclusions International residence was the most important predictor of longer intervals to RT start, but type of insurance among US patients also affected time to begin RT. Delays were not associated with race, ethnicity, or distance from the treatment center for domestic patients. Subsequent analysis can determine if longer interval to starting RT was associated with inferior outcomes.*Clinical Relevance/Application In this study, we use a large multi-institution cohort to evaluate factors associated with increased time to proton RT for pediatric ependymoma patients, which may impact treatment efficacy.

RESULTS

197 patients (age 1-21 yo) met the inclusion criteria, 143 (73%) of whom started radiation within 56 days of diagnosis. The median days from diagnosis to RT start was 45 days (range 12-135 days). Compared to international patients, US patients were more likely to start radiation within 56 days (82% vs 39%, p <0.01), and had fewer average days to start (46.5 days vs 68.6 days, p<0.01). US patients with private/employer insurance were also more likely to start radiation before day 57 (87% vs 68%, p=0.02) and had shorter average intervals to starting RT (45.1 vs 54.8 days, p<0.01). Other factors, including race and ethnicity among US patients, did not affect time to RT start.

CLINICAL RELEVANCE/APPLICATION

In this study, we use a large multi-institution cohort to evaluate factors associated with increased time to proton RT for pediatric ependymoma patients, which may impact treatment efficacy.

SSRO01-5 Analysis Of Virtual Versus In-Person Prospective Peer Review Workflow In A Multisite Academic Radiation Oncology Department

Participants
Shearwood McClelland III, MD, Indianapolis, Indiana (*Presenter*) Nothing to Disclose

PURPOSE

In Radiation Oncology, peer review (also known as chart rounds) is a process where subjective treatment planning decisions are assessed by those independent of the prescribing physician. Similar to the function of morbidity and mortality in many medical disciplines, peer review plays a key role in quality management and improvement and is attended by all physicians and representatives of medical dosimetry and physics. Performed retrospectively at most institutions, in 2018 we presented our experience with prospective daily peer review demonstrating improved plan quality without delaying patient care. Prior to March 2020, all peer review sessions occurred in person; however due to the COVID-19 pandemic, the peer-review workflow was transitioned from in-person to virtual. We sought to assess the plan quality and patient care timeliness achieved by virtual versus in-person prospective peer review.*Methods and Materials Patients scheduled to receive non-emergent non-procedural radiation

therapy (RT) were presented daily (Monday-Friday) at prospective peer-review prior to the start of RT administration. Planning software was used, with critical evaluation of treatment intent, radiation dose fractionation, radiation treatment modality, contour definition, treatment target coverage, and risk to critical structures. A deviation was defined as any suggested plan revision; minor deviations were not required for treatment, while major deviations were strongly recommended prior to administration of the next treatment fraction. Statistical analysis involved Fisher's exact test (p=0.05 for significance).*Results 274 treatment plans evaluated in-person were compared with 195 plans evaluated virtually. There were significant differences in palliative intent (36% vs. 22%; p=0.002), but not in total time between simulation and the start of treatment (9.2 vs. 10.0 days; p=0.10), or in minor deviations (4.0% of in-person vs. 1.5% of virtual plans; p=0.17). Major deviations (4.4% vs. 1.0%; p=0.051) trended towards significance. Overall deviations (8.4% in-person vs. 2.6% virtual; p=0.009) were significantly reduced in virtual peer review.*Conclusions Prospective daily peer review of Radiation Oncology treatment plans can be performed virtually with similar efficacy of plan quality and timeliness of patient care compared with in-person peer review. The reduced deviations observed in virtual peer review may be due to the documented inverse relationship between deviation frequency and duration of prospective peer review initiation (Ballo et al., 2014) and deserve further investigation.*Clinical Relevance/Application These findings indicate that virtual workflow does not compromise patient care, and should be considered as standard-of-care.

RESULTS

274 treatment plans evaluated in-person were compared with 195 plans evaluated virtually. There were significant differences in palliative intent (36% vs. 22%; p=0.002), but not in total time between simulation and the start of treatment (9.2 vs. 10.0 days; p=0.10), or in minor deviations (4.0% of in-person vs. 1.5% of virtual plans; p=0.17). Major deviations (4.4% vs. 1.0%; p=0.051) trended towards significance. Overall deviations (8.4% in-person vs. 2.6% virtual; p=0.009) were significantly reduced in virtual peer review.

CLINICAL RELEVANCE/APPLICATION

These findings indicate that virtual workflow does not compromise patient care, and should be considered as standard-of-care.

SSGI09-1 Influence Of Positive, Neutral And Dark CT Oral Contrast On CT Radiation Dose When Using Automatic Exposure Control In A Phantom Model

Participants
Yuxin Sun, BS,MSc, San Francisco, California (*Presenter*) Stockholder, Nextrast, Inc

PURPOSE

To assess relative CT radiation dose associated with automated exposure control in the setting of enteric positive, neutral, and experimental dark borosilicate contrast material (DBCM, which now has FDA IND) in an adult and small adult phantom model*Methods and Materials An adult (27 x 32 cm diameter) and a small adult (21 x 27 cm diameter) anthropomorphic CT phantom, 30 cm in z-axis, were constructed of polyurethane to simulate soft tissue density, and included 2 cm diameter polyethylene corrugated tubing to simulate bowel, and bone meal urethane cast to simulate the spine. The phantom bowel was serially filled with 1000 mL of three types of oral contrast: positive (barium sulfate 2% w/w, Readi-Cat 2TM, Bracco), neutral (barium sulfate 0.1% w/w, VoLumenTM, Bracco), and dark (experimental DBCM, Nextrast, Inc) and scanned 10 times each on three different CT platforms (750 HD and Revolution, General Electric Healthcare, Waukesha, WI, Noise Index 20; IQon, Philips Healthcare, Cleveland, OH, DoseRight Index 18) at 120 kVp and 2.5 or 2 mm slice thickness using automatic exposure control. The CTDIvol was recorded for each scan and compared between contrast agents by Wilcoxon Signed Rank tests.*Results The mean CT attenuation for the positive, neutral, and dark oral contrast agents were 307, 26, and -118 for the 750 HD, 316, 25, and -137 for the Revolution, and 332, 25, and -131 for the IQon, respectively. For the 750 HD, Revolution, and the IQon scanners, the mean CTDIvol for the adult phantom scans was lower for the dark oral contrast (10.0, 8.6 and 7.9 mGy, respectively) than for the neutral (10.3, 9.0 and 8.1 mGy, p<0.05 each) and the positive (10.6, 9.6 and 8.2 mGy, p<0.05 each) contrast agents. The mean CTDIvol for the small sized phantom scans was lower for the dark oral contrast (3.4, 3.8 and 4.9 mGy, respectively) than for the neutral (3.5, 3.9 and 4.9 mGy, p<0.05 for 750 HD and Revolution, p=0.45 for IQon) and the positive (3.7, 4.0 and 5.1 mGy, p<0.05 each) contrast agents.*Conclusions Use of dark oral contrast may reduce the required radiation dose at abdominal CT imaging compared to positive and neutral oral agents when using automated exposure control.*Clinical Relevance/Application The use of dark oral contrast agents in place of positive or neutral oral agents at abdominal CT should allow for lower radiation doses. Further clinical studies are warranted to assess diagnostic impact.

RESULTS

The mean CT attenuation for the positive, neutral, and dark oral contrast agents were 307, 26, and -118 for the 750 HD, 316, 25, and -137 for the Revolution, and 332, 25, and -131 for the IQon, respectively. For the 750 HD, Revolution, and the IQon scanners, the mean CTDIvol for the adult phantom scans was lower for the dark oral contrast (10.0, 8.6 and 7.9 mGy, respectively) than for the neutral (10.3, 9.0 and 8.1 mGy, p<0.05 each) and the positive (10.6, 9.6 and 8.2 mGy, p<0.05 each) contrast agents. The mean CTDIvol for the small sized phantom scans was lower for the dark oral contrast (3.4, 3.8 and 4.9 mGy, respectively) than for the neutral (3.5, 3.9 and 4.9 mGy, p<0.05 for 750 HD and Revolution, p=0.45 for IQon) and the positive (3.7, 4.0 and 5.1 mGy, p<0.05 each) contrast agents.

CLINICAL RELEVANCE/APPLICATION

The use of dark oral contrast agents in place of positive or neutral oral agents at abdominal CT should allow for lower radiation doses. Further clinical studies are warranted to assess diagnostic impact.

SSGI09-2 Incidentally Detected Pancreatic Duct Dilation On Abdominal Ultrasound: Assessment Of Yield Of Subsequent MRCP

Participants
Abraham Fourie Bezuidenhout, MBChB,MMed, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

The clinical significance and current management of patients with an incidentally detected dilated pancreatic duct (PD) on abdominal ultrasound with no visualized underlying cause are not clear. Our purpose was to assess the diagnostic yield of subsequent MRCP and to identify additional predictors that may be associated with underlying pancreaticobiliary malignancy.*Methods and Materials We included consecutive patients in whom MRCP was performed for further evaluation of an incidentally detected dilated PD on abdominal ultrasound from 2011-2017. We reviewed MRCP scans and retrieved clinical data retrospectively from our hospital information system. Histology or clinical follow-up was used as reference standard. Chi-square test was performed to determine the association between categorical variables.*Results 58 patients were identified with mean age of 65 years, 35 (60%) being female. 36/58 (62%) had PD dilation on MRCP, the others did not. In 17/36 (47%) patients a specific

pancreaticobiliary cause for PD dilation was identified on MRCP [7 (19%) malignant and 10 (28%) benign]. In the remaining 19/36 (53%) patients, no cause was identified. On bivariate analysis, patients with associated common bile duct (CBD) dilation were more likely to have underlying pancreaticobiliary malignancy (p = .002). No patient with initial negative MRCP had pancreaticobiliary malignancy on subsequent work-up.*Conclusions Incidentally detected PD dilation on ultrasound should prompt referral to MRCP. MRCP is an accurate non-invasive method for identifying the underlying cause in these patients and in detecting life threatening pancreaticobiliary malignancy. Patients with associated CBD dilation are more likely to have underlying pancreaticobiliary malignancy.*Clinical Relevance/Application Incidentally detected PD dilatation at US with no sonographically evident cause should not be considered an insignificant finding, as a substantial number of our patients had underlying pancreaticobiliary malignancy.MRCP offers a non-invasive and accurate means to identify the underlying cause of PD dilatation in the majority of these patients and can exclude the presence of pancreaticobiliary malignancy.

RESULTS

58 patients were identified with mean age of 65 years, 35 (60%) being female. 36/58 (62%) had PD dilation on MRCP, the others did not. In 17/36 (47%) patients a specific pancreaticobiliary cause for PD dilation was identified on MRCP [7 (19%) malignant and 10 (28%) benign]. In the remaining 19/36 (53%) patients, no cause was identified. On bivariate analysis, patients with associated common bile duct (CBD) dilation were more likely to have underlying pancreaticobiliary malignancy (p = .002). No patient with initial negative MRCP had pancreaticobiliary malignancy on subsequent work-up.

CLINICAL RELEVANCE/APPLICATION

Incidentally detected PD dilatation at US with no sonographically evident cause should not be considered an insignificant finding, as a substantial number of our patients had underlying pancreaticobiliary malignancy.MRCP offers a non-invasive and accurate means to identify the underlying cause of PD dilatation in the majority of these patients and can exclude the presence of pancreaticobiliary malignancy.

SSGI09-3 Ultrasound Elastography In Pancreatic Transplantation: Normal Values And Its Application In Evaluating Rejection.

Participants
Clara Bassaganyas-Vancells, MD, Barcelona, Spain (*Presenter*) Nothing to Disclose

PURPOSE

Rejection is the second cause of pancreatic graft loss after technical complications. Conventional imaging techniques lack sensitivity and specificity to assess rejection. Elastography by Acoustic Radiation Force Impulse (ARFI) quantification is a non-invasive ultrasonographic technique that allows quantification of tissue elasticity. It has been proposed as a complementary tool to detect rejection in liver and kidney transplantation. Unfortunately, there is no data on pancreas transplantation.*Methods and Materials Prospective study including all pancreas transplantations in our center from October 2016 to January 2020. All allografts were evaluated by ARFI (m/s) at 1 week after surgery. Posteriorly, an ARFI evaluation and a protocolized biopsy were performed at 3 weeks and 12 months post-transplantation, and whenever a graft dysfunction was suspected. Allografts with postoperative surgical complications were excluded from the analysis. Grafts were classified according to the biopsy result into two groups (rejection/no rejection). Those cases without biopsy or with an inconclusive biopsy result were classified according to the clinical management. ARFI values were analyzed in each group and compared between them.*Results During this period, 124 ARFI evaluations and 78 biopsies were performed in 54 patients. Three patients were excluded because of postoperative complications (5 evaluations). Both groups showed a high dispersion of the ARFI median values during the first three months: non-rejection group (n=88, 1.52±0.68 m/s) and rejection group (n=31, 1.55±0.46 m/s). These values were attributed to postoperative factors and therefore excluded from the analysis. After the first 3 months, the median ARFI values in the non-rejection group decreased to 0.98±0.32 m/s (n=55), which is similar to values reported in the native pancreas, whereas the rejection group reached a value of 1.45±0.31 m/s (n=16). This difference was found out to be statistically significant (p-value 0.0001). A cut-off value of 1.24 cm/s demonstrated a sensitivity and a specificity of 0.94 and 0.73 respectively (AUC 0.83), for the diagnosis of rejection in grafts older than 3 months.*Conclusions Ultrasound elastography of the pancreatic graft presents high values and dispersion during the first 3 months, probably due to postsurgical factors, making them less reliable. After this period, ARFI may be a useful non-invasive complementary tool to detect pancreatic graft rejection.*Clinical Relevance/Application There are no specific markers to early diagnose pancreatic allograft rejection. ARFI could be a non-invasive tool to detect those cases that may benefit from an early biopsy or an early treatment.

RESULTS

During this period, 124 ARFI evaluations and 78 biopsies were performed in 54 patients. Three patients were excluded because of postoperative complications (5 evaluations). Both groups showed a high dispersion of the ARFI median values during the first three months: non-rejection group (n=88, 1.52±0.68 m/s) and rejection group (n=31, 1.55±0.46 m/s). These values were attributed to postoperative factors and therefore excluded from the analysis. After the first 3 months, the median ARFI values in the non-rejection group decreased to 0.98±0.32 m/s (n=55), which is similar to values reported in the native pancreas, whereas the rejection group reached a value of 1.45±0.31 m/s (n=16). This difference was found out to be statistically significant (p-value 0.0001). A cut-off value of 1.24 cm/s demonstrated a sensitivity and a specificity of 0.94 and 0.73 respectively (AUC 0.83), for the diagnosis of rejection in grafts older than 3 months.

CLINICAL RELEVANCE/APPLICATION

There are no specific markers to early diagnose pancreatic allograft rejection. ARFI could be a non-invasive tool to detect those cases that may benefit from an early biopsy or an early treatment.

SSGI09-4 Personalized Iodine Contrast Algorithm Enabling Optimal And Reproduceable Liver Enhancement: A Prospective Multicenter Study

Participants
Hugues G. Brat, MD, Sion, Switzerland (*Presenter*) Speaker, General Electric Company

PURPOSE

To determine the ability of an iodine contrast optimization algorithm to predict image quality for contrast-enhanced liver CT.*Methods and Materials 254 prospective patients (mean FFM 46.5kg (23.0-66.9), mean age 60.9years (18.3-94.5years)) underwent a standardized multi-phase liver CT examination (kVp range 80-120) in a multicenter imaging network. A patient-specific algorithm based on impedencemetric-determined Fat Free Mass (FFM), tube voltage and contrast media concentration calculated

the appropriate amount of i.v. contrast volume and flow to predict an optimal liver parenchymal enhancement of 40-60 Hounsfield Units (HUtarget). Level of enhancement was determined by attenuation difference between portal and unenhanced parenchyma (HUliver). HUliver histograms were compared to HUtarget through mean and standard deviation (SD). Total amount of iodine dose was estimated by median and interquartile range (IQR) and stratified per contrast media concentration (350_AccupaqueTM/370_IopamirolTM mgI/ml), kVp and gender. Upper and lower limit were set in the algorithm to avoid off label usage of the contrast media (minimal CM dose for AccupaqueTM : 30gI)*Results Mean HUliver was 55.4HU+/-9.7, with 70.4% between 40-60HU and 89.8% between 40-70HU. Median iodine dose was 27.8gI (IQR=6.4gI). Per contrast media type, median iodine dose was 30.2gI/26.4gI for 350/370 iodine concentration (p<0.001). Per kVp, median iodine dose significantly (p<0.01) increased from 18.6/27.8/36.3gI for 80/100/120 kVp. Per gender, women needed significantly lower (p<0.01) dose than men (25.2vs30.2gI).*Conclusions The developed algorithm enabled a diagnostically appropriate and reproduceable mean liver enhancement of 55.4HU, independently of patient habitus, contrast concentration or tube voltage. Lower limit iodine dose due to off label use caused a higher than needed contrast dose for the 350mgI/ml contrast media concentration.*Clinical Relevance/Application Clinical relevance of this patient-to-patient uniformity of liver enhancement translates in significant improvement of liver lesion assessment and reporting accuracy in diagnostic and follow-up CT examinations.

RESULTS

Mean HUliver was 55.4HU+/-9.7, with 70.4% between 40-60HU and 89.8% between 40-70HU. Median iodine dose was 27.8gI (IQR=6.4gI). Per contrast media type, median iodine dose was 30.2gI/26.4gI for 350/370 iodine concentration (p<0.001). Per kVp, median iodine dose significantly (p<0.01) increased from 18.6/27.8/36.3gI for 80/100/120 kVp. Per gender, women needed significantly lower (p<0.01) dose than men (25.2vs30.2gI).

CLINICAL RELEVANCE/APPLICATION

Clinical relevance of this patient-to-patient uniformity of liver enhancement translates in significant improvement of liver lesion assessment and reporting accuracy in diagnostic and follow-up CT examinations.

SSGI09-5 Systematic Review And Meta-analysis Of Diagnostic Performance Of CT For Assessing Resectability Of Pancreatic Ductal Adenocarcinoma After Neoadjuvant Therapy: Importance Of CT Criteria

Participants
Hyun Kyung Yang, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To assess the CT diagnostic performance for evaluating resectability of pancreatic ductal adenocarcinoma (PDAC) after neoadjuvant therapy and identify the factor(s) that affect(s) diagnostic performance.*Methods and Materials Databases were searched to identify studies published from January 1, 2000, to November 5, 2019, that evaluated the CT diagnostic performance for assessing resectability of post-neoadjuvant PDAC. Two reviewers independently extracted data and assessed the study quality. A meta-analysis was performed to obtain summary sensitivity and specificity values using a bivariate random-effects model, and heterogeneity across studies was assessed. Univariable meta-regression analysis was performed with eight variables, including the different CT criteria for resectability, conventional National Comprehensive Cancer Network (NCCN) criteria for upfront surgery, and modified criteria for post-neoadjuvant surgery.*Results Ten studies with 311 patients were included and analyzed. The summary sensitivity and specificity for resectability were 78% (95% CI, 68%-86%) and 60% (95% CI, 44%-74%), respectively. No significant heterogeneity was identified (bivariate correlation coefficient ? = -1, p-value for hierarchical summary receiver operating characteristics model ß = 0.667). The two different CT criteria showed different diagnostic performance (p < 0.01), with higher sensitivity (81% [95% CI, 73%-90%] vs. 28% [95% CI, 15%-42%], p < 0.01) and lower specificity (57% [95% CI, 41%-73%] vs. 90% [95% CI, 80%-100%], p < 0.01) for the modified criteria. No other variables affected the diagnostic performance.*Conclusions CT criteria was the only factor that affected the diagnostic performance. Modification of the conventional criteria improved sensitivity but lowered specificity. Further modifications are required to improve specificity and uniformity.*Clinical Relevance/Application When conventional CT criteria for upfront surgery was used to assess resectability of post-neoadjuvant pancreatic ductal adenocarcinoma, sensitivity was low, and specificity was high. When modified CT criteria, considering treatment-related changes, was used to assess resectability of post-neoadjuvant pancreatic ductal adenocarcinoma, sensitivity for identifying R0 resection increased, at the expense of higher likelihood of R1 resection.

RESULTS

Ten studies with 311 patients were included and analyzed. The summary sensitivity and specificity for resectability were 78% (95% CI, 68%-86%) and 60% (95% CI, 44%-74%), respectively. No significant heterogeneity was identified (bivariate correlation coefficient ? = -1, p-value for hierarchical summary receiver operating characteristics model ß = 0.667). The two different CT criteria showed different diagnostic performance (p < 0.01), with higher sensitivity (81% [95% CI, 73%-90%] vs. 28% [95% CI, 15%-42%], p < 0.01) and lower specificity (57% [95% CI, 41%-73%] vs. 90% [95% CI, 80%-100%], p < 0.01) for the modified criteria. No other variables affected the diagnostic performance.

CLINICAL RELEVANCE/APPLICATION

When conventional CT criteria for upfront surgery was used to assess resectability of post-neoadjuvant pancreatic ductal adenocarcinoma, sensitivity was low, and specificity was high. When modified CT criteria, considering treatment-related changes, was used to assess resectability of post-neoadjuvant pancreatic ductal adenocarcinoma, sensitivity for identifying R0 resection increased, at the expense of higher likelihood of R1 resection.

SSGI09-6 Radiomic Features Of Entropy And Uniformity On CT Imaging Correlate With Pancreatic Fibrosis In Patients With Recurrent Acute And Chronic Pancreatitis

Participants
Farhad Pishgar, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

To study the association between different radiomic features on CT imaging and pancreatic fibrosis in adult patients with recurrent acute pancreatitis (RAP) or chronic pancreatitis (CP) who underwent total pancreatectomy with islet autotransplantation (TPIAT).*Methods and Materials There were 45 patients with RAP or CP who underwent a contrast-enhanced abdominal CT (CECT) scan prior to TPIAT between 2010 and 2018. The extent and distribution of fibrosis were evaluated using excisional biopsies obtained from the pancreatic head as well as the body/tail at the time of TPIAT, using the Ammann Fibrosis (overall, perilobular, and intralobular) and Japanese Fibrosis (overall, perilobular, interlobular fibrosis, collagen content, sublobular atrophy, and lobular

atrophy) scoring systems. On the contrast-enhanced CT (CECT) before TPIAT, the pancreas was outlined by drawing region of interest (ROI) and 52 radiomic features were extracted from each ROI. Using the correlation matrix followed by hierarchical clustering (5 clusters with =5 features in each cluster), 5 radiomic features showing maximum variability within each cluster were selected. Associations between radiomic features and fibrosis scores were studied using multiple linear regression adjusted for age, sex, and body mass index. Multiple comparisons of the p-values were corrected using the Benjamini-Hochberg method.*Results The mean age of the patients was 37.0±13.4 and 26[57.8%] were women. The degree of fibrosis was the highest in CP (n = 19) followed by ARP (n = 14) followed by suspected CP (n = 12). Of the 52 radiomic features, 5 features (1st order energy, entropy, mean, uniformity, and GLCM autocorrelation) were selected based on maximum variability within each cluster. Entropy and uniformity were associated with overall (ß: 7.1 [2.5 - 11.7] and -7.1 [-11.6 - -2.6], respectively), perilobular, and intralobular fibrosis score. Using the Japanese Fibrosis score, entropy and uniformity were associated with overall (ß: 7.9 [2.4 - 13.4] and -8.2 [-13.6 - -2.9]), perilobular, interlobular fibrosis, collagen content, and lobular atrophy scores.*Conclusions CECT-derived radiomic features of entropy and uniformity are associated with the extent of pancreatic fibrosis in patients with recurrent acute pancreatitis or chronic pancreatitis, showing promise for identifying quantitative biomarkers for pancreatic fibrosis.*Clinical Relevance/Application Radiomic features derived from CECT scans before the TPIAT are associated with the extent of pancreatic fibrosis in patients with pancreatitis. The noninvasive diagnosis of fibrosis could have a myriad of clinical applications.

RESULTS

The mean age of the patients was 37.0±13.4 and 26[57.8%] were women. The degree of fibrosis was the highest in CP (n = 19) followed by ARP (n = 14) followed by suspected CP (n = 12). Of the 52 radiomic features, 5 features (1st order energy, entropy, mean, uniformity, and GLCM autocorrelation) were selected based on maximum variability within each cluster. Entropy and uniformity were associated with overall (ß: 7.1 [2.5 - 11.7] and -7.1 [-11.6 - -2.6], respectively), perilobular, and intralobular fibrosis score. Using the Japanese Fibrosis score, entropy and uniformity were associated with overall (ß: 7.9 [2.4 - 13.4] and -8.2 [-13.6 - -2.9]), perilobular, interlobular fibrosis, collagen content, and lobular atrophy scores.

CLINICAL RELEVANCE/APPLICATION

Radiomic features derived from CECT scans before the TPIAT are associated with the extent of pancreatic fibrosis in patients with pancreatitis. The noninvasive diagnosis of fibrosis could have a myriad of clinical applications.

SSHN02-2   Dose-efficient Temporal Bone Imaging Using High-resolution Photon-counting Detector (PCD) CT

Participants

John I. Lane, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate improved spatial resolution/critical structure visualization for temporal bone imaging using a photon-counting-detector (PCD) CT system.*Methods and Materials Patients referred for clinically indicated temporal bone CT were scanned on a conventional energy-integrating detector (EID) CT using our routine clinical protocol (120 kV, comb-based ultra-high-resolution (ultra-HR), CTDIvol = 55 mGy) and an investigational PCD-CT system (SOMATOM Count Plus, Siemens Healthineers, 120 kV, non-comb-based HR, CTDIvol = 35.7 mGy). CT images were reconstructed in axial, coronal and Poschl planes using the smallest available slice thickness (0.4 mm for EID-CT, 0.2 mm for PCD-CT). Images were reconstructed using Ur77 (EID-CT) and Hr84 (PCD-CT) kernels to maximize spatial resolution at acceptable noise levels. Two radiologists blindly evaluated randomized and paired EID-CT and PCD-CT images, and scored PCD-CT against EID-CT. Critical structures (round window, incudomallear joint, modiolus, oval window, scutum and incudostapedial joint, as well as ossicular prosthesis when present) were individually scored for spatial resolution/visualization, and a final overall score given for statistical evaluation. Image scoring was performed using a 5-point Likert scale (1 = inferior resolution with degraded visualization, 2 = slightly inferior resolution without affecting visualization, 3 = equivalent resolution and visualization, 4 = slightly superior resolution without affecting visualization, 5 = superior spatial resolution with improved visualization). Wilcoxon rank-sum test was used for statistical analysis, and descriptive analyses (mean and median scores) were performed for individual critical structures.*Results A total of 13 patients were enrolled. CT images were reconstructed separately for left and right sides, yielding 26 image sets for evaluation. Despite a 35% decrease in the CT dose, HR images from PCD-CT were significantly preferred over EID-CT (p < 0.0001) with a mean overall score of 4.62 (individual median score of 5 for PCD-CT from both readers).*Conclusions Reduced dose PCD-CT demonstrated significantly better spatial resolution/visualization for temporal bone structures compared to conventional EID-CT.*Clinical Relevance/Application Substantially better visualization of critical structures within the temporal bone from PCD-CT may yield superior diagnostic capabilities in evaluation of the inner ear.

RESULTS

A total of 13 patients were enrolled. CT images were reconstructed separately for left and right sides, yielding 26 image sets for evaluation. Despite a 35% decrease in the CT dose, HR images from PCD-CT were significantly preferred over EID-CT (p < 0.0001) with a mean overall score of 4.62 (individual median score of 5 for PCD-CT from both readers).

CLINICAL RELEVANCE/APPLICATION

Substantially better visualization of critical structures within the temporal bone from PCD-CT may yield superior diagnostic capabilities in evaluation of the inner ear.

SSHN02-3   Combining CT Radiomic And Pathomic Features From H;E Tissue Images For Prognosticating Outcome In P16+ Oropharyngeal Squamous Cell Carcinoma

Participants

Bolin Song, MS, Cleveland, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

The current paradigm for low-risk patients with p16+ oropharyngeal squamous cell carcinoma (OPSCC) is to reduce the dosage of radio-chemo therapy (treatment de-intensification). The purpose of this study was to combine the pathomic features from digitized H&E images with CT radiomic features to create a prognostic classifier that could enable accurate risk stratification of p16+ OPSCC patients.*Methods and Materials 304 p16+ OPSCC cases from three institutions (N1=100, N2=94, and validation cohort N3=110) were included in this study. The radiomic signature capturing tumor CT textural heterogeneity was trained on pre-treatment CT scans from N1. The tumor infiltrating lymphocytes (TILs)-related features (pathomic) were trained on N2, which quantifies the spatial arrangement of the TILs proximity using network graph metrics. Next, 3 radiomic and 5 pathomic features most associated with disease-free survival (DFS) were identified from N1 and N2, respectively, and used to train Cox regression models. Median of the radiomic and pathomic signatures from N1, N2 were used as cut-off for defining high vs low-risk groups. We then applied the consensus clustering on isomap embedding of the rad-pathomic features on N3, from which two patient clusters were generated.

Kaplan-Meier survival analysis was used to quantify the DFS difference between risk groups or clusters (Figure 1).*Results Hazard ratios (HR) for comparing DFS of high vs low-risk groups for the radiomic and the pathomic signatures in validation cohort N3 are 1.99 (95% CI, 0.896-4.42, p=0.0912) and 2.37 (95% CI, 1.09-5.16, p=0.0302). The two clusters from isomap of rad-pathomic resulted in an improved HR of 3.36 (95% CI, 1.52-7.39, p=0.00264). The rad-pathomic consensus matrix approach yielded higher sensitivity (0.88) in detecting recurrence than either individual radiomic (0.76) or pathomic signatures (0.76).*Conclusions Combing CT radiomic features with pathomic features from H&E slides enabled improved prognosis prediction for p16+ OPSCC.*Clinical Relevance/Application With additional validation, the fused rad-pathomic signature could allow for identifying p16+ OPSCC patients who will benefit from treatment de-intensification.

RESULTS

Hazard ratios (HR) for comparing DFS of high vs low-risk groups for the radiomic and the pathomic signatures in validation cohort N3 are 1.99 (95% CI, 0.896-4.42, p=0.0912) and 2.37 (95% CI, 1.09-5.16, p=0.0302). The two clusters from isomap of rad-pathomic resulted in an improved HR of 3.36 (95% CI, 1.52-7.39, p=0.00264). The rad-pathomic consensus matrix approach yielded higher sensitivity (0.88) in detecting recurrence than either individual radiomic (0.76) or pathomic signatures (0.76).

CLINICAL RELEVANCE/APPLICATION

With additional validation, the fused rad-pathomic signature could allow for identifying p16+ OPSCC patients who will benefit from treatment de-intensification.

SSHN02-4   Impact Of Acceleration On Bone Depiction Quality By Ultrashort Echo Time Magnetic Resonance Bone Imaging Sequences In Medication-related Osteonecrosis Of The Jaw

Participants
Jonas Getzmann, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To assess the impact on bone depiction quality by decreasing number of radial acquisitions (RA) of an ultrashort echo time (UTE) magnetic resonance (MR) bone imaging sequence in medication-related osteonecrosis of the jaw (MRONJ).*Methods and Materials UTE MR bone imaging sequences using pointwise encoding time reduction with RA (PETRA) with 60'000, 30'000 and 10'000 RA were prospectively acquired in 16 patients with clinically confirmed MRONJ and in a control group of 16 healthy volunteers. Blinded readout sessions were performed by two radiologists. Qualitative analysis of the different image series was performed by comparing the detection of osteolytic lesions and productive bony changes (medullary osteosclerosis or periosteal thickening) in the different PETRA sequences of the patients with MRONJ. Quantitative analysis was performed by comparing the different sequences in the control group with regard to differences in image artifacts, contrast-to-noise ratio (CNR) and image noise. Cohen's kappa (?) was used to assess interreader agreement. Standard statistical tests were used for sequence comparison.*Results Acquisition times were reduced from 315 to 165 and 65 seconds (60'000, 30'000, 10'000 RA, respectively), resulting in a fewer number of severe motion artifacts. Bone delineation was significantly different among PETRA sequences (P < 0.05) with increasingly blurred appearance when reducing the number of RA but without any trade-off in terms of diagnostic performance. Interreader agreement for the detection of pathognomonic osteolysis was moderate (? = 0.538) for 60'000 RA and decreased to fair (? = 0.227 and ? = 0.390) when comparing 30'000 and 10'000 RA, respectively. Image quality between sequences was comparable regarding CNR, image noise and artifact dimensions without significant differences (all P > 0.05).*Conclusions UTE MR bone imaging sequences with a lower number of RA provide sufficient image quality for detecting osteolytic lesions and productive bony changes in MRONJ subjects at faster acquisition times compared to the respective standard UTE MR bone imaging sequence.*Clinical Relevance/Application UTE MR bone imaging sequences with a lower number of radial acquisitions allow for shorter image acquisitions with fewer motion artifacts which can be essential in the older MRONJ patient population.

RESULTS

Acquisition times were reduced from 315 to 165 and 65 seconds (60'000, 30'000, 10'000 RA, respectively), resulting in a fewer number of severe motion artifacts. Bone delineation was significantly different among PETRA sequences (P < 0.05) with increasingly blurred appearance when reducing the number of RA but without any trade-off in terms of diagnostic performance. Interreader agreement for the detection of pathognomonic osteolysis was moderate (? = 0.538) for 60'000 RA and decreased to fair (? = 0.227 and ? = 0.390) when comparing 30'000 and 10'000 RA, respectively. Image quality between sequences was comparable regarding CNR, image noise and artifact dimensions without significant differences (all P > 0.05).

CLINICAL RELEVANCE/APPLICATION

UTE MR bone imaging sequences with a lower number of radial acquisitions allow for shorter image acquisitions with fewer motion artifacts which can be essential in the older MRONJ patient population.

SSHN02-5   The Impact Of Surveillance Imaging On Mortality For Head And Neck Squamous Cell Carcinoma (hnscc): The Analysis Of The State Cancer Registry And All-payer Claims Data

Participants
Yoshimi Anzai, MD,MPH, Salt Lake City, Utah (*Presenter*) Nothing to Disclose

PURPOSE

The goal of surveillance cancer imaging is to detect early recurrence before clinical symptoms. Following treatment, anatomical distortion or inflammatory changes make clinical evaluation challenging. Currently, there is no high level of evidence to support clinical guideline on whether surveillance imaging improves mortality among HNC patients. Single-institution studies are often biased due to regional practice patterns and physicians' preferences for imaging use. The purpose of this study is to investigate whether surveillance imaging improves mortality for head and neck squamous cell carcinoma (HNSCC) using the statewide cancer registry data, All-Payer Claims data, statewide healthcare facility data, and electronic health records.*Methods and Materials We identified a cohort of 902 HNSCC patients diagnosed between 2012-2017 in the Utah Cancer Registry. We used CPT codes to identify surveillance imaging procedures, including CT, MRI, and PET/CT. Cox proportional hazards models were used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for the risk of death with adjustment for potential confounders, including sex, race/ethnicity, age at cancer diagnosis, rural residence, health insurance, diagnosis year, cancer sequence number, cancer stage, and cancer subsite.*Results HNSCC patients who had surveillance imaging codes did not have overall lower mortality compared to patients who did not have surveillance imaging codes after the end of cancer treatment (Fig 1) (HR: 0.78, 95%CI: 0.58, 1.05). In the stratified analyses by cancer stage, the risk of death was lower among patients with surveillance imaging for regionalized cancer stage (HR: 0.61, 95%CI: 0.40, 0.94), and distant cancer stage (HR: 0.33, 95%CI: 0.16, 0.67). The protective association

was observed in the first two years and the first 5 years from the end of cancer treatment.*Conclusions The State Cancer Registry and population data analysis demonstrates the protective effects of the surveillance imaging among HNSCC patients with the regionalized or distant disease by SEER staging. The protective association was observed up to 5 years after the completion of treatment.SEER cancer staginghttps://training.seer.cancer.gov/staging/systems/summary/*Clinical Relevance/Application This state cancer registry study suggests that surveillance imaging reduces the mortality of patients with HNSCC with regionalized and distance cancer stages, adjusted for confounding variables.

RESULTS

HNSCC patients who had surveillance imaging codes did not have overall lower mortality compared to patients who did not have surveillance imaging codes after the end of cancer treatment (Fig 1) (HR: 0.78, 95%CI: 0.58, 1.05). In the stratified analyses by cancer stage, the risk of death was lower among patients with surveillance imaging for regionalized cancer stage (HR: 0.61, 95%CI: 0.40, 0.94), and distant cancer stage (HR: 0.33, 95%CI: 0.16, 0.67). The protective association was observed in the first two years and the first 5 years from the end of cancer treatment.

CLINICAL RELEVANCE/APPLICATION

This state cancer registry study suggests that surveillance imaging reduces the mortality of patients with HNSCC with regionalized and distance cancer stages, adjusted for confounding variables.

Sub-Events

SSIN03-2   The Federated Tumor Segmentation Initiative: The First Real-world Large-scale Federation Focusing On Neurooncology

Participants

Sarthak Pati, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Towards ensuring robustness and generalizability of artificial intelligent (AI) methods, ample and diverse multi-site patient datasets are desired. However, various factors hinder access to such data in the current paradigm of multi-site collaborations, such as data ownership & legal considerations. To address these, we introduce the Federated Tumor Segmentation (FeTS) Initiative, which includes an open-source package for collaborative learning of AI methods across multiple international sites using federated learning (FL). FL is a novel paradigm for data-private multi-site collaborations, where AI models leverage available data at participating sites, without sharing data between them. As an initial use-case, FeTS focused on the quantification and detection of brain tumor boundaries in MRI scans.*Methods and Materials We designed the FeTS tool with 4 modes of operation: 1) MRI data pre-processing, including co-registration to an anatomical atlas & brain extraction, 2) delineation of brain tumor sub-regions by label fusion of a library of top-performing pretrained models in the BraTS challenge, 3) drawing tools to manually refine the delineations, and 4) federated model training using the OpenFL library. 60 international collaborating sites identified local retrospective data of glioblastoma patients and after using the first 3 modes of operation of FeTS they generated the ground truth labels for the apparent tumor sub-regions. They then trained the same AI model architecture on their local data, and share the model weight updates to an aggregator, which combines the updates from all collaborators to generate a consensus model and shares it back.*Results For the initial training of the FeTS consensus model, 23 institutions participated with data of 2200 glioblastoma patients. We observe an improvement of 11.1% in the accuracy of the model on each collaborator's validation data when compared to a model trained on the publicly available BraTS data.*Conclusions There is no data sharing across participating sites and the final consensus FeTS model will be made publicly available for further research and analyses. From the initial training phase, the model performance is expected to improve further when trained with all 60 institutions, as supported by our preliminary findings. FeTS enables training an AI model with knowledge from data of geographically distinct collaborators, without ever having to share the data, overcoming hurdles relating to legal, ownership, and technical concerns.*Clinical Relevance/Application Federated Learning allows training of AI models using diverse datasets without sharing the data. This would result in more robust models without stepping on ethical dilemmas.

RESULTS

For the initial training of the FeTS consensus model, 23 institutions participated with data of 2200 glioblastoma patients. We observe an improvement of 11.1% in the accuracy of the model on each collaborator's validation data when compared to a model trained on the publicly available BraTS data.

CLINICAL RELEVANCE/APPLICATION

Federated Learning allows training of AI models using diverse datasets without sharing the data. This would result in more robust models without stepping on ethical dilemmas.

SSIN03-4   Analysis Of Changes In Follow-up Liver Metastases In Cect By Automatic Volumetric Simultaneous Deep Learning Classification

Participants

Leo Joskowicz, Jerusalem, Israel (*Presenter*) Officer, HighRAD Ltd

PURPOSE

To evaluate the performance of a novel method that identifies and analyzes the changes of the volume of liver metastasis in contrast enhanced abdominal CT (CECT) between the current and the prior scans by deep learning classification performed simultaneously.*Methods and Materials We developed a novel end-to-end method for the automatic identification and comprehensive quantification of volumetric changes in liver metastases between current and prior CECT scans by simultaneous (analysis of both scans concurrently) deep learning volumetric lesion changes classification. The method consist of five steps: 1) liver region of interest (ROI) segmentation in each scan; 2) pairwise liver ROI deformable registration; 3) simultaneous liver metastases detection and segmentation in the liver ROIs with a new simultaneous 3D U-Net classifier; 4) liver metastases changes detection by bipartite lesions matching; 5) liver metastases changes analysis by computation of volumetric changes of each metastasis between the prior and the current scans.We evaluated our method with 68 pairs of retrospective clinical CECT scans (50 used for training and validation, 18 used for testing) of patients with metastatic (breast, colon, pancreas) disease with a total of 2,042 liver metastases manually delineated by an expert radiologist. We quantified the performance on the test set by comparing it to a standalone method (separate analysis of each scan) with a standard 3D U-Net trained on 102 CECT other scans with a total

of 1,739 liver metastases manually delineated by an expert radiologist. We reported the liver metastasis Precision/Recall detection and the segmentation Dice coefficient.*Results The simultaneous method Precision/Recall outperforms the standalone method by 5.5/24.1% and 20.5/2.2% for liver metastases of diameter > 5mm and > 10mm, respectively: simultaneous Precision/Recall of 0.76/0.75 (std=0.28/0.24) and 0.94/0.93 (std=0.13/0.16) vs standalone Precision/Recall of 0.72/0.72 (std=0.26/0.19) and 0.78/0.91 (std=0.23/0.15) respectively. The simultaneous segmentation Dice coefficient also outperforms the standalone one by 5.1% and 7.3% for liver metastases of diameter > 5mm and > 10mm, respectively: simultaneous 0.81 (std=0.2) and 0.88 (0.08) vs standalone 0.78 (std=0.1) and 0.82 (0.09) respectively.*Conclusions Simultaneous deep learning based detection and quantitative analysis of liver metastases follow-up changes analysis in CECT outperforms standard standalone detection.*Clinical Relevance/Application Computer-aided liver metastases volume change analysis by simultaneous analysis of the current and prior CECT scans may improve the estimation of changes in neoplastic involvement of the liver and the accuracy of disease status evaluation.

RESULTS

The simultaneous method Precision/Recall outperforms the standalone method by 5.5/24.1% and 20.5/2.2% for liver metastases of diameter > 5mm and > 10mm, respectively: simultaneous Precision/Recall of 0.76/0.75 (std=0.28/0.24) and 0.94/0.93 (std=0.13/0.16) vs standalone Precision/Recall of 0.72/0.72 (std=0.26/0.19) and 0.78/0.91 (std=0.23/0.15) respectively. The simultaneous segmentation Dice coefficient also outperforms the standalone one by 5.1% and 7.3% for liver metastases of diameter > 5mm and > 10mm, respectively: simultaneous 0.81 (std=0.2) and 0.88 (0.08) vs standalone 0.78 (std=0.1) and 0.82 (0.09) respectively.

CLINICAL RELEVANCE/APPLICATION

Computer-aided liver metastases volume change analysis by simultaneous analysis of the current and prior CECT scans may improve the estimation of changes in neoplastic involvement of the liver and the accuracy of disease status evaluation.

SSIN03-6   Deep Learning DXA-age From Whole-body Dual-energy Absorptiometry (DEXA) Images: Prediction Of Incident Morbidity And Mortality Versus Chronological Age In The UK Biobank

Participants
Vineet Raghu, PhD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Chronological age is an imperfect measure of biologic processes underlying aging-related diseases. Image-based estimates of age may more accurately assess underlying aging processes and improve risk assessment. We tested whether deep learning could use a whole-body dual energy absorptiometry (DXA) image to estimate a DXA-Age in years, and whether this DXA-Age was associated with incident morbidity and mortality beyond prevalent risk factors.*Methods and Materials We developed an ensemble convolutional neural network model to estimate DXA-Age using baseline whole body DXA images from 7,582 individuals in the UK Biobank, an observational study of healthy volunteers in the UK. Labels for model training were based on age-at-death for those who died during follow-up and estimated age-at-death using an externally derived survival model for those who survived. 31,948 additional UK Biobank participants were reserved as an independent testing dataset. Continuous DXA-Age estimates in years were converted into three risk groups (Low: DXA-Age more than 3 years younger than chronological age, Medium: DXA-Age within 3 years, and High: DXA-Age more than 3 years older). Cox proportional hazards regression was used to test the association between ordinal risk groups and incident morbidity and mortality adjusted for chronological age, sex, smoking, Charlson co-morbidity index, prevalent diabetes, prevalent hypertension, and body composition indices (height, weight, waist circumference, and BMI). Results are provided for the testing dataset only.*Results In the testing dataset (N = 31,948; mean age 64.6±7.5; 51.7% female;mean follow-up time 2.5±1.2 years), individuals in the high-risk groupaccording to DXA-Age were at higher risk than the low-risk group for all-cause mortality(aHR 2.99 95% CI [1.5,5.9]; p < 0.001), incident cardiovascular disease (aHR1.35 [0.9,2.0], p = 0.12), incident type 2 diabetes (aHR 2.76 [1.6,4.6], p <0.001) and incident cancer (aHR 2.11 [1.4,3.1], p < 0.001) after adjustment.*Conclusions Based on a whole-body DXA image, a deep learning model can estimate a DXA-Age that predicts incident morbidity and mortality beyond chronological age, body composition, and risk factors, suggesting it might be capturing an element of biological aging.*Clinical Relevance/Application DXA-Age may help direct prevention and screening interventions to those at high-risk for chronic disease.

RESULTS

In the testing dataset (N = 31,948; mean age 64.6±7.5; 51.7% female;mean follow-up time 2.5±1.2 years), individuals in the high-risk groupaccording to DXA-Age were at higher risk than the low-risk group for all-cause mortality(aHR 2.99 95% CI [1.5,5.9]; p < 0.001), incident cardiovascular disease (aHR1.35 [0.9,2.0], p = 0.12), incident type 2 diabetes (aHR 2.76 [1.6,4.6], p <0.001) and incident cancer (aHR 2.11 [1.4,3.1], p < 0.001) after adjustment.

CLINICAL RELEVANCE/APPLICATION

DXA-Age may help direct prevention and screening interventions to those at high-risk for chronic disease.

SSCA09-1 Diagnostic Accuracy And Prognostic Significance Of Coronary Artery Calcification On Contrast-enhanced Versus Non-contrast Chest CT In Relation To Agatston Calcium Scores

Participants

Camila Urzua Fresno, MD, Toronto, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study was to evaluate the diagnostic accuracy and prognostic value of coronary artery calcification (CAC) on contrast enhanced (CE) and non-contrast (NC) non-gated chest CT in comparison to Agatston CAC scores.*Methods and Materials Consecutive patients who underwent non-gated chest CT and cardiac CT within a 6-month interval between 2010-2014 were included. A blinded observer scored CAC visually on chest CT using an ordinal scale (absent, mild, moderate or severe). Agatston calcium scores were evaluated on cardiac CT using dedicated post-processing software according to established guidelines. Major adverse cardiac events (MACE) were assessed as a composite of cardiovascular death and myocardial infarction. Statistical analysis included Spearman correlation and Cox proportional hazards models.*Results 260 patients were included (60±11 years, 61% male, 45% CE chest CT) with median follow-up of 5.5 years. Agatston CAC scores correlated strongly with ordinal visual CAC scores on both CE (r=0.94, p<0.001) and NC chest CT (r=0.93, p<0.001). CE and NC chest CT both had high sensitivity (83% [62/75] and 90% [85/95], respectively) and specificity (100% [41/41] and 100% [49/49], respectively) for presence of CAC on cardiac CT. Diagnostic accuracy did not differ significantly between CE and NC chest CT (p=0.21). CAC was misclassified as absent on 13 CE and 10 NC chest CTs; in all cases the Agatston score was very low (<30) and none of these patients experienced MACE. CAC was strongly associated with MACE on both cardiac CT (HR 1.04, 95%CI 1.01-1.06, p=0.010) and chest CT (HR 2.7, 95%CI 1.5-4.8, p=0.001). Severe CAC on chest CT was associated with 12 times higher risk of MACE compared to no CAC (HR 12.5, 95%CI 2.5-63, p=0.002).*Conclusions Simple ordinal visual assessment of CAC on contrast-enhanced and non-contrast chest CT has high diagnostic accuracy and is strongly associated with adverse outcomes, comparable to Agatston calcium scoring. Assessment and reporting of CAC on all chest CT studies could identify a large number of patients who might not otherwise have been considered candidates for preventative medical therapy, but who may receive a benefit from treatment.*Clinical Relevance/Application Current guidelines recommend evaluation of CAC on non-contrast chest CT only. This data suggests that assessment of CAC using a simple visual ordinal scale should be recommended on all chest CT studies.

RESULTS

260 patients were included (60±11 years, 61% male, 45% CE chest CT) with median follow-up of 5.5 years. Agatston CAC scores correlated strongly with ordinal visual CAC scores on both CE (r=0.94, p<0.001) and NC chest CT (r=0.93, p<0.001). CE and NC chest CT both had high sensitivity (83% [62/75] and 90% [85/95], respectively) and specificity (100% [41/41] and 100% [49/49], respectively) for presence of CAC on cardiac CT. Diagnostic accuracy did not differ significantly between CE and NC chest CT (p=0.21). CAC was misclassified as absent on 13 CE and 10 NC chest CTs; in all cases the Agatston score was very low (<30) and none of these patients experienced MACE. CAC was strongly associated with MACE on both cardiac CT (HR 1.04, 95%CI 1.01-1.06, p=0.010) and chest CT (HR 2.7, 95%CI 1.5-4.8, p=0.001). Severe CAC on chest CT was associated with 12 times higher risk of MACE compared to no CAC (HR 12.5, 95%CI 2.5-63, p=0.002).

CLINICAL RELEVANCE/APPLICATION

Current guidelines recommend evaluation of CAC on non-contrast chest CT only. This data suggests that assessment of CAC using a simple visual ordinal scale should be recommended on all chest CT studies.

SSCA09-3 Machine Learning For Time-to-Event Analysis In Patients With Suspected Coronary Artery Disease: Increased Long-term Prognostic Value Of Coronary CT Angiography-derived Measures And Clinical Parameters

Participants

Maximilian Bauer, MEd, Munich, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To assess the long-term prognostic value of machine learning (ML) in time-to-event analyses on coronary CT angiography (CCTA)-derived measures and clinical parameters.*Methods and Materials Datasets of 5457 patients (61.1 ± 11.1 years, 66.8% male) with suspected coronary artery disease who underwent CCTA were retrospectively analyzed. Major adverse cardiovascular events (MACE) were defined as composite of all-cause death, myocardial infarction, instable angina, or late revascularization (>90 days after index scan). Demographic parameters, clinical cardiovascular risk factors, CCTA-derived plaque features, and established CCTA-derived risk scores were assessed as predictors of MACE and incorporated into two models: a) A Cox proportional hazards

(CPH) model with recursive feature elimination as reference. b) A ML model based on random survival forests with log-rank as splitting rule. Both models were trained and validated employing repeated nested cross-validation. Harrell's concordance index (C-index) was used to assess the predictive power.*Results During the median follow-up of 7.3 years (IQR: 4.5 - 9.8 years), MACE was observed in 304 patients (5.6 %). The predictive power of the ML model (C-index 0.74 [95%CI 0.71-0.76]) was significantly higher compared to the CPH model (C-index 0.71 [95%CI 0.68-0.74], p=0.02). The ML model also outperformed single CCTA-derived parameters (C-indices 0.44-0.69, all p<0.001) including the segment stenosis score (C-index 0.69 [95%CI 0.66-0.72], p<0.001) and the number of segments with spotty calcifications (C-index 0.66 [95%CI 0.63-0.69], p<0.001). Similar results were observed compared to the clinical predictors (C-indices 0.48-0.66, all p<0.001) including patients' age (C-index 0.66 [95%CI 0.63-0.69], p<0.001) and the Framingham risk score (C-index 0.65 [95%CI 0.62-0.69], p<0.001).*Conclusions ML-based time-to-event analysis was found to predict MACE more accurately than existing clinical or CCTA-derived metrics and a conventional Cox-based model integrating these features.*Clinical Relevance/Application ML may improve risk stratification by enhanced integration of clinical and CCTA-derived risk predictors. Despite efforts to incorporate plaque analysis into the evaluation of CCTA data, the clinical relevance of CCTA-based risk stratification so far has been limited. By introducing time-to-event analysis to machine learning models that integrate clinical and CCTA-derived predictors, our approach has the potential to increase the precision of personalized risk predictions.

RESULTS

During the median follow-up of 7.3 years (IQR: 4.5 - 9.8 years), MACE was observed in 304 patients (5.6 %). The predictive power of the ML model (C-index 0.74 [95%CI 0.71-0.76]) was significantly higher compared to the CPH model (C-index 0.71 [95%CI 0.68-0.74], p=0.02). The ML model also outperformed single CCTA-derived parameters (C-indices 0.44-0.69, all p<0.001) including the segment stenosis score (C-index 0.69 [95%CI 0.66-0.72], p<0.001) and the number of segments with spotty calcifications (C-index 0.66 [95%CI 0.63-0.69], p<0.001). Similar results were observed compared to the clinical predictors (C-indices 0.48-0.66, all p<0.001) including patients' age (C-index 0.66 [95%CI 0.63-0.69], p<0.001) and the Framingham risk score (C-index 0.65 [95%CI 0.62-0.69], p<0.001).

CLINICAL RELEVANCE/APPLICATION

ML may improve risk stratification by enhanced integration of clinical and CCTA-derived risk predictors. Despite efforts to incorporate plaque analysis into the evaluation of CCTA data, the clinical relevance of CCTA-based risk stratification so far has been limited. By introducing time-to-event analysis to machine learning models that integrate clinical and CCTA-derived predictors, our approach has the potential to increase the precision of personalized risk predictions.

SSCA09-6   Using Machine-learning Based CAD-RADS From Radiological Reports And Non-curated Electronic Medical Records Data For Adverse Cardiac Events Prediction

Participants
Marly van Assen, MSc, Atlanta, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this retrospective study is to evaluate whether integration of standard Coronary Artery Disease Reporting & Data System score (CADRADs) extracted from radiology reports and non-curated data from the electronic medical records (EMR) can be used as a predictor for forecasting 5-year risk of adverse cardiac events (ACE) using a machine learning (ML) approach.*Methods and Materials This study included CCTA images of 2407 patients (55% male, mean age 57 years). Two groups of ACE, ischemic ACE (ICD-10:I20-25) and other ACE (ICD-10:I30-39) within 5 years of CCTA were considered as targeted outcome. A Natural Language Processing model which achieved high precision for the same task against expert evaluation, was used to extract CADRADs from structured (formatted using CADRADs) and unstructured (historical) radiology reports. We designed a multimodal ML model that used EMR data such as demographics, co-morbidities (based on ICD and CTP codes), medications, and laboratory test results; all recorded before the day of CCTA exam. Two type of fusion models were evaluated, an early fusion model where features from all EMR modalities were concatenated, normalized, and processed through a predictor; and a late fusion model where cardiac event probabilities, estimated using individual predictors for each EMR modality, were concatenated and passed through a meta-learner for prediction. An XGBoost was used for early fusion and as meta-learner for late fusion. We fine-tuned hyper-parameters using grid-search. The models were evaluated using standard statistical metrics - accuracy and F1 scores.*Results A total of 331(14%) and 400(17%) patients had ischemic ACE or other ACE, respectively. Using CADRADs for the prediction of outcome resulted in an accuracy of 0.68 and 0.74 for ischemic ACE and other ACE. F1-scores for no events were 0.79 and 0.84 for both outcome classes and F1-scores for events were 0.32 and 0.19, respectively. The early/late fusion models resulted in a similar accuracy of 0.68/0.62 and 0.75/0.72 for ischemic ACE, and other ACE, respectively. F1-scores for no events were 0.79/0.75 and 0.84/0.82 for both outcome classes and F1-scores for events were 0.38/0.27 and 0.43/0.3, respectively.*Conclusions ML-CADRADS and non-curated EMR data could predict adverse cardiac events with moderate accuracy. EMR model shows better performance for event prediction, since a large amount of clinical data are included in comparison with report-derived CADRADs. The early/late fusion models resulted in a similar prediction accuracy.*Clinical Relevance/Application Using ML on multi-modal non-curated data is a time-efficient way to assess cardiac event risk. This approach uses a wide variety of clinical, lab and imaging variables without requiring human labor.

RESULTS

A total of 331(14%) and 400(17%) patients had ischemic ACE or other ACE, respectively. Using CADRADs for the prediction of outcome resulted in an accuracy of 0.68 and 0.74 for ischemic ACE and other ACE. F1-scores for no events were 0.79 and 0.84 for both outcome classes and F1-scores for events were 0.32 and 0.19, respectively. The early/late fusion models resulted in a similar accuracy of 0.68/0.62 and 0.75/0.72 for ischemic ACE, and other ACE, respectively. F1-scores for no events were 0.79/0.75 and 0.84/0.82 for both outcome classes and F1-scores for events were 0.38/0.27 and 0.43/0.3, respectively.

CLINICAL RELEVANCE/APPLICATION

Using ML on multi-modal non-curated data is a time-efficient way to assess cardiac event risk. This approach uses a wide variety of clinical, lab and imaging variables without requiring human labor.

SSRO03-1   Follow-up Imaging In Patients Operated For Ovarian Cancer; Is It Really Necessary When Ca 125 Levels Are Normal? A Preliminary Study

Participants
Riccardo Valletta, MD, Verona, Italy (*Presenter*) Nothing to Disclose

PURPOSE

To correlate follow-up CT and PET-CT imaging findings in patients who underwent surgery for malignant ovarian neoplasms with CA 125 serum levels at the moment of examination.*Methods and Materials We included in our IRB-approved retrospective study 33 consecutive patients (mean age 58 ± 14 years) with histologically proven malignant ovarian neoplasms (21 serous carcinomas, 7 endometrioid carcinomas and 4 mucinous carcinomas) who underwent oncologic surgery and follow-up in our institution. Pre- and post-operative CA 125 serum levels were retrieved from institutional database. Two radiologists, unaware of clinical and laboratory data, independently analyzed CT and PET-CT examinations performed during follow-up. Every examination was classified as negative or positive for the presence of disease; moreover, the disease trend was classified as complete response (CR), partial response (PR), stable disease (SD) or progressive disease (PD). Discrepancies were solved by consensus. Imaging findings were finally compared with serum CA 125 levels at the moment of examination (±15 days) and with their trend (stable/decrease/increase).*Results We examined 83 CTs (0,83 CT per patient per year) and 60 PET-CTs (0,49 PET-CT per patient per year). At the moment of examination, serum CA 125 levels were normal (<35 U/mL) in 97/143 cases (68%) and above the limit (=35 U/m) in 46/143 cases (32%). When serum CA 125 levels were normal we observed 96/97 cases of CR (96%) and 4/97 cases of PD (4%). When a PD was observed with normal serum CA 125 levels in 1 case it resulted to be a false positive whereas in the remaining 3 cases the marker serum levels showed a significant increase in comparison to the previous levels. When serum CA 125 levels were above the limit we observed 29/46 cases of PD (63%), 7/46 cases of SD (15%), 4/46 cases of PR (9%) and 6/46 cases of CR (13%). In 38 cases the serum CA 125 levels rised above the limit in comparison to the prior serum levels and imaging showed a PD in 32 cases (84%); in the remaining 6 cases a PD was found in the subsequent radiological examination.*Conclusions In no patient with normal serum CA 125 serum levels at the moment of imaging CT/PET-CT showed the presence of disease. Therefore, imaging is not indicated in the follow-up of patients treated for malignant ovarian cancer if CA 125 serum levels are normal.*Clinical Relevance/Application CT/PET-CTs examinations should be avoided in the follow up of patients treated for malignant ovarian neoplasms until CA 125 serum values are normal, reducing both radiation exposure and costs.

RESULTS

We examined 83 CTs (0,83 CT per patient per year) and 60 PET-CTs (0,49 PET-CT per patient per year). At the moment of examination, serum CA 125 levels were normal (<35 U/mL) in 97/143 cases (68%) and above the limit (=35 U/m) in 46/143 cases (32%). When serum CA 125 levels were normal we observed 96/97 cases of CR (96%) and 4/97 cases of PD (4%). When a PD was observed with normal serum CA 125 levels in 1 case it resulted to be a false positive whereas in the remaining 3 cases the marker serum levels showed a significant increase in comparison to the previous levels. When serum CA 125 levels were above the limit we observed 29/46 cases of PD (63%), 7/46 cases of SD (15%), 4/46 cases of PR (9%) and 6/46 cases of CR (13%). In 38 cases the serum CA 125 levels rised above the limit in comparison to the prior serum levels and imaging showed a PD in 32 cases (84%); in the remaining 6 cases a PD was found in the subsequent radiological examination.

CLINICAL RELEVANCE/APPLICATION

CT/PET-CTs examinations should be avoided in the follow up of patients treated for malignant ovarian neoplasms until CA 125 serum values are normal, reducing both radiation exposure and costs.

SSRO03-2   Hypofractionated Radiation Leads To More Rapid Bleeding Cessation In Women With Vaginal Bleeding Secondary To Gynecologic Malignancy

Participants
Luke Moradi, Birmingham, Alabama (*Presenter*) Nothing to Disclose

PURPOSE

Vaginal bleeding is a common complication in women with gynecologic (GYN) malignancies and in some cases may be severe, resulting in anemia, need for transfusion, hospitalization and in rare cases may even be life-threatening. Radiation therapy (RT) is commonly used both in the definitive treatment of GYN cancers and for palliation of bleeding. The historical dogma is that high dose per fraction radiation (i.e. hypofractionation) leads to more rapid cessation of bleeding, yet there is scant data to actually support this claim. Therefore, we sought to examine the effect of RT fraction size on bleeding via retrospective analysis of patients receiving hypofractionated radiation therapy (HFRT) compared to conventionally fractionated radiation therapy (CFRT) for control of bleeding secondary to GYN malignancies.*Methods and Materials We identified patients receiving external beam radiation therapy

for continuous vaginal bleeding related to underlying GYN malignancy that were treated in our department from 2010-2020. Radiation was classified as HFRT (>2.4 Gy/fx) or CFRT (1.8 - 2.0 Gy/fx). Demographic information, disease characteristics, and treatment details were collected. The primary endpoint was days from RT initiation until complete bleeding resolution. Baseline characteristics between groups were compared via the Chi-square test. Time to bleeding cessation was assessed via Kaplan-Meier and log-rank test. Univariate Cox-proportional hazards was used to identify factors associated with bleeding cessation.*Results We identified 44 patients meeting inclusion criteria with 26 patients receiving CFRT and 18 patients receiving HFRT. The only identified statistically significant differences in baseline characteristics between the CFRT and HFRT groups included age (p<0.001), menopausal status (p<0.001), and receipt of concurrent chemotherapy (p<0.001). Time to bleeding cessation was significantly shorter for patients receiving HFRT on log-rank testing (p=0.042) with median time to bleeding cessations of 5 days (HFRT) vs. 16 days (CFRT). Cox univariate regression revealed RT fractionation was the only statistically significant indicator of bleeding cessation with a hazard ratio of 1.92 (p=0.040).*Conclusions Patients with continuous vaginal bleeding from GYN tumors receiving HFRT experienced more rapid bleeding cessation than those receiving CFRT. For patients with significant vaginal bleeding, initiation of HFRT to control malignancy related bleeding quickly may be warranted.*Clinical Relevance/Application Vaginal bleeding is a common complication of GYN malignancies but data regarding optimal radiation dosing for cessation of bleeding is scant. Our data suggests that hypofractionated RT resolves bleeding more rapidly.

RESULTS

We identified 44 patients meeting inclusion criteria with 26 patients receiving CFRT and 18 patients receiving HFRT. The only identified statistically significant differences in baseline characteristics between the CFRT and HFRT groups included age (p<0.001), menopausal status (p<0.001), and receipt of concurrent chemotherapy (p<0.001). Time to bleeding cessation was significantly shorter for patients receiving HFRT on log-rank testing (p=0.042) with median time to bleeding cessations of 5 days (HFRT) vs. 16 days (CFRT). Cox univariate regression revealed RT fractionation was the only statistically significant indicator of bleeding cessation with a hazard ratio of 1.92 (p=0.040).

CLINICAL RELEVANCE/APPLICATION

Vaginal bleeding is a common complication of GYN malignancies but data regarding optimal radiation dosing for cessation of bleeding is scant. Our data suggests that hypofractionated RT resolves bleeding more rapidly.

SSRO03-3   Multi-modal Deep-learning Based Prediction Of Stereotactic Body Radiotherapy Induced Vertebral Compression Fracture

Participants
Seoyoung Lee, MS, Daejeon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The spine is one of the most common sites of malignant tumor metastasis. Stereotactic body radiotherapy therapy (SBRT) has been widely used to treat spinal bone metastases (SBM). However, it has been reported that patients may later suffer from an SBRT-induced vertebral compression fracture (VCF). VCF can degrade a patient's quality of life by causing severe pain and also disrupt future surgical plans. Therefore, it is necessary to identify the potential risk groups and inform them of VCF prevention prior to performing SBRT. The purpose of the proposed research is to develop a prediction model that can produce a quantitative probability of occurrence of VCF in metastatic spine tumor patients who received SBRT.*Methods and Materials The cohort of 131 patients received SBRT for SBM at Samsung Medical Center (SMC), South Korea. Prognostic factors of SBRT-induced VCF can be divided into three categories: clinical factors, anatomical image factors, and radiotherapy factors. We developed a deep-learning-based multi-modal network that effectively combines those different types of information. A combined model of the multi-layer perceptron and convolutional neural network was selected as our model. Based on the registered dose map information, relevant tomographic image region-of-interests (ROIs) were selected and fed forward to the network. Appropriate data augmentation was performed in CT image data.*Results The network yielded a prediction accuracy of higher than 90% in the validation study. Other metrics such as high average precision (AP = 0.722) and high area-under-curve (AUC = 0.992) suggest that our multi-modal network can successfully predict the VCF probability after the SBRT. The proposed network showed the best result among other single-modal networks.*Conclusions We developed a multi-modal network-based SBRT-induced VCF prediction model. The network successfully integrated clinical factors, anatomical image factors, and radiotherapy factors, and produced a meaningful quantitative prediction. The prediction model would play a valuable role not only in the treated patients' welfare but also in the treatment planning for those patients.*Clinical Relevance/Application We propose a method of directly estimating the probability of occurrence of SBRT-induced VCF for SBM patients by use of clinical records, anatomical images, and radiotherapy factors in a deep-neural-network framework.

RESULTS

The network yielded a prediction accuracy of higher than 90% in the validation study. Other metrics such as high average precision (AP = 0.722) and high area-under-curve (AUC = 0.992) suggest that our multi-modal network can successfully predict the VCF probability after the SBRT. The proposed network showed the best result among other single-modal networks.

CLINICAL RELEVANCE/APPLICATION

We propose a method of directly estimating the probability of occurrence of SBRT-induced VCF for SBM patients by use of clinical records, anatomical images, and radiotherapy factors in a deep-neural-network framework.

SSRO03-6   Computational Models Forecasting Response Of High-grade Glioma During Adaptive Radiation Therapy

Participants
Maguy Farhat, MD, Houston, Texas (*Presenter*) Nothing to Disclose

PURPOSE

To determine if multi-parametric magnetic resonance imaging (mpMRI) collected during adaptive radiation therapy (RT) can personalize a mechanism-based model to spatially forecast response in patients with high-grade glioma (HGG) prior to the completion of therapy.*Methods and Materials Following maximal safe resection, patients with pathologically confirmed HGG planned for 6 weeks of concurrent RT and chemotherapy were enrolled into a prospective single-arm adaptive RT trial (target n=80). Patients were imaged weekly with mpMRI over 6 weeks and with contrast at baseline and at week 3 of RT. Extent of tumor burden was defined on post contrast T1 weighted MRI and on T2 FLAIR images; as well as tumor cellularity evaluated by the apparent diffusion coefficient on diffusion imaging. Each patient's MRI data was used to initialize and calibrate a 3D two-species

mathematical model describing the enhancing and non-enhancing tumor volume during RT. We investigated the ability of this model calibrated with different subsets of imaging data to predict the size and distribution of the tumor during the final week of RT (week 6). The predictive accuracy was assessed using model parameters calibrated with different imaging time points. The error in predictions was evaluated at the global level by using percent error in the total number of estimated tumor cells, the percent error in tumor volume, and the Dice correlation value; as well as the local voxel levels by assessing spatial agreement via the Pearson correlation coefficient (PCC), and the concordance correlation coefficient (CCC).*Results We present the preliminary results for two patients using baseline and weekly (during RT) mpMRI data to predict tumor extent at week 6 of RT. The global percent error in total cell count and tumor volume decrease with increasing weeks of data used to calibrate the model. At week 3 (contrast mpMRI), we observed a dramatic improvement in prediction with 11.4% and 12.1% error in tumor volume in these two cases with Dice of values 0.87 and 0.82 respectively, and greater than 0.82 PCC and 0.73 CCC at the local level.*Conclusions Using our two species mathematical model for tumor growth, we demonstrated the ability to forecast the tumors' extent during the final week of RT using the baseline and weekly mpMRI data during RT with particular improvement with repeated enhanced mpMRI data at Week 3.*Clinical Relevance/Application Currently the entire course of RT for HGG is based on a treatment plan using baseline MRI. Adaptive RT is technically feasible but is adapted in reaction to anatomical tumor changes. This study demonstrates the potential to use mathematical models to forecast tumor progression during therapy enabling anticipatory adaptive radiotherapy to improve outcomes for patients with HGG.

RESULTS

We present the preliminary results for two patients using baseline and weekly (during RT) mpMRI data to predict tumor extent at week 6 of RT. The global percent error in total cell count and tumor volume decrease with increasing weeks of data used to calibrate the model. At week 3 (contrast mpMRI), we observed a dramatic improvement in prediction with 11.4% and 12.1% error in tumor volume in these two cases with Dice of values 0.87 and 0.82 respectively, and greater than 0.82 PCC and 0.73 CCC at the local level.

CLINICAL RELEVANCE/APPLICATION

Currently the entire course of RT for HGG is based on a treatment plan using baseline MRI. Adaptive RT is technically feasible but is adapted in reaction to anatomical tumor changes. This study demonstrates the potential to use mathematical models to forecast tumor progression during therapy enabling anticipatory adaptive radiotherapy to improve outcomes for patients with HGG.

SSCA06-1 Left Atrial Strain Correlates With Severity Of Cardiac Involvement In Fabry's Disease

Participants
Tilman Emrich, MD, Charleston, South Carolina (*Presenter*) Speaker, Siemens AG;Travel support, Siemens AG

PURPOSE

Fabry's disease (FD) is characterized by sphingolipid accumulation, leading to increased myocardial mass and shortened myocardial T1, resulting in the pathological alteration of myocardial geometry and function, which correlates with adverse events. Treatment with enzyme replacement therapy (ERT) is restricted to patients with evidence of organ involvement in FD. However, inefficient ERT has been demonstrated in later stages of cardiac involvement. Therefore, it is crucial to detect early stages of cardiac involvement in FD. The aim of this study was to evaluate the changes in LA strain in correlation to FD severity and demonstrate the improvement in diagnostic performance by combining functional LA parameters and conventional markers for myocardial involvement assessment.*Methods and Materials Fifty-seven FD patients (including 17 patients in the per-hypertrophic stage, and 40 patients with cardiac involvement) and 50 healthy volunteers who had previously undergone cardiac MRI at 3T were included in this retrospective study. Myocardial T1 maps and cine images were analyzed. Global longitudinal strain of the LA was calculated from 2-, 3-, and 4-chamber cine acquisitions using the feature-tracking technique.*Results There were significant differences between healthy volunteers and FD patients in T1 (1175 ± 50 ms vs 1124 ± 65 ms, $p<0.001$), myocardial mass (54.6 ± 9.8 g/m2 vs 75.2 ± 24.7 g/m2, $p<0.001$), and LA reservoir strain (41.6 ± 7.8 % vs 32.8 ± 10.2 %, $p<0.001$). LA reservoir strain correlated with T1 ($r=0.421$, $p=0.023$) and inversely correlated with left ventricular myocardial mass ($r=-0.489$, $p<0.001$). Combining LA function parameters with myocardial mass and T1 improved the diagnostic performance to detect FD in every disease stage and provided an excellent diagnostic performance (AUC = 0.93, sensitivity 91.8%, specificity 86.1%), outperforming conventional parameters used to assess myocardial involvement (e.g. LV Mass: AUC=0.80; T1: AUC= 0.62; all $p<0.01$).*Conclusions LA strain parameters have the potential to complement current multiparametric approaches to diagnose myocardial involvement in FD, especially in the early pre-hypertrophic phase of disease.*Clinical Relevance/Application Atrial strain parameters could complement existing multiparametric approaches in order to evaluate disease severity and progression in FD, guide initiation of medical therapy and monitor treatment success.

RESULTS

There were significant differences between healthy volunteers and FD patients in T1 (1175 ± 50 ms vs 1124 ± 65 ms, $p<0.001$), myocardial mass (54.6 ± 9.8 g/m2 vs 75.2 ± 24.7 g/m2, $p<0.001$), and LA reservoir strain (41.6 ± 7.8 % vs 32.8 ± 10.2 %, $p<0.001$). LA reservoir strain correlated with T1 ($r=0.421$, $p=0.023$) and inversely correlated with left ventricular myocardial mass ($r=-0.489$, $p<0.001$). Combining LA function parameters with myocardial mass and T1 improved the diagnostic performance to detect FD in every disease stage and provided an excellent diagnostic performance (AUC = 0.93, sensitivity 91.8%, specificity 86.1%), outperforming conventional parameters used to assess myocardial involvement (e.g. LV Mass: AUC=0.80; T1: AUC= 0.62; all $p<0.01$).

CLINICAL RELEVANCE/APPLICATION

Atrial strain parameters could complement existing multiparametric approaches in order to evaluate disease severity and progression in FD, guide initiation of medical therapy and monitor treatment success.

SSCA06-2 Right Ventricular Involvement Precedes Left Ventricular Phenotypic Changes In Fabry's Disease

Participants
Tilman Emrich, MD, Charleston, South Carolina (*Presenter*) Speaker, Siemens AG;Travel support, Siemens AG

PURPOSE

The accumulation of sphingolipids in Fabry's disease (FD) leads to increased left ventricular hypertrophy (LVH) and shortened myocardial T1. Previous studies have shown a diagnostic gap between the onset of accumulation and detectable myocardial changes. However, early detection of myocardial involvement is essential for the timely initiation and efficacy of enzyme replacement therapy (ERT). The aim of this study was to investigate early changes in right ventricular (RV) mass and feature-tracking-based strains in FD patients and evaluate their diagnostic accuracy.*Methods and Materials Sixty-two genetically proven FD patients and a control group of 62 healthy volunteers (HV) underwent cardiac MR (CMR) imaging at 3T including T1 mapping and cine acquisitions. FD patients were stratified based on findings suggested by existing literature (I: phenotypically healthy, normal or low myocardial T1, no LVH; II: low myocardial T1, moderate LVH, no late gadolinium enhancement (LGE); III: low myocardial T1, positive LGE, severe LVH). RV strains and myocardial mass were evaluated using commercially available CMR software (cvi42 Circle).*Results Left ventricular (LV) CMR volumetric parameters (ejection fraction, indexed myocardial mass (LVMi)) and T1 mapping showed no significant difference between HV and group I FD patients (P>0.05 for all). Indexed right ventricular myocardial mass (RVMi) was significantly increased and RV global longitudinal strain (RV-GLS) was significantly impaired in group I FD patients

compared to HV (p< 0.05). RV-GLS was able to increase diagnostic accuracy in FD compared to LVMi and myocardial T1 (RV GLS: AUC 0.81 vs. LVMi and T1 mapping: AUC 0.65).*Conclusions Morphological and functional changes in the RV precede phenotypic changes in the LV in FD. RVMi and RV-GLS can help detect altered myocardial deformation patterns in previously assumed phenotypically negative FD patients.*Clinical Relevance/Application These findings may lead to an earlier initiation of ERT, which in turn can slow or even prevent LVH and the associated long-term risks. The addition of RVMi and RV-GLS improved diagnostic accuracies, which is necessary in order to confidently rule out cardiac involvement in young patients or initiate a life-long treatment like ERT.

RESULTS

Left ventricular (LV) CMR volumetric parameters (ejection fraction, indexed myocardial mass (LVMi)) and T1 mapping showed no significant difference between HV and group I FD patients (P>0.05 for all). Indexed right ventricular myocardial mass (RVMi) was significantly increased and RV global longitudinal strain (RV-GLS) was significantly impaired in group I FD patients compared to HV (p< 0.05). RV-GLS was able to increase diagnostic accuracy in FD compared to LVMi and myocardial T1 (RV GLS: AUC 0.81 vs. LVMi and T1 mapping: AUC 0.65).

CLINICAL RELEVANCE/APPLICATION

These findings may lead to an earlier initiation of ERT, which in turn can slow or even prevent LVH and the associated long-term risks. The addition of RVMi and RV-GLS improved diagnostic accuracies, which is necessary in order to confidently rule out cardiac involvement in young patients or initiate a life-long treatment like ERT.

SSCA06-3   T1 And T1-RHO Mapping For Early Detection Of Chemotherapy-related Subclinical Cardiac Injury In Patients With Breast Cancer

Participants
Satoshi Higuchi, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Chemotherapy-related cardiac dysfunction is a serious adverse effect of chemotherapy that worsens patients' prognosis. Cardiac magnetic resonance (CMR) has the potential to detect early changes in myocardial tissue characteristics and cardiac function. The purpose of this prospective study was to evaluate whether T1 and T1-rho mapping serve as imaging biomarkers for the early detection of chemotherapy-related cardiac injury in patients with breast cancer.*Methods and Materials Thirty-two chemotherapy-native female patients with breast cancer (56 ± 13 years) scheduled for preoperative chemotherapy were prospectively enrolled. The regimen included anthracyclines for all patients. All patients underwent serial CMR examinations with a 3T whole-body MR scanner at baseline and six months after chemotherapy. Cine MR images, native T1-rho maps, native T1 maps, and extracellular volume (ECV) maps were acquired. Native T1-rho weighted images were acquired using a spin-lock preparation pulse with durations of 0ms and 20ms. Pre- and post-contrast T1 maps were generated using modified Look-Locker inversion recovery methods. Left ventricular ejection fraction (EF), end-systolic volume index, end-diastolic volume index, and mass index (ESVI, ESVI, and MI) were obtained based on short-axis stacks of cine images. Native T1-rho, native T1, and ECV values were measured by placing the regions of interests on the mid-wall of the interventricular septum in the mid-segment. Serial changes of MR parameters were evaluated using paired student's t-tests. P < 0.05 indicated statistical significance.*Results Left ventricular EDVI and ESVI were significantly increased after chemotherapy (EDVI: 63.4 ± 12.2 vs. 68.8 ± 15.9 ml/m2, p < 0.01; ESVI: 21.6 ± 8.9 vs. 26.7 ± 11.3 ml/m2, p < 0.01, respectively), and EF was significantly reduced (65.8 ± 8.7 vs. 62.2 ± 7.8 %, p = 0.02). MI showed no significant difference after chemotherapy. Native T1 and T1 rho values significantly elevated after chemotherapy (native T1: 1268 ± 38 vs. 1298 ± 47 ms, p < 0.01; T1 rho: 56.6 ± 4.0 vs. 59.0 ± 5.3 ms, p = 0.02, respectively), although ECV showed no significant difference.*Conclusions Native T1-rho and T1 values were elevated along with reduced cardiac function after anthracycline chemotherapy in patients with breast cancer. Non-invasive CMR may play a role in the early detection of chemotherapy-related cardiac injury.*Clinical Relevance/Application Native T1-rho and T1 values in CMR may become an emerging non-invasive biomarker for the early detection of cancer therapeutics-related cardiac injury in patients with breast cancer.

RESULTS

Left ventricular EDVI and ESVI were significantly increased after chemotherapy (EDVI: 63.4 ± 12.2 vs. 68.8 ± 15.9 ml/m2, p < 0.01; ESVI: 21.6 ± 8.9 vs. 26.7 ± 11.3 ml/m2, p < 0.01, respectively), and EF was significantly reduced (65.8 ± 8.7 vs. 62.2 ± 7.8 %, p = 0.02). MI showed no significant difference after chemotherapy. Native T1 and T1 rho values significantly elevated after chemotherapy (native T1: 1268 ± 38 vs. 1298 ± 47 ms, p < 0.01; T1 rho: 56.6 ± 4.0 vs. 59.0 ± 5.3 ms, p = 0.02, respectively), although ECV showed no significant difference.

CLINICAL RELEVANCE/APPLICATION

Native T1-rho and T1 values in CMR may become an emerging non-invasive biomarker for the early detection of cancer therapeutics-related cardiac injury in patients with breast cancer.

SSCA06-5   Untilization And Prognostic Value Of Cardiac Magnetic Resonance In Patients With Peripartum Cardiomyopathy

Participants
Huayan Xu, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

To detect the heterogeneity of myocardial injury with Cardiac magnetic resonance (CMR) late gadolinium enhancement (LGE) in peripartum cardiomyopathy (PPCM), and further create a predictive model to investigate the role of LGE in long-term prognosis for poor outcomes.*Methods and Materials This study collected data from 106 patients with PPCM at four high-ranking Chinese medical centres from January, 2010, to December, 2019. All patients underwent CMR after PPCM was diagnosed. Moreover, clinical characteristics, laboratory results, echocardiographic and electrocardiographic findings at diagnosis, as well as main clinical outcomes, including major adverse cardiac events (MACEs), non-recovered left ventricular ejection fraction (LVEF) and recovered LVEF, were recorded and compared.*Results Among the 106 women with PPCM (mean age, 29.93±5.34 years) who were studied, LGE was detected on the CMR images of 47 (44.34%) patients, indicating myocardial damages. Patients with diffuse LGE were more likely to experience MACEs [4 (17.39%) deaths, 4 (17.39%) heart transplantations and 4 (17.39%) readmissions to the hospital due to heart failure] than those with focal LGE (OR: 8.229; 95% CI: 1.144 to 59.167, p=0.003) and no LGE (OR: 20.229; 95% CI: 2.747 to 148.974, p=0.000). The event-free rates for MACEs (Log-rank ?2=12, p=0.002) and non-recovered LVEF (Log-rank ?2=18.4, p<0.001) of PPCM patients with diffuse LGE and focal LGE were significantly lower than those without LGE. The multivariate model

demonstrated that LGE (hazard ratio (HR), 2.431; 95% CI, 1.453-4.067; P=0.001) was an independent prognostic factor for MACEs and non-recovered LVEF. The predictive nomogram of LGE showed good discrimination for MACEs and non-recovered LVEF (C index=0.78; 95% CI, 0.61-0.95).*Conclusions LGE is an incremental, independent predictor of MACEs and non-recovered LVEF in PPCM. Cardiovascular magnetic resonance assessments of LGE should be recommended for the risk stratification and clinical management of PPCM patients.*Clinical Relevance/Application In summary, CMR LGE is clinically and prognostically relevant for PPCM. Although almost all PPCM patients without LGE had a good prognosis, significant numbers of such women still had a high risk of myocardial tissue injury, potentially leading to increased deterioration during follow-up. The available information also suggests that LGE could be an important prognostic factor for poor outcomes such as MACEs or non-recovered LVEF and provide risk stratification for PPCM. Therefore, monitoring myocardial involvement with CMR LGE is therefore recommended for the long-term management of PPCM and prevention of detrimental consequences.

RESULTS

Among the 106 women with PPCM (mean age, 29.93±5.34 years) who were studied, LGE was detected on the CMR images of 47 (44.34%) patients, indicating myocardial damages. Patients with diffuse LGE were more likely to experience MACEs [4 (17.39%) deaths, 4 (17.39%) heart transplantations and 4 (17.39%) readmissions to the hospital due to heart failure] than those with focal LGE (OR: 8.229; 95% CI: 1.144 to 59.167, p=0.003) and no LGE (OR: 20.229; 95% CI: 2.747 to 148.974, p=0.000). The event-free rates for MACEs (Log-rank ?2=12, p=0.002) and non-recovered LVEF (Log-rank ?2=18.4, p<0.001) of PPCM patients with diffuse LGE and focal LGE were significantly lower than those without LGE. The multivariate model demonstrated that LGE (hazard ratio (HR), 2.431; 95% CI, 1.453-4.067; P=0.001) was an independent prognostic factor for MACEs and non-recovered LVEF. The predictive nomogram of LGE showed good discrimination for MACEs and non-recovered LVEF (C index=0.78; 95% CI, 0.61-0.95).

CLINICAL RELEVANCE/APPLICATION

In summary, CMR LGE is clinically and prognostically relevant for PPCM. Although almost all PPCM patients without LGE had a good prognosis, significant numbers of such women still had a high risk of myocardial tissue injury, potentially leading to increased deterioration during follow-up. The available information also suggests that LGE could be an important prognostic factor for poor outcomes such as MACEs or non-recovered LVEF and provide risk stratification for PPCM. Therefore, monitoring myocardial involvement with CMR LGE is therefore recommended for the long-term management of PPCM and prevention of detrimental consequences.

SSCA06-6   Cardiac MRI Versus FDG-PET For The Detection Of Cardiac Sarcoidosis: A Comparative Diagnostic Test Accuracy Systematic Review And Meta-analysis

Participants
Matthew Aitken, MBChB, Toronto, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

Detection of cardiac sarcoidosis (CS) is important given poor prognosis if it is untreated. The optimal cardiac imaging modality for assessment has not been established. The purpose of this study was to perform a comparative diagnostic test accuracy systematic review and meta-analysis comparing cardiac MRI and 18F-FDG PET for detection of CS.*Methods and Materials Ovid MEDLINE, Ovid Epub, Cochrane CENTRAL, EMBASE, Ovid EMCARE, and Scopus were searched from inception until December 2020. Inclusion criteria included studies that evaluated the diagnostic accuracy of cardiac MRI with late gadolinium enhancement (LGE) and/or 18F-FDG PET in adult patients with suspected CS and included sufficient data for compilation of 2x2 tables. Demographic, methodologic, and diagnostic test accuracy data were independently extracted by two investigators and differences were resolved by consensus. Accuracy metrics were obtained using bivariate random-effects meta-analysis. The impact of different covariates on accuracy estimates was assessed using a meta-regression model. Risk of bias was assessed using the Quality Assessment of Diagnostic Accuracy Studies (QUADAS)-2 tool. PROSPERO: CRD42021214776*Results Thirty-two studies including 1875 patients with suspected CS were included (623 with CS), 25 studies evaluated PET (1241 patients) and 15 evaluated MRI (920 patients). Only 4 studies directly compared PET and MRI in the same patients. Sensitivity for PET and MRI was 85% (95%CI 76-91%) and 95% (95%CI 87-98%), respectively. Specificity for PET and MRI was 83% (95%CI 76-88%) and 85% (95%CI 69-94%), respectively. The greater observed sensitivity of MRI was preserved in the meta-regression model (p=0.030), while no difference in specificity was detected (p=0.97). Covariate analysis demonstrated that diagnostic accuracy was significantly lower in studies with direct vs. indirect comparison (p=0.044). Many studies were at high risk of bias.*Conclusions MRI has higher sensitivity than PET and therefore may be advantageous for ruling out CS. However, limitations in the literature, including risk of bias and only a few studies with direct comparison, necessitate additional methodologically rigorous study.*Clinical Relevance/Application This is the first meta-analysis comparing the diagnostic performance of PET and MRI in CS. These results suggest that cardiac MRI may be an appropriate first imaging test although further study is needed.

RESULTS

Thirty-two studies including 1875 patients with suspected CS were included (623 with CS), 25 studies evaluated PET (1241 patients) and 15 evaluated MRI (920 patients). Only 4 studies directly compared PET and MRI in the same patients. Sensitivity for PET and MRI was 85% (95%CI 76-91%) and 95% (95%CI 87-98%), respectively. Specificity for PET and MRI was 83% (95%CI 76-88%) and 85% (95%CI 69-94%), respectively. The greater observed sensitivity of MRI was preserved in the meta-regression model (p=0.030), while no difference in specificity was detected (p=0.97). Covariate analysis demonstrated that diagnostic accuracy was significantly lower in studies with direct vs. indirect comparison (p=0.044). Many studies were at high risk of bias.

CLINICAL RELEVANCE/APPLICATION

This is the first meta-analysis comparing the diagnostic performance of PET and MRI in CS. These results suggest that cardiac MRI may be an appropriate first imaging test although further study is needed.

SSPD01-2 Recovery Of Compression Fracture Of The Vertebral Bodies In Patients With Chronic Nonbacterial Osteomyelitis (CNO)

Participants
Mikhael Sebaaly, MD, Iowa City, Iowa (*Presenter*) Nothing to Disclose

PURPOSE

Vertebral body compression fractures are the most common fractures seen in patients with CNO, and in our experience seen in up to 16% of patients with long term follow up. In this presentation we will review the course and potential recovery in patients with pathologic vertebral loss of height secondary to CNO.*Methods and Materials A retrospective review of patients with CNO and pathologic compression deformities of the vertebral bodies was performed at our institution. A PACS review was done for reports that had CNO and vertebral compression fractures. A total of 60 exams that were performed between June 2006 and August 2020 were identified. To be included, patients had to have at least 2 CT or MRI exams. Vertebral body loss of height was measured in relation to the average of the height of the 2 adjacent vertebral bodies if there is involvement of the posterior wall or to the vertebral body posterior wall if only anterior wedging using Carestream PACS measurement tools. We gathered data on medications, demographics, trauma, back pain and bone marrow edema.*Results 42 vertebral bodies with loss of height in 18 patients with CNO were identified, 41 in thoracic spine,1 in cervical spine. Age ranged between 5 and 22 yr, 28% males and 72% females, 62% of fractures had bone marrow edema and 56% had back pain. There was recovery of vertebral body height in 16 vertebral bodies. 7 out of 18 patients had recovery of vertebral body height of one or more levels. The recovery of vertebral body height was partial at 9 levels and complete at 7 levels. One level had worsening of the vertebral body height loss on follow up. 6 of 7 patients with vertebral body height recovery were on NSAIDS, vs 7 of 11 patients with no vertebral body height recovery. 3 of 7 patients with vertebral body height recovery were on bisphosphonates vs 3 out of 11 in patients that did not have height recovery. The age of patients with recovery of height was between 6 and 11 years (average:7.4yr) at diagnosis vs 5 to 22 years (average:12.7yr).*Conclusions Patient with CNO pathologic vertebral height loss can partially or completely recover vertebral body height. This is why early, accurate diagnosis and appropriate treatment are important to avoiding potential long term consequences. Favorable factors for vertebral body height recovery include age at development of compression deformity (between 6 and 11 yr), bisphosphonate and NSAIDS therapy, female gender and loss of height less than 70%.*Clinical Relevance/Application Compression fractures are the most common pathologic fractures seen in patients with CNO. It is important for radiologists to know that there is potential for vertebral body height recovery. Making a timely diagnosis of CNO and starting appropriate treatment early are important factors in avoiding long term sequelae.

RESULTS

42 vertebral bodies with loss of height in 18 patients with CNO were identified, 41 in thoracic spine,1 in cervical spine. Age ranged between 5 and 22 yr, 28% males and 72% females, 62% of fractures had bone marrow edema and 56% had back pain. There was recovery of vertebral body height in 16 vertebral bodies. 7 out of 18 patients had recovery of vertebral body height of one or more levels. The recovery of vertebral body height was partial at 9 levels and complete at 7 levels. One level had worsening of the vertebral body height loss on follow up. 6 of 7 patients with vertebral body height recovery were on NSAIDS, vs 7 of 11 patients with no vertebral body height recovery. 3 of 7 patients with vertebral body height recovery were on bisphosphonates vs 3 out of 11 in patients that did not have height recovery. The age of patients with recovery of height was between 6 and 11 years (average:7.4yr) at diagnosis vs 5 to 22 years (average:12.7yr).

CLINICAL RELEVANCE/APPLICATION

Compression fractures are the most common pathologic fractures seen in patients with CNO. It is important for radiologists to know that there is potential for vertebral body height recovery. Making a timely diagnosis of CNO and starting appropriate treatment early are important factors in avoiding long term sequelae.

SSPD01-4 Contrast-enhanced Subharmonic Aided Pressure Estimation (SHAPE) For Assessment Of Intracranial Pressure In Vivo

Participants
Ryne Didier, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Intracranial pressure (ICP) measurements in children require invasive techniques. We investigated subharmonic aided pressure estimation (SHAPE) as a noninvasive contrast-enhanced ultrasound (CEUS) tool for assessing ICP in fetal lambs.*Methods and Materials After induction of maternal anesthesia and hysterotomy, 17 fetal lambs (107-138 days gestational age; term = 145 days) underwent externalization and placement of a subdural pressure catheter to measure ICP as part of an IACUC approved protocol. A

modified Logiq E10 ultrasound (US) system (GE Healthcare, Waukesha, WI) optimized with SHAPE software and a curvi-linear C2-9 transducer were used to image the brain in the coronal plane. Definity (Lantheus Medical Imaging, N Billerica, MA) US contrast was administered as an infusion at 120 mL/min via a uterine choroidal vessel which drained into the umbilical vein and fetal circulation. After SHAPE calibration was performed to determine optimal US mechanical index, saline was infused via the subdural catheter to transiently increase ICP from baseline (7-10 mmHg) to approximately 40 mmHg. Multiple five-second SHAPE cine clips of the brain were obtained at various pressures. Experiments were repeated in triplicate for each lamb. Data points were excluded if ICP instability was observed; defined as standard deviation = 3 mmHg. CEUS subharmonic intensity values of the whole brain and thalami were determined and correlated with ICP values using mixed effects linear regression analyses and the strength of the relationship was evaluated by Spearman's rank-order correlation.*Results 47 experiments resulted in 696 datapoints including SHAPE intensity values as well as mean ICP measurements. There was a statistically significant inverse relationship between SHAPE intensity values and ICP measurements in the whole brain and thalami (chi-squared = 1301.7 and 1336.9, respectively; p<0.001; Spearman's rho = -0.21; p<0.001).*Conclusions SHAPE intensity values of the brain demonstrate an inverse and statistically significant correlation with in vivo ICP measurements obtained in an animal model.*Clinical Relevance/Application SHAPE can be used for noninvasive estimation of ICP which has potential for broader applications and may aid clinical evaluations of neurological injury.

RESULTS

47 experiments resulted in 696 datapoints including SHAPE intensity values as well as mean ICP measurements. There was a statistically significant inverse relationship between SHAPE intensity values and ICP measurements in the whole brain and thalami (chi-squared = 1301.7 and 1336.9, respectively; p<0.001; Spearman's rho = -0.21; p<0.001).

CLINICAL RELEVANCE/APPLICATION

SHAPE can be used for noninvasive estimation of ICP which has potential for broader applications and may aid clinical evaluations of neurological injury.

SSPD01-5   Brain Resting State Functional Networks In Infants With Prenatal Opioid And Substance Exposure

Participants
Rupa Radhakrishnan, MS,MBBS, Indianapolis, Indiana (*Presenter*) Nothing to Disclose

PURPOSE

Infants of mothers with prenatal opioid and substance use can present with early withdrawal symptoms and are at risk of poor neurodevelopmental outcomes in later childhood. Early brain imaging in infancy has the potential to identify early brain developmental alterations that could help prognosticate neurodevelopmental outcomes in these children and provide opportunities for early intervention. In this study, we aim to identify differences in global brain network connectivity in infants with prenatal opioid and drug exposure compared to healthy control infants, using resting-state functional MRI performed at less than 2 months completed gestational age.*Methods and Materials In this prospective IRB-approved study, we recruited 20 infants (14 female) with prenatal opioid exposure and their mothers and 20 healthy opioid naïve infants (11 female) and their mothers. Anatomic imaging and resting-state functional MRI was performed at less than 48 weeks corrected gestational age. After appropriate preprocessing, rs-fMRI images were coregistered to the UNC neonate brain template and 90 anatomic atlas labeled regions. Covariate Assisted Principal (CAP) regression was performed to identify brain networks within which functional connectivity is associated with opioid exposure adjusting for sex and gestational age. A corrected p-value of less than .05 was considered statistically significant.*Results Group functional connectivity matrices for the opioid exposed infants and non-opioid exposed infants were obtained. There were five CAP components that were significantly different in the opioid exposed versus control infants. The component most distinct between the two groups (CAP5, p= 3.86 x 10-6) included the right inferior temporal gyrus, bilateral hesch's gyrus, left thalamus, left suprmarginal gyrus, left inferior parietal lobule, left superior parietal gyrus, right anterior cingulate gyrus, right gyrus rectus left supplementary motor area and left pars triangularis. Functional connectivity in this network was lower in the infants with prenatal opioid exposure compared to non-opioid exposed infants.*Conclusions In this study we show global network alterations in infants with prenatal opioid exposure compared to non-opioid exposed infants. Future studies should be aimed at identifying clinical significance of this altered connectivity.*Clinical Relevance/Application Opioid and substance use in pregnancy is a huge public health problem and identification of methods to identify early, the consequences of substance exposure on the developing brain can help to initiate early therapies to improve outcomes in prenatal opioid and substance exposure.

RESULTS

Group functional connectivity matrices for the opioid exposed infants and non-opioid exposed infants were obtained. There were five CAP components that were significantly different in the opioid exposed versus control infants. The component most distinct between the two groups (CAP5, p= 3.86 x 10-6) included the right inferior temporal gyrus, bilateral hesch's gyrus, left thalamus, left suprmarginal gyrus, left inferior parietal lobule, left superior parietal gyrus, right anterior cingulate gyrus, right gyrus rectus left supplementary motor area and left pars triangularis. Functional connectivity in this network was lower in the infants with prenatal opioid exposure compared to non-opioid exposed infants.

CLINICAL RELEVANCE/APPLICATION

Opioid and substance use in pregnancy is a huge public health problem and identification of methods to identify early, the consequences of substance exposure on the developing brain can help to initiate early therapies to improve outcomes in prenatal opioid and substance exposure.

SSNMMI03-2   Time-dependent Severity Of FDG Brain Hypometabolism In Post-SARS-CoV-2 Infection With Neurological Involvement

Participants
Anna Lisa Martini, Bologna, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Clinical reports indicate that coronaviruses can have a neuro-invasive potential. Aim of this study was to characterize time-dependent brain functional impairment in SARS-CoV-2 patients with newly originated neurological symptoms and to suggest physiopathology mechanisms underlying central nervous system involvement.*Methods and Materials We included 9 patients with past SARS-CoV-2 acute infection and associated newly originated neurological symptoms and 5 patients with neurological symptoms and ongoing acute SARS-CoV-2 infection. The patients with past infection underwent baseline FDG-PET scan, together with neurological and cognitive assessment, at different time-points from the acute phase. The patients in acute SARS-CoV-2 infection underwent FDG-PET scan, but the cognitive assessment was not possible. One patient was evaluated with a follow-up FDG-PET scan after a significant remission of clinical symptoms. Brain metabolism was analysed using optimised and validated voxel-based SPM method at the single-subject level (p = 0.01), based on comparisons with large and well-selected healthy control dataset.*Results The 5 patients with ongoing acute SARS-CoV-2 infection featured widespread hypometabolism affecting almost all brain cortices. Among the cases with past SARS-CoV-2 acute infection, 5 patients with FDG-PET scan within 2 months from the infection showed extended orbital-, prefrontal and temporal-parietal cortex hypometabolism, and pathological MMSE values. 3 patients with FDG-PET scans 5 months after SARS-CoV-2 acute phase showed normal brain metabolism and normal cognitive scores. The patient evaluated twice showed at baseline, close to the acute phase, an extended, severe hypometabolism affecting almost all brain cortices and only slight hypometabolism in orbitofrontal and medial frontal cortices at follow up.*Conclusions The present results demonstrated that 1. patients with ongoing SARS-CoV-2 infection featured widespread hypometabolism affecting almost all brain cortices, while 2. patients evaluated in post SARS-CoV-2 infection phase, presented with a rather extended cortical hypometabolism only close to the acute phase and 3. along with remission of clinical and cognitive symptoms, the brain hypometabolism reduces progressively as function of time from acute phase. The cortical functional impairment observed in neuro-SARS-CoV-2 patients is likely to be transient and almost reversible, and possibly due to synergistic effects of systemic virus-mediated inflammation sustained by systemic cytokine release and transient hypoxia inducing neuronal dysfunction and local microglial activation.*Clinical Relevance/Application none

RESULTS

The 5 patients with ongoing acute SARS-CoV-2 infection featured widespread hypometabolism affecting almost all brain cortices. Among the cases with past SARS-CoV-2 acute infection, 5 patients with FDG-PET scan within 2 months from the infection showed extended orbital-, prefrontal and temporal-parietal cortex hypometabolism, and pathological MMSE values. 3 patients with FDG-PET scans 5 months after SARS-CoV-2 acute phase showed normal brain metabolism and normal cognitive scores. The patient evaluated twice showed at baseline, close to the acute phase, an extended, severe hypometabolism affecting almost all brain cortices and only slight hypometabolism in orbitofrontal and medial frontal cortices at follow up.

CLINICAL RELEVANCE/APPLICATION

SSNMMI03-3   99mTc-vitamin C SPECT/CT Imaging In Patients With SARS-COV-2 Associated Pneumonia

Participants
Haluk Sayman, MD, Istanbul, Turkey (*Presenter*) Nothing to Disclose

PURPOSE

High-dose intravenous vitamin C has been shown to reduce systemic inflammation by reducing the cytokine storm. In patients with severe sepsis and acute respiratory distress syndrome in particular, it can prevent lung injury. Additionally, it may be beneficial in

patients with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection. Therefore, we sought to determine if intravenous vitamin C labeled with 99mTc can be used to assess the utility of Vitamin C in typical lung lesions in patients who are being treated for SARS-CoV-2-associated pneumonia.*Methods and Materials In this small series of patients, four patients with SARS-CoV-2 infection underwent 99mTc-Vitamin C single photon emission computed tomography/computed tomography (SPECT/CT) imaging.*Results Baseline CT images of all patients showed mostly peripheral patchy and ground glass opacities in both lungs, consistent with SARS-CoV-2-associated pneumonia. Active lung lesions were characterized by high 99mTc-Vitamin C uptake on SPECT images. At day 5 of hospitalization, following standard anti-viral and anti-inflammatory treatment, 99mTc-Vitamin C SPECT images showed no abnormal uptake corresponding to lung CT findings. Follow-up SPECT/CT at 3 months after the diagnosis of SARS-CoV-2-associated pneumonia showed that all previous lung findings were resolved for all patients; no 99mTc-Vitamin C uptake was demonstrated on SPECT images.*Conclusions Multifocal pulmonary uptake of 99mTc-Vitamin C could be considered as a feature of active pulmonary involvement with SARS-CoV-2 infection in the regions with expansive spread of the disease.*Clinical Relevance/Application While 99mTc-Vitamin C SPECT/CT imaging cannot be routinely used in the emergency setting and is generally not recommended for the imaging of infectious/inflammatory diseases, this small case series nevertheless suggests that 99m Tc-Vitamin C SPECT/CT imaging could be a promising non-invasive approach to identify the presence and potentially monitor the persistence and progression of Vitamin C lung action.

RESULTS

Baseline CT images of all patients showed mostly peripheral patchy and ground glass opacities in both lungs, consistent with SARS-CoV-2-associated pneumonia. Active lung lesions were characterized by high 99mTc-Vitamin C uptake on SPECT images. At day 5 of hospitalization, following standard anti-viral and anti-inflammatory treatment, 99mTc-Vitamin C SPECT images showed no abnormal uptake corresponding to lung CT findings. Follow-up SPECT/CT at 3 months after the diagnosis of SARS-CoV-2-associated pneumonia showed that all previous lung findings were resolved for all patients; no 99mTc-Vitamin C uptake was demonstrated on SPECT images.

CLINICAL RELEVANCE/APPLICATION

While 99mTc-Vitamin C SPECT/CT imaging cannot be routinely used in the emergency setting and is generally not recommended for the imaging of infectious/inflammatory diseases, this small case series nevertheless suggests that 99m Tc-Vitamin C SPECT/CT imaging could be a promising non-invasive approach to identify the presence and potentially monitor the persistence and progression of Vitamin C lung action.

SSNMMI03-4 Imaging Features And Detection Of COVID-19 Using FDG PET/CT During The Peak Of The New York City Pandemic

Participants
Rick Wray, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

To determine the imaging findings and potential clinical utility of FDG PET/CT in patients with laboratory-confirmed COVID-19.*Methods and Materials We performed a single-institution retrospective review of patients diagnosed with COVID-19 using real-time reverse transcription-polymerase chain reaction (RT-PCR) and who underwent FDG PET/CT for routine cancer care between March 1, 2020, and April 30, 2020, during the height of the pandemic in New York City, United States. PET/CT scans were retrospectively reviewed for imaging findings suspicious for COVID-19. For positive imaging findings, the location, FDG-avidity (SUVmax), and CT findings were recorded. Patient demographics and COVID-19 specific clinical data, including symptoms and hospitalizations, were collected and analyzed for FDG PET/CT data.*Results Thirty-one patients (21 males and 10 females, mean age 57 years ± 16) were evaluated. Thirteen patients (41.9%) had positive PET/CT scans, and eighteen patients (58.1%) had negative scans. Patients with positive scans had significantly higher rates of symptomatic COVID-19 infection (77% vs 28%, p=0.01) and hospitalizations (46% vs. 0%, p=0.002) compared to patients with negative scans. Eleven of 13 patients (84.6%) with positive scans had FDG-avid lung findings, with mean lung SUVmax of 5.36 + 3.36. Six of 13 patients (46.2%) had extrapulmonary findings of FDG-avid thoracic lymph nodes. No patients had findings outside of the thorax. Sensitivity of FDG PET/CT for detecting COVID-19 was 41.9%; it was significantly lower when the PET scan was performed before RT-PCR versus after RT-PCR (18.8% (n = 3/16) vs. 66.7% (n=10/15), p=0.009). Lung SUVmax was not associated with COVID-19 symptoms, severity, or disease course.*Conclusions FDG PET/CT has limited sensitivity for detecting COVID-19 infection. However, a positive PET scan is associated with a higher risk of symptomatic infection and hospitalizations, which may help predict disease severity.*Clinical Relevance/Application PET/CT imaging is used frequently in Oncology and can add additional prognostic information for patients with COVID-19 infection. Oncology patients tend to be immunocompromised and with the difficulty in treating COVID-19 additional information such as severity and symptomaticity can benefit these at-risk patients.

RESULTS

Thirty-one patients (21 males and 10 females, mean age 57 years ± 16) were evaluated. Thirteen patients (41.9%) had positive PET/CT scans, and eighteen patients (58.1%) had negative scans. Patients with positive scans had significantly higher rates of symptomatic COVID-19 infection (77% vs 28%, p=0.01) and hospitalizations (46% vs. 0%, p=0.002) compared to patients with negative scans. Eleven of 13 patients (84.6%) with positive scans had FDG-avid lung findings, with mean lung SUVmax of 5.36 + 3.36. Six of 13 patients (46.2%) had extrapulmonary findings of FDG-avid thoracic lymph nodes. No patients had findings outside of the thorax. Sensitivity of FDG PET/CT for detecting COVID-19 was 41.9%; it was significantly lower when the PET scan was performed before RT-PCR versus after RT-PCR (18.8% (n = 3/16) vs. 66.7% (n=10/15), p=0.009). Lung SUVmax was not associated with COVID-19 symptoms, severity, or disease course.

CLINICAL RELEVANCE/APPLICATION

PET/CT imaging is used frequently in Oncology and can add additional prognostic information for patients with COVID-19 infection. Oncology patients tend to be immunocompromised and with the difficulty in treating COVID-19 additional information such as severity and symptomaticity can benefit these at-risk patients.

SSNMMI03-5 F18-FDG Uptake After COVID-19 Vaccination In Oncological PET/CT: Frequency, Intensity And Potential Clinical Impact

Participants
Stephan Skawran, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To assess the frequency, intensity and clinical impact of F18-FDG-avidity of axillary lymph nodes after vaccination with COVID-19 vaccines BNT162b2 (Pfizer-BioNTech) and mRNA-1273 (Moderna) in patients referred for oncological FDG PET/CT.*Methods and Materials One hundred forty patients referred for FDG PET/CT during February and March 2021 after first or second vaccination with Pfizer-BioNTech or Moderna were retrospectively included. FDG-avidity of ipsilateral axillary lymph nodes was measured and compared. Metastatic risk was analyzed by two readers and clinical impact was evaluated.*Results FDG PET/CT showed FDG-avid lymph nodes ipsilateral to the vaccine injection in 75/140 (54%) patients with a mean SUVmax of 5.1 (range 2.0 - 17.3). FDG-avid lymph nodes were more frequent in patients vaccinated with Moderna than Pfizer-BioNTech (36/50 [72%] vs. 39/90 [43%] cases, p<0.001). Metastatic risk of unilateral FDG-avid axillary lymph nodes was rated unlikely in 52/75 (37%), potential in 15/75 (11%) and likely in 8/75 (6%) cases. Clinical management was affected in 17/140 (12%) cases.*Conclusions FDG-avid axillary lymph nodes are common after COVID-19 vaccination. The avidity of lymph nodes is more frequent in Moderna compared to Pfizer-BioNTech vaccines.*Clinical Relevance/Application To avoid relatively frequent clinical dilemmas, we recommend carefully taking the history for prior vaccination in patients undergoing FDG PET/CT and administering the vaccine contralateral to the primary cancer.

RESULTS

FDG PET/CT showed FDG-avid lymph nodes ipsilateral to the vaccine injection in 75/140 (54%) patients with a mean SUVmax of 5.1 (range 2.0 - 17.3). FDG-avid lymph nodes were more frequent in patients vaccinated with Moderna than Pfizer-BioNTech (36/50 [72%] vs. 39/90 [43%] cases, p<0.001). Metastatic risk of unilateral FDG-avid axillary lymph nodes was rated unlikely in 52/75 (37%), potential in 15/75 (11%) and likely in 8/75 (6%) cases. Clinical management was affected in 17/140 (12%) cases.

CLINICAL RELEVANCE/APPLICATION

To avoid relatively frequent clinical dilemmas, we recommend carefully taking the history for prior vaccination in patients undergoing FDG PET/CT and administering the vaccine contralateral to the primary cancer.

SSNMMI03-6 Axillary Lymph Node FDG PET/CT Uptake Post Covid-19 Mrna Vaccination And Its Association With Age And Immune Status

Participants
Michal Eifer, MD, Ramat Gan, Israel (*Presenter*) Nothing to Disclose

PURPOSE

With hundreds of millions of coronavirus disease 2019 (COVID-19) mRNA-based vaccine doses planned to be delivered worldwide in the upcoming months, little is known about positron emission tomography with computed tomography (PET/CT) findings in recently vaccinated immunocompetent or immunocompromised patients. We aimed to assess PET/CT uptake in the deltoid muscle and axillary lymph nodes of patients that received a COVID-19 mRNA-based vaccine, and to evaluate its association with patients' age and immune status.*Methods and Materials All consecutive adult subjects undergoing PET/CT scans at our center during the first month of a national COVID-19 vaccination rollout (between 23 December 2020 and January 27, 2021) were included. Data regarding clinical status, laterality and time interval from recent COVID-19 mRNA was prospectively collected and retrospectively analyzed, and correlated with deltoid muscle and axillary lymph nodes uptake.*Results Of 426 eligible, recently vaccinated, subjects (median age, 67±12 years; 49% female), 377 (88%) underwent PET/CT with 18F-fluorodeoxyglucose (FDG) and positive axillary lymph node uptake was seen in 45% of them. Multivariate logistic regression analysis revealed a strong inverse association between positive FDG uptake in ipsilateral lymph nodes and patients' age (Odds Ratio [OR]=0.57, 95% CI, 0.45-0.72; p<.001), immunosuppressive treatment (OR=0.37, 95% CI, 0.20-0.64; p=0.003) and presence of hematological disease (OR=0.44, 95% CI, 0.24-0.8; p=0.021). No such association was found for deltoid muscle uptake. The number of days from the last vaccination and the number of vaccination doses were also significantly associated with increased odds of positive lymph nodes uptake.*Conclusions In about half of the patients receiving the novel mRNA-based COVID-19 vaccine, PET/CT showed avid ipsilateral lymphadenopathy, which was significantly less common in immunocompromised and elderly patients.*Clinical Relevance/Application Recognition of axillary lymph node FDG uptake post COVID 19 vaccination may reduce misinterpretation thus avoiding unnecessary workup and may hint to the patient's immune response to the vaccine.

RESULTS

Of 426 eligible, recently vaccinated, subjects (median age, 67±12 years; 49% female), 377 (88%) underwent PET/CT with 18F-fluorodeoxyglucose (FDG) and positive axillary lymph node uptake was seen in 45% of them. Multivariate logistic regression analysis revealed a strong inverse association between positive FDG uptake in ipsilateral lymph nodes and patients' age (Odds Ratio [OR]=0.57, 95% CI, 0.45-0.72; p<.001), immunosuppressive treatment (OR=0.37, 95% CI, 0.20-0.64; p=0.003) and presence of hematological disease (OR=0.44, 95% CI, 0.24-0.8; p=0.021). No such association was found for deltoid muscle uptake. The number of days from the last vaccination and the number of vaccination doses were also significantly associated with increased odds of positive lymph nodes uptake.

CLINICAL RELEVANCE/APPLICATION

Recognition of axillary lymph node FDG uptake post COVID 19 vaccination may reduce misinterpretation thus avoiding unnecessary workup and may hint to the patient's immune response to the vaccine.

SPR-CH-10 Integration Of A Deep Learning Algorithm Into The Clinically Established PanCan Model For Malignancy Risk Estimation Of Screen-detected Pulmonary Nodules In First Screening CT

Participants
Kiran Vaidhya Venkadesh, MSc, Nijmegen, Netherlands (*Presenter*) Employee, Predible Health;Stockholder, Predible Health

PURPOSE

To quantify the added value of integrating a deep learning algorithm (DLA)'s output to the existing Pan-Canadian Early Detection of Lung Cancer Study (PanCan) models for estimating malignancy risk of screen-detected pulmonary nodules.*Methods and Materials Our DLA was trained on a cohort of 14,828 benign and 1,249 malignant nodules from the National Lung Screening Trial. In the present study, we derived a new multivariable logistic regression model on the PanCan data that included the DLA risk score and the original variables from the PanCan model 2b except for "nodule type" and "spiculation" as these are already encoded in the DLA risk score. The new model was externally validated on baseline nodules from the Danish Lung Cancer Screening Trial (DLCST). For comparison, the performances of the existing PanCan model 2b and of our DLA stand-alone were also calculated.*Results 6024 benign and 86 malignant nodules from the PanCan data were included as the development set, and 818 benign and 34 malignant nodules from the Danish Lung Cancer Screening Trial (DLCST) were included as the validation set. The area under the receiver operating characteristic curve (AUC) for the DLA, PanCan model 2b, and the new model in the PanCan cohort were 0.944 (95% confidence interval = 0.917 - 0.968), 0.941 (0.908 - 0.969), and 0.944 (0.909 - 0.975), respectively. In the DLCST cohort, the AUCs were 0.917 (0.851 - 0.968), 0.896 (0.841 - 0.944), and 0.927 (0.878 - 0.969), respectively.*Conclusions Using our DLA risk score to derive a new multivariable logistic regression model on the PanCan data does not appear to significantly improve the predictive performance in high-risk screening participants, but may serve as a replacement for the "nodule type" and "spiculation" parameters that are known to have substantial interobserver variability.*Clinical Relevance/Application Our DLA has a comparable nodule malignancy risk estimation performance to the PanCan models. This may help to make the computation of nodule risk scores easier and less subjective.

RESULTS

6024 benign and 86 malignant nodules from the PanCan data were included as the development set, and 818 benign and 34 malignant nodules from the Danish Lung Cancer Screening Trial (DLCST) were included as the validation set. The area under the receiver operating characteristic curve (AUC) for the DLA, PanCan model 2b, and the new model in the PanCan cohort were 0.944 (95% confidence interval = 0.917 - 0.968), 0.941 (0.908 - 0.969), and 0.944 (0.909 - 0.975), respectively. In the DLCST cohort, the AUCs were 0.917 (0.851 - 0.968), 0.896 (0.841 - 0.944), and 0.927 (0.878 - 0.969), respectively.

CLINICAL RELEVANCE/APPLICATION

Our DLA has a comparable nodule malignancy risk estimation performance to the PanCan models. This may help to make the computation of nodule risk scores easier and less subjective.

SPR-CH-11 Low-dose CT Characteristics Of Lung Nodules In A Middle-aged Population Of Never-smokers Versus Smokers: The Imalife Study

Participants
Rozemarijn Vliegenthart, MD, PhD, Groningen, Netherlands (*Presenter*) Institutional Research Grant, Siemens AG

PURPOSE

To compare computed tomography (CT) features of lung nodules between never smokers and smokers (former and current) in a Western middle-aged general population.*Methods and Materials We included 1,788 individuals aged 45-60 years from the Dutch Lifelines cohort who had undergone low-dose chest CT as part of the ImaLife study, with at least one lung nodule (=30 mm3) on CT. Smoking variables were collected. CT scans were evaluated for qualitative (count, shape, edge, location, density) and quantitative (diameter and volume) nodule characteristics. Differences in nodule characteristics between never-, former and current smoker groups were examined by Pearson's chi-square testing.*Results Overall, 41.8% were never smokers, 35.9% former smokers and 22.3% current smokers. The median age was 53 years (IQR 48-58), similar across smoking categories; 48.6% were men, with higher prevalence of current smoking among men and higher prevalence of former and never smoking among women. In total, 3,343 nodules were registered. The prevalence of multiple (>1) nodules was higher in current smokers (45%) than in former (39%) and never smokers (36%) (p=0.045, p=0.002). Larger sized nodules were more prevalent in current and former smokers than in never smokers (volume >300mm3: 2.1% and 3.0% vs 1.8%, p=0.028, p=0.013). The percentage of lung nodules categorized as non-solid was higher in former smokers (8.1%) than in current (5.2%) and never smokers (5.8%) (p=0.023, p=0.013). Irregular-shaped and non-smooth nodules were more often identified in current smokers than in former and never smokers (p=0.035, p=0.031), whereas calcified nodules were more often present in never smokers (6.5%) than in former (4.2%) and current smokers (5.0%) (p=0.032).*Conclusions Significant differences in nodule imaging features were found by smoking status: compared to smokers, never smokers with nodules more likely had smaller nodule size, lower proportion of non-solid nodules and of irregular or non-smooth nodules, and higher proportion of calcified nodules.*Clinical Relevance/Application Most evidence for lung nodule imaging features related to probability for lung cancer is based on high-risk (smoking) populations. This study adds evidence in

never smokers, which may help in the future to optimize nodule management of incidentally detected lung nodules in the general population as nodule features seem generally more benign in never smokers.

RESULTS

Overall, 41.8% were never smokers, 35.9% former smokers and 22.3% current smokers. The median age was 53 years (IQR 48-58), similar across smoking categories; 48.6% were men, with higher prevalence of current smoking among men and higher prevalence of former and never smoking among women. In total, 3,343 nodules were registered. The prevalence of multiple (>1) nodules was higher in current smokers (45%) than in former (39%) and never smokers (36%) (p=0.045, p=0.002). Larger sized nodules were more prevalent in current and former smokers than in never smokers (volume >300mm3: 2.1% and 3.0% vs 1.8%, p=0.028, p=0.013). The percentage of lung nodules categorized as non-solid was higher in former smokers (8.1%) than in current (5.2%) and never smokers (5.8%) (p=0.023, p=0.013). Irregular-shaped and non-smooth nodules were more often identified in current smokers than in former and never smokers (p=0.035, p=0.031), whereas calcified nodules were more often present in never smokers (6.5%) than in former (4.2%) and current smokers (5.0%) (p=0.032).

CLINICAL RELEVANCE/APPLICATION

Most evidence for lung nodule imaging features related to probability for lung cancer is based on high-risk (smoking) populations. This study adds evidence in never smokers, which may help in the future to optimize nodule management of incidentally detected lung nodules in the general population as nodule features seem generally more benign in never smokers.

SPR-CH-13   Psoas Muscle Density Evaluated By Chest CT And Long-term Mortality In COPD Patients

Participants
Ana Ezponda, MD, Pamplona, Spain (*Presenter*) Nothing to Disclose

PURPOSE

Poor muscle quality in COPD patients relates to exercise intolerance and mortality. Muscle quality can be estimated on computed tomography (CT) by estimating psoas density (PsD). We tested the hypothesis that PsD is lower in COPD patients than in controls and relates to allcause mortality.*Methods and Materials At baseline, PsD was measured using axial low-dose chest CT images in 220 COPD patients, 80% men, who were 65±8 years old with mild to severe airflow limitation and in a control group of 58 subjects matched by age, sex , body mass index (BMI) and body surface area (BSA). COPD patients were prospectively followed for 76.5 (48-119) months. Anthropometrics, smoking history, BMI, dyspnoea, lung function, exercise capacity, BODE index and exacerbations history were recorded. Cox proportional risk analysis determined the factors more strongly associated with long-term mortality.*Results PsD was lower in COPD patients than in controls (40.5 vs 42.5, p=0.045). During the follow-up, 54 (24.5%) deaths occurred in the COPD group. PsD as well as age, sex, pack-year history, FEV1%, 6MWD, mMRC, BODE index, were independently associated with mortality. Multivariate analysis showed that age (HR 1.06; 95% CI 1.02-1.12, p=0.006) and CT-assessed PsD (HR 0.97; 95%CI 0.94-0.99, p = 0.023) were the variables independently associated with all-cause mortality.*Conclusions In COPD patients with mild to severe airflow limitation, chest CT-assessed psoas muscle density was lower than in matched controls and independently associated with long-term mortality. Muscle quality using the easy to evaluate psoas muscle density from chest CT may provide clinicians with important prognostic information in COPD.*Clinical Relevance/Application Chest-CT assessed PsD is an independent predictor of all-cause mortality in patients with mild to severe COPD.if our findingsare confirmed in other studies, an effort may be made to guarantee that CT's include the psoasas a target to measure in routine CT scans of the chest. Furthermore, new algorithms wouldallow automatic detection of the L3 slice on whole body CT and determination of psoas andother muscles mass and density.

RESULTS

PsD was lower in COPD patients than in controls (40.5 vs 42.5, p=0.045). During the follow-up, 54 (24.5%) deaths occurred in the COPD group. PsD as well as age, sex, pack-year history, FEV1%, 6MWD, mMRC, BODE index, were independently associated with mortality. Multivariate analysis showed that age (HR 1.06; 95% CI 1.02-1.12, p=0.006) and CT-assessed PsD (HR 0.97; 95%CI 0.94-0.99, p = 0.023) were the variables independently associated with all-cause mortality.

CLINICAL RELEVANCE/APPLICATION

Chest-CT assessed PsD is an independent predictor of all-cause mortality in patients with mild to severe COPD.if our findingsare confirmed in other studies, an effort may be made to guarantee that CT's include the psoasas a target to measure in routine CT scans of the chest. Furthermore, new algorithms wouldallow automatic detection of the L3 slice on whole body CT and determination of psoas andother muscles mass and density.

SPR-CH-14   Performance Of Clinical Readers In Detecting Chronic Thromboembolic Pulmonary Hypertension (CTEPH) On Computed Tomography Pulmonary Angiograms (CTPAs): A Pilot Study.

Participants
Deepa Gopalan, MRCP, FRCR, Stockholm, Sweden (*Presenter*) Speakers Bureau, Bayer AG and Actelion

PURPOSE

Chronic thromboembolic pulmonary hypertension (CTEPH) is an underdiagnosed form of pulmonary hypertension characterized by obstruction of the pulmonary vasculature by thromboembolic material. CTEPH.AI software aims to support radiologists by assessing computed tomography pulmonary angiograms (CTPAs) to identify salient features of CTEPH. We present baseline data from an ongoing pilot study on the performance of readers unaided by CTEPH.AI to detect CTEPH.*Methods and Materials The CTEPH.AI pilot is a multiple-reader, multiple-case, retrospective study of data from 100 selected adult patients who underwent CTPA in routine clinical practice (30 CTEPH positive, 70 CTEPH negative). Twenty board-certified readers (16 community-based and four cardiothoracic radiologists) reviewed all cases unaided. Prior to the study, all readers were informed of the study purpose to detect CTEPH. The primary endpoint is the area under the receiver operating characteristic curve (AUC) and the secondary endpoints are sensitivity and specificity to detect CTEPH. Results were assessed overall and in community and cardiothoracic reader subgroups.*Results Performance was variable amongst unaided readers. AUC ranged from 0.68 to 0.88 with a mean of 0.78 (95% confidence interval [CI] 0.69-0.88), a mean (95% CI) sensitivity of 0.63 (0.46-0.80), and a mean specificity of 0.81 (0.54-1.00). Performance was slightly higher in cardiothoracic radiologists (mean AUC [95% CI], 0.80 [0.74-0.86]; sensitivity, 0.66 [0.63-0.69]; specificity, 0.87 [0.71-1.00]) than community radiologists (mean AUC [95% CI], 0.78 [0.67-0.88]; sensitivity, 0.62 [0.43-0.82]; specificity, 0.80 [0.51-1.00]).*Conclusions Despite awareness of the study purpose, almost a third of CTEPH cases were missed by unaided readers with wide variability amongst readers, demonstrating a high unmet diagnostic need. There is therefore a potential role for CTEPH.AI in improving the diagnosis of CTEPH.*Clinical Relevance/Application The CTEPH.AI pilot study evaluates the

performance of radiologists to detect CTEPH unaided when specifically reviewing CTPAs for CTEPH and reveals a high unmet need to increase diagnostic accuracy.

RESULTS

Performance was variable amongst unaided readers. AUC ranged from 0.68 to 0.88 with a mean of 0.78 (95% confidence interval [CI] 0.69-0.88), a mean (95% CI) sensitivity of 0.63 (0.46-0.80), and a mean specificity of 0.81 (0.54-1.00). Performance was slightly higher in cardiothoracic radiologists (mean AUC [95% CI], 0.80 [0.74-0.86]; sensitivity, 0.66 [0.63-0.69]; specificity, 0.87 [0.71-1.00]) than community radiologists (mean AUC [95% CI], 0.78 [0.67-0.88]; sensitivity, 0.62 [0.43-0.82]; specificity, 0.80 [0.51-1.00]).

CLINICAL RELEVANCE/APPLICATION

The CTEPH.AI pilot study evaluates the performance of radiologists to detect CTEPH unaided when specifically reviewing CTPAs for CTEPH and reveals a high unmet need to increase diagnostic accuracy.

SPR-CH-15   Can CTAnalysis Predict Esophageal Fistula In Patients With Advanced Esophageal Cancer Treated By Chemotherapy Or Chemoradiotherapy: Exploration And Validation

Participants
Yiyuan Wei, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Esophageal fistula entailing high mortality is one of the most serious complications of chemotherapy or chemoradiotherapy (CRT) for advanced esophageal cancer leading to additional procedures. This study aimed to evaluate the performance of quantitative computed tomography (CT) analysis and to establish a practical imaging model for predicting esophageal fistula in esophageal cancer patients administered chemotherapy or chemoradiotherapy.*Methods and Materials This study retrospectively enrolled 204 esophageal cancer patients (54 patients with fistula, 150 patients without fistula) and all patients were allocated to the test and validation cohorts according to the time of inclusion in a 1:1 ratio. Ulcer depth, tumor thickness and length, and minimum and maximum enhanced values for esophageal cancer were measured in pretreatment CT imaging.*Results Exploration: What predictive value can quantitative CT provide when used between SCC patients with esophageal fistula and non-esophageal fistula SCC patients? In baseline CT's quantitative analysis, logistic regression analysis revealed that esophageal cancer with high R-ulcer had elevated predicted rate of esophageal fistula. Lower R-HU value and higher THK-tumor was associated with higher rate of esophageal fistula after treatment. This quantitative CT model containing R-ulcer, R-HU and THK-tumor for predicting esophageal fistula had great performance with an AUC of 0.946 and an accuracy of 92.2% in the test cohort.Validation: How is the performance of using quantitative CT parameters for predicting risks of esophageal fistula in SCC patients treated by chemotherapy or chemoradiotherapy? Quantitative CT model was used to validate the predictive performance of esophageal fistula in the validation cohort and revealed a same high results as showing in the test cohort with an AUC of 0.841 and an accuracy of 78.4%.*Conclusions We provide and validate a handy and effective imaging model based on quantitative pretreatment CT parameters with excellent performance in predicting the risk of fistula formation in esophageal cancer patients administered chemotherapy or CRT. This model offers an individualized assessment approach for esophageal SCC patients to guide clinical treatment for esophageal cancer with high risk of esophageal fistula.*Clinical Relevance/Application To facilitate clinical use, a nomogram based on quantitative CT parameters, including THK-tumor, R-ulcer and R-HU, was developed. The probability of fistula formation after treatment ranged from 0 to 1. A probability nearing 1 indicated high odds of esophageal fistula. Patients with esophageal cancer could benefit from this prediction model.

RESULTS

Exploration: What predictive value can quantitative CT provide when used between SCC patients with esophageal fistula and non-esophageal fistula SCC patients? In baseline CT's quantitative analysis, logistic regression analysis revealed that esophageal cancer with high R-ulcer had elevated predicted rate of esophageal fistula. Lower R-HU value and higher THK-tumor was associated with higher rate of esophageal fistula after treatment. This quantitative CT model containing R-ulcer, R-HU and THK-tumor for predicting esophageal fistula had great performance with an AUC of 0.946 and an accuracy of 92.2% in the test cohort.Validation: How is the performance of using quantitative CT parameters for predicting risks of esophageal fistula in SCC patients treated by chemotherapy or chemoradiotherapy? Quantitative CT model was used to validate the predictive performance of esophageal fistula in the validation cohort and revealed a same high results as showing in the test cohort with an AUC of 0.841 and an accuracy of 78.4%.

CLINICAL RELEVANCE/APPLICATION

To facilitate clinical use, a nomogram based on quantitative CT parameters, including THK-tumor, R-ulcer and R-HU, was developed. The probability of fistula formation after treatment ranged from 0 to 1. A probability nearing 1 indicated high odds of esophageal fistula. Patients with esophageal cancer could benefit from this prediction model.

SPR-CH-19   Challenges Of Diagnosing Interstitial Lung Abnormality (ILA) According To Fleischner Society Guideline By Using Routine Chest CT For A Health Screening: Comparative Analysis With ILA Quantification

Participants
Minseon Kim, Incheon, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the reproducibility of radiological criteria of interstitial lung abnormality (ILA) proposed by Fleischner Society and test a fully automated screening tool for ILA in routine chest CT.*Methods and Materials In this retrospective study, patients who underwent chest CT for a health screening were consecutively screened for ILA by thoracic radiologist (R1). Patients who were positive for ILA or equivocal for ILA, and negative for ILA were matched at a ratio of 1:2 by using age and sex variables. A total of 192 patients (55 patients with ILA) were included. Two thoracic radiologists (R2 and R3) independently reviewed the CT images according to Fleischner Society guideline and rated the presence (ILA, equivocal ILA, no ILA) and subtype of ILA, and semi-quantitatively evaluated the extent of ILA in each lung zone. We tested the dedicated automated screening tool for ILA, which provide ILA quantification according to guideline using deep learning based CT quantification, using each readers' diagnosis as a gold standard.*Results Among total patients, 19 patients underwent routine dose nonenhanced chest CT and 173 patients underwent routine dose enhanced chest CT. Interreader agreement for ILA (no ILA, equivocal ILA or ILA) between two radiologists was substantial (weighted ? = 0.69) and for ILA subtype was moderate (? = 0.44). The mean quantified ILA of the lung zone

visually rated more than 5% were about 7% (interquartile range: 1-13) and of the zone rated less than 5% was 2.5% to 3.7% (interquartile range: 0-6). The diagnosis of presence of ILA based on automatic tool quantifying total extent of ILA in each zones with 5% cut-off, had a sensitivity of 62.2% and a specificity of 66.9% for the detection of ILA for R2 diagnosis and a sensitivity of 56.1% and a specificity of 64.5% for R3 diagnosis.*Conclusions Significant interreader variability exists for diagnosing ILA according to Fleischner society guideline. Screening with quantification may aid the diagnosis to define the extent of ILA objectively and according to guideline but the diagnostic sensitivity should be improved.*Clinical Relevance/Application The current radiological criteria of the ILA may not be highly reproducible. Screening with quantification can provide a more reproducible assessment and have potential in aiding the diagnosis and follow-up of ILA.

RESULTS

Among total patients, 19 patients underwent routine dose nonenhanced chest CT and 173 patients underwent routine dose enhanced chest CT. Interreader agreement for ILA (no ILA, equivocal ILA or ILA) between two radiologists was substantial (weighted ? = 0.69) and for ILA subtype was moderate (? = 0.44). The mean quantified ILA of the lung zone visually rated more than 5% were about 7% (interquartile range: 1-13) and of the zone rated less than 5% was 2.5% to 3.7% (interquartile range: 0-6). The diagnosis of presence of ILA based on automatic tool quantifying total extent of ILA in each zones with 5% cut-off, had a sensitivity of 62.2% and a specificity of 66.9% for the detection of ILA for R2 diagnosis and a sensitivity of 56.1% and a specificity of 64.5% for R3 diagnosis.

CLINICAL RELEVANCE/APPLICATION

The current radiological criteria of the ILA may not be highly reproducible. Screening with quantification can provide a more reproducible assessment and have potential in aiding the diagnosis and follow-up of ILA.

SPR-CH-20   Personalized Chest CT: Optimal Examination Protocols For The Detection Of Fibrosis, Nodules, And Pneumonia.

Participants
Markus Kopp, Erlangen, Germany (*Presenter*) Speakers Bureau, Siemens AG

PURPOSE

The purpose of this study was to evaluate the minimum diagnostic radiation dose level for the detection of high-resolution (HR) lung structures, pulmonary nodules (PN), and infectious diseases (ID).*Methods and Materials Preclinical CT examinations were performed with a human cadaver in exponential radiation dose settings. We used tin filter-based spectral shaping protocols starting with the applicable minimum and ranging up to the institutional standard full dose protocol. Image findings were evaluated on a 5-point Likert scale, with 3 representing the minimum image quality. Subgroup analysis was carried out for optimal detection (Likert = 4) of HR lung structures, PN, and ID. We developed three specific protocols (HR-,PN- and ID-CT) and one minimum dose protocol (MIN-CT). Those protocols were prospectively used in 88 consecutive patients. We compared radiation dose parameters, objective and subjective image quality.*Results Optimal or perfect lesion detection (Likert = 4) was achieved for HR-, PN-, and ID-CT under consideration of the individual clinical focus. HR-CT (CTDIvol: 5.4 (± 1.4) mGy*cm) was performed in 38 patients, PN-CT (1.2 (± 0.4) mGy*cm) in 21 patients, ID-CT (0.6 (± 0.2) mGy*cm) in 20 patients and MIN-CT (ED: 0.2 (± 0.1) mGy*cm) in 9 patients. CTDIvol differed significantly within the study groups, and also post-hoc analysis was significant (p < 0.001), except for the comparison of ID-CT and MIN-CT (p = 0.262). Dose normalized contrast to noise ratio (CNRD) was comparable between all groups (p = 0.087). Overall image quality (OA) and delineation for HR structures, PN, and ID differed significantly within the study groups (p < 0.001). Post-hoc analysis showed no significant difference between PN- and ID-CT protocols for OA, HR lung structures, PN and ID (p = 0.575, p = 1.000, p = 0.681, p = 1.000). Comparison of HR- and PN-CT protocols was not significant for the detection of PN and ID (p = 0.051, p = 0.177). MIN-CT showed borderline image quality (Likert = 3) for the delineation of PN and ID, was insufficient for HR structures, and reached a dose reduction up to 96.7% compared to HR-CT.*Conclusions Personalized chest CT protocols tailored to specific clinical indications lead to substantial dose reduction without reducing interpretability.*Clinical Relevance/Application The use of personalized chest CT protocols leads to significant dose reduction without reducing interpretability under consideration of the clinical indication. Additionally, this study suggests a validated low-dose CT protocol for detecting pneumonia in the COVID-19 pandemic. MIN-CT allows to control or exclude pulmonary pathologies at dose levels comparable to a chest radiograph in two planes.

RESULTS

Optimal or perfect lesion detection (Likert = 4) was achieved for HR-, PN-, and ID-CT under consideration of the individual clinical focus. HR-CT (CTDIvol: 5.4 (± 1.4) mGy*cm) was performed in 38 patients, PN-CT (1.2 (± 0.4) mGy*cm) in 21 patients, ID-CT (0.6 (± 0.2) mGy*cm) in 20 patients and MIN-CT (ED: 0.2 (± 0.1) mGy*cm) in 9 patients. CTDIvol differed significantly within the study groups, and also post-hoc analysis was significant (p < 0.001), except for the comparison of ID-CT and MIN-CT (p = 0.262). Dose normalized contrast to noise ratio (CNRD) was comparable between all groups (p = 0.087). Overall image quality (OA) and delineation for HR structures, PN, and ID differed significantly within the study groups (p < 0.001). Post-hoc analysis showed no significant difference between PN- and ID-CT protocols for OA, HR lung structures, PN and ID (p = 0.575, p = 1.000, p = 0.681, p = 1.000). Comparison of HR- and PN-CT protocols was not significant for the detection of PN and ID (p = 0.051, p = 0.177). MIN-CT showed borderline image quality (Likert = 3) for the delineation of PN and ID, was insufficient for HR structures, and reached a dose reduction up to 96.7% compared to HR-CT.

CLINICAL RELEVANCE/APPLICATION

The use of personalized chest CT protocols leads to significant dose reduction without reducing interpretability under consideration of the clinical indication. Additionally, this study suggests a validated low-dose CT protocol for detecting pneumonia in the COVID-19 pandemic. MIN-CT allows to control or exclude pulmonary pathologies at dose levels comparable to a chest radiograph in two planes.

SPR-CH-21   Application Of AI - Based Emphysema Quantification Algorithm On 512 And 1024-matrix Chest CT Images: Variability Demands Standardization

Participants
Shadi Ebrahimian, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Ultra-high-resolution acquisition mode on modern multidetector-row CT scanners allows reconstruction of 512-matrix as well as 1024-matrix images. With emerging improvements in CT technology, in-plane resolution is expected to reach 2048-matrix. We

assessed variations in lung and lobe distribution of the low attenuation area (LAA< -950HU) quantified with AI-based emphysema algorithm on chest CT images reconstructed with 512- and 1024 matrix.*Methods and Materials With IRB approval and HIPAA compliance, we included 77 patients (mean age 70 ± 14 years; male: female 34:43) who were scanned on a 512-slice, single-source, MDCT scanner (GE Revolution CT) using High-Definition acquisition mode where the scanner acquires 2496 views per gantry rotation instead of 984 views in regular mode. We reconstructed two transverse image series using 512 and 1024 square matrix (both with 0.625 mm section thickness and HD-Detail reconstruction algorithm with a commercial, ASIRv iterative reconstruction technique at a strength of 30%). Deidentified 512- and 1024-matrix image series were separately processed on an offline commercial AI-based emphysema quantification algorithm (Coreline, South Korea). Data were analyzed to determine the difference (Student t test) between volume of LAA on the two series.*Results Overall, 46/77 CT had evidence of emphysema and the remaining 31/77 patients had no emphysema. There was a significant difference in LAA percentage volume (regarded significant when difference >5%) estimated from 512- and 1024-matrix images (p=0.014). In 21/77 patients, LAA in 1024-matrix images was substantially higher than on 512-matrix (5-13% change). In 4/77 patients, LAA percentage volume was greater on 512-matrix images than on 1024-matrix (5-9% change). The absolute LAA volumes on 512-matrix (LAA volume = 96.2±165.3 ml) and 1024-matrix images (391.3±404.3 ml) were substantially different (p<0.001). Subjective analysis revealed differences in image noise, texture, and sharpness of small pulmonary structures between the two-image series.*Conclusions Differences in reconstructed matrix size (512 vs. 1024) is associated with random variations in estimation of low-attenuation areas (< -950 HU) for CT-based emphysema quantification.*Clinical Relevance/Application When using emphysema quantification algorithms, users must pay close attention to the matrix size to avoid technique-related variations in estimation of low-attenuation areas on chest CT.

RESULTS

Overall, 46/77 CT had evidence of emphysema and the remaining 31/77 patients had no emphysema. There was a significant difference in LAA percentage volume (regarded significant when difference >5%) estimated from 512- and 1024-matrix images (p=0.014). In 21/77 patients, LAA in 1024-matrix images was substantially higher than on 512-matrix (5-13% change). In 4/77 patients, LAA percentage volume was greater on 512-matrix images than on 1024-matrix (5-9% change). The absolute LAA volumes on 512-matrix (LAA volume = 96.2±165.3 ml) and 1024-matrix images (391.3±404.3 ml) were substantially different (p<0.001). Subjective analysis revealed differences in image noise, texture, and sharpness of small pulmonary structures between the two-image series.

CLINICAL RELEVANCE/APPLICATION

When using emphysema quantification algorithms, users must pay close attention to the matrix size to avoid technique-related variations in estimation of low-attenuation areas on chest CT.

SPR-CH-22 AI - Based Lung Features Extraction, Classification, And Quantification In Interstitial Lung Diseases

Participants
Shadi Ebrahimian, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Variations in classification and quantitation of interstitial lung diseases (ILD) are known limitations of qualitative interpretation of chest CT in ILD. We assessed the role of an AI algorithm in extraction, classification, and quantification of lung features from thin-section CT in ILD patients.*Methods and Materials Our IRB approved study included 194 patients with ILD (mean age 69±12year; M:F 108:86) on thin-section chest CTs. Two thoracic radiologists recorded lobar distribution, finding types (such as groundglass, reticulations, honeycombing, cysts, consolidation), and classification of scan patterns (UIP, probable UIP, indeterminate for UIP, and alternative diagnosis) according to the ATS/ERS/JRS/ALAT Practice Guideline for idiopathic pulmonary fibrosis (IPF). Surgical pathology, clinical and/or radiologic diagnosis were obtained from medical records. Thin-section CTs were processed with the Lung Texture AI algorithm (Coreline, S. Korea) for lung feature extraction and computing volumes of honeycombing, reticulation, emphysema, consolidation, GGO, and normal lung in the whole lung and each lobe separately. Data were analyzed with independent sample t-test, one-way ANOVA, and area under the ROC curve (AUC).*Results AI-based volumes of reticulation (AUC=0.87) and honeycombing (AUC=0.80) were the best differentiators between the different scan patterns (p<0.001). Higher AUCs were calculated from extracted reticulation and honeycombing volumes from lower lobes (AUC=0.82) than upper and middle lobes (AUC=0.69) (p<0.001). AI predicted the presence of honeycombing, reticulation, and consolidation with AUCs of 0.81, 0.93, and 0.78, respectively. AI differentiated chest CT with IPF from other diseases with AUCs of 0.88, 0.82, and 0.72 (p<0.001) for the volume of reticulation, consolidation, and honeycombing, respectively. The highest AUCs for differentiating hypersensitivity pneumonitis was noted for reticulation (AUC=0.85), honeycombing (AUC=0.73), and consolidation (AUC=0.74) (p<0.001).*Conclusions The Lung Texture AI can help extract and quantify volume of different chest CT findings in ILD as well as aid in classifying scan patterns in patients with IPF. This can help reduce interobserver discordance and quantify disease burden.*Clinical Relevance/Application Fully-automated, AI-based extraction and classification of ILD/IPF-related findings along with whole lung and lobar quantification can help predict disease patterns and differentiate common ILDs.

RESULTS

AI-based volumes of reticulation (AUC=0.87) and honeycombing (AUC=0.80) were the best differentiators between the different scan patterns (p<0.001). Higher AUCs were calculated from extracted reticulation and honeycombing volumes from lower lobes (AUC=0.82) than upper and middle lobes (AUC=0.69) (p<0.001). AI predicted the presence of honeycombing, reticulation, and consolidation with AUCs of 0.81, 0.93, and 0.78, respectively. AI differentiated chest CT with IPF from other diseases with AUCs of 0.88, 0.82, and 0.72 (p<0.001) for the volume of reticulation, consolidation, and honeycombing, respectively. The highest AUCs for differentiating hypersensitivity pneumonitis was noted for reticulation (AUC=0.85), honeycombing (AUC=0.73), and consolidation (AUC=0.74)(p<0.001).

CLINICAL RELEVANCE/APPLICATION

Fully-automated, AI-based extraction and classification of ILD/IPF-related findings along with whole lung and lobar quantification can help predict disease patterns and differentiate common ILDs.

SPR-CH-23 Pulmonary Arterial Thrombosis 3 Months After A SARS-Cov2 Infection: Frequency On Dual-Energy CT (DECT) Angiographic Examinations In 55 Patients

Participants
Martine J. Remy-Jardin, MD, PhD, Lille, France (*Presenter*) Research Grant, Siemens AG;Speaker, Siemens AG

PURPOSE

During COVID-19, the main manifestations of the disease are not only pneumonia but also coagulation disorders. We present preliminary data on the pulmonary vascular abnormalities detectable 3 months after hospitalization for severe SARS-Cov2 infection.*Methods and Materials Among the 320 patients with confirmed COVID-19 hospitalized between March and April 2020 who participated in a systematic follow-up at 3 months, 67 patients with residual respiratory symptoms were referred for specialized follow-up. Fifty-five of them (30 males; 25 females; mean age: 60.4 yr) underwent a DECT angiographic examination on a 3rd-generation dual-source CT system (Force, Siemens Healthineers) with reconstruction of perfusion images (Lung PBV).*Results All patients had partial (n=40; 72.7%) or complete (n=15; 27.3%) resolution of COVID-19 lung infiltration. CT angiographic images were normal in 52 patients (52/55; 94.6%) and showed non-obstructive thrombi in 3 patients (3/55; 5.4%) at the level of (a) one (n=1) and two (n=1) segmental arteries of a single lobe; and (b) central and peripheral arteries of both lungs (n=1); none showed features of lung infarction. Lung perfusion was rated as non-interpretable in 2 patients (3.6%; shoulder prosthesis/morbid obesity), normal in 17 patients (30.9%) and abnormal in 36 patients (65.5%), the latter group comprising 32 patients with residual COVID-19 opacities (32/55; 58%) and 4 patients with normal lung parenchyma (4/55; 7%). Perfusion abnormalities consisted of (a) patchy perfusion defects in both lungs (30/36; 83%), (b) PE-type perfusion defects (6/36; 16.6%) in presence (n=1) or absence of proximal thrombosis (n=5); and (c) focal areas of hypoperfusion (2/36; 5.5%).*Conclusions DECT depicted non-obstructive proximal thrombosis in 5.4% of patients and perfusion abnormalities suggestive of widespread microangiopathy in 65.5% of patients. Lung microcirculation was abnormal in 7% of patients with a normal lung parenchyma.*Clinical Relevance/Application DECT depicted unexpected arterial thrombosis (5.4%), perfusion abnormalities suggestive of microangiopathy (65.5%) and areas of increased perfusion matching residual SARS-CoV-2 pneumonia abnormalities.

RESULTS

All patients had partial (n=40; 72.7%) or complete (n=15; 27.3%) resolution of COVID-19 lung infiltration. CT angiographic images were normal in 52 patients (52/55; 94.6%) and showed non-obstructive thrombi in 3 patients (3/55; 5.4%) at the level of (a) one (n=1) and two (n=1) segmental arteries of a single lobe; and (b) central and peripheral arteries of both lungs (n=1); none showed features of lung infarction. Lung perfusion was rated as non-interpretable in 2 patients (3.6%; shoulder prosthesis/morbid obesity), normal in 17 patients (30.9%) and abnormal in 36 patients (65.5%), the latter group comprising 32 patients with residual COVID-19 opacities (32/55; 58%) and 4 patients with normal lung parenchyma (4/55; 7%). Perfusion abnormalities consisted of (a) patchy perfusion defects in both lungs (30/36; 83%), (b) PE-type perfusion defects (6/36; 16.6%) in presence (n=1) or absence of proximal thrombosis (n=5); and (c) focal areas of hypoperfusion (2/36; 5.5%).

CLINICAL RELEVANCE/APPLICATION

DECT depicted unexpected arterial thrombosis (5.4%), perfusion abnormalities suggestive of microangiopathy (65.5%) and areas of increased perfusion matching residual SARS-CoV-2 pneumonia abnormalities.

SPR-CH-24 Immune-related Thyroiditis In Patients With Advanced Lung Cancer Treated With Immune-checkpoint Inhibitors: The Incidence, Imaging Features, And Clinical Implications

Participants
Hyesun Park, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the incidence and imaging characteristics of thyroiditis in the setting of immune-checkpoint inhibitor (ICI) therapy and correlate with clinical features.*Methods and Materials The study included 534 patients with advanced non-small cell lung cancer (NSCLC) treated with ICI using PD-1/PD-L1 inhibitors. The imaging and medical records were retrospectively reviewed with IRB approval. Two radiologists independently reviewed the baseline and serial follow-up scans (chest CT and F18-FDG-PET-CT) during ICI therapy, without access to the clinical records. The imaging findings indicative of thyroiditis included morphology (enlargement or atrophy) and attenuation (diffusely hypodense or heterogeneous) on CT, and hypermetabolism on PET-CT, which was new on follow-up scans. Discordant cases were reviewed by the third reader to determine the final interpretation.*Results Among 534 patients, 50 patients (9.4%) had imaging findings indicative of thyroiditis. The median time from the initiation of therapy to the first positive scan was 9.5 weeks (range, 0.9-87.4 weeks). Most common finding was diffuse hypoattenuation of the glands (36/50, 72%), with gland enlargement in 15 and atrophy in 12 patients. Heterogeneous attenuation of the glands was noted in 12 patients (12/50, 24%), with enlargement in 7 and atrophy in one patient. Diffuse increased FDG uptake in the glands on PET-CT was noted in 2 patients (2/50, 4%) without morphologic changes. Seventy-seven patients had clinically diagnosed thyroiditis with abnormal TSH, including 22 with both clinical and radiological diagnoses. Among 77 clinically diagnosed cases, patients who also had positive CT/PET findings more frequently received hormone replacement therapy than those without CT/PET findings (20/22 vs. 20/55; Fisher p<0.0001).*Conclusions Immune-related thyroiditis during ICI therapy commonly presents with diffuse hypoattenuation of thyroid glands on chest CT, with or without enlargement or atrophy, and was noted in 9.4% of advanced NSCLC patients.*Clinical Relevance/Application Awareness of the imaging findings of immune-related thyroiditis on chest CT is important because of the therapeutic implications for thyroiditis.

RESULTS

Among 534 patients, 50 patients (9.4%) had imaging findings indicative of thyroiditis. The median time from the initiation of therapy to the first positive scan was 9.5 weeks (range, 0.9-87.4 weeks). Most common finding was diffuse hypoattenuation of the glands (36/50, 72%), with gland enlargement in 15 and atrophy in 12 patients. Heterogeneous attenuation of the glands was noted in 12 patients (12/50, 24%), with enlargement in 7 and atrophy in one patient. Diffuse increased FDG uptake in the glands on PET-CT was noted in 2 patients (2/50, 4%) without morphologic changes. Seventy-seven patients had clinically diagnosed thyroiditis with abnormal TSH, including 22 with both clinical and radiological diagnoses. Among 77 clinically diagnosed cases, patients who also had positive CT/PET findings more frequently received hormone replacement therapy than those without CT/PET findings (20/22 vs. 20/55; Fisher p<0.0001).

CLINICAL RELEVANCE/APPLICATION

Awareness of the imaging findings of immune-related thyroiditis on chest CT is important because of the therapeutic implications for thyroiditis.

SPR-CH-25 Can Dual-Energy CT Lung Perfusion Detect Abnormalities At The Level Of Lung Circulation In Systemic Sclerosis (SSc)? Preliminary Experience In 101 Patients

Participants
Martine J. Remy-Jardin, MD, PhD, Lille, France (*Presenter*) Research Grant, Siemens AG;Speaker, Siemens AG

PURPOSE

To evaluate lung perfusion in patients with systemic sclerosis (SSc) and search for potential relationships between perfusion abnormalities and clinical, functional and hemodynamic characteristics.*Methods and Materials The study population included 101 patients who underwent dual-energy CT (DECT) angiography in the follow-up of SSc. CT examinations were obtained on a 3rd-generation dual-source CT system (Force, Siemens Healthineers) with reconstruction of morphologic and perfusion images. All patients underwent pulmonary function tests within two months of the follow-up CT scan. Fifteen patients had right heart catheterization-proven PH.*Results Based on HRCT scans, our population included patients without SSc-lung involvement (Group A; n=37), patients with SSc-related ILD (Group B; n=56) of variable extent (Group B mild: =10% of lung parenchyma: n=17; Group B moderate: between 11-50%: n=31; Group B severe: >50%: n=8) and patients with pulmonary veno-occlusive disease/pulmonary capillary hemangiomatosis (PVOD/PCH) (Group C; n=8). Lung perfusion was abnormal in 8 patients in Group A (21.6%), 14 patients in Group B (25%) and 7 patients in Group C (87.5%). Perfusion changes were mainly composed of bilateral perfusion defects, including patchy, PE-type perfusion defects and areas of hypoperfusion of variable size. In Group A and Group B mild (n=54): (a) patients with abnormal lung perfusion (n=14) had a significantly higher proportion of NYHA III/IV scores of dyspnea (p=0.031), a shorter mean walking distance at the 6MWT (p=0.042) and a trend towards lower mean DLCO% (p=0.055) when compared to patients with normal lung perfusion (n=40); (b) a negative albeit weak correlation was found between the iodine concentration in both lungs and the DLCO% (r=-0.27; p=0.059) whereas no correlation was found with the PAPs (r=0.16; p=0.29) and walking distance during the 6MWT (r=-0.029; p=0.84).*Conclusions DECT lung perfusion provides complementary information to standard HRCT scans, depicting perfusion changes in SSc patients with normal or minimally infiltrated lung parenchyma.*Clinical Relevance/Application Our results show a clinically relevant complementarity between morphology and perfusion in the evaluation of SSc patients, suggesting a greater role for dual-energy CT in patient management.

RESULTS

Based on HRCT scans, our population included patients without SSc-lung involvement (Group A; n=37), patients with SSc-related ILD (Group B; n=56) of variable extent (Group B mild: =10% of lung parenchyma: n=17; Group B moderate: between 11-50%: n=31; Group B severe: >50%: n=8) and patients with pulmonary veno-occlusive disease/pulmonary capillary hemangiomatosis (PVOD/PCH) (Group C; n=8). Lung perfusion was abnormal in 8 patients in Group A (21.6%), 14 patients in Group B (25%) and 7 patients in Group C (87.5%). Perfusion changes were mainly composed of bilateral perfusion defects, including patchy, PE-type perfusion defects and areas of hypoperfusion of variable size. In Group A and Group B mild (n=54): (a) patients with abnormal lung perfusion (n=14) had a significantly higher proportion of NYHA III/IV scores of dyspnea (p=0.031), a shorter mean walking distance at the 6MWT (p=0.042) and a trend towards lower mean DLCO% (p=0.055) when compared to patients with normal lung perfusion (n=40); (b) a negative albeit weak correlation was found between the iodine concentration in both lungs and the DLCO% (r=-0.27; p=0.059) whereas no correlation was found with the PAPs (r=0.16; p=0.29) and walking distance during the 6MWT (r=-0.029; p=0.84).

CLINICAL RELEVANCE/APPLICATION

Our results show a clinically relevant complementarity between morphology and perfusion in the evaluation of SSc patients, suggesting a greater role for dual-energy CT in patient management.

SPR-CH-26 Pulmonary MR Imaging With Ultra-short TE: Capability For Nodule Detection And Lung-RADS Classification Compared With That Of Standard- And Reduced-dose CTs

Participants
Yoshiharu Ohno, MD,PhD, Toyoake, Japan (*Presenter*) Research Grant, Canon Medical Systems Corporation;Research Grant, DAIICHI SANKYO Group

PURPOSE

Pulmonary MR imaging with ultra-short echo time (UTE) has been tested for nodule detection or nodule subtype classification compared with standard- or reduced-dose CTs. However, no reports have been published regarding a direct comparison of these methods' capabilities for Lung-RADS evaluation. The purpose of this study was to compare the capabilities of pulmonary MR imaging with UTE with those of standard- or reduced-dose thin-section CTs for nodule detection and Lung-RADS classification in screening situation.*Methods and Materials Standard- and reduced-dose chest CTs (270 mA and 60 mA) and MR imaging with UTE were used to examine 365 subjects, 209 males (mean age, 64±8 years [mean±standard deviation]) and 156 females (mean age, 64±9 years) as lung cancer screening. Probability of nodule presence was assessed for all methods with a 5-point visual scoring system. All detected nodules were then classified based on Lung-RADS classification using each method. To compare nodule detection capability of the three methods, consensus for performances was rated by using jackknife free-response receiver operating characteristic analysis. Then, sensitivity and false positive rate (/data set) for consensus assessment were also compared among the three methods by using McNemar's test or the signed rank test. In addition, weighted kappa statistics were used to determine the agreement of Lung-RADS classification obtained with each method with standard reference.*Results Sensitivity (SE) of pulmonary MR imaging with UTE (SE=0.88) was significantly higher than that of standard-dose CT (SE=0.87, p=0.008) and reduced-dose CT (SE=0.87, p=0.004), although there was no significant difference in figure of merit among the three methods (F=3.0, p=0.25). Moreover, there were no significant differences of in false-positive rate/case in consensus evaluation among of all methods (p>0.05). Agreements for Lung-RADS among all methods were determined as significant or almost perfect (standard-dose CT: ?=0.82, p<0.0001; reduced-dose CT: ?=0.82, p<0.0001; pulmonary MR imaging with UTE: ?=0.81, p<0.0001).*Conclusions Pulmonary MR imaging with UTE was found to be as useful for nodule detection and Lung-RADS classification evaluation as standard- or reduced-dose CTs in lung cancer screening.*Clinical Relevance/Application Pulmonary MR imaging with UTE was found to be as useful for nodule detection and Lung-RADS classification evaluation as standard- or reduced-dose CTs in lung cancer screening.

RESULTS

Sensitivity (SE) of pulmonary MR imaging with UTE (SE=0.88) was significantly higher than that of standard-dose CT (SE=0.87, p=0.008) and reduced-dose CT (SE=0.87, p=0.004), although there was no significant difference in figure of merit among the three methods (F=3.0, p=0.25). Moreover, there were no significant differences of in false-positive rate/case in consensus evaluation among of all methods (p>0.05). Agreements for Lung-RADS among all methods were determined as significant or almost perfect (standard-dose CT: ?=0.82, p<0.0001; reduced-dose CT: ?=0.82, p<0.0001; pulmonary MR imaging with UTE: ?=0.81, p<0.0001).

CLINICAL RELEVANCE/APPLICATION

Pulmonary MR imaging with UTE was found to be as useful for nodule detection and Lung-RADS classification evaluation as standard- or reduced-dose CTs in lung cancer screening.

SPR-CH-3 Identification Of Risk Factors For Brain Metastasis In Newly Diagnosed Non-Small Cell Lung Cancer: A Cohort Study

Participants
Sohee Park, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To identify risk factors for brain metastasis from staging chest CT and clinical characteristics in patients with newly diagnosed non-small cell lung cancer (NSCLC) dichotomized according to resectability.*Methods and Materials Patients newly diagnosed with NSCLC of clinical stages II-IV between November 2017 and October 2018 were enrolled and classified into resectable (TNM stage II and IIIA) and unresectable stages (TNM stage IIIB/C and IV) on chest CT. Associations of clinicopathological characteristics and staging chest CT findings with brain metastasis were analyzed using univariable and multivariable logistic regression for each stage group. Predictive models were constructed, and their performances were evaluated using receiver operating characteristics curve analysis. A subgroup analysis for unresectable-stage patients with known epidermal growth factor receptor gene (EGFR) mutation was also performed.*Results 911 NSCLC patients (mean age, 65 ± 11 years; 620 men), of whom 194 were diagnosed with brain metastasis. 335 patients (25 brain metastases) were classified as resectable stages and 576 patients (169 brain metastases) as unresectable stages. Independent risk factors for brain metastasis were as follows: N2-stage, absence of air-bronchogram/bubble lucency, and presence of spiculation for resectable stages; and younger age, female, extrathoracic metastasis, and adenocarcinoma for unresectable stages. The predictive models gave areas under the curve (AUCs) of 0.736 for resectable stages and 0.675-0.766 for unresectable stages. In the subgroup with known EGFR-mutation status, extrathoracic metastasis and positive EGFR mutation were independent risk factors, with the model showing AUCs of 0.641-0.732.*Conclusions CT-derived imaging features, clinical stages, lung cancer subtype, and EGFR mutation were associated with brain metastasis in patients with newly diagnosed NSCLC. The risk factors were completely different between resectable and unresectable stages.*Clinical Relevance/Application CT-derived imaging features, clinical stage, lung cancer subtype, and EGFR mutation were risk factors for brain metastasis in patients with newly diagnosed NSCLC, which showed different associations depending on resectability.

RESULTS

911 NSCLC patients (mean age, 65 ± 11 years; 620 men), of whom 194 were diagnosed with brain metastasis. 335 patients (25 brain metastases) were classified as resectable stages and 576 patients (169 brain metastases) as unresectable stages. Independent risk factors for brain metastasis were as follows: N2-stage, absence of air-bronchogram/bubble lucency, and presence of spiculation for resectable stages; and younger age, female, extrathoracic metastasis, and adenocarcinoma for unresectable stages. The predictive models gave areas under the curve (AUCs) of 0.736 for resectable stages and 0.675-0.766 for unresectable stages. In the subgroup with known EGFR-mutation status, extrathoracic metastasis and positive EGFR mutation were independent risk factors, with the model showing AUCs of 0.641-0.732.

CLINICAL RELEVANCE/APPLICATION

CT-derived imaging features, clinical stage, lung cancer subtype, and EGFR mutation were risk factors for brain metastasis in patients with newly diagnosed NSCLC, which showed different associations depending on resectability.

SPR-CH-4 Differences In Prognostic Implication Of Ground-glass Opacity At CT In Resectable Lung Cancers According To Nodal Status

Participants
Sohee Park, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

Although the presence of GGO on CT indicated a favorable prognosis in early-stage non-small cell lung cancer (NSCLC), it is still unclear whether this impact will be preserved in resectable NSCLCs with more advanced stages. This study was aimed to clarify the prognostic significance of GGO component according to tumor stage and pathological nodal status in resectable NSCLCs.*Methods and Materials Patients who underwent curative resection for NSCLC between July 2010 and December 2017 were retrospectively included in this study. Patients were divided into GGO and solid groups based on the presence of GGO component. The interaction (a) between the presence of the GGO and pathological nodal status and (b) between the presence of GGO and cT stage on survival was evaluated. Cox regression was conducted in each subgroup stratified according to their interactions.*Results Out of 1,545 patients (mean age, 63 years; 908 men), 548 patients were classified into GGO group (pN0: 457, pN1/2: 91) and 997 patients into solid group (pN0: 660, pN1/2: 337). There were interactions between the presence of GGO and pathological nodal metastasis on both for 5-year disease-free survival (DFS) (p=0.006) and 5-year overall survival (OS) (p=0.02). The multivariable analysis revealed that 5-year DFS and 5-year OS of patients in GGO group were better than those of patients in solid group, only in pN0 stage (hazard ratio [HR], 0.63; p=0.003 and HR, 0.56; p=0.02, respectively), but not in pN1/2 stage. Moreover, in pN0 stage, the favorable prognostic value of GGO was limited to cT1 stage for 5-year DFS (adjusted HR, 0.48; p<0.001) and cT1/2 stage for 5-year OS (adjusted HR, 0.36; p=0.001).*Conclusions The presence of GGO was a favorable predictor for survival only in pN0 stage. Further, its significance was valid only in cT1 stage for DFS and cT1/2 stage for OS.*Clinical Relevance/Application In patients without pathological nodal metastasis, the presence of GGO provided additional prognostic value in a favorable direction, which may help further patient stratification and prognostication beyond the current staging system.

RESULTS

Out of 1,545 patients (mean age, 63 years; 908 men), 548 patients were classified into GGO group (pN0: 457, pN1/2: 91) and 997 patients into solid group (pN0: 660, pN1/2: 337). There were interactions between the presence of GGO and pathological nodal metastasis on both for 5-year disease-free survival (DFS) (p=0.006) and 5-year overall survival (OS) (p=0.02). The multivariable analysis revealed that 5-year DFS and 5-year OS of patients in GGO group were better than those of patients in solid group, only in pN0 stage (hazard ratio [HR], 0.63; p=0.003 and HR, 0.56; p=0.02, respectively), but not in pN1/2 stage. Moreover, in pN0 stage, the favorable prognostic value of GGO was limited to cT1 stage for 5-year DFS (adjusted HR, 0.48; p<0.001) and cT1/2 stage for 5-year OS (adjusted HR, 0.36; p=0.001).

CLINICAL RELEVANCE/APPLICATION

In patients without pathological nodal metastasis, the presence of GGO provided additional prognostic value in a favorable direction, which may help further patient stratification and prognostication beyond the current staging system.

SPR-CH-5 A Multi-modality Tumor And Non-tumor Radiomics Model For Recurrence Risk-stratification In Non-

small Cell Lung Cancer

Participants
Jaryd Christie, BMedSc, London, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

To develop a multi-modal model integrating quantitative imaging features from the tumor and non-tumor regions of interest, qualitative features, and clinical data to improve recurrence risk-stratification of patients with non-small cell lung cancer (NSCLC) over cancer staging.*Methods and Materials A dataset of 135 patients with early-stage NSCLC who had surgery as their primary form of treatment was analyzed. The tumor and peri-tumoral volumes on both pre-treatment CT and PET were segmented, while the bone marrow (L3-L5 vertebral bodies) was segmented on PET. The Quantitative Image Feature Engine was used to compute shape, size, first-order, and texture radiomic features from these volumes. Combined with the clinical and qualitative CT features, feature selection was performed using the least absolute shrinkage and selection operator (LASSO) on the 1030 features to select the top features to predict time to any recurrence in the training cohort (n=94). A Cox model was built in the training cohort and evaluated on the testing cohort (n=41). Model performance was assessed using the concordance index and compared to a clinical stage-only model. Kaplan-Meier curves were generated to separate patients into high- and low-risk groups using the median risk score in the training cohort.*Results A total of 14 features were selected as the top performing features to predict post-surgical recurrence. Twelve of the top features were texture features (two CT tumor, six CT peri-tumoral, two PET peri-tumoral, and two PET bone marrow) with the remaining two features being cancer stage and patient age. Patients with a more heterogenous texture in the tumor and non-tumor regions were more likely to recur. The model significantly stratified patients into high- and low-risk groups in the training (n=94, p<0.005) and testing (n=41, p=0.01) cohorts, respectively. The radiomics based model achieved a concordance of 0.84 and 0.81, outperforming the clinical stage-only model, with concordances of 0.69 and 0.68 in the training and testing cohorts, respectively.*Conclusions Our radiomics model outperformed the stage-only model for NSCLC recurrence risk stratification. These results demonstrate that non-invasive radiomic features from the tumor and non-tumor regions on CT and PET could aid physicians in identifying patients who are at higher risk of treatment failure.*Clinical Relevance/Application CT and PET radiomics have the potential to augment staging to improve recurrence risk-stratification and could aid physicians in identifying patients that may benefit from more aggressive treatment options.

RESULTS

A total of 14 features were selected as the top performing features to predict post-surgical recurrence. Twelve of the top features were texture features (two CT tumor, six CT peri-tumoral, two PET peri-tumoral, and two PET bone marrow) with the remaining two features being cancer stage and patient age. Patients with a more heterogenous texture in the tumor and non-tumor regions were more likely to recur. The model significantly stratified patients into high- and low-risk groups in the training (n=94, p<0.005) and testing (n=41, p=0.01) cohorts, respectively. The radiomics based model achieved a concordance of 0.84 and 0.81, outperforming the clinical stage-only model, with concordances of 0.69 and 0.68 in the training and testing cohorts, respectively.

CLINICAL RELEVANCE/APPLICATION

CT and PET radiomics have the potential to augment staging to improve recurrence risk-stratification and could aid physicians in identifying patients that may benefit from more aggressive treatment options.

SPR-CH-6   Validation Of Definitions Of Central Tumors On CT In Patients With Clinical T1N0M0 Non-small Cell Lung Cancer: A Dual-institution, Multi-reader Study

Participants
Hyungjin Kim, MD, Seoul, Korea, Republic Of (*Presenter*) Stockholder, Medical IP;Stock options, Medical IP;Research Grant, Lunit Inc

PURPOSE

Definitions for central lung cancer have been ambiguous in guidelines, causing difficulty in selecting candidates for invasive mediastinal staging among patients with radiologically node-negative, early-stage lung cancer. We aimed to validate the proposed definitions for central lung cancer with further extensions using a methodology designed to complement the paucity of existing evidence in patients with clinical T1N0M0 lung cancer.*Methods and Materials Two retrospective cohorts were evaluated for the associations of central lung cancer according to 13 definitions based on chest CT with occult nodal metastasis. Univariable and multivariable ordinal logistic regression analyses were performed with the pathological N category as an ordinal outcome. Robust definitions, which retained statistical significance across multi-reader, dual-institutional datasets, were identified. For these definitions, binary diagnostic performance and inter-reader agreement were investigated.*Results In the two cohorts, 807 patients (median age, 63 years; interquartile range, 56-71 years; 410 women; 33 pN1, 48 pN2, and 1 pN3) and 510 patients (median age, 65 years; interquartile range, 58-71 years; 267 women; 33 pN1, 20 pN2, and no pN3) were included, respectively. Three definitions robust to inter-reader variation and dataset heterogeneity were identified: definition 7 (concentric lines arising from the midline, inner one-third, medial margin; adjusted odds ratio [OR], 2.10; 95% confidence interval [CI], 1.13-3.51; P=0.02), definition 10 (location index-based inner one-third, center; adjusted OR, 3.60; 95% CI, 1.49-8.25; P=0.003), and definition 12 (location index-based inner one-third, medial margin; adjusted OR, 3.57; 95% CI, 1.91-6.52; P<0.001). Definition 12 showed higher inter-reader agreement than definition 7 (Cohen ?, 0.80 vs. 0.66; P=0.005). Nevertheless, the sensitivity and positive predictive value of the three definitions were below 50%.*Conclusions Three robust definitions for central lung cancer were verified. However, candidate selection for invasive mediastinal staging solely based on a central tumor location would be suboptimal.*Clinical Relevance/Application We verified three definitions for CLC that are robust to perturbations due to reader and institutional variation, and can be assessed qualitatively or quantitatively using distance measurements on CT. However, a prediction model to ensure high sensitivity for occult nodal metastasis is needed.

RESULTS

In the two cohorts, 807 patients (median age, 63 years; interquartile range, 56-71 years; 410 women; 33 pN1, 48 pN2, and 1 pN3) and 510 patients (median age, 65 years; interquartile range, 58-71 years; 267 women; 33 pN1, 20 pN2, and no pN3) were included, respectively. Three definitions robust to inter-reader variation and dataset heterogeneity were identified: definition 7 (concentric lines arising from the midline, inner one-third, medial margin; adjusted odds ratio [OR], 2.10; 95% confidence interval [CI], 1.13-3.51; P=0.02), definition 10 (location index-based inner one-third, center; adjusted OR, 3.60; 95% CI, 1.49-8.25; P=0.003), and definition 12 (location index-based inner one-third, medial margin; adjusted OR, 3.57; 95% CI, 1.91-6.52; P<0.001). Definition 12 showed higher inter-reader agreement than definition 7 (Cohen ?, 0.80 vs. 0.66; P=0.005). Nevertheless, the sensitivity and positive predictive value of the three definitions were below 50%.

CLINICAL RELEVANCE/APPLICATION

We verified three definitions for CLC that are robust to perturbations due to reader and institutional variation, and can be assessed qualitatively or quantitatively using distance measurements on CT. However, a prediction model to ensure high sensitivity for occult nodal metastasis is needed.

SPR-CH-7   Predicting Progression-free Survival In NSCLC Undergoing EGFR-TKI Therapy Based On Intratumoral And Peritumoral Radiomic Features From Time Serial CT Imaging

Participants
Xiaobo Zhang, Nanning, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the value of time serial CT radiomics features in predicting progression-free survival (PFS) for non-small cell lung cancer (NSCLC) patients after epidermal growth factor receptor- tyrosine kinase inhibitor (EGFR-TKI) therapy.*Methods and Materials One hundred and eighteen NSCLC patients treated with EGFR-TKI therapy between January 2015 and September 2020 were retrospectively enrolled and randomly divided into training and validation cohorts with a 7:3 ratio. PFS was defined as the duration from therapy initiation to disease progression. Intratumoral and peritumoral features were extracted from time serial non-contrast chest CT (including pre-therapy and 1st follow-up images); moreover, the percentage variation per unit time (day) was introduced to adjust for the different follow-up period of each patient. Test-retest was performed to exclude irreproducible features, while Boruta algorithm was used to select critical radiomic features. Random forest survival models were constructed in the training cohort with baseline features alone, as well as combining time serial radiomics features. The added value of time serial features was further evaluated in the validation cohort by comparing the concordance index (C-index) between models.*Results This study included 118 patients (68 women, 57.6%; 56.9 ± 11.4 years), with 84 in the training cohort (median PFS 9.0 months; interquartile range, 7.00-12.00 months) and 34 in the validation cohort (median PFS 9.0 months; interquartile range, 6.25-11.75 months). In the combined model, 7 of the 10 most important contributors were unit time feature variation. The combination of time serial features outperformed the pre-therapy baseline features alone in predicting PFS (C-Index in training: 0.80, 95% CI: [0.71, 0.89] versus 0.72, 95% CI: [0.63, 0.81], p = 0.006; C-Index in validation: 0.72, 95% CI: [0.58, 0.87] versus 0.64, 95% CI: [0.49, 0.78], p = 0.030).*Conclusions Compared to the radiomic features from pre-therapy images alone, time serial features provided additional information and improved PFS prediction in NSCLC patients treated with EGFR-TKIs.*Clinical Relevance/Application The dynamic concept of percentage variation per unit time holds promise of monitoring treatment response and achieving personalized management.

RESULTS

This study included 118 patients (68 women, 57.6%; 56.9 ± 11.4 years), with 84 in the training cohort (median PFS 9.0 months; interquartile range, 7.00-12.00 months) and 34 in the validation cohort (median PFS 9.0 months; interquartile range, 6.25-11.75 months). In the combined model, 7 of the 10 most important contributors were unit time feature variation. The combination of time serial features outperformed the pre-therapy baseline features alone in predicting PFS (C-Index in training: 0.80, 95% CI: [0.71, 0.89] versus 0.72, 95% CI: [0.63, 0.81], p = 0.006; C-Index in validation: 0.72, 95% CI: [0.58, 0.87] versus 0.64, 95% CI: [0.49, 0.78], p = 0.030).

CLINICAL RELEVANCE/APPLICATION

The dynamic concept of percentage variation per unit time holds promise of monitoring treatment response and achieving personalized management.

SPR-CH-8   Application Of Computer-aided Detection (CAD) For Lung-RADS Categorization In CT Screening For Lung Cancer: Effect On Inter-reader Agreement

Participants
Sohee Park, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the effects of computer-aided detection (CAD) on inter-reader agreement in Lung Imaging Reporting and Data System (Lung-RADS) categorization.*Methods and Materials Two hundred baseline CT scans covering all Lung-RADS categories were randomly selected from the National Lung Cancer Screening Trial. Five radiologists independently reviewed the CT scans and assigned Lung-RADS categories without CAD and then with CAD. The CAD system presented up to five of the most risk-dominant nodules with measurements and suggested Lung-RADS category. Inter-reader agreement was analyzed using multirater Fleiss ? statistics.*Results The five readers had 139-151 negative screening results without CAD and 126-142 with CAD. With CAD, readers tended to upstage (average, 12.3%) rather than downstage Lung-RADS category (average, 4.4%), leading to slightly shortened follow-up intervals (average, 9.4 vs. 8.9 months). Inter-reader agreement of the five readers for Lung-RADS categorization was moderate (kappa, 0.60) without CAD, and slightly improved to substantial (kappa, 0.65) with CAD. The major cause for disagreement was assignment of different risk-dominant nodules in both reading sessions without and with CAD (54.2% [201/371] vs. 62.7% [229/365]). The proportion of disagreement in nodule size measurement was reduced from 27.5% (102/371) to 17.0% (62/365) with the use of CAD. In 31 cancer-positive cases, substantial management discrepancies among reader pairs, referring to a difference in follow-up interval of at least 9 months (category 1/2 vs. 4A/B), decreased with application of CAD by 50% (32/310 vs. 16/310).*Conclusions Application of CAD demonstrated a minor improvement in inter-reader agreement of Lung-RADS category, while CAD had the potential to reduce measurement variability and substantial management change in cancer-positive cases.*Clinical Relevance/Application Application of computer-aided detection demonstrated a minor improvement in inter-reader agreement of Lung-RADS category, while showing the potential to reduce measurement variability and substantial management change in cancer-positive cases.

RESULTS

The five readers had 139-151 negative screening results without CAD and 126-142 with CAD. With CAD, readers tended to upstage (average, 12.3%) rather than downstage Lung-RADS category (average, 4.4%), leading to slightly shortened follow-up intervals (average, 9.4 vs. 8.9 months). Inter-reader agreement of the five readers for Lung-RADS categorization was moderate (kappa, 0.60) without CAD, and slightly improved to substantial (kappa, 0.65) with CAD. The major cause for disagreement was assignment of different risk-dominant nodules in both reading sessions without and with CAD (54.2% [201/371] vs. 62.7% [229/365]). The proportion of disagreement in nodule size measurement was reduced from 27.5% (102/371) to 17.0% (62/365) with the use of CAD. In 31 cancer-positive cases, substantial management discrepancies among reader pairs, referring to a difference in follow-up interval of at least 9 months (category 1/2 vs. 4A/B), decreased with application of CAD by 50% (32/310 vs. 16/310).

SPR-CH-9   Radiologist Level End-to-end Incidental Pulmonary Nodule Diagnosis In Diagnostic Chest CTs

Participants
Ryan Najafi, PhD, Palo Alto, California (*Presenter*) Employee, Alphabet Inc;Stockholder, Alphabet Inc

PURPOSE

Diagnostic chest CTs, commonly performed on symptomatic patients, can display a broader spectrum of abnormalities and imaging protocols than screening CTs. Incidental Pulmonary Nodule (IPN) assessment may not necessarily be a primary focus during interpretation in patients without lung cancer suspicion. Previous AI approaches have focused on lung CT screening, where reader pools tend to be specialized, and with guidelines more consistently followed. We aimed to develop an end-to-end AI system for assessing IPNs in diagnostic CTs.*Methods and Materials 109,756 screening and diagnostic chest CT volumes were collected from a US hospital system and NLST for training. A biopsy confirmed cancer within two years after imaging (6290 cases) resulted in a positive label, whereas no cancer-suspicious follow-ups resulted in a negative label. We trained a two-stage architecture to process single CT volumes, starting with a single-shot detector using an inflated Inception-V1 based feature extractor. The detections were then fed to a similar architecture for classification to produce a malignancy score. The system was evaluated on diagnostic CT data meeting IPN criteria (age = 35, non-immunocompromised, no prior cancer) from an independent site (261 patients, 12 with contrast, 53 positives). Six board certified radiologists (avg. 10 years of experience) interpreted the cases with access to priors CTs and provided management recommendations and malignancy suspicion scores. They were free to use the Fleischner criteria or their own judgment. The model results were compared against the readers.*Results Our system had comparable performance to radiologists in detecting malignant IPNs (89.3% for radiologists vs. 89.5% for the model with no significant difference, P=0.87).*Conclusions We have presented a system offering radiologist-level performance in assessing IPN malignancy under challenging conditions of greater variability and more background findings than in screening CT. Integrating this model into workflows may aid as either a background or concurrent reader for IPNs.*Clinical Relevance/Application Diagnostic chest CTs, among the most frequent CT acquisitions, have IPNs at rates around 31%. Our AI achieves radiologist-level lung cancer diagnosis on these challenging and diverse cases.

RESULTS

Our system had comparable performance to radiologists in detecting malignant IPNs (89.3% for radiologists vs. 89.5% for the model with no significant difference, P=0.87).

CLINICAL RELEVANCE/APPLICATION

Diagnostic chest CTs, among the most frequent CT acquisitions, have IPNs at rates around 31%. Our AI achieves radiologist-level lung cancer diagnosis on these challenging and diverse cases.

SSNR11-2 Deep-learning Based MR Image Reconstruction Of The Spine Produces Similar Image Quality To Conventional Imaging

Participants
Sanders Chang, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning algorithms can improve the quality of images via denoising and enhancing image resolution while overall decreasing acquisition time. This project aims to compare the image quality of spine MR images acquired by a deep learning enhancement algorithm known as SubtleMRTM ("subtle") against conventionally acquired images.*Methods and Materials SubtleMR and conventional spine MR imaging case-control pairs were prospectively acquired from 43 subjects (mean, 51.6 ± 18.2 years of age; range, 20-89 years of age), totaling 98 image sets. Each case included conventional T1- and T2-weighted, STIR and deep-learning based reconstructions of the cervical, thoracic, and/or lumbar spine on sagittal view. Images were randomized and independently assessed by 2 blinded neuroradiologists for diagnostic quality on a binary scale (usable for diagnosis vs. unusable for diagnosis), legibility of osseous and extraosseous structures (all or most anatomic landmarks identifiable vs. few or none of the anatomic landmarks identifiable), and presence of artifacts.*Results Interobserver agreement was very good (? agreement = 0.85). No significant difference in diagnostic quality was found between conventional and subtle images across all sequences (p > 0.05). Legibility of both osseous and extraosseous structures were observed in = 98% of cases and were not significantly different between conventional and subtle images (p > 0.05). Artifacts were observed in 30.1% of conventional cases and 36.1% of subtle cases over all sequences (p > 0.05). Most observed artifacts overall were secondary to susceptibility from hardware (16.2%) and motion (14.9%). *Conclusions Overall imaging quality of a deep learning image enhancement algorithm was similar to that of conventionally acquired T1- and T2-weighted, and STIR sequences of the spine.*Clinical Relevance/Application Spine MR imaging enhanced by deep learning methods can produce quality similar to conventionally acquired images. This may help improve acquisition times and in turn allow for improved patient experience and better imaging efficiency.

RESULTS

Interobserver agreement was very good (? agreement = 0.85). No significant difference in diagnostic quality was found between conventional and subtle images across all sequences (p > 0.05). Legibility of both osseous and extraosseous structures were observed in = 98% of cases and were not significantly different between conventional and subtle images (p > 0.05). Artifacts were observed in 30.1% of conventional cases and 36.1% of subtle cases over all sequences (p > 0.05). Most observed artifacts overall were secondary to susceptibility from hardware (16.2%) and motion (14.9%).

CLINICAL RELEVANCE/APPLICATION

Spine MR imaging enhanced by deep learning methods can produce quality similar to conventionally acquired images. This may help improve acquisition times and in turn allow for improved patient experience and better imaging efficiency.

SSNR11-3 Lateral Cervical Puncture: Anatomic Features Relevant To Procedural Safety

Participants
Ross Frederick, MD, Phoenix, Arizona (*Presenter*) Nothing to Disclose

PURPOSE

Lateral cervical puncture is perceived to be more dangerous to perform than lumbar puncture. Injury to the posterior inferior cerebellar artery or a vertebral artery course overlying the posterior third of the spinal canal are of primary concern. In addition, the width of the dorsal subarachnoid space at the C1-2 level influences the difficulty of accessing the CSF without contacting the spinal cord. The purpose of this study is to analyze the location of PICA and the vertebral artery and the size of the target subarachnoid space at the C1-2 level to assess the risk of vascular and spinal cord injury in lateral cervical puncture.*Methods and Materials In this retrospective study 420 consecutive CT angiograms were evaluated by 2 radiologist investigators. The inferior extent of the PICA (or AICA-PICA) and the PICA origins and the location of the vertebral artery at the C1-2 level were recorded. The width of the posterior subarachnoid space at the C1-2 level was measured. The soft tissue distance from skin surface to target was measured.*Results 400 cases meeting criteria were evaluated. 32 total PICA loops extended below the foramen magnum but above the inferior margin of C1. 6 PICA origins were found between the foramen magnum and C1. No origins or loops were seen below C1. The vertebral artery at the C1-2 level was anterior to the canal in 742/778 (95%) arteries. None reached the posterior 1/3 of the canal. The width of the dorsal subarachnoid space at the C1-2 level was 2mm- 8mm, average 5mm.*Conclusions No PICA origins or loops were found below the C1 level, and no vertebral arteries extended to the posterior 1/3 of the canal, thus were not at risk in lateral C1-2 puncture. The dorsal subarachnoid space was equal to or greater than 2mm in all subjects. These results increase confidence in the safe application of this procedure.*Clinical Relevance/Application We found no patients with vascular anatomy that would put them at risk of injury with C1-2 puncture. Under CT guidance, the spinal cord and dorsal subarachnoid

space are easily seen for targeting. Many patients require CSF sampling but have site-specific contraindications to lumbar puncture. These results increase confidence in the safe application of this important procedure.

RESULTS

400 cases meeting criteria were evaluated. 32 total PICA loops extended below the foramen magnum but above the inferior margin of C1. 6 PICA origins were found between the foramen magnum and C1. No origins or loops were seen below C1. The vertebral artery at the C1-2 level was anterior to the canal in 742/778 (95%) arteries. None reached the posterior 1/3 of the canal. The width of the dorsal subarachnoid space at the C1-2 level was 2mm- 8mm, average 5mm.

CLINICAL RELEVANCE/APPLICATION

We found no patients with vascular anatomy that would put them at risk of injury with C1-2 puncture. Under CT guidance, the spinal cord and dorsal subarachnoid space are easily seen for targeting. Many patients require CSF sampling but have site-specific contraindications to lumbar puncture. These results increase confidence in the safe application of this important procedure.

SSNR11-4   Proximity Of DTI And Compression Ratio Measurements To Site Of Injury Has Significant Relationship To Predicting Neurologic Impairment In Acute Spinal Cord Injury (SCI)

Participants
Arichena Manmatharayan, MBBS, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Diffusion tensor imaging (DTI) can be used to evaluate microstructural changes in the spinal cord post-injury, however, the optimal rostral-caudal spinal cord location to obtain the measurements is not well understood. The purpose of this study was to conduct a comprehensive analysis of diffusion and structural measurements at specific spinal cord levels and correlate them with motor, sensory and AIS examination scores to determine where the strongest relationship to neurologic function exists.*Methods and Materials Data from 62 acute cervical spinal cord injury (SCI) patients and 21 healthy controls were analyzed retrospectively and stratified into hemorrhagic cord (HC; n=14) and non-hemorrhagic cord (NHC, n=48). Axial gradient echo sequence was used to measure compression ratio (CR) using Spinal Cord Toolbox. DTI metrics were obtained from single-shot echo-planar imaging (EPI) sequence or a zonally magnified oblique multi-slice EPI technique. Tensor metrics (Fractional Anisotropy, Axial (AD), Radial (RD) and Mean Diffusivity (MD) were extracted and adjusted with metrics values from controls generating Z-scores. Holocord regions of interest were obtained at five levels: two and one vertebral level rostral to upper limit of lesion, injury epicenter, one and two vertebral levels caudal to the lower limit of lesion. Spearman correlation was done between diffusion metric Z-scores and CR with upper and lower motor index scores (UEMS & LEMS), lower extremity sensory score (LESS), and ASIA impairment scale (AIS). $p<0.05$ was considered significant.*Results In HC, CR strongly correlated with AIS at 2 levels above (r= -0.77) and at 1 level below the lesion (r= -0.75) and with LESS (r= =0.75). At the injury epicenter in HC, FA strongly correlated with LEMS (r= -0.66), LESS (r = -0.61) and AIS (r= -0.61), AD correlated with UESS (r= -0.70) and RD correlated with LEMS (r= 0.59). In NHC, significant weak correlations were seen at the injury epicenter between AD and LESS (r= 0.32), RD and LEMS (r=0.29) and LESS (r= 0.49).*Conclusions This study suggests that diffusion and structural measures can be reliably obtained immediately adjacent to the lesion epicenter in addition to the injury epicenter in acute cervical SCI for correlation with neurologic impairment scales.*Clinical Relevance/Application Our results suggest that DTI and structural measures adjacent to lesion epicenter and at the injury epicenter show strong correlation to clinical scores in acute SCI. MRI and DTI biomarkers obtained at these locations could potentially supplement clinical examinations, especially in those patients where a complete evaluation is not possible.

RESULTS

In HC, CR strongly correlated with AIS at 2 levels above (r= -0.77) and at 1 level below the lesion (r= -0.75) and with LESS (r= =0.75). At the injury epicenter in HC, FA strongly correlated with LEMS (r= -0.66), LESS (r = -0.61) and AIS (r= -0.61), AD correlated with UESS (r= -0.70) and RD correlated with LEMS (r= 0.59). In NHC, significant weak correlations were seen at the injury epicenter between AD and LESS (r= 0.32), RD and LEMS (r=0.29) and LESS (r= 0.49).

CLINICAL RELEVANCE/APPLICATION

Our results suggest that DTI and structural measures adjacent to lesion epicenter and at the injury epicenter show strong correlation to clinical scores in acute SCI. MRI and DTI biomarkers obtained at these locations could potentially supplement clinical examinations, especially in those patients where a complete evaluation is not possible.

SSNR11-5   Detection Of Critical Spinal Epidural Pathologies On CT Using A Machine Learning Algorithm

Participants
Robert Harris, PhD, Eden Prairie, Minnesota (*Presenter*) Scientist, Virtual Radiologic Corporation

PURPOSE

Critical pathologies in the spinal epidural space can cause paralysis if left untreated. Patients with these pathologies often present emergently and are first imaged with CT. We hypothesized that we could train a machine learning algorithm to identify epidural pathologies on CT images and use this model as part of quality assurance to notify radiologists in real time if an epidural pathology has been potentially missed.*Methods and Materials Natural language processing (NLP) of radiology CT reports was used retrospectively to identify 114 studies containing epidural hematoma, abscess, phlegmon, or fluid collection. A sagittal image series from each of these studies was annotated by a Board Certified radiologist by segmenting the epidural pathology using an in-house brush tool. These segmentations were converted into bounding boxes; 475 annotated images were used as positives, and 475 sagittal CT images with no epidural pathology were used as negatives in the training dataset. A yolo-v3 bounding box model was used for training. The model was applied to a test dataset consisting of 20 negative studies and 11 positive studies for epidural pathology, including 4 studies where the epidural pathology had been missed by the reading radiologist. This model was then integrated with our teleradiology practice to screen prospective patients for critical epidural pathologies for an eight-week period.*Results The model achieved an AUC of 0.965 on the test dataset, with 3 of the 4 cases missed by the radiologist classified as positive. For live prospective data, 38,620 CT studies were inferenced, of which 7 were positive for a critical epidural pathology. The model correctly identified 5 of these for a sensitivity of 71.4% and specificity of 86.8%.*Conclusions An artificial intelligence model was trained to identify critical spinal epidural pathologies on CT imaging and was implemented in a real-time clinical workflow. To our knowledge, this is the first use of machine learning to identify spinal epidural pathologies on CT images. This model is currently undergoing iterative retraining with false positives and false negatives from prospective data and is being updated to include input from axial CT images.*Clinical Relevance/Application Critical epidural pathologies are sometimes missed by radiologists on CT and can lead to preventable long-term injury. A model to assist with detection of sometimes critical epidural disease may

prevent missed diagnoses and improve patient care.

RESULTS

The model achieved an AUC of 0.965 on the test dataset, with 3 of the 4 cases missed by the radiologist classified as positive. For live prospective data, 38,620 CT studies were inferenced, of which 7 were positive for a critical epidural pathology. The model correctly identified 5 of these for a sensitivity of 71.4% and specificity of 86.8%.

CLINICAL RELEVANCE/APPLICATION

Critical epidural pathologies are sometimes missed by radiologists on CT and can lead to preventable long-term injury. A model to assist with detection of sometimes critical epidural disease may prevent missed diagnoses and improve patient care.

SSNR11-6   Pulsed Radiofrequency For Sciatica And Disc Herniation: A Randomized Trial

Participants
Alessandro Napoli, MD, Rome, Italy (*Presenter*) Nothing to Disclose

PURPOSE

Sciatica can be disabling and evidence regarding effective non-operative management remains limited. We performed a randomized clinical trial to determine whether combined treatment using pulsed radiofrequency (PRF) and epidural steroid injection (TFESI) was superior to TFESI-alone for acute sciatica due to lumbar disc herniation (LDH)*Methods and Materials This multicenter, double-blind, randomized clinical trial involved patients with sciatica due to LDH not responsive to conventional medical and/or physical treatment (NCT04209322). Eligible patients were randomly assigned to receive a single session of PRF+TFESI, or TFESI-alone.The primary outcome was the leg-pain intensity score (numerical rating scale, NRS, range 0 to 10) at week 1 following the intervention; and at week 52 as a secondary time point. Secondary outcomes included Roland Disability Questionnaire for Sciatica and Oswestry Disability Index at 4, 12, and 52 weeks.*Results Among 289 patients who were randomized, 145 received PRF/TFESI and 144 underwent TFESI. At baseline, NRS was 8.1±1.1 in the PRF/TFESI group and 7.9±1.1 in the TFESI group. At week 1, NRS was 3.3±0.2 in PRF/TFESI group and 5.0±0.2 in TFESI group (adjusted mean difference, 1.67; 95% Confidence Interval [CI] 1.09 to 2.26; P<0.001); at week 52, NRS was 1.5±0.2 in PRF/TFESI group and 2.7±0.3 in TFESI group (adjusted mean difference, 1.19; 95% CI, 0.52 to 1.86; P<0.001). Secondary outcomes were in the same direction as the primary outcome. No severe adverse events were reported. Eleven patients in the PRF/TFESI group and 24 patients in the TFESI group required further interventional or surgical management.*Conclusions In this trial of patients with acute sciatica caused by LDH, PRF+TFESI demonstrated faster and more durable control of leg pain over the course of 1 year follow-up as compared to TFESI-alone.*Clinical Relevance/Application Patients with sciatica not responding to conventional treatment may benefit from a combination of PRF-TFESI (10 min session) as a means of durable treatment, avoiding further interventions including surgery.

RESULTS

Among 289 patients who were randomized, 145 received PRF/TFESI and 144 underwent TFESI. At baseline, NRS was 8.1±1.1 in the PRF/TFESI group and 7.9±1.1 in the TFESI group. At week 1, NRS was 3.3±0.2 in PRF/TFESI group and 5.0±0.2 in TFESI group (adjusted mean difference, 1.67; 95% Confidence Interval [CI] 1.09 to 2.26; P<0.001); at week 52, NRS was 1.5±0.2 in PRF/TFESI group and 2.7±0.3 in TFESI group (adjusted mean difference, 1.19; 95% CI, 0.52 to 1.86; P<0.001). Secondary outcomes were in the same direction as the primary outcome. No severe adverse events were reported. Eleven patients in the PRF/TFESI group and 24 patients in the TFESI group required further interventional or surgical management.

CLINICAL RELEVANCE/APPLICATION

Patients with sciatica not responding to conventional treatment may benefit from a combination of PRF-TFESI (10 min session) as a means of durable treatment, avoiding further interventions including surgery.

SSCA10-1 AI Vs Manual Cardiac MRI Measurements - Clinical Benchmarking Using Heart Catheterization And Mortality Prediction

Participants

Andrew Swift, BMedSc, FRCR, Sheffield, United Kingdom (*Presenter*) Consultant, Johnson & Johnson;Consultant, General Electric Company

PURPOSE

Cardiac magnetic resonance (CMR) is the gold standard to measure biventricular volumes and function and has been shown to have diagnostic value and predict mortality. The aim of this study is to compare artificial intelligence (AI) and manually obtained CMR measurements against clinically objective outcomes such as invasive right heart catheterization (RHC) and mortality prediction.*Methods and Materials A deep learning model for CMR segmentation was developed in a multi-pathology and multi-vendor (Siemens and General Electric) cohort. The training cohort included patients with left heart and lung disease and pulmonary hypertension (n = 400, ASPIRE registry). The CMRs of a retrospective cohort of 2204 patients with a median follow-up of 4 years were analysed both manually and with the AI segmentation tool. Manual cardiac segmentation was performed as part of routine clinical practice by expert cardiac MRI readers. Mortality prediction was estimated using hazard ratios (HR) from univariate Cox regression models and calculated for both the manual and AI-derived CMR measurements. CMR measurements in the Cox regression were corrected for age and sex. Variable normalisation was performed by subtracting the mean for each variable and dividing it by its standard deviation. Of the retrospective cohort, 1305 patients had RHC within 48 hours of the CMR. Spearman correlation coefficient (rho) was calculated to compare CMR with RHC-thermodilution derived left ventricular stroke volume (LVSV) and RVEF with mean pulmonary artery pressure (mPAP) and pulmonary vascular resistance (PVR).*Results CMR measurements correlated with RHC and showed a more robust relationship with the AI measurements. The correlation coefficient graphs showed a tighter spread of variables in the AI parameters. The rho for AI-RVEF with mPAP and PVR was -0.62 and -0.67, respectively, compared to -0.59 and 0.60, respectively, for manual-RVEF. The mortality rate was 38% over the 4 year follow-up period. Most CMR measurements were significant predictors of mortality. The AI measurements showed similar univariate hazard ratios with slightly larger effect sizes compared to manual measurements.*Conclusions In a large cohort, AI obtained CMR measurements outperformed manual assessment when compared to objective clinical benchmarks including invasive heart catheterization and mortality prediction.*Clinical Relevance/Application CMR is essential in the workup and follow-up of several cardiac diseases. AI-powered fully automated biventricular measurements further improve the utility of CMR in a clinical setting.

RESULTS

CMR measurements correlated with RHC and showed a more robust relationship with the AI measurements. The correlation coefficient graphs showed a tighter spread of variables in the AI parameters. The rho for AI-RVEF with mPAP and PVR was -0.62 and -0.67, respectively, compared to -0.59 and 0.60, respectively, for manual-RVEF. The mortality rate was 38% over the 4 year follow-up period. Most CMR measurements were significant predictors of mortality. The AI measurements showed similar univariate hazard ratios with slightly larger effect sizes compared to manual measurements.

CLINICAL RELEVANCE/APPLICATION

CMR is essential in the workup and follow-up of several cardiac diseases. AI-powered fully automated biventricular measurements further improve the utility of CMR in a clinical setting.

SSCA10-2 Deep Learning Based Automated Coronary Labeling For Structured Reporting Of Coronary CT Angiography

Participants

Verena Brandt, MD, Charleston, South Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate a novel deep learning (DL)-based automated coronary labeling approach for structured reporting of coronary artery labeling according to the guidelines of the Society of Cardiovascular Computed Tomography (SCCT) on Coronary CT Angiography (CCTA).*Methods and Materials A retrospective cohort of 106 patients with a median age of 63 (range 28 - 84) years (61% male) who had undergone prospective ECG-gated CCTA were included. Coronary centerlines were automatically extracted, labeled, and validated by two expert readers according to SCCT guidelines. The DL algorithm has been trained on 706 radiologist-annotated cases for the task of automatically labeling coronary artery centerlines. The architecture leverages Tree-structured Long Short Term Memory (Tree-LSTM) recurrent neural networks to capture the full topological information of the coronary trees by using a two-step approach: a bottom-up encoding step, followed by a top-down decoding step. The first module encodes each sub-tree into fixed-sized vector representations. The decoding module then selectively attends to the aggregated global context to perform

the local assignation of labels.*Results A total number of 1491 segments were identified. The AI-based software approach yielded a diagnostic accuracy of 94.4% for coronary artery labeling with an average computational time of 0.5s per case. The resulting labeling accuracy for SCCT coronary segments are presented in Table 1, which shows the percent overlap measures between the algorithm detected versus human annotated labels averaged across patients, respectively.*Conclusions Our approach of DL-based coronary artery labeling provides fast and precise fully automated structured reporting of CCTA, which improves user variability and therefore allows standardization of radiological reports.*Clinical Relevance/Application The DL approach enables high diagnostic accuracy for structured CCTA reporting which may have utility to improve diagnostic workflows in a more time-efficient manner.

RESULTS

A total number of 1491 segments were identified. The AI-based software approach yielded a diagnostic accuracy of 94.4% for coronary artery labeling with an average computational time of 0.5s per case. The resulting labeling accuracy for SCCT coronary segments are presented in Table 1, which shows the percent overlap measures between the algorithm detected versus human annotated labels averaged across patients, respectively.

CLINICAL RELEVANCE/APPLICATION

The DL approach enables high diagnostic accuracy for structured CCTA reporting which may have utility to improve diagnostic workflows in a more time-efficient manner.

SSCA10-3   Feasibility And Diagnostic Performance Of A New CCTA-derived And AI-based Fully Automated System For Detection Of Coronary Artery Disease

Participants
Verena Brandt, MD, Charleston, South Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate a novel coronary CT angiography (CCTA)-derived fully automated artificial intelligence (AI)-based software solution for automated coronary artery segmentation and stenosis assessment using the Coronary Artery Disease Reporting & Data System (CAD-RADS).*Methods and Materials Image datasets of 100 consecutive patients (48% male, 48.3±10.8 years) who underwent clinically indicated CCTA were retrospectively analyzed. Two readers independently evaluated CCTAs for the degree of coronary artery stenosis on a per-segment level using the 18-coronary artery segment model with subsequent CAD-RADS classification according to SCCT guidelines. A fully automated investigational AI-based software prototype by Siemens was designed and tested on the CCTA datasets and compared to human reading. Inter-reader agreement was assessed using Cohen's kappa. Subsequently, the diagnostic performance of the software prototype for detection of diseased coronary artery segments were assessed.*Results Forty-one patients had CAD with stenosis in at least one segment. Agreement between expert readers was 0.83 for CAD-RADS and 0.89 for the identification of diseased segments. The software prototype yielded a sensitivity of 97.6% (92.8-100), and a negative predictive value of 96.9% (90.8-100) for the detection of diseased segments, respectively. The software prototype reliably detected 40 out of 41 patients with CAD. One patient who was not correctly identified had a small, calcified plaque without associated coronary artery stenosis (CAD-RADS 1). The average computational time of the software prototype was 240s per case.*Conclusions The fully automated investigational AI-based software prototype demonstrated fast and reliable identification of patients with coronary artery stenosis on CCTA with high diagnostic accuracy.*Clinical Relevance/Application Fully automated coronary segmentation and stenosis detection using AI may have utility to improve diagnostic accuracy in a more time-efficient manner.

RESULTS

Forty-one patients had CAD with stenosis in at least one segment. Agreement between expert readers was 0.83 for CAD-RADS and 0.89 for the identification of diseased segments. The software prototype yielded a sensitivity of 97.6% (92.8-100), and a negative predictive value of 96.9% (90.8-100) for the detection of diseased segments, respectively. The software prototype reliably detected 40 out of 41 patients with CAD. One patient who was not correctly identified had a small, calcified plaque without associated coronary artery stenosis (CAD-RADS 1). The average computational time of the software prototype was 240s per case.

CLINICAL RELEVANCE/APPLICATION

Fully automated coronary segmentation and stenosis detection using AI may have utility to improve diagnostic accuracy in a more time-efficient manner.

SSCA10-6   Fully Automated Deep Learning Based Flow Quantification Of Cardiovascular 2D Phase Contrast MRI: Machine Vs Human Performance

Participants
Maurice Pradella, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

2D Phase Contrast (2D-PC) MRI allows for analysis of blood flow in many cardiovascular (CV) abnormities such as valve disease. Due to close anatomical relations between aorta, pulmonary artery (PA) and other vascular structures, accurate delineation of vessel contours is necessary to achieve reliable flow quantification. The goal of this study was to evaluate the feasibility of a Deep Learning (DL) application for fully automated contour delineation and subsequent flow quantification of 2D-PC data compared to manual analysis by a CV radiologist.*Methods and Materials We included 25 consecutive patients (pts) who underwent CV MRI with PC imaging in November 2020. All pts received 2D-PC flow measurements at the sinotubular junction (STJ). In a subgroup (n=11), 2D-PC data was also collected for the main PA. All exams were performed on 1.5T MRI systems (Siemens, Germany).A CV radiologist with 3 years of experience performed the manual analysis. The outer vessel contour was delineated on the first time point of the magnitude image, forwarded and adjusted for each time point. The DL application (Circle, Canada) autonomously identified the scan location (STJ or PA) and performed automated vessel contour detection across all cardiac time points. STL and PA net flow was calculated for both DL and manual analysis. Manual and DL contours were compared using mean dice scores (DSC).*Results 36 2D-PC MRI measurements (STJ: 25, PA: 11) were performed with a median of 30 cardiac time points (range: 20-30). Mean manual measurement times were 2:40±0:57min at STJ and 3:00±0:47min at PA. DL analysis was performed for 34 data sets (34/36, 95%; STJ: 24, PA: 10) with analysis time of 1s/case; in 2 cases no results were produced by DL. Mean DL vs human DSC at STJ was 0.84 (interquartile range (IQR): 0.04), and 0.82 (IQR: 0.12) at PA.Bland Altman plots showed DL vs human mean differences for net flow of 2.82ml (limits of agreement (LoA): -20.15-25.79ml) for STJ and 1.71ml (LoA: -4.98-8.39ml) for PA. LoA at STJ was strongly influenced by a congenital heart disease case with incorrect delineation of STJ contours by DL. With this outlier removed, DL performance substantially improved (STJ LoA: -10.06-9.98ml) indicating reliable DL measurements in 33/36 (92%) of

cases.*Conclusions Fully automated DL flow quantification provided reliable results compared to an experienced human observer in 92% of enrolled patients with significantly reduced analysis times. Complex anatomy resulted in erroneous segmentations in two cases, indicating the need for further refinement of the DL analysis workflow by including more complex cases in the training set.*Clinical Relevance/Application The evaluated software tool supports radiologists by providing reliable, expert-level flow measurements in 92% of cases.

RESULTS

36 2D-PC MRI measurements (STJ: 25, PA: 11) were performed with a median of 30 cardiac time points (range: 20-30). Mean manual measurement times were 2:40±0:57min at STJ and 3:00±0:47min at PA. DL analysis was performed for 34 data sets (34/36, 95%; STJ: 24, PA: 10) with analysis time of 1s/case; in 2 cases no results were produced by DL. Mean DL vs human DSC at STJ was 0.84 (interquartile range (IQR): 0.04), and 0.82 (IQR: 0.12) at PA.Bland Altman plots showed DL vs human mean differences for net flow of 2.82ml (limits of agreement (LoA): -20.15-25.79ml) for STJ and 1.71ml (LoA: -4.98-8.39ml) for PA. LoA at STJ was strongly influenced by a congenital heart disease case with incorrect delineation of STJ contours by DL. With this outlier removed, DL performance substantially improved (STJ LoA: -10.06-9.98ml) indicating reliable DL measurements in 33/36 (92%) of cases.

CLINICAL RELEVANCE/APPLICATION

The evaluated software tool supports radiologists by providing reliable, expert-level flow measurements in 92% of cases.

SSNR12-1   The MIITRA Multimodal Templates Of Older Adult Brain At 0.5mm Resolution: Creation And Evaluation

Participants

Yingjuan Wu, MS,BEng, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

The Multichannel Illinois Institute of Technology & Rush university Aging (MIITRA) atlas project aims at developing a multimodal older adult brain atlas with high spatial resolution. The goal of this work was to develop high quality T1-weighted (T1w) and diffusion tensor imaging (DTI) multimodal templates at 0.5mm resolution for the MIITRA atlas using data from a large, diverse, community cohort of non-demented older adults and quantitatively evaluate the new templates.*Methods and MaterialsData: T1w and DTI data were collected on 400 non-demented older adults (50% male; 65-99 yrs; 54% white, 43% black; 318 with no cognitive impairment, 82 with mild cognitive impairment) participating in longitudinal cohort studies of aging with two 3T MRI scanners.Template Construction: First, a recently introduced approach for the development of high quality multimodal templates was conducted in a 0.5mm isotropic resolution space. Spatial normalization was driven by T1w and DTI information alternatively and the resulting transformations were applied on both modalities. Then an approach for the development of high spatial resolution templates based on principles of super-resolution was used to eliminate interpolations in conventional template building methods. The resulting templates are named MIITRA templates.Evaluation: The MIITRA templates were compared to other standardized templates in terms of the inter-subject and inter-modality spatial normalization accuracy when each template was used as a reference for normalization from 202 T1w and DTI older adult data from ADNI3.*Results Visual inspection showed that the MIITRA T1w and DTI templates with 0.5mm isotropic voxels exhibit high sharpness and are free of artifacts. It was demonstrated that the MIITRA templates provided higher inter-subject spatial normalization accuracy of older adult data and required less deformation than other templates. Finally, the MIITRA T1w and DTI templates exhibited high spatial matching to each other and allowed higher inter-modality spatial matching of normalized older adult data.*Conclusions This work developed high quality T1w and DTI multimodal templates at 0.5mm resolution for the MIITRA atlas using data from a large, diverse, community cohort of non-demented older adults. The new templates allowed higher inter-subject and inter-modality spatial normalization of older adult data compared to other templates.*Clinical Relevance/Application The 0.5mm T1w and DTI multimodal templates developed in this work allowed higher inter-subject and inter-modality spatial normalization of older adult data compared to other templates.

RESULTS

Visual inspection showed that the MIITRA T1w and DTI templates with 0.5mm isotropic voxels exhibit high sharpness and are free of artifacts. It was demonstrated that the MIITRA templates provided higher inter-subject spatial normalization accuracy of older adult data and required less deformation than other templates. Finally, the MIITRA T1w and DTI templates exhibited high spatial matching to each other and allowed higher inter-modality spatial matching of normalized older adult data.

CLINICAL RELEVANCE/APPLICATION

The 0.5mm T1w and DTI multimodal templates developed in this work allowed higher inter-subject and inter-modality spatial normalization of older adult data compared to other templates.

SSNR12-2   Spatial Stability Of Functional Networks: A Measure To Assess The Robustness Of Graph-theoretical Metrics To Spatial Errors Related To Brain Parcellation

Participants

Luca Pasquini, MD, New York City, New York (*Presenter*) Nothing to Disclose

PURPOSE

Brain parcellation represents a crucial step for graph-theoretical analysis of brain networks from functional MRI (fMRI). However, this procedure has multiple shortcomings which can affect inter and intra subject variability: anatomical and physiological cortical differences, shape variations from ageing and diseases. Discrepancies in brain boundaries can reflect on connectivity maps, since network properties are affected by node definition. In this study, we define the measure of spatial stability (SS) of functional networks, i.e. impact of parcellation changes on functional connectivity (FC), by testing the variability of multiple graph-theoretical measures to parcellation-related spatial errors.*Methods and Materials 110 subjects with anatomical and rs-fMRI data were included. Two atlases were used for parcellation (64 Standard Parcels-SP and 150 SP). A modification algorithm was implemented to simulate 100 new atlases on Freesurfer, by introducing random variations equal to 10% of parcel volume. New atlases contained the same number of Modified Parcels (MP) of the original. Rs-fMRI was used to develop functional networks from each generated parcellation from both atlases (200 networks per subject). 27 graph-theoretical measures were calculated for every network,

including centrality, clustering, core, degree, distance, modularity, physical connectivity and similarity. SS for every measure was defined by a variation factor (VF) equal to the mean variation of its value across generated networks.*Results The lowest VF values were obtained for Characteristic path length (<1%), Density and Transitivity, suggesting high stability to parcel variation. Intermediate SS was found for modularity, degree, clustering, core, distance and similarity. Katz and Bonachich centrality showed the higher VF values, suggesting lower stability.*Conclusions Our method reproduces inter and intra subjects parcellation variability to assess the impact of small parcellation changes on global and local connectivity measures. Some graph-theoretical measures are less stable than others, particularly Katz and Bonachich centrality. Our results suggest to pay close attention to parcellation-related spatial errors produced by inter- and intra-subject variability, since they may affect brain connectivity analysis as depicted by SS variations.*Clinical Relevance/Application Brain parcellation is a crucial step for every connectivity analysis. We demonstrated that graph theoretical measures are subject to significant variation depending on brain parcellation. Since gyral anatomy changes across subjects, parcellation-related spatial errors may affect the value of calculated metrics.

RESULTS

The lowest VF values were obtained for Characteristic path length (<1%), Density and Transitivity, suggesting high stability to parcel variation. Intermediate SS was found for modularity, degree, clustering, core, distance and similarity. Katz and Bonachich centrality showed the higher VF values, suggesting lower stability.

CLINICAL RELEVANCE/APPLICATION

Brain parcellation is a crucial step for every connectivity analysis. We demonstrated that graph theoretical measures are subject to significant variation depending on brain parcellation. Since gyral anatomy changes across subjects, parcellation-related spatial errors may affect the value of calculated metrics.

SSNR12-4   High-resolution Gray Matter Labels Of The MIITRA Atlas: Development And Evaluation

Participants
Mohammad Rakeen Niaz, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

The Multichannel Illinois Institute of Technology & Rush university Aging (MIITRA) atlas contains high resolution (0.5mm) T1-weighted (T1w) and diffusion tensor imaging (DTI) templates, constructed using high quality MRI data from non-demented older adults. The purpose of this work was twofold: a) to construct high resolution gray matter labels for the MIITRA atlas based on manually edited gray matter labels of the older adults included in the atlas, and b) to evaluate the performance of the new labels in labeling the gray matter of a separate group of older adults.*Methods and Materials T1w images (400 images, 1mm isotropic) from the older adults included in the MIITRA atlas (50% male; 64.9-98.9 age-range; 54% white, 43% black) were processed with Freesurfer's standard recon-all pipeline, which segmented subcortical and cortical gray matter into 84 regions according to the Desikan Killiany atlas. The Freesurfer output for all images was manually edited. The ANTs-derived transformations applied on individual T1w images to build the MIITRA T1w template were used to map the corresponding gray matter labels from raw space to exact physical locations in the final MIITRA space. The label in a 0.5mm isotropic voxel in MIITRA space was calculated using majority voting among all the labels that were mapped to that voxel. The performance of the MIITRA gray matter labels in segmentation of the gray matter of a separate group of 100 older adult individuals was evaluated in terms of label overlap, geometry, and dissimilarity when comparing the MIITRA labels warped to each individual's space, to the respective manually edited reference labels.*Results The measures of overlap were generally high, with an average Dice coefficient of 0.82±0.10, Jaccard coefficient of 0.70±0.13, sensitivity of 0.77±0.13, and specificity of 0.89±0.09. There was a high correlation in label geometry both in terms of the average volume (correlation coefficient=0.997, p-value<10-10) and in terms of the average surface area (correlation coefficient=0.988, p-value<10-10). The values of dissimilarity were low, with an average volume error of 0.18±0.18 and an average Hausdorff distance of 8.69±8.78.*Conclusions This work developed high-resolution gray matter labels for the MIITRA atlas. The new labels, in combination with the high-resolution (0.5mm isotropic) T1w template of the atlas, allow segmentation of the gray matter of older adults that is in good agreement with the manually-edited Freesurfer-based segmentation.*Clinical Relevance/Application The MIITRA gray matter labels, in combination with the high-resolution T1w template of the atlas, allow segmentation of the gray matter of older adults that is in good agreement with the manually-edited Freesurfer-based segmentation.

RESULTS

The measures of overlap were generally high, with an average Dice coefficient of 0.82±0.10, Jaccard coefficient of 0.70±0.13, sensitivity of 0.77±0.13, and specificity of 0.89±0.09. There was a high correlation in label geometry both in terms of the average volume (correlation coefficient=0.997, p-value<10-10) and in terms of the average surface area (correlation coefficient=0.988, p-value<10-10). The values of dissimilarity were low, with an average volume error of 0.18±0.18 and an average Hausdorff distance of 8.69±8.78.

CLINICAL RELEVANCE/APPLICATION

The MIITRA gray matter labels, in combination with the high-resolution T1w template of the atlas, allow segmentation of the gray matter of older adults that is in good agreement with the manually-edited Freesurfer-based segmentation.

SSNR12-5   Statistical Parametric Mapping In Amyloid Positron Emission Tomography: Use Cases And Future Directions

Participants
Natasha Smith, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

Statistical Parametric Mapping (SPM) is a technique comparing single-subject Positron Emission Tomography (PET) to a healthy cohort. While routinely used in FDG-PET, SPM's utility in amyloid PET for Alzheimer's disease (AD) diagnosis is less established. Amyloid PET interpretations often employ binary terms (positive/negative), yet it is known that amyloid deposits occur in 20-30% of cognitively normal individuals. By providing stereotactic surface projections (SSP) of amyloid avidity relative to a cognitively normal sample, SPM could enhance diagnostic performance of amyloid PET. Our purpose was to build an atlas of amyloid PET scans from cognitively normal subjects and evaluate the feasibility of SPM analysis with our atlas.*Methods and Materials Following IRB approval, 34 cognitively normal individuals (22 F, 12 M; age 50-85) underwent amyloid PET/CT with 11C-Pittsburgh compound B (PiB). All subjects had a normal CSF analysis for AD-related biomarkers (t-tau=400?pg/mL, p-tau =60?pg/mL and Aß42 =?550? pg/mL)1 and had a mean mini-mental state examination (MMSE) of 29 +/- 1.0. To create the atlas, images were fit to the Montreal Neurological Institute standard space with syngo.va MI Neurology Workflow (cerebellar normalization, 12 mm FWHM, 75% brightest

voxels).Our test cases were two cognitively normal test subjects (S1: 58 y/o, F, MMSE: 30, totalTau = 295, ptau = 59, Aß42 = 1,090); S2: 73 y/o, M, MMSE: 30, totalTau = 236, ptau = 38, Aß42 = 496) and a subject with known AD (S3: 60 y/o, F). PiB PET/CT was performed per published protocol. Two physician-raters provided interpretations of the standard amyloid PET images. SPM analysis was performed with the atlas and SSP visualizations were created.*Results Both raters deemed S1 "amyloid positive" after evaluation of standard amyloid PET. However, SPM demonstrated that no region had a z-score for amyloid avidity over 2.6. S2 (positive for CSF Aß42 AD biomarker) was called "amyloid negative" by both raters from standard images, while SPM demonstrated that the middle cingulate, precuneus, and superior/middle temporal regions had z-scores over 5.8. S3 (known AD) demonstrated robust amyloid-avidity with z-scores up to 23.9.*Conclusions This feasibility study demonstrates the application of SPM in amyloid targeted PET and suggests that SPM may enhance diagnostic performance. We aim to validate this atlas on a larger cohort to ascertain if SPM improves accuracy of amyloid PET. With disease-modifying therapies for AD on the horizon, the accurate diagnosis of AD from amyloid PET will become increasingly important, and SPM could be a valuable tool to mitigate false positives and negatives.*Clinical Relevance/Application SPM could improve the diagnostic accuracy of amyloid PET imaging in the diagnosis of AD.

RESULTS

Both raters deemed S1 "amyloid positive" after evaluation of standard amyloid PET. However, SPM demonstrated that no region had a z-score for amyloid avidity over 2.6. S2 (positive for CSF Aß42 AD biomarker) was called "amyloid negative" by both raters from standard images, while SPM demonstrated that the middle cingulate, precuneus, and superior/middle temporal regions had z-scores over 5.8. S3 (known AD) demonstrated robust amyloid-avidity with z-scores up to 23.9.

CLINICAL RELEVANCE/APPLICATION

SPM could improve the diagnostic accuracy of amyloid PET imaging in the diagnosis of AD.

SSNMMI08-1 First In Human Imaging Of Fluorinated NP-59 (FNP-59): A New Technique To Image Cholesterol Metabolism Noninvasively

Participants

Benjamin Viglianti, MD,PhD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

NP-59, 6-beta-iodomethyl-19-norcholesterol, was first reported in 1975 and developed at the University of Michigan for non-invasive identification of abnormal cholesterol utilization focusing on adrenal cortical disorders, notably primary aldosterone's. Given the imaging limitations of iodine radionuclides and high radiation dosimetry, use ofNP-59 was limited. It was recognized at the time that a fluorine-18 variant of NP-59 (FNP-59) would be an improved alternative. For the past ~40 yrs all routes to the agent have failed, until now.*Methods and Materials We describe herein the development and validation of the synthesis for FNP-59 from cholesterol, radiation dosimetry/distribution in rats from 1 to 6 hours, toxicology study, PET imaging validation in normal and ApoE-/- mice, and rabbit models. Finally, first in human PET/CT images of FNP-59 in a normal patient was performed at 1, 3, and 6 hours after injection.*Results We successfully prepared FNP-59 and demonstrated an adrenal to liver ratio of 5:1 at 6 hrs in rats. Radiation dosimetry was significantly less compared to the historical data of I-131 NP-59, particularly in the gonads and thyroid. Animal toxicology studies demonstrated the agent had no adverse effects at a dose 1000 times greater than used for a PET/CT imaging study. Imaging of mice and rabbits demonstrated uptake in the expected locations including areas of pathology that accumulate cholesterol. First in human images also demonstrate imaging in expected tissues (liver and adrenal glands).*Conclusions FNP-59 has been successfully prepared and demonstrated to be safe in initial studies, offering the opportunity to image cholesterol metabolism noninvasively, making an old technique newly applicable again.*Clinical Relevance/Application When validated FNP-59 could allow detection of unilateral versus bilateral primary aldosteronism non-invasivly in the adrenal gland. Additionally, it may be able to quantify atherosclerotic disease improving risk stratification of patients who might need intervention.

RESULTS

We successfully prepared FNP-59 and demonstrated an adrenal to liver ratio of 5:1 at 6 hrs in rats. Radiation dosimetry was significantly less compared to the historical data of I-131 NP-59, particularly in the gonads and thyroid. Animal toxicology studies demonstrated the agent had no adverse effects at a dose 1000 times greater than used for a PET/CT imaging study. Imaging of mice and rabbits demonstrated uptake in the expected locations including areas of pathology that accumulate cholesterol. First in human images also demonstrate imaging in expected tissues (liver and adrenal glands).

CLINICAL RELEVANCE/APPLICATION

When validated FNP-59 could allow detection of unilateral versus bilateral primary aldosteronism non-invasivly in the adrenal gland. Additionally, it may be able to quantify atherosclerotic disease improving risk stratification of patients who might need intervention.

SSNMMI08-2 First In-human Trial Of Delta Like Ligand 3 (DLL3)-targeted PET Imaging Of Neuroendocrine Tumors With Zr-89 SC16.56.

Participants

Matthew Agee, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

DLL3 is a neuroendocrine tumor-specific cell surface protein, commonly overexpressed in NETs and well-validated as an important new therapeutic target, for which a non-invasive in vivo target biomarker assay is urgently needed.?? We are conducting a first-in-human?phase I?trial?of the humanized anti-DLL3 monoclonal antibody SC16.56, labeled with Zirconium-89 (89Zr-DFO-SC16.56) for PET imaging in patients with newly diagnosed or recurrent small cell lung cancer (SCLC).? The purpose of this report is to present our promising preliminary data.?*Methods and Materials SCLC?patients with?tumors having high DLL3-expression (=50% cells DLL3-positive by IHC)?received?2?mCi?of?89Zr-DFO-SC16.56 (mass ~2.5 mg).?89Zr-DFO-SC16.56 body PET/CT scans were obtained? approximately?1-4 hours, 1 day, 3 days, and 7 days post-injection.??*Results All patients (n=3 to-date)?tolerated 89Zr-DFO-SC16.56 with no side-effects. All known tumor sites (n=13) were detectable early, by 3 days?post injection, even sub-centimeter metastases, with tumors SUV continuing to increase to 7 days?post?injection;?with average tumor SUV 10.5?±11.7?(range?1.6-54.4).?Tracer uptake in normal tissues was scant (other than liver uptake,) providing excellent?tumor: muscle?uptake ratios of? 13.4±14.7.??*Conclusions Our first in-human demonstrates the feasibility of in vivo radiological detection of tumor DLL3?expression and?indicates Zr-89 DFO-SC16.56 PET imaging is a very promising, first-of-kind imaging biomarker of tumor DLL3 expression, with potential applications as a diagnostic, predictive and prognostic biomarker for NETs and in DLL3-targeted therapy.*Clinical Relevance/Application Tumor DLL3 expression is an important new oncotherapeutic target for which predictive biomarker assays are urgently needed. We hypothesize Zr-89 SC16.56 PET is a fit-for-purpose, first-of-kind DLL3 imaging biomarker in NET with multiple

clinical applications including tumor detection and response prediction.

RESULTS

All patients (n=3 to-date)?tolerated 89Zr-DFO-SC16.56 with no side-effects. All known tumor sites (n=13) were detectable early, by 3 days?post injection, even sub-centimeter metastases, with tumors SUV continuing to increase to 7 days?post?injection;?with average tumor SUV 10.5?±11.7?(range?1.6-54.4).?Tracer uptake in normal tissues was scant (other than liver uptake,) providing excellent?tumor: muscle?uptake ratios of?13.4±14.7.??

CLINICAL RELEVANCE/APPLICATION

Tumor DLL3 expression is an important new oncotherapeutic target for which predictive biomarker assays are urgently needed. We hypothesize Zr-89 SC16.56 PET is a fit-for-purpose, first-of-kind DLL3 imaging biomarker in NET with multiple clinical applications including tumor detection and response prediction.

SSNMMI08-5   CXCR4 PET Imaging For Post-treatment Evaluation Of Gastric Mucosa-associated Lymphoid Tissue (MALT) Lymphoma: A Biopsy-controlled Prospective Study

Participants
Marius Mayerhoefer, MD,PhD, New York, New York (*Presenter*) Speaker, Siemens AG;Speaker, Bristol-Myers Squibb Company;Speaker, General Electric Company

PURPOSE

Follow-up of gastric mucosa-associated lymphoid tissue (MALT) lymphoma currently relies on esophagogastroduodenoscopy with multi-site biopsies. The aim of this study was to evaluate PET with the novel CXCR4 (G-protein-coupled C-X-C chemokine receptor type 4) tracer [68Ga]Pentixafor as an alternative to biopsies in this setting, given that MALT lymphoma has previously demonstrated CXCR4 overexpression.*Methods and Materials In this prospective study, 46 [68Ga]Pentixafor-PET/MRI examinations of 26 gastric MALT lymphoma patients post helicobacter pylori eradication (with/without additional systemic immuno- or chemotherapy), and 20 [68Ga]Pentixafor-PET/MRI examinations of 20 control group patients with head/neck cancer or pancreatic adenocarcinoma were analyzed. In the MALT lymphoma group, matched gastric biopsies, and in the control group, same-day MRI and follow-up imaging were used as reference standard. Examination-based accuracy, sensitivity, specificity, and positive and negative predictive value (PPV, NPV) of [68Ga]Pentixafor-PET for detection of gastric MALT lymphoma and respective 95% confidence intervals (CI) were calculated. SUVmax, SUVmean, and tumor-to-background ratios (TBR-liver and TBR-blood) were also measured.*Results [68Ga]Pentixafor-PET was false-negative in two patients/scans with low-level MALT lymphoma infiltration at histology; and false-positive in one patient with chronic gastritis. There was no false-positives in the control group. Accordingly, accuracy, sensitivity, and specificity of [68Ga]Pentixafor-PET were 95.5% (CI, 86.4-98.6%), 95.0% (CI, 80.9-98.8%), and 96.2% (CI, 77.2-99.5%); and PPV and NPV were 97.4% (CI, 83.1-99.7%) and 92.6% (CI, 74.8-98.1%), respectively. MALT lymphoma mean SUVmax, SUVmean,TBR-liver, and TBR-blood, were 7.1±3.0, 3.7±0.8, 5.1±3.4, and 3.6±2.1.*Conclusions CXCR4 imaging with [68Ga]Pentixafor-PET is feasible for the detection of gastric MALT lymphoma at post-treatment follow-up, showing high sensitivity and specificity, and providing high lesion-to-background contrast.*Clinical Relevance/Application CXCR4 PET imaging may offer a reasonably accurate alternative to routine esophagogastroduodenoscopy for post-treatment follow-up of gastric MALT lymphoma.

RESULTS

[68Ga]Pentixafor-PET was false-negative in two patients/scans with low-level MALT lymphoma infiltration at histology; and false-positive in one patient with chronic gastritis. There was no false-positives in the control group. Accordingly, accuracy, sensitivity, and specificity of [68Ga]Pentixafor-PET were 95.5% (CI, 86.4-98.6%), 95.0% (CI, 80.9-98.8%), and 96.2% (CI, 77.2-99.5%); and PPV and NPV were 97.4% (CI, 83.1-99.7%) and 92.6% (CI, 74.8-98.1%), respectively. MALT lymphoma mean SUVmax, SUVmean,TBR-liver, and TBR-blood, were 7.1±3.0, 3.7±0.8, 5.1±3.4, and 3.6±2.1.

CLINICAL RELEVANCE/APPLICATION

CXCR4 PET imaging may offer a reasonably accurate alternative to routine esophagogastroduodenoscopy for post-treatment follow-up of gastric MALT lymphoma.

SSNMMI08-6   Validation Of Multimodal Hypoxia Imaging Using Po2 EPR, FMISO PET, and DCE MRI with H;E and CD31 Staining On SCC7 Squamous Cell Carcinomas

Participants
Inna Gertsenshteyn, BA, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

Hypoxic tumors are resistant to radiation, and hypoxia correlates negatively with patient prognosis and survival. 18F-Misonidazole (FMISO) PET is used in clinical trials to localize tumor hypoxia with disputed accuracy. Electron paramagnetic resonance (EPR) imaging measures near-absolute pO2, with hypoxia defined by pO2 < 10 mmHg, but is not available clinically. Here we imaged hypoxic tumors with FMISO PET and perfusion images from Dynamic Contrast Enhanced (DCE) MRI, using EPR pO2 images as the reference standard of hypoxia. Immunohistochemical (IHC) H&E and CD31 stained slides were used to identify necrotic regions and vessels within the tumor. The purpose of this study was to use IHC to validate necrotic and vascular properties previously assumed based on in vivo imaging.*Methods and Materials 16 mice with SCC7 squamous cell carcinomas were imaged in a hybrid 720 MHz EPR/PET imager two hours post injection of ~230 μCi of FMISO tail-vein bolus for a 30 min static PET image. Near-absolute pO2 EPR images were acquired with an infusion of an oxygen sensitive spin probe. T2-weighted (for tumor/muscle contouring) and DCE MRI (Ktrans and ve) images were acquired in 9.4T scanner (Bruker, Germany). Two tumors with surrounding musculoskeletal structures were excised, formalin preserved, and decalcified. Ten-μm axial slices were stained with H&E and CD31 every 500 μm. MR and EPR/PET images were registered via embedded fiducials, then resampled to isotropic 0.5 mm voxel resolution in Matlab. Using morphological boundaries shown on H&E slides, a qualitative comparison of H&E and CD31 stains was made with in vivo MRI/EPR/PET images. Tumor vessels were thresholded based on brown CD31 stains using QuPath software.*Results Tumor regions with hypoxia shown in EPR (pO2 < 10 mmHg) and PET (TMR > 2.2), and low Ktrans and high ve, were consistent with H&E sections that showed necrosis and CD31 sections with little to no vasculature. Regions at edges of the tumor showed larger, more densely packed vessels and tumor nuclei, consistent with oxygenated regions shown in EPR/PET that also had high Ktrans and low ve. Work in HIF1-a staining to further validate hypoxia shown by EPR is ongoing.*Conclusions Using H&E and CD31 staining, pO2 EPR images were validated by showing deeply hypoxic tumor regions qualitatively correlated with necrotic regions without vasculature, as well as low Ktrans and high ve.*Clinical Relevance/Application Characterizing the hypoxic tumor microenvironment through in vivo and ex vivo imaging is valuable to validate the accuracy of FMISO PET and pO2 EPR imaging for future use in human clinical trials, as well

as potential DCE MRI correlates.

RESULTS

Tumor regions with hypoxia shown in EPR (pO2 < 10 mmHg) and PET (TMR > 2.2), and low Ktrans and high ve, were consistent with H&E sections that showed necrosis and CD31 sections with little to no vasculature. Regions at edges of the tumor showed larger, more densely packed vessels and tumor nuclei, consistent with oxygenated regions shown in EPR/PET that also had high Ktrans and low ve. Work in HIF1-a staining to further validate hypoxia shown by EPR is ongoing.

CLINICAL RELEVANCE/APPLICATION

Characterizing the hypoxic tumor microenvironment through in vivo and ex vivo imaging is valuable to validate the accuracy of FMISO PET and pO2 EPR imaging for future use in human clinical trials, as well as potential DCE MRI correlates.

SSMK03-1   Rethinking The Dexa Scan: Can We Utilize Deep Learning To Obtain Bone Mineral Density From Diagnosticimaging?

Participants
Simukayi Mutasa, MD, Newport Beach, California (*Presenter*) Nothing to Disclose

PURPOSE

While DEXA scans and extremity imaging utilize a similarly small amount of radiation, DEXA imaging provides no other diagnostic information. Our aim is to show that a convolutional neural network (CNN) can obtain bone mineral density from diagnostic imaging performed for other purposes, beginning with hip radiographs.*Methods and Materials We applied a natural language processing tool to perform a retrospective search of all DEXA scans performed at our institution since 2010 along with all the hip and pelvic radiographs obtained during the same time period in patients over 25. The results were cross-referenced to find patients whoobtained both a DEXA scan and radiograph within one year of each other. Over 4400 patients met inclusion criteria. A script was applied to extract quantitative and qualitative bone density labels. Qualitative labels consisted of normal bone density, osteopenia, and osteoporosis. Quantitative labelswere the average of the T-score from the hip, L-spine, femur, and forearm when available.Manual bounding box annotation of Ward's triangle on AP view was performed for each radiograph. A novel 40-layer CNN based on the focal loss principle was trained from random initialization to isolate Ward's triangle on AP view radiographs of the hip based on the annotations. Asecond CNN classified the images of each hip as containing osteoporosis or osteopenia, with a third and fourth class for normal hips and images not containing the hip respectively.10% of the patients were sequestered to be utilized as a testing set. 20% were used for validation and the remaining 70% for training. Accuracy, aggregate sensitivity and specificity, and average AUC were used as performance metrics.*Results Patients ranged in age from 20 to 93. 89% of the patients were female. Preliminary qualitative validation results on 515 images from 389 patients demonstrate a CNN classification accuracy of 81.16% with aggregate sensitivity and specificity of 0.838 and 0.772 respectively at the chosen operating point.The aggregate AUC was 0.809. Data is preliminary and further training on the remaining 4000 patients is ongoing for a more robust model.*Conclusions A deep learning system, when applied to extremity radiographs such as the hip, can diagnose abnormalities in bone mineral density similar to a DEXA scan.*Clinical Relevance/Application Bone mineral density can now be obtained from diagnostic imaging performed for other purposes.

RESULTS

Patients ranged in age from 20 to 93. 89% of the patients were female. Preliminary qualitative validation results on 515 images from 389 patients demonstrate a CNN classification accuracy of 81.16% with aggregate sensitivity and specificity of 0.838 and 0.772 respectively at the chosen operating point.The aggregate AUC was 0.809. Data is preliminary and further training on the remaining 4000 patients is ongoing for a more robust model.

CLINICAL RELEVANCE/APPLICATION

Bone mineral density can now be obtained from diagnostic imaging performed for other purposes.

SSMK03-2   Diagnosis On Foot Deformity With Automated Landmark Identification Using A Cascade Convolutional Neural Network On Foot Standing Lateral Radiographs

Participants
Seung Min Ryu, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate diagnosis on foot deformity with automated identification of landmarks using a cascade convolutional neural network (CNN) on foot standing lateral radiographs.*Methods and Materials A total of 1200 foot standing lateral radiographs was acquired from the Regional Military Manpower Administration of the Republic of Korea from April 2019 to Dec 2019. These radiographs were obtained using X-ray system while examinees were standing on a table with their feet in neutral position. Randomly selected 1050 X-rays were included as the train set, and the 150 X-rays as test set. One orthopedic surgeon (A) with 8 years of clinical experience and 3 years of military service experience to classify conscripted examinee according to orthopedic disease including pes planus and pes cavus identified the 25 anatomic landmarks per radiograph using a Visual Geometry Group (VGG) Image Annotator, which was regarded as the gold standard. Two orthopedic surgeons (A and B with 8 years of clinical experience) and general physician (GP) independently identified the landmarks of test dataset using same method. After 2 weeks later, Surgeon B and GP independently identified the landmarks once again under the guidance of the artificial intelligence (AI) CNN model. Mean absolute distance (MAD) and foot deformity angles including talo-first metatarsal angle (TMA), and calcaneal pitch angle (CPA) between

landmarks of gold standard and model prediction were evaluated. After 2 weeks later, all observers (A, B and GP) independently identified the landmarks of randomly selected 50 X-rays in test set without any guidance.*Results The overall detection errors for AI, Surgeon B, and GP were 0.85 ± 0.74 mm, 1.23 ± 1.13 mm, and 1.42 ± 1.40 mm, in MAD, 0.58 ± 1.68°, 2.57 ± 2.21 °, and 0.09 ± 2.50 °, in TMA, 0.22 ± 0.46°, 0.09 ± 0.47 °, and 0.12 ± 0.74 °, in CPA, respectively. In addition, the overall AI guided detection errors with Surgeon B and GP were 0.9 ± 0.3 mm and 1.2 ± 0.3 mm, in MAD, 1.83 ± 2.17 ° and 2.36 ± 2.31 °, in TMA, 0.07 ± 0.45 ° and 0.13 ± 0.55°, in CPA, respectively. Intra-observer difference of the landmarks for A, B and GP were 0.62 ± 0.08 mm, 0.83 ± 0.15 mm and 1.06 ± 0.35 mm.*Conclusions Guidance with this CNN model showed better and more consistent outcome in inexperienced doctors for classifying foot deformity and determine landmarks. With the help of AI, inexperienced doctors can identify the anatomic landmarks better than without.*Clinical Relevance/Application The automated foot deformity landmark detection model may aid preliminary screening and accurate measurement for diagnosis of foot deformity.

RESULTS

The overall detection errors for AI, Surgeon B, and GP were 0.85 ± 0.74 mm, 1.23 ± 1.13 mm, and 1.42 ± 1.40 mm, in MAD, 0.58 ± 1.68°, 2.57 ± 2.21 °, and 0.09 ± 2.50 °, in TMA, 0.22 ± 0.46°, 0.09 ± 0.47 °, and 0.12 ± 0.74 °, in CPA, respectively. In addition, the overall AI guided detection errors with Surgeon B and GP were 0.9 ± 0.3 mm and 1.2 ± 0.3 mm, in MAD, 1.83 ± 2.17 ° and 2.36 ± 2.31 °, in TMA, 0.07 ± 0.45 ° and 0.13 ± 0.55°, in CPA, respectively. Intra-observer difference of the landmarks for A, B and GP were 0.62 ± 0.08 mm, 0.83 ± 0.15 mm and 1.06 ± 0.35 mm.

CLINICAL RELEVANCE/APPLICATION

The automated foot deformity landmark detection model may aid preliminary screening and accurate measurement for diagnosis of foot deformity.

SSMK03-3   Deep Learning Identifies Body Composition Changes Over Time In Total-body DXA Imaging To Predict All-cause Mortality

Participants
Yannik Glaser, Honolulu, Hawaii (*Presenter*) Nothing to Disclose

PURPOSE

From total body dual energy X-ray absorptiometry (TBDXA) scans it is known that older adults who lose higher muscle mass and weight than expected have a higher mortality risk compared to those who preserve muscle. Based on this, we propose two additions to mortality risk models. First, we hypothesize that TBDXA scans provide relevant body composition information beyond what is reflected in traditional risk factors. Second, we hypothesize that tracking changes in body composition over time further improves mortality models.*Methods and Materials Deep neural network (DNN) models were trained on 3075 patient's records from the Health, Aging and Body Composition study (HealthABC), a prospective cohort study of white and black men and women aged 70 to 79 years, with 1992 deaths over the 15 years of observation. HealthABC DXA scans were taken with a Hologic system (Hologic Inc., MA) in addition to traditional mortality risk factors: blood markers, general fitness indicators, and disability. Participants were split into training (70%) and validation (10%) sets for model tuning, and a test (20%) set for final evaluation. For both "single-record" and "record-sequence" scenarios, DNNs were trained on traditional risk factors, only TBDXA scans, and both modalities combined.*Results Hypothesis one was confirmed by comparing test set AUROC scores of the three models trained on isolated records: 0.69 for traditional risk factors, 0.63 for image-only, and 0.71 for combined modalities. Hypothesis two was confirmed by comparing test set AUROC scores for models trained on multi-record sequences: 0.76 for traditional risk factors, 0.73 for image-only, and 0.79 for combined modalities.*Conclusions This study is the first to examine baseline and sequential TBDXA scans combined with traditional mortality risk factors. The single-record performance shows that TBDXA contains complementary information to known risk factors, while the sequence model performance gains indicate that changes in body composition over time are stronger predictors of mortality than isolated datapoints. We demonstrate that deep learning can extract this information to improve all-cause mortality predictions.*Clinical Relevance/Application This approach provides a powerful way to study overall change in body composition characteristics coupled to clinical risk factors, paving a way for better intervention strategies to prolong lifespan.

RESULTS

Hypothesis one was confirmed by comparing test set AUROC scores of the three models trained on isolated records: 0.69 for traditional risk factors, 0.63 for image-only, and 0.71 for combined modalities. Hypothesis two was confirmed by comparing test set AUROC scores for models trained on multi-record sequences: 0.76 for traditional risk factors, 0.73 for image-only, and 0.79 for combined modalities.

CLINICAL RELEVANCE/APPLICATION

This approach provides a powerful way to study overall change in body composition characteristics coupled to clinical risk factors, paving a way for better intervention strategies to prolong lifespan.

SSMK03-4   Deep Neural Network And Radiomics Nomograms For Predicting The Intraoperative Massive Blood Loss Of Pelvic And Sacral Tumors

Participants
Ping Yin, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

Patients with pelvic and sacral tumors are prone to massive blood loss (MBL) during surgery, which may endanger their lives. Preoperative prediction of the likelihood of MBL in these patients is necessary because misjudgment in preoperative evaluation may endanger the patient's life or cause the waste of blood products. This study aimed to determine the feasibility of using deep neural network (DNN) and radiomics nomogram (RN) based on 3D computed tomography (CT) features and clinical characteristics to predict the intraoperative MBL of pelvic and sacral tumors.*Methods and Materials This single-center retrospective analysis included 810 patients (445 males, 365 females; mean age of 42.5 ± 17.3 years, range 4-85 years) with pelvic and sacral tumors. 1316 CT and CT enhanced radiomics features were extracted. RN1 and RN2 were constructed by random grouping and time node grouping, respectively. The DNN models were constructed for comparison with RN. The following risk factors that were potentially associated with MBL were analyzed: sex, age, maximal tumor size, tumor type (chondrosarcoma, osteosarcoma, chordoma, giant cell tumor, multiple myeloma, schwannoma, neurofibroma, Ewing's sarcoma, metastatic tumor, and others), tumor location, neoadjuvant chemo-radiotherapy, surgical methods, surgical approaches, surgical operator, preoperative embolization, and aortic balloon occlusion. The area under the receiver operating characteristic curve (AUC) and accuracy (ACC) were used to evaluate

different models.*Results The overall blood loss ranged from 50 mL to 11000 mL with a median of 1500 (800, 2387.5) mL. Radscore, tumor type, tumor location, and sex were significant predictors of the MBL of pelvic and sacral tumors (P < 0.05), of which radscore (OR, ranging from 2.109 to 4.706, P < 0.001) was the most important. The clinical-DNN and clinical-RN performed better than DNN and RN. Both clinical-DNN and clinical-RN could be powerful tools for preoperatively predicting the MBL of patients with pelvic and sacral tumors, but the clinical-DNN model based on CT features was superior. The best-performing clinical-DNN model based on CT features exhibited an AUC of 0.92 and an ACC of 0.97 in the training set, and an AUC of 0.92 and an ACC of 0.75 in the validation set.*Conclusions The clinical-DNN and clinical-RN can be powerful tools for preoperatively predicting the MBL of patients with pelvic and sacral tumors, reducing the risk of surgical failure due to the preoperative misjudgment of blood loss.*Clinical Relevance/Application Our model could help clinicians develop individualized treatment plans, prepare blood products in advance, and reduce the risk of surgical failure and waste of blood products.

RESULTS

The overall blood loss ranged from 50 mL to 11000 mL with a median of 1500 (800, 2387.5) mL. Radscore, tumor type, tumor location, and sex were significant predictors of the MBL of pelvic and sacral tumors (P < 0.05), of which radscore (OR, ranging from 2.109 to 4.706, P < 0.001) was the most important. The clinical-DNN and clinical-RN performed better than DNN and RN. Both clinical-DNN and clinical-RN could be powerful tools for preoperatively predicting the MBL of patients with pelvic and sacral tumors, but the clinical-DNN model based on CT features was superior. The best-performing clinical-DNN model based on CT features exhibited an AUC of 0.92 and an ACC of 0.97 in the training set, and an AUC of 0.92 and an ACC of 0.75 in the validation set.

CLINICAL RELEVANCE/APPLICATION

Our model could help clinicians develop individualized treatment plans, prepare blood products in advance, and reduce the risk of surgical failure and waste of blood products.

SSMK03-5 Evaluation Of The Medical Impact Of Artificial Intelligence For Limb And Pelvic Bone Fracture Detection

Participants
Nor-Eddine Regnard, MMed, Paris, France (*Presenter*) Founder, GLEAMER;Officer, GLEAMER;Stockholder, GLEAMER

PURPOSE

To compare the performance of routine radiological interpretation and artificial intelligence (AI) in the detection of limb and pelvic bone fractures and assess its impact in terms of changes in medical care.*Methods and Materials We retrospectively evaluated all X-ray exams performed for a suspected limb or pelvic bone fracture during 3 consecutive months (Jan.-Mar. 2017) in a private imaging group of 17 centers. Each exam was analyzed by the AI BoneViewTM and its results were compared to those of the initial report. In case of discrepancy, the exam was reviewed by a senior skeletal radiologist to settle on the presence of one or several fractures. He specified whether a complementary imaging exam was necessary following the change in diagnosis and evaluated the possible consequences of a delay in therapeutic care (0: none, 1: low, 2: impact on limb function, 3: vital).*Results A total of 4774 exams (0-103 y.o., 30% pediatrics, 49% women) were included in the study. The anatomical locations of the exams were: hand (22%), wrist (4%), foot (13%), ankle (11%), leg (5%), knee (23%), arm (3%), elbow (2%), shoulder (9%), pelvis (8%). There were a total of 703 discordant exams reviewed by the senior radiologist. Of the 785 positive exams, 903 fractures were detected by either the AI and the initial report together (n=651, 72.1%) or by the senior radiologist in discordant cases (n=252, 27.9%). Of these 252 fractures, the senior radiologist confirmed the presence of 235 fractures detected by the AI and not mentioned in the initial report (26%) and of 17 fractures (1.9%) present in the initial report but not pointed by the AI. Among these 235 fractures, 46 were second fractures. Of the 235 additional fractures detected by the AI, 69 (29.4%) should have led to another imaging exam (CT or MRI) to confirm the diagnosis (n=61, 26%) or to characterize the severity of the fracture (n=48, 20.4%). The knowledge of the fracture could have led to a change in therapeutic care for 144 fractures (61.3%) and a possible surgery for 51 (21.7%). The consequences of a delay in therapeutic care were evaluated as low (score 1) for 155 fractures (66%) and as a source of impact on limb function (score 2) for 24 fractures (10.2%). Of the 235 additional fractures, 32 were impactful fractures: 6 pelvises, 5 scaphoids, 4 tibial plateau, 16 distal radii, and 1 fibula neck.*Conclusions On a clinical routine dataset with natural prevalence, the AI detected 235 additional fractures with 46 multi-fracture exams, corresponding to an increase of 26% in fracture detection. Overall, 5% of exams were subject to medical errors. The best performances were obtained by the radiologist + AI.*Clinical Relevance/Application AI-aid has the potential to prevent medical errors like missed fractures on initial X-ray exams thus impacting patient care.

RESULTS

A total of 4774 exams (0-103 y.o., 30% pediatrics, 49% women) were included in the study. The anatomical locations of the exams were: hand (22%), wrist (4%), foot (13%), ankle (11%), leg (5%), knee (23%), arm (3%), elbow (2%), shoulder (9%), pelvis (8%). There were a total of 703 discordant exams reviewed by the senior radiologist. Of the 785 positive exams, 903 fractures were detected by either the AI and the initial report together (n=651, 72.1%) or by the senior radiologist in discordant cases (n=252, 27.9%). Of these 252 fractures, the senior radiologist confirmed the presence of 235 fractures detected by the AI and not mentioned in the initial report (26%) and of 17 fractures (1.9%) present in the initial report but not pointed by the AI. Among these 235 fractures, 46 were second fractures. Of the 235 additional fractures detected by the AI, 69 (29.4%) should have led to another imaging exam (CT or MRI) to confirm the diagnosis (n=61, 26%) or to characterize the severity of the fracture (n=48, 20.4%). The knowledge of the fracture could have led to a change in therapeutic care for 144 fractures (61.3%) and a possible surgery for 51 (21.7%). The consequences of a delay in therapeutic care were evaluated as low (score 1) for 155 fractures (66%) and as a source of impact on limb function (score 2) for 24 fractures (10.2%). Of the 235 additional fractures, 32 were impactful fractures: 6 pelvises, 5 scaphoids, 4 tibial plateau, 16 distal radii, and 1 fibula neck.

CLINICAL RELEVANCE/APPLICATION

AI-aid has the potential to prevent medical errors like missed fractures on initial X-ray exams thus impacting patient care.

SSNPM01-2 Underrepresentation Of Female Speakers At Musculoskeletal Radiology Conferences - Potential Strategies To Mitigate Gender Gap

Participants
Aline Serfaty Sr, MD, Cabo Frio, Brazil (*Presenter*) Nothing to Disclose

PURPOSE

Our objectives are to assess gender distribution and disparities in the musculoskeletal field at radiology conferences and to identify factors associated with imbalance of women as speakers.*Methods and Materials This cross-sectional study evaluated data publicly available online from seven musculoskeletal radiology conference programs from different radiological societies across 3 regions (Europe, North and South Americas) from 2016 to 2020.Gender of invited speakers, moderators and planning committee members, as well as the occurrence of single gender panels for general and plenary sessions of each conference were assessed. Statistical analysis was performed to determine associations between the proportion of female participation and radiologists' gender composition of include dregions.*Results A total of 531 sessions, 2580 speakers, 603 moderators and 231 planning committee members were assessed. Women accounted for 26.6% of total speakers (P<0.001), 33.3% of moderators (P<0.001) and 31.2% of planning committee members (P=0.381). All-male panels were 26.7%, with 21.1% of women moderating these panels (P<0.001). The proportion of female speakers in musculoskeletal sessions in regard to the radiology specialty gender composition, was29.7% in North American, 26.6% in European and 12.9% in South American conferences (all P<0.05), while the proportion of female speakers in plenary sessions was 34.6 % in North American (P<0.052), 25.0% in European(P>0.199) and 13.6% in South American (P=0.001). The proportion of female moderators in musculoskeletal sessions was 35.0% in North American (P=0.002), 37.1% in European (P=0.914), and 13.8% in South American conferences(P<0.001). A linear relationship was observed in the proportion of women as speakers, moderators and as planning committee members (P<0.05).*Conclusions Women were underrepresented as speakers in the musculoskeletal field of radiological conferences worldwide, with significant differences in Europe and South America in all years evaluated. Women as moderators were also significantly underrepresented in South America, and in all-male panels in all regions.*Clinical Relevance/Application Women have consistently been underrepresented in radiology globally. Acknowledging gender biases and increasing the number of women on planning committees may help address gender imbalance and promote gender equity.

RESULTS

A total of 531 sessions, 2580 speakers, 603 moderators and 231 planning committee members were assessed. Women accounted for 26.6% of total speakers (P<0.001), 33.3% of moderators (P<0.001) and 31.2% of planning committee members (P=0.381). All-male panels were 26.7%, with 21.1% of women moderating these panels (P<0.001). The proportion of female speakers in musculoskeletal sessions in regard to the radiology specialty gender composition, was29.7% in North American, 26.6% in European and 12.9% in South American conferences (all P<0.05), while the proportion of female speakers in plenary sessions was 34.6 % in North American (P<0.052), 25.0% in European(P>0.199) and 13.6% in South American (P=0.001). The proportion of female moderators in musculoskeletal sessions was 35.0% in North American (P=0.002), 37.1% in European (P=0.914), and 13.8% in South American conferences(P<0.001). A linear relationship was observed in the proportion of women as speakers, moderators and as planning committee members (P<0.05).

CLINICAL RELEVANCE/APPLICATION

Women have consistently been underrepresented in radiology globally. Acknowledging gender biases and increasing the number of women on planning committees may help address gender imbalance and promote gender equity.

SSNPM01-3 Recent Changes In Women Representation In The United States Diagnostic Radiology Residency Programs: Opportunities Or Unintentional Consequences?

Participants
Faezeh Sodagari, MD, New Haven, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

To assess recent trends in the proportion of female residents and faculty members in diagnostic radiology residency programs in the United States (US).*Methods and Materials Using the American Medical Association Fellowship and Residency Electronic Interactive Database (FREIDA), diagnostic radiology residency programs in the US were identified and the program-reported data such as the type of residency programs, number of faculty members, as well as the proportions of female faculty and female residents were extracted in 2015, 2018, and 2021 and the data were compared between 2015 and 2021.*Results The number of diagnostic radiology residency programs increased from 184 programs in 2015 to 193 in 2018 and 195 in 2021. These programs consisted of 101 (52%) university-based, 66 (34%) university-affiliated, 19 (10%) community, and 7 (4%) military programs in 2021. The number of programs that reported their residents' gender diversity information increased from 82 (47%) programs in 2015 to 121

(62%) programs in 2021. There was no significant change between the proportions of female faculty (26.5% ±10.4% vs 26.6% ± 9.9%, P: 0.91) or female resident (24.8% ± 9.1% vs 25.7% ± 10.1%, P: 0.42) between 2015 and 2021. The proportion of female residents did not show a significant correlation with program female faculty proportion or the size of the residency program and was independent of the program director gender (all P> 0.05). Although not statistically significant, community programs without affiliation with universities showed a marked visual decline in the median proportions of female residents (30.3% to 17.9%, P: 0.28) and female faculty (24.2% to 12.3%, P: 0.15) between 2015 to 2021, while the university-based programs showed a slight visual increase from 20.8% to 26.7% (P: 0.12) and 26.4% to 28.1% (P: 0.15), respectively.*Conclusions Despite recent initiatives to increase traditional gender diversity in radiology, no significant overall change is observed in female faculty or resident representation in radiology departments in the US between 2015 to 2021. Declining trends in the proportion of female faculty members and residents are perceived in community programs while academic programs show a slight but not statistically significant increase in female representation.*Clinical Relevance/Application Without addressing the pipeline of female medical students entering radiology residency programs, the overall female representation in radiology appears unchanged in recent years. The perceived increased recruiting efforts in academic programs without an increase in the pipeline resulted in a shift of female residents and faculty from community to university-based programs without affecting the overall gender diversity in the specialty.

RESULTS

The number of diagnostic radiology residency programs increased from 184 programs in 2015 to 193 in 2018 and 195 in 2021. These programs consisted of 101 (52%) university-based, 66 (34%) university-affiliated, 19 (10%) community, and 7 (4%) military programs in 2021. The number of programs that reported their residents' gender diversity information increased from 82 (47%) programs in 2015 to 121 (62%) programs in 2021. There was no significant change between the proportions of female faculty (26.5% ±10.4% vs 26.6% ± 9.9%, P: 0.91) or female resident (24.8% ± 9.1% vs 25.7% ± 10.1%, P: 0.42) between 2015 and 2021. The proportion of female residents did not show a significant correlation with program female faculty proportion or the size of the residency program and was independent of the program director gender (all P> 0.05). Although not statistically significant, community programs without affiliation with universities showed a marked visual decline in the median proportions of female residents (30.3% to 17.9%, P: 0.28) and female faculty (24.2% to 12.3%, P: 0.15) between 2015 to 2021, while the university-based programs showed a slight visual increase from 20.8% to 26.7% (P: 0.12) and 26.4% to 28.1% (P: 0.15), respectively.

CLINICAL RELEVANCE/APPLICATION

Without addressing the pipeline of female medical students entering radiology residency programs, the overall female representation in radiology appears unchanged in recent years. The perceived increased recruiting efforts in academic programs without an increase in the pipeline resulted in a shift of female residents and faculty from community to university-based programs without affecting the overall gender diversity in the specialty.

SSNPM01-4 Advancing Culture Change In Radiology Through Communication: The Value Of Large Versus Small Group Discussions

Participants
Amber Simmons, BS, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

Our department, as part of a concerted institutional effort, adopted a strategic framework to address institutional health inequities, bias, and racism and advance culture change. Understanding the importance of employees' voices in this process, we deployed two forms of communication-based initiatives, of variable group sizes, to solicit ideas, identify critical action items, and generate feedback from employees. However, the ideal methods of departmental communication and the effect of group size, especially regarding DEI discussions, are not well understood.*Methods and Materials A 60-minute large group (LG) and seven 90-minute small group (SG) sessions were conducted virtually. All sessions consisted of a heterogenous group of employees, except two SGs of trainees only. All participants could communicate verbally or by chat during the session, or through an anonymous online form before and after each session. De-identified written transcripts were recorded and anonymous surveys conducted after each session. Our primary outcome was employee perception of effectiveness of LG versus SG sessions, assessed through the anonymous survey. Our secondary outcomes were the effectiveness of SG versus LG and homogeneous (Group A-SG) versus heterogeneous (Group B-SG) SGs in generating action ideas. To assess this, a scale of 0-5 was developed to grade the strength of an action proposal and a score was assigned by three blinded reviewers. Chi-squared and Fischer exact tests were performed.*Results There were 156 LG and 155 SG participants, with 22 survey responses from the LG and 38 from the SGs (14.1% and 24.5% response rate, respectively). There were 11 group A-SG and 27 group B-SG responders. Of 16 survey questions, 9 showed significant differences between LG and SG using Chi-squared trend test, with 5 also significant by Fisher exact (Figure 1). Only one question demonstrated significant difference on Fischer exact test between group A-SG and B-SG. Of 412 comments, 400 were from SGs with only 12 from the LG, precluding statistical comparison. There was no difference in comment strength between Group A-SG or Group B-SG (p-value 0.643).*Conclusions Our study shows that, compared to LG, SG settings are perceived by employees as more effective in having purposeful discussions and for idea generation with less fear of judgement and bias, with trainee-only SGs more likely to express fear of judgement from leadership. It also highlights significant limitations of LGs in facilitating idea generation and sharing, even with expanded avenues to provide comments.*Clinical Relevance/Application These findings can serve as a guide to engaging employees and promoting organization culture change, especially as it relates to diversity, equity, and inclusion.

RESULTS

There were 156 LG and 155 SG participants, with 22 survey responses from the LG and 38 from the SGs (14.1% and 24.5% response rate, respectively). There were 11 group A-SG and 27 group B-SG responders. Of 16 survey questions, 9 showed significant differences between LG and SG using Chi-squared trend test, with 5 also significant by Fisher exact (Figure 1). Only one question demonstrated significant difference on Fischer exact test between group A-SG and B-SG. Of 412 comments, 400 were from SGs with only 12 from the LG, precluding statistical comparison. There was no difference in comment strength between Group A-SG or Group B-SG (p-value 0.643).

CLINICAL RELEVANCE/APPLICATION

These findings can serve as a guide to engaging employees and promoting organization culture change, especially as it relates to diversity, equity, and inclusion.

SSNPM01-5 Temporal And Geospatial Variations Among The Female Interventional Radiology Physician Workforce In The United States.

Participants
Suryansh Bajaj, New Haven, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

With the growing role of IR in patient management across a broad spectrum of disease processes and with the aging patient population, it is imperative to maintain an adequate Vascular and Interventional Radiology (VIR) workforce across the country in order to provide adequate access to specialized interventional care to our patients. This study aims to analyze the temporal trends and state-wise geospatial variations in the Vascular and Interventional Radiology (VIR) female physician workforce in the United States and compare its growth rate with the female physician workforce of other surgical fields.*Methods and Materials The State Physician Workforce Data was accessed for years 2015, 2017, and 2019. The variables collected for each state included total active female physicians, total female physicians per specialty, and total female physicians per 100,000 population in VIR. Comparative data were obtained for otolaryngology (ENT), general surgery (GS), interventional cardiology (IC), neurosurgery (NSG), ophthalmology (OP), orthopedic surgery (OS), plastic surgery (PS), thoracic surgery (TS), vascular surgery (VS) and urology (UR). The annual growth rate for female physicians in each state was computed for each specialty.*Results From 2015 to 2019, the total active female physicians in the United States grew by 3.82% per year. 34.61% of total physicians are female, and out of the specialties analyzed, ophthalmology has the highest number of female physicians at 22.14%, whereas females made up only 3.04% of VIR workforce. The annual growth rate of female physicians was highest in VS (12.61%) which was followed by IR (7.80%), IC (7.48%), NSG (7.15%), UR (6.12%), PS (5.02%), TS (4.51%), OP (4.09%), ENT (3.86%) and OS (3.28%). The state of Massachusetts has the highest proportion of women in VIR at 19%. Utah had the highest growth rate in the number of female VIR physicians at 16.55%.*Conclusions Female VIR physicians make up a small fraction of the VIR workforce, but their numbers have increased at a faster rate than most surgical specialties except vascular surgery. There is a substantial geographic variation in the distribution of the female VIR physician workforce.*Clinical Relevance/Application Improving the gender diversity amongst interventional radiologists is imperative to provide optimal healthcare to the population. Gender diversity among health professionals has been shown to improve access to care, patient satisfaction with their treatment, and communication with their provider.

RESULTS

From 2015 to 2019, the total active female physicians in the United States grew by 3.82% per year. 34.61% of total physicians are female, and out of the specialties analyzed, ophthalmology has the highest number of female physicians at 22.14%, whereas females made up only 3.04% of VIR workforce. The annual growth rate of female physicians was highest in VS (12.61%) which was followed by IR (7.80%), IC (7.48%), NSG (7.15%), UR (6.12%), PS (5.02%), TS (4.51%), OP (4.09%), ENT (3.86%) and OS (3.28%). The state of Massachusetts has the highest proportion of women in VIR at 19%. Utah had the highest growth rate in the number of female VIR physicians at 16.55%.

CLINICAL RELEVANCE/APPLICATION

Improving the gender diversity amongst interventional radiologists is imperative to provide optimal healthcare to the population. Gender diversity among health professionals has been shown to improve access to care, patient satisfaction with their treatment, and communication with their provider.

SSNPM01-6 If We Want Diversity, We Have To Pay For It: The Effects Of Compensation And Promotion Practices On Retaining Diverse Resident Graduates As Future Faculty.

Participants
Daniel T. Kawakyu-O'Connor, MD, Pittsford, New York (*Presenter*) Nothing to Disclose

PURPOSE

To assess the distribution of resident graduates by gender and ethnic identity from a university-based radiology department across local radiology practices and survey how compensation and promotion policies influence choice of practice environment*Methods and Materials A roster of radiologists completing a university based residency between 2010 and 2020 reviewed to identify those who entered practice within 75 miles. The distribution of radiologists by gender and ethnic identity across practice settings was analyzed. Former residents were surveyed regarding compensation and promotion practices as factors in their choice of practice setting.*Results Resident graduates who identified as women or non White overwhelmingly favored non university based practices. Residents who were hired as faculty at the university practice were more likely to leave within 3 years than those who joined other practices. Faculty retention at the university practice favored radiologists who identified as White men. Participants indicated several factors as influencing their choice of practice. Lower compensation at the university-based practice was a leading factor in the decision to join other practices. Incentive compensation plans and academic promotion practices at the university-based practice were perceived as less favorable for women and non-White faculty.*Conclusions Radiologists graduating from a university residency program identifying as women or non White favored practices other than the university group, a concerning finding for an academic institution. The leading factor was lower compensation in the university setting, suggesting that the long standing practice of compensating academic radiologists less than community peers contributes to the lack of diverse representation in some academic settings. Incentive based compensation and promotion practices were both perceived to favor non White male faculty, which is aligned with literature showing that women and non-White ethnic groups publish less, serve on fewer and less influential committees, and are less likely to have leadership roles, all of which are common metrics for incentivized compensation and promotion. This finding implicates academic environments as maintaining institutional and structural bias as an impediment promoting equity and inclusion.*Clinical Relevance/Application Promoting equitable compensation between academic and non-academic radiology practices is an overlooked opportunity in promoting diversity. Incentive compensation plans and promotion criteria should be reassessed to eliminate policies that embed bias against women and non-White faculty. Promoting a culture of equity and inclusion alone without these interventions is of lesser value.

RESULTS

Resident graduates who identified as women or non White overwhelmingly favored non university based practices. Residents who were hired as faculty at the university practice were more likely to leave within 3 years than those who joined other practices. Faculty retention at the university practice favored radiologists who identified as White men. Participants indicated several factors as influencing their choice of practice. Lower compensation at the university-based practice was a leading factor in the decision to join other practices. Incentive compensation plans and academic promotion practices at the university-based practice were perceived as less favorable for women and non-White faculty.

CLINICAL RELEVANCE/APPLICATION

Promoting equitable compensation between academic and non-academic radiology practices is an overlooked opportunity in promoting diversity. Incentive compensation plans and promotion criteria should be reassessed to eliminate policies that embed bias against women and non-White faculty. Promoting a culture of equity and inclusion alone without these interventions is of lesser value.

SSGI20-1   **Diagnostic Performance Of Ultrasound Texture Parameters Extracted Using Various Beamforming Sound Speeds In Detecting Hepatic Steatosis**

Participants

Kibo Nam, PhD, Philadelphia, Pennsylvania (*Presenter*) Equipment support from Canon Medical Systems Corporation and GE Healthcare, Material support from Lantheus Medical Imaging, Research fund support from Canon Medical Systems Corporation

PURPOSE

Conventional ultrasound uses an assumed speed of sound (SOS) for beamforming, which may cause an image texture change by defocusing if the actual tissue SOS mismatches the assumed one. Fat build-up by hepatic steatosis lowers a liver SOS and its image texture has been quantified to detect hepatic steatosis. However, the texture features extracted using a single (1540 m/s) beamforming SOS failed to achieve reliable diagnostic performance. The aim of this study was to investigate if the texture features extracted using various beamforming SOSs can improve the diagnostic reliability in detecting hepatic steatosis*Methods and Materials Patients with suspected non-alcoholic fatty liver disease (NAFLD) undergoing liver biopsy or MRI proton density fat fraction (PDFF), were prospectively recruited. Subjects were imaged with a C1-6 probe on a Logiq E9 scanner (GE Healthcare). The radio-frequency (RF) data from subjects' right lobe were collected using 6 beamforming SOSs: 1300, 1350, 1400, 1450, 1500, and 1540 m/s and analyzed offline using Matlab (MathWorks). The texture parameters, i.e. contrast, correlation, energy, and homogeneity from gray-level co-occurrence matrix of normalized envelope were obtained from the region of interest (ROI) in the liver parenchyma. The diagnostic performance of texture parameters from each beamforming SOS was assessed independently and in combination (by averaging its values from multiple beamforming SOSs) using a receiver operating characteristic analysis.*Results To date, 21 subjects were included in the analysis. 13 subjects were diagnosed of NAFLD (7 by biopsy steatosis = 5% and 6 by MRI-PDFF = 6.5%) and 8 subjects had normal liver (5 by biopsy steatosis < 5% and 3 by MRI-PDFF < 6.5%). The correlation values from either 1300 (AUC: 0.82; specificity: 85%; sensitivity: 63%), 1350 (AUC: 0.88; specificity: 85%; sensitivity: 100%), or 1400 m/s (AUC: 0.90; specificity: 85%; sensitivity: 88%) were significantly lower (p<0.03) in the NAFLD livers than in normal livers. The diagnostic performance of correlation was improved or comparably achieved by averaging its values from multiple beamforming SOSs (1350-1400 m/s, 1300-1400 m/s or 1300-1540 m/s). The averaged correlation value from 1350-1400 m/s showed the highest accuracy of 91% with 85% specificity and 100% sensitivity.*Conclusions The diagnostic reliability of ultrasound texture parameter in detecting hepatic steatosis may be improved by averaging its values extracted using various beamforming SOSs.*Clinical Relevance/Application It may be possible to improve the diagnostic performance of ultrasound texture parameter in detecting hepatic steatosis using images acquired with various beamforming SOSs.

RESULTS

To date, 21 subjects were included in the analysis. 13 subjects were diagnosed of NAFLD (7 by biopsy steatosis = 5% and 6 by MRI-PDFF = 6.5%) and 8 subjects had normal liver (5 by biopsy steatosis < 5% and 3 by MRI-PDFF < 6.5%). The correlation values from either 1300 (AUC: 0.82; specificity: 85%; sensitivity: 63%), 1350 (AUC: 0.88; specificity: 85%; sensitivity: 100%), or 1400 m/s (AUC: 0.90; specificity: 85%; sensitivity: 88%) were significantly lower (p<0.03) in the NAFLD livers than in normal livers. The diagnostic performance of correlation was improved or comparably achieved by averaging its values from multiple beamforming SOSs (1350-1400 m/s, 1300-1400 m/s or 1300-1540 m/s). The averaged correlation value from 1350-1400 m/s showed the highest accuracy of 91% with 85% specificity and 100% sensitivity.

CLINICAL RELEVANCE/APPLICATION

It may be possible to improve the diagnostic performance of ultrasound texture parameter in detecting hepatic steatosis using images acquired with various beamforming SOSs.

SSGI20-2   **Targeted Liver Biopsy: Using Logistic Regression Model To Choose Ultrasound Versus CT Guidance**

Participants

Yarab Al Bulushi, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

While most institutions perform targeted liver biopsies on a daily basis, no clear guidelines exist on modality choice for image guidance. Ultrasound is usually preferred given the lack of ionizing radiation, wide availability, and low cost. However, some liver lesions can be difficult to visualize or target with ultrasound guidance causing delay in care, anxiety and inconvenience to the patients. Our goal was to determine the factors that limit ultrasound targeting of liver lesions, build a model that will predict feasibility of US-guided liver lesion biopsy and thus aid in counseling the patient and in appropriate allocation of the radiology resources.*Methods and Materials This is IRB-approved HIPAA-compliant retrospective review of consecutive targeted liver ultrasound-guided biopsies performed or attempted between January 2018 and September 2020 at a single tertiary academic

institution by fellowship-trained abdominal radiologist and a trainee with a total of 511 patients included. Mann-Whitney and chi-squared tests were used to compare continuous and categorical variables respectively. Logistic regression model was used to predict feasibility of successful ultrasound guided biopsy.*Results Liver lesion biopsy could not be performed with US guidance in 73/511 (14.3%) patients. Lesions not amenable for US biopsy were smaller (median size 1.6 cm vs 3.3 cm, p<0.0001) and deeper within the liver (median depth 9.0 cm vs 5.8 cm, p<0.0001). Lesions located within segments II (75%) and VIII (78%) were significantly less amenable for US targeted biopsy (p<0.03), while lesions in segments V (94%) and IVb (96%) were more feasible targets (p<0.003). US targeting in patients with 1 or 2 lesions was less feasible than in patients with 3 or more lesions, 127/182 (70%) vs 303/321 (94%), (p<0.0001). Subsequent successful biopsy was performed in 31/72 (43%) patients (29 by CT and 2 surgically). Model including lesion size, depth and location, and number of lesions predicts feasibility of US guided biopsy with area under the ROC curve AUC = 0.92.*Conclusions Linear logistic regression model that includes lesion size, depth and location, and number of lesions is highly successful in predicting feasibility of ultrasound guided biopsy for liver lesions. In general, smaller lesions, deeper lesions, lesions in segment II and VIII in patients with less than 3 lesions were less feasible for ultrasound-guided biopsy of liver lesions.*Clinical Relevance/Application Model accurately predicting feasibility of targeted liver biopsy with ultrasound allows for counseling patient ahead of the biopsy, aid in appropriate allocation of radiology resources, limiting delay in care and patient anxiety.

RESULTS

Liver lesion biopsy could not be performed with US guidance in 73/511 (14.3%) patients. Lesions not amenable for US biopsy were smaller (median size 1.6 cm vs 3.3 cm, p<0.0001) and deeper within the liver (median depth 9.0 cm vs 5.8 cm, p<0.0001). Lesions located within segments II (75%) and VIII (78%) were significantly less amenable for US targeted biopsy (p<0.03), while lesions in segments V (94%) and IVb (96%) were more feasible targets (p<0.003). US targeting in patients with 1 or 2 lesions was less feasible than in patients with 3 or more lesions, 127/182 (70%) vs 303/321 (94%), (p<0.0001). Subsequent successful biopsy was performed in 31/72 (43%) patients (29 by CT and 2 surgically). Model including lesion size, depth and location, and number of lesions predicts feasibility of US guided biopsy with area under the ROC curve AUC = 0.92.

CLINICAL RELEVANCE/APPLICATION

Model accurately predicting feasibility of targeted liver biopsy with ultrasound allows for counseling patient ahead of the biopsy, aid in appropriate allocation of radiology resources, limiting delay in care and patient anxiety.

SSGI20-3   Liver Reporting And Data System (LI-RADS) Major Features: Individual Patient Data Meta-analysis Of Diagnostic Accuracy Studies For Diagnosis Of Hepatocellular Carcinoma

Participants
Mustafa Bashir, MD, Cary, North Carolina (*Presenter*) Research Grant, Siemens AGResearch Grant, NGM Biopharmaceuticals, IncResearch Grant, Madrigal Pharmaceuticals, IncResearch Grant, Metacrine, IncResearch Grant, ProSciento, IncResearch Grant, Medscape, LLCResearch Grant, Carmot Therapeutics Inc

PURPOSE

The Liver Reporting and Data System (LI-RADS) assigns a risk category for hepatocellular carcinoma (HCC) to observations on imaging. Establishing the contributions of major features for diagnosis of HCC can inform system improvement. The purpose of this study is to perform a systematic review and individual patient meta-analysis to establish the probability of HCC for each LI-RADS major feature using CT/MRI and contrast-enhanced ultrasound (CEUS) LI-RADS in high-risk patients.*Methods and Materials Multiple databases were searched up to September 2019 for studies evaluating the accuracy of CT, MRI and CEUS for HCC using LI-RADS (CT/MRI v2014/v2017/v2018; CEUS v2016/v2017). Study data were collected and centralized into a single dataset. Clustering was addressed at the study/patient levels using mixed models. Adjusted odds ratios (OR) with 95% confidence intervals (95%CI) were determined for each major feature using multivariable logistic regression with stepwise selection. The preferred reference standard was histopathology, otherwise a composite clinical reference standard was accepted. Risk of bias was assessed using QUADAS-2.*Results 32 studies were included with 1,170 observations on CT, 3,341 on MRI and 853 on CEUS. On multivariable analysis of CT/MRI LI-RADS, all major features were significantly associated with HCC except threshold growth (OR 1.64, 95%CI 0.74-3.63). Nonperipheral washout (OR 13.15, 95%CI 9.00-19.22) and nonrim arterial phase hyperenhancement (APHE) (OR 10.25, 95%CI 6.73-15.62) had stronger associations with HCC than enhancing capsule (OR 2.39, 95%CI 1.65-3.46) which persisted on sensitivity analysis limited to observations from studies at low risk of bias. Using CEUS, APHE (OR 7.26, 95%CI 4.60-11.48), late and mild washout (OR 4.12, 95%CI 2.56-6.63) and size =20 mm (OR 1.61, 95%CI 1.04 - 2.50) were associated with HCC. Twenty-five studies (78%) were at high risk of bias due to reporting ambiguity or study design flaws.*Conclusions LI-RADS major features have different independent associations with HCC. Well-designed research studies with lower risk of bias are needed to inform optimization of the system.*Clinical Relevance/Application Most CT/MRI and CEUS LI-RADS major features have independent associations with HCC; APHE and washout pattern have strong association whereas for CT/MRI LI-RADS, threshold growth has no association.

RESULTS

32 studies were included with 1,170 observations on CT, 3,341 on MRI and 853 on CEUS. On multivariable analysis of CT/MRI LI-RADS, all major features were significantly associated with HCC except threshold growth (OR 1.64, 95%CI 0.74-3.63). Nonperipheral washout (OR 13.15, 95%CI 9.00-19.22) and nonrim arterial phase hyperenhancement (APHE) (OR 10.25, 95%CI 6.73-15.62) had stronger associations with HCC than enhancing capsule (OR 2.39, 95%CI 1.65-3.46) which persisted on sensitivity analysis limited to observations from studies at low risk of bias. Using CEUS, APHE (OR 7.26, 95%CI 4.60-11.48), late and mild washout (OR 4.12, 95%CI 2.56-6.63) and size =20 mm (OR 1.61, 95%CI 1.04 - 2.50) were associated with HCC. Twenty-five studies (78%) were at high risk of bias due to reporting ambiguity or study design flaws.

CLINICAL RELEVANCE/APPLICATION

Most CT/MRI and CEUS LI-RADS major features have independent associations with HCC; APHE and washout pattern have strong association whereas for CT/MRI LI-RADS, threshold growth has no association.

SSGI20-5   Factors Affecting The Diagnostic Sensitivity Of Early-stage LI-RADS-5 (LR-5) Hepatocellular Carcinoma By Dynamic Contrast Enhanced Magnetic Resonance Imaging (MRI)

Participants
Anum Aslam, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

Our study's purpose was to quantify the impact of patient and technical factors on the sensitivity of Liver Imaging Reporting and Data System (LI-RADS) MRI Category-5 (LR-5) in cirrhosis patients per surgical pathology as the reference standard.*Methods and Materials We conducted a retrospective cohort study among three academic centers in the U.S. including 245 patients with histologically-confirmed untreated HCCs between 2009 and 2019, who had multiphasic MRI with extracellular contrast agent within 3 months of liver resection or liver transplantation. Patients beyond Milan criteria by pathology (late-stage, n=56) and HCCs = 1cm (sub-clinical, n=14) were excluded. Patient demographics, cirrhosis etiology and Child Pugh score were extracted from medical records. Two radiologists per institution independently reviewed pre-surgical MRI images and subjectively recorded technical factors, including overall image quality, motion-related image degradation, quality-limiting ascites, and arterial phase timing, as well as size and location of LR-5 observations. We used logistic regression analyses to evaluate the impact of each patient and technical factor on the lesion-level false negative rate (FNR)=(1-sensitvity), of LR-5. Clustering effect due to multiple lesions and/or multiple readers was corrected using generalized estimating equation (GEE).*Results In 175 patients with early-stage HCC, 186 tumors were confirmed on resection (n=134) and explant (n=40) specimens. Median age was 61.3 years (IQR: 57.5-66.3 years), with 136 (78%) males. Overall sensitivity of LR-5 for HCC was 0.52 [95%CI 0.48,0.56]. Child Pugh C, poor image quality, motion degradation and inadequate arterial phase timing resulted in 2.5 [95%CI 5.56,1.14], 2.56 [95%CI 4.50, 1.44], 4.5 [95% CI 20,1.02], and 3.1 [95% CI 7.69,1.29] -fold increased odds of missing LR-5 observations, respectively (Table 1).*Conclusions Factors affecting sensitivity (1-FNR) for early-stage HCC by dynamic contrast-enhanced MRI include Child C cirrhosis, overall image quality, motion degradation, and inadequate arterial phase timing.*Clinical Relevance/Application Advances in technology to remediate quality limiting factors e.g., motion compensation and automatic bolus detection, may improve sensitivity of MRI for early-stage HCC in patients with cirrhosis.

RESULTS

In 175 patients with early-stage HCC, 186 tumors were confirmed on resection (n=134) and explant (n=40) specimens. Median age was 61.3 years (IQR: 57.5-66.3 years), with 136 (78%) males. Overall sensitivity of LR-5 for HCC was 0.52 [95%CI 0.48,0.56]. Child Pugh C, poor image quality, motion degradation and inadequate arterial phase timing resulted in 2.5 [95%CI 5.56,1.14], 2.56 [95%CI 4.50, 1.44], 4.5 [95% CI 20,1.02], and 3.1 [95% CI 7.69,1.29] -fold increased odds of missing LR-5 observations, respectively (Table 1).

CLINICAL RELEVANCE/APPLICATION

Advances in technology to remediate quality limiting factors e.g., motion compensation and automatic bolus detection, may improve sensitivity of MRI for early-stage HCC in patients with cirrhosis.

SSGI20-6   Diagnostic Performance and Positive Predict Value For HCC of CEUS and CT/MRI LI-RADS : A Systematic Review And Meta-analysis

Participants
Zhengyi Qin, Tianjin, China (*Presenter*) Nothing to Disclose

PURPOSE

To compare the proportion of HCC (hepatocellular carcinoma) in each CEUS LI-RADS and CT/MRI LI-RADS category and the diagnostic performance of LR-5/M.*Methods and Materials We searched PubMed, Embase, and Cochrane Central from 2014 to October 2020 for studies on CT/MRI LI-RADS V2014, V2017, and V2018 and CEUS LI-RADS V2016 and V2017. The proportion of HCC and overall malignancy in each LI-RADS category and the sensitivity and specificity of LR-5 and LR-M categories were determined using a random effects model. The quality of the included studies was assessed using the QADAS-2 tool.*Results Initially, 534 studies were identified, of which only 34 were included: CEUS LI-RADS and CT/MRI LI-RADS (n=1), CEUS LI-RADS (n=7), and CT/MRI LI-RADS (n=26). The CT/MRI studies comprised 4,656 patients with 5,839 lesions, including 4,088 HCCs, and the CEUS studies comprised 4,977 patients with 5,464 lesions, including 3,994 HCCs. There was no HCC in LR-1, and there was no significant difference in the proportion of HCC in LR-2--5 between CEUS and CT/MRI LI-RADS. The sensitivity and specificity of CEUS LR-5 for HCC were 0.73 (95% CI: 0.68--0.78) and 0.94 (95% CI: 0.90--0.96), respectively, and the area under the SROC curve was 0.72. The LR-5 sensitivity and specificity of CT/MRI were 0.69 (95% CI: 0.64--0.74) and 0.92 (95% CI: 0.89--0.94), respectively, and the area under the SROC curve was 0.74. There were no significant differences in the sensitivity and specificity of CEUS and CT/MRI LR-5. The sensitivity and specificity of CEUS LR-M for non-HCC malignant tumors were 0.80 (95% CI: 0.88--0.88) and 0.92 (95% CI: 0.87-0.95), respectively, and the area under the SROC curve was 0.89. The sensitivity and specificity of CT/MRI LR-M were 0.67 (95% CI: 0.61--0.72) and 0.97 (95% CI: 0.95--0.99), respectively, and the area under the SROC curve was 0.79. The differences in sensitivity and specificity of CEUS and CT/MRI LR-M were statistically significant.*Conclusions Both CEUS and CT/MRI LR-5 have similar diagnostic performance and can be efficient tools in HCC diagnosis. With the increase in LI-RADS category, the proportion of HCC increased. CEUS and CT/MRI had similar positive predictive values for HCC in LR-1-5 categories. For non-HCC malignancies, CEUS LR-M had higher sensitivity and may be helpful for diagnosis.*Clinical Relevance/Application 1.CEUS and CT/MRI LI-RADS have similar PPV of HCC in each category. So there may be no need to manage observations in same category differently.2.CEUS and CT/MRI LR-M have their own advantage for diagnosing non-HCC malignancies , a combination of multiple imaging and laboratory examination may diagnose LR-M observations better.

RESULTS

Initially, 534 studies were identified, of which only 34 were included: CEUS LI-RADS and CT/MRI LI-RADS (n=1), CEUS LI-RADS (n=7), and CT/MRI LI-RADS (n=26). The CT/MRI studies comprised 4,656 patients with 5,839 lesions, including 4,088 HCCs, and the CEUS studies comprised 4,977 patients with 5,464 lesions, including 3,994 HCCs. There was no HCC in LR-1, and there was no significant difference in the proportion of HCC in LR-2--5 between CEUS and CT/MRI LI-RADS. The sensitivity and specificity of CEUS LR-5 for HCC were 0.73 (95% CI: 0.68--0.78) and 0.94 (95% CI: 0.90--0.96), respectively, and the area under the SROC curve was 0.72. The LR-5 sensitivity and specificity of CT/MRI were 0.69 (95% CI: 0.64--0.74) and 0.92 (95% CI: 0.89--0.94), respectively, and the area under the SROC curve was 0.74. There were no significant differences in the sensitivity and specificity of CEUS and CT/MRI LR-5. The sensitivity and specificity of CEUS LR-M for non-HCC malignant tumors were 0.80 (95% CI: 0.88--0.88) and 0.92 (95% CI: 0.87-0.95), respectively, and the area under the SROC curve was 0.89. The sensitivity and specificity of CT/MRI LR-M were 0.67 (95% CI: 0.61--0.72) and 0.97 (95% CI: 0.95--0.99), respectively, and the area under the SROC curve was 0.79. The differences in sensitivity and specificity of CEUS and CT/MRI LR-M were statistically significant.

CLINICAL RELEVANCE/APPLICATION

1.CEUS and CT/MRI LI-RADS have similar PPV of HCC in each category. So there may be no need to manage observations in same category differently.2.CEUS and CT/MRI LR-M have their own advantage for diagnosing non-HCC malignancies , a combination of multiple imaging and laboratory examination may diagnose LR-M observations better.

SSMS02-1   Assessment Of Endothelial Dysfunction In Type 2 Diabetics By Carotid Artery Intimal Medial Thickness(CIMT) And Brachial Artery Flow-mediated Dilation (FMD) Response.

Participants
Chetankumar Mehta, MBBS,MD, Vadodara, India (*Presenter*) Nothing to Disclose

PURPOSE

Endothelial dysfunction is an important determinant of altered vascular reactivity and plays a major role in the genesis of micro- and macro-vascular complications in diabetes. Endothelial dysfunction can be expressed as the impairment of endothelial dependent vasodilation and increased CIMT which is a non-invasive marker of atherosclerosis. The purpose of this study is to assess the endothelial function in patients with Type 2 diabetes mellitus (T2DM) using brachial artery flow-mediated dilation (FMD) response and carotid artery intima-media thickness (CIMT) and to assess the correlation between the two parameters.*Methods and Materials T2DM patients with and without complications who had visited the OPD were enrolled for the study. Individuals with hypertension, impaired renal function, dyslipidaemia, smokers and those with any other major disease were excluded. 37 T2DM patients were included. 37 age and sex matched controls were enrolled. They were examined using 5-12 MHz linear array transducer of Phillips Affiniti 50G at the Radiology Department. CIMT was measured at the posterior wall of the common carotid artery, 2 cm before the bifurcation, as the distance between first and second echogenic lines of anterior and posterior arterial walls in supine position. Brachial artery diameter was measured from two-dimensional images 2-15 cm above the elbow. The lumen diameter (LD) was measured: (i) at baseline after at least 10 min of rest in the supine position; (ii) during reactive hyperaemia induced by a forearm cuff inflated to supra-systolic levels for 5 min. The difference between the two LD was expressed as percentage change related to the baseline scan (FMD).The data was analysed with standard statistical tests.*Results Brachial artery FMD value in type 2 diabetic (4.67±2.53%) was significantly lower (P < 0.05) when compared with the control (9.87±3.72%). CIMT in type 2 diabetic (1.03±0.17mm) was significantly higher (P < 0.05) as compared with the control (0.55±0.15mm). FMD correlated negatively with CIMT (r = -0.14, P < 0.05).*Conclusions Abnormal FMD and increased CIMT were present in type 2 diabetic patients. Both these parameters negatively correlated with each other which suggest an independent association between impaired FMD and endothelial dysfunction.*Clinical Relevance/Application Increased CIMT and impaired FMD in the brachial artery reflect changes of endothelial dysfunction; the initial step in diabetic vascular complications and atherosclerosis which may be reversible in early stages. CIMT and FMD can hence be used for screening of endothelial dysfunction in patients with T2DM and prevention of complications by early initiation of prophylaxis.

RESULTS

Brachial artery FMD value in type 2 diabetic (4.67±2.53%) was significantly lower (P < 0.05) when compared with the control (9.87±3.72%). CIMT in type 2 diabetic (1.03±0.17mm) was significantly higher (P < 0.05) as compared with the control (0.55±0.15mm). FMD correlated negatively with CIMT (r = -0.14, P < 0.05).

CLINICAL RELEVANCE/APPLICATION

Increased CIMT and impaired FMD in the brachial artery reflect changes of endothelial dysfunction; the initial step in diabetic vascular complications and atherosclerosis which may be reversible in early stages. CIMT and FMD can hence be used for screening of endothelial dysfunction in patients with T2DM and prevention of complications by early initiation of prophylaxis.

SSMS02-2   Bridging The Gap: Examining Disparities In Cancer Screening Among Asian Subgroups

Participants
Eric Davis, MD, San Francisco, California (*Presenter*) Nothing to Disclose

PURPOSE

While Asian Americans are the fastest growing racial minority group in the United States, little research exist examining cancer screening disparities in this population. As breast cancer and colorectal cancer (CRC) rates have been increasing in Asian Americans, we aimed to examine the racial differences in breast cancer screening and CRC screening adherence as they pertain to Asian Americans.*Methods and Materials Retrospective analysis of the 2018 National Health Interview Survey (NHIS) data was performed. This dataset was a nationally representative, annual federal cross-sectional survey (response rate 64%). Multiple variable analyses evaluated the association between all Asians and Asian ethnic subgroups with breast cancer and colorectal cancer screening adherence, accounting for complex survey design.*Results Regarding CRC screening, 11,003 respondents between 50-75 years old were included. Of eligible respondents, 65.2% reported receiving recommended CRC screening, while 54.8% of Asian participants reported receiving recommended CRC screening. Multiple variable analyses revealed that Asian participants were less likely to report recommended CRC screening (OR 0.58, 95% CI 0.46 to 0.75, p < 0.001), compared with Whites. Compared with Whites, Asian Indian (OR 0.46, 95% CI 0.28 to 0.76, p = 0.003) and Other Asian participants (OR 0.52, 95% CI 0.36 to 0.76, p =

0.001) were less likely to report recommended CRC screening. Regarding breast cancer screening, 7,511 respondents between 40-74 years old were included. Of eligible respondents, 58.8% reported receiving breast cancer screening within 1 year, 54.1% of Asian participants reported receiving breast cancer screening. Multiple variable analyses revealed that Asian participants were less likely to report breast cancer screening (OR 0.74, 95% CI 0.55 to 0.99, p = 0.049), compared with Whites. No statistically significant differences were found comparing individual Asian subgroups with Whites.*Conclusions When compared to Whites, Asian Americans are less likely to be up-to-date with recommended CRC screening. Additionally, Asian Americans had a lower odds of reporting breast cancer screening when compared to Whites. As the incidence of breast cancer and CRC increases in Asian Americans, targeted interventions are needed to improve care and reduce health disparities in this population.*Clinical Relevance/Application To the authors' knowledge, this is the largest study to date examining breast cancer screening and CRC screening in Asian Americans. Also, it is the largest study examining screening difference and sociodemographic differences between Asian American subgroups.

RESULTS

Regarding CRC screening, 11,003 respondents between 50-75 years old were included. Of eligible respondents, 65.2% reported receiving recommended CRC screening, while 54.8% of Asian participants reported receiving recommended CRC screening. Multiple variable analyses revealed that Asian participants were less likely to report recommended CRC screening (OR 0.58, 95% CI 0.46 to 0.75, p < 0.001), compared with Whites. Compared with Whites, Asian Indian (OR 0.46, 95% CI 0.28 to 0.76, p = 0.003) and Other Asian participants (OR 0.52, 95% CI 0.36 to 0.76, p = 0.001) were less likely to report recommended CRC screening. Regarding breast cancer screening, 7,511 respondents between 40-74 years old were included. Of eligible respondents, 58.8% reported receiving breast cancer screening within 1 year, 54.1% of Asian participants reported receiving breast cancer screening. Multiple variable analyses revealed that Asian participants were less likely to report breast cancer screening (OR 0.74, 95% CI 0.55 to 0.99, p = 0.049), compared with Whites. No statistically significant differences were found comparing individual Asian subgroups with Whites.

CLINICAL RELEVANCE/APPLICATION

To the authors' knowledge, this is the largest study to date examining breast cancer screening and CRC screening in Asian Americans. Also, it is the largest study examining screening difference and sociodemographic differences between Asian American subgroups.

SSMS02-3   Clinical Utility, Safety ; Efficacy Of ClariscanTM - Multinational Experience From Two Post Marketing Surveillance Studies.

Participants
Anand Bherwani, MD, Brookfield, Wisconsin (*Presenter*) Leaders Program, General Electric Company;Medical Director, General Electric Company

PURPOSE

To evaluate the safety, efficacy and clinical usage patterns of ClariscanTM (gadoterate meglumine) in multi-regional, multi-ethnic population subgroups in a real-world clinical setting from different regions of the globe.*Methods and Materials Data was obtained from two individual cross-sectional multicenter observational studies with prospective recruitment in different regions [Europe (2018-2019) & South Korea (2019-2020)] for patients undergoing CE (contrast enhanced) - MR imaging with Clariscan as part of their routine clinical workup. Demographic information, clinical diagnoses, relevant medical histories, concomitant medications, indication for CE-MR, contrast dosage and procedure details were recorded for all the participating patients by trained study staff. The diagnostic efficacy was based on the data collected by the local radiologist including changes in radiological diagnosis, diagnostic confidence, and image quality on a 4-point scale (poor, fair, good, excellent). Any spontaneous reports of AEs (adverse events) were recorded up to 7 days after MR procedure and classified in terms of severity, course of treatment and latency (immediate: <1h post-injection, delayed: 1h-7d post-injection).*Results A total of 1513 patients from 8 centers across 5 European countries and 1379 patients from 6 centers in South Korea were included. For the total cohort of 2892 patients, mean age was 54 ±21 years, 56% were females, 522 patients (18%) suffered from comorbid conditions and 129 patients (4.5%) had a history of allergy. The indication for CE-MR examinations included CNS in 53%, musculoskeletal in 14%, abdominal 11%, breast 8% and others 14%. The mean dose of Clariscan administered was 0.11 mmol/kg (body weight). Change in radiological diagnosis was recorded in 39% of the patients and enhanced diagnostic confidence in 93% of the patients. The percentage of cases with level of confidence >80% increased from 21.4% at baseline to 66.4% after CM (contrast media) administration. Image quality after administration of CM was considered good in 39% cases and excellent in 59%. A total of 14 patients (0.5%) reported AEs with only 1 (0.03%) considered serious. All the AEs were treated conservatively and resolved spontaneously.*Conclusions This multi-national study confirmed the real-world clinical usage of Clariscan for a wide range of indications with an excellent safety and efficacy profile.*Clinical Relevance/Application The recent concerns from gadolinium retention have led to a steady decline in the use of linear agents and shift of clinical trend towards usage of macrocyclic agents. The current study looks at the real-world CM usage patterns, safety & efficacy of Clariscan™ (gadoterate meglumine) in multi-regional, multi-ethnic population.

RESULTS

A total of 1513 patients from 8 centers across 5 European countries and 1379 patients from 6 centers in South Korea were included. For the total cohort of 2892 patients, mean age was 54 ±21 years, 56% were females, 522 patients (18%) suffered from comorbid conditions and 129 patients (4.5%) had a history of allergy. The indication for CE-MR examinations included CNS in 53%, musculoskeletal in 14%, abdominal 11%, breast 8% and others 14%. The mean dose of Clariscan administered was 0.11 mmol/kg (body weight). Change in radiological diagnosis was recorded in 39% of the patients and enhanced diagnostic confidence in 93% of the patients. The percentage of cases with level of confidence >80% increased from 21.4% at baseline to 66.4% after CM (contrast media) administration. Image quality after administration of CM was considered good in 39% cases and excellent in 59%. A total of 14 patients (0.5%) reported AEs with only 1 (0.03%) considered serious. All the AEs were treated conservatively and resolved spontaneously.

CLINICAL RELEVANCE/APPLICATION

The recent concerns from gadolinium retention have led to a steady decline in the use of linear agents and shift of clinical trend towards usage of macrocyclic agents. The current study looks at the real-world CM usage patterns, safety & efficacy of Clariscan™ (gadoterate meglumine) in multi-regional, multi-ethnic population.

SSMS02-4   Frequent Whole-body MRI Plus Serological Follow-up Identifies Some But Not All Smoldering Multiple Myeloma Patients Before Progressing Into Symptomatic Disease With End-Organ Damage

Participants
Markus Wennmann, MD, Heidelberg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

The goal of this prospective study was to investigate the clinical course of smoldering multiple myeloma (SMM) patients with whole-body magnetic resonance imaging (wb-MRI) and serological follow-up every 6 months for the study.*Methods and Materials From 2014 to 2019, ninety-six SMM patients negative for end-organ damage and SLiM-criteria at initial assessment were prospectively included in this study. Wb-MRI and serological follow-up were performed at baseline and every 6 months thereafter for the study, and every patient was seen every 3 months either at our center or by an experienced, local oncologist. Primary endpoint was time to progression into MM according to SLiM-CRAB-criteria. This study was approved by the institutional review board.*Results The 1-, 2- and 3-year progression rates according to the current SLiM-CRAB-criteria of the International Myeloma Working Group (IMWG) were 10%, 19% and 25%, respectively. Seven of the 22 patients (32%) who progressed into MM showed SLiM-criteria but no end-organ damage. Of these, 4 progressed with > 1 focal lesion (FL) or a growing FL, and 3 due to serum free light-chain (SLFC)-ratio >=100. Fifteen out of the 22 progressing patients (68%) however, had end-organ damage at progression. Four of those 7 patients who only progressed by SLiM-criteria without end-organ damage were identified by MRI only. In all but one patient, osteolytic lesions (OL) showed corresponding FL in the wb-MRI at time of their initial diagnosis. The time between first appearance of the corresponding FL and the diagnosis of the respective OL was highly variable between patients.*Conclusions The updated disease definition of the IMWG reduced the proportion of patients with end-organ damage at progression by only one third. Therefore, further improvement of prognostic factors and closer follow-up intervals are needed. Wb-MRI accounts for detection of more than half of patients who progress with SLiM-criteria only, and consequently is crucial to reduce the appearance of end-organ damage in SMM patients.*Clinical Relevance/Application In 2014, SLiM-criteria (including >1 FL in MRI) were added to the definition of MM in order to enable earlier therapy initiation to avoid occurrence of end-organ damage.

RESULTS

The 1-, 2- and 3-year progression rates according to the current SLiM-CRAB-criteria of the International Myeloma Working Group (IMWG) were 10%, 19% and 25%, respectively. Seven of the 22 patients (32%) who progressed into MM showed SLiM-criteria but no end-organ damage. Of these, 4 progressed with > 1 focal lesion (FL) or a growing FL, and 3 due to serum free light-chain (SLFC)-ratio >=100. Fifteen out of the 22 progressing patients (68%) however, had end-organ damage at progression. Four of those 7 patients who only progressed by SLiM-criteria without end-organ damage were identified by MRI only. In all but one patient, osteolytic lesions (OL) showed corresponding FL in the wb-MRI at time of their initial diagnosis. The time between first appearance of the corresponding FL and the diagnosis of the respective OL was highly variable between patients.

CLINICAL RELEVANCE/APPLICATION

In 2014, SLiM-criteria (including >1 FL in MRI) were added to the definition of MM in order to enable earlier therapy initiation to avoid occurrence of end-organ damage.

SSMS02-6   Automatic MRI Analysis In Multiple Myeloma: A Framework Combining Deep Learning For Automatic Pelvic Bone Marrow Segmentation And Radiomics For Prediction Of Plasma Cell Infiltration In Multiple Myeloma Patients

Participants
Markus Wennmann, MD, Heidelberg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To establish an automated framework including (I) automatic pelvic bone marrow (BM) segmentation from MRI and (II) a radiomics model to predict the plasma cell infiltration (PCI) in Multiple Myeloma (MM) patients.*Methods and Materials Five cohorts including a total of 541 MRIs from 270 patients were included; 158 patients had received MRI on one 1.5T MRI Scanner and had information on PCI from concomitant biopsy at the iliac crest available. MRIs without biopsy data were used for training of the nnU-Net only, which is state of the art for medical image segmentation. MRIs with biopsy data were split by date into a training-set (n=116) for both, nnU-Net and radiomics model, and an independent test-set for the framework (n=42). BM segmentations of the right and left pelvic bone on coronal T1tse images on the training cohort were used for training of the nnU-Net. A random forest classifier was trained on the pelvic radiomics features to predict PCI. The framework was then tested on the independent test-set. Dice scores report accuracy of segmentations and mean absolute error (MAE) in [%PCI] reports the accuracy of the PCI prediction. For comparison, two radiologists rated the diffuse infiltration according to 3 levels of severity (none-to-mild vs. moderate vs. severe). The mean PCI within each severity level from the training set was determined and assigned as a prediction to patients with the same level diffuse infiltration in the test-set (the radiologists` PCI prediction). This study was approved by the institutional review board.*Results The mean Dice score of the nnU-Net segmentation for right / left pelvic bone marrow on 8 cases of the test-set (last 8 by acquisition date) were 0.94 and 0.94, respectively, the mean Dice score between manual pelvic BM segmentation of two radiologists on these 8 cases were 0.87 and 0.88. The MAE of the prediction of PCI by the automated framework was 14.3 [%PCI]. The MAE of the radiologists PCI predictions were 16.1 [%PCI] (rater 1) and 16.7 [%PCI] (rater2).*Conclusions We established automatic BM segmentation with radiologist level precision, which is a critical step towards automated analysis of MM MRI. Radiomics analysis of these segmentations can predict PCI with considerable accuracy. Further improvement of the PCI prediction model is necessary and is currently in progress, by (I) adding T2 and DWI sequences, (II) adding 600 additional cases from a second institution, (III) a prospective, multi-scanner radiomics feature stability study (recruitment and measurements completed, data analysis in progress).*Clinical Relevance/Application Automatic bone marrow (BM) segmentation is a crucial step to automate reading of multiple myeloma (MM) MRI. Plasma cell infiltration (PCI) is a critical marker for staging and risk assessment in MM.

RESULTS

The mean Dice score of the nnU-Net segmentation for right / left pelvic bone marrow on 8 cases of the test-set (last 8 by acquisition date) were 0.94 and 0.94, respectively, the mean Dice score between manual pelvic BM segmentation of two radiologists on these 8 cases were 0.87 and 0.88. The MAE of the prediction of PCI by the automated framework was 14.3 [%PCI]. The MAE of the radiologists PCI predictions were 16.1 [%PCI] (rater 1) and 16.7 [%PCI] (rater2).

CLINICAL RELEVANCE/APPLICATION

Automatic bone marrow (BM) segmentation is a crucial step to automate reading of multiple myeloma (MM) MRI. Plasma cell

infiltration (PCI) is a critical marker for staging and risk assessment in MM.

SSBR08-3   Evaluation Of ADC In Regard To Reproducibility And Diagnostic Accuracy As Well As Possible Significance Of Pre - And Post - Contrast Acquisition And Employment Of Different B Values.

Participants
Raoul Varga, Vienna, Austria (*Presenter*) Nothing to Disclose

PURPOSE

Quantative evaluation of the apparent diffuse coefficient (ADC) obtain by DWI imaging has been proven as a viable decision guidance tool to determined malignancy in a lesion.An international working group recommends certain parameters for breast DWI. We evaluated the reproducibility and accuracy of ADC calculated from the suggested b-value combinations and investigated the influence of contrast media (CM) administration on the ADC.*Methods and Materials In this IRB approved, monocentric, cross-sectional retrospective study patients with a histologically verified suspicious finding who underwent breast MRI were included. The 3T breast MRI protocol included a DWI sequence with multiple b-values, which was acquired prospectively before and after CM administration. ADC maps were calculated by in-line monoexponential fitting with b-values 0 /800 mm/s2 and 50 and 800mm/s2).Two independent readers (R1, R2) reviewed the images in separate sessions for 0/800 and 50/800 pre- and post-CM. The standard of reference was histology.Bland Altmann plots as well as intraclass correlation coefficients (ICCs) for intrareader and interreader agreement, different b values (0/800, 50/800 s/mm2) and pre- and post-CM was calculated. Diagnostic accuracy was evaluated and compared by calculating the area under the ROC curve (AUC).*Results 91 lesions in 89 patients were examined (mean age 50.7 years, standard deviation 13.9). ADC values were significantly lower post-CM compared to pre-CM (pre-CM 1.08, 95% CI1.01- 1.15 x 10-3 mm2/s; post-CM 1.13, 95% CI 1.06- 1.19 x 10-3 mm2/s, P<0.001) for both b-values 0/800 and 50/800 s/mm2.We found an almost perfect inter-reader agreement pre-/post-CM and with b values 0/800 and 50/800 (ICC ranging from 0.853 to 0.939). We found an almost perfect intra-reader agreement with ICC ranging from 0.919 to 0.957. Bland Altman plot demonstrated no systematic difference between readers.ROC diagnostic performance analysis revealed good diagnostic accuracy between b values 0/800 and 50/800 s/mm2 as well as pre- and post- without significant differences (P>0,05)*Conclusions High reproducibility and diagnostic accuracy prove reliable use of ADC characteristics, with no significant difference between pre- and post-CM and between different b values 0/800 and 50/800.*Clinical Relevance/Application Since pre- and post-contrast and adjusted b value sequences revealed no significant difference, individual tailoring of the image protocol to clinical needs becomes possible.

RESULTS

91 lesions in 89 patients were examined (mean age 50.7 years, standard deviation 13.9). ADC values were significantly lower post-CM compared to pre-CM (pre-CM 1.08, 95% CI1.01- 1.15 x 10-3 mm2/s; post-CM 1.13, 95% CI 1.06- 1.19 x 10-3 mm2/s, P<0.001) for both b-values 0/800 and 50/800 s/mm2.We found an almost perfect inter-reader agreement pre-/post-CM and with b values 0/800 and 50/800 (ICC ranging from 0.853 to 0.939). We found an almost perfect intra-reader agreement with ICC ranging from 0.919 to 0.957. Bland Altman plot demonstrated no systematic difference between readers.ROC diagnostic performance analysis revealed good diagnostic accuracy between b values 0/800 and 50/800 s/mm2 as well as pre- and post- without significant differences (P>0,05)

CLINICAL RELEVANCE/APPLICATION

Since pre- and post-contrast and adjusted b value sequences revealed no significant difference, individual tailoring of the image protocol to clinical needs becomes possible.

SSBR08-6   Introduction Of A Bi-RADS Analogous Breast Apparent Diffusion Coefficient (bADC) Category System Derived From A Multicentric Breast MRI Database.

Participants
Hubert Bickel, MD, Vienna, Austria (*Presenter*) Nothing to Disclose

PURPOSE

Diffusion weighted imaging (DWI) is increasingly used as an additional MRI tool to improve the diagnosis of breast lesions. This calls

for a simple tool to integrate Apparent Diffusion Coefficient (ADC) into clinical breast MRI reporting, such as the Breast Imaging Reporting and Data System (BI-RADS). The purpose of this study was to develop a simple, generally applicable breast ADC category (bADC) system comparable to the BI-RADS classification system.*Methods and Materials 1625 females (mean age: 55.9 (13.8) years) with 1736 pathologically verified breast lesions from eleven study populations from seven different institutions with different DWI acquisition schemes were included in this IRB approved retrospective study. Mean ADC values of different tumor subtypes were calculated and compared using one-way ANOVA and Games-Howell post-hoc test. Five BI-RADS analogous bADC categories (bADC I-V) were developed by plotting ADC versus cumulative malignancy rates and receiver operating characteristics (ROC) analysis.*Results Mean ADC differed significantly between benign and malignant lesions (p < .001), as well as between invasive cancers, ductal carcinoma in situ and benign lesions (p < .001). The calculated thresholds for the bADC categories were: bADC I =1.9 x 10-3 mm2/s (cumulative malignancy rate < 0.1%); bADC II 1.5 to <1.9 x 10-3 mm2/s (0.1 - 1.7 %); bADC III 1.2 to <1.5 x 10-3 mm2/s (1.8 - 10 %); bADC IV 1.0 to <1.2 x 10-3 mm2/s (10 - 24.5%); and bADC V <1.0 x 10-3 mm2/s (>24.5 %). The latter threshold was chosen at a positive predictive value of 95.8% for invasive versus non-invasive breast cancer according to the ROC-analysis.*Conclusions The presented bADC category system provides generally applicable, simple thresholds including rule-in and rule-out criteria, comparable to BI-RADS, to guide clinical decision making.*Clinical Relevance/Application The bADC category system provides a simple tool to in order to integrate ADC into clinical breast MRI reporting.

RESULTS

Mean ADC differed significantly between benign and malignant lesions (p < .001), as well as between invasive cancers, ductal carcinoma in situ and benign lesions (p < .001). The calculated thresholds for the bADC categories were: bADC I =1.9 x 10-3 mm2/s (cumulative malignancy rate < 0.1%); bADC II 1.5 to <1.9 x 10-3 mm2/s (0.1 - 1.7 %); bADC III 1.2 to <1.5 x 10-3 mm2/s (1.8 - 10 %); bADC IV 1.0 to <1.2 x 10-3 mm2/s (10 - 24.5%); and bADC V <1.0 x 10-3 mm2/s (>24.5 %). The latter threshold was chosen at a positive predictive value of 95.8% for invasive versus non-invasive breast cancer according to the ROC-analysis.

CLINICAL RELEVANCE/APPLICATION

The bADC category system provides a simple tool to in order to integrate ADC into clinical breast MRI reporting.

SSCH02-2   Costal Pleura-attached Noncalcified Nodules Newly Seen On Annual Low-dose Ct Screenings

Participants
Ye Qing Zhu, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

It has previously been demonstrated that solid costal pleura-attached noncalcified nodules (CP-NCN) with average diameter<10.0 mm and lentiform, oval, semicircular (LOS) or triangular shapes and smooth margins on baseline CT do not need short-term follow-up and instead can be recommended to return for annual repeat screening. Determine whether the same criteria apply for new CP-NCNs seen on annual repeat screening rounds.*Methods and Materials In 111,102 annual screening scans in the International Early Lung Cancer Action Program between 1992 and 2019, we identified 21 new solid CP-NCNs, 3.0 mm to 30.0 mm in average diameter that were lung cancer (median months to diagnosis:1.8, IQR: 1.1-4.7). In 4,425 annual screening scans in the Mount Sinai Early Lung and Cardiac Action Program between 2010 and 2019, we identified 56 new solid CP-NCNs, 3.0 mm to 30.0 mm; 55 were benign (median follow-up: 79.6 months, IQR:61.0-102.5). Shape (triangular, LOS, polygonal, round, or irregular), margin (smooth or non-smooth), pleural attachment (broad or narrow), emphysema and fibrosis within 10 mm of each CP-NCN was determined. Intra- and inter-reader agreements (B statistic) on triangular/LOS shaped solid CP-NCN with smooth margin were assessed.*Results Mean age of the participants with the 76 CP-NCNs was 72.2 years (SD= 8.8 at time of annual repeat CT, median pack-years of smoking was 40.2 (IQR: 27.5-53.8); 35 (46.1%) were men and 41 (54.0%) women. Size, shape, margin, and emphysema and fibrosis within a 10.0mm radius of the CP-NCNs were significant predictors of malignancy status. The median diameter of the 55 solid benign CP-NCNs was significantly smaller than of the 21 solid malignant CP-NCNs (4.2 mm vs. 11.0 mm, p < .001). Emphysema and fibrosis within a 10.0 mm radius of the CP-NCN was significant as malignant CP-NCNs more frequently had emphysema [17 (81.0%) vs. 21 (38.2%), p=.003] and fibrosis [4 (19.0%) vs. 2 (3.6%), p=.045]. CP-NCN shape were significantly different between benign and malignant CP-NCNs (p=.02). All CP-NCNs< 10.0 mm in average diameter with triangular or LOS shapes and smooth margins were benign. None of the 21 malignant CP-NCNs of any size had triangular or LOS shapes and smooth margins when they were first identified on annual repeat screening round. Intra- and interobserver agreement for triangular or LOS shaped CP-NCNs with smooth margins were almost perfect based on the B-statistic.*Conclusions The same follow-up recommendation can be used for CP-NCNs newly seen on annual screening rounds that were developed for baseline CP-NCNs.*Clinical Relevance/Application New solid CP-NCNs<10 mm with triangular or LOS shapes and smooth margins on annual screening rounds were all benign. Annual follow-up is recommended rather than immediate work-up.

RESULTS

Mean age of the participants with the 76 CP-NCNs was 72.2 years (SD= 8.8 at time of annual repeat CT, median pack-years of smoking was 40.2 (IQR: 27.5-53.8); 35 (46.1%) were men and 41 (54.0%) women. Size, shape, margin, and emphysema and fibrosis within a 10.0mm radius of the CP-NCNs were significant predictors of malignancy status. The median diameter of the 55 solid benign CP-NCNs was significantly smaller than of the 21 solid malignant CP-NCNs (4.2 mm vs. 11.0 mm, p < .001). Emphysema and fibrosis within a 10.0 mm radius of the CP-NCN was significant as malignant CP-NCNs more frequently had emphysema [17 (81.0%) vs. 21 (38.2%), p=.003] and fibrosis [4 (19.0%) vs. 2 (3.6%), p=.045]. CP-NCN shape were significantly different between benign and malignant CP-NCNs (p=.02). All CP-NCNs< 10.0 mm in average diameter with triangular or LOS shapes and smooth margins were benign. None of the 21 malignant CP-NCNs of any size had triangular or LOS shapes and smooth margins when they were first identified on annual repeat screening round. Intra- and interobserver agreement for triangular or LOS shaped CP-NCNs with smooth margins were almost perfect based on the B-statistic.

CLINICAL RELEVANCE/APPLICATION

New solid CP-NCNs<10 mm with triangular or LOS shapes and smooth margins on annual screening rounds were all benign. Annual follow-up is recommended rather than immediate work-up.

SSCH02-3   Accuracy Of Nodule Volume Measurement For Lung Cancer Screening On A Photon-counting-detector (PCD) CT Scanner

Participants
Chelsea Dunning, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the accuracy of nodule volume quantification in lung cancer screening using an investigational whole-body photon-counting-detector (PCD) CT compared to conventional energy-integrating detector (EID) CT.*Methods and Materials Sixteen lung nodules at low and high contrasts (-630 & 100 HU), three sizes (5, 8, & 10 mm diameter), and two shapes (round and star) were attached throughout an anthropomorphic chest phantom (Lungman, Kyoto Kagaku). The phantom was scanned with a conventional

dual-source EID-CT scanner (SOMATOM Force, Siemens) using 100 kV with an added tin beam-shaping filter (100Sn) at three dose levels (volume CT dose index (CTDIvol): 0.3, 0.6, and 1.2 mGy). The phantom was also scanned with a whole-body PCD-CT (NAEOTOM Alpha, Siemens) at 100Sn kV using high-resolution mode at three dose levels that were approximately matched to those on the EID-CT. A high-dose scan was also acquired at 120 kV and 9.2 mGy, which is used as a reference. All images were reconstructed with quantitative kernels with iterative reconstruction or noise reduction (Qr54-3 for EID-CT; Qr56-3 for PCD-CT). The volumes of all nodules and the noise in each image series were measured using a semi-automated segmentation tool (MM Oncology, Siemens). The volume measurement accuracy was expressed as the percent difference between the segmented volume at each dose level and that of the highest dose for both EID-CT and PCD-CT.*Results PCD-CT reduced the image noise by 36%, 35%, and 45% at the three dose levels. For the high-contrast nodules, the percent errors for PCD-CT at 0.3 mGy (-7.5%, -2.7%, & -1.8% for 5, 8, & 10mm round nodules and -8.6%, -5.9%, & -4.8% for star-shaped nodules) were similar to EID-CT at 0.6 mGy (1.5%, -3.5%, & -0.4% for 5, 8, & 10mm round nodules and -8.1%, -1%, & -1.9% for star-shaped nodules). Among all the low-contrast nodules, the percent error ranged between -10.8% & -3.8% for PCD-CT at 0.3 mGy; which was comparable to the percent error range of -9.8% & 0% for EID-CT at 0.6 mGy.*Conclusions Volume measurement accuracy for lung cancer screening was maintained for both low- and high-contrast nodules for PCD-CT at a reduced dose, with the added benefit of reduced noise, compared to EID-CT.*Clinical Relevance/Application Measurement of nodule volume for lung cancer screening can be done on a PCD-CT scanner at lower radiation dose and noise without compromising volume accuracy.

RESULTS

PCD-CT reduced the image noise by 36%, 35%, and 45% at the three dose levels. For the high-contrast nodules, the percent errors for PCD-CT at 0.3 mGy (-7.5%, -2.7%, & -1.8% for 5, 8, & 10mm round nodules and -8.6%, -5.9%, & -4.8% for star-shaped nodules) were similar to EID-CT at 0.6 mGy (1.5%, -3.5%, & -0.4% for 5, 8, & 10mm round nodules and -8.1%, -1%, & -1.9% for star-shaped nodules). Among all the low-contrast nodules, the percent error ranged between -10.8% & -3.8% for PCD-CT at 0.3 mGy; which was comparable to the percent error range of -9.8% & 0% for EID-CT at 0.6 mGy.

CLINICAL RELEVANCE/APPLICATION

Measurement of nodule volume for lung cancer screening can be done on a PCD-CT scanner at lower radiation dose and noise without compromising volume accuracy.

SSCH02-5 Learning Curve For CT-guided Percutaneous Transthoracic Core Needle Biopsy In A Tertiary Referral Hospital

Participants
Rohee Park, MD, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

The experience required to adequately perform CT-guided percutaneous transthoracic needle biopsy (PTNB) has not been clearly determined. We aimed to investigate the learning curve for CT-guided PTNB in a tertiary referral hospital and determine the number of procedures required.*Methods and Materials From March 2011 to August 2017, 17 new operators performed CT-guided PTNBs. Up to 200 consecutive procedures were enrolled for each operator. Learning curves for CT-guided PTNB with respect to diagnostic performance, false negative rate, pneumothorax, and hemoptysis were evaluated using a cumulative summation method. Acceptable failure rates were defined as 0.1 for diagnostic performance and false negative rate; 0.25 for pneumothorax; and 0.05 for hemoptysis. A subgroup analysis according to prior experience of PTNB was performed.*Results A total of 3261 procedures in 3134 patients (mean age, 67.7±12.1 years; 1876 men) were included. Overall diagnostic accuracy was 94.2% (2191/3141). All 17 operators learnt the procedure with acceptable diagnostic performance (median required procedures, 33; range, 19-67). For an acceptable false negative rate for all 17 operators, 95 procedures were required (median, 33; range, 19-95). Operators with and without previous experience required a similar number of procedures to achieve acceptable diagnostic performance (median, 40 and 35, respectively). Pneumothorax occurred in 32.6% of procedures (1063/3261) and hemoptysis in 2.7% (89/3261). The learning curve for achieving an acceptable pneumothorax rate was highly variable (median, 34 procedures; range, 8-164), and only 10 operators achieved it. However, all but one operator achieved an acceptable hemoptysis rate (median, 55 procedures).*Conclusions At least 70 procedures were required for all operators to become proficient in CT-guided percutaneous transthoracic core needle biopsy with acceptable diagnostic performance, and 100 procedures may be required to achieve an acceptable false negative rate. Our study shows the number of procedures required to learn CT-guided percutaneous transthoracic needle biopsy, which can be used to determine when new operators perform it independently.*Clinical Relevance/Application At least 70 procedures were required for all operators to become proficient in CT-guided percutaneous transthoracic core needle biopsy with acceptable diagnostic performance, and 100 procedures may be required to achieve an acceptable false negative rate. Our study shows the number of procedures required to learn CT-guided percutaneous transthoracic needle biopsy, which can be used to determine when new operators perform it independently.

RESULTS

A total of 3261 procedures in 3134 patients (mean age, 67.7±12.1 years; 1876 men) were included. Overall diagnostic accuracy was 94.2% (2191/3141). All 17 operators learnt the procedure with acceptable diagnostic performance (median required procedures, 33; range, 19-67). For an acceptable false negative rate for all 17 operators, 95 procedures were required (median, 33; range, 19-95). Operators with and without previous experience required a similar number of procedures to achieve acceptable diagnostic performance (median, 40 and 35, respectively). Pneumothorax occurred in 32.6% of procedures (1063/3261) and hemoptysis in 2.7% (89/3261). The learning curve for achieving an acceptable pneumothorax rate was highly variable (median, 34 procedures; range, 8-164), and only 10 operators achieved it. However, all but one operator achieved an acceptable hemoptysis rate (median, 55 procedures).

CLINICAL RELEVANCE/APPLICATION

At least 70 procedures were required for all operators to become proficient in CT-guided percutaneous transthoracic core needle biopsy with acceptable diagnostic performance, and 100 procedures may be required to achieve an acceptable false negative rate. Our study shows the number of procedures required to learn CT-guided percutaneous transthoracic needle biopsy, which can be used to determine when new operators perform it independently.

SSCH02-6 Clinical Significance Of Lung Nodules Seen On Non-targeted CT Scans Of The Upper Lung Zones

Participants
Sonali Lala, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

To determine the clinical significance of incidentally noted lung nodules on non-targeted CT scans of the upper lungs.*Methods and Materials A search of the EMR was performed at an academic medical center from 5/2011 to 12/2018 for incidental lung nodules identified on CT scan reports of the shoulder, cervical spine and neck in patients over 35 yrs. old. Patient demographics, clinical history, and original radiologist recommendations were recorded. Two fellowship-trained chest radiologists assessed all CTs for nodule characteristics and follow-up chest CTs for nodule change and relevant lung findings. The endpoint of lung cancer was determined based on EMR review. A positive outcome was documented lung cancer at any subsequent time point.*Results 101 cases were analyzed (mean age 68.8 years, 65.3% F, 34.6% M). At the time of initial CT scan, 39.6% (n=40) of patients had risk factors for lung cancer and 19.8% (n=20) had a preexisting non-lung cancer. 86.1% (n=87) of the nodules were in the upper lobes. 43.5% (n=44) cases demonstrated more than one nodule. The average largest nodule size was 5.33 ± 3.17 mm. The average length of clinical follow-up for patients was 652 ± 630.66 days (range 0-3217 days) with 42.5% (n=43) having at least 2 years of follow-up and 22.7% (n=23) having at least 3 years of follow-up. Pulmonary malignancy was identified in only 2% (n=2) of patients; 1 with metastatic lung disease from an uncertain primary on follow-up CT and 1 with primary lung cancer per clinical history. Original CT reports recommended follow-up as per the Fleischner criteria in 53.4% (n=54), though only 15.6% (n=16) of patients had a follow up chest CT. 75% (n=12) of nodules with follow-up CT were stable. Relevant pulmonary findings were found in 50% (n=8) of the follow-up CTs, including metastatic disease, nodules elsewhere in the chest, or systemic disease such as sarcoid.*Conclusions Few patients obtain follow-up CT imaging in the setting of incidentally noted lung nodules on shoulder, neck and cervical spine CT imaging, however the likelihood of primary lung cancer is low in this population. Follow-up CTs showed most nodules were stable, though did provide additional relevant information in half of cases.*Clinical Relevance/Application Incidentally noted lung nodules on CT scans of the upper extremities, neck and spine are often not malignant despite an upper lobe location that is thought to increase risk of malignancy.

RESULTS

101 cases were analyzed (mean age 68.8 years, 65.3% F, 34.6% M). At the time of initial CT scan, 39.6% (n=40) of patients had risk factors for lung cancer and 19.8% (n=20) had a preexisting non-lung cancer. 86.1% (n=87) of the nodules were in the upper lobes. 43.5% (n=44) cases demonstrated more than one nodule. The average largest nodule size was 5.33 ± 3.17 mm. The average length of clinical follow-up for patients was 652 ± 630.66 days (range 0-3217 days) with 42.5% (n=43) having at least 2 years of follow-up and 22.7% (n=23) having at least 3 years of follow-up. Pulmonary malignancy was identified in only 2% (n=2) of patients; 1 with metastatic lung disease from an uncertain primary on follow-up CT and 1 with primary lung cancer per clinical history. Original CT reports recommended follow-up as per the Fleischner criteria in 53.4% (n=54), though only 15.6% (n=16) of patients had a follow up chest CT. 75% (n=12) of nodules with follow-up CT were stable. Relevant pulmonary findings were found in 50% (n=8) of the follow-up CTs, including metastatic disease, nodules elsewhere in the chest, or systemic disease such as sarcoid.

CLINICAL RELEVANCE/APPLICATION

Incidentally noted lung nodules on CT scans of the upper extremities, neck and spine are often not malignant despite an upper lobe location that is thought to increase risk of malignancy.

SSGU06-1 Risk Of Contrast Media-induced Acute Kidney Injury Following Abdominal Computed Tomography Using Iodixanol 270 And Iobitridol 300 Contrast Media In Hospitalized Old Patients

Participants
Seo Young Park, MD, Daegu, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To assess the association between a low-osmolar (Iobitridol 300) or an iso-osmolar(Iodixanol 270) contrast media (CM) exposure and acute kidney injury (AKI) in the hospitalized old patients by comparing with a propensity score-matched CM with two different osmolarity patient sample undergoing CT.*Methods and Materials Hospitalized old patients > 60 years with stable kidney function and available SCr measurement before and after CT with Iobitridol 300 or Iodixanol 270 between January 2015 and April 2020 were identified. The 1:1 propensity score matching was performed by using 21 covariates, stratified by eGFR before CT (= 60 mL/min/1.73m2 or, < 60 mL/min/1.73m2). AKI after CT was defined as Acute Kidney Injury Network SCr-related criteria. Univariable and multivariable logistic regression analyses were performed to assess the association between CM types and other covariates with the development of AKI after CT.*Results Total 1886 unique patients were included in the propensity score-matched samples (Iobitridol 300, 943 samples; 66.6 years ± 5.2 and Iodixanol 270, 943 samples; 72.2 years ± 4.8). The incidence of AKI with eGFR = 60 mL/min/1.73m2 was 2.48 % (22/885) and 2.25% (20/885) for Iobitridol 300 and Iodixanol 270, and with eGFR < 60 mL/min/1.73m2 was 12.0% (7/58) and 8.6% (5/58), respectively. Significant multivariable predictors of AKI were eGFR before CT, age, body mass index, presence of a chronic kidney disease, and nephrotoxic drug exposure. CM type was not predictive.*Conclusions Hospitalized old patients had a similar frequency of AKI compared with a propensity score-matched patient sample exposed to the Iobitridol 300 and Iodixanol 270.*Clinical Relevance/Application Contrast media, Iobitridol, Iodixanol, Acute kidney injury

RESULTS

Total 1886 unique patients were included in the propensity score-matched samples (Iobitridol 300, 943 samples; 66.6 years ± 5.2 and Iodixanol 270, 943 samples; 72.2 years ± 4.8). The incidence of AKI with eGFR = 60 mL/min/1.73m2 was 2.48 % (22/885) and 2.25% (20/885) for Iobitridol 300 and Iodixanol 270, and with eGFR < 60 mL/min/1.73m2 was 12.0% (7/58) and 8.6% (5/58), respectively. Significant multivariable predictors of AKI were eGFR before CT, age, body mass index, presence of a chronic kidney disease, and nephrotoxic drug exposure. CM type was not predictive.

CLINICAL RELEVANCE/APPLICATION

Contrast media, Iobitridol, Iodixanol, Acute kidney injury

SSGU06-2 Evaluation Of Renal Function In Healthy Volunteers And Patients With Chronic Kidney Disease With Varying Degrees Of Renal Damage By Apt Sequence

Participants
Ye Ju, Dalian, China (*Presenter*) Nothing to Disclose

PURPOSE

This study explored the value of amide proton transfer-weighted (APTw) MRI in the diagnosis and monitoring of chronic kidney disease (CKD).*Methods and Materials This retrospective study was approved by the institutional IRB. 57 patients who underwent kidney axial APTw imaging at 3.0T (Ingenia CX, Philips Healthcare, Best, the Netherlands) in our hospital between August and October 2019 were included into this study. Imaging parameters detailed in Table 1. Among the 57 patients, 32 had clinically confirmed CKD, who were divided into a moderate group (Group A, n=15) and a severe group (Group B, n=17) based on their CKD severity. The rest 25 patients with no kidney disease history and symptoms formed the control group (Group C, n=25). Written informed consent was waived for this retrospective study. All the image measurements were performed on a IntelliSpace Portal workstation (Philips Healthcare). ROIs (5-7 mm2) were placed by a radiologist (XX with xx years of radiology experience) on the APTw images on the upper, middle, and lower kidney for both the renal cortex and medulla (hence 6 ROIs per patient). The sinus renalis, the blood vessels, and the surrounding tissues were avoided in ROI drawing with reference to the T2w images. The mean cortex and medulla APTw values (MTRasym) were averaged among the upper, middle, and lower kidney and were compared between the three groups using a ROC curve analysis (SPSS 26.0). P<0.05 was considered statistically significant.*Results As shown in Table 2, both cortex and medulla APTw values were highest in the severe group and lowest in the control group (P<0.05). Cortex APTw values were significantly higher than medulla in all three groups (P<0.05). As shown in Table 3, cortex APTw value yielded an AUC of 0.951 in differentiating control group and moderate group (cut-off 1.97%, sensitivity 100%, specific 92%). These numbers were 0.807, 1.95%, 71.4%, and 84% for medulla APTw values. Cortex APTw value yielded an AUC of 0.915 in differentiating moderate group and severe group (cut-off 3.20%, sensitivity 87.5%, specific 93%). These numbers were 0.991,

2.87%, 93.8%, and 100% if medulla APTw values were used.*Conclusions APTw MRI, in both renal cortex and medulla, has provided a reliable non-invasive tool to differentiate between healthy kidney and CKD and between moderate and severe CKD, both with high sensitivity and high specificity. The mechanism behind might be associated to the acidic environment in CKD tissue. With increased kidney function damage, ion-exchange rate increases, and the kidney tissue becomes more acidic, leading to increased APTw signal.*Clinical Relevance/Application Clinically , it can provide a new and non - invasive method , and have certain application prospects .

RESULTS

As shown in Table 2, both cortex and medulla APTw values were highest in the severe group and lowest in the control group (P<0.05). Cortex APTw values were significantly higher than medulla in all three groups (P<0.05). As shown in Table 3, cortex APTw value yielded an AUC of 0.951 in differentiating control group and moderate group (cut-off 1.97%, sensitivity 100%, specific 92%). These numbers were 0.807, 1.95%, 71.4%, and 84% for medulla APTw values. Cortex APTw value yielded an AUC of 0.915 in differentiating moderate group and severe group (cut-off 3.20%, sensitivity 87.5%, specific 93%). These numbers were 0.991, 2.87%, 93.8%, and 100% if medulla APTw values were used.

CLINICAL RELEVANCE/APPLICATION

Clinically , it can provide a new and non - invasive method , and have certain application prospects .

SSGU06-3 Non-invasive Characterization Of Racial Histologic Diversity In Small Renal Masses With The MRI Clear Cell Likelihood Score

Participants
Louis Vazquez, BS, Dallas, Texas (*Presenter*) Nothing to Disclose

PURPOSE

To develop a diagnostic model to estimate the distribution of histologic subtypes in SRM and assess the diagnostic performance of ccLS for patients with different racial and demographic backgrounds.*Methods and Materials Bi-institution retrospective cohort study in academic hospital and safety net hospital system. Patients with SRM underwent MRI and received ccLS prospectively with subsequent pathologic confirmation. Age, sex, race, body mass index (BMI) and ccLS were tabulated for each mass. Clinical pathology report was the reference standard. Univariate and multivariable analysis with generalized estimating equations were performed to estimate distributions in the proportion of ccRCC, pRCC, benign histology and other diagnosis across different patient subgroups.*Results 239 SRM in 231 patients were included. Race, BMI, and ccLS (p &lt 0.001) were associated with benign and malignant histology. Obese Hispanics had the highest estimated rate of ccRCC (48.3% in ccLS 1-2; 85.8% in ccLS 3; 97.3% in ccLS 4-5) and normal-weight non-Hispanic Black (NHB) the lowest (0.1% in ccLS 1-2; 2.1% in ccLS 3; 15.1% in ccLS 4-5). Normal-weight NHB had the highest estimated rate of pRCC (92.5% in ccLS 1-2; 39.5% in ccLS 3; 11.5% in ccLS 4-5) and obese Hispanics the lowest (28.6% in ccLS 1-2; 0.9% in ccLS 3; &lt 0.1% in ccLS 4-5).*Conclusions ccLS, race, and BMI offer synergistic information in the prediction of the proportion of specific histologic subtypes in SRM and can assist in management decisions for patients with SRM.*Clinical Relevance/Application The synergistic effects of ccLS, race and BMI in the proportion of specific histologic subtypes in SRM provides a platform for a predictive model that can assist in management decisions for these patients.

RESULTS

239 SRM in 231 patients were included. Race, BMI, and ccLS (p &lt 0.001) were associated with benign and malignant histology. Obese Hispanics had the highest estimated rate of ccRCC (48.3% in ccLS 1-2; 85.8% in ccLS 3; 97.3% in ccLS 4-5) and normal-weight non-Hispanic Black (NHB) the lowest (0.1% in ccLS 1-2; 2.1% in ccLS 3; 15.1% in ccLS 4-5). Normal-weight NHB had the highest estimated rate of pRCC (92.5% in ccLS 1-2; 39.5% in ccLS 3; 11.5% in ccLS 4-5) and obese Hispanics the lowest (28.6% in ccLS 1-2; 0.9% in ccLS 3; &lt 0.1% in ccLS 4-5).

CLINICAL RELEVANCE/APPLICATION

The synergistic effects of ccLS, race and BMI in the proportion of specific histologic subtypes in SRM provides a platform for a predictive model that can assist in management decisions for these patients.

SSGU06-4 Detecting Muscle Invasion Of Bladder Cancer Using A Proposed MRI Strategy

Participants
Xiangyu Wang, Shenzhen, China (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the diagnostic performance of a new MRI strategy based on the integration of the VI-RADS and tumor contact length (TCL) for the diagnosis of muscle-invasive bladder cancer (MIBC).*Methods and Materials Three radiologists independently graded the VI-RADS score and measured the TCL on index lesion images. A proposed MRI strategy called VI-RADS_TCL was introduced by modifying the VI-RADS score, which was downgraded to VI-RADS 3F (equal to a VI-RADS score of 2) if VI-RADS=3 and TCL<3 cm. Intraclass correlation coefficients (ICCs), Mann-Whitney U test, chi-square tests, receiver operating characteristic (ROC) curves and 2×2 contingency tables were applied.*Results A group of 179 patients with a mean age of 67 years (range, 24.0-96.0) underwent multiparametric MRI (mpMRI) before surgery, including 147 (82.1%) males and 32 (17.9%) females. Twenty-four (13.4%), 90 (50.3%), 43 (24.0%), 15 (8.4%) and 7 (3.9%) cases were Ta, T1, T2, T3 and T4, respectively. Inter-reader agreement values were 0.941 (95% CI, 0.924-0.955) and 0.934 (95% CI, 0.916-0.948) for the TCL and VI-RADS score. The TCL was significantly increased in the MIBC group (6.40 - 6.85 cm) compared with the NMIBC group (1.98- 2.45 cm) (P<0.05). The specificity and positive predictive values (PPV) of VI-RADS_TCL were 82.46%- 7.72% and 90.91%-91.59%, which were significantly greater than VI-RADS score (P<0.05). Additionally, 52.17%-55.88% NMIBC lesions with VI-RADS 3 were downgraded to 3F by using VI-RADS_TCL.*Conclusions The proposed MRI strategy could reduce the false-positive rate of lesions with a VI-RADS score of 3 while retaining sensitivity.*Clinical Relevance/Application a) tumor contact length (TCL) was defined as the maximal curvilinear contact length between the tumor and the bladder wall. The TCL metric showed a significant difference between NMIBC and MIBC in our results. Furthermore, measuring the TCL does not require an additional examination sequence, avoiding an increase the patient's time-consuming or examination cost.b) A proposed MRI strategy called VI-RADS_TCL was introduced by modifying the VI-RADS score, which was downgraded to VI-RADS 3F (equal to a VI-RADS score of 2) if VI-RADS=3 and TCL<3 cm. When using the VI-RADS_TCL scoring approach, 52.17%-55.88% of lesions with a VI-RADS score of 3 were downgraded to VI-RADS 3F and were pathologically confirmed as NMIBC.

RESULTS

A group of 179 patients with a mean age of 67 years (range, 24.0-96.0) underwent multiparametric MRI (mpMRI) before surgery, including 147 (82.1%) males and 32 (17.9%) females. Twenty-four (13.4%), 90 (50.3%), 43 (24.0%), 15 (8.4%) and 7 (3.9%) cases were Ta, T1, T2, T3 and T4, respectively. Inter-reader agreement values were 0.941 (95% CI, 0.924-0.955) and 0.934 (95% CI, 0.916-0.948) for the TCL and VI-RADS score. The TCL was significantly increased in the MIBC group (6.40 - 6.85 cm) compared with the NMIBC group (1.98- 2.45 cm) (P<0.05). The specificity and positive predictive values (PPV) of VI-RADS_TCL were 82.46%-7.72% and 90.91%-91.59%, which were significantly greater than VI-RADS score (P<0.05). Additionally, 52.17%-55.88% NMIBC lesions with VI-RADS 3 were downgraded to 3F by using VI-RADS_TCL.

CLINICAL RELEVANCE/APPLICATION

a) tumor contact length (TCL) was defined as the maximal curvilinear contact length between the tumor and the bladder wall. The TCL metric showed a significant difference between NMIBC and MIBC in our results. Furthermore, measuring the TCL does not require an additional examination sequence, avoiding an increase the patient's time-consuming or examination cost.b) A proposed MRI strategy called VI-RADS_TCL was introduced by modifying the VI-RADS score, which was downgraded to VI-RADS 3F (equal to a VI-RADS score of 2) if VI-RADS=3 and TCL<3 cm. When using the VI-RADS_TCL scoring approach, 52.17%-55.88% of lesions with a VI-RADS score of 3 were downgraded to VI-RADS 3F and were pathologically confirmed as NMIBC.

SSNR08-2   Brain Glymphatic System Is Impaired In TBI Found With MRI: The First Human Study

Participants
Jianfeng Bao, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

The pathology of neurodegeneration and dementia following the traumatic brain injury (TBI) is still unknown. Recently, a new found/defined brain waste clearance system, named 'glymphatic system', was proved to be damaged in TBI rodent studies. Herein, the functionality of human brain glymphatic system of TBI patients and related healthy controls was evaluated and compared using MRI.*Methods and Materials The glymphatic function was assessed by T1W MRI scans with intrathecal gadolinium injection as tracer. Images were obtained from TBI patients (n = 16) and relatively healthy controls (n = 7) at 4 time points. Along the cerebrospinal fluid (CSF) drawing pathway, Fig.1, 4 predefined regions of interest (ROIs), were automatically generated using standard brain atlas templates. Each ROI was subsequently split into sub-ROIs including CSF and gray matter (GM) separately for analyzing the signal enhancement characteristics. The signal intensity on T1 weighted images at 4 time points of each ROI was extracted and normalized. The percentage changes of signal enhancements were used for group comparisons.*Results As shown in Fig.2, after 24 h contrast agent injection, the percentage changes of T1 signal intensity were significant higher in TBI patients than controls for CSF and GM, but not for WM in all ROIs (not show here). The CSF enhancement seems more pronounced than GM enhancement. The higher T1 signal in TBI patient at 24 h can be attributed to the reduced efficiency of the contrast agent clearance, which is the key function of glymphatic system.*Conclusions The significant delayed enhancements in CSF and GM in TBI group indicate the brain glymphatic system is impaired for TBI patients. Glymphatic dysfunction may provide a new clue to understanding its pathogenesis of the cognitive impairments along with TBI in the later life. What's more, this study reconfirmed the MRI scan with gadolinium intrathecal administration may hold a potential to explore the glymphatic function in human.*Clinical Relevance/Application The glymphatic system, brain waste clearance pathway, is impaired, which is prior to other dementia symptoms and maybe useful in predicting future cognitive decline and risk of dementia in TBI people.

RESULTS

As shown in Fig.2, after 24 h contrast agent injection, the percentage changes of T1 signal intensity were significant higher in TBI patients than controls for CSF and GM, but not for WM in all ROIs (not show here). The CSF enhancement seems more pronounced than GM enhancement. The higher T1 signal in TBI patient at 24 h can be attributed to the reduced efficiency of the contrast agent clearance, which is the key function of glymphatic system.

CLINICAL RELEVANCE/APPLICATION

The glymphatic system, brain waste clearance pathway, is impaired, which is prior to other dementia symptoms and maybe useful in predicting future cognitive decline and risk of dementia in TBI people.

SSNR08-3   Automated Detection Of Intracranial Hemorrhage With Artificial Intelligence (RAPID-ICH): Initial Clinical Experience

Participants
Warren Chang, MD,MBA, Pittsburgh, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Intracranial hemorrhage (ICH) has high morbidity and mortality with nearly 50% 30 day mortality for patients admitted to the ICU and as few as 20% of survivors demonstrating full neurologic recovery. Early intervention has been shown to improve clinical outcomes. Given high mortality and morbidity, prompt identification of ICH has high clinical utility. Several applications have emerged using artificial intelligence (AI) for automated detection of ICH, including RAPID ICH (iSchemaView, Menlo Park, CA). We present our initial clinical experience with RAPID ICH in a busy Level 1 trauma center.*Methods and Materials The study was performed under the supervision of the local institutional review board.Patients presenting to the emergency department (ED) receiving CT scans of the brain and inpatients (IP) scanned on the ED scanner at one level 1 trauma center were included in the study. The RAPID ICH output ("no ICH" or "suspected ICH") was recorded for each study. The initial interpreting emergency radiologist or neuroradiologist had access to the RAPID ICH output. Radiology reports reporting ICH were considered positive and

those reporting no ICH were considered negative. A board certified neuroradiologist reviewed each case who had access to the initial report, RAPID ICH output, and all subsequent examinations. In cases with disagreement between the readers, a third reader adjudicated the result and their decision was considered final. The expert reads were used as the gold standard and sensitivity, specificity, negative predictive value (NPV) and positive predictive value (PPV) were calculated.*Results A total of 1388 patients were included in the study, 1251 from the ED and 137 IP. For the ED patients, 139 had ICH and 1112 did not, where as in the IP cohort, 100 had ICH and 37 did not. RAPID ICH demonstrated overall sensitivity of 79% (73% ED, 88% IP), overall specificity of 95% (96% ED, 84% IP), overall PPV of 76% (65% ED, 94% IP) and overall NPV of 96% (97% ED, 72% IP).*Conclusions RAPID ICH demonstrated relatively high sensitivity and very high specificity for ICH, with lower sensitivity and higher specificity in the ED, and higher sensitivity but lower specificity in the inpatient setting. Using AI applications such as RAPID ICH for active worklist reprioritization may allow timely triage of potentially positive studies, allowing early intervention and potentially leading to improved clinical outcomes, especially in the inpatient setting with longer average turnaround times for routine studies.*Clinical Relevance/Application RAPID ICH demonstrated relatively high sensitivity and specificity in both IP and ED settings. Active worklist reprioritization using RAPID ICH may improve turnaround times and allow earlier intervention and improved clinical outcomes.

RESULTS

A total of 1388 patients were included in the study, 1251 from the ED and 137 IP. For the ED patients, 139 had ICH and 1112 did not, where as in the IP cohort, 100 had ICH and 37 did not. RAPID ICH demonstrated overall sensitivity of 79% (73% ED, 88% IP), overall specificity of 95% (96% ED, 84% IP), overall PPV of 76% (65% ED, 94% IP) and overall NPV of 96% (97% ED, 72% IP).

CLINICAL RELEVANCE/APPLICATION

RAPID ICH demonstrated relatively high sensitivity and specificity in both IP and ED settings. Active worklist reprioritization using RAPID ICH may improve turnaround times and allow earlier intervention and improved clinical outcomes.

SSNR08-4   Positive CT Head Rate Performed Post Head Injury According To National Institute For Health And Care Excellence (NICE) Guidelines

Participants
Mark Woodward, MBChB,BSC, Salford, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

With an ever increasing demand for radiological investigations in the National Health Service (NHS), there is immense strain on radiology departments in the UK. Of the cross sectional investigations performed, CT head far outnumbers any other. Clinicians in the UK use NICE guidelines for head injury to help determine if a patient requires an acute CT head. Experience suggested that these recommendations are all encompassing and therefore qualify almost every patient for a CT head, even though most are negative. To assess this hypothesis, we undertook a dual center study to objectively determine the positive rate of CT heads performed according to the NICE guidelines for head injury.*Methods and Materials Data was collected retrospectively at two UK NHS District General Hospitals using the Computerised Radiology Information System (CRIS) software. CT heads performed during two random and continuous two week time periods were assessed; prior to the COVID-19 pandemic and during it. All adult A&E and inpatient acute CT heads performed for referrals that met the NICE guidelines for head injury were included. Reported intracranial hemorrhage or skull fracture were deemed a positive CT head, whilst incidental findings were classed as a negative scan.*Results In the two weeks prior to the pandemic, n=265 scans met the inclusion criteria, and n=216 during it. The mean age of patients prior to the COVID-19 pandemic was 65.2 years and 68.9 years during it. Prior to the pandemic there were n=18 positive CT heads (6.8%), and n=7 (3.2%) during it.*Conclusions As predicted, less CT heads were performed for head injury during the pandemic compared to prior to it. This was reflected by a 57% reduction in the number of patients presenting to A and E departments in the UK during April 2020 of the pandemic compared to the previous year. There was concern amongst the medical community in the UK that even patients with serious acute pathologies were not presenting to hospital. We hypothesised this more selective group of symptomatic patients would lead to a higher positive rate of CT heads. However, this was not the case, as shown by our results, which suggest that the NICE guidelines for CT head post head injury are too all encompassing and possibly need reviewing to improve selection criteria.*Clinical Relevance/Application This study has highlighted the possible need for review of the NICE guidelines for performing CT head post head injury to formulate stricter criterion. This should lead to clinicians relying on their clinical acumen to select patients for CT head, leading to less unnecessary scans being performed. This would reduce radiation exposure to patients and conserve limited NHS resources.

RESULTS

In the two weeks prior to the pandemic, n=265 scans met the inclusion criteria, and n=216 during it. The mean age of patients prior to the COVID-19 pandemic was 65.2 years and 68.9 years during it. Prior to the pandemic there were n=18 positive CT heads (6.8%), and n=7 (3.2%) during it.

CLINICAL RELEVANCE/APPLICATION

This study has highlighted the possible need for review of the NICE guidelines for performing CT head post head injury to formulate stricter criterion. This should lead to clinicians relying on their clinical acumen to select patients for CT head, leading to less unnecessary scans being performed. This would reduce radiation exposure to patients and conserve limited NHS resources.

SSNR08-5   A Multi Scanner Study Of Corpus Callosum Diffusion Imaging And Clinical Outcomes In Mild Traumatic Brain Injury

Participants
Alexander Asturias, Henderson, Nevada (*Presenter*) Nothing to Disclose

PURPOSE

To analyze associations between symptom presentation and longevity in chronic phase mild traumatic brain injury (mTBI) using corpus callosal (CC) diffusion tensor image (DTI).*Methods and Materials Clinical data were obtained retrospectively on 450 mTBI subjects (avg age 42 range 12-82) documenting incidence and longevity of 7 common mTBI clinical symptoms. Subjects were excluded if MRI showed hemorrhages or contusions. Median time between scanning and injury was 100 days. DTI data was obtained from 8 different 3T MRI scanners (3 GE: 2 Signa HDxt, 1 Signa Excite; 1 Philips Intera; 4 Siemens: 3 Verio, 1 TrioTim). Scanning parameters varied slightly but were at minimum 33 directions and 2.4 mm slice thickness with 90 flip angle. DTI post processing was performed on the Olea Sphere V3.0 SP12 free-standing workstation with motion correction. Hand traced fractional anisotropy (FA) values were calculated from regions of interests across the CC. Data harmonization was processed with MATLAB 2020b utilizing the published ComBat harmonization technique to reduce FA scanner variability. Logistic regression modeling was used to assess CC FA

values and symptom presentation/improvement associations. Symptom longevity was modeled in semi-parametric Cox proportional hazard models.*Results No regional FA values were associated significantly with symptom presentation. Increased longevity of post-concussive cognitive deficits was significantly associated with small FA values in the whole (p=0.01), anterior (p<0.01), and medial (p=0.03) CC. Small FA values in the posterior CC were significantly associated with longer duration of post concussive depression (p=0.04) and emotional lability (p=0.01). Subject age was negatively related to FA (p<0.001), but only 2.1% to 9.0% of the variation in FA was explained by age.*Conclusions This study reveals a number of significant associations between decreased CC FA values and longevity of mTBI symptomological sequalae, particularly cognitive.*Clinical Relevance/Application Corpus Callosal DTI may assist in predicting clinical outcomes in chronic phase mTBI subjects.

RESULTS

No regional FA values were associated significantly with symptom presentation. Increased longevity of post-concussive cognitive deficits was significantly associated with small FA values in the whole (p=0.01), anterior (p<0.01), and medial (p=0.03) CC. Small FA values in the posterior CC were significantly associated with longer duration of post concussive depression (p=0.04) and emotional lability (p=0.01). Subject age was negatively related to FA (p<0.001), but only 2.1% to 9.0% of the variation in FA was explained by age.

CLINICAL RELEVANCE/APPLICATION

Corpus Callosal DTI may assist in predicting clinical outcomes in chronic phase mTBI subjects.

SSNR08-6   Delayed Posttraumatic Intracranial Hemorrhage In Patients On Anticoagulant/antiplatelet Medications: Three Year Experience

Participants
Warren Chang, MD,MBA, Pittsburgh, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

The risk of delayed postraumatic intracranial hemorrhage (DH) in patients on anticoagulant/antiplatelet medications, especially patients on direct oral anticoagulant medications (DOAC), is not well established. The prevalence of DOACs is increasing and in a recent study on anticoagulated patients was as high as 50%. In our study, a majority of anticoagulated patients were taking DOACs. Some groups found a low risk of posttraumatic DH in patients taking warfarin/clopidogrel, however, newer reports have found >7% rate of DH and others found 1% mortality. We report our 3-year experience with DH including patients taking DOACs.*Methods and Materials This study was performed under the supervision of the local Institutional Review Board.Patients were included in the study if they were on antiplatelet and anticoagulant medications, including DOACs, and suffered head trauma. The radiology reports for the initial examinations on these patients included a recommendation for repeat imaging to evaluate for DH. Approximately 50% of patients in which repeat imaging was recommended received repeat imaging. Repeat examinations were typically performed within 24 hours (average follow-up time was 21 hours and 99% were within 3 days). Patients who had repeat examinations within the same hospitalization/incident were included in the study if their initial examination was interpreted as negative and there were no additional instances of trauma between the examinations. All positive studies were reviewed by two board certified neuroradiologists. Patients were excluded from the study if hemorrhage was retrospectively identified on the initial examination. Cases were reclassified as negative if hemorrhage on the follow-up examination was thought to be not present or thought to be artifactual. Cases were considered positive if the initial examination was considered negative and the follow-up examination demonstrated new hemorrhage.*Results A total of 1046 patients were included in the study, with 1.8% incidence of DH and 0.4% overall mortality. Patients on warfarin and clopidogrel had a higher rate of DH (3.2%), compared to 0.9% in the DOAC group, and the difference was statistically significant (p<0.01). All deaths were in the clopidogrel/warfarin group.*Conclusions Our study found 1.8% rate of DH with 0.4% mortality, higher than some previously published reports. DOACs demonstrated significantly lower risk of both DH and mortality than warfarin/clopidogrel.*Clinical Relevance/Application Patients on clopidogrel and warfarin had both significantly higher rate of DH and mortality from DH compared to patients taking DOACs. Repeat head CT should be considered on trauma patients on anticoagulant/antiplatelet medications, especially warfarin and/or clopidogrel.

RESULTS

A total of 1046 patients were included in the study, with 1.8% incidence of DH and 0.4% overall mortality. Patients on warfarin and clopidogrel had a higher rate of DH (3.2%), compared to 0.9% in the DOAC group, and the difference was statistically significant (p<0.01). All deaths were in the clopidogrel/warfarin group.

CLINICAL RELEVANCE/APPLICATION

Patients on clopidogrel and warfarin had both significantly higher rate of DH and mortality from DH compared to patients taking DOACs. Repeat head CT should be considered on trauma patients on anticoagulant/antiplatelet medications, especially warfarin and/or clopidogrel.

SSPH07-1   Evaluation Of Iodine Quantification Accuracy In Spectral Images Derived From A Full Field-of-view Photon-counting-detector CT

Participants
Kishore Rajendran, PhD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the quantitative accuracy of iodine concentration in material maps and iodine CT numbers in virtual monoenergetic images (VMI) from a 50 cm field-of-view photon-counting-detector (PCD) CT.*Methods and Materials Multi-energy CT phantoms (head size: 20 cm diameter; body size: 30 cm height and 40 cm lateral width) with solid iodine inserts (2, 5, 10 and 15 mg/cc) were scanned on an investigational dual-source whole-body PCD-CT system (NAEOTOM Alpha, Siemens Healthineers). Scan parameters used were 144 x 0.4 mm collimation, 120 kV with 20 and 65 keV thresholds, 140 kV with 20 and 70 keV thresholds, head CTDIvol = 36 mGy and abdomen CTDIvol = 12 mGy. Images were reconstructed using a quantitative kernel (Qr40, iterative reconstruction strength 3) at 3 mm slice thickness. Vendor-provided software was used to generate iodine maps and VMIs from 40 to 140 keV. Quantitative accuracy of iodine maps was assessed using the root-mean-squared-error (RMSE) between measured and true iodine concentrations. For VMI accuracy, the iodine CT number at each concentration and VMI energy level (keV setting) was compared to the expected monoenergetic CT numbers calculated using NIST data. Percent error was calculated between measured and expected VMI CT numbers. VMI and iodine maps were evaluated for each phantom size and acquisition kV.*Results Iodine maps demonstrated a RMSE of 0.27 mg/cc and 0.24 mg/cc for the head size phantom at 120 kV and 140 kV, respectively, and 1.06 mg/cc and 0.5 mg/cc for the body size phantom at 120 kV and 140 kV, respectively. For VMIs, the percent error was 4.89% and 4.05% for the head size at 120 kV and 140 kV, respectively. The percent error for the body size phantom was 14.94% and 9.44% for 120 kV and 140 kV, respectively. For both iodine maps and VMIs, the 140 kV acquisition yielded the lowest RMSE and percent error, respectively, owing to better spectral separation in the multi-energy data.*Conclusions At the same dose, use of 140 kV results in higher quantitative accuracy for PCD-CT spectral imaging. The evaluated PCD-CT system demonstrated quantitative accuracy for iodine maps and VMIs similar to or better than published results using dual-energy CT systems.*Clinical Relevance/Application Our study evaluated quantitative accuracy of iodine maps and VMI from a whole-body PCD-CT to determine optimal tube potential for clinical multi-energy applications, which was found to be 140 kV.

RESULTS

Iodine maps demonstrated a RMSE of 0.27 mg/cc and 0.24 mg/cc for the head size phantom at 120 kV and 140 kV, respectively, and 1.06 mg/cc and 0.5 mg/cc for the body size phantom at 120 kV and 140 kV, respectively. For VMIs, the percent error was 4.89% and 4.05% for the head size at 120 kV and 140 kV, respectively. The percent error for the body size phantom was 14.94% and 9.44% for 120 kV and 140 kV, respectively. For both iodine maps and VMIs, the 140 kV acquisition yielded the lowest RMSE and percent error, respectively, owing to better spectral separation in the multi-energy data.

CLINICAL RELEVANCE/APPLICATION

Our study evaluated quantitative accuracy of iodine maps and VMI from a whole-body PCD-CT to determine optimal tube potential for clinical multi-energy applications, which was found to be 140 kV.

SSPH07-2   High-pitch Photon-counting Detector CT For Angiography Of The Aorta - Intraindividual Comparison To Radiation Dose-matched Energy-integrating Detector CT With Automatic Tube Voltage Selection

Participants
Andre Euler, MD, Zurich, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To compare objective and subjective image quality of high-pitch CT angiography of the aorta between clinical photon-counting detector CT (PCD-CT) and conventional energy-integrating detector CT (EID-CT) with automatic tube voltage selection (ATVS) in the same patients at equal radiation dose.*Methods and Materials Patients receiving a follow-up CT angiography of the thoracoabdominal aorta were prospectively screened for prior imaging on a third-generation EID-CT in high-pitch mode and ATVS (CarekV, reference tube voltage 100kV). Follow-up was performed on a first-generation clinical dual-source PCD-CT in high-pitch and QuantumPlus mode at 120kV using the same contrast media protocol. Radiation dose between the two scans was matched by adapting tube current. Polychromatic images for both EID-CT and PCD-CT (T3D) and spectral-based virtual monoenergetic images at 40, 45, 50, 55 keV for PCD-CT were reconstructed. CT numbers were measured at multiple locations in the aorta. Noise was defined as the standard deviation of the CT number in the psoas muscle. Contrast-to-noise ratio (CNR) was calculated. Subjective image quality (noise, vessel attenuation, vessel sharpness, overall quality) was rated by two radiologists. Non-parametric tests (Kruskal-wallis and Krippendorf a) were performed.*Results Twenty-five consecutive patients were included (mean age, 64.3±10.3

years, 3 females, mean body mass index, 27.1±5.9 kg/m2). ATVS selected 70, 80, 90, 100, 110, 120kV in 1, 8, 8, 5, 1, 2 patients, respectively. Mean CNR was 15.7±7.5 for EID-CT, and 21.9±7.3, 19.7±6.5, 17.5±5.8, 15.5±5.1, 11.5±3.6 for PCD-CT at 40, 45, 50, 55keV, and T3D, respectively. CNR was significantly higher for 40 and 45keV of PCD-CT as compared to EID-CT (both, p<.05). Interreader agreement was substantial (a=.66). Subjective noise was rated superior for EID-CT and T3D as compared to 40-55 keV (all, p<.05). Vessel attenuation was significantly lower for T3D compared to the other reconstructions (all, p<.05). There was no significant difference among the reconstructions for vessel sharpness (p=.78) and overall quality (p=.84).*Conclusions High-pitch PCD-CT with VMI at 40 and 45 keV resulted in significantly increased CNR, inferior subjective noise but similar overall image quality as compared to EID-CT with ATVS for dose-matched CT angiography of the aorta.*Clinical Relevance/Application Increased CNR of PCD-CT could be used to reduce the amount of contrast media in CT angiography of the aorta.

RESULTS

Twenty-five consecutive patients were included (mean age, 64.3±10.3 years, 3 females, mean body mass index, 27.1±5.9 kg/m2). ATVS selected 70, 80, 90, 100, 110, 120kV in 1, 8, 8, 5, 1, 2 patients, respectively. Mean CNR was 15.7±7.5 for EID-CT, and 21.9±7.3, 19.7±6.5, 17.5±5.8, 15.5±5.1, 11.5±3.6 for PCD-CT at 40, 45, 50, 55keV, and T3D, respectively. CNR was significantly higher for 40 and 45keV of PCD-CT as compared to EID-CT (both, p<.05). Interreader agreement was substantial (a=.66). Subjective noise was rated superior for EID-CT and T3D as compared to 40-55 keV (all, p<.05). Vessel attenuation was significantly lower for T3D compared to the other reconstructions (all, p<.05). There was no significant difference among the reconstructions for vessel sharpness (p=.78) and overall quality (p=.84).

CLINICAL RELEVANCE/APPLICATION

Increased CNR of PCD-CT could be used to reduce the amount of contrast media in CT angiography of the aorta.

SSPH07-3 High-pitch, High Temporal Resolution, Multi-energy Cardiac Imaging On A Whole Body, Dual-Source Photon-Counting-Detector CT

Participants
David Campeau, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

To assess the performance of a high-pitch, multi-energy (ME) scan mode on an investigational whole-body dual-source photon-counting-detector (DS-PCD) CT using phantom and patient studies.*Methods and Materials A scan mode (ME-Flash; 66 ms temporal resolution) on an investigational DS-PCD-CT system (NAEOTOM Alpha) permits multi-energy (ME) cardiac imaging with high helical pitch (3.2), fast rotation time (0.25 second) and energy discrimination capabilities. To assess temporal and spectral performance of this mode, a cardiac motion phantom containing a cylindrical iodine rod (20 mg/cc, QRM) was scanned at 120 kV, 100 effective mAs, and 7.26 mGy CTDIvol. A lateral motion profile with a 3mm amplitude triangle wave at 60bpm (velocity of 12 mm/s) was used, and scans were repeated 20 times. For comparison, the same phantom was also scanned with gated and non-gated spiral modes, both with 120 kV and 100 effective mAs (CTDIvol of 32.9 mGy and 7.26 mGy, respectively). The same phantom was also scanned without motion to create reference images. Iodine map and virtual monoenergetic images (VMI at 55 keV) were created using 1 mm thick images reconstructed with a quantitative kernel (Qr40). Contrast and noise were measured and artifacts assessed in axial and volume rendered images. Iodine concentration was measured for a region of interest in the iodine map, and diameter and circularity of the rod were calculated for each scan mode and compared. With IRB approval, a patient with suspected coronary artery disease was scanned using the ME-Flash mode and image quality assessed.*Results Moving iodine rods were clearly delineated without noticeable distortion, with similar contrast and noise as when static. Mean iodine concentration was 20.6 mg/cc, 3% higher than reference. Minor artifacts were observed in the uniform background close to the iodine rod that did not affect the rod shape or boundaries (diameter 4.42 vs 4.47mm, and circularity 0.954 vs 0.946 for static and motion phantoms, respectively). Patient images clearly delineated all coronary arteries and showed no evidence of motion artifacts. VMI and iodine map demonstrated the multi-energy capability of the ME-Flash mode, allowing assessment of anatomic information and material quantification.*Conclusions The ME-Flash mode on the DS-PCD-CT system enables high temporal resolution (66 ms), quantitatively accurate multi-energy (<=3% error) cardiac imaging at much lower radiation dose levels than conventional retrospectively-gated cardiac scanning.*Clinical Relevance/Application Flash mode PCD-CT can provide accurate quantitation of iodine enhancement using the highest temporal resolution available, potentially increasing the diagnostic value of coronary CTA.

RESULTS

Moving iodine rods were clearly delineated without noticeable distortion, with similar contrast and noise as when static. Mean iodine concentration was 20.6 mg/cc, 3% higher than reference. Minor artifacts were observed in the uniform background close to the iodine rod that did not affect the rod shape or boundaries (diameter 4.42 vs 4.47mm, and circularity 0.954 vs 0.946 for static and motion phantoms, respectively). Patient images clearly delineated all coronary arteries and showed no evidence of motion artifacts. VMI and iodine map demonstrated the multi-energy capability of the ME-Flash mode, allowing assessment of anatomic information and material quantification.

CLINICAL RELEVANCE/APPLICATION

Flash mode PCD-CT can provide accurate quantitation of iodine enhancement using the highest temporal resolution available, potentially increasing the diagnostic value of coronary CTA.

SSPH07-4 Spectral-based Virtual Removal Of Calcified Vascular Plaques In Dual Source Multi-energy Photon Counting CT

Participants
Thomas G. Flohr, PhD, Forchheim, Germany (*Presenter*) Employee, Siemens AG

PURPOSE

In case of cardio-vascular CT angiography examinations, calcified plaques often pose a challenge in the assessment of the true vessel lumen due to blooming and partial volume effects. We assessed the performance of a newly developed image reconstruction method utilizing spectral information to remove only the calcified parts of the volume while leaving the rest of the image intact via a modified in-place two-material decomposition for non-moving and moving calcified structures.*Methods and Materials For the study a dual source multi-energy photon counting CT (Siemens Healthineers) was used, which allows the readout of 4 energy thresholds. Scans were performed in standard and gated scan mode at 120 kV tube voltage and 100, 200 and 400 eff. mAs. In order to simulate various levels of stenosis, artificial stenosis phantoms (QRM, Möhrendorf, Germany) with three different vessel diameters (10 mm, 5mm and 3mm) were used, each of them equipped with three different levels of calcified stenosis: 15, 25 and 50%. To

simulate a realistic patient attenuation, the vessel phantoms were scanned submerged in a water bath, surrounded by a thorax phantom - with and without attenuation extension rings. Vessel phantoms were scanned at rest, and using a typical cardiac motion profile at 60, 70 and 90 bmp. To assess the quality of the plaque removal, we evaluated both - the visual quality and difference in stenosis levels as objective measure compared to the gold standard (phantom specification).*Results The visual impression of the calcium-removed stenosis matches the expectation given by the phantom specification. The deterioration in overall image quality towards lower exposure levels, due to an increase in image noise or due to vessel phantom motion with increasing heart rate is comparable between calcium removed and standard reconstructions. The quantitative stenosis evaluation based on voxel mask matching did exhibit a significant dependency on the applied heart rate.*Conclusions The presented method of reconstructing virtual calcium-removed images may provide additional information in the assessment of the true lumen in vessels with a high calcium burden in CT angiography examinations, by means of removing calcified plaques and the associated blooming artifacts.*Clinical Relevance/Application Virtual calcium-removed images calculated from multi-energy photon-counting CT have potential to aid in the assessment of stenosis.

RESULTS

The visual impression of the calcium-removed stenosis matches the expectation given by the phantom specification. The deterioration in overall image quality towards lower exposure levels, due to an increase in image noise or due to vessel phantom motion with increasing heart rate is comparable between calcium removed and standard reconstructions. The quantitative stenosis evaluation based on voxel mask matching did exhibit a significant dependency on the applied heart rate.

CLINICAL RELEVANCE/APPLICATION

Virtual calcium-removed images calculated from multi-energy photon-counting CT have potential to aid in the assessment of stenosis.

SSPH07-5 Characterization And Potential Standardization Of Energy Independent CT Reconstruction Techniques Using An Investigational Dual-Source Photon-Counting CT System - Preliminary Phantom Study

Participants
Fides Schwartz, MD, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To assess the performance and the potential of an investigational dual-source photon-counting CT system (PCCT) for standardized image output independent of acquisition parameters.*Methods and Materials A Gammex multi-energy phantom (20 cm insert) was scanned on an investigational full field-of-view PCCT system (NAEOTOM Alpha, Siemens Healthineers) using diverse kV (90, Sn100, 120, and 140) with corresponding CTDI values (14.5, 3.2, 24 and 24 mGy, respectively). In all cases quantum or quantum plus standard modes were used (M4, with 352 um pixel size at isocenter). Images were reconstructed with Qr40 kernel, using monoenergetic images at 70 keV, and a slice thickness of 3 mm. Hounsfield units [HU] were measured in triplicate in three target inserts (insert 1: iodine at 15 mg/cc, insert 2: iodine at 10 mg/cc, insert 3: calcium at 50 mg/cc) as well as the background. Mean attenuation, noise, signal to noise ratio (SNR) and contrast to noise ratio (CNR=attenuationinsert - attenuationbackground/noise) as well as a dose weighted SNRD (SNR/sqrt(CTDIvol) and CNRD (CNR/sqrt(CTDIvol)) were calculated.*Results Average difference in CT number attenuation across the evaluated inserts was 4% (range: 0.9-14%). Mean HU of insert 1 was 396 ± 3, 392 ± 3, 371 ± 4, and 397 ± 8 at 140, 120, 90, and Sn100 kV, respectively. The corresponding values for inserts 2 and 3 where 269 ± 3 and 111 ± 3, 265 ± 3 and 108 ± 3, 246 ± 4 and 93 ± 4, and 273 ± 7 and 109 ± 6. SNRD had an average difference of 6.7% across the evaluated inserts (range: 0.6-15%). CNRD had an average difference of 3.8 % across the evaluated inserts (range: 1-11%).*Conclusions PCCT technology may enable standardization of attenuation values (HU) of iodine containing structures irrespective of the kV scanning technique. Image output can be standardized to produce comparable CT attenuation numbers in preliminary phantom data from an investigational photon-counting CT.*Clinical Relevance/Application Standardization of attenuation values (HU) irrespective of the kV selection may result in improved clinical implementation of patient-specific tube voltage modulation techniques.

RESULTS

Average difference in CT number attenuation across the evaluated inserts was 4% (range: 0.9-14%). Mean HU of insert 1 was 396 ± 3, 392 ± 3, 371 ± 4, and 397 ± 8 at 140, 120, 90, and Sn100 kV, respectively. The corresponding values for inserts 2 and 3 where 269 ± 3 and 111 ± 3, 265 ± 3 and 108 ± 3, 246 ± 4 and 93 ± 4, and 273 ± 7 and 109 ± 6. SNRD had an average difference of 6.7% across the evaluated inserts (range: 0.6-15%). CNRD had an average difference of 3.8 % across the evaluated inserts (range: 1-11%).

CLINICAL RELEVANCE/APPLICATION

Standardization of attenuation values (HU) irrespective of the kV selection may result in improved clinical implementation of patient-specific tube voltage modulation techniques.

SSCA07-1   Pre-Procedural CTA-based Left And Right Ventricular Longitudinal Strain Provides Superior Prediction Of Mortality Compared To Ejection Fraction In Transcatheter Aortic Valve Replacement

Participants
Gilberto Aquino, MD, Charleston, South Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To assess the predictive value of pre-procedural, multiphasic cardiac CT-based left (LV) and right ventricular (RV) long axis strain (LAS) for mortality in patients undergoing transcatheter aortic valve replacement (TAVR).*Methods and Materials One hundred and seventy-five patients (78.8 ± 8.9 years) with severe aortic stenosis who had previously undergone TAVR were retrospectively evaluated in this 24-months follow up study. Mortality was the primary endpoint. Pre-TAVR CTAs with 10-100% phases were analyzed in 4-chamber view. For LV-LAS, the distance between the epicardial border of the LV apex and the middle of the mitral plane was measured in both endsystole and enddiastole. For RV-LAS, the distance between the LV apex and the middle of the tricuspid plane was measured. LAS was then computed by LAS= ([lengthendsystole - lengthenddiastole)] / lengthenddiastole) x 100. ROC curve analysis was performed to acquire the optimal cutoff for LV-LAS and RV-LAS and these were then divided into normal or abnormal LAS. Survival analysis was done to obtain hazard ratios (HR) and Harrell's c-index was used to evaluate risk models. LV-LAS and RV-LAS were each adjusted for the Society of Thoracic Surgeons (STS) score for mortality currently used to risk stratify TAVR patients.*Results Median follow-up was 21 months. There were 38 deaths (22%). The optimal cutoffs for LV-LAS and RV-LAS were -9.0% and -11.4%, respectively. Abnormal LV-LAS (HR 2.8; 95% CI 1.2-6.6; p=0.022) and RV-LAS (HR 2.7; 1.3-5.6; p=0.008) were independently associated with mortality after adjustment for variables predictive on univariable analysis and LV and RV ejection fraction. When adjusted for the STS risk score, LV-LAS (HR 3.4; 1.5-7.7; p=0.004) and RV-LAS (HR 2.4; 1.2-4.8; p=0.016) remained significantly predictive. C-indices for LV-LAS and RV-LAS were 0.624 and 0.640, respectively. Adding LV-LAS and RV-LAS to the STS score significantly improved its c-index from 0.636 to 0.684 for prediction of mortality.*Conclusions Pre-TAVR, LV-LAS and RV-LAS independently predict post-TAVR mortality beyond ventricular ejection fraction and improve the current clinical risk-stratifying tool.*Clinical Relevance/Application CTA-based left and right ventricular longitudinal strain have the potential to improve risk stratification and post-treatment surveillance in patients undergoing TAVR.

RESULTS

Median follow-up was 21 months. There were 38 deaths (22%). The optimal cutoffs for LV-LAS and RV-LAS were -9.0% and -11.4%, respectively. Abnormal LV-LAS (HR 2.8; 95% CI 1.2-6.6; p=0.022) and RV-LAS (HR 2.7; 1.3-5.6; p=0.008) were independently associated with mortality after adjustment for variables predictive on univariable analysis and LV and RV ejection fraction. When adjusted for the STS risk score, LV-LAS (HR 3.4; 1.5-7.7; p=0.004) and RV-LAS (HR 2.4; 1.2-4.8; p=0.016) remained significantly predictive. C-indices for LV-LAS and RV-LAS were 0.624 and 0.640, respectively. Adding LV-LAS and RV-LAS to the STS score significantly improved its c-index from 0.636 to 0.684 for prediction of mortality.

CLINICAL RELEVANCE/APPLICATION

CTA-based left and right ventricular longitudinal strain have the potential to improve risk stratification and post-treatment surveillance in patients undergoing TAVR.

SSCA07-2   Feasibility And Comparison Of Resting Full-cycle Ratio And CT Fractional Flow Reserve In Patients With Relevant Aortic Valve Stenosis

Participants
Marcel Langenbach, MD, Cologne, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Data on the evaluation of either CT-derived fractional flow reserve (CT-FFR) or resting full-circle ration (RFR) in patients with severe aortic valve stenosis (AS) undergoing transcatheter aortic valve replacement (TAVR) are unknown. Therefore, purpose of the present study was to evaluate the diagnostic performance of CT-FFR derived from TAVR-planning CT compared to invasive RFR in patients with relevant AS and intermediate coronary stenosis.*Methods and Materials The study included patients with relevant AS undergoing ICA with pressure wire assessment and routine contrast enhanced pre-TAVR CTA without an additional coronary CTA. CT-FFR analysis were performed using on-site CT-FFR software (Siemens Healthineers, Inc) by two experienced CT angiographers.*Results 41 patients with 46 coronary lesions were investigated using RFR and CT-FFR. The mean age of the subjects was 80.1 ± 6.2 years. Of these patients, 21 (51.2%) were female. No complication during CTA or pressure wire assessment were observed. The RFR showed a significant correlation with CT-FFR (Pearson correlation coefficient, R =0.76, p<0.001). On a per-patient basis, diagnostic accuracy, sensitivity, specificity, positive predictive value (PPV), and negative

predictive (NPV) value of CT-FFR were 84.8% (Sensitivity, 95% CI?=?71.1; 93.7), 72.7% (Specificity, 95% CI?=?49.8%; 89.3%), 95.8% (PPV, 95% CI?=?78.9%; 99.9%), 94.1% (NPV, 95% CI?=?69.8; 99.1), and 79.3% (PPV, 95% CI?=?65.8; 88.4), respectively. The optimal CT-FFR cut-off value for RFR =0.89 prediction was 0.795. Per-patient receiver operator curve using RFR = 0.89 as the reference standard analysis showed a larger area under the curve (AUC) for CT-FFR 0.91 (95% CI 0.83-0.99) compared with that for CTA >50% 0.56 (95% CI 0.40-0.73) and CTA >70% 0.72 (95% CI 0.56-0.87).*Conclusions CT-FFR assessed by routine pre-TAVR CTA is a safe and feasible method showing a significant correlation with invasive RFR in patients with relevant AS. Diagnostic accuracy of CT-FFR is superior to analysis of the coronary arteries in ICA, and percentage stenosis grading in CTA >50% and >70% in assessing the hemodynamic relevance of coronary lesions in patients with relevant AS.*Clinical Relevance/Application CT-FFR derived from routing pre-TAVR CTA in patients with relevant AS can be used for non-invasive assessment of the hemodynamic relevance of coronary lesions with the potential to reduce unnecessary pre-TAVR ICA in the present of intermediate coronary stenosis.

RESULTS

41 patients with 46 coronary lesions were investigated using RFR and CT-FFR. The mean age of the subjects was 80.1 ± 6.2 years. Of these patients, 21 (51.2%) were female. No complication during CTA or pressure wire assessment were observed. The RFR showed a significant correlation with CT-FFR (Pearson correlation coefficient, R =0.76, p<0.001). On a per-patient basis, diagnostic accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive (NPV) value of CT-FFR were 84.8% (Sensitivity, 95% CI?=?71.1; 93.7), 72.7% (Specificity, 95% CI?=?49.8%; 89.3%), 95.8% (PPV, 95% CI?=?78.9%; 99.9%), 94.1% (NPV, 95% CI?=?69.8; 99.1), and 79.3% (PPV, 95% CI?=?65.8; 88.4), respectively. The optimal CT-FFR cut-off value for RFR =0.89 prediction was 0.795. Per-patient receiver operator curve using RFR = 0.89 as the reference standard analysis showed a larger area under the curve (AUC) for CT-FFR 0.91 (95% CI 0.83-0.99) compared with that for CTA >50% 0.56 (95% CI 0.40-0.73) and CTA >70% 0.72 (95% CI 0.56-0.87).

CLINICAL RELEVANCE/APPLICATION

CT-FFR derived from routing pre-TAVR CTA in patients with relevant AS can be used for non-invasive assessment of the hemodynamic relevance of coronary lesions with the potential to reduce unnecessary pre-TAVR ICA in the present of intermediate coronary stenosis.

SSCA07-3   Pre-Procedural CTA-based Left Atrial Function Independently Predicts Mortality In Transcatheter Aortic Valve Replacement

Participants
Gilberto Aquino, MD, Charleston, South Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To assess the predictive value of pre-procedural, multiphasic cardiac CT-based left atrial (LA) volume (LAV) and function for all-cause mortality in patients undergoing transcatheter aortic valve replacement (TAVR).*Methods and Materials One hundred and seventy-five patients (78.8 ± 8.9 years) with severe aortic stenosis who had previously undergone TAVR were retrospectively evaluated. All-cause mortality was the primary endpoint over a 24-month follow up period. Pre-TAVR CTAs with 10-100% phases were analyzed using the area-length method to measure maximum and minimum LAV in 2-chamber and 4-chamber views, and indexed LAV (LAVI = LAV/BSA) were then used. LA emptying fraction (LAEF) was obtained as (LAVmax-LAVmin)/LAVmax. LAVI and LAEF were divided into quintiles for analysis. Cox regression was performed for survival analysis to obtain hazard ratios (HR) and Harrell's c-index was used to evaluate risk models. LAV and LAEF were each adjusted for the Society of Thoracic Surgeons (STS) score for mortality currently used to risk stratify TAVR patients.*Results Median follow-up was 21 months. There were 38 deaths (22%). LAEF (HR 0.69; 95% CI 0.49-0.97; p=0.035; per quintile) was independently associated with mortality after adjustment for variables predictive on univariable analysis. LAVImax (HR 1.25; 0.93-1.69; p=0.147; per quintile) and LAVImin (HR 1.35; 0.90-2.03; p=0.147; per quintile) were not significant when adjusted for all of these confounders. When adjusted for the STS risk score, LAVImax (HR 1.32; 1.04-1.69; p=0.025), LAVImin (HR 1.42; 1.10-1.84; p=0.007), and LAEF (HR 0.73; 0.57-0.94; p=0.016) were significantly predictive for mortality. LAVImax, LAVImin, and LAEF had a c-index of 0.633, 0.668, and 0.667 for prediction of death, respectively, while STS score had a c-index of 0.636. Adding LAEF to the STS score significantly improved its c-index to 0.700 for prediction of mortality.*Conclusions Pre-TAVR, CTA-based LA volume and LA emptying fraction independently predict mortality post-TAVR and improve the current clinical risk-stratifying tool.*Clinical Relevance/Application CTA-based LAV and LAEF have the potential to improve risk stratification and post-treatment surveillance in patients undergoing TAVR.

RESULTS

Median follow-up was 21 months. There were 38 deaths (22%). LAEF (HR 0.69; 95% CI 0.49-0.97; p=0.035; per quintile) was independently associated with mortality after adjustment for variables predictive on univariable analysis. LAVImax (HR 1.25; 0.93-1.69; p=0.147; per quintile) and LAVImin (HR 1.35; 0.90-2.03; p=0.147; per quintile) were not significant when adjusted for all of these confounders. When adjusted for the STS risk score, LAVImax (HR 1.32; 1.04-1.69; p=0.025), LAVImin (HR 1.42; 1.10-1.84; p=0.007), and LAEF (HR 0.73; 0.57-0.94; p=0.016) were significantly predictive for mortality. LAVImax, LAVImin, and LAEF had a c-index of 0.633, 0.668, and 0.667 for prediction of death, respectively, while STS score had a c-index of 0.636. Adding LAEF to the STS score significantly improved its c-index to 0.700 for prediction of mortality.

CLINICAL RELEVANCE/APPLICATION

CTA-based LAV and LAEF have the potential to improve risk stratification and post-treatment surveillance in patients undergoing TAVR.

SSCA07-5   Combined Coronary CT-angiography And TAVI-planning For Ruling-out Significant Coronary Artery Disease: Added Value Of Machine-learning Based CT-FFR

Participants
Robin Gohmann, MD, Leipzig, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To analyze the ability of machine learning (ML)-based CT-derived fractional flow reserve (CT-FFR) to further increase the diagnostic performance of coronary CTA (cCTA) for ruling-out significant Coronary artery disease (CAD) during pre-transcatheter aortic valve implantation (TAVI) evaluation in patients with a high pre-test probability for CAD.*Methods and Materials Overall, 460 patients (79.6±7.4 years) undergoing pre-TAVI CT were included and examined with an ECG-gated CT-scan of the heart and high-pitch-scan of the vascular access route. Images were evaluated for significant CAD. Patients routinely underwent invasive coronary

angiography (ICA) (388/460), which was omitted at the discretion of the local Heart Team if CAD could be effectively ruled out on cCTA (72/460). CT-examinations where CAD could not be ruled out (CAD+) (n=272) underwent additional ML-based CT-FFR.*Results ML-based CT-FFR was performed successfully in 79.4% (216/272) of all CAD+ patients and correctly reclassified 25 patients as CAD negative. CT-FFR was not feasible in 20.6% because of reduced image quality (37/56) or anatomical variants (19/56). Sensitivity, specificity, PPV, and NPV were 94.9%, 55.2%, 53.9%, and 95.2%, respectively. The additional evaluation with ML-based CT-FFR increased accuracy by ?+5.4% (CAD+: ?+9.7%) and raised the total number of exams negative for CAD to 44.1% (138/460).*Conclusions ML-based CT-FFR may further improve the diagnostic performance of cCTA by correctly reclassifying a considerable proportion of TAVI patients with morphological signs of CAD on cCTA.*Clinical Relevance/Application CAD is a frequent co-morbidity in patients undergoing TAVI. Current guidelines recommend its assessment prior to TAVI. If significant CAD can be excluded on cCTA, ICA may be omitted.Although cCTA is a very sensitive test, it is limited by relatively low specificity and positive predictive value, particularly in high-risk patients. CT-FFR has the potential to improve the specificity and PPV of cCTA and to further reduce the need for ICA in this challenging elderly patient group prior to TAVI.

RESULTS

ML-based CT-FFR was performed successfully in 79.4% (216/272) of all CAD+ patients and correctly reclassified 25 patients as CAD negative. CT-FFR was not feasible in 20.6% because of reduced image quality (37/56) or anatomical variants (19/56). Sensitivity, specificity, PPV, and NPV were 94.9%, 55.2%, 53.9%, and 95.2%, respectively. The additional evaluation with ML-based CT-FFR increased accuracy by ?+5.4% (CAD+: ?+9.7%) and raised the total number of exams negative for CAD to 44.1% (138/460).

CLINICAL RELEVANCE/APPLICATION

CAD is a frequent co-morbidity in patients undergoing TAVI. Current guidelines recommend its assessment prior to TAVI. If significant CAD can be excluded on cCTA, ICA may be omitted.Although cCTA is a very sensitive test, it is limited by relatively low specificity and positive predictive value, particularly in high-risk patients. CT-FFR has the potential to improve the specificity and PPV of cCTA and to further reduce the need for ICA in this challenging elderly patient group prior to TAVI.

SSCA07-6 Retrospectively Gated Cardiac CT For Predicting Left Ventricular Dysfunction Following Mitral Valve Repair: Comparison With Echocardiography

Participants
Prajwal Reddy, MD, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

Current guidelines emphasize prophylactic mitral valve repair based on echocardiographic left ventricular ejection fraction (LV, LVEF) and end systolic diameter (LVESD) cutoffs to prevent irreversible LV dysfunction. Coronary CTA (CCTA) has been shown to be a viable alternative to invasive coronary angiography for preoperative assessment of coronary artery disease in patients undergoing mitral repair. Retrospectively gated CCTA can provide the same indices of LV size and function as echocardiography but has not been validated for this purpose. We sought to compare CCTA and echocardiography as predictors of post-mitral-repair systolic dysfunction.*Methods and Materials In this IRB-approved study, we retrospectively identified 243 adult patients (>18 years old) with primary mitral valve regurgitation who underwent repair between 2008 and 2018. Inclusion criteria were availability of standard of care pre-operative echocardiography, pre-operative retrospectively-gated CCTA, and post-operative echocardiogram after 6-36 months. Exclusion criteria included greater than mild mitral regurgitation at echocardiographic follow-up and inadequate CT image quality. Several indices of LV size and function measured on CCTA were compared with echocardiography in terms of predicting post-operative LV systolic dysfunction (echocardiographic LVEF < 50%). Area under the receiver operating characteristic curve (AUC) was used as the primary metric. The effect of biometric indexing with respect to body surface area was evaluated.*Results The best CCTA predictors of post-operative LV systolic dysfunction were LVEF (AUC 0.84) and indexed LV end systolic volume (LVESVi; AUC 0.88) and the best echocardiographic predictors were LVEF (AUC 0.70) and LVESD (AUC 0.79; Figure 1). CCTA-derived LVEF was a significantly better predictor of post-operative LV systolic dysfunction than echocardiography-derived LVEF (p = 0.02). LVESVi was a significantly better predictor than echocardiographic LVESD (p = 0.03).*Conclusions Retrospectively gated CCTA is superior to echocardiography in predicting left ventricular systolic dysfunction following mitral valve repair.*Clinical Relevance/Application Risk stratification based on CCTA-derived measures of LV size and function may reduce the incidence of postoperative LV dysfunction.

RESULTS

The best CCTA predictors of post-operative LV systolic dysfunction were LVEF (AUC 0.84) and indexed LV end systolic volume (LVESVi; AUC 0.88) and the best echocardiographic predictors were LVEF (AUC 0.70) and LVESD (AUC 0.79; Figure 1). CCTA-derived LVEF was a significantly better predictor of post-operative LV systolic dysfunction than echocardiography-derived LVEF (p = 0.02). LVESVi was a significantly better predictor than echocardiographic LVESD (p = 0.03).

CLINICAL RELEVANCE/APPLICATION

Risk stratification based on CCTA-derived measures of LV size and function may reduce the incidence of postoperative LV dysfunction.

SPR-MS-1   Association Of Language With Image Utilization In An Emergency Department

Participants
Youyun Zheng, BS,BA, BOSTON, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Patients with Limited English Proficiency (LEP) are frequently encountered in the Emergency Department (ED). We hypothesize that patients with LEP will experience increased imaging compared to patients without these limitations, controlling for similar chief complaints and demographic factors.*Methods and Materials This IRB-approved retrospective study included patient visits to an academic quaternary ED from April to August 2019 and accompanying imaging data for 4 imaging modalities (CT, X-ray, MRI, and ultrasound). Imaging utilization on a per-patient basis was tallied for each patient within a 24-hour timeframe from the time of arrival. LEP status is formally recorded as a flag in our electronic health record as patients "requiring interpreter". Multivariable linear regression models were then constructed to identify the association between LEP, other baseline clinical covariates, and demographic variables with imaging study utilization.*Results 35646 ED patient visits were included (M 51.5%, F 48.5%, age 50 ± 22.2). Interpreters were required at the point of care in 11.8% of these patient visits. In total, we identified 11136 CTs, 15860 X-rays, 2744 MRIs, and 1854 ultrasound imaging records connected to these ED visits, with 24.0%, 32.8%, 3.9%, and 5.0% patients having at least 1 scan of each of the modalities respectively. Patients with LEP received on average 9.4% more CT scans (mean 0.32 scan per patient) and 9.1% more X-rays (mean 0.44 X-ray per patient). Moreover, we found other variables significantly associated with more CT and X-ray imaging including an emergent arrival method, having abdominal pain or chest pain, and age. Our analysis did not find a significant association between LEP status and neither MRI nor ultrasound imaging.*Conclusions These findings highlight the need for interpreter services, provider training with those services, and improved patient-provider communication in the ED.*Clinical Relevance/Application Overutilization of imaging for patients with LEP due to ED inefficiencies can be costly for the patient and institution. Better training and access to language services can improve care for these patients.

RESULTS

35646 ED patient visits were included (M 51.5%, F 48.5%, age 50 ± 22.2). Interpreters were required at the point of care in 11.8% of these patient visits. In total, we identified 11136 CTs, 15860 X-rays, 2744 MRIs, and 1854 ultrasound imaging records connected to these ED visits, with 24.0%, 32.8%, 3.9%, and 5.0% patients having at least 1 scan of each of the modalities respectively. Patients with LEP received on average 9.4% more CT scans (mean 0.32 scan per patient) and 9.1% more X-rays (mean 0.44 X-ray per patient). Moreover, we found other variables significantly associated with more CT and X-ray imaging including an emergent arrival method, having abdominal pain or chest pain, and age. Our analysis did not find a significant association between LEP status and neither MRI nor ultrasound imaging.

CLINICAL RELEVANCE/APPLICATION

Overutilization of imaging for patients with LEP due to ED inefficiencies can be costly for the patient and institution. Better training and access to language services can improve care for these patients.

SPR-MS-10   Optimizing Windowing Of Pancreatic And Kidney Pathology On Dual Energy CT Using A Simplex Algorithm

Participants
Gili Dar, MD, Jerusalem, Israel (*Presenter*) Nothing to Disclose

PURPOSE

To determine optimal window settings for conspicuity of inflammatory pancreatic and kidney processes on 50keV low-monoenergetic images derived from dual-layer spectral detector CT images.*Methods and Materials Fifteen patients each with either clinically proven pancreatitis or pyelonephritis with foci of inflammation on Dual energy abdominal CT scans (30 patients total) were identified and selected to serve as reference populations. 50keV low-monoenergetic images in the portal venous phase were iteratively evaluated by 6 abdominal radiologists in multiple different windows (7-350 center; 120-580 width). Each reader graded the parenchymal hypodense lesions conspicuity on a scale of 1-5 (1- impossible, 2- poor, 3 - acceptable, 4 - good, 5 - optimal), as well as the overall image background quality on a scale of 1-3 (1 - poor, 2- acceptable, 3 - optimal). Simplex algorithm, an efficient mathematical tool for solving linear programing problems to optimize system parameters was used in order to determine optimal window settings for lesion conspicuity . Three-dimensional contour maps expressing the relationship between window setting and overall reader grade were constructed for both pancreas and kidney, as well as for overall background quality.*Results Convergence was achieved over 18 iterations over a total of 3780 reads (twenty-one windows setting x 6 readers x 30 cases). Optimal conspicuity (grade >4.5±0.04) of hypodense pancreas parenchymal lesions ranged from 100-145 center over 420-460 width, whereas hypodense pyelonephritis foci had optimal conspicuity with a center ranging 160-260 and width 420-450. Optimal visualization of background structures was optimal at a lower 50-150 center maintaining a 400-540 width. An ideal range for visualizing both pancreas and kidney lesions together were 150/440 (>4±0.18), substantially higher than manufacturer recommended settings of 60/400 (center/width).*Conclusions 50keV low monoenergetic images require specific window setting to achieve optimal visualization of pathology in different abdominal organs. Simplex optimization may offer a robust method to tailor

settings to enable better lesion conspicuity compared to default window settings potentially improving diagnostic accuracy.*Clinical Relevance/Application We demonstrate the need and provide a robust method for organ-specific optimization of window settings to improve parenchymal lesion conspicuity and visualization at CT. Simplex algorithm optimization can be a powerful tool for tailored optimal default window setting definition for many diagnostic applications.

RESULTS

Convergence was achieved over 18 iterations over a total of 3780 reads (twenty-one windows setting x 6 readers x 30 cases). Optimal conspicuity (grade >4.5±0.04) of hypodense pancreas parenchymal lesions ranged from 100-145 center over 420-460 width, whereas hypodense pyelonephritis foci had optimal conspicuity with a center ranging 160-260 and width 420-450. Optimal visualization of background structures was optimal at a lower 50-150 center maintaining a 400-540 width. An ideal range for visualizing both pancreas and kidney lesions together were 150/440 (>4±0.18), substantially higher than manufacturer recommended settings of 60/400 (center/width).

CLINICAL RELEVANCE/APPLICATION

We demonstrate the need and provide a robust method for organ-specific optimization of window settings to improve parenchymal lesion conspicuity and visualization at CT. Simplex algorithm optimization can be a powerful tool for tailored optimal default window setting definition for many diagnostic applications.

SPR-MS-12   Role Of Cervical Spine Multi Detector Computed Tomography With The Assessment Of Paraspinal Fat Pad And Additional Parameters In Detecting Ligament, Intervertebral Disc, And Spinal Cord Injury In Adult Obtunded Suspected Cervical Spine Injury Patient

Participants
Pradeep Roul, MBBS, Rishikesh, India (*Presenter*) Nothing to Disclose

PURPOSE

To assess the diagnostic accuracy of masking of paraspinal fat pad (PFP) in only disco-ligamentous injury in cervical spine injury (CSI) and its comparison with prior defined cut-off of various measurements. We try to look for any significant correlation of masking of PFP and spondylolisthesis with posterior ligament complex (PLC), anterior and posterior longitudinal ligament injury and spinal cord signal changes. We also investigated whether there is significant correlation of grade of isolated reduction and angle of posterior widening of intervertebral disc (IVD) with disc injury.*Methods and Materials This prospective work enrolled 1045 patients after taking institutional ethical clearance and consent from legal guardian. Contraindication to MRI or previous surgery in cervical spine region was our exclusion criteria. Masking of PFP was graded from 0 to IV based on percentage of masked PFP volume; 0- no, I - 0-25 %, II - 26-50%, III - 51-75 %, and IV - 76-100%. Facet joint subluxation was graded from 0 to VI based on the percentage of articular surface in contact; 0- 100 %, I - 76-100 %, II - 51-75 %, III- 26-50 %; IV- 1-25 %, V- perched, and VI-locked facet joint. Angle of posterior widening of IVD and facet joint distance was measured in mid sagittal plane. For grading of spondylolisthesis, we used Meyerding Classification. The grade of reduction was graded from 0 to IV based upon percentage of reduction of IVD height in comparison to mean of just above and below IVD; 0= no reduction, 1= 1-25 %, 2= 26-50 %, 3=61-75 % and 4 = 75-100 % reduction. Patient was followed up after 4-6 weeks of institutional discharge.*Results Masking of PFP has sensitivity and specificity of around 87.5 % and 93.3 % respectively in detecting only disco-ligamentous injury (106 patients). Masking of PFP has significant associated with PLC injury (Odds ratio, 140.2, P<0.001). Grade = II of spondylolisthesis is associated with longitudinal ligament injury (odds ratio, 92.3, P<0.001) and spinal cord changes (odds ratio, 42.3, P<0.002). The angle of posterior widening more than 11 degree was associated with disc injury significantly (odds ratio, 32.3, P<0.01).*Conclusions Masking of paraspinal fat pad is has higher sensitivity, specificity and positive predictive value in detecting disc-ligamentous injury without any obvious bony or alignment abnormality in MDCT than various cervical spine measurements.*Clinical Relevance/Application 1. Masking of PFP can better guide of requirement of MRI cervical spine.2. Can predict ligament injury and help in further management in MRI contraindicated case.3. More confident CSI clearance with MDCT.

RESULTS

Masking of PFP has sensitivity and specificity of around 87.5 % and 93.3 % respectively in detecting only disco-ligamentous injury (106 patients). Masking of PFP has significant associated with PLC injury (Odds ratio, 140.2, P<0.001). Grade = II of spondylolisthesis is associated with longitudinal ligament injury (odds ratio, 92.3, P<0.001) and spinal cord changes (odds ratio, 42.3, P<0.002). The angle of posterior widening more than 11 degree was associated with disc injury significantly (odds ratio, 32.3, P<0.01).

CLINICAL RELEVANCE/APPLICATION

1. Masking of PFP can better guide of requirement of MRI cervical spine.2. Can predict ligament injury and help in further management in MRI contraindicated case.3. More confident CSI clearance with MDCT.

SPR-MS-13   'Disaster' CT - Validation Of An Abbreviated Whole Body Trauma CT Protocol For Use In Mass Casualty Incidents

Participants
Muhammad Israr Ahmad, MBBS, Vancouver, British Columbia (*Presenter*) Nothing to Disclose

PURPOSE

In a Mass Casualty Incident (MCI), CT is and important tool for triage but can be a bottleneck to patient care. Improved scan efficiency allows more rapid patient throughput, helping more patients be assessed/treated. We propose that an abbreviated 'Disaster' whole body trauma CT (WBCT) protocol with minimal phases/reformats is an acceptable substitution for conventional WBCT in an MCI and is non-inferior for detecting acute traumatic injuries. This protocol expedites scanning/reformat creation and network traffic as less images are generated.*Methods and Materials This IRB-approved retrospective comparative study identified 10 complex trauma WBCT examinations. Only the required series (axial CT head, axial CT angiogram vertex to pelvis, sagittal reformat cervical spine) were isolated to a separate folder, anonymised, and interpreted by 4 fellowship-trained emergency radiologists (2 fellows, 2 staff) using speech-dictation and without time limit. Multi-planar reformat (MPR) creation was not permitted. Readers were blinded to clinical details, prior imaging and report/remaining series for index WBCT. Resultant reports were with compared with dictated reports for each WBCT and discrepancies documented. Missed findings were reviewed on reference CT and their likelihood of requiring immediate management determined. Data analysis was performed using appropriate quantitative/qualitative methods.*Results Across all readers, 92% of acute traumatic findings were detected (87% by fellows, 97%

by staff). Low grade cerebrovascular injury was the most common missed finding (n=10). Lack of MPRs may be contributory. Other missed findings included: intracranial hemorrhage (n=1), low grade solid organ injury (n=2 liver/n=1 spleen/n=3 kidney), hemoperitoneum (n=1), hemopneumothorax/lung contusion (n=4), cervical spine injury (n=2). Most missed injuries were low grade and would not require immediate treatment in an MCI. 9 false positive solid organ injury interpretations (n=7 kidney/n=2 spleen) were likely partly due to only arterial phase images being provided. Missed findings were more likely in fellows (2.5% v 1.25%) and false positives were more likely in staff (6.5% v 1.5%) suggesting experience with injury patterns impacts interpretation.*Conclusions An abbreviated 'Disaster' WBCT protocol, is non-inferior to standard protocol WBCT for detection of acute traumatic findings requiring immediate treatment in an MCI and may expedite patient triage. However, it is suboptimal for detection of low grade cerebrovascular injuries.*Clinical Relevance/Application Use of an abbreviated whole body trauma CT protocol in a mass casualty incident can expedite imaging without missing those injuries that require immediate treatment.

RESULTS

Across all readers, 92% of acute traumatic findings were detected (87% by fellows, 97% by staff). Low grade cerebrovascular injury was the most common missed finding (n=10). Lack of MPRs may be contributory. Other missed findings included: intracranial hemorrhage (n=1), low grade solid organ injury (n=2 liver/n=1 spleen/n=3 kidney), hemoperitoneum (n=1), hemopneumothorax/lung contusion (n=4), cervical spine injury (n=2). Most missed injuries were low grade and would not require immediate treatment in an MCI. 9 false positive solid organ injury interpretations (n=7 kidney/n=2 spleen) were likely partly due to only arterial phase images being provided. Missed findings were more likely in fellows (2.5% v 1.25%) and false positives were more likely in staff (6.5% v 1.5%) suggesting experience with injury patterns impacts interpretation.

CLINICAL RELEVANCE/APPLICATION

Use of an abbreviated whole body trauma CT protocol in a mass casualty incident can expedite imaging without missing those injuries that require immediate treatment.

SPR-MS-2   Radiological Findings In Victims Of Intimate Partner Violence On The Trauma Service - A Retrospective Analysis Of Two Level 1 Trauma Centers

Participants
Ellen Sun, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To identify and classify diagnostic imaging patterns of intimate partner violence (IPV) related injuries in patients presenting to the trauma service in the emergency departments (ED) based on anatomic location and mechanism of injury.*Methods and Materials We searched the trauma registry of two Level 1 trauma centers for adult patients reporting "abuse" over 3 and 5 years to identify IPV victims. Imaging and electronic medical records were then reviewed for the following information: type of abuse, demographics, type of injury, IPV/injury severity scores, days of hospitalization, level of inpatient care, and any previous or subsequent presentations for presumed IPV.*Results 29/18465 (0.2%) adult patients seen on trauma service had reported IPV. There were 26 females and 3 males (mean age 37, range 19-84). Majority of patients were Caucasian (20/29) and more than half had &9;psychiatric (55%) or substance use (52%) comorbidities. Blunt trauma (22/29) was more common than penetrating trauma (10/29) as the mechanism of injury; 3 patients had both injury types. Knife was used as a weapon in 80% of penetrating injuries. Craniofacial injuries were the most frequent (19/29), particularly midface soft tissue injuries (14/29). Thoracic injuries were the second most common (12/29), mainly rib fractures (7/12), followed by injuries to the upper and lower extremities, as well as the abdomen (11/29 each). No cervical spine fractures were observed in this cohort; however, 6 patients had either cervical soft tissue injury or ligamentous strain. Of the 3 patients with injury to the thoracolumbar spine, all had upper lumbar spine (L1 and L2) fractures. The average injury severity scale was 11.6 with 28/29 patients scoring grade 3 or 4 on the IPV severity grading scale. Average hospital stay was 5.5 days. Eight patients required ICU-level care and the average ICU stay was 3.9 days. 45% (13/29) of patients reported prior history of IPV. Four patients had prior ED presentations for IPV or suspected IPV. In all cases, the reported injuries were less severe than the index presentation.*Conclusions Despite its high prevalence, IPV remains underreported in patients presenting to trauma service in the ED. While craniofacial injuries dominate, thoracoabdominal, extremity and spinal injuries can also be the manifestations of IPV.*Clinical Relevance/Application IPV is not restricted to superficial bruises and contusions but can lead to severe multiorgan and life-threatening injuries. Early detection and intervention are critical to avoid escalating cycle of abuse and injuries. Our goal with this work is to create awareness of severity of IPV injuries.

RESULTS

29/18465 (0.2%) adult patients seen on trauma service had reported IPV. There were 26 females and 3 males (mean age 37, range 19-84). Majority of patients were Caucasian (20/29) and more than half had &9;psychiatric (55%) or substance use (52%) comorbidities. Blunt trauma (22/29) was more common than penetrating trauma (10/29) as the mechanism of injury; 3 patients had both injury types. Knife was used as a weapon in 80% of penetrating injuries. Craniofacial injuries were the most frequent (19/29), particularly midface soft tissue injuries (14/29). Thoracic injuries were the second most common (12/29), mainly rib fractures (7/12), followed by injuries to the upper and lower extremities, as well as the abdomen (11/29 each). No cervical spine fractures were observed in this cohort; however, 6 patients had either cervical soft tissue injury or ligamentous strain. Of the 3 patients with injury to the thoracolumbar spine, all had upper lumbar spine (L1 and L2) fractures. The average injury severity scale was 11.6 with 28/29 patients scoring grade 3 or 4 on the IPV severity grading scale. Average hospital stay was 5.5 days. Eight patients required ICU-level care and the average ICU stay was 3.9 days. 45% (13/29) of patients reported prior history of IPV. Four patients had prior ED presentations for IPV or suspected IPV. In all cases, the reported injuries were less severe than the index presentation.

CLINICAL RELEVANCE/APPLICATION

IPV is not restricted to superficial bruises and contusions but can lead to severe multiorgan and life-threatening injuries. Early detection and intervention are critical to avoid escalating cycle of abuse and injuries. Our goal with this work is to create awareness of severity of IPV injuries.

SPR-MS-4   Reduced Rate Of Brain Waste Clearance For TBI Patients: Glymphatic Function Assessed Via MRI Within A Short Time

Participants
Xiao Wang, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

Dementia is commonly observed in traumatic brain injury (TBI) patients, however, there is no consensus on the exact mechanism of

how TBI promotes susceptibility to the development of dementia. Recent studies have shown that the glymphatic function was significantly affected in TBI mice. In this work, the TBI glymphatic function was assessed via MRI within a short time (1 hour) by measuring the rate of brain waste clearance.*Methods and Materials This study includes 16 TBI patients (5 females, mean age = 38, SD =3.7; rang 25-67 years) & 7 relative healthy controls (6 females, mean age=41, SD=2.5; rang 40-62) with no history of TBI. All the MRI experiments were performed on a 3.0 T Prisma scanner (Siemens, German) with a 64-channel head coil. Participants were instructed to keep awake during the scan on head first supine position. 3D high resolution T1 weighted brain images were obtained three times with 20 min intervals using MP2RAGE sequences after 4 hours lumbar intrathecal injections of gadolinium. Along the pathway of cerebrospinal fluid propagation, 4 regions(inferior frontal gyrus, parahippocampal gyrus, thalamus, Pons)in each hemisphere were predefined using standard atlas. The signal intensity of CSF nearby above regions was extracted for analyses. The rate of T1 signal change of two time points was simply calculated using the following equations $R2=(S2-S1)/S1$ & $R3=(S3-S1)/S1$, where Ri is the rate & Si is the signal intensity of corresponding time point.*Results As shown in Fig.1, significantly higher signal change rates were observed in 7 predefined CSF ROIs in TBI patients compared to controls within 1 hour scan after 4 hour injection gadolinium. The TBI patients show relatively slow clearance ability of gadolinium tracer for almost all predefined CSF regions.*Conclusions Besides previously reported the delayed enhancement after 24 hours injection of tracer, this work proved the glymphatic dysfunction can be assessed by signal intensity dynamic change rate within 20 min after 4 hour injection of the tracer as well. The deduced rate of tracer clearance in TBI patients may reflect damage of brain glymphatic system.*Clinical Relevance/Application The glymphatic impairment may cause the following dementia in TBI patients. The proposed rate of brain waste clearance in short time could be used as a novel biomarker to assess the glymphatic function.

RESULTS

As shown in Fig.1, significantly higher signal change rates were observed in 7 predefined CSF ROIs in TBI patients compared to controls within 1 hour scan after 4 hour injection gadolinium. The TBI patients show relatively slow clearance ability of gadolinium tracer for almost all predefined CSF regions.

CLINICAL RELEVANCE/APPLICATION

The glymphatic impairment may cause the following dementia in TBI patients. The proposed rate of brain waste clearance in short time could be used as a novel biomarker to assess the glymphatic function.

SPR-MS-5   Relationship Of Systemic And Pulmonary Thromboembolic Complications With The Severity Of Pulmonary Parenchymal Disease In COVID-19

Participants
Ali Elmokadem, MD,PhD, Mansoura, Egypt (*Presenter*) Nothing to Disclose

PURPOSE

To correlate thromboembolic (TE) complications secondary to COVID-19 with the extent of the pulmonary parenchymal disease using CT or CXR severity scores and other comorbidities. *Methods and Materials The final study cohort consisted of 144 patients after exclusion of 10 patients with non-diagnostic CT pulmonary angiography. Patients were classified into two groups based on the presence or absence of thromboembolic complications. The TE group included 40 patients with a mean age of 59.6±9.8 while the non-TE group included 104 patients with a mean age of 55.3±12.4. Thromboembolic complications were categorized based on location. Chest CT was used to assess the pulmonary parenchymal disease severity in 120 patients and CXR in 24 patients.*Results Thromboembolic complications were detected in 40 patients (27.7%). Patients with BMI>30 kg/m2 or having a history of smoking and HTN were found more frequently in the TE group (p<0.05). Patients admitted to ICU were significantly higher in the TE group (p =0.001). There was no statistically significant difference (p>0.05) in chest CT-SS between the TE group (25.4±8.4) and non-TE group (22.6±5.5), and CXR-SS between the TE group (11.8±4.7) and non-TE group (8.9±5.1). The percentage of moderate and severe parenchymal disease in the TE group was significantly higher compared to the non-TE group (p<0.05). Severe parenchymal disease, BMI>30kg/m2, smoking, and HTN had a higher and more significant odds ratio for developing TE complications.*Conclusions The present data suggest that severe pulmonary parenchymal disease secondary to COVID-19 associated with a higher incidence of thromboembolic complications.*Clinical Relevance/Application • Relationship of thromboembolic complication with the pulmonary parenchymal disease in COVID-19 patients. • Assessment of pulmonary parenchymal disease severity using chest CT and X-ray severity scoring. • Relationship of thromboembolic complication with comorbidities in COVID-19 patients.

RESULTS

Thromboembolic complications were detected in 40 patients (27.7%). Patients with BMI>30 kg/m2 or having a history of smoking and HTN were found more frequently in the TE group (p<0.05). Patients admitted to ICU were significantly higher in the TE group (p =0.001). There was no statistically significant difference (p>0.05) in chest CT-SS between the TE group (25.4±8.4) and non-TE group (22.6±5.5), and CXR-SS between the TE group (11.8±4.7) and non-TE group (8.9±5.1). The percentage of moderate and severe parenchymal disease in the TE group was significantly higher compared to the non-TE group (p<0.05). Severe parenchymal disease, BMI>30kg/m2, smoking, and HTN had a higher and more significant odds ratio for developing TE complications.

CLINICAL RELEVANCE/APPLICATION

• Relationship of thromboembolic complication with the pulmonary parenchymal disease in COVID-19 patients. • Assessment of pulmonary parenchymal disease severity using chest CT and X-ray severity scoring. • Relationship of thromboembolic complication with comorbidities in COVID-19 patients.

SPR-MS-7   Predictive Value Of Textural And Hybrid Imaging Features In Comparison To Laboratory Parameters In Patients With Diffuse Large B-cell Lymphoma Undergoing Car T Cell Therapy: Preliminary Results

Participants
Christian Reinert, MD, Tuebingen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the predictive value of textural and hybrid imaging features in comparison to laboratory parameters in patients with diffuse large B-cell lymphoma (DLBCL) undergoing chimeric antigen receptor (CAR) T cell therapy.*Methods and Materials We retrospectively analyzed whole-body metabolic tumor volume (MTV) and total lesion glycolysis (TLG) derived from 18F-FDG-PET/CT, the 1st order textural features mean, entropy, uniformity and skewness as well as laboratory parameters (C-reactive protein [CRP], lactate dehydrogenase [LDH], leucocytes) at baseline and after CAR T cell therapy in 21 patients with DLBCL (mean age 57.7±14.7 yr.; 7 female). The interleukin 6 (IL-6) and interleukin-2 receptor (IL-2R) peaks were monitored immediately after CAR T cell treatment onset and compared with patient outcome judged by follow-up 18F-FDG-PET/CT.*Results In 12/21 patients (57%), a

complete remission (CR) was observed after CAR T cell therapy, whereas 9/21 patients (43%) showed a partial remission (PR). At baseline 18F-FDG-PET/CT, the whole-body MTV and TLG were significantly lower in patients achieving CR (35±38 cm3 and 319±362) compared to patients achieving PR (88±110 cm3 and 1487±2254; p<0.05). At baseline, the "entropy" proved lower (1.81±0.09) and the "uniformity" higher (0.33±0.02) in patients with CR compared to PR (2.08±0.22 and 0.28±0.47; p<0.05). Concerning the laboratory parameters, patients achieving CR had lower CRP, LDH and leucocytes at baseline compared to patients achieving PR (p<0.05). In the entire patient cohort, the whole-body MTV (62±86 cm3 vs. 4±5 cm3) and whole-body-TLG (925±1722 vs. 33±59) significantly decreased after therapy onset (p<0.01) becoming not measurable in the CR-group. Correspondingly, the leucocytes (5348±2514 1/µl vs. 2954±2024 1/µl) and CRP (2.8±5.6 µg/dl vs. 0.1±0.2 µg/dl significantly dropped in the cohort after CAR T cell therapy (p<0.01). The IL-6 (867±951 ng/L vs. 9121±11266 ng/L) and IL-2R peaks (2483±1164 U/mL vs. 5548±3949 U/mL) after therapy were lower in patients with CR compared to PR without statistical significance (p>0.05).*Conclusions Tumor volumetric parameters derived from 18F-FDG-PET/CT and 1st order textural features are predictive for therapy response in patients with DLBCL undergoing CAR T cell therapy.*Clinical Relevance/Application CD19-CAR-T cell therapy leads to strong immunological response with T-cell activation and cytokine release.The intention of this study was to identify potential prognostic biomarkers for DLBCL response to CD19-CAR-T cell therapy both in the baseline setting and shortly after treatment onset using morphologic and metabolic imaging parameters including quantification of radiomic metrics as well as of serologic markers.

RESULTS

In 12/21 patients (57%), a complete remission (CR) was observed after CAR T cell therapy, whereas 9/21 patients (43%) showed a partial remission (PR). At baseline 18F-FDG-PET/CT, the whole-body MTV and TLG were significantly lower in patients achieving CR (35±38 cm3 and 319±362) compared to patients achieving PR (88±110 cm3 and 1487±2254; p<0.05). At baseline, the "entropy" proved lower (1.81±0.09) and the "uniformity" higher (0.33±0.02) in patients with CR compared to PR (2.08±0.22 and 0.28±0.47; p<0.05). Concerning the laboratory parameters, patients achieving CR had lower CRP, LDH and leucocytes at baseline compared to patients achieving PR (p<0.05). In the entire patient cohort, the whole-body MTV (62±86 cm3 vs. 4±5 cm3) and whole-body-TLG (925±1722 vs. 33±59) significantly decreased after therapy onset (p<0.01) becoming not measurable in the CR-group. Correspondingly, the leucocytes (5348±2514 1/µl vs. 2954±2024 1/µl) and CRP (2.8±5.6 µg/dl vs. 0.1±0.2 µg/dl significantly dropped in the cohort after CAR T cell therapy (p<0.01). The IL-6 (867±951 ng/L vs. 9121±11266 ng/L) and IL-2R peaks (2483±1164 U/mL vs. 5548±3949 U/mL) after therapy were lower in patients with CR compared to PR without statistical significance (p>0.05).

CLINICAL RELEVANCE/APPLICATION

CD19-CAR-T cell therapy leads to strong immunological response with T-cell activation and cytokine release.The intention of this study was to identify potential prognostic biomarkers for DLBCL response to CD19-CAR-T cell therapy both in the baseline setting and shortly after treatment onset using morphologic and metabolic imaging parameters including quantification of radiomic metrics as well as of serologic markers.

SPR-MS-8   Blinded Reader Validation Study For Generalizable Deep Learning Denoising Reconstruction (DLR) Throughout Multiple Anatomies At 1.5T And 3T

Participants
Shelton Caruthers, PhD, Cleveland, Ohio (*Presenter*) Employee, Canon Medical Systems Corporation

PURPOSE

The purpose is to evaluate, in a prospective, randomized, blinded, multi-reader study, the hypothesis that a generalizable DLR technique, as compared to predicates, can be effectively extended to multiple sub-anatomical regions at both 1.5T & 3T. Recently, a generalizable DLR technique, based on a convolutional neural network, was published (Magn Reson Med Sci. 2020; 19: 195) with the intended use—and hence validation—limited to brain and knee. Herein, we evaluate if it can be applied, without re-training, to additional anatomies including abdominal, cardiac, spinal, pelvic, and musculoskeletal systems.*Methods and Materials MR images of typical weightings were acquired in 112 subjects at 1.5T (52) and 3T (60) covering a range of sub-anatomies from the categories above. The raw image data were stored and reconstructed 4 times employing the DLR technique and 3 commonly preferred clinical post-processing filters. De-identified images were presented, in random order, to 16 blinded board-certified Radiologists or Cardiologists, 3 per anatomy, by their specialty. They scored the images by a modified 5-point Likert scale in 8 categories focused on either overall image quality metrics or anatomy-specific feature quality metrics, e.g., noise, sharpness, and diagnostic confidence. Additionally, reviewers force ranked each of the 4 reconstructions. Scoring data was visualized as mean of pooled reviewer scores. However, statistical analysis was performed on un-pooled data using generalized estimating equations (GEE).*Results The DLR technique performed well in anatomies tested. All datasets scored as clinically diagnostic. Pooling reviewer data, the average scores for DLR were consistently better than or equal to the clinical standard filters. On individualized GEE analysis—with 972 total comparisons of the filters across reviewers, anatomies, and categories—596 had DLR scoring better, 329 the same, and 47 lower than the standards. Considering only forced ranking results for reviewer preference, DLR was statistically best (or tied as best) at 1.5T for 12/18 (4/18) and at 3T for 5/18 (10/18) of the rankings. When averaged, reviewer rankings put DLR as best (or tied) in all anatomies.*Conclusions The DLR technique can be effectively extended to these anatomies for clinical use. When ranked on preference by the blinded reviewers, in anatomies and field strengths tested, the DLR technique was preferred, i.e., ranked statistically as best or tied as best, 86% of the time, with 1.5T showing slightly greater benefit than 3T.*Clinical Relevance/Application This deep learning denoising reconstruction can, without additional training, be applied effectively to multiple anatomies and, in blinded review, is often preferred over existing clinical imaging filters.

RESULTS

The DLR technique performed well in anatomies tested. All datasets scored as clinically diagnostic. Pooling reviewer data, the average scores for DLR were consistently better than or equal to the clinical standard filters. On individualized GEE analysis—with 972 total comparisons of the filters across reviewers, anatomies, and categories—596 had DLR scoring better, 329 the same, and 47 lower than the standards. Considering only forced ranking results for reviewer preference, DLR was statistically best (or tied as best) at 1.5T for 12/18 (4/18) and at 3T for 5/18 (10/18) of the rankings. When averaged, reviewer rankings put DLR as best (or tied) in all anatomies.

CLINICAL RELEVANCE/APPLICATION

This deep learning denoising reconstruction can, without additional training, be applied effectively to multiple anatomies and, in blinded review, is often preferred over existing clinical imaging filters.

SPR-MS-9   Diagnostic Accuracy Of Ultra-low-dose Chest CT Versus Chest X-ray In Patients Suspected Of Non-

traumatic Pulmonary Disease At The Emergency Department

Participants
Maadrika Kanglie, MD, Amsterdam, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

To compare the diagnostic accuracy of ultra-low-dose chest computed tomography (ULDCT) with that of chest X-ray (CXR) in the detection of pulmonary diseases at the emergency department (ED).*Methods and Materials In the OPTIMACT trial, ED patients suspected of non-traumatic pulmonary disease were randomized to either ULDCT or CXR. A radiological diagnosis was made in a standardized manner by a radiologist at the ED. An independent panel used all patient record information until 28 days after ED presentation to assign a day 28 diagnosis as reference standard. The following diagnoses were included in the present analysis: pneumonia, bronchitis/bronchiolitis, diseases presenting with pulmonary congestion (decompensated heart failure, fluid overload (iatrogenic or in renal failure) or acute respiratory distress syndrome), pleural effusion, interstitial lung disease, and lung cancer and pulmonary metastases. Estimates of sensitivity and specificity of the initial ULDCT and CXR diagnosis against day 28 diagnosis were calculated and compared between imaging modalities with a Chi-square test.*Results In total 1161 ULDCT and 1151 CXR patients were included. ULDCT had a higher sensitivity for pneumonia and bronchitis/bronchiolitis compared to CXR: 91% (256/281) versus 81% (169/210), P<0.01 and 47% (57/121) versus 12% (14/116), P<0.01, respectively. ULDCT had a lower specificity for pneumonia and bronchitis/bronchiolitis compared to CXR: 92% (811/880) versus 96% (902/941) P<0.01 and 87% (905/1040) versus 95% (985/1035), P<0.01, respectively. ULDCT had a higher specificity for pulmonary congestion compared to CXR: 98% (1068/1090) versus 95% (984/1039), P<0.01. For other diagnoses no significant differences were found.*Conclusions ULDCT is more sensitive and less specific in detecting pneumonia and bronchitis/bronchiolitis compared to CXR. Furthermore, ULDCT is more specific in detecting pulmonary congestion compared to CXR. For the other pulmonary diseases at the ED, ULDCT and CXR have comparable diagnostic estimates.*Clinical Relevance/Application ULDCT could be considered as first line diagnostic imaging modality in case of suspected pneumonia or bronchitis/bronchiolitis at the ED.

RESULTS

In total 1161 ULDCT and 1151 CXR patients were included. ULDCT had a higher sensitivity for pneumonia and bronchitis/bronchiolitis compared to CXR: 91% (256/281) versus 81% (169/210), P<0.01 and 47% (57/121) versus 12% (14/116), P<0.01, respectively. ULDCT had a lower specificity for pneumonia and bronchitis/bronchiolitis compared to CXR: 92% (811/880) versus 96% (902/941) P<0.01 and 87% (905/1040) versus 95% (985/1035), P<0.01, respectively. ULDCT had a higher specificity for pulmonary congestion compared to CXR: 98% (1068/1090) versus 95% (984/1039), P<0.01. For other diagnoses no significant differences were found.

CLINICAL RELEVANCE/APPLICATION

ULDCT could be considered as first line diagnostic imaging modality in case of suspected pneumonia or bronchitis/bronchiolitis at the ED.

SSGU03-2   A Randomized Controlled Trial On The Role Of MRI For Prostate Cancer Screening - Prostate Cancer Secondary Screening In Sapienza - PROSA: Preliminary Results

Participants
Emanuele Messina, MD, Roma, Italy (*Presenter*) Nothing to Disclose

PURPOSE

(I)To investigate the role of MRI with a bi-parametric approach (without injection of paramagnetic contrast medium), as a secondary prevention test for the early diagnosis of prostate cancer, comparing it with the serum PSA test. (II) Comparison of the different combination of screening tests in terms of carcinoma detection rate, non-clinically significant and clinically significant cancer detection rate*Methods and Materials Monocentric, prospective, interventional randomized controlled trial. 168 men have been enrolled and blindly randomized in two different arms. Arm a) 52 patients performed MRI with a bi-parametric approach (without contrast medium) regardless their PSA value; Arm b) 54 patients performed MRI with a bi-parametric approach (without contrast medium) due to elevated PSA (>4 ng/ml or 2.5 ng/ml if positive family history). 62 patients of the same arm did not undergo MRI due to normal PSA. 64 patients were enrolled as control group. Patients with positive MRI defined as bPI-RADS =3, were directed to MRI targeted prostate biopsy using the TRUS-MRI image fusion technique.*Results We found that about 30 % of patients from arm a had a bPI-RADS = 3 and were directed to prostate biopsy, among those 89% had clinically significant prostate cancer. Among patients in arm b about 40% were directed to biopsy, and 36% had clinically significant cancer. The difference in accuracy was statistically different (p<0.05). Specificity, sensitivity, PPV and NPV were calculated for both arms and TRUS/MRI fusion biopsy was considered the gold standard. Interreader agreement was excellent (k=0.863). Limited sample size due to in-itinere analysis of the trial*Conclusions Prostate MRI without contrast media injection showed promising results compared to PSA as screening tool in men between 49-69 years of age.*Clinical Relevance/Application The use of non-contrast MRI in the screening setting, will likely reduce the number of useless prostate biopsies.

RESULTS

We found that about 30 % of patients from arm a had a bPI-RADS = 3 and were directed to prostate biopsy, among those 89% had clinically significant prostate cancer. Among patients in arm b about 40% were directed to biopsy, and 36% had clinically significant cancer. The difference in accuracy was statistically different (p<0.05). Specificity, sensitivity, PPV and NPV were calculated for both arms and TRUS/MRI fusion biopsy was considered the gold standard. Interreader agreement was excellent (k=0.863). Limited sample size due to in-itinere analysis of the trial

CLINICAL RELEVANCE/APPLICATION

The use of non-contrast MRI in the screening setting, will likely reduce the number of useless prostate biopsies.

SSGU03-5   Reduction Of Acquisition Time Of T2-weighted Imaging Of The Prostate Using Deep Learning Image Reconstruction

Participants
Sebastian Gassenmaier, MD, Tuebingen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Multiparametric MRI (mpMRI) of the prostate has become standard of care in prostate cancer evaluation. Recently, deep learning image reconstruction (DLR) methods have been introduced with promising results regarding scan acceleration. Therefore, the purpose of this study was to investigate the impact of DLR in T2-weighted TSE imaging of the prostate on acquisition time, image quality, diagnostic confidence, and PI-RADS T2 score and overall PI-RADS score as compared to standard T2 imaging.*Methods and Materials 51 patients for evaluation of prostate cancer using 3T mpMRI were prospectively enrolled in this institutional review board-approved study between October 2020 and February 2021. After acquisition of standard T2 TSE imaging (T2S), the novel T2 TSE sequence with DLR (T2DLR) was applied in three planes. Overall, TA for T2S resulted in 10:21 min versus 3:50 min for T2DLR, providing a reduction of acquisition time above 60%. Image evaluation was performed by two radiologists independently in a blinded random order using a Likert scale ranging from 1-4 (4 best) regarding the following criteria: noise levels, artifacts, overall image quality, diagnostic confidence, and lesion conspicuity. Additionally, T2 and PI-RADS scoring was performed.*Results Mean patient age was 68±8 years (range 49-84 years). Noise levels as well as extent of artifacts were evaluated to be significantly improved in T2DLR versus T2S by both readers (p<0.05). Overall image quality was also evaluated to be superior in T2DLR versus T2S in all three planes (p<0.001 for axial, p=0.002 for coronal, and p=0.001 for sagittal). Lesion conspicuity was rated by both readers with a median of 4 in T2DLR versus a median of 3 in T2S (p<0.001). Inter-reader agreement regarding T2 and PI-RADS scoring ranged from 0.806 (T2 scoring using T2S) to 0.952 (PI-RADS scoring using T2DLR).*Conclusions T2DLR of the prostate is feasible with

improvement of image quality and allows an acquisition time reduction of more than 60%.*Clinical Relevance/Application DLR might be the door opener for ultra-fast screening protocols.

RESULTS

Mean patient age was 68±8 years (range 49-84 years). Noise levels as well as extent of artifacts were evaluated to be significantly improved in T2DLR versus T2S by both readers (p<0.05). Overall image quality was also evaluated to be superior in T2DLR versus T2S in all three planes (p<0.001 for axial, p=0.002 for coronal, and p=0.001 for sagittal). Lesion conspicuity was rated by both readers with a median of 4 in T2DLR versus a median of 3 in T2S (p<0.001). Inter-reader agreement regarding T2 and PI-RADS scoring ranged from 0.806 (T2 scoring using T2S) to 0.952 (PI-RADS scoring using T2DLR).

CLINICAL RELEVANCE/APPLICATION

DLR might be the door opener for ultra-fast screening protocols.

SSGU03-6   Baseline Quantitative Prostate ADC Predicts Pathology And Immunohistochemistry Markers Of Response To Intense Neoadjuvant Androgen Deprivation Therapy In Localized High-risk Prostate Cancer Patients

Participants
Fiona Fennessy, MD,PhD, Brookline, Massachusetts (*Presenter*) Consultant, VirtualScopics, Inc

PURPOSE

Patients with high-risk localized prostate cancer (PCa) are at increased risk of recurrence and death from PCa. As part of a phase 2 trial investigating the impact of intense androgen deprivation (IAD) on pathologic complete response (pCR) after radical prostatectomy (RP) in high-risk PCa patients (NCT02903368), we evaluated whether baseline tumor ADC (tADC) values from prostate MRI can predict pCR to IAD and if they correlate with immunohistochemistry (IHC) markers of response to therapy.*Methods and Materials Inclusion criteria for the trial were a Gleason score =4+3=7, PSA >20 ng/mL or T3 disease on MRI. Patients were prospectively consented for 2 prostate MRIs, at baseline and after 6 cycles (1 cycle=28 days) of IAD, followed by RP. MR imaging used a non-ecoil PI-RADS protocol on a GE Signa HDx 3.0T magnet (GE Healthcare, WI). ADC values (x 10-6mm2/sec) were obtained from DWI (b0, 1400 s/mm2). Tumors were contoured on ADC maps using 3D Slicer (www.slicer.org). RP specimen review determined pCR or minimum residual disease (MRD, tumor =5 mm). Residual tumor IHC biomarkers of response (AR, Ki67 and PTEN/ERG expression) was determined. Paired t-test compared tADC pre/post-IAD and an independent t-test compared tADC in those with and without pCR/MRD. Spearmans's correlation measured association between residual tumor volume on MR and pathology. Kruskal-Wallis test compared tADC in those with pCR/MRD to those with Ki67, AR and PTEN/ERG positive staining status.*Results 69 patients (median age 61; median Gleason score 8; median PSA 8.61 ng/ml) had both MRIs and underwent RP. 17 patients had pCR/MRD. Baseline tADC (mean ± SD) was significantly lower compared to post-IAD (866±149 pre vs. 959 ±163 post; p<0.001). Baseline tADC was higher in those who had a pCR/MRD (961±184) vs. those without (834 ±122), p=0.015. Post-IAD tumor volume correlated with residual cancer at RP (r=0.49, P<0.0001). Baseline tADC differed between those with a pCR/MRD (no staining), Ki67 0-1% and Ki67 >1% staining, and also between those with a pCR, strong AR and moderate-weak AR staining. There was no evidence that tADC differed amongst PTEN/ERG status.*Conclusions Baseline tADC can predict pCR/MRD and IHC markers of response positivity to IAD in high-risk localized PCa patients. Post-IAD tumor volume correlates with pathological tumor volume.*Clinical Relevance/Application Baseline quantitative ADC can predict which high-risk prostate cancer patients will optimally respond to intense androgen deprivation, based upon pathological complete response and immunohistochemistry markers of response.

RESULTS

69 patients (median age 61; median Gleason score 8; median PSA 8.61 ng/ml) had both MRIs and underwent RP. 17 patients had pCR/MRD. Baseline tADC (mean ± SD) was significantly lower compared to post-IAD (866±149 pre vs. 959 ±163 post; p<0.001). Baseline tADC was higher in those who had a pCR/MRD (961±184) vs. those without (834 ±122), p=0.015. Post-IAD tumor volume correlated with residual cancer at RP (r=0.49, P<0.0001). Baseline tADC differed between those with a pCR/MRD (no staining), Ki67 0-1% and Ki67 >1% staining, and also between those with a pCR, strong AR and moderate-weak AR staining. There was no evidence that tADC differed amongst PTEN/ERG status.

CLINICAL RELEVANCE/APPLICATION

Baseline quantitative ADC can predict which high-risk prostate cancer patients will optimally respond to intense androgen deprivation, based upon pathological complete response and immunohistochemistry markers of response.

SSPH09-1   Radiation Dose Estimates For A Novel Spiral Breast CT Imager

Participants
Sojin Shim, Zurich, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

Our study aimed to estimate the amount of radiation dose irradiated to the breast during a novel breast computed tomography (CT) scan on 1,037 patients. By assessing the correlation of the radiation dose with the breast structural features, the CT breast dose could be predicted for individual breasts without a lengthy simulation.*Methods and Materials For the retrospective radiation dose analysis, 1,037 spiral breast CT images acquired using a fixed exposure setup (x-ray tube current=32mA) during opportunistic or diagnostic breast scans were used. The breast images were segmented by our automatic segmentation method (implemented specifically for breast CT images using in-house developed image processing algorithms) into four components: adipose tissue, glandular tissue, skin and pectoralis major muscle. The automatically segmented images were validated against reference human readings according to five experienced radiologists' evaluation in a five-point Likert scale, resulting in good agreement (good (4)-excellent (5)). The breast and skin volume and the breast density were measured as breast features on the segmented image and a Monte Carlo (MC) dose simulation was performed on the resulting dataset. The MC simulation was then validated by the CT dose index (CTDI) comparison to the measurement on a CTDI phantom using an ionization chamber. The mean absorbed dose in the breast (MAD), mean glandular dose (MGD), mean skin dose (MSD), max 5% glandular dose (MaxGD), and max 5% skin dose (MaxSD) were calculated based on the MC dose calculation. The five dose parameters were correlated to the breast features.*Results The breast volume had the highest correlation with the dose parameters. Each dose parameter was correlated to the breast volume in a mono- or bi-exponential model. 70% of breasts had a volume larger than 390cm3; for these breasts the average MAD, MGD, MSD, MaxGD, and MaxSD values were equal to 6.6±0.4, 6.3±0.4, 10.7±0.5, 10.3±0.8 and 19.3±0.6mGy, respectively. The corresponding values for the smaller 30% of breasts were 7.7±0.8, 7.3±0.7, 11.6±0.8, 12.2±0.7, and 20.2±1.1mGy.*Conclusions We established for the first time a radiation dose estimation model for spiral breast CT scans that requires only a simple breast volume measurement. Our study discovered that, with the current exposure setup for a medium-large breast, the opportunistic and diagnostic breast CT scan results in MGD values compatible to or lower than the dose limit for a two-view mammography screening on a medium-large breast mandated by the European commission (<6-13mGy).*Clinical Relevance/Application Individual breast's radiation dose can be prospectively estimated based on the volume of the breast. The exposure setup can be adjusted in advance depending on the breast size.

RESULTS

The breast volume had the highest correlation with the dose parameters. Each dose parameter was correlated to the breast volume in a mono- or bi-exponential model. 70% of breasts had a volume larger than 390cm3; for these breasts the average MAD, MGD, MSD, MaxGD, and MaxSD values were equal to 6.6±0.4, 6.3±0.4, 10.7±0.5, 10.3±0.8 and 19.3±0.6mGy, respectively. The corresponding values for the smaller 30% of breasts were 7.7±0.8, 7.3±0.7, 11.6±0.8, 12.2±0.7, and 20.2±1.1mGy.

CLINICAL RELEVANCE/APPLICATION

Individual breast's radiation dose can be prospectively estimated based on the volume of the breast. The exposure setup can be adjusted in advance depending on the breast size.

SSPH09-2   The Problem With Synthetic Minority Oversampling: A Case Study Using Contrast-enhanced Mammography Data

Participants
Avishek Chatterjee, Maastricht, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

For Machine Learning classification, it is traditional to use a training set that is balanced with respect to the modeled outcome, as this improves balance between sensitivity and specificity. To achieve balance, Synthetic Minority Over-sampling Technique (SMOTE) has gained popularity in Radiomics, a domain that has high feature dimensionality. We hypothesized that SMOTE increases the correlation between radiomic features and the outcome, which incorrectly inflates training set performance.*Methods and Materials The dataset comprised 525 contrast-enhanced mammograms (250 benign, 275 malignant), and 3259 derived radiomic features. It was randomly sampled to create a baseline balanced set (250 per class), and feature selection was performed. First, features with AUCs > 0.6 or 0.7 or 0.8 (loose, medium, or tight selection, respectively) were retained. Then, pairwise feature

elimination was performed: if two features were highly correlated with each other (|R|>0.9), the one with lower AUC was removed. From each discovery set, four levels of imbalanced sets were randomly sampled (2:1, 3:1, 4:1, 5:1), each level instantiated 100 times. Each imbalanced set was balanced ten times using SMOTE, to estimate average effect. Scatter plots were made of Spearman correlations (?) between radiomic features and the outcome at baseline (x-axis) and the same for SMOTE-d set (y-axis) and fit to y = mx. This slope m captures the factor by which correlation gets inflated; m (median and 95% range for 100 imbalance level instances) was compared between the four imbalance levels, and between the three feature dimensionalities.*Results For loose selection (146 features), m at 2:1 imbalance was 1.04 (95% range: 0.94-1.09), and at 5:1 imbalance was 1.07 (0.93-1.24). For medium selection (72 features), the corresponding slopes were 1.02 (0.93-1.08) and 1.05 (0.93-1.19). For tight selection (26 features), the corresponding slopes were 1.01 (0.94-1.06) and 1.05 (0.92-1.14).*Conclusions SMOTE increases the correlation between radiomic features and the outcome. The effect is worsened with increasing imbalance and increasing feature dimensionality. Training on SMOTE-d data causes inflated performance estimation.*Clinical Relevance/Application We showed the danger of using synthetic minority oversampling on high-dimensional features. Biomarkers created using oversampling should be subjected to increased scrutiny before clinical adaptation.

RESULTS

For loose selection (146 features), m at 2:1 imbalance was 1.04 (95% range: 0.94-1.09), and at 5:1 imbalance was 1.07 (0.93-1.24). For medium selection (72 features), the corresponding slopes were 1.02 (0.93-1.08) and 1.05 (0.93-1.19). For tight selection (26 features), the corresponding slopes were 1.01 (0.94-1.06) and 1.05 (0.92-1.14).

CLINICAL RELEVANCE/APPLICATION

We showed the danger of using synthetic minority oversampling on high-dimensional features. Biomarkers created using oversampling should be subjected to increased scrutiny before clinical adaptation.

SSPH09-3 A Large Retrospective Study Of Non-Compliance Findings At Half Yearly Medical Physics Tests Of Digital Mammography Devices (DM) Using A Vendor Neutral (European) Test Protocol

Participants
Hannelore Verhoeven, MSc, Leuven, Belgium (*Presenter*) Nothing to Disclose

PURPOSE

The national breast cancer screening program requires obligatory half yearly medical physics tests following the vendor neutral European protocol for mammography equipment. This study tallied and categorized protocol non-compliant findings for a cohort of digital mammography (DM) devices over time.*Methods and Materials All 131 DM devices used within the mammography network between 2016 and 2020 were included in this retrospective study. Data were analyzed from the Acceptance test until the end of 2020 (103 devices) or until end of service if prior to 2020 (28 devices). All devices also undergo daily QC in which image receptor uniformity and automatic exposure control (AEC) reproducibility are analyzed. A total of 1752 half yearly reports were reviewed for all faults flagged by medical physics QC. All remarks were categorized and marked as "severe" if they exceeded the levels in EU document RP162 on Acceptability Criteria i.e. 'suspension required if the issue would not be solved'.*Results In total, 472 faults were found, of which 144 were severe, but none resulted in detector replacement. The remarks were divided as follows: homogeneity: 119 (no severe remarks), alignment of the x-ray field: 81 (80 severe), compression: 69 (20 severe), AEC thickness compensation: 42 (35 severe), AEC reproducibility: 39, change in clinical settings: 29, dosimetry: 23, tube voltage error: 23 (1 severe), local dense area test: 14, low contrast detectability (LCD): 11 (8 severe), software problems: 7, noise: 3 and other issues 12. For 28 devices with complete lifetime analysis, most problems were found at Acceptance (25 remarks in the first 10% of life time of 28 devices) and remained approx. constant for the remaining device lifetime (13 issues per 10% of device lifetime). Compression, AEC and LCD problems tended to occur early on in the device lifetime while alignment problems were more frequent towards the end.*Conclusions Medical physics testing detected a significant number of problems, notwithstanding daily QC and the department's active involvement in many quality initiatives. Problems can occur over the entire device lifetime, and are more frequent early on.*Clinical Relevance/Application Continued on-site, half-yearly medical physics testing, as prescribed in the (European) guidelines, ensures DM systems remain within EU Acceptable Performance criteria.

RESULTS

In total, 472 faults were found, of which 144 were severe, but none resulted in detector replacement. The remarks were divided as follows: homogeneity: 119 (no severe remarks), alignment of the x-ray field: 81 (80 severe), compression: 69 (20 severe), AEC thickness compensation: 42 (35 severe), AEC reproducibility: 39, change in clinical settings: 29, dosimetry: 23, tube voltage error: 23 (1 severe), local dense area test: 14, low contrast detectability (LCD): 11 (8 severe), software problems: 7, noise: 3 and other issues 12. For 28 devices with complete lifetime analysis, most problems were found at Acceptance (25 remarks in the first 10% of life time of 28 devices) and remained approx. constant for the remaining device lifetime (13 issues per 10% of device lifetime). Compression, AEC and LCD problems tended to occur early on in the device lifetime while alignment problems were more frequent towards the end.

CLINICAL RELEVANCE/APPLICATION

Continued on-site, half-yearly medical physics testing, as prescribed in the (European) guidelines, ensures DM systems remain within EU Acceptable Performance criteria.

SSPH09-4 A Stationary Breast Tomosynthesis System Using A Two Dimensional Multiple X-ray Source Array With Thermionic Cathodes

Participants
John Boone, PhD, Sacramento, California (*Presenter*) Board of Directors, Izotropic Corporation;Shareholder, Izotropic Corporation;Co-author with royalties, Wolters Kluwer nv;Patent agreement, The Phantom Laboratory;In-kind support, Canon Medical Systems Corporation

PURPOSE

Current breast tomosynthesis systems use an x-ray source swept through an arc above the patient breast to acquire projection data. X-ray source motion during acquisition causes motion blurring, and the 4-25 second scan times can lead to patient motion. A stationary tomosynthesis system is proposed with multiple x-ray sources positioned in 2D above the patient's breast, enabling a sub-second scan times with no source motion.*Methods and Materials A 11 x-ray source array (MXA) was fabricated from molybdenum to produce 11 anode discs on a single long shaft. A rotor, stator, and bearings from commercial x-ray tubes were used to rotate the shaft. Eleven cathodes were fabricated using tungsten filaments and mounted into grid assemblies opposite the

anodes. The whole assembly was mounted in a custom-built vacuum chamber. The MXA was mounted 70 cm above a flat panel detector with 0.127 mm detector element spacing. Custom electronics were developed to allow independent source pulsing synchrony with the detector acquisition frames. The detector was translated between three different positions to simulate a 2D source array, creating 33 source positions 10 cm apart. A clutter phantom was manufactured to simulate the breast with two 2.5 cm layers of small plastic spheres inserted into a water phantom. Between the two clutter phantoms, a thin sheet of plastic with holes with 3 different diameters, allowing signal difference to noise ratios (SDNR) to be assessed. Image reconstruction was performed with a penalized weighted least squares approach with Huber regularization with cutoff at 0.0005/mm. A volume with 0.5x0.5x0.5 mm voxels was reconstructed by optimizing the cost function with projection data.*Results Images were reconstructed and the SDNR was measured for disk images from the test object plane between the clutter phantoms. For the central linear source array, the SDNR values were 2.5, 2.2, and 2.3 for the 3, 4, and 5 mm disks. For the two dimensional source array using all 33 source locations, the corresponding SDNR values were 7.0, 6.9 and 6.0, with an average improvement of a factor of 2.85 (sd: 0.27).*Conclusions The 2D source geometry demonstrated in this work will fundamentally improve breast tomosynthesis images while delivering more symmetric and thinner slice sensitivity profiles. Eliminating source motion combined with sub-second acquisition times will also reduce motion blurring and improve spatial resolution for breast tomo synthesis.*Clinical Relevance/Application The proposed 2D MXA breast tomosynthesis system has the potential to revolutionize breast cancer screening with dramatically improved tomosynthesis images.

RESULTS

Images were reconstructed and the SDNR was measured for disk images from the test object plane between the clutter phantoms. For the central linear source array, the SDNR values were 2.5, 2.2, and 2.3 for the 3, 4, and 5 mm disks. For the two dimensional source array using all 33 source locations, the corresponding SDNR values were 7.0, 6.9 and 6.0, with an average improvement of a factor of 2.85 (sd: 0.27).

CLINICAL RELEVANCE/APPLICATION

The proposed 2D MXA breast tomosynthesis system has the potential to revolutionize breast cancer screening with dramatically improved tomosynthesis images.

SSPH09-5　Breast Imaging Using Deep-Learning-Enhanced High Resolution, Whole Body, Photon-Counting-Detector CT

Participants
Nathan Huber, Rochester, Minnesota (*Presenter*) Nothing to Disclose

PURPOSE

Imaging of primary breast cancer is generally not performed with CT due to intrinsic spatial and contrast resolution limitations. We sought to determine if high-resolution (HR) CT breast imaging using a whole-body photon-counting-detector (PCD) CT system, combined with a dedicated deep-learning-based CT image denoising algorithm, might permit visualization of breast microcalcifications associated with breast cancer.*Methods and Materials An investigational whole-body PCD-CT scanner (NAEOTOM Alpha, Siemens Healthineers) was used to image a Mammography Quality Standards Act (MQSA) certified phantom in HR mode at our routine clinical dose for CT evaluation of breast implants (CTDIvol=15 mGy), both with the MQSA phantom suspended in air (no torso attenuation) and placed under an anthropomorphic phantom (realistic patient attenuation). All scans were reconstructed with a high-resolution kernel (Br84) to generate near-isotropic, 150 um voxels. Deep learning image processing was performed using an in-house Generalizable noise and Artifact Reduction NETwork (GARNET). One patient with history of breast cancer and clinically indicated breast MRI and mammographic exams was scanned under IRB in HR mode using a CTDIvol of 15 mGy. Acquired data were reconstructed and processed with the same settings as the MQSA phantom, and images were reviewed by an experienced breast radiologist with attention to the detection of calcifications. CT images were compared to the patient's prior mammographic exam.*Results When the MQSA phantom was scanned in air, 0.32 mm calcifications were clearly visible. When the MQSA phantom was scanned beneath an anthropomorphic phantom, the increased noise obscured the calcifications. Following GARNET image processing, noise in the MQSA phantom image was reduced by 74 % and 0.4 mm microcalcifications were visible. When tested on a patient exam, calcifications visualized on the HR PCD-CT images with GARNET processing matched those seen on the mammographic reference images.*Conclusions High resolution whole-body PCD-CT with deep learning GARNET image processing permitted visualization of breast calcifications in the MQSA phantom when using realistic attenuation levels and also in patient images.*Clinical Relevance/Application High resolution PCD-CT with deep learning image processing permits visualization of breast microcalcifications, expanding the potential role of CT in breast imaging beyond implant evaluation.

RESULTS

When the MQSA phantom was scanned in air, 0.32 mm calcifications were clearly visible. When the MQSA phantom was scanned beneath an anthropomorphic phantom, the increased noise obscured the calcifications. Following GARNET image processing, noise in the MQSA phantom image was reduced by 74 % and 0.4 mm microcalcifications were visible. When tested on a patient exam, calcifications visualized on the HR PCD-CT images with GARNET processing matched those seen on the mammographic reference images.

CLINICAL RELEVANCE/APPLICATION

High resolution PCD-CT with deep learning image processing permits visualization of breast microcalcifications, expanding the potential role of CT in breast imaging beyond implant evaluation.

SSPH09-6　Plug-and-play Reconstruction With Deep Learning Denoising For Improving Detectability Of Microcalcifications In Digital Breast Tomosynthesis Images

Participants
Mingjie Gao, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

We proposed a plug-and-play (PnP) algorithm for digital breast tomosynthesis (DBT) reconstruction to reduce noise and improve the conspicuity of microcalcifications (MCs) in DBT images.*Methods and Materials We followed the alternating direction method of multiplier (ADMM) algorithm as the framework and plugged in a pre-trained deep convolutional neural network (DCNN) denoiser as regularizer for PnP DBT reconstruction. We dropped the Lagrangian multiplier term for simplicity. We previously developed the DCNN denoisers and found them to be effective for denoising DBT images. To handle the wide range of noise levels for different DBTs to be denoised, we trained the denoisers with virtual phantom DBT images generated with VICTRE and MCGPU that had a variety of

breast thicknesses (range: 3.1 cm to 6.2 cm), densities (glandular volume fraction range: 5% to 60%), and x-ray exposures (a factor of 0.25 to 1.4 times the estimated AEC settings). We grouped the virtual DBT images according to the estimated noise levels and then trained one denoiser for each group, resulting in a set of 12 denoisers. The reconstruction algorithm estimated the image noise level at the current iteration and selected a denoiser trained for a similar noise level for deployment. We found that 3 ADMM iterations were needed. The PnP algorithm was evaluated with a physical phantom containing 622 MCs of three nominal diameters ranging from 0.150 to 0.250 mm, and 9 human subject DBT scans with a total of 301 marked MCs. The DBT scans had 9 projections with a 24º scan angle.*Results We calculated the contrast-to-noise ratio (CNR) and the detectability index (d') using the non-prewhitening matched filter model observer with eye filter for individual MCs. The PnP algorithm significantly (p<0.0001) improved the CNR by 45.6-84.3% and d' by 43.6-63.3% for the phantom MCs, and the CNR by 70.4% and d' by 50.5% on average for human MCs compared to the unregularized SART algorithm. The parenchymal patterns in the reconstructed images were visually satisfactory without patchy appearance.*Conclusions The PnP reconstruction regularized with DCNN denoiser has the potential to reduce noise, enhance subtle MCs, and improve the detectability of MCs for DBTs.*Clinical Relevance/Application The PnP reconstruction approach has the potential to reduce patient dose for DBT imaging and increase the sensitivity of MC detection for breast cancer screening.

RESULTS

We calculated the contrast-to-noise ratio (CNR) and the detectability index (d') using the non-prewhitening matched filter model observer with eye filter for individual MCs. The PnP algorithm significantly (p<0.0001) improved the CNR by 45.6-84.3% and d' by 43.6-63.3% for the phantom MCs, and the CNR by 70.4% and d' by 50.5% on average for human MCs compared to the unregularized SART algorithm. The parenchymal patterns in the reconstructed images were visually satisfactory without patchy appearance.

CLINICAL RELEVANCE/APPLICATION

The PnP reconstruction approach has the potential to reduce patient dose for DBT imaging and increase the sensitivity of MC detection for breast cancer screening.

SSCA02-2   Optimal Protocol Selection Methodology To Quantify Coronary Stenosis In Cardiac CT Images

Participants

Mojtaba Zarei, MSc, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To utilize a patient-informed Estimability index (e') in a comprehensive multi-factorial platform to optimize CT imaging for coronary plaque and stenosis.*Methods and Materials An estimability index was formulated as a basis to ascertain the dependency of the coronary stenosis measurement accuracy across clinical parameters affecting cardiac CT acquisition and to use the dependencies to determine optimum protocols. Factors included rotation time, pixel size, kernel sharpness, noise magnitude, and patient specifications such as vessel radius, cardiac motion velocity, plaque, and lumen materials, as informed by the CT Angiography Biomarker initiative of the RSNA Quantitative Imaging Biomarker Alliance (QIBA). An algorithm was developed to systematically assess and determine optimized CT acquisition parameters that maximize e' for a given set of un-controllable patient attributes. The findings were validated using 170 cases from the cardiac CT PROMISE clinical trial in which the patient attributes and acquisition protocols complied with QIBA that had been categorized by users as either high- or low-quality. For each case, we calculated e' for the applied protocol and derived the discrimination threshold from the associated ROC curve. The model was then used to find adjustments to the acquisition protocol that would have rendered a more favorable e' for each case.*Results In > 98% of the cases, the optimized protocols resulted in a better e' than the initial protocol. More specifically, in 33% of low-quality cases, the model indicated that the images could have been obtained to achieve a higher quality image. In the remaining 67% of such cases, the low quality was constrained by the condition of the patient and not the imaging condition.*Conclusions We developed a tool that selects CT acquisition parameters based on optimal patient attributes for a precise evaluation of stenosis percentages in CTA images.*Clinical Relevance/Application The critical need for reliable management of heart disease can be met by a modeling approach that can predict the likelihood of accurate quantification of stenosis in CTA images.

RESULTS

In > 98% of the cases, the optimized protocols resulted in a better e' than the initial protocol. More specifically, in 33% of low-quality cases, the model indicated that the images could have been obtained to achieve a higher quality image. In the remaining 67% of such cases, the low quality was constrained by the condition of the patient and not the imaging condition.

CLINICAL RELEVANCE/APPLICATION

The critical need for reliable management of heart disease can be met by a modeling approach that can predict the likelihood of accurate quantification of stenosis in CTA images.

SSCA02-5   Coronary Calcium Scoring With First Generation Dual-source Photon-counting CT And Quantum Technology - Phantom And In-vivo Experience

Participants

Matthias Eberhard, MD, Unterseen, Switzerland (*Presenter*) Nothing to Disclose

PURPOSE

To compare the accuracy of coronary artery calcium (CAC) scoring on a first generation dual-source photon-counting detector CT (PCD-CT) using monoenergetic reconstructions and Quantum Iterative Reconstruction (QIR).*Methods and Materials In this IRB-approved prospective study, we scanned an anthropomorphic chest phantom, optimized for spectral imaging, containing 9 calcification inserts. Sequential acquisition on a first generation PCD-CT with Quantum Technology (tube voltage, 120kV) was performed at four different image quality (IQ) levels (20, 40, 60 and 80) resulting in a CTDIvol of 1.97, 3.84, 6.44, and 8.58 mGy. Images were reconstructed with T3D (conventional 120kV reconstruction), 75keV, 70keV, 65keV, and 60 keV with filtered back projection (FBP) or various QIR strength levels (QIR 1-4). For reference, the same chest phantom was scanned on a single-source energy-integrating detector CT (sequential acquisition; tube voltage, 120kV; image reconstruction, FBP) with identical CTDIvol. Sequential PCD-CT scans for CAC scoring in 10 patients (mean age, 74±12 years; tube voltage, 120kV; IQ level 20; mean CTDIvol, 3.8±1.3 mGy) were reconstructed as detailed above. The Friedman test was used to assess differences between related samples.*Results Results: For the phantom study, there were no significant differences between CAC scores of different IQ levels (P=<.90). For IQ level 20, the reference CAC score of the phantom was 653 AU. In comparison, CAC scores for all image reconstructions were slightly lower with a relative difference of -2.8% (60keV, FBP; CAC score, 635 AU) to -20% (75keV, QIR at strength level 4; CAC score, 523 AU). Reconstructions with FBP had significantly higher CAC scores compared to QIR at strength

level 2-4 (all, P<.001). The patient study (median CAC score, 179 [inter-quartile range: 33-1049] at 60keV with FBP) confirmed relationships and differences between reconstruction algorithms (all, P<.001) with highest scores for FBP and lowest scores for QIR at strength level 4.*Conclusions First phantom and in-vivo experience of calcium scoring on a clinically used dual-source PCD-CT suggest reliable values for CAC scores using monoenergetic reconstructions.*Clinical Relevance/Application Our study shows the clinical applicability of CT calcium scoring using monoenergetic reconstructions on a first generation dual-source photon-counting detector CT with Quantum Technology.

RESULTS

Results: For the phantom study, there were no significant differences between CAC scores of different IQ levels (P=<.90). For IQ level 20, the reference CAC score of the phantom was 653 AU. In comparison, CAC scores for all image reconstructions were slightly lower with a relative difference of -2.8% (60keV, FBP; CAC score, 635 AU) to -20% (75keV, QIR at strength level 4; CAC score, 523 AU). Reconstructions with FBP had significantly higher CAC scores compared to QIR at strength level 2-4 (all, P<.001). The patient study (median CAC score, 179 [inter-quartile range: 33-1049] at 60keV with FBP) confirmed relationships and differences between reconstruction algorithms (all, P<.001) with highest scores for FBP and lowest scores for QIR at strength level 4.

CLINICAL RELEVANCE/APPLICATION

Our study shows the clinical applicability of CT calcium scoring using monoenergetic reconstructions on a first generation dual-source photon-counting detector CT with Quantum Technology.

SPR-IR-1 Interventional Optical Imaging Permits Instant Visualization Of Three Pathological Zones Of Ablated Tumor Periphery

Participants
Xuefeng Kan, MD,PhD, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

To develop a real-time optical imaging (OI) technique for in-vivo visualization of the three distinct pathological zones of ablated tumors, and thereby allowing for instant detection of residual viable tumor during a single ablation session.*Methods and Materials This study included three phases: (1) optimizing protocol of indocyanine green (ICG) parameters to achieve high-quality ICG-based OI; (2) in-vitro evaluating functionality/sensitivity of the interventional OI system using VX2 tumor cells; and (3) in-vivo validating the technical feasibility of the new ICG-based interventional OI system to instantly visualize three pathological zones of ablated tumor periphery on rabbit orthotopic VX2 tumor models. For optimizing ICG protocol, 3×10^5 cells were labeled with various ICG concentrations (0 to 200 μg/mL) and different incubation times (0 min to 48 h). Fluorescence signal intensities (SI) of different cell groups were measured by optical/x-ray imaging. For in-vitro evaluation, we first built the interventional OI system, which was then used to differentiate 1.5-mm3 living ICG-treated cells (ICG-cells) from 1.5-mm3 dead ICG-cells. For in-vivo validation, sixteen rabbits with orthotopic hepatic tumors were divided into two groups: incomplete radiofrequency ablation (RFA) and complete RFA. The ICG-based interventional OI system was used to differentiate residual viable tumors at the transition zone and completely ablated tumors. The average signal-to-background ratios (SBRs) among the residual viable tumors, transition zone, and completely ablated tumors were quantitatively compared. Subsequent ex-vivo OI and pathologic correlation were performed to confirm the findings of interventional OI.*Results Of in-vitro experiments, the optimal concentration and time-window for ICG-based OI were 100 μg/mL at 24 hours. ICG SI of untreated living cells was significantly higher than dead cells (187.0 ± 9.4 au vs. 65.1 ± 4.0 au, p < 0.001). Of in-vivo experiments, the interventional OI visualized three distinct pathological zones of incompletely or completely ablated tumor peripheries. The average SBR of residual viable tumors from incomplete RFA was significantly higher than those from transition zone and completely ablated tumors (2.77 ± 0.32 vs. 1.41 ± 0.04 vs. 0.57 ± 0.05, p < 0.001). Findings of interventional OI were confirmed by both ex-vivo OI and pathology (Figure).*Conclusions Interventional OI permits in-vivo visualization of three distinct pathological zones of ablated tumor periphery, which thus enables to differentiate incomplete and completed tumor ablation.*Clinical Relevance/Application This capability may open new avenues for instantly guiding complete tumor eradication during a single interventional ablation session.

RESULTS

Of in-vitro experiments, the optimal concentration and time-window for ICG-based OI were 100 μg/mL at 24 hours. ICG SI of untreated living cells was significantly higher than dead cells (187.0 ± 9.4 au vs. 65.1 ± 4.0 au, p < 0.001). Of in-vivo experiments, the interventional OI visualized three distinct pathological zones of incompletely or completely ablated tumor peripheries. The average SBR of residual viable tumors from incomplete RFA was significantly higher than those from transition zone and completely ablated tumors (2.77 ± 0.32 vs. 1.41 ± 0.04 vs. 0.57 ± 0.05, p < 0.001). Findings of interventional OI were confirmed by both ex-vivo OI and pathology (Figure).

CLINICAL RELEVANCE/APPLICATION

This capability may open new avenues for instantly guiding complete tumor eradication during a single interventional ablation session.

SPR-IR-2 Development Of A Bioresorbable Mesenchymal Stem Cell-loaded Radiopaque Polymer To Improve Rates Of Arteriovenous Fistula Maturation And Long-term Patency

Participants
Joy Vanessa Perez, Houston, Texas (*Presenter*) Nothing to Disclose

PURPOSE

To develop a bioresorbable, perivascular polymeric scaffold loaded with bone marrow-derived mesenchymal stem cells (MSCs) and test its efficacy in reducing neointimal hyperplasia (NIH) to the outflow vein of an arteriovenous fistula (AVF) in Sprague Dawley rats. A secondary goal was to assess the use of positron emission tomography (PET) in detecting inflammation following AVF creation.*Methods and Materials The perivascular scaffold wraps were fabricated by electrospinning method from a polymeric mixture of polycaprolactone and gold nanoparticles (Au-PCL). Allogenic MSCs were collected from the bone marrow of euthanized rats and were seeded at 100,000 cells per scaffold. Chronic kidney disease models in Sprague Dawley rats were created by subtotal nephrectomy. Four weeks thereafter, an end-to-side external jugular vein to common carotid artery AVF was created and confirmation of arterial flow through the fistula was confirmed by color Doppler ultrasound 2 weeks following creation. Rats were divided into 3 groups (N=2/group): control AVF (no wrap), Au-PCL (non-seeded wrap), and Au-PCL+MSC (wrap seeded with MSC). The wraps were applied to the outflow vein at the time of AVF creation. Four weeks post-AVF creation, animals underwent 18F-FDG PET imaging followed by necropsy and histomorphometric analysis of the outflow vein within 0.5 mm of the anastomosis.*Results Compared to controls, the addition of biodegradable perivascular wraps increased luminal area while

simultaneously decreasing the intima:lumen (I:L) and intima:media (I:M) ratios; the I:L and I:M ratios decreased 81.6% and 74.9% for the AVFs wrapped in Au-PCL alone and 89.6% and 89.1%, respectively, for the AVFs wrapped in Au-PCL+MSC. Relative to controls, PET imaging at 4 weeks demonstrated 16.9% reduction in SUVmax of the AVF wrapped with Au-PCL alone and 57.5% reduction of the AVF wrapped with Au-PCL+MSC.*Conclusions Addition of a bioresorbable polymer scaffold around the outflow vein of an AVF improved outward remodeling (i.e. luminal expansion and wall thickening), which is associated with AVF maturation. Inhibition of NIH, a key driver of AVF failure, was also observed. Appreciable PET signal suggests that the evaluation of local inflammation can potentially be used to assess AVF maturation and NIH outcomes.*Clinical Relevance/Application Neointimal hyperplasia (NIH) is responsible for failure of arteriovenous fistula (AVF) maturation in patients with chronic kidney disease on hemodialysis. Mesenchymal stem cells (MSCs) are anti-inflammatory and have been shown to reduce NIH formation, but their efficacy is limited by rapid washout. MSC delivery and survival can be achieved by loading them onto a radiopaque bioresorbable polymer scaffold wrapped around the outflow vein

RESULTS

Compared to controls, the addition of biodegradable perivascular wraps increased luminal area while simultaneously decreasing the intima:lumen (I:L) and intima:media (I:M) ratios; the I:L and I:M ratios decreased 81.6% and 74.9% for the AVFs wrapped in Au-PCL alone and 89.6% and 89.1%, respectively, for the AVFs wrapped in Au-PCL+MSC. Relative to controls, PET imaging at 4 weeks demonstrated 16.9% reduction in SUVmax of the AVF wrapped with Au-PCL alone and 57.5% reduction of the AVF wrapped with Au-PCL+MSC.

CLINICAL RELEVANCE/APPLICATION

Neointimal hyperplasia (NIH) is responsible for failure of arteriovenous fistula (AVF) maturation in patients with chronic kidney disease on hemodialysis. Mesenchymal stem cells (MSCs) are anti-inflammatory and have been shown to reduce NIH formation, but their efficacy is limited by rapid washout. MSC delivery and survival can be achieved by loading them onto a radiopaque bioresorbable polymer scaffold wrapped around the outflow vein

SPR-IR-3 Impact Of Chemo-Embolic Choice On The Tumor Microenvironment And Local Immune Response To Transarterial Chemoembolization In A VX2 Rabbit Liver Tumor Model

Participants
Antonia Berz, New Haven, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

To characterize the impact of various chemoembolic regimens on immune response and immune checkpoint marker expression in the setting of transarterial chemoembolization (TACE) in a VX2 rabbit liver tumor model.*Methods and Materials Approved by the institutional animal care and use committee (IACUC), twenty-four VX2 tumor-bearing New Zealand White rabbits were assigned to seven groups (n=3/group) undergoing locoregional therapy as follows: A) bicarbonate (BC) infusion, B) conventional TACE (cTACE) with Lipiodol, drug-eluting bead (DEB)-TACE with either C) Idarubicin-loaded OncozeneTM microspheres (40μm) or D) Doxorubicin-loaded LUMITM beads (40-90μm). To each therapy arm (B-D), a separate group treated with additional BC infusion was added to evaluate the effect of pH modification on the immune response. Three untreated rabbits served as controls. Tissue was harvested 24h post-treatment, followed by digital immunohistochemistry quantification (APERIO ImageScope) of tumor-infiltrating CD3+ T-cells, HLA-DR+ antigen-presenting cells (APCs), and the CTLA-4, and PD-1/L1 pathway axis expression. Statistical analysis was performed using the Kruskal-Wallis test (p=0.05).*Results Treatment with LUMITM bead TACE induced more APC recruitment in the tumor core than OncozeneTM TACE (HLA-DR: p=0.0113) and more intra-tumoral T-cell and APC infiltration than cTACE (CD3: p=0.0003, HLA-DR: p<0.0001). Additionally, LUMITM bead TACE treated tumors had higher intra-tumoral immune checkpoint marker expression as compared to OncozeneTM TACE (CTLA-4: p=0.0002, PD-1: p<0.0001, PD-L1: p=0.0021) and cTACE (CTLA-4: p<0.0001, PD-1: p<0.0001, PD-L1: p=0.002). Additional BC administration demonstrated the most significant effect on cTACE, showing increased intra-tumoral T-cell infiltration as compared to cTACE alone (p=0.0003).*Conclusions This preclinical study reveals marked differences in local immune response and immune checkpoint marker expression between various types of chemoembolic agents used for TACE. Doxorubicin-eluting LUMITM beads and BC-buffered cTACE might be the most promising options to achieve intra-tumoral T-cell infiltration when combining TACE with immune checkpoint inhibition (ICI).*Clinical Relevance/Application Prospective clinical trials evaluating the combination of TACE with ICI should consider the effects of chemoembolic regimens on the immune system to avoid confounded results.

RESULTS

Treatment with LUMITM bead TACE induced more APC recruitment in the tumor core than OncozeneTM TACE (HLA-DR: p=0.0113) and more intra-tumoral T-cell and APC infiltration than cTACE (CD3: p=0.0003, HLA-DR: p<0.0001). Additionally, LUMITM bead TACE treated tumors had higher intra-tumoral immune checkpoint marker expression as compared to OncozeneTM TACE (CTLA-4: p=0.0002, PD-1: p<0.0001, PD-L1: p=0.0021) and cTACE (CTLA-4: p<0.0001, PD-1: p<0.0001, PD-L1: p=0.002). Additional BC administration demonstrated the most significant effect on cTACE, showing increased intra-tumoral T-cell infiltration as compared to cTACE alone (p=0.0003).

CLINICAL RELEVANCE/APPLICATION

Prospective clinical trials evaluating the combination of TACE with ICI should consider the effects of chemoembolic regimens on the immune system to avoid confounded results.

SPR-IR-4 Magnetic Resonance Image Guided High Focused Ultrasound Surgery Of Adenomyosis Model Of Bama Pigs

Participants
Qi Zhang, Shang Hai, China (*Presenter*) Nothing to Disclose

PURPOSE

Magnetic resonance image guided focused ultrasound surgery (MRgFUS) ablation has been widely used as a non-surgical therapy for adenomyosis. Due to the noninvasive nature of the method, sampling cannot be done frequently and invasively from the adenomyosis patient. Therefore, using MRgFUS to treat adenomyosis animal model is beneficial to further study the process of the disease after ablation. The purpose of this study was to explore the feasibility of MRgFUS in the treatment of adenomyosis model of Bama pigs.*Methods and Materials Three healthy adult female Bama pigs were purchased and the uterine adenomyosis model of Bama pigs was established by autologous endometrial implantation method. Three months after modeling surgery, surgical sampling and imaging methods were used to evaluate disease progression. Adenomyosis lesions were successfully constructed in all three

Bama pigs and then treated with MRgFUS. Enhanced T1 scan was performed immediately after ablation. The uterine thickness of pigs was measured before and after ablation. Venous blood was extracted from pigs before and two months after treatment, and the levels of CA125 and CA199 were detected by enzyme linked immunosorbent assay (ELISA).*Results The adenomyosis model was successfully established by pathology after sampling of the three Bama pigs. All Bama pigs successfully constructed adenomyosis lesions received ablation treatment. The total ablation time of three Bama pigs was 163min, 102min and 85min, respectively. Bama pigs were all in good condition after the operation, and no obvious skin scald was observed. Before ablation, the average thickness of the uterus at the thickest part of the Bama pigs was 3.83±0.26cm. Two months after ablation, the mean uterine thickness at the thickest part was 2.97±0.25cm. The serum levels of CA125 and CA199 in Bama pigs were 83.02±10.31 pg/ml and 11.33±2.79ng/ml before ablation, and 72.78±11.86 pg/ml and 9.90±3.32 ng/ml after ablation, respectively.*Conclusions It is a safe and effective method to treat adenomyosis model of Bama pigs with MRgFUS. After ablation treatment, the uterine thickness and serum CA125 and CA199 levels of Bama pigs decreased compared with those before ablation, which was consistent with the clinical manifestations after adenomyosis treatment. It can be used to further study the mechanism of adenomyosis after MRgFUS.*Clinical Relevance/Application Using MRgFUS to treat adenomyosis animal model is beneficial to further study the process of the disease after ablation. It can be used to further study the mechanism of adenomyosis after MRgFUS.

RESULTS

The adenomyosis model was successfully established by pathology after sampling of the three Bama pigs. All Bama pigs successfully constructed adenomyosis lesions received ablation treatment. The total ablation time of three Bama pigs was 163min, 102min and 85min, respectively. Bama pigs were all in good condition after the operation, and no obvious skin scald was observed. Before ablation, the average thickness of the uterus at the thickest part of the Bama pigs was 3.83±0.26cm. Two months after ablation, the mean uterine thickness at the thickest part was 2.97±0.25cm. The serum levels of CA125 and CA199 in Bama pigs were 83.02±10.31 pg/ml and 11.33±2.79ng/ml before ablation, and 72.78±11.86 pg/ml and 9.90±3.32 ng/ml after ablation, respectively.

CLINICAL RELEVANCE/APPLICATION

Using MRgFUS to treat adenomyosis animal model is beneficial to further study the process of the disease after ablation. It can be used to further study the mechanism of adenomyosis after MRgFUS.

SPR-IR-5   Development Of A Computed Tomography-based Radiomics Nomogram For Prediction Of Transarterial Chemoembolization Refractoriness In Hepatocellular Carcinoma

Participants
Xiangke Niu, MD,MS, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a computed tomography (CT)-based radiomics nomogram for the pre-treatment prediction of TACE refractoriness.*Methods and Materials This retrospective study consisted of a training dataset (n = 137) and an external validation dataset (n = 81) of patients with clinically/pathologically confirmed HCC who underwent repeated TACE from March 2009 to March 2016. Radiomics features were retrospectively extracted from preoperative CT images of the arterial phase. The pre-treatment radiomics signature was generated using least absolute shrinkage and selection operator Cox regression analysis. A CT-based radiomics nomogram incorporating clinical risk factors and the radiomics signature was built and verified by calibration curve and decision curve analyses. The usefulness of the CT-based radiomics nomogram was assessed by Kaplan-Meier curve analysis. We used the concordance index to conduct head-to-head comparisons of the radiomics nomogram with the other four models. All analyses were conducted according to the transparent reporting of a multivariable prediction model for individual prognosis or diagnosis statement.*Results The median number of TACE sessions was 4 (range, 3-7) in bothcohorts. Eight radiomics features were chosen from 869 candidate features to build a radiomics signature. The CT-based radiomics nomogram included the radiomics score (hazard ratio = 3.9, 95% confidence interval: 3.1-8.8, P < 0.001) and four clinical factors and classified patients into high-risk (score > 3.5) and low-risk (score = 3.5) groups with markedly different prognoses (overall survival: 12.3 mo vs 23.6 mo, P < 0.001). The accuracy of the nomogram was considerably higher than that of the other four models. The calibration curve and decision curve analyses verified the usefulness of the CT-based radiomics nomogram for clinical practice.*Conclusions The newly constructed CT-based radiomics nomogram can be used for the pre-treatment prediction of TACE refractoriness, which may provide better guidance for decision making regarding further TACE treatment.*Clinical Relevance/Application The main finding of this study is that our computed tomography (CT)-based radiomics nomogram can be used to individually predict patients' refractory state before the first session of TACE. This CT-based radiomics nomogram may provide an unprecedented opportunity to improve clinical decision making for the patients who are repeatedly treated by TACE and, eventually, improve the overall survival of these patients.

RESULTS

The median number of TACE sessions was 4 (range, 3-7) in bothcohorts. Eight radiomics features were chosen from 869 candidate features to build a radiomics signature. The CT-based radiomics nomogram included the radiomics score (hazard ratio = 3.9, 95% confidence interval: 3.1-8.8, P < 0.001) and four clinical factors and classified patients into high-risk (score > 3.5) and low-risk (score = 3.5) groups with markedly different prognoses (overall survival: 12.3 mo vs 23.6 mo, P < 0.001). The accuracy of the nomogram was considerably higher than that of the other four models. The calibration curve and decision curve analyses verified the usefulness of the CT-based radiomics nomogram for clinical practice.

CLINICAL RELEVANCE/APPLICATION

The main finding of this study is that our computed tomography (CT)-based radiomics nomogram can be used to individually predict patients' refractory state before the first session of TACE. This CT-based radiomics nomogram may provide an unprecedented opportunity to improve clinical decision making for the patients who are repeatedly treated by TACE and, eventually, improve the overall survival of these patients.

SPR-IR-7   Application And Quality Reserve Of Digital Variance Angiography And Color-coded Digital Variance Angiography In Prostatic Artery Embolization

Participants
Leona Alizadeh, MD, Frankfurt, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Kinetic imaging is defined as a novel X-ray image processing method for the visualization of contrast motion. The algorithm produces so-called Digital Variance Angiography (DVA) images. The study objective was to compare the performance of DVA versus

standard digital subtraction angiography (DSA) for vascular intervention in Prostatic Artery Embolization (PAE).*Methods and Materials The retrospective observational study enrolled 37 patients (mean age 67.47, SD 9.76, range 42-82) undergoing PAE at our institution between May and October of 2020. Altogether 142 acquisitions were included in the analysis. DSA and DVA images were generated from the same raw series. The CNR values were calculated, and the image quality was evaluated by 4 experienced readers in a randomized blinded survey, using a 5-grade-Likert-scale. Data were expressed as median and interquartile ranges (IQR) and analyzed by the Wilcoxon signed rank test.*Results DVA images provided 4.1 times higher CNR than DSA images, the median (IQR) CNR values were 29.5 (19.5-45.4) and 7.2 (4.9-11.1), respectively, p<0.001. DSA images received significantly higher Likert score than DSA images, the median (IQR) values were 4.33 (4.00-4.67) and 3.67 (3.00-4.00), respectively, p< 0.001.*Conclusions The data in this initial retrospective trial indicate that DVA has significantly higher CNR and enhanced image quality compared to DSA in PAE procedures. This quality reserve of DVA provides the opportunity for significant reduction of radiation exposure and iodinated contrast agent in PAE.*Clinical Relevance/Application Radiation dose and amount of contrast agent used during complex procedures, such as PAE, is needed to be further reduced to improve patient safety.

RESULTS

DVA images provided 4.1 times higher CNR than DSA images, the median (IQR) CNR values were 29.5 (19.5-45.4) and 7.2 (4.9-11.1), respectively, p<0.001. DSA images received significantly higher Likert score than DSA images, the median (IQR) values were 4.33 (4.00-4.67) and 3.67 (3.00-4.00), respectively, p< 0.001.

CLINICAL RELEVANCE/APPLICATION

Radiation dose and amount of contrast agent used during complex procedures, such as PAE, is needed to be further reduced to improve patient safety.

SPR-IR-8   Volume Flow-assisted Angioplasty Of Dysfunctional Autologous Arteriovenous Fistula: The Vola Pilot Study

Participants
Stavros Spiliopoulos, MD,PhD, Athens, Greece (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the feasibility of volume flow-assisted angioplasty (VFA) in dysfunctional arteriovenous fistula (AVF) using sequential intraprocedural duplex ultrasound (DUS), and utilize intraprocedural VF as a quantifiable, functional endpoint in endovascular treatment.*Methods and Materials This was a prospective study (clinicaltrials.gov NCT04430478) which included 20 consecutive patients (23 lesions; 16 men; mean age 67±16 years) with dysfunctional AVF undergoing fluoroscopically-guided, balloon angioplasty between June 2019-May 2020. Primary endpoints included: quantification of outcome using sequential VF DUS analysis following each dilation, procedural success (achievement of a postprocedural VF value =to the baseline steady-state access) and 6-months target lesion re-intervention (TLR)-free rate. Secondary endpoints included 6-months lesion late lumen loss (LLL), and correlation of VF values with balloon diameters and LLL measurements.*Results Mean VF increase after angioplasty was 168.5%±102.5% (range:24.24%-493.33%). Procedural success was 80% (16/20 cases). VFA improved procedural success by 20% (4/20 cases) compared to standard assessment (<30% residual stenosis and palpable thrill). TLR-free rate was 78.3%, 67.3% at 6 and 12 months. Significantly less TLR was noted in cases of procedural success (82.4% vs. 66.7% 6-months;p=0.041). Unweighted linear regression showed a significant positive relationship between the diameter of the balloon and VF (146.9±42.3ml/min VF gain per mm of balloon diameter;p=0.001,R2=0.23) and a significant negative relationship between LLL and VF decline at follow-up (102.0±34.6ml/min loss per mm of LLL;p=0.01,R2=0.35). Optimal postprocedural VF and percentile VF increase cut off values to predict access failure were 720 ml/min (sensitivity 58.3%, specificity 71.4%) and 153% (sensitivity 66.7%, specificity 85.7%); respectively.*Conclusions Intraprocedural VFA using DUS could optimize AVF angioplasty outcomes.*Clinical Relevance/Application Contrary to peripheral arterial procedures, the quantification of angioplasty outcomes in dialysis AVF, either by visual estimation or using the gold standard of quantitative vessel analysis can be extremely inaccurate, as AVF circuits usually include dilated or aneurysmal segments and different unaffected vessel diameters across the entire access conduit. The authors investigated the feasibility of Volume-Flow (VF)-assisted balloon angioplasty in dysfunctional AVF using sequential, intraprocedural VF assessment with percutaneous Duplex ultrasound in order to develop a novel simple, non-invasive strategy to accurately quantify a novel functional endpoint of AVF endovascular treatment.

RESULTS

Mean VF increase after angioplasty was 168.5%±102.5% (range:24.24%-493.33%). Procedural success was 80% (16/20 cases). VFA improved procedural success by 20% (4/20 cases) compared to standard assessment (<30% residual stenosis and palpable thrill). TLR-free rate was 78.3%, 67.3% at 6 and 12 months. Significantly less TLR was noted in cases of procedural success (82.4% vs. 66.7% 6-months;p=0.041). Unweighted linear regression showed a significant positive relationship between the diameter of the balloon and VF (146.9±42.3ml/min VF gain per mm of balloon diameter;p=0.001,R2=0.23) and a significant negative relationship between LLL and VF decline at follow-up (102.0±34.6ml/min loss per mm of LLL;p=0.01,R2=0.35). Optimal postprocedural VF and percentile VF increase cut off values to predict access failure were 720 ml/min (sensitivity 58.3%, specificity 71.4%) and 153% (sensitivity 66.7%, specificity 85.7%); respectively.

CLINICAL RELEVANCE/APPLICATION

Contrary to peripheral arterial procedures, the quantification of angioplasty outcomes in dialysis AVF, either by visual estimation or using the gold standard of quantitative vessel analysis can be extremely inaccurate, as AVF circuits usually include dilated or aneurysmal segments and different unaffected vessel diameters across the entire access conduit. The authors investigated the feasibility of Volume-Flow (VF)-assisted balloon angioplasty in dysfunctional AVF using sequential, intraprocedural VF assessment with percutaneous Duplex ultrasound in order to develop a novel simple, non-invasive strategy to accurately quantify a novel functional endpoint of AVF endovascular treatment.

SSNR13-1   Fully Automatic Segmentation And Treatment Response Assessment Of Brain Metastases On Magnetic Resonance Imaging

Participants
Jay Patel, Charlestown, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Measuring treatment response is vital for assessing efficacy of current treatment regimens for patients with brain metastases (BM). Given that patients often have multiple BM, longitudinal tracking of individual lesions on magnetic resonance (MR) imaging is challenging due to the time-consuming nature of manual tumor annotation. To overcome this challenge, we propose an automatic deep learning approach to longitudinally segment BM and to automate the quantification of measurable tumor burden as defined by the Response Assessment for Neuro-Oncology Brain Metastases (RANO-BM) criteria.*Methods and Materials A primary dataset of 82 patients (182 time-points total) with T1-weighted post-contrast MPRAGE sequences was retrospectively acquired from one institution, along with a secondary dataset of 133 patients (847 time-points total) acquired from a second institution. Ground truth segmentations were performed by expert neuroradiologists for all patient time-points. Using the primary dataset, a 3D UNet convolutional neural network (CNN) was trained to segment BM. This trained network was used to generate automatic segmentations for all time-points in the secondary dataset. Next, all time-points for a patient were co-registered to the baseline visit, and all lesions were automatically given a unique identifier to track them across time-points. Finally, an automatic RANO-BM measure was derived by summing the longest axial diameter of the patient's five largest target lesions (where a target lesion is defined as greater than 10mm in longest diameter). Segmentation performance was evaluated by the Dice similarity coefficient, and RANO-BM measures by the two-way mixed, single measure intra-class correlation coefficient (ICC).*Results For automatic segmentation of BM on the secondary dataset of 847 time-points, the median dice score was 0.819. Comparing the RANO-BM measure computed from the ground truth segmentations to that computed from the predicted segmentations, the ICC was 0.88.*Conclusions We developed a fully automatic pipeline that segments BM and computes a RANO-BM assessment. Moreover, we show high agreement between the RANO measure computed from the ground truth segmentations and the predicted segmentations, demonstrating the clinical utility of our automated method to quantify measurable tumor burden.*Clinical Relevance/Application This tool may help in clinical practice as well as in clinical trials by expediting accurate measurement of tumor burden and quantifying treatment response.

RESULTS

For automatic segmentation of BM on the secondary dataset of 847 time-points, the median dice score was 0.819. Comparing the RANO-BM measure computed from the ground truth segmentations to that computed from the predicted segmentations, the ICC was 0.88.

CLINICAL RELEVANCE/APPLICATION

This tool may help in clinical practice as well as in clinical trials by expediting accurate measurement of tumor burden and quantifying treatment response.

SSNR13-2   Deep Learning Enables 60% Accelerated Volumetric Brain MRI While Preserving Quantitative Performance-A Prospective, Multicenter, Multireader Trial

Participants
Suzie Bash, MD, Woodland Hills, California (*Presenter*) Consultant, CorTechs Labs, Inc;Consultant, icoMetrix NV;Consultant, Subtle Medical, Inc;Consultant, Darmiyan, Inc

PURPOSE

In this prospective, multicenter, multireader study, we evaluate the impact on both image quality and quantitative image analysis consistency (NeuroQuant™) of 60% accelerated volumetric MRI scans processed with a commercially available, vendor agnostic, DICOM-based deep learning (DL) tool (SubtleMR™) compared to that of the standard of care (SOC).*Methods and Materials With IRB approval and patient consent, 40 subjects underwent brain MRI exams on 6 scanners from 5 institutions. SOC and accelerated (FAST) datasets were acquired for each subject. The FAST scans were then enhanced with DL processing (FAST-DL). Both SOC and FAST-DL were subjected to quantitative volumetric analysis with NeuroQuant™ and classification by a neuroradiologist into clinical disease categories based on results. Quantitative biomarker concordance of SOC and FAST-DL was assessed. To evaluate subjective image quality, randomized, side-by-side, multiplanar datasets (360 series) were presented blinded to 2 neuroradiologists. Images were preference rated on a 5-point Likert scale for apparent signal-to-noise ratio, image sharpness, artifacts, lesion conspicuity, image contrast, and gray-white differentiation.*Results FAST-DL was statistically superior to SOC for perceived quality

across all imaging features despite a 60% scan time reduction (all p-values <0.05). Both FAST-DL and SOC were superior to FAST for all quality features. There was high inter-reader agreement of the Likert image quality ratings between the 2 neuroradiologists. Paired T-test analysis demonstrated excellent agreement of quantitative data between the SOC and FAST-DL datasets. Linear Regression graphs and Bland-Altman plot graph analysis further demonstrated strong concordance in quantitative values across the range of conditions (normal, MCI, Alzheimer's Disease). There was 100% agreement in clinical disease classification for both the SOC and FAST-DL datasets (n=29 normal/MCI and n=11 dementia).*Conclusions DL reconstruction allows 60% scan time reduction while maintaining high volumetric quantification accuracy, consistent clinical classification, and what radiologists perceive as superior image quality when compared with SOC.*Clinical Relevance/Application This trial supports the reliability, efficiency, and utility of DL based enhancement for quantitative imaging. Shorter scan times may boost utilization of volumetric quantitative MRI in routine clinical settings.

RESULTS

FAST-DL was statistically superior to SOC for perceived quality across all imaging features despite a 60% scan time reduction (all p-values <0.05). Both FAST-DL and SOC were superior to FAST for all quality features. There was high inter-reader agreement of the Likert image quality ratings between the 2 neuroradiologists. Paired T-test analysis demonstrated excellent agreement of quantitative data between the SOC and FAST-DL datasets. Linear Regression graphs and Bland-Altman plot graph analysis further demonstrated strong concordance in quantitative values across the range of conditions (normal, MCI, Alzheimer's Disease). There was 100% agreement in clinical disease classification for both the SOC and FAST-DL datasets (n=29 normal/MCI and n=11 dementia).

CLINICAL RELEVANCE/APPLICATION

This trial supports the reliability, efficiency, and utility of DL based enhancement for quantitative imaging. Shorter scan times may boost utilization of volumetric quantitative MRI in routine clinical settings.

SSNR13-4   Early Prediction Of Cognitive Deficit Using Quantitative Structural MRI In Very Preterm Infants With Ensemble Learning

Participants
Zhiyuan Li, BS,MS, Oxford, Ohio (*Presenter*) Nothing to Disclose

PURPOSE

To develop an ensemble learning model using quantitative structural MRI features acquired at term equivalent age (TEA) for early prediction of cognitive deficits at 2 years corrected age (CA) in very preterm infants (VPIs; gestational age =32 weeks).*Methods and Materials Cohort. We included 197 VPIs (47.2% male) that had a mean (SD) gestational age at birth of 29.4 (2.4) weeks from Cincinnati Children's Hospital. At TEA, all subjects were imaged during unsedated sleep on a 3T Philips Ingenia scanner. T2-weighted imaging parameters: TR/TE 18567/166 ms, FA 90°, resolution 1.0 × 1.0 × 1.0 mm3. Each infant was assessed using Bayley III test at 2 years CA. Based on cognitive scores, we dichotomized the infants into low-risk (>85; N=129) vs. high-risk (=85; N=68) groups. Feature Quantification. We segmented the brain into 87 regions using a developing Human Connectome Project pipeline. For each region, the pipeline calculates brain volumes and cortical maturation features, including thickness, sulcal depth, curvature, gyrification index, and surface area. This resulted in 510 features for each VPI. Ensemble Learning Model. The model in the figure contains 1) six eXtreme Gradient Boosting (XGB) classifiers and each produces an individual probability of developing cognitive deficits using brain volumes/ cortical maturation features; 2) a neural network that takes the prior predicted probabilities and produces a final probability of developing cognitive deficit. We used a hybrid sampling algorithm to balance training data. Model performance was assessed using Leave-One-Out Cross-Validation.*Results Our model was able to identify high-risk infants for cognitive deficits with an accuracy of 68.0%, a sensitivity of 70.2%, and a specificity of 67.3%. It achieved a better AUC of 0.73 than a XGB classifier (AUC = 0.62) and a neural network (AUC = 0.61).*Conclusions The proposed model outperformed the peer models and incorporating multimodal MRI features is likely to further improve the performance.*Clinical Relevance/Application The proposed study may potentially facilitate risk stratification and enable early intervention strategies to improve developmental outcomes in infants at high risk for cognitive deficits.

RESULTS

Our model was able to identify high-risk infants for cognitive deficits with an accuracy of 68.0%, a sensitivity of 70.2%, and a specificity of 67.3%. It achieved a better AUC of 0.73 than a XGB classifier (AUC = 0.62) and a neural network (AUC = 0.61).

CLINICAL RELEVANCE/APPLICATION

The proposed study may potentially facilitate risk stratification and enable early intervention strategies to improve developmental outcomes in infants at high risk for cognitive deficits.

SSNR13-5   Machine Learning Model For Motion Detection And Quantification On Brain MR: A Multicenter Testing Study

Participants
Bernardo Bizzo, MD,PhD, Newton, Massachusetts (*Presenter*) Consultant, Diagnosticos da America (Dasa)

PURPOSE

Detection and quantitation of motion artifacts can help automate repeated acquisition and avoid interpretation pitfalls related to motion-impaired MR images and patient recall. We developed a machine learning-based Image Quality Dashboard (IQD) for detecting and quantifying motion artifacts for brain MR and tested its application in a multicenter study.*Methods and Materials For model development, we used a natural language processing approach to identify 1530 brain MR exams from US Site A (24 MR scanners from 2 vendors) presenting mention of motion artifacts in the radiology reports and containing six common sequences (T1 sagittal, T2 axial, T2 axial FLAIR, T1 axial pre-contrast, T1 axial post-contrast, and susceptibility-weighted angiography). We then built an XGBoost ensemble model (IQD) using four artificial neural networks based on Inception V3 framework; the model output scores represent weighted averages of probability. For testing, in addition to the primary test set from US Site A, we identified and processed brain MRs from US Site B (n=444; 11 MR scanners from 2 vendors with identical sequences) and Brazil Site C (n= 544; 19 MR scanners from 4 vendors; 9 sequences with additional sequences of T2 sagittal, T2 coronal and T2* axial). A panel of three radiologists graded motion severity (none, mild, moderate, and severe) at an image level for all exams from the three sites, unaware of IQD scores. We determined ranking accuracy (correct accuracy of IQD divided by the number of total rankings) to compare motion severity between radiologists and IQD.*Results Compared to the panel of radiologists, IQD accurately predicted the presence and severity of motion artifacts at the three testing sites (ranking accuracy- Site A: 91-100%; Site B: 94-98%; Site C:

90-100%). We noted a consistently high image-level performance of the IQD model across different MR sequences (ranking accuracy from 90% [T2* axial] to 100% [T1 axial post contrast]), MR units from four different vendors, or magnet strengths (accuracy - 1.5T: 94-98%; 3T: 100%).*Conclusions Multicenter testing study demonstrates that motion artifacts can be accurately detected and quantified with IQD for different MR scanners and sequences.*Clinical Relevance/Application IQD can help technologists trigger reacquisition of specific MR sequences in presence of motion artifacts, aid radiologists to avoid motion-related pitfalls in the interpretation of brain MR and decrease patient recall due to motion-degraded exams.

RESULTS

Compared to the panel of radiologists, IQD accurately predicted the presence and severity of motion artifacts at the three testing sites (ranking accuracy- Site A: 91-100%; Site B: 94-98%; Site C: 90-100%). We noted a consistently high image-level performance of the IQD model across different MR sequences (ranking accuracy from 90% [T2* axial] to 100% [T1 axial post contrast]), MR units from four different vendors, or magnet strengths (accuracy - 1.5T: 94-98%; 3T: 100%).

CLINICAL RELEVANCE/APPLICATION

IQD can help technologists trigger reacquisition of specific MR sequences in presence of motion artifacts, aid radiologists to avoid motion-related pitfalls in the interpretation of brain MR and decrease patient recall due to motion-degraded exams.

SSNR13-6   Mapping Whole Exome Sequencing To Noninvasive Imaging With Stereotactic Localization And Deep Learning

Participants
Jason Parker, PhD, Indianapolis, Indiana (*Presenter*) Nothing to Disclose

PURPOSE

Evaluate the potential for predicting exome-wide mutation events from non-invasive imaging by combining stereotactic localization of tumor tissue samples and a feedforward dense network.*Methods and Materials Ten (10) treatment-naïve glioma patients underwent multiparametric MR (T1w, T1w+gad, T2w, T2w-FLAIR, DWI) a maximum of 7 days prior to surgery. Stereotactic localization of up to 4 tumor tissue samples was captured for each patient and used to identify spatially-correlated voxels in the pre-surgical images (Figure 1A). The tissue samples were processed immediately in the OR using a portable mass spectrometer and then flash frozen and studied using whole-exome sequencing, whole-exome methylation, and RNA Seq v2. A computational biology supercomputing framework was designed to identify important genomic targets by polymorphism discovery (Mutect2) against the GRCh38 human reference genome. The chromosomal locations for eight (8) mutational gene targets specific to glioma were then annotated by variant type (SnpSift) including PTEN, IDH1, TP53, EGFR, PIK3R1, PIK3CA, NF1, and RB1. At the time of this writing, a total of 8 patients have completed the genomic processing pipeline and proceeded to final analysis. For prediction analysis we implemented a 4 layer feedforward dense network using 8 nodes for the first layer, 16 nodes for second, 32 for the third, and finally mapping into the 8 output nodes for the exon outputs. Dropout was set to 0.75 and stochastic gradient descent optimization with binary cross entropy as a loss function was used. A total of 8 iterations of 25 epochs each were run in leave-one-patient-out cross validation design.*Results With all 8 exons included, the mean accuracy of the leave-one-patient-out analysis across all mutational targets was 76.5% ± 15% (Figure 1C). Individual patient prediction accuracy ranged from 0.54 to 0.997. The modes of exons 4 and 7 (EGFR and NF1, respectively) were found to be 0 across all patients (Figure 1B) and thus could have been removed to improve classification accuracy. This is the subject of current analyses.*Conclusions We have demonstrated the ability to predict single nucleotide point mutations from non-invasive imaging. We expect the accuracy of this classification will improve in currently ongoing analyses utilizing better tuning of hyperparameters, optimization of included exons, the addition of more patients, and matched-normal somatic variant calling using blood samples.*Clinical Relevance/Application Heterogeneity of solid tumors is the primary cause of treatment resistance and disease recurrence. Methods to map molecular and cellular properties across space hold the potential to overcome the sampling error of biopsy and dramatically reshape individualized therapy protocols.

RESULTS

With all 8 exons included, the mean accuracy of the leave-one-patient-out analysis across all mutational targets was 76.5% ± 15% (Figure 1C). Individual patient prediction accuracy ranged from 0.54 to 0.997. The modes of exons 4 and 7 (EGFR and NF1, respectively) were found to be 0 across all patients (Figure 1B) and thus could have been removed to improve classification accuracy. This is the subject of current analyses.

CLINICAL RELEVANCE/APPLICATION

Heterogeneity of solid tumors is the primary cause of treatment resistance and disease recurrence. Methods to map molecular and cellular properties across space hold the potential to overcome the sampling error of biopsy and dramatically reshape individualized therapy protocols.

SSCH07-1   False Lumen Arc Length Is A Predictor For Late Complications In Initially Uncomplicated Type B Aortic Dissection: A Multicenter Study

Participants
Joost Hop, BMedSc, Groningen, Netherlands (*Presenter*) Nothing to Disclose

PURPOSE

Morphologic CT features such as maximum aortic diameter and false lumen angle are known predictors of late complications in patients with initially uncomplicated type B aortic dissection (uTBAD). Although maximum aortic diameter has shown to be a robust measure, the interobserver reliability of the false lumen angle is poor. False lumen arc length is a more reliable measurement than false lumen angle. We therefore consider false lumen arc length a potential replacement for false lumen angle. However, the association between false lumen arc length and late uTBAD complications is unknown. We aimed to evaluate whether false lumen arc length is associated with late complications.*Methods and Materials Baseline CT scans of uTBAD patients from a multicenter study were retrospectively analyzed for known morphologic features including (i) maximum aortic diameter (mm); (ii) false lumen angle (°); (iii) false lumen outflow volume (mL/min), and (iv) number of identifiable intercostal arteries (n). Additionally, (v) false lumen arc length (mm) was assessed as a novel marker. Univariate association of false lumen arc length with late complications was evaluated using the Youden Index, Kaplan Meier method, and Cox regression. Multicollinearity was defined as a variance inflation factor (VIF)>5. A previous Cox model was rebuilt with imaging features i-iv in addition to presence of connective tissue disease. Subsequently, false lumen angle was replaced by false lumen arc length in an updated Cox model. C-statistics were compared.*Results 313 patients with uTBAD were included with median (interquartile range) follow-up of 604 (190-1501) days. 147 (47%) patients developed late complications. Median false lumen arc length for patients that did and did not develop late complications were 85 (74-101) mm and 76 (66-88) mm, respectively. Kaplan Meier and Cox regression analyses indicated univariate association between a false lumen arc length >77.35 mm and late complications, with a hazard ratio (HR) of 1.93/mm (1.35-2.77, p<0.001). No indication for multicollinearity was found with VIFs between 1.0 and 1.6. The original Cox model with imaging features i-iv and presence of connective tissue disease resulted in a c-statistic of 0.69 (0.63-0.73). HRs were 1.08/mm (1.06-1.10, p<0.001) for maximum aortic diameter and 1.00/° (1.00-1.01, p=0.06) for false lumen angle. Replacing false lumen angle by false lumen arc length resulted in a similar c-statistic of 0.68 (0.63-0.73) and HR 1.01/mm (1.00-1.02, p=0.02).*Conclusions Our study showed that false lumen arc length is independently associated with late complications in uTBAD.*Clinical Relevance/Application False lumen arc length may replace false lumen angle as more robust image feature to predict late complications.

RESULTS

313 patients with uTBAD were included with median (interquartile range) follow-up of 604 (190-1501) days. 147 (47%) patients developed late complications. Median false lumen arc length for patients that did and did not develop late complications were 85 (74-101) mm and 76 (66-88) mm, respectively. Kaplan Meier and Cox regression analyses indicated univariate association between a false lumen arc length >77.35 mm and late complications, with a hazard ratio (HR) of 1.93/mm (1.35-2.77, p<0.001). No indication for multicollinearity was found with VIFs between 1.0 and 1.6. The original Cox model with imaging features i-iv and presence of connective tissue disease resulted in a c-statistic of 0.69 (0.63-0.73). HRs were 1.08/mm (1.06-1.10, p<0.001) for maximum aortic diameter and 1.00/° (1.00-1.01, p=0.06) for false lumen angle. Replacing false lumen angle by false lumen arc length resulted in a similar c-statistic of 0.68 (0.63-0.73) and HR 1.01/mm (1.00-1.02, p=0.02).

CLINICAL RELEVANCE/APPLICATION

False lumen arc length may replace false lumen angle as more robust image feature to predict late complications.

SSCH07-2   Prediction Of Lung Malignancy Progression And Survival With Machine Learning Based On Pre-Treatment FDG-PET/CT

Participants
John Sollee, BS, Providence, Rhode Island (*Presenter*) Nothing to Disclose

PURPOSE

Pre-treatment FDG-PET/CT scans were analyzed with machine learning to predict progression of lung malignancies and overall survival (OS).*Methods and Materials A retrospective review across four institutions identified patients that had a pre-procedure FDG-PET/CT and an associated malignancy diagnosis by biopsy or surgery. 1168 lesions were manually segmented (n=965 patients), and progression occurrence was collected. Lesions were split 7:2:1 between training, validation, and test sets, and convolutional neural networks (CNNs) were trained using CT/PET inputs to predict malignancy progression. Model performance was evaluated using area under the receiver operating curve (AUC-ROC), accuracy, sensitivity, and specificity. Image features were extracted

using the penultimate dense neuron layer of each CNN. Random survival forests (RSFs) were constructed to predict OS using the extracted features. OS predictions were evaluated with concordance index (C-index) and integrated brier score (IBS).*Results Of the 1168 lesions, 793 had progression and 375 were progression-free. The most common malignancies were adenocarcinoma (n=728) and squamous cell carcinoma (n=190). The CT CNN model predicted progression with an accuracy of 0.790 [95% confidence interval: 0.786, 0.831], AUC-ROC of 0.877, sensitivity of 0.736 [0.704, 0.765], and specificity of 0.964 [0.939, 0.979]. The PET progression model achieved an accuracy of 0.697 [0.611, 0.666], AUC-ROC of 0.553, sensitivity of 0.857 [0.831, 0.880], and specificity of 0.178 [0.143, 0.220]. A PET/CT ensemble model achieved an accuracy of 0.798 [0.768, 0.815], AUC-ROC of 0.871, sensitivity of 0.813 [0.784, 0.839], and specificity of 0.750 [0.704, 0.791]. The average OS length was 697 days (standard deviation: 605 days). The CT feature only RSF achieved a C-index of 0.715 and an IBS of 0.152, while a PET feature only RSF achieved a C-index of 0.709 and an IBS of 0.130. The combined CT+PET RSF achieved a C-index of 0.735 and an IBS of 0.132.*Conclusions CNNs trained using pre-treatment FDG-PET/CT data achieve good performance in prediction of progression of lung malignancy and OS. Metabolic information via PET further improves prediction compared to CT alone.*Clinical Relevance/Application Machine learning based on FDG-PET/CT can be used to assess progression and OS risk for lung malignancies, which is essential for accurate prognostication and planning of care.

RESULTS

Of the 1168 lesions, 793 had progression and 375 were progression-free. The most common malignancies were adenocarcinoma (n=728) and squamous cell carcinoma (n=190). The CT CNN model predicted progression with an accuracy of 0.790 [95% confidence interval: 0.786, 0.831], AUC-ROC of 0.877, sensitivity of 0.736 [0.704, 0.765], and specificity of 0.964 [0.939, 0.979]. The PET progression model achieved an accuracy of 0.697 [0.611, 0.666], AUC-ROC of 0.553, sensitivity of 0.857 [0.831, 0.880], and specificity of 0.178 [0.143, 0.220]. A PET/CT ensemble model achieved an accuracy of 0.798 [0.768, 0.815], AUC-ROC of 0.871, sensitivity of 0.813 [0.784, 0.839], and specificity of 0.750 [0.704, 0.791]. The average OS length was 697 days (standard deviation: 605 days). The CT feature only RSF achieved a C-index of 0.715 and an IBS of 0.152, while a PET feature only RSF achieved a C-index of 0.709 and an IBS of 0.130. The combined CT+PET RSF achieved a C-index of 0.735 and an IBS of 0.132.

CLINICAL RELEVANCE/APPLICATION

Machine learning based on FDG-PET/CT can be used to assess progression and OS risk for lung malignancies, which is essential for accurate prognostication and planning of care.

SSCH07-3　Diagnosis Of Emphysema In Low-dose CT Screenings For Lung Cancer Screening Using Multiple Instance Transfer Learning

Participants
Jordan Fuhrman, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

To develop a deep learning pipeline that infers the presence of emphysema and identifies important regions within the scan to extract additional clinically relevant information.*Methods and Materials This retrospective study utilized 868 CT scans obtained for lung cancer screening as part of the International-Early Lung Cancer Action Program. A trained radiologist evaluated each scan for the presence of emphysema and indicated disease severity based on extent and presentation, with these clinical assessments serving as ground truth for deep network training and evaluation. A multiple instance transfer learning approach was utilized to infer disease state. The framework evaluates bags of instances in which a bag prediction is determined based on the collection of instances; CT scans and sections are treated as bags and instances, respectively. In this study, features were extracted from CT sections using a pre-trained VGG19 architecture, pooled using an attention-based weight factor, and merged with a classifier to determine presence of emphysema in the scan. Performance was evaluated using ROC analysis with the area under the ROC curve (AUC) as the performance metric. The impact of variations in the presentation of emphysema is assessed relative to severity and associated CT features - bronchial wall thickening, ground glass opacity, micronodules, reticular/linear opacities, bronchiectasis, atelectasis, and architectural distortions.*Results The AUC for the task of diagnosing emphysema within lung cancer screening scans was 0.93 +/- 0.04, which is comparable or better than current values in published literature.*Conclusions The novel deep multiple instance transfer learning method developed in this study has strong potential in evaluating lung cancer screening scans for emphysema, and further investigation is needed to understand its ability to localize and characterize disease.*Clinical Relevance/Application With the rapidly increasing global use of CT for lung cancer screening, automatic detection and characterization of other diseases, such as emphysema, within the scan range is critical and achievable through the use of deep learning.

RESULTS

The AUC for the task of diagnosing emphysema within lung cancer screening scans was 0.93 +/- 0.04, which is comparable or better than current values in published literature.

CLINICAL RELEVANCE/APPLICATION

With the rapidly increasing global use of CT for lung cancer screening, automatic detection and characterization of other diseases, such as emphysema, within the scan range is critical and achievable through the use of deep learning.

SSCH07-4　Performance Of AI PE Triage On Suboptimal CT Pulmonary Angiography

Participants
Shadi Ebrahimian, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

Suboptimal CT pulmonary angiography (sCTPA) from motion artifacts or limited contrast enhancement is not uncommon. We evaluated and compared performance of acute pulmonary embolism (PE) detection artificial intelligence (PE-AI) algorithm in sCTPA and optimal CTPA (oCTPA).*Methods and Materials Following IRB approval with waiver of informed consent, we identified 104 consecutive sCTPA which were deemed as suboptimal for PE evaluation in radiology reports due to motion, artifacts or inadequate contrast enhancement. We enriched this dataset, with additional 226 oCTPA (over same timeframe as sCTPA) with and without PE. Two thoracic radiologists (ground truth) independently reviewed all 330 CTPA for adequacy (to assess PE down to distal segmental level), reason for sCTPA (artifacts or poor contrast enhancement), as well as for presence and location of PE. CT numbers (HU) were measured in the main pulmonary artery. When available (n= 80 patients), repeat and/or follow-up CTPA were reviewed for same attributes. All CTPA were processed with a commercial PE-AI algorithm (Aidoc). Data were analyzed with receiver operating characteristics to obtain area under the curve (AUC) for assessing presence of PE on sCTPA and oCTPA.*Results In the 104 sCTPA

(age= 56 ± 15), 24/104 (23%) were misclassified as "suboptimal for PE" in the radiology reports but were rated as optimal in ground truth evaluation (sCTPA). On sCTPA, the average contrast enhancement in the main pulmonary trunk was 282.9±140.1 HU, and the average patient weight was 94.9±30.4 kg. sCTPA were deemed suboptimal for up to segmental PE due to poor contrast (n= 41) and/or motion artifacts (n=44). PEs were present in 87/330 CTPA. PE-AI had almost identical performance on sCTPA (sensitivity 100%; specificity 93%; AUC 0.97, 95% CI 0.93-1.00) and oCTPA (sensitivity 98%; specificity 91%; AUC 0.90, 95% CI 0.86-0.95). PE-AI detected all PEs regardless of quality of the CTPA.*Conclusions Suboptimal CTPA examinations do not impair high performance of PE-AI which retains clinically meaningful sensitivity and high specificity, similar to thoracic radiologists.*Clinical Relevance/Application PE-AI algorithm can help detect pulmonary emboli, avoid misclassification of CTPA as inadequate, and thus, decrease need for unnecessary repeat imaging and additional radiation dose.

RESULTS

In the 104 sCTPA (age= 56 ± 15), 24/104 (23%) were misclassified as "suboptimal for PE" in the radiology reports but were rated as optimal in ground truth evaluation (sCTPA). On sCTPA, the average contrast enhancement in the main pulmonary trunk was 282.9±140.1 HU, and the average patient weight was 94.9±30.4 kg. sCTPA were deemed suboptimal for up to segmental PE due to poor contrast (n= 41) and/or motion artifacts (n=44). PEs were present in 87/330 CTPA. PE-AI had almost identical performance on sCTPA (sensitivity 100%; specificity 93%; AUC 0.97, 95% CI 0.93-1.00) and oCTPA (sensitivity 98%; specificity 91%; AUC 0.90, 95% CI 0.86-0.95). PE-AI detected all PEs regardless of quality of the CTPA.

CLINICAL RELEVANCE/APPLICATION

PE-AI algorithm can help detect pulmonary emboli, avoid misclassification of CTPA as inadequate, and thus, decrease need for unnecessary repeat imaging and additional radiation dose.

SSCH07-5   Racial Disparities In COVID-19 Associated Pulmonary Embolism

Participants
Brandon Metra, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

Pulmonary embolism is an important clinical complication of COVID-19. We sought to investigate potential racial disparities in COVID-19-associated pulmonary embolism by using a large multicenter electronic health record database.*Methods and Materials In this retrospective cohort study, we examined adults diagnosed with COVID-19 from January 20 to September 30, 2020, with TriNetX, a global research network aggregating the real-time electronic health records of over 73 million patients. We analyzed clinical outcomes of non-Hispanic white and black patients with COVID-19, with the primary outcomes of development of pulmonary embolism (PE) or mortality within 30 days of diagnosis of COVID-19. We used propensity matching to balance cohorts by sociodemographic and clinical variables (hypertension, diabetes, obesity, etc.).*Results A total of 346,953 patients were identified with COVID-19, 3879 of whom developed pulmonary embolism (1.18%). 157,049 white and 50,376 black patients were identified. Compared to white patients, black patients had a higher risk of mortality (risk ratio 1.890 [95% CI 1.727-2.067]; p < 0.0001) and pulmonary embolism (risk ratio 1.537 [95% CI 1.380-1.711]; p < 0.0001). Additionally, black patients with both COVID-19 and pulmonary embolism had a higher rate of 30-day mortality compared to white patients (risk ratio 1.397 [95% CI 1.059-1.084]; p = 0.0174). All outcome differences persisted in balanced cohorts after propensity matching.*Conclusions Black patients have a higher risk of pulmonary embolism and mortality after COVID-19, even after controlling for demographic and clinical variables. Additionally, black patients with COVID-19 and associated pulmonary embolism have a higher risk of mortality compared to white patients.*Clinical Relevance/Application Clinicians should consider racial disparities in the surveillance and management of pulmonary embolism associated with COVID-19.

RESULTS

A total of 346,953 patients were identified with COVID-19, 3879 of whom developed pulmonary embolism (1.18%). 157,049 white and 50,376 black patients were identified. Compared to white patients, black patients had a higher risk of mortality (risk ratio 1.890 [95% CI 1.727-2.067]; p < 0.0001) and pulmonary embolism (risk ratio 1.537 [95% CI 1.380-1.711]; p < 0.0001). Additionally, black patients with both COVID-19 and pulmonary embolism had a higher rate of 30-day mortality compared to white patients (risk ratio 1.397 [95% CI 1.059-1.084]; p = 0.0174). All outcome differences persisted in balanced cohorts after propensity matching.

CLINICAL RELEVANCE/APPLICATION

Clinicians should consider racial disparities in the surveillance and management of pulmonary embolism associated with COVID-19.

SSCH07-6   Non-aneurysmal Non-atherosclerotic Aortic Thrombus (NANAAT): Clinical And CT Imaging Findings In A Symptomatic Cohort

Participants
Kaitlin Marquis, MD, Saint Louis, Missouri (*Presenter*) Nothing to Disclose

PURPOSE

The purpose of this study is to evaluate the clinical characteristics, imaging distribution, imaging appearance, and treatment outcome in symptomatic patients with non-atherosclerotic, non-aneurysmal aortic thrombi (NANAAT).*Methods and Materials A retrospective study was conducted at one tertiary care center using a search for "thoracic aortic mobile thrombus", "aortic thrombus", and "TAMT" conducted on the institution's radiology information system. Dates included an 8 year period from 2013 to 2021. Only patients with aortic thrombi with no or mild atherosclerosis (and no atherosclerosis at the site of the thrombus) and no aneurysm were included. All patients included in the study were symptomatic with definable sites of embolization via imaging examinations. All CT images were reviewed by a board-certified radiologist, C.R., with 15 years of experience, a fellow, R.S., and a third-year resident, K.M., via consensus.*Results 28 patients (ages 37-68, mean 53) were included in the analysis. 15 were female, 13 were male. 14/28 (50%) of patients were found to have a hypercoagulable condition, 10 with hematologic disorders or clinical histories of thrombi, 2 with malignancies, and 2 who were recently post-surgery. 36 total aortic thrombi were observed with 22 patients having a single thrombus and 6 patients having multiple thrombi. 22 of the thrombi were pedunculated and 14 were sessile. Average maximum dimension of the thrombi was 27 mm (range 2-138 mm). 56% were located in the descending thoracic aorta, 22% in the ascending aorta, 11% in the arch, and 11% in the abdominal aorta. Medical therapy was the primary initial treatment in 21 patients and was successful or partially successful in 12 patients, unsuccessful in 7 patients, and of unknown result in 2 patients. Of the patients who failed medical therapy all had at least one pedunculated thrombus. 5 patients required endovascular repair, 1 went for initial surgical repair, and 2 of the patients who failed medical treatment went on for open surgical repair.*Conclusions In this study, 50% of patients with NANAAT were found to have an underlying hypercoagulable condition. NANAAT were most

commonly seen in the descending thoracic aorta, but were identified in the ascending aorta in 22% of patients, a greater percentage than typically reported elsewhere in the literature. In patients who failed medical therapy or who required endovascular or open surgical treatment, 12/13 (92%) had a pedunculated appearance suggesting this configuration may require more aggressive management.*Clinical Relevance/Application NANAAT is an important imaging diagnosis that must be recognized. A pedunculated configuration may not respond adequately to medical therapy and require more aggressive intervention.

RESULTS

28 patients (ages 37-68, mean 53) were included in the analysis. 15 were female, 13 were male. 14/28 (50%) of patients were found to have a hypercoagulable condition, 10 with hematologic disorders or clinical histories of thrombi, 2 with malignancies, and 2 who were recently post-surgery. 36 total aortic thrombi were observed with 22 patients having a single thrombus and 6 patients having multiple thrombi. 22 of the thrombi were pedunculated and 14 were sessile. Average maximum dimension of the thrombi was 27 mm (range 2-138 mm). 56% were located in the descending thoracic aorta, 22% in the ascending aorta, 11% in the arch, and 11% in the abdominal aorta. Medical therapy was the primary initial treatment in 21 patients and was successful or partially successful in 12 patients, unsuccessful in 7 patients, and of unknown result in 2 patients. Of the patients who failed medical therapy all had at least one pedunculated thrombus. 5 patients required endovascular repair, 1 went for initial surgical repair, and 2 of the patients who failed medical treatment went on for open surgical repair.

CLINICAL RELEVANCE/APPLICATION

NANAAT is an important imaging diagnosis that must be recognized. A pedunculated configuration may not respond adequately to medical therapy and require more aggressive intervention.

SSPH12-1   Beyond Iodine: Dose Reduction Potential With Patient-Specific Prefiltration In Hafnium-Enhanced CT Scans With Energy Integrating And Photon Counting Detectors

Participants
Joerg Steidel, BSC, Heidelberg, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To analyze the impact of the contrast agent type on the potential dose reduction achievable with patient-specific prefilters in single energy CT applications.*Methods and Materials Prefilters mainly remove the low energy x-ray photons and thus help to significantly reduce patient dose. The most common CT contrast agent is iodine. However, due to its low k-edge energy of 33 keV iodine-to-soft tissue contrast is highest at low energies and is therefore reduced by prefiltration unless low tube voltages are used. Other possible contrast agents have higher k-edge energies. Hafnium's is at 65 keV. We here investigate how the difference in absorption impacts the dose reduction potential of prefiltration. For this purpose semiantropomorphic liver phantoms containing iodine and hafnium contrast inserts with the same number of atoms per volume were simulated at different sizes: 15×10 (child), 30×20 (adult) and 50×40 cm (obese). We simulated 0 to 5 mm prefilter thickness and 40 to 150 kV tube voltage with a maximum mAs product of 1000 mAs. Dose was assessed using Monte Carlo simulations of a 32 cm CTDI phantom. Contrast-to-noise ratios at unit dose (CNRD) were calculated for iodine and hafnium contrast. Dose reduction compared to reference scans without additional prefiltration and iodine contrast was determined for CT with energy integrating detector and with photon counting detector (given in parentheses).*Results Child, adult and obese phantoms showed dose reductions of 43%, 79%, 83% (26%, 68%, 79%) with hafnium and 57%, 49%, 39% (41%, 25%, 8%) with iodine. Except for the child, dose reduction with hafnium is far higher than with iodine. However, the child requires 50 kV. Today's lower voltage limit is 70 kV and unlikely to decrease. With this restriction iodine contrast dose reduction achievable with optimized prefiltration is as low as 3% (2%) for the child case, while hafnium is unaffected: 43% (26%).*Conclusions Dose reduction through the use of patient-specific prefilters is significantly higher in hafnium-contrasted scans than with iodine. This also applies to other high k-edge contrast agents such as gadolinium, tungsten and bismuth.*Clinical Relevance/Application Dose reduction in clinical CT is important for patient safety.

RESULTS

Child, adult and obese phantoms showed dose reductions of 43%, 79%, 83% (26%, 68%, 79%) with hafnium and 57%, 49%, 39% (41%, 25%, 8%) with iodine. Except for the child, dose reduction with hafnium is far higher than with iodine. However, the child requires 50 kV. Today's lower voltage limit is 70 kV and unlikely to decrease. With this restriction iodine contrast dose reduction achievable with optimized prefiltration is as low as 3% (2%) for the child case, while hafnium is unaffected: 43% (26%).

CLINICAL RELEVANCE/APPLICATION

Dose reduction in clinical CT is important for patient safety.

SSPH12-2   Can A Deep Learning Model Trained From One Clinical Site Be Applied To Other Sites?A Case Report From COVID-19 Pneumonia Classification Using Chest X-ray Radiographs

Participants
Ran Zhang, PhD, Madison, Wisconsin (*Presenter*) Nothing to Disclose

PURPOSE

Many artificial-intelligence (AI) based algorithms have been proposed for the detection of COVID-19 in chest x-ray radiographs. While the reported performance on an individual test set shows great promise, it is unclear how well a model trained from one site can be generalized to other sites. The purpose of this work was to evaluate the generalizability of a trained AI algorithm using multiple well-curated test sets.*Methods and Materials A deep neural network model was developed using 19,784 images (5,725 positive COVID-19 cases) from four sites within the Henry Ford Health System. Small datasets from the four sites were withheld for model validation purposes. To test the model's generalizability, seven external test sets were curated. These include: [A] A hold-out clinical site within the Henry Ford Health System that was not used for model development; [B] A publicly available database from Spain, i.e., the BIMCV-COVID19 dataset; [C] Dataset collected at the University of Wisconsin Hospitals and Clinics; [D] Dataset curated by RSNA, i.e., International COVID-19 Open Radiology Database (positive only); [E] Dataset curated and made publicly available from Italy, i.e., BrixIA Covid-19 dataset (positive only); [F] A public dataset from Arkansas, COVID-19-AR (positive only); [G] A public dataset from the MIMIC-CXR database (negative only).*Results For internal validation, the AUC ranges from 0.84 to 0.87 among the four internal test sites. In contrast, for external test datasets, the performance in terms of AUC and the corresponding 95% CI (confidence interval) are given below for all 7 external test data sets: [A] 0.83 (0.81-0.85); [B] 0.78 (0.78-0.79); [C] 0.77 (0.74-0.79). For COVID positive only test sets [D], [E], and [F], the sensitivity values are 76%, 85%, and

82%, respectively. For COVID negative-only test set [G], the specificity is 71%.*Conclusions 1. Test performance drops from internal test datasets to external test datasets to show a generalization gap; 2. Performance for the seven external test datasets varies and the generalization gap varies from 0.01 to 0.10.*Clinical Relevance/Application The results from this study give the very first set of scientific data regarding the generalizability of AI models in radiology. The AI models trained from one, or a limited number of clinical sites, will drop in performance when they are applied to external test datasets.

RESULTS

For internal validation, the AUC ranges from 0.84 to 0.87 among the four internal test sites. In contrast, for external test datasets, the performance in terms of AUC and the corresponding 95% CI (confidence interval) are given below for all 7 external test data sets: [A] 0.83 (0.81-0.85); [B] 0.78 (0.78-0.79); [C] 0.77 (0.74-0.79). For COVID positive only test sets [D], [E], and [F], the sensitivity values are 76%, 85%, and 82%, respectively. For COVID negative-only test set [G], the specificity is 71%.

CLINICAL RELEVANCE/APPLICATION

The results from this study give the very first set of scientific data regarding the generalizability of AI models in radiology. The AI models trained from one, or a limited number of clinical sites, will drop in performance when they are applied to external test datasets.

SSPH12-3   Deep Voxel Forecast: Combining Auto-encoder Image Representations With Multiscale Features To Predict Chemoradiation Spatial Response Patterns On FDG PET

Participants
Stephen Bowen, PhD, Seattle, Washington (*Presenter*) Nothing to Disclose

PURPOSE

Spatial response prediction on longitudinal FDG PET imaging during chemoradiation (CRT) can support precise multimodality treatment intensification and adaptive targeting of resistant cancer phenotypes. Current techniques such as imaging biomarker regression, radiomics, spatial statistical learning, and image-to-image deep learning all have different strengths / limitations. We developed a new prediction model, Deep Voxel Forecast, to combine spatially homogeneous features (patient-level), spatially heterogeneous features (voxel-level), and deep image representations (neighborhood-level) for predicting PET spatial response patterns.*Methods and Materials Within a trial of risk-adaptive CRT for unresectable non-small cell lung cancer (NSCLC), 25 patients underwent baseline (PETpre) and week 3 on-treatment (PETmid) imaging. Deep Voxel Forecast models of voxel response between PETpre and PETmid used custom generalized least squares to incorporate patient-level features (tumor volume, mean SUV, mean CRT dose), voxel-level feature maps (SUV, centroid distance, CRT dose), and neighborhood-level feature maps (auto-encoder network layer representations). Feature dimensionality was reduced via principal component analysis. Patient-specific Matérn variograms were constructed to learn spatial correlation structure in voxel-level and neighborhood-level feature maps. Leave-one-patient-out cross-validated root mean squared error (RMSE) of Deep Voxel Forecast was benchmarked against the previously published Voxel Forecast algorithm.*Results Over 11,100 voxels, 3 patient-level features, 3 voxel-level feature maps, and an average of 80 auto-encoder image representation feature maps (range: 63-132), the Deep Voxel Forecast multiscale model achieved a predicted tumor voxel response RMSE of 0.22, which was equivalent to the Voxel Forecast multiscale model RMSE of 0.22 (p=0.20) and superior to the patient-scale model RMSE of 0.33 (p<0.0001). Voxel-level feature maps were most important for spatial response prediction relative to patient-level features and neighborhood-level feature maps.*Conclusions Deep Voxel Forecast incorporated auto-encoder image representations with spatial and non-spatial data to predict PET tumor voxel response patterns during CRT. Equivalent performance to the Voxel Forecast benchmark motivates further study on optimal combinations of deep feature maps and multiscale features to improve clinical decision support of adaptive cancer therapies.*Clinical Relevance/Application Forecasting spatially variant cancer response dynamics and future image states in individual patients provides powerful clinical decision support for the growing therapeutic arsenal in precision oncology.

RESULTS

Over 11,100 voxels, 3 patient-level features, 3 voxel-level feature maps, and an average of 80 auto-encoder image representation feature maps (range: 63-132), the Deep Voxel Forecast multiscale model achieved a predicted tumor voxel response RMSE of 0.22, which was equivalent to the Voxel Forecast multiscale model RMSE of 0.22 (p=0.20) and superior to the patient-scale model RMSE of 0.33 (p<0.0001). Voxel-level feature maps were most important for spatial response prediction relative to patient-level features and neighborhood-level feature maps.

CLINICAL RELEVANCE/APPLICATION

Forecasting spatially variant cancer response dynamics and future image states in individual patients provides powerful clinical decision support for the growing therapeutic arsenal in precision oncology.

SSPH12-4   Texture Analysis And Deep Learning In The Diagnosis Of Hip Fractures In The Emergency Room Setting

Participants
Karen Drukker, PhD, Chicago, Illinois (*Presenter*) Royalties, Hologic

PURPOSE

To develop a texture analysis and deep learning method for the identification of subtle fractures in hip radiographs acquired in the emergency department.*Methods and Materials A deep learning texture and image analysis model was developed to identify hip radiographs with subtle fractures. Two experts (with 5 and 2 years of experience) indicated a region of interest of variable size that included the proximal femur (femoral head, right femoral neck as well as the intertrochanteric region), and manually outlined any fractures as reference standard. Texture images were calculated as the pixel value standard deviation within a roaming 32x32 pixel window. Texture images as well as the original images were sectioned into image patches, with each patch resized to 150 x 150 pixels and serving as the inputs to a VGG-19-based deep learning method. The method was trained and evaluated using a 5-fold cross-validation with stratification on the patient level to avoid leaking of information between training and test folds (64%/16%/20% training/validation/test folds). The dataset in this pilot study consisted of hip radiographs of 112 patients (25 normals, 18 obvious fractures, and 69 subtle fractures). Performance was evaluated using ROC and precision recall-analyses, both when including and when excluding the obvious fracture cases from the test set.*Results On a by-image-patch level, the area under the ROC curve (AUCROC), in the task of distinguishing between radiographs with/without fracture, reached 0.86 while by-patient AUCROC values were 0.75, with 95% confidence interval [0.60; 0.84], and 0.72 [0.57; 0.82] including and excluding the obvious fracture cases, respectively. The corresponding areas under the precision-recall curves, AUCPR, for this task were 0.88

[0.78; 0.94] and 0.84 [0.72; 0.91], respectively.*Conclusions In this pilot study, image texture analysis combined with deep learning demonstrated promise the task of identifying hip radiographs with subtle fractures that may go unnoticed in the emergency room setting.*Clinical Relevance/Application Mischaracterizing or missing a fracture in a radiograph can have severe consequences for patients, resulting in delayed treatment and poor recovery of function. Using image texture analysis combined with deep learning to aid radiologists has the potential of increasing the diagnostic accuracy and speed of radiologists in diagnosing hip fractures in the emergency setting and as a result, reducing patient morbidity.

RESULTS

On a by-image-patch level, the area under the ROC curve (AUCROC), in the task of distinguishing between radiographs with/without fracture, reached 0.86 while by-patient AUCROC values were 0.75, with 95% confidence interval [0.60; 0.84], and 0.72 [0.57; 0.82] including and excluding the obvious fracture cases, respectively. The corresponding areas under the precision-recall curves, AUCPR, for this task were 0.88 [0.78; 0.94] and 0.84 [0.72; 0.91], respectively.

CLINICAL RELEVANCE/APPLICATION

Mischaracterizing or missing a fracture in a radiograph can have severe consequences for patients, resulting in delayed treatment and poor recovery of function. Using image texture analysis combined with deep learning to aid radiologists has the potential of increasing the diagnostic accuracy and speed of radiologists in diagnosing hip fractures in the emergency setting and as a result, reducing patient morbidity.

SSPH12-5   A Mathematical Framework To Quantitatively Balance Clinical And Radiation Risk In Computed Tomography

Participants
Francesco Ria, DMP, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

Risk in medical imaging is a combination of radiation risk and clinical risk, which is largely driven by the effective diagnosis. While radiation risk has traditionally been the main focus of Computed Tomography (CT) optimization, such a goal cannot be achieved without considering clinical risk. The purpose of this study was to develop a comprehensive mathematical framework that considers both radiation and clinical risks based on the specific task, the investigated disease, and the interpretive performance (i.e., false positive and false negative rates), tested across a representative clinical CT population.*Methods and Materials The proposed mathematical framework defined the radiation risk to be a linear function of the radiation dose, the population prevalence of the disease, and the false positive rate. The clinical risk was defined to be a function of the population prevalence, the expected life-expectancy loss for an incorrect diagnosis, and the interpretative performance in terms of the AUC as a function of radiation dose. A Total Risk (TR) was defined as the sum of the radiation risk and the clinical risk. With IRB approval, the mathematical function was applied to a dataset of 80 adult CT studies investigating localized stage liver cancer (LLC) for a specific false positive rate of 5% reconstructed with both Filtered Back Projection (FBP) and Iterative Reconstruction (IR) algorithm. Linear mixed effects models were evaluated to determine the relationship between radiation dose and radiation risk and interpretative performance, respectively. Lastly, the analytical minimum of the TR curve was determined and reported.*Results TR is largely affected by clinical risk for low radiation dose whereas radiation risk is dominant at high radiation dose. Concerning the application to the LLC population, the median minimum risk in terms of mortality per 100 patients was 0.04 in FBP and 0.03 in IR images; the corresponding CTDIvol values were 38.5 mGy and 25.7 mGy, respectively.*Conclusions The proposed mathematical framework offers a complete quantitative description of risk in CT enabling a comprehensive risk-to-benefit assessment essential in the effective justification of radiological procedures and in the design of optimal clinical protocols.*Clinical Relevance/Application The quantification of both radiation and clinical risk using comparable units allows the calculation of the overall risk paving the road towards a comprehensive risk-to-benefit assessment in CT.

RESULTS

TR is largely affected by clinical risk for low radiation dose whereas radiation risk is dominant at high radiation dose. Concerning the application to the LLC population, the median minimum risk in terms of mortality per 100 patients was 0.04 in FBP and 0.03 in IR images; the corresponding CTDIvol values were 38.5 mGy and 25.7 mGy, respectively.

CLINICAL RELEVANCE/APPLICATION

The quantification of both radiation and clinical risk using comparable units allows the calculation of the overall risk paving the road towards a comprehensive risk-to-benefit assessment in CT.

SSPH12-6   Quantification Of Perfusion Defect Distal To Pulmonary Embolism Using Computed Tomography Angiography: Validation In A Swine Model

Participants
Sabee Y. Molloi, PhD, Irvine, California (*Presenter*) Research Grant, Canon Medical Systems Corporation

PURPOSE

Computed tomography pulmonary angiography (CTPA) is a first-line diagnostic technique used to assess patients with suspected pulmonary embolism (PE). PE risk stratification is necessary for the optimal patient management. This study validated an automated minimum-cost path (MCP) technique to enable accurate calculation of the subtended lung tissue distal to a PE using CTPA.*Methods and Materials A Swan-Ganz catheter was placed in the left pulmonary artery for 7 swine (body weight: 27-53 kg) to produce different severity PEs. A total of 33 PE conditions were generated, where the balloon tip was adjusted distally to proximally under fluoroscopic guidance via balloon inflation (balloon diameter: 2-4 mm). Under each PE condition, pulmonary angiography and dynamic CT perfusion (CTP) scans were acquired using a 320-slice CT scanner after a 0.5 ml/kg of contrast material injection followed by a 0.5 ml/kg saline chaser. The MCP technique was used to assign perfusion territories that were supplied by the nearest pulmonary arteries. The pulmonary artery tree was divided into distal and proximal portions based on the location of the balloon tip, where the distal territory was defined as the subtended PE-related territory. Dynamic CTP images were used as the reference standard PE-related perfusion defect territory. The accuracy of the MCP technique was evaluated by quantitatively comparing the MCP-derived perfusion territories to the reference standard territories by Dice coefficient, linear regression, and t-test.*Results All MCP PE-related territory masses (MMCP, g) and all reference standard perfusion 'defect' territory masses (MRS, g) were related by MMCP=1.04MRS+1.23 (r = 0.97, p=0.20). The mean Dice coefficient is 0.86.*Conclusions The perfusion defect distal to a pulmonary embolism can be accurately calculated using CTPA images. This technique can potentially be used for PE risk stratification.*Clinical Relevance/Application The quantification of PE severity with the MCP technique using CTPA

image data could potentially be used to select the most appropriate management approach for individual patients.

RESULTS

All MCP PE-related territory masses (MMCP, g) and all reference standard perfusion 'defect' territory masses (MRS, g) were related by MMCP=1.04MRS+1.23 (r = 0.97, p=0.20). The mean Dice coefficient is 0.86.

CLINICAL RELEVANCE/APPLICATION

The quantification of PE severity with the MCP technique using CTPA image data could potentially be used to select the most appropriate management approach for individual patients.

SSGU01-1 Use Of Contrast-Enhanced Ultrasound To Evaluate Uterine Fibroid Microvascularity Pre And Post Uterine Artery Embolization

Participants
Priscilla Machado, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

To assess fibroid microvascularity before and after uterine artery embolization (UAE) using contrast-enhanced ultrasound (CEUS).*Methods and Materials To date 38 women with symptomatic uterine fibroids scheduled for UAE have been enrolled in this ongoing IRB-approved study. The women underwent 3 CEUS examinations (day 0 {pre-UAE} and days 15 and 90 post-UAE) using an Aplio i800 scanner (Canon Medical Systems, Tustin, CA, USA) with a curvilinear array (8C1). The ultrasound contrast agent Lumason (Bracco, Milan, Italy) was administered IV (dose: 2.0 ml). Digital CEUS clips were acquired for all cases, randomized off-line and assessed qualitatively by two independent radiologists that classified the fibroids as vascular or non-vascular. ImageJ (NIH, Bethesda, MD, USA) was used to quantify the fractional vascularity of the fibroids (FV). The pre procedure MRI and the post procedure clinical outcomes were used as the reference standard, and compared to CEUS. Results were analyzed using repeated ANOVAs and nonparametric Wilcoxon Sign Rank tests.*Results All 38 cases underwent the pre-UAE CEUS study, and so far 35 cases underwent the 15 days post-UAE CEUS study, while 28 cases underwent the 90 days post-UAE CEUS study, completing their enrollment in the study. The results showed excellent inter-reader agreement for all time points (p=0.67; kappa=0.96). The reference standard showed excellent agreement between the readers and the pre-UAE MRI (p=0.58). In addition, post-UAE clinical follow-ups agreed well with CEUS examinations performed at both 15 (p=0.38) and 90 days (p=0.39). Quantitative analysis of the FV across time points showed statistically significant differences between pre-UAE and the 2 post-UAE time points (p<0.0001).*Conclusions Results indicate that CEUS pre and post UAE can accurately evaluate fibroid microvascularity and, thus, can be a noninvasive and accurate alternative to monitoring treatment results; albeit based on a small sample size.*Clinical Relevance/Application UAE is a nonsurgical therapy to block blood flow to fibroids. CEUS can accurately evaluate fibroid microvascularity and, thus, can become a noninvasive and accurate alternative for monitoring treatment outcomes.

RESULTS

All 38 cases underwent the pre-UAE CEUS study, and so far 35 cases underwent the 15 days post-UAE CEUS study, while 28 cases underwent the 90 days post-UAE CEUS study, completing their enrollment in the study. The results showed excellent inter-reader agreement for all time points (p=0.67; kappa=0.96). The reference standard showed excellent agreement between the readers and the pre-UAE MRI (p=0.58). In addition, post-UAE clinical follow-ups agreed well with CEUS examinations performed at both 15 (p=0.38) and 90 days (p=0.39). Quantitative analysis of the FV across time points showed statistically significant differences between pre-UAE and the 2 post-UAE time points (p<0.0001).

CLINICAL RELEVANCE/APPLICATION

UAE is a nonsurgical therapy to block blood flow to fibroids. CEUS can accurately evaluate fibroid microvascularity and, thus, can become a noninvasive and accurate alternative for monitoring treatment outcomes.

SSGU01-2 Diagnostic Performance Of Ultrasound Algorithms For Evaluation Of Adnexal Masses: ACR-ORADS, GI-RADS, IOTA SR: Which Path Clears The Maze?

Participants
Shabnam Grover, MD,DMRD, Greater Noida, India (*Presenter*) Nothing to Disclose

PURPOSE

The aim of this study was to compare the diagnostic performance of ultrasound (US) based ACR-ORADS, GI-RADS and IOTA SR, for characterization and malignancy risk stratification of adnexal masses and propose the best amongst the three. The reference standard was histopathology.*Methods and Materials The Institutional Review Board approved prospective study, comprised of 100 patients with adnexal masses. After informed consent the patients underwent US examination by the same examiners, first & second author, all on a Siemens Acuson S3000 equipment. Using the recommended algorithms, O-RADS category, GI-RADS category and IOTA SR category was assigned to each examined tumor by consensus. The diagnostic performance of each system was subsequently assessed either by histopathology from biopsied/operated tumors as reference standard; or biannual survey of 12 months for conservatively managed tumors. Sensitivity, specificity, positive & negative predictive values, & diagnostic accuracy were computed for all three systems.*Results Of the evaluated tumors, 40 were benign & 60 were malignant. O-RADS and GI-RADS classification could be applied to all evaluated tumors, while IOTA simple rules could be applied to 85 tumors. The sensitivity, specificity, PPV & NPV for ACR O-RADS was found to be 100%, 55%, 77.5% & 100%. The sensitivity, specificity, PPV & NPV for GI-

RADS was found to be 93.3%, 60%, 77.8% & 85.7% respectively. For IOTA SR sensitivity, specificity, PPV & NPV was 90%, 80%, 87.1% & 84.2% respectively. Diagnostic accuracy for ACR O-RADS was 82.6%, for GI-RADS it was 80% and for IOTA SR it was 86%.*Conclusions ACR-ORADS algorithm was found to have the highest sensitivity, and highest NPV, the latter confirming benignity and suggesting recommended conservative management in this group. IOTA SR had the best specificity, however, PPV and diagnostic accuracy were found to be almost similar for O-RADS, GI-RADS and IOTA SR. Thus, the O-RADS algorithm appears to be the best path to clear the maze.*Clinical Relevance/Application Improved prognosis of ovarian malignancy is mainly impacted by early diagnosis & appropriate stratification for management & both factors are based on application of the best ultrasound algorithm.

RESULTS

Of the evaluated tumors, 40 were benign & 60 were malignant. O-RADS and GI-RADS classification could be applied to all evaluated tumors, while IOTA simple rules could be applied to 85 tumors. The sensitivity, specificity, PPV & NPV for ACR O-RADS was found to be 100%, 55%, 77.5% & 100%. The sensitivity, specificity, PPV & NPV for GI-RADS was found to be 93.3%, 60%, 77.8% & 85.7% respectively. For IOTA SR sensitivity, specificity, PPV & NPV was 90%, 80%, 87.1% & 84.2% respectively. Diagnostic accuracy for ACR O-RADS was 82.6%, for GI-RADS it was 80% and for IOTA SR it was 86%.

CLINICAL RELEVANCE/APPLICATION

Improved prognosis of ovarian malignancy is mainly impacted by early diagnosis & appropriate stratification for management & both factors are based on application of the best ultrasound algorithm.

SSGU01-3 A Fully Automated Deep Learning Pipeline For The Detection Of Clinically Significant Prostate Cancer Using Multiparametric MRI

Participants
Jason Cai, MD, Bronx, New York (*Presenter*) Nothing to Disclose

PURPOSE

Prostate cancer is the most common solid-organ malignancy in men. Multiparametric MRI (mpMRI) can be used to identify clinically significant prostate cancer (csPca), defined as Gleason Grade 2 or higher. However, reader experience and interobserver variability may affect the performance of PI-RADS. In contrast, deep learning (DL) produces deterministic outputs and can perform well in imaging tasks. We trained a fully automated DL pipeline to predict the presence of csPca.*Methods and Materials IRB approval was obtained. All patients without a history of csPca who underwent MRI from 2017-2019 were reviewed. Examinations originated from three sites and two scanner manufacturers. Inclusion criteria were: (1) patients undergoing screening or active surveillance who had pathological confirmation within 1 year after MRI, and (2) patients undergoing screening who had PI-RADS score 1 or 2 without pathological confirmation (considered as negative cases). Patients with poor quality DWI were excluded (n=56). Of 4731 patients (5734 examinations), 1373 had csPca. A 3D U-Net was trained to segment the prostate on ADC/DWI, T2, and dynamic T1 contrast-enhanced sequences. From each segmentation, a bounding box was created to crop the prostate gland. A VGG-style 3D convolutional neural network was trained on these images to predict the presence of csPca. The train:validation:test split was 80:10:10 at patient level. We evaluated our pipeline on an internal test set and the ProstateX dataset (lesion location information from ProstateX was not used). We also compared it to human performance (PI-RADS score) on the internal test set. Saliency maps were used for tumor localization. The DeLong test was used to compare AUC.*Results On the internal test set, the classifier had 0.87 AUC (0.80-0.92), 78% sensitivity, 86% specificity, and 83% accuracy, whereas PI-RADS score had 0.89 AUC (0.84-0.93), 82% sensitivity, 88% specificity, and 86% accuracy (p=0.51). On the ProstateX dataset, the classifier had 0.85 AUC (0.82-0.91) 87% sensitivity, 74% specificity, and 78% accuracy. For true positive cases, saliency maps consistently demonstrated increased activation over tumor regions.*Conclusions DL can accurately detect csPca on mpMRI without manual input. Saliency maps can be used to verify the prediction and identify the region of interest.*Clinical Relevance/Application Our fully automated DL pipeline can be a valuable adjunct to the clinical evaluation of prostate cancer on mpMRI.

RESULTS

On the internal test set, the classifier had 0.87 AUC (0.80-0.92), 78% sensitivity, 86% specificity, and 83% accuracy, whereas PI-RADS score had 0.89 AUC (0.84-0.93), 82% sensitivity, 88% specificity, and 86% accuracy (p=0.51). On the ProstateX dataset, the classifier had 0.85 AUC (0.82-0.91) 87% sensitivity, 74% specificity, and 78% accuracy. For true positive cases, saliency maps consistently demonstrated increased activation over tumor regions.

CLINICAL RELEVANCE/APPLICATION

Our fully automated DL pipeline can be a valuable adjunct to the clinical evaluation of prostate cancer on mpMRI.

SSGU01-4 MRI-targeted Fusion Prostate Biopsy: Impact Of Additional Systematic Cores And Reasons For Missing Clinically Significant Prostate Cancer

Participants
Lars Schimmoeller, MD, Dusseldorf, Germany (*Presenter*) Nothing to Disclose

PURPOSE

This study evaluates the diagnostic impact of systematic biopsies (SB) in addition to MRI-guided targeted biopsies (TB) and cases with clinically significant prostate cancer (csPCa) missed by targeted biopsy (TB) in a large patient collective.*Methods and Materials Consecutive patients with 3T multi-parametric MRI of the prostate and subsequent TB plus 12-core SB were included in this study from 01/2014 to 04/2019. The study objectives were the analysis of cases with a csPCa missed by TB, PCa detection with additional SB, the PCa detection and the correlation with clinical and MRI parameters.*Results In total 785 patients met the inclusion criteria. 342 patients had a csPCa (median PSAD 0.29 ng/ml/cm3). Additional SB misclassified 40% of csPCa and detected 9.5% additional insignificant PCa. In 42 patients (13%), a csPCa was detected only by SB. In 36 of these cases, the localization of the positive SB cores matched with the cancer suspicious region described on mpMRI (mCSR). Cases with a csPCA missed by TB showed either an insufficient MRI segmentation (prostate boundary correlation) (31%) and/or insufficient lesion registration (lesion transfer, tracking, and/or matching) (48%), a missed small lesion (14%), or a failed center of a large lesion (10%). Median PSAD of patients with nsPCa detected by SB was 0.15 ng/ml/cm3.*Conclusions Main reasons for missing a csPCa by TB were insufficient prostate segmentation or imprecise lesion registration within MRI/US fusion-guided biopsy. Consequently, verification of MRI quality, exact mCSR assessment, and advanced biopsy experience may improve accuracy. Altogether, an additional SB adds limited clinical benefit, especially in men with PSAD =0.15 ng/ml/cm3.*Clinical Relevance/Application MRI-targeted biopsy (TB) can miss MRI cancer suspicious regions (mCSR) and csPCA. Main reasons missing csPCa were insufficient segmentation (MRI/US correlation of the

prostate boundary) or imprecise registration (inaccurate lesion transfer, tracking or matching) within MRI/US fusion-guided biopsy. Pre-biopsy verification of MR image and report quality, segmentation, and registration next to clinical experience seems essential. Additional SB might cover inaccuracies of TB, but our data suggests that additional SB adds limited clinical value in cases with PSAD = 0.15 ng/ml/cm3.

RESULTS

In total 785 patients met the inclusion criteria. 342 patients had a csPCa (median PSAD 0.29 ng/ml/cm3). Additional SB misclassified 40% of csPCa and detected 9.5% additional insignificant PCa. In 42 patients (13%), a csPCa was detected only by SB. In 36 of these cases, the localization of the positive SB cores matched with the cancer suspicious region described on mpMRI (mCSR). Cases with a csPCA missed by TB showed either an insufficient MRI segmentation (prostate boundary correlation) (31%) and/or insufficient lesion registration (lesion transfer, tracking, and/or matching) (48%), a missed small lesion (14%), or a failed center of a large lesion (10%). Median PSAD of patients with nsPCa detected by SB was 0.15 ng/ml/cm3.

CLINICAL RELEVANCE/APPLICATION

MRI-targeted biopsy (TB) can miss MRI cancer suspicious regions (mCSR) and csPCA. Main reasons missing csPCa were insufficient segmentation (MRI/US correlation of the prostate boundary) or imprecise registration (inaccurate lesion transfer, tracking or matching) within MRI/US fusion-guided biopsy. Pre-biopsy verification of MR image and report quality, segmentation, and registration next to clinical experience seems essential. Additional SB might cover inaccuracies of TB, but our data suggests that additional SB adds limited clinical value in cases with PSAD = 0.15 ng/ml/cm3.

SSGU01-5 Diagnostic Accuracy And Inter-observer Reliability Of The O-rads Scoring System Amongst Staff Radiologists In North American Academic Clinical Setting

Participants
Yeli Pi, MD, Edmonton, Alberta (*Presenter*) Nothing to Disclose

PURPOSE

The objective of this study is to evaluate the diagnostic accuracy, interobserver variability, and common lexicon pitfalls of the ACR O-RADS scoring system amongst staff radiologists without prior experience to O-RADS.*Methods and Materials After independent review of the ACR O-RADS publications and 30 training cases, three fellowship-trained, board-certified staff radiologists scored 50 testing cases using the O-RADS system. The diagnostic accuracy and area under receiver operating characteristic were analyzed for each reader. Overall agreement and pair-wise agreement between readers was also analyzed.*Results Excellent specificities (92 to 100%) and negative predictive values (92 to 100%) were achieved. Variable sensitivities (72 to 100%) and positive predictive values (66 to 100%) were observed. Considering O-RADS 4 and O-RADS 5 as predictors of malignancy, individual reader AUC values range from 0.94-0.98 (p<0.001). Overall inter-reader agreement for all 3 readers was "very good", k = 0.82 (0.73 to 0.90, 95% CI, p < 0.001). Pair-wise agreement between readers were also "very good", k=0.86-0.92. Fourteen out of 150 lesions were misclassified, with the most common error represented by down-scoring of a solid lesion with irregular outer contours.*Conclusions Even without specific training, experienced ultrasound readers in North America can achieve excellent diagnostic performance and high inter-reader reliability with self-directed review of guidelines and cases.*Clinical Relevance/Application The study highlights the effectiveness of ACR O-RADS as a stratification tool for radiologists and supports its continued use in practice.

RESULTS

Excellent specificities (92 to 100%) and negative predictive values (92 to 100%) were achieved. Variable sensitivities (72 to 100%) and positive predictive values (66 to 100%) were observed. Considering O-RADS 4 and O-RADS 5 as predictors of malignancy, individual reader AUC values range from 0.94-0.98 (p<0.001). Overall inter-reader agreement for all 3 readers was "very good", k = 0.82 (0.73 to 0.90, 95% CI, p < 0.001). Pair-wise agreement between readers were also "very good", k=0.86-0.92. Fourteen out of 150 lesions were misclassified, with the most common error represented by down-scoring of a solid lesion with irregular outer contours.

CLINICAL RELEVANCE/APPLICATION

The study highlights the effectiveness of ACR O-RADS as a stratification tool for radiologists and supports its continued use in practice.

SSNMMI07-2   The Relationship Between Bone Marrow Involvement On18F-fluorodeoxyglucose Positron Emission Tomography/computed Tomography And Bone Marrow Biopsy In Patients With Multiple Myeloma

Participants
KIFLOM Gebreslassea, MD, Cape Town, South Africa (*Presenter*) Nothing to Disclose

PURPOSE

Multiple myeloma is a plasma cell neoplasm characterized by unrestrained monoclonal proliferation of malignant plasma cells, which develop from B lymphocytes within the bone marrow. Bone marrow biopsy plays a crucial role in the diagnosis and assessment of treatment response in myeloma. 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT) has been shown to be a complementary measure of marrow involvement in lymphomas, particularly in Hodgkin lymphoma and diffuse large B cell lymphoma. However, only limited information is available on its potential role in the assessment of bone marrow involvement and its relationship with bone marrow biopsy in patients with multiple myeloma. Therefore, this study is aimed to compare these two modalities in assessing bone marrow involvement and/or tumor burden.*Methods and Materials From a retrospective review of 190 patients with multiple myeloma from January 2013 to July 2020, 103 patients were included. Plasma cell infiltration (PCI) on bone marrow biopsy was compared for three visual patterns of 18F-FDG bone marrow uptake (irregular, diffuse less than or equal to the liver, and diffuse greater than liver). The PCI was based on bone marrow biopsy and aspiration results. The 18F-FDG uptake at the site of bone marrow biopsy was assessed visually and semiquantitatively. A Kruskal-Wallis rank test and quantile regression were used to compare the two modalities.*Results Eighty-four patients had diffuse bone marrow uptake. Of these 25/84 had uptake greater than liver, all having PCI =60% and a median value of 85%. Of the 84 patients, the 59 patients with uptake less than or equal to liver had PCI <10% in 57.6% (34/59), and =10% in 42.4% (25/59) with a median value of 8%. Nineteen patients had irregular bone marrow uptake. Of these 4/19 (21.1%) had PCI of <10% and 15/19 (78.9%) =10%, with a median value of 23%. The median percentage of PCI across the three described patterns of FDG uptake was significantly different (P=0.0001).*Conclusions Bone marrow biopsy and 18F-FDG PET/CT showed a good concordance in patients with diffuse bone marrow 18F-FDG uptake in assessing the tumor burden in patients with multiple myeloma. However, bone marrow biopsy may underestimate the tumor burden in patients with an irregular pattern of 18F-FDG uptake with a potential risk of undertreatment of the patient.*Clinical Relevance/Application Based on our results 18F-FDG PET/CT may replace bone marrow biopsy in the majority of the patients with a diffuse and irregular pattern of bone marrow 18F-FDG uptake. However, its sensitivity in detecting PCI may be limited in low-grade bone marrow infiltration when compared to the bone marrow biopsy.

RESULTS

Eighty-four patients had diffuse bone marrow uptake. Of these 25/84 had uptake greater than liver, all having PCI =60% and a median value of 85%. Of the 84 patients, the 59 patients with uptake less than or equal to liver had PCI <10% in 57.6% (34/59), and =10% in 42.4% (25/59) with a median value of 8%. Nineteen patients had irregular bone marrow uptake. Of these 4/19 (21.1%) had PCI of <10% and 15/19 (78.9%) =10%, with a median value of 23%. The median percentage of PCI across the three described patterns of FDG uptake was significantly different (P=0.0001).

CLINICAL RELEVANCE/APPLICATION

Based on our results 18F-FDG PET/CT may replace bone marrow biopsy in the majority of the patients with a diffuse and irregular pattern of bone marrow 18F-FDG uptake. However, its sensitivity in detecting PCI may be limited in low-grade bone marrow infiltration when compared to the bone marrow biopsy.

SSNMMI07-4   Effects Of Anti-TNF-therapy On Osteoblastic Activity In Ankylosing Spondylitis - Results From A Prospective Study Using PET-MRI Of SIJ And Spine

Participants
Nils Bruckmann, MD, Duesseldorf, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Assess the effect of TNF-inhibitors on inflammatory and post-inflammatory lesions in relation to the effects on osteoblastic activity assessed by Na[18F]F PET/MRI in the axial skeleton of r-axSpA patients prior (baseline, BL) and up to 6 months after (follow-up, FU) treatment.*Methods and Materials Clinically active r-axSpA patients (11 male, 5 female, mean age 38.6±12.0 years) prospectively underwent Na[18F]F PET/MR images of the SIJ (n=16 patients) and the whole spine (n=10 patients) at BL and FU.

Three independent blinded readers (1 for PET/MRI, 2 for conventional MRI) evaluated all images. Inflammation (bone marrow edema, BME), structural lesions (fat lesions (FL), sclerosis, erosions and ankylosis) and Na[18F]F uptake were recorded on the level of sacroiliac joint quadrants (SIJ-Q) and vertebral quadrants (VQ). Chi-Square test was applied for comparisons between timepoints.*Results Overall, 11 male and 5 female patients (mean age 38.6±12.0 years) were followed up over a mean of 4.6 (3-6) months. A total of 128 SIJ-Q and 920 VQs were analyzed at each timepoint. At BL, Na[18F]F uptake was found in 96.0% SIJ-Qs with BME, 94.2% with sclerosis and 88.3% with FL at BL. At FU, 65.3% of SIJ-Q with BME (p<0.01), 33.8% with sclerosis (p=0.23) and 24.5% with FL (p=0.01) showed decrease of 1 Na[18F]F uptake. In VQ, Na[18F]F uptake was found in 81.5% with sclerosis, 41.9% with FL and 33.7% with BME at BL. At FU, 73.5% VQ with BME, 53.3% with FL and 55.6% with sclerosis showed decrease of Na[18F]F uptake.*Conclusions Anti-TNF treatment led to a significant decrease of osteoblastic activity within 4 months, which was most prominent at sites with inflammation.*Clinical Relevance/Application These data support the early anti-inflammatory treatment initiation for prevention of radiographic progression in axSpA.

RESULTS

Overall, 11 male and 5 female patients (mean age 38.6±12.0 years) were followed up over a mean of 4.6 (3-6) months. A total of 128 SIJ-Q and 920 VQs were analyzed at each timepoint. At BL, Na[18F]F uptake was found in 96.0% SIJ-Qs with BME, 94.2% with sclerosis and 88.3% with FL at BL. At FU, 65.3% of SIJ-Q with BME (p<0.01), 33.8% with sclerosis (p=0.23) and 24.5% with FL (p=0.01) showed decrease of 1 Na[18F]F uptake. In VQ, Na[18F]F uptake was found in 81.5% with sclerosis, 41.9% with FL and 33.7% with BME at BL. At FU, 73.5% VQ with BME, 53.3% with FL and 55.6% with sclerosis showed decrease of Na[18F]F uptake.

CLINICAL RELEVANCE/APPLICATION

These data support the early anti-inflammatory treatment initiation for prevention of radiographic progression in axSpA.

SSNR04-1 Clinical And Imaging Prognostic Factors Of Stroke-like Migraine Attack After Radiation Therapy (SMART) Syndrome

Participants
Yoshiaki Ota, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

This study was aimed to assess clinical and imaging features to predict the clinical outcome of stroke-like migraine attacks after radiation therapy (SMART) syndrome.*Methods and Materials We retrospectively reviewed the clinical manifestations and imaging findings of 21 patients with SMART syndrome (mean age 47.9 ± 13.7, 6 females) diagnosed in multiple international centers between August 2015 and January 2020. Patients' demographics and MRI imaging features at the diagnosis of SMART syndrome were reviewed. This cohort was divided into the completely clinically recovered (CR) group and the incompletely clinically recovered (IR) group. The diagnosis of SMART syndrome was performed by neuroradiology and neurology consensus at each institution. The numerical variables were compared by t-test or Mann-Whitney U test, and categorical variables were by Fisher's exact test between 2 groups. As for MRI imaging findings, the inter-reader agreement was assessed by kappa analysis. All statistical tests were two-sided and p = 0.05 was considered to be statistically significant.*Results CR group (n=11, 2 females) and IR group (n=10, 4 females) constituted this study cohort.As for patients' demographic, there were statistically significant differences between CR and IR in age (mean age 41.4 ± 8.4 vs 55.0 ± 15.2 years, P= .018), months of follow-up (median (range): 1(1-24) vs 15 (1-70); P= .006), and presence of administration of steroid treatment at the diagnosis of SMART syndrome (CR vs IR: 3/11 vs 8/10, P= .03). As for MRI imaging findings, there were statistically significant differences between CR and IR in presence of SWI/T2*WI abnormality and restricted diffusion in the region of the gyral enhancement, which were more frequent in IR than CR (CR vs IR: 3/11 vs 9/10; P=.008, 0/11 vs 4/10; P=.035, respectively). Inter-reader agreement for MRI imaging findings was substantial to almost perfect (? = 0.7-1).*Conclusions Incomplete recovery was associated with older age, use of steroid treatment at the diagnosis of SMART syndrome, and MRI findings of abnormal susceptibility signal and restricted diffusion in the region of the gyral enhancement.*Clinical Relevance/Application The clinical outcome of SMART syndrome can be predicted from patient age and MRI imaging findings of local abnormal susceptibility signal and restricted diffusion. The worse clinical outcomes in the SMART group who underwent steroid administration in our study may suggest that the pros and cons of steroid use should be carefully considered prior to steroid treatment.

RESULTS

CR group (n=11, 2 females) and IR group (n=10, 4 females) constituted this study cohort.As for patients' demographic, there were statistically significant differences between CR and IR in age (mean age 41.4 ± 8.4 vs 55.0 ± 15.2 years, P= .018), months of follow-up (median (range): 1(1-24) vs 15 (1-70); P= .006), and presence of administration of steroid treatment at the diagnosis of SMART syndrome (CR vs IR: 3/11 vs 8/10, P= .03). As for MRI imaging findings, there were statistically significant differences between CR and IR in presence of SWI/T2*WI abnormality and restricted diffusion in the region of the gyral enhancement, which were more frequent in IR than CR (CR vs IR: 3/11 vs 9/10; P=.008, 0/11 vs 4/10; P=.035, respectively). Inter-reader agreement for MRI imaging findings was substantial to almost perfect (? = 0.7-1).

CLINICAL RELEVANCE/APPLICATION

The clinical outcome of SMART syndrome can be predicted from patient age and MRI imaging findings of local abnormal susceptibility signal and restricted diffusion. The worse clinical outcomes in the SMART group who underwent steroid administration in our study may suggest that the pros and cons of steroid use should be carefully considered prior to steroid treatment.

SSNR04-2 Combining Deep Learning And Radiomics Features From Preoperative MRI For Predicting CDKN2A/B Gene Loss In Patients With Glioblastoma

Participants
Evan Calabrese, MD, PhD, San Francisco, California (*Presenter*) Nothing to Disclose

PURPOSE

CDKN2A/B gene loss is a poor prognostic marker identified in approximately 50% of glioblastomas. Ongoing clinical trials have shown that downstream oncogenic pathways affected by CDKN2A/B loss can be inhibited using investigational drugs, yet assessment of CDKN2A/B status in glioblastomas remains uncommon. The purpose of this study was to non-invasively predict CDKN2A/B loss in patients with glioblastoma by using both engineered radiomics features and learned deep features from preoperative MRI.*Methods and Materials We analyzed 400 adult patients who had preoperative brain MRI, first time glioblastoma resection, and subsequent CDKN2A/B genetic assessment. The MRI protocol included 3D pre and post-contrast T1-, T2-, FLAIR-, diffusion-, and susceptibility-weighted images as well as DTI and ASL perfusion.Image preprocessing steps included co-registration, skull stripping, intensity

normalization, and tumor segmentation using a custom deep convolutional neural network (dCNN). Radiomics features were extracted from the tumor region using Pyradiomics 3.0.A 3D dCNN was developed to predict CDKN2A/B loss using multimodal whole tumor images and radiomics features. Deep features were learned using a 10-layer convolutional encoding limb with 3 max pooling steps. Radiomics features were combined with deep features via a dense CNN limb consisting of 2 hidden layers and a final output layer for predicting CDKN2A/B status. 5-fold cross validation was accomplished using 2 Nvidia V100 GPUs.*Results CDKN2A/B loss was identified in the study cohort with a prevalence of 53% by genetic sequencing. Cross-validation of the combined deep- and radiomics-feature model yielded accurate predictions of CDKN2A/B loss in the test dataset with a best point sensitivity of 0.70, a specificity of 0.88, and an area under the curve of 0.84. The combined model performed better than models based on radiomics or deep features alone.*Conclusions A deep neural network combining learned deep features and engineered radiomics features from preoperative MRI can non-invasively predict CDKN2A/B loss in patients with glioblastoma with moderate accuracy.*Clinical Relevance/Application Non-invasive identification of CDKN2A/B gene loss in glioblastomas could provide important prognostic information and help guide the use of investigational molecular targeted therapies.

RESULTS

CDKN2A/B loss was identified in the study cohort with a prevalence of 53% by genetic sequencing. Cross-validation of the combined deep- and radiomics-feature model yielded accurate predictions of CDKN2A/B loss in the test dataset with a best point sensitivity of 0.70, a specificity of 0.88, and an area under the curve of 0.84. The combined model performed better than models based on radiomics or deep features alone.

CLINICAL RELEVANCE/APPLICATION

Non-invasive identification of CDKN2A/B gene loss in glioblastomas could provide important prognostic information and help guide the use of investigational molecular targeted therapies.

SSNR04-3   Interrater Reliability Of A Standardized Reporting System For Brain Tumor MRIs

Participants
Maxwell Cooper, MD, Atlanta, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

The Brain Tumor Reporting and Data System (BT-RADS) is a structured radiology reporting algorithm designed to decrease subjectivity among radiologists interpreting MRI exams of treatment response in brain tumor patients. The purpose of this study was to determine the agreement and interrater reliability for multiple radiologists using BT-RADS to score the same cohort of primary brain tumor MRI exams.*Methods and Materials A retrospective search was conducted for all adult patients with a primary parenchymal brain tumor receiving an MRI over a 2 month period at a single institution. Six radiologists were selected for this study, 4 faculty neuroradiologists and 2 radiology residents. Each reader scored all 103 patient's MRIs using the BT-RADS system (Fig 1A). Readers were blind to the MRI report and the BT-RADS score assigned by the radiologist that initially read the patient's imaging. Interrater agreement between readers were calculated using rates of exact agreement and linear weighted kappa extended to multiple raters using Light's method with bootstrapped confidence intervals. Consensus scoring was determined as agreement between all 4 faculty readers.*Results 103 consecutive primary brain tumor MRIs from 98 patients were included. Average patient age was 46.1 years (range 21-84). The majority of the tumors were an astrocytoma (79/103, 76.7%), with 45 (43.7%) classified as Grade 4 glioblastoma (Fig. 1B). The majority of MRI studies (54/103, 52.4%) received a score of 2 (Fig. 1C). The linear weighted kappa for all six readers was 0.62 (95% CI: 0.53, 0.70) (substantial agreement). All 6 readers agreed on 43.7% of cases. All 4 faculty readers and 3 of 4 faculty readers agreed on 52.4% (54/103) and 73.4% (76/103) of MRI studies, respectively (Fig. 1D).*Conclusions This study was the first quantifiable analysis of blinded interrater reliability for utilizing BT-RADS to score MRIs in brain tumor patients. All readers agreed on a significant fraction of the cases (43.7%), which likely represented cases with less challenging or conflicting findings. The interrater agreement was good although not perfect. This likely reflects intrinsic uncertainty in reading highly complex posttreatment brain tumor scans and the high number and heterogeneity of readers in this study. Further work is needed to understand the reasons for these individual discrepancies, to determine if system improvements can reduce variability, and how these structured scores correlate with patient outcome.*Clinical Relevance/Application The goal of BT-RADS is to maximize consistency between brain MRI reports to aid with monitoring treatment response and disease progression, serving as a guide for clinical management decisions.

RESULTS

103 consecutive primary brain tumor MRIs from 98 patients were included. Average patient age was 46.1 years (range 21-84). The majority of the tumors were an astrocytoma (79/103, 76.7%), with 45 (43.7%) classified as Grade 4 glioblastoma (Fig. 1B). The majority of MRI studies (54/103, 52.4%) received a score of 2 (Fig. 1C). The linear weighted kappa for all six readers was 0.62 (95% CI: 0.53, 0.70) (substantial agreement). All 6 readers agreed on 43.7% of cases. All 4 faculty readers and 3 of 4 faculty readers agreed on 52.4% (54/103) and 73.4% (76/103) of MRI studies, respectively (Fig. 1D).

CLINICAL RELEVANCE/APPLICATION

The goal of BT-RADS is to maximize consistency between brain MRI reports to aid with monitoring treatment response and disease progression, serving as a guide for clinical management decisions.

SSNR04-4   Impact Of MR Simulation Prior To Chemoradiation On Tumor Response And Pseudoprogression Reporting In High Grade Gliomas.

Participants
Divya Yadav, MBBS, Houston, Texas (*Presenter*) Nothing to Disclose

PURPOSE

Radiological changes and even tumor progression can occur for high grade gliomas (HGG) between the post-operative (post-op) MRI and start of radiation (RT), motivating the growing use of a dedicated MR simulation (MRsim) for RT planning. The aim of this study was to determine the impact on tumor response assessment and reported pseudoprogression (PsP) at first follow-up (FU1) after completing RT when MRsim images are used as the baseline compared to the immediate post-op MRI.*Methods and Materials Patients with histologically confirmed HGG and planned for 6 weeks RT on a prospective study evaluating serial MRI for personalized RT, with available post-op MRI and at least 3 months follow up were included in this study. Pertinent patient, tumor and treatment characteristics were extracted. Scans were reviewed independently by 3 reviewers in a blinded manner using Response Assessment in Neuro-Oncology (RANO) criteria. PsP was defined as an enlarging area of contrast enhancement at FU1 which subsided or stabilized at subsequent follow-up scans without a change in therapy. Descriptive statistics were used to compare *the differences

in reported tumor response using the post-op MRI vs. MRsim as the baseline, and interobserver agreement between reviewers was evaluated.*Results Thirty patients (4 WHO grade 3; 26 WHO grade 4) with a median age of 59 years (range 25-68 years) at diagnosis were included. Median interval between surgery and RT was 34 days, and median follow-up after RT was 9.4 months (range 3-21 months). Overall, 7 patients had PsP at a median of 2 months after RT. In 9 patients (30%), tumor response at FU1 was partial response compared to MRsim vs. progressive disease (PD) or stable disease (SD) compared to post-op MRI. Similarly, 8 patients (26.7%) had SD at FU1 from MRsim but were reported to have PD or PsP from post-op MRI. The remaining 13 patients (43.3%) were reported analogous on both comparisons. Median overall survival from diagnosis (OS) for the entire cohort was not reached.*Conclusions Tumor response assessment differed in about 57% of our HGG patients when the baseline study for comparison was MRsim vs. immediate post-op MRI.*Clinical Relevance/Application MR simulation can better guide radiation treatment planning and serve as an updated baseline MR for treatment response.

RESULTS

Thirty patients (4 WHO grade 3; 26 WHO grade 4) with a median age of 59 years (range 25-68 years) at diagnosis were included. Median interval between surgery and RT was 34 days, and median follow-up after RT was 9.4 months (range 3-21 months). Overall, 7 patients had PsP at a median of 2 months after RT. In 9 patients (30%), tumor response at FU1 was partial response compared to MRsim vs. progressive disease (PD) or stable disease (SD) compared to post-op MRI. Similarly, 8 patients (26.7%) had SD at FU1 from MRsim but were reported to have PD or PsP from post-op MRI. The remaining 13 patients (43.3%) were reported analogous on both comparisons. Median overall survival from diagnosis (OS) for the entire cohort was not reached.

CLINICAL RELEVANCE/APPLICATION

MR simulation can better guide radiation treatment planning and serve as an updated baseline MR for treatment response.

SSNR04-5   Temporal DCE Profile Of Brain Metastasis With A Comparison Of Pseudoprogression Cases

Participants
Sevcan Turk, MD, Ann Arbor, Michigan (*Presenter*) Nothing to Disclose

PURPOSE

To demonstrate Dynamic Contrast-Enhanced (DCE) perfusion changes in brain mets patients after chemoradiation therapy and to compare with pseudoprogression group.*Methods and Materials 38 treatment response patients with brain metastasis (13 melanoma, 11 lung, 7 breast, 6 others) with 3 consecutive follow-up (pretreatment, early follow-up, and late follow-up) MRI and DCE perfusion and 7 melanoma patients with 10 pseudoprogression lesions with DCE perfusion were evaluated. All DCE MRI parameters including SER, wash-in, wash-out, KEP, VP, VE, Ktrans, TME, peak, curve-washout, peak-enhancement, AUC, and washout graphs increase (rapid, slow, medium) and course pattern (washout, plateau, persistent) were analyzed using SPSS and Phyton software. Paired t-test and Mann Whitney U were used to compare mean values of DCE parameters. Automatic assessment of washout curves by Olea Brain Software was reviewed.*Results Pretreatment wash-in mean value was significantly higher than that of post-treatment (15.3 ± 24.7 vs 5.80 ± 10.2, P<0.01). Pretreatment mean AUC value was significantly higher than that of post-treatment (141113 ± 184644 vs 79378 ± 119120, P<0.04). There was no statistically significant difference between pre- and post-treatment in the other perfusion parameters and washout graphs. There was no statistically significant difference between early and late follow-up DCE parameters for treatment response group. There was no statistically significant difference between true treatment response and pseudoprogression group.*Conclusions Wash-in and AUC values in DCE perfusion are significantly decreased after chemoradiation therapy. No statistically significant difference is shown between treatment response and pseudoprogression group; thus DCE may help identify lesions that are responding or demonstrate pseudoprogression. More research can be done to separate treatment responders and pseudoprogression from true progressive disease.*Clinical Relevance/Application DCE perfusion may provide further quantitative assessment of post-treatment changes and help identify lesions that show treatment response or pseudoprogression.

RESULTS

Pretreatment wash-in mean value was significantly higher than that of post-treatment (15.3 ± 24.7 vs 5.80 ± 10.2, P<0.01). Pretreatment mean AUC value was significantly higher than that of post-treatment (141113 ± 184644 vs 79378 ± 119120, P<0.04). There was no statistically significant difference between pre- and post-treatment in the other perfusion parameters and washout graphs. There was no statistically significant difference between early and late follow-up DCE parameters for treatment response group. There was no statistically significant difference between true treatment response and pseudoprogression group.

CLINICAL RELEVANCE/APPLICATION

DCE perfusion may provide further quantitative assessment of post-treatment changes and help identify lesions that show treatment response or pseudoprogression.

SSNR04-6   The Role Of Arterial Spin Labelling (ASL) Post Stereotactic Radiosurgery (SRS) Treatment

Participants
Meghavi Mashar, MBBCh, London, United Kingdom (*Presenter*) Nothing to Disclose

PURPOSE

Pseudocontinuous Arterial spin labelling (pCASL) allows quantification of cerebral blood flow that may aid stratification of patients with cerebral metastases. We aimed to study the utility of pCASL for patient stratification following stereotactic radiosurgery treatment from our single centre.*Methods and Materials 45 patients (25 female, mean age: 60.2 years) with intracranial metastases (primary 21 lung, 8 breast, 8 melanoma, 2 renal, 6 other) who had a first SRS treatment between 03/17 and 10/19 and pCASL sequence at first follow up (mean: 6.35 weeks post treatment). pCASL perfusion weighted image (PWI) was visually classified as either positive or negative (ASL+/-) by an experienced neuroradiologist. Three regions of interest: area of the lesion, perilesional area and contralateral grey matter were manually defined using Carestream PACS software. Ratios of signal intensity (SI) were calculated using Excel and GraphPad Prism v7. Radiological response post SRS and at 6 months (n=29) was categorised into non-progression and progression. Survival at 6 months was assessed (Alive n=39, Deceased n=6).*Results 15 had an ASL+ post-operative scan. The ratio of mean SI in the lesion to perilesional area (contrast to noise ratio) was higher in ASL+ scans (1.86 ± 0.15) versus ASL- (0.77 ± 0.05) (P<0.05) and similarly for the ratios of maximum SI [ASL+ (1.82 ± 0.23), ASL- (0.98±0.05)]. No difference relative to SI of contralateral grey matter. Treatment response at first follow up was similar in both groups: ASL+, non-progression n=15, 94%; ASL-, non-progression n=27, 93%, as was patients deceased at 6 months: ASL+, n=2, 13%; ASL-, n=4, 13%. Whilst there was limited follow up available for patients at 6 months (n=29), a higher proportion in the ASL- group had radiologically progressive disease at 6 months: n=11, 52% versus ASL+, n=1, 12.5%.*Conclusions This is one of few studies

investigating ASL in cerebral metastases and demonstrates that pCASL at first follow up post-SRS can stratify patients at 6 months. Visual assessment of pCASL PWI allows accurate classification of perfusion in metastases, highlighting the ease of this technique in clinical practice. There may be a correlation between ASL positivity and disease non-progression, which may represent increased vascularity secondary to a more powerful treatment effect.*Clinical Relevance/Application Cerebral metastases affect up to 26% of those whose cause of death is malignancy and incidence is increasing as life-prolonging treatments are developed. Appropriate management can improve neuro-cognitive symptoms and quality of life. pCASL may allow better characterisation of post-operative treatment response and recurrence for metastases.

RESULTS

15 had an ASL+ post-operative scan. The ratio of mean SI in the lesion to perilesional area (contrast to noise ratio) was higher in ASL+ scans (1.86 ± 0.15) versus ASL- (0.77 ± 0.05) (P<0.05) and similarly for the ratios of maximum SI [ASL+ (1.82 ± 0.23), ASL- (0.98±0.05)]. No difference relative to SI of contralateral grey matter. Treatment response at first follow up was similar in both groups: ASL+, non-progression n=15, 94%; ASL-, non-progression n=27, 93%, as was patients deceased at 6 months: ASL+, n=2, 13%; ASL-, n=4, 13%. Whilst there was limited follow up available for patients at 6 months (n=29), a higher proportion in the ASL- group had radiologically progressive disease at 6 months: n=11, 52% versus ASL+, n=1, 12.5%.

CLINICAL RELEVANCE/APPLICATION

Cerebral metastases affect up to 26% of those whose cause of death is malignancy and incidence is increasing as life-prolonging treatments are developed. Appropriate management can improve neuro-cognitive symptoms and quality of life. pCASL may allow better characterisation of post-operative treatment response and recurrence for metastases.

SSIN01-2   Impact Of AI-assisted Indication Selection On Appropriateness Order Scoring Using A Commercial Imaging Clinical Decision Support System

Participants
Lauren Shreve, MD, Philadelphia, Pennsylvania (*Presenter*) Nothing to Disclose

PURPOSE

The Protecting Access to Medicare Act requires clinicians to consult appropriate use criteria via a qualified Clinical Decision Support Mechanism (qCDSM) when ordering advanced imaging for Medicare patients. qCDSM only scores order appropriateness when a structured indication is selected at order entry. In our health system, 60% of outpatient imaging orders are not scored due to free-text only indications. We evaluated the impact of AI generated structured indications for free-text only orders on the rate of scored orders.*Methods and Materials An AI tool for free-text only orders was implemented within the qCDSM at our large multi-hospital system on 10/19/21. On order entry, clinicians enter a free-text indication, structured indication, or both. For free-text only orders, if established structured indications could be mapped to the free-text by the AI tool, the indication(s) were provided for selection. If a structured indication was chosen, the order was placed with both free-text and structured indications. Alternatively, providers could indicate a lack of a suitable structured indication or exit the tool. Final orders were categorized as free-text only, structured indication only, both, or neither. We examined all orders ten weeks before (7/13/20-9/21/20) and after (10/20/20-12/29/21) AI tool implementation. A chi-square test was used to compare the proportions of scored orders before and after AI deployment.*Results 98,303 advanced imaging orders were placed over the study period; 47,595 before and 50,708 after AI implementation. Scored orders increased from 31.8% (15,142/47,595) to 50.9% (25,801/50,708) after AI tool deployment (p<0.001). Free-text only orders declined from 59.3% (28,209/47,595) to 31.6% (16,005/50,708). Concomitantly, orders containing both structured and free-text indications rose from 6.7% (3,176/47,595) to 29.6% (15,023/50,708). Among the 16,005 free-text orders following AI deployment, users indicated a lack of an appropriate structured indication in 36.2% (5,792/16,005) of orders.*Conclusions Structured indications provided by an AI tool based on free-text entry increased the fraction of qCDSM scored orders and decreased the fraction of orders with free-text only indications. Even after intervention, one-third of orders lacked structured indications and half of orders remained unscored.*Clinical Relevance/Application Free-text imaging orders can be reduced using an AI tool; however, additional measures will be needed to address the half of orders which remain unscored.

RESULTS

98,303 advanced imaging orders were placed over the study period; 47,595 before and 50,708 after AI implementation. Scored orders increased from 31.8% (15,142/47,595) to 50.9% (25,801/50,708) after AI tool deployment (p<0.001). Free-text only orders declined from 59.3% (28,209/47,595) to 31.6% (16,005/50,708). Concomitantly, orders containing both structured and free-text indications rose from 6.7% (3,176/47,595) to 29.6% (15,023/50,708). Among the 16,005 free-text orders following AI deployment, users indicated a lack of an appropriate structured indication in 36.2% (5,792/16,005) of orders.

CLINICAL RELEVANCE/APPLICATION

Free-text imaging orders can be reduced using an AI tool; however, additional measures will be needed to address the half of orders which remain unscored.

SSIN01-3   Clinical Study Distribution Using Reinforcement Learning

Participants
Sun Young Park, San Diego, California (*Presenter*) Employee, IBM Corporation;

PURPOSE

We present new reinforcement learning methods that optimize clinical study distribution with multiple objectives including fairness, workload balance and personalization. The models are integrated into an automatic study distribution system that recommends readers for the incoming studies in a PACS system.*Methods and Materials We trained a reinforcement learning model to address fairness, workload balance and study priority optimization within a PACS distribution engine. We model the state of the worklist environment as a matrix of personalized radiologist status data (specialties, capacity, preferences, reading time, etc.) and a vector representing an incoming study. Our reinforcement learning algorithm sends the state to a two-input CNN that recommends a policy

for distributing the study to the radiologists. Our agent is rewarded for maximizing fair workload balance, correct allocation according to preference and specialty, and meeting deadlines for priority studies. Performance was evaluated versus an existing rule-based study distribution system.*Results We trained on simulations of real clinical sites (up to 1000 studies per hour), with realistic variance in RVUs, study types, and reading times. X-rays comprised 30-50% of the incoming studies, with the remaining studies divided among other sub-specialties. Some studies were also given priority due times. Each radiologist could read x-rays or one sub-specialty, and had personalized study preferences, chance of rejecting assigned studies and reading rate for each study type. We applied five distribution rules: lowest load (# of studies or RVUs), round robin, highest skill level, and a weighted combination, and applied six comparison metrics: average completion time per study, success rate in meeting priority study deadlines, and the standard deviations of the assigned RVUs, the average study preference level, the number of x-rays read, and the study rejection rates of each radiologist. Combining these factors into an overall score, our algorithm outperformed the five rules by 19.2%[16.3-21.7], 6.2%[3.2-9.1], 51.5%[47.6-55.69], 58.3%[49.6-67.0], and 9.6%[5.71-13.6] with 95% confidence intervals.*Conclusions We present a novel reinforcement learning framework for clinical study distribution that optimizes several factors. We have shown that our algorithm provides a more balanced, efficient, and comfortable study distribution than rule-based PACS distribution engines.*Clinical Relevance/Application We present a reinforcement learning system that optimizes clinical study distribution. The system accounts for personal preferences and specialties, ensuring that radiologists can work in their comfort zone as often as possible, which results in better patient outcomes.

RESULTS

We trained on simulations of real clinical sites (up to 1000 studies per hour), with realistic variance in RVUs, study types, and reading times. X-rays comprised 30-50% of the incoming studies, with the remaining studies divided among other sub-specialties. Some studies were also given priority due times. Each radiologist could read x-rays or one sub-specialty, and had personalized study preferences, chance of rejecting assigned studies and reading rate for each study type. We applied five distribution rules: lowest load (# of studies or RVUs), round robin, highest skill level, and a weighted combination, and applied six comparison metrics: average completion time per study, success rate in meeting priority study deadlines, and the standard deviations of the assigned RVUs, the average study preference level, the number of x-rays read, and the study rejection rates of each radiologist. Combining these factors into an overall score, our algorithm outperformed the five rules by 19.2%[16.3-21.7], 6.2%[3.2-9.1], 51.5%[47.6-55.69], 58.3%[49.6-67.0], and 9.6%[5.71-13.6] with 95% confidence intervals.

CLINICAL RELEVANCE/APPLICATION

We present a reinforcement learning system that optimizes clinical study distribution. The system accounts for personal preferences and specialties, ensuring that radiologists can work in their comfort zone as often as possible, which results in better patient outcomes.

SSIN01-4 Clinical Decision Support For CT Ordering In Pediatric Imaging: Results From A Quaternary Care Pediatric Hospital

Participants
Andrew Sher, MD, Houston, Texas (*Presenter*) Nothing to Disclose

PURPOSE

To analyze the effect of point-of-care ACR-clinical decision support (CDS) software embedded in the electronic health records (EHR) on CT ordering patterns in a quaternary care pediatric hospital.*Methods and Materials This study was HIPAA compliant and exempt from IRB approval. All CT exams across the enterprise ordered on patients less than 21 years old from 9/18/18 to 3/31/2021 were categorized by CDS software. ACR-CDS scores were recorded: Red (1-3; usually not appropriate), Yellow (4-6; may be appropriate), Green (7-9; usually appropriate) and a category of "no score". From 9/18/18 to 8/7/2019, no feedback was provided to the ordering provider (n = 12795). From 12/8/2019 to 3/31/2021, best practice alerts (BPA) provided feedback to the provider (n = 19914). Changes in order behavior were recorded and compared between the pre-BPA and post-BPA activation. Chi-square test for proportions was conducted.*Results Pre- versus post-BPA there was a statistically significant decrease in the rate of Red (14.4% vs 7.5%) scored and an increase in Green (49.2% vs 56%) scored studies, both (p<0.0001). Yellow (19.4% vs 18.9%) and 'No Score' (17% vs 17.7%) studies showed no statistically significant difference (p = .25 and p =.12 respectively). For Red scored studies, 7% (n = 104) of studies were changed or not signed after receiving a BPA; the remainder proceeded as ordered. Top reasons for bypassing the BPA included: Disagree with Appropriateness Score (20%), Consulted with Other Specialist (18%), Consulted with Radiology (6%), and Modality Unavailable (5%). 26% of bypassed orders provided no reason for proceeding.*Conclusions ACR-CDS recommendations decrease the ratio of clinically inappropriate to appropriate CT exams ordered by referring physicians. When CDS feedback stated "not inappropriate", only a small percentage of CT exams were actually changed. This baseline study can serve as a foundation to measure future incremental positive change in CT appropriateness after additional clinical educational outreach and improved EHR CDS user interfaces have been effected.*Clinical Relevance/Application ACR-CDS recommendations decrease the ratio of clinically inappropriate to appropriate CT exams ordered by referring physicians in a pediatric practice. Further work is needed to elucidate whether the improved ratio translates into improved and more timely patient care.

RESULTS

Pre- versus post-BPA there was a statistically significant decrease in the rate of Red (14.4% vs 7.5%) scored and an increase in Green (49.2% vs 56%) scored studies, both (p<0.0001). Yellow (19.4% vs 18.9%) and 'No Score' (17% vs 17.7%) studies showed no statistically significant difference (p = .25 and p =.12 respectively). For Red scored studies, 7% (n = 104) of studies were changed or not signed after receiving a BPA; the remainder proceeded as ordered. Top reasons for bypassing the BPA included: Disagree with Appropriateness Score (20%), Consulted with Other Specialist (18%), Consulted with Radiology (6%), and Modality Unavailable (5%). 26% of bypassed orders provided no reason for proceeding.

CLINICAL RELEVANCE/APPLICATION

ACR-CDS recommendations decrease the ratio of clinically inappropriate to appropriate CT exams ordered by referring physicians in a pediatric practice. Further work is needed to elucidate whether the improved ratio translates into improved and more timely patient care.

SSIN01-6 Patient Image Access Through Electronic Health Record Patient Portals: A Multi-institutional Experience

Participants
Hailey Choi, MD, San Francisco, California (*Presenter*) Nothing to Disclose

PURPOSE

To determine how patient access to viewing radiology images through an online patient portal affects radiologists*Methods and Materials Patient access to a web-based image viewer through patient portals was implemented at 3 academic institutions within the past 3 years. All 3 institutions were already sharing radiology reports with patients at time of implementation. At institution 1, all radiology and point-of-care (POC) imaging - except exams that could indicate pregnancy in teens - were shared. At institution 2, all radiographs and breast imaging were shared. At institution 3, all radiology, POC, and endoscopic images were shared. An anonymized survey was distributed to radiologists at the 3 institutions. The survey addressed how patient imaging access affected the radiologists' role, and whether radiologists were contacted by patients for imaging-related concerns.*Results A total of 254 radiologists responded to the survey. Majority (78.3%) responded that patient access had no impact on their role as a radiologist, 9.6% reported a positive impact, and 12.1% negative. Most radiologists (65.3%) were never approached by a patient for imaging-related concerns. Of the 86 who were contacted, 47.1% were contacted once or twice thus far, 47.1% 3-4 times a year, and 4.7% 3-4 times a month. In free text comments, 71 radiologists felt this was a positive step towards transparent medicine. 17 radiologists responded that workflow adjustments - i.e. attention to image annotation and report wording - are needed. Other concerns included creating patient confusion or anxiety and causing increased workload for radiologists and providers.*Conclusions Patients' online access to viewing their own radiology exams had little to no impact on radiologists. Only a minority of radiologists were contacted by patients for their imaging, typically a few times a year. While many radiologists feel that patients' access to radiology imaging is a positive step, some are also worried it would confuse and alarm patients. Minor workflow modifications may be warranted.*Clinical Relevance/Application Patients' access to their imaging exams through online portals did not significantly affect radiologists' workload, contrary to some perceived fears. Many radiologists are supportive of the change, and minor workflow alterations can be considered.

RESULTS

A total of 254 radiologists responded to the survey. Majority (78.3%) responded that patient access had no impact on their role as a radiologist, 9.6% reported a positive impact, and 12.1% negative. Most radiologists (65.3%) were never approached by a patient for imaging-related concerns. Of the 86 who were contacted, 47.1% were contacted once or twice thus far, 47.1% 3-4 times a year, and 4.7% 3-4 times a month. In free text comments, 71 radiologists felt this was a positive step towards transparent medicine. 17 radiologists responded that workflow adjustments - i.e. attention to image annotation and report wording - are needed. Other concerns included creating patient confusion or anxiety and causing increased workload for radiologists and providers.

CLINICAL RELEVANCE/APPLICATION

Patients' access to their imaging exams through online portals did not significantly affect radiologists' workload, contrary to some perceived fears. Many radiologists are supportive of the change, and minor workflow alterations can be considered.

SSGU05-3 Pivotal Trial Of Magnetic Resonance Imaging-guided Transurethral Ultrasound Ablation In Men With Localized Prostate Cancer: Three-year Follow-up And Multiparametric Magnetic Resonance Imaging Prediction Of Salvage Treatment

Participants

Steven Raman, MD, Santa Monica, California (*Presenter*) Consultant, Johnson & Johnson;Consultant, Bayer AG;Consultant, Merck & Co, Inc;Consultant, Amgen Inc;Consultant, Profound Medical Inc

PURPOSE

MRI-guided transurethral ultrasound ablation (TULSA) is a minimally invasive procedure for prostate ablation using directional ultrasound. The treatment is controlled in real-time using MRI thermometry feedback. We report 3 year outcomes from the pivotal TULSA-PRO Ablation Clinical Trial (TACT).*Methods and Materials TACT enrolled 115 men with organ-confined prostate cancer (=T2b, PSA =15 ng/ml, Grade Group 1-2) across 13 centers. Treatment was whole-gland sparing the urethra and urinary sphincter. Primary endpoints were safety and PSA reduction at 1 year. Secondary endpoints included 1 year prostate volume reduction, mpMRI, and 10 core biopsy. Three year follow-up included adverse events, quality of life and PSA for men who are salvage-free, and mpMRI prediction of salvage therapy.*Results Median (IQR) baseline age was 65 (59-69) years, median PSA 6.3 (4.6-7.9) ng/mL, with Grade Group (GG) =2 disease in 72/115 men (63%). Targeted prostate volumes of 40 (32-50) cc were ablated in 51 (39-66) min. Grade 3 adverse events in 9 (8%) men included GU infection, stricture, retention, urethral calculus and pain, and urinoma, all resolved before 1 year. There were no rectal injuries or Grade =4 events. By 3 years, 15 men (13%) received salvage treatment. At 1 year MRI and biopsy, median prostate volume decreased from 37 to 3 cc, GG2 disease was eliminated in 54/68 (79%) men, and 72/111 (65%) had no evidence of any cancer. Median PSA decreased 95% to a nadir of 0.26 ng/mL, stable from 0.53 ng/mL at 1 year to 0.70 ng/ml (n=56) at 3 years. Median IPSS decreased from 7 at baseline to 4 (n=61) by 3 years. Moderate urinary incontinence (Grade 2, pads) in 3 men (2.6%) at 1 year persisted to 3 years in 1 patient, with no new incontinence past 1 year. The rate of moderate erectile dysfunction (Grade 2, responding to medication) was 23% at 1 year and 24% at 3 years. Median change in IIEF-5 was -2 from baseline to 1 year, and nil from 1 to 3 years (n=61). Erections sufficient for penetration (IIEF Q2 =2) were maintained by 36/50 (72%) and 40/50 (80%) men at 1 and 3 years. On follow-up mpMRI, a visible lesion was predictive of persistent or recurrent disease and salvage therapy at 3 years (p=0.001; aOR 31.0, CI [6.4,150.0]).*Conclusions With 3 year follow-up, MRI-guided transurethral ultrasound ablation (TULSA) showed durable control of localized prostate cancer with low toxicity and stable quality of life. The presence of a visible lesion on follow-up mpMRI predicted for persistent or recurrent disease and salvage therapy.*Clinical Relevance/Application Whole-gland ablation using MRI-guided TULSA achieves effective disease control at 3 years with favourable functional and safety outcomes. The 1 year follow-up mpMRI is predictive of salvage therapy by 3 years.

RESULTS

Median (IQR) baseline age was 65 (59-69) years, median PSA 6.3 (4.6-7.9) ng/mL, with Grade Group (GG) =2 disease in 72/115 men (63%). Targeted prostate volumes of 40 (32-50) cc were ablated in 51 (39-66) min. Grade 3 adverse events in 9 (8%) men included GU infection, stricture, retention, urethral calculus and pain, and urinoma, all resolved before 1 year. There were no rectal injuries or Grade =4 events. By 3 years, 15 men (13%) received salvage treatment. At 1 year MRI and biopsy, median prostate volume decreased from 37 to 3 cc, GG2 disease was eliminated in 54/68 (79%) men, and 72/111 (65%) had no evidence of any cancer. Median PSA decreased 95% to a nadir of 0.26 ng/mL, stable from 0.53 ng/mL at 1 year to 0.70 ng/ml (n=56) at 3 years. Median IPSS decreased from 7 at baseline to 4 (n=61) by 3 years. Moderate urinary incontinence (Grade 2, pads) in 3 men (2.6%) at 1 year persisted to 3 years in 1 patient, with no new incontinence past 1 year. The rate of moderate erectile dysfunction (Grade 2, responding to medication) was 23% at 1 year and 24% at 3 years. Median change in IIEF-5 was -2 from baseline to 1 year, and nil from 1 to 3 years (n=61). Erections sufficient for penetration (IIEF Q2 =2) were maintained by 36/50 (72%) and 40/50 (80%) men at 1 and 3 years. On follow-up mpMRI, a visible lesion was predictive of persistent or recurrent disease and salvage therapy at 3 years (p=0.001; aOR 31.0, CI [6.4,150.0]).

CLINICAL RELEVANCE/APPLICATION

Whole-gland ablation using MRI-guided TULSA achieves effective disease control at 3 years with favourable functional and safety outcomes. The 1 year follow-up mpMRI is predictive of salvage therapy by 3 years.

SSGU05-4 Development Of A Prostate Cancer Diagnosis Tool With Deep Neural Networks: Explainable Deep Learning Using PI-RADS Imaging Features

Participants
Charlie Hamm, MD, Berlin, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To develop and test the performance of an explainable 3D deep learning system (DLS) that detects and classifies prostatic lesions on bi-parametric magnetic resonance imaging (bpMRI) and justifies its predictions using PI-RADS imaging features.*Methods and Materials This study included 1136 consecutive patients, who underwent bpMRI and consecutive transrectal ultrasound-guided biopsy resulting in a total of 3186 histologically proven prostatic lesions. A total of 1058 prostate cancer (PCa) (347 Gleason Score (GS)=6; 711 GS=7) and 2128 benign lesions (physiologic tissue, benign prostatic hyperplasia, cyst, prostatitis) were included in this data set and used to develop and train a DLS, of which 276 lesions were additionally labeled with PI-RADS imaging features on bpMRI. Based on prostate segmentations and balanced training sets, the DLS was trained to a) detect the target lesion within the segmented prostate, b) classify PCa and benign lesions and c) to justify its predictions with PI-RADS imaging features. A receiver operating characteristic area under the curve (AUC) of the model was determined using a hold-out test set comprising 15% of all lesions.*Results The DLS reliably detected the target lesion using a voxel-wise prediction score generating a colormap-overlay in the T2w axial sequence. In classifying PCa and benign lesions, the explainable DLS achieved an accuracy of 85%, sensitivity (Sn) of 81%, and specificity (Sp) of 87% with an AUC of 90% indicative of a very good performance. Furthermore, the DLS demonstrated good performance in identifying 11 PI-RADS imaging features with an average accuracy of 84%, Sn 81% and Sp of 76%. Specifically, intensity-based features achieved a better accuracy and Sn (85% and 88%) compared to structural imaging features (82% and 72%), while the Sp were almost identical (75% and 76%).*Conclusions This study introduces a novel comprehensive explainable DLS that reliably detects and classifies suspicious prostatic lesions on bpMRI. Thereby, it overcomes the traditional black box design of previous deep neural networks by explaining and visualizing its decision-making using PI-RADS imaging features in a custom interface.*Clinical Relevance/Application This explainable DLS approach for prostate MRI provides a transparent decision support tool for radiologists, which can potentially enhance the acceptance and facilitate the translation of artificial intelligence into the clinical routine.

RESULTS

The DLS reliably detected the target lesion using a voxel-wise prediction score generating a colormap-overlay in the T2w axial sequence. In classifying PCa and benign lesions, the explainable DLS achieved an accuracy of 85%, sensitivity (Sn) of 81%, and specificity (Sp) of 87% with an AUC of 90% indicative of a very good performance. Furthermore, the DLS demonstrated good performance in identifying 11 PI-RADS imaging features with an average accuracy of 84%, Sn 81% and Sp of 76%. Specifically, intensity-based features achieved a better accuracy and Sn (85% and 88%) compared to structural imaging features (82% and 72%), while the Sp were almost identical (75% and 76%).

CLINICAL RELEVANCE/APPLICATION

This explainable DLS approach for prostate MRI provides a transparent decision support tool for radiologists, which can potentially enhance the acceptance and facilitate the translation of artificial intelligence into the clinical routine.

SSGU05-6   Comprehensive Analysis Of MR-Based Imaging Characteristics Of Prostate Lesions Against PIRADS Assessment Guideline And Correlations With Gleason Scores

Participants
Marwan Sati, PhD, Mississauga, Ontario (*Presenter*) Employee, IBM Corporation

PURPOSE

To cross validate appearance of prostate lesions in magnetic resonance (MR) images against PIRADS guideline and investigate correlations with pathological findings.*Methods and Materials Our dataset comprises of 1381 lesions identified in bi- or multi-parametric MR images of 930 patients collected from 6 centers in 4 countries using 23 different MR machines (1.5T and 3T) and variety of acquisition parameters (ex. slice/pixel spacing, repetition time, echo time, etc.). We employed single-read protocol and asked 4 experienced radiologists to use dense contours for annotating each lesion in every sequence (T2w, DWI, and DCE if available) and follow PIRADS v2.1 guideline strictly, for assigning labels. Radiologists had an option to not annotate PIRADS 1&2 and especially BPH lesions. The labels comprise of PIRADS score, zone, morphology (focal (F), encapsulated (E), round (R), linear/wedge (L), focal+round (FR), focal+round+encapsulated (FRE)), homogeneity (homogeneous (H), inhomogeneous (I)), intensity (hyper-(HPER) and hypo-intense (HPO), moderately hyper- (MHPER) and hypo-intense (MHPO)), and margin (circumscribed (C), non-circumscribed (NC)). In addition, the Gleason scores for 369 lesions from 272 patients were assigned using pathology reports driven from either targeted biopsy or prostatectomy. The pathology reports were not accessible by radiologists during annotations to ensure unbiased PIRADS scoring. Once they were revealed, the radiologists could not change the PIRADS scores or any other labels.*Results Our results demonstrate good correlation between PIRADS and Gleason scores through lesion imaging characteristics intensity as shown in table, which substantiates effectiveness of PIRADS guidelines for identifying prostate clinically significant lesions. In particular, the correlation is found to be significant when malignant lesions are considered to be given PIRADS 4&5 and Gleason>=4+3 scores. As recommended by PIRADS v.2.1 guideline, focality and intensity are the most discriminative imaging features for lesion detection and malignancy assessment, which are corroborated in our pathological findings.*Conclusions Strictness of adherence to PIRADS v.2.1 criteria ensures good agreement with Gleason scores and performance reproducibility across different MR scanners, protocols, and readers.*Clinical Relevance/Application Since advanced artificial intelligence (AI) algorithms and especially deep learning models are viable solutions for learning and strictly applying PIRAD criteria, it is expected that AI could play a major role in prostate cancer assessment.

RESULTS

Our results demonstrate good correlation between PIRADS and Gleason scores through lesion imaging characteristics intensity as shown in table, which substantiates effectiveness of PIRADS guidelines for identifying prostate clinically significant lesions. In particular, the correlation is found to be significant when malignant lesions are considered to be given PIRADS 4&5 and Gleason>=4+3 scores. As recommended by PIRADS v.2.1 guideline, focality and intensity are the most discriminative imaging features for lesion detection and malignancy assessment, which are corroborated in our pathological findings.

CLINICAL RELEVANCE/APPLICATION

Since advanced artificial intelligence (AI) algorithms and especially deep learning models are viable solutions for learning and strictly applying PIRAD criteria, it is expected that AI could play a major role in prostate cancer assessment.

SSGI04-1 Comparison Of The Accuracy Of 3.0T MRI And CT In Evaluating Resectability Of Locally Advanced Esophageal Squamous Cell Carcinoma

Participants
Keke Zhao, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

The accuracy of 3.0T MRI and CT in evaluating whether locally advanced ESCC invading aorta, tracheobronchial was compared to determine the resectability of tumor.*Methods and Materials Patients with ESCC pathologically confirmed by biopsy from November 2018 to November 2020 were prospectively enrolled, both MRI and CT were acquired within one week before tracheoscopy or surgery. The MRI scanning sequences included BLADE-TSE-T2WI,DWI and post-contrast enhanced Star-VIBE. Two readers evaluated whether the aorta, tracheobronchial were invaded by MRI and CT images using double-blind method independently. The inter-reader agreement between two readers were calculated using Kappa test. Combined intra-reader observation and post-operative pathological or fiberobronchoscopy as the gold standard, the sensitivity, specificity and accuracy of MRI and CT evaluated ESCC invaded aorta, tracheobronchial were calculated respectively and analyzed by Fisher's exact test.*Results A total of 37 patients were enrolled, the inter-reader agreement of the results by two readers were excellent (Kappa=0.87, p<0.05), the accuracy of MRI evaluated ESCC invading aorta, tracheobronchial were 90.0%, 83.3 %, respectively, and the CT results were 40.0%, 23.3%, respectively. The difference between two techniques was statistically significant (p<0.05).*Conclusions The accuracy of MRI in determining whether ESCC invading aorta, tracheobronchial is significantly higher than CT, which could better judge the resectability of the tumor.*Clinical Relevance/Application The study suggests that preoperative MRI examination can better judge whether locally advanced ESCC invading aorta, tracheobronchial, therefore, MRI can better guide the selection of clinical treatment methods for locally advanced ESCC.

RESULTS

A total of 37 patients were enrolled, the inter-reader agreement of the results by two readers were excellent (Kappa=0.87, p<0.05), the accuracy of MRI evaluated ESCC invading aorta, tracheobronchial were 90.0%, 83.3 %, respectively, and the CT results were 40.0%, 23.3%, respectively. The difference between two techniques was statistically significant (p<0.05).

CLINICAL RELEVANCE/APPLICATION

The study suggests that preoperative MRI examination can better judge whether locally advanced ESCC invading aorta, tracheobronchial, therefore, MRI can better guide the selection of clinical treatment methods for locally advanced ESCC.

SSGI04-2 Accuracy Of CT For Metastatic Lymph Nodes Detection In Gastric Adenocarcinoma

Participants
Chiara Zanon, MD,MS, Padova, Italy (*Presenter*) Nothing to Disclose

PURPOSE

to investigate which is the most accurate Computed Tomography (CT) measurement technique for metastatic lymph node (LN) detection in patients affected by gastric adenocarcinoma.*Methods and Materials 107 patients (F=38, median age: 74,5; M= 69, median age 76,7; range 35 - 98 years) affected by gastric adenocarcinoma were retrospectively enrolled. 443 nodal groups were harvested during surgery and subsequently analyzed at histopathology. Contrast-enhanced CTs at diagnosis were jointly reviewed by two expert radiologists, including only loco-regional LNs with a short axis (SA) = 5 mm.In each node group, largest lymph node's SA, volume and SA/long axis (LA) ratio, together with SAs sum and SAs/LAs average ratio were plotted in ROC curves, comparing as control the presence/absence of metastasis at histopathology. SAs sum of all LNs per group and the sum of SAs, volumes and SA/LA of the largest LNs per group were also plotted with ROC curve.*Results 173/443 of the nodal groups proved to be metastatic at histopathology. 64/107 patients had at least one metastatic nodal group. On a nodal group-basis the sum of the SAs showed the best AUC (0.721; 95% CI: 0.677-0.762) with sensitivity of 62.4% and a specificity of 72.6% at Youden's index analysis with a >8 mm cut-off. In the per patient analysis the sum of the SAs of all the LNs in the nodal groups showed the best AUC (0.787; 95% CI: 0.697-0.860) with a sensitivity of 65.6% and a specificity of 83.7% at Youden's index analysis with a >39 mm cut-off.*Conclusions the sum of the SAs of the LNs is the best predictor both of metastatic invasion of the nodal group and of the presence of metastatic LNs in the patient.*Clinical Relevance/Application This paper highlights the important role of CT in predicting lymph nodes metastasis in patient with gastric adenocarcinoma. The SAs sum of the loco regional LNs is the most accurate predictor.

RESULTS

173/443 of the nodal groups proved to be metastatic at histopathology. 64/107 patients had at least one metastatic nodal group.

On a nodal group-basis the sum of the SAs showed the best AUC (0.721; 95% CI: 0.677-0.762) with sensitivity of 62.4% and a specificity of 72.6% at Youden's index analysis with a >8 mm cut-off. In the per patient analysis the sum of the SAs of all the LNs in the nodal groups showed the best AUC (0.787; 95% CI: 0.697-0.860) with a sensitivity of 65.6% and a specificity of 83.7% at Youden's index analysis with a >39 mm cut-off.

CLINICAL RELEVANCE/APPLICATION

This paper highlights the important role of CT in predicting lymph nodes metastasis in patient with gastric adenocarcinoma. The SAs sum of the loco regional LNs is the most accurate predictor.

SSGI04-3   The Value Of DWI And DCE-MRI Quantitive Parameters In Predicting HER2 Status Of Gastric Cancer

Participants
Xiao Zhang JR, BMedSc, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

To explore the value of the quantitive parameters of difusion weighted imaging (DWI) and dynamic contrast enhancement MRI (DCE-MRI) in evaluating the status of HER2 in gastric.*Methods and Materials The clinical and imaging data of 67 patients with gastric cancer confirmed by pathology were retrospectively analyzed. The DWI and DCE-MRI images before surgery were analyzed. Quantitative paremeters including the mean, minimum and maximum of ADC (ADCmean, ADCmin, ADCmax) of DWI and Ktrans, Kep and Ve of DCE-MRI were obtained. According to the results of HER2 immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH), the patients were divided into HER2 negative group (IHC0 or IHC1+ or IHC2+/FISH-positive) and HER2 positive group (IHC3+ or IHC2+/FISH-negative). Mann-Whitney U test was used to compare the quantitative parameters between the two groups. The efficacy of identifying HER2 status was determined by receiver operating characteristic (ROC) curves.*Results There were 49 patients in the HER2 negative group and 18 patients in the HER2 positive group. The values of ADCmean, ADCmax, Ktrans and Kep in the HER2 positive group were significantly higher than those in the HER2 negative group (P < 0.05). ROC curves showed that the area under the curve (AUC) of Ktrans was the largest (AUC=0.870), followed by ADCmax (AUC=0.849). The diagnostic efficiency of Ktrans combined with ADCmax was higher than that of Ktrans or ADCmax alone. The AUC was 0.940 and sensitivity and specificity were 94.4% and 89.8%, respectively.*Conclusions Quantitative parameters of DWI and DCE-MRI are benifical to evaluate the status of HER2 in gastric cancer. Ktrans shows the highest diagnostic efficacy and the combination of Ktrans and ADCmax can improve the predictive efficacy.*Clinical Relevance/Application HER2 is one of the most interesting biomarkers for targeted therapy of gastric cancer. HER2 status should be repeatedly detected after tumor recurrence or metastasis and before second-line HER2-targeted therapy due to HER2 status may change during the treatment. However, it is not feasible in clinical practice to reassess the HER2 status through tissue biopsies. Therefore, a non-invasive method is needed to monitor HER2 status.

RESULTS

There were 49 patients in the HER2 negative group and 18 patients in the HER2 positive group. The values of ADCmean, ADCmax, Ktrans and Kep in the HER2 positive group were significantly higher than those in the HER2 negative group (P < 0.05). ROC curves showed that the area under the curve (AUC) of Ktrans was the largest (AUC=0.870), followed by ADCmax (AUC=0.849). The diagnostic efficiency of Ktrans combined with ADCmax was higher than that of Ktrans or ADCmax alone. The AUC was 0.940 and sensitivity and specificity were 94.4% and 89.8%, respectively.

CLINICAL RELEVANCE/APPLICATION

HER2 is one of the most interesting biomarkers for targeted therapy of gastric cancer. HER2 status should be repeatedly detected after tumor recurrence or metastasis and before second-line HER2-targeted therapy due to HER2 status may change during the treatment. However, it is not feasible in clinical practice to reassess the HER2 status through tissue biopsies. Therefore, a non-invasive method is needed to monitor HER2 status.

SSGI04-4   Body Composition, Treatment Tolerance, And Mortality In Patients With Esophageal And Gastric Adenocarcinoma

Participants
Mariana Defreitas, MD, Durham, North Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To assess the relationship between patient features, body composition imaging features, tumor features, and clinical outcomes (including neoadjuvant treatment tolerance and mortality) in patients with esophageal and gastric adenocarcinoma.*Methods and Materials 142 patients were retrospectively identified with biopsy-proven esophageal or gastric adenocarcinoma and available pretreatment CT scans who had received neoadjuvant treatment. Electronic medical records were reviewed to obtain: patient specific data (age, gender, body mass index, and mortality), tumor specific data (location and stage), and neoadjuvant chemotherapy strategy (low, medium, and high toxicity). Staging CTs were analyzed for body composition using a deep learning semantic segmentation algorithm based on the nnU-Net framework. Cross-sectional areas of muscle, visceral adipose tissue, and subcutaneous adipose tissue were measured at the level of the L3 vertebral body. Skeletal muscle index (SMI) was calculated as muscle area/height2. Univariate analyses (t-tests for continuous variables and chi-squared tests for categorical variables) were performed between the clinical and imaging features and the following outcomes: neoadjuvant therapy breaks and dose reductions, early termination of neoadjuvant therapy, hospitalization and emergency department visits during neoadjuvant therapy, surgical candidacy after neoadjuvant therapy, and all-cause mortality. The Bonferroni-Holm method was used to correct for multiple comparisons.*Results The 142 patients included 30 females and 112 males. Average age at diagnosis was 64 years (range 21-88), and average body mass index was 27.8 kg/m2 (range 16-48). Cancer stages at the time of diagnosis varied from stage I through stage IV, with the majority of cases being stage III (94 patients). After correction for multiple comparisons, higher age was associated with more neoadjuvant therapy breaks (p=0.04) and decreased likelihood of surgical candidacy (p=0.001). Lower muscle area was associated with more neoadjuvant therapy breaks (p=0.05). Lower SMI was associated with more chemotherapy breaks (p=0.04) and decreased survival (p=0.03).*Conclusions CT-based measures of skeletal muscle index may be independent predictors of chemotherapy tolerance and mortality in patients with esophageal or gastric adenocarcinoma.*Clinical Relevance/Application Current methods for treatment planning for esophageal and gastric adenocarcinoma take into consideration subjective clinical assessments of functional status. Establishing the relationship of other patient specific factors, such as body composition, and adverse clinical outcomes (including poor neoadjuvant chemotherapy tolerance) can supplement these methods.

RESULTS

The 142 patients included 30 females and 112 males. Average age at diagnosis was 64 years (range 21-88), and average body

mass index was 27.8 kg/m2 (range 16-48). Cancer stages at the time of diagnosis varied from stage I through stage IV, with the majority of cases being stage III (94 patients). After correction for multiple comparisons, higher age was associated with more neoadjuvant therapy breaks (p=0.04) and decreased likelihood of surgical candidacy (p=0.001). Lower muscle area was associated with more neoadjuvant therapy breaks (p=0.05). Lower SMI was associated with more chemotherapy breaks (p=0.04) and decreased survival (p=0.03).

CLINICAL RELEVANCE/APPLICATION

Current methods for treatment planning for esophageal and gastric adenocarcinoma take into consideration subjective clinical assessments of functional status. Establishing the relationship of other patient specific factors, such as body composition, and adverse clinical outcomes (including poor neoadjuvant chemotherapy tolerance) can supplement these methods.

SSMS05-1   Lung Nodule Detection In Whole Body Trauma CT: Is AI Leading The Way Out Of A Diagnostic Dilemma?

Participants
Thorsten Fleiter, MD, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Whole body computer tomography (WBCT) is the standard imaging tool for the assessment of poly-trauma patients. The indications for WBCT broadened with the availability of faster and dose efficient CT scanners challenging the radiologists to generate a final report in 15-20 min - increasing the risk to miss incidental findings like lung nodule. AI algorithms for lung nodules detection within this time window became recently available. The purpose of the study is therefore to compare AI lung nodule detection with nodules reported by trauma radiologists.*Methods and Materials 150 WBCT of acute trauma patients (Age 77-86) were analyzed using a two-step AI system with initial nodule candidate generation and consecutive false positive reduction (Siemens, Princeton, NJ). Only non-calcified nodules >=4mm were included. The AI algorithm reviewed the exact same images as the radiologist. The algorithm returned location and size (2D+3D recist) of the detected nodules. The results were compared to the final radiologist reports. Time of the report and the radiologist ID were recorded. All AI results were reviewed and verified by trauma radiologists with > 10 year experience. Standard statistical tests were applied.*Results The radiologists reported 14 lung nodules versus 76 detected and verified by the AI system (p<0.001) The radiologist reports were correct for 77 of the performed WBCT versus 114 for the AI system (correct positive and negative for lung nodules) (P<0.001). There was no correlation between the time of the WBCT (day/night), reading radiologists and the number of missed lung nodules. There was no significant difference regarding location and size of missed nodules. The largest diameter of nodules not mentioned in the radiologist report was (2D recist) 2.9 cm in the apex of the right upper lobe, 3.7 cm in the right hilum, 2.3 cm in the left upper lobe and 2.7 cm in the left lower lobe. 3 false negative findings for the AI system included 2x6mm solid nodules and a 1.2 cm ground glass lesion in the left upper lobe. There were positive findings for the algorithm due to scars (4), contusions (2), exostosis/fracture of ribs (5) + sternum (2), and the diaphragm (1).*Conclusions The AI driven algorithm detected a significant number of additional actionable lung nodules that were not mentioned in the original WBCT reports revealing the under-reporting of this incidental finding in standard trauma imaging. There was no correlation between the reading radiologists and the number of missed lung nodules - indicating that missing lung nodules in acute trauma scans is likely a systematic issue.*Clinical Relevance/Application Fast AI algorithms have the potential to significantly improve the detection of lung nodules as incidental finding in whole body trauma CT

RESULTS

The radiologists reported 14 lung nodules versus 76 detected and verified by the AI system (p<0.001) The radiologist reports were correct for 77 of the performed WBCT versus 114 for the AI system (correct positive and negative for lung nodules) (P<0.001). There was no correlation between the time of the WBCT (day/night), reading radiologists and the number of missed lung nodules. There was no significant difference regarding location and size of missed nodules. The largest diameter of nodules not mentioned in the radiologist report was (2D recist) 2.9 cm in the apex of the right upper lobe, 3.7 cm in the right hilum, 2.3 cm in the left upper lobe and 2.7 cm in the left lower lobe. 3 false negative findings for the AI system included 2x6mm solid nodules and a 1.2 cm ground glass lesion in the left upper lobe. There were positive findings for the algorithm due to scars (4), contusions (2), exostosis/fracture of ribs (5) + sternum (2), and the diaphragm (1).

CLINICAL RELEVANCE/APPLICATION

Fast AI algorithms have the potential to significantly improve the detection of lung nodules as incidental finding in whole body trauma CT

SSMS05-2   Correlation Of Body Mass Index With Cervical Prevertebral Soft Tissue Thickness

Participants
John Schilling, MD, Chicago, Illinois (*Presenter*) Nothing to Disclose

PURPOSE

Radiologists rely on normative values including upper limits of normal for cervical prevertebral soft tissue thickness (PSTT) to aid in detection of osseous or soft tissue injuries in the setting of neck trauma. Given the epidemic increase in obesity rates over multiple decades, evaluation of the effect of body habitus as measured by body mass index (BMI) on these normative values is needed to assess their reliability in obese patients.*Methods and Materials PSTT measurements were made retrospectively at C1, C2, C3, C6, and C7 in 166 patients who underwent computed tomography of the neck, after excluding patients with known or suspected pathology affecting PSTT. Mean PSTT was calculated within clinical BMI categories (normal, overweight, obese, and morbidly obese) and compared to normative values from the literature at each cervical level. A multiple linear regression analysis was

performed using BMI, age, and gender as predictive variables for PSTT.*Results The morbidly obese group had significantly increased mean PSTT compared to normative mean values from the literature at all measured cervical levels (p < 0.001 at C1, C2, C3, and C6; p < 0.05 at C7), and were near or above described upper limits of normal at C1, C2, and C3. Mean PSTT was also increased in the overweight group at C2 and C6 (p < 0.05) and obese group at C1, C2, and C3 (p < 0.001). Multiple linear regression found BMI was significantly associated with increased PSTT at all cervical levels (p < 0.001 at C1, C2, C3, and C6; p < 0.05 at C7). Male gender was also associated with increased PSTT at all levels except C3 (p < 0.001). BMI was the strongest predictor of PSTT in the regression model at all cervical levels when comparing standardized beta coefficients. PSTT was estimated to increase by approximately 1 mm for every increase of 10 in BMI.*Conclusions Increased BMI is associated with increased PSTT and is the strongest predictor of PSTT compared to age or gender. Established PSTT normative values may be unreliable in overweight and obese patients and are likely to produce increased false-positive results, particularly in the upper cervical spine and in morbidly obese patients. This unreliability is expected to worsen as obesity rates continue to increase. Further study is needed to assess whether BMI-corrected models improve the reliability and accuracy of these normative PSTT values.*Clinical Relevance/Application Cervical PSTT is an important indicator of osseous or soft tissue injury in the setting of trauma. The current study shows a significant effect of BMI on PSTT. Established normative PSTT values may not be reliable to assess obese patients who make up an increasingly larger percentage of the population.

RESULTS

The morbidly obese group had significantly increased mean PSTT compared to normative mean values from the literature at all measured cervical levels (p < 0.001 at C1, C2, C3, and C6; p < 0.05 at C7), and were near or above described upper limits of normal at C1, C2, and C3. Mean PSTT was also increased in the overweight group at C2 and C6 (p < 0.05) and obese group at C1, C2, and C3 (p < 0.001). Multiple linear regression found BMI was significantly associated with increased PSTT at all cervical levels (p < 0.001 at C1, C2, C3, and C6; p < 0.05 at C7). Male gender was also associated with increased PSTT at all levels except C3 (p < 0.001). BMI was the strongest predictor of PSTT in the regression model at all cervical levels when comparing standardized beta coefficients. PSTT was estimated to increase by approximately 1 mm for every increase of 10 in BMI.

CLINICAL RELEVANCE/APPLICATION

Cervical PSTT is an important indicator of osseous or soft tissue injury in the setting of trauma. The current study shows a significant effect of BMI on PSTT. Established normative PSTT values may not be reliable to assess obese patients who make up an increasingly larger percentage of the population.

SSMS05-3   Interpretable Identification Of Various Diseases In The Emergency Brain CTs Using Anomaly Detection With A Deep Neural Network Trained Only With Normal Brain CTs

Participants
Seungjun Lee, BS, Seoul, Korea, Republic Of (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate an anomaly detection algorithm using a deep neural network trained only with normal brain CTs for classifying emergency brain CTs with various diseases.*Methods and Materials We developed a Style-based Generative Adversarial Networks (StyleGAN2)-based model with a training set of 34,080 normal brain CTs collected from Asan Medical Center between January 1, 2000, and August 31, 2018. This model learns to reconstruct a 2D query image into a normal "style" image, then the reconstruction error quantifies the anomaly score to evaluate the severity of the query image, which also provides attention to lesions. 534 consecutive brain CTs comprised the internal validation set, collected from the emergency department of Asan Medical Center between February 1, 2019, and February 28, 2019. 1760 consecutive brain CTs comprised the external validation set, collected from Gangneung Asan Hospital between January 1, 2019, and May 31, 2019. The label of the severity of emergency brain CT scans was defined to request rapid or urgent interventions to the patients or not. Per-patient classification of the algorithm was assessed with the area under the receiver operating characteristic curve (AUC) and its results were analyzed according to the various diseases including tumor, acute infarction, intracranial hemorrhage, hydrocephalus, and others.*Results The AUC, sensitivity, specificity, and accuracy of this algorithm were 0.85, 0.84, 0.72, and 0.74, respectively in the internal validation, and 0.83, 0.78, 0.74, and 0.75, respectively in the external validation. According to the disease subgroups, AUCs of brain tumors, acute infarction, intracranial hemorrhage, hydrocephalus, and others were 0,92, 0.92, 0.80, 0.90, and 0.86, respectively in the internal validation, and 0.92, 0.89, 0.85, 0.90, and 0.78, respectively in the external validation.*Conclusions The anomaly detection with StyleGAN2-based deep learning algorithm could classify the emergency brain CTs with various diseases by learning only normal data distribution and showed more than moderate performance, which could be more robust in the actual clinical situation.*Clinical Relevance/Application The anomaly detection model could be useful for screening and triaging emergency patients with various diseases by detecting emergency anomalies on brain CTs.

RESULTS

The AUC, sensitivity, specificity, and accuracy of this algorithm were 0.85, 0.84, 0.72, and 0.74, respectively in the internal validation, and 0.83, 0.78, 0.74, and 0.75, respectively in the external validation. According to the disease subgroups, AUCs of brain tumors, acute infarction, intracranial hemorrhage, hydrocephalus, and others were 0,92, 0.92, 0.80, 0.90, and 0.86, respectively in the internal validation, and 0.92, 0.89, 0.85, 0.90, and 0.78, respectively in the external validation.

CLINICAL RELEVANCE/APPLICATION

The anomaly detection model could be useful for screening and triaging emergency patients with various diseases by detecting emergency anomalies on brain CTs.

SSMS05-4   Blunt Splenic Trauma: Volumetric Measurements Of Hemoperitoneum Predict Failure Of Non-operative Management In Patients Followed With CT

Participants
Theresa Yu, BA, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Follow-up CT may be used to monitor hemodynamically stable patients selected for non-operative management (NOM) along with serial hemoglobin (Hgb). Prior work has shown that changes on follow-up CT may warrant splenectomy, with emphasis on subjective hemoperitoneum grading. We assess quantitative measurements of hemoperitoneum (HPvol), subcapsular hematoma (SCHvol), and splenic laceration (LACvol) for the outcome of splenic salvage vs splenectomy.*Methods and Materials All adult patients who underwent a trial of non-operative management with at least one follow-up CT between 2017-2019 were included (n=60).

Splenectomy was performed in 7 pts. Voxelwise measurements of HPvol, SCHvol, and LACvol were derived from PVP images of initial and follow-up scans using 3D slicer. ? in volume/day, final volume, new or persistent pseudoaneurysm (PSA), and change in Hgb were assessed. Independent predictors of decision to perform splenectomy were determined with logistic regression.*Results Univariate predictors (p<0.05) included final HPvol, final SCHvol, and new/persistent PSA. Independent predictors in logistic regression were final HPvol (ß= 0.003—units of the regression coefficient: ? in log odds of splenectomy/mL hemoperitoneum, p= 0.012) and PSA (p= 0.018). With PSA held constant, increases in follow-up hemoperitoneum volume of 200, 400, 800, and 1200 mL increased the odds of splenectomy by 82%, 232%, 1002%, and 3560% respectively. New or persistent PSA was present on follow-up in 5/7 splenectomy patients, but also present in 17/60 patients with splenic salvage. AUC of hemoperitoneum, PSA, and the model incorporating both variables was 0.87, 0.74, and 0.90.*Conclusions Hemoperitoneum volume (in mL) on follow-up CT was the most important predictor of splenectomy. New or persistent PSA was also significant but was present in 17 of 60 (28%) of patients with successful splenic salvage and is not an absolute determinant of need for splenectomy.*Clinical Relevance/Application HP volume complements identification of new or persistent PSA as an objective granular quantitative imaging biomarker for predicting splenectomy versus salvage on follow-up CTs in patients trialed with NOM.

RESULTS

Univariate predictors (p<0.05) included final HPvol, final SCHvol, and new/persistent PSA. Independent predictors in logistic regression were final HPvol (ß= 0.003—units of the regression coefficient: ? in log odds of splenectomy/mL hemoperitoneum, p= 0.012) and PSA (p= 0.018). With PSA held constant, increases in follow-up hemoperitoneum volume of 200, 400, 800, and 1200 mL increased the odds of splenectomy by 82%, 232%, 1002%, and 3560% respectively. New or persistent PSA was present on follow-up in 5/7 splenectomy patients, but also present in 17/60 patients with splenic salvage. AUC of hemoperitoneum, PSA, and the model incorporating both variables was 0.87, 0.74, and 0.90.

CLINICAL RELEVANCE/APPLICATION

HP volume complements identification of new or persistent PSA as an objective granular quantitative imaging biomarker for predicting splenectomy versus salvage on follow-up CTs in patients trialed with NOM.

SSMS05-5 COVID-19 Resource Utilization Prediction Using Fusion AI Model

Participants
Imon Banerjee, Atlanta, Georgia (*Presenter*) Nothing to Disclose

PURPOSE

Strain on healthcare resources brought forth by recent COVID-19 pandemic has highlighted the need for efficient planning and allocation through prediction of future consumption. Machine learning can predict resource utilization such as the need for hospitalization based on past medical data stored in electronic medical records (EMR).*Methods and Materials We conducted this study on 3194 patients (46% male with mean age 56.7 (+/-16.8), 56% African American, 7% Hispanic) flagged as COVID-19 positive cases in 12 centers under Emory Healthcare network from February 2020 to September 2020. We designed our fusion learning experiments to be able to predict whether a patient who is COVID-19 positive will need hospitalization after testing positive for COVID-19. Past medical information prior to COVID-19 testing was used as features for predictive modeling which includes demographic, medication, past medical procedures, comorbidities, and laboratory results. Models were evaluated in terms of precision, recall, F1-score (within 95% confidence interval).*Results Fusion models (late, middle and early) predict whether a patient will need hospitalization at some point after infection, with early fusion being the most effective with 84% overall F1-score [CI 82.1-86.1] and 0.92 AUROC. The predictive performance of the model drops by 6 % when clinical data only from the recent past is used, omitting the long-term medical history. Feature importance analysis indicates that history of cardiovascular disease, emergency room visits in the past year prior to testing, and demographic factors are predictive of disease trajectory of COVID-19 patients.*Conclusions With fusion predictive modeling, past medical history and current treatment data can be used to efficiently forecast the need for hospitalization for patients infected with COVID-19 at the time of RT-PCR test which shows that the medical history can predict whether a patient will be asymptomatic or require hospitalization after COVID-19 infection.*Clinical Relevance/Application Fusion based AI models that combine comprehensive information from various types of data available in the electronic medical record (EMR) such as demographic, past medication and procedures, comorbidities and laboratory results, can predict future events like the need for hospitalization for patients infected with COVID-19. In contrast with other published works, our models solely rely on historical information generated before RT-PCR testing. Moreover, our investigation of feature importance of such models reveals important factors that determine patient response to SARS-CoV-2 virus.

RESULTS

Fusion models (late, middle and early) predict whether a patient will need hospitalization at some point after infection, with early fusion being the most effective with 84% overall F1-score [CI 82.1-86.1] and 0.92 AUROC. The predictive performance of the model drops by 6 % when clinical data only from the recent past is used, omitting the long-term medical history. Feature importance analysis indicates that history of cardiovascular disease, emergency room visits in the past year prior to testing, and demographic factors are predictive of disease trajectory of COVID-19 patients.

CLINICAL RELEVANCE/APPLICATION

Fusion based AI models that combine comprehensive information from various types of data available in the electronic medical record (EMR) such as demographic, past medication and procedures, comorbidities and laboratory results, can predict future events like the need for hospitalization for patients infected with COVID-19. In contrast with other published works, our models solely rely on historical information generated before RT-PCR testing. Moreover, our investigation of feature importance of such models reveals important factors that determine patient response to SARS-CoV-2 virus.

SSMS05-6 Can Dual-Energy Marrow Imaging And Cinematic Rendering Improve Pelvic Fracture Severity Grading?

Participants
Theresa Yu, BA, Baltimore, Maryland (*Presenter*) Nothing to Disclose

PURPOSE

Instability grading after pelvic fractures is challenging, and instability is further obscured by pelvic binders. Dual energy CT (DECT) marrow imaging and cinematic rendering can provide MRI-like ancillary information regarding osteoligamentous integrity, however, the added utility for classifying pelvic fracture severity for these post-processing tools remain unknown. We compare performance of conventional CT imaging (group 1), CT + marrow imaging (group 2), and CT + marrow imaging + cinematic rendering (CR) (group

3) for classification of pelvic instability in a cohort of patients with pelvic binders.*Methods and Materials 54 consecutive adult patients with pelvic binders scanned in dual energy mode using a 128-section Siemens SOMATOM Force scanner were included. Young-Burgess (YB) grading by orthopedists served as the reference standard. Two radiologists performed blinded consensus review in three reading sessions as above, spaced one month apart. LC-1 and APC-1 injuries were considered stable, LC-2 and APC-2 rotationally unstable, and LC-3, APC-3, and VS vertically/globally unstable. Diagnostic performance for predicting rotational and vertical instability was assessed.*Results AUC under the ROC curve for instability grading overall was 'poor' with conventional CT (0.67). AUC increased to 'fair' (0.75) with the addition of marrow imaging, and to 'good' (0.82) with further addition of CR. Vertical instability (VI) was associated with decision to perform pelvic packing and angioembolization and subanalysis of presence/absence of VI is emphasized. AUC for VI increased from 0.80 (group 1), to 0.91 (group 2), to 0.95 (group 3) (p = 0.037 for marrow + CR vs CT only). Sensitivity increased from 67% to 87% to 93%. Specificity increased from 92% to 95%, to 97%. +LR (36.4) and -LR (0.07) were in the strong/conclusive range. Weighted kappa between radiologist and orthopedist grade increased from 0.44 to 0.64 to 0.76.*Conclusions The combined use of marrow imaging and CR improved instability assessment over conventional CT. In the future, these tools may potentially improve triage to angioembolization and pelvic packing.*Clinical Relevance/Application DECT marrow imaging and cinematic rendering improves instability grading of pelvic fractures obscured by pelvic binders when compared to conventional CT.

RESULTS

AUC under the ROC curve for instability grading overall was 'poor' with conventional CT (0.67). AUC increased to 'fair' (0.75) with the addition of marrow imaging, and to 'good' (0.82) with further addition of CR. Vertical instability (VI) was associated with decision to perform pelvic packing and angioembolization and subanalysis of presence/absence of VI is emphasized. AUC for VI increased from 0.80 (group 1), to 0.91 (group 2), to 0.95 (group 3) (p = 0.037 for marrow + CR vs CT only). Sensitivity increased from 67% to 87% to 93%. Specificity increased from 92% to 95%, to 97%. +LR (36.4) and -LR (0.07) were in the strong/conclusive range. Weighted kappa between radiologist and orthopedist grade increased from 0.44 to 0.64 to 0.76.

CLINICAL RELEVANCE/APPLICATION

DECT marrow imaging and cinematic rendering improves instability grading of pelvic fractures obscured by pelvic binders when compared to conventional CT.

SSMS05-7　A Systematic Review Of The Incidence Of Hypersensitivity Reactions And Post-contrast Acute Kidney Injury After Intravenous Administration Of Ioversol In More Than 57,000 Patients

Participants
Aart J. van der Molen, MD, Bennebroek, Netherlands (*Presenter*) Consultant, Guerbet SA;Author with royalties, Thieme Medical Publishers, Inc

PURPOSE

The aim of this systematic review was to evaluate the incidence of adverse drug reactions (ADRs), including hypersensitivity reactions (HSRs) and post-contrast acute kidney injury (PC-AKI), after intravenous (IV) administration of ioversol, and to position its safety profile among different iodinated contrast media (ICM).*Methods and Materials A systematic literature search was performed (1989-2021) and studies documenting IV use of ioversol and presence or absence of ADRs, HSRs or PC-AKI were selected. Key information including patients' characteristics, indication and dose of ioversol, safety outcome incidence, intensity and seriousness were extracted. When available, data on other ICM from comparative studies were also extracted.*Results Fifteen studies were selected, including two on pediatric patients, with more than 57000 patients (including 13419 pediatric patients). The reported incidences were 0.13%-0.28% for ADRs (3 studies), 0.20-0.66% for HSRs (2 studies), 0.23-1.80% for acute events (4 studies). Severe reactions were rare (0-0.02%), and none were reported amongst pediatric patients. Incidence of ADRs and HSRs with ioversol, especially those of severe intensity, was among the lowest compared to other ICM of the same class. PC-AKI incidence was variable (1-42% in 5 studies), depending on study population and definition of PC-AKI used. Ioversol exposure per se did not increase PC-AKI incidence.*Conclusions When administered by IV route, ioversol has a low incidence of severe / serious ADRs overall, and particularly HSRs. In patients receiving ioversol IV, PC-AKI incidence does not seem to be increased compared to patients who did not receive ioversol.*Clinical Relevance/Application When appropriately used, ioversol has a good safety profile comparable to other ICM within the same class

RESULTS

Fifteen studies were selected, including two on pediatric patients, with more than 57000 patients (including 13419 pediatric patients). The reported incidences were 0.13%-0.28% for ADRs (3 studies), 0.20-0.66% for HSRs (2 studies), 0.23-1.80% for acute events (4 studies). Severe reactions were rare (0-0.02%), and none were reported amongst pediatric patients. Incidence of ADRs and HSRs with ioversol, especially those of severe intensity, was among the lowest compared to other ICM of the same class. PC-AKI incidence was variable (1-42% in 5 studies), depending on study population and definition of PC-AKI used. Ioversol exposure per se did not increase PC-AKI incidence.

CLINICAL RELEVANCE/APPLICATION

When appropriately used, ioversol has a good safety profile comparable to other ICM within the same class

SSMK09-1 A Fully Automated Pipeline For Multi-vertebral Level Quantification And Characterization Of Muscle And Adipose Tissue On Chest Computed Tomography

Participants

Christopher Bridge, Boston, Massachusetts (*Presenter*) Institutional support, NVIDIA Corporation;Institutional support, General Electric Company;Institutional support, Nuance Communications, Inc

PURPOSE

To broaden the applicability of automated body composition analysis to chest imaging by developing and validating a fully automated analysis pipeline for multi-vertebral level quantification and characterization of muscle and adipose tissue on routine chest CT.*Methods and Materials We developed a slice-selection network (DenseNet) to identify single axial images at the level of the 5th, 8th, and 10th thoracic vertebral bodies and a segmentation network (U-Net) to identify pixels representing muscle and adipose tissue on these images. Training used ground truth from radiologist-guided manual level selection and segmentation. Our dataset consisted of 629 chest CT scans from 629 patients (55% female, mean±SD age 67±10 years) with lung cancer at three institutions obtained between 2014 and 2017. 471 scans were used for training, 63 for validation, and 94 for testing. 87% of patients had early-stage lung cancer and mean±SD body mass index was 27±5kg/m2. 37 different scanners from 4 manufacturers were represented in the dataset; 56% with intravenous contrast; slice thickness range 1.25mm-5mm; peak tube voltage range 80kV-140kV. We tested each network individually and the full pipeline (slice-selection + segmentation networks). We assessed predictive performance of cross-sectional area (CSA, in cm2) and attenuation in Hounsfield units (HU) for all combinations of tissue, vertebral body level, measurement, and network. We performed root cause analysis for outliers identified with the two-sided Grubbs test.*Results In the full pipeline, median absolute error, and intra-class correlation coefficients (ICCs) for both tissues were 3.6% (IQR 1.3-7.0%) and 0.959-0.998 for CSA, and 1.0 HU (IQR 0.0- 2.0HU) and 0.95-0.99 for median attenuation. The performance of the segmentation network on the ground-truth slice was higher than on the automatically-selected slice, with ICCs>0.99 for CSA and attenuation. In the slice selection network, median absolute error was 7.5mm (IQR 3.3-12.6mm). All outliers of the full pipeline were due to slice selection.*Conclusions We demonstrate accurate and reliable fully automated quantification and characterization of muscle and adipose tissue at multiple thoracic levels on routine chest CT.*Clinical Relevance/Application Recent work has demonstrated that body composition analysis of routine chest CT can inform pre-operative risk assessment in patients with lung cancer. Automation makes clinical translation feasible.

RESULTS

In the full pipeline, median absolute error, and intra-class correlation coefficients (ICCs) for both tissues were 3.6% (IQR 1.3-7.0%) and 0.959-0.998 for CSA, and 1.0 HU (IQR 0.0- 2.0HU) and 0.95-0.99 for median attenuation. The performance of the segmentation network on the ground-truth slice was higher than on the automatically-selected slice, with ICCs>0.99 for CSA and attenuation. In the slice selection network, median absolute error was 7.5mm (IQR 3.3-12.6mm). All outliers of the full pipeline were due to slice selection.

CLINICAL RELEVANCE/APPLICATION

Recent work has demonstrated that body composition analysis of routine chest CT can inform pre-operative risk assessment in patients with lung cancer. Automation makes clinical translation feasible.

SSMK09-2 Opportunistic CT Assessment Of Biological Aging: Comparing 2D Versus 3D Metrics For Muscle And Adipose Tissue

Participants

Robert Boutin, MD, Stanford, California (*Presenter*) Nothing to Disclose

PURPOSE

Fully-automated tissue segmentation is transitioning to clinical use, but there is a paucity of work comparing 2D vs 3D analysis of muscle and adipose tissue. Our objective was to compare standard cross-sectional (2D) and new volumetric (3D) segmentation methods for muscle and adipose tissue.*Methods and Materials An IRB-approved multi-institutional retrospective study of 110 oncology patients undergoing abdominopelvic CT was performed using a commercially available, CNN-based, fully-automated segmentation software (DAFS 3.0, Voronoi Health Analytics). 2D metrics obtained using a single axial image at the mid L3 level were muscle area (MA) and density (MD-2D), visceral adipose tissue area (VATA) and density (VATD-2D), and subcutaneous adipose tissue area (SATA) and density (SATD-2D). 3D metrics from the mid L1 to mid L5 level were muscle volume (MV) and density (MD-3D), visceral adipose tissue volume (VATV) and density (VATD-3D), and subcutaneous adipose tissue volume (SATV) and density

(SATD-3D). 18 cases were excluded due to CT image artifacts or segmentations errors based on independent review by two musculoskeletal radiologists. In the remaining 92 patients (57% M, 43% F; mean age, 63.2 years; mean BMI, 29.3), 2D and 3D metrics were compared using Pearson correlation coefficients (r) and mean absolute percent errors (%).*Results 2D tissue mean (SD) areas were MA = 128.7 cm2 (33.9), VATA = 184.2 cm2 (118.9), SATA = 231.7 cm2 (124.6); corresponding 3D mean (SD) volumes were MV = 40.0 cm3 (17.5), VATV = 62.4 cm3 (46.9), SATV = 75.4 cm3 (54.2). 2D tissue mean (SD) densities were MD-2D = 37.7 HU (10.3), VATD-2D = -89.9 HU (9.9), SATD-2D = -99.9 HU (6.9); corresponding 3D mean (SD) densities were MD-3D = 38.5 HU (10.1), VATD-3D = -87.2 HU (10.7), SATD-3D = -99.2 HU (6.9). All 2D metrics were highly correlated with corresponding 3D metrics, each at p < 0.001: MA vs MV, r=0.99; MD-2D vs MD-3D, r=0.98; VATA vs VATV, r=0.99; VATD-2D vs VATD-3D, r=0.98; SATA vs SATV, r=0.99; SATD-2D vs SATD-3D, r=0.98. Comparing 2D to 3D, the mean absolute percent errors were: MA vs MV, 3.1%; MD-2D vs MD-3D, 4.8%; VATA vs VATV, 9.5%; VATD-2D vs VATD-3D, 3.4%; SATA vs SATV, 4.9%; SATD-2D vs SATD-3D, 1.1%.*Conclusions 3D volumetric segmentations of muscle and adipose tissue are highly correlated with standard 2D areal segmentations. The least conserved metrics between 2D and 3D analyses are visceral adipose tissue area and volume. Further work is needed to determine if fully-automated 3D segmentations add value over 2D segmentations in predicting clinical outcomes.*Clinical Relevance/Application Fully-automated 3D segmentations of muscle and adipose tissue on CT are increasingly feasible, and provide another dimension for opportunistic biomarker measurements associated with biological aging.

RESULTS

2D tissue mean (SD) areas were MA = 128.7 cm2 (33.9), VATA = 184.2 cm2 (118.9), SATA = 231.7 cm2 (124.6); corresponding 3D mean (SD) volumes were MV = 40.0 cm3 (17.5), VATV = 62.4 cm3 (46.9), SATV = 75.4 cm3 (54.2). 2D tissue mean (SD) densities were MD-2D = 37.7 HU (10.3), VATD-2D = -89.9 HU (9.9), SATD-2D = -99.9 HU (6.9); corresponding 3D mean (SD) densities were MD-3D = 38.5 HU (10.1), VATD-3D = -87.2 HU (10.7), SATD-3D = -99.2 HU (6.9). All 2D metrics were highly correlated with corresponding 3D metrics, each at p < 0.001: MA vs MV, r=0.99; MD-2D vs MD-3D, r=0.98; VATA vs VATV, r=0.99; VATD-2D vs VATD-3D, r=0.98; SATA vs SATV, r=0.99; SATD-2D vs SATD-3D, r=0.98. Comparing 2D to 3D, the mean absolute percent errors were: MA vs MV, 3.1%; MD-2D vs MD-3D, 4.8%; VATA vs VATV, 9.5%; VATD-2D vs VATD-3D, 3.4%; SATA vs SATV, 4.9%; SATD-2D vs SATD-3D, 1.1%.

CLINICAL RELEVANCE/APPLICATION

Fully-automated 3D segmentations of muscle and adipose tissue on CT are increasingly feasible, and provide another dimension for opportunistic biomarker measurements associated with biological aging.

SSMK09-3   Diagnostic Accuracy Of Quantitative Dual-energy CT-based Volumetric Bone Mineral Density Assessment For The Prediction Of Osteoporosis-associated Fractures

Participants
Leon Gruenewald, Frankfurt am Main, Germany (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the predictive value of volumetric phantomless trabecular bone mineral density (BMD) assessment of the lumbar spine derived from dual-energy computed tomography (DECT)-based material decomposition as an indicator for the 2-year occurrence risk of osteoporosis-associated fractures.*Methods and Materials Lumbar vertebrae of 92 patients (46 men, 46 women; mean age, 64 years; range, 19-103 years) who had undergone third-generation dual-source DECT between January 2016 and December 2018 were retrospectively analyzed. For phantomless trabecular BMD assessment, dedicated DECT postprocessing software using material decomposition was applied. Digital files of all patients were sighted for 2 years following DECT to obtain the incidence of osteoporotic fractures. Receiver-operating characteristic (ROC) analysis was used to calculate cut-off values, and logistic regression models were applied to determine associations of BMD, sex and age with the occurrence of osteoporotic fractures.*Results A DECT-derived BMD cut-off value of 93.70 mg/cm³ yielded 85.45% sensitivity and 89.19% specificity for the prediction to sustain one or more osteoporosis-associated fractures within 2 years after BMD measurement. DECT-derived BMD was significantly associated with the occurrence of new fractures (Odds ratio of 0.8710, 95% CI, 0.091-0.9375, p < .001), indicating a protective effect of increased DECT-derived BMD values. Overall AUC was 0.9373 (CI, 0.867-0.977, p < .001) for the differentiation of patients that sustained osteoporosis-associated fractures within 2 years of BMD assessment. The regression model was statistically significant (p < .001) and showed high goodness of fit (ROC derived AUC = 0.962, CI, 0.900-0.991).*Conclusions Retrospective DECT-based volumetric trabecular BMD assessment of the lumbar spine can accurately predict the 2-year risk to sustain an osteoporosis-associated fracture in at risk patients without requiring a calibration phantom. Lower DECT-based BMD values are strongly associated with increased risk to sustain fragility fractures.*Clinical Relevance/Application Phantomless opportunistic DECT-based BMD assessment may reduce the social and economic burdens associated with osteoporosis by early identification of patients at risk to sustain an osteoporosis-associated fracture.

RESULTS

A DECT-derived BMD cut-off value of 93.70 mg/cm³ yielded 85.45% sensitivity and 89.19% specificity for the prediction to sustain one or more osteoporosis-associated fractures within 2 years after BMD measurement. DECT-derived BMD was significantly associated with the occurrence of new fractures (Odds ratio of 0.8710, 95% CI, 0.091-0.9375, p < .001), indicating a protective effect of increased DECT-derived BMD values. Overall AUC was 0.9373 (CI, 0.867-0.977, p < .001) for the differentiation of patients that sustained osteoporosis-associated fractures within 2 years of BMD assessment. The regression model was statistically significant (p < .001) and showed high goodness of fit (ROC derived AUC = 0.962, CI, 0.900-0.991).

CLINICAL RELEVANCE/APPLICATION

Phantomless opportunistic DECT-based BMD assessment may reduce the social and economic burdens associated with osteoporosis by early identification of patients at risk to sustain an osteoporosis-associated fracture.

SSMK09-4   Evaluation Of Deep-learning Reconstructed High-resolution 3D Lumbar Spine MRI To Improve Image Quality

Participants
Simon Sun, MD, New York, New York (*Presenter*) Nothing to Disclose

PURPOSE

To compare interobserver agreement and image quality assessment of 3D T2-weighted fast spin echo (T2w-FSE) lumbar spine (L-spine) MRI, with and without deep learning (DLRecon) reconstructions, as well as standard-of-care (SOC) 2D T2w-FSE MRI. We hypothesized that while decreasing acquisition time, DLRecon 3D T2w-FSE would also allow for similar interobserver agreement and

improved image quality compared to both standard 3D and SOC 2D T2w-FSE.*Methods and Materials Under IRB-approval, imaging from 15 patients who underwent routine 3T L-spine MRI, with both SOC 2D and isotropic 3D T2w-FSE sequences, were retrospectively reviewed. Sequences included 3D T2w-FSE, 2D T2w-FSE sagittal and axial (parallel to L4-5 disc space). A 2D DLRecon algorithm (AIR Recon DL), with denoising and sharpening properties, was retrained for 3D image reconstruction. 3D SOC, 3D DLRecon, and 2D SOC images were obtained, anonymized, and randomized for evaluation by 3 radiologists. Images were evaluated for motion artifact, image quality, central/foraminal stenosis, disc degeneration, annular fissure, presence of facet cysts and disc herniations using a grading scale validated by current literature. Inter-rater agreement for each graded variable was evaluated using Conger's kappa (K) as well as unadjusted percent agreement.*Results Preliminary interobserver agreement for major imaging variables of interest was overall similar between all 3 sequences with K for foraminal stenosis ranging from 0.62-0.88 for DLRecon 3D T2w-FSE, 0.57-0.82 for SOC 3D T2w-FSE and 0.62-0.88 for SOC 2D FSE. Similarly, K for central stenosis at L4-5 was 0.85, 0.82 and 0.90 respectively, ranged from 0.54-0.84, 0.51-0.87, 0.27-0.84 respectively for disc herniation (L3-4 and L4-5) and ranged from 0.47-0.65, 0.55-0.82 and 0.59-0.84 respectively for disc degeneration (L3-4 to L5-S1). Evaluation of image quality showed that 3D DLRecon images were more often graded as of excellent quality (17/44) when compared to SOC 3D T2w-FSE (4/44), 2D axial (5/44) and 2D sagittal (1/44) sequences. Additionally, DLRecon 3D T2w-FSE cases were most often devoid of motion artifact (33/44) compared to SOC 3D T2w-FSE (20/44), 2D axial (16/44) and 2D sagittal (9/44) sequences. Final evaluation will evaluate 35 cases per observer, based on a pre-study power analysis.*Conclusions DLRecon 3D T2w-FSE L-spine MRI demonstrated a similar interobserver agreement for graded variables of interest when compared to 2D imaging and was also more often graded as having excellent image quality.*Clinical Relevance/Application DL Recon 3D T2w-FSE L-spine MRI can facilitate substantial time savings and the ability to reformat sequences freely without compromising interobserver agreement for evaluation of clinically relevant pathology.

RESULTS

Preliminary interobserver agreement for major imaging variables of interest was overall similar between all 3 sequences with K for foraminal stenosis ranging from 0.62-0.88 for DLRecon 3D T2w-FSE, 0.57-0.82 for SOC 3D T2w-FSE and 0.62-0.88 for SOC 2D FSE. Similarly, K for central stenosis at L4-5 was 0.85, 0.82 and 0.90 respectively, ranged from 0.54-0.84, 0.51-0.87, 0.27-0.84 respectively for disc herniation (L3-4 and L4-5) and ranged from 0.47-0.65, 0.55-0.82 and 0.59-0.84 respectively for disc degeneration (L3-4 to L5-S1). Evaluation of image quality showed that 3D DLRecon images were more often graded as of excellent quality (17/44) when compared to SOC 3D T2w-FSE (4/44), 2D axial (5/44) and 2D sagittal (1/44) sequences. Additionally, DLRecon 3D T2w-FSE cases were most often devoid of motion artifact (33/44) compared to SOC 3D T2w-FSE (20/44), 2D axial (16/44) and 2D sagittal (9/44) sequences. Final evaluation will evaluate 35 cases per observer, based on a pre-study power analysis.

CLINICAL RELEVANCE/APPLICATION

DL Recon 3D T2w-FSE L-spine MRI can facilitate substantial time savings and the ability to reformat sequences freely without compromising interobserver agreement for evaluation of clinically relevant pathology.

SSMK09-5 Evaluation Of Adipose Tissue And Muscle CT Attenuation As Quantitative Biomarkers In Predicting Outcomes In Patient With Multiple Myeloma

Participants
Iclal Erdem Toslak, MD, Antalya, Turkey (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate radiologic measures of visceral and subcutaneous adiposity using CT images in predicting patient outcomes in patients with multiple myeloma.*Methods and Materials From January 2014 to through December 2018, 86 patients with a diagnosis of multiple myeloma who underwent FDG-PET/CT were included in this retrospective study. Electronically recorded non-contrast CT images were transferred to a workstation, and cross-sectional areas and attenuation (Hounsfield Unit) of abdominal subcutaneous and visceral adipose tissue (SAT and VAT, respectively) and attenuation of psoas muscle were measured. Clinical information was acquired from patient medical records. Patients were classified into stages (22 stage 1, 30 stage2, and 34 stage 3) based on clinical data. Clinical response to treatment and recurrence were noted. Statistical analyses were performed to calculate clinical associations between radiological measures.*Results Higher SAT and SAT/VAT area values as well as lower subcutaneous and visceral attenuation values were found in those with lower stages of the disease (p<0.05). No statistically significant association was detected between disease stage and psoas muscle attenuation. VAT area values were significantly decreased and visceral attenuation values were significantly increased in patients with lytic bone lesions. On the other hand SAT, VAT, SAT/VAT area and psoas muscle attenuation values were not associated with therapy response and recurrence of the disease.*Conclusions SAT, SAT/VAT area values were strongly associated with the stage of disease in patients with multiple myeloma. Patients with lytic bone lesions had significantly lower VAT area values and higher visceral adipose tissue attenuation values. Quantitative measures of visceral or subcutaneous adipose tissue were not useful in predicting therapy response and recurrence of the disease but can predict the severity of the disease.*Clinical Relevance/Application CT quantification of adipose tissue and muscle can help improve patient management and outcomes in multiple myeloma

RESULTS

Higher SAT and SAT/VAT area values as well as lower subcutaneous and visceral attenuation values were found in those with lower stages of the disease (p<0.05). No statistically significant association was detected between disease stage and psoas muscle attenuation. VAT area values were significantly decreased and visceral attenuation values were significantly increased in patients with lytic bone lesions. On the other hand SAT, VAT, SAT/VAT area and psoas muscle attenuation values were not associated with therapy response and recurrence of the disease.

CLINICAL RELEVANCE/APPLICATION

CT quantification of adipose tissue and muscle can help improve patient management and outcomes in multiple myeloma

SSMK09-6 Novel Deep Learning-based T1- And T2-weighted Imaging Of The Spine: Significant Acceleration Of Image Acquisition With Preservation Of Excellent Image Quality And Diagnostic Confidence

Participants
Judith Herrmann, MD, Tuebingen, Germany (*Presenter*) Nothing to Disclose

PURPOSE

Deep learning (DL) image reconstruction could potentially disrupt the realm of MRI by significantly accelerating image acquisition. The goal of this study is to introduce a novel deep learning-based T1 and T2 weighted turbo spine echo reconstructions (TSEDL) in

spine MRI and investigate its impact on examination time, image quality and diagnostic confidence in comparison to standard T1 and T2 weighted turbo spin echo imaging (TSE).*Methods and Materials A total of 37 patients with various spinal pathologies were prospectively enrolled in this institutional review board-approved study. Very recently, the novel deep learning-based sagittal T1- and T2-weighted TSE sequence (TSEDL) was developed and trained on 10,000 high resolution slices from 1.5T and 3T scanners. After acquisition of standard T1 and T2 TSE images, the T1 and T2 TSEDL were applied. Parallel imaging acceleration factor of 3 and 4 for T1 and T2 TSEDL were utilized, respectively. Image evaluation was performed by two radiologists in a blinded and a randomized manner using a Likert scale ranging from 1-4, 4 being the best. Outcome measures were: sharpness of anatomical structures: (intervertebral discs, spinal canal, facet joints and neuroforamina), artifacts, noise, overall image quality, diagnostic confidence and acquisition time. Finally, interrater agreement was analyzed.*Results Mean patient age was 46±19 years (range 18-87 years, 39% females). A total of 28 exams were performed at 1.5 T and 9 exams at 3T. A total of 29 MRI exams of the lumbar spine, 5 of the thoracic spine 4 of the cervical spine were performed. All images were reconstructed successfully. TSEDL enabled 60% to 75% reduction of acquisition time for sagittal T1 (TSE: 2:13 min vs, TSEDL: 0:52 min) and sagittal T2 (TSE: 2:29 min vs TSEDL: 0:40 min)) weighted images. For TSEDL image noise was rated significantly superior by both readers (all $p < 0.01$). There was no statistically significant difference between TSE and TSEDL regarding overall image quality, diagnostic confidence or sharpness of intervertebral discs, spinal canal, facet joints or neuroforamina. Interreater reliability was high (K> 0.7)*Conclusions The data-driven deep learning-based T1- and T2-weighted TSE imaging of the spine is feasible enabling a significant improvement of image noise and allowing an acquisition time reduction of up to 75 % while preserving excellent image quality and diagnostic confidence. Consequently, the DL technique might set the stage for ultra-fast spine MRI.*Clinical Relevance/Application Reducing scan time up to 75% without compromising image quality could set the stage for ultra-fast spine MRI, which has numerous benefits in the context of an aging population and increased workload.

RESULTS

Mean patient age was 46±19 years (range 18-87 years, 39% females). A total of 28 exams were performed at 1.5 T and 9 exams at 3T. A total of 29 MRI exams of the lumbar spine, 5 of the thoracic spine 4 of the cervical spine were performed. All images were reconstructed successfully. TSEDL enabled 60% to 75% reduction of acquisition time for sagittal T1 (TSE: 2:13 min vs, TSEDL: 0:52 min) and sagittal T2 (TSE: 2:29 min vs TSEDL: 0:40 min)) weighted images. For TSEDL image noise was rated significantly superior by both readers (all $p < 0.01$). There was no statistically significant difference between TSE and TSEDL regarding overall image quality, diagnostic confidence or sharpness of intervertebral discs, spinal canal, facet joints or neuroforamina. Interreater reliability was high (K> 0.7)

CLINICAL RELEVANCE/APPLICATION

Reducing scan time up to 75% without compromising image quality could set the stage for ultra-fast spine MRI, which has numerous benefits in the context of an aging population and increased workload.

SPR-RI-1   Diagnostic Performance Of ACR O-RADS Ultrasound Risk Stratification In Average Risk US Women

Participants
Priyanka Jha, MBBS, San Francisco, California (*Presenter*) Nothing to Disclose

PURPOSE

1. Evaluate applicability of Ovarian-Adnexal Reporting and Data System (O-RADS) risk stratification scoring system to a multi-institutional, non-selected, average risk population in US, obtain risk of malignancy in each O-RADS category & assess concordance with malignancy risk proposed by current O-RADS risk stratification system.2. Assess risk of cancer & O-RADS performance with menopausal status of the patient.*Methods and Materials This retrospective multi-center, IRB-approved study included a non-selected, average risk women presenting to US radiology departments for routine pelvic US. All US exams were reviewed by study radiologists blinded to final diagnosis. The following O-RADS defined findings were excluded: follicles, corpus luteal cysts and cystic lesions <1cm (in postmenopausal women). All other adnexal lesions were assessed using O-RADS. Medical records were reviewed for surgical pathology, minimum 2 years of imaging and/or clinical follow-up as reference standard. Distribution of lesions and frequency of cancer in O-RADS 2-5 categories was calculated.Considering O-RADS 2 & 3 as benign & O-RADS 4 and 5 malignant, descriptive statistics were performed. Univariate & multivariate analyses were also performed.*Results 913 women with 1014 adnexal lesions were included. Average age was 42.4 years(+13.9 years).Frequency of lesion distribution per O-RADS category was:O-RADS 2:64.8%(657/1014), O-RADS 3: 11.2%(114/1014), O-RADS 4: 16.9%(171/1014) & O-RADS 5:7.1%(72/1014).Frequency of malignancy per O-RADS category was: O-RADS 2:0.5% (3/657), O-RADS 3:4.4%(5/114), O-RADS 4:14.6%(25/171) & O-RADS 5:61.1%(43/72). O-RADS 4 lesions with solid components have higher risk of malignancy 20.7%(25/121) compared to the lesions without solid components 0% (0/50),(p<0.01).O-RADS sensitivity & specificity for malignancy diagnosis are 96.1% & 70.0%, with PPV of 20.6% and NPV of 99.5%.Rate of cancer was higher in postmenopausal women 13.4% (32/238), compared to 4.15% (28/675) in premenopausal women (p<0.01).*Conclusions 1. Calculated frequency of malignancy for each O-RADS category in our study falls within the range as reported by the O-RADS algorithm.2. The frequency of malignancy in O-RADS 4 was concordant with the proposed risk, however, it was on the lower range. O-RADS 4 lesions with solid components have higher risk of malignancy compared to lesions without solid components.3. Rate of cancer per O-RADS category is higher in postmenopausal compared to premenopausal women.*Clinical Relevance/Application 1. O-RADS risk stratification is applicable to general non-selected US population. The system has a high NPV but a low PPV for malignancy.2. O-RADS 4 category may be modified to improve specificity and PPV for malignancy.

RESULTS

913 women with 1014 adnexal lesions were included. Average age was 42.4 years(+13.9 years).Frequency of lesion distribution per O-RADS category was:O-RADS 2:64.8%(657/1014), O-RADS 3: 11.2%(114/1014), O-RADS 4: 16.9%(171/1014) & O-RADS 5:7.1% (72/1014).Frequency of malignancy per O-RADS category was: O-RADS 2:0.5% (3/657), O-RADS 3:4.4%(5/114), O-RADS 4:14.6% (25/171) & O-RADS 5:61.1%(43/72). O-RADS 4 lesions with solid components have higher risk of malignancy 20.7%(25/121) compared to the lesions without solid components 0% (0/50),(p<0.01).O-RADS sensitivity & specificity for malignancy diagnosis are 96.1% & 70.0%, with PPV of 20.6% and NPV of 99.5%.Rate of cancer was higher in postmenopausal women 13.4% (32/238), compared to 4.15% (28/675) in premenopausal women (p<0.01).

CLINICAL RELEVANCE/APPLICATION

1. O-RADS risk stratification is applicable to general non-selected US population. The system has a high NPV but a low PPV for malignancy.2. O-RADS 4 category may be modified to improve specificity and PPV for malignancy.

SPR-RI-10   External Validation Of Orads Ultrasound Risk Stratification System To Discriminate Benign And Malignancy Adnexal Masses Diagnosis

Participants
Kalesha Hack, MD, FRCPC, Toronto, Ontario (*Presenter*) Nothing to Disclose

PURPOSE

The objective of this study was to externally validate the performance of the Ovarian-Adnexal Reporting and Data System (ORADS) Ultrasound Risk Stratification System to distinguish benign and malignant adnexal masses.*Methods and Materials This was a retrospective diagnostic accuracy study of 227 consecutive patients with 262 adnexal lesions who underwent pelvic transvaginal ultrasound at a single-site radiology department within a tertiary care oncology center between August 2015 and April 2017. Adnexal masses were assessed by two independent readers using the ORADS lexicon and assigned ORADS risk category score of 2-5. Readers were blinded to the clinical outcome and histopathologic diagnosis. Descriptors and clinical indices for the IOTA ADNEX model were also assessed used to determine the ADNEX overall risk of malignancy. The reference standard was histopathology or minimum 2-year follow up imaging. Receiver-operating characteristics (ROC) curve analysis was used to assess the performance of the ORADS model and to compare the ORADS and ADNEX models.*Results Of the 262 adnexal lesions, 188 (72%) were benign (88 histopathology, 100 conservative follow up) and 74 were malignant (72 histopathology, 2 interval growth at follow up). All ORADS 2 lesions were benign. Frequency of malignant outcome by ORADS category was 3% (1/32) for ORADS 3, 35% (22/63) for ORADS 4

and 77.3% (51/66) for ORADS 5. Interrater agreement for ORADS category was 99% (260/262). The AUC for ORADS was 0.91 (95% CI 0.92-0.97) and for ADNEX was 0.95 (95% CI 0.92-0.97) which was statistically significant (p<0.05). Adding acoustic shadowing as an independent variable to the ORADS model increased the AUC to 0.94 (CI 0.91-0.96) with no statistically significant difference compared to ADNEX. The optimal cut-off point was ORADS 4 with sensitivity of 99% (95% CI 0.96-1.0) and specificity of 70% (95% CI 0.64-0.77). At this cut-off, negative predictive value is 0.99 and positive predictive value 0.57. Using ORADS 3 as a cut-off improves sensitivity to 100%, however, with corresponding decrease in specificity to 53% (95% CI 0.46-0.61).*Conclusions The ORADS Ultrasound Risk Stratification System can discriminate between benign and malignant adnexal masses with high diagnostic accuracy. The IOTA-ADNEX model showed a small but statistically significant better performance, however, when acoustic shadowing was added to the ORADS model, there was no statistically significant difference between the two.*Clinical Relevance/Application This is the first North American external validation study of the ORADS system to our knowledge. It is also the first study evaluating modified ORADS with addition of acoustic shadowing.

RESULTS

Of the 262 adnexal lesions, 188 (72%) were benign (88 histopathology, 100 conservative follow up) and 74 were malignant (72 histopathology, 2 interval growth at follow up). All ORADS 2 lesions were benign. Frequency of malignant outcome by ORADS category was 3% (1/32) for ORADS 3, 35% (22/63) for ORADS 4 and 77.3% (51/66) for ORADS 5. Interrater agreement for ORADS category was 99% (260/262). The AUC for ORADS was 0.91 (95% CI 0.92-0.97) and for ADNEX was 0.95 (95% CI 0.92-0.97) which was statistically significant (p<0.05). Adding acoustic shadowing as an independent variable to the ORADS model increased the AUC to 0.94 (CI 0.91-0.96) with no statistically significant difference compared to ADNEX. The optimal cut-off point was ORADS 4 with sensitivity of 99% (95% CI 0.96-1.0) and specificity of 70% (95% CI 0.64-0.77). At this cut-off, negative predictive value is 0.99 and positive predictive value 0.57. Using ORADS 3 as a cut-off improves sensitivity to 100%, however, with corresponding decrease in specificity to 53% (95% CI 0.46-0.61).

CLINICAL RELEVANCE/APPLICATION

This is the first North American external validation study of the ORADS system to our knowledge. It is also the first study evaluating modified ORADS with addition of acoustic shadowing.

SPR-RI-11   Challenges Of O-RADS US And MRI In The Assessment Of Complex Ovarian-adnexal Cysts >= 5 Cm

Participants
Yang Guo, MD, Boston, Massachusetts (*Presenter*) Nothing to Disclose

PURPOSE

To assess inter-reader agreement and diagnostic performance of O-RADS ultrasound (US) and MRI for characterization of complex adnexal cysts = 5 cm, and to assess concordance between US and MRI risk stratification of these lesions.*Methods and Materials This IRB-approved HIPAA-compliant retrospective study was performed at a large academic center. From our ultrasound electronic reporting database, we identified all patients with a pelvic US from 7/1/2017 to 6/30/2020 in whom "complex cyst(s)" = 5 cm were reported on US and pelvic MRI was performed within one year of the US without intervening procedures or treatment. In patients with more than one US, the one closest to the MRI was used. Two blinded US subspecialists independently reviewed the US images and assigned O-RADS US category, and third served as adjudicator for discrepancies. Three different abdominal radiologists reviewed the MRI in similar fashion as US (two readers, one adjudicator). The final lesion outcome was recorded based on pathology or follow-up imaging. Inter-reader agreement between two primary readers were assessed for US and MRI by Cohen's kappa test. The associated cancer risk for each O-RADS US and MRI category was calculated. The concordance between the US and MRI reads was assessed.*Results Among 1,003 pelvic sonograms that reported at least one 5 cm or larger complex cyst, 80 patients underwent pelvic MRI within one-year. A total of 69 lesions were assigned an O-RADS US category and 74 lesions assigned an O-RADS MR category. We identified 58 lesions seen both on US and MRI in 54 women (mean age 40 years, SD 12.4, 7 post-menopausal) that comprised the final cohort. Mean maximal dimension of the lesions was 9.1 cm (SD 3.2) on US and 8.5 cm (SD 3.6) on MR (p=0.17). Inter-reader agreement between two primary readers was fair for US (weighted kappa=0.31) and moderate for MRI (weighted kappa=0.43). Forty-eight lesions were benign, nine malignant and one with unknown outcome. For O-RADS US 2, 3, 4, and 5 categories, the rate of malignancy was 3%, 10%, 27% and 80%, while for O-RADS MRI 2, 3, 4, and 5, the rate of malignancy was 3%, 0%, 80% and 100%, respectively. The agreement between US and MR risk categorization was moderate (weighted kappa=0.58).*Conclusions There was significant interobserver variability in risk-stratification of = 5 cm complex adnexal cysts using both O-RADS US and MRI. There was moderate concordance between risk categorization between O-RADS US and MRI. The rate of malignancy for O-RADS 4 and 5 lesions was high for both US and MRI.*Clinical Relevance/Application Our study demonstrates significant inter-reader variability in O-RADS US and MRI in the assessment of complex ovarian and adnexal cysts. Further radiologist training may increase inter-reader agreement.

RESULTS

Among 1,003 pelvic sonograms that reported at least one 5 cm or larger complex cyst, 80 patients underwent pelvic MRI within one-year. A total of 69 lesions were assigned an O-RADS US category and 74 lesions assigned an O-RADS MR category. We identified 58 lesions seen both on US and MRI in 54 women (mean age 40 years, SD 12.4, 7 post-menopausal) that comprised the final cohort. Mean maximal dimension of the lesions was 9.1 cm (SD 3.2) on US and 8.5 cm (SD 3.6) on MR (p=0.17). Inter-reader agreement between two primary readers was fair for US (weighted kappa=0.31) and moderate for MRI (weighted kappa=0.43). Forty-eight lesions were benign, nine malignant and one with unknown outcome. For O-RADS US 2, 3, 4, and 5 categories, the rate of malignancy was 3%, 10%, 27% and 80%, while for O-RADS MRI 2, 3, 4, and 5, the rate of malignancy was 3%, 0%, 80% and 100%, respectively. The agreement between US and MR risk categorization was moderate (weighted kappa=0.58).

CLINICAL RELEVANCE/APPLICATION

Our study demonstrates significant inter-reader variability in O-RADS US and MRI in the assessment of complex ovarian and adnexal cysts. Further radiologist training may increase inter-reader agreement.

SPR-RI-2   The Texture Model Of "Coronal And Sagittal" Planes On T2wi Could Accurately Predict Placenta Accreta Spectrum

Participants
Hainan Ren, BMedSc, Sendai, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Prenatal differentiation between normal placenta and placenta accreta spectrum (PAS) is necessary to perform safe delivery. We

performed visual and texture analysis on the axial, coronal, and sagittal planes of T2-weighted images (T2WI) separately and identified the optimal method in differentiating between normal placenta and PAS.*Methods and Materials The Institutional Review Board approved this retrospective study and the requirement for informed consent was waived. Between May 2010 and August 2019, eighty consecutive patients (normal group (n=50) and PAS (n=30)) underwent preoperative magnetic resonance imaging (MRI). A scoring system (0-2) was used to evaluate the abnormality in visual analysis (bulging, abnormal vascularity, heterogeneity, T2 dark band) on T2WI. Manual segmentations of placenta were performed on the axial, coronal, and sagittal planes of T2WI separately to obtain texture features. Seven combinations were obtained from the three planes as follows: axial, coronal, sagittal, axial and coronal, axial and sagittal, coronal and sagittal, as well as axial and coronal and sagittal. Feature selection by least absolute shrinkage and selection operator (LASSO) method and model construction by support vector machine (SVM) algorithm with k-fold cross-validation were performed. Area under the curve (AUC) of receiver operating characteristic (ROC) curve analysis was used to compare the diagnostic performance between visual and texture analysis.*Results The AUC of visual analysis was 0.75. The model "coronal and sagittal" had highest AUC of 0.98 among seven combinations. The 5-fold cross-validation for model "coronal and sagittal" showed AUCs of 0.85 and 0.97 in training and validation sets. Using the model "coronal and sagittal" for all subjects, AUC of the model was significantly higher than that of visual analysis (0.98 vs. 0.75, p<.0001).*Conclusions The texture analysis composed of features from "coronal and sagittal" planes of T2WI was selected as optimal for differentiating between normal placenta and PAS. The diagnostic performance of texture analysis was higher than that of visual analysis.*Clinical Relevance/Application Texture analysis on coronal and sagittal T2-weighted images outperformed the visual analysis in differentiating between normal placenta and placenta accreta spectrum.

RESULTS

The AUC of visual analysis was 0.75. The model "coronal and sagittal" had highest AUC of 0.98 among seven combinations. The 5-fold cross-validation for model "coronal and sagittal" showed AUCs of 0.85 and 0.97 in training and validation sets. Using the model "coronal and sagittal" for all subjects, AUC of the model was significantly higher than that of visual analysis (0.98 vs. 0.75, p<.0001).

CLINICAL RELEVANCE/APPLICATION

Texture analysis on coronal and sagittal T2-weighted images outperformed the visual analysis in differentiating between normal placenta and placenta accreta spectrum.

SPR-RI-3   Noninvasive Magnetic Resonance Imaging-derived Radiomics Analysis Improves Pretreatment Identification Of Multimodality Therapy Candidates In Early-stage Cervical Cancer

Participants
Jing Ren, MD,MD, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To develop and validate a clinical-radiomics model that incorporates the radiomics signature and pretreatment clinicopathological parameters for identification of multimodality therapy candidates in early-stage cervical cancer.*Methods and Materials From January 2017 to February 2021, a total of 235 patients with IB1-IIA1 cervical cancer who underwent radical hysterectomy were enrolled and divided into a training set (n = 194, training: validation = 8:2) and a testing set (n = 41) according to the surgical time. Radiomics features of each patient were extracted from preoperative sagittal T2-weighted images. Significance testing, Pearson's correlation analysis, and Least absolute shrinkage and selection operator was applied to select radiomic features associated with the administration of multimodality therapy. A clinical-radiomics model incorporating radiomics signature, age, FIGO stage, menopausal status, and preoperative biopsy histological type was developed to identify multimodality therapy candidates. Nomogram and decision curve analysis were developed to facilitate ease of clinical application.*Results The clinical-radiomics model showed excellent predictive performance, with an area under the curve, sensitivity and specificity of 0.885 (95% CI: 0.781-0.989), 78.9% and 81.8% in the testing set. Decision curve analysis demonstrated that when the threshold probability was >20%, the clinical-radiomics model/nomogram could could bring more net benefit than the treat-all or treat-none strategies.*Conclusions The clinical-radiomics model is of great potential for pretreatment identification of multimodality therapy candidates in early-stage cervical cancer.*Clinical Relevance/Application Clinical-radiomics model for pretreatment identification of multimodality therapy candidates helps to select optimal primary treatment (radical surgery or definitive radiotherapy) for early-stage cervical cancer

RESULTS

The clinical-radiomics model showed excellent predictive performance, with an area under the curve, sensitivity and specificity of 0.885 (95% CI: 0.781-0.989), 78.9% and 81.8% in the testing set. Decision curve analysis demonstrated that when the threshold probability was >20%, the clinical-radiomics model/nomogram could could bring more net benefit than the treat-all or treat-none strategies.

CLINICAL RELEVANCE/APPLICATION

Clinical-radiomics model for pretreatment identification of multimodality therapy candidates helps to select optimal primary treatment (radical surgery or definitive radiotherapy) for early-stage cervical cancer

SPR-RI-4   High-resolution Diffusion-weighted Imaging In Endometrial Cancer Staging: A Comparison Of Multiplexed Sensitivity Encoding Versus Reduced Field-of-view Techniques

Participants
Takashi Ota, MD,PhD, Suita, Japan (*Presenter*) Nothing to Disclose

PURPOSE

To compare the image quality and diagnostic performance of high-resolution diffusion-weighted imaging using multiplexed sensitivity encoding (MUSE-DWI) versus reduced field-of-view imaging (rFOV-DWI) in endometrial cancer.*Methods and Materials MUSE-DWI and rFOV-DWI were obtained preoperatively in 44 women with endometrial cancer. For both techniques, two radiologists qualitatively assessed the image qualities and measured apparent diffusion coefficient (ADC) and signal-to-noise ratio (SNR) of the endometrial cancer and myometrium, as well as contrast-to-noise ratio (CNR) between them. Three independent radiologists assessed superficial (SMI) and deep myometrial invasion (DMI) using both techniques separately. Qualitative scores and quantitative parameters were compared using Wilcoxon signed-rank test and paired t-test, respectively. Diagnostic performances of both techniques were compared using McNemar's test and receiver operating characteristic analysis.*Results Artifacts, sharpness, and overall image quality were significantly better with MUSE-DWI compared to rFOV-DWI in both readers (p< .05). Tumor and myometrial ADC values did not differ significantly. SNR on rFOV-DWI was significantly higher than that on MUSE-DWI (p= .012 and <

.001 for the tumors and the myometrium, respectively), whereas CNR did not differ statistically. Regarding SMI assessment, mean accuracies and area under the curve (AUC) were 67.4% and 0.80, respectively with MUSE-DWI, and 75% and 0.80, respectively with rFOV-DWI. In DMI assessment, mean accuracies and AUC were 86.4% and 0.92, respectively with MUSE-DWI, and 83.3% and 0.87, respectively with rFOV-DWI. Although there were no significant differences in the diagnostic performances between the two techniques in all three readers, SMI assessment was superior with rFOV-DWI in all three readers while DMI assessment was more accurate with MUSE-DWI in two readers.*Conclusions MUSE-DWI had higher image quality than rFOV-DWI. Although not significant, SMI assessment tended to be accurate with rFOV-DWI while DMI assessment tended to be accurate with MUSE-DWI.*Clinical Relevance/Application MUSE-DWI yields high image quality and may be a preferred choice in routine endometrial cancer staging while rFOV-DWI may be a reliable option in patient selection for fertility sparing treatment.

RESULTS

Artifacts, sharpness, and overall image quality were significantly better with MUSE-DWI compared to rFOV-DWI in both readers (p< .05). Tumor and myometrial ADC values did not differ significantly. SNR on rFOV-DWI was significantly higher than that on MUSE-DWI (p= .012 and < .001 for the tumors and the myometrium, respectively), whereas CNR did not differ statistically. Regarding SMI assessment, mean accuracies and area under the curve (AUC) were 67.4% and 0.80, respectively with MUSE-DWI, and 75% and 0.80, respectively with rFOV-DWI. In DMI assessment, mean accuracies and AUC were 86.4% and 0.92, respectively with MUSE-DWI, and 83.3% and 0.87, respectively with rFOV-DWI. Although there were no significant differences in the diagnostic performances between the two techniques in all three readers, SMI assessment was superior with rFOV-DWI in all three readers while DMI assessment was more accurate with MUSE-DWI in two readers.

CLINICAL RELEVANCE/APPLICATION

MUSE-DWI yields high image quality and may be a preferred choice in routine endometrial cancer staging while rFOV-DWI may be a reliable option in patient selection for fertility sparing treatment.

SPR-RI-5   Superb Microvascular Imaging: Preliminary Results In Assessment The Response To Chemoradiotherapy In Locally Advanced Cervical Cancer

Participants
Yi Zhu, Chengdu, China (*Presenter*) Nothing to Disclose

PURPOSE

The place of ultrasound in the diagnostics and monitoring of cervical cancer remains controversial. Superb microvascular imaging (SMI) is a new ultrasound image processing technique. SMI can extract and visualize flow signals from vessels through advanced clutter suppression technology, especially the very small vascular which were previously invisible without the use of a contrast agent. In this work, we aim to analyze the usefulness of SMI in the diagnosis of cervical cancer and the possibility of evaluating the effect of chemoradiotherapy in patients with locally advanced cervical cancer.*Methods and Materials Patients with locally advanced cervical cancer were underwent SMI examinations with an Aplio i800 ultrasound system (Toshiba Medical Systems, Tokyo, Japan) before, during and after chemoradiotherapy. Cervical lesions volume and vascularity index (VI) via SMI were obtained using a linear 3 - 11 MHz endovaginal transducer. For continuous variables, the means VI of the cervical area at different treatment timepoint were compared by using analysis of variance (ANOVA).*Results The study included 56 patients with locally advanced cervical cancer based on histological diagnosis. Of these, 23 were newly diagnosed and untreated, 13 were receiving chemoradiotherapy, and 20 have completed treatment with normal ultrasound and cervical cytology findings. In most of the patients, SMI achieved the excellent visualization of microvascular structures, revealing abnormal vasculature in 23 out of 23 (100%) examinations of the untreated patients, 11/13 (84.6%) examination of the patients who were during the treatment. SMI was superior to doppler imaging for depicting the microvascular structures. The untreated patients with cervical cancer had significantly higher median VI (41.1 ± 3.2 %) compared to that of patients during or after treatment (24.8 ± 5.8 %, 4.1 ± 1.4 %, respectively). The VI showed a significant downward trend with the course of treatment (P < 0.01).*Conclusions SMI is especially useful for depicting the microvascular flow and quantitative assessment based on a novel parameter such as VI for locally advanced cervical cancer.*Clinical Relevance/Application Quantitative assessment based on VI visa SMI can aid in the diagnosis and treatment monitoring for patients with locally advanced cervical cancer.

RESULTS

The study included 56 patients with locally advanced cervical cancer based on histological diagnosis. Of these, 23 were newly diagnosed and untreated, 13 were receiving chemoradiotherapy, and 20 have completed treatment with normal ultrasound and cervical cytology findings. In most of the patients, SMI achieved the excellent visualization of microvascular structures, revealing abnormal vasculature in 23 out of 23 (100%) examinations of the untreated patients, 11/13 (84.6%) examination of the patients who were during the treatment. SMI was superior to doppler imaging for depicting the microvascular structures. The untreated patients with cervical cancer had significantly higher median VI (41.1 ± 3.2 %) compared to that of patients during or after treatment (24.8 ± 5.8 %, 4.1 ± 1.4 %, respectively). The VI showed a significant downward trend with the course of treatment (P < 0.01).

CLINICAL RELEVANCE/APPLICATION

Quantitative assessment based on VI visa SMI can aid in the diagnosis and treatment monitoring for patients with locally advanced cervical cancer.

SPR-RI-6   Comparison Of 2D Multi-slice And 3D Compressed Sensing Accelerated High Resolution T2 Weighted Imaging In Detection Of Endometriosis

Participants
Xulun Lu, Dalian, China (*Presenter*) Nothing to Disclose

PURPOSE

we compare the performance of compressed sensing (CS) accelerated 3D high-resolution and conventional 2D multi-slice T2-SPAIR images on visualization of pelvic ectopic lesions. Results indicate that 3D-CS-HR imaging can be more reliable for discovery of DIE lesions.*Methods and Materials 15 DIE patient were scanned using a 3.0 T MR scanner (Ingenia CX, Philips Healthcare, the Netherlands) . The MR protocol included 2D multi-slice T2-SPAIR, 3D-CS-HR-T2WI and dynamic contrast enhanced scans with parameters listed in Table 1. 3D-CS-HR-T2WI images were reconstructed along directions of the broad ligament and the central direction of the bottom of uterus. Two imaging physicians read the images independently to determine whether the common endometriosis in the original and reconstructed images were affected. The evaluated locations included: ovary , broad ligament,

sacral ligament, round ligament, rectovaginal pouch or rectum adhesion and abdominal wall. Except for ovarian lesions, other locations were compared with enhanced images to see if they were (diffuse or focal) ligament thickening and enhanced in enhanced image, and intraoperative records were compared to determine whether the detected lesions were involved areas. The interobserver reliability on qualitative evaluation was assessed via Cohen's kappa test. The kappa test was also used to evaluated the consistency of T2-SPAIR and 3D pelvis view results with the surgical records, respectively. The kappa values, sensitivity and specificity were compared to see the performance of 2D T2WI and 3D pelvis view for the diagnosis of DIE.*Results Measurement consistency between the two observers was good (kappa value > 0.75). 3D-CS-HR-T2WI shows better detection performance (Table 2). In this set of data, the sensitivity and specificity of T2WI and 3D-CS-HR-T2WI for the detection of lesions at ovary, broad ligament, sacral ligament, round ligament, rectovaginal pouch or rectum and abdominal wall are:100% and 100%, 100% and 77.8%, 100% and 77.8%, 100% and 88.3%, 100% and 25.0%, 100% and 100%. The specificity of 3D-CS-HR-T2WI for the detection of lesions at ovary, broad ligament, sacral ligament, round ligament, rectovaginal pouch or rectum and abdominal wall are:100% and 100%, 100% and 85.7%, 100% and 85.7%, 100% and 100%,100% and 30.0%, 100% and 100%(Figure 1 and 2).The specificity of 3D-CS-HR-T2WI were higher than T2WI in detect of endometriosis located in road ligament, sacral ligament, round ligament, rectovaginal pouch or rectum.*Conclusions 3D-CS-HR-T2WI is potentially a promising and valuable non-invasive method in detection of DIE.*Clinical Relevance/Application indicate that the 3D T2WI imaging were reliable in finding ectopic lesions in each ligament of the pelvic floor.

RESULTS

Measurement consistency between the two observers was good (kappa value > 0.75). 3D-CS-HR-T2WI shows better detection performance (Table 2). In this set of data, the sensitivity and specificity of T2WI and 3D-CS-HR-T2WI for the detection of lesions at ovary, broad ligament, sacral ligament, round ligament, rectovaginal pouch or rectum and abdominal wall are:100% and 100%, 100% and 77.8%, 100% and 77.8%, 100% and 88.3%, 100% and 25.0%, 100% and 100%. The specificity of 3D-CS-HR-T2WI for the detection of lesions at ovary, broad ligament, sacral ligament, round ligament, rectovaginal pouch or rectum and abdominal wall are:100% and 100%, 100% and 85.7%, 100% and 85.7%, 100% and 100%,100% and 30.0%, 100% and 100%(Figure 1 and 2).The specificity of 3D-CS-HR-T2WI were higher than T2WI in detect of endometriosis located in road ligament, sacral ligament, round ligament, rectovaginal pouch or rectum.

CLINICAL RELEVANCE/APPLICATION

indicate that the 3D T2WI imaging were reliable in finding ectopic lesions in each ligament of the pelvic floor.

SPR-RI-7   3.0T Versus 1.5T MRI For The Evaluation Of Placenta Accreta Spectrum Disorders: A Matched Case-Control Study

Participants
Charis Bourgioti, MD, Athens, Greece (*Presenter*) Nothing to Disclose

PURPOSE

To investigate differences between 1.5T and 3.0T MRI for prediction of Placenta Accreta Spectrum (PAS) and extrauterine placental spread.*Methods and Materials Between 3/2016 and 9/2020, 189 pregnant women at high risk for PAS underwent dedicated prenatal MRI for placental evaluation with 1.5T and 3.0T units. All women underwent C-section within 6 weeks from MRI. Prospectively collected data were evaluated by two experienced genitourinary radiologists for presence and extent of PAS. A matched case-control study was designed to investigate differences in predictive ability between 1.5T and 3.0T MRI groups. Sensitivity (SE), specificity (SP), negative and positive prognostic values relative to intraoperative/histological findings, were computed for both groups. Sensitivity and specificity between groups were compared using chi-square tests.*Results Ninety-three/189 gravid women (49.2%) were evaluated with 1.5T (mean age:35years, mean gestational age:32.5weeks) and 96/189 (50.8%) with 3.0T MRI (mean age: 34.9years; mean gestational age:32.1weeks). Patient characteristics were similar for both groups (p>.05). 1.5T MRI exhibited 95.7% SE and 83.3% SP and 3.0T MRI 92.9% SE and 83.3%SP for PAS identification, without significant differences between the two groups (p=0.514 and p>0.999, respectively). MRI showed excellent predictive ability for detecting extrauterine placental spread with 100% SE, 96.7% SP for 1.5T and 97%, 96.8% SP for 3.0T, without significant differences between the two groups (p>0.999). Prominent intraplacental fetal vessels was the most frequently detected MRI sign for both 1.5T and 3.0T groups.*Conclusions 3.0T imaging is not superior to 1.5T for imaging PAS disorders.*Clinical Relevance/Application Prenatal placental MRI for PAS can be reliably performed with 1.5T MR units, overcoming availability issues and safety considerations related to higher field strengths.

RESULTS

Ninety-three/189 gravid women (49.2%) were evaluated with 1.5T (mean age:35years, mean gestational age:32.5weeks) and 96/189 (50.8%) with 3.0T MRI (mean age: 34.9years; mean gestational age:32.1weeks). Patient characteristics were similar for both groups (p>.05). 1.5T MRI exhibited 95.7% SE and 83.3% SP and 3.0T MRI 92.9% SE and 83.3%SP for PAS identification, without significant differences between the two groups (p=0.514 and p>0.999, respectively). MRI showed excellent predictive ability for detecting extrauterine placental spread with 100% SE, 96.7% SP for 1.5T and 97%, 96.8% SP for 3.0T, without significant differences between the two groups (p>0.999). Prominent intraplacental fetal vessels was the most frequently detected MRI sign for both 1.5T and 3.0T groups.

CLINICAL RELEVANCE/APPLICATION

Prenatal placental MRI for PAS can be reliably performed with 1.5T MR units, overcoming availability issues and safety considerations related to higher field strengths.

SPR-RI-9   Predicting Tumor Recurrence In Cervical Cancer Treated With Chemoradiotherapy - Additional Value Of Intravoxel Incoherent Motion Diffusion-weighted Imaging

Participants
Qi Zhang, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To determine whether intravoxel incoherent motion (IVIM) DWI derived parameters may improve the prediction of tumor recurrence for locally advanced cervical cancer (LACC) patients following concurrent chemoradiotherapy (CCRT) after integrating into clinical variables.*Methods and Materials Between March 2014 and November 2019, 86 consecutive LACC were prospectively enrolled and underwent pelvic MRI examinations with IVIM sequence before treatment. The primary outcome was disease-free survival (DFS). IVIM-derived parameters (true diffusion coefficient,D; pseudo-diffusion coefficient, D* and perfusion fraction,f), conventional

imaging features (tumor maximum size, lymph node metastasis[LNM], primary tumor infiltration) and clinical prognosis variables (age, FIGO2018 staging system, tumor subtype, serum levels of squamous cell carcinoma antigen[SCC-Ag] and hemoglobin) were collected. Univariate and multivariate Cox hazard regression analyses were performed to evaluate these parameters in predicting DFS. The independent and prognosis-interested predictors were combined to build a prediction model, which was compared with clinical FIGO2018 staging system by using the time-dependent ROC curves (tROC). Survive curves were generated using the Kaplan-Meier method and compared with the log-rank test.*Results The median follow-up was 700.5 days for all patients. f, LNM and SCC-Ag were independently associated with tumor recurrence (HR: < 0.001, 4.553, 1.036; P = 0.018, <0.001, 0.046) . The combined prognostic model based on f, tumor maximum size, LNM and SCC-Ag demonstrated a moderate predictive capability in identifying LACC with a high risk of tumor recurrence; the model was more accurate than FIGO2018 staging system alone (c-index: 0.753 vs. 0.618) and the combination of the FIGO2018 staging system, SCC-Ag and f (c-index: 0.753 vs. 0.712).The AUC of the combined prognostic model for predicting 2-year DFS (0.810, 95%CI: 0.701 - 0.920) was significantly superior compared with the FIGO 2018 staging system (0.709, 95% CI: 0.582-0.837; P = 0.029). Moreover, patients were grouped into low-, medial- and high-risk levels based on tumor maximum size, positive LNM, SCC-Ag > 6ng/ml and f < 0.115, with which the 2-year DFS was significantly stratified (P < 0.001).*Conclusions f value could be used as a useful and accurate biomarker to predict DFS in CCRT treated LACC patients as an assistant of clinical prognosis variables.*Clinical Relevance/Application The prognostic prediction model based on the integration of tumor maximum size, f, LNM and SCC-Ag, might provide a more effective prediction of tumor recurrence for LACC patients following CCRT, which might help make therapeutic decisions and tailor follow-up strategies based on individual risk.

RESULTS

The median follow-up was 700.5 days for all patients. f, LNM and SCC-Ag were independently associated with tumor recurrence (HR: < 0.001, 4.553, 1.036; P = 0.018, <0.001, 0.046) . The combined prognostic model based on f, tumor maximum size, LNM and SCC-Ag demonstrated a moderate predictive capability in identifying LACC with a high risk of tumor recurrence; the model was more accurate than FIGO2018 staging system alone (c-index: 0.753 vs. 0.618) and the combination of the FIGO2018 staging system, SCC-Ag and f (c-index: 0.753 vs. 0.712).The AUC of the combined prognostic model for predicting 2-year DFS (0.810, 95%CI: 0.701 - 0.920) was significantly superior compared with the FIGO 2018 staging system (0.709, 95% CI: 0.582-0.837; P = 0.029). Moreover, patients were grouped into low-, medial- and high-risk levels based on tumor maximum size, positive LNM, SCC-Ag > 6ng/ml and f < 0.115, with which the 2-year DFS was significantly stratified (P < 0.001).

CLINICAL RELEVANCE/APPLICATION

The prognostic prediction model based on the integration of tumor maximum size, f, LNM and SCC-Ag, might provide a more effective prediction of tumor recurrence for LACC patients following CCRT, which might help make therapeutic decisions and tailor follow-up strategies based on individual risk.

SPR-VA-10 **Quiescent-interval Slice-selective (QISS) MRA Accurately Estimates Intravascular Stent Dimensions Prior To Intervention In Patients With Peripheral Artery Disease**

Participants
Josua Decker, MD, Charleston, South Carolina (*Presenter*) Nothing to Disclose

PURPOSE

To evaluate the feasibility of non-contrast quiescent-interval slice-selective (QISS) magnetic resonance angiography (MRA) for the prediction of intravascular stent dimensions in patients with peripheral artery disease (PAD), compared to computed tomography angiography (CTA), and the true stent dimensions used for intervention at digital subtraction angiography (DSA) as reference standard.*Methods and Materials PAD patients (n=33, 68±9 years, 18 men) who had previously undergone QISS MRA, CTA, and DSA of the lower extremity run-off in a prospective research study were included in this retrospective analysis. Stenotic lesion length and diameter were quantified to estimate the dimensions of the stent necessary to reinstate blood flow in the respective arteries. Measured dimensions were corrected for the closest stent size available. Estimated dimensions were compared between QISS MRA and CTA, and validated against the stent size used for intervention. The Friedman test with subsequent pairwise paired Wilcoxon signed-rank test was used for analysis.*Results No significant difference was observed between estimated stent diameter in QISS MRA, CTA and DSA with 8.9 ± 2.9, 8.8 ± 3.0 and 8.8 ± 3.8 mm respectively (Friedman ?²=1.45, p=0.483). There was slight underestimation in estimation of stent length for both QISS MRA and CTA, compared to DSA with lengths of 45.8 ± 27.8, 46.4 ± 29.3 and 50.4 ± 34.0 mm respectively (Friedman ?²=11.96, p=0.003) which could be corrected when measurements were adjusted to the next available stent's length (Friedman ?²=2.38, p=0.303).*Conclusions QISS MRA is a reliable method for pre-procedural intervention planning in PAD patients and represents an alternative in patients with contraindications to contrast administration.*Clinical Relevance/Application The evaluated non-contrast QISS MRA sequence represents a reliable pre-procedural imaging option for PAD patients with contraindications to intravenous contrast administration.

RESULTS

No significant difference was observed between estimated stent diameter in QISS MRA, CTA and DSA with 8.9 ± 2.9, 8.8 ± 3.0 and 8.8 ± 3.8 mm respectively (Friedman ?²=1.45, p=0.483). There was slight underestimation in estimation of stent length for both QISS MRA and CTA, compared to DSA with lengths of 45.8 ± 27.8, 46.4 ± 29.3 and 50.4 ± 34.0 mm respectively (Friedman ?²=11.96, p=0.003) which could be corrected when measurements were adjusted to the next available stent's length (Friedman ?²=2.38, p=0.303).

CLINICAL RELEVANCE/APPLICATION

The evaluated non-contrast QISS MRA sequence represents a reliable pre-procedural imaging option for PAD patients with contraindications to intravenous contrast administration.

SPR-VA-11 **Advanced Non-contrast Fresh Blood Imaging (FBI) MRA: Three-station Peripheral Runoffs With Less Than 6 Minutes**

Participants
Vadim Malis, PhD, La Jolla, California (*Presenter*) Nothing to Disclose

PURPOSE

To advance fresh blood imaging (FBI)1,2 in peripheral non-contrast MR angiography (NC-MRA) using a new centric ky-kz trajectory3 and an exponential flop angle scheme to shorten scan time and yet increase contrast-to-noise ratio (CNR).*Methods and Materials FBI utilizes a physiological signal difference between systolic and diastolic triggered images. The centric ky-kz trajectory is implemented in FBI (cFBI), acquiring multiple slice-encodings (SEs) and phase-encodings (PEs) per TR, whereas standard FBI acquires one SE per TR. By applying exponential flop angle (eFA), cFBI enables reduction of SAR. The design of eFA has high flop angles (Hflop) at the center of k space for bright blood imaging and exponentially decreasing flop angles at periphery of k space. Imaging of cFBI was performed maintaining Hflop and varying low flop angles (Lflop), Hflop/Lflop of 180/180, 180/90, 180/60, 180/30 and 180/2 deg. Simulation of blood signal using eFA with various Lflop angles is also performed. All experiments were performed using a 3T clinical system on healthy volunteers (5 males, 24-68 yo). Parameters used in this experiment were TEeff of 60 ms (TEeff of 30 ms for iliac), 1NAQ, 368x336 matrix, 120 1.8-mm slices, FOV of 46-50x40 cm, parallel imaging of 4, and resolution of 0.68(PE)x0.60(RO)x 0.9(SE) mm after interpolation. CNR of each major vessel was calculated using C=|Sa -Sb|/d0 where Sa is the diastolic signal intensity, Sb is the systolic signal intensity, and d0 is the standard deviation (SD) of the systolic signal.*Results All CNR of major arteries at the iliac, femoral, and popliteal stations were improved using Lflop around 2 and 30 degrees. Figure 1 shows the result of the cFBI using Lflop of 2 deg and standard FBI of three stations. Note that scan time in cFBI is less than half of standard FBI. As lowering the LFlop angle, both signals of blood and background are returned to the +Mz longitudinal magnetization that improved the CNR.*Conclusions The cFBI with eFA permits faster recovery of longitudinal magnetization and improvement in CNR. The scan time reduction of three station run-offs was achieved to less than 6 minutes.References: 1. Miyazaki M, Sugiura S, Tateishi F, et al. J. Magn Reson Imaging 2000;12:776-783.2. Miyazaki M, Takai H, Sugiura S, et al. Radiology 2003;227:890-896. 3. Busse RF, Brau ACS, Vu A, et al. Magn Reson in Med 2008;60:640-649.*Clinical Relevance/Application Advanced cFBI with

appropriate eFA allows tremendous reduction of scan time in three runoffs stations. This shortening of scan time is essential in patients with peripheral artery disease.

RESULTS

All CNR of major arteries at the iliac, femoral, and popliteal stations were improved using Lflop around 2 and 30 degrees. Figure 1 shows the result of the cFBI using Lflop of 2 deg and standard FBI of three stations. Note that scan time in cFBI is less than half of standard FBI. As lowering the LFlop angle, both signals of blood and background are returned to the +Mz longitudinal magnetization that improved the CNR.

CLINICAL RELEVANCE/APPLICATION

Advanced cFBI with appropriate eFA allows tremendous reduction of scan time in three runoffs stations. This shortening of scan time is essential in patients with peripheral artery disease.

SPR-VA-12 Classification Of Dermal Back Flow Patterns In Photoacoustic Lymphangiography: Comparison With Near-infrared Fluorescence Lymphangiography In Lymphedema Patients

Participants
Yushi Suzuki, Tokyo, Japan (*Presenter*) Nothing to Disclose

PURPOSE

Lymphedema is a disease in which lymphatic flow is obstructed due to lymphatic hypoplasia or lymph node dissection during cancer treatment. We used a novel technology, photoacoustic lymphangiography (PAL), to assess the lymphatic system and compared the results with those of near-infrared fluorescence (NIRF) imaging in patients with lymphedema. Lymphedema limb shows various findings in NIRF imaging correlating with their clinical stage. By comparing NIRF and PAL, we reveal the feasibility of PAL in lymphedema diagnosis and surgical treatment.*Methods and Materials Patients with lower extremity secondary lymphedema after gynecologic cancer surgery were enrolled. First, NIRF was performed by injecting 5.0 mg/mL of indocyanine green subcutaneously in the first and fourth interdigital spaces in the foot and lateral malleolus . PAL examination was performed following the NIRF procedure, and the findings from each method were compared.*Results Seventeen patients with secondary lymphedema were enrolled. The patients' mean age was 61 ± 11 years. Eleven patients had left lower extremity imaging, five patients had right lower extremity imaging, and one patient had bilateral imaging. The imaging sites were the medial lower leg in 15 patients, the posterior lower leg in nine patients, the lateral lower leg in seven patients, the medial knee in four patients, and other areas in three patients. A total of 38 pictures were taken. Five distinct lymphatic patterns were observed using PAL over the entire sample: straight, winding, spiderweb, nebulous, and black-out. These patterns correlate with four classifications of lymphedema dermal backflow patterns in NIRF which are widely used in lymphedema surgery: linear, splash, stardust, and diffuse patterns.*Conclusions NIRF is a common examination method used in lymphedema and can provide a sensitive diagnosis. The correlation between PAL and NIRF indicates that PAL may play an important role in lymphedema treatment.*Clinical Relevance/Application NIRF findings are widely used, and there are strong correlations between the findings and the surgical result. PAL can visualize the lymphatic vessel more clearly than the previous modality. Expectations regarding the future performance of this system are high.Acknowledgment: This research was funded by a grant from The Japan Agency for Medical Research and Development (AMED) 20he2302002h0502.

RESULTS

Seventeen patients with secondary lymphedema were enrolled. The patients' mean age was 61 ± 11 years. Eleven patients had left lower extremity imaging, five patients had right lower extremity imaging, and one patient had bilateral imaging. The imaging sites were the medial lower leg in 15 patients, the posterior lower leg in nine patients, the lateral lower leg in seven patients, the medial knee in four patients, and other areas in three patients. SPR-VA-2 Yolov4 Neural Network Based Carotid Plaque Recognition From Ultrasound Dynamic Videos

Participants
Yao Wei, Beijing, China (*Presenter*) Nothing to Disclose

PURPOSE

To establish an automatic recognition system for carotid plaque via deep learning based on the YOLOv4 neural network and achieve real-time and synchronous diagnosis during ultrasound examination.*Methods and Materials A total of 445 subjects (aged 40-80 years) with ultrasound (US) carotid examination were enrolled in our study. The carotid cross-sectional US dynamic videos of each subjects were segmented automatically by the algorithm. Each carotid cross-sectional image was labeled as "negative" or "positive" with the plaque annotated in the image manually by experienced ultrasound doctors. The carotid plaque parameters were extracted and saved for comparison with the automatic method.*Results 3259 carotid cross-sectional images were collected and labeled manually. In the 554 testing dataset images, YOLOv4 and manual method are consistent in diagnosis of carotid plaque (Kappa = 0.967,P < 0.001). The YOLOv4 yielded an accuracy of 98.4%, a sensitivity of 98.3% and a specificity of 98.5%. Comparison of the YOLOv4 performance among the different equipment-sourced images suggested that there were no significant differences in sensitivity, specificity and accuracy (P = 0.339, P = 0.493, P = 0.545, respectively). The mean average precision (mAP) of our method was 91.5%, and the recognition speed based on NVIDIA Tesla V100 graphics processing units (GPU) was 39 frames per second (FPS).*Conclusions Compared with the diagnosis of experienced US doctors, the YOLOv4 has comparable performance for the recognition of carotid plaque. The recognition performance in different equipment-sourced images were compatible. The experimental results demonstrate that YOLOv4 has an advantage in accuracy and speed that can achieve the effect of real-time recognition.*Clinical Relevance/Application The study established an automatic recognition system for carotid plaque via deep learning based on the YOLOv4 neural network and achieve real-time and synchronous diagnosis during US examination to help sonographers in screening and assessing the burden of carotid plaque.

RESULTS

3259 carotid cross-sectional images were collected and labeled manually. In the 554 testing dataset images, YOLOv4 and manual method are consistent in diagnosis of carotid plaque (Kappa = 0.967,P < 0.001). The YOLOv4 yielded an accuracy of 98.4%, a sensitivity of 98.3% and a specificity of 98.5%. Comparison of the YOLOv4 performance among the different equipment-sourced images suggested that there were no significant differences in sensitivity, specificity and accuracy (P = 0.339, P = 0.493, P = 0.545, respectively). The mean average precision (mAP) of our method was 91.5%, and the recognition speed based on NVIDIA Tesla V100 graphics processing units (GPU) was 39 frames per second (FPS).

CLINICAL RELEVANCE/APPLICATION

The study established an automatic recognition system for carotid plaque via deep learning based on the YOLOv4 neural network and achieve real-time and synchronous diagnosis during US examination to help sonographers in screening and assessing the burden of carotid plaque.

SPR-VA-3   Contrast-enhanced Perfusion Patterns, Risk Factors And Serum Lipid Signatures Specific Of Vulnerable Plaque In Predicting Stroke: A Cohort Study Of Carotid Stenosis In Chinese Patients

Participants
Huang Qian, Shanghai, China (*Presenter*) Nothing to Disclose

PURPOSE

To investigate the correlation between Contrast-enhanced Ultrasound (CEUS) perfusion patterns , Risk factors and Serum lipid signatures specific of carotid artery vulnerable plaque with the degree of carotid stenosis, which provide the basis for early diagnosis of cerebral ischemic stroke.*Methods and Materials From March to June in 2018 years, we screened 2039 patients with plaque of the carotid arteries for routine ultrasound of the carotid arteries. We asked participants to complete questionnaires to obtain information about demographics and Risk factors. Physical examination was performed prior to the Ultrasound examination, including the measurements of BMI and blood pressure. Finally, 80 patients completed CEUS baseline study were analyzed (exclusion criteria were age < 18 or > 85 years, plaque thickness less than 1.5 mm, patients disagrees with the CEUS examination, have a history of myocardial infarction in two weeks, participants who refuse filling out questionnaires, who not underwent CTA or DSA within 1 week after CEUS and participants with poor image quality). All subjects underwent contrast-enhanced ultrasound, CTA or DSA, and Serum lipid testing. The appearance of enhancement in plaques were observed and the enhancement level of the plaques was divided into I-IV grades according to enhanced ultrasound findings of carotid plaques.*Results The CEUS perfusion pattern with patients were divided into plaque base entering mode (52 cases) and plaque surface entering mode (28 cases) when the contrast agent entering plaque. The contrast agent enhancement levels and the CEUS perfusion patterns in plaque were significantly associated with the degree of carotid stenosis (P<0.05), Serum free fatty acid was significantly associated with the different contrast agent enhancement level (P<0.05). Hypertension and APOE were significantly associated with the CEUS perfusion pattern of carotid plaque (P<0.05).*Conclusions The contrast agent mainly infuses from the surface to the interior of the plaque on CEUS and increased serum FFA levels are indicative of vulnerable carotid plaques, we speculate the appearance of hypertension, APOE and FFA may cause the variation of the Contrast-enhanced perfusion patterns. Together these factors may provide evidence of vulnerable plaques in those with carotid artery stenosis, which may be useful for the prediction of stroke in patients with carotid artery disease.*Clinical Relevance/Application To establish a diagnostic model for Contrast-enhanced perfusion patterns, Risk factors and Serum lipid signatures specific of vulnerable plaques, in order to reduce the incidence of cardiovascular accidents in the whole population.

RESULTS

The CEUS perfusion pattern with patients were divided into plaque base entering mode (52 cases) and plaque surface entering mode (28 cases) when the contrast agent entering plaque. The contrast agent enhancement levels and the CEUS perfusion patterns in plaque were significantly associated with the degree of carotid stenosis (P<0.05), Serum free fatty acid was significantly associated with the different contrast agent enhancement level (P<0.05). Hypertension and APOE were significantly associated with the CEUS perfusion pattern of carotid plaque (P<0.05).

CLINICAL RELEVANCE/APPLICATION

To establish a diagnostic model for Contrast-enhanced perfusion patterns, Risk factors and Serum lipid signatures specific of vulnerable plaques, in order to reduce the incidence of cardiovascular accidents in the whole population.

SPR-VA-4   A Novel Subtraction Method (s-mar) To Reduce Metal Artifacts Of Cerebral Aneurysm Embolism Coils Using Dual-layer Spectral CT.

Participants
Hanpei Zheng, Wuhan, China (*Presenter*) Nothing to Disclose

PURPOSE

This study aimed to initially investigate the feasibility of a novel subtraction method, the combination of O-MAR and subtraction algorithms (S-MAR) by subtracting VMIMAR from VNC images to remove the metal artifacts of coils after endovascular embolotherapy of intracranial aneurysms.*Methods and Materials In this retrospective study, 29 patients with 38 coils after endovascular embolotherapy of intracranial aneurysms who underwent cerebral CT using a dual-layer detector spectral CT were included. Conventional CT images (CI), VMI (range: 40-200 KeV), and Virtual Non-enhanced Images (VNC) were reconstructed. These images were then postprocessed to CIMAR, VMIMAR and VNCMAR with O-MAR (Metal Artifact Reduction for Orthopedic Implants) to reduce the metal artifact of coils. The novel subtraction method (S-MAR) was used to get subtraction imaging between VNCMAR and VMIMAR. Contrast-to-noise (CNR) and Noise (Background) of CI, CIMAR, VMI and VMIMAR were calculated. The coil artifacts score (CA score) of these images were determined by two radiologists separately. Differences of the CNR, Noise (Background) and CA score among all sets of images were analyzed using the paired-samples t-test. A P value <0.001 indicated a statistically significant difference.*Results Significant differences were found in the CNR, Noise (Background), and CA score (P < 0.001) between CI and CIMAR, as well as between VMI and VMIMAR of 50 KeV, indicating that O-MAR could effectively remove metal artifacts and enhance image quality. S-MAR showed significantly better performance compared with CI, CIMAR, VMI, and VMIMAR in reducing metal coil artifacts according to the CA score (1.34 ± 0.48 vs 4.71 ± 0.65, 3.08 ± 0.88, 4.65 ± 0.67, and 3.05 ± 0.80) (P < 0.001). S-MAR was an effective method for reducing metal coil artifacts and showed good performance for depicting cerebral vessel visualization even in coils of relatively large size (diameter > 5mm).*Conclusions In conclusion, S-MAR provides significant advantages for reducing metal coil artifact reduction and elevating visualization of cerebral vessels adjacent to coils

compared to conventional images and traditional MAR and VMI methods. S-MAR proved to be a promising method in elevating the performance of CTA for the evaluating of post-coil embolization compared with O-MAR alone.*Clinical Relevance/Application This study was a first trial of investigating S-MAR, as a novel method which combines metal artifact reduction algorithm (MAR), virtual monochromatic imaging (VMI) and subtraction algorithm to remove metal coil artifacts and enhance the vessel visualization.

RESULTS

Significant differences were found in the CNR, Noise (Background), and CA score (P < 0.001) between CI and CIMAR, as well as between VMI and VMIMAR of 50 KeV, indicating that O-MAR could effectively remove metal artifacts and enhance image quality. S-MAR showed significantly better performance compared with CI, CIMAR, VMI, and VMIMAR in reducing metal coil artifacts according to the CA score (1.34 ± 0.48 vs 4.71 ± 0.65, 3.08 ± 0.88, 4.65 ± 0.67, and 3.05 ± 0.80) (P < 0.001). S-MAR was an effective method for reducing metal coil artifacts and showed good performance for depicting cerebral vessel visualization even in coils of relatively large size (diameter > 5mm).

CLINICAL RELEVANCE/APPLICATION

This study was a first trial of investigating S-MAR, as a novel method which combines metal artifact reduction algorithm (MAR), virtual monochromatic imaging (VMI) and subtraction algorithm to remove metal coil artifacts and enhance the vessel visualization.

SPR-VA-5   The Feasibility And Performance Evaluation Of Artificial Intelligence-based Technology For Fast And Accurate Bolus-tracking Process In Aortic Abdominal Artery CT Angiography Compared With Manual Operation By Technicians

Participants
Ya Li I, Zhengzhou, China (*Presenter*) Nothing to Disclose

PURPOSE

This study aims to research performance of AI-based technology for fast and accurate bolus-tracking process in aortic abdominal artery CT angiography compared with manual operation by technicians.*Methods and Materials Thirty patients were enrolled in this study underwent the contrast-enhanced aortic abdominal artery CTA using the SmartPrep triggering technique on GE Revolution CT. The study was approved by our institutional review board and the informed consent with all patients were waived. The image acquisitions were performed from the thoracic aperture to the below symphysis pubis. The scanning parameters were as follows: tube voltage 100kVp, automatic mAs, pitch~1, helical acquisition mode, matrix size 512×512, slice thickness and slice interval 1.25mm. Manually placing the ROI in descending aorta for dynamic contrast-enhancement monitoring, and triggering the CTA scans after reaching the threshold. Simultaneously recording the scan time between the appearance of monitoring location and the start time of CTA. The results of the group were recorded as the control group. The scout scans and time-resolved images were then imported into the SmartPlan software to automatically determine the monitoring location in terms of placing ROI and generating TDC curve, and the results were recorded as the experimental group. The consistency and time consuming of the location selection and the peak value of TDC curve triggering the scan between the experimental and control groups were analyzed using paired sample t-test. P < 0.05 was considered statistically significant.*Results There was significant difference in monitoring location between the experimental group (-116.89±60.32mm) and control group (-119.74±65.56mm, P<0.05). However, monitoring locations differences were found no real clinical impact due to the variation of technicians' personal judgement. There was significant difference in the peak value of TDC curves between the experimental group (211.80±18.28 HU) and the control group (192.19±23.28, P=0.001). The average time consuming were found significant decreased in the experimental group compared with the control group (600ms vs 18.18±1.17s, P<0.05).*Conclusions The above technique has great performance and clinical feasibility in AAA CTA compared with manual operation by technicians.*Clinical Relevance/Application This technique can improve the diagnostic confidence and enhance the disease detectability, especially important for an emergency scan for abdominal aneurism or aortic artery dissection patients, and optimize the workflow, improve the operative technology utilization, it can reduce the heavy workload for CT technicians, especially for new technicians.

RESULTS

There was significant difference in monitoring location between the experimental group (-116.89±60.32mm) and control group (-119.74±65.56mm, P<0.05). However, monitoring locations differences were found no real clinical impact due to the variation of technicians' personal judgement. There was significant difference in the peak value of TDC curves between the experimental group (211.80±18.28 HU) and the control group (192.19±23.28, P=0.001). The average time consuming were found significant decreased in the experimental group compared with the control group (600ms vs 18.18±1.17s, P<0.05).

CLINICAL RELEVANCE/APPLICATION

This technique can improve the diagnostic confidence and enhance the disease detectability, especially important for an emergency scan for abdominal aneurism or aortic artery dissection patients, and optimize the workflow, improve the operative technology utilization, it can reduce the heavy workload for CT technicians, especially for new technicians.

SPR-VA-7   Achieving Consistent Diagnostic Accuracy Fordifferent Segments Oflower Extremity Arteries Inct Angiography With Dual-energy Spectral Imagingmode

Participants
Qian Tian, Xi'an, China (*Presenter*) Nothing to Disclose

PURPOSE

Investigate the application of using low energy images in dual-energy spectral CT angiography (CTA) for consistently achieving high diagnostic accuracy for different segments of lower extremity arteries.*Methods and Materials 110 patients (88 males, mean age, 67.32±10.17 years) underwent lower extremity artery CTA with spectral imaging mode were continuously collected (, and the 50keV image was used for analyzing the diagnostic accuracy using the results of digital subtraction angiography (DSA) as the gold standard. The lower extremity arteries were divided into three segments: abdominal iliac segment (AIS), femoral popliteal segment (FPS) and lower knee segment (LKS). The CT value and standard deviation of a total of 11 arterial vessels were measured to calculate the signal to noise ratio (SNR) and contrast noise ratio (CNR) of each segment. The subjective image quality of each segment was evaluated using 4-point evaluation criteria. The subjective and objective quality and diagnostic accuracy of lower extremity artery images among different segments were compared.*Results In AIS, FPS and LKS, the CT values were 670.60±118.91HU, 640.05±115.10HU and 544.91±106.37HU, SNR values were 43.62±11.43, 42.85±13.80, 19.92±9.39, CNR values were 55.78±18.29, 55.64±21.57 and 45.60±16.61, respectively, with values adequate for diagnosis. The subjective scores were

3.40±0.65, 3.47±0.57 and 3.41±0.65 for the three segments with no statistically significant difference (P>0.05) The diagnostic accuracies were 98.18%, 96.14%, 95.91% for the =50% stenoses, and 98.48%, 97.05%, 94.32% for the occlusive patients in AIS, FPS and LKS, respectively. There was no statistical difference in the diagnostic accuracy among AIS, FPS and LKS (P>0.05).*Conclusions The use of low energy (50keV) images in the dual-energy spectral CTA significantly improves the vascular display and increases diagnostic confidence for distal vessels, which is especially useful for maintaining the consistency of diagnostic accuracy of all segments of the lower knee arteries.*Clinical Relevance/Application The low energy images in spectral CTA provides high diagnostic accuracy for lower extremity arteries, especially the lower knee segment arteries.

RESULTS

In AIS, FPS and LKS, the CT values were 670.60±118.91HU, 640.05±115.10HU and 544.91±106.37HU, SNR values were 43.62±11.43, 42.85±13.80, 19.92±9.39, CNR values were 55.78±18.29, 55.64±21.57 and 45.60±16.61, respectively, with values adequate for diagnosis. The subjective scores were 3.40±0.65, 3.47±0.57 and 3.41±0.65 for the three segments with no statistically significant difference (P>0.05) The diagnostic accuracies were 98.18%, 96.14%, 95.91% for the =50% stenoses, and 98.48%, 97.05%, 94.32% for the occlusive patients in AIS, FPS and LKS, respectively. There was no statistical difference in the diagnostic accuracy among AIS, FPS and LKS (P>0.05).

CLINICAL RELEVANCE/APPLICATION

The low energy images in spectral CTA provides high diagnostic accuracy for lower extremity arteries, especially the lower knee segment arteries.

SSNPM02

SSNPM02-1 Top Five Most Missed Pediatric Cases: An Emergency Radiology Simulation Analysis

Participants

Priya Sharma, MD, Gainesville, Florida (*Presenter*) Nothing to Disclose

PURPOSE

The Wisdom in Diagnostic Imaging SIMulation (WIDI SIM) is a strategically designed computer aided simulation of an emergency imaging shift that has been rigorously tested and proven to be a reliable means for assessing resident preparedness to competently and independently cover radiology call. This has been utilized as a call-readiness simulation for radiology residents from all over the country. Pediatric patients can often be the most challenging population, not only for the emergency physician but also for the radiologist with non-specific complaints and challenging or subtle imaging findings. The purpose of this study was to identify the five most missed pediatric radiology cases in the past nearly 10 years of simulation testing.*Methods and Materials During each simulation examination, consisting of an 8-hour simulated call shift, radiology residents were provided with a total of 65 cases across multiple modalities and areas of specialty for interpretation. These cases were of varying difficulty, including normal studies. A quarter of the test cases included were pediatric cases. The residents responded using free text, which was then scored by radiology faculty members utilizing a robust grading rubric with a 10 -point scale. A score below 3 was considered a "missed" case.*Results Over 1200 residents have participated in UF WIDI SIM program since its inception in 2012. Resident participants include all years of diagnostic radiology residency with the predominant group being R1 and R2. During the past 9 years of simulation testing residents have been tested on a wide variety of pediatric pathologies utilizing all imaging modalities. Analysis of data revealed that the five most missed pediatric case pathologies varied in system and modality. Pathologies that were missed the most in pediatric radiology included: non-accidental trauma, pancreatic laceration and suppurative adenitis.*Conclusions Residents may need more teaching in order to recognize imaging findings of certain pediatric pathologies encountered in the emergency call setting prior to taking independent call. It is important for radiology educators to identify those pathologies that might require careful teaching especially in the pediatric setting. Furthermore, identifying which cases are "more difficult" allows for careful tailoring of the residency curriculum.*Clinical Relevance/Application Emergency clinicians rely upon the radiologists to help recognize pertinent findings that can significantly affect management. This has great implications for programs where a radiology attending is not present as it raises the concern that certain pediatric emergencies may be missed by residents taking call.

RESULTS

Over 1200 residents have participated in UF WIDI SIM program since its inception in 2012. Resident participants include all years of diagnostic radiology residency with the predominant group being R1 and R2. During the past 9 years of simulation testing residents have been tested on a wide variety of pediatric pathologies utilizing all imaging modalities. Analysis of data revealed that the five most missed pediatric case pathologies varied in system and modality. Pathologies that were missed the most in pediatric radiology included: non-accidental trauma, pancreatic laceration and suppurative adenitis.

CLINICAL RELEVANCE/APPLICATION

Emergency clinicians rely upon the radiologists to help recognize pertinent findings that can significantly affect management. This has great implications for programs where a radiology attending is not present as it raises the concern that certain pediatric emergencies may be missed by residents taking call.

SSNPM02-2 Comparison Of Oncologic Imaging Usage Between Telemedicine And In-Person Clinic Visits During The COVID-19 Recovery

Participants

Joseph Erinjeri, MD,PhD, New York, New York (*Presenter*) Advisory Board, AstraZeneca PLC;Consultant, Canon Medical Systems Corporation;

PURPOSE

To compare oncologic imaging usage of patients who had telemedicine vs in-person visits during the COVID-19 recovery.*Methods and Materials This retrospective study examined records of 1,020,753 outpatient ambulatory clinic visits and 412,614 radiology exams (CT, MRI, PET, US, CR - computed radiography, BI - breast imaging, NM - nuclear medicine, and IR) at a cancer center from 1/12/2020 to 4/10/21. Data were collected during three periods: 1) pre-surge, 2) COVID-19 surge (3/15-5/30), and 3) recovery. During the recovery, visits were categorized by type (telemedicine vs. in-person) and exams by imaging modality. An exam performed within +/-14 days of a visit was associated with that visit. Imaging usage was computed as exams per clinic visit (expressed as percentages) and compared using two sample t-tests.*Results During the COVID-19 recovery, the aggregate usage of cross-sectional modalities (CT/MR/PET) was 15% higher for telemedicine vs. in-person visits (0.218 vs 0.189, p<0.001).

Telemedicine visits were associated with significantly higher imaging usage than in-person visits for CT (+20%), MR (+6%), PET (+17%) and IR (+28%). Telemedicine visits were associated with significantly lower imaging usage than in-person visits for US (-24%), CR (-17%) BI (-63%), NM (-28%) and IR (-28%).*Conclusions Telemedicine clinic visits were associated with higher cross-sectional imaging and IR usage than in-person clinic visits during the COVID-19 recovery.*Clinical Relevance/Application Higher usage rates of imaging with telemedicine clinic visits should be considered during resource planning.

RESULTS

During the COVID-19 recovery, the aggregate usage of cross-sectional modalities (CT/MR/PET) was 15% higher for telemedicine vs. in-person visits (0.218 vs 0.189, p<0.001). Telemedicine visits were associated with significantly higher imaging usage than in-person visits for CT (+20%), MR (+6%), PET (+17%) and IR (+28%). Telemedicine visits were associated with significantly lower imaging usage than in-person visits for US (-24%), CR (-17%) BI (-63%), NM (-28%) and IR (-28%).

CLINICAL RELEVANCE/APPLICATION

Higher usage rates of imaging with telemedicine clinic visits should be considered during resource planning.

SSNPM02-4 The Impact Of Emerging Technologies On Residency Selection By Medical Students: 2017 Vs. 2021

Participants
Michael K. Atalay, MD, PhD, Providence, Rhode Island (*Presenter*) Nothing to Disclose

PURPOSE

Artificial intelligence (AI) and other technologies promise to change the way medicine is practiced. How medical students anticipate these changes may affect their career choices. Our objective was to determine the perceived impact of AI on various specialties by medical students and how this might affect their residency selections.*Methods and Materials We conducted an anonymous online survey of all medical students (MS1-4) at a single institution in November 2017 and January 2021. Survey questions were designed to measure the perceived effect that AI will have on future job prospects for each specialty. Data were analyzed using generalized linear modeling.*Results Response rates were 72% (384/532) and 54% (321/598) for 2017 and 2021, respectively. Figure 1A illustrates students perceived AI would reduce job prospects for pathology, radiology, and anesthesiology, but they perceived AI would enhance job prospects for all other specialties (p<.01) except dermatology. These results did not significantly change between 2017 and 2021, except that pathology became more extreme. These perceptions may affect behavior: asked if there were any specialties they were NOT considering because AI would render these specialties obsolete, 23% said radiology for both 2017 and 2021, higher than all other specialties (p<.01), followed by pathology and anesthesiology. In comparison, students selected most other specialties under 5% in both surveys. When comparing MS1 students in 2017 with MS4 in 2021 (same cohort), 49.5% (51/103) said AI would "reduce" job prospects for radiology in 2017, increasing to 70.8% (63/89) in 2021, p<.01. In 2017, 20% (21/103) of MS1 said they explicitly would not consider radiology because of AI; 3 years later as MS4, 23% (20/89) said the same.*Conclusions Current perceptions of AI likely affect residency selection for medical students, which may impact the future of various specialties, especially diagnostic radiology.*Clinical Relevance/Application A large proportion of medical students will reportedly not consider radiology owing to the anticipated impact of AI. Faculty should engage both students and the curriculum to improve and modify these perceptions.

RESULTS

Response rates were 72% (384/532) and 54% (321/598) for 2017 and 2021, respectively. Figure 1A illustrates students perceived AI would reduce job prospects for pathology, radiology, and anesthesiology, but they perceived AI would enhance job prospects for all other specialties (p<.01) except dermatology. These results did not significantly change between 2017 and 2021, except that pathology became more extreme. These perceptions may affect behavior: asked if there were any specialties they were NOT considering because AI would render these specialties obsolete, 23% said radiology for both 2017 and 2021, higher than all other specialties (p<.01), followed by pathology and anesthesiology. In comparison, students selected most other specialties under 5% in both surveys. When comparing MS1 students in 2017 with MS4 in 2021 (same cohort), 49.5% (51/103) said AI would "reduce" job prospects for radiology in 2017, increasing to 70.8% (63/89) in 2021, p<.01. In 2017, 20% (21/103) of MS1 said they explicitly would not consider radiology because of AI; 3 years later as MS4, 23% (20/89) said the same.

CLINICAL RELEVANCE/APPLICATION

A large proportion of medical students will reportedly not consider radiology owing to the anticipated impact of AI. Faculty should engage both students and the curriculum to improve and modify these perceptions.

SSNPM02-5 How COVID-19 Kick-started Online Learning In Medical Education - Results Of An International, Multicenter Study

Participants
Fabian Stoehr, Mainz, Germany (*Presenter*) Nothing to Disclose

PURPOSE

The coronavirus disease 2019 (COVID-19) pandemic led to far-reaching restrictions of social and professional life, affecting societies all over the world. To contain the virus, medical schools had to restructure their curriculum by switching to online learning. However, only few medical schools had implemented such novel learning concepts. We aimed to evaluate students' attitudes to online learning to provide a broad scientific basis to guide future development of medical education.*Methods and Materials Overall, 3286 medical students from 12 different countries participated in this cross-sectional study investigating various aspects of online learning in medical education. On a 7-point Likert scale, participants rated the online learning situation during the pandemic at their medical schools, technical and social aspects, and the current and future role of online learning in medical education.*Results The majority of medical schools managed the rapid switch to online learning (78%) and most students were satisfied with the quantity (67%) and quality (62%) of the courses. Online learning provided greater flexibility (84%) and led to unchanged or even higher attendance of courses (70%). Possible downsides included motivational problems (42%), insufficient possibilities for interaction with fellow students (67%) and thus the risk of social isolation (64%). The vast majority felt comfortable using the software solutions (80%). Most were convinced that medical education lags behind current capabilities regarding online learning (78%) and estimated the proportion of online learning before the pandemic at only 14%. For the future, they wished for a more prominent role, involving around 42% of online learning compared to on-site teaching (Figure 1).*Conclusions This study demonstrates the positive attitude of medical students towards online learning. Furthermore, it reveals a considerable discrepancy between what students demand and what the curriculum offers.*Clinical Relevance/Application We believe that the lessons learned from the pandemic might work as a catalyst for a new "online era" in medical education. The future challenge will be to sustainably integrate innovative teaching

concepts into the current curriculum.

RESULTS

The majority of medical schools managed the rapid switch to online learning (78%) and most students were satisfied with the quantity (67%) and quality (62%) of the courses. Online learning provided greater flexibility (84%) and led to unchanged or even higher attendance of courses (70%). Possible downsides included motivational problems (42%), insufficient possibilities for interaction with fellow students (67%) and thus the risk of social isolation (64%). The vast majority felt comfortable using the software solutions (80%). Most were convinced that medical education lags behind current capabilities regarding online learning (78%) and estimated the proportion of online learning before the pandemic at only 14%. For the future, they wished for a more prominent role, involving around 42% of online learning compared to on-site teaching (Figure 1).

CLINICAL RELEVANCE/APPLICATION

We believe that the lessons learned from the pandemic might work as a catalyst for a new "online era" in medical education. The future challenge will be to sustainably integrate innovative teaching concepts into the current curriculum.

SSNPM02-6 Development And Pilot Randomized Study Of A Patient Decision Aid For Small Renal Mass Management

Participants
Shailin Thomas, BS, Stamford, Connecticut (*Presenter*) Nothing to Disclose

PURPOSE

To develop a patient decision aid (DA) about small renal masses (SRMs) and conduct a pilot trial on DA effectiveness in improving knowledge and preparation to discuss current guideline-recognized options of active surveillance, percutaneous ablation, and surgery.*Methods and Materials We conducted a rapid qualitative assessment on informational needs using 3 focus groups and 10 semi-structured interviews of patients, urologists, and radiologists. A printed DA was designed and followed the International Patient Decision Aid Standards on content accessibility and clarity to address these needs. The design committee included two urologists, an internist, interventional radiologist, diagnostic radiologist, and experimental psychologist. Usability assessment with 10 patients in urology clinic informed iterative revisions. A pilot randomized study was conducted in 2 clinics with 30 patients deciding on SRM management. Patients were randomized to receive the DA or an existing prose institutional pamphlet on SRM treatment options. After viewing the pamphlet or DA, patients answered pre-visit questionnaires on demographic information, knowledge items, and preference for shared decisions. After the visit, patients completed a questionnaire on 16 validated decision satisfaction and shared decision making items. Proportions between arms were compared using Chi-Square and decision measures were compared with Mann-Whitney tests.*Results Patient informational needs included the risk of tumor spread during active surveillance and ablation, significance of comorbidities including chronic kidney disease, and the recovery period after ablation and surgery. In the pilot study, 100% completed viewing of information in both arms. DA use significantly improved patient knowledge about SRM risks and treatment options ([63% correct items for DA vs. 20% for pamphlet], p<0.001). DA use increased the proportion of patients discussing ablation with their doctors, trending toward significance (p=0.05), while no difference was found for surveillance or surgery; shared decisions increased, but not significantly (scale effect size 0.6, p=0.09). Decision satisfaction measures were similar (4.37 vs. 4.34 for DA and pamphlet; p=0.55).*Conclusions Patients receiving evidence-based risk communication and educational information in a DA are more likely to be sufficiently knowledgeable and prepared to discuss all treatment options. DA use in clinic is feasible and will be evaluated in a larger trial for impact on decision making.*Clinical Relevance/Application As renal mass ablation, surgery, and surveillance are increasingly recognized options for small renal tumors in society guidelines, a decision aid likely enables informed, better quality decisions.

RESULTS

Patient informational needs included the risk of tumor spread during active surveillance and ablation, significance of comorbidities including chronic kidney disease, and the recovery period after ablation and surgery. In the pilot study, 100% completed viewing of information in both arms. DA use significantly improved patient knowledge about SRM risks and treatment options ([63% correct items for DA vs. 20% for pamphlet], p<0.001). DA use increased the proportion of patients discussing ablation with their doctors, trending toward significance (p=0.05), while no difference was found for surveillance or surgery; shared decisions increased, but not significantly (scale effect size 0.6, p=0.09). Decision satisfaction measures were similar (4.37 vs. 4.34 for DA and pamphlet; p=0.55).

CLINICAL RELEVANCE/APPLICATION

As renal mass ablation, surgery, and surveillance are increasingly recognized options for small renal tumors in society guidelines, a decision aid likely enables informed, better quality decisions.
